For the “A1 128-bit SIMD vector” and “A1 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#).
This encoding must be unconditional.

For the “T1 128-bit SIMD vector” and “T1 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Dd>

Is the 64-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field.

<Dm>

Is the 64-bit name of the SIMD&FP source register, encoded in the “M:Vm” field.

<Qd>

Is the 128-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field as <Qd>*2.

<Qm>

Is the 128-bit name of the SIMD&FP source register, encoded in the “M:Vm” field as <Qm>*2.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();
    for r = 0 to regs-1 do
        for e = 0 to elements-1 do
            D(d+r)[e*:esize] = BitCount(D(m+r)[e*:esize])[esize-1:0];
        end;
    end;
end;
```

C6.1.54 VCVT (between double-precision and single-precision)

Convert between double-precision and single-precision does one of the following:

- Converts the value in a double-precision register to single-precision and writes the result to a single-precision register.
- Converts the value in a single-precision register to double-precision and writes the result to a double-precision register.

Depending on settings in the [CPACR](#), [NSACR](#), [HCPTR](#), and [FPEXC](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding for the Single-precision to double-precision variant

Applies when (size == 10)

```
VCVT{<c>}{<q>}.F64.F32 <Dd>, <Sm>
```

Encoding for the Double-precision to single-precision variant

Applies when (size == 11)

```
VCVT{<c>}{<q>}.F32.F64 <Sd>, <Dm>
```

Decode for all variants of this encoding

```
let double_to_single : boolean = (size == '11');
let d : integer = if double_to_single then UInt(Vd::D) else UInt(D::Vd);
let m : integer = if double_to_single then UInt(M::Vm) else UInt(Vm::M);
```

T1

Encoding for the Single-precision to double-precision variant

Applies when (size == 10)

```
VCVT{<c>}{<q>}.F64.F32 <Dd>, <Sm>
```

Encoding for the Double-precision to single-precision variant

Applies when (size == 11)

VCVT{<c>}{<q>}.F32.F64 <Sd>, <Dm>

Decode for all variants of this encoding

```
let double_to_single : boolean = (size == '11');
let d : integer = if double_to_single then UInt(Vd::D) else UInt(D::Vd);
let m : integer = if double_to_single then UInt(M::Vm) else UInt(Vm::M);
```

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

<Dd>

Is the 64-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field.

<Sm>

Is the 32-bit name of the SIMD&FP source register, encoded in the “Vm:M” field.

<Sd>

Is the 32-bit name of the SIMD&FP destination register, encoded in the “Vd:D” field.

<Dm>

Is the 64-bit name of the SIMD&FP source register, encoded in the “M:Vm” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckVFPEEnabled(TRUE);
    if double_to_single then
        S(d) = FPConvert{32, 64}(D(m), EffectiveFPCR());
    else
        D(d) = FPConvert{64, 32}(S(m), EffectiveFPCR());
    end;
end;
```

C6.1.55 VCVT (between half-precision and single-precision, Advanced SIMD)

Vector Convert between half-precision and single-precision converts each element in a vector from single-precision to half-precision floating-point, or from half-precision to single-precision, and places the results in a second vector.

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding for the Half-precision to single-precision variant

Applies when (op == 1)

VCVT{<c>}{<q>}.F32.F16 <Qd>, <Dm>

Encoding for the Single-precision to half-precision variant

Applies when (op == 0)

VCVT{<c>}{<q>}.F16.F32 <Dd>, <Qm>

Decode for all variants of this encoding

```

if size != '01' then Undefined(); end;
if op == '1' && Vd[0] == '1' then Undefined(); end;
if op == '0' && Vm[0] == '1' then Undefined(); end;
let half_to_single : boolean = (op == '1');
let esize : integer{} = 16;
let elements : integer = 4;
let m : integer = UInt(M::Vm);
let d : integer = UInt(D::Vd);

```

T1

Encoding for the Half-precision to single-precision variant

Applies when (op == 1)

VCVT{<c>}{<q>}.F32.F16 <Qd>, <Dm>

Encoding for the Single-precision to half-precision variant

Applies when (op == 0)

VCVT{<c>}{<q>}.F16.F32 <Dd>, <Qm>

Decode for all variants of this encoding

```
if size != '01' then Undefined(); end;
if op == '1' && Vd[0] == '1' then Undefined(); end;
if op == '0' && Vm[0] == '1' then Undefined(); end;
let half_to_single : boolean = (op == '1');
let esize : integer = 16;
let elements : integer = 4;
let m : integer = UInt(M::Vm);
let d : integer = UInt(D::Vd);
```

Assembler Symbols

Assembler Symbols

<c>

For the “A1 128-bit SIMD vector” and “A1 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#). This encoding must be unconditional.

For the “T1 128-bit SIMD vector” and “T1 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<dt1>

Is the data type for the elements of the destination vector, encoded in “op:U”:

op	U	<dt1>
00	x	F16
01	0	S16
01	1	U16
10	x	F32
11	0	S32
11	1	U32

<dt2>

Is the data type for the elements of the source vector, encoded in “op:U”:

op	U	<dt2>
00	0	S16
00	1	U16
01	x	F16
10	0	S32
10	1	U32
11	x	F32

<Dd>

Is the 64-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field.

<Dm>

Is the 64-bit name of the SIMD&FP source register, encoded in the “M:Vm” field.

<fbits>

The number of fraction bits in the fixed point number, in the range 1 to 32 for 32-bit elements, or in the range 1 to 16 for 16-bit elements:

- (64 - <fbits>) is encoded in imm6.

An assembler can permit an <fbits> value of 0. This is encoded as floating-point to integer or integer to floating-point instruction, see [VCVT \(between floating-point and integer, Advanced SIMD\)](#).

<Qd>

Is the 128-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field as <Qd>*2.

<Qm>

Is the 128-bit name of the SIMD&FP source register, encoded in the “M:Vm” field as <Qm>*2.

Operation

```

if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();
    var result : bits(esize);
    let fpcr : FPCR_Type = StandardFPCR();
    for r = 0 to regs-1 do
        for e = 0 to elements-1 do
            let operand1 : bits(esize) = D(m+r)[e*:esize];
            if to_fixed then
                result = FPToFixed{esize, esize}(operand1, frac_bits, unsigned, fpcr,
                                                    FPRounding_ZERO);
            else
                result = FixedToFP{esize, esize}(operand1, frac_bits, unsigned, fpcr,
                                                    FPRounding_TIEEVEN);
            end;
            D(d+r)[e*:esize] = result;
        end;
    end;
end;

```

C6.1.60 VCVT (between floating-point and fixed-point, floating-point)

Convert between floating-point and fixed-point converts a value in a register from floating-point to fixed-point, or from fixed-point to floating-point. Software can specify the fixed-point value as either signed or unsigned.

The fixed-point value can be 16-bit or 32-bit. Conversions from fixed-point values take their operand from the low-order bits of the source register and ignore any remaining bits. Signed conversions to fixed-point values sign-extend the result value to the destination register width. Unsigned conversions to fixed-point values zero-extend the result value to the destination register width.

The floating-point to fixed-point operation uses the Round towards Zero rounding mode. The fixed-point to floating-point operation uses the Round to Nearest rounding mode.

Depending on settings in the [CPACR](#), [NSACR](#), [HCPTR](#), and [FPEXC](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding for the Single-precision scalar variant

Applies when (op == 0 && sf == 10)

```
VCVT{<c>}{<q>}.F32.<dt> <Sdm>, <Sdm>, #<fbits>
```

Encoding for the Single-precision scalar variant

Applies when (op == 1 && sf == 10)

```
VCVT{<c>}{<q>}.<dt>.F32 <Sdm>, <Sdm>, #<fbits>
```

Encoding for the Double-precision scalar variant

Applies when (op == 0 && sf == 11)

```
VCVT{<c>}{<q>}.F64.<dt> <Ddm>, <Ddm>, #<fbits>
```

Encoding for the Double-precision scalar variant

Applies when (op == 1 && sf == 11)

```
VCVT{<c>}{<q>}.<dt>.F64 <Ddm>, <Ddm>, #<fbits>
```

Decode for all variants of this encoding

```
if sf != '1x' then Undefined(); end;
let to_fixed : boolean = (op == '1');
let unsigned : boolean = (U == '1');
let size : integer{} = if sx == '0' then 16 else 32;
let frac_bits : integer = size - UInt(imm4::i);
let fp_size : integer = 8 << UInt(sf);
let d : integer = if sf == '11' then UInt(D::Vd) else UInt(Vd::D);
if frac_bits < 0 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `frac_bits < 0`, then one of the following behaviors must occur:

- The instruction is **UNDEFINED**.
- The instruction executes as **NOP**.
- The value in the destination register is **UNKNOWN**.

T1

Encoding for the Single-precision scalar variant

Applies when (op == 0 && sf == 10)

```
VCVT{<c>}{<q>}.F32.<dt> <Sdm>, <Sdm>, #<fbits>
```

Encoding for the Single-precision scalar variant

Applies when (op == 1 && sf == 10)

```
VCVT{<c>}{<q>}.<dt>.F32    <Sdm>, <Sdm>, #<fbits>
```

Encoding for the Double-precision scalar variant

Applies when (op == 0 && sf == 11)

```
VCVT{<c>}{<g>}.F64.<dt> <Ddm>, <Ddm>, #<fbits>
```

Encoding for the Double-precision scalar variant

Applies when (op == 1 && sf == 11)

```
VCVT{<c>}{<q>}.<dt>.F64    <Ddm>, <Ddm>, #<fbits>
```

Decode for all variants of this encoding

```

if sf != 'lx' then Undefined(); end;
let to_fixed : boolean = (op == '1');
let unsigned : boolean = (U == '1');
let size : integer{} = if sx == '0' then 16 else 32;
let frac_bits : integer = size - UInt(imm4::i);
let fp_size : integer = 8 << UInt(sf);
let d : integer = if sf == '11' then UInt(D::Vd) else UInt(Vd::D);
if frac_bits < 0 then UnpredictableProcedure(); end;

```

CONSTRAINED UNPREDICTABLE behavior

If `frac bits < 0`, then one of the following behaviors must occur:

- The instruction is **UNDEFINED**.
- The instruction executes as **NOP**.
- The value in the destination register is **UNKNOWN**.

For more information about the **CONSTRAINED UNPREDICTABLE** behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly [VCVT \(between floating-point and fixed-point\)](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<dt>

Is the data type for the fixed-point number, encoded in “U:sx”:

U	sx	<dt>
0	0	S16
0	1	S32
1	0	U16
1	1	U32

<Sdm>

Is the 32-bit name of the SIMD&FP destination and source register, encoded in the “Vd:D” field.

<fbits>

The number of fraction bits in the fixed-point number:

- If <dt> is S16 or U16, <fbits> must be in the range 0-16. (16 - <fbits>) is encoded in [imm4, i]
- If <dt> is S32 or U32, <fbits> must be in the range 1-32. (32 - <fbits>) is encoded in [imm4, i].

<Ddm>

Is the 64-bit name of the SIMD&FP destination and source register, encoded in the “D:Vd” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckVFPEEnabled(TRUE);
    let fpcr : FPCR_Type = EffectiveFPCR();
    if to_fixed then
        var result : bits(size);
        case fp_size of
            when 32 =>
                result = FPToFixed{size, 32}(S(d), frac_bits, unsigned, fpcr, FPRounding_ZERO);
                S(d) = Extend{32}(result, unsigned);
            when 64 =>
                result = FPToFixed{size, 64}(D(d), frac_bits, unsigned, fpcr, FPRounding_ZERO);
                D(d) = Extend{64}(result, unsigned);
        end;
    else
        case fp_size of
            when 32 =>
                S(d) = FixedToFP{32, size}(S(d)[size-1:0], frac_bits, unsigned, fpcr,
                    FPRounding_TIEEVEN);
            when 64 =>
                D(d) = FixedToFP{64, size}(D(d)[size-1:0], frac_bits, unsigned, fpcr,
                    FPRounding_TIEEVEN);
        end;
    end;
end;
```

C6.1.61 VCVTA (Advanced SIMD)

Vector Convert floating-point to integer with Round to Nearest with Ties to Away

Vector Convert floating-point to integer with Round to Nearest with Ties to Away converts each element in a vector from floating-point to integer using the Round to Nearest with Ties to Away rounding mode, and places the results in a second vector.

The operand vector elements are floating-point numbers.

The result vector elements are integers, and the same size as the operand vector elements. Signed and unsigned integers are distinct.

Depending on settings in the [CPACR](#), [NSACR](#), [HCPTR](#), and [FPEXC](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding for the 64-bit SIMD vector variant

Applies when ($Q == 0$)

VCVTA{<α>}.<dt>.<dt2> <Dd>, <Dm>

Encoding for the 128-bit SIMD vector variant

Applies when $(Q == 1)$

VCVTA{<α>}.<dt>.<dt2> <Qd>, <Qm>

Decode for all variants of this encoding

```

if Q == '1' && (Vd[0] == '1' || Vm[0] == '1') then Undefined(); end;
if size != '10' then Undefined(); end;
let rounding : FPRounding = FPDecoderRM(RM);
let unsigned : boolean = (op == '1');
let esize : integer{} = 32;
let elements : integer = 64 DIV esize;
let d : integer = UInt(D::Vd);
let m : integer = UInt(M::Vm);
let regs : integer = if Q == '0' then 1 else 2;

```

T1

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0)

VCVTA{<q>}.<dt>.<dt2> <Dd>, <Dm>

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

VCVTA{<q>}.<dt>.<dt2> <Qd>, <Qm>

Decode for all variants of this encoding

```
if InITBlock() then UnpredictableProcedure(); end;
if Q == '1' && (Vd[0] == '1' || Vm[0] == '1') then Undefined(); end;
if size != '10' then Undefined(); end;
let rounding : FPRounding = FPDecodeRM(RM);
let unsigned : boolean = (op == '1');
let esize : integer{} = 32;
let elements : integer = 64 DIV esize;
let d : integer = UInt(D::Vd);
let m : integer = UInt(M::Vm);
let regs : integer = if Q == '0' then 1 else 2;
```

CONSTRAINED UNPREDICTABLE behavior

If InITBlock(), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

Assembler Symbols

<q>

See [Standard assembler syntax fields](#).

<dt>

Is the data type for the elements of the destination, encoded in “op:size”:

Is the 64-bit name of the SIMD&FP source register, encoded in the “M:Vm” field.

Operation

```
EncodingSpecificOperations();
CheckVFPEEnabled(TRUE);
let fpcr : FPCR_Type = EffectiveFPCR();
case esize of
  when 32 =>
    S(d) = FPToFixed{32, 32}(S(m), 0, unsigned, fpcr, rounding);
  when 64 =>
    S(d) = FPToFixed{32, 64}(D(m), 0, unsigned, fpcr, rounding);
end;
```

C6.1.63 VCVTB

Convert to or from a half-precision value in the bottom half of a single-precision register

Convert to or from a half-precision value in the bottom half of a single-precision register does one of the following:

- Converts the half-precision value in the bottom half of a single-precision register to single-precision and writes the result to a single-precision register.
- Converts the half-precision value in the bottom half of a single-precision register to double-precision and writes the result to a double-precision register.
- Converts the single-precision value in a single-precision register to half-precision and writes the result into the bottom half of a single-precision register, preserving the other half of the destination register.
- Converts the double-precision value in a double-precision register to half-precision and writes the result into the bottom half of a single-precision register, preserving the other half of the destination register.

Depending on settings in the [CPACR](#), [NSACR](#), [HCPTR](#), and [FPEXC](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

if size != '10' then Undefined(); end;
let rounding : FPRounding = FPDecodeRM(RM);
let unsigned : boolean = (op == '1');
let esize : integer{} = 32;
let elements : integer = 64 DIV esize;
let d : integer = UInt(D::Vd);
let m : integer = UInt(M::Vm);
let regs : integer = if Q == '0' then 1 else 2;
```

T1

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0)

```
VCVTM{<q>}.<dt>.<dt2> <Dd>, <Dm>
```

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

VCVTM{<q>}.<dt>.<dt2> <Qd>, <Qm>

Decode for all variants of this encoding

```
if InITBlock() then UnpredictableProcedure(); end;
if Q == '1' && (Vd[0] == '1' || Vm[0] == '1') then Undefined(); end;
if size != '10' then Undefined(); end;
let rounding : FPRounding = FPDecodeRM(RM);
let unsigned : boolean = (op == '1');
let esize : integer{} = 32;
let elements : integer = 64 DIV esize;
let d : integer = UInt(D::Vd);
let m : integer = UInt(M::Vm);
let regs : integer = if Q == '0' then 1 else 2;
```

CONSTRAINED UNPREDICTABLE behavior

If InITBlock(), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

Assembler Symbols

<q>

See [Standard assembler syntax fields](#).

<dt>

Is the data type for the elements of the destination, encoded in “op:size”:

op	size	<dt>
0	01	S16
0	10	S32
1	01	U16
1	10	U32

<dt2>

Is the data type for the elements of the source vector, encoded in “size”:

size	<dt2>
01	F16
10	F32

<Dd>

Is the 64-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field.

<Dm>

Is the 64-bit name of the SIMD&FP source register, encoded in the “M:Vm” field.

<Qd>

Is the 128-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field as <Qd>*2.

<Qm>

Is the 128-bit name of the SIMD&FP source register, encoded in the “M:Vm” field as <Qm>*2.

Operation

```
EncodingSpecificOperations();
CheckAdvSIMDEnabled();
let fpcr : FPCR_Type = StandardFPCR();
for r = 0 to regs-1 do
    for e = 0 to elements-1 do
        D(d+r)[e*:esize] = FPToFixed{esize, esize}(D(m+r)[e*:esize],
                                                    0, unsigned, fpcr, rounding);
    end;
end;
```

C6.1.65 VCVTM (floating-point)

Convert floating-point to integer with Round towards -Infinity converts a value in a register from floating-point to a 32-bit integer using the Round towards -Infinity rounding mode, and places the result in a second register.

Depending on settings in the [CPACR](#), [NSACR](#), [HCPTR](#), and [FPEXC](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding for the Single-precision scalar variant

Applies when (size == 10)

VCVTM{<q>}.<dt>.F32 <Sd>, <Sm>

Encoding for the Double-precision scalar variant

Applies when (size == 11)

VCVTM{<q>}.<dt>.F64 <Sd>, <Dm>

Decode for all variants of this encoding

```

if size != 'lx' then Undefined(); end;
let rounding : FPRounding = FPDecodeRM(RM);
let unsigned : boolean = (op == '0');
let esize : integer{} = 8 << UInt(size);
let d : integer = UInt(Vd::D);
let m : integer = if size == '11' then UInt(M::Vm) else UInt(Vm::M);

```

T1

Encoding for the Single-precision scalar variant

Applies when (size == 10)

VCVTM{<q>}.<dt>.F32 <Sd>, <Sm>

Encoding for the Double-precision scalar variant

Applies when (size == 11)

VCVTM{<q>}.<dt>.F64 <Sd>, <Dm>

Decode for all variants of this encoding

```
if InITBlock() then UnpredictableProcedure(); end;
if size != '1x' then Undefined(); end;
let rounding : FPRounding = FPDecodeRM(RM);
let unsigned : boolean = (op == '0');
let esize : integer{} = 8 << UInt(size);
let d : integer = UInt(Vd::D);
let m : integer = if size == '11' then UInt(M::Vm) else UInt(Vm::M);
```

CONSTRAINED UNPREDICTABLE behavior

If InITBlock(), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

Assembler Symbols

<q>

See [Standard assembler syntax fields](#).

<dt>

Is the data type for the elements of the destination, encoded in “op”:

op	<dt>
0	U32
1	S32

<Sd>

Is the 32-bit name of the SIMD&FP destination register, encoded in the “Vd:D” field.

<Sm>

Is the 32-bit name of the SIMD&FP source register, encoded in the “Vm:M” field.

<Dm>

Is the 64-bit name of the SIMD&FP source register, encoded in the “M:Vm” field.

Operation

```
EncodingSpecificOperations();
CheckVFPEEnabled(TRUE);
let fpcr : FPCR_Type = EffectiveFPCR();
case esize of
  when 32 =>
    S(d) = FPToFixed{32, 32}(S(m), 0, unsigned, fpcr, rounding);
  when 64 =>
    S(d) = FPToFixed{32, 64}(D(m), 0, unsigned, fpcr, rounding);
end;
```

C6.1.66 VCVTN (Advanced SIMD)

Vector Convert floating-point to integer with Round to Nearest converts each element in a vector from floating-point to integer using the Round to Nearest rounding mode, and places the results in a second vector.

The operand vector elements are floating-point numbers.

The result vector elements are integers, and the same size as the operand vector elements. Signed and unsigned integers are distinct.

Depending on settings in the [CPACR](#), [NSACR](#), [HCPTR](#), and [FPEXC](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0)

VCVTN{<q>}.<dt>.<dt2> <Dd>, <Dm>

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

VCVTN{<q>}.<dt>.<dt2> <Qd>, <Qm>

Decode for all variants of this encoding

```

if Q == '1' && (Vd[0] == '1' || Vm[0] == '1') then Undefined(); end;
if size != '10' then Undefined(); end;
let rounding : FPRounding = FPDecodeRM(RM);
let unsigned : boolean = (op == '1');
let esize : integer{} = 32;
let elements : integer = 64 DIV esize;
let d : integer = UInt(D::Vd);
let m : integer = UInt(M::Vm);
let regs : integer = if Q == '0' then 1 else 2;

```

T1

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0)

VCVTN{<q>}.<dt>.<dt2> <Dd>, <Dm>

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

VCVTN{<q>}.<dt>.<dt2> <Qd>, <Qm>

Decode for all variants of this encoding

```
if InITBlock() then UnpredictableProcedure(); end;
if Q == '1' && (Vd[0] == '1' || Vm[0] == '1') then Undefined(); end;
if size != '10' then Undefined(); end;
let rounding : FPRounding = FPDecodeRM(RM);
let unsigned : boolean = (op == '1');
let esize : integer() = 32;
let elements : integer = 64 DIV esize;
let d : integer = UInt(D::Vd);
let m : integer = UInt(M::Vm);
let regs : integer = if Q == '0' then 1 else 2;
```

CONSTRAINED UNPREDICTABLE behavior

If InITBlock(), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

Assembler Symbols

<q>

See [Standard assembler syntax fields](#).

<dt>

op	size	<dt>
0	01	S16
0	10	S32
1	01	U16
1	10	U32

<dt2>

Is the data type for the elements of the source vector, encoded in “size”:

size	<dt2>
01	F16
10	F32

<Dd>

Is the 64-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field.

<Dm>

Is the 64-bit name of the SIMD&FP source register, encoded in the “M:Vm” field.

<Qd>

Is the 128-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field as <Qd>*2.

<Qm>

Is the 128-bit name of the SIMD&FP source register, encoded in the “M:Vm” field as <Qm>*2.

Operation

```
EncodingSpecificOperations();  
CheckAdvSIMDEnabled();  
let fpcr : FPCR_Type = StandardFPCR();  
for r = 0 to regs-1 do  
    for e = 0 to elements-1 do  
        D(d+r)[e*:esize] = FPToFixed{esize, esize}(D(m+r)[e*:esize],  
                                                    0, unsigned, fpcr, rounding);  
    end;  
end;
```

C6.1.67 VCVTN (floating-point)

Convert floating-point to integer with Round to Nearest converts a value in a register from floating-point to a 32-bit integer using the Round to Nearest rounding mode, and places the result in a second register.

Depending on settings in the **CPACR**, **NSACR**, **HCPTR**, and **FPEXC** registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be **UNDEFINED**, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding for the Single-precision scalar variant

Applies when (size == 10)

VCVTN{<q>}.<dt>.F32 <Sd>, <Sm>

Encoding for the Double-precision scalar variant

Applies when (size == 11)

VCVTN{<q>}.<dt>.F64 <Sd>, <Dm>

Decode for all variants of this encoding

```

if size != '1x' then Undefined(); end;
let rounding : FPRounding = FPDecodeRM(RM);
let unsigned : boolean = (op == '0');
let esize : integer{} = 8 << UInt(size);
let d : integer = UInt(Vd::D);
let m : integer = if size == '1l' then UInt(M::Vm) else UInt(Vm::M);

```

T1

Encoding for the Single-precision scalar variant

Applies when (size == 10)

VCVTN{<q>}.<dt>.F32 <Sd>, <Sm>

Encoding for the Double-precision scalar variant

Applies when (size == 11)

VCVTN{<α>}.<dt>.F64 <Sd>, <Dm>

Decode for all variants of this encoding

```
if InITBlock() then UnpredictableProcedure(); end;
if size != '1x' then Undefined(); end;
let rounding : FPRounding = FPDecodeRM(RM);
let unsigned : boolean = (op == '0');
let esize : integer{} = 8 << UInt(size);
let d : integer = UInt(Vd::D);
let m : integer = if size == '11' then UInt(M::Vm) else UInt(Vm::M);
```

CONSTRAINED UNPREDICTABLE behavior

If InITBlock(), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

Assembler Symbols

<q>

case esize of
  when 32 =>
    S(d) = FPToFixed{32, 32}(S(m), 0, unsigned, fpcr, rounding);
  when 64 =>
    S(d) = FPToFixed{32, 64}(D(m), 0, unsigned, fpcr, rounding);
end;
```

C6.1.70 VCVTR

Convert floating-point to integer converts a value in a register from floating-point to a 32-bit integer, using the rounding mode specified by the [FPSCR](#) and places the result in a second register.

[VCVT \(between floating-point and fixed-point, floating-point\)](#) describes conversions between floating-point and 16-bit integers.

Depending on settings in the [CPACR](#), [NSACR](#), [HCPTR](#), and [FPEXC](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding for the Single-precision scalar variant

Applies when (opc2 == 100 && size == 10)

```
VCVTR{<c>}{<q>}.U32.F32 <Sd>, <Sm>
```

Encoding for the Single-precision scalar variant

Applies when (opc2 == 101 && size == 10)

```
VCVTR{<c>}{<q>}.S32.F32 <Sd>, <Sm>
```

Encoding for the Double-precision scalar variant

Applies when (opc2 == 100 && size == 11)

```
VCVTR{<c>}{<q>}.U32.F64 <Sd>, <Dm>
```

Encoding for the Double-precision scalar variant

Applies when (opc2 == 101 && size == 11)

```
VCVTR{<c>}{<q>}.S32.F64 <Sd>, <Dm>
```

Decode for all variants of this encoding

```
if opc2 != '000' && opc2 != '10x' then See("Related encodings"); end;
if size != '1x' then Undefined(); end;
let esize : integer{} = 8 << UInt(size);
let d : integer = if size == '11' && opc2[2] == '0' then UInt(D::Vd) else UInt(Vd::D);
let m : integer = if size == '11' && opc2[2] == '1' then UInt(M::Vm) else UInt(Vm::M);
let to_integer : boolean = (opc2[2] == '1');
let unsigned : boolean = (if to_integer then opc2[0] else op) == '0';
let zero_rounding : boolean = to_integer && op == '1';
```

CONSTRAINED UNPREDICTABLE behavior

If `size == '01'` && `cond != '1110'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

T1

Encoding for the Single-precision scalar variant

Applies when `(opc2 == 100 && size == 10)`

```
VCVTR{<c>}{<q>}.U32.F32 <Sd>, <Sm>
```

Encoding for the Single-precision scalar variant

Applies when `(opc2 == 101 && size == 10)`

```
VCVTR{<c>}{<q>}.S32.F32 <Sd>, <Sm>
```

                S(d) = FPToFixed{32, 64}(D(m), 0, unsigned, fpcr, rounding);
        end;
    else
        case esize of
            when 32 =>
                S(d) = FixedToFP{32, 32}(S(m), 0, unsigned, fpcr, rounding);
            when 64 =>
                D(d) = FixedToFP{64, 32}(S(m), 0, unsigned, fpcr, rounding);
        end;
    end;
end;
end;

```

C6.1.71 VCVTT

Convert to or from a half-precision value in the top half of a single-precision register

Convert to or from a half-precision value in the top half of a single-precision register does one of the following:

- Converts the half-precision value in the top half of a single-precision register to single-precision and writes the result to a single-precision register.
- Converts the half-precision value in the top half of a single-precision register to double-precision and writes the result to a double-precision register.
- Converts the single-precision value in a single-precision register to half-precision and writes the result into the top half of a single-precision register, preserving the other half of the destination register.
- Converts the double-precision value in a double-precision register to half-precision and writes the result into the top half of a single-precision register, preserving the other half of the destination register.

Depending on settings in the [CPACR](#), [NSACR](#), [HCPTR](#), and [FPExc](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding for the Half-precision to single-precision variant

Applies when (op == 0 && sz == 0)

VCVTT{<c>}{<q>}.F32.F16 <Sd>, <Sm>

Encoding for the Half-precision to double-precision variant

Applies when (op == 0 && sz == 1)

VCVTT{<c>}{<q>}.F64.F16 <Dd>, <Sm>

Encoding for the Single-precision to half-precision variant

Applies when (op == 1 && sz == 0)

VCVTT{<c>}{<q>}.F16.F32 <Sd>, <Sm>

Encoding for the Double-precision to half-precision variant

Applies when (op == 1 && sz == 1)

VCVTT{<c>}{<q>}.F16.F64 <Sd>, <Dm>

Decode for all variants of this encoding

```

let d : integer = if sz == '1' && op == '0' then UInt(D::Vd) else UInt(Vd::D);
let m : integer = if sz == '1' && op == '1' then UInt(M::Vm) else UInt(Vm::M);
let uses_double : boolean = (sz == '1');
let convert_from_half : boolean = (op == '0');
let lowbit : integer{} = (if T == '1' then 16 else 0);

```

T1

Encoding for the Half-precision to single-precision variant

Applies when (op == 0 && sz == 0)

VCVTT{<c>}{<q>}.F32.F16 <Sd>, <Sm>

Encoding for the Half-precision to double-precision variant

Applies when (op == 0 && sz == 1)

VCVTT{<c>}{<q>}.F64.F16 <Dd>, <Sm>

Encoding for the Single-precision to half-precision variant

Applies when (op == 1 && sz == 0)

VCVTT{<c>}{<q>}.F16.F32 <Sd>, <Sm>

Encoding for the Double-precision to half-precision variant

Applies when (op == 1 && sz == 1)

VCVTT{<c>}{<q>}.F16.F64 <Sd>, <Dm>

Decode for all variants of this encoding

```
let d : integer = if sz == '1' && op == '0' then UInt(D::Vd) else UInt(Vd::D);
let m : integer = if sz == '1' && op == '1' then UInt(M::Vm) else UInt(Vm::M);
let uses_double : boolean = (sz == '1');
let convert_from_half : boolean = (op == '0');
let lowbit : integer{} = (if T == '1' then 16 else 0);
```

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Sd>

Is the 32-bit name of the SIMD&FP destination register, encoded in the “Vd:D” field.

<Sm>

Is the 32-bit name of the SIMD&FP source register, encoded in the “Vm:M” field.

<Dd>

Is the 64-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field.

<Dm>

Is the 64-bit name of the SIMD&FP source register, encoded in the “M:Vm” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckVFPEEnabled(TRUE);
    var hp : bits(16);
    let fpcr : FPCR_Type = EffectiveFPCR();
    if convert_from_half then
        hp = S(m)[lowbit+15:lowbit];
        if uses_double then
            D(d) = FPConvert{64, 16}(hp, fpcr);
        else
            S(d) = FPConvert{32, 16}(hp, fpcr);
        end;
    else
        if uses_double then
            hp = FPConvert{16, 64}(D(m), fpcr);
        else
            hp = FPConvert{16, 32}(S(m), fpcr);
        end;
        S(d)[lowbit+15:lowbit] = hp;
    end;
end;
```

C6.1.72 VDIV

Divide divides one floating-point value by another floating-point value and writes the result to a third floating-point register.

Depending on settings in the [CPACR](#), [NSACR](#), [HCPTR](#), and [FPEXC](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding for the Single-precision scalar variant

Applies when (size == 10)

```
VDIV{<c>}{<q>}.F32 {<Sd>, }<Sn>, <Sm>
```

Encoding for the Double-precision scalar variant

Applies when (size == 11)

```
VDIV{<c>}{<q>}.F64 {<Dd>, }<Dn>, <Dm>
```

Decode for all variants of this encoding

```
if FPSCR().Len != '000' || FPSCR().Stride != '00' then Undefined(); end;
if size != '1x' then Undefined(); end;
let esize : integer{} = 8 << UInt(size);
let d : integer = if size == '11' then UInt(D::Vd) else UInt(Vd::D);
let n : integer = if size == '11' then UInt(N::Vn) else UInt(Vn::N);
let m : integer = if size == '11' then UInt(M::Vm) else UInt(Vm::M);
```

CONSTRAINED UNPREDICTABLE behavior

If size == '01' && cond != '1110', then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

T1

Encoding for the Single-precision scalar variant

Applies when (size == 10)

VDIV{<c>}{<q>}.F32 {<Sd>, }<Sn>, <Sm>

Encoding for the Double-precision scalar variant

Applies when (size == 11)

VDIV{<c>}{<q>}.F64 {<Dd>, }<Dn>, <Dm>

Decode for all variants of this encoding

```
if FPSCR().Len != '000' || FPSCR().Stride != '00' then Undefined(); end;
if size != '1x' then Undefined(); end;
let esize : integer{} = 8 << UInt(size);
let d : integer = if size == '11' then UInt(D::Vd) else UInt(Vd::D);
let n : integer = if size == '11' then UInt(N::Vn) else UInt(Vn::N);
let m : integer = if size == '11' then UInt(M::Vm) else UInt(Vm::M);
```

CONSTRAINED UNPREDICTABLE behavior

If size == '01' && InITBlock(), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Sd>

Is the 32-bit name of the SIMD&FP destination register, encoded in the “Vd:D” field.

<Sn>

Is the 32-bit name of the first SIMD&FP source register, encoded in the “Vn:N” field.

<Sm>

Is the 32-bit name of the second SIMD&FP source register, encoded in the “Vm:M” field.

<Dd>

Is the 64-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field.

<Dn>

Is the 64-bit name of the first SIMD&FP source register, encoded in the “N:Vn” field.

<Dm>

Is the 64-bit name of the second SIMD&FP source register, encoded in the “M:Vm” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckVFPEEnabled(TRUE);
    let fpcr : FPCR_Type = EffectiveFPCR();
    case esize of
        when 32 =>
            S(d) = FPDIV{32}(S(n), S(m), fpcr);
        when 64 =>
            D(d) = FPDIV{64}(D(n), D(m), fpcr);
    end;
end;
```

C6.1.73 VDUP (general-purpose register)

Duplicate general-purpose register to vector duplicates an element from a general-purpose register into every element of the destination vector.

The destination vector elements can be 8-bit, 16-bit, or 32-bit fields. The source element is the least significant 8, 16, or 32 bits of the general-purpose register. There is no distinction between data types.

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0)

```
VDUP{<c>}{<q>}.<size> <Dd>, <Rt>
```

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

```
VDUP{<c>}{<q>}.<size> <Qd>, <Rt>
```

Decode for all variants of this encoding

```
if Q == '1' && Vd[0] == '1' then Undefined(); end;
let d : integer = UInt(D::Vd);
let t : integer = UInt(Rt);
let regs : integer = if Q == '0' then 1 else 2;
if B::E == '11' then Undefined(); end;
let esize : integer{} = 32 >> UInt(B::E);
let elements : integer = 64 DIV esize;
// Armv8-A removes UNPREDICTABLE for R13
if t == 15 then UnpredictableProcedure(); end;
```

T1

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0)

```
VDUP{<c>}{<q>}.<size> <Dd>, <Rt>
```

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

```
VDUP{<c>}{<q>}.<size> <Qd>, <Rt>
```

Decode for all variants of this encoding

```
if Q == '1' && Vd[0] == '1' then Undefined(); end;
let d : integer = UInt(D::Vd);
let t : integer = UInt(Rt);
let regs : integer = if Q == '0' then 1 else 2;
if B::E == '11' then Undefined(); end;
let esize : integer{} = 32 >> UInt(B::E);
let elements : integer = 64 DIV esize;
// Armv8-A removes UNPREDICTABLE for R13
if t == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#). Arm strongly recommends that any VDUP instruction is unconditional, see [Conditional execution](#).

<q>

See [Standard assembler syntax fields](#).

<size>

The data size for the elements of the destination vector. It must be one of:

- 8** Encoded as [b, e] = 0b10.
- 16** Encoded as [b, e] = 0b01.
- 32** Encoded as [b, e] = 0b00.

<Dd>

The destination vector for a doubleword operation.

<Rt>

The Arm source register.

<Qd>

The destination vector for a quadword operation.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();
    let scalar : bits(esize) = R(t)[esize-1:0];
    for r = 0 to regs-1 do
        for e = 0 to elements-1 do
            D(d+r)[e*esize] = scalar;
        end;
    end;
end;
```

C6.1.74 VDUP (scalar)

Duplicate vector element to vector duplicates a single element of a vector into every element of the destination vector.

The scalar, and the destination vector elements, can be any one of 8-bit, 16-bit, or 32-bit fields. There is no distinction between data types.

For more information about scalars see [Advanced SIMD scalars](#).

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

Applies when (Q == 0)

VDUP{<c>}{<q>}.<size> <Dd>, <Dm[x]>

Encoding

Applies when (Q == 1)

VDUP{<c>}{<q>}.<size> <Qd>, <Dm[x]>

Decode for all variants of this encoding

```

if imm4 == 'x000' then Undefined(); end;
if Q == '1' && Vd[0] == '1' then Undefined(); end;
let lsb : integer{} = LowestSetBit(imm4[2:0]);
let esize : integer{} = 8 << lsb;
let index : integer = UInt(imm4[3:lsb+1]);
let d : integer = UInt(D::Vd);
let m : integer = UInt(M::Vm);
let elements : integer{} = 64 DIV esize;
let regs : integer = if Q == '0' then 1 else 2;

```

T1

Encoding

Applies when (Q == 0)

VDUP{<c>}{<q>}.<size> <Dd>, <Dm[x]>

Encoding

Applies when (Q == 1)

VDUP{<c>}{<q>}.<size> <Qd>, <Dm[x]>

Decode for all variants of this encoding

```
if imm4 == 'x000' then Undefined(); end;
if Q == '1' && Vd[0] == '1' then Undefined(); end;
let lsb : integer{} = LowestSetBit(imm4[2:0]);
let esize : integer{} = 8 << lsb;
let index : integer = UInt(imm4[3:lsb+1]);
let d : integer = UInt(D::Vd);
let m : integer = UInt(M::Vm);
let elements : integer{} = 64 DIV esize;
let regs : integer = if Q == '0' then 1 else 2;
```

Assembler Symbols

<c>

For the “A1 Advanced SIMD duplicate (scalar)” variant: see [Standard assembler syntax fields](#). This encoding must be unconditional.

For the “T1 Advanced SIMD duplicate (scalar)” variant: see [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<size>

The data size. It must be one of:

- 8** Encoded as imm4<0> = ‘1’. imm4<3:1> encodes the index [x] of the scalar.
- 16** Encoded as imm4<1:0> = ‘10’. imm4<3:2> encodes the index [x] of the scalar.
- 32** Encoded as imm4<2:0> = ‘100’. imm4<3> encodes the index [x] of the scalar.

<Dd>

Is the 64-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field.

<Dm[x]>

The scalar. For details of how [x] is encoded, see the description of <size>.

<Qd>

Is the 128-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field as <Qd>*2.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();
    let scalar : bits(esize) = D(m)[index*esize];
    for r = 0 to regs-1 do
        for e = 0 to elements-1 do
            D(d+r)[e*esize] = scalar;
        end;
    end;
end;
```

C6.1.75 VEOR

Vector Bitwise Exclusive-OR performs a bitwise exclusive-OR operation between two registers, and places the result in the destination register. The operand and result registers can be quadword or doubleword. They must all be the same size.

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0)

VEOR{<c>}{<q>}{.<dt>} {<Dd>, }<Dn>, <Dm>

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

VEOR{<c>}{<q>}{.<dt>} {<Qd>, }<Qn>, <Qm>

Decode for all variants of this encoding

```

if Q == '1' && (Vd[0] == '1' || Vn[0] == '1' || Vm[0] == '1') then Undefined(); end;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);
let regs : integer = if Q == '0' then 1 else 2;

```

T1

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0)

VEOR{<c>}{<q>}{.<dt>} {<Dd>, }<Dn>, <Dm>

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

VEOR{<c>}{<q>}{.<dt>} {<Qd>, }<Qn>, <Qm>

Decode for all variants of this encoding

```

if Q == '1' && (Vd[0] == '1' || Vn[0] == '1' || Vm[0] == '1') then Undefined(); end;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);
let regs : integer = if Q == '0' then 1 else 2;

```

Assembler Symbols

<c>

For the “A1 128-bit SIMD vector” and “A1 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#). This encoding must be unconditional.

For the “T1 128-bit SIMD vector” and “T1 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<dt>

An optional data type. It is ignored by assemblers, and does not affect the encoding.

<Dd>

Is the 64-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field.

<Dn>

Is the 64-bit name of the first SIMD&FP source register, encoded in the “N:Vn” field.

<Dm>

Is the 64-bit name of the second SIMD&FP source register, encoded in the “M:Vm” field.

<Qd>

Is the 128-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field as <Qd>*2.

<Qn>

Is the 128-bit name of the first SIMD&FP source register, encoded in the “N:Vn” field as <Qn>*2.

<Qm>

Is the 128-bit name of the second SIMD&FP source register, encoded in the “M:Vm” field as <Qm>*2.

Operation

```

if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();
    for r = 0 to regs-1 do
        D(d+r) = D(n+r) XOR D(m+r);
    end;
end;

```

C6.1.76 VEXT (byte elements)

Vector Extract extracts elements from the bottom end of the second operand vector and the top end of the first, concatenates them and places the result in the destination vector.

The elements of the vectors are treated as being 8-bit fields. There is no distinction between data types.

Figure C6-1 VEXT doubleword operation for imm = 3

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

This instruction is used by the pseudo-instruction [VEXT \(multibyte elements\)](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

31									23	22	21	20	19		16	15			12	11		8	7	6	5	4	3	0
1	1	1	1	0	0	1	0	1	D	1	1		Vn			Vd			imm4			N	Q	M	0		Vm	

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0)

VEXT{<c>}{<q>}.8 {<Dd>, }<Dn>, <Dm>, #<imm>

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

VEXT{<c>}{<q>}.8 {<Qd>, }<Qn>, <Qm>, #<imm>

Decode for all variants of this encoding

```
if Q == '1' && (Vd[0] == '1' || Vn[0] == '1' || Vm[0] == '1') then Undefined(); end;
if Q == '0' && imm4[3] == '1' then Undefined(); end;
let quadword_operation : boolean = (Q == '1');
let position : integer{} = 8 * UInt(imm4);
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);
```

T1

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0)

```
VEXT{<c>}{<q>}.8 {<Dd>, }<Dn>, <Dm>, #<imm>
```

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

```
VEXT{<c>}{<q>}.8 {<Qd>, }<Qn>, <Qm>, #<imm>
```

Decode for all variants of this encoding

```
if Q == '1' && (Vd[0] == '1' || Vn[0] == '1' || Vm[0] == '1') then Undefined(); end;
if Q == '0' && imm4[3] == '1' then Undefined(); end;
let quadword_operation : boolean = (Q == '1');
let position : integer{} = 8 * UInt(imm4);
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);
```

Assembler Symbols

<c>

For the “A1 128-bit SIMD vector” and “A1 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#). This encoding must be unconditional.

For the “T1 128-bit SIMD vector” and “T1 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Dd>

Is the 64-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field.

<Dn>

Is the 64-bit name of the first SIMD&FP source register, encoded in the “N:Vn” field.

<Dm>

Is the 64-bit name of the second SIMD&FP source register, encoded in the “M:Vm” field.

<imm>

For the “A1 64-bit SIMD vector” and “T1 64-bit SIMD vector” variants: is the location of the extracted result in the concatenation of the operands, as a number of bytes from the least significant end, in the range 0 to 7, encoded in the “imm4” field.

For the “A1 128-bit SIMD vector” and “T1 128-bit SIMD vector” variants: is the location of the extracted result in the concatenation of the operands, as a number of bytes from the least significant end, in the range 0 to 15, encoded in the “imm4” field.

<Qd>

Is the 128-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field as <Qd>*2.

<Qn>

Is the 128-bit name of the first SIMD&FP source register, encoded in the “N:Vn” field as <Qn>*2.

<Qm>

Is the 128-bit name of the second SIMD&FP source register, encoded in the “M:Vm” field as <Qm>*2.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();
    if quadword_operation then
        Q(d>>1) = (Q(m>>1)::Q(n>>1))[position+127:position];
    else
        D(d) = (D(m)::D(n))[position+63:position];
    end;
end;
```

C6.1.77 VEXT (multibyte elements)

Vector Extract extracts elements from the bottom end of the second operand vector and the top end of the first, concatenates them and places the result in the destination vector.

This is a pseudo-instruction of [VEXT \(byte elements\)](#). This means:

- The encodings in this description are named to match the encodings of [VEXT \(byte elements\)](#).
- The assembler syntax is used only for assembly, and is not used on disassembly.
- The description of [VEXT \(byte elements\)](#) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

31								23	22	21	20	19	16		15	12		11	8		7	6	5	4	3	0

Assembler Symbols

<c>

For the “A1 128-bit SIMD vector” and “A1 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#). This encoding must be unconditional.

For the “T1 128-bit SIMD vector” and “T1 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<size>

For the “A1 64-bit SIMD vector” and “T1 64-bit SIMD vector” variants: is the size of the operation, and can be one of 16 or 32.

For the “A1 128-bit SIMD vector” and “T1 128-bit SIMD vector” variants: is the size of the operation, and can be one of 16, 32, or 64.

<Dd>

Is the 64-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field.

<Dn>

Is the 64-bit name of the first SIMD&FP source register, encoded in the “N:Vn” field.

<Dm>

Is the 64-bit name of the second SIMD&FP source register, encoded in the “M:Vm” field.

<imm>

For the “A1 64-bit SIMD vector” and “T1 64-bit SIMD vector” variants: is the location of the extracted result in the concatenation of the operands, as a number of bytes from the least significant end, in the range 0 to $(128/<size>)-1$.

For the “A1 128-bit SIMD vector” and “T1 128-bit SIMD vector” variants: is the location of the extracted result in the concatenation of the operands, as a number of bytes from the least significant end, in the range 0 to $(64/<size>)-1$.

<Qd>

Is the 128-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field as $<Qd>*2$.

<Qn>

Is the 128-bit name of the first SIMD&FP source register, encoded in the “N:Vn” field as $<Qn>*2$.

<Qm>

Is the 128-bit name of the second SIMD&FP source register, encoded in the “M:Vm” field as $<Qm>*2$.

Operation

The description of [VEXT \(byte elements\)](#) gives the operational pseudocode for this instruction.

C6.1.78 VFMA

Vector Fused Multiply Accumulate multiplies corresponding elements of two vectors, and accumulates the results into the elements of the destination vector. The instruction does not round the result of the multiply before the accumulation.

Depending on settings in the [CPACR](#), [NSACR](#), [HCPTR](#), and [FPEXC](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#) and [A2](#)) and T32 ([T1](#) and [T2](#)).

A1

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0)

VFMA{<c>}{<q>}.<dt> <Dd>, <Dn>, <Dm>

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

VFMA{<c>}{<q>}.<dt> <Qd>, <Qn>, <Qm>

Decode for all variants of this encoding

```

if Q == '1' && (Vd[0] == '1' || Vn[0] == '1' || Vm[0] == '1') then Undefined(); end;
if sz == '1' then Undefined(); end;
let advsimd : boolean = TRUE;
let opl_neg : boolean = (op == '1');
let esize : integer{} = 32;
let elements : integer = 64 DIV esize;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);
let regs : integer = if Q == '0' then 1 else 2;

```

A2

Encoding for the Single-precision scalar variant

Applies when (size == 10)

VFMA{<c>}{<q>}.F32 <Sd>, <Sn>, <Sm>

Encoding for the Double-precision scalar variant

Applies when (size == 11)

VFMA{<c>}{<q>}.F64 <Dd>, <Dn>, <Dm>

Decode for all variants of this encoding

```
if FPSCR().Len != '000' || FPSCR().Stride != '00' then Undefined(); end;
if size != '1x' then Undefined(); end;
let advsimd : boolean = FALSE;
let opl_neg : boolean = (op == '1');
let esize : integer{} = 8 << UInt(size);
let d : integer = if size == '11' then UInt(D::Vd) else UInt(Vd::D);
let n : integer = if size == '11' then UInt(N::Vn) else UInt(Vn::N);
let m : integer = if size == '11' then UInt(M::Vm) else UInt(Vm::M);
let floating_point : boolean = ARBITRARY : boolean;
let regs : integer = ARBITRARY : integer;
let elements : integer = ARBITRARY : integer;
```

CONSTRAINED UNPREDICTABLE behavior

If size == '01' && cond != '1110', then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

T1

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0)

VFMA{<c>}{<q>}.<dt> <Dd>, <Dn>, <Dm>

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

VFMA{<c>}{<q>}.<dt> <Qd>, <Qn>, <Qm>

Decode for all variants of this encoding

```
if Q == '1' && (Vd[0] == '1' || Vn[0] == '1' || Vm[0] == '1') then Undefined(); end;
if sz == '1' then Undefined(); end;
let advsimd : boolean = TRUE;
let opl_neg : boolean = (op == '1');
let esize : integer{} = 32;
let elements : integer = 64 DIV esize;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);
let regs : integer = if Q == '0' then 1 else 2;
```

CONSTRAINED UNPREDICTABLE behavior

If `sz == '1'` && `InITBlock()`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

T2

Encoding for the Single-precision scalar variant

Applies when `(size == 10)`

`VFMA{<c>}{<q>}.F32 <Sd>, <Sn>, <Sm>`

Encoding for the Double-precision scalar variant

Applies when `(size == 11)`

`VFMA{<c>}{<q>}.F64 <Dd>, <Dn>, <Dm>`

Decode for all variants of this encoding

```

if FPSCR().Len != '000' || FPSCR().Stride != '00' then Undefined(); end;
if size != '1x' then Undefined(); end;
let advsimd : boolean = FALSE;
let opl_neg : boolean = (op == '1');
let esize : integer{} = 8 << UInt(size);
let d : integer = if size == '11' then UInt(D::Vd) else UInt(Vd::D);
let n : integer = if size == '11' then UInt(N::Vn) else UInt(Vn::N);
let m : integer = if size == '11' then UInt(M::Vm) else UInt(Vm::M);
let floating_point : boolean = ARBITRARY : boolean;
let regs : integer = ARBITRARY : integer;
let elements : integer = ARBITRARY : integer;

```

CONSTRAINED UNPREDICTABLE behavior

If `size == '01'` && `InITBlock()`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

Assembler Symbols

            S(d) = FPMulAdd{32}(FPNeg{32}(S(d), fpcr), op32, S(m), fpcr);
        when 64 =>
            let op64 : bits(64) = if op1_neg then FPNeg{64}(D(n), fpcr) else D(n);
            D(d) = FPMulAdd{64}(FPNeg{64}(D(d), fpcr), op64, D(m), fpcr);
    end;
end;
```

C6.1.81 VFNMS

Vector Fused Negate Multiply Subtract multiplies together two floating-point register values, adds the negation of the floating-point value in the destination register to the product, and writes the result back to the destination register. The instruction does not round the result of the multiply before the addition.

Depending on settings in the [CPACR](#), [NSACR](#), [HCPTR](#), and [FPEXC](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding for the Single-precision scalar variant

Applies when (size == 10)

VFNMS{<c>}{<q>}.F32 <Sd>, <Sn>, <Sm>

Encoding for the Double-precision scalar variant

Applies when (size == 11)

VFNMS{<c>}{<q>}.F64 <Dd>, <Dn>, <Dm>

Decode for all variants of this encoding

```
if FPSCR().Len != '000' || FPSCR().Stride != '00' then Undefined(); end;
if size != '1x' then Undefined(); end;
let opl_neg : boolean = (op == '1');
let esize : integer{} = 8 << UInt(size);
let d : integer = if size == '11' then UInt(D::Vd) else UInt(Vd::D);
let n : integer = if size == '11' then UInt(N::Vn) else UInt(Vn::N);
let m : integer = if size == '11' then UInt(M::Vm) else UInt(Vm::M);
```

CONSTRAINED UNPREDICTABLE behavior

If size == '01' && cond != '1110', then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

T1

Encoding for the Single-precision scalar variant

Applies when (size == 10)

VFNMS{<c>}{<q>}.F32 <Sd>, <Sn>, <Sm>

Encoding for the Double-precision scalar variant

Applies when (size == 11)

VFNMS{<c>}{<q>}.F64 <Dd>, <Dn>, <Dm>

Decode for all variants of this encoding

```
if FPSCR().Len != '000' || FPSCR().Stride != '00' then Undefined(); end;
if size != '1x' then Undefined(); end;
let opl_neg : boolean = (op == '1');
let esize : integer() = 8 << UInt(size);
let d : integer = if size == '11' then UInt(D::Vd) else UInt(Vd::D);
let n : integer = if size == '11' then UInt(N::Vn) else UInt(Vn::N);
let m : integer = if size == '11' then UInt(M::Vm) else UInt(Vm::M);
```

CONSTRAINED UNPREDICTABLE behavior

If size == '01' && InITBlock(), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Sd>

Is the 32-bit name of the SIMD&FP destination register, encoded in the “Vd:D” field.

<Sn>

Is the 32-bit name of the first SIMD&FP source register, encoded in the “Vn:N” field.

<Sm>

Is the 32-bit name of the second SIMD&FP source register, encoded in the “Vm:M” field.

<Dd>

Is the 64-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field.

<Dn>

Is the 64-bit name of the first SIMD&FP source register, encoded in the “N:Vn” field.

<Dm>

Is the 64-bit name of the second SIMD&FP source register, encoded in the “M:Vm” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckVFPEEnabled(TRUE);
    let fpcr : FPCR_Type = EffectiveFPCR();
    case esize of
        when 32 =>
            let op32 : bits(32) = if opl_neg then FPNeg{32}(S(n), fpcr) else S(n);
            S(d) = FPMulAdd{32}(FPNeg{32}(S(d), fpcr), op32, S(m), fpcr);
        when 64 =>
            let op64 : bits(64) = if opl_neg then FPNeg{64}(D(n), fpcr) else D(n);
            D(d) = FPMulAdd{64}(FPNeg{64}(D(d), fpcr), op64, D(m), fpcr);
    end;
end;
```

C6.1.82 VHADD

Vector Halving Add adds corresponding elements in two vectors of integers, shifts each result right one bit, and places the final results in the destination vector. The results of the halving operations are truncated. For rounded results, see [VRHADD](#)).

The operand and result elements are all the same type, and can be any one of:

- 8-bit, 16-bit, or 32-bit signed integers.
- 8-bit, 16-bit, or 32-bit unsigned integers.

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0)

VHADD{<c>}{<q>}.<dt> {<Dd>, }<Dn>, <Dm>

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

VHADD{<c>}{<q>}.<dt> {<Qd>, }<Qn>, <Qm>

Decode for all variants of this encoding

```

if Q == '1' && (Vd[0] == '1' || Vn[0] == '1' || Vm[0] == '1') then Undefined(); end;
if size == '11' then Undefined(); end;
let add : boolean = (op == '0');
let unsigned : boolean = (U == '1');
let esize : integer{} = 8 << UInt(size);
let elements : integer{} = 64 DIV esize;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);
let regs : integer = if Q == '0' then 1 else 2;

```

T1

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0)

VHADD{<c>}{<q>}.<dt> {<Dd>, }<Dn>, <Dm>

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

VHADD{<c>}{<q>}.<dt> {<Qd>, }<Qn>, <Qm>

Decode for all variants of this encoding

```
if Q == '1' && (Vd[0] == '1' || Vn[0] == '1' || Vm[0] == '1') then Undefined(); end;
if size == '11' then Undefined(); end;
let add : boolean = (op == '0');
let unsigned : boolean = (U == '1');
let esize : integer{} = 8 << UInt(size);
let elements : integer{} = 64 DIV esize;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);
let regs : integer = if Q == '0' then 1 else 2;
```

Assembler Symbols

<c>

For the “A1 128-bit SIMD vector” and “A1 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#). This encoding must be unconditional.

For the “T1 128-bit SIMD vector” and “T1 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<dt>

Is the data type for the elements of the operands, encoded in “U:size”:

U	size	<dt>
0	00	S8
0	01	S16
0	10	S32
1	00	U8
1	01	U16
1	10	U32

<Dd>

Is the 64-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field.

<Dn>

Is the 64-bit name of the first SIMD&FP source register, encoded in the “N:Vn” field.

<Dm>

Is the 64-bit name of the second SIMD&FP source register, encoded in the “M:Vm” field.

<Qd>

Is the 128-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field as <Qd>*2.

<Qn>

Is the 128-bit name of the first SIMD&FP source register, encoded in the “N:Vn” field as <Qn>*2.

<Qm>

Is the 128-bit name of the second SIMD&FP source register, encoded in the “M:Vm” field as <Qm>*2.

Operation

```

if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();
    for r = 0 to regs-1 do
        for e = 0 to elements-1 do
            let op1elt : bits(esize) = D(n+r)[e*:esize];
            let op2elt : bits(esize) = D(m+r)[e*:esize];
            let element1 : integer = if unsigned then UInt(op1elt) else SInt(op1elt);
            let element2 : integer = if unsigned then UInt(op2elt) else SInt(op2elt);
            let result : integer = (if add then element1+element2 else element1-element2) >> 1;
            D(d+r)[e*:esize] = result[esize-1:0];
        end;
    end;
end;

```

C6.1.83 VHSUB

Vector Halving Subtract subtracts the elements of the second operand from the corresponding elements of the first operand, shifts each result right one bit, and places the final results in the destination vector. The results of the halving operations are truncated. There is no rounding version.

The operand and result elements are all the same type, and can be any one of:

- 8-bit, 16-bit, or 32-bit signed integers.
- 8-bit, 16-bit, or 32-bit unsigned integers.

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0)

VHSUB{<c>}{<q>}.<dt> {<Dd>, }<Dn>, <Dm>

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

VHSUB{<c>}{<q>}.<dt> {<Qd>, }<Qn>, <Qm>

Decode for all variants of this encoding

```

if Q == '1' && (Vd[0] == '1' || Vn[0] == '1' || Vm[0] == '1') then Undefined(); end;
if size == '11' then Undefined(); end;
let add : boolean = (op == '0');
let unsigned : boolean = (U == '1');
let esize : integer{} = 8 << UInt(size);
let elements : integer{} = 64 DIV esize;

let m : integer = UInt(M::Vm);
let regs : integer = if Q == '0' then 1 else 2;
```

Assembler Symbols

<c>

For the “A1 128-bit SIMD vector” and “A1 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#).
This encoding must be unconditional.

For the “T1 128-bit SIMD vector” and “T1 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<dt>

Is the data type for the elements of the operands, encoded in “U:size”:

U	size	<dt>
0	00	S8
0	01	S16
0	10	S32
1	00	U8
1	01	U16
1	10	U32

<Dd>

Is the 64-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field.

<Dn>

Is the 64-bit name of the first SIMD&FP source register, encoded in the “N:Vn” field.

<Dm>

Is the 64-bit name of the second SIMD&FP source register, encoded in the “M:Vm” field.

<Qd>

Is the 128-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field as <Qd>*2.

<Qn>

Is the 128-bit name of the first SIMD&FP source register, encoded in the “N:Vn” field as <Qn>*2.

<Qm>

Is the 128-bit name of the second SIMD&FP source register, encoded in the “M:Vm” field as <Qm>*2.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();
    for r = 0 to regs-1 do
        for e = 0 to elements-1 do
            let op1elt : bits(esize) = D(n+r)[e*:esize];
            let op2elt : bits(esize) = D(m+r)[e*:esize];
            let element1 : integer = if unsigned then UInt(op1elt) else SInt(op1elt);
            let element2 : integer = if unsigned then UInt(op2elt) else SInt(op2elt);
            let result : integer = (if add then element1+element2 else element1-element2) >> 1;
            D(d+r)[e*:esize] = result[esize-1:0];
        end;
    end;
end;
```

C6.1.84 VLD1 (single element to one lane)

Load single 1-element structure to one lane of one register loads one element from memory into one element of a register. Elements of the register that are not loaded are unchanged. For details of the addressing mode, see [Advanced SIMD addressing mode](#).

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be `UNDEFINED`, or trapped to Hyp mode. For more information, see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#), [A2](#), and [A3](#)) and T32 ([T1](#), [T2](#), and [T3](#)).

A1

Encoding for the Offset variant

Applies when (Rm == 1111)

```
VLD1{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]
```

Encoding for the Post-indexed variant

Applies when (Rm == 1101)

```
VLD1{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]!
```

Encoding for the Post-indexed variant

Applies when ($R_m \neq 11 \times 1$)

VLD1{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}], <Rm>

Decode for all variants of this encoding

```

if size == '11' then See("VLD1 (single element to all lanes)"); end;
if index_align[0] != '0' then Undefined(); end;

if n == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

For the “A1 Offset”, “A1 Post-indexed”, “A2 Offset”, “A2 Post-indexed”, “A3 Offset”, and “A3 Post-indexed” variants: see [Standard assembler syntax fields](#). This encoding must be unconditional.

For the “T1 Offset”, “T1 Post-indexed”, “T2 Offset”, “T2 Post-indexed”, “T3 Offset”, and “T3 Post-indexed” variants: see [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<size>

Is the data size, encoded in “size”:

size	<size>
00	8
01	16
10	32

<list>

Is a list containing the single 64-bit name of the SIMD&FP register holding the element.

The list must be { <Dd>[<index>] }.

The register <Dd> is encoded in the “D:Vd” field.

The permitted values and encoding of <index> depend on <size>:

<size> == **8** <index> is in the range 0 to 7, encoded in the “index_align<3:1>” field.

<size> == **16** <index> is in the range 0 to 3, encoded in the “index_align<3:2>” field.

<size> == **32** <index> is 0 or 1, encoded in the “index_align<3>” field.

<Rn>

Is the general-purpose base register, encoded in the “Rn” field.

<align>

When <size> = 8, <align> must be omitted, otherwise it is the optional alignment.

Whenever <align> is omitted, the standard alignment is used, see [Unaligned data access](#), and the encoding depends on <size>:

<size> = 8 Encoded in the “index_align<0>” field as 0.
<size> = 16 Encoded in the “index_align<1:0>” field as 0b00.
<size> = 32 Encoded in the “index_align<2:0>” field as 0b000.

Whenever <align> is present, the permitted values and encoding depend on <size>:

<size> = 16 <align> is 16, meaning 16-bit alignment, encoded in the “index_align<1:0>” field as 0b01.
<size> = 32 <align> is 32, meaning 32-bit alignment, encoded in the “index_align<2:0>” field as 0b011.

: is the preferred separator before the <align> value, but the alignment can be specified as @<align>, see [Advanced SIMD addressing mode](#).

<Rm>

Is the general-purpose index register containing an offset applied after the access, encoded in the “Rm” field.

For more information about the variants of this instruction, see [Advanced SIMD addressing mode](#).

Operation

```

if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();

    let address : bits(32) = R(n);

    let nontemporal : boolean = FALSE;
    let privileged : boolean = PSTATE.EL != EL0;
    let accdesc : AccessDescriptor = CreateAccDescASIMD(MemOp_LOAD, nontemporal, privileged);
    if !IsAlignedSize(address, alignment) then
        let fault : FaultRecord = AlignmentFault(accdesc, ZeroExtend{64}(address));
        AArch32_Abort(fault);
    end;

    D(d)[index:(8*ebytes)] = MemU{8*ebytes}(address);
    if wback then
        if register_index then
            R(n) = R(n) + R(m);
        else
            R(n) = R(n) + ebytes;
        end;
    end;
end;
end;

```

C6.1.85 VLD1 (single element to all lanes)

Load single 1-element structure and replicate to all lanes of one register

Load single 1-element structure and replicate to all lanes of one register loads one element from memory into every element of one or two vectors. For details of the addressing mode, see [Advanced SIMD addressing mode](#).

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be `UNDEFINED`, or trapped to Hyp mode. For more information, see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding for the Offset variant

Applies when (Rm == 1111)

```
VLD1{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]
```

Encoding for the Post-indexed variant

Applies when (Rm == 1101)

```
VLD1{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]!
```

Encoding for the Post-indexed variant

Applies when (Rm != 11x1)

$$\text{VLD1}\{\langle c \rangle\}\{\langle g \rangle\}.\langle \text{size} \rangle \langle \text{list} \rangle, [\langle \text{Rn} \rangle\{:\langle \text{align} \rangle\}], \langle \text{Rm} \rangle$$

Decode for all variants of this encoding

```

if size == '11' || (size == '00' && a == '1') then Undefined(); end;
let ebytes : integer{} = 1 << UInt(size);
let regs : integer = if T == '0' then 1 else 2;
let alignment : integer{} = if a == '0' then 1 else ebytes;
let d : integer = UInt(D::Vd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let wback : boolean = (m != 15);
let register_index : boolean = (m != 15 && m != 13);
if n == 15 || d+regs > 32 then UnpredictableProcedure(); end;

```

CONSTRAINED UNPREDICTABLE behavior

If $d_{\text{+regs}} > 32$, then one of the following behaviors must occur:

- The instruction is **UNDEFINED**.
- The instruction executes as **NOP**.
- One or more of the SIMD and floating-point registers are **UNKNOWN**. If the instruction specifies writeback, the base register becomes **UNKNOWN**. This behavior does not affect any general-purpose registers.

T1

Encoding for the Offset variant

Applies when (Rm == 1111)

```
VLD1{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]
```

Encoding for the Post-indexed variant

Applies when (Rm == 1101)

```
VLD1{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]!
```

Encoding for the Post-indexed variant

Applies when (Rm != 11x1)

$$\text{VLD1}\{\langle c \rangle\}\{\langle q \rangle\}.\langle \text{size} \rangle \quad \langle \text{list} \rangle, \quad [\langle \text{Rn} \rangle\{:\langle \text{align} \rangle\}], \quad \langle \text{Rm} \rangle$$

Decode for all variants of this encoding

```

if size == '11' || (size == '00' && a == '1') then Undefined(); end;
let ebytes : integer{} = 1 << UInt(size);
let regs : integer = if T == '0' then 1 else 2;
let alignment : integer{} = if a == '0' then 1 else ebytes;
let d : integer = UInt(D::Vd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let wback : boolean = (m != 15);
let register_index : boolean = (m != 15 && m != 13);
if n == 15 || d+regs > 32 then UnpredictableProcedure(); end;

```

CONSTRAINED UNPREDICTABLE behavior

If $d_{\text{regs}} > 32$, then one of the following behaviors must occur:

- The instruction is `UNDEFINED`.
- The instruction executes as `NOP`.
- One or more of the SIMD and floating-point registers are `UNKNOWN`. If the instruction specifies writeback, the base register becomes `UNKNOWN`. This behavior does not affect any general-purpose registers.

For more information about the **CONSTRAINED UNPREDICTABLE** behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly **VLD1** (single element to all lanes).

Assembler Symbols

<c>

For the “A1 Offset” and “A1 Post-indexed” variants: see [Standard assembler syntax fields](#). This encoding must be unconditional.

For the “T1 Offset” and “T1 Post-indexed” variants: see [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<size>

Is the data size, encoded in “size”:

size	<size>
00	8
01	16
10	32

<list>

Is a list containing the 64-bit names of the SIMD&FP registers.

The list must be one of:

{ <Dd>[] } Encoded in the “T” field as 0.

{ <Dd>[], <Dd+1>[] } Encoded in the “T” field as 1.

The register <Dd> is encoded in the “D:Vd” field.

<Rn>

Is the general-purpose base register, encoded in the “Rn” field.

<align>

When <size> == 8, <align> must be omitted, otherwise it is the optional alignment.

Whenever <align> is omitted, the standard alignment is used, see [Unaligned data access](#), and is encoded in the “a” field as 0.

Whenever <align> is present, the permitted values and encoding depend on <size>:

<size> == 16 <align> is 16, meaning 16-bit alignment, encoded in the “a” field as 1.

<size> == 32 <align> is 32, meaning 32-bit alignment, encoded in the “a” field as 1.

: is the preferred separator before the <align> value, but the alignment can be specified as @<align>, see [Advanced SIMD addressing mode](#).

<Rm>

Is the general-purpose index register containing an offset applied after the access, encoded in the “Rm” field.

For more information about the variants of this instruction, see [Advanced SIMD addressing mode](#).

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();

    let address : bits(32) = R(n);

    let nontemporal : boolean = FALSE;
    let privileged : boolean = PSTATE.EL != ELO;
    let accdesc : AccessDescriptor = CreateAccDescASIMD(MemOp_LOAD, nontemporal, privileged);
    if !IsAlignedSize(address, alignment) then
        let fault : FaultRecord = AlignmentFault(accdesc, ZeroExtend{64}(address));
        AArch32_Abort(fault);
    end;

    let esize : integer{} = 8 * ebytes;
    let element : bits(esize) = MemU{8*ebytes}(address);
    let replicated_element : bits(64) = Replicate{}(element);
    for r = 0 to regs-1 do
        D(d+r) = replicated_element;
    end;
    if wback then
        if register_index then
            R(n) = R(n) + R(m);
        else
            R(n) = R(n) + ebytes;
        end;
    end;
end;
```

C6.1.86 VLD1 (multiple single elements)

Load multiple single 1-element structures to one, two, three, or four registers

Load multiple single 1-element structures to one, two, three, or four registers loads elements from memory into one, two, three, or four registers, without de-interleaving. Every element of each register is loaded. For details of the addressing mode, see [Advanced SIMD addressing mode](#).

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be `UNDEFINED`, or trapped to Hyp mode. For more information, see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 (A1, A2, A3, and A4) and T32 (T1, T2, T3, and T4).

A1

Encoding for the Offset variant

Applies when (Rm == 1111)

```
VLD1{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]
```

Encoding for the Post-indexed variant

Applies when (Rm == 1101)

```
VLD1{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]!
```

Encoding for the Post-indexed variant

Applies when ($R_m \neq 11 \times 1$)

VLD1{<c>}{<q>}.<size> <list>, [(<Rn>{:<align>})], <Rm>

Decode for all variants of this encoding

```

if align[1] == '1' then Undefined(); end;
let alignment : integer{} = if align == '00' then 1 else 4 << UInt(align);
let regs : integer = 1;
let ebytes : integer{} = 1 << UInt(size);
let elements : integer = 8 DIV ebytes;

```

CONSTRAINED UNPREDICTABLE behavior

If $d + \text{regs} > 32$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

T3

Encoding for the Offset variant

Applies when (Rm == 1111)

```
VLD1{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]
```

Encoding for the Post-indexed variant

Applies when (Rm == 1101)

```
VLD1{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]!
```

Encoding for the Post-indexed variant

Applies when (Rm != 11x1)

```
VLD1{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}], <Rm>
```

Decode for all variants of this encoding

```
if align[1] == '1' then Undefined(); end;
let alignment : integer{} = if align == '00' then 1 else 4 << UInt(align);
let regs : integer = 3;
let ebytes : integer{} = 1 << UInt(size);
let elements : integer = 8 DIV ebytes;
let d : integer = UInt(D::Vd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let wback : boolean = (m != 15);
let register_index : boolean = (m != 15 && m != 13);
if n == 15 || d+regs > 32 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If d+regs > 32, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

T4

Encoding for the Offset variant

Applies when (Rm == 1111)

```
VLD1{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]
```

Encoding for the Post-indexed variant

Applies when (Rm == 1101)

```
VLD1{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]!
```

Encoding for the Post-indexed variant

Applies when (Rm != 11x1)

```
VLD1{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}], <Rm>
```

Decode for all variants of this encoding

```
let regs : integer = 4;
let alignment : integer{} = if align == '00' then 1 else 4 << UInt(align);
let ebytes : integer{} = 1 << UInt(size);
let elements : integer = 8 DIV ebytes;
let d : integer = UInt(D::Vd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let wback : boolean = (m != 15);
let register_index : boolean = (m != 15 && m != 13);
if n == 15 || d+regs > 32 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `d+regs > 32`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly [VLD1 \(multiple single elements\)](#).

Related encodings: See [Advanced SIMD element or structure load/store](#) for the T32 instruction set, or [Advanced SIMD element or structure load/store](#) for the A32 instruction set.

Assembler Symbols

<c>

For the “A1 Offset”, “A1 Post-indexed”, “A2 Offset”, “A2 Post-indexed”, “A3 Offset”, “A3 Post-indexed”, “A4 Offset”, and “A4 Post-indexed” variants: see [Standard assembler syntax fields](#). This encoding must be unconditional.

For the “T1 Offset”, “T1 Post-indexed”, “T2 Offset”, “T2 Post-indexed”, “T3 Offset”, “T3 Post-indexed”, “T4 Offset”, and “T4 Post-indexed” variants: see [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<size>

Is the data size, encoded in “size”:

size	<size>
00	8
01	16
10	32
11	64

<list>

Is a list containing the 64-bit names of the SIMD&FP registers.

The list must be one of:

- { <Dd> } Single register. Selects the A1 and T1 encodings of the instruction.
- { <Dd>, <Dd+1> } Two single-spaced registers. Selects the A2 and T2 encodings of the instruction.
- { <Dd>, <Dd+1>, <Dd+2> } Three single-spaced registers. Selects the A3 and T3 encodings of the instruction.
- { <Dd>, <Dd+1>, <Dd+2>, <Dd+3> } Four single-spaced registers. Selects the A4 and T4 encodings of the instruction.

The register <Dd> is encoded in the “D:Vd” field.

<Rn>

Is the general-purpose base register, encoded in the “Rn” field.

<align>

Is the optional alignment.

Whenever <align> is omitted, the standard alignment is used, see [Unaligned data access](#), and is encoded in the “align” field as 0b00.

Whenever <align> is present, the permitted values are:

- 64** 64-bit alignment, encoded in the “align” field as 0b01.
- 128** 128-bit alignment, encoded in the “align” field as 0b10. Available only if <list> contains two or four registers.
- 256** 256-bit alignment, encoded in the “align” field as 0b11. Available only if <list> contains four registers.

: is the preferred separator before the <align> value, but the alignment can be specified as @<align>, see [Advanced SIMD addressing mode](#).

<Rm>

Is the general-purpose index register containing an offset applied after the access, encoded in the “Rm” field.

For more information about the variants of this instruction, see [Advanced SIMD addressing mode](#).

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();

    var address : bits(32) = R(n);

    let nontemporal : boolean = FALSE;
```

```

let privileged : boolean = PSTATE.EL != EL0;
let accdesc : AccessDescriptor = CreateAccDescASIMD(MemOp_LOAD, nontemporal, privileged);
if !IsAlignedSize(address, alignment) then
    let fault : FaultRecord = AlignmentFault(accdesc, ZeroExtend{64}(address));
    AArch32_Abort(fault);
end;

for r = 0 to regs-1 do
    for e = 0 to elements-1 do
        var data : bits(ebytes*8);
        if ebytes != 8 then
            data = MemU{8*ebytes}(address);
        else
            if !IsAlignedSize(address, ebytes) && AlignmentEnforced() then
                let fault : FaultRecord = AlignmentFault(accdesc, ZeroExtend{64}(address));
                AArch32_Abort(fault);
            end;

            if BigEndian(AccessType_ASIMD) then
                data[31:0] = MemU{32}(address+4);
                data[63:32] = MemU{32}(address);
            else
                data[31:0] = MemU{32}(address);
                data[63:32] = MemU{32}(address+4);
            end;
        end;

        D(d+r)[e:(8*ebytes)] = data;
        address = address + ebytes;
    end;
end;

if wback then
    if register_index then
        R(n) = R(n) + R(m);
    else
        R(n) = R(n) + 8*regs;
    end;
end;
end;

```

C6.1.87 VLD2 (single 2-element structure to one lane)

Load single 2-element structure to one lane of two registers loads one 2-element structure from memory into corresponding elements of two registers. Elements of the registers that are not loaded are unchanged. For details of the addressing mode, see [Advanced SIMD addressing mode](#).

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information, see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#), [A2](#), and [A3](#)) and T32 ([T1](#), [T2](#), and [T3](#)).

A1

Encoding for the Offset variant

Applies when (Rm == 1111)

VLD2{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]

Encoding for the Post-indexed variant

Applies when (Rm == 1101)

VLD2{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]!

Encoding for the Post-indexed variant

Applies when (Rm != 11x1)

VLD2{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}], <Rm>

Decode for all variants of this encoding

```

if size == '11' then See("VLD2 (single 2-element structure to all lanes)"); end;
let ebytes : integer{} = 1;

let wback : boolean = (m != 15);
let register_index : boolean = (m != 15 && m != 13);
if n == 15 || d2 > 31 then UnpredictableProcedure(); end;

```

CONSTRAINED UNPREDICTABLE behavior

If d2 > 31, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

A2

Encoding for the Offset variant

Applies when (Rm == 1111)

```
VLD2{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]
```

Encoding for the Post-indexed variant

Applies when (Rm == 1101)

```
VLD2{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]!
```

Encoding for the Post-indexed variant

Applies when (Rm != 11x1)

```
VLD2{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}], <Rm>
```

Decode for all variants of this encoding

```
if size == '11' then See("VLD2 (single 2-element structure to all lanes)"); end;
let ebytes : integer{} = 2;
let index : integer = UInt(index_align[3:2]);
let inc : integer = if index_align[1] == '0' then 1 else 2;
let alignment : integer{} = if index_align[0] == '0' then 1 else 4;
let d : integer = UInt(D::Vd);
let d2 : integer = d + inc;
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let wback : boolean = (m != 15);
let register_index : boolean = (m != 15 && m != 13);
if n == 15 || d2 > 31 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If d2 > 31, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

A3

Encoding for the Offset variant

Applies when (Rm == 1111)

```
VLD2{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]
```

Encoding for the Post-indexed variant

Applies when (Rm == 1101)

```
VLD2{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]!
```

Encoding for the Post-indexed variant

Applies when (Rm != 11x1)

```
VLD2{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}], <Rm>
```

Decode for all variants of this encoding

```
if size == '11' then See("VLD2 (single 2-element structure to all lanes)"); end;

```

CONSTRAINED UNPREDICTABLE behavior

If d2 > 31, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly [VLD2 \(single 2-element structure to one lane\)](#).

Assembler Symbols

<c>

For the “A1 Offset”, “A1 Post-indexed”, “A2 Offset”, “A2 Post-indexed”, “A3 Offset”, and “A3 Post-indexed” variants: see [Standard assembler syntax fields](#). This encoding must be unconditional.

For the “T1 Offset”, “T1 Post-indexed”, “T2 Offset”, “T2 Post-indexed”, “T3 Offset”, and “T3 Post-indexed” variants: see [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<size>

Is the data size, encoded in “size”:

size	<size>
00	8
01	16
10	32

<list>

Is a list containing the 64-bit names of the two SIMD&FP registers holding the element.

The list must be one of:

{ <Dd>[<index>], <Dd+1>[<index>] } Single-spaced registers, encoded as “spacing” = 0.
{ <Dd>[<index>], <Dd+2>[<index>] } Double-spaced registers, encoded as “spacing” = 1. Not permitted when <size> = 8.

The encoding of “spacing” depends on <size>:

<size> = 16 “spacing” is encoded in the “index_align<1>” field.
<size> = 32 “spacing” is encoded in the “index_align<2>” field.

The register <Dd> is encoded in the “D:Vd” field.

The permitted values and encoding of <index> depend on <size>:

<size> = 8 <index> is in the range 0 to 7, encoded in the “index_align<3:1>” field.
<size> = 16 <index> is in the range 0 to 3, encoded in the “index_align<3:2>” field.
<size> = 32 <index> is 0 or 1, encoded in the “index_align<3>” field.

<Rn>

Is the general-purpose base register, encoded in the “Rn” field.

<align>

Is the optional alignment.

Whenever <align> is omitted, the standard alignment is used, see [Unaligned data access](#), and the encoding depends on <size>:

<size> = 8 Encoded in the “index_align<0>” field as 0.
<size> = 16 Encoded in the “index_align<0>” field as 0.
<size> = 32 Encoded in the “index_align<1:0>” field as 0b00.

Whenever <align> is present, the permitted values and encoding depend on <size>:

$\langle \text{size} \rangle == 8$ $\langle \text{align} \rangle$ is 16, meaning 16-bit alignment, encoded in the “index_align<0>” field as 1.
 $\langle \text{size} \rangle == 16$ $\langle \text{align} \rangle$ is 32, meaning 32-bit alignment, encoded in the “index_align<0>” field as 1.
 $\langle \text{size} \rangle == 32$ $\langle \text{align} \rangle$ is 64, meaning 64-bit alignment, encoded in the “index_align<1:0>” field as 0b01.

: is the preferred separator before the $\langle \text{align} \rangle$ value, but the alignment can be specified as @ $\langle \text{align} \rangle$, see [Advanced SIMD addressing mode](#).

<Rm>

Is the general-purpose index register containing an offset applied after the access, encoded in the “Rm” field.

For more information about the variants of this instruction, see [Advanced SIMD addressing mode](#).

Operation

```

if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();

    let address : bits(32) = R(n);

    let nontemporal : boolean = FALSE;
    let privileged : boolean = PSTATE.EL != EL0;
    let accdesc : AccessDescriptor = CreateAccDescASIMD(MemOp_LOAD, nontemporal, privileged);
    if !IsAlignedSize(address, alignment) then
        let fault : FaultRecord = AlignmentFault(accdesc, ZeroExtend{64}(address));
        AArch32_Abort(fault);
    end;

    D(d)[index*:(8*bytes)] = MemU{8*bytes}(address);
    D(d2)[index*:(8*bytes)] = MemU{8*bytes}(address+bytes);
    if wback then
        if register_index then
            R(n) = R(n) + R(m);
        else
            R(n) = R(n) + 2*bytes;
        end;
    end;
end;
end;

```

C6.1.88 VLD2 (single 2-element structure to all lanes)

Load single 2-element structure and replicate to all lanes of two registers

Load single 2-element structure and replicate to all lanes of two registers loads one 2-element structure from memory into all lanes of two registers. For details of the addressing mode, see [Advanced SIMD addressing mode](#).

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be `UNDEFINED`, or trapped to Hyp mode. For more information, see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding for the Offset variant

Applies when (Rm == 1111)

VLD2{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]

Encoding for the Post-indexed variant

Applies when (Rm == 1101)

```
VLD2{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]!
```

Encoding for the Post-indexed variant

Applies when ($R_m \neq 11 \times 1$)

VLD2{<c>}{<q>}.<size> <list>, [**<Rn>**{:<align>}], <Rm>

Decode for all variants of this encoding

```

if size == '11' then Undefined(); end;
let ebytes : integer{} = 1 << UInt(size);
let alignment : integer{} = if a == '0' then 1 else 2*ebytes;
let inc : integer = if T == '0' then 1 else 2;
let d : integer = UInt(D::Vd);
let d2 : integer = d + inc;
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let wback : boolean = (m != 15);
let register_index : boolean = (m != 15 && m != 13);
if n == 15 || d2 > 31 then UnpredictableProcedure(); end;

```

CONSTRAINED UNPREDICTABLE behavior

If $d_2 > 31$, then one of the following behaviors must occur:

- The instruction is `UNDEFINED`.
- The instruction executes as `NOP`.
- One or more of the SIMD and floating-point registers are `UNKNOWN`. If the instruction specifies writeback, the base register becomes `UNKNOWN`. This behavior does not affect any general-purpose registers.

T1

Encoding for the Offset variant

Applies when (Rm == 1111)

```
VLD2{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]
```

Encoding for the Post-indexed variant

Applies when (Rm == 1101)

```
VLD2{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]!
```

Encoding for the Post-indexed variant

Applies when (Rm != 11x1)

$$\text{VLD2}\{\langle c \rangle\}\{\langle q \rangle\}.\langle \text{size} \rangle \quad \langle \text{list} \rangle, \quad [\langle \text{Rn} \rangle\{:\langle \text{align} \rangle\}], \quad \langle \text{Rm} \rangle$$

Decode for all variants of this encoding

```

if size == '11' then Undefined(); end;
let ebytes : integer{} = 1 << UInt(size);
let alignment : integer{} = if a == '0' then 1 else 2*ebytes;
let inc : integer = if T == '0' then 1 else 2;
let d : integer = UInt(D::Vd);
let d2 : integer = d + inc;
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let wback : boolean = (m != 15);
let register_index : boolean = (m != 15 && m != 13);
if n == 15 || d2 > 31 then UnpredictableProcedure(); end;

```

CONSTRAINED UNPREDICTABLE behavior

If $d_2 > 31$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

For more information about the **CONSTRAINED UNPREDICTABLE** behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly **VLD2** (single 2-element structure to all lanes).

Assembler Symbols

<c>

For the “A1 Offset” and “A1 Post-indexed” variants: see [Standard assembler syntax fields](#). This encoding must be unconditional.

For the “T1 Offset” and “T1 Post-indexed” variants: see [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<size>

Is the data size, encoded in “size”:

size	<size>
00	8
01	16
10	32

<list>

Is a list containing the 64-bit names of two SIMD&FP registers.

The list must be one of:

{ <Dd>[], <Dd+1>[] } Single-spaced registers, encoded in the “T” field as 0.

{ <Dd>[], <Dd+2>[] } Double-spaced registers, encoded in the “T” field as 1.

The register <Dd> is encoded in the “D:Vd” field.

<Rn>

Is the general-purpose base register, encoded in the “Rn” field.

<align>

Is the optional alignment.

Whenever <align> is omitted, the standard alignment is used, see [Unaligned data access](#), and is encoded in the “a” field as 0.

Whenever <align> is present, the permitted values and encoding depend on <size>:

<size> == 8 <align> is 16, meaning 16-bit alignment, encoded in the “a” field as 1.

<size> == 16 <align> is 32, meaning 32-bit alignment, encoded in the “a” field as 1.

<size> == 32 <align> is 64, meaning 64-bit alignment, encoded in the “a” field as 1.

: is the preferred separator before the <align> value, but the alignment can be specified as @<align>, see [Advanced SIMD addressing mode](#).

<Rm>

Is the general-purpose index register containing an offset applied after the access, encoded in the “Rm” field.

For more information about the variants of this instruction, see [Advanced SIMD addressing mode](#).

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();

    let address : bits(32) = R(n);

    let nontemporal : boolean = FALSE;
    let privileged : boolean = PSTATE.EL != EL0;
    let accdesc : AccessDescriptor = CreateAccDescASIMD(MemOp_LOAD, nontemporal, privileged);
    if !IsAlignedSize(address, alignment) then
        let fault : FaultRecord = AlignmentFault(accdesc, ZeroExtend{64}(address));
        AArch32_Abort(fault);
    end;

    let esize : integer{} = 8 * ebytes;
    let element1 : bits(esize) = MemU{8*ebytes}(address);
    let element2 : bits(esize) = MemU{8*ebytes}(address+ebytes);
    D(d) = Replicate{64}(element1);
    D(d2) = Replicate{64}(element2);

    if wback then
        if register_index then
            R(n) = R(n) + R(m);
        else
            R(n) = R(n) + 2*ebytes;
        end;
    end;
end;
```

C6.1.89 VLD2 (multiple 2-element structures)

Load multiple 2-element structures to two or four registers loads multiple 2-element structures from memory into two or four registers, with de-interleaving. For more information, see [Element and structure load/store instructions](#). Every element of each register is loaded. For details of the addressing mode, see [Advanced SIMD addressing mode](#).

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information, see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#) and [A2](#)) and T32 ([T1](#) and [T2](#)).

A1

Encoding for the Offset variant

Applies when (Rm == 1111)

VLD2{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]

Encoding for the Post-indexed variant

Applies when (Rm == 1101)

VLD2{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]!

Encoding for the Post-indexed variant

Applies when (Rm != 11x1)

VLD2{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}], <Rm>

Decode for all variants of this encoding

```

if align == '11' then Undefined(); end;

```

CONSTRAINED UNPREDICTABLE behavior

If d2+pairs > 32, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly [VLD2 \(multiple 2-element structures\)](#).

Related encodings: See [Advanced SIMD element or structure load/store](#) for the T32 instruction set, or [Advanced SIMD element or structure load/store](#) for the A32 instruction set.

Assembler Symbols

<c>

For the “A1 Offset”, “A1 Post-indexed”, “A2 Offset”, and “A2 Post-indexed” variants: see [Standard assembler syntax fields](#). This encoding must be unconditional.

For the “T1 Offset”, “T1 Post-indexed”, “T2 Offset”, and “T2 Post-indexed” variants: see [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<size>

Is the data size, encoded in “size”:

size	<size>
00	8
01	16
10	32

<list>

Is a list containing the 64-bit names of the SIMD&FP registers.

The list must be one of:

- { <Dd>, <Dd+1> } Two single-spaced registers. Selects the A1 and T1 encodings of the instruction, and encoded in the “itype” field as 0b1000.
- { <Dd>, <Dd+2> } Two double-spaced registers. Selects the A1 and T1 encodings of the instruction, and encoded in the “itype” field as 0b1001.
- { <Dd>, <Dd+1>, <Dd+2>, <Dd+3> } Three single-spaced registers. Selects the A2 and T2 encodings of the instruction.

The register <Dd> is encoded in the “D:Vd” field.

<Rn>

Is the general-purpose base register, encoded in the “Rn” field.

<align>

Is the optional alignment.

Whenever <align> is omitted, the standard alignment is used, see [Unaligned data access](#), and is encoded in the “align” field as 0b00.

Whenever <align> is present, the permitted values are:

- 64** 64-bit alignment, encoded in the “align” field as 0b01.
- 128** 128-bit alignment, encoded in the “align” field as 0b10.
- 256** 256-bit alignment, encoded in the “align” field as 0b11. Available only if <list> contains four registers.

: is the preferred separator before the <align> value, but the alignment can be specified as @<align>, see [Advanced SIMD addressing mode](#).

<Rm>

Is the general-purpose index register containing an offset applied after the access, encoded in the “Rm” field.

For more information about the variants of this instruction, see [Advanced SIMD addressing mode](#).

Operation

```

if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();

    var address : bits(32) = R(n);

    let nontemporal : boolean = FALSE;
    let privileged : boolean = PSTATE.EL != EL0;
    let accdesc : AccessDescriptor = CreateAccDescASIMD(MemOp_LOAD, nontemporal, privileged);
    if !IsAlignedSize(address, alignment) then
        let fault : FaultRecord = AlignmentFault(accdesc, ZeroExtend{64}(address));
        AArch32_Abort(fault);
    end;

    for r = 0 to pairs-1 do
        for e = 0 to elements-1 do
            D(d+r)[e:(8*ebytes)] = MemU{8*ebytes}(address);
            D(d2+r)[e:(8*ebytes)] = MemU{8*ebytes}(address+ebytes);
            address = address + 2*ebytes;
        end;
    end;

    if wback then
        if register_index then
            R(n) = R(n) + R(m);
        else
            R(n) = R(n) + 16*pairs;
        end;
    end;
end;

```

C6.1.90 VLD3 (single 3-element structure to one lane)

Load single 3-element structure to one lane of three registers loads one 3-element structure from memory into corresponding elements of three registers. Elements of the registers that are not loaded are unchanged. For details of the addressing mode, see [Advanced SIMD addressing mode](#).

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information, see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#), [A2](#), and [A3](#)) and T32 ([T1](#), [T2](#), and [T3](#)).

A1

Encoding for the Offset variant

Applies when (Rm == 1111)

VLD3{<c>}{<q>}.<size> <list>, [<Rn>]

Encoding for the Post-indexed variant

Applies when (Rm == 1101)

VLD3{<c>}{<q>}.<size> <list>, [<Rn>]!

Encoding for the Post-indexed variant

Applies when (Rm != 11x1)

VLD3{<c>}{<q>}.<size> <list>, [<Rn>], <Rm>

Decode for all variants of this encoding

```

if size == '11' then See("VLD3 (single 3-element structure to all lanes)"); end;
if index_align[0] != '0' then Undefined(); end;
let ebytes : integer{} = 1;
let index : integer = UInt(index_align[3:1]);
let inc : integer = 1;
let d : integer = UInt(D::Vd);
let d2 : integer = d + inc;
let d3 : integer = d2 + inc;

```

CONSTRAINED UNPREDICTABLE behavior

If d3 > 31, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly [VLD3 \(single 3-element structure to one lane\)](#).

Assembler Symbols

<c>

For the “A1 Offset”, “A1 Post-indexed”, “A2 Offset”, “A2 Post-indexed”, “A3 Offset”, and “A3 Post-indexed” variants: see [Standard assembler syntax fields](#). This encoding must be unconditional.

For the “T1 Offset”, “T1 Post-indexed”, “T2 Offset”, “T2 Post-indexed”, “T3 Offset”, and “T3 Post-indexed” variants: see [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<size>

Is the data size, encoded in “size”:

size	<size>
00	8
01	16
10	32

<list>

Is a list containing the 64-bit names of the three SIMD&FP registers holding the element.

The list must be one of:

{ <Dd>[<index>], <Dd+1>[<index>], <Dd+2>[<index>] } Single-spaced registers, encoded as “spacing” = 0.

{ <Dd>[<index>], <Dd+2>[<index>], <Dd+4>[<index>] } Double-spaced registers, encoded as “spacing” = 1. Not permitted when <size> == 8.

The encoding of “spacing” depends on <size>:

<size> == 8 “spacing” is encoded in the “index_align<0>” field.

<size> == 16 “spacing” is encoded in the “index_align<1>” field, and “index_align<0>” is set to 0.

<size> == 32 “spacing” is encoded in the “index_align<2>” field, and “index_align<1:0>” is set to 0b00.

The register <Dd> is encoded in the “D:Vd” field.

The permitted values and encoding of <index> depend on <size>:

<size> == 8 <index> is in the range 0 to 7, encoded in the “index_align<3:1>” field.

<size> == 16 <index> is in the range 0 to 3, encoded in the “index_align<3:2>” field.

<size> == 32 <index> is 0 or 1, encoded in the “index_align<3>” field.

<Rn>

Is the general-purpose base register, encoded in the “Rn” field.

<Rm>

Is the general-purpose index register containing an offset applied after the access, encoded in the “Rm” field.

For more information about the variants of this instruction, see [Advanced SIMD addressing mode](#).

Alignment

Standard alignment rules apply, see Alignment support.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();
    let address : bits(32) = R(n);
    D(d)[index*:(8*ebytes)] = MemU{8*ebytes}(address);
    D(d2)[index*:(8*ebytes)] = MemU{8*ebytes}(address+ebytes);
    D(d3)[index*:(8*ebytes)] = MemU{8*ebytes}(address+2*ebytes);
    if wback then
        if register_index then
            R(n) = R(n) + R(m);
        else
            R(n) = R(n) + 3*ebytes;
        end;
    end;
end;
```

C6.1.91 VLD3 (single 3-element structure to all lanes)

Load single 3-element structure and replicate to all lanes of three registers

Load single 3-element structure and replicate to all lanes of three registers loads one 3-element structure from memory into all lanes of three registers. For details of the addressing mode, see [Advanced SIMD addressing mode](#).

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be `UNDEFINED`, or trapped to Hyp mode. For more information, see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding for the Offset variant

Applies when (Rm == 1111)

VLD3{<c>} {<q>}.<size> <list>, [<Rn>]

Encoding for the Post-indexed variant

Applies when (Rm == 1101)

```
VLD3{<c>}{<q>}.<size> <list>, [<Rn>]!
```

Encoding for the Post-indexed variant

Applies when (Rm != 11x1)

Assembler Symbols

<c>

For the “A1 Offset” and “A1 Post-indexed” variants: see [Standard assembler syntax fields](#). This encoding must be unconditional.

For the “T1 Offset” and “T1 Post-indexed” variants: see [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<size>

Is the data size, encoded in “size”:

size	<size>
00	8
01	16
10	32

<list>

Is a list containing the 64-bit names of three SIMD&FP registers.

The list must be one of:

{ <Dd>[], <Dd+1>[], <Dd+2>[] } Single-spaced registers, encoded in the “T” field as 0.

{ <Dd>[], <Dd+2>[], <Dd+4>[] } Double-spaced registers, encoded in the “T” field as 1.

The register <Dd> is encoded in the “D:Vd” field.

<Rn>

Is the general-purpose base register, encoded in the “Rn” field.

<Rm>

Is the general-purpose index register containing an offset applied after the access, encoded in the “Rm” field.

For more information about the variants of this instruction, see [Advanced SIMD addressing mode](#).

Alignment

Standard alignment rules apply, see Alignment support.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();
    let address : bits(32) = R(n);
    let esize : integer{} = ebytes * 8;
    let element1 : bits(esize) = MemU{8*ebytes}(address);
    let element2 : bits(esize) = MemU{8*ebytes}(address+ebytes);
    let element3 : bits(esize) = MemU{8*ebytes}(address+2*ebytes);

    D(d) = Replicate{64}(element1);
    D(d2) = Replicate{64}(element2);
    D(d3) = Replicate{64}(element3);
    if wback then
        if register_index then
```

```
        R(n) = R(n) + R(m);  
    else  
        R(n) = R(n) + 3*ebytes;  
    end;  
end;  
end;
```

C6.1.92 VLD3 (multiple 3-element structures)

Load multiple 3-element structures to three registers loads multiple 3-element structures from memory into three registers, with de-interleaving. For more information, see [Element and structure load/store instructions](#). Every element of each register is loaded. For details of the addressing mode, see [Advanced SIMD addressing mode](#).

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be `UNDEFINED`, or trapped to Hyp mode. For more information, see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding for the Offset variant

Applies when (Rm == 1111)

VLD3{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]

Encoding for the Post-indexed variant

Applies when (Rm == 1101)

```
VLD3{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]!
```

Encoding for the Post-indexed variant

Applies when (Rm != 11x1)

VLD3{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}], <Rm>

Decode for all variants of this encoding

```

if itype != '010x' then See("Related encodings"); end;
if size == '11' || align[1] == '1' then Undefined(); end;

let wback : boolean = (m != 15);
let register_index : boolean = (m != 15 && m != 13);
if n == 15 || d3 > 31 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If d3 > 31, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly [VLD3 \(multiple 3-element structures\)](#).

Related encodings: See [Advanced SIMD element or structure load/store](#) for the T32 instruction set, or [Advanced SIMD element or structure load/store](#) for the A32 instruction set.

Assembler Symbols

<c>

For the “A1 Offset” and “A1 Post-indexed” variants: see [Standard assembler syntax fields](#). This encoding must be unconditional.

For the “T1 Offset” and “T1 Post-indexed” variants: see [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<size>

Is the data size, encoded in “size”:

size	<size>
00	8
01	16
10	32

<list>

Is a list containing the 64-bit names of the SIMD&FP registers.

The list must be one of:

- { <Dd>, <Dd+1>, <Dd+2> } Single-spaced registers, encoded in the “itype” field as 0b0100.
- { <Dd>, <Dd+2>, <Dd+4> } Double-spaced registers, encoded in the “itype” field as 0b0101.

The register <Dd> is encoded in the “D:Vd” field.

<Rn>

Is the general-purpose base register, encoded in the “Rn” field.

<align>

Is the optional alignment.

Whenever <align> is omitted, the standard alignment is used, see [Unaligned data access](#), and is encoded in the “align” field as 0b00.

Whenever <align> is present, the only permitted values is 64, meaning 64-bit alignment, encoded in the “align” field as 0b01.

: is the preferred separator before the <align> value, but the alignment can be specified as @<align>, see [Advanced SIMD addressing mode](#).

<Rm>

Is the general-purpose index register containing an offset applied after the access, encoded in the “Rm” field.

For more information about <Rn>, !, and <Rm>, see [Advanced SIMD addressing mode](#).

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();

var address : bits(32) = R(n);
```

```
let nontemporal : boolean = FALSE;
let privileged : boolean = PSTATE.EL != ELO;
let accdesc : AccessDescriptor = CreateAccDescASIMD(MemOp_LOAD, nontemporal, privileged);
if !IsAlignedSize(address, alignment) then
    let fault : FaultRecord = AlignmentFault(accdesc, ZeroExtend{64}(address));
    AArch32_Abort(fault);
end;

for e = 0 to elements-1 do
    D(d)[e:(8*bytes)] = MemU{8*bytes}(address);
    D(d2)[e:(8*bytes)] = MemU{8*bytes}(address+bytes);
    D(d3)[e:(8*bytes)] = MemU{8*bytes}(address+2*bytes);
    address = address + 3*bytes;
end;

if wback then
    if register_index then
        R(n) = R(n) + R(m);
    else
        R(n) = R(n) + 24;
    end;
end;
end;
```

C6.1.93 VLD4 (single 4-element structure to one lane)

Load single 4-element structure to one lane of four registers loads one 4-element structure from memory into corresponding elements of four registers. Elements of the registers that are not loaded are unchanged. For details of the addressing mode, see [Advanced SIMD addressing mode](#).

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information, see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#), [A2](#), and [A3](#)) and T32 ([T1](#), [T2](#), and [T3](#)).

A1

Encoding for the Offset variant

Applies when (Rm == 1111)

VLD4{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]

Encoding for the Post-indexed variant

Applies when (Rm == 1101)

VLD4{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]!

Encoding for the Post-indexed variant

Applies when (Rm != 11x1)

VLD4{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}], <Rm>

Decode for all variants of this encoding

```

if size == '11' then See("VLD4 (single 4-element structure to all lanes)"); end;
let ebytes : integer{} = 1;
let index : integer = UInt(index_align[3:1]);
let inc : integer = 1;
let alignment : integer{} = if index_align[0] == '0' then 1 else 4;
let d : integer = UInt(D::Vd);
let d2 : integer = d + inc;
let d3 : integer = d2 + inc;
let d4 : integer = d3 + inc;
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let wback : boolean = (m != 15);
let register_index : boolean = (m != 15 && m != 13);
if n == 15 || d4 > 31 then UnpredictableProcedure(); end;

```

CONSTRAINED UNPREDICTABLE behavior

If d4 > 31, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

A2

Encoding for the Offset variant

Applies when (Rm == 1111)

```
VLD4{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]
```

Encoding for the Post-indexed variant

Applies when (Rm == 1101)

```
VLD4{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]!
```

Encoding for the Post-indexed variant

Applies when (Rm != 11x1)

```
VLD4{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}], <Rm>
```

Decode for all variants of this encoding

```
if size == '11' then See("VLD4 (single 4-element structure to all lanes)"); end;

let wback : boolean = (m != 15);
let register_index : boolean = (m != 15 && m != 13);
if n == 15 || d4 > 31 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If d4 > 31, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly [VLD4 \(single 4-element structure to one lane\)](#).

Assembler Symbols

<c>

For the “A1 Offset”, “A1 Post-indexed”, “A2 Offset”, “A2 Post-indexed”, “A3 Offset”, and “A3 Post-indexed” variants: see [Standard assembler syntax fields](#). This encoding must be unconditional.

For the “T1 Offset”, “T1 Post-indexed”, “T2 Offset”, “T2 Post-indexed”, “T3 Offset”, and “T3 Post-indexed” variants: see [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<size>

Is the data size, encoded in “size”:

size	<size>
00	8
01	16
10	32

<list>

Is a list containing the 64-bit names of the four SIMD&FP registers holding the element.

The list must be one of:

{ <Dd>[<index>], <Dd+1>[<index>], <Dd+2>[<index>], <Dd+3>[<index>] } Single-spaced registers, encoded as “spacing” = 0.

{ <Dd>[<index>], <Dd+2>[<index>], <Dd+4>[<index>], <Dd+6>[<index>] } Double-spaced registers, encoded as “spacing” = 1. Not permitted when <size> == 8.

The encoding of “spacing” depends on <size>:

<size> == 16 “spacing” is encoded in the “index_align<1>” field.

<size> == 32 “spacing” is encoded in the “index_align<2>” field.

The register <Dd> is encoded in the “D:Vd” field.

The permitted values and encoding of <index> depend on <size>:

<size> == 8 <index> is in the range 0 to 7, encoded in the “index_align<3:1>” field.

<size> == 16 <index> is in the range 0 to 3, encoded in the “index_align<3:2>” field.

<size> == 32 <index> is 0 or 1, encoded in the “index_align<3>” field.

<Rn>

Is the general-purpose base register, encoded in the “Rn” field.

<align>

Is the optional alignment.

Whenever <align> is omitted, the standard alignment is used, see [Unaligned data access](#), and the encoding depends on <size>:

<size> == 8 Encoded in the “index_align<0>” field as 0.

<size> == 16 Encoded in the “index_align<0>” field as 0.

<size> == 32 Encoded in the “index_align<1:0>” field as 0b00.

Whenever <align> is present, the permitted values and encoding depend on <size>:

$\langle \text{size} \rangle == 8$ $\langle \text{align} \rangle$ is 32, meaning 32-bit alignment, encoded in the “index_align<0>” field as 1.
 $\langle \text{size} \rangle == 16$ $\langle \text{align} \rangle$ is 64, meaning 64-bit alignment, encoded in the “index_align<0>” field as 1.
 $\langle \text{size} \rangle == 32$ $\langle \text{align} \rangle$ can be 64 or 128. 64-bit alignment is encoded in the “index_align<1:0>” field as 0b01,
and 128-bit alignment is encoded in the “index_align<1:0>” field as 0b10.

: is the preferred separator before the $\langle \text{align} \rangle$ value, but the alignment can be specified as @ $\langle \text{align} \rangle$, see [Advanced SIMD addressing mode](#).

<Rm>

Is the general-purpose index register containing an offset applied after the access, encoded in the “Rm” field.

For more information about the variants of this instruction, see [Advanced SIMD addressing mode](#).

Operation

```

if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();

    let address : bits(32) = R(n);

    let nontemporal : boolean = FALSE;
    let privileged : boolean = PSTATE.EL != EL0;
    let accdesc : AccessDescriptor = CreateAccDescASIMD(MemOp_LOAD, nontemporal, privileged);
    if !IsAlignedSize(address, alignment) then
        let fault : FaultRecord = AlignmentFault(accdesc, ZeroExtend{64}(address));
        AArch32_Abort(fault);
    end;

    D(d)[index*:(8*abytes)] = MemU{8*abytes}(address);
    D(d2)[index*:(8*abytes)] = MemU{8*abytes}(address+abytes);
    D(d3)[index*:(8*abytes)] = MemU{8*abytes}(address+2*abytes);
    D(d4)[index*:(8*abytes)] = MemU{8*abytes}(address+3*abytes);
    if wback then
        if register_index then
            R(n) = R(n) + R(m);
        else
            R(n) = R(n) + 4*abytes;
        end;
    end;
end;
end;

```

C6.1.94 VLD4 (single 4-element structure to all lanes)

Load single 4-element structure and replicate to all lanes of four registers

Load single 4-element structure and replicate to all lanes of four registers loads one 4-element structure from memory into all lanes of four registers. For details of the addressing mode, see [Advanced SIMD addressing mode](#).

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be `UNDEFINED`, or trapped to Hyp mode. For more information, see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 (A1) and T32 (T1).

A1

Encoding for the Offset variant

Applies when (Rm == 1111)

VLD4{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]

Encoding for the Post-indexed variant

Applies when (Rm == 1101)

```
VLD4{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]!
```

Encoding for the Post-indexed variant

Applies when (Rm != 11x1)

VLD4{<c>}{<q>}.<size> <list>, [**<Rn>**:{<align>}], <Rm>

Decode for all variants of this encoding

```

if size == '11' && a == '0' then Undefined(); end;
let ebytes : integer{} = if size == '11' then 4 else 1 << UInt(size);
let alignment : integer{} = (if a == '0' && size != '11' then 1
                             else 4 << (UInt(size[1]) + UInt(size[0])));
let inc : integer = if T == '0' then 1 else 2;
let d : integer = UInt(D::Vd);
let d2 : integer = d + inc;
let d3 : integer = d2 + inc;
let d4 : integer = d3 + inc;
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let wback : boolean = (m != 15);
let register_index : boolean = (m != 15 && m != 13);
if n == 15 || d4 > 31 then UnpredictableProcedure(); end;

```

CONSTRAINED UNPREDICTABLE behavior

If $d_4 > 31$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

T1

Encoding for the Offset variant

Applies when (Rm == 1111)

```
VLD4{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]
```

Encoding for the Post-indexed variant

Applies when (Rm == 1101)

```
VLD4{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]!
```

Encoding for the Post-indexed variant

Applies when (Rm != 11x1)

```
VLD4{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}], <Rm>
```

Decode for all variants of this encoding

```
if size == '11' && a == '0' then Undefined(); end;
let ebytes : integer{} = if size == '11' then 4 else 1 << UInt(size);
let alignment : integer{} = (if a == '0' && size != '11' then 1
                             else 4 << (UInt(size[1]) + UInt(size[0])));
let inc : integer = if T == '0' then 1 else 2;
let d : integer = UInt(D::Vd);
let d2 : integer = d + inc;
let d3 : integer = d2 + inc;
let d4 : integer = d3 + inc;
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let wback : boolean = (m != 15);
let register_index : boolean = (m != 15 && m != 13);
if n == 15 || d4 > 31 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If d4 > 31, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly [VLD4 \(single 4-element structure to all lanes\)](#).

Assembler Symbols

<c>

For the “A1 Offset” and “A1 Post-indexed” variants: see [Standard assembler syntax fields](#). This encoding must be unconditional.

For the “T1 Offset” and “T1 Post-indexed” variants: see [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<size>

Is the data size, encoded in “size”:

size	<size>
00	8
01	16
1x	32

<list>

Is a list containing the 64-bit names of four SIMD&FP registers.

The list must be one of:

{ <Dd>[], <Dd+1>[], <Dd+2>[], <Dd+3>[] } Single-spaced registers, encoded in the “T” field as 0.

{ <Dd>[], <Dd+2>[], <Dd+4>[], <Dd+6>[] } Double-spaced registers, encoded in the “T” field as 1.

The register <Dd> is encoded in the “D:Vd” field.

<Rn>

Is the general-purpose base register, encoded in the “Rn” field.

<align>

Is the optional alignment.

Whenever <align> is omitted, the standard alignment is used, see [Unaligned data access](#), and is encoded in the “a” field as 0.

Whenever <align> is present, the permitted values and encoding depend on <size>:

<size> == 8 <align> is 32, meaning 32-bit alignment, encoded in the “a” field as 1.

<size> == 16 <align> is 64, meaning 64-bit alignment, encoded in the “a” field as 1.

<size> == 32 <align> can be 64 or 128. 64-bit alignment is encoded in the “a:size<0>” field as 0b10, and 128-bit alignment is encoded in the “a:size<0>” field as 0b11.

: is the preferred separator before the <align> value, but the alignment can be specified as @<align>, see [Advanced SIMD addressing mode](#).

<Rm>

Is the general-purpose index register containing an offset applied after the access, encoded in the “Rm” field.

For more information about the variants of this instruction, see [Advanced SIMD addressing mode](#).

Operation

```

if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();

    let address : bits(32) = R(n);

    let nontemporal : boolean = FALSE;
    let privileged : boolean = PSTATE.EL != EL0;
    let accdesc : AccessDescriptor = CreateAccDescASIMD(MemOp_LOAD, nontemporal, privileged);
    if !IsAlignedSize(address, alignment) then
        let fault : FaultRecord = AlignmentFault(accdesc, ZeroExtend{64}(address));
        AArch32_Abort(fault);
    end;

    let esize : integer{} = ebytes * 8;
    let element1 : bits(esize) = MemU{8*ebytes}(address);
    let element2 : bits(esize) = MemU{8*ebytes}(address+ebytes);
    let element3 : bits(esize) = MemU{8*ebytes}(address+2*ebytes);
    let element4 : bits(esize) = MemU{8*ebytes}(address+3*ebytes);
    D(d) = Replicate{64}(element1);
    D(d2) = Replicate{64}(element2);
    D(d3) = Replicate{64}(element3);
    D(d4) = Replicate{64}(element4);
    if wback then
        if register_index then
            R(n) = R(n) + R(m);
        else
            R(n) = R(n) + 4*ebytes;
        end;
    end;
end;
end;

```

C6.1.95 VLD4 (multiple 4-element structures)

Load multiple 4-element structures to four registers loads multiple 4-element structures from memory into four registers, with de-interleaving. For more information, see [Element and structure load/store instructions](#). Every element of each register is loaded. For details of the addressing mode, see [Advanced SIMD addressing mode](#).

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be `UNDEFINED`, or trapped to Hyp mode. For more information, see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding for the Offset variant

Applies when (Rm == 1111)

```
VLD4{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]
```

Encoding for the Post-indexed variant

Applies when (Rm == 1101)

VLD4{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]!

Encoding for the Post-indexed variant

Applies when ($R_m \neq 11 \times 1$)

VLD4{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}], <Rm>

Decode for all variants of this encoding

```

if itype != '000x' then See("Related encodings"); end;
if size == '11' then Undefined(); end;
let inc : integer = if itype[0] == '0' then 1 else 2;
let alignment : integer{} = if align == '00' then 1 else 4 << UInt(align);
let ebytes : integer{} = 1 << UInt(size);
let elements : integer = 8 DIV ebytes;
let d : integer = UInt(D::Vd);
let d2 : integer = d + inc;
let d3 : integer = d2 + inc;
let d4 : integer = d3 + inc;
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let wback : boolean = (m != 15);
let register_index : boolean = (m != 15 && m != 13);
if n == 15 || d4 > 31 then UnpredictableProcedure(); end;

```

CONSTRAINED UNPREDICTABLE behavior

If $d4 > 31$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

T1

Encoding for the Offset variant

Applies when $(Rm == 1111)$

```
VLD4{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]
```

Encoding for the Post-indexed variant

Applies when $(Rm == 1101)$

```
VLD4{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]!
```

Encoding for the Post-indexed variant

Applies when $(Rm != 11x1)$

```
VLD4{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}], <Rm>
```

Decode for all variants of this encoding

```
if itype != '000x' then See("Related encodings"); end;
if size == '11' then Undefined(); end;
let inc : integer = if itype[0] == '0' then 1 else 2;
let alignment : integer{} = if align == '00' then 1 else 4 << UInt(align);
let ebytes : integer{} = 1 << UInt(size);
let elements : integer = 8 DIV ebytes;
let d : integer = UInt(D::Vd);
let d2 : integer = d + inc;
let d3 : integer = d2 + inc;
let d4 : integer = d3 + inc;
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let wback : boolean = (m != 15);
let register_index : boolean = (m != 15 && m != 13);
if n == 15 || d4 > 31 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `d4 > 31`, then one of the following behaviors must occur:

- The instruction is `UNDEFINED`.
- The instruction executes as `NOP`.
- One or more of the SIMD and floating-point registers are `UNKNOWN`. If the instruction specifies writeback, the base register becomes `UNKNOWN`. This behavior does not affect any general-purpose registers.

For more information about the `CONSTRAINED UNPREDICTABLE` behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly [VLD4 \(multiple 4-element structures\)](#).

Related encodings: See [Advanced SIMD element or structure load/store](#) for the T32 instruction set, or [Advanced SIMD element or structure load/store](#) for the A32 instruction set.

Assembler Symbols

<c>

For the “A1 Offset” and “A1 Post-indexed” variants: see [Standard assembler syntax fields](#). This encoding must be unconditional.

For the “T1 Offset” and “T1 Post-indexed” variants: see [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<size>

Is the data size, encoded in “size”:

size	<size>
00	8
01	16
10	32

<list>

Is a list containing the 64-bit names of the SIMD&FP registers.

The list must be one of:

- { `<Dd>`, `<Dd+1>`, `<Dd+2>`, `<Dd+3>` } Single-spaced registers, encoded in the “itype” field as `0b0000`.
- { `<Dd>`, `<Dd+2>`, `<Dd+4>`, `<Dd+6>` } Double-spaced registers, encoded in the “itype” field as `0b0001`.

The register `<Dd>` is encoded in the “D:Vd” field.

<Rn>

Is the general-purpose base register, encoded in the “Rn” field.

<align>

Is the optional alignment.

Whenever `<align>` is omitted, the standard alignment is used, see [Unaligned data access](#), and is encoded in the “align” field as `0b00`.

Whenever `<align>` is present, the permitted values are:

- 64** 64-bit alignment, encoded in the “align” field as 0b01.
- 128** 128-bit alignment, encoded in the “align” field as 0b10.
- 256** 256-bit alignment, encoded in the “align” field as 0b11.

: is the preferred separator before the <align> value, but the alignment can be specified as @<align>, see [Advanced SIMD addressing mode](#).

<Rm>

Is the general-purpose index register containing an offset applied after the access, encoded in the “Rm” field.

For more information about the variants of this instruction, see [Advanced SIMD addressing mode](#).

Operation

```

if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();

    var address : bits(32) = R(n);

    let nontemporal : boolean = FALSE;
    let privileged : boolean = PSTATE.EL != EL0;
    let accdesc : AccessDescriptor = CreateAccDescASIMD(MemOp_LOAD, nontemporal, privileged);
    if !IsAlignedSize(address, alignment) then
        let fault : FaultRecord = AlignmentFault(accdesc, ZeroExtend{64}(address));
        AArch32_Abort(fault);
    end;

    for e = 0 to elements-1 do
        D(d)[e:(8*bytes)] = MemU{8*bytes}(address);
        D(d2)[e:(8*bytes)] = MemU{8*bytes}(address+bytes);
        D(d3)[e:(8*bytes)] = MemU{8*bytes}(address+2*bytes);
        D(d4)[e:(8*bytes)] = MemU{8*bytes}(address+3*bytes);
        address = address + 4*bytes;
    end;

    if wback then
        if register_index then
            R(n) = R(n) + R(m);
        else
            R(n) = R(n) + 32;
        end;
    end;
end;

```

C6.1.96 VLDM, VLDMDB, VLDMIA

Load Multiple SIMD&FP registers loads multiple registers from consecutive locations in the Advanced SIMD and floating-point register file using an address from a general-purpose register.

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information, see [Enabling Advanced SIMD and floating-point support](#).

This instruction is used by the alias [VPOP](#).

It has encodings from the following instruction sets: A32 ([A1](#) and [A2](#)) and T32 ([T1](#) and [T2](#)).

A1

Encoding for the Decrement Before variant

Applies when (P == 1 && U == 0 && W == 1)

```
VLDMDB{<c>}{<q>}{.<size>} <Rn>!, <dreglist>
```

Encoding for the Increment After variant

Applies when (P == 0 && U == 1)

```
VLDM{<c>}{<q>}{.<size>} <Rn>{!}, <dreglist> // (Preferred syntax)
```

```
VLDMIA{<c>}{<q>}{.<size>} <Rn>{!}, <dreglist>
```

Decode for all variants of this encoding

```
if P == '0' && U == '0' && W == '0' then See("Related encodings"); end;
if P == '1' && W == '0' then See("VLDR"); end;
if P == U && W == '1' then Undefined(); end;
// Remaining combinations are PUW = 010 (IA without !), 011 (IA with !), 101 (DB with !)
let single_regs : boolean = FALSE;
let add : boolean = (U == '1');
let wback : boolean = (W == '1');
let d : integer = UInt(D::Vd);
let n : integer = UInt(Rn);
let imm32 : bits(32) = ZeroExtend{(imm8::'00')};
let regs : integer = UInt(imm8) DIVRM 2; // If UInt(imm8) is odd, see "FLDM*X".
if n == 15 && (wback || CurrentInstrSet() != InstrSet_A32) then UnpredictableProcedure(); end;
if regs == 0 || regs > 16 || (d+regs) > 32 then UnpredictableProcedure(); end;
if imm8[0] == '1' && (d+regs) > 16 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If regs == 0, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction operates as a VLDM with the same addressing mode but loads no registers.

If regs > 16 || (d+regs) > 32, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

A2

Encoding for the Decrement Before variant

Applies when (P == 1 && U == 0 && W == 1)

```
VLDMDB{<c>}{<q>}{.<size>} <Rn>!, <sreglist>
```

Encoding for the Increment After variant

Applies when (P == 0 && U == 1)

```
VLDM{<c>}{<q>}{.<size>} <Rn>{!}, <sreglist> // (Preferred syntax)
```

```
VLDMIA{<c>}{<q>}{.<size>} <Rn>{!}, <sreglist>
```

Decode for all variants of this encoding

```
if P == '0' && U == '0' && W == '0' then See("Related encodings"); end;
if P == '1' && W == '0' then See("VLDR"); end;
if P == U && W == '1' then Undefined(); end;
// Remaining combinations are PUW = 010 (IA without !), 011 (IA with !), 101 (DB with !)
let single_regs : boolean = TRUE;
let add : boolean = (U == '1');
let wback : boolean = (W == '1');
let d : integer = UInt(Vd::D);
let n : integer = UInt(Rn);
let imm32 : bits(32) = ZeroExtend{(imm8::'00')};
let regs : integer = UInt(imm8);
if n == 15 && (wback || CurrentInstrSet() != InstrSet_A32) then UnpredictableProcedure(); end;
if regs == 0 || (d+regs) > 32 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If regs == 0, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction operates as a VLDM with the same addressing mode but loads no registers.

If (d+regs) > 32, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

T1

Encoding for the Decrement Before variant

Applies when (P == 1 && U == 0 && W == 1)

```
VLDMDB{<c>}{<q>}{.<size>} <Rn>!, <dreglist>
```

Encoding for the Increment After variant

Applies when (P == 0 && U == 1)

```
VLDM{<c>}{<q>}{.<size>} <Rn>{!}, <dreglist> // (Preferred syntax)
```

```
VLDmia{<c>}{<q>}{.<size>} <Rn>{!}, <dreglist>
```

Decode for all variants of this encoding

```

if P == '0' && U == '0' && W == '0' then See("Related encodings"); end;
if P == '1' && W == '0' then See("VLDR"); end;
if P == U && W == '1' then Undefined(); end;
// Remaining combinations are PUW = 010 (IA without !), 011 (IA with !), 101 (DB with !)
let single_regs : boolean = FALSE;
let add : boolean = (U == '1');
let wback : boolean = (W == '1');
let d : integer = UInt(D::Vd);
let n : integer = UInt(Rn);
let imm32 : bits(32) = ZeroExtend{}(imm8::'00');
let regs : integer = UInt(imm8) DIVRM 2; // If UInt(imm8) is odd, see "FLDM*X".
if n == 15 && (wback || CurrentInstrSet() != InstrSet_A32) then UnpredictableProcedure(); end;
if regs == 0 || regs > 16 || (d+regs) > 32 then UnpredictableProcedure(); end;
if imm8[0] == '1' && (d+regs) > 16 then UnpredictableProcedure(); end;

```

CONSTRAINED UNPREDICTABLE behavior

If `reqs == 0`, then one of the following behaviors must occur:

- The instruction is **UNDEFINED**.
- The instruction executes as **NOP**.
- The instruction operates as a **VLDM** with the same addressing mode but loads no registers.

If $\text{regs} > 16 \ || \ (\text{d+regs}) > 32$, then one of the following behaviors must occur:

- The instruction is `UNDEFINED`.
- The instruction executes as `NOP`.
- One or more of the SIMD and floating-point registers are `UNKNOWN`. If the instruction specifies writeback, the base register becomes `UNKNOWN`. This behavior does not affect any general-purpose registers.

T2

Encoding for the Decrement Before variant

Applies when (P == 1 && U == 0 && W == 1)

```
VLDMDB{<c>}{<q>}{.<size>} <Rn>!, <sreglist>
```

Encoding for the Increment After variant

Applies when (P == 0 && U == 1)

```
VLDM{<c>}{<q>}{.<size>} <Rn>{!}, <sreglist> // (Preferred syntax)
```

```
VLDmia{<c>}{<q>}{.<size>} <Rn>{!}, <sreglist>
```

Decode for all variants of this encoding

```

if P == '0' && U == '0' && W == '0' then See("Related encodings"); end;
if P == '1' && W == '0' then See("VLDR"); end;
if P == U && W == '1' then Undefined(); end;
// Remaining combinations are PUW = 010 (IA without !), 011 (IA with !), 101 (DB with !)
let single_regs : boolean = TRUE;
let add : boolean = (U == '1');
let wback : boolean = (W == '1');
let d : integer = UInt(Vd:D);
let n : integer = UInt(Rn);
let imm32 : bits(32) = ZeroExtend{}(imm8::'00');
let regs : integer = UInt(imm8);
if n == 15 && (wback || CurrentInstrSet() != InstrSet_A32) then UnpredictableProcedure(); end;
if regs == 0 || (dregs) > 32 then UnpredictableProcedure(); end;

```

CONSTRAINED UNPREDICTABLE behavior

If `regs == 0`, then one of the following behaviors must occur:

- The instruction is **UNDEFINED**.
- The instruction executes as **NOP**.
- The instruction operates as a **VLDM** with the same addressing mode but loads no registers.

If $(d + \text{regs}) > 32$, then one of the following behaviors must occur:

- The instruction is **UNDEFINED**.
- The instruction executes as **NOP**.
- One or more of the SIMD and floating-point registers are **UNKNOWN**. If the instruction specifies writeback, the base register becomes **UNKNOWN**. This behavior does not affect any general-purpose registers.

For more information about the **CONSTRAINED UNPREDICTABLE** behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly [VLDM](#).

Related encodings: See [Advanced SIMD and floating-point 64-bit move](#) for the T32 instruction set, or [Advanced SIMD and floating-point 64-bit move](#) for the A32 instruction set.

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<size>

An optional data size specifier. If present, it must be equal to the size in bits, 32 or 64, of the registers being transferred.

<Rn>

Is the general-purpose base register, encoded in the “Rn” field. If writeback is not specified, the PC can be used.

<dreglist>

Is the list of consecutively numbered 64-bit SIMD&FP registers to be transferred. The first register in the list is encoded in “D:Vd”, and “imm8” is set to twice the number of registers in the list. The list must contain at least one register, and must not contain more than 16 registers.

!

Specifies base register writeback, encoded in “W”:

W	!
0	[absent]
1	[present]

<sreglist>

Is the list of consecutively numbered 32-bit SIMD&FP registers to be transferred. The first register in the list is encoded in “Vd:D”, and “imm8” is set to the number of registers in the list. The list must contain at least one register.

Alias Conditions

Alias	Is preferred when
VPOP	P == '0' && U == '1' && W == '1' && Rn == '1101'

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckVFPEEnabled(TRUE);
    var address : bits(32) = if add then R(n) else R(n)-imm32;

    for r = 0 to regs-1 do
        if single_regs then
            S(d+r) = MemA{32}(address);
            address = address+4;
        else
```

```
    let word1 : bits(32) = MemA{32}(address);
    let word2 : bits(32) = MemA{32}(address+4);
    address = address+8;

    // Combine the word-aligned words in the correct order for current endianness.
    D(d+r) = if BigEndian(AccessType_ASIMD) then word1::word2 else word2::word1;
end;

end;

if wback then R(n) = if add then R(n)+imm32 else R(n)-imm32; end;
end;
```

C6.1.97 VLDR (immediate)

Load SIMD&FP register (immediate) loads a single register from the Advanced SIMD and floating-point register file, using an address from a general-purpose register, with an optional offset.

Depending on settings in the [CPACR](#), [NSACR](#), [HCPTR](#), and [FPEXC](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information, see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding for the Single-precision scalar variant

Applies when (size == 10)

```
VLDR{<c>}{<q>}{.32} <Sd>, [<Rn> {, #(+/-)<imm>}]
```

Encoding for the Double-precision scalar variant

Applies when (size == 11)

```
VLDR{<c>}{<q>}{.64} <Dd>, [<Rn> {, #(+/-)<imm>}]
```

Decode for all variants of this encoding

```
if size != '1x' then Undefined(); end;
let add : boolean = (U == '1');
let esize : integer{} = 8 << UInt(size);
let imm32 : integer = UInt(imm8) << (if size == '01' then 1 else 2);
let d : integer = if size == '11' then UInt(D::Vd) else UInt(Vd::D);
let n : integer = UInt(Rn);
```

CONSTRAINED UNPREDICTABLE behavior

If size == '01' && cond != '1110', then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

T1

Encoding for the Single-precision scalar variant

Applies when (size == 10)

```
VLDLDR{<c>}{<q>}{.32} <Sd>, [<Rn> {, #(+/-)<imm>}]
```

Encoding for the Double-precision scalar variant

Applies when (size == 11)

```
VLDLDR{<c>}{<q>}{.64} <Dd>, [<Rn> {, #(+/-)<imm>}]
```

Decode for all variants of this encoding

```
if size != 'lx' then Undefined(); end;
let add : boolean = (U == '1');
let esize : integer{} = 8 << UInt(size);
let imm32 : integer = UInt(imm8) << (if size == '01' then 1 else 2);
let d : integer = if size == '11' then UInt(D::Vd) else UInt(Vd::D);
let n : integer = UInt(Rn);
```

CONSTRAINED UNPREDICTABLE behavior

If size == '01' && InITBlock(), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

.32

Is an optional data size specifier for 32-bit memory accesses that can be used in the assembler source code, but is otherwise ignored.

<Sd>

Is the 32-bit name of the SIMD&FP destination register, encoded in the “Vd:D” field.

<Rn>

Is the general-purpose base register, encoded in the “Rn” field.

+/-

Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in “U”:

U	+/-
0	–
1	+

<imm>

is the optional unsigned immediate byte offset, a multiple of 4, in the range 0 to 1020, defaulting to 0, and encoded in the “imm8” field as <imm>/4.

.64

Is an optional data size specifier for 64-bit memory accesses that can be used in the assembler source code, but is otherwise ignored.

<Dd>

Is the 64-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckVFPEnabled(TRUE);
    let base : bits(32) = if n == 15 then AlignDownSize(PC32(),4) else R(n);
    let address : bits(32) = if add then (base + imm32) else (base - imm32);
    case esize of
        when 32 =>
            S(d) = MemA{32}(address);
        when 64 =>
            let word1 : bits(32) = MemA{32}(address);
            let word2 : bits(32) = MemA{32}(address+4);
            // Combine the word-aligned words in the correct order for current endianness.
            D(d) = if BigEndian(AccessType_ASIMD) then word1::word2 else word2::word1;
    end;
end;
```

C6.1.98 VLDR (literal)

Load SIMD&FP register (literal) loads a single register from the Advanced SIMD and floating-point register file, using an address from the PC value and an immediate offset.

Depending on settings in the **CPACR**, **NSACR**, **HCPTR**, and **FPEXC** registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be **UNDEFINED**, or trapped to Hyp mode. For more information, see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding for the Single-precision scalar variant

Applies when (size == 10)

```
VLDR{<c>}{<q>}{.32} <Sd>, <label> // (Preferred syntax)
```

```
VLDR{<c>}{<q>}{.32} <Sd>, [PC, # {+/-}<imm>]
```

Encoding for the Double-precision scalar variant

Applies when (size == 11)

```
VLDR{<c>}{<q>}{.64} <Dd>, <label> // (Preferred syntax)
```

```
VLDR{<c>}{<q>}{.64} <Dd>, [PC, # {+/-}<imm>]
```

Decode for all variants of this encoding

```
if size != '1x' then Undefined(); end;
let add : boolean = (U == '1');
let esize : integer{} = 8 << UInt(size);
let imm32 : integer = UInt(imm8) << (if size == '01' then 1 else 2);
let d : integer = if size == '11' then UInt(D::Vd) else UInt(Vd::D);
let n : integer = UInt(Rn);
```

CONSTRAINED UNPREDICTABLE behavior

If `size == '01' && cond != '1110'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

T1

Encoding for the Single-precision scalar variant

Applies when (size == 10)

```
VLDR{<c>}{<q>}{.32} <Sd>, <label> // (Preferred syntax)
```

```
VLDR{<c>}{<q>}{.32} <Sd>, [PC, # {+/-}<imm>]
```

Encoding for the Double-precision scalar variant

Applies when (size == 11)

```
VLDR{<c>}{<q>}{.64} <Dd>, <label> // (Preferred syntax)
```

```
VLDR{<c>}{<q>}{.64} <Dd>, [PC, # {+/-}<imm>]
```

Decode for all variants of this encoding

```
if size != '1x' then Undefined(); end;
let add : boolean = (U == '1');
let esize : integer{} = 8 << UInt(size);
let imm32 : integer = UInt(imm8) << (if size == '01' then 1 else 2);
let d : integer = if size == '11' then UInt(D::Vd) else UInt(Vd::D);
let n : integer = UInt(Rn);
```

CONSTRAINED UNPREDICTABLE behavior

If `size == '01' && InITBlock()`, then one of the following behaviors must occur:

- The instruction is **UNDEFINED**.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as **NOP**. This means it behaves as if it fails the Condition code check.

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

 $\langle q \rangle$

See [Standard assembler syntax fields](#).

.32

Is an optional data size specifier for 32-bit memory accesses that can be used in the assembler source code, but is otherwise ignored.

<Sd>

Is the 32-bit name of the SIMD&FP destination register, encoded in the “Vd:D” field.

<label>

The label of the literal data item to be loaded.

For the single-precision scalar or double-precision scalar variants: the assembler calculates the required value of the offset from the Align(PC, 4) value of the instruction to this label. Permitted values are multiples of 4 in the range -1020 to 1020.

For the half-precision scalar variant: the assembler calculates the required value of the offset from the Align(PC, 4) value of the instruction to this label. Permitted values are multiples of 2 in the range -510 to 510.

If the offset is zero or positive, imm32 is equal to the offset and add == TRUE.

If the offset is negative, imm32 is equal to minus the offset and add == FALSE.

+/-

Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in “U”:

U	+/-
0	-
1	+

<imm>

is the optional unsigned immediate byte offset, a multiple of 4, in the range 0 to 1020, defaulting to 0, and encoded in the “imm8” field as <imm>/4.

.64

Is an optional data size specifier for 64-bit memory accesses that can be used in the assembler source code, but is otherwise ignored.

<Dd>

Is the 64-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field.

The alternative syntax permits the addition or subtraction of the offset and the immediate offset to be specified separately, including permitting a subtraction of 0 that cannot be specified using the normal syntax. For more information, see [Use of labels in UAL instruction syntax](#).

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckVFPEEnabled(TRUE);
    let base : bits(32) = if n == 15 then AlignDownSize(PC32(),4) else R(n);
    let address : bits(32) = if add then (base + imm32) else (base - imm32);
    case esize of
        when 32 =>
            S(d) = MemA{32}(address);
        when 64 =>
            let word1 : bits(32) = MemA{32}(address);
            let word2 : bits(32) = MemA{32}(address+4);
            // Combine the word-aligned words in the correct order for current endianness.
            D(d) = if BigEndian(AccessType_ASIMD) then word1::word2 else word2::word1;
    end;
end;
```

C6.1.99 VMAX (floating-point)

Vector Maximum (floating-point)

Vector Maximum compares corresponding elements in two vectors, and copies the larger of each pair into the corresponding element in the destination vector.

The operand vector elements are floating-point numbers.

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0)

VMAX{<c>}{<q>}.<dt> {<Dd>, }<Dn>, <Dm>

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

VMAX{<c>}{<q>}.<dt> {<Qd>, }<Qn>, <Qm>

Decode for all variants of this encoding

```

if Q == '1' && (Vd[0] == '1' || Vn[0] == '1' || Vm[0] == '1') then Undefined(); end;
if sz == '1' then Undefined(); end;
let maximum : boolean = (op == '0');
let esize : integer = 32;
let elements : integer = 64 DIV esize;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);
let regs : integer = if Q == '0' then 1 else 2;

```

T1

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0)

VMAX{<c>}{<q>}.<dt> {<Dd>, }<Dn>, <Dm>

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

VMAX{<c>}{<q>}.<dt> {<Qd>, <Qn>, <Qm>}

Decode for all variants of this encoding

```
if Q == '1' && (Vd[0] == '1' || Vn[0] == '1' || Vm[0] == '1') then Undefined(); end;
if sz == '1' then Undefined(); end;
let maximum : boolean = (op == '0');
let esize : integer{} = 32; let elements : integer{} = 2;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);
let regs : integer = if Q == '0' then 1 else 2;
```

CONSTRAINED UNPREDICTABLE behavior

If sz == '1' && InITBlock(), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

Assembler Symbols

<c>

For the “A1 128-bit SIMD vector” and “A1 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#). This encoding must be unconditional.

For the “T1 128-bit SIMD vector” and “T1 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<dt>

Is the data type for the elements of the vectors, encoded in “sz”:

sz	<dt>
0	F32
1	F16

<Dd>

Is the 64-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field.

<Dn>

Is the 64-bit name of the first SIMD&FP source register, encoded in the “N:Vn” field.

<Dm>

Is the 64-bit name of the second SIMD&FP source register, encoded in the “M:Vm” field.

<Qd>

Is the 128-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field as <Qd>*2.

<Qn>

Is the 128-bit name of the first SIMD&FP source register, encoded in the “N:Vn” field as <Qn>*2.

<Qm>

Is the 128-bit name of the second SIMD&FP source register, encoded in the “M:Vm” field as <Qm>*2.

Floating-point maximum and minimum

- $\max(+0.0, -0.0) = +0.0$
- If any input is a NaN, the corresponding result element is the default NaN.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();
    let fpcr : FPCR_Type = StandardFPCR();
    for r = 0 to regs-1 do
        for e = 0 to elements-1 do
            let op1 : bits(esize) = D(n+r)[e*:esize];
            let op2 : bits(esize) = D(m+r)[e*:esize];
            if maximum then
                D(d+r)[e*:esize] = FPMax{esize}(op1, op2, fpcr);
            else
                D(d+r)[e*:esize] = FPMin{esize}(op1, op2, fpcr);
            end;
        end;
    end;
end;
end;
```

C6.1.100 VMAX (integer)

Vector Maximum (integer)

Vector Maximum compares corresponding elements in two vectors, and copies the larger of each pair into the corresponding element in the destination vector.

The operand vector elements can be any one of:

- 8-bit, 16-bit, or 32-bit signed integers.
- 8-bit, 16-bit, or 32-bit unsigned integers.

The result vector elements are the same size as the operand vector elements.

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0)

VMAX{<c>}{<q>}.<dt> {<Dd>, }<Dn>, <Dm>

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

VMAX{<c>}{<q>}.<dt> {<Qd>, }<Qn>, <Qm>

Decode for all variants of this encoding

```

if Q == '1' && (Vd[0] == '1' || Vn[0] == '1' || Vm[0] == '1') then Undefined(); end;
if size == '11' then Undefined(); end;
let maximum : boolean = (op == '0');
let unsigned : boolean = (U == '1');
let esize : integer{} = 8 << UInt(size);
let elements : integer = 64 DIV esize;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);
let regs : integer = if Q == '0' then 1 else 2;

```

T1

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0)

VMAX{<c>}{<q>}.<dt> {<Dd>, }<Dn>, <Dm>

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

VMAX{<c>}{<q>}.<dt> {<Qd>, }<Qn>, <Qm>

Decode for all variants of this encoding

```
if Q == '1' && (Vd[0] == '1' || Vn[0] == '1' || Vm[0] == '1') then Undefined(); end;
if size == '11' then Undefined(); end;
let maximum : boolean = (op == '0');
let unsigned : boolean = (U == '1');
let esize : integer{} = 8 << UInt(size);
let elements : integer = 64 DIV esize;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);
let regs : integer = if Q == '0' then 1 else 2;
```

Assembler Symbols

<c>

For the “A1 128-bit SIMD vector” and “A1 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#). This encoding must be unconditional.

For the “T1 128-bit SIMD vector” and “T1 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<dt>

Is the data type for the elements of the operands, encoded in “U:size”:

U	size	<dt>
0	00	S8
0	01	S16
0	10	S32
1	00	U8
1	01	U16
1	10	U32

<Dd>

Is the 64-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field.

<Dn>

Is the 64-bit name of the first SIMD&FP source register, encoded in the “N:Vn” field.

<Dm>

Is the 64-bit name of the second SIMD&FP source register, encoded in the “M:Vm” field.

<Qd>

Is the 128-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field as <Qd>*2.

<Qn>

Is the 128-bit name of the first SIMD&FP source register, encoded in the “N:Vn” field as <Qn>*2.

<Qm>

Is the 128-bit name of the second SIMD&FP source register, encoded in the “M:Vm” field as <Qm>*2.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();
    for r = 0 to regs-1 do
        for e = 0 to elements-1 do
            let op1elt : bits(esize) = D(n+r)[e*:esize];
            let op2elt : bits(esize) = D(m+r)[e*:esize];
            let element1 : integer = if unsigned then UInt(op1elt) else SInt(op1elt);
            let element2 : integer = if unsigned then UInt(op2elt) else SInt(op2elt);
            let result : integer = (if maximum then Max(element1, element2)
                                   else Min(element1, element2));
            D(d+r)[e*:esize] = result[esize-1:0];
        end;
    end;
end;
```

C6.1.101 **VMAXNM**

Floating-point Maximum Number

This instruction determines the floating-point maximum number.

It handles NaNs in consistence with the IEEE 754-2008 specification. It returns the numerical operand when one operand is numerical and the other is a quiet NaN, but otherwise the result is identical to floating-point `VMAX`.

This instruction is not conditional.

It has encodings from the following instruction sets: A32 (A1 and A2) and T32 (T1 and T2).

A1

Encoding for the 64-bit SIMD vector variant

Applies when ($Q == 0$)

VMAXNM{ <q> } .<dt> <Dd> , <Dn> , <Dm>

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

$$\text{VMAXNM}\{\langle q \rangle\}.\langle dt \rangle \quad \langle Qd \rangle, \langle Qn \rangle, \langle Qm \rangle$$
Decode for all variants of this encoding

```

if Q == '1' && (Vd[0] == '1' || Vn[0] == '1' || Vm[0] == '1') then Undefined(); end;
if sz == '1' then Undefined(); end;
let maximum : boolean = (op == '0');
let advsimd : boolean = TRUE;
let esize : integer{} = 32;
let elements : integer = 64 DIV esize;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);
let regs : integer = if Q == '0' then 1 else 2;

```

A2

Encoding for the Single-precision scalar variant

Applies when (size == 10)

```
VMAXNM{<q>}.F32 <Sd>, <Sn>, <Sm> // (Cannot be conditional)
```

Encoding for the Double-precision scalar variant

Applies when (size == 11)

```
VMAXNM(<q>).F64 <Dd>, <Dn>, <Dm> // (Cannot be conditional)
```

Decode for all variants of this encoding

```
if size != '1x' then Undefined(); end;
let advsimd : boolean = FALSE;
let maximum : boolean = (op == '0');
let esize : integer{} = 8 << UInt(size);
let d : integer = if size == '11' then UInt(D::Vd) else UInt(Vd::D);
let n : integer = if size == '11' then UInt(N::Vn) else UInt(Vn::N);
let m : integer = if size == '11' then UInt(M::Vm) else UInt(Vm::M);
let regs : integer = ARBITRARY : integer;
let elements : integer = ARBITRARY : integer;
```

T1

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0)

```
VMAXNM(<q>).<dt> <Dd>, <Dn>, <Dm>
```

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

```
VMAXNM(<q>).<dt> <Qd>, <Qn>, <Qm>
```

Decode for all variants of this encoding

```
if Q == '1' && (Vd[0] == '1' || Vn[0] == '1' || Vm[0] == '1') then Undefined(); end;
if sz == '1' then Undefined(); end;
let maximum : boolean = (op == '0');
let advsimd : boolean = TRUE;
let esize : integer{} = 32;
let elements : integer = 2;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);
let regs : integer = if Q == '0' then 1 else 2;
```

CONSTRAINED UNPREDICTABLE behavior

If InITBlock(), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

T2

Encoding for the Single-precision scalar variant

Applies when (size == 10)

```
VMAXNM(<q>).F32 <Sd>, <Sn>, <Sm> // (Not permitted in IT block)
```

Encoding for the Double-precision scalar variant

Applies when (size == 11)

```
VMAXNM(<q>).F64 <Dd>, <Dn>, <Dm> // (Not permitted in IT block)
```

Decode for all variants of this encoding

```
if InITBlock() then UnpredictableProcedure(); end;
if size != '1x' then Undefined(); end;
let advsimd : boolean = FALSE;
let maximum : boolean = (op == '0');
let esize : integer{} = 8 << UInt(size);
let d : integer = if size == '11' then UInt(D::Vd) else UInt(Vd::D);
let n : integer = if size == '11' then UInt(N::Vn) else UInt(Vn::N);
let m : integer = if size == '11' then UInt(M::Vm) else UInt(Vm::M);
let regs : integer = ARBITRARY : integer;
let elements : integer = ARBITRARY : integer;
```

CONSTRAINED UNPREDICTABLE behavior

If InITBlock(), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Architectural Constraints on UNPREDICTABLE behaviors.

Assembler Symbols

<q>

See Standard assembler syntax fields.

<dt>

Is the data type for the elements of the vectors, encoded in “sz”:

sz	<dt>
0	F32

sz	<dt>
1	F16

<Dd>

Is the 64-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field.

<Dn>

Is the 64-bit name of the first SIMD&FP source register, encoded in the “N:Vn” field.

<Dm>

Is the 64-bit name of the second SIMD&FP source register, encoded in the “M:Vm” field.

<Qd>

Is the 128-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field as <Qd>*2.

<Qn>

Is the 128-bit name of the first SIMD&FP source register, encoded in the “N:Vn” field as <Qn>*2.

<Qm>

Is the 128-bit name of the second SIMD&FP source register, encoded in the “M:Vm” field as <Qm>*2.

<Sd>

Is the 32-bit name of the SIMD&FP destination register, encoded in the “Vd:D” field.

<Sn>

Is the 32-bit name of the first SIMD&FP source register, encoded in the “Vn:N” field.

<Sm>

Is the 32-bit name of the second SIMD&FP source register, encoded in the “Vm:M” field.

Operation

```
EncodingSpecificOperations();
CheckAdvSIMDOrVFPEEnabled(TRUE, advsimd);
if advsimd then // Advanced SIMD instruction
    let fpcr : FPCR_Type = StandardFPCR();
    for r = 0 to regs-1 do
        for e = 0 to elements-1 do
            let operand1 : bits(esize) = D(n+r)[e*:esize];
            let operand2 : bits(esize) = D(m+r)[e*:esize];
            if maximum then
                D(d+r)[e*:esize] = FPMaxNum{esize}(operand1, operand2, fpcr);
            else
                D(d+r)[e*:esize] = FPMinNum{esize}(operand1, operand2, fpcr);
            end;
        end;
    end;
else // VFP instruction
    let fpcr : FPCR_Type = EffectiveFPCR();
    case esize of
        when 32 =>
            if maximum then
                S(d) = FPMaxNum{32}(S(n), S(m), fpcr);
            else
                S(d) = FPMinNum{32}(S(n), S(m), fpcr);
```

```
        end;  
    when 64 =>  
        if maximum then  
            D(d) = FPMaxNum{64}(D(n), D(m), fpcr);  
        else  
            D(d) = FPMinNum{64}(D(n), D(m), fpcr);  
        end;  
    end;  
end;  
end;
```

C6.1.102 VMIN (floating-point)

Vector Minimum (floating-point)

Vector Minimum compares corresponding elements in two vectors, and copies the smaller of each pair into the corresponding element in the destination vector.

The operand vector elements are floating-point numbers.

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0)

```
VMIN{<c>}{<q>}.<dt> {<Dd>, }<Dn>, <Dm>
```

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

```
VMIN{<c>}{<q>}.<dt> {<Qd>, }<Qn>, <Qm>
```

Decode for all variants of this encoding

```
if Q == '1' && (Vd[0] == '1' || Vn[0] == '1' || Vm[0] == '1') then Undefined(); end;
if sz == '1' then Undefined(); end;
let maximum : boolean = (op == '0');
let esize : integer{} = 32;
let elements : integer = 64 DIV esize;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);
let regs : integer = if Q == '0' then 1 else 2;
```

T1

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0)

```
VMIN{<c>}{<q>}.<dt> {<Dd>, }<Dn>, <Dm>
```

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

VMIN{<c>}{<q>}.<dt> {<Qd>, <Qn>, <Qm>}

Decode for all variants of this encoding

```
if Q == '1' && (Vd[0] == '1' || Vn[0] == '1' || Vm[0] == '1') then Undefined(); end;
if sz == '1' then Undefined(); end;
let maximum : boolean = (op == '0');
let esize : integer{} = 32; let elements : integer{} = 2;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);
let regs : integer = if Q == '0' then 1 else 2;
```

CONSTRAINED UNPREDICTABLE behavior

If sz == '1' && InITBlock(), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

Assembler Symbols

<c>

For the “A1 128-bit SIMD vector” and “A1 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#). This encoding must be unconditional.

For the “T1 128-bit SIMD vector” and “T1 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<dt>

Is the data type for the elements of the vectors, encoded in “sz”:

sz	<dt>
0	F32
1	F16

<Dd>

Is the 64-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field.

<Dn>

Is the 64-bit name of the first SIMD&FP source register, encoded in the “N:Vn” field.

<Dm>

Is the 64-bit name of the second SIMD&FP source register, encoded in the “M:Vm” field.

<Qd>

Is the 128-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field as <Qd>*2.

<Qn>

Is the 128-bit name of the first SIMD&FP source register, encoded in the “N:Vn” field as <Qn>*2.

<Qm>

Is the 128-bit name of the second SIMD&FP source register, encoded in the “M:Vm” field as <Qm>*2.

Floating-point minimum

- $\min(+0.0, -0.0) = -0.0$
- If any input is a NaN, the corresponding result element is the default NaN.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();
    let fpcr : FPCR_Type = StandardFPCR();
    for r = 0 to regs-1 do
        for e = 0 to elements-1 do
            let op1 : bits(esize) = D(n+r)[e*:esize];
            let op2 : bits(esize) = D(m+r)[e*:esize];
            if maximum then
                D(d+r)[e*:esize] = FPMax{esize}(op1, op2, fpcr);
            else
                D(d+r)[e*:esize] = FPMin{esize}(op1, op2, fpcr);
            end;
        end;
    end;
end;
end;
```

C6.1.103 VMIN (integer)

Vector Minimum (integer)

Vector Minimum compares corresponding elements in two vectors, and copies the smaller of each pair into the corresponding element in the destination vector.

The operand vector elements can be any one of:

- 8-bit, 16-bit, or 32-bit signed integers.
- 8-bit, 16-bit, or 32-bit unsigned integers.

The result vector elements are the same size as the operand vector elements.

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0)

VMIN{<c>}{<q>}.<dt> {<Dd>, }<Dn>, <Dm>

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

VMIN{<c>}{<q>}.<dt> {<Qd>, }<Qn>, <Qm>

Decode for all variants of this encoding

```

if Q == '1' && (Vd[0] == '1' || Vn[0] == '1' || Vm[0] == '1') then Undefined(); end;
if size == '11' then Undefined(); end;
let maximum : boolean = (op == '0');
let unsigned : boolean = (U == '1');
let esize : integer{} = 8 << UInt(size);
let elements : integer = 64 DIV esize;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);
let regs : integer = if Q == '0' then 1 else 2;

```

T1

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0)

VMIN{<c>}{<q>}.<dt> {<Dd>, }<Dn>, <Dm>

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

VMIN{<c>}{<q>}.<dt> {<Qd>, }<Qn>, <Qm>

Decode for all variants of this encoding

```
if Q == '1' && (Vd[0] == '1' || Vn[0] == '1' || Vm[0] == '1') then Undefined(); end;
if size == '11' then Undefined(); end;
let maximum : boolean = (op == '0');
let unsigned : boolean = (U == '1');
let esize : integer{} = 8 << UInt(size);
let elements : integer = 64 DIV esize;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);
let regs : integer = if Q == '0' then 1 else 2;
```

Assembler Symbols

<c>

For the “A1 128-bit SIMD vector” and “A1 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#).
This encoding must be unconditional.

For the “T1 128-bit SIMD vector” and “T1 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<dt>

Is the data type for the elements of the operands, encoded in “U:size”:

U	size	<dt>
0	00	S8
0	01	S16
0	10	S32
1	00	U8
1	01	U16
1	10	U32

<Dd>

Is the 64-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field.

<Dn>

Is the 64-bit name of the first SIMD&FP source register, encoded in the “N:Vn” field.

<Dm>

Is the 64-bit name of the second SIMD&FP source register, encoded in the “M:Vm” field.

<Qd>

Is the 128-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field as <Qd>*2.

<Qn>

Is the 128-bit name of the first SIMD&FP source register, encoded in the “N:Vn” field as <Qn>*2.

<Qm>

Is the 128-bit name of the second SIMD&FP source register, encoded in the “M:Vm” field as <Qm>*2.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();
    for r = 0 to regs-1 do
        for e = 0 to elements-1 do
            let op1elt : bits(esize) = D(n+r)[e*:esize];
            let op2elt : bits(esize) = D(m+r)[e*:esize];
            let element1 : integer = if unsigned then UInt(op1elt) else SInt(op1elt);
            let element2 : integer = if unsigned then UInt(op2elt) else SInt(op2elt);
            let result : integer = (if maximum then Max(element1, element2)
                                   else Min(element1, element2));
            D(d+r)[e*:esize] = result[esize-1:0];
        end;
    end;
end;
```

C6.1.104 VMINNM

Floating-point Minimum Number

This instruction determines the floating point minimum number.

It handles NaNs in consistence with the IEEE 754-2008 specification. It returns the numerical operand when one operand is numerical and the other is a quiet NaN, but otherwise the result is identical to floating-point `VMIN`.

This instruction is not conditional.

It has encodings from the following instruction sets: A32 ([A1](#) and [A2](#)) and T32 ([T1](#) and [T2](#)).

A1

Encoding for the 64-bit SIMD vector variant

Applies when (`Q == 0`)

`VMINNM(<q>).<dt> <Dd>, <Dn>, <Dm>`

Encoding for the 128-bit SIMD vector variant

Applies when (`Q == 1`)

`VMINNM(<q>).<dt> <Qd>, <Qn>, <Qm>`

Decode for all variants of this encoding

```
if Q == '1' && (Vd[0] == '1' || Vn[0] == '1' || Vm[0] == '1') then Undefined(); end;
if sz == '1' then Undefined(); end;
let maximum : boolean = (op == '0');
let advsimd : boolean = TRUE;
let esize : integer{} = 32;
let elements : integer = 64 DIV esize;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);
let regs : integer = if Q == '0' then 1 else 2;
```

A2

Encoding for the Single-precision scalar variant

Applies when (`size == 10`)

`VMINNM(<q>).F32 <Sd>, <Sn>, <Sm> // (Cannot be conditional)`

Encoding for the Double-precision scalar variant

Applies when (size == 11)

VMINNM(<q>).F64 <Dd>, <Dn>, <Dm> // (Cannot be conditional)

Decode for all variants of this encoding

```
if size != '1x' then Undefined(); end;
let advsimd : boolean = FALSE;
let maximum : boolean = (op == '0');
let esize : integer{} = 8 << UInt(size);
let d : integer = if size == '11' then UInt(D::Vd) else UInt(Vd::D);
let n : integer = if size == '11' then UInt(N::Vn) else UInt(Vn::N);
let m : integer = if size == '11' then UInt(M::Vm) else UInt(Vm::M);
let regs : integer = ARBITRARY : integer;
let elements : integer = ARBITRARY : integer;
```

T1

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0)

VMINNM(<q>).<dt> <Dd>, <Dn>, <Dm>

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

VMINNM(<q>).<dt> <Qd>, <Qn>, <Qm>

Decode for all variants of this encoding

```
if Q == '1' && (Vd[0] == '1' || Vn[0] == '1' || Vm[0] == '1') then Undefined(); end;
if sz == '1' then Undefined(); end;
let maximum : boolean = (op == '0');
let advsimd : boolean = TRUE;
let esize : integer{} = 32;
let elements : integer = 2;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);
let regs : integer = if Q == '0' then 1 else 2;
```

CONSTRAINED UNPREDICTABLE behavior

If InITBlock(), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

T2

Encoding for the Single-precision scalar variant

Applies when (size == 10)

```
VMINNM(<q>).F32 <Sd>, <Sn>, <Sm> // (Not permitted in IT block)
```

Encoding for the Double-precision scalar variant

Applies when (size == 11)

```
VMINNM(<q>).F64 <Dd>, <Dn>, <Dm> // (Not permitted in IT block)
```

Decode for all variants of this encoding

```
if InITBlock() then UnpredictableProcedure(); end;
if size != '1x' then Undefined(); end;
let advsimd : boolean = FALSE;
let maximum : boolean = (op == '0');
let esize : integer{} = 8 << UInt(size);
let d : integer = if size == '11' then UInt(D::Vd) else UInt(Vd::D);
let n : integer = if size == '11' then UInt(N::Vn) else UInt(Vn::N);
let m : integer = if size == '11' then UInt(M::Vm) else UInt(Vm::M);
let regs : integer = ARBITRARY : integer;
let elements : integer = ARBITRARY : integer;
```

CONSTRAINED UNPREDICTABLE behavior

If InITBlock(), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Architectural Constraints on UNPREDICTABLE behaviors.

Assembler Symbols

<q>

See Standard assembler syntax fields.

<dt>

Is the data type for the elements of the vectors, encoded in “sz”:

sz	<dt>
0	F32

sz	<dt>
1	F16

<Dd>

Is the 64-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field.

<Dn>

Is the 64-bit name of the first SIMD&FP source register, encoded in the “N:Vn” field.

<Dm>

Is the 64-bit name of the second SIMD&FP source register, encoded in the “M:Vm” field.

<Qd>

Is the 128-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field as <Qd>*2.

<Qn>

Is the 128-bit name of the first SIMD&FP source register, encoded in the “N:Vn” field as <Qn>*2.

<Qm>

Is the 128-bit name of the second SIMD&FP source register, encoded in the “M:Vm” field as <Qm>*2.

<Sd>

Is the 32-bit name of the SIMD&FP destination register, encoded in the “Vd:D” field.

<Sn>

Is the 32-bit name of the first SIMD&FP source register, encoded in the “Vn:N” field.

<Sm>

Is the 32-bit name of the second SIMD&FP source register, encoded in the “Vm:M” field.

Operation

```
EncodingSpecificOperations();
CheckAdvSIMDOrVFPEEnabled(TRUE, advsimd);
if advsimd then // Advanced SIMD instruction
    let fpcr : FPCR_Type = StandardFPCR();
    for r = 0 to regs-1 do
        for e = 0 to elements-1 do
            let operand1 : bits(esize) = D(n+r)[e*:esize];
            let operand2 : bits(esize) = D(m+r)[e*:esize];
            if maximum then
                D(d+r)[e*:esize] = FPMaxNum{esize}(operand1, operand2, fpcr);
            else
                D(d+r)[e*:esize] = FPMinNum{esize}(operand1, operand2, fpcr);
            end;
        end;
    end;
else // VFP instruction
    let fpcr : FPCR_Type = EffectiveFPCR();
    case esize of
        when 32 =>
            if maximum then
                S(d) = FPMaxNum{32}(S(n), S(m), fpcr);
            else
                S(d) = FPMinNum{32}(S(n), S(m), fpcr);
            end;
    end;
```

```
        end;  
    when 64 =>  
        if maximum then  
            D(d) = FPMaxNum{64}(D(n), D(m), fpcr);  
        else  
            D(d) = FPMinNum{64}(D(n), D(m), fpcr);  
        end;  
    end;  
end;  
end;
```

C6.1.105 VMLA (floating-point)

Vector Multiply Accumulate (floating-point)

Vector Multiply Accumulate multiplies corresponding elements in two vectors, and accumulates the results into the elements of the destination vector.

Depending on settings in the [CPACR](#), [NSACR](#), [HCPTR](#), and [FPEXC](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#) and [A2](#)) and T32 ([T1](#) and [T2](#)).

A1

Encoding for the 64-bit SIMD vector variant

Applies when ($Q == 0$)

`VMLA{<c>}{<q>}.<dt> <Dd>, <Dn>, <Dm>`

Encoding for the 128-bit SIMD vector variant

Applies when ($Q == 1$)

`VMLA{<c>}{<q>}.<dt> <Qd>, <Qn>, <Qm>`

Decode for all variants of this encoding

```
if Q == '1' && (Vd[0] == '1' || Vn[0] == '1' || Vm[0] == '1') then Undefined(); end;
if sz == '1' then Undefined(); end;
let advsimd : boolean = TRUE;
let add : boolean = (op == '0');
let esize : integer{} = 32;
let elements : integer = 64 DIV esize;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);
let regs : integer = if Q == '0' then 1 else 2;
```

A2

Encoding for the Single-precision scalar variant

Applies when ($size == 10$)

`VMLA{<c>}{<q>}.F32 <Sd>, <Sn>, <Sm>`

Encoding for the Double-precision scalar variant

Applies when (size == 11)

VMLA{<c>}{<q>}.F64 <Dd>, <Dn>, <Dm>

Decode for all variants of this encoding

```
if size != '1x' then Undefined(); end;
if FPSCR().Len != '000' || FPSCR().Stride != '00' then Undefined(); end;
let advsimd : boolean = FALSE;
let add : boolean = (op == '0');
let esize : integer{} = 8 << UInt(size);
let d : integer = if size == '11' then UInt(D::Vd) else UInt(Vd::D);
let n : integer = if size == '11' then UInt(N::Vn) else UInt(Vn::N);
let m : integer = if size == '11' then UInt(M::Vm) else UInt(Vm::M);
let floating_point : boolean = ARBITRARY : boolean;
let regs : integer = ARBITRARY : integer;
let elements : integer = ARBITRARY : integer;
```

CONSTRAINED UNPREDICTABLE behavior

If size == '01' && cond != '1110', then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

T1

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0)

VMLA{<c>}{<q>}.<dt> <Dd>, <Dn>, <Dm>

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

VMLA{<c>}{<q>}.<dt> <Qd>, <Qn>, <Qm>

Decode for all variants of this encoding

```
if Q == '1' && (Vd[0] == '1' || Vn[0] == '1' || Vm[0] == '1') then Undefined(); end;
if sz == '1' then Undefined(); end;
let advsimd : boolean = TRUE;
let add : boolean = (op == '0');
let esize : integer{} = 32;
let elements : integer = 64 DIV esize;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);
let regs : integer = if Q == '0' then 1 else 2;
```

CONSTRAINED UNPREDICTABLE behavior

If `sz == '1'` && `InITBlock()`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

T2

Encoding for the Single-precision scalar variant

Applies when `(size == 10)`

`VMLA{<c>}{<q>}.F32 <Sd>, <Sn>, <Sm>`

Encoding for the Double-precision scalar variant

Applies when `(size == 11)`

`VMLA{<c>}{<q>}.F64 <Dd>, <Dn>, <Dm>`

Decode for all variants of this encoding

```

if size != '1x' then Undefined(); end;
if FPSCR().Len != '000' || FPSCR().Stride != '00' then Undefined(); end;
let advsimd : boolean = FALSE;
let add : boolean = (op == '0');
let esize : integer{} = 8 << UInt(size);
let d : integer = if size == '11' then UInt(D::Vd) else UInt(Vd::D);
let n : integer = if size == '11' then UInt(N::Vn) else UInt(Vn::N);
let m : integer = if size == '11' then UInt(M::Vm) else UInt(Vm::M);
let floating_point : boolean = ARBITRARY : boolean;
let regs : integer = ARBITRARY : integer;
let elements : integer = ARBITRARY : integer;

```

CONSTRAINED UNPREDICTABLE behavior

If `size == '01'` && `InITBlock()`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

Is the 128-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field as <Qd>*2.

<Qn>

Is the 128-bit name of the first SIMD&FP source register, encoded in the “N:Vn” field as <Qn>*2.

<Qm>

Is the 128-bit name of the second SIMD&FP source register, encoded in the “M:Vm” field as <Qm>*2.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();
    for r = 0 to regs-1 do
        for e = 0 to elements-1 do
            let op1elt : bits(esize) = Din(n+r)[e*:esize];
            let op2elt : bits(esize) = Din(m+r)[e*:esize];
            let element1 : integer = if unsigned then UInt(op1elt) else SInt(op1elt);
            let element2 : integer = if unsigned then UInt(op2elt) else SInt(op2elt);
            let product : integer = element1 * element2;
            let addend : integer = if add then product else -product;
            if long_destination then
                Q(d>>1)[e*:(2*esize)] = Qin(d>>1)[e*:(2*esize)] + addend;
            else
                D(d+r)[e*:esize] = Din(d+r)[e*:esize] + addend;
            end;
        end;
    end;
end;
```

C6.1.107 VMLA (by scalar)

Vector Multiply Accumulate (by scalar)

Vector Multiply Accumulate multiplies elements of a vector by a scalar, and adds the products to corresponding elements of the destination vector.

For more information about scalars see [Advanced SIMD scalars](#).

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0)

VMLA{<c>}{<q>}.<dt> <Dd>, <Dn>, <Dm[x]>

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

VMLA{<c>}{<q>}.<dt> <Qd>, <Qn>, <Dm[x]>

Decode for all variants of this encoding

```

if size == '11' then See("Related encodings"); end;
if size == '00' || (F == '1' && size == '01') then Undefined(); end;
if Q == '1' && (Vd[0] == '1' || Vn[0] == '1') then Undefined(); end;
let unsigned : boolean = FALSE; // "Don't care" value: TRUE produces same functionality
let add : boolean = (op == '0');
let floating_point : boolean = (F == '1');
let long_destination : boolean = FALSE;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let regs : integer = if Q == '0' then 1 else 2;
let esize : integer() = 8 << UInt(size);
let elements : integer = 64 DIV esize;
let m : integer = if size == '01' then UInt(Vm[2:0]) else UInt(Vm);
let index : integer = if size == '01' then UInt(M::Vm[3]) else UInt(M);

```

T1

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0)

VMLA{<c>}{<q>}.<dt> <Dd>, <Dn>, <Dm[x]>

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

VMLA{<c>}{<q>}.<dt> <Qd>, <Qn>, <Dm[x]>

Decode for all variants of this encoding

```
if size == '11' then See("Related encodings"); end;
if size == '00' || (F == '1' && size == '01') then Undefined(); end;
if Q == '1' && (Vd[0] == '1' || Vn[0] == '1') then Undefined(); end;
let unsigned : boolean = FALSE; // "Don't care" value: TRUE produces same functionality
let add : boolean = (op == '0');
let floating_point : boolean = (F == '1');
let long_destination : boolean = FALSE;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let regs : integer = if Q == '0' then 1 else 2;
let esize : integer{} = 8 << UInt(size);
let elements : integer = 64 DIV esize;
let m : integer = if size == '01' then UInt(Vm[2:0]) else UInt(Vm);
let index : integer = if size == '01' then UInt(M::Vm[3]) else UInt(M);
```

CONSTRAINED UNPREDICTABLE behavior

If F == '1' && size == '01' && InITBlock(), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

Related encodings: See [Advanced SIMD data-processing](#) for the T32 instruction set, or [Advanced SIMD data-processing](#) for the A32 instruction set.

Assembler Symbols

<c>

For the “A1 128-bit SIMD vector” and “A1 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#). This encoding must be unconditional.

For the “T1 128-bit SIMD vector” and “T1 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<dt>

Is the data type for the scalar and the elements of the operand vector, encoded in “F:size”:

F	size	<dt>
0	01	I16

F	size	<dt>
0	10	I32
1	01	F16
1	10	F32

<Dd>

Is the 64-bit name of the SIMD&FP register holding the accumulate vector, encoded in the “D:Vd” field.

<Dn>

Is the 64-bit name of the first SIMD&FP source register, encoded in the “N:Vn” field.

<Dm[x]>

Is the 64-bit name of the second SIMD&FP source register holding the scalar. If <dt> is I16 or F16, Dm is restricted to D0-D7. Dm is encoded in “Vm<2:0>”, and x is encoded in “M:Vm<3>”. If <dt> is I32 or F32, Dm is restricted to D0-D15. Dm is encoded in “Vm”, and x is encoded in “M”.

<Qd>

Is the 128-bit name of the SIMD&FP register holding the accumulate vector, encoded in the “D:Vd” field as <Qd>*2.

<Qn>

Is the 128-bit name of the first SIMD&FP source register, encoded in the “N:Vn” field as <Qn>*2.

Operation

```

if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();
    let fpcr : FPCR_Type = StandardFPCR();
    let op2elt : bits(esize) = Din(m)[index*:esize];
    for r = 0 to regs-1 do
        for e = 0 to elements-1 do
            let op1elt : bits(esize) = Din(n+r)[e*:esize];
            if floating_point then
                let fp_addend : bits(esize) = (if add then FPMul{esize}(op1elt, op2elt, fpcr)
                                                else FPNeg{esize}(FPMul{esize}(op1elt, op2elt,
                                                                    fpcr),
                                                                    fpcr));
                D(d+r)[e*:esize] = FPAdd{esize}(Din(d+r)[e*:esize], fp_addend, fpcr);
            else
                let element1 : integer = if unsigned then UInt(op1elt) else SInt(op1elt);
                let element2 : integer = if unsigned then UInt(op2elt) else SInt(op2elt);
                let addend : integer = if add then element1*element2 else -element1*element2;
                if long_destination then
                    Q(d>>1)[e*:(2*esize)] = Qin(d>>1)[e*:(2*esize)] + addend;
                else
                    D(d+r)[e*:esize] = Din(d+r)[e*:esize] + addend;
                end;
            end;
        end;
    end;
end;
end;
end;

```

C6.1.108 VMLAL (integer)

Vector Multiply Accumulate Long (integer)

Vector Multiply Accumulate Long multiplies corresponding elements in two vectors, and add the products to the corresponding element of the destination vector. The destination vector element is twice as long as the elements that are multiplied.

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

VMLAL{<c>}{<q>}.<dt> <Qd>, <Dn>, <Dm>

Decode for this encoding

```

if size == '11' then See("Related encodings"); end;
if Vd[0] == '1' then Undefined(); end;
let add : boolean = (op == '0');
let long_destination : boolean = TRUE;
let unsigned : boolean = (U == '1');
let esize : integer{} = 8 << UInt(size);
let elements : integer = 64 DIV esize;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);
let regs : integer = 1;

```

T1

Encoding

VMLAL{<c>}{<q>}.<dt> <Qd>, <Dn>, <Dm>

Decode for this encoding

```
if size == '11' then See("Related encodings"); end;
if Vd[0] == '1' then Undefined(); end;
let add : boolean = (op == '0');
let long_destination : boolean = TRUE;
let unsigned : boolean = (U == '1');
let esize : integer{} = 8 << UInt(size);
let elements : integer = 64 DIV esize;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);
let regs : integer = 1;
```

Related encodings: See [Advanced SIMD data-processing](#) for the T32 instruction set, or [Advanced SIMD data-processing](#) for the A32 instruction set.

Assembler Symbols

        end;
    end;
end;
end;

```

C6.1.110 VMLS (floating-point)

Vector Multiply Subtract (floating-point)

Vector Multiply Subtract multiplies corresponding elements in two vectors, subtracts the products from corresponding elements of the destination vector, and places the results in the destination vector.

Note

Arm recommends that software does not use the VMLS instruction in the Round towards Plus Infinity and Round towards Minus Infinity rounding modes, because the rounding of the product and of the sum can change the result of the instruction in opposite directions, defeating the purpose of these rounding modes.

Depending on settings in the CPACR, NSACR, HCPTR, and FPEXC registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 (A1 and A2) and T32 (T1 and T2).

A1

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0)

VMLS{<c>}{<q>}.<dt> <Dd>, <Dn>, <Dm>

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

VMLS{<c>}{<q>}.<dt> <Qd>, <Qn>, <Qm>

Decode for all variants of this encoding

```
if Q == '1' && (Vd[0] == '1' || Vn[0] == '1' || Vm[0] == '1') then Undefined(); end;
if sz == '1' then Undefined(); end;
let advsimd : boolean = TRUE;
let add : boolean = (op == '0');
let esize : integer = 32;
let elements : integer = 64 DIV esize;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);
let regs : integer = if Q == '0' then 1 else 2;
```

A2

Encoding for the Single-precision scalar variant

Applies when (size == 10)

VMLS{<c>}{<q>}.F32 <Sd>, <Sn>, <Sm>

Encoding for the Double-precision scalar variant

Applies when (size == 11)

VMLS{<c>}{<q>}.F64 <Dd>, <Dn>, <Dm>

Decode for all variants of this encoding

```
if size != '1x' then Undefined(); end;
if FPSCR().Len != '000' || FPSCR().Stride != '00' then Undefined(); end;
let advsimd : boolean = FALSE;
let add : boolean = (op == '0');
let esize : integer{} = 8 << UInt(size);
let d : integer = if size == '11' then UInt(D::Vd) else UInt(Vd::D);
let n : integer = if size == '11' then UInt(N::Vn) else UInt(Vn::N);
let m : integer = if size == '11' then UInt(M::Vm) else UInt(Vm::M);
let floating_point : boolean = ARBITRARY;
let regs : integer = ARBITRARY;
let elements : integer = ARBITRARY;
```

CONSTRAINED UNPREDICTABLE behavior

If size == '01' && cond != '1110', then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

T1

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0)

VMLS{<c>}{<q>}.<dt> <Dd>, <Dn>, <Dm>

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

VMLS{<c>}{<q>}.<dt> <Qd>, <Qn>, <Qm>

Decode for all variants of this encoding

```
if Q == '1' && (Vd[0] == '1' || Vn[0] == '1' || Vm[0] == '1') then Undefined(); end;
if sz == '1' then Undefined(); end;
let advsimd : boolean = TRUE;
let add : boolean = (op == '0');
let esize : integer{} = 32;
let elements : integer = 64 DIV esize;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);
let regs : integer = if Q == '0' then 1 else 2;
```

CONSTRAINED UNPREDICTABLE behavior

If `sz == '1'` && `InITBlock()`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

T2

Encoding for the Single-precision scalar variant

Applies when `(size == 10)`

VMLS{<c>}{<q>}.F32 <Sd>, <Sn>, <Sm>

Encoding for the Double-precision scalar variant

Applies when `(size == 11)`

VMLS{<c>}{<q>}.F64 <Dd>, <Dn>, <Dm>

Decode for all variants of this encoding

```
if size != '1x' then Undefined(); end;
if FPSCR().Len != '000' || FPSCR().Stride != '00' then Undefined(); end;
let advsimd : boolean = FALSE;
let add : boolean = (op == '0');
let esize : integer{} = 8 << UInt(size);
let d : integer = if size == '11' then UInt(D::Vd) else UInt(Vd::D);
let n : integer = if size == '11' then UInt(N::Vn) else UInt(Vn::N);
let m : integer = if size == '11' then UInt(M::Vm) else UInt(Vm::M);
let floating_point : boolean = ARBITRARY : boolean;
let regs : integer = ARBITRARY : integer;
let elements : integer = ARBITRARY : integer;
```

CONSTRAINED UNPREDICTABLE behavior

If `size == '01'` && `InITBlock()`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

Is the 128-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field as <Qd>*2.

<Qn>

Is the 128-bit name of the first SIMD&FP source register, encoded in the “N:Vn” field as <Qn>*2.

<Qm>

Is the 128-bit name of the second SIMD&FP source register, encoded in the “M:Vm” field as <Qm>*2.

<Sd>

Is the 32-bit name of the SIMD&FP destination register, encoded in the “Vd:D” field.

<Sn>

Is the 32-bit name of the first SIMD&FP source register, encoded in the “Vn:N” field.

<Sm>

Is the 32-bit name of the second SIMD&FP source register, encoded in the “Vm:M” field.

Operation

```

if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDorVFPEEnabled(TRUE, advsimd);
    if advsimd then // Advanced SIMD instruction
        let fpcr : FPCR_Type = StandardFPCR();
        for r = 0 to regs-1 do
            for e = 0 to elements-1 do
                var addend : bits(esize) = FPMul{}(D(n+r)[e*:esize], D(m+r)[e*:esize], fpcr);
                if !add then addend = FPNeg{esize}(addend, fpcr); end;
                D(d+r)[e*:esize] = FPAdd{esize}(D(d+r)[e*:esize], addend, fpcr);
            end;
        end;
    else // VFP instruction
        let fpcr : FPCR_Type = EffectiveFPCR();
        case esize of
            when 32 =>
                var addend32 : bits(32) = FPMul{}(S(n), S(m), fpcr);
                if !add then addend32 = FPNeg{32}(addend32, fpcr); end;
                S(d) = FPAdd{32}(S(d), addend32, fpcr);
            when 64 =>
                var addend64 : bits(64) = FPMul{}(D(n), D(m), fpcr);
                if !add then addend64 = FPNeg{64}(addend64, fpcr); end;
                D(d) = FPAdd{64}(D(d), addend64, fpcr);
        end;
    end;
end;
end;

```

C6.1.111 VMLS (integer)

Vector Multiply Subtract (integer)

Vector Multiply Subtract multiplies corresponding elements in two vectors, and subtracts the products from the corresponding elements of the destination vector.

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0)

VMLS{<c>}{<q>}.<dt> <Dd>, <Dn>, <Dm>

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

VMLS{<c>}{<q>}.<dt> <Qd>, <Qn>, <Qm>

Decode for all variants of this encoding

```

if size == '11' then Undefined(); end;
if Q == '1' && (Vd[0] == '1' || Vn[0] == '1' || Vm[0] == '1') then Undefined(); end;
let add : boolean = (op == '0');
let long_destination : boolean = FALSE;
let unsigned : boolean = FALSE; // "Don't care" value: TRUE produces same functionality
let esize : integer() = 8 << UInt(size);
let elements : integer = 64 DIV esize;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);
let regs : integer = if Q == '0' then 1 else 2;

```

T1

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0)

VMLS{<c>}{<q>}.<dt> <Dd>, <Dn>, <Dm>

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

VMLS{<c>}{<q>}.<dt> <Qd>, <Qn>, <Qm>

Decode for all variants of this encoding

```
if size == '11' then Undefined(); end;
if Q == '1' && (Vd[0] == '1' || Vn[0] == '1' || Vm[0] == '1') then Undefined(); end;
let add : boolean = (op == '0');
let long_destination : boolean = FALSE;
let unsigned : boolean = FALSE; // "Don't care" value: TRUE produces same functionality
let esize : integer{} = 8 << UInt(size);
let elements : integer = 64 DIV esize;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);
let regs : integer = if Q == '0' then 1 else 2;
```

Assembler Symbols

<c>

For the “A1 128-bit SIMD vector” and “A1 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#). This encoding must be unconditional.

For the “T1 128-bit SIMD vector” and “T1 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<dt>

Is the data type for the elements of the operands, encoded in “size”:

size	<dt>
00	I8
01	I16
10	I32

<Dd>

Is the 64-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field.

<Dn>

Is the 64-bit name of the first SIMD&FP source register, encoded in the “N:Vn” field.

<Dm>

Is the 64-bit name of the second SIMD&FP source register, encoded in the “M:Vm” field.

<Qd>

Is the 128-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field as <Qd>*2.

<Qn>

Is the 128-bit name of the first SIMD&FP source register, encoded in the “N:Vn” field as <Qn>*2.

<Qm>

Is the 128-bit name of the second SIMD&FP source register, encoded in the “M:Vm” field as <Qm>*2.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();
    for r = 0 to regs-1 do
        for e = 0 to elements-1 do
            let op1elt : bits(esize) = Din(n+r)[e*:esize];
            let op2elt : bits(esize) = Din(m+r)[e*:esize];
            let element1 : integer = if unsigned then UInt(op1elt) else SInt(op1elt);
            let element2 : integer = if unsigned then UInt(op2elt) else SInt(op2elt);
            let product : integer = element1 * element2;
            let addend : integer = if add then product else -product;
            if long_destination then
                Q(d>>1)[e*:(2*esize)] = Qin(d>>1)[e*:(2*esize)] + addend;
            else
                D(d+r)[e*:esize] = Din(d+r)[e*:esize] + addend;
            end;
        end;
    end;
end;
```

C6.1.112 VMLS (by scalar)

Vector Multiply Subtract (by scalar)

Vector Multiply Subtract multiplies elements of a vector by a scalar, and either subtracts the products from corresponding elements of the destination vector.

For more information about scalars see [Advanced SIMD scalars](#).

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0)

VMLS{<c>}{<q>}.<dt> <Dd>, <Dn>, <Dm[x]>

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

VMLS{<c>}{<q>}.<dt> <Qd>, <Qn>, <Dm[x]>

Decode for all variants of this encoding

```

if size == '11' then See("Related encodings"); end;
if size == '00' || (F == '1' && size == '01') then Undefined(); end;
if Q == '1' && (Vd[0] == '1' || Vn[0] == '1') then Undefined(); end;
let unsigned : boolean = FALSE; // "Don't care" value: TRUE produces same functionality
let add : boolean = (op == '0');
let floating_point : boolean = (F == '1');
let long_destination : boolean = FALSE;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let regs : integer = if Q == '0' then 1 else 2;
let esize : integer() = 8 << UInt(size);
let elements : integer = 64 DIV esize;
let m : integer = if size == '01' then UInt(Vm[2:0]) else UInt(Vm);
let index : integer = if size == '01' then UInt(M::Vm[3]) else UInt(M);

```

T1

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0)

VMLS{<c>}{<q>}.<dt> <Dd>, <Dn>, <Dm[x]>

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

VMLS{<c>}{<q>}.<dt> <Qd>, <Qn>, <Dm[x]>

Decode for all variants of this encoding

```
if size == '11' then See("Related encodings"); end;
if size == '00' || (F == '1' && size == '01') then Undefined(); end;
if Q == '1' && (Vd[0] == '1' || Vn[0] == '1') then Undefined(); end;
let unsigned : boolean = FALSE; // "Don't care" value: TRUE produces same functionality
let add : boolean = (op == '0');
let floating_point : boolean = (F == '1');
let long_destination : boolean = FALSE;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let regs : integer = if Q == '0' then 1 else 2;
let esize : integer{} = 8 << UInt(size);
let elements : integer = 64 DIV esize;
let m : integer = if size == '01' then UInt(Vm[2:0]) else UInt(Vm);
let index : integer = if size == '01' then UInt(M::Vm[3]) else UInt(M);
```

CONSTRAINED UNPREDICTABLE behavior

If F == '1' && size == '01' && InITBlock(), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

Related encodings: See [Advanced SIMD data-processing](#) for the T32 instruction set, or [Advanced SIMD data-processing](#) for the A32 instruction set.

Assembler Symbols

<c>

For the “A1 128-bit SIMD vector” and “A1 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#). This encoding must be unconditional.

For the “T1 128-bit SIMD vector” and “T1 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<dt>

Is the data type for the scalar and the elements of the operand vector, encoded in “F:size”:

F	size	<dt>
0	01	I16

F	size	<dt>
0	10	I32
1	01	F16
1	10	F32

<Dd>

Is the 64-bit name of the SIMD&FP register holding the accumulate vector, encoded in the “D:Vd” field.

<Dn>

Is the 64-bit name of the first SIMD&FP source register, encoded in the “N:Vn” field.

<Dm[x]>

Is the 64-bit name of the second SIMD&FP source register holding the scalar. If <dt> is I16 or F16, Dm is restricted to D0-D7. Dm is encoded in “Vm<2:0>”, and x is encoded in “M:Vm<3>”. If <dt> is I32 or F32, Dm is restricted to D0-D15. Dm is encoded in “Vm”, and x is encoded in “M”.

<Qd>

Is the 128-bit name of the SIMD&FP register holding the accumulate vector, encoded in the “D:Vd” field as <Qd>*2.

<Qn>

Is the 128-bit name of the first SIMD&FP source register, encoded in the “N:Vn” field as <Qn>*2.

Operation

```

if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();
    let fpcr : FPCR_Type = StandardFPCR();
    let op2elt : bits(esize) = Din(m)[index*:esize];
    for r = 0 to regs-1 do

```

C6.1.115 VMOV (between two general-purpose registers and a doubleword floating-point register)

Copy two general-purpose registers to or from a SIMD&FP register copies two words from two general-purpose registers into a doubleword register in the Advanced SIMD and floating-point register file, or from a doubleword register in the Advanced SIMD and floating-point register file to two general-purpose registers.

Depending on settings in the CPACR, NSACR, HCPTR, and FPEXC registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 (A1) and T32 (T1).

A1

Encoding for the From general-purpose registers variant

Applies when (op == 0)

VMOV{<c>}{<q>} <Dm>, <Rt>, <Rt2>

Encoding for the To general-purpose registers variant

Applies when (op == 1)

VMOV{<c>}{<q>} <Rt>, <Rt2>, <Dm>

Decode for all variants of this encoding

```

let to_arm_registers : boolean = (op == '1');
let t : integer = UInt(Rt);
let t2 : integer = UInt(Rt2);
let m : integer = UInt(M::Vm);
// Armv8-A removes UNPREDICTABLE for R13
if t == 15 || t2 == 15 then UnpredictableProcedure(); end;
if to_arm_registers && t == t2 then UnpredictableProcedure(); end;

```

CONSTRAINED UNPREDICTABLE behavior

If to_arm_registers && t == t2, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The value in the destination register is UNKNOWN.

T1

Encoding for the From general-purpose registers variant

Applies when (op == 0)

```
VMOV{<c>}{<q>} <Dm>, <Rt>, <Rt2>
```

Encoding for the To general-purpose registers variant

Applies when (op == 1)

```
VMOV{<c>}{<q>} <Rt>, <Rt2>, <Dm>
```

Decode for all variants of this encoding

```
let to_arm_registers : boolean = (op == '1');
let t : integer = UInt(Rt);
let t2 : integer = UInt(Rt2);
let m : integer = UInt(M::Vm);
// Armv8-A removes UNPREDICTABLE for R13
if t == 15 || t2 == 15 then UnpredictableProcedure(); end;
if to_arm_registers && t == t2 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If to_arm_registers && t == t2, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The value in the destination register is UNKNOWN.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly [VMOV \(between two general-purpose registers and a doubleword floating-point register\)](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Dm>

Is the 64-bit name of the SIMD&FP register to be transferred, encoded in the “M:Vm” field.

<Rt>

Is the first general-purpose register that <Dm>[31:0] will be transferred to or from, encoded in the “Rt” field.

<Rt2>

Is the second general-purpose register that <Dm>[63:32] will be transferred to or from, encoded in the “Rt2” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckVFPEEnabled(TRUE);
    if to_arm_registers then
        R(t) = D(m)[31:0];
        R(t2) = D(m)[63:32];
    else
        D(m)[31:0] = R(t);
        D(m)[63:32] = R(t2);
    end;
end;
```

C6.1.116 VMOV (immediate)

Copy immediate value to a SIMD&FP register places an immediate constant into every element of the destination register.

Depending on settings in the CPACR, NSACR, HCPTR, and FPEXC registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 (A1, A2, A3, A4, and A5) and T32 (T1, T2, T3, T4, and T5).

A1

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0)

```
VMOV{<c>}{<q>}.I32 <Dd>, #<imm>
```

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

```
VMOV{<c>}{<q>}.I32 <Qd>, #<imm>
```

Decode for all variants of this encoding

```
if op == '0' && cmode[0] == '1' && cmode[3:2] != '11' then See("VORR (immediate)"); end;
if op == '1' && cmode != '1110' then See("Related encodings"); end;
if Q == '1' && Vd[0] == '1' then Undefined(); end;
let advsimd : boolean = TRUE;
let esize : integer{} = 64;
let imm : bits(esize) = AdvSIMDEExpandImm(op, cmode, i::imm3::imm4);
let d : integer = UInt(D::Vd);
let regs : integer = if Q == '0' then 1 else 2;
```

A2

Encoding for the Single-precision scalar variant

Applies when (size == 10)

```
VMOV{<c>}{<q>}.F32 <Sd>, #<imm>
```

Encoding for the Double-precision scalar variant

Applies when (size == 11)

```
VMOV{<c>}{<q>}.F64 <Dd>, #<imm>
```

Decode for all variants of this encoding

```
if FPSCR().Len != '000' || FPSCR().Stride != '00' then Undefined(); end;
if size != '1x' then Undefined(); end;
let esize : integer() = 8 << UInt(size);
let imm : bits(esize) = VFPEExpandImm{}(imm4H::imm4L);
let advsimd : boolean = FALSE;
let d : integer = if size == '11' then UInt(D::Vd) else UInt(Vd::D);
let regs : integer = if size == '11' then 1 else 0;
```

CONSTRAINED UNPREDICTABLE behavior

If size == '01' && cond != '1110', then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

A3

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0)

```
VMOV{<c>}{<q>}.I16 <Dd>, #<imm>
```

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

```
VMOV{<c>}{<q>}.I16 <Qd>, #<imm>
```

Decode for all variants of this encoding

```
if op == '0' && cmode[0] == '1' && cmode[3:2] != '11' then See("VORR (immediate)"); end;
if op == '1' && cmode != '1110' then See("Related encodings"); end;
if Q == '1' && Vd[0] == '1' then Undefined(); end;
let advsimd : boolean = TRUE;
let esize : integer() = 64;
let imm : bits(esize) = AdvSIMDEExpandImm(op, cmode, i::imm3::imm4);
let d : integer = UInt(D::Vd);
let regs : integer = if Q == '0' then 1 else 2;
```

A4

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0)

```
VMOV{<c>}{<q>}.<dt> <Dd>, #<imm>
```

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

```
VMOV{<c>}{<q>}.<dt> <Qd>, #<imm>
```

Decode for all variants of this encoding

```
if op == '0' && cmode[0] == '1' && cmode[3:2] != '11' then See("VORR (immediate)"); end;
if op == '1' && cmode != '1110' then See("Related encodings"); end;
if Q == '1' && Vd[0] == '1' then Undefined(); end;
let advsimd : boolean = TRUE;
let esize : integer{} = 64;
let imm : bits(esize) = AdvSIMDExpandImm(op, cmode, i::imm3::imm4);
let d : integer = UInt(D::Vd);
let regs : integer = if Q == '0' then 1 else 2;
```

A5

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0)

```
VMOV{<c>}{<q>}.I64 <Dd>, #<imm>
```

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

```
VMOV{<c>}{<q>}.I64 <Qd>, #<imm>
```

Decode for all variants of this encoding

```

if op == '0' && cmode[0] == '1' && cmode[3:2] != '11' then See("VORR (immediate)"); end;
if op == '1' && cmode != '1110' then See("Related encodings"); end;
if Q == '1' && Vd[0] == '1' then Undefined(); end;
let advsimd : boolean = TRUE;
let esize : integer{} = 64;
let imm : bits(esize) = AdvSIMDEExpandImm(op, cmode, i::imm3::imm4);
let d : integer = UInt(D::Vd);
let regs : integer = if Q == '0' then 1 else 2;

```

T1

let regs : integer = if Q == '0' then 1 else 2;
```

Related encodings: See [Advanced SIMD one register and modified immediate](#) for the T32 instruction set, or [Advanced SIMD one register and modified immediate](#) for the A32 instruction set.

Assembler Symbols

<c>

For the “A1 128-bit SIMD vector”, “A1 64-bit SIMD vector”, “A3 128-bit SIMD vector”, “A3 64-bit SIMD vector”, “A4 128-bit SIMD vector”, “A4 64-bit SIMD vector”, “A5 128-bit SIMD vector”, and “A5 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#). This encoding must be unconditional.

For the “A2 Double-precision scalar”, “A2 Single-precision scalar”, “T1 128-bit SIMD vector”, “T1 64-bit SIMD vector”, “T2 Double-precision scalar”, “T2 Single-precision scalar”, “T3 128-bit SIMD vector”, “T3 64-bit SIMD vector”, “T4 128-bit SIMD vector”, “T4 64-bit SIMD vector”, “T5 128-bit SIMD vector”, and “T5 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Dd>

Is the 64-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field.

<imm>

For the “A1 128-bit SIMD vector”, “A1 64-bit SIMD vector”, “A3 128-bit SIMD vector”, “A3 64-bit SIMD vector”, “A4 128-bit SIMD vector”, “A4 64-bit SIMD vector”, “A5 128-bit SIMD vector”, “A5 64-bit SIMD vector”, “T1 128-bit SIMD vector”, “T1 64-bit SIMD vector”, “T3 128-bit SIMD vector”, “T3 64-bit SIMD vector”, “T4 128-bit SIMD vector”, “T4 64-bit SIMD vector”, “T5 128-bit SIMD vector”, and “T5 64-bit SIMD vector” variants: is a constant of the specified type that is replicated to fill the destination register. For details of the range of constants available and the encoding of <imm>, see [Modified immediate constants in T32 and A32 Advanced SIMD instructions](#).

For the “A2 Double-precision scalar”, “A2 Single-precision scalar”, “T2 Double-precision scalar”, and “T2 Single-precision scalar” variants: is a signed floating-point constant with 3-bit exponent and normalized 4 bits of precision, encoded in “imm4H:imm4L”. For details of the range of constants available and the encoding of <imm>, see [Modified immediate constants in T32 and A32 floating-point instructions](#).

<Qd>

Is the 128-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field as <Qd>*2.

<Sd>

Is the 32-bit name of the SIMD&FP destination register, encoded in the “Vd:D” field.

<dt>

The data type, encoded in “cmode”:

cmode	<dt>
110x	I32
1110	I8
1111	F32

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDorVFPEEnabled(TRUE, advsimd);
    if esize <= 32 then
        S(d) = ZeroExtend{32}(imm);
    else
        for r = 0 to regs-1 do
            D(d+r) = ZeroExtend{64}(imm);
        end;
    end;
end;
```

C6.1.117 VMOV (register)

Copy between FP registers copies the contents of one FP register to another.

Depending on settings in the [CPACR](#), [NSACR](#), [HCPTR](#), and [FPEXC](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A2](#)) and T32 ([T2](#)).

A2

Encoding for the Single-precision scalar variant

Applies when (size == 10)

VMOV{<c>}{<q>}.F32 <Sd>, <Sm>

Encoding for the Double-precision scalar variant

Applies when (size == 11)

VMOV{<c>}{<q>}.F64 <Dd>, <Dm>

Decode for all variants of this encoding

```
if FPSCR().Len != '000' || FPSCR().Stride != '00' then Undefined(); end;
let d : integer = if size == '11' then UInt(D::Vd) else UInt(Vd::D);
let m : integer = if size == '11' then UInt(M::Vm) else UInt(Vm::M);
let single_register : boolean = (size == '10');
let advsimd : boolean = FALSE;
```

T2

Encoding for the Single-precision scalar variant

Applies when (size == 10)

VMOV{<c>}{<q>}.F32 <Sd>, <Sm>

Encoding for the Double-precision scalar variant

Applies when (size == 11)

VMOV{<c>}{<q>}.F64 <Dd>, <Dm>

Decode for all variants of this encoding

```
if FPSCR().Len != '000' || FPSCR().Stride != '00' then Undefined(); end;
let d : integer = if size == '11' then UInt(D::Vd) else UInt(Vd::D);
let m : integer = if size == '11' then UInt(M::Vm) else UInt(Vm::M);
let single_register : boolean = (size == '10');
let advsimd : boolean = FALSE;
```

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Sd>

Is the 32-bit name of the SIMD&FP destination register, encoded in the “Vd:D” field.

<Sm>

Is the 32-bit name of the SIMD&FP source register, encoded in the “Vm:M” field.

<Dd>

Is the 64-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field.

<Dm>

Is the 64-bit name of the SIMD&FP source register, encoded in the “M:Vm” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDOrVFPEEnabled(TRUE, advsimd);
    if single_register then
        S(d) = S(m);
    else
        D(d) = D(m);
    end;
end;
```

C6.1.118 VMOV (general-purpose register to scalar)

Copy a general-purpose register to a vector element copies a byte, halfword, or word from a general-purpose register into an Advanced SIMD scalar.

On a Floating-point-only system, this instruction transfers one word to the upper or lower half of a double-precision floating-point register from a general-purpose register. This is an identical operation to the Advanced SIMD single word transfer.

For more information about scalars see [Advanced SIMD scalars](#).

Depending on settings in the [CPACR](#), [NSACR](#), [HCPTR](#), and [FPExc](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

```
VMOV{<c>} {<q>} {.<size>} <Dd[x]>, <Rt>
```

Decode for this encoding

```

let opc : bits(4) = opc1::opc2;
if opc == '0x10' then Undefined(); end;
let lsb : integer{} = LowestSetBit(opc[0,3]);
let esize : integer{} = 8 << lsb;
let index : integer = UInt(opc[2:lsb]);
let advsimd : boolean = (esize < 32);
let d : integer = UInt(D::Vd);
let t : integer = UInt(Rt);
// Armv8-A removes UNPREDICTABLE for R13
if t == 15 then UnpredictableProcedure(); end;

```

T1

Encoding

```
VMOV{<c>}{<q>}{.<size>} <Dd[x]>, <Rt>
```

Decode for this encoding

```
let opc : bits(4) = opc1::opc2;
if opc == '0x10' then Undefined(); end;
let lsb : integer{} = LowestSetBit(opc[0,3]);
let esize : integer{} = 8 << lsb;
let index : integer = UInt(opc[2:lsb]);
let advsimd : boolean = (esize < 32);
let d : integer = UInt(D::Vd);
let t : integer = UInt(Rt);
// Armv8-A removes UNPREDICTABLE for R13
if t == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<size>

The data size. It must be one of:

8 Encoded as `opc1<1> = 1`. [x] is encoded in `opc1<0>`, `opc2`.

16 Encoded as `opc1<1> = 0`, `opc2<0> = 1`. [x] is encoded in `opc1<0>`, `opc2<1>`.

32 Encoded as `opc1<1> = 0`, `opc2 = 0b00`. [x] is encoded in `opc1<0>`.

omitted Equivalent to 32.

<Dd|x>

The scalar. The register <Dd> is encoded in D:Vd. For details of how [x] is encoded, see the description of <size>.

<Rt>

The source general-purpose register.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDOrVFPEEnabled(TRUE, advsimd);
    D(d)[index*esize] = R(t)[esize-1:0];
end;
```

C6.1.119 VMOV (between general-purpose register and single-precision)

Copy a general-purpose register to or from a 32-bit SIMD&FP register. This instruction transfers the value held in a 32-bit SIMD&FP register to a general-purpose register, or the value held in a general-purpose register to a 32-bit SIMD&FP register.

Depending on settings in the CPACR, NSACR, HCPTR, and FPEXC registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 (A1) and T32 (T1).

A1

31	28	27	21				20	19	16	15	12		11	8	7	6	0						
!=1111				1	1	1	0	0	0	0	op	Vn			Rt		1	0	1	0	N	(0)(0)1(0)(0)(0)(0)	

└── cond

Encoding for the From general-purpose register variant

Applies when (op == 0)

VMOV{<c>}{<q>} <Sn>, <Rt>

Encoding for the To general-purpose register variant

Applies when (op == 1)

VMOV{<c>}{<q>} <Rt>, <Sn>

Decode for all variants of this encoding

```
let to_arm_register : boolean = (op == '1');
let t : integer = UInt(Rt);
let n : integer = UInt(Vn::N);
// Armv8-A removes UNPREDICTABLE for R13
if t == 15 then UnpredictableProcedure(); end;
```

Applies when (op == 0)

VMOV{<c>}{<q>} <Sn>, <Rt>

Encoding for the To general-purpose register variant

Applies when (op == 1)

VMOV{<c>}{<q>} <Rt>, <Sn>

Decode for all variants of this encoding

```
let to_arm_register : boolean = (op == '1');  
let t : integer = UInt(Rt);  
let n : integer = UInt(Vn::N);  
// Armv8-A removes UNPREDICTABLE for R13  
if t == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Sn>

Is the 32-bit name of the SIMD&FP register to be transferred, encoded in the “Vn:N” field.

<Rt>

Is the general-purpose register that <Sn> will be transferred to or from, encoded in the “Rt” field.

Operation

```
if ConditionPassed() then  
  EncodingSpecificOperations();  
  CheckVFPEEnabled(TRUE);  
  if to_arm_register then  
    R(t) = S(n);  
  else  
    S(n) = R(t);  
  end;  
end;
```

C6.1.120 VMOV (scalar to general-purpose register)

Copy a vector element to a general-purpose register with sign or zero extension

Copy a vector element to a general-purpose register with sign or zero extension copies a byte, halfword, or word from an Advanced SIMD scalar to a general-purpose register. Bytes and halfwords can be either zero-extended or sign-extended.

On a Floating-point-only system, this instruction transfers one word from the upper or lower half of a double-precision floating-point register to a general-purpose register. This is an identical operation to the Advanced SIMD single word transfer.

For more information about scalars see [Advanced SIMD scalars](#).

Depending on settings in the [CPACR](#), [NSACR](#), [HCPTR](#), and [FPXEC](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

```
VMOV{ <c> } { <q> } { .<dt> } <Rt>, <Dn[x]>
```

Decode for this encoding

```
let opc : bits(4) = opc1::opc2;
if (U::opc) IN {'10x00', 'x0x10'} then Undefined(); end;
let lsb : integer{} = LowestSetBit(opc[0,3]);
let esize : integer{} = 8 << lsb;
let index : integer = UInt(opc[2:lsb]);
let advsimd : boolean = (esize < 32);
let unsigned : boolean = (U == '1');
let t : integer = UInt(Rt);
let n : integer = UInt(N::Vn);
// Armv8-A removes UNPREDICTABLE for R13
if t == 15 then UnpredictableProcedure(); end;
```

T1

Encoding

```
VMOV{ <c> } { <q> } { . <dt> } <Rt>, <Dn[x]>
```

Decode for this encoding

```
let opc : bits(4) = opc1::opc2;
if (U::opc) IN {'10x00', 'x0x10'} then Undefined(); end;
let lsb : integer{} = LowestSetBit(opc[0,3]);
let esize : integer{} = 8 << lsb;
let index : integer = UInt(opc[2:lsb]);
let advsimd : boolean = (esize < 32);
let unsigned : boolean = (U == '1');
let t : integer = UInt(Rt);
let n : integer = UInt(N::Vn);
// Armv8-A removes UNPREDICTABLE for R13
if t == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<dt>

The data type. It must be one of:

S8 Encoded as U = 0, opc1<1> = 1. [x] is encoded in opc1<0>, opc2.

S16 Encoded as U = 0, opc1<1> = 0, opc2<0> = 1. [x] is encoded in opc1<0>, opc2<1>.

U8 Encoded as U = 1, opc1<1> = 1. [x] is encoded in opc1<0>, opc2.

U16 Encoded as U = 1, opc1<1> = 0, opc2<0> = 1. [x] is encoded in opc1<0>, opc2<1>.

32 Encoded as U = 0, opc1<1> = 0, opc2 = 0b00. [x] is encoded in opc1<0>.

omitted Equivalent to 32.

<Rt>

The destination general-purpose register.

<Dn[x]>

The scalar. For details of how [x] is encoded see the description of <dt>.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDOrVFPEEnabled(TRUE, advsimd);
    if unsigned then
        R(t) = ZeroExtend{32}(D(n)[index*esize]);
    else
        R(t) = SignExtend{32}(D(n)[index*esize]);
    end;
end;
```

C6.1.121 VMOV (between two general-purpose registers and two single-precision registers)

Copy two general-purpose registers to a pair of 32-bit SIMD&FP registers transfers the contents of two consecutively numbered single-precision Floating-point registers to two general-purpose registers, or the contents of two general-purpose registers to a pair of single-precision Floating-point registers. The general-purpose registers do not have to be contiguous.

Depending on settings in the CPACR, NSACR, HCPTR, and FPEXC registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 (A1) and T32 (T1).

A1

Encoding for the From general-purpose registers variant

Applies when (op == 0)

VMOV{<c>}{<q>} <Sm>, <Sml>, <Rt>, <Rt2>

Encoding for the To general-purpose registers variant

Applies when (op == 1)

VMOV{<c>}{<q>} <Rt>, <Rt2>, <Sm>, <Sml>

Decode for all variants of this encoding

```

let t : integer = UInt(Rt);
let t2 : integer = UInt(Rt2);
let m : integer = UInt(Vm::M);
let m2 : integer = m + 1;
let to_arm_registers : boolean = (op == '1');
if t == 15 || t2 == 15 || m == 31 then UnpredictableProcedure(); end;
if to_arm_registers && t == t2 then UnpredictableProcedure(); end;

```

CONSTRAINED UNPREDICTABLE behavior

If to_arm_registers && t == t2, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The value in the destination register is UNKNOWN.

If m == 31, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- One or more of the single-precision registers become UNKNOWN for a move to the single-precision register. The general-purpose registers listed in the instruction become UNKNOWN for a move from the single-precision registers. This behavior does not affect any other general-purpose registers.

T1

Encoding for the From general-purpose registers variant

Applies when (`op == 0`)

```
VMOV{<c>} {<q>} <Sm>, <Sm1>, <Rt>, <Rt2>
```

Encoding for the To general-purpose registers variant

Applies when `(op == 1)`

```
VMOV{<c>}{<q>}    <Rt>, <Rt2>, <Sm>, <Sm1>
```

Decode for all variants of this encoding

```

let t : integer = UInt(Rt);
let t2 : integer = UInt(Rt2);
let m : integer = UInt(Vm::M);
let m2 : integer = m + 1;
let to_arm_registers : boolean = (op == '1');
if t == 15 || t2 == 15 || m == 31 then UnpredictableProcedure(); end;
if to_arm_registers && t == t2 then UnpredictableProcedure(); end;

```

CONSTRAINED UNPREDICTABLE behavior

If to arm registers $\&\& t == t2$, then one of the following behaviors must occur:

- The instruction is **UNDEFINED**.
- The instruction executes as **NOP**.
- The value in the destination register is **UNKNOWN**.

If $m = 31$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- One or more of the single-precision registers become UNKNOWN for a move to the single-precision register. The general-purpose registers listed in the instruction become UNKNOWN for a move from the single-precision registers. This behavior does not affect any other general-purpose registers.

For more information about the **CONSTRAINED UNPREDICTABLE** behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly **VMOV** (between two general-purpose registers and two single-precision registers).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Sm>

Is the 32-bit name of the first SIMD&FP register to be transferred, encoded in the “Vm:M” field.

<Sm1>

Is the 32-bit name of the second SIMD&FP register to be transferred. This is the next SIMD&FP register after <Sm>.

<Rt>

Is the first general-purpose register that <Sm> will be transferred to or from, encoded in the “Rt” field.

<Rt2>

Is the second general-purpose register that <Sm1> will be transferred to or from, encoded in the “Rt2” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckVFPEEnabled(TRUE);
    if to_arm_registers then
        R(t) = S(m);
        R(t2) = S(m2);
    else
        S(m) = R(t);
        S(m2) = R(t2);
    end;
end;
```

C6.1.122 VMOV (register, SIMD)

Copy between SIMD registers copies the contents of one SIMD register to another.

This is an alias of [VORR \(register\)](#). This means:

- The encodings in this description are named to match the encodings of [VORR \(register\)](#).
- The description of [VORR \(register\)](#) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding for the 64-bit SIMD vector variant

Applies when ($Q == 0$)

$VMOV\{<c>\}\{<q>\}\{.<dt>\}\ \ <Dd>, \ <Dm>$

is equivalent to

$VORR\{<c>\}\{<q>\}\{.<dt>\}\ \ \{<Dd>, \ \}<Dm>, \ <Dm>$

and is the preferred disassembly when $N :: Vn == M :: Vm$.

Encoding for the 128-bit SIMD vector variant

Applies when ($Q == 1$)

$VMOV\{<c>\}\{<q>\}\{.<dt>\}\ \ <Qd>, \ <Qm>$

is equivalent to

$VORR\{<c>\}\{<q>\}\{.<dt>\}\ \ \{<Qd>, \ \}<Qm>, \ <Qm>$

and is the preferred disassembly when $N :: Vn == M :: Vm$.

T1

Encoding for the 64-bit SIMD vector variant

Applies when ($Q == 0$)

$VMOV\{<c>\}\{<q>\}\{.<dt>\}\ \ <Dd>, \ <Dm>$

is equivalent to

VORR{<c>}{<q>}{.<dt>} {<Dd>, }<Dm>, <Dm>

and is the preferred disassembly when $N :: V_n == M :: V_m$.

Encoding for the 128-bit SIMD vector variant

Applies when ($Q == 1$)

VMOV{<c>}{<q>}{.<dt>} <Qd>, <Qm>

is equivalent to

VORR{<c>}{<q>}{.<dt>} {<Qd>, }<Qm>, <Qm>

and is the preferred disassembly when $N :: V_n == M :: V_m$.

Assembler Symbols

<c>

For the “A1 128-bit SIMD vector” and “A1 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#).
This encoding must be unconditional.

For the “T1 128-bit SIMD vector” and “T1 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<dt>

An optional data type. <dt> must not be F64, but it is otherwise ignored.

<Dd>

Is the 64-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field.

<Dm>

Is the 64-bit name of the SIMD&FP source register, encoded in the “N:Vn” and “M:Vm” field.

<Qd>

Is the 128-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field as <Qd>*2.

<Qm>

Is the 128-bit name of the SIMD&FP source register, encoded in the “N:Vn” and “M:Vm” field as <Qm>*2.

Operation

The description of [VORR \(register\)](#) gives the operational pseudocode for this instruction.

C6.1.123 VMOVL

Vector Move Long takes each element in a doubleword vector, sign or zero-extends them to twice their original length, and places the results in a quadword vector.

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

Applies when (imm3H IN {001, 010, 100})

VMOVL{<c>}{<q>}.<dt> <Qd>, <Dm>

Decode for this encoding

```

if imm3H == '000' then See("Related encodings"); end;
if ! imm3H IN {'001', '010', '100'} then See("VSHLL"); end;
if Vd[0] == '1' then Undefined(); end;
let esize : integer{} = 8 << HighestSetBitNZ(imm3H);
let elements : integer = 64 DIV esize;
let d : integer = UInt(D::Vd);
let m : integer = UInt(M::Vm);
let unsigned : boolean = (U == '1');

```

T1

Encoding

Applies when (imm3H IN {001, 010, 100})

VMOVL{<c>}{<q>}.<dt> <Qd>, <Dm>

Decode for this encoding

```
if imm3H == '000' then See("Related encodings"); end;
if ! imm3H IN {'001', '010', '100'} then See("VSHLL"); end;
if Vd[0] == '1' then Undefined(); end;
let esize : integer{} = 8 << HighestSetBitNZ(imm3H);
let elements : integer = 64 DIV esize;
let d : integer = UInt(D::Vd);
let m : integer = UInt(M::Vm);
let unsigned : boolean = (U == '1');
```

Related encodings: See [Advanced SIMD one register and modified immediate](#) for the T32 instruction set, or [Advanced SIMD one register and modified immediate](#) for the A32 instruction set.

Assembler Symbols

<c>

For the “A1” variant: see [Standard assembler syntax fields](#). This encoding must be unconditional.
For the “T1” variant: see [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<dt>

Is the data type for the elements of the operand, encoded in “U:imm3H”:

U	imm3H	<dt>
0	001	S8
0	010	S16
0	100	S32
1	001	U8
1	010	U16
1	100	U32

<Qd>

Is the 128-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field as <Qd>*2.

<Dm>

Is the 64-bit name of the SIMD&FP source register, encoded in the “M:Vm” field.

Operation

```
if ConditionPassed() then
  EncodingSpecificOperations();
  CheckAdvSIMDEnabled();
  for e = 0 to elements-1 do
    let op1elt : bits(esize) = Din(m)[e*:esize];
    let result : integer = if unsigned then UInt(op1elt) else SInt(op1elt);
    Q(d>>1)[e*:(2*esize)] = result[2*esize-1:0];
  end;
end;
```

C6.1.124 VMOVN

Vector Move and Narrow copies the least significant half of each element of a quadword vector into the corresponding elements of a doubleword vector.

The operand vector elements can be any one of 16-bit, 32-bit, or 64-bit integers. There is no distinction between signed and unsigned integers.

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

This instruction is used by the pseudo-instructions [VRSHRN \(zero\)](#) and [VSHRN \(zero\)](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

31	28	27	26	25	24	23	22	21	20	19	18	17	16	15	12	11	10	7	6	5	4	3	0
1	1	1	1	0	0	1	1	D	1	1	size	1	0	Vd	0	0	1	0	0	0	M	0	Vm
opc1														opc2				Q					

Encoding

VMOVN{<c>}{<q>}.<dt> <Dd>, <Qm>

Decode for this encoding

```

if size == '11' then Undefined(); end;
if Vm[0] == '1' then Undefined(); end;
let esize : integer() = 8 << UInt(size);
let elements : integer = 64 DIV esize;
let d : integer = UInt(D::Vd);
let m : integer = UInt(M::Vm);

```

T1

15	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	12	11	10	7	6	5	4	3	0	
1	1	1	1	1	1	1	1	D	1	1	size	1	0		Vd		0	0	1	0	0	0	M	0	Vm
opc1														opc2				Q							

Encoding

VMOVN{<c>}{<q>}.<dt> <Dd>, <Qm>

Decode for this encoding

```

if size == '11' then Undefined(); end;
if Vm[0] == '1' then Undefined(); end;
let esize : integer() = 8 << UInt(size);
let elements : integer = 64 DIV esize;
let d : integer = UInt(D::Vd);
let m : integer = UInt(M::Vm);

```

Assembler Symbols

<c>

For the “A1” variant: see [Standard assembler syntax fields](#). This encoding must be unconditional.

For the “T1” variant: see [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<dt>

Is the data type for the elements of the operand, encoded in “size”:

size	<dt>
00	I 16
01	I 32
10	I 64
11	RESERVED

<Dd>

Is the 64-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field.

<Qm>

Is the 128-bit name of the SIMD&FP source register, encoded in the “M:Vm” field as <Qm>*2.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();
    for e = 0 to elements-1 do
        D(d)[e*:esize] = Qin(m>>1)[e*:(2*esize)][esize-1:0];
    end;
end;
```

C6.1.125 VMRS

Move SIMD&FP Special register to general-purpose register moves the value of an Advanced SIMD and floating-point System register to a general-purpose register. When the specified System register is the **FPSCR**, a form of the instruction transfers the **FPSCR**.{N, Z, C, V} condition flags to the **APSR**.{N, Z, C, V} condition flags.

Depending on settings in the **CPACR**, **NSACR**, **HCPTR**, and **FPEXC** registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

When these settings permit the execution of Advanced SIMD and floating-point instructions, if the specified floating-point System register is not the **FPSCR**, the instruction is UNDEFINED if executed in User mode.

In an implementation that includes EL2, when **HCR.TID0** is set to 1, any **VMRS** access to **FPSID** from a Non-secure EL1 mode that would be permitted if **HCR.TID0** was set to 0 generates a Hyp Trap exception. For more information, see [EL2 configurable controls](#).

For simplicity, the **VMRS** pseudocode does not show the possible trap to Hyp mode.

It has encodings from the following instruction sets: A32 (**A1**) and T32 (**T1**).

A1

Encoding

VMRS{<c>}{<q>} <Rt>, <spec_reg>

Decode for this encoding

```
let t : integer = UInt(Rt);
if ! reg IN {'000x', '0101', '011x', '1000'} then UnpredictableProcedure(); end;
// Armv8-A removes UNPREDICTABLE for R13
if t == 15 && reg != '0001' then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If ! reg IN {'000x', '0101', '011x', '1000'}, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction transfers an UNKNOWN value to the specified target register. When the Rt field holds the value 0b1111, the specified target register is the **APSR**.{N, Z, C, V} bits, and these bits become UNKNOWN. Otherwise, the specified target register is the register specified by the **Rt** field, R0 - R14.

T1

Encoding

VMRS{<c>}{<q>} <Rt>, <spec_reg>

Decode for this encoding

```
let t : integer = UInt(Rt);
if ! reg IN {'000x', '0101', '011x', '1000'} then UnpredictableProcedure(); end;
// Armv8-A removes UNPREDICTABLE for R13
if t == 15 && reg != '0001' then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If ! reg IN {'000x', '0101', '011x', '1000'}, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction transfers an UNKNOWN value to the specified target register. When the Rt field holds the value 0b1111, the specified target register is the APSR.{N, Z, C, V} bits, and these bits become UNKNOWN. Otherwise, the specified target register is the register specified by the Rt field, R0 - R14.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rt>

Is the general-purpose destination register, encoded in the “Rt” field. Is one of:

R0-R14 General-purpose register.

APSR_nzcv Permitted only when <spec_reg> is FPSCR. Encoded as 0b1111. The instruction transfers the **FPSCR**.{N, Z, C, V} condition flags to the **APSR**.{N, Z, C, V} condition flags.

<spec_reg>

Is the source Advanced SIMD and floating-point System register, encoded in “reg”:

reg	<spec_reg>
0000	FPSID
0001	FPSCR
001x	UNPREDICTABLE
0100	UNPREDICTABLE
0101	MVFR2
0110	MVFR1
0111	MVFR0
1000	FPEXC

reg	<spec_reg>
1001	UNPREDICTABLE
101x	UNPREDICTABLE
11xx	UNPREDICTABLE

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    if reg == '0001' then // FPSCR
        CheckVFPEnabled(TRUE);
        if t == 15 then
            PSTATE.[N,Z,C,V] = FPSCR().[N,Z,C,V];
        else
            R(t) = FPSCR();
        end;
    elseif PSTATE.EL == ELO then
        Undefined(); // Non-FPSCR registers accessible only at PL1 or above
    else
        CheckVFPEnabled(FALSE); // Non-FPSCR registers are not affected by FPEXC.EN
        AArch32_CheckAdvSIMDorFPRegisterTraps(reg);
        case reg of
            when '0000' => R(t) = FPSID();
            when '0101' => R(t) = MVFR2();
            when '0110' => R(t) = MVFR1();
            when '0111' => R(t) = MVFR0();
            when '1000' => R(t) = FPEXC();
            otherwise => unreachable; // Dealt with above or in encoding-specific pseudocode
        end;
    end;
end;
```

C6.1.126 VMSR

Move general-purpose register to SIMD&FP Special register moves the value of a general-purpose register to a floating-point System register.

Depending on settings in the [CPACR](#), [NSACR](#), [HCPTR](#), and [FPEXC](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

When these settings permit the execution of Advanced SIMD and floating-point instructions:

- If the specified floating-point System register is [FPSID](#) or [FPEXC](#), the instruction is UNDEFINED if executed in User mode.
- If the specified floating-point System register is the [FPSID](#) and the instruction is executed in a mode other than User mode, the instruction is ignored.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

VMSR{<c>}{<q>} <spec_reg>, <Rt>

Decode for this encoding

```
let t : integer = UInt(Rt);
if reg != '000x' && reg != '1000' then
    let c : Constraint = ConstrainUnpredictable(Unpredictable_VMSR);
    assert c IN {Constraint_UNDEF, Constraint_NOP};
    case c of
        when Constraint_UNDEF =>
            Undefined();
        when Constraint_NOP =>
            ExecuteAsNOP();
    end;
end;
end;
// Armv8-A removes UNPREDICTABLE for R13
if t == 15 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `reg != '000x' && reg != '1000'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction transfers the value in the general-purpose register to one of the allocated registers accessible using VMSR at the same Exception level.

T1

Encoding

VMSR{<c>}{<q>} <spec_reg>, <Rt>

Decode for this encoding

```
let t : integer = UInt(Rt);
if reg != '000x' && reg != '1000' then
  let c : Constraint = ConstrainUnpredictable(Unpredictable_VMSR);
  assert c IN {Constraint_UNDEF, Constraint_NOP};
  case c of
    when Constraint_UNDEF =>
      Undefined();
    when Constraint_NOP =>
      ExecuteAsNOP();
  end;
end;
// Armv8-A removes UNPREDICTABLE for R13
if t == 15 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If reg != '000x' && reg != '1000', then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction transfers the value in the general-purpose register to one of the allocated registers accessible using VMSR at the same Exception level.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<spec_reg>

Is the destination Advanced SIMD and floating-point System register, encoded in “reg”:

reg	<spec_reg>
0000	FPSID

reg	<spec_reg>
0001	FPSCR
001x	UNPREDICTABLE
01xx	UNPREDICTABLE
1000	FPEXC
1001	UNPREDICTABLE
101x	UNPREDICTABLE
11xx	UNPREDICTABLE

<Rt>

Is the general-purpose source register, encoded in the “Rt” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    if reg == '0001' then                                // FPSCR
        CheckVFPEEnabled(TRUE);
        FPSCR() = R(t);
    elsif PSTATE.EL == ELO then
        Undefined();                                     // Non-FPSCR registers accessible only at PL1 or above
    else
        CheckVFPEEnabled(FALSE);                         // Non-FPSCR registers are not affected by FPEXC.EN
        case reg of
            when '0000' =>                                // VMSR access to FPSID is ignored
                pass;
            when '1000' =>
                FPEXC() = R(t);
            otherwise =>
                unreachable; // Dealt with above or in encoding-specific pseudocode
        end;
    end;
end;
```

C6.1.127 VMUL (floating-point)

Vector Multiply (floating-point)

Vector Multiply multiplies corresponding elements in two vectors, and places the results in the destination vector.

Depending on settings in the [CPACR](#), [NSACR](#), [HCPTR](#), and [FPEXC](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#) and [A2](#)) and T32 ([T1](#) and [T2](#)).

A1

Encoding for the 64-bit SIMD vector variant

Applies when ($Q == 0$)

```
VMUL{<c>}{<q>}.<dt> {<Dd>, }<Dn>, <Dm>
```

Encoding for the 128-bit SIMD vector variant

Applies when ($Q == 1$)

```
VMUL{<c>}{<q>}.<dt> {<Qd>, }<Qn>, <Qm>
```

Decode for all variants of this encoding

```
if Q == '1' && (Vd[0] == '1' || Vn[0] == '1' || Vm[0] == '1') then Undefined(); end;
if sz == '1' then Undefined(); end;
let advsimd : boolean = TRUE;
let esize : integer{} = 32 >> UInt(sz);
let elements : integer = 64 DIV esize;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);
let regs : integer = if Q == '0' then 1 else 2;
```

A2

Encoding for the Single-precision scalar variant

Applies when ($size == 10$)

```
VMUL{<c>}{<q>}.F32 {<Sd>, }<Sn>, <Sm>
```

Encoding for the Double-precision scalar variant

Applies when (size == 11)

```
VMUL{<c>}{<q>}.F64 {<Dd>, }<Dn>, <Dm>
```

Decode for all variants of this encoding

```
if FPSCR().Len != '000' || FPSCR().Stride != '00' then Undefined(); end;
if size != '1x' then Undefined(); end;
let advsimd : boolean = FALSE;
let esize : integer{} = 8 << UInt(size);
let d : integer = if size == '11' then UInt(D::Vd) else UInt(Vd::D);
let n : integer = if size == '11' then UInt(N::Vn) else UInt(Vn::N);
let m : integer = if size == '11' then UInt(M::Vm) else UInt(Vm::M);
let floating_point : boolean = ARBITRARY : boolean;
let regs : integer = ARBITRARY : integer;
let elements : integer = ARBITRARY : integer;
```

CONSTRAINED UNPREDICTABLE behavior

If size == '01' && cond != '1110', then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

T1

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0)

```
VMUL{<c>}{<q>}.<dt> {<Dd>, }<Dn>, <Dm>
```

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

```
VMUL{<c>}{<q>}.<dt> {<Qd>, }<Qn>, <Qm>
```

Decode for all variants of this encoding

```
if Q == '1' && (Vd[0] == '1' || Vn[0] == '1' || Vm[0] == '1') then Undefined(); end;
if sz == '1' then Undefined(); end;
let advsimd : boolean = TRUE;
let esize : integer{} = 32 >> UInt(sz);
let elements : integer = 64 DIV esize;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);
let regs : integer = if Q == '0' then 1 else 2;
```

CONSTRAINED UNPREDICTABLE behavior

If `sz == '1'` && `InITBlock()`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

T2

Encoding for the Single-precision scalar variant

Applies when `(size == 10)`

```
VMUL{<c>}{<q>}.F32 {<Sd>, }<Sn>, <Sm>
```

Encoding for the Double-precision scalar variant

Applies when `(size == 11)`

```
VMUL{<c>}{<q>}.F64 {<Dd>, }<Dn>, <Dm>
```

Decode for all variants of this encoding

```
if FPSCR().Len != '000' || FPSCR().Stride != '00' then Undefined(); end;
if size != '1x' then Undefined(); end;
let advsimd : boolean = FALSE;
let esize : integer{} = 8 << UInt(size);
let d : integer = if size == '11' then UInt(D::Vd) else UInt(Vd::D);
let n : integer = if size == '11' then UInt(N::Vn) else UInt(Vn::N);
let m : integer = if size == '11' then UInt(M::Vm) else UInt(Vm::M);
let floating_point : boolean = ARBITRARY : boolean;
let regs : integer = ARBITRARY : integer;
let elements : integer = ARBITRARY : integer;
```

CONSTRAINED UNPREDICTABLE behavior

If `size == '01'` && `InITBlock()`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

Assembler Symbols

<c>

For the “A1 128-bit SIMD vector” and “A1 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#). This encoding must be unconditional.

For the “A2 Double-precision scalar”, “A2 Single-precision scalar”, “T1 128-bit SIMD vector”, “T1 64-bit SIMD vector”, “T2 Double-precision scalar”, and “T2 Single-precision scalar” variants: see [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<dt>

Is the data type for the elements of the vectors, encoded in “sz”:

sz	<dt>
0	F32
1	F16

<Dd>

Is the 64-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field.

<Dn>

Is the 64-bit name of the first SIMD&FP source register, encoded in the “N:Vn” field.

<Dm>

Is the 64-bit name of the second SIMD&FP source register, encoded in the “M:Vm” field.

<Qd>

Is the 128-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field as <Qd>*2.

<Qn>

Is the 128-bit name of the first SIMD&FP source register, encoded in the “N:Vn” field as <Qn>*2.

<Qm>

Is the 128-bit name of the second SIMD&FP source register, encoded in the “M:Vm” field as <Qm>*2.

<Sd>

Is the 32-bit name of the SIMD&FP destination register, encoded in the “Vd:D” field.

<Sn>

Is the 32-bit name of the first SIMD&FP source register, encoded in the “Vn:N” field.

<Sm>

Is the 32-bit name of the second SIMD&FP source register, encoded in the “Vm:M” field.

Operation

```

if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDorVFPEEnabled(TRUE, advsimd);
    if advsimd then // Advanced SIMD instruction
        let fpcr : FPCR_Type = StandardFPCR();
        for r = 0 to regs-1 do
            for e = 0 to elements-1 do
                D(d+r)[e*:esize] = FPMul{esize}(D(n+r)[e*:esize], D(m+r)[e*:esize], fpcr);
            end;
        end;
    else // VFP instruction
        let fpcr : FPCR_Type = EffectiveFPCR();
        case esize of
            when 32 =>
                S(d) = FPMul{32}(S(n), S(m), fpcr);
            when 64 =>
                D(d) = FPMul{64}(D(n), D(m), fpcr);
        end;
    end;
end;

```

C6.1.128 VMUL (integer and polynomial)

Vector Multiply (integer and polynomial)

Vector Multiply multiplies corresponding elements in two vectors.

For information about multiplying polynomials, see Polynomial arithmetic over {0, 1}.

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information, see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0)

VMUL{<c>}{<q>}.<dt> {<Dd>, }<Dn>, <Dm>

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

VMUL{<c>}{<q>}.<dt> {<Qd>, }<Qn>, <Qm>

Decode for all variants of this encoding

```

if size == '11' || (op == '1' && size != '00') then Undefined(); end;
if Q == '1' && (Vd[0] == '1' || Vn[0] == '1' || Vm[0] == '1') then Undefined(); end;
let unsigned : boolean = FALSE; // "Don't care" value: TRUE produces same functionality
let polynomial : boolean = (op == '1');
let long_destination : boolean = FALSE;
let esize : integer{} = 8 << UInt(size);
let elements : integer = 64 DIV esize;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);
let regs : integer = if Q == '0' then 1 else 2;

```

T1

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0)

VMUL{<c>}{<q>}.<dt> {<Dd>, }<Dn>, <Dm>

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

VMUL{<c>}{<q>}.<dt> {<Qd>, }<Qn>, <Qm>

Decode for all variants of this encoding

```
if size == '11' || (op == '1' && size != '00') then Undefined(); end;
if Q == '1' && (Vd[0] == '1' || Vn[0] == '1' || Vm[0] == '1') then Undefined(); end;
let unsigned : boolean = FALSE; // "Don't care" value: TRUE produces same functionality
let polynomial : boolean = (op == '1');
let long_destination : boolean = FALSE;
let esize : integer{} = 8 << UInt(size);
let elements : integer = 64 DIV esize;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);
let regs : integer = if Q == '0' then 1 else 2;
```

Assembler Symbols

<c>

For the “A1 128-bit SIMD vector” and “A1 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#). This encoding must be unconditional.

For the “T1 128-bit SIMD vector” and “T1 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<dt>

Is the data type for the elements of the operands, encoded in “op:size”:

op	size	<dt>
0	00	I8
0	01	I16
0	10	I32
1	00	P8

<Dd>

Is the 64-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field.

<Dn>

Is the 64-bit name of the first SIMD&FP source register, encoded in the “N:Vn” field.

<Dm>

Is the 64-bit name of the second SIMD&FP source register, encoded in the “M:Vm” field.

<Qd>

Is the 128-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field as <Qd>*2.

<Qn>

Is the 128-bit name of the first SIMD&FP source register, encoded in the “N:Vn” field as <Qn>*2.

<Qm>

Is the 128-bit name of the second SIMD&FP source register, encoded in the “M:Vm” field as <Qm>*2.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();
    for r = 0 to regs-1 do
        for e = 0 to elements-1 do
            let op1elt : bits(esize) = Din(n+r)[e*:esize];
            let op2elt : bits(esize) = Din(m+r)[e*:esize];
            var product : bits(2 * esize);
            if polynomial then
                product = PolynomialMult{esize, esize}(op1elt, op2elt);
            else
                let element1 : integer = if unsigned then UInt(op1elt) else SInt(op1elt);
                let element2 : integer = if unsigned then UInt(op2elt) else SInt(op2elt);
                product = (element1 * element2)[2*esize-1:0];
            end;
            if long_destination then
                Q(d>>1)[e*:(2*esize)] = product;
            else
                D(d+r)[e*:esize] = product[esize-1:0];
            end;
        end;
    end;
end;
```

C6.1.129 VMUL (by scalar)

Vector Multiply (by scalar)

Vector Multiply multiplies each element in a vector by a scalar, and places the results in a second vector.

For more information about scalars see [Advanced SIMD scalars](#).

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0)

VMUL{<c>}{<q>}.<dt> {<Dd>, <Dn>, <Dm>[<index>]}

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

VMUL{<c>}{<q>}.<dt> {<Qd>, <Qn>, <Dm>[<index>]}

Decode for all variants of this encoding

```

if size == '11' then See("Related encodings"); end;
if size == '00' || (F == '1' && size == '01') then Undefined(); end;
if Q == '1' && (Vd[0] == '1' || Vn[0] == '1') then Undefined(); end;
let unsigned : boolean = FALSE; // "Don't care" value: TRUE produces same functionality
let floating_point : boolean = (F == '1');
let long_destination : boolean = FALSE;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let regs : integer = if Q == '0' then 1 else 2;
let esize : integer{} = 8 << UInt(size);
let elements : integer = 64 DIV esize;
let m : integer = if size == '01' then UInt(Vm[2:0]) else UInt(Vm);
let index : integer = if size == '01' then UInt(M::Vm[3]) else UInt(M);

```

T1

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0)

VMUL{<c>}{<q>}.<dt> {<Dd>, }<Dn>, <Dm>[<index>]

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

VMUL{<c>}{<q>}.<dt> {<Qd>, }<Qn>, <Dm>[<index>]

Decode for all variants of this encoding

```
if size == '11' then See("Related encodings"); end;
if size == '00' || (F == '1' && size == '01') then Undefined(); end;
if Q == '1' && (Vd[0] == '1' || Vn[0] == '1') then Undefined(); end;
let unsigned : boolean = FALSE; // "Don't care" value: TRUE produces same functionality
let floating_point : boolean = (F == '1');
let long_destination : boolean = FALSE;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let regs : integer = if Q == '0' then 1 else 2;
let esize : integer() = 8 << UInt(size);
let elements : integer = 64 DIV esize;
let m : integer = if size == '01' then UInt(Vm[2:0]) else UInt(Vm);
let index : integer = if size == '01' then UInt(M::Vm[3]) else UInt(M);
```

CONSTRAINED UNPREDICTABLE behavior

If F == '1' && size == '01' && InITBlock(), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

Related encodings: See [Advanced SIMD data-processing](#) for the T32 instruction set, or [Advanced SIMD data-processing](#) for the A32 instruction set.

Assembler Symbols

<c>

For the “A1 128-bit SIMD vector” and “A1 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#). This encoding must be unconditional.

For the “T1 128-bit SIMD vector” and “T1 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<dt>

Is the data type for the scalar and the elements of the operand vector, encoded in “F:size”:

F	size	<dt>
0	01	I16
0	10	I32
1	01	F16
1	10	F32

<Dd>

Is the 64-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field.

<Dn>

Is the 64-bit name of the first SIMD&FP source register, encoded in the “N:Vn” field.

<Dm>

Is the 64-bit name of the second SIMD&FP source register. When <dt> is I16 or F16, this is encoded in the “Vm<2:0>” field. Otherwise it is encoded in the “Vm” field.

<index>

Is the element index. When <dt> is I16 or F16, this is in the range 0 to 3 and is encoded in the “M:Vm<3>” field. Otherwise it is in the range 0 to 1 and is encoded in the “M” field.

<Qd>

Is the 128-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field as <Qd>*2.

<Qn>

Is the 128-bit name of the first SIMD&FP source register, encoded in the “N:Vn” field as <Qn>*2.

Operation

```

if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();
    let fpcr : FPCR_Type = StandardFPCR();
    let op2elt : bits(esize) = Din(m)[index*esize];
    for r = 0 to regs-1 do
        for e = 0 to elements-1 do
            let op1elt : bits(esize) = Din(n+r)[e*esize];
            if floating_point then
                D(d+r)[e*esize] = FPMul{esize}(op1elt, op2elt, fpcr);
            else
                let element1 : integer = if unsigned then UInt(op1elt) else SInt(op1elt);
                let element2 : integer = if unsigned then UInt(op2elt) else SInt(op2elt);
                if long_destination then
                    Q(d>>1)[e*(2*esize)] = (element1 * element2)[2*esize-1:0];
                else
                    D(d+r)[e*esize] = (element1 * element2)[esize-1:0];
                end;
            end;
        end;
    end;
end;
end;
end;

```

C6.1.130 VMULL (integer and polynomial)

Vector Multiply Long (integer and polynomial)

Vector Multiply Long multiplies corresponding elements in two vectors. The destination vector elements are twice as long as the elements that are multiplied.

For information about multiplying polynomials see Polynomial arithmetic over {0, 1}.

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

31	28	27	26	25	24	23	22	21	20	19	16	15	12	11	10	9	8	7	6	5	4	3	0

let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);
let elements : integer = 64 DIV esize;
let regs : integer = 1;
```

CONSTRAINED UNPREDICTABLE behavior

If `op == '1' && size == '10' && InITBlock()`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Related encodings: See [Advanced SIMD data-processing](#) for the T32 instruction set, or [Advanced SIMD data-processing](#) for the A32 instruction set.

Assembler Symbols

<c>

For the “A1” variant: see [Standard assembler syntax fields](#). This encoding must be unconditional.

For the “T1” variant: see [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<dt>

Is the data type for the elements of the operands, encoded in “op:U:size”:

op	U	size	<dt>
0	0	00	S8
0	0	01	S16
0	0	10	S32
0	1	00	U8
0	1	01	U16
0	1	10	U32
1	0	00	P8

op	U	size	<dt>
1	0	10	P64

<Qd>

Is the 128-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field as <Qd>*2.

<Dn>

Is the 64-bit name of the first SIMD&FP source register, encoded in the “N:Vn” field.

<Dm>

Is the 64-bit name of the second SIMD&FP source register, encoded in the “M:Vm” field.

Operation

```

if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();
    for r = 0 to regs-1 do
        for e = 0 to elements-1 do
            let op1elt : bits(esize) = Din(n+r)[e*:esize];
            let op2elt : bits(esize) = Din(m+r)[e*:esize];
            var product : bits(2 * esize);
            if polynomial then
                product = PolynomialMult{esize, esize}(op1elt, op2elt);
            else
                let element1 : integer = if unsigned then UInt(op1elt) else SInt(op1elt);
                let element2 : integer = if unsigned then UInt(op2elt) else SInt(op2elt);
                product = (element1 * element2)[2*esize-1:0];
            end;
            if long_destination then
                Q(d>>1)[e*:(2*esize)] = product;
            else
                D(d+r)[e*:esize] = product[esize-1:0];
            end;
        end;
    end;
end;

```

C6.1.131 VMULL (by scalar)

Vector Multiply Long (by scalar)

Vector Multiply Long multiplies each element in a vector by a scalar, and places the results in a second vector. The destination vector elements are twice as long as the elements that are multiplied.

For more information about scalars see [Advanced SIMD scalars](#).

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

VMULL{<c>}{<q>}.<dt> <Qd>, <Dn>, <Dm>[<index>]

Decode for this encoding

```

if size == '11' then See("Related encodings"); end;
if size == '00' || Vd[0] == '1' then Undefined(); end;
let unsigned : boolean = (U == '1');
let long_destination : boolean = TRUE;
let floating_point : boolean = FALSE;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let regs : integer = 1;
let esize : integer{} = 8 << UInt(size);
let elements : integer = 64 DIV esize;
let m : integer = if size == '01' then UInt(Vm[2:0]) else UInt(Vm);
let index : integer = if size == '01' then UInt(M::Vm[3]) else UInt(M);

```

T1

Encoding

VMULL{<c>}{<q>}.<dt> <Qd>, <Dn>, <Dm>[<index>]

Decode for this encoding

```
if size == '11' then See("Related encodings"); end;
if size == '00' || Vd[0] == '1' then Undefined(); end;
let unsigned : boolean = (U == '1');
let long_destination : boolean = TRUE;
let floating_point : boolean = FALSE;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let regs : integer = 1;
let esize : integer{} = 8 << UInt(size);
let elements : integer = 64 DIV esize;
let m : integer = if size == '01' then UInt(Vm[2:0]) else UInt(Vm);
let index : integer = if size == '01' then UInt(M::Vm[3]) else UInt(M);
```

Related encodings: See [Advanced SIMD data-processing](#) for the T32 instruction set, or [Advanced SIMD data-processing](#) for the A32 instruction set.

Assembler Symbols

<c>

For the “A1” variant: see [Standard assembler syntax fields](#). This encoding must be unconditional.
For the “T1” variant: see [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<dt>

Is the data type for the scalar and the elements of the operand vector, encoded in “U:size”:

U	size	<dt>
0	01	S16
0	10	S32
1	01	U16
1	10	U32

<Qd>

Is the 128-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field as <Qd>*2.

<Dn>

Is the 64-bit name of the first SIMD&FP source register, encoded in the “N:Vn” field.

<Dm>

Is the 64-bit name of the second SIMD&FP source register, encoded in the “Vm<2:0>” field when <dt> is S16 or U16, otherwise the “Vm” field.

<index>

Is the element index in the range 0 to 3, encoded in the “M:Vm<3>” field when <dt> is S16 or U16, otherwise in range 0 to 1, encoded in the “M” field.

Operation

```

if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();
    let fpcr : FPCR_Type = StandardFPCR();
    let op2elt : bits(esize) = Din(m)[index*:esize];
    for r = 0 to regs-1 do
        for e = 0 to elements-1 do
            let op1elt : bits(esize) = Din(n+r)[e*:esize];
            if floating_point then
                D(d+r)[e*:esize] = FPMul{esize}(op1elt, op2elt, fpcr);
            else
                let element1 : integer = if unsigned then UInt(op1elt) else SInt(op1elt);
                let element2 : integer = if unsigned then UInt(op2elt) else SInt(op2elt);
                if long_destination then
                    Q(d>>1)[e*:(2*esize)] = (element1 * element2)[2*esize-1:0];
                else
                    D(d+r)[e*:esize] = (element1 * element2)[esize-1:0];
                end;
            end;
        end;
    end;
end;
end;
end;

```

C6.1.132 VMVN (immediate)

Vector Bitwise NOT (immediate) places the bitwise inverse of an immediate integer constant into every element of the destination register.

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#), [A2](#), and [A3](#)) and T32 ([T1](#), [T2](#), and [T3](#)).

A1

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0)

```
VMVN{<c>}{<q>}.I32 <Dd>, #<imm>
```

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

```
VMVN{<c>}{<q>}.I32 <Qd>, #<imm>
```

Decode for all variants of this encoding

```
if (cmode[0] == '1' && cmode[3:2] != '11') || cmode[3:1] == '111' then
    See("Related encodings");
end;
if Q == '1' && Vd[0] == '1' then Undefined(); end;
let imm64 : bits(64) = AdvSIMDExpandImm('1', cmode, i::imm3::imm4);
let d : integer = UInt(D::Vd);
let regs : integer = if Q == '0' then 1 else 2;
```

A2

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0)

```
VMVN{<c>}{<q>}.I16 <Dd>, #<imm>
```

Encoding for the 128-bit SIMD vector variant

Applies when ($Q == 1$)

```
VMVN{<c>}{<q>}.I16 <Qd>, #<imm>
```

Decode for all variants of this encoding

```

if (cmode[0] == '1' && cmode[3:2] != '11') || cmode[3:1] == '111' then
  See("Related encodings");
end;

if Q == '1' && Vd[0] == '1' then Undefined(); end;

let imm64 : bits(64) = AdvSIMDExpandImm('1', cmode, i::imm3::imm4);
let d : integer = UInt(D::Vd);
let regs : integer = if Q == '0' then 1 else 2;

```

A3

Encoding for the 64-bit SIMD vector variant

Applies when ($Q == 0$)

```
VMVN{<c>}{<q>}.I32 <Dd>, #<imm>
```

Encoding for the 128-bit SIMD vector variant

Applies when ($Q == 1$)

```
VMVN{<c>}{<q>}.I32 <Qd>, #<imm>
```

Decode for all variants of this encoding

```

if (cmode[0] == '1' && cmode[3:2] != '11') || cmode[3:1] == '111' then
  See("Related encodings");
end;

if Q == '1' && Vd[0] == '1' then Undefined(); end;

let imm64 : bits(64) = AdvSIMDExpandImm('1', cmode, i::imm3::imm4);
let d : integer = UInt(D::Vd);
let regs : integer = if Q == '0' then 1 else 2;

```

T1

Encoding for the 64-bit SIMD vector variant

Applies when ($Q == 0$)

```
VMVN{<c>}{<q>}.I32 <Dd>, #<imm>
```

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

VMVN{<c>}{<q>}.I32 <Qd>, #<imm>

Decode for all variants of this encoding

```
if (cmode[0] == '1' && cmode[3:2] != '11') || cmode[3:1] == '111' then
    See("Related encodings");

let d : integer = UInt(D::Vd);
let regs : integer = if Q == '0' then 1 else 2;
```

T2

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0)

VMVN{<c>}{<q>}.I16 <Dd>, #<imm>

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

VMVN{<c>}{<q>}.I16 <Qd>, #<imm>

Decode for all variants of this encoding

```
if (cmode[0] == '1' && cmode[3:2] != '11') || cmode[3:1] == '111' then
    See("Related encodings");
end;
if Q == '1' && Vd[0] == '1' then Undefined(); end;
let imm64 : bits(64) = AdvSIMDExpandImm('1', cmode, i::imm3::imm4);
let d : integer = UInt(D::Vd);
let regs : integer = if Q == '0' then 1 else 2;
```

T3

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0)

VMVN{<c>}{<q>}.I32 <Dd>, #<imm>

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

```
VMVN{<c>}{<q>}.I32 <Qd>, #<imm>
```

Decode for all variants of this encoding

```
if (cmode[0] == '1' && cmode[3:2] != '11') || cmode[3:1] == '111' then
    See("Related encodings");
end;
if Q == '1' && Vd[0] == '1' then Undefined(); end;
let imm64 : bits(64) = AdvSIMDExpandImm('1', cmode, i::imm3::imm4);
let d : integer = UInt(D::Vd);
let regs : integer = if Q == '0' then 1 else 2;
```

Related encodings: See [Advanced SIMD one register and modified immediate](#) for the T32 instruction set, or [Advanced SIMD one register and modified immediate](#) for the A32 instruction set.

Assembler Symbols

<c>

For the “A1 128-bit SIMD vector”, “A1 64-bit SIMD vector”, “A2 128-bit SIMD vector”, “A2 64-bit SIMD vector”, “A3 128-bit SIMD vector”, and “A3 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#). This encoding must be unconditional.

For the “T1 128-bit SIMD vector”, “T1 64-bit SIMD vector”, “T2 128-bit SIMD vector”, “T2 64-bit SIMD vector”, “T3 128-bit SIMD vector”, and “T3 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Dd>

Is the 64-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field.

<imm>

Is a constant of the specified type that is replicated to fill the destination register. For details of the range of constants available and the encoding of <imm>, see [Modified immediate constants in T32 and A32 Advanced SIMD instructions](#).

<Qd>

Is the 128-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field as <Qd>*2.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();
    for r = 0 to regs-1 do
        D(d+r) = NOT(imm64);
    end;
end;
```

C6.1.133 VMVN (register)

Vector Bitwise NOT (register) takes a value from a register, inverts the value of each bit, and places the result in the destination register. The registers can be either doubleword or quadword.

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0)

VMVN{<c>}{<q>}{.<dt>} <Dd>, <Dm>

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

VMVN{<c>}{<q>}{.<dt>} <Qd>, <Qm>

Decode for all variants of this encoding

```

if size != '00' then Undefined(); end;
if Q == '1' && (Vd[0] == '1' || Vm[0] == '1') then Undefined(); end;
let d : integer = UInt(D::Vd);
let m : integer = UInt(M::Vm);
let regs : integer = if Q == '0' then 1 else 2;

```

T1

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0)

VMVN{<c>}{<q>}{.<dt>} <Dd>, <Dm>

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

VMVN{<c>}{<q>}{.<dt>} <Qd>, <Qm>

Decode for all variants of this encoding

```

if size != '00' then Undefined(); end;
if Q == '1' && (Vd[0] == '1' || Vm[0] == '1') then Undefined(); end;
let d : integer = UInt(D::Vd);
let m : integer = UInt(M::Vm);
let regs : integer = if Q == '0' then 1 else 2;

```

Assembler Symbols

<c>

For the “A1 128-bit SIMD vector” and “A1 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#). This encoding must be unconditional.

For the “T1 128-bit SIMD vector” and “T1 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<dt>

An optional data type. It is ignored by assemblers, and does not affect the encoding.

<Dd>

Is the 64-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field.

<Dm>

Is the 64-bit name of the SIMD&FP source register, encoded in the “M:Vm” field.

<Qd>

Is the 128-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field as <Qd>*2.

<Qm>

Is the 128-bit name of the SIMD&FP source register, encoded in the “M:Vm” field as <Qm>*2.

Operation

```

if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();
    for r = 0 to regs-1 do
        D(d+r) = NOT(D(m+r));
    end;
end;

```

C6.1.134 VNEG

Vector Negate negates each element in a vector, and places the results in a second vector. The floating-point version only inverts the sign bit.

Depending on settings in the [CPACR](#), [NSACR](#), [HCPTR](#), and [FPEXC](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#) and [A2](#)) and T32 ([T1](#) and [T2](#)).

A1

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0)

VNEG{<c>}{<q>}.<dt> <Dd>, <Dm>

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

VNEG{<c>}{<q>}.<dt> <Qd>, <Qm>

Decode for all variants of this encoding

```

if size == '11' || (F == '1' && size != '10') then Undefined(); end;
if Q == '1' && (Vd[0] == '1' || Vm[0] == '1') then Undefined(); end;
let advsimd : boolean = TRUE;
let floating_point : boolean = (F == '1');
let esize : integer{} = 8 << UInt(size);
let elements : integer = 64 DIV esize;
let d : integer = UInt(D::Vd);
let m : integer = UInt(M::Vm);
let regs : integer = if Q == '0' then 1 else 2;

```

A2

Encoding for the Single-precision scalar variant

Applies when (size == 10)

VNEG{<c>}{<q>}.F32 <Sd>, <Sm>

Encoding for the Double-precision scalar variant

Applies when (size == 11)

VNEG{<c>} {<q>} .F64 <Dd>, <Dm>

Decode for all variants of this encoding

```
if size != '1x' then Undefined(); end;
if FPSCR().Len != '000' || FPSCR().Stride != '00' then Undefined(); end;
let advsimd : boolean = FALSE;
let esize : integer{} = 8 << UInt(size);
let d : integer = if size == '1l' then UInt(D::Vd) else UInt(Vd::D);
let m : integer = if size == '1l' then UInt(M::Vm) else UInt(Vm::M);
let floating_point : boolean = ARBITRARY : boolean;
let regs : integer = ARBITRARY : integer;
let elements : integer = ARBITRARY : integer;
```

CONSTRAINED UNPREDICTABLE behavior

If `size == '01' && cond != '1110'`, then one of the following behaviors must occur:

- The instruction is `UNDEFINED`.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as `NOP`. This means it behaves as if it fails the Condition code check.

T1

let m : integer = if size == '11' then UInt(M::Vm) else UInt(Vm::M);
let floating_point : boolean = ARBITRARY : boolean;
let regs : integer = ARBITRARY : integer;
let elements : integer = ARBITRARY : integer;

```

CONSTRAINED UNPREDICTABLE behavior

If `size == '01' && InITBlock()`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

Assembler Symbols

<c>

For the “A1 128-bit SIMD vector” and “A1 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#). This encoding must be unconditional.

For the “A2 Double-precision scalar”, “A2 Single-precision scalar”, “T1 128-bit SIMD vector”, “T1 64-bit SIMD vector”, “T2 Double-precision scalar”, and “T2 Single-precision scalar” variants: see [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<dt>

Is the data type for the elements of the vectors, encoded in “F:size”:

F	size	<dt>
0	00	S8
0	01	S16
0	10	S32
1	01	F16
1	10	F32

<Dd>

Is the 64-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field.

<Dm>

Is the 64-bit name of the SIMD&FP source register, encoded in the “M:Vm” field.

<Qd>

Is the 128-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field as <Qd>*2.

<Qm>

Is the 128-bit name of the SIMD&FP source register, encoded in the “M:Vm” field as <Qm>*2.

<Sd>

Is the 32-bit name of the SIMD&FP destination register, encoded in the “Vd:D” field.

<Sm>

Is the 32-bit name of the SIMD&FP source register, encoded in the “Vm:M” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDOrVFPEEnabled(TRUE, advsimd);
    if advsimd then // Advanced SIMD instruction
        let fpcr : FPCR_Type = StandardFPCR();
        for r = 0 to regs-1 do
            for e = 0 to elements-1 do
                if floating_point then
                    D(d+r)[e*:esize] = FPNeg(esize)(D(m+r)[e*:esize], fpcr);
                else
                    let result : integer = -SInt(D(m+r)[e*:esize]);
                    D(d+r)[e*:esize] = result[esize-1:0];
                end;
            end;
        end;
    else // VFP instruction
        let fpcr : FPCR_Type = EffectiveFPCR();
        case esize of
```

```
        when 32 => S(d) = FPNeg{32}(S(m), fpcr);  
        when 64 => D(d) = FPNeg{64}(D(m), fpcr);  
    end;  
end;  
end;
```

C6.1.135 VNMLA

Vector Negate Multiply Accumulate multiplies together two floating-point register values, adds the negation of the floating-point value in the destination register to the negation of the product, and writes the result back to the destination register.

Note

Arm recommends that software does not use the VNMLA instruction in the Round towards Plus Infinity and Round towards Minus Infinity rounding modes, because the rounding of the product and of the sum can change the result of the instruction in opposite directions, defeating the purpose of these rounding modes.

Depending on settings in the CPACR, NSACR, HCPTR, and FPEXC registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 (A1) and T32 (T1).

A1

Encoding for the Single-precision scalar variant

Applies when (size == 10)

VNMLA{<c>}{<q>}.F32 <Sd>, <Sn>, <Sm>

Encoding for the Double-precision scalar variant

Applies when (size == 11)

VNMLA{<c>}{<q>}.F64 <Dd>, <Dn>, <Dm>

Decode for all variants of this encoding

```
if FPSCR().Len != '000' || FPSCR().Stride != '00' then Undefined(); end;
if size != '1x' then Undefined(); end;
let vtype : VFPNegMul = if op == '1' then VFPNegMul_VNMLA else VFPNegMul_VNMLS;
let esize : integer() = 8 << UInt(size);
let d : integer = if size == '11' then UInt(D::Vd) else UInt(Vd::D);
let n : integer = if size == '11' then UInt(N::Vn) else UInt(Vn::N);
let m : integer = if size == '11' then UInt(M::Vm) else UInt(Vm::M);
```

CONSTRAINED UNPREDICTABLE behavior

If size == '01' && cond != '1110', then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

T1

Encoding for the Single-precision scalar variant

Applies when (size == 10)

VNMLA{<c>}{<q>}.F32 <Sd>, <Sn>, <Sm>

Encoding for the Double-precision scalar variant

Applies when (size == 11)

VNMLA{<c>}{<q>}.F64 <Dd>, <Dn>, <Dm>

Decode for all variants of this encoding

```

if FPSCR().Len != '000' || FPSCR().Stride != '00' then Undefined(); end;
if size != '1x' then Undefined(); end;
let vtype : VFPNegMul = if op == '1' then VFPNegMul_VNMLA else VFPNegMul_VNMLS;
let esize : integer{} = 8 << UInt(size);
let d : integer = if size == '11' then UInt(D:D) else UInt(Vd:D);
let n : integer = if size == '11' then UInt(N:Vn) else UInt(Vn:N);
let m : integer = if size == '11' then UInt(M:Vm) else UInt(Vm:M);

```

CONSTRAINED UNPREDICTABLE behavior

If `size == '01' && InITBlock()`, then one of the following behaviors must occur:

- The instruction is `UNDEFINED`.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as `NOP`. This means it behaves as if it fails the Condition code check.

Assembler Symbols

 $\langle c \rangle$

See [Standard assembler syntax fields](#).

 $\langle q \rangle$

See [Standard assembler syntax fields](#).

<Sd>

Is the 32-bit name of the SIMD&FP destination register, encoded in the “Vd:D” field.

<Sn>

Is the 32-bit name of the first SIMD&FP source register, encoded in the “Vn:N” field.

<Sm>

Is the 32-bit name of the second SIMD&FP source register, encoded in the “Vm:M” field.

<Dd>

Is the 64-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field.

<Dn>

Is the 64-bit name of the first SIMD&FP source register, encoded in the “N:Vn” field.

<Dm>

Is the 64-bit name of the second SIMD&FP source register, encoded in the “M:Vm” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckVFPEEnabled(TRUE);
    let fpcr : FPCR_Type = EffectiveFPCR();
    case esize of
        when 32 =>
            let product32 : bits(32) = FPMul{}(S(n), S(m), fpcr);
            case vtype of
                when VFPNegMul_VNMLA => S(d) = FPAdd{32}(FPNeg{32}(S(d), fpcr),
                                                            FPNeg{32}(product32, fpcr), fpcr);
                when VFPNegMul_VNMLS => S(d) = FPAdd{32}(FPNeg{32}(S(d), fpcr), product32, fpcr);
                when VFPNegMul_VNMUL => S(d) = FPNeg{32}(product32, fpcr);
            end;

end;

```

C6.1.138 VORN (register)

Vector bitwise OR NOT (register) performs a bitwise OR NOT operation between two registers, and places the result in the destination register. The operand and result registers can be quadword or doubleword. They must all be the same size.

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0)

VORN{<c>}{<q>}{.<dt>} {<Dd>, }<Dn>, <Dm>

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

VORN{<c>}{<q>}{.<dt>} {<Qd>, }<Qn>, <Qm>

Decode for all variants of this encoding

```
if Q == '1' && (Vd[0] == '1' || Vn[0] == '1' || Vm[0] == '1') then Undefined(); end;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);
let regs : integer = if Q == '0' then 1 else 2;
```

T1

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0)

VORN{<c>}{<q>}{.<dt>} {<Dd>, }<Dn>, <Dm>

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

VORN{<c>}{<q>}{.<dt>} {<Qd>, }<Qn>, <Qm>

Decode for all variants of this encoding

```

if Q == '1' && (Vd[0] == '1' || Vn[0] == '1' || Vm[0] == '1') then Undefined(); end;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);
let regs : integer = if Q == '0' then 1 else 2;

```

Assembler Symbols

<c>

For the “A1 128-bit SIMD vector” and “A1 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#). This encoding must be unconditional.

For the “T1 128-bit SIMD vector” and “T1 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<dt>

An optional data type. It is ignored by assemblers, and does not affect the encoding.

<Dd>

Is the 64-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field.

<Dn>

Is the 64-bit name of the first SIMD&FP source register, encoded in the “N:Vn” field.

<Dm>

Is the 64-bit name of the second SIMD&FP source register, encoded in the “M:Vm” field.

<Qd>

Is the 128-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field as <Qd>*2.

<Qn>

Is the 128-bit name of the first SIMD&FP source register, encoded in the “N:Vn” field as <Qn>*2.

<Qm>

Is the 128-bit name of the second SIMD&FP source register, encoded in the “M:Vm” field as <Qm>*2.

Operation

```

if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();
    for r = 0 to regs-1 do
        D(d+r) = D(n+r) OR NOT(D(m+r));
    end;
end;

```

C6.1.139 VORN (immediate)

Vector Bitwise OR NOT (immediate) performs a bitwise OR between a register value and the complement of an immediate value, and returns the result into the destination vector.

This is a pseudo-instruction of [VORR \(immediate\)](#). This means:

- The encodings in this description are named to match the encodings of [VORR \(immediate\)](#).
- The assembler syntax is used only for assembly, and is not used on disassembly.
- The description of [VORR \(immediate\)](#) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

It has encodings from the following instruction sets: A32 ([A1](#) and [A2](#)) and T32 ([T1](#) and [T2](#)).

A1

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0)

VORN{<c>}{<q>}.I32 {<Dd>, }<Dd>, #<imm>

is equivalent to

VORR{<c>}{<q>}.I32 <Dd>, #~<imm>

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

VORN{<c>}{<q>}.I32 {<Qd>, }<Qd>, #<imm>

is equivalent to

VORR{<c>}{<q>}.I32 <Qd>, #~<imm>

A2

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0)

VORN{<c>}{<q>}.I16 {<Dd>, }<Dd>, #<imm>

is equivalent to

VORR{<c>}{<q>}.I16 <Dd>, #~<imm>

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

VORN{<c>}{<q>}.I16 {<Qd>, }<Qd>, #<imm>

is equivalent to

VORR{<c>}{<q>}.I16 <Qd>, #~<imm>

T1

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0)

VORN{<c>}{<q>}.I32 {<Dd>, }<Dd>, #<imm>

is equivalent to

VORR{<c>}{<q>}.I32 <Dd>, #~<imm>

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

VORN{<c>}{<q>}.I32 {<Qd>, }<Qd>, #<imm>

is equivalent to

VORR{<c>}{<q>}.I32 <Qd>, #~<imm>

T2

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0)

VORN{<c>}{<q>}.I16 {<Dd>, }<Dd>, #<imm>

is equivalent to

VORR{<c>}{<q>}.I16 <Dd>, #~<imm>

Encoding for the 128-bit SIMD vector variant

Applies when ($Q == 1$)

VORN{<c>}{<q>}.I16 {<Qd>, }<Qd>, #<imm>

is equivalent to

VORR{<c>}{<q>}.I16 <Qd>, #~<imm>

Assembler Symbols

<c>

For the “A1 128-bit SIMD vector”, “A1 64-bit SIMD vector”, “A2 128-bit SIMD vector”, and “A2 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#). This encoding must be unconditional.

For the “T1 128-bit SIMD vector”, “T1 64-bit SIMD vector”, “T2 128-bit SIMD vector”, and “T2 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Dd>

Is the 64-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field.

<imm>

Is a constant of the specified type that is replicated to fill the destination register. For details of the range of constants available and the encoding of <imm>, see [Modified immediate constants in T32 and A32 Advanced SIMD instructions](#).

<Qd>

Is the 128-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field as <Qd>*2.

Operation

The description of [VORR \(immediate\)](#) gives the operational pseudocode for this instruction.

C6.1.140 VORR (immediate)

Vector Bitwise OR (immediate) performs a bitwise OR between a register value and an immediate value, and returns the result into the destination vector.

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

This instruction is used by the pseudo-instruction [VORN \(immediate\)](#).

It has encodings from the following instruction sets: A32 ([A1](#) and [A2](#)) and T32 ([T1](#) and [T2](#)).

A1

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0)

```
VORR{<c>}{<q>}.I32 {<Dd>, }<Dd>, #<imm>
```

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

```
VORR{<c>}{<q>}.I32 {<Qd>, }<Qd>, #<imm>
```

Decode for all variants of this encoding

```
if cmode[0] == '0' || cmode[3:2] == '11' then See("VMOV (immediate)"); end;
if Q == '1' && Vd[0] == '1' then Undefined(); end;
let imm64 : bits(64) = AdvSIMDExpandImm('0', cmode, i::imm3::imm4);
let d : integer = UInt(D::Vd);
let regs : integer = if Q == '0' then 1 else 2;
```

A2

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0)

```
VORR{<c>}{<q>}.I16 {<Dd>, }<Dd>, #<imm>
```

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

```
VORR{<c>}{<q>}.I16 {<Qd>, }<Qd>, #<imm>
```

Decode for all variants of this encoding

```
if cmode[0] == '0' || cmode[3:2] == '11' then See("VMOV (immediate)"); end;
if Q == '1' && Vd[0] == '1' then Undefined(); end;
let imm64 : bits(64) = AdvSIMDExpandImm('0', cmode, i::imm3::imm4);
let d : integer = UInt(D::Vd);
let regs : integer = if Q == '0' then 1 else 2;
```

T1

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0)

```
VORR{<c>}{<q>}.I32 {<Dd>, }<Dd>, #<imm>
```

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

```
VORR{<c>}{<q>}.I32 {<Qd>, }<Qd>, #<imm>
```

Decode for all variants of this encoding

```
if cmode[0] == '0' || cmode[3:2] == '11' then See("VMOV (immediate)"); end;
if Q == '1' && Vd[0] == '1' then Undefined(); end;
let imm64 : bits(64) = AdvSIMDExpandImm('0', cmode, i::imm3::imm4);
let d : integer = UInt(D::Vd);
let regs : integer = if Q == '0' then 1 else 2;
```

T2

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0)

```
VORR{<c>}{<q>}.I16 {<Dd>, }<Dd>, #<imm>
```

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

```
VORR{<c>}{<q>}.I16 {<Qd>, }<Qd>, #<imm>
```

Decode for all variants of this encoding

```

if cmode[0] == '0' || cmode[3:2] == '11' then See("VMOV (immediate)"); end;
if Q == '1' && Vd[0] == '1' then Undefined(); end;
let imm64 : bits(64) = AdvSIMDEExpandImm('0', cmode, i::imm3::imm4);
let d : integer = UInt(D::Vd);
let regs : integer = if Q == '0' then 1 else 2;

```

Assembler Symbols

<c>

For the “A1 128-bit SIMD vector”, “A1 64-bit SIMD vector”, “A2 128-bit SIMD vector”, and “A2 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#). This encoding must be unconditional.

For the “T1 128-bit SIMD vector”, “T1 64-bit SIMD vector”, “T2 128-bit SIMD vector”, and “T2 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Dd>

Is the 64-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field.

<imm>

Is a constant of the specified type that is replicated to fill the destination register. For details of the range of constants available and the encoding of <imm>, see [Modified immediate constants in T32 and A32 Advanced SIMD instructions](#).

<Qd>

Is the 128-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field as <Qd>*2.

The I8, I64, and F32 data types are permitted as pseudo-instructions, if the immediate can be represented by this instruction, and are encoded using a permitted encoding of the I16 or I32 data type.

Operation

```

if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();
    for r = 0 to regs-1 do
        D(d+r) = D(d+r) OR imm64;
    end;
end;

```

C6.1.141 VORR (register)

Vector bitwise OR (register) performs a bitwise OR operation between two registers, and places the result in the destination register. The operand and result registers can be quadword or doubleword. They must all be the same size.

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

This instruction is used by the alias [VMOV \(register, SIMD\)](#).

This instruction is used by the pseudo-instructions [VRSHR \(zero\)](#) and [VSHR \(zero\)](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0)

VORR{<c>}{<q>}{.<dt>} {<Dd>, }<Dn>, <Dm>

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

VORR{<c>}{<q>}{.<dt>} {<Qd>, }<Qn>, <Qm>

Decode for all variants of this encoding

```

if Q == '1' && (Vd[0] == '1' || Vn[0] == '1' || Vm[0] == '1') then Undefined(); end;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);
let regs : integer = if Q == '0' then 1 else 2;

```

T1

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0)

VORR{<c>}{<q>}{.<dt>} {<Dd>, }<Dn>, <Dm>

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

VORR{<c>}{<q>}{.<dt>} {<Qd>, }<Qn>, <Qm>

Decode for all variants of this encoding

```
if Q == '1' && (Vd[0] == '1' || Vn[0] == '1' || Vm[0] == '1') then Undefined(); end;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);
let regs : integer = if Q == '0' then 1 else 2;
```

Assembler Symbols

- <c>
For the “A1 128-bit SIMD vector” and “A1 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#). This encoding must be unconditional.
For the “T1 128-bit SIMD vector” and “T1 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#).
- <q>
See [Standard assembler syntax fields](#).
- <dt>
An optional data type. It is ignored by assemblers, and does not affect the encoding.
- <Dd>
Is the 64-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field.
- <Dn>
Is the 64-bit name of the first SIMD&FP source register, encoded in the “N:Vn” field.
- <Dm>
Is the 64-bit name of the second SIMD&FP source register, encoded in the “M:Vm” field.
- <Qd>
Is the 128-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field as <Qd>*2.
- <Qn>
Is the 128-bit name of the first SIMD&FP source register, encoded in the “N:Vn” field as <Qn>*2.
- <Qm>
Is the 128-bit name of the second SIMD&FP source register, encoded in the “M:Vm” field as <Qm>*2.

Alias Conditions

Alias	Is preferred when
VMOV (register, SIMD)	N : Vn == M : Vm
VRSHR (zero)	Never

Alias	Is preferred when
VSHR (zero)	Never

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();
    for r = 0 to regs-1 do
        D(d+r) = D(n+r) OR D(m+r);
    end;
end;
```

C6.1.142 VPADAL

Vector Pairwise Add and Accumulate Long adds adjacent pairs of elements of a vector, and accumulates the results into the elements of the destination vector.

The vectors can be doubleword or quadword. The operand elements can be 8-bit, 16-bit, or 32-bit integers. The result elements are twice the length of the operand elements.

Figure C6-2 VPADAL doubleword operation for data type S16

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0)

VPADAL{<c>}{<q>}.<dt> <Dd>, <Dm>

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

VPADAL{<c>}{<q>}.<dt> <Qd>, <Qm>

Decode for all variants of this encoding

```
if size == '11' then Undefined(); end;
if Q == '1' && (Vd[0] == '1' || Vm[0] == '1') then Undefined(); end;
let unsigned : boolean = (op == '1');
let esize : integer{} = 8 << UInt(size);
let elements : integer = 64 DIV esize;
let d : integer = UInt(D::Vd);
let m : integer = UInt(M::Vm);
let regs : integer = if Q == '0' then 1 else 2;
```

T1

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0)

```
VPADAL{<c>}{<q>}.<dt> <Dd>, <Dm>
```

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

```
VPADAL{<c>}{<q>}.<dt> <Qd>, <Qm>
```

Decode for all variants of this encoding

```
if size == '11' then Undefined(); end;
if Q == '1' && (Vd[0] == '1' || Vm[0] == '1') then Undefined(); end;
let unsigned : boolean = (op == '1');
let esize : integer{} = 8 << UInt(size);
let elements : integer = 64 DIV esize;
let d : integer = UInt(D::Vd);
let m : integer = UInt(M::Vm);
let regs : integer = if Q == '0' then 1 else 2;
```

Assembler Symbols

<c>

For the “A1 128-bit SIMD vector” and “A1 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#). This encoding must be unconditional.

For the “T1 128-bit SIMD vector” and “T1 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<dt>

Is the data type for the elements of the vectors, encoded in “op:size”:

op	size	<dt>
0	00	S8
0	01	S16
0	10	S32
x	11	RESERVED
1	00	U8
1	01	U16

op	size	<dt>
1	10	U32

<Dd>

Is the 64-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field.

<Dm>

Is the 64-bit name of the SIMD&FP source register, encoded in the “M:Vm” field.

<Qd>

Is the 128-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field as <Qd>*2.

<Qm>

Is the 128-bit name of the SIMD&FP source register, encoded in the “M:Vm” field as <Qm>*2.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();
    let h : integer = elements DIV 2;

    for r = 0 to regs-1 do
        for e = 0 to h-1 do
            let op1elt : bits(esize) = D(m+r)[(2*e)*:esize];
            let op2elt : bits(esize) = D(m+r)[(2*e+1)*:esize];
            let element1 : integer = if unsigned then UInt(op1elt) else SInt(op1elt);
            let element2 : integer = if unsigned then UInt(op2elt) else SInt(op2elt);
            let result : integer = element1 + element2;
            D(d+r)[e*:(2*esize)] = D(d+r)[e*:(2*esize)] + result;
        end;
    end;
end;
```

C6.1.143 VPADD (floating-point)

Vector Pairwise Add (floating-point) adds adjacent pairs of elements of two vectors, and places the results in the destination vector.

The operands and result are doubleword vectors.

The operand and result elements are floating-point numbers.

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

VPADD{<c>}{<q>}.<dt> {<Dd>, }<Dn>, <Dm>

Decode for this encoding

```

if Q == '1' then Undefined(); end;
if sz == '1' then Undefined(); end;
let esize : integer{} = 32 >> UInt(sz);
let elements : integer = 64 DIV esize;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);
    
```

T1

Encoding

VPADD{<c>}{<q>}.<dt> {<Dd>, }<Dn>, <Dm>

Decode for this encoding

```

if Q == '1' then Undefined(); end;
if sz == '1' then Undefined(); end;
let esize : integer{} = 32 >> UInt(sz);
let elements : integer = 64 DIV esize;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);
    
```

CONSTRAINED UNPREDICTABLE behavior

If `sz == '1' && InITBlock()`, then one of the following behaviors must occur:

- The instruction is `UNDEFINED`.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as `NOP`. This means it behaves as if it fails the Condition code check.

Assembler Symbols

`<c>`

For the “A1” variant: see [Standard assembler syntax fields](#). This encoding must be unconditional.

For the “T1” variant: see [Standard assembler syntax fields](#).

`<q>`

See [Standard assembler syntax fields](#).

`<dt>`

Is the data type for the elements of the vectors, encoded in “sz”:

sz	<dt>
0	F32
1	F16

`<Dd>`

Is the 64-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field.

`<Dn>`

Is the 64-bit name of the first SIMD&FP source register, encoded in the “N:Vn” field.

`<Dm>`

Is the 64-bit name of the second SIMD&FP source register, encoded in the “M:Vm” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();
    let fpcr : FPCR_Type = StandardFPCR();
    var dest : bits(64);
    let h : integer = elements DIV 2;

    for e = 0 to h-1 do
        dest[e*:esize] = FPAdd(esize) (D(n) [(2*e)*:esize], D(n) [(2*e+1)*:esize], fpcr);
        dest[(e+h)*:esize] = FPAdd(esize) (D(m) [(2*e)*:esize], D(m) [(2*e+1)*:esize], fpcr);
    end;

    D(d) = dest;
end;
```

C6.1.144 VPADD (integer)

Vector Pairwise Add (integer) adds adjacent pairs of elements of two vectors, and places the results in the destination vector.

The operands and result are doubleword vectors.

The operand and result elements must all be the same type, and can be 8-bit, 16-bit, or 32-bit integers. There is no distinction between signed and unsigned integers.

Figure C6-3 VPADD doubleword operation for data type I16

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

VPADD{<c>}{<q>}.<dt> {<Dd>, }<Dn>, <Dm>

Decode for this encoding

```

if size == 'l1' || Q == '1' then Undefined(); end;

let elements : integer = 64 DIV esize;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);

```

T1

Encoding

VPADD{<c>}{<q>}.<dt> {<Dd>, }<Dn>, <Dm>

Decode for this encoding

```
if size == '11' || Q == '1' then Undefined(); end;
let esize : integer{} = 8 << UInt(size);
let elements : integer = 64 DIV esize;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);
```

Assembler Symbols

<c>
For the “A1” variant: see [Standard assembler syntax fields](#). This encoding must be unconditional.
For the “T1” variant: see [Standard assembler syntax fields](#).

<q>
See [Standard assembler syntax fields](#).

<dt>
Is the data type for the elements of the vectors, encoded in “size”:

size	<dt>
00	I8
01	I16
10	I32

<Dd>
Is the 64-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field.

<Dn>
Is the 64-bit name of the first SIMD&FP source register, encoded in the “N:Vn” field.

<Dm>
Is the 64-bit name of the second SIMD&FP source register, encoded in the “M:Vm” field.

Operation

```
if ConditionPassed() then
  EncodingSpecificOperations();
  CheckAdvSIMDEnabled();
  var dest : bits(64);
  let h : integer = elements DIV 2;

  for e = 0 to h-1 do
    dest[e*:esize] = D(n)[(2*e)*:esize] + D(n)[(2*e+1)*:esize];
    dest[(e+h)*:esize] = D(m)[(2*e)*:esize] + D(m)[(2*e+1)*:esize];
  end;

  D(d) = dest;
end;
```

C6.1.145 VPADDL

Vector Pairwise Add Long adds adjacent pairs of elements of two vectors, and places the results in the destination vector.

The vectors can be doubleword or quadword. The operand elements can be 8-bit, 16-bit, or 32-bit integers. The result elements are twice the length of the operand elements.

Figure C6-4 VPADDL doubleword operation for data type S16

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

<q>

See [Standard assembler syntax fields](#).

<dt>

Is the data type for the elements of the vectors, encoded in “op:size”:

op	size	<dt>
0	00	S8
0	01	S16
0	10	S32
x	11	RESERVED
1	00	U8
1	01	U16

op	size	<dt>
1	10	U32

<Dd>

Is the 64-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field.

<Dm>

Is the 64-bit name of the SIMD&FP source register, encoded in the “M:Vm” field.

<Qd>

Is the 128-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field as <Qd>*2.

<Qm>

Is the 128-bit name of the SIMD&FP source register, encoded in the “M:Vm” field as <Qm>*2.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();
    let h : integer = elements DIV 2;

    for r = 0 to regs-1 do
        for e = 0 to h-1 do
            let op1elt : bits(esize) = D(m+r)[(2*e)*:esize];
            let op2elt : bits(esize) = D(m+r)[(2*e+1)*:esize];
            let element1 : integer = if unsigned then UInt(op1elt) else SInt(op1elt);
            let element2 : integer = if unsigned then UInt(op2elt) else SInt(op2elt);
            let result : integer = element1 + element2;
            D(d+r)[e*(2*esize):] = result[2*esize-1:0];
        end;
    end;
end;
```

C6.1.146 VPMAX (floating-point)

Vector Pairwise Maximum (floating-point)

Vector Pairwise Maximum compares adjacent pairs of elements in two doubleword vectors, and copies the larger of each pair into the corresponding element in the destination doubleword vector.

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

VPMAX{<c>}{<q>}.<dt> {<Dd>, }<Dn>, <Dm>

Decode for this encoding

```

if sz == '1' then Undefined(); end;
let maximum : boolean = (op == '0');
let esize : integer{} = 32;
let elements : integer = 64 DIV esize;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);
  
```

T1

Encoding

VPMAX{<c>}{<q>}.<dt> {<Dd>, }<Dn>, <Dm>

Decode for this encoding

```

if sz == '1' then Undefined(); end;
let maximum : boolean = (op == '0');
let esize : integer{} = 32;
let elements : integer = 64 DIV esize;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);
  
```

CONSTRAINED UNPREDICTABLE behavior

If `sz == '1' && InITBlock()`, then one of the following behaviors must occur:

- The instruction is `UNDEFINED`.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as `NOP`. This means it behaves as if it fails the Condition code check.

Assembler Symbols

`<c>`

For the “A1” variant: see [Standard assembler syntax fields](#). This encoding must be unconditional.

For the “T1” variant: see [Standard assembler syntax fields](#).

`<q>`

See [Standard assembler syntax fields](#).

`<dt>`

Is the data type for the elements of the vectors, encoded in “sz”:

sz	<dt>
0	F32
1	F16

`<Dd>`

Is the 64-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field.

`<Dn>`

Is the 64-bit name of the first SIMD&FP source register, encoded in the “N:Vn” field.

`<Dm>`

Is the 64-bit name of the second SIMD&FP source register, encoded in the “M:Vm” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();
    var dest : bits(64);
    let fpcr : FPCR_Type = StandardFPCR();
    let h : integer = elements DIV 2;

    for e = 0 to h-1 do
        var op1elt : bits(esize) = D(n)[(2*e)*:esize];
        var op2elt : bits(esize) = D(n)[(2*e+1)*:esize];
        dest[e*:esize] = (if maximum then FPMMax(esize)(op1elt, op2elt, fpcr)
                        else FPMMin(esize)(op1elt, op2elt, fpcr));

        op1elt = D(m)[(2*e)*:esize];
        op2elt = D(m)[(2*e+1)*:esize];
        dest[(e+h)*:esize] = (if maximum then FPMMax(esize)(op1elt, op2elt, fpcr)
                            else FPMMin(esize)(op1elt, op2elt, fpcr));

    end;

    D(d) = dest;
end;
```

C6.1.147 VPMAX (integer)

Vector Pairwise Maximum (integer)

Vector Pairwise Maximum compares adjacent pairs of elements in two doubleword vectors, and copies the larger of each pair into the corresponding element in the destination doubleword vector.

Figure C6-5 VPMAX doubleword operation for data type S16 or U16

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

31	28	27	26	25	24	23	22	21	20	19	16	15	12	11	8	7	6	5	4	3	0
1	1	1	1	0	0	1	U	0	D	size	Vn	Vd	1	0	1	0	N	0	M	0	Vm
														opc		Q		op			

Encoding

VPMAX{<c>}{<q>}.<dt> {<Dd>, }<Dn>, <Dm>

Decode for this encoding

```

if size == 'l1' then Undefined(); end;
let maximum : boolean = (op == '0');
let unsigned : boolean = (U == '1');
let esize : integer{} = 8 << UInt(size);
let elements : integer = 64 DIV esize;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);

```

T1

15	13	12	11	10	9	8	7	6	5	4	3	0	15	12	11	8	7	6	5	4	3	0	
1	1	1	U	1	1	1	1	0	D	size	Vn		Vd		1	0	1	0	N	0	M	0	Vm
																opc		Q		op			

Encoding

VPMAX{<c>}{<q>}.<dt> {<Dd>, }<Dn>, <Dm>

Decode for this encoding

```
if size == '11' then Undefined(); end;
let maximum : boolean = (op == '0');
let unsigned : boolean = (U == '1');
let esize : integer{} = 8 << UInt(size);
let elements : integer = 64 DIV esize;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);
```

Assembler Symbols

<c>
For the “A1” variant: see [Standard assembler syntax fields](#). This encoding must be unconditional.
For the “T1” variant: see [Standard assembler syntax fields](#).

<q>
See [Standard assembler syntax fields](#).

<dt>
Is the data type for the elements of the operands, encoded in “U:size”:

U	size	<dt>
0	00	S8
0	01	S16
0	10	S32
1	00	U8
1	01	U16
1	10	U32

<Dd>
Is the 64-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field.

<Dn>
Is the 64-bit name of the first SIMD&FP source register, encoded in the “N:Vn” field.

<Dm>
Is the 64-bit name of the second SIMD&FP source register, encoded in the “M:Vm” field.

Operation

```
if ConditionPassed() then
  EncodingSpecificOperations();
  CheckAdvSIMDEnabled();
  var dest : bits(64);
  let h : integer = elements DIV 2;
```

```
for e = 0 to h-1 do
    var op1elt : bits(esize) = D(n)[(2*e)*:esize];
    var op2elt : bits(esize) = D(n)[(2*e+1)*:esize];
    var element1 : integer = if unsigned then UInt(op1elt) else SInt(op1elt);
    var element2 : integer = if unsigned then UInt(op2elt) else SInt(op2elt);
    var result : integer = if maximum then Max(element1, element2) else Min(element1, element2);
    dest[e*:esize] = result[esize-1:0];
    op1elt = D(m)[(2*e)*:esize];
    op2elt = D(m)[(2*e+1)*:esize];
    element1 = if unsigned then UInt(op1elt) else SInt(op1elt);
    element2 = if unsigned then UInt(op2elt) else SInt(op2elt);
    result = if maximum then Max(element1, element2) else Min(element1, element2);
    dest[(e+h)*:esize] = result[esize-1:0];
end;

D(d) = dest;
end;
```

C6.1.148 VPMIN (floating-point)

Vector Pairwise Minimum (floating-point)

Vector Pairwise Minimum compares adjacent pairs of elements in two doubleword vectors, and copies the smaller of each pair into the corresponding element in the destination doubleword vector.

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

VPMIN{<c>}{<q>}.<dt> {<Dd>, }<Dn>, <Dm>

Decode for this encoding

```

if sz == '1' then Undefined(); end;
let maximum : boolean = (op == '0');
let esize : integer{} = 32;
let elements : integer = 64 DIV esize;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);
  
```

T1

Encoding

VPMIN{<c>}{<q>}.<dt> {<Dd>, }<Dn>, <Dm>

Decode for this encoding

```

if sz == '1' then Undefined(); end;
let maximum : boolean = (op == '0');
let esize : integer{} = 32;
let elements : integer = 64 DIV esize;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);
  
```

CONSTRAINED UNPREDICTABLE behavior

If `sz == '1' && InITBlock()`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

Assembler Symbols

<c>

For the “A1” variant: see [Standard assembler syntax fields](#). This encoding must be unconditional.

For the “T1” variant: see [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<dt>

Is the data type for the elements of the vectors, encoded in “sz”:

sz	<dt>
0	F32
1	F16

<Dd>

Is the 64-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field.

<Dn>

Is the 64-bit name of the first SIMD&FP source register, encoded in the “N:Vn” field.

<Dm>

Is the 64-bit name of the second SIMD&FP source register, encoded in the “M:Vm” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();
    var dest : bits(64);
    let fpcr : FPCR_Type = StandardFPCR();
    let h : integer = elements DIV 2;

    for e = 0 to h-1 do
        var op1elt : bits(esize) = D(n)[(2*e)*:esize];
        var op2elt : bits(esize) = D(n)[(2*e+1)*:esize];
        dest[e*:esize] = (if maximum then FPCrMax(esize)(op1elt, op2elt, fpcr)
                        else FPCrMin(esize)(op1elt, op2elt, fpcr));

        op1elt = D(m)[(2*e)*:esize];
        op2elt = D(m)[(2*e+1)*:esize];
        dest[(e+h)*:esize] = (if maximum then FPCrMax(esize)(op1elt, op2elt, fpcr)
                            else FPCrMin(esize)(op1elt, op2elt, fpcr));

    end;

    D(d) = dest;
end;
```

C6.1.149 VPMIN (integer)

Vector Pairwise Minimum (integer)

Vector Pairwise Minimum compares adjacent pairs of elements in two doubleword vectors, and copies the smaller of each pair into the corresponding element in the destination doubleword vector.

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

VPMIN{<c>}{<q>}.<dt> {<Dd>, }<Dn>, <Dm>

Decode for this encoding

```

if size == '11' then Undefined(); end;
let maximum : boolean = (op == '0');
let unsigned : boolean = (U == '1');
let esize : integer{} = 8 << UInt(size);
let elements : integer = 64 DIV esize;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);

```

T1

Encoding

VPMIN{<c>}{<q>}.<dt> {<Dd>, }<Dn>, <Dm>

Decode for this encoding

```

if size == '11' then Undefined(); end;
let maximum : boolean = (op == '0');
let unsigned : boolean = (U == '1');
let esize : integer{} = 8 << UInt(size);
let elements : integer = 64 DIV esize;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);

```

Assembler Symbols

<c>

For the “A1” variant: see [Standard assembler syntax fields](#). This encoding must be unconditional.

For the “T1” variant: see [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<dt>

Is the data type for the elements of the operands, encoded in “U:size”:

U	size	<dt>
0	00	S8
0	01	S16
0	10	S32
1	00	U8
1	01	U16
1	10	U32

<Dd>

Is the 64-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field.

<Dn>

Is the 64-bit name of the first SIMD&FP source register, encoded in the “N:Vn” field.

<Dm>

Is the 64-bit name of the second SIMD&FP source register, encoded in the “M:Vm” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();
    var dest : bits(64);
    let h : integer = elements DIV 2;

    for e = 0 to h-1 do
        var op1elt : bits(esize) = D(n)[(2*e)*:esize];
        var op2elt : bits(esize) = D(n)[(2*e+1)*:esize];

        op1elt = D(m)[(2*e)*:esize];
        op2elt = D(m)[(2*e+1)*:esize];
        element1 = if unsigned then UInt(op1elt) else SInt(op1elt);
        element2 = if unsigned then UInt(op2elt) else SInt(op2elt);
        result = if maximum then Max(element1, element2) else Min(element1, element2);
        dest[(e+h)*:esize] = result[esize-1:0];
    end;

    D(d) = dest;
```

end;

C6.1.150 VPOP

Pop SIMD&FP registers from stack loads multiple consecutive Advanced SIMD and floating-point register file registers from the stack.

This is an alias of [VLDM](#), [VLDMDB](#), [VLDMIA](#). This means:

- The encodings in this description are named to match the encodings of [VLDM](#), [VLDMDB](#), [VLDMIA](#).
- The description of [VLDM](#), [VLDMDB](#), [VLDMIA](#) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

It has encodings from the following instruction sets: A32 ([A1](#) and [A2](#)) and T32 ([T1](#) and [T2](#)).

A1

Encoding for the Increment After variant

VPOP{<c>}{<q>}{.<size>} <dreglist>

is equivalent to

VLDM{<c>}{<q>}{.<size>} SP!, <dreglist>

and is always the preferred disassembly.

A2

Encoding for the Increment After variant

VPOP{<c>}{<q>}{.<size>} <sreglist>

is equivalent to

VLDM{<c>}{<q>}{.<size>} SP!, <sreglist>

and is always the preferred disassembly.

T1

Encoding for the Increment After variant

VPOP{<c>}{<q>}{.<size>} <dreglist>

is equivalent to

VLDM{<c>}{<q>}{.<size>} SP!, <dreglist>

and is always the preferred disassembly.

T2

Encoding for the Increment After variant

VPOP{<c>}{<q>}{.<size>} <sreglist>

is equivalent to

VLDM{<c>}{<q>}{.<size>} SP!, <sreglist>

and is always the preferred disassembly.

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<size>

An optional data size specifier. If present, it must be equal to the size in bits, 32 or 64, of the registers being transferred.

<dreglist>

Is the list of consecutively numbered 64-bit SIMD&FP registers to be transferred. The first register in the list is encoded in “D:Vd”, and “imm8” is set to twice the number of registers in the list. The list must contain at least one register, and must not contain more than 16 registers.

<sreglist>

Is the list of consecutively numbered 32-bit SIMD&FP registers to be transferred. The first register in the list is encoded in “Vd:D”, and “imm8” is set to the number of registers in the list. The list must contain at least one register.

Operation

The description of [VLDM](#), [VLDMDB](#), [VLDMIA](#) gives the operational pseudocode for this instruction.

C6.1.151 VPUSH

Push SIMD&FP registers to stack stores multiple consecutive registers from the Advanced SIMD and floating-point register file to the stack.

This is an alias of [VSTM](#), [VSTMDB](#), [VSTMIA](#). This means:

- The encodings in this description are named to match the encodings of [VSTM](#), [VSTMDB](#), [VSTMIA](#).
- The description of [VSTM](#), [VSTMDB](#), [VSTMIA](#) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

It has encodings from the following instruction sets: A32 ([A1](#) and [A2](#)) and T32 ([T1](#) and [T2](#)).

A1

Encoding for the Decrement Before variant

VPUSH{<c>}{<q>}{.<size>} <dreglist>

is equivalent to

VSTMDB{<c>}{<q>}{.<size>} SP!, <dreglist>

and is always the preferred disassembly.

A2

Encoding for the Decrement Before variant

VPUSH{<c>}{<q>}{.<size>} <sreglist>

is equivalent to

VSTMDB{<c>}{<q>}{.<size>} SP!, <sreglist>

and is always the preferred disassembly.

T1

Encoding for the Decrement Before variant

VPUSH{<c>}{<q>}{.<size>} <dreglist>

is equivalent to

VSTMDB{<c>}{<q>}{.<size>} SP!, <dreglist>

and is always the preferred disassembly.

T2

Encoding for the Decrement Before variant

VPUSH{<c>}{<q>}{.<size>} <sreglist>

is equivalent to

VSTMDB{<c>}{<q>}{.<size>} SP!, <sreglist>

and is always the preferred disassembly.

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<size>

An optional data size specifier. If present, it must be equal to the size in bits, 32 or 64, of the registers being transferred.

<dreglist>

Is the list of consecutively numbered 64-bit SIMD&FP registers to be transferred. The first register in the list is encoded in “D:Vd”, and “imm8” is set to twice the number of registers in the list. The list must contain at least one register, and must not contain more than 16 registers.

<sreglist>

Is the list of consecutively numbered 32-bit SIMD&FP registers to be transferred. The first register in the list is encoded in “Vd:D”, and “imm8” is set to the number of registers in the list. The list must contain at least one register.

Operation

The description of [VSTM](#), [VSTMDB](#), [VSTMIA](#) gives the operational pseudocode for this instruction.

C6.1.152 VQABS

Vector Saturating Absolute takes the absolute value of each element in a vector, and places the results in the destination vector.

If any of the results overflow, they are saturated. The cumulative saturation bit, **FPSCR.QC**, is set if saturation occurs. For details see [Pseudocode details of saturation](#).

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be `UNDEFINED`, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding for the 64-bit SIMD vector variant

Applies when ($Q == 0$)

VOABS{<c>}{<q>}.<dt> <Dd>, <Dm>

Encoding for the 128-bit SIMD vector variant

Applies when ($Q == 1$)

$$\text{VOABS}\{\langle c \rangle\}\{\langle q \rangle\}.\langle dt \rangle \quad \langle Qd \rangle, \quad \langle Qm \rangle$$

Decode for all variants of this encoding

```

if size == '11' then Undefined(); end;
if Q == '1' && (Vd[0] == '1' || Vm[0] == '1') then Undefined(); end;
let esize : integer{} = 8 << UInt(size);
let elements : integer = 64 DIV esize;
let d : integer = UInt(D:~Vd);
let m : integer = UInt(M:~Vm);
let regs : integer = if O == '0' then 1 else 2;

```

T1

Encoding for the 64-bit SIMD vector variant

Applies when ($Q == 0$)

$$VQABS\{\langle c \rangle\}\{\langle q \rangle\}.\langle dt \rangle \quad \langle Dd \rangle, \quad \langle Dm \rangle$$

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

VQABS{<c>}{<q>}.<dt> <Qd>, <Qm>

Decode for all variants of this encoding

```
if size == '11' then Undefined(); end;
if Q == '1' && (Vd[0] == '1' || Vm[0] == '1') then Undefined(); end;
let esize : integer{} = 8 << UInt(size);
let elements : integer = 64 DIV esize;
let d : integer = UInt(D::Vd);
let m : integer = UInt(M::Vm);
let regs : integer = if Q == '0' then 1 else 2;
```

Assembler Symbols

<c>

For the “A1 128-bit SIMD vector” and “A1 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#). This encoding must be unconditional.

For the “T1 128-bit SIMD vector” and “T1 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<dt>

Is the data type for the elements of the vectors, encoded in “size”:

size	<dt>
00	S8
01	S16
10	S32
11	RESERVED

<Dd>

Is the 64-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field.

<Dm>

Is the 64-bit name of the SIMD&FP source register, encoded in the “M:Vm” field.

<Qd>

Is the 128-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field as <Qd>*2.

<Qm>

Is the 128-bit name of the SIMD&FP source register, encoded in the “M:Vm” field as <Qm>*2.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();
    for r = 0 to regs-1 do
        for e = 0 to elements-1 do
            let result : integer = Abs(SInt(D(m+r)[e*:esize]));
            let (res, sat) : (bits(esize), boolean) = SignedSatQ{esize}(result);
            D(d+r)[e*:esize] = res;
            if sat then FPSCR().QC = '1'; end;
        end;
    end;
end;
```

C6.1.153 VQADD

Vector Saturating Add adds the values of corresponding elements of two vectors, and places the results in the destination vector.

If any of the results overflow, they are saturated. The cumulative saturation bit, **FPSCR.QC**, is set if saturation occurs. For details see [Pseudocode details of saturation](#).

Depending on settings in the **CPACR**, **NSACR**, and **HCPTTR** registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be **UNDEFINED**, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 (**A1**) and T32 (**T1**).

A1

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0)

VQADD{<c>}{<q>}.<dt> {<Dd>, }<Dn>, <Dm>

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

VQADD{<c>}{<q>}.<dt> {<Qd>, }<Qn>, <Qm>

Decode for all variants of this encoding

```
if Q == '1' && (Vd[0] == '1' || Vn[0] == '1' || Vm[0] == '1') then Undefined(); end;
let unsigned : boolean = (U == '1');
let esize : integer{} = 8 << UInt(size);
let elements : integer = 64 DIV esize;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);
let regs : integer = if Q == '0' then 1 else 2;
```

T1

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0)

VQADD{<c>}{<q>}.<dt> {<Dd>, }<Dn>, <Dm>

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

VQADD{<c>}{<q>}.<dt> {<Qd>, }<Qn>, <Qm>

Decode for all variants of this encoding

```
if Q == '1' && (Vd[0] == '1' || Vn[0] == '1' || Vm[0] == '1') then Undefined(); end;
let unsigned : boolean = (U == '1');
let esize : integer{} = 8 << UInt(size);
let elements : integer = 64 DIV esize;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);
let regs : integer = if Q == '0' then 1 else 2;
```

Assembler Symbols

0	10	S32
0	11	S64
1	00	U8
1	01	U16
1	10	U32
1	11	U64

<Dd>

Is the 64-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field.

<Dn>

Is the 64-bit name of the first SIMD&FP source register, encoded in the “N:Vn” field.

<Dm>

Is the 64-bit name of the second SIMD&FP source register, encoded in the “M:Vm” field.

<Qd>

Is the 128-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field as <Qd>*2.

<Qn>

Is the 128-bit name of the first SIMD&FP source register, encoded in the “N:Vn” field as <Qn>*2.

<Qm>

Is the 128-bit name of the second SIMD&FP source register, encoded in the “M:Vm” field as <Qm>*2.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();
    for r = 0 to regs-1 do
        for e = 0 to elements-1 do
            let op1elt : bits(esize) = D(n+r)[e*:esize];
            let op2elt : bits(esize) = D(m+r)[e*:esize];
            let element1 : integer = if unsigned then UInt(op1elt) else SInt(op1elt);
            let element2 : integer = if unsigned then UInt(op2elt) else SInt(op2elt);
            let sum : integer = element1 + element2;
            let (res, sat) : (bits(esize), boolean) = SatQ{esize}(sum, unsigned);
            D(d+r)[e*:esize] = res;
            if sat then FPSCR().QC = '1'; end;
        end;
    end;
end;
```

C6.1.154 VQDMLAL

Vector Saturating Doubling Multiply Accumulate Long multiplies corresponding elements in two doubleword vectors, doubles the products, and accumulates the results into the elements of a quadword vector.

The second operand can be a scalar instead of a vector. For more information about scalars see [Advanced SIMD scalars](#).

If any of the results overflow, they are saturated. The cumulative saturation bit, **FPSCR.QC**, is set if saturation occurs. For details see [Pseudocode details of saturation](#).

Depending on settings in the **CPACR**, **NSACR**, and **HCPTTR** registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be **UNDEFINED**, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#) and [A2](#)) and T32 ([T1](#) and [T2](#)).

A1

Encoding

VQDMLAL{<c>}{<q>}.<dt> <Qd>, <Dn>, <Dm>

Decode for this encoding

```

if size == '11' then See("Related encodings"); end;
if size == '00' || Vd[0] == '1' then Undefined(); end;
let add : boolean = (op == '0');
let scalar_form : boolean = FALSE;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);
let esize : integer{} = 8 << UInt(size);
let elements : integer = 64 DIV esize;
let index : integer = ARBITRARY : integer;

```

A2

Encoding

VQDMLAL{<c>}{<q>}.<dt> <Qd>, <Dn>, <Dm>[<index>]

Decode for this encoding

```

if size == '11' then See("Related encodings"); end;
if size == '00' || Vd[0] == '1' then Undefined(); end;
let add : boolean = (op == '0');
let scalar_form : boolean = TRUE;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = if size == '01' then UInt(Vm[2:0]) else UInt(Vm);
let index : integer = if size == '01' then UInt(M::Vm[3]) else UInt(M);
let esize : integer{} = 8 << UInt(size);
let elements : integer = 64 DIV esize;

```

T1

Encoding

VQDMLAL{<c>}{<q>}.<dt> <Qd>, <Dn>, <Dm>

Decode for this encoding

```

if size == '11' then See("Related encodings"); end;
if size == '00' || Vd[0] == '1' then Undefined(); end;
let add : boolean = (op == '0');
let scalar_form : boolean = FALSE;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);
let esize : integer{} = 8 << UInt(size);
let elements : integer = 64 DIV esize;
let index : integer = ARBITRARY : integer;

```

T2

Encoding

VQDMLAL{<c>}{<q>}.<dt> <Qd>, <Dn>, <Dm>[<index>]

Decode for this encoding

```
if size == '11' then See("Related encodings"); end;
if size == '00' || Vd[0] == '1' then Undefined(); end;
let add : boolean = (op == '0');
let scalar_form : boolean = TRUE;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);

let elements : integer = 64 DIV esize;
```

Related encodings: See [Advanced SIMD data-processing](#) for the T32 instruction set, or [Advanced SIMD data-processing](#) for the A32 instruction set.

Assembler Symbols

<c>

For the “A1” and “A2” variants: see [Standard assembler syntax fields](#). This encoding must be unconditional.
For the “T1” and “T2” variants: see [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<dt>

Is the data type for the elements of the operands, encoded in “size”:

size	<dt>
01	S16
10	S32

<Qd>

Is the 128-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field as <Qd>*2.

<Dn>

Is the 64-bit name of the first SIMD&FP source register, encoded in the “N:Vn” field.

<Dm>

For the “A1” and “T1” variants: is the 64-bit name of the second SIMD&FP source register, encoded in the “M:Vm” field.
For the “A2” and “T2” variants: is the 64-bit name of the second SIMD&FP source register, encoded in the “Vm<2:0>” field when <dt> is S16, otherwise the “Vm” field.

<index>

Is the element index in the range 0 to 3, encoded in the “M:Vm<3>” field when <dt> is S16, otherwise in range 0 to 1, encoded in the “M” field.

Operation

```

if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();
    var op2 : integer;
    if scalar_form then op2 = SInt(Din(m)[index*:esize]); end;
    for e = 0 to elements-1 do
        if !scalar_form then op2 = SInt(Din(m)[e*:esize]); end;
        let op1 : integer = SInt(Din(n)[e*:esize]);
        // The following only saturates if both op1 and op2 equal -(2^(esize-1))
        let (product, sat1) : (bits(2*esize), boolean) = SignedSatQ{2*esize}(2*op1*op2);
        var result : integer;
        if add then
            result = SInt(Qin(d>>1)[e*:(2*esize)]) + SInt(product);
        else
            result = SInt(Qin(d>>1)[e*:(2*esize)]) - SInt(product);
        end;
        var sat2 : boolean;
        var res : bits(2*esize);
        (res, sat2) = SignedSatQ{2*esize}(result);
        Q(d>>1)[e*:(2*esize)] = res;
        if sat1 || sat2 then FPSCR().QC = '1'; end;
    end;
end;

```

C6.1.155 VQDMLSL

Vector Saturating Doubling Multiply Subtract Long multiplies corresponding elements in two doubleword vectors, subtracts double the products from corresponding elements of a quadword vector, and places the results in the same quadword vector.

The second operand can be a scalar instead of a vector. For more information about scalars see [Advanced SIMD scalars](#).

If any of the results overflow, they are saturated. The cumulative saturation bit, [FPSCR.QC](#), is set if saturation occurs. For details see [Pseudocode details of saturation](#).

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#) and [A2](#)) and T32 ([T1](#) and [T2](#)).

A1

Encoding

VQDMLSL{<c>}{<q>}.<dt> <Qd>, <Dn>, <Dm>

Decode for this encoding

```

if size == '11' then See("Related encodings"); end;

let elements : integer = 64 DIV esize;
```

Related encodings: See [Advanced SIMD data-processing](#) for the T32 instruction set, or [Advanced SIMD data-processing](#) for the A32 instruction set.

Assembler Symbols

<c>

For the “A1 128-bit SIMD vector”, “A1 64-bit SIMD vector”, “A2 128-bit SIMD vector”, and “A2 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#). This encoding must be unconditional.

For the “T1 128-bit SIMD vector”, “T1 64-bit SIMD vector”, “T2 128-bit SIMD vector”, and “T2 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<dt>

Is the data type for the elements of the operands, encoded in “size”:

size	<dt>
01	S16
10	S32

<Dd>

Is the 64-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field.

<Dn>

Is the 64-bit name of the first SIMD&FP source register, encoded in the “N:Vn” field.

<Dm>

Is the 64-bit name of the second SIMD&FP source register, encoded in the “M:Vm” field.

<Qd>

Is the 128-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field as <Qd>*2.

<Qn>

Is the 128-bit name of the first SIMD&FP source register, encoded in the “N:Vn” field as <Qn>*2.

<Qm>

Is the 128-bit name of the second SIMD&FP source register, encoded in the “M:Vm” field as <Qm>*2.

<Dm[x]>

Is the 64-bit name of the second SIMD&FP source register holding the scalar. If <dt> is S16, Dm is restricted to D0-D7. Dm is encoded in “Vm<2:0>”, and x is encoded in “M:Vm<3>”. If <dt> is S32, Dm is restricted to D0-D15. Dm is encoded in “Vm”, and x is encoded in “M”.

Operation

```

if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();
    var op2 : integer;
    if scalar_form then op2 = SInt(D(m)[index*:esize]); end;
    for r = 0 to regs-1 do
        for e = 0 to elements-1 do
            if !scalar_form then op2 = SInt(D(m+r)[e*:esize]); end;
            let op1 : integer = SInt(D(n+r)[e*:esize]);

<Dm>
Is the 64-bit name of the second SIMD&FP source register, encoded in the “M:Vm” field.

<Dm[x]>
Is the 64-bit name of the second SIMD&FP source register holding the scalar. If <dt> is S16, Dm is restricted to D0-D7. Dm is encoded in “Vm<2:0>”, and x is encoded in “M:Vm<3>”. If <dt> is S32, Dm is restricted to D0-D15. Dm is encoded in “Vm”, and x is encoded in “M”.

Operation

```
if ConditionPassed() then
  EncodingSpecificOperations();
  CheckAdvSIMDEnabled();
  var op2 : integer;
  if scalar_form then op2 = SInt(Din(m)[index*esize]); end;
  for e = 0 to elements-1 do
    if !scalar_form then op2 = SInt(Din(m)[e*esize]); end;
```

```
    let op1 : integer = SInt(Din(n)[e*:esize]);  
    // The following only saturates if both op1 and op2 equal  $-(2^{(esize-1)})$   
    let (product, sat) : (bits(2*esize), boolean) = SignedSatQ{2*esize}(2*op1*op2);  
    Q(d>>1)[e*:(2*esize)] = product;  
    if sat then FPSCR().QC = '1'; end;  
end;  
end;
```

C6.1.158 VQMOVN, VQMOVUN

Vector Saturating Move and Narrow copies each element of the operand vector to the corresponding element of the destination vector.

The operand is a quadword vector. The elements can be any one of:

- 16-bit, 32-bit, or 64-bit signed integers.
- 16-bit, 32-bit, or 64-bit unsigned integers.

The result is a doubleword vector. The elements are half the length of the operand vector elements. If the operand is unsigned, the results are unsigned. If the operand is signed, the results can be signed or unsigned.

If any of the results overflow, they are saturated. The cumulative saturation bit, **FPSCR.QC**, is set if saturation occurs. For details see [Pseudocode details of saturation](#).

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be `UNDEFINED`, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

This instruction is used by the pseudo-instructions `VQRSHRN (zero)`, `VQRSHRUN (zero)`, `VQSHRN (zero)`, and `VQSHRUN (zero)`.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding for the Signed result variant

Applies when (op == 1x)

VQMOVN{<c>} {<q>} .<dt> <Dd>, <Qm>

Encoding for the Unsigned result variant

Applies when (op == 01)

VQMOVUN{<c>} {<q>}.<dt> <Dd>, <Qm>

Decode for all variants of this encoding

```

if op == '00' then See("VMOVN"); end;
if size == '11' || Vm[0] == '1' then Undefined(); end;
let src_unsigned : boolean = (op == '11');
let dest_unsigned : boolean = (op[0] == '1');
let esize : integer{} = 8 << UInt(size);
let elements : integer = 64 DIV esize;
let d : integer = UInt(D::Vd);
let m : integer = UInt(M::Vm);

```

T1

Encoding for the Signed result variant

Applies when (op == 1x)

VQMOVN{<c>}{<q>}.<dt> <Dd>, <Qm>

Encoding for the Unsigned result variant

Applies when (op == 01)

VQMOVUN{<c>}{<q>}.<dt> <Dd>, <Qm>

Decode for all variants of this encoding

```
if op == '00' then See("VMOVN"); end;  
if size == '11' || Vm[0] == '1' then Undefined(); end;  
let src_unsigned : boolean = (op == '11');  
let dest_unsigned : boolean = (op[0] == '1');  
let esize : integer{} = 8 << UInt(size);  
let elements : integer = 64 DIV esize;  
let d : integer = UInt(D::Vd);  
let m : integer = UInt(M::Vm);
```

Assembler Symbols

<c>

For the “A1 Signed result” and “A1 Unsigned result” variants: see [Standard assembler syntax fields](#). This encoding must be unconditional.

For the “T1 Signed result” and “T1 Unsigned result” variants: see [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<dt>

For the “A1 Signed result” and “T1 Signed result” variants: is the data type for the elements of the operand, encoded in “op:size”:

op	size	<dt>
10	00	S16
10	01	S32
10	10	S64
1x	11	RESERVED
11	00	U16

op	size	<dt>
11	01	U32
11	10	U64

For the “A1 Unsigned result” and “T1 Unsigned result” variants: is the data type for the elements of the operand, encoded in “size”:

size	<dt>
00	S16
01	S32
10	S64
11	RESERVED

<Dd>

Is the 64-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field.

<Qm>

Is the 128-bit name of the SIMD&FP source register, encoded in the “M:Vm” field as <Qm>*2.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();
    for e = 0 to elements-1 do
        let opelt : bits(2*esize) = Qin(m>>1)[e:(2*esize)];
        let element : integer = if src_unsigned then UInt(opelt) else SInt(opelt);
        let (res, sat) : (bits(esize), boolean) = SatQ{esize}(element, dest_unsigned);
        D(d)[e*:esize] = res;
        if sat then FPSCR().QC = '1'; end;
    end;
end;
```

C6.1.159 VQNEG

Vector Saturating Negate negates each element in a vector, and places the results in the destination vector.

If any of the results overflow, they are saturated. The cumulative saturation bit, **FPSCR.QC**, is set if saturation occurs. For details see [Pseudocode details of saturation](#).

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be `UNDEFINED`, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 (A1) and T32 (T1).

A1

Encoding for the 64-bit SIMD vector variant

Applies when ($Q = 0$)

VONEG{<c>}{<q>}.<dt> <Dd>, <Dm>

Encoding for the 128-bit SIMD vector variant

Applies when ($Q == 1$)

$$\text{VQNEG}\{\langle c \rangle\}\{\langle q \rangle\}.\langle dt \rangle \quad \langle Qd \rangle, \langle Qm \rangle$$

Decode for all variants of this encoding

```

if size == '11' then Undefined(); end;
if Q == '1' && (Vd[0] == '1' || Vm[0] == '1') then Undefined(); end;
let esize : integer{} = 8 << UInt(size);
let elements : integer = 64 DIV esize;
let d : integer = UInt(D:~Vd);
let m : integer = UInt(M:~Vm);
let regs : integer = if Q == '0' then 1 else 2;

```

T1

Encoding for the 64-bit SIMD vector variant

Applies when ($Q == 0$)

VQNEG{<c>}{<q>}.<dt> <Dd>, <Dm>

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

VQNEG{<c>}{<q>}.<dt> <Qd>, <Qm>

Decode for all variants of this encoding

```
if size == '11' then Undefined(); end;
if Q == '1' && (Vd[0] == '1' || Vm[0] == '1') then Undefined(); end;
let esize : integer{} = 8 << UInt(size);
let elements : integer = 64 DIV esize;
let d : integer = UInt(D::Vd);
let m : integer = UInt(M::Vm);
let regs : integer = if Q == '0' then 1 else 2;
```

Assembler Symbols

<c>

For the “A1 128-bit SIMD vector” and “A1 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#). This encoding must be unconditional.

For the “T1 128-bit SIMD vector” and “T1 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<dt>

Is the data type for the elements of the vectors, encoded in “size”:

size	<dt>
00	S8
01	S16
10	S32
11	RESERVED

<Dd>

Is the 64-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field.

<Dm>

Is the 64-bit name of the SIMD&FP source register, encoded in the “M:Vm” field.

<Qd>

Is the 128-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field as <Qd>*2.

<Qm>

Is the 128-bit name of the SIMD&FP source register, encoded in the “M:Vm” field as <Qm>*2.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();
    for r = 0 to regs-1 do
        for e = 0 to elements-1 do
            let result : integer = -SInt(D(m+r)[e*:esize]);
            let (res, sat) : (bits(esize), boolean) = SignedSatQ{esize}(result);
            D(d+r)[e*:esize] = res;
            if sat then FPSCR().QC = '1'; end;
        end;
    end;
end;
```

C6.1.160 VQRDMULH

Vector Saturating Rounding Doubling Multiply Returning High Half multiplies corresponding elements in two vectors, doubles the results, and places the most significant half of the final results in the destination vector. The results are rounded. For truncated results see [VQDMULH](#).

The second operand can be a scalar instead of a vector. For more information about scalars see [Advanced SIMD scalars](#).

If any of the results overflow, they are saturated. The cumulative saturation bit, [FPSCR.QC](#), is set if saturation occurs. For details see [Pseudocode details of saturation](#).

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#) and [A2](#)) and T32 ([T1](#) and [T2](#)).

A1

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0)

VQRDMULH{<c>}{<q>}.<dt> {<Dd>, }<Dn>, <Dm>

Encoding for the 128-bit SIMD vector variant

For the “T1 128-bit SIMD vector”, “T1 64-bit SIMD vector”, “T2 128-bit SIMD vector”, and “T2 64-bit SIMD vector” variants: see Standard assembler syntax fields.

<q>

See Standard assembler syntax fields.

<dt>

Is the data type for the elements of the operands, encoded in “size”:

size	<dt>
01	S16
10	S32

<Dd>

Is the 64-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field.

<Dn>

Is the 64-bit name of the first SIMD&FP source register, encoded in the “N:Vn” field.

<Dm>

Is the 64-bit name of the second SIMD&FP source register, encoded in the “M:Vm” field.

<Qd>

Is the 128-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field as <Qd>*2.

<Qn>

Is the 128-bit name of the first SIMD&FP source register, encoded in the “N:Vn” field as <Qn>*2.

<Qm>

Is the 128-bit name of the second SIMD&FP source register, encoded in the “M:Vm” field as <Qm>*2.

<Dm[x]>

Is the 64-bit name of the second SIMD&FP source register holding the scalar. If <dt> is S16, Dm is restricted to D0-D7. Dm is encoded in “Vm<2:0>”, and x is encoded in “M:Vm<3>”. If <dt> is S32, Dm is restricted to D0-D15. Dm is encoded in “Vm”, and x is encoded in “M”.

Operation

```

if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();
    var op2 : integer;
    let round : boolean = TRUE;
    if scalar_form then op2 = SInt(D(m)[index*:esize]); end;
    for r = 0 to regs-1 do
        for e = 0 to elements-1 do
            let op1 : integer = SInt(D(n+r)[e*:esize]);
            if !scalar_form then op2 = SInt(D(m+r)[e*:esize]); end;
            let rdmulh : integer = RShr(2*op1*op2, esize, round);
            let (result, sat) : (bits(esize), boolean) = SignedSatQ{esize}(rdmulh);
            D(d+r)[e*:esize] = result;
            if sat then FPSCR().QC = '1'; end;
        end;
    end;
end;
end;

```

C6.1.161 VQRSHL

Vector Saturating Rounding Shift Left takes each element in a vector, shifts them by a value from the least significant byte of the corresponding element of a second vector, and places the results in the destination vector. If the shift value is positive, the operation is a left shift. Otherwise, it is a right shift.

For truncated results see [VQSHL \(register\)](#).

The first operand and result elements are the same data type, and can be any one of:

- 8-bit, 16-bit, 32-bit, or 64-bit signed integers.
- 8-bit, 16-bit, 32-bit, or 64-bit unsigned integers.

The second operand is a signed integer of the same size.

If any of the results overflow, they are saturated. The cumulative saturation bit, [FPSCR.QC](#), is set if saturation occurs. For details see [Pseudocode details of saturation](#).

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding for the 64-bit SIMD vector variant

            let opelt : bits(esize) = D(m+r)[e*:esize];
            var element : integer = if unsigned then UInt(opelt) else SInt(opelt);
            var shift : integer = SInt(D(n+r)[e*:esize][7:0]);
            if shift >= 0 then // left shift
                element = element << shift;
            else // rounding right shift
                shift = -shift;
                element = (element + (1 << (shift - 1))) >> shift;
            end;
            (result, sat) = SatQ(esize)(element, unsigned);
            D(d+r)[e*:esize] = result;
            if sat then FPSCR().QC = '1'; end;
        end;
    end;
end;

```

C6.1.162 VQRSHRN, VQRSHRUN

Vector Saturating Rounding Shift Right, Narrow takes each element in a quadword vector of integers, right shifts them by an immediate value, and places the rounded results in a doubleword vector.

For truncated results, see [VQSHRN](#) and [VQSHRUN](#).

The operand elements must all be the same size, and can be any one of:

- 16-bit, 32-bit, or 64-bit signed integers.
- 16-bit, 32-bit, or 64-bit unsigned integers.

The result elements are half the width of the operand elements. If the operand elements are signed, the results can be either signed or unsigned. If the operand elements are unsigned, the result elements must also be unsigned.

If any of the results overflow, they are saturated. The cumulative saturation bit, [FPSCR.QC](#), is set if saturation occurs. For details see [Pseudocode details of saturation](#).

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

let elements : integer = 64 DIV esize;
let shift_amount : integer = (esize << 1) - UInt(imm6);
let src_unsigned : boolean = (U == '1' && op == '1');
let dest_unsigned : boolean = (U == '1');
let d : integer = UInt(D::Vd);
let m : integer = UInt(M::Vm);
```

Related encodings: See [Advanced SIMD one register and modified immediate](#) for the T32 instruction set, or [Advanced SIMD one register and modified immediate](#) for the A32 instruction set.

Assembler Symbols

<c>

For the “A1 Signed result” and “A1 Unsigned result” variants: see [Standard assembler syntax fields](#). This encoding must be unconditional.

For the “T1 Signed result” and “T1 Unsigned result” variants: see [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<type>

For the “A1 Signed result” and “T1 Signed result” variants: is the data type for the elements of the vectors, encoded in “U”:

U	<type>
0	S

1	U
---	---

For the “A1 Unsigned result” and “T1 Unsigned result” variants: is S when “U” is 1, and is encoded in “U”.

<size>

Is the data size for the elements of the vectors, encoded in “imm6”:

imm6	<size>
001xxx	16
01xxxx	32
1xxxxx	64

<Dd>

Is the 64-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field.

<Qm>

Is the 128-bit name of the SIMD&FP source register, encoded in the “M:Vm” field as <Qm>*2.

<imm>

Is an immediate value, in the range 1 to <size>/2, encoded in the “imm6” field as <size>/2 - <imm>.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();
    let round : boolean = TRUE;
    for e = 0 to elements-1 do
        let opelt : bits(2*esize) = Qin(m>>1)[e*:(2*esize)];
        let element : integer = if src_unsigned then UInt(opelt) else SInt(opelt);
        let rshrn : integer = RShr(element, shift_amount, round);
        let (result, sat) : (bits(esize), boolean) = SatQ(esize)(rshrn, dest_unsigned);
        D(d)[e*:(esize)] = result;
        if sat then FPSCR().QC = '1'; end;
    end;
end;
```

C6.1.163 VQRSHRN (zero)

Vector Saturating Rounding Shift Right, Narrow takes each element in a quadword vector of integers, right shifts them by an immediate value, and places the signed rounded results in a doubleword vector.

This is a pseudo-instruction of [VQMOVN](#), [VQMOVUN](#). This means:

- The encodings in this description are named to match the encodings of [VQMOVN](#), [VQMOVUN](#).
- The assembler syntax is used only for assembly, and is not used on disassembly.
- The description of [VQMOVN](#), [VQMOVUN](#) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

31	28	27	26	25	24	23	22	21	20	19	18	17	16	15	12	11	10	8	7	6	5	4	3	0
1	1	1	1	0	0	1	1	D	1	1	size	1	0	Vd	0	0	1	0	1	x	M	0	Vm	
└─opc1														└─op										

Encoding for the Signed result variant

VQRSHRN{<c>}{<q>}.<dt> <Dd>, <Qm>, #0

is equivalent to

VQMOVN{<c>}{<q>}.<dt> <Dd>, <Qm>

T1

15	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	12	11	10	8	7	6	5	4	3	0

Encoding for the Unsigned result variant

VQRSHRUN{<c>}{<q>}.<dt> <Dd>, <Qm>, #0

is equivalent to

VQMOVUN{<c>}{<q>}.<dt> <Dd>, <Qm>

Assembler Symbols

<c>

For the “A1 Unsigned result” variant: see [Standard assembler syntax fields](#). This encoding must be unconditional.

For the “T1 Unsigned result” variant: see [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<dt>

Is the data type for the elements of the operand, encoded in “size”:

size	<dt>
00	S16
01	S32
10	S64
11	RESERVED

<Dd>

Is the 64-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field.

<Qm>

Is the 128-bit name of the SIMD&FP source register, encoded in the “M:Vm” field as <Qm>*2.

Operation

The description of [VQMOVN](#), [VQMOVUN](#) gives the operational pseudocode for this instruction.

C6.1.165 VQSHL, VQSHLU (immediate)

Vector Saturating Shift Left (immediate) takes each element in a vector of integers, left shifts them by an immediate value, and places the results in a second vector.

The operand elements must all be the same size, and can be any one of:

- 8-bit, 16-bit, 32-bit, or 64-bit signed integers.
- 8-bit, 16-bit, 32-bit, or 64-bit unsigned integers.

The result elements are the same size as the operand elements. If the operand elements are signed, the results can be either signed or unsigned. If the operand elements are unsigned, the result elements must also be unsigned.

If any of the results overflow, they are saturated. The cumulative saturation bit, [FPSCR.QC](#), is set if saturation occurs. For details see [Pseudocode details of saturation](#).

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

31						25	24	23	22	21						16	15						12	11						9	8	7	6	5	4	3						0
1	1	1	1	0	0	1	U	1	D	imm6					Vd					0					1	1	op	L	Q	M	1	Vm										

Encoding for the 64-bit SIMD vector, signed result variant

Applies when (op == 1 && Q == 0 && !(imm6[5:3] == 000 && L == 0))

```
VQSHL{<c>}{<q>}.<type><size> {<Dd>, }<Dm>, #<imm>
```

Encoding for the 64-bit SIMD vector, unsigned result variant

Applies when (U == 1 && op == 0 && Q == 0 && !(imm6[5:3] == 000 && L == 0))

```
VQSHLU{<c>}{<q>}.<type><size> {<Dd>, }<Dm>, #<imm>
```

Encoding for the 128-bit SIMD vector, signed result variant

Applies when (op == 1 && Q == 1 && !(imm6[5:3] == 000 && L == 0))

```
VQSHL{<c>}{<q>}.<type><size> {<Qd>, }<Qm>, #<imm>
```

Encoding for the 128-bit SIMD vector, unsigned result variant

For the “A1 128-bit SIMD vector, signed result”, “A1 128-bit SIMD vector, unsigned result”, “A1 64-bit SIMD vector, signed result”, and “A1 64-bit SIMD vector, unsigned result” variants: see [Standard assembler syntax fields](#). This encoding must be unconditional.

For the “T1 128-bit SIMD vector, signed result”, “T1 128-bit SIMD vector, unsigned result”, “T1 64-bit SIMD vector, signed result”, and “T1 64-bit SIMD vector, unsigned result” variants: see [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<type>

Is the data type for the elements of the vectors, encoded in “U”:

U	<type>
0	S
1	U

<size>

Is the data size for the elements of the vectors, encoded in “L:imm6”:

L	imm6	<size>
0	001xxx	8
0	01xxxx	16
0	1xxxxx	32
1	xxxxxx	64

<Dd>

Is the 64-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field.

<Dm>

Is the 64-bit name of the SIMD&FP source register, encoded in the “M:Vm” field.

<imm>

Is an immediate value, in the range 0 to <size>-1, encoded in the “imm6” field.

<Qd>

Is the 128-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field as <Qd>*2.

<Qm>

Is the 128-bit name of the SIMD&FP source register, encoded in the “M:Vm” field as <Qm>*2.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();
    for r = 0 to regs-1 do
        for e = 0 to elements-1 do
            let opelt : bits(esize) = D(m+r)[e*:esize];
            let element : integer = if src_unsigned then UInt(opelt) else SInt(opelt);
            let (result, sat) : (bits(esize), boolean) = SatQ(esize)(element << shift_amount,
                                                                    dest_unsigned);

            D(d+r)[e*:esize] = result;
            if sat then FPSCR().QC = '1'; end;
        end;
    end;
end;
```

C6.1.166 VQSHL (register)

Vector Saturating Shift Left (register) takes each element in a vector, shifts them by a value from the least significant byte of the corresponding element of a second vector, and places the results in the destination vector. If the shift value is positive, the operation is a left shift. Otherwise, it is a right shift.

The results are truncated. For rounded results, see [VQRSHL](#).

The first operand and result elements are the same data type, and can be any one of:

- 8-bit, 16-bit, 32-bit, or 64-bit signed integers.
- 8-bit, 16-bit, 32-bit, or 64-bit unsigned integers.

The second operand is a signed integer of the same size.

If any of the results overflow, they are saturated. The cumulative saturation bit, [FPSCR.QC](#), is set if saturation occurs. For details see [Pseudocode details of saturation](#).

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding for the 64-bit SIMD vector variant

            else
                (result,sat) = SatQ{esize}(element >> -shift, unsigned);
            end;
            D(d+r)[e*:esize] = result;
            if sat then FPSCR().QC = '1'; end;
        end;
    end;
end;

```

C6.1.167 VQSHRN, VQSHRUN

Vector Saturating Shift Right, Narrow takes each element in a quadword vector of integers, right shifts them by an immediate value, and places the truncated results in a doubleword vector.

For rounded results, see [VQRSHRN](#) and [VQRSHRUN](#).

The operand elements must all be the same size, and can be any one of:

- 16-bit, 32-bit, or 64-bit signed integers.
- 16-bit, 32-bit, or 64-bit unsigned integers.

The result elements are half the width of the operand elements. If the operand elements are signed, the results can be either signed or unsigned. If the operand elements are unsigned, the result elements must also be unsigned.

If any of the results overflow, they are saturated. The cumulative saturation bit, [FPSCR.QC](#), is set if saturation occurs. For details see [Pseudocode details of saturation](#).

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

Is the 64-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field.

<Qm>

Is the 128-bit name of the SIMD&FP source register, encoded in the “M:Vm” field as <Qm>*2.

<imm>

Is an immediate value, in the range 1 to <size>/2, encoded in the “imm6” field as <size>/2 - <imm>.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();
    for e = 0 to elements-1 do
        let opelt : bits(2*esize) = Qin(m>>1)[e*:(2*esize)];
        let element : integer = if src_unsigned then UInt(opelt) else SInt(opelt);
        let (result, sat) : (bits(esize), boolean) = SatQ(esize)(element >> shift_amount,
                                                                    dest_unsigned);

        D(d)[e*esize] = result;
        if sat then FPSCR().QC = '1'; end;
    end;
end;
```

C6.1.168 VQSHRN (zero)

Vector Saturating Shift Right, Narrow takes each element in a quadword vector of integers, right shifts them by an immediate value, and places the signed truncated results in a doubleword vector.

This is a pseudo-instruction of [VQMOVN](#), [VQMOVUN](#). This means:

- The encodings in this description are named to match the encodings of [VQMOVN](#), [VQMOVUN](#).
- The assembler syntax is used only for assembly, and is not used on disassembly.
- The description of [VQMOVN](#), [VQMOVUN](#) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

31	28	27	26	25	24	23	22	21	20	19	18	17	16	15	12	11	10	8	7	6	5	4	3	0
1	1	1	1	0	0	1	1	D	1	1	size	1	0	Vd	0	0	1	0	1	x	M	0	Vm	
														</										

<dt>

Is the data type for the elements of the operand, encoded in “op:size”:

op	size	<dt>
10	00	S16
10	01	S32
10	10	S64
1x	11	RESERVED
11	00	U16
11	01	U32
11	10	U64

<Dd>

Is the 64-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field.

<Qm>

Is the 128-bit name of the SIMD&FP source register, encoded in the “M:Vm” field as <Qm>*2.

Operation

The description of [VQMOVN](#), [VQMOVUN](#) gives the operational pseudocode for this instruction.

C6.1.169 VQSHRUN (zero)

Vector Saturating Shift Right, Narrow takes each element in a quadword vector of integers, right shifts them by an immediate value, and places the unsigned truncated results in a doubleword vector.

This is a pseudo-instruction of [VQMOVN](#), [VQMOVUN](#). This means:

- The encodings in this description are named to match the encodings of [VQMOVN](#), [VQMOVUN](#).
- The assembler syntax is used only for assembly, and is not used on disassembly.
- The description of [VQMOVN](#), [VQMOVUN](#) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

31	28	27	26	25	24	23	22	21	20	19	18	17	16	15	12	11	10	8	7	6	5	4	3	0
1	1	1	1	0	0	1	1	D	1	1	size	1	0	Vd	0	0	1	0	0	1	M	0	Vm	
└─opc1														└─op										

Encoding for the Unsigned result variant

VQSHRUN{<c>}{<q>}.<dt> <Dd>, <Qm>, #0

is equivalent to

VQMOVUN{<c>}{<q>}.<dt> <Dd>, <Qm>

T1

15	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	12	11	10	8	7	6	5	4	3	0	
1	1	1	1	1	1	1	1	D	1	1	size	1	0		Vd		0	0	1	0	0	1	M	0		Vm
└opc1														└op												

Encoding for the Unsigned result variant

VQSHRUN{<c>}{<q>}.<dt> <Dd>, <Qm>, #0

is equivalent to

VQMOVUN{<c>}{<q>}.<dt> <Dd>, <Qm>

Assembler Symbols

<c>

For the “A1 Unsigned result” variant: see [Standard assembler syntax fields](#). This encoding must be unconditional.

For the “T1 Unsigned result” variant: see [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<dt>

Is the data type for the elements of the operand, encoded in “size”:

size	<dt>
00	S16
01	S32
10	S64
11	RESERVED

<Dd>

Is the 64-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field.

<Qm>

Is the 128-bit name of the SIMD&FP source register, encoded in the “M:Vm” field as <Qm>*2.

Operation

The description of [VQMOVN](#), [VQMOVUN](#) gives the operational pseudocode for this instruction.

C6.1.170 VQSUB

Vector Saturating Subtract subtracts the elements of the second operand vector from the corresponding elements of the first operand vector, and places the results in the destination vector. Signed and unsigned operations are distinct.

The operand and result elements must all be the same type, and can be any one of:

- 8-bit, 16-bit, 32-bit, or 64-bit signed integers.
- 8-bit, 16-bit, 32-bit, or 64-bit unsigned integers.

If any of the results overflow, they are saturated. The cumulative saturation bit, **FPSCR.QC**, is set if saturation occurs. For details see [Pseudocode details of saturation](#).

Depending on settings in the **CPACR**, **NSACR**, and **HCPTTR** registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be **UNDEFINED**, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 (**A1**) and T32 (**T1**).

A1

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0)

VQSUB{<c>}{<q>}.<dt> {<Dd>, }<Dn>, <Dm>

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

VQSUB{<c>}{<q>}.<dt> {<Qd>, }<Qn>, <Qm>

Decode for all variants of this encoding

```

if Q == '1' && (Vd[0] == '1' || Vn[0] == '1' || Vm[0] == '1') then Undefined(); end;
let unsigned : boolean = (U == '1');
let esize : integer{} = 8 << UInt(size);
let elements : integer = 64 DIV esize;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);
let regs : integer = if Q == '0' then 1 else 2;

```

T1

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0)

VQSUB{<c>}{<q>}.<dt> {<Dd>, }<Dn>, <Dm>

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

VQSUB{<c>}{<q>}.<dt> {<Qd>, }<Qn>, <Qm>

Decode for all variants of this encoding

```
if Q == '1' && (Vd[0] == '1' || Vn[0] == '1' || Vm[0] == '1') then Undefined(); end;
let unsigned : boolean = (U == '1');
let esize : integer{} = 8 << UInt(size);
let elements : integer = 64 DIV esize;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);
let regs : integer = if Q == '0' then 1 else 2;
```

Assembler Symbols

<c>

For the “A1 128-bit SIMD vector” and “A1 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#). This encoding must be unconditional.

For the “T1 128-bit SIMD vector” and “T1 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<dt>

Is the data type for the elements of the vectors, encoded in “U:size”:

U	size	<dt>
0	00	S8
0	01	S16
0	10	S32
0	11	S64
1	00	U8
1	01	U16
1	10	U32
1	11	U64

<Dd>

Is the 64-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field.

<Dn>

Is the 64-bit name of the first SIMD&FP source register, encoded in the “N:Vn” field.

<Dm>

Is the 64-bit name of the second SIMD&FP source register, encoded in the “M:Vm” field.

<Qd>

Is the 128-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field as <Qd>*2.

<Qn>

Is the 128-bit name of the first SIMD&FP source register, encoded in the “N:Vn” field as <Qn>*2.

<Qm>

Is the 128-bit name of the second SIMD&FP source register, encoded in the “M:Vm” field as <Qm>*2.

Operation

```

if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();
    for r = 0 to regs-1 do
        for e = 0 to elements-1 do
            let op1elt : bits(esize) = D(n+r)[e*:esize];
            let op2elt : bits(esize) = D(m+r)[e*:esize];
            let element1 : integer = if unsigned then UInt(op1elt) else SInt(op1elt);
            let element2 : integer = if unsigned then UInt(op2elt) else SInt(op2elt);
            let diff : integer = element1 - element2;
            let (res, sat) : (bits(esize), boolean) = SatQ{esize}(diff, unsigned);
            D(d+r)[e*:esize] = res;
            if sat then FPSCR().QC = '1'; end;
        end;
    end;
end;

```

C6.1.171 VRADDHN

Vector Rounding Add and Narrow, returning High Half adds corresponding elements in two quadword vectors, and places the most significant half of each result in a doubleword vector. The results are rounded. For truncated results, see [VADDHN](#).

The operand elements can be 16-bit, 32-bit, or 64-bit integers. There is no distinction between signed and unsigned integers.

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

VRADDHN{<c>}{<q>}.<dt> <Dd>, <Qn>, <Qm>

Decode for this encoding

```

if size == '11' then See("Related encodings"); end;
if Vn[0] == '1' || Vm[0] == '1' then Undefined(); end;
let esize : integer{} = 8 << UInt(size);
let elements : integer = 64 DIV esize;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);

```

T1

Encoding

VRADDHN{<c>}{<q>}.<dt> <Dd>, <Qn>, <Qm>

Decode for this encoding

```

if size == '11' then See("Related encodings"); end;
if Vn[0] == '1' || Vm[0] == '1' then Undefined(); end;
let esize : integer{} = 8 << UInt(size);
let elements : integer = 64 DIV esize;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);

```

Related encodings: See [Advanced SIMD data-processing](#) for the T32 instruction set, or [Advanced SIMD data-processing](#) for the A32 instruction set.

Assembler Symbols

<c>

For the “A1” variant: see [Standard assembler syntax fields](#). This encoding must be unconditional.

For the “T1” variant: see [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<dt>

Is the data type for the elements of the operands, encoded in “size”:

size	<dt>
00	I16
01	I32
10	I64

<Dd>

Is the 64-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field.

<Qn>

Is the 128-bit name of the first SIMD&FP source register, encoded in the “N:Vn” field as <Qn>*2.

<Qm>

Is the 128-bit name of the second SIMD&FP source register, encoded in the “M:Vm” field as <Qm>*2.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();
    let round : boolean = TRUE;
    for e = 0 to elements-1 do
        let result : integer = (RShr(UInt(Qin(n>>1)[e:(2*esize)] +
                                   Qin(m>>1)[e:(2*esize)]), esize, round));
        D(d)[e*:esize] = result[esize-1:0];
    end;
end;
```

C6.1.172 VRECPE

Vector Reciprocal Estimate finds an approximate reciprocal of each element in the operand vector, and places the results in the destination vector.

The operand and result elements are the same type, and can be floating-point numbers or unsigned integers.

For details of the operation performed by this instruction see [Floating-point reciprocal square root estimate and step](#).

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be `UNDEFINED`, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding for the 64-bit SIMD vector variant

Applies when ($Q = 0$)

VRECPE{<c>}{<q>}.<dt> <Dd>, <Dm>

Encoding for the 128-bit SIMD vector variant

Applies when ($Q == 1$)

VRECPE{<c>}{<q>}.<dt> <Qd>, <Qm>

Decode for all variants of this encoding

```

if Q == '1' && (Vd[0] == '1' || Vm[0] == '1') then Undefined(); end;
if size != '10' then Undefined(); end;
let floating_point : boolean = (F == '1');
let esize : integer{} = 8 << UInt(size);
let elements : integer = 64 DIV esize;
let d : integer = UInt(D::Vd);
let m : integer = UInt(M::Vm);
let regs : integer = if Q == '0' then 1 else 2;

```

T1

Encoding for the 64-bit SIMD vector variant

Applies when ($Q = 0$)

VRECPE{<c>}{<q>}.<dt> <Dd>, <Dm>

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

VRECPE{<c>}{<q>}.<dt> <Qd>, <Qm>

Decode for all variants of this encoding

```
if Q == '1' && (Vd[0] == '1' || Vm[0] == '1') then Undefined(); end;
if size != '10' then Undefined(); end;
let floating_point : boolean = (F == '1');
let esize : integer{} = 8 << UInt(size);
let elements : integer = 64 DIV esize;
let d : integer = UInt(D::Vd);
let m : integer = UInt(M::Vm);
let regs : integer = if Q == '0' then 1 else 2;
```

CONSTRAINED UNPREDICTABLE behavior

If size == '01' && InITBlock(), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

Assembler Symbols

<c>

For the “A1 128-bit SIMD vector” and “A1 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#). This encoding must be unconditional.

For the “T1 128-bit SIMD vector” and “T1 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<dt>

Is the data type for the elements of the vectors, encoded in “F:size”:

F	size	<dt>
0	10	U32
1	01	F16
1	10	F32

<Dd>

Is the 64-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field.

<Dm>

Is the 64-bit name of the SIMD&FP source register, encoded in the “M:Vm” field.

<Qd>

Is the 128-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field as <Qd>*2.

<Qm>

Is the 128-bit name of the SIMD&FP source register, encoded in the “M:Vm” field as <Qm>*2.

Newton-Raphson iteration

For details of the operation performed and how it can be used in a Newton-Raphson iteration to calculate the reciprocal of a number, see [Floating-point reciprocal estimate and step](#).

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();
    let fpcr : FPCR_Type = StandardFPCR();
    for r = 0 to regs-1 do
        for e = 0 to elements-1 do
            if floating_point then
                D(d+r)[e*:size] = FPRecipEstimate{size}(D(m+r)[e*:size], fpcr);
            else
                D(d+r)[e*:size] = UnsignedRecipEstimate{size}(D(m+r)[e*:size]);
            end;
        end;
    end;
end;
```

C6.1.173 VRECPS

Vector Reciprocal Step multiplies the elements of one vector by the corresponding elements of another vector, subtracts each of the products from 2.0, and places the results into the elements of the destination vector.

The operand and result elements are floating-point numbers.

For details of the operation performed by this instruction see [Floating-point reciprocal estimate and step](#).

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0)

VRECPS{<c>}{<q>}.<dt> {<Dd>, }<Dn>, <Dm>

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

VRECPS{<c>}{<q>}.<dt> {<Qd>, }<Qn>, <Qm>

Decode for all variants of this encoding

```

if Q == '1' && (Vd[0] == '1' || Vn[0] == '1' || Vm[0] == '1') then Undefined(); end;
if sz == '1' then Undefined(); end;
let esize : integer() = 32 >> UInt(sz);
let elements : integer = 64 DIV esize;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);
let regs : integer = if Q == '0' then 1 else 2;

```

T1

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0)

VRECPS{<c>}{<q>}.<dt> {<Dd>, }<Dn>, <Dm>

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

VRECPS{<c>}{<q>}.<dt> {<Qd>, }<Qn>, <Qm>

Decode for all variants of this encoding

```
if Q == '1' && (Vd[0] == '1' || Vn[0] == '1' || Vm[0] == '1') then Undefined(); end;
if sz == '1' then Undefined(); end;
let esize : integer{} = 32 >> UInt(sz);
let elements : integer = 64 DIV esize;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);
let regs : integer = if Q == '0' then 1 else 2;
```

CONSTRAINED UNPREDICTABLE behavior

If size == '01' && InITBlock(), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

Is the 64-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field.

<Dm>

Is the 64-bit name of the SIMD&FP source register, encoded in the “M:Vm” field.

<Qd>

Is the 128-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field as <Qd>*2.

<Qm>

Is the 128-bit name of the SIMD&FP source register, encoded in the “M:Vm” field as <Qm>*2.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();

    var result : bits(64);
    var element : integer;
    var rev_element : integer;
    for r = 0 to regs-1 do
        element = 0;
        for c = 0 to containers-1 do
            rev_element = (element + elements_per_container) - 1;
            for e = 0 to elements_per_container-1 do
                result[rev_element*:esize] = D(m+r)[element*:esize];
                element = element + 1;
                rev_element = rev_element - 1;
            end;
        end;
        D(d+r) = result;
    end;
end;
```

C6.1.175 VREV32

Vector Reverse in words reverses the order of 8-bit or 16-bit elements in each word of the vector, and places the result in the corresponding destination vector.

There is no distinction between data types, other than size.

VREV32.8, doubleword

VREV32.16, doubleword

        end;
    end;
end;
```

C6.1.178 VRINTA (Advanced SIMD)

Vector Round floating-point to integer towards Nearest with Ties to Away

Vector Round floating-point to integer towards Nearest with Ties to Away rounds a vector of floating-point values to integral floating-point values of the same size using the Round to Nearest with Ties to Away rounding mode. A zero input gives a zero result with the same sign, an infinite input gives an infinite result with the same sign, and a NaN is propagated as for normal arithmetic.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding for the 64-bit SIMD vector variant

Applies when ($Q == 0$)

```
VRINTA{<q>}.<dt> <Dd>, <Dm>
```

Encoding for the 128-bit SIMD vector variant

Applies when ($Q == 1$)

```
VRINTA{ <q> } .<dt>    <Od> ,  <Om>
```

Decode for all variants of this encoding

```

if op[2] != op[0] then See("Related encodings"); end;
if Q == '1' && (Vd[0] == '1' || Vm[0] == '1') then Undefined(); end;
if size != '10' then Undefined(); end;
// Rounding encoded differently from other VCVT and VRINT instructions
let rounding : FPRounding = FPDecodeRM(op[2]::NOT(op[1]));
let exact : boolean = FALSE;
let esize : integer{} = 32;
let elements : integer = 64 DIV esize;
let d : integer = UInt(D::Vd);
let m : integer = UInt(M::Vm);
let regs : integer = if Q == '0' then 1 else 2;

```

T1

Encoding for the 64-bit SIMD vector variant

Applies when ($Q == 0$)

```
VRINTA{ <q> } .<dt>    <Dd> ,  <Dm>
```

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

VRINTA(<q>).<dt> <Qd>, <Qm>

Decode for all variants of this encoding

```
if op[2] != op[0] then See("Related encodings"); end;
if InITBlock() then UnpredictableProcedure(); end;
if Q == '1' && (Vd[0] == '1' || Vm[0] == '1') then Undefined(); end;
if size != '10' then Undefined(); end;
// Rounding encoded differently from other VCVT and VRINT instructions
let rounding : FPRounding = FPDecodeRM(op[2]::NOT(op[1]));
let exact : boolean = FALSE;
let esize : integer{} = 32;
let elements : integer = 64 DIV esize;
let d : integer = UInt(D::Vd);
let m : integer = UInt(M::Vm);
let regs : integer = if Q == '0' then 1 else 2;
```

CONSTRAINED UNPREDICTABLE behavior

If InITBlock(), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

Related encodings: See [Advanced SIMD two registers misc](#) for the T32 instruction set, or [Advanced SIMD two registers misc](#) for the A32 instruction set.

Assembler Symbols

<q>

See [Standard assembler syntax fields](#).

<dt>

Is the data type for the elements of the vectors, encoded in “size”:

Is the 128-bit name of the SIMD&FP source register, encoded in the “M:Vm” field as <Qm>*2.

Operation

```
EncodingSpecificOperations();  
CheckAdvSIMDEnabled();  
let fpcr : FPCR_Type = StandardFPCR();  
for r = 0 to regs-1 do  
    for e = 0 to elements-1 do  
        let operand1 : bits(usize) = D(m+r)[e*:usize];  
        let result : bits(usize) = FPRoundInt{}(operand1, fpcr, rounding, exact);  
        D(d+r)[e*:usize] = result;  
    end;  
end;  
end;
```

C6.1.181 VRINTM (floating-point)

Round floating-point to integer towards -Infinity rounds a floating-point value to an integral floating-point value of the same size using the Round towards -Infinity rounding mode. A zero input gives a zero result with the same sign, an infinite input gives an infinite result with the same sign, and a NaN is propagated as for normal arithmetic.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding for the Single-precision scalar variant

Applies when (size == 10)

```
VRINTM(<q>).F32 <Sd>, <Sm>
```

Encoding for the Double-precision scalar variant

Applies when (size == 11)

```
VRINTM(<q>).F64 <Dd>, <Dm>
```

Decode for all variants of this encoding

```
if size != '1x' then Undefined(); end;
let rounding : FPRounding = FPDecodeRM(RM);
let exact : boolean = FALSE;
let esize : integer{} = 8 << UInt(size);
let d : integer = if size == '11' then UInt(D::Vd) else UInt(Vd::D);
let m : integer = if size == '11' then UInt(M::Vm) else UInt(Vm::M);
```

T1

Encoding for the Single-precision scalar variant

Applies when (size == 10)

```
VRINTM(<q>).F32 <Sd>, <Sm>
```

Encoding for the Double-precision scalar variant

Applies when (size == 11)

```
VRINTM(<q>).F64 <Dd>, <Dm>
```

Decode for all variants of this encoding

```

if InITBlock() then UnpredictableProcedure(); end;
if size != '1x' then Undefined(); end;
let rounding : FPRounding = FPDecodeRM(RM);
let exact : boolean = FALSE;
let esize : integer{} = 8 << UInt(size);
let d : integer = if size == '11' then UInt(D::Vd) else UInt(Vd::D);
let m : integer = if size == '11' then UInt(M::Vm) else UInt(Vm::M);

```

CONSTRAINED UNPREDICTABLE behavior

If `InITBlock()`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<q>

See [Standard assembler syntax fields](#).

<Sd>

Is the 32-bit name of the SIMD&FP destination register, encoded in the “Vd:D” field.

<Sm>

Is the 32-bit name of the SIMD&FP source register, encoded in the “Vm:M” field.

<Dd>

Is the 64-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field.

<Dm>

Is the 64-bit name of the SIMD&FP source register, encoded in the “M:Vm” field.

Operation

```

EncodingSpecificOperations();
CheckVFPEEnabled(TRUE);
let fpcr : FPCR_Type = EffectiveFPCR();
case esize of
    when 32 =>
        S(d) = FPRoundInt{32}(S(m), fpcr, rounding, exact);
    when 64 =>
        D(d) = FPRoundInt{64}(D(m), fpcr, rounding, exact);
end;

```

C6.1.182 VRINTN (Advanced SIMD)

Vector Round floating-point to integer to Nearest rounds a vector of floating-point values to integral floating-point values of the same size using the Round to Nearest rounding mode. A zero input gives a zero result with the same sign, an infinite input gives an infinite result with the same sign, and a NaN is propagated as for normal arithmetic.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding for the 64-bit SIMD vector variant

Applies when ($Q = 0$)

```
VRINTN{<q>}.<dt> <Dd>, <Dm>
```

Encoding for the 128-bit SIMD vector variant

Applies when ($Q == 1$)

```
VRINTN{ <q> } .<dt>    <Qd>, <Qm>
```

Decode for all variants of this encoding

```

if op[2] != op[0] then See("Related encodings"); end;
if Q == '1' && (Vd[0] == '1' || Vm[0] == '1') then Undefined(); end;
if size != '10' then Undefined(); end;
// Rounding encoded differently from other VCVT and VRINT instructions
let rounding : FPRounding = FPDecodeRM(op[2]::NOT(op[1]));
let exact : boolean = FALSE;
let esize : integer{} = 32;
let elements : integer = 64 DIV esize;
let d : integer = UInt(D::Vd);
let m : integer = UInt(M::Vm);
let regs : integer = if Q == '0' then 1 else 2;

```

T1

Encoding for the 64-bit SIMD vector variant

Applies when ($Q == 0$)

```
VRINTN{<q>}.<dt> <Dd>, <Dm>
```

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

VRINTN(<q>).<dt> <Qd>, <Qm>

Decode for all variants of this encoding

```
if op[2] != op[0] then See("Related encodings"); end;
if InITBlock() then UnpredictableProcedure(); end;
if Q == '1' && (Vd[0] == '1' || Vm[0] == '1') then Undefined(); end;
if size != '10' then Undefined(); end;
// Rounding encoded differently from other VCVT and VRINT instructions
let rounding : FPRounding = FPDecodeRM(op[2]::NOT(op[1]));
let exact : boolean = FALSE;
let esize : integer{} = 32;
let elements : integer = 64 DIV esize;
let d : integer = UInt(D::Vd);
let m : integer = UInt(M::Vm);
let regs : integer = if Q == '0' then 1 else 2;
```

CONSTRAINED UNPREDICTABLE behavior

If InITBlock(), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

Related encodings: See [Advanced SIMD two registers misc](#) for the T32 instruction set, or [Advanced SIMD two registers misc](#) for the A32 instruction set.

Assembler Symbols

<q>

See [Standard assembler syntax fields](#).

<dt>

Is the data type for the elements of the vectors, encoded in “size”:

size	<dt>
01	F16
10	F32

<Dd>

Is the 64-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field.

<Dm>

Is the 64-bit name of the SIMD&FP source register, encoded in the “M:Vm” field.

<Qd>

Is the 128-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field as <Qd>*2.

<Qm>

Is the 128-bit name of the SIMD&FP source register, encoded in the “M:Vm” field as <Qm>*2.

Operation

```
EncodingSpecificOperations();  
CheckAdvSIMDEnabled();  
let fpcr : FPCR_Type = StandardFPCR();  
for r = 0 to regs-1 do  
    for e = 0 to elements-1 do  
        let operand1 : bits(usize) = D(m+r)[e*:usize];  
        let result : bits(usize) = FPRoundInt{}(operand1, fpcr, rounding, exact);  
        D(d+r)[e*:usize] = result;  
    end;  
end;  
end;
```

C6.1.183 VRINTN (floating-point)

Round floating-point to integer to Nearest rounds a floating-point value to an integral floating-point value of the same size using the Round to Nearest rounding mode. A zero input gives a zero result with the same sign, an infinite input gives an infinite result with the same sign, and a NaN is propagated as for normal arithmetic.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1).

A1

Encoding for the Single-precision scalar variant

Applies when (size == 10)

```
VRINTN(<q>).F32 <Sd>, <Sm>
```

Encoding for the Double-precision scalar variant

Applies when (size == 11)

```
VRINTN(<q>).F64 <Dd>, <Dm>
```

Decode for all variants of this encoding

```
if size != '1x' then Undefined(); end;
let rounding : FPRounding = FPDecodeRM(RM);
let exact : boolean = FALSE;
let esize : integer{} = 8 << UInt(size);
let d : integer = if size == '11' then UInt(D::Vd) else UInt(Vd::D);
let m : integer = if size == '11' then UInt(M::Vm) else UInt(Vm::M);
```

T1

Encoding for the Single-precision scalar variant

Applies when (size == 10)

```
VRINTN(<q>).F32 <Sd>, <Sm>
```

Encoding for the Double-precision scalar variant

Applies when (size == 11)

```
VRINTN(<q>).F64 <Dd>, <Dm>
```

Decode for all variants of this encoding

```
if InITBlock() then UnpredictableProcedure(); end;
if size != '1x' then Undefined(); end;
let rounding : FPRounding = FPDecodeRM(RM);
let exact : boolean = FALSE;
let esize : integer{} = 8 << UInt(size);
let d : integer = if size == '11' then UInt(D::Vd) else UInt(Vd::D);
let m : integer = if size == '11' then UInt(M::Vm) else UInt(Vm::M);
```

CONSTRAINED UNPREDICTABLE behavior

If `InITBlock()`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<q>

See [Standard assembler syntax fields](#).

<Sd>

Is the 32-bit name of the SIMD&FP destination register, encoded in the “Vd:D” field.

<Sm>

Is the 32-bit name of the SIMD&FP source register, encoded in the “Vm:M” field.

<Dd>

Is the 64-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field.

<Dm>

Is the 64-bit name of the SIMD&FP source register, encoded in the “M:Vm” field.

Operation

```
EncodingSpecificOperations();
CheckVFPEEnabled(TRUE);
let fpcr : FPCR_Type = EffectiveFPCR();
case esize of
  when 32 =>
    S(d) = FPRoundInt{32}(S(m), fpcr, rounding, exact);
  when 64 =>
    D(d) = FPRoundInt{64}(D(m), fpcr, rounding, exact);
end;
```

C6.1.184 VRINTP (Advanced SIMD)

Vector Round floating-point to integer towards +Infinity rounds a vector of floating-point values to integral floating-point values of the same size using the Round towards +Infinity rounding mode. A zero input gives a zero result with the same sign, an infinite input gives an infinite result with the same sign, and a NaN is propagated as for normal arithmetic.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding for the 64-bit SIMD vector variant

Applies when ($Q == 0$)

```
VRINTP{ <q> } . <dt> <Dd>, <Dm>
```

Encoding for the 128-bit SIMD vector variant

Applies when ($Q == 1$)

```
VRINTP{<q>}.<dt> <Qd>, <Qm>
```

Decode for all variants of this encoding

```

if op[2] != op[0] then See("Related encodings"); end;
if Q == '1' && (Vd[0] == '1' || Vm[0] == '1') then Undefined(); end;
if size != '10' then Undefined(); end;
// Rounding encoded differently from other VCVT and VRINT instructions
let rounding : FPRounding = FPDecodeRM(op[2]::NOT(op[1]));
let exact : boolean = FALSE;
let esize : integer{} = 32;
let elements : integer = 64 DIV esize;
let d : integer = UInt(D::Vd);
let m : integer = UInt(M::Vm);
let reqs : integer = if Q == '0' then 1 else 2;

```

T1

Encoding for the 64-bit SIMD vector variant

Applies when $(Q == 0)$

```
VRINTP{ <q> } . <dt> <Dd> , <Dm>
```

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

VRINTP(<q>).<dt> <Qd>, <Qm>

Decode for all variants of this encoding

```
if op[2] != op[0] then See("Related encodings"); end;
if InITBlock() then UnpredictableProcedure(); end;
if Q == '1' && (Vd[0] == '1' || Vm[0] == '1') then Undefined(); end;
if size != '10' then Undefined(); end;
// Rounding encoded differently from other VCVT and VRINT instructions
let rounding : FPRounding = FPDecodeRM(op[2]::NOT(op[1]));
let exact : boolean = FALSE;
let esize : integer{} = 32;
let elements : integer = 64 DIV esize;
let d : integer = UInt(D::Vd);
let m : integer = UInt(M::Vm);
let regs : integer = if Q == '0' then 1 else 2;
```

CONSTRAINED UNPREDICTABLE behavior

If InITBlock(), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

Related encodings: See [Advanced SIMD two registers misc](#) for the T32 instruction set, or [Advanced SIMD two registers misc](#) for the A32 instruction set.

Assembler Symbols

Is the 64-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field.

<Dm>

Is the 64-bit name of the SIMD&FP source register, encoded in the “M:Vm” field.

Operation

```

EncodingSpecificOperations();
CheckVFPEEnabled(TRUE);
let fpcr : FPCR_Type = EffectiveFPCR();
case esize of
    when 32 =>
        S(d) = FPRoundInt{32}(S(m), fpcr, rounding, exact);
    when 64 =>
        D(d) = FPRoundInt{64}(D(m), fpcr, rounding, exact);
end;

```

C6.1.186 VRINTR

Round floating-point to integer rounds a floating-point value to an integral floating-point value of the same size using the rounding mode specified in the FPSCR. A zero input gives a zero result with the same sign, an infinite input gives an infinite result with the same sign, and a NaN is propagated as for normal arithmetic.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1).

A1

Encoding for the Single-precision scalar variant

Applies when (size == 10)

```
VRINTR{<c>}{<q>}.F32 <Sd>, <Sm>
```

Encoding for the Double-precision scalar variant

Applies when (size == 11)

```
VRINTR{<c>}{<q>}.F64 <Dd>, <Dm>
```

Decode for all variants of this encoding

```
if size != '1x' then Undefined(); end;
let zero_rounding : boolean = (op == '1');
let exact : boolean = FALSE;
let esize : integer{} = 8 << UInt(size);
let d : integer = if size == '11' then UInt(D::Vd) else UInt(Vd::D);
let m : integer = if size == '11' then UInt(M::Vm) else UInt(Vm::M);
```

T1

Encoding for the Single-precision scalar variant

Applies when (size == 10)

```
VRINTR{<c>}{<q>}.F32 <Sd>, <Sm>
```

Encoding for the Double-precision scalar variant

Applies when (size == 11)

```
VRINTR{<c>}{<q>}.F64 <Dd>, <Dm>
```

Decode for all variants of this encoding

```
if size != '1x' then Undefined(); end;
let zero_rounding : boolean = (op == '1');
let exact : boolean = FALSE;
let esize : integer{} = 8 << UInt(size);
let d : integer = if size == '11' then UInt(D::Vd) else UInt(Vd::D);
let m : integer = if size == '11' then UInt(M::Vm) else UInt(Vm::M);
```

CONSTRAINED UNPREDICTABLE behavior

If `InITBlock()`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

            D(d) = FPRoundInt{64}(D(m), fpcr, rounding, exact);
    end;
end;
```

C6.1.187 VRINTX (Advanced SIMD)

Vector round floating-point to integer inexact rounds a vector of floating-point values to integral floating-point values of the same size, using the Round to Nearest rounding mode, and raises the Inexact exception when the result value is not numerically equal to the input value. A zero input gives a zero result with the same sign, an infinite input gives an infinite result with the same sign, and a NaN is propagated as for normal arithmetic.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding for the 64-bit SIMD vector variant

Applies when ($Q == 0$)

```
VRINTX{ <q> } .<dt>    <Dd>, <Dm>
```

Encoding for the 128-bit SIMD vector variant

Applies when ($Q == 1$)

```
VRINTX{<q>}.<dt> <Qd>, <Qm>
```

Decode for all variants of this encoding

```

if Q == '1' && (Vd[0] == '1' || Vm[0] == '1') then Undefined(); end;
if size != '10' then Undefined(); end;
let rounding : FPRounding = FPRounding_TIEEVEN;
let exact : boolean = TRUE;
let esize : integer{} = 32;
let elements : integer = 64 DIV esize;
let d : integer = UInt(D::Vd);
let m : integer = UInt(M::Vm);
let regs : integer = if Q == '0' then 1 else 2;

```

T1

Encoding for the 64-bit SIMD vector variant

Applies when ($Q == 0$)

```
VRINTX{ <q> } . <dt> <Dd>, <Dm>
```

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

VRINTX{<q>}.<dt> <Qd>, <Qm>

Decode for all variants of this encoding

```
if Q == '1' && (Vd[0] == '1' || Vm[0] == '1') then Undefined(); end;
if size != '10' then Undefined(); end;
let rounding : FPRounding = FPRounding_TIEEVEN;
let exact : boolean = TRUE;
let esize : integer{} = 32;
let elements : integer = 64 DIV esize;
let d : integer = UInt(D::Vd);
let m : integer = UInt(M::Vm);
let regs : integer = if Q == '0' then 1 else 2;
if InITBlock() then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If InITBlock(), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

if size != '1x' then Undefined(); end;
let exact : boolean = TRUE;
let esize : integer{} = 8 << UInt(size);
let d : integer = if size == '11' then UInt(D::Vd) else UInt(Vd::D);
let m : integer = if size == '11' then UInt(M::Vm) else UInt(Vm::M);
```

T1

Encoding for the Single-precision scalar variant

Applies when (size == 10)

```
VRINTX{<c>}{<q>}.F32 <Sd>, <Sm>
```

Encoding for the Double-precision scalar variant

Applies when (size == 11)

```
VRINTX{<c>}{<q>}.F64 <Dd>, <Dm>
```

Decode for all variants of this encoding

```
if size != '1x' then Undefined(); end;
let exact : boolean = TRUE;
let esize : integer{} = 8 << UInt(size);
let d : integer = if size == '11' then UInt(D::Vd) else UInt(Vd::D);
let m : integer = if size == '11' then UInt(M::Vm) else UInt(Vm::M);
```

CONSTRAINED UNPREDICTABLE behavior

If `InITBlock()`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Sd>

Is the 32-bit name of the SIMD&FP destination register, encoded in the “Vd:D” field.

<Sm>

Is the 32-bit name of the SIMD&FP source register, encoded in the “Vm:M” field.

<Dd>

Is the 64-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field.

<Dm>

Is the 64-bit name of the SIMD&FP source register, encoded in the “M:Vm” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckVFPEEnabled(TRUE);
    let fpcr : FPCR_Type = EffectiveFPCR();
    let rounding : FPRounding = FPRoundingMode(fpcr);
    case esize of
        when 32 =>
            S(d) = FPRoundInt{32}(S(m), fpcr, rounding, exact);
        when 64 =>
            D(d) = FPRoundInt{64}(D(m), fpcr, rounding, exact);
    end;
end;
```

C6.1.189 VRINTZ (Advanced SIMD)

Vector round floating-point to integer towards Zero rounds a vector of floating-point values to integral floating-point values of the same size, using the Round towards Zero rounding mode. A zero input gives a zero result with the same sign, an infinite input gives an infinite result with the same sign, and a NaN is propagated as for normal arithmetic.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding for the 64-bit SIMD vector variant

Applies when ($Q = 0$)

```
VRINTZ{ <q> } . <dt> <Dd> , <Dm>
```

Encoding for the 128-bit SIMD vector variant

Applies when ($Q == 1$)

```
VRINTZ{<q>}.<dt> <Qd>, <Qm>
```

Decode for all variants of this encoding

```

if Q == '1' && (Vd[0] == '1' || Vm[0] == '1') then Undefined(); end;
if size != '10' then Undefined(); end;
let rounding : FPRounding = FPRounding_ZERO;
let exact : boolean = FALSE;
let esize : integer{} = 32; let elements : integer{} = 2;
let d : integer = UInt(D::Vd);
let m : integer = UInt(M::Vm);
let regs : integer = if Q == '0' then 1 else 2;

```

T1

Encoding for the 64-bit SIMD vector variant

Applies when ($Q == 0$)

```
VRINTZ{<q>}.<dt> <Dd>, <Dm>
```

Encoding for the 128-bit SIMD vector variant

Applies when ($Q == 1$)

```
VRINTZ{<q>}.<dt> <Qd>, <Qm>
```

Decode for all variants of this encoding

```
if Q == '1' && (Vd[0] == '1' || Vm[0] == '1') then Undefined(); end;
if size != '10' then Undefined(); end;
let rounding : FPRounding = FPRounding_ZERO;
let exact : boolean = FALSE;
let esize : integer{} = 32;
let elements : integer = 64 DIV esize;
let d : integer = UInt(D::Vd);
let m : integer = UInt(M::Vm);
let regs : integer = if Q == '0' then 1 else 2;
if InITBlock() then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If InITBlock(), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<q>

See [Standard assembler syntax fields](#).

<dt>

Is the data type for the elements of the vectors, encoded in “size”:

size	<dt>
01	F16
10	F32

<Dd>

Is the 64-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field.

<Dm>

Is the 64-bit name of the SIMD&FP source register, encoded in the “M:Vm” field.

<Qd>

Is the 128-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field as <Qd>*2.

<Qm>

Is the 128-bit name of the SIMD&FP source register, encoded in the “M:Vm” field as <Qm>*2.

Operation

```
EncodingSpecificOperations();  
CheckAdvSIMDEnabled();  
let fpcr : FPCR_Type = StandardFPCR();  
for r = 0 to regs-1 do  
    for e = 0 to elements-1 do  
        let operand1 : bits(usize) = D(m+r)[e*:usize];  
        let result : bits(usize) = FPRoundInt{}(operand1, fpcr, rounding, exact);  
        D(d+r)[e*:usize] = result;  
    end;  
end;  
end;
```

C6.1.190 VRINTZ (floating-point)

Round floating-point to integer towards Zero rounds a floating-point value to an integral floating-point value of the same size, using the Round towards Zero rounding mode. A zero input gives a zero result with the same sign, an infinite input gives an infinite result with the same sign, and a NaN is propagated as for normal arithmetic.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding for the Single-precision scalar variant

Applies when (size == 10)

```
VRINTZ{<c>}{<q>}.F32 <Sd>, <Sm>
```

Encoding for the Double-precision scalar variant

Applies when (size == 11)

```
VRINTZ{<c>}{<q>}.F64 <Dd>, <Dm>
```

Decode for all variants of this encoding

```
if size != '1x' then Undefined(); end;
let zero_rounding : boolean = (op == '1');
let exact : boolean = FALSE;
let esize : integer{} = 8 << UInt(size);
let d : integer = if size == '11' then UInt(D::Vd) else UInt(Vd::D);
let m : integer = if size == '11' then UInt(M::Vm) else UInt(Vm::M);
```

T1

Encoding for the Single-precision scalar variant

Applies when (size == 10)

```
VRINTZ{<c>}{<q>}.F32 <Sd>, <Sm>
```

Encoding for the Double-precision scalar variant

Applies when (size == 11)

```
VRINTZ{<c>}{<q>}.F64 <Dd>, <Dm>
```

Decode for all variants of this encoding

```
if size != '1x' then Undefined(); end;
let zero_rounding : boolean = (op == '1');
let exact : boolean = FALSE;
let esize : integer{} = 8 << UInt(size);
let d : integer = if size == '11' then UInt(D::Vd) else UInt(Vd::D);
let m : integer = if size == '11' then UInt(M::Vm) else UInt(Vm::M);
```

CONSTRAINED UNPREDICTABLE behavior

If `InITBlock()`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Sd>

Is the 32-bit name of the SIMD&FP destination register, encoded in the “Vd:D” field.

<Sm>

Is the 32-bit name of the SIMD&FP source register, encoded in the “Vm:M” field.

<Dd>

Is the 64-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field.

<Dm>

Is the 64-bit name of the SIMD&FP source register, encoded in the “M:Vm” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckVFPEEnabled(TRUE);
    let fpcr : FPCR_Type = EffectiveFPCR();
    let rounding : FPRounding = if zero_rounding then FPRounding_ZERO else FPRoundingMode(fpcr);
    case esize of
        when 32 =>
            S(d) = FPRoundInt{32}(S(m), fpcr, rounding, exact);
        when 64 =>
            D(d) = FPRoundInt{64}(D(m), fpcr, rounding, exact);
    end;
end;
```

C6.1.191 VRSHL

Vector Rounding Shift Left takes each element in a vector, shifts them by a value from the least significant byte of the corresponding element of a second vector, and places the results in the destination vector. If the shift value is positive, the operation is a left shift. If the shift value is negative, it is a rounding right shift. For a truncating shift, see VSHL.

The first operand and result elements are the same data type, and can be any one of:

- 8-bit, 16-bit, 32-bit, or 64-bit signed integers.
- 8-bit, 16-bit, 32-bit, or 64-bit unsigned integers.

The second operand is always a signed integer of the same size.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 (A1) and T32 (T1).

A1

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0)

```
VRSHL{<c>}{<q>}.<dt> {<Dd>, }<Dm>, <Dn>
```

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

```
VRSHL{<c>}{<q>}.<dt> {<Qd>, }<Qm>, <Qn>
```

Decode for all variants of this encoding

```
if Q == '1' && (Vd[0] == '1' || Vm[0] == '1' || Vn[0] == '1') then Undefined(); end;
let unsigned : boolean = (U == '1');
let esize : integer{} = 8 << UInt(size);
let elements : integer = 64 DIV esize;
let d : integer = UInt(D::Vd);
let m : integer = UInt(M::Vm);
let n : integer = UInt(N::Vn);
let regs : integer = if Q == '0' then 1 else 2;
```

T1

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0)

VRSHL{<c>}{<q>}.<dt> {<Dd>, }<Dm>, <Dn>

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

VRSHL{<c>}{<q>}.<dt> {<Qd>, }<Qm>, <Qn>

Decode for all variants of this encoding

```
if Q == '1' && (Vd[0] == '1' || Vm[0] == '1' || Vn[0] == '1') then Undefined(); end;
let unsigned : boolean = (U == '1');
let esize : integer{} = 8 << UInt(size);
let elements : integer = 64 DIV esize;
let d : integer = UInt(D::Vd);
let m : integer = UInt(M::Vm);
let n : integer = UInt(N::Vn);
let regs : integer = if Q == '0' then 1 else 2;
```

Assembler Symbols

<c>

For the “A1 128-bit SIMD vector” and “A1 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#).
This encoding must be unconditional.

For the “T1 128-bit SIMD vector” and “T1 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<dt>

Is the data type for the elements of the vectors, encoded in “U:size”:

U	size	<dt>
0	00	S8
0	01	S16
0	10	S32
0	11	S64
1	00	U8
1	01	U16
1	10	U32
1	11	U64

<Dd>

Is the 64-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field.

<Dm>

Is the 64-bit name of the second SIMD&FP source register, encoded in the “M:Vm” field.

<Dn>

Is the 64-bit name of the first SIMD&FP source register, encoded in the “N:Vn” field.

<Qd>

Is the 128-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field as <Qd>*2.

<Qm>

Is the 128-bit name of the second SIMD&FP source register, encoded in the “M:Vm” field as <Qm>*2.

<Qn>

Is the 128-bit name of the first SIMD&FP source register, encoded in the “N:Vn” field as <Qn>*2.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();
    var result : integer;
    for r = 0 to regs-1 do
        for e = 0 to elements-1 do
            let opelt : bits(esize) = D(m+r)[e*:esize];
            let element : integer = if unsigned then UInt(opelt) else SInt(opelt);
            var shift : integer = SInt(D(n+r)[e*:esize][7:0]);
            if shift >= 0 then // left shift
                result = element << shift;
            else // rounding right shift
                shift = -shift;
                result = (element + (1 << (shift - 1))) >> shift;
            end;
            D(d+r)[e*:esize] = result[esize-1:0];
        end;
    end;
end;
```

C6.1.192 VRSHR

Vector Rounding Shift Right takes each element in a vector, right shifts them by an immediate value, and places the rounded results in the destination vector. For truncated results, see [VSHR](#).

The operand and result elements must be the same size, and can be any one of:

- 8-bit, 16-bit, 32-bit, or 64-bit signed integers.
- 8-bit, 16-bit, 32-bit, or 64-bit unsigned integers.

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0 && !(imm6[5:3] == 000 && L == 0))

```
VRSHR{<c>}{<q>}.<type><size> {<Dd>, }<Dm>, #<imm>
```

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1 && !(imm6[5:3] == 000 && L == 0))

```
VRSHR{<c>}{<q>}.<type><size> {<Qd>, }<Qm>, #<imm>
```

Decode for all variants of this encoding

```
if (L::imm6) == '0000xxx' then See("Related encodings"); end;
if Q == '1' && (Vd[0] == '1' || Vm[0] == '1') then Undefined(); end;
let esize : integer{} = 8 << HighestSetBitNZ((L::imm6)[6:3]);
let elements : integer = 64 DIV esize;
let shift_amount : integer = (esize * 2) - UInt(L::imm6);
let unsigned : boolean = (U == '1');
let d : integer = UInt(D::Vd);
let m : integer = UInt(M::Vm);
let regs : integer = if Q == '0' then 1 else 2;
```

T1

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0 && !(imm6[5:3] == 000 && L == 0))

```
VRSHR{<c>}{<q>}.<type><size> {<Dd>, }<Dm>, #<imm>
```

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1 && !(imm6[5:3] == 000 && L == 0))

VRSHR{<c>}{<q>}.<type><size> {<Qd>, }<Qm>, #<imm>

Decode for all variants of this encoding

```
if (L::imm6) == '0000xxx' then See("Related encodings"); end;
if Q == '1' && (Vd[0] == '1' || Vm[0] == '1') then Undefined(); end;
let esize : integer{} = 8 << HighestSetBitNZ((L::imm6)[6:3]);
let elements : integer = 64 DIV esize;
let shift_amount : integer = (esize * 2) - UInt(L::imm6);
let unsigned : boolean = (U == '1');
let d : integer = UInt(D::Vd);
let m : integer = UInt(M::Vm);
let regs : integer = if Q == '0' then 1 else 2;
```

Related encodings: See [Advanced SIMD one register and modified immediate](#) for the T32 instruction set, or [Advanced SIMD one register and modified immediate](#) for the A32 instruction set.

Assembler Symbols

<c>

For the “A1 128-bit SIMD vector” and “A1 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#). This encoding must be unconditional.

For the “T1 128-bit SIMD vector” and “T1 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<type>

Is the data type for the elements of the vectors, encoded in “U”:

U	<type>
0	S
1	U

<size>

Is the data size for the elements of the vectors, encoded in “L:imm6”:

L	imm6	<size>
0	001xxx	8
0	01xxxx	16
0	1xxxxxx	32
1	xxxxxxx	64

<Dd>

Is the 64-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field.

<Dm>

Is the 64-bit name of the SIMD&FP source register, encoded in the “M:Vm” field.

<imm>

Is an immediate value, in the range 1 to <size>, encoded in the “imm6” field as <size> - <imm>.

<Qd>

Is the 128-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field as <Qd>*2.

<Qm>

Is the 128-bit name of the SIMD&FP source register, encoded in the “M:Vm” field as <Qm>*2.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();
    let round : boolean = TRUE;
    for r = 0 to regs-1 do
        for e = 0 to elements-1 do
            let opelt : bits(esize) = D(m+r)[e*:esize];
            let element : integer = if unsigned then UInt(opelt) else SInt(opelt);
            let result : integer = RShr(element, shift_amount, round);
            D(d+r)[e*:esize] = result[esize-1:0];
        end;
    end;
end;
```

C6.1.193 VRSHR (zero)

Vector Rounding Shift Right copies the contents of one SIMD register to another.

This is a pseudo-instruction of [VORR \(register\)](#). This means:

- The encodings in this description are named to match the encodings of [VORR \(register\)](#).
- The assembler syntax is used only for assembly, and is not used on disassembly.
- The description of [VORR \(register\)](#) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding for the 64-bit SIMD vector variant

Applies when ($Q == 0$)

`VRSHR{<c>}{<q>}.<dt> <Dd>, <Dm>, #0`

is equivalent to

`VORR{<c>}{<q>}{.<dt>} {<Dd>, }<Dm>, <Dm>`

Encoding for the 128-bit SIMD vector variant

Applies when ($Q == 1$)

`VRSHR{<c>}{<q>}.<dt> <Qd>, <Qm>, #0`

is equivalent to

`VORR{<c>}{<q>}{.<dt>} {<Qd>, }<Qm>, <Qm>`

T1

Encoding for the 64-bit SIMD vector variant

Applies when ($Q == 0$)

`VRSHR{<c>}{<q>}.<dt> <Dd>, <Dm>, #0`

is equivalent to

`VORR{<c>}{<q>}{.<dt>} {<Dd>, }<Dm>, <Dm>`

Encoding for the 128-bit SIMD vector variant

Applies when ($Q == 1$)

$VRSHR\{<c>\}\{<q>\}.<dt>\ <Qd>, <Qm>, \#0$

is equivalent to

$VORR\{<c>\}\{<q>\}\{.<dt>\}\ \{<Qd>, \}<Qm>, <Qm>$

Assembler Symbols

<c>

For the “A1 128-bit SIMD vector” and “A1 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#). This encoding must be unconditional.

For the “T1 128-bit SIMD vector” and “T1 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<dt>

Is the data type for the elements of the vectors, and must be one of: S8, S16, S32, S64, U8, U16, U32 or U64.

<Dd>

Is the 64-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field.

<Dm>

Is the 64-bit name of the SIMD&FP source register, encoded in the “N:Vn” and “M:Vm” field.

<Qd>

Is the 128-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field as $<Qd>*2$.

<Qm>

Is the 128-bit name of the SIMD&FP source register, encoded in the “N:Vn” and “M:Vm” field as $<Qm>*2$.

Operation

The description of [VORR \(register\)](#) gives the operational pseudocode for this instruction.

C6.1.194 VRSHRN

Vector Rounding Shift Right and Narrow takes each element in a vector, right shifts them by an immediate value, and places the rounded results in the destination vector. For truncated results, see [VSHRN](#).

The operand elements can be 16-bit, 32-bit, or 64-bit integers. There is no distinction between signed and unsigned integers. The destination elements are half the size of the source elements.

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

```
VRSHRN(<c>){<q>}.I<size> <Dd>, <Qm>, #<imm>
```

Decode for this encoding

```

if imm6 == '000xxx' then See("Related encodings"); end;
if Vm[0] == '1' then Undefined(); end;
let esize : integer{} = 8 << HighestSetBitNZ(imm6[5:3]);
let elements : integer = 64 DIV esize;
let shift_amount : integer = (esize << 1) - UInt(imm6);
let d : integer = UInt(D::Vd);
let m : integer = UInt(M::Vm);
  
```

T1

Encoding

```
VRSHRN(<c>){<q>}.I<size> <Dd>, <Qm>, #<imm>
```

Decode for this encoding

```

if imm6 == '000xxx' then See("Related encodings"); end;
if Vm[0] == '1' then Undefined(); end;
let esize : integer{} = 8 << HighestSetBitNZ(imm6[5:3]);
let elements : integer = 64 DIV esize;
let shift_amount : integer = (esize << 1) - UInt(imm6);
let d : integer = UInt(D::Vd);
let m : integer = UInt(M::Vm);
  
```

Related encodings: See [Advanced SIMD one register and modified immediate](#) for the T32 instruction set, or [Advanced SIMD one register and modified immediate](#) for the A32 instruction set.

Assembler Symbols

<c>

For the “A1” variant: see [Standard assembler syntax fields](#). This encoding must be unconditional.
For the “T1” variant: see [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<size>

Is the data size for the elements of the vectors, encoded in “imm6”:

imm6	<size>
001xxx	16
01xxxx	32
1xxxxx	64

<Dd>

Is the 64-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field.

<Qm>

Is the 128-bit name of the SIMD&FP source register, encoded in the “M:Vm” field as <Qm>*2.

<imm>

Is an immediate value, in the range 1 to <size>/2, encoded in the “imm6” field as <size>/2 - <imm>.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();
    let round : boolean = TRUE;
    for e = 0 to elements-1 do
        let result : integer = RShr(UInt(Qin(m>>1)[e*(2*esize)]), shift_amount, round);
        D(d)[e*esize] = result[esize-1:0];
    end;
end;
```

C6.1.195 VRSHRN (zero)

Vector Rounding Shift Right and Narrow takes each element in a vector, right shifts them by an immediate value, and places the rounded results in the destination vector.

This is a pseudo-instruction of [VMOVN](#). This means:

- The encodings in this description are named to match the encodings of [VMOVN](#).
- The assembler syntax is used only for assembly, and is not used on disassembly.
- The description of [VMOVN](#) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

31	28	27	26	25	24	23	22	21	20	19	18	17	16	15	12	11	10	7	6	5	4	3	0
1	1	1	1	0	0	1	1	D	1	1	size	1	0	Vd	0	0	1	0	0	0	M	0	Vm
opc1														opc2				Q					

Encoding for the A1 variant

VRSHRN{<c>}{<q>}.<dt> <Dd>, <Qm>, #0

is equivalent to

VMOVN{<c>}{<q>}.<dt> <Dd>, <Qm>

T1

15	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	12	11	10	7	6	5	4	3	0	
1	1	1	1	1	1	1	1	D	1	1	size	1	0		Vd		0	0	1	0	0	0	M	0	Vm
└opc1														opc2┐				└0							

Encoding for the T1 variant

VRSHRN{<c>}{<q>}.<dt> <Dd>, <Qm>, #0

is equivalent to

VMOVN{<c>}{<q>}.<dt> <Dd>, <Qm>

Assembler Symbols

<c>

For the “A1” variant: see [Standard assembler syntax fields](#). This encoding must be unconditional.

For the “T1” variant: see [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<dt>

Is the data type for the elements of the operand, encoded in “size”:

size	<dt>
00	I 16
01	I 32
10	I 64
11	RESERVED

<Dd>

Is the 64-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field.

<Qm>

Is the 128-bit name of the SIMD&FP source register, encoded in the “M:Vm” field as <Qm>*2.

Operation

The description of [VMOVN](#) gives the operational pseudocode for this instruction.

C6.1.196 VRSQRTE

Vector Reciprocal Square Root Estimate finds an approximate reciprocal square root of each element in a vector, and places the results in a second vector.

The operand and result elements are the same type, and can be floating-point numbers or unsigned integers.

For details of the operation performed by this instruction see [Floating-point reciprocal estimate and step](#).

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be `UNDEFINED`, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding for the 64-bit SIMD vector variant

Applies when ($Q = 0$)

VRSORTE{<c>}{<q>}.<dt> <Dd>, <Dm>

Encoding for the 128-bit SIMD vector variant

Applies when ($Q == 1$)

VRSORTE{<c>}{<q>}.<dt> <Qd>, <Qm>

Decode for all variants of this encoding

```

if Q == '1' && (Vd[0] == '1' || Vm[0] == '1') then Undefined(); end;
if size != '10' then Undefined(); end;
let floating_point : boolean = (F == '1');
let esize : integer{} = 8 << UInt(size);
let elements : integer = 64 DIV esize;
let d : integer = UInt(D::Vd);
let m : integer = UInt(M::Vm);
let regs : integer = if Q == '0' then 1 else 2;

```

T1

Encoding for the 64-bit SIMD vector variant

Applies when ($Q = 0$)

VRSORTE{<c>}{<q>}.<dt> <Dd>, <Dm>

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

VRSQRTE{<c>}{<q>}.<dt> <Qd>, <Qm>

Decode for all variants of this encoding

```
if Q == '1' && (Vd[0] == '1' || Vm[0] == '1') then Undefined(); end;
if size != '10' then Undefined(); end;
let floating_point : boolean = (F == '1');
let esize : integer{} = 8 << UInt(size);
let elements : integer = 64 DIV esize;
let d : integer = UInt(D::Vd);
let m : integer = UInt(M::Vm);
let regs : integer = if Q == '0' then 1 else 2;
```

CONSTRAINED UNPREDICTABLE behavior

If size == '01' && InITBlock(), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

Assembler Symbols

<c>

For the “A1 128-bit SIMD vector” and “A1 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#). This encoding must be unconditional.

For the “T1 128-bit SIMD vector” and “T1 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<dt>

Is the data type for the elements of the vectors, encoded in “F:size”:

F	size	<dt>
0	10	U32
1	01	F16
1	10	F32

<Dd>

Is the 64-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field.

<Dm>

Is the 64-bit name of the SIMD&FP source register, encoded in the “M:Vm” field.

<Qd>

Is the 128-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field as <Qd>*2.

<Qm>

Is the 128-bit name of the SIMD&FP source register, encoded in the “M:Vm” field as <Qm>*2.

Newton-Raphson iteration

For details of the operation performed and how it can be used in a Newton-Raphson iteration to calculate the reciprocal of the square root of a number, see [Floating-point reciprocal estimate and step](#).

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();
    let fpcr : FPCR_Type = StandardFPCR();
    for r = 0 to regs-1 do
        for e = 0 to elements-1 do
            if floating_point then
                D(d+r)[e*:size] = FPRSqrtEstimate{size}(D(m+r)[e*:size], fpcr);
            else
                D(d+r)[e*:size] = UnsignedRSqrtEstimate{size}(D(m+r)[e*:size]);
            end;
        end;
    end;
end;
```

C6.1.197 VRSQRTS

Vector Reciprocal Square Root Step multiplies the elements of one vector by the corresponding elements of another vector, subtracts each of the products from 3.0, divides these results by 2.0, and places the results into the elements of the destination vector.

The operand and result elements are floating-point numbers.

For details of the operation performed by this instruction see [Floating-point reciprocal estimate and step](#).

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0)

VRSQRTS{<c>}{<q>}.<dt> {<Dd>, }<Dn>, <Dm>

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

VRSQRTS{<c>}{<q>}.<dt> {<Qd>, }<Qn>, <Qm>

Decode for all variants of this encoding

```

if Q == '1' && (Vd[0] == '1' || Vn[0] == '1' || Vm[0] == '1') then Undefined(); end;
if sz == '1' then Undefined(); end;
let esize : integer{} = 32 >> UInt(sz);
let elements : integer = 64 DIV esize;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);
let regs : integer = if Q == '0' then 1 else 2;

```

T1

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0)

VRSQRTS{<c>}{<q>}.<dt> {<Dd>, }<Dn>, <Dm>

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

VRSQRTS{<c>}{<q>}.<dt> {<Qd>, }<Qn>, <Qm>

Decode for all variants of this encoding

```
if Q == '1' && (Vd[0] == '1' || Vn[0] == '1' || Vm[0] == '1') then Undefined(); end;
if sz == '1' then Undefined(); end;
let esize : integer{} = 32 >> UInt(sz);
let elements : integer = 64 DIV esize;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);
let regs : integer = if Q == '0' then 1 else 2;
```

CONSTRAINED UNPREDICTABLE behavior

If size == '01' && InITBlock(), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

Assembler Symbols

<c>

For the “A1 128-bit SIMD vector” and “A1 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#). This encoding must be unconditional.

For the “T1 128-bit SIMD vector” and “T1 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<dt>

Is the data type for the elements of the vectors, encoded in “sz”:

sz	<dt>
0	F32
1	F16

<Dd>

Is the 64-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field.

<Dn>

Is the 64-bit name of the first SIMD&FP source register, encoded in the “N:Vn” field.

<Dm>

Is the 64-bit name of the second SIMD&FP source register, encoded in the “M:Vm” field.

<Qd>

Is the 128-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field as <Qd>*2.

<Qn>

Is the 128-bit name of the first SIMD&FP source register, encoded in the “N:Vn” field as <Qn>*2.

<Qm>

Is the 128-bit name of the second SIMD&FP source register, encoded in the “M:Vm” field as <Qm>*2.

Newton-Raphson iteration

For details of the operation performed and how it can be used in a Newton-Raphson iteration to calculate the reciprocal of the square root of a number, see [Floating-point reciprocal estimate and step](#).

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();
    for r = 0 to regs-1 do
        for e = 0 to elements-1 do
            D(d+r)[e*:esize] = FPRSqrtStep{esize}(D(n+r)[e*:esize], D(m+r)[e*:esize]);
        end;
    end;
end;
```

C6.1.198 VRSRA

Vector Rounding Shift Right and Accumulate takes each element in a vector, right shifts them by an immediate value, and accumulates the rounded results into the destination vector. For truncated results, see [VSRA](#).

The operand and result elements must all be the same type, and can be any one of:

- 8-bit, 16-bit, 32-bit, or 64-bit signed integers.
- 8-bit, 16-bit, 32-bit, or 64-bit unsigned integers.

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

31	25	24	23	22	21	16	15	12	11	8	7	6	5	4	3	0									
1	1	1	1	0	0	1	U	1	D	imm6			Vd			0	0	1	1	L	Q	M	1	Vm	
											└─ opc														

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0 && !(imm6[5:3] == 000 && L == 0))

VRSRA{<c>}{<q>}.<type><size> {<Dd>, }<Dm>, #<imm>

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1 && !(imm6[5:3] == 000 && L == 0))

VRSRA{<c>}{<q>}.<type><size> {<Qd>, }<Qm>, #<imm>

Decode for all variants of this encoding

```

if (L::imm6) == '0000xxx' then See("Related encodings"); end;
if Q == '1' && (Vd[0] == '1' || Vm[0] == '1') then Undefined(); end;
let esize : integer{} = 8 << HighestSetBitNZ((L::imm6)[6:3]);
let elements : integer = 64 DIV esize;
let shift_amount : integer = (esize * 2) - UInt(L::imm6);
let unsigned : boolean = (U == '1');
let d : integer = UInt(D::Vd);
let m : integer = UInt(M::Vm);
let regs : integer = if Q == '0' then 1 else 2;

```

T1

15	13	12	11	7	6	5	0	15	12	11	8	7	6	5	4	3	0								
1	1	1	U	1	1	1	1	1	D	imm6				Vd		0	0	1	1	L	Q	M	1	Vm	
															└─ opc										

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0 && !(imm6[5:3] == 000 && L == 0))

VRSRA{<c>}{<q>}.<type><size> {<Dd>, }<Dm>, #<imm>

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1 && !(imm6[5:3] == 000 && L == 0))

VRSRA{<c>}{<q>}.<type><size> {<Qd>, }<Qm>, #<imm>

Decode for all variants of this encoding

```
if (L::imm6) == '0000xxx' then See("Related encodings"); end;
if Q == '1' && (Vd[0] == '1' || Vm[0] == '1') then Undefined(); end;
let esize : integer{} = 8 << HighestSetBitNZ((L::imm6)[6:3]);
let elements : integer = 64 DIV esize;
let shift_amount : integer = (esize * 2) - UInt(L::imm6);
let unsigned : boolean = (U == '1');
let d : integer = UInt(D::Vd);
let m : integer = UInt(M::Vm);
let regs : integer = if Q == '0' then 1 else 2;
```

Related encodings: See [Advanced SIMD one register and modified immediate](#) for the T32 instruction set, or [Advanced SIMD one register and modified immediate](#) for the A32 instruction set.

Assembler Symbols

<c>

For the “A1 128-bit SIMD vector” and “A1 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#). This encoding must be unconditional.

For the “T1 128-bit SIMD vector” and “T1 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<type>

Is the data type for the elements of the vectors, encoded in “U”:

U	<type>
0	S
1	U

<size>

Is the data size for the elements of the vectors, encoded in “L:imm6”:

L	imm6	<size>
0	001xxx	8
0	01xxxx	16
0	1xxxxxx	32
1	xxxxxxx	64

<Dd>

Is the 64-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field.

<Dm>

Is the 64-bit name of the SIMD&FP source register, encoded in the “M:Vm” field.

<imm>

Is an immediate value, in the range 1 to <size>, encoded in the “imm6” field as <size> - <imm>.

<Qd>

Is the 128-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field as <Qd>*2.

<Qm>

Is the 128-bit name of the SIMD&FP source register, encoded in the “M:Vm” field as <Qm>*2.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();
    let round : boolean = TRUE;
    for r = 0 to regs-1 do
        for e = 0 to elements-1 do
            let opelt : bits(esize) = D(m+r)[e*:esize];
            let element : integer = if unsigned then UInt(opelt) else SInt(opelt);
            let result : integer = RShr(element, shift_amount, round);
            D(d+r)[e*:esize] = D(d+r)[e*:esize] + result;
        end;
    end;
end;
```

C6.1.199 VRSUBHN

Vector Rounding Subtract and Narrow, returning High Half subtracts the elements of one quadword vector from the corresponding elements of another quadword vector, takes the most significant half of each result, and places the final results in a doubleword vector. The results are rounded. For truncated results, see [VSUBHN](#).

The operand elements can be 16-bit, 32-bit, or 64-bit integers. There is no distinction between signed and unsigned integers.

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

VRSUBHN{<c>}{<q>}.<dt> <Dd>, <Qn>, <Qm>

Decode for this encoding

```

if size == '11' then See("Related encodings"); end;
if Vn[0] == '1' || Vm[0] == '1' then Undefined(); end;
let esize : integer{} = 8 << UInt(size);
let elements : integer = 64 DIV esize;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);

```

T1

Encoding

VRSUBHN{<c>}{<q>}.<dt> <Dd>, <Qn>, <Qm>

Decode for this encoding

```

if size == '11' then See("Related encodings"); end;
if Vn[0] == '1' || Vm[0] == '1' then Undefined(); end;
let esize : integer{} = 8 << UInt(size);
let elements : integer = 64 DIV esize;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);

```

Related encodings: See [Advanced SIMD data-processing](#) for the T32 instruction set, or [Advanced SIMD data-processing](#) for the A32 instruction set.

Assembler Symbols

<c>

For the “A1” variant: see [Standard assembler syntax fields](#). This encoding must be unconditional.

For the “T1” variant: see [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<dt>

Is the data type for the elements of the operands, encoded in “size”:

size	<dt>
00	I16
01	I32
10	I64

<Dd>

Is the 64-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field.

<Qn>

Is the 128-bit name of the first SIMD&FP source register, encoded in the “N:Vn” field as <Qn>*2.

<Qm>

Is the 128-bit name of the second SIMD&FP source register, encoded in the “M:Vm” field as <Qm>*2.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();
    let round : boolean = TRUE;
    for e = 0 to elements-1 do
        let result : integer = (RShr(UInt(Qin(n>>1)[e:(2*esize)] -
                                   Qin(m>>1)[e:(2*esize)]), esize, round));
        D(d)[e*:esize] = result[esize-1:0];
    end;
end;
```

C6.1.200 VSELEQ, VSELGE, VSELGT, VSELVS

Floating-point conditional select allows the destination register to take the value in either one or the other source register according to the condition codes in the [APSR](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding for the Equal, single-precision scalar variant

Applies when (cc == 00 && size == 10)

```
VSELEQ.F32 <Sd>, <Sn>, <Sm> // (Cannot be conditional)
```

Encoding for the Equal, double-precision scalar variant

Applies when (cc == 00 && size == 11)

```
VSELEQ.F64 <Dd>, <Dn>, <Dm> // (Cannot be conditional)
```

Encoding for the Greater than or Equal, single-precision scalar variant

Applies when `(cc == 10 && size == 10)`

```
VSELGE.F32 <Sd>, <Sn>, <Sm> // (Cannot be conditional)
```

Encoding for the Greater than or Equal, double-precision scalar variant

Applies when `(cc == 10 && size == 11)`

```
VSELGE.F64  <Dd>, <Dn>, <Dm> // (Cannot be conditional)
```

Encoding for the Greater than, single-precision scalar variant

Applies when (cc == 11 && size == 10)

```
VSELGT.F32  <Sd>, <Sn>, <Sm> // (Cannot be conditional)
```

Encoding for the Greater than, double-precision scalar variant

Applies when `(cc == 11 && size == 11)`

```
VSELGT.F64  <Dd>, <Dn>, <Dm> // (Cannot be conditional)
```

Encoding for the Unordered, single-precision scalar variant

Applies when (cc == 01 && size == 10)

```
VSELVS.F32  <Sd>, <Sn>, <Sm> // (Cannot be conditional)
```

Encoding for the Unordered, double-precision scalar variant

Applies when (cc == 01 && size == 11)

```
VSELVS.F64  <Dd>, <Dn>, <Dm> // (Cannot be conditional)
```

Decode for all variants of this encoding

```
if size != '1x' then Undefined(); end;
let esize : integer() = 8 << UInt(size);
let d : integer = if size == '11' then UInt(D::Vd) else UInt(Vd::D);
let n : integer = if size == '11' then UInt(N::Vn) else UInt(Vn::N);
let m : integer = if size == '11' then UInt(M::Vm) else UInt(Vm::M);
let condition : bits(4) = cc::(cc[1] XOR cc[0])::'0';
```

T1

Encoding for the Equal, single-precision scalar variant

Applies when (cc == 00 && size == 10)

```
VSELEQ.F32 <Sd>, <Sn>, <Sm> // (Not permitted in IT block)
```

Encoding for the Equal, double-precision scalar variant

Applies when (cc == 00 && size == 11)

```
VSELEQ.F64 <Dd>, <Dn>, <Dm> // (Not permitted in IT block)
```

Encoding for the Greater than or Equal, single-precision scalar variant

Applies when (cc == 10 && size == 10)

```
VSELGE.F32 <Sd>, <Sn>, <Sm> // (Not permitted in IT block)
```

Encoding for the Greater than or Equal, double-precision scalar variant

Applies when (cc == 10 && size == 11)

```
VSELGE.F64 <Dd>, <Dn>, <Dm> // (Not permitted in IT block)
```

Encoding for the Greater than, single-precision scalar variant

Applies when (cc == 11 && size == 10)

```
VSELGT.F32 <Sd>, <Sn>, <Sm> // (Not permitted in IT block)
```

Encoding for the Greater than, double-precision scalar variant

Applies when (cc == 11 && size == 11)

```
VSELGT.F64 <Dd>, <Dn>, <Dm> // (Not permitted in IT block)
```

Encoding for the Unordered, single-precision scalar variant

Applies when (cc == 01 && size == 10)

```
VSELVS.F32 <Sd>, <Sn>, <Sm> // (Not permitted in IT block)
```

Encoding for the Unordered, double-precision scalar variant

Applies when (cc == 01 && size == 11)

VSELVS.F64 <Dd>, <Dn>, <Dm> // (Not permitted in IT block)

Decode for all variants of this encoding

```
if InITBlock() then UnpredictableProcedure(); end;
if size != '1x' then Undefined(); end;
let esize : integer() = 8 << UInt(size);
let d : integer = if size == '11' then UInt(D::Vd) else UInt(Vd::D);
let n : integer = if size == '11' then UInt(N::Vn) else UInt(Vn::N);
let m : integer = if size == '11' then UInt(M::Vm) else UInt(Vm::M);
let condition : bits(4) = cc::(cc[1] XOR cc[0])::'0';
```

CONSTRAINED UNPREDICTABLE behavior

If InITBlock(), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

Assembler Symbols

<Sd>

Is the 32-bit name of the SIMD&FP destination register, encoded in the “Vd:D” field.

<Sn>

Is the 32-bit name of the first SIMD&FP source register, encoded in the “Vn:N” field.

<Sm>

Is the 32-bit name of the second SIMD&FP source register, encoded in the “Vm:M” field.

<Dd>

Is the 64-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field.

<Dn>

Is the 64-bit name of the first SIMD&FP source register, encoded in the “N:Vn” field.

<Dm>

Is the 64-bit name of the second SIMD&FP source register, encoded in the “M:Vm” field.

Operation

```
EncodingSpecificOperations();
CheckVFPEEnabled(TRUE);
case esize of
  when 32 =>
    S(d) = if ConditionHolds(condition) then S(n) else S(m);
  when 64 =>
    D(d) = if ConditionHolds(condition) then D(n) else D(m);
end;
```

C6.1.201 VSHL (immediate)

Vector Shift Left (immediate) takes each element in a vector of integers, left shifts them by an immediate value, and places the results in the destination vector.

Bits shifted out of the left of each element are lost.

The elements must all be the same size, and can be 8-bit, 16-bit, 32-bit, or 64-bit integers. There is no distinction between signed and unsigned integers.

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0 && !(imm6[5:3] == 000 && L == 0))

VSHL{<c>}{<q>}.I<size> {<Dd>, }<Dm>, #<imm>

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1 && !(imm6[5:3] == 000 && L == 0))

VSHL{<c>}{<q>}.I<size> {<Qd>, }<Qm>, #<imm>

Decode for all variants of this encoding

```

if (L::imm6) == '0000xxx' then See("Related encodings"); end;
if Q == '1' && (Vd[0] == '1' || Vm[0] == '1') then Undefined(); end;
let esize : integer{} = 8 << HighestSetBitNZ((L::imm6)[6:3]);
let elements : integer = 64 DIV esize;
let shift_amount : integer = UInt(L::imm6) - esize;
let d : integer = UInt(D::Vd);
let m : integer = UInt(M::Vm);
let regs : integer = if Q == '0' then 1 else 2;

```

T1

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0 && !(imm6[5:3] == 000 && L == 0))

VSHL{<c>}{<q>}.I<size> {<Dd>, }<Dm>, #<imm>

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1 && !(imm6[5:3] == 000 && L == 0))

VSHL{<c>}{<q>}.I<size> {<Qd>, }<Qm>, #<imm>

Decode for all variants of this encoding

```
if (L::imm6) == '0000xxx' then See("Related encodings"); end;
if Q == '1' && (Vd[0] == '1' || Vm[0] == '1') then Undefined(); end;
let esize : integer{} = 8 << HighestSetBitNZ((L::imm6)[6:3]);
let elements : integer = 64 DIV esize;
let shift_amount : integer = UInt(L::imm6) - esize;
let d : integer = UInt(D::Vd);
let m : integer = UInt(M::Vm);
let regs : integer = if Q == '0' then 1 else 2;
```

Related encodings: See [Advanced SIMD one register and modified immediate](#) for the T32 instruction set, or [Advanced SIMD one register and modified immediate](#) for the A32 instruction set.

Assembler Symbols

<c>

For the “A1 128-bit SIMD vector” and “A1 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#). This encoding must be unconditional.

For the “T1 128-bit SIMD vector” and “T1 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<size>

Is the data size for the elements of the vectors, encoded in “L:imm6”:

L	imm6	<size>
0	001xxx	8
0	01xxxx	16
0	1xxxxxx	32
1	xxxxxxx	64

<Dd>

Is the 64-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field.

<Dm>

Is the 64-bit name of the SIMD&FP source register, encoded in the “M:Vm” field.

<imm>

Is an immediate value, in the range 0 to <size>-1, encoded in the “imm6” field.

<Qd>

Is the 128-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field as <Qd>*2.

<Qm>

Is the 128-bit name of the SIMD&FP source register, encoded in the “M:Vm” field as <Qm>*2.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();
    for r = 0 to regs-1 do
        for e = 0 to elements-1 do
            D(d+r)[e*:esize] = LSL{esize} (D(m+r)[e*:esize], shift_amount);
        end;
    end;
end;
```

C6.1.202 VSHL (register)

Vector Shift Left (register) takes each element in a vector, shifts them by a value from the least significant byte of the corresponding element of a second vector, and places the results in the destination vector. If the shift value is positive, the operation is a left shift. If the shift value is negative, it is a truncating right shift.

For a rounding shift, see [VRSHL](#).

The first operand and result elements are the same data type, and can be any one of:

- 8-bit, 16-bit, 32-bit, or 64-bit signed integers.
- 8-bit, 16-bit, 32-bit, or 64-bit unsigned integers.

The second operand is always a signed integer of the same size.

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0)

VSHL{<c>}{<q>}.<dt> {<Dd>, }<Dm>, <Dn>

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

VSHL{<c>}{<q>}.<dt> {<Qd>, }<Qm>, <Qn>

Decode for all variants of this encoding

```

if Q == '1' && (Vd[0] == '1' || Vm[0] == '1' || Vn[0] == '1') then Undefined(); end;
let unsigned : boolean = (U == '1');
let esize : integer{} = 8 << UInt(size);
let elements : integer = 64 DIV esize;
let d : integer = UInt(D::Vd);
let m : integer = UInt(M::Vm);
let n : integer = UInt(N::Vn);
let regs : integer = if Q == '0' then 1 else 2;

```

T1

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0)

VSHL{<c>}{<q>}.<dt> {<Dd>, }<Dm>, <Dn>

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

VSHL{<c>}{<q>}.<dt> {<Qd>, }<Qm>, <Qn>

Decode for all variants of this encoding

```
if Q == '1' && (Vd[0] == '1' || Vm[0] == '1' || Vn[0] == '1') then Undefined(); end;
let unsigned : boolean = (U == '1');
let esize : integer{} = 8 << UInt(size);
let elements : integer = 64 DIV esize;
let d : integer = UInt(D::Vd);
let m : integer = UInt(M::Vm);
let n : integer = UInt(N::Vn);
let regs : integer = if Q == '0' then 1 else 2;
```

Assembler Symbols

<c>

For the “A1 128-bit SIMD vector” and “A1 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#). This encoding must be unconditional.

For the “T1 128-bit SIMD vector” and “T1 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<dt>

Is the data type for the elements of the vectors, encoded in “U:size”:

U	size	<dt>
0	00	S8
0	01	S16
0	10	S32
0	11	S64
1	00	U8
1	01	U16
1	10	U32
1	11	U64

<Dd>

Is the 64-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field.

<Dm>

Is the 64-bit name of the second SIMD&FP source register, encoded in the “M:Vm” field.

<Dn>

Is the 64-bit name of the first SIMD&FP source register, encoded in the “N:Vn” field.

<Qd>

Is the 128-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field as <Qd>*2.

<Qm>

Is the 128-bit name of the second SIMD&FP source register, encoded in the “M:Vm” field as <Qm>*2.

<Qn>

Is the 128-bit name of the first SIMD&FP source register, encoded in the “N:Vn” field as <Qn>*2.

Operation

```

if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();
    for r = 0 to regs-1 do
        for e = 0 to elements-1 do
            let shift : integer = SInt(D(n+r)[e*:esize][7:0]);
            let opelt : bits(esize) = D(m+r)[e*:esize];
            let element : integer = if unsigned then UInt(opelt) else SInt(opelt);
            var result : integer;
            if shift >= 0 then
                result = element << shift;
            else
                result = element >> -shift;
            end;
            D(d+r)[e*:esize] = result[esize-1:0];
        end;
    end;
end;

```

C6.1.203 VSHLL

Vector Shift Left Long takes each element in a doubleword vector, left shifts them by an immediate value, and places the results in a quadword vector.

The operand elements can be:

- 8-bit, 16-bit, or 32-bit signed integers.
- 8-bit, 16-bit, or 32-bit unsigned integers.
- 8-bit, 16-bit, or 32-bit untyped integers, maximum shift only.

The result elements are twice the length of the operand elements.

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#) and [A2](#)) and T32 ([T1](#) and [T2](#)).

A1

Encoding

Applies when (imm6 IN {100001, 10001x, 1001xx, 101xxx, 11xxxx, 010001, 01001x, 0101xx, 011xxx, 001001, 00101x, 0011xx})

VSHLL{<c>}{<q>}.<type><size> <Qd>, <Dm>, #<imm>

Decode for this encoding

```

if imm6 == '000xxx' then See("Related encodings"); end;
if imm6 IN {'001000', '010000', '100000'} then See("VMOVL"); end;
if Vd[0] == '1' then Undefined(); end;
let esize : integer{} = 8 << HighestSetBitNZ(imm6[5:3]);
let elements : integer = 64 DIV esize;
let shift_amount : integer = UInt(imm6) - esize;
let unsigned : boolean = (U == '1');
let d : integer = UInt(D::Vd);
let m : integer = UInt(M::Vm);

```

A2

Encoding

VSHLL{<c>}{<q>}.<type><size> <Qd>, <Dm>, #<imm>

Decode for this encoding

```
if size == '11' || Vd[0] == '1' then Undefined(); end;
let esize : integer() = 8 << UInt(size);
let elements : integer = 64 DIV esize;
let shift_amount : integer = esize;
let unsigned : boolean = FALSE; // Or TRUE without change of functionality
let d : integer = UInt(D::Vd);
let m : integer = UInt(M::Vm);
```

T1

Encoding

Applies when (imm6 IN {100001, 10001x, 1001xx, 101xxx, 11xxxx, 010001, 01001x, 0101xx, 011xxx, 001001, 00101x, 0011xx})

VSHLL{<c>}{<q>}.<type><size> <Qd>, <Dm>, #<imm>

Decode for this encoding

```
if imm6 == '000xxx' then See("Related encodings"); end;
if imm6 IN {'001000', '010000', '100000'} then See("VMOVL"); end;
if Vd[0] == '1' then Undefined(); end;
let esize : integer() = 8 << HighestSetBitNZ(imm6[5:3]);
let elements : integer = 64 DIV esize;
let shift_amount : integer = UInt(imm6) - esize;
let unsigned : boolean = (U == '1');
let d : integer = UInt(D::Vd);
let m : integer = UInt(M::Vm);
```

T2

Encoding

VSHLL{<c>}{<q>}.<type><size> <Qd>, <Dm>, #<imm>

Decode for this encoding

```
if size == '11' || Vd[0] == '1' then Undefined(); end;
let esize : integer() = 8 << UInt(size);
let elements : integer = 64 DIV esize;
let shift_amount : integer = esize;
let unsigned : boolean = FALSE; // Or TRUE without change of functionality
let d : integer = UInt(D::Vd);
let m : integer = UInt(M::Vm);
```

Related encodings: See [Advanced SIMD one register and modified immediate](#) for the T32 instruction set, or [Advanced SIMD one register and modified immediate](#) for the A32 instruction set.

Assembler Symbols

<c>

For the “A1” and “A2” variants: see [Standard assembler syntax fields](#). This encoding must be unconditional.
For the “T1” and “T2” variants: see [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<size>

The data size for the elements of the operand. The following table shows the permitted values and their encodings:

<size>	Encoding T1/A1	Encoding T2/A2
8	Encoded as imm6<5:3> = 0b001	Encoded as size = 0b00
16	Encoded as imm6<5:4> = 0b01	Encoded as size = 0b01
32	Encoded as imm6<5> = 1	Encoded as size = 0b10

<Qd>

Is the 128-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field as <Qd>*2.

<Dm>

Is the 64-bit name of the SIMD&FP source register, encoded in the “M:Vm” field.

<imm>

The immediate value. <imm> must lie in the range 1 to <size>, and:

- If <size> == <imm>, the encoding is T2/A2.
- Otherwise, the encoding is T1/A1, and:
 - If <size> == 8, <imm> is encoded in imm6<2:0>.
 - If <size> == 16, <imm> is encoded in imm6<3:0>.
 - If <size> == 32, <imm> is encoded in imm6<4:0>.

<type>

The data type for the elements of the operand. It must be one of:

- S** Signed. In encoding T1/A1, encoded as U = 0.
- U** Unsigned. In encoding T1/A1, encoded as U = 1.
- I** Untyped integer, Available only in encoding T2/A2.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();
    for e = 0 to elements-1 do
        let opelt : bits(esize) = Din(m)[e*:esize];
        let element : integer = if unsigned then UInt(opelt) else SInt(opelt);
        let result : integer = element << shift_amount;
        Q(d>>1)[e*:(2*esize)] = result[2*esize-1:0];
    end;
end;
```

C6.1.204 VSHR

Vector Shift Right takes each element in a vector, right shifts them by an immediate value, and places the truncated results in the destination vector. For rounded results, see [VRSHR](#).

The operand and result elements must be the same size, and can be any one of:

- 8-bit, 16-bit, 32-bit, or 64-bit signed integers.
- 8-bit, 16-bit, 32-bit, or 64-bit unsigned integers.

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding for the 64-bit SIMD vector variant

Applies when ($Q == 0 \ \&\& \ !(imm6[5:3] == 000 \ \&\& \ L == 0)$)

VSHR{<c>}{<q>}.<type><size> {<Dd>, }<Dm>, #<imm>

Encoding for the 128-bit SIMD vector variant

Applies when ($Q == 1 \ \&\& \ !(imm6[5:3] == 000 \ \&\& \ L == 0)$)

VSHR{<c>}{<q>}.<type><size> {<Qd>, }<Qm>, #<imm>

Decode for all variants of this encoding

```

if (L::imm6) == '0000xxx' then See("Related encodings"); end;
if Q == '1' && (Vd[0] == '1' || Vm[0] == '1') then Undefined(); end;
let esize : integer{} = 8 << HighestSetBitNZ((L::imm6)[6:3]);
let elements : integer = 64 DIV esize;
let shift_amount : integer = (esize * 2) - UInt(L::imm6);
let unsigned : boolean = (U == '1');
let d : integer = UInt(D::Vd);
let m : integer = UInt(M::Vm);
let regs : integer = if Q == '0' then 1 else 2;

```

T1

Encoding for the 64-bit SIMD vector variant

Applies when ($Q == 0 \ \&\& \ !(imm6[5:3] == 000 \ \&\& \ L == 0)$)

VSHR{<c>}{<q>}.<type><size> {<Dd>, }<Dm>, #<imm>

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1 && !(imm6[5:3] == 000 && L == 0))

VSHR{<c>}{<q>}.<type><size> {<Qd>, }<Qm>, #<imm>

Decode for all variants of this encoding

```
if (L::imm6) == '0000xxx' then See("Related encodings"); end;
if Q == '1' && (Vd[0] == '1' || Vm[0] == '1') then Undefined(); end;
let esize : integer{} = 8 << HighestSetBitNZ((L::imm6)[6:3]);
let elements : integer = 64 DIV esize;
let shift_amount : integer = (esize * 2) - UInt(L::imm6);
let unsigned : boolean = (U == '1');
let d : integer = UInt(D::Vd);
let m : integer = UInt(M::Vm);
let regs : integer = if Q == '0' then 1 else 2;
```

Related encodings: See [Advanced SIMD one register and modified immediate](#) for the T32 instruction set, or [Advanced SIMD one register and modified immediate](#) for the A32 instruction set.

Assembler Symbols

<c>

For the “A1 128-bit SIMD vector” and “A1 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#). This encoding must be unconditional.

For the “T1 128-bit SIMD vector” and “T1 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<type>

Is the data type for the elements of the vectors, encoded in “U”:

U	<type>
0	S
1	U

<size>

Is the data size for the elements of the vectors, encoded in “L:imm6”:

L	imm6	<size>
0	001xxx	8
0	01xxxx	16
0	1xxxxxx	32
1	xxxxxxx	64

<Dd>

Is the 64-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field.

<Dm>

Is the 64-bit name of the SIMD&FP source register, encoded in the “M:Vm” field.

<imm>

Is an immediate value, in the range 1 to <size>, encoded in the “imm6” field as <size> - <imm>.

<Qd>

Is the 128-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field as <Qd>*2.

<Qm>

Is the 128-bit name of the SIMD&FP source register, encoded in the “M:Vm” field as <Qm>*2.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();
    for r = 0 to regs-1 do
        for e = 0 to elements-1 do
            let opelt : bits(esize) = D(m+r)[e*:esize];
            let element : integer = if unsigned then UInt(opelt) else SInt(opelt);
            let result : integer = element >> shift_amount;
            D(d+r)[e*:esize] = result[esize-1:0];
        end;
    end;
end;
```

C6.1.205 VSHR (zero)

Vector Shift Right copies the contents of one SIMD register to another.

This is a pseudo-instruction of [VORR \(register\)](#). This means:

- The encodings in this description are named to match the encodings of [VORR \(register\)](#).
- The assembler syntax is used only for assembly, and is not used on disassembly.
- The description of [VORR \(register\)](#) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding for the 64-bit SIMD vector variant

Applies when ($Q == 0$)

VSHR{<c>}{<q>}.<dt> <Dd>, <Dm>, #0

is equivalent to

VORR{<c>}{<q>}{.<dt>} {<Dd>, }<Dm>, <Dm>

Encoding for the 128-bit SIMD vector variant

Applies when ($Q == 1$)

VSHR{<c>}{<q>}.<dt> <Qd>, <Qm>, #0

is equivalent to

VORR{<c>}{<q>}{.<dt>} {<Qd>, }<Qm>, <Qm>

T1

Encoding for the 64-bit SIMD vector variant

Applies when ($Q == 0$)

VSHR{<c>}{<q>}.<dt> <Dd>, <Dm>, #0

is equivalent to

VORR{<c>}{<q>}{.<dt>} {<Dd>, }<Dm>, <Dm>

Encoding for the 128-bit SIMD vector variant

Applies when ($Q == 1$)

VSHR{<c>}{<q>}.<dt> <Qd>, <Qm>, #0

is equivalent to

VORR{<c>}{<q>}{.<dt>} {<Qd>, }<Qm>, <Qm>

Assembler Symbols

<c>

For the “A1 128-bit SIMD vector” and “A1 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#).
This encoding must be unconditional.

For the “T1 128-bit SIMD vector” and “T1 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<dt>

Is the data type for the elements of the vectors, and must be one of: S8, S16, S32, S64, U8, U16, U32 or U64.

<Dd>

Is the 64-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field.

<Dm>

Is the 64-bit name of the SIMD&FP source register, encoded in the “N:Vn” and “M:Vm” field.

<Qd>

Is the 128-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field as <Qd>*2.

<Qm>

Is the 128-bit name of the SIMD&FP source register, encoded in the “N:Vn” and “M:Vm” field as <Qm>*2.

Operation

The description of [VORR \(register\)](#) gives the operational pseudocode for this instruction.

C6.1.206 VSHRN

Vector Shift Right Narrow takes each element in a vector, right shifts them by an immediate value, and places the truncated results in the destination vector. For rounded results, see [VRSHRN](#).

The operand elements can be 16-bit, 32-bit, or 64-bit integers. There is no distinction between signed and unsigned integers. The destination elements are half the size of the source elements.

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

VSHRN{<c>}{<q>}.I<size> <Dd>, <Qm>, #<imm>

Decode for this encoding

```

if imm6 == '000xxx' then See("Related encodings"); end;
if Vm[0] == '1' then Undefined(); end;
let esize : integer{} = 8 << HighestSetBitNZ(imm6[5:3]);
let elements : integer = 64 DIV esize;
let shift_amount : integer = (2 * esize) - UInt(imm6);
let d : integer = UInt(D::Vd);
let m : integer = UInt(M::Vm);
  
```

T1

Encoding

VSHRN{<c>}{<q>}.I<size> <Dd>, <Qm>, #<imm>

Decode for this encoding

```

if imm6 == '000xxx' then See("Related encodings"); end;
if Vm[0] == '1' then Undefined(); end;
let esize : integer{} = 8 << HighestSetBitNZ(imm6[5:3]);
let elements : integer = 64 DIV esize;
let shift_amount : integer = (2 * esize) - UInt(imm6);
let d : integer = UInt(D::Vd);
let m : integer = UInt(M::Vm);
  
```

Related encodings: See [Advanced SIMD one register and modified immediate](#) for the T32 instruction set, or [Advanced SIMD one register and modified immediate](#) for the A32 instruction set.

Assembler Symbols

<c>

For the “A1” variant: see [Standard assembler syntax fields](#). This encoding must be unconditional.
For the “T1” variant: see [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<size>

Is the data size for the elements of the vectors, encoded in “imm6”:

imm6	<size>
001xxx	16
01xxxx	32
1xxxxx	64

<Dd>

Is the 64-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field.

<Qm>

Is the 128-bit name of the SIMD&FP source register, encoded in the “M:Vm” field as <Qm>*2.

<imm>

Is an immediate value, in the range 1 to <size>/2, encoded in the “imm6” field as <size>/2 - <imm>.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();
    for e = 0 to elements-1 do
        let result : bits(2*esize) = LSR(Qin(m>>1)[e*:(2*esize)], shift_amount);
        D(d)[e*esize] = result[esize-1:0];
    end;
end;
```

C6.1.207 VSHRN (zero)

Vector Shift Right Narrow takes each element in a vector, right shifts them by an immediate value, and places the truncated results in the destination vector.

This is a pseudo-instruction of **VMOVN**. This means:

- The encodings in this description are named to match the encodings of **VMOVN**.
- The assembler syntax is used only for assembly, and is not used on disassembly.
- The description of **VMOVN** gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

It has encodings from the following instruction sets: A32 (**A1**) and T32 (**T1**).

A1

Encoding for the A1 variant

VSHRN{<c>}{<q>}.<dt> <Dd>, <Qm>, #0

is equivalent to

VMOVN{<c>}{<q>}.<dt> <Dd>, <Qm>

T1

Encoding for the T1 variant

VSHRN{<c>}{<q>}.<dt> <Dd>, <Qm>, #0

is equivalent to

VMOVN{<c>}{<q>}.<dt> <Dd>, <Qm>

Assembler Symbols

<c>

For the “A1” variant: see [Standard assembler syntax fields](#). This encoding must be unconditional.

For the “T1” variant: see [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<dt>

Is the data type for the elements of the operand, encoded in “size”:

size	<dt>
00	I 16
01	I 32
10	I 64
11	RESERVED

<Dd>

Is the 64-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field.

<Qm>

Is the 128-bit name of the SIMD&FP source register, encoded in the “M:Vm” field as <Qm>*2.

Operation

The description of [VMOVN](#) gives the operational pseudocode for this instruction.

C6.1.208 VSLI

Vector Shift Left and Insert takes each element in the operand vector, left shifts them by an immediate value, and inserts the results in the destination vector. Bits shifted out of the left of each element are lost.

The elements must all be the same size, and can be 8-bit, 16-bit, 32-bit, or 64-bit. There is no distinction between data types.

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding for the 64-bit SIMD vector variant

Applies when ($Q == 0 \ \&\& \ !(imm6[5:3] == 000 \ \&\& \ L == 0)$)

VSLI{<c>}{<q>}.<size> {<Dd>, }<Dm>, #<imm>

Encoding for the 128-bit SIMD vector variant

Applies when ($Q == 1 \ \&\& \ !(imm6[5:3] == 000 \ \&\& \ L == 0)$)

VSLI{<c>}{<q>}.<size> {<Qd>, }<Qm>, #<imm>

Decode for all variants of this encoding

```

if (L::imm6) == '0000xxx' then See("Related encodings"); end;
if Q == '1' && (Vd[0] == '1' || Vm[0] == '1') then Undefined(); end;
let esize : integer{} = 8 << HighestSetBitNZ((L::imm6)[6:3]);
let elements : integer = 64 DIV esize;
let shift_amount : integer = UInt(L::imm6) - esize;
let d : integer = UInt(D::Vd);
let m : integer = UInt(M::Vm);
let regs : integer = if Q == '0' then 1 else 2;

```

T1

Encoding for the 64-bit SIMD vector variant

Applies when ($Q == 0 \ \&\& \ !(imm6[5:3] == 000 \ \&\& \ L == 0)$)

VSLI{<c>}{<q>}.<size> {<Dd>, }<Dm>, #<imm>

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1 && !(imm6[5:3] == 000 && L == 0))

VSLI{<c>}{<q>}.<size> {<Qd>, }<Qm>, #<imm>

Decode for all variants of this encoding

```
if (L::imm6) == '0000xxx' then See("Related encodings"); end;
if Q == '1' && (Vd[0] == '1' || Vm[0] == '1') then Undefined(); end;
let esize : integer() = 8 << HighestSetBitNZ((L::imm6)[6:3]);
let elements : integer = 64 DIV esize;
let shift_amount : integer = UInt(L::imm6) - esize;
let d : integer = UInt(D::Vd);
let m : integer = UInt(M::Vm);
let regs : integer = if Q == '0' then 1 else 2;
```

Related encodings: See [Advanced SIMD one register and modified immediate](#) for the T32 instruction set, or [Advanced SIMD one register and modified immediate](#) for the A32 instruction set.

Assembler Symbols

<c>

For the “A1 128-bit SIMD vector” and “A1 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#). This encoding must be unconditional.

For the “T1 128-bit SIMD vector” and “T1 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<size>

Is the data size for the elements of the vectors, encoded in “L:imm6”:

L	imm6	<size>
0	001xxx	8
0	01xxxx	16
0	1xxxxxx	32
1	xxxxxxx	64

<Dd>

Is the 64-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field.

<Dm>

Is the 64-bit name of the SIMD&FP source register, encoded in the “M:Vm” field.

<imm>

Is an immediate value, in the range 0 to <size>-1, encoded in the “imm6” field.

<Qd>

Is the 128-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field as <Qd>*2.

<Qm>

Is the 128-bit name of the SIMD&FP source register, encoded in the “M:Vm” field as <Qm>*2.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();
    let mask : bits(esize) = LSL{}(Ones(esize), shift_amount);
    for r = 0 to regs-1 do
        for e = 0 to elements-1 do
            let shifted_op : bits(esize) = LSL{}(D(m+r)[e*:esize], shift_amount);
            D(d+r)[e*:esize] = (D(d+r)[e*:esize] AND NOT(mask)) OR shifted_op;
        end;
    end;
end;
```

C6.1.209 VSQRT

Square Root calculates the square root of the value in a floating-point register and writes the result to another floating-point register.

Depending on settings in the [CPACR](#), [NSACR](#), [HCPTR](#), and [FPEXC](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding for the Single-precision scalar variant

Applies when (size == 10)

```
VSQRT{<c>}{<q>}.F32 <Sd>, <Sm>
```

Encoding for the Double-precision scalar variant

Applies when (size == 11)

```
VSQRT{<c>}{<q>}.F64 <Dd>, <Dm>
```

Decode for all variants of this encoding

```
if size != '1x' then Undefined(); end;
if FPSCR().Len != '000' || FPSCR().Stride != '00' then Undefined(); end;
let esize : integer() = 8 << UInt(size);
let d : integer = if size == '11' then UInt(D::Vd) else UInt(Vd::D);
let m : integer = if size == '11' then UInt(M::Vm) else UInt(Vm::M);
```

CONSTRAINED UNPREDICTABLE behavior

If size == '01' && cond != '1110', then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

T1

Encoding for the Single-precision scalar variant

Applies when (size == 10)

```
VSQRT{<c>}{<q>}.F32 <Sd>, <Sm>
```

Encoding for the Double-precision scalar variant

Applies when (size == 11)

VSQRT{<c>}{<q>}.F64 <Dd>, <Dm>

Decode for all variants of this encoding

```
if size != '1x' then Undefined(); end;
if FPSCR().Len != '000' || FPSCR().Stride != '00' then Undefined(); end;
let esize : integer() = 8 << UInt(size);
let d : integer = if size == '11' then UInt(D::Vd) else UInt(Vd::D);
let m : integer = if size == '11' then UInt(M::Vm) else UInt(Vm::M);
```

CONSTRAINED UNPREDICTABLE behavior

If size == '01' && InITBlock(), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Sd>

Is the 32-bit name of the SIMD&FP destination register, encoded in the “Vd:D” field.

<Sm>

Is the 32-bit name of the SIMD&FP source register, encoded in the “Vm:M” field.

<Dd>

Is the 64-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field.

<Dm>

Is the 64-bit name of the SIMD&FP source register, encoded in the “M:Vm” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckVFPEEnabled(TRUE);
    let fpcr : FPCR_Type = EffectiveFPCR();
    case esize of
        when 32 => S(d) = FPSqrt{32}(S(m), fpcr);
        when 64 => D(d) = FPSqrt{64}(D(m), fpcr);
    end;
end;
```

C6.1.210 VSRA

Vector Shift Right and Accumulate takes each element in a vector, right shifts them by an immediate value, and accumulates the truncated results into the destination vector. For rounded results, see [VRSRA](#).

The operand and result elements must all be the same type, and can be any one of:

- 8-bit, 16-bit, 32-bit, or 64-bit signed integers.
- 8-bit, 16-bit, 32-bit, or 64-bit unsigned integers.

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0 && !(imm6[5:3] == 000 && L == 0))

```
VSRA{<c>}{<q>}.<type><size> {<Dd>, }<Dm>, #<imm>
```

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1 && !(imm6[5:3] == 000 && L == 0))

```
VSRA{<c>}{<q>}.<type><size> {<Qd>, }<Qm>, #<imm>
```

Decode for all variants of this encoding

```
if (L::imm6) == '0000xxx' then See("Related encodings"); end;
if Q == '1' && (Vd[0] == '1' || Vm[0] == '1') then Undefined(); end;
let esize : integer{} = 8 << HighestSetBitNZ((L::imm6)[6:3]);
let elements : integer = 64 DIV esize;
let shift_amount : integer = (esize * 2) - UInt(L::imm6);
let unsigned : boolean = (U == '1');
let d : integer = UInt(D::Vd);
let m : integer = UInt(M::Vm);
let regs : integer = if Q == '0' then 1 else 2;
```

T1

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0 && !(imm6[5:3] == 000 && L == 0))

```
VSRA{<c>}{<q>}.<type><size> {<Dd>, }<Dm>, #<imm>
```

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1 && !(imm6[5:3] == 000 && L == 0))

VSRA{<c>}{<q>}.<type><size> {<Qd>, }<Qm>, #<imm>

Decode for all variants of this encoding

```
if (L::imm6) == '0000xxx' then See("Related encodings"); end;
if Q == '1' && (Vd[0] == '1' || Vm[0] == '1') then Undefined(); end;
let esize : integer{} = 8 << HighestSetBitNZ((L::imm6)[6:3]);
let elements : integer = 64 DIV esize;
let shift_amount : integer = (esize * 2) - UInt(L::imm6);
let unsigned : boolean = (U == '1');
let d : integer = UInt(D::Vd);
let m : integer = UInt(M::Vm);
let regs : integer = if Q == '0' then 1 else 2;
```

Related encodings: See [Advanced SIMD one register and modified immediate](#) for the T32 instruction set, or [Advanced SIMD one register and modified immediate](#) for the A32 instruction set.

Assembler Symbols

<c>

For the “A1 128-bit SIMD vector” and “A1 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#). This encoding must be unconditional.

For the “T1 128-bit SIMD vector” and “T1 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<type>

Is the data type for the elements of the vectors, encoded in “U”:

U	<type>
0	S
1	U

<size>

Is the data size for the elements of the vectors, encoded in “L:imm6”:

L	imm6	<size>
0	001xxx	8
0	01xxxx	16
0	1xxxxxx	32
1	xxxxxxx	64

<Dd>

Is the 64-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field.

<Dm>

Is the 64-bit name of the SIMD&FP source register, encoded in the “M:Vm” field.

<imm>

Is an immediate value, in the range 1 to <size>, encoded in the “imm6” field as <size> - <imm>.

<Qd>

Is the 128-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field as <Qd>*2.

<Qm>

Is the 128-bit name of the SIMD&FP source register, encoded in the “M:Vm” field as <Qm>*2.

Operation

```

if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();
    for r = 0 to regs-1 do
        for e = 0 to elements-1 do
            let opelt : bits(esize) = D(m+r)[e*:esize];
            let element : integer = if unsigned then UInt(opelt) else SInt(opelt);
            let result : integer = element >> shift_amount;
            D(d+r)[e*:esize] = D(d+r)[e*:esize] + result;
        end;
    end;
end;
end;

```

C6.1.211 VSRI

Vector Shift Right and Insert takes each element in the operand vector, right shifts them by an immediate value, and inserts the results in the destination vector. Bits shifted out of the right of each element are lost.

The elements must all be the same size, and can be 8-bit, 16-bit, 32-bit, or 64-bit. There is no distinction between data types.

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0 && !(imm6[5:3] == 000 && L == 0))

VSRI{<c>}{<q>}.<size> {<Dd>, }<Dm>, #<imm>

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1 && !(imm6[5:3] == 000 && L == 0))

VSRI{<c>}{<q>}.<size> {<Qd>, }<Qm>, #<imm>

Decode for all variants of this encoding

```

if (L::imm6) == '0000xxx' then See("Related encodings"); end;
if Q == '1' && (Vd[0] == '1' || Vm[0] == '1') then Undefined(); end;
let esize : integer{} = 8 << HighestSetBitNZ((L::imm6)[6:3]);
let elements : integer = 64 DIV esize;
let shift_amount : integer = (esize * 2) - UInt(L::imm6);
let d : integer = UInt(D::Vd);
let m : integer = UInt(M::Vm);
let regs : integer = if Q == '0' then 1 else 2;

```

T1

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0 && !(imm6[5:3] == 000 && L == 0))

VSRI{<c>}{<q>}.<size> {<Dd>, }<Dm>, #<imm>

Encoding for the 128-bit SIMD vector variant

Applies when $(Q == 1 \ \&\& \ !(\text{imm6}[5:3] == 000 \ \&\& \ L == 0))$

VSRI{<c>}{<q>}.<size> {<Qd>, }<Qm>, #<imm>

Decode for all variants of this encoding

```
if (L::imm6) == '0000xxx' then See("Related encodings"); end;
if Q == '1' && (Vd[0] == '1' || Vm[0] == '1') then Undefined(); end;
let esize : integer() = 8 << HighestSetBitNZ((L::imm6)[6:3]);

let d : integer = UInt(D::Vd);
let m : integer = UInt(M::Vm);
let regs : integer = if Q == '0' then 1 else 2;
```

Related encodings: See [Advanced SIMD one register and modified immediate](#) for the T32 instruction set, or [Advanced SIMD one register and modified immediate](#) for the A32 instruction set.

Assembler Symbols

<c>

For the “A1 128-bit SIMD vector” and “A1 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#). This encoding must be unconditional.

For the “T1 128-bit SIMD vector” and “T1 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<size>

Is the data size for the elements of the vectors, encoded in “L:imm6”:

L	imm6	<size>
0	001xxx	8
0	01xxxx	16
0	1xxxxxx	32
1	xxxxxxx	64

<Dd>

Is the 64-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field.

<Dm>

Is the 64-bit name of the SIMD&FP source register, encoded in the “M:Vm” field.

<imm>

Is an immediate value, in the range 1 to <size>, encoded in the “imm6” field as <size> - <imm>.

<Qd>

Is the 128-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field as <Qd>*2.

<Qm>

Is the 128-bit name of the SIMD&FP source register, encoded in the “M:Vm” field as <Qm>*2.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();
    let mask : bits(esize) = LSR(Ones{esize}, shift_amount);
    for r = 0 to regs-1 do
        for e = 0 to elements-1 do
            let shifted_op : bits(esize) = LSR(D(m+r)[e*:esize], shift_amount);
            D(d+r)[e*:esize] = (D(d+r)[e*:esize] AND NOT(mask)) OR shifted_op;
        end;
    end;
end;
```

C6.1.212 VST1 (single element from one lane)

Store single element from one lane of one register stores one element to memory from one element of a register. For details of the addressing mode, see [Advanced SIMD addressing mode](#).

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information, see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 (A1, A2, and A3) and T32 (T1, T2, and T3).

A1

Encoding for the Offset variant

Applies when (Rm == 1111)

VST1{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]

Encoding for the Post-indexed variant

Applies when (Rm == 1101)

```
VST1{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]!
```

Encoding for the Post-indexed variant

Applies when (Rm != 11x1)

$$\text{VST1}\{\langle c \rangle\}\{\langle q \rangle\}.\langle \text{size} \rangle \quad \langle \text{list} \rangle, \quad [\langle \text{Rn} \rangle\{:\langle \text{align} \rangle\}], \quad \langle \text{Rm} \rangle$$

Decode for all variants of this encoding

```

```

Encoding for the Post-indexed variant

Applies when (Rm == 1101)

```
VST1{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]!
```

Encoding for the Post-indexed variant

Applies when (Rm != 11x1)

$$\text{VST1}\{\langle c \rangle\}\{\langle q \rangle\}.\langle \text{size} \rangle \quad \langle \text{list} \rangle, \quad [\langle \text{Rn} \rangle\{:\langle \text{align} \rangle\}], \quad \langle \text{Rm} \rangle$$

Decode for all variants of this encoding

```

if size == '1l' then Undefined(); end;
if index_align[0] != '0' then Undefined(); end;
let ebytes : integer{} = 1;
let index : integer = UInt(index_align[3:1]);
let alignment : integer{} = 1;
let d : integer = UInt(D::Vd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);

let wback : boolean = (m != 15);

let register_index : boolean = (m != 15 && m != 13);
if n == 15 then UnpredictableProcedure(); end;

```

T2

Encoding for the Offset variant

Applies when (Rm == 1111)

```
VST1{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]
```

Encoding for the Post-indexed variant

Applies when (Rm == 1101)

VST1{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]!

Encoding for the Post-indexed variant

Applies when (Rm != 11x1)

VST1{<c>}{<q>}.<size> <list>, [(<Rn>{:<align>})], <Rm>

Decode for all variants of this encoding

```

if size == '11' then Undefined(); end;
if index_align[1] != '0' then Undefined(); end;
let ebytes : integer{} = 2;
let index : integer = UInt(index_align[3:2]);
let alignment : integer{} = if index_align[0] == '0' then 1 else 2;
let d : integer = UInt(D::Vd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let wback : boolean = (m != 15);
let register_index : boolean = (m != 15 && m != 13);
if n == 15 then UnpredictableProcedure(); end;

```

T3

Encoding for the Offset variant

Applies when (Rm == 1111)

VST1{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]

Encoding for the Post-indexed variant

Applies when (Rm == 1101)

```
VST1{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]!
```

Encoding for the Post-indexed variant

Applies when (Rm != 11x1)

VSTl{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}], <Rm>

Decode for all variants of this encoding

```
if size == '11' then Undefined(); end;
if index_align[2] != '0' then Undefined(); end;
if index_align[1:0] != '00' && index_align[1:0] != '11' then Undefined(); end;
let ebytes : integer{} = 4;
let index : integer = UInt(index_align[3]);
let alignment : integer{} = if index_align[1:0] == '00' then 1 else 4;
let d : integer = UInt(D::Vd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let wback : boolean = (m != 15);
let register_index : boolean = (m != 15 && m != 13);
if n == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

For the “A1 Offset”, “A1 Post-indexed”, “A2 Offset”, “A2 Post-indexed”, “A3 Offset”, and “A3 Post-indexed” variants: see [Standard assembler syntax fields](#). This encoding must be unconditional.

For the “T1 Offset”, “T1 Post-indexed”, “T2 Offset”, “T2 Post-indexed”, “T3 Offset”, and “T3 Post-indexed” variants: see [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<size>

Is the data size, encoded in “size”:

size	<size>
00	8
01	16
10	32

<list>

Is a list containing the single 64-bit name of the SIMD&FP register holding the element.

The list must be { <Dd>[<index>] }.

The register <Dd> is encoded in the “D:Vd” field.

The permitted values and encoding of <index> depend on <size>:

<size> == **8** <index> is in the range 0 to 7, encoded in the “index_align<3:1>” field.

<size> == **16** <index> is in the range 0 to 3, encoded in the “index_align<3:2>” field.

<size> == **32** <index> is 0 or 1, encoded in the “index_align<3>” field.

<Rn>

Is the general-purpose base register, encoded in the “Rn” field.

<align>

When <size> == 8, <align> must be omitted, otherwise it is the optional alignment.

Whenever <align> is omitted, the standard alignment is used, see [Unaligned data access](#), and the encoding depends on <size>:

<size> == 8 Encoded in the “index_align<0>” field as 0.
<size> == 16 Encoded in the “index_align<1:0>” field as 0b00.
<size> == 32 Encoded in the “index_align<2:0>” field as 0b000.

Whenever <align> is present, the permitted values and encoding depend on <size>:

<size> == 16 <align> is 16, meaning 16-bit alignment, encoded in the “index_align<1:0>” field as 0b01.
<size> == 32 <align> is 32, meaning 32-bit alignment, encoded in the “index_align<2:0>” field as 0b011.

: is the preferred separator before the <align> value, but the alignment can be specified as @<align>, see [Advanced SIMD addressing mode](#).

<Rm>

Is the general-purpose index register containing an offset applied after the access, encoded in the “Rm” field.

For more information about the variants of this instruction, see [Advanced SIMD addressing mode](#).

Operation

```

if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();

    let address : bits(32) = R(n);

    let nontemporal : boolean = FALSE;
    let privileged : boolean = PSTATE.EL != EL0;
    let accdesc : AccessDescriptor = CreateAccDescASIMD(MemOp_STORE, nontemporal, privileged);
    if !IsAlignedSize(address, alignment) then
        let fault : FaultRecord = AlignmentFault(accdesc, ZeroExtend{64}(address));
        AArch32_Abort(fault);
    end;

    MemU{8*bytes}(address) = D(d)[index*:(8*bytes)];
    if wback then
        if register_index then
            R(n) = R(n) + R(m);
        else
            R(n) = R(n) + ebytes;
        end;
    end;
end;
end;

```

C6.1.213 VST1 (multiple single elements)

Store multiple single elements from one, two, three, or four registers

Store multiple single elements from one, two, three, or four registers stores elements to memory from one, two, three, or four registers, without interleaving. Every element of each register is stored. For details of the addressing mode, see [Advanced SIMD addressing mode](#).

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information, see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 (A1, A2, A3, and A4) and T32 (T1, T2, T3, and T4).

A1

Encoding for the Offset variant

Applies when (Rm == 1111)

VST1{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]

Encoding for the Post-indexed variant

Applies when (Rm == 1101)

$$\text{VST1}\{\langle c \rangle\}\{\langle q \rangle\}.\langle \text{size} \rangle \quad \langle \text{list} \rangle, \quad [\langle \text{Rn} \rangle\{\langle \text{align} \rangle\}]!$$

Encoding for the Post-indexed variant

Applies when ($R_m \neq 11 \times 1$)

$$\text{VST1}\{\langle c \rangle\}\{\langle q \rangle\}.\langle \text{size} \rangle \quad \langle \text{list} \rangle, \quad [\langle \text{Rn} \rangle\{:\langle \text{align} \rangle\}], \quad \langle \text{Rm} \rangle$$

Decode for all variants of this encoding

```

if align[1] == '1' then Undefined(); end;
let alignment : integer{} = if align == '00' then 1 else 4 << UInt(align);
let regs : integer = 1;
let ebytes : integer{} = 1 << UInt(size);
let elements : integer = 8 DIV ebytes;
let d : integer = UInt(D::Vd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let wback : boolean = (m != 15);
let register_index : boolean = (m != 15 && m != 13);
if n == 15 then UnpredictableProcedure(); end;

```

A2

Encoding for the Offset variant

Applies when (Rm == 1111)

VST1{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]

Encoding for the Post-indexed variant

Applies when (Rm == 1101)

VST1{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]!

Encoding for the Post-indexed variant

Applies when (Rm != 11x1)

VST1{<c>}{<q>}.<size> <list>, [(<Rn>{:<align>})], <Rm>

Decode for all variants of this encoding

```

if align == '11' then Undefined(); end;
let alignment : integer{} = if align == '00' then 1 else 4 << UInt(aligned);
let regs : integer = 2;
let ebytes : integer{} = 1 << UInt(size);
let elements : integer = 8 DIV ebytes;
let d : integer = UInt(D::Vd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let wback : boolean = (m != 15);
let register_index : boolean = (m != 15 && m != 13);
if n == 15 || d+regs > 32 then UnpredictableProcedure(); end;

```

CONSTRAINED UNPREDICTABLE behavior

If $\text{d+regs} > 32$, then one of the following behaviors must occur:

- The instruction is `UNDEFINED`.
- The instruction executes as `NOP`.
- The memory locations specified by the instruction and the number of registers specified by the instruction become `UNKNOWN`. If the instruction specifies writeback, then that register becomes `UNKNOWN`. This behavior does not affect any other memory locations.

A3

Encoding for the Offset variant

Applies when (Rm == 1111)

```
VST1{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]
```

Encoding for the Post-indexed variant

Applies when (Rm == 1101)

```
VST1{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]!
```

Encoding for the Post-indexed variant

Applies when ($R_m \neq 11 \times 1$)

$$\text{VST1}\{\langle c \rangle\}\{\langle q \rangle\}.\langle \text{size} \rangle \quad \langle \text{list} \rangle, \quad [\langle \text{Rn} \rangle\{\langle \text{align} \rangle\}], \quad \langle \text{Rm} \rangle$$

Decode for all variants of this encoding

```

if align[1] == '1' then Undefined(); end;
let alignment : integer{} = if align == '00' then 1 else 4 << UInt(align);
let regs : integer = 3;
let ebytes : integer{} = 1 << UInt(size);

if n == 15 || d+regs > 32 then UnpredictableProcedure(); end;

```

CONSTRAINED UNPREDICTABLE behavior

If $d + \text{regs} > 32$, then one of the following behaviors must occur:

- The instruction is `UNDEFINED`.
- The instruction executes as `NOP`.
- The memory locations specified by the instruction and the number of registers specified by the instruction become `UNKNOWN`. If the instruction specifies writeback, then that register becomes `UNKNOWN`. This behavior does not affect any other memory locations.

A4

Encoding for the Offset variant

Applies when (Rm == 1111)

```
VSTl{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]
```

Encoding for the Post-indexed variant

Applies when (Rm == 1101)

```
VSTl{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]!
```

Encoding for the Post-indexed variant

Applies when (Rm != 11x1)

```
VSTl{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}], <Rm>
```

Decode for all variants of this encoding

```
let regs : integer = 4;
let alignment : integer{} = if align == '00' then 1 else 4 << UInt(align);
let ebytes : integer{} = 1 << UInt(size);
let elements : integer = 8 DIV ebytes;
let d : integer = UInt(D::Vd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let wback : boolean = (m != 15);
let register_index : boolean = (m != 15 && m != 13);
if n == 15 || d+regs > 32 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If d+regs > 32, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The memory locations specified by the instruction and the number of registers specified by the instruction become UNKNOWN. If the instruction specifies writeback, then that register becomes UNKNOWN. This behavior does not affect any other memory locations.

T1

Encoding for the Offset variant

Applies when (Rm == 1111)

```
VST1{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]
```

Encoding for the Post-indexed variant

Applies when (Rm == 1101)

VST1{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]!

Encoding for the Post-indexed variant

Applies when (Rm != 11x1)

VST1{<c>}{<q>}.<size> <list>, [(<Rn>{:<align>})], <Rm>

Decode for all variants of this encoding

```

if align[1] == '1' then Undefined(); end;
let alignment : integer{} = if align == '00' then 1 else 4 << UInt(align);
let regs : integer = 1;

```

CONSTRAINED UNPREDICTABLE behavior

If `d+regs > 32`, then one of the following behaviors must occur:

- The instruction is `UNDEFINED`.
- The instruction executes as `NOP`.
- The memory locations specified by the instruction and the number of registers specified by the instruction become `UNKNOWN`. If the instruction specifies writeback, then that register becomes `UNKNOWN`. This behavior does not affect any other memory locations.

For more information about the `CONSTRAINED UNPREDICTABLE` behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly [VST1 \(multiple single elements\)](#).

Related encodings: See [Advanced SIMD element or structure load/store](#) for the T32 instruction set, or [Advanced SIMD element or structure load/store](#) for the A32 instruction set.

Assembler Symbols

`<c>`

For the “A1 Offset”, “A1 Post-indexed”, “A2 Offset”, “A2 Post-indexed”, “A3 Offset”, “A3 Post-indexed”, “A4 Offset”, and “A4 Post-indexed” variants: see [Standard assembler syntax fields](#). This encoding must be unconditional.

For the “T1 Offset”, “T1 Post-indexed”, “T2 Offset”, “T2 Post-indexed”, “T3 Offset”, “T3 Post-indexed”, “T4 Offset”, and “T4 Post-indexed” variants: see [Standard assembler syntax fields](#).

`<q>`

See [Standard assembler syntax fields](#).

`<size>`

Is the data size, encoded in “size”:

size	<size>
00	8
01	16
10	32
11	64

`<list>`

Is a list containing the 64-bit names of the SIMD&FP registers.

The list must be one of:

- { `<Dd>` } Single register. Selects the A1 and T1 encodings of the instruction.
- { `<Dd>`, `<Dd+1>` } Two single-spaced registers. Selects the A2 and T2 encodings of the instruction.
- { `<Dd>`, `<Dd+1>`, `<Dd+2>` } Three single-spaced registers. Selects the A3 and T3 encodings of the instruction.
- { `<Dd>`, `<Dd+1>`, `<Dd+2>`, `<Dd+3>` } Four single-spaced registers. Selects the A4 and T4 encodings of the instruction.

The register `<Dd>` is encoded in the “D:Vd” field.

`<Rn>`

Is the general-purpose base register, encoded in the “Rn” field.

<align>

Is the optional alignment.

Whenever <align> is omitted, the standard alignment is used, see [Unaligned data access](#), and is encoded in the “align” field as 0b00.

Whenever <align> is present, the permitted values are:

- 64** 64-bit alignment, encoded in the “align” field as 0b01.
- 128** 128-bit alignment, encoded in the “align” field as 0b10. Available only if <list> contains two or four registers.
- 256** 256-bit alignment, encoded in the “align” field as 0b11. Available only if <list> contains four registers.

: is the preferred separator before the <align> value, but the alignment can be specified as @<align>, see [Advanced SIMD addressing mode](#).

<Rm>

Is the general-purpose index register containing an offset applied after the access, encoded in the “Rm” field.

For more information about <Rn>, !, and <Rm>, see [Advanced SIMD addressing mode](#).

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();

    var address : bits(32) = R(n);

    let nontemporal : boolean = FALSE;
    let privileged : boolean = PSTATE.EL != EL0;
    let accdesc : AccessDescriptor = CreateAccDescASIMD(MemOp_STORE, nontemporal, privileged);
    if !IsAlignedSize(address, alignment) then
        let fault : FaultRecord = AlignmentFault(accdesc, ZeroExtend{64}(address));
        AArch32_Abort(fault);
    end;

        for e = 0 to elements-1 do
            if ebytes != 8 then
                MemU{8*ebytes}(address) = D(d+r)[e*(8*ebytes)];
            else
                if !IsAlignedSize(address, ebytes) && AlignmentEnforced() then
                    let fault : FaultRecord = AlignmentFault(accdesc, ZeroExtend{64}(address));
                    AArch32_Abort(fault);
                end;

                let data : bits(64) = D(d+r)[e*64];
                if BigEndian(AccessType_ASIMD) then
                    MemU{32}(address) = data[63:32];
                    MemU{32}(address+4) = data[31:0];
                else
                    MemU{32}(address) = data[31:0];
                    MemU{32}(address+4) = data[63:32];
                end;
            end;
            address = address + ebytes;
        end;
    end;

    if wback then
        if register_index then
            R(n) = R(n) + R(m);
        else
            R(n) = R(n) + 8*regs;
        end;
    end;
```

```
        end;  
    end;  
end;
```

C6.1.214 VST2 (single 2-element structure from one lane)

Store single 2-element structure from one lane of two registers stores one 2-element structure to memory from corresponding elements of two registers. For details of the addressing mode, see [Advanced SIMD addressing mode](#).

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be `UNDEFINED`, or trapped to Hyp mode. For more information, see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 (A1, A2, and A3) and T32 (T1, T2, and T3).

A1

Encoding for the Offset variant

Applies when (Rm == 1111)

```
VST2{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]
```

Encoding for the Post-indexed variant

Applies when (Rm == 1101)

$$\text{VST2}\{\langle c \rangle\}\{\langle q \rangle\}.\langle \text{size} \rangle \quad \langle \text{list} \rangle, \quad [\langle \text{Rn} \rangle\{\langle \text{align} \rangle\}]!$$

Encoding for the Post-indexed variant

Applies when (Rm != 11x1)

$$\text{VST2}\{\langle c \rangle\}\{\langle q \rangle\}.\langle \text{size} \rangle \quad \langle \text{list} \rangle, \quad [\langle \text{Rn} \rangle\{:\langle \text{align} \rangle\}], \quad \langle \text{Rm} \rangle$$

Decode for all variants of this encoding

```

if size == '11' then Undefined(); end;
let ebytes : integer{} = 1;
let index : integer = UInt(index_align[3:1]);
let inc : integer = 1;
let alignment : integer{} = if index_align[0] == '0' then 1 else 2;
let d : integer = UInt(D::Vd);
let d2 : integer = d + inc;
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let wback : boolean = (m != 15);
let register_index : boolean = (m != 15 && m != 13);
if n == 15 || d2 > 31 then UnpredictableProcedure(); end;

```

CONSTRAINED UNPREDICTABLE behavior

If $d_2 > 31$, then one of the following behaviors must occur:

- The instruction is `UNDEFINED`.
- The instruction executes as `NOP`.
- The memory locations specified by the instruction and the number of registers specified by the instruction become `UNKNOWN`. If the instruction specifies writeback, then that register becomes `UNKNOWN`. This behavior does not affect any other memory locations.

A2

Encoding for the Offset variant

Applies when (Rm == 1111)

```
VST2{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]
```

Encoding for the Post-indexed variant

Applies when (Rm == 1101)

```
VST2{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]!
```

Encoding for the Post-indexed variant

Applies when (Rm != 11x1)

```
VST2{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}], <Rm>
```

Decode for all variants of this encoding

```
if size == 'l1' then Undefined(); end;
let ebytes : integer{} = 2;
let index : integer = UInt(index_align[3:2]);
let inc : integer = if index_align[1] == '0' then 1 else 2;
let alignment : integer{} = if index_align[0] == '0' then 1 else 4;
let d : integer = UInt(D::Vd);
let d2 : integer = d + inc;
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let wback : boolean = (m != 15);
let register_index : boolean = (m != 15 && m != 13);
if n == 15 || d2 > 31 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If d2 > 31, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The memory locations specified by the instruction and the number of registers specified by the instruction become UNKNOWN. If the instruction specifies writeback, then that register becomes UNKNOWN. This behavior does not affect any other memory locations.

A3

Encoding for the Offset variant

Applies when (Rm == 1111)

```
VST2{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]
```

Encoding for the Post-indexed variant

Applies when (Rm == 1101)

```
VST2{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]!
```

Encoding for the Post-indexed variant

Applies when (Rm != 11x1)

```
VST2{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}], <Rm>
```

Decode for all variants of this encoding

```
if size == 'l1' then Undefined(); end;
if index_align[1] != '0' then Undefined(); end;
let ebytes : integer{} = 4;
let index : integer = UInt(index_align[3]);
let inc : integer = if index_align[2] == '0' then 1 else 2;
let alignment : integer{} = if index_align[0] == '0' then 1 else 8;
let d : integer = UInt(D:Vd);

if n == 15 || d2 > 31 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If d2 > 31, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The memory locations specified by the instruction and the number of registers specified by the instruction become UNKNOWN. If the instruction specifies writeback, then that register becomes UNKNOWN. This behavior does not affect any other memory locations.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly [VST2 \(single 2-element structure from one lane\)](#).

Assembler Symbols

<c>

For the “A1 Offset”, “A1 Post-indexed”, “A2 Offset”, “A2 Post-indexed”, “A3 Offset”, and “A3 Post-indexed” variants: see [Standard assembler syntax fields](#). This encoding must be unconditional.

For the “T1 Offset”, “T1 Post-indexed”, “T2 Offset”, “T2 Post-indexed”, “T3 Offset”, and “T3 Post-indexed” variants: see [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<size>

Is the data size, encoded in “size”:

size	<size>
00	8
01	16
10	32

<list>

Is a list containing the 64-bit names of the two SIMD&FP registers holding the element.

The list must be one of:

{ <Dd>[<index>], <Dd+1>[<index>] } Single-spaced registers, encoded as “spacing” = 0.
{ <Dd>[<index>], <Dd+2>[<index>] } Double-spaced registers, encoded as “spacing” = 1. Not permitted when <size> = 8.

The encoding of “spacing” depends on <size>:

<size> = 16 “spacing” is encoded in the “index_align<1>” field.
<size> = 32 “spacing” is encoded in the “index_align<2>” field.

The register <Dd> is encoded in the “D:Vd” field.

The permitted values and encoding of <index> depend on <size>:

<size> = 8 <index> is in the range 0 to 7, encoded in the “index_align<3:1>” field.
<size> = 16 <index> is in the range 0 to 3, encoded in the “index_align<3:2>” field.
<size> = 32 <index> is 0 or 1, encoded in the “index_align<3>” field.

<Rn>

Is the general-purpose base register, encoded in the “Rn” field.

<align>

Is the optional alignment.

Whenever <align> is omitted, the standard alignment is used, see [Unaligned data access](#), and the encoding depends on <size>:

<size> = 8 Encoded in the “index_align<0>” field as 0.
<size> = 16 Encoded in the “index_align<0>” field as 0.
<size> = 32 Encoded in the “index_align<1:0>” field as 0b00.

Whenever <align> is present, the permitted values and encoding depend on <size>:

$\langle \text{size} \rangle == 8$ $\langle \text{align} \rangle$ is 16, meaning 16-bit alignment, encoded in the “index_align<0>” field as 1.
 $\langle \text{size} \rangle == 16$ $\langle \text{align} \rangle$ is 32, meaning 32-bit alignment, encoded in the “index_align<0>” field as 1.
 $\langle \text{size} \rangle == 32$ $\langle \text{align} \rangle$ is 64, meaning 64-bit alignment, encoded in the “index_align<1:0>” field as 0b01.

: is the preferred separator before the $\langle \text{align} \rangle$ value, but the alignment can be specified as @ $\langle \text{align} \rangle$, see [Advanced SIMD addressing mode](#).

<Rm>

Is the general-purpose index register containing an offset applied after the access, encoded in the “Rm” field.

For more information about the variants of this instruction, see [Advanced SIMD addressing mode](#).

Operation

```

if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();

    let address : bits(32) = R(n);

    let nontemporal : boolean = FALSE;
    let privileged : boolean = PSTATE.EL != EL0;
    let accdesc : AccessDescriptor = CreateAccDescASIMD(MemOp_STORE, nontemporal, privileged);
    if !IsAlignedSize(address, alignment) then
        let fault : FaultRecord = AlignmentFault(accdesc, ZeroExtend{64}(address));
        AArch32_Abort(fault);
    end;

    MemU{8*bytes}(address) = D(d)[index*:(8*bytes)];
    MemU{8*bytes}(address+bytes) = D(d2)[index*:(8*bytes)];
    if wback then
        if register_index then
            R(n) = R(n) + R(m);
        else
            R(n) = R(n) + 2*bytes;
        end;
    end;
end;
end;

```

C6.1.215 VST2 (multiple 2-element structures)

Store multiple 2-element structures from two or four registers stores multiple 2-element structures from two or four registers to memory, with interleaving. For more information, see [Element and structure load/store instructions](#). Every element of each register is saved. For details of the addressing mode, see [Advanced SIMD addressing mode](#).

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be `UNDEFINED`, or trapped to Hyp mode. For more information, see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#) and [A2](#)) and T32 ([T1](#) and [T2](#)).

A1

Encoding for the Offset variant

Applies when (Rm == 1111)

VST2{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]

Encoding for the Post-indexed variant

Applies when (Rm == 1101)

```
VST2{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]!
```

Encoding for the Post-indexed variant

Applies when ($R_m \neq 11 \times 1$)

$$\text{VST2}\{\langle c \rangle\}\{\langle q \rangle\}.\langle \text{size} \rangle \quad \langle \text{list} \rangle, \quad [\langle \text{Rn} \rangle\{:\langle \text{align} \rangle\}], \quad \langle \text{Rm} \rangle$$

Decode for all variants of this encoding

```

if align == '11' then Undefined(); end;
if size == '11' then Undefined(); end;
let pairs : integer = 1;
let inc : integer = if itype == '1001' then 2 else 1;
let alignment : integer{} = if align == '00' then 1 else 4 << UInt(align);
let ebytes : integer{} = 1 << UInt(size);
let elements : integer = 8 DIV ebytes;
let d : integer = UInt(D:Vd);
let d2 : integer = d + inc;
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let wback : boolean = (m != 15);
let register_index : boolean = (m != 15 && m != 13);
if n == 15 || d2+pairs > 32 then UnpredictableProcedure(); end;

```

CONSTRAINED UNPREDICTABLE behavior

If $d_{2+\text{pairs}} > 32$, then one of the following behaviors must occur:

- The instruction is `UNDEFINED`.
- The instruction executes as `NOP`.
- The memory locations specified by the instruction and the number of registers specified by the instruction become `UNKNOWN`. If the instruction specifies writeback, then that register becomes `UNKNOWN`. This behavior does not affect any other memory locations.

A2

Encoding for the Offset variant

Applies when (Rm == 1111)

```
VST2{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]
```

Encoding for the Post-indexed variant

Applies when (Rm == 1101)

```
VST2{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]!
```

Encoding for the Post-indexed variant

Applies when (Rm != 11x1)

```
VST2{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}], <Rm>
```

Decode for all variants of this encoding

```
if size == 'l1' then Undefined(); end;
let pairs : integer = 2;
let inc : integer = 2;
let alignment : integer{} = if align == '00' then 1 else 4 << UInt(align);

let d2 : integer = d + inc;
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let wback : boolean = (m != 15);
let register_index : boolean = (m != 15 && m != 13);
if n == 15 || d2+pairs > 32 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If d2+pairs > 32, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The memory locations specified by the instruction and the number of registers specified by the instruction become UNKNOWN. If the instruction specifies writeback, then that register becomes UNKNOWN. This behavior does not affect any other memory locations.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly [VST2 \(multiple 2-element structures\)](#).

Related encodings: See [Advanced SIMD element or structure load/store](#) for the T32 instruction set, or [Advanced SIMD element or structure load/store](#) for the A32 instruction set.

Assembler Symbols

<c>

For the “A1 Offset”, “A1 Post-indexed”, “A2 Offset”, and “A2 Post-indexed” variants: see [Standard assembler syntax fields](#). This encoding must be unconditional.

For the “T1 Offset”, “T1 Post-indexed”, “T2 Offset”, and “T2 Post-indexed” variants: see [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<size>

Is the data size, encoded in “size”:

size	<size>
00	8
01	16
10	32

<list>

Is a list containing the 64-bit names of the SIMD&FP registers.

The list must be one of:

- { <Dd>, <Dd+1> } Two single-spaced registers. Selects the A1 and T1 encodings of the instruction, and encoded in the “itype” field as 0b1000.
- { <Dd>, <Dd+2> } Two double-spaced registers. Selects the A1 and T1 encodings of the instruction, and encoded in the “itype” field as 0b1001.
- { <Dd>, <Dd+1>, <Dd+2>, <Dd+3> } Three single-spaced registers. Selects the A2 and T2 encodings of the instruction.

The register <Dd> is encoded in the “D:Vd” field.

<Rn>

Is the general-purpose base register, encoded in the “Rn” field.

<align>

Is the optional alignment.

Whenever <align> is omitted, the standard alignment is used, see [Unaligned data access](#), and is encoded in the “align” field as 0b00.

Whenever <align> is present, the permitted values are:

- 64** 64-bit alignment, encoded in the “align” field as 0b01.
- 128** 128-bit alignment, encoded in the “align” field as 0b10.
- 256** 256-bit alignment, encoded in the “align” field as 0b11. Available only if <list> contains four registers.

: is the preferred separator before the <align> value, but the alignment can be specified as @<align>, see [Advanced SIMD addressing mode](#).

<Rm>

Is the general-purpose index register containing an offset applied after the access, encoded in the “Rm” field.

For more information about the variants of this instruction, see [Advanced SIMD addressing mode](#).

Operation

```

if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();

    var address : bits(32) = R(n);

    let nontemporal : boolean = FALSE;
    let privileged : boolean = PSTATE.EL != EL0;
    let accdesc : AccessDescriptor = CreateAccDescASIMD(MemOp_STORE, nontemporal, privileged);
    if !IsAlignedSize(address, alignment) then
        let fault : FaultRecord = AlignmentFault(accdesc, ZeroExtend{64}(address));
        AArch32_Abort(fault);
    end;

    for r = 0 to pairs-1 do
        for e = 0 to elements-1 do
            MemU{8*bytes}(address      ) = D(d+r)[e:(8*bytes)];
            MemU{8*bytes}(address+ebytes) = D(d2+r)[e:(8*bytes)];
            address = address + 2*bytes;
        end;
    end;

    if wback then
        if register_index then
            R(n) = R(n) + R(m);
        else
            R(n) = R(n) + 16*pairs;
        end;
    end;
end;

```

C6.1.216 VST3 (single 3-element structure from one lane)

Store single 3-element structure from one lane of three registers stores one 3-element structure to memory from corresponding elements of three registers. For details of the addressing mode, see [Advanced SIMD addressing mode](#).

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be `UNDEFINED`, or trapped to Hyp mode. For more information, see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 (A1, A2, and A3) and T32 (T1, T2, and T3).

A1

Encoding for the Offset variant

Applies when (Rm == 1111)

VST3{<c>}{<q>}.<size> <list>, [<Rn>]

Encoding for the Post-indexed variant

if n == 15 || d3 > 31 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If d3 > 31, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The memory locations specified by the instruction and the number of registers specified by the instruction become UNKNOWN. If the instruction specifies writeback, then that register becomes UNKNOWN. This behavior does not affect any other memory locations.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly [VST3 \(single 3-element structure from one lane\)](#).

Assembler Symbols

<c>

For the “A1 Offset”, “A1 Post-indexed”, “A2 Offset”, “A2 Post-indexed”, “A3 Offset”, and “A3 Post-indexed” variants: see [Standard assembler syntax fields](#). This encoding must be unconditional.

For the “T1 Offset”, “T1 Post-indexed”, “T2 Offset”, “T2 Post-indexed”, “T3 Offset”, and “T3 Post-indexed” variants: see [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<size>

Is the data size, encoded in “size”:

size	<size>
00	8
01	16
10	32

<list>

Is a list containing the 64-bit names of the three SIMD&FP registers holding the element.

The list must be one of:

{ <Dd>[<index>], <Dd+1>[<index>], <Dd+2>[<index>] } Single-spaced registers, encoded as “spacing” = 0.

{ <Dd>[<index>], <Dd+2>[<index>], <Dd+4>[<index>] } Double-spaced registers, encoded as “spacing” = 1. Not permitted when <size> == 8.

The encoding of “spacing” depends on <size>:

<size> == 8 “spacing” is encoded in the “index_align<0>” field.

<size> == 16 “spacing” is encoded in the “index_align<1>” field, and “index_align<0>” is set to 0.

<size> == 32 “spacing” is encoded in the “index_align<2>” field, and “index_align<1:0>” is set to 0b00.

The register <Dd> is encoded in the “D:Vd” field.

The permitted values and encoding of <index> depend on <size>:

<size> == 8 <index> is in the range 0 to 7, encoded in the “index_align<3:1>” field.

<size> == 16 <index> is in the range 0 to 3, encoded in the “index_align<3:2>” field.

<size> == 32 <index> is 0 or 1, encoded in the “index_align<3>” field.

<Rn>

Is the general-purpose base register, encoded in the “Rn” field.

<Rm>

Is the general-purpose index register containing an offset applied after the access, encoded in the “Rm” field.

For more information about the variants of this instruction, see [Advanced SIMD addressing mode](#).

Alignment

Standard alignment rules apply, see Alignment support.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();
    let address : bits(32) = R(n);
    MemU{8*bytes}(address) = D(d)[index*:(8*bytes)];
    MemU{8*bytes}(address+ebytes) = D(d2)[index*:(8*bytes)];
    MemU{8*bytes}(address+2*ebytes) = D(d3)[index*:(8*bytes)];
    if wback then
        if register_index then
            R(n) = R(n) + R(m);
        else
            R(n) = R(n) + 3*ebytes;
        end;
    end;
end;
```

C6.1.217 VST3 (multiple 3-element structures)

Store multiple 3-element structures from three registers stores multiple 3-element structures to memory from three registers, with interleaving. For more information, see [Element and structure load/store instructions](#). Every element of each register is saved. For details of the addressing mode, see [Advanced SIMD addressing mode](#).

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be `UNDEFINED`, or trapped to Hyp mode. For more information, see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding for the Offset variant

Applies when (Rm == 1111)

VST3{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]

Encoding for the Post-indexed variant

Applies when (Rm == 1101)

```
VST3{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]!
```

Encoding for the Post-indexed variant

Applies when ($R_m \neq 11 \times 1$)

$$\text{VST3}\{\langle c \rangle\}\{\langle q \rangle\}.\langle \text{size} \rangle \quad \langle \text{list} \rangle, \quad [\langle \text{Rn} \rangle\{:\langle \text{align} \rangle\}], \quad \langle \text{Rm} \rangle$$

Decode for all variants of this encoding

```

if size == '11' || align[1] == '1' then Undefined(); end;
var inc : integer;
case itype of
  when '0100' =>
    inc = 1;
  when '0101' =>
    inc = 2;
  otherwise =>
    See("Related encodings");
end;

let alignment : integer{} = if align[0] == '0' then 1 else 8;
let ebytes : integer{} = 1 << UInt(size);
let elements : integer = 8 DIV ebytes;
let d : integer = UInt(D::Vd);
let d2 : integer = d + inc;
let d3 : integer = d2 + inc;
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let wback : boolean = (m != 15);
let register_index : boolean = (m != 15 && m != 13);
if n == 15 || d3 > 31 then UnpredictableProcedure(); end;

```

CONSTRAINED UNPREDICTABLE behavior

If $d3 > 31$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The memory locations specified by the instruction and the number of registers specified by the instruction become UNKNOWN. If the instruction specifies writeback, then that register becomes UNKNOWN. This behavior does not affect any other memory locations.

T1

Encoding for the Offset variant

Applies when $(Rm == 1111)$

VST3{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]

Encoding for the Post-indexed variant

Applies when $(Rm == 1101)$

VST3{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]!

Encoding for the Post-indexed variant

Applies when $(Rm != 11x1)$

VST3{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}], <Rm>

Decode for all variants of this encoding

```

if size == '11' || align[1] == '1' then Undefined(); end;
var inc : integer;
case itype of
  when '0100' =>
    inc = 1;
  when '0101' =>
    inc = 2;
  otherwise =>
    See("Related encodings");
end;
let alignment : integer{} = if align[0] == '0' then 1 else 8;
let ebytes : integer{} = 1 << UInt(size);
let elements : integer = 8 DIV ebytes;
let d : integer = UInt(D::Vd);
let d2 : integer = d + inc;
let d3 : integer = d2 + inc;
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let wback : boolean = (m != 15);
let register_index : boolean = (m != 15 && m != 13);
if n == 15 || d3 > 31 then UnpredictableProcedure(); end;

```

CONSTRAINED UNPREDICTABLE behavior

If $d3 > 31$, then one of the following behaviors must occur:

- The instruction is **UNDEFINED**.
- The instruction executes as **NOP**.
- The memory locations specified by the instruction and the number of registers specified by the instruction become **UNKNOWN**. If the instruction specifies writeback, then that register becomes **UNKNOWN**. This behavior does not affect any other memory locations.

For more information about the **CONSTRAINED UNPREDICTABLE** behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly [VST3 \(multiple 3-element structures\)](#).

Related encodings: See [Advanced SIMD element or structure load/store](#) for the T32 instruction set, or [Advanced SIMD element or structure load/store](#) for the A32 instruction set.

Assembler Symbols

<c>

For the “A1 Offset” and “A1 Post-indexed” variants: see [Standard assembler syntax fields](#). This encoding must be unconditional.

For the “T1 Offset” and “T1 Post-indexed” variants: see [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<size>

Is the data size, encoded in “size”:

size	<size>
00	8
01	16
10	32

<list>

Is a list containing the 64-bit names of the SIMD&FP registers.

The list must be one of:

- { <Dd>, <Dd+1>, <Dd+2> } Single-spaced registers, encoded in the “itype” field as 0b0100.
- { <Dd>, <Dd+2>, <Dd+4> } Double-spaced registers, encoded in the “itype” field as 0b0101.

The register <Dd> is encoded in the “D:Vd” field.

<Rn>

Is the general-purpose base register, encoded in the “Rn” field.

<align>

Is the optional alignment.

Whenever <align> is omitted, the standard alignment is used, see [Unaligned data access](#), and is encoded in the “align” field as 0b00.

Whenever <align> is present, the only permitted values is 64, meaning 64-bit alignment, encoded in the “align” field as 0b01.

: is the preferred separator before the <align> value, but the alignment can be specified as @<align>, see [Advanced SIMD addressing mode](#).

<Rm>

Is the general-purpose index register containing an offset applied after the access, encoded in the “Rm” field.

For more information about the variants of this instruction, see [Advanced SIMD addressing mode](#).

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();

    var address : bits(32) = R(n);

    let nontemporal : boolean = FALSE;
    let privileged : boolean = PSTATE.EL != EL0;
    let accdesc : AccessDescriptor = CreateAccDescASIMD(MemOp_STORE, nontemporal, privileged);
    if !IsAlignedSize(address, alignment) then
        let fault : FaultRecord = AlignmentFault(accdesc, ZeroExtend{64}(address));
        AArch32_Abort(fault);
    end;

    for e = 0 to elements-1 do
        MemU{8*bytes}(address) = D(d)[e:(8*bytes)];
        MemU{8*bytes}(address+ebytes) = D(d2)[e:(8*bytes)];
        MemU{8*bytes}(address+2*ebytes) = D(d3)[e:(8*bytes)];
        address = address + 3*ebytes;
    end;

    if wback then
        if register_index then
            R(n) = R(n) + R(m);
        else
            R(n) = R(n) + 24;
        end;
    end;
end;
```

C6.1.218 VST4 (single 4-element structure from one lane)

Store single 4-element structure from one lane of four registers stores one 4-element structure to memory from corresponding elements of four registers. For details of the addressing mode, see [Advanced SIMD addressing mode](#).

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information, see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#), [A2](#), and [A3](#)) and T32 ([T1](#), [T2](#), and [T3](#)).

Encoding for the Offset variant

Applies when (Rm == 1111)

VST4{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]

Encoding for the Post-indexed variant

Applies when (Rm == 1101)

```
VST4{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]!
```

Encoding for the Post-indexed variant

Applies when (Rm != 11x1)

$$\text{VST4}\{\langle c \rangle\}\{\langle g \rangle\}.\langle \text{size} \rangle \quad \langle \text{list} \rangle, \quad [\langle \text{Rn} \rangle\{:\langle \text{align} \rangle\}], \quad \langle \text{Rm} \rangle$$

Decode for all variants of this encoding

```

if size == '11' then Undefined(); end;
if size != '10' then See("Related encodings"); end;
if index_align[1:0] == '11' then Undefined(); end;
let ebytes : integer{} = 4;
let index : integer = UInt(index_align[3]);
let inc : integer = if index_align[2] == '0' then 1 else 2;
let alignment : integer{} = if index_align[1:0] == '00' then 1 else 4 << UInt(index_align[1:0]);
let d : integer = UInt(D::Vd);
let d2 : integer = d + inc;
let d3 : integer = d2 + inc;
let d4 : integer = d3 + inc;
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let wback : boolean = (m != 15);
let register_index : boolean = (m != 15 && m != 13);
if n == 15 || d4 > 31 then UnpredictableProcedure(); end;

```

CONSTRAINED UNPREDICTABLE behavior

If $d_4 > 31$, then one of the following behaviors must occur:

- The instruction is `UNDEFINED`.
- The instruction executes as `NOP`.
- The memory locations specified by the instruction and the number of registers specified by the instruction become `UNKNOWN`. If the instruction specifies writeback, then that register becomes `UNKNOWN`. This behavior does not affect any other memory locations.

For more information about the **CONSTRAINED UNPREDICTABLE** behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly [VST4 \(single 4-element structure from one lane\)](#).

Assembler Symbols

<c>

For the “A1 Offset”, “A1 Post-indexed”, “A2 Offset”, “A2 Post-indexed”, “A3 Offset”, and “A3 Post-indexed” variants: see [Standard assembler syntax fields](#). This encoding must be unconditional.

For the “T1 Offset”, “T1 Post-indexed”, “T2 Offset”, “T2 Post-indexed”, “T3 Offset”, and “T3 Post-indexed” variants: see [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<size>

Is the data size, encoded in “size”:

size	<size>
00	8
01	16
10	32

<list>

Is a list containing the 64-bit names of the four SIMD&FP registers holding the element.

The list must be one of:

{ <Dd>[<index>], <Dd+1>[<index>], <Dd+2>[<index>], <Dd+3>[<index>] } Single-spaced registers, encoded as “spacing” = 0.

{ <Dd>[<index>], <Dd+2>[<index>], <Dd+4>[<index>], <Dd+6>[<index>] } Double-spaced registers, encoded as “spacing” = 1. Not permitted when <size> == 8.

The encoding of “spacing” depends on <size>:

<size> == 16 “spacing” is encoded in the “index_align<1>” field.

<size> == 32 “spacing” is encoded in the “index_align<2>” field.

The register <Dd> is encoded in the “D:Vd” field.

The permitted values and encoding of <index> depend on <size>:

<size> == 8 <index> is in the range 0 to 7, encoded in the “index_align<3:1>” field.

<size> == 16 <index> is in the range 0 to 3, encoded in the “index_align<3:2>” field.

<size> == 32 <index> is 0 or 1, encoded in the “index_align<3>” field.

<Rn>

Is the general-purpose base register, encoded in the “Rn” field.

<align>

Is the optional alignment.

Whenever <align> is omitted, the standard alignment is used, see [Unaligned data access](#), and the encoding depends on <size>:

<size> == 8 Encoded in the “index_align<0>” field as 0.

<size> == 16 Encoded in the “index_align<0>” field as 0.

<size> == 32 Encoded in the “index_align<1:0>” field as 0b00.

Whenever <align> is present, the permitted values and encoding depend on <size>:

<size> == **8** <align> is 32, meaning 32-bit alignment, encoded in the “index_align<0>” field as 1.
<size> == **16** <align> is 64, meaning 64-bit alignment, encoded in the “index_align<0>” field as 1.
<size> == **32** <align> can be 64 or 128. 64-bit alignment is encoded in the “index_align<1:0>” field as 0b01,
and 128-bit alignment is encoded in the “index_align<1:0>” field as 0b10.

: is the preferred separator before the <align> value, but the alignment can be specified as @<align>, see [Advanced SIMD addressing mode](#).

<Rm>

Is the general-purpose index register containing an offset applied after the access, encoded in the “Rm” field.

For more information about the variants of this instruction, see [Advanced SIMD addressing mode](#).

Operation

```

if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();

    let address : bits(32) = R(n);

    let nontemporal : boolean = FALSE;
    let privileged : boolean = PSTATE.EL != EL0;
    let accdesc : AccessDescriptor = CreateAccDescASIMD(MemOp_STORE, nontemporal, privileged);
    if !IsAlignedSize(address, alignment) then
        let fault : FaultRecord = AlignmentFault(accdesc, ZeroExtend{64}(address));
        AArch32_Abort(fault);
    end;

    MemU{8*bytes}(address) = D(d)[index*:(8*bytes)];
    MemU{8*bytes}(address+bytes) = D(d2)[index*:(8*bytes)];
    MemU{8*bytes}(address+2*bytes) = D(d3)[index*:(8*bytes)];
    MemU{8*bytes}(address+3*bytes) = D(d4)[index*:(8*bytes)];
    if wback then
        if register_index then
            R(n) = R(n) + R(m);
        else
            R(n) = R(n) + 4*bytes;
        end;
    end;
end;
end;

```

C6.1.219 VST4 (multiple 4-element structures)

Store multiple 4-element structures from four registers stores multiple 4-element structures to memory from four registers, with interleaving. For more information, see [Element and structure load/store instructions](#). Every element of each register is saved. For details of the addressing mode, see [Advanced SIMD addressing mode](#).

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be `UNDEFINED`, or trapped to Hyp mode. For more information, see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding for the Offset variant

Applies when (Rm == 1111)

VST4{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]

Encoding for the Post-indexed variant

Applies when (Rm == 1101)

```
VST4{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]!
```

Encoding for the Post-indexed variant

Applies when ($R_m \neq 11 \times 1$)

VST4{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}], <Rm>

Decode for all variants of this encoding

```

if size == '11' then Undefined(); end;
if itype != '000x' then See("Related encodings"); end;
let inc : integer = if itype[0] == '0' then 1 else 2;
let alignment : integer{} = if align == '00' then 1 else 4 << UInt(align);
let ebytes : integer{} = 1 << UInt(size);
let elements : integer = 8 DIV ebytes;
let d : integer = UInt(D:Vd);
let d2 : integer = d + inc;
let d3 : integer = d2 + inc;
let d4 : integer = d3 + inc;
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let wback : boolean = (m != 15);
let register_index : boolean = (m != 15 && m != 13);
if n == 15 || d4 > 31 then UnpredictableProcedure(); end;

```

CONSTRAINED UNPREDICTABLE behavior

If $d4 > 31$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The memory locations specified by the instruction and the number of registers specified by the instruction become UNKNOWN. If the instruction specifies writeback, then that register becomes UNKNOWN. This behavior does not affect any other memory locations.

T1

Encoding for the Offset variant

Applies when $(Rm == 1111)$

```
VST4{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]
```

Encoding for the Post-indexed variant

Applies when $(Rm == 1101)$

```
VST4{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]!
```

Encoding for the Post-indexed variant

Applies when $(Rm != 11x1)$

```
VST4{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}], <Rm>
```

Decode for all variants of this encoding

```
if size == '11' then Undefined(); end;
if itype != '000x' then See("Related encodings"); end;
let inc : integer = if itype[0] == '0' then 1 else 2;
let alignment : integer{} = if align == '00' then 1 else 4 << UInt(align);
let ebytes : integer{} = 1 << UInt(size);
let elements : integer = 8 DIV ebytes;
let d : integer = UInt(D::Vd);
let d2 : integer = d + inc;
let d3 : integer = d2 + inc;
let d4 : integer = d3 + inc;
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let wback : boolean = (m != 15);
let register_index : boolean = (m != 15 && m != 13);
if n == 15 || d4 > 31 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `d4 > 31`, then one of the following behaviors must occur:

- The instruction is `UNDEFINED`.
- The instruction executes as `NOP`.
- The memory locations specified by the instruction and the number of registers specified by the instruction become `UNKNOWN`. If the instruction specifies writeback, then that register becomes `UNKNOWN`. This behavior does not affect any other memory locations.

For more information about the `CONSTRAINED UNPREDICTABLE` behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly [VST4 \(multiple 4-element structures\)](#).

Related encodings: See [Advanced SIMD element or structure load/store](#) for the T32 instruction set, or [Advanced SIMD element or structure load/store](#) for the A32 instruction set.

Assembler Symbols

`<c>`

For the “A1 Offset” and “A1 Post-indexed” variants: see [Standard assembler syntax fields](#). This encoding must be unconditional.

For the “T1 Offset” and “T1 Post-indexed” variants: see [Standard assembler syntax fields](#).

`<q>`

See [Standard assembler syntax fields](#).

`<size>`

Is the data size, encoded in “size”:

size	<size>
00	8
01	16
10	32

`<list>`

Is a list containing the 64-bit names of the SIMD&FP registers.

The list must be one of:

- { `<Dd>`, `<Dd+1>`, `<Dd+2>`, `<Dd+3>` } Single-spaced registers, encoded in the “itype” field as `0b0000`.
- { `<Dd>`, `<Dd+2>`, `<Dd+4>`, `<Dd+6>` } Double-spaced registers, encoded in the “itype” field as `0b0001`.

The register `<Dd>` is encoded in the “D:Vd” field.

`<Rn>`

Is the general-purpose base register, encoded in the “Rn” field.

`<align>`

Is the optional alignment.

Whenever `<align>` is omitted, the standard alignment is used, see [Unaligned data access](#), and is encoded in the “align” field as `0b00`.

Whenever `<align>` is present, the permitted values are:

- 64** 64-bit alignment, encoded in the “align” field as 0b01.
- 128** 128-bit alignment, encoded in the “align” field as 0b10.
- 256** 256-bit alignment, encoded in the “align” field as 0b11.

: is the preferred separator before the <align> value, but the alignment can be specified as @<align>, see [Advanced SIMD addressing mode](#).

<Rm>

Is the general-purpose index register containing an offset applied after the access, encoded in the “Rm” field.

For more information about the variants of this instruction, see [Advanced SIMD addressing mode](#).

Operation

```

if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();

    var address : bits(32) = R(n);

    let nontemporal : boolean = FALSE;
    let privileged : boolean = PSTATE.EL != EL0;
    let accdesc : AccessDescriptor = CreateAccDescASIMD(MemOp_STORE, nontemporal, privileged);
    if !IsAlignedSize(address, alignment) then
        let fault : FaultRecord = AlignmentFault(accdesc, ZeroExtend{64}(address));
        AArch32_Abort(fault);
    end;

    for e = 0 to elements-1 do
        MemU{8*abytes}(address) = D(d)[e:(8*abytes)];
        MemU{8*abytes}(address+abytes) = D(d2)[e:(8*abytes)];
        MemU{8*abytes}(address+2*abytes) = D(d3)[e:(8*abytes)];
        MemU{8*abytes}(address+3*abytes) = D(d4)[e:(8*abytes)];
        address = address + 4*abytes;
    end;

    if wback then
        if register_index then
            R(n) = R(n) + R(m);
        else
            R(n) = R(n) + 32;
        end;
    end;
end;

```

C6.1.220 VSTM, VSTMDB, VSTMIA

Store multiple SIMD&FP registers stores multiple registers from the Advanced SIMD and floating-point register file to consecutive memory locations using an address from a general-purpose register.

Depending on settings in the CPACR, NSACR, HCPTR, and FPExc registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information, see [Enabling Advanced SIMD and floating-point support](#).

This instruction is used by the alias VPUSH.

It has encodings from the following instruction sets: A32 (A1 and A2) and T32 (T1 and T2).

A1

Encoding for the Decrement Before variant

Applies when (P == 1 && U == 0 && W == 1)

VSTMDB{<c>}{<q>}{.<size>} <Rn>!, <dreglist>

Encoding for the Increment After variant

Applies when (P == 0 && U == 1)

VSTM{<c>}{<q>}{.<size>} <Rn>{!}, <dreglist> // (Preferred syntax)

VSTMIA{<c>}{<q>}{.<size>} <Rn>{!}, <dreglist>

Decode for all variants of this encoding

```

if P == '0' && U == '0' && W == '0' then See("Related encodings"); end;
if P == '1' && W == '0' then See("VSTR"); end;
if P == U && W == '1' then Undefined(); end;
// Remaining combinations are PUW = 010 (IA without !), 011 (IA with !), 101 (DB with !)
let single_regs : boolean = FALSE;
let add : boolean = (U == '1');
let wback : boolean = (W == '1');
let d : integer = UInt(D::Vd);
let n : integer = UInt(Rn);
let imm32 : bits(32) = ZeroExtend{(imm8::'00')};
let regs : integer = UInt(imm8) DIVRM 2; // If UInt(imm8) is odd, see "FSTDBMX, FSTMIAX".
if n == 15 && (wback || CurrentInstrSet() != InstrSet_A32) then UnpredictableProcedure(); end;
if regs == 0 || regs > 16 || (d+regs) > 32 then UnpredictableProcedure(); end;
if imm8[0] == '1' && (d+regs) > 16 then UnpredictableProcedure(); end;

```

CONSTRAINED UNPREDICTABLE behavior

If regs == 0, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction operates as a VSTM with the same addressing mode but stores no registers.

If regs > 16 || (d+regs) > 32, then one of the following behaviors must occur:

- The instruction is `UNDEFINED`.
- The instruction executes as `NOP`.
- The memory locations specified by the instruction and the number of registers specified by the instruction become `UNKNOWN`. If the instruction specifies writeback, then that register becomes `UNKNOWN`. This behavior does not affect any other memory locations.

A2

Encoding for the Decrement Before variant

Applies when (P == 1 && U == 0 && W == 1)

```
VSTMDB{<c>}{<q>}{.<size>} <Rn>!, <sreglist>
```

Encoding for the Increment After variant

Applies when (P == 0 && U == 1)

```
VSTM{<c>}{<q>}{.<size>} <Rn>{!}, <sreglist> // (Preferred syntax)
```

VSTMIA{<c>}{<q>}{.<size>} <Rn>{!}, <sreglist>

Decode for all variants of this encoding

```

if P == '0' && U == '0' && W == '0' then See("Related encodings"); end;
if P == '1' && W == '0' then See("VSTR"); end;
if P == U && W == '1' then Undefined(); end;
// Remaining combinations are PUW = 010 (IA without !), 011 (IA with !), 101 (DB with !)
let single_regs : boolean = TRUE;
let add : boolean = (U == '1');
let wback : boolean = (W == '1');
let d : integer = UInt(Vd::D);
let n : integer = UInt(Rn);
let imm32 : bits(32) = ZeroExtend{}(imm8::'00');
let regs : integer = UInt(imm8);
if n == 15 && (wback || CurrentInstrSet() != InstrSet_A32) then UnpredictableProcedure(); end;
if regs == 0 || (d+regs) > 32 then UnpredictableProcedure(); end;

```

CONSTRAINED UNPREDICTABLE behavior

If $\text{reqs} == 0$, then one of the following behaviors must occur:

- The instruction is **UNDEFINED**.
- The instruction executes as **NOP**.
- The instruction operates as a **VSTM** with the same addressing mode but stores no registers.

If $(d + \text{reqs}) > 32$, then one of the following behaviors must occur:

- The instruction is `UNDEFINED`.
- The instruction executes as `NOP`.
- The memory locations specified by the instruction and the number of registers specified by the instruction become `UNKNOWN`. If the instruction specifies writeback, then that register becomes `UNKNOWN`. This behavior does not affect any other memory locations.

T1

Encoding for the Decrement Before variant

Applies when (P == 1 && U == 0 && W == 1)

VSTMDB{<c>}{<q>}{.<size>} <Rn>!, <dreglist>

Encoding for the Increment After variant

Applies when (P == 0 && U == 1)

```
VSTM{<c>}{<q>}{.<size>} <Rn>{!}, <dreglist> // (Preferred syntax)
```

VSTMIA{<c>}{<q>}{,<size>} <Rn>{!}, <dreglist>

Decode for all variants of this encoding

```

if P == '0' && U == '0' && W == '0' then See("Related encodings"); end;
if P == '1' && W == '0' then See("VSTR"); end;
if P == U && W == '1' then Undefined(); end;

// Remaining combinations are PUW = 010 (IA without !), 011 (IA with !), 101 (DB with !)
let single_regs : boolean = FALSE;
let add : boolean = (U == '1');
let wback : boolean = (W == '1');
let d : integer = UInt(D::Vd);
let n : integer = UInt(Rn);
let imm32 : bits(32) = ZeroExtend{}(imm8::'00');
let regs : integer = UInt(imm8) DIVRM 2; // If UInt(imm8) is odd, see "FSTDBMX, FSTMIAX".
if n == 15 && (wback || CurrentInstrSet() != InstrSet_A32) then UnpredictableProcedure(); end;
if regs == 0 || regs > 16 || (d+regs) > 32 then UnpredictableProcedure(); end;
if imm8[0] == '1' && (d+regs) > 16 then UnpredictableProcedure(); end;

```

CONSTRAINED UNPREDICTABLE behavior

If `regs == 0`, then one of the following behaviors must occur:

- The instruction is `UNDEFINED`.
- The instruction executes as `NOP`.
- The instruction operates as a `VSTM` with the same addressing mode but stores no registers.

If $\text{regs} > 16 \ || \ (\text{d+regs}) > 32$, then one of the following behaviors must occur:

- The instruction is `UNDEFINED`.
- The instruction executes as `NOP`.
- The memory locations specified by the instruction and the number of registers specified by the instruction become `UNKNOWN`. If the instruction specifies writeback, then that register becomes `UNKNOWN`. This behavior does not affect any other memory locations.

T2

Encoding for the Decrement Before variant

Applies when (P == 1 && U == 0 && W == 1)

VSTMDB{<c>}{<q>}{.<size>} <Rn>!, <sreglist>

Encoding for the Increment After variant

Applies when (P == 0 && U == 1)

VSTM{<c>}{<q>}{.<size>} <Rn>{!}, <sreglist> // (Preferred syntax)

VSTMIA{<c>}{<q>}{.<size>} <Rn>{!}, <sreglist>

Decode for all variants of this encoding

```

if P == '0' && U == '0' && W == '0' then See("Related encodings"); end;
if P == '1' && W == '0' then See("VSTR"); end;
if P == U && W == '1' then Undefined(); end;
// Remaining combinations are PUW = 010 (IA without !), 011 (IA with !), 101 (DB with !)
let single_regs : boolean = TRUE;
let add : boolean = (U == '1');
let wback : boolean = (W == '1');
let d : integer = UInt(Vd::D);
let n : integer = UInt(Rn);
let imm32 : bits(32) = ZeroExtend{}(imm8::'00');
let regs : integer = UInt(imm8);
if n == 15 && (wback || CurrentInstrSet() != InstrSet_A32) then UnpredictableProcedure(); end;
if regs == 0 || (d+regs) > 32 then UnpredictableProcedure(); end;

```

CONSTRAINED UNPREDICTABLE behavior

If `regs == 0`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction operates as a VSTM with the same addressing mode but stores no registers.

If $(d + \text{regs}) > 32$, then one of the following behaviors must occur:

- The instruction is `UNDEFINED`.
- The instruction executes as `NOP`.
- The memory locations specified by the instruction and the number of registers specified by the instruction become `UNKNOWN`. If the instruction specifies writeback, then that register becomes `UNKNOWN`. This behavior does not affect any other memory locations.

For more information about the **CONSTRAINED UNPREDICTABLE** behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly [VSTM](#).

Related encodings: See [Advanced SIMD and floating-point 64-bit move](#) for the T32 instruction set, or [Advanced SIMD and floating-point 64-bit move](#) for the A32 instruction set.

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<size>

An optional data size specifier. If present, it must be equal to the size in bits, 32 or 64, of the registers being transferred.

<Rn>

Is the general-purpose base register, encoded in the “Rn” field. If writeback is not specified, the PC can be used. However, Arm deprecates use of the PC.

<dreglist>

Is the list of consecutively numbered 64-bit SIMD&FP registers to be transferred. The first register in the list is encoded in “D:Vd”, and “imm8” is set to twice the number of registers in the list. The list must contain at least one register, and must not contain more than 16 registers.

!

Specifies base register writeback, encoded in “W”:

W	!
0	[absent]
1	[present]

<sreglist>

Is the list of consecutively numbered 32-bit SIMD&FP registers to be transferred. The first register in the list is encoded in “Vd:D”, and “imm8” is set to the number of registers in the list. The list must contain at least one register.

Alias Conditions

Alias	Is preferred when
VPUSH	P == '1' && U == '0' && W == '1' && Rn == '1101'

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckVFPEEnabled(TRUE);
    var address : bits(32) = if add then R(n) else R(n)-imm32;
    for r = 0 to regs-1 do
        if single_regs then
            MemA{32}(address) = S(d+r);
            address = address+4;
        else
```

```
        // Store as two word-aligned words in the correct order for current endianness.
        if BigEndian(AccessType_ASIMD) then
            MemA{32}(address) = D(d+r)[63:32];
            MemA{32}(address+4) = D(d+r)[31:0];
        else
            MemA{32}(address) = D(d+r)[31:0];
            MemA{32}(address+4) = D(d+r)[63:32];
        end;

        address = address+8;
    end;
end;

if wback then R(n) = if add then R(n)+imm32 else R(n)-imm32; end;
end;
```

C6.1.221 VSTR

Store SIMD&FP register stores a single register from the Advanced SIMD and floating-point register file to memory, using an address from a general-purpose register, with an optional offset.

Depending on settings in the [CPACR](#), [NSACR](#), [HCPTR](#), and [FPEXC](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information, see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding for the Single-precision scalar variant

Applies when (size == 10)

```
VSTR{<c>}{<q>}{.32} <Sd>, [<Rn>{, #<+/-><imm>}]
```

Encoding for the Double-precision scalar variant

Applies when (size == 11)

```
VSTR{<c>}{<q>}{.64} <Dd>, [<Rn>{, #<+/-><imm>}]
```

Decode for all variants of this encoding

```
if size IN { '00', '01' } then Undefined(); end;
let add : boolean = (U == '1');
let esize : integer = 8 << UInt(size);
let imm32 : integer = UInt(imm8) << (if size == '01' then 1 else 2);
let d : integer = if size == '11' then UInt(D::Vd) else UInt(Vd::D);
let n : integer = UInt(Rn);
if n == 15 && CurrentInstrSet() != InstrSet_A32 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If size == '01' && cond != '1110', then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

T1

Encoding for the Single-precision scalar variant

Applies when (size == 10)

VSTR{<c>}{<q>}{.32} <Sd>, [<Rn>{, #<+/-><imm>}]

Encoding for the Double-precision scalar variant

Applies when (size == 11)

VSTR{<c>}{<q>}{.64} <Dd>, [<Rn>{, #<+/-><imm>}]

Decode for all variants of this encoding

```
if size IN { '00', '01' } then Undefined(); end;
let add : boolean = (U == '1');
let esize : integer{} = 8 << UInt(size);
let imm32 : integer = UInt(imm8) << (if size == '01' then 1 else 2);
let d : integer = if size == '11' then UInt(D::Vd) else UInt(Vd::D);
let n : integer = UInt(Rn);
if n == 15 && CurrentInstrSet() != InstrSet_A32 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If size == '01' && InITBlock(), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

.32

Is an optional data size specifier for 32-bit memory accesses that can be used in the assembler source code, but is otherwise ignored.

<Sd>

Is the 32-bit name of the SIMD&FP source register, encoded in the “Vd:D” field.

<Rn>

Is the general-purpose base register, encoded in the “Rn” field. The PC can be used, but this is deprecated.

+/-

Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in “U”:

U	+/-
0	-
1	+

<imm>

is the optional unsigned immediate byte offset, a multiple of 4, in the range 0 to 1020, defaulting to 0, and encoded in the “imm8” field as <imm>/4.

.64

Is an optional data size specifier for 64-bit memory accesses that can be used in the assembler source code, but is otherwise ignored.

<Dd>

Is the 64-bit name of the SIMD&FP source register, encoded in the “D:Vd” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckVFPEEnabled(TRUE);
    let address : bits(32) = if add then (R(n) + imm32) else (R(n) - imm32);
    case esize of
        when 32 =>
            MemA{32}(address) = S(d);
        when 64 =>
            // Store as two word-aligned words in the correct order for current endianness.
            if BigEndian(AccessType_ASIMD) then
                MemA{32}(address) = D(d)[63:32];
                MemA{32}(address+4) = D(d)[31:0];
            else
                MemA{32}(address) = D(d)[31:0];
                MemA{32}(address+4) = D(d)[63:32];
            end;
    end;
end;
```

C6.1.222 VSUB (floating-point)

Vector Subtract (floating-point) subtracts the elements of one vector from the corresponding elements of another vector, and places the results in the destination vector.

Depending on settings in the [CPACR](#), [NSACR](#), [HCPTR](#), and [FPEXC](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#) and [A2](#)) and T32 ([T1](#) and [T2](#)).

A1

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0)

VSUB{<c>}{<q>}.<dt> {<Dd>, }<Dn>, <Dm>

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

VSUB{<c>}{<q>}.<dt> {<Qd>, }<Qn>, <Qm>

Decode for all variants of this encoding

```

if Q == '1' && (Vd[0] == '1' || Vn[0] == '1' || Vm[0] == '1') then Undefined(); end;
if sz == '1' then Undefined(); end;
let advsimd : boolean = TRUE;
let esize : integer{} = 32 >> UInt(sz);
let elements : integer = 64 DIV esize;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);
let regs : integer = if Q == '0' then 1 else 2;

```

A2

Encoding for the Single-precision scalar variant

Applies when (size == 10)

VSUB{<c>}{<q>}.F32 {<Sd>, }<Sn>, <Sm>

Encoding for the Double-precision scalar variant

Applies when (size == 11)

VSUB{<c>} {<q>}.F64 {<Dd>, }<Dn>, <Dm>

Decode for all variants of this encoding

```

if FPSCR().Len != '000' || FPSCR().Stride != '00' then Undefined(); end;
if size != '1x' then Undefined(); end;
let advsimd : boolean = FALSE;
let esize : integer{} = 8 << UInt(size);
let d : integer = if size == '11' then UInt(D::Vd) else UInt(Vd::D);
let n : integer = if size == '11' then UInt(N::Vn) else UInt(Vn::N);
let m : integer = if size == '11' then UInt(M::Vm) else UInt(Vm::M);
let regs : integer = ARBITRARY : integer;
let elements : integer = ARBITRARY : integer;

```

CONSTRAINED UNPREDICTABLE behavior

If `size == '01' && cond != '1110'`, then one of the following behaviors must occur:

- The instruction is `UNDEFINED`.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as `NOP`. This means it behaves as if it fails the Condition code check.

T1

Encoding for the 64-bit SIMD vector variant

Applies when ($Q == 0$)

VSUB{<c>}{<q>},<dt> {<Dd>,<Dn>,<Dm>

Encoding for the 128-bit SIMD vector variant

Applies when ($Q == 1$)

VSUB{<c>} {<q>}.<dt> {<Qd>, }<Qn>, <Qm>

Decode for all variants of this encoding

```

if Q == '1' && (Vd[0] == '1' || Vn[0] == '1' || Vm[0] == '1') then Undefined(); end;
if sz == '1' then Undefined(); end;
let advsimd : boolean = TRUE;
let esize : integer{} = 32 >> UInt(sz);
let elements : integer = 64 DIV esize;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);
let regs : integer = if Q == '0' then 1 else 2;

```

CONSTRAINED UNPREDICTABLE behavior

If `sz == '1'` && `InITBlock()`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

T2

Encoding for the Single-precision scalar variant

Applies when `(size == 10)`

```
VSUB{<c>}{<q>}.F32 {<Sd>, }<Sn>, <Sm>
```

Encoding for the Double-precision scalar variant

Applies when `(size == 11)`

```
VSUB{<c>}{<q>}.F64 {<Dd>, }<Dn>, <Dm>
```

Decode for all variants of this encoding

```
if FPSCR().Len != '000' || FPSCR().Stride != '00' then Undefined(); end;
if size != '1x' then Undefined(); end;
let advsimd : boolean = FALSE;
let esize : integer{} = 8 << UInt(size);
let d : integer = if size == '11' then UInt(D::Vd) else UInt(Vd::D);
let n : integer = if size == '11' then UInt(N::Vn) else UInt(Vn::N);
let m : integer = if size == '11' then UInt(M::Vm) else UInt(Vm::M);
let regs : integer = ARBITRARY : integer;
let elements : integer = ARBITRARY : integer;
```

CONSTRAINED UNPREDICTABLE behavior

If `size == '01'` && `InITBlock()`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

Assembler Symbols

<c>

For the “A1 128-bit SIMD vector” and “A1 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#). This encoding must be unconditional.

For the “A2 Double-precision scalar”, “A2 Single-precision scalar”, “T1 128-bit SIMD vector”, “T1 64-bit SIMD vector”, “T2 Double-precision scalar”, and “T2 Single-precision scalar” variants: see [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<dt>

Is the data type for the elements of the vectors, encoded in “sz”:

sz	<dt>
0	F32
1	F16

<Dd>

Is the 64-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field.

<Dn>

Is the 64-bit name of the first SIMD&FP source register, encoded in the “N:Vn” field.

<Dm>

Is the 64-bit name of the second SIMD&FP source register, encoded in the “M:Vm” field.

<Qd>

Is the 128-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field as <Qd>*2.

<Qn>

Is the 128-bit name of the first SIMD&FP source register, encoded in the “N:Vn” field as <Qn>*2.

<Qm>

Is the 128-bit name of the second SIMD&FP source register, encoded in the “M:Vm” field as <Qm>*2.

<Sd>

Is the 32-bit name of the SIMD&FP destination register, encoded in the “Vd:D” field.

<Sn>

Is the 32-bit name of the first SIMD&FP source register, encoded in the “Vn:N” field.

<Sm>

Is the 32-bit name of the second SIMD&FP source register, encoded in the “Vm:M” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDOrVFPEEnabled(TRUE, advsimd);
    if advsimd then // Advanced SIMD instruction
        let fpcr : FPCR_Type = StandardFPCR();
        for r = 0 to regs-1 do
            for e = 0 to elements-1 do
                D(d+r)[e*:esize] = FPSub{esize}(D(n+r)[e*:esize], D(m+r)[e*:esize], fpcr);
            end;
        end;
    else // VFP instruction
```

```
    let fpcr : FPCR_Type = EffectiveFPCR();  
    case esize of  
        when 32 =>  
            S(d) = FPSub{32}(S(n), S(m), fpcr);  
        when 64 =>  
            D(d) = FPSub{64}(D(n), D(m), fpcr);  
    end;  
end;  
end;
```

C6.1.223 VSUB (integer)

Vector Subtract (integer) subtracts the elements of one vector from the corresponding elements of another vector, and places the results in the destination vector.

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0)

`VSUB{<c>}{<q>}.<dt> {<Dd>, }<Dn>, <Dm>`

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

`VSUB{<c>}{<q>}.<dt> {<Qd>, }<Qn>, <Qm>`

Decode for all variants of this encoding

```

if Q == '1' && (Vd[0] == '1' || Vn[0] == '1' || Vm[0] == '1') then Undefined(); end;
let esize : integer{} = 8 << UInt(size);
let elements : integer = 64 DIV esize;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);
let regs : integer = if Q == '0' then 1 else 2;

```

T1

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0)

`VSUB{<c>}{<q>}.<dt> {<Dd>, }<Dn>, <Dm>`

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

```
VSUB{<c>}{<q>}.<dt> {<Qd>, }<Qn>, <Qm>
```

Decode for all variants of this encoding

```
if Q == '1' && (Vd[0] == '1' || Vn[0] == '1' || Vm[0] == '1') then Undefined(); end;
let esize : integer{} = 8 << UInt(size);
let elements : integer = 64 DIV esize;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);
let regs : integer = if Q == '0' then 1 else 2;
```

Assembler Symbols

<c>

For the “A1 128-bit SIMD vector” and “A1 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#). This encoding must be unconditional.

For the “T1 128-bit SIMD vector” and “T1 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<dt>

Is the data type for the elements of the vectors, encoded in “size”:

size	<dt>
00	I8
01	I16
10	I32
11	I64

<Dd>

Is the 64-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field.

<Dn>

Is the 64-bit name of the first SIMD&FP source register, encoded in the “N:Vn” field.

<Dm>

Is the 64-bit name of the second SIMD&FP source register, encoded in the “M:Vm” field.

<Qd>

Is the 128-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field as <Qd>*2.

<Qn>

Is the 128-bit name of the first SIMD&FP source register, encoded in the “N:Vn” field as <Qn>*2.

<Qm>

Is the 128-bit name of the second SIMD&FP source register, encoded in the “M:Vm” field as <Qm>*2.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();
    for r = 0 to regs-1 do
        for e = 0 to elements-1 do
            D(d+r)[e*:esize] = D(n+r)[e*:esize] - D(m+r)[e*:esize];
        end;
    end;
end;
```

C6.1.224 VSUBHN

Vector Subtract and Narrow, returning High Half subtracts the elements of one quadword vector from the corresponding elements of another quadword vector, takes the most significant half of each result, and places the final results in a doubleword vector. The results are truncated. For rounded results, see [VRSUBHN](#).

There is no distinction between signed and unsigned integers.

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

VSUBHN{<c>}{<q>}.<dt> <Dd>, <Qn>, <Qm>

Decode for this encoding

```

if size == '11' then See("Related encodings"); end;
if Vn[0] == '1' || Vm[0] == '1' then Undefined(); end;
let esize : integer{} = 8 << UInt(size);
let elements : integer = 64 DIV esize;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);

```

T1

Encoding

VSUBHN{<c>}{<q>}.<dt> <Dd>, <Qn>, <Qm>

Decode for this encoding

```

if size == '11' then See("Related encodings"); end;
if Vn[0] == '1' || Vm[0] == '1' then Undefined(); end;
let esize : integer{} = 8 << UInt(size);
let elements : integer = 64 DIV esize;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);

```

Related encodings: See [Advanced SIMD data-processing](#) for the T32 instruction set, or [Advanced SIMD data-processing](#) for the A32 instruction set.

Assembler Symbols

<c>

For the “A1” variant: see [Standard assembler syntax fields](#). This encoding must be unconditional.

For the “T1” variant: see [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<dt>

Is the data type for the elements of the operands, encoded in “size”:

size	<dt>
00	I16
01	I32
10	I64

<Dd>

Is the 64-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field.

<Qn>

Is the 128-bit name of the first SIMD&FP source register, encoded in the “N:Vn” field as <Qn>*2.

<Qm>

Is the 128-bit name of the second SIMD&FP source register, encoded in the “M:Vm” field as <Qm>*2.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();
    for e = 0 to elements-1 do
        let result : bits(2*esize) = Qin(n>>1)[e*(2*esize)] - Qin(m>>1)[e*(2*esize)];
        D(d)[e*esize] = result[2*esize-1:esize];
    end;
end;
```

C6.1.225 VSUBL

Vector Subtract Long subtracts the elements of one doubleword vector from the corresponding elements of another doubleword vector, and places the results in a quadword vector. Before subtracting, it sign-extends or zero-extends the elements of both operands.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 (A1) and T32 (T1).

A1

Encoding

VSUBL{<c>}{<q>}.<dt> <Qd>, <Dn>, <Dm>

Decode for this encoding

```

if size == '11' then See("Related encodings"); end;
if Vd[0] == '1' || (op == '1' && Vn[0] == '1') then Undefined(); end;
let unsigned : boolean = (U == '1');
let is_vsubw : boolean = (op == '1');
let esize : integer{} = 8 << UInt(size);
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);
let elements : integer = 64 DIV esize;

```

T1

Encoding

VSUBL{<c>}{<q>}.<dt> <Qd>, <Dn>, <Dm>

Decode for this encoding

```

if size == '11' then See("Related encodings"); end;
if Vd[0] == '1' || (op == '1' && Vn[0] == '1') then Undefined(); end;
let unsigned : boolean = (U == '1');
let is_vsubw : boolean = (op == '1');
let esize : integer{} = 8 << UInt(size);
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);
let elements : integer = 64 DIV esize;

```

Related encodings: See [Advanced SIMD data-processing](#) for the T32 instruction set, or [Advanced SIMD data-processing](#) for the A32 instruction set.

Assembler Symbols

<c>

For the “A1” variant: see [Standard assembler syntax fields](#). This encoding must be unconditional.
For the “T1” variant: see [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<dt>

Is the data type for the elements of the second operand vector, encoded in “U:size”:

U	size	<dt>
0	00	S8
0	01	S16
0	10	S32
1	00	U8
1	01	U16
1	10	U32

<Qd>

Is the 128-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field as <Qd>*2.

<Dn>

Is the 64-bit name of the first SIMD&FP source register, encoded in the “N:Vn” field.

<Dm>

Is the 64-bit name of the second SIMD&FP source register, encoded in the “M:Vm” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();
    for e = 0 to elements-1 do
        var element1 : integer;
        if is_vsubw then
            let op1elt : bits(2*esize) = Qin(n>>1)[e*:(2*esize)];
            element1 = if unsigned then UInt(op1elt) else SInt(op1elt);
        else
            let op1elt : bits(esize) = Din(n)[e*:(esize)];
            element1 = if unsigned then UInt(op1elt) else SInt(op1elt);
        end;
        let op2elt : bits(esize) = Din(m)[e*:(esize)];
        let element2 : integer = if unsigned then UInt(op2elt) else SInt(op2elt);
        let result : integer = element1 - element2;
        Q(d>>1)[e*:(2*esize)] = result[2*esize-1:0];
    end;
end;
```

C6.1.226 VSUBW

Vector Subtract Wide subtracts the elements of a doubleword vector from the corresponding elements of a quadword vector, and places the results in another quadword vector. Before subtracting, it sign-extends or zero-extends the elements of the doubleword operand.

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

31	28	27	26	25	24	23	22	21	20	19	16	15	12	11	9	8	7	6	5	4	3	0			
1	1	1	1	0	0	1	U	1	D	!=11	Vn		Vd		0	0	1	1	N	0	M	0	Vm		
										size														op	

Encoding

VSUBW{<c>}{<q>}.<dt> {<Qd>, }<Qn>, <Dm>

Decode for this encoding

```

if size == '11' then See("Related encodings"); end;
if Vd[0] == '1' || (op == '1' && Vn[0] == '1') then Undefined(); end;
let unsigned : boolean = (U == '1');
let is_vsubw : boolean = (op == '1');
let esize : integer{} = 8 << UInt(size);
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);
let elements : integer = 64 DIV esize;

```

T1

15	13	12	11	10	9	8	7	6	5	4	3	0	15	12	11	9	8	7	6	5	4	3	0	
1	1	1	U	1	1	1	1	D	!=11	Vn			Vd			0	0	1	1	N	0	M	0	Vm
										size												op		

Encoding

VSUBW{<c>}{<q>}.<dt> {<Qd>, }<Qn>, <Dm>

Decode for this encoding

```

if size == '11' then See("Related encodings"); end;
if Vd[0] == '1' || (op == '1' && Vn[0] == '1') then Undefined(); end;
let unsigned : boolean = (U == '1');
let is_vsubw : boolean = (op == '1');
let esize : integer{} = 8 << UInt(size);
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);
let elements : integer = 64 DIV esize;

```

Related encodings: See [Advanced SIMD data-processing](#) for the T32 instruction set, or [Advanced SIMD data-processing](#) for the A32 instruction set.

Assembler Symbols

For the “A1” variant: see [Standard assembler syntax fields](#). This encoding must be unconditional.
For the “T1” variant: see [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<dt>

Is the data type for the elements of the second operand vector, encoded in “U:size”:

U	size	<dt>
0	00	S8
0	01	S16
0	10	S32
1	00	U8
1	01	U16
1	10	U32

<Qd>

Is the 128-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field as <Qd>*2.

<Qn>

Is the 128-bit name of the first SIMD&FP source register, encoded in the “N:Vn” field as <Qn>*2.

<Dm>

Is the 64-bit name of the second SIMD&FP source register, encoded in the “M:Vm” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();
    for e = 0 to elements-1 do
        var element1 : integer;
        if is_vsubw then
            let op1elt : bits(2*esize) = Qin(n>>1)[e*:(2*esize)];
            element1 = if unsigned then UInt(op1elt) else SInt(op1elt);
        else
            let op1elt : bits(esize) = Din(n)[e*:esize];
            element1 = if unsigned then UInt(op1elt) else SInt(op1elt);
        end;
        let op2elt : bits(esize) = Din(m)[e*:esize];
        let element2 : integer = if unsigned then UInt(op2elt) else SInt(op2elt);
        let result : integer = element1 - element2;
        Q(d>>1)[e*:(2*esize)] = result[2*esize-1:0];
    end;
end;
```

C6.1.227 VSWP

Vector Swap exchanges the contents of two vectors. The vectors can be either doubleword or quadword. There is no distinction between data types.

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding for the 64-bit SIMD vector variant

Applies when $(Q == 0)$

VSWP{<c>}{<q>}{.<dt>} <Dd>, <Dm>

Encoding for the 128-bit SIMD vector variant

Applies when ($Q == 1$)

$$\text{VSWP}\{\langle c \rangle\}\{\langle q \rangle\}\{.\langle dt \rangle\} \quad \langle Qd \rangle, \langle Qm \rangle$$

Decode for all variants of this encoding

```

if size != '00' then Undefined(); end;
if Q == '1' && (Vd[0] == '1' || Vm[0] == '1') then Undefined(); end;
let d : integer = UInt(D::Vd);
let m : integer = UInt(M::Vm);
let regs : integer = if Q == '0' then 1 else 2;

```

T1

Encoding for the 64-bit SIMD vector variant

Applies when ($Q == 0$)

VSWP{<c>}{<q>}{.<dt>} <Dd>, <Dm>

Encoding for the 128-bit SIMD vector variant

Applies when $(Q == 1)$

VSWP{<c>}{<q>}{.<dt>} <Qd>, <Qm>

Decode for all variants of this encoding

```

if size != '00' then Undefined(); end;
if Q == '1' && (Vd[0] == '1' || Vm[0] == '1') then Undefined(); end;
let d : integer = UInt(D::Vd);
let m : integer = UInt(M::Vm);
let regs : integer = if Q == '0' then 1 else 2;

```

Assembler Symbols

<c>

For the “A1 128-bit SIMD vector” and “A1 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#). This encoding must be unconditional.

For the “T1 128-bit SIMD vector” and “T1 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<dt>

An optional data type. It is ignored by assemblers, and does not affect the encoding.

<Dd>

Is the 64-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field.

<Dm>

Is the 64-bit name of the SIMD&FP source register, encoded in the “M:Vm” field.

<Qd>

Is the 128-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field as <Qd>*2.

<Qm>

Is the 128-bit name of the SIMD&FP source register, encoded in the “M:Vm” field as <Qm>*2.

Operation

```

if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();
    for r = 0 to regs-1 do
        if d == m then
            D(d+r) = ARBITRARY : bits(64);
        else
            D(d+r) = Din(m+r);
            D(m+r) = Din(d+r);
        end;
    end;
end;

```

C6.1.228 VTBL, VTBX

Vector Table Lookup and Extension

Vector Table Lookup uses byte indexes in a control vector to look up byte values in a table and generate a new vector. Indexes out of range return 0.

Vector Table Extension works in the same way, except that indexes out of range leave the destination element unchanged.

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

31	23	22	21	20	19	16	15	12	11	10	9	8	7	6	5	4	3	0						
1	1	1	1	0	0	1	1	1	D	1	1	Vn		Vd		1	0	len	N	op	M	0	Vm	

Encoding for the VTBL variant

Applies when (op == 0)

VTBL{<c>}{<q>}.8 <Dd>, <list>, <Dm>

Encoding for the VTBX variant

Applies when (op == 1)

VTBX{<c>}{<q>}.8 <Dd>, <list>, <Dm>

Decode for all variants of this encoding

```
let is_vtbl : boolean = (op == '0');
let length : integer = UInt(len)+1;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);
if n+length > 32 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If n + length > 32, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- One or more of the SIMD and floating-point registers are UNKNOWN. This behavior does not affect any general-purpose registers.

T1

15															7	6	5	4	3	0															15	12	11	10	9	8	7	6	5	4	3	0																																																																																																																																			
1															1	1	1	1	1	1	1	1	1	1	D															1	1	Vn															Vd															1															0	len															N															op															M															0															Vm														

Encoding for the VTBL variant

Applies when (`op == 0`)

VTBL{<c>}{<q>}.8 <Dd>, <list>, <Dm>

Encoding for the VTBX variant

Applies when ($\text{op} == 1$)

VTBX{<c>}{<q>}.8 <Dd>, <list>, <Dm>

Decode for all variants of this encoding

```
let is_vtbl : boolean = (op == '0');
let length : integer = UInt(len)+1;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);
if n+length > 32 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If $n + \text{length} > 32$, then one of the following behaviors must occur:

- The instruction is `UNDEFINED`.
- The instruction executes as `NOP`.
- One or more of the SIMD and floating-point registers are `UNKNOWN`. This behavior does not affect any general-purpose registers.

For more information about the **CONSTRAINED UNPREDICTABLE** behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

 $\langle c \rangle$

For the “A1 VTBL” and “A1 VTBX” variants: see [Standard assembler syntax fields](#). This encoding must be unconditional.

For the “T1 VTBL” and “T1 VTBX” variants: see [Standard assembler syntax fields](#).

 $\langle q \rangle$

See [Standard assembler syntax fields](#).

<Dd>

Is the 64-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field.

<list>

The vectors containing the table. It must be one of:

{<Dn>} Encoded as len = 0b00.
{<Dn>, <Dn+1>} Encoded as len = 0b01.
{<Dn>, <Dn+1>, <Dn+2>} Encoded as len = 0b10.
{<Dn>, <Dn+1>, <Dn+2>, <Dn+3>} Encoded as len = 0b11.

<Dm>

Is the 64-bit name of the SIMD&FP source register holding the indices, encoded in the “M:Vm” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();

    // Create 256-bit = 32-byte table variable, with zeros in entries that will not be used.
    let table3 : bits(64) = if length == 4 then D(n+3) else Zeros{64};
    let table2 : bits(64) = if length >= 3 then D(n+2) else Zeros{64};
    let table1 : bits(64) = if length >= 2 then D(n+1) else Zeros{64};
    let table : bits(256) = table3 :: table2 :: table1 :: D(n);

    for i = 0 to 7 do
        let index : integer = UInt(D(m)[i*8]);
        if index < 8*length then
            D(d)[i*8] = table[index*8];
        else
            if is_vtbl then
                D(d)[i*8] = Zeros{8};
            // else D[d]<i*8> unchanged
            end;
        end;
    end;
end;
```

C6.1.229 VTRN

Vector Transpose treats the elements of its operand vectors as elements of 2 x 2 matrices, and transposes the matrices.

The elements of the vectors can be 8-bit, 16-bit, or 32-bit. There is no distinction between data types.

Figure C6-9 VTRN doubleword operations

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

This instruction is used by the pseudo-instructions VUZP (alias) and VZIP (alias).

It has encodings from the following instruction sets: A32 (A1) and T32 (T1).

A1

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0)

VTRN{<c>}{<q>}.<dt> <Dd>, <Dm>

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

VTRN{<c>}{<q>}.<dt> <Qd>, <Qm>

Decode for all variants of this encoding

```
if size == '11' then Undefined(); end;
if Q == '1' && (Vd[0] == '1' || Vm[0] == '1') then Undefined(); end;
let esize : integer{} = 8 << UInt(size);
let elements : integer = 64 DIV esize;
let d : integer = UInt(D::Vd);
let m : integer = UInt(M::Vm);
let regs : integer = if Q == '0' then 1 else 2;
```

T1

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0)

VTRN{<c>}{<q>}.<dt> <Dd>, <Dm>

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

VTRN{<c>}{<q>}.<dt> <Qd>, <Qm>

Decode for all variants of this encoding

```
if size == '11' then Undefined(); end;
if Q == '1' && (Vd[0] == '1' || Vm[0] == '1') then Undefined(); end;
let esize : integer{} = 8 << UInt(size);
let elements : integer = 64 DIV esize;
let d : integer = UInt(D::Vd);
let m : integer = UInt(M::Vm);
let regs : integer = if Q == '0' then 1 else 2;
```

Assembler Symbols

<c>

For the “A1 128-bit SIMD vector” and “A1 64-bit SIMD vector” variants: see Standard assembler syntax fields. This encoding must be unconditional.

For the “T1 128-bit SIMD vector” and “T1 64-bit SIMD vector” variants: see Standard assembler syntax fields.

<q>

See Standard assembler syntax fields.

<dt>

Is the data type for the elements of the vectors, encoded in “size”:

size	<dt>
00	8
01	16
10	32
11	RESERVED

<Dd>

Is the 64-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field.

<Dm>

Is the 64-bit name of the SIMD&FP source register, encoded in the “M:Vm” field.

<Qd>

Is the 128-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field as <Qd>*2.

<Qm>

Is the 128-bit name of the SIMD&FP source register, encoded in the “M:Vm” field as <Qm>*2.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();
    let h : integer = elements DIV 2;

    for r = 0 to regs-1 do
        if d == m then
            D(d+r) = ARBITRARY : bits(64);
        else
            for e = 0 to h-1 do
                D(d+r)[(2*e+1)*:esize] = Din(m+r)[(2*e)*:esize];
                D(m+r)[(2*e)*:esize] = Din(d+r)[(2*e+1)*:esize];
            end;
        end;
    end;
end;
```

C6.1.230 VTST

Vector Test Bits takes each element in a vector, and bitwise ANDs it with the corresponding element of a second vector. If the result is not zero, the corresponding element in the destination vector is set to all ones. Otherwise, it is set to all zeros.

The operand vector elements can be any one of:

- 8-bit, 16-bit, or 32-bit fields.

The result vector elements are fields the same size as the operand vector elements.

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be `UNDEFINED`, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding for the 64-bit SIMD vector variant

Applies when ($Q == 0$)

VTST{<c>}{<q>}.<dt> {<Dd>, }<Dn>, <Dm>

Encoding for the 128-bit SIMD vector variant

Applies when ($Q == 1$)

VTST{<c>}{<q>}.<dt> {<Qd>, }<Qn>, <Qm>

Decode for all variants of this encoding

```

if Q == '1' && (Vd[0] == '1' || Vn[0] == '1' || Vm[0] == '1') then Undefined(); end;
if size == '11' then Undefined(); end;
let esize : integer{} = 8 << UInt(size);
let elements : integer = 64 DIV esize;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);
let regs : integer = if Q == '0' then 1 else 2;

```

T1

Encoding for the 64-bit SIMD vector variant

Applies when ($Q == 0$)

VTST{<c>}{<q>}.<dt> {<Dd>, }<Dn>, <Dm>

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

VTST{<c>}{<q>}.<dt> {<Qd>, }<Qn>, <Qm>

Decode for all variants of this encoding

```

C6.1.232 VUZP (alias)

Vector Unzip de-interleaves the elements of two vectors.

This is a pseudo-instruction of [VTRN](#). This means:

- The encodings in this description are named to match the encodings of [VTRN](#).
- The assembler syntax is used only for assembly, and is not used on disassembly.
- The description of [VTRN](#) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding for the 64-bit SIMD vector variant

VUZP{<c>} {<q>}.32 <Dd>, <Dm>

is equivalent to

VTRN{<c>} {<q>}.<dt> <Dd>, <Dm>

T1

Encoding for the 64-bit SIMD vector variant

VUZP{<c>} {<q>}.32 <Dd>, <Dm>

is equivalent to

VTRN{<c>} {<q>}.<dt> <Dd>, <Dm>

Assembler Symbols

<c>

    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();
    if quadword_operation then
        if d == m then
            Q(d>>1) = ARBITRARY : bits(128);
        else
            var zipped_q : bits(256);
            for e = 0 to (128 DIV esize) - 1 do
                zipped_q[(2*e)*:esize] = Q(d>>1)[e*:esize];
                zipped_q[(2*e+1)*:esize] = Q(m>>1)[e*:esize];
            end;
            Q(d>>1) = zipped_q[127:0]; Q(m>>1) = zipped_q[255:128];
        end;
    else
        if d == m then
            D(d) = ARBITRARY : bits(64);
        else
            var zipped_d : bits(128);
            for e = 0 to (64 DIV esize) - 1 do
                zipped_d[(2*e)*:esize] = D(d)[e*:esize];
                zipped_d[(2*e+1)*:esize] = D(m)[e*:esize];
            end;
            D(d) = zipped_d[63:0]; D(m) = zipped_d[127:64];
        end;
    end;
end;
end;

```

C6.1.234 VZIP (alias)

Vector Zip interleaves the elements of two vectors.

This is a pseudo-instruction of [VTRN](#). This means:

- The encodings in this description are named to match the encodings of [VTRN](#).
- The assembler syntax is used only for assembly, and is not used on disassembly.
- The description of [VTRN](#) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding for the 64-bit SIMD vector variant

VZIP{<c>}{<q>}.32 <Dd>, <Dm>

is equivalent to

VTRN{<c>}{<q>}.<dt> <Dd>, <Dm>

T1

Encoding for the 64-bit SIMD vector variant

VZIP{<c>}{<q>}.32 <Dd>, <Dm>

is equivalent to

VTRN{<c>}{<q>}.<dt> <Dd>, <Dm>

Assembler Symbols

<c>

For the “A1 64-bit SIMD vector” variant: see [Standard assembler syntax fields](#). This encoding must be unconditional.

For the “T1 64-bit SIMD vector” variant: see [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Dd>

Is the 64-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field.

<Dm>

Is the 64-bit name of the SIMD&FP source register, encoded in the “M:Vm” field.

Operation

The description of [VTRN](#) gives the operational pseudocode for this instruction.

The AArch32 System Level Architecture

Part D

Chapter D1

The AArch32 System Level Programmers' Model

This chapter gives a system level description of the programmers' model for execution in AArch32 state. It contains the following sections:

- [About the AArch32 System level programmers' model](#)
- [Exception levels](#)
- [Exception terminology](#)
- [Execution state](#)
- [Instruction Set state](#)
- [Virtualization](#)
- [AArch32 state PE modes](#)
- [AArch32 general-purpose registers, the PC, and the Special-purpose registers](#)
- [Process state, PSTATE](#)
- [Instruction set states](#)
- [Handling exceptions](#)
- [Routing of aborts](#)
- [Exception return to an Exception level using AArch32](#)
- [Asynchronous exception behavior for exceptions taken from AArch32 state](#)
- [AArch32 state exception descriptions](#)
- [Reset into AArch32 state](#)
- [Mechanisms for entering a low-power state](#)
- [The AArch32 System register interface](#)
- [Advanced SIMD and floating-point support](#)
- [Configurable instruction controls](#)

D1.1 About the AArch32 System level programmers' model

An application programmer has only a restricted view of the system. The System level programmers' model supports this application level view of the system, and includes features that are required for one or both of an operating system (OS) and a hypervisor to provide the programming environment seen by an application. This chapter describes the System level programmers' model when executing at EL1 or higher in an Exception level that is using AArch32.

The system level programmers' model includes all of the system features required to support operating systems and to handle hardware events.

The following sections give a system level introduction to the basic concepts of the Arm architecture AArch32 state, and the terminology that is used for describing the architecture when executing in this state:

- [Exception levels.](#)
- [Exception terminology.](#)
- [Execution state.](#)
- [Instruction Set state.](#)
- [Virtualization.](#)

The rest of this chapter describes the system level programmers' model when executing in AArch32 state.

The other chapters in this part describe:

- The memory system architecture, as seen when executing in an Exception level that is using AArch32:
 - [The AArch32 System Level Memory Model](#) describes the general features of the Armv8 memory model, when executing in AArch32 state, that are not visible at the application level.

Note

[The AArch32 Application Level Memory Model](#) describes the application level view of the memory model.

- The AArch32 System registers, see [AArch32 System Register Descriptions](#).

Note

The T32 and A32 instruction sets include instructions that provide system level functionality, such as returning from an exception. See, for example, ERET.

D1.2 Exception levels

The architecture defines a set of Exception levels, EL0 to EL2, where:

- If EL n is the Exception level, increased values of n indicate increased software execution privilege.
- Execution at EL0 is called *unprivileged execution*.
- EL2 provides support for virtualization.

All implementations must include EL0, EL1 and EL2.

Execution can move between Exception levels only on taking an exception or on returning from an exception:

- On taking an exception, the Exception level can only increase or remain the same.
- On returning from an exception, the Exception level can only decrease or remain the same.

The Exception level that execution changes to or remains in on taking an exception is called the *target Exception level* of the exception.

Each exception type has a target Exception level that is either:

- Implicit in the nature of the exception.
- Defined by configuration bits in the System registers.

An exception cannot target EL0.

D1.2.1 Typical Exception level usage model

The architecture does not specify what software uses which Exception level. Such choices are outside the scope of the architecture. However, the following is a common usage model for the Exception levels:

EL0	Applications.
EL1	OS kernel and associated functions that are typically described as <i>privileged</i> .
EL2	Hypervisor.

D1.2.2 Limited use of Privilege level

As described in the [Protected Memory System Architecture](#), a *translation regime* maps a virtual address (VA) to the corresponding physical address (PA). The PMSAv8-32 translation regimes are defined by the Exception levels that use them.

[Table D1-1](#) shows how the PE modes map to these Privilege levels:

Table D1-1 Mapping of PE modes to AArch32 Privilege levels

Privilege level	
PL2	Hyp
PL1	System, FIQ, IRQ, Supervisor, Abort, Undefined
PL0	User

Each privilege level maps to the corresponding Exception level. For example, PL1 maps to EL1.

D1.3 Exception terminology

The following subsections define the terms that are used when describing exceptions:

- [Terminology for taking an exception.](#)
- [Terminology for returning from an exception.](#)
- [Exception levels.](#)
- [Definition of a precise exception.](#)
- [Definitions of synchronous and asynchronous exceptions.](#)

D1.3.1 Terminology for taking an exception

An exception is *generated* when the PE first responds to an exceptional condition. The PE state at this time is the state that the exception is *taken from*. The PE state immediately after taking the exception is the state that the exception is *taken to*.

D1.3.2 Terminology for returning from an exception

To return from an exception, the PE must execute an exception return instruction. The PE state when an exception return instruction is committed for execution is the state the exception *returns from*. The PE state immediately after the execution of that instruction is the state that the exception *returns to*.

D1.3.3 Exception levels

An Exception level, ELn , with a larger value of n than another Exception level, is described as being a *higher* Exception level than the other Exception level. For example, $EL2$ is a higher Exception level than $EL1$.

An Exception level with a smaller value of n than another Exception level is described as being a *lower* Exception level than the other Exception level. For example, $EL0$ is a lower Exception level than $EL1$.

D1.3.4 Definition of a precise exception

An exception is described as *precise* when the exception handler receives the PE state and memory system state that is consistent with the PE having executed all of the instructions up to but not including the point in the instruction stream where the exception was taken, and none afterwards.

An exception is described as *imprecise* if it is not precise.

Other than the SError exception all exceptions that are taken are required to be precise. For each occurrence of an SError exception, whether the interrupt is precise or imprecise is IMPLEMENTATION DEFINED.

The terms precise and imprecise can also apply to Debug state entry. See [Imprecise entry to Debug state](#).

Where a synchronous exception is generated as part of an instruction that performs more than one single-copy atomic memory access, the definition of precise permits that the values in registers or memory affected by those instructions can be UNKNOWN, provided that:

- The accesses affecting those registers or memory locations do not, themselves, generate exceptions.
- The registers are not involved in the calculation of the memory address that is used by the instruction.

Examples of instructions that perform more than one single-copy atomic memory access are the LDM and STM instructions.

Note

For the definition of a single-copy atomic access, see [Properties of single-copy atomic accesses](#).

D1.3.5 Definitions of synchronous and asynchronous exceptions

An exception is described as *synchronous* if all of the following apply:

- The exception is generated as a result of direct execution or attempted execution of an instruction.
- The return address presented to the exception handler is guaranteed to indicate the instruction that caused the exception.
- The exception is precise.

An exception is described as *asynchronous* if any of the following apply:

- The exception is not generated as a result of direct execution or attempted execution of the instruction stream.
- The return address presented to the exception handler is not guaranteed to indicate the instruction that caused the exception.
- The exception is imprecise.

For more information about exceptions, see [Handling exceptions](#).

D1.4 Execution state

The Execution state is AArch32, the 32-bit Execution state.

All Exception levels, EL0, EL1 and EL2, *use* AArch32 Execution state. This means that the PE cannot change Execution states at either reset or change of Exception level.

D1.4.1 About the AArch32 PE modes

AArch32 state provides a set of *PE modes* that support normal software execution and handle exceptions. The current mode determines the set of registers that are available, as described in [AArch32 general-purpose registers, the PC, and the Special-purpose registers](#).

The AArch32 modes are:

- Hyp mode. This mode always executes at EL2.
- System, Supervisor, Abort, Undefined, IRQ, and FIQ modes. These modes execute at EL1.
- User mode. This mode always executes at EL0.

For more information on modes, see [AArch32 state PE modes](#).

The mode in use immediately before an exception is taken is described as the mode the exception is *taken from*. The mode that is used on taking the exception is described as the mode the exception is *taken to*.

All of the following define the mode that an exception is taken to:

- The type of exception.
- The mode the exception is taken from.
- Configuration settings defined at EL2.

Hyp mode can create system traps that cause exceptions to EL2. There is an architected hierarchy where EL2 configuration settings affect a common condition, for example interrupt routing. When no traps are enabled for a particular condition, the AArch32 mode an exception is taken to is called the *default mode* for that exception.

A number of different modes can exist at the same Exception level. All modes at a particular Exception level have the same *execution privilege*, meaning they have the same access rights for accesses to memory and to System registers.

D1.5 Instruction Set state

In AArch32 state, the *Instruction Set state* determines the instruction set that the PE is executing. In an implementation that follows the Arm recommendations, the available Instruction Set states are:

T32 state The PE is executing T32 instructions.

A32 state The PE is executing A32 instructions.

Note

In previous versions of the Arm architecture:

- The T32 instruction set was called the Thumb instruction set.
 - The A32 instruction set was called the ARM instruction set.
-

For more information, see [Process state, PSTATE](#).

D1.6 Virtualization

A PE is in *Hyp mode* when it is executing at EL2. An exception return from Hyp mode to software running at EL1 or EL0 is performed using the `ERET` instruction.

EL2 provides a set of features that support virtualizing the state of an R-profile AArch32 implementation. The basic model of a virtualized system involves:

- A hypervisor, running in EL2, that is responsible for switching between *virtual machines*. A virtual machine is comprised of EL1 and EL0.
- A number of Guest operating systems, that each run in EL1, on a virtual machine.
- For each Guest operating system, applications, that usually run in EL0, on a virtual machine.

Note

In some systems, a Guest RTOS is unaware that it is running on a virtual machine, and is unaware of any other Guest RTOS. In other systems, a hypervisor makes the Guest RTOS aware of these facts. The architecture supports both of these models.

The hypervisor assigns a VMID to each virtual machine.

EL2 is implemented to support Guest RTOS management. EL2 provides controls to:

- Provide virtual values for the contents of a small number of identification registers. A read of one of these registers by a Guest RTOS or the applications for a Guest RTOS returns the virtual value.
- *Trap* various operations, including memory management operations and accesses to many other registers. A trapped operation generates an exception that is taken to EL2.
- Route interrupts to the appropriate one of:
 - The current Guest RTOS.
 - A Guest RTOS that is not currently running.
 - The hypervisor.

For memory accesses:

- The implementation provides an independent *translation regime* for memory accesses from EL2.
- For the PL1&0 translation regime, address translation occurs in two stages:
 - Stage 1 maps the *virtual address* (VA) to an *intermediate physical address* (IPA). This is managed at EL1, usually by a Guest RTOS. The Guest RTOS believes that the IPA is the *physical address* (PA).
 - Stage 2 maps the IPA to the PA. This is managed at EL2. The Guest RTOS might be unaware of this stage.

For more information on the translation regimes, see [Protected Memory System Architecture](#).

D1.6.1 The effect of implementing EL2 on the Exception model

An implementation that includes EL2 implements the following exceptions:

- Hypervisor Call (HVC) exception.
- Traps to EL2. [EL2 configurable controls](#), describes these.
- All of the virtual interrupts:
 - Virtual SError.
 - Virtual IRQ.
 - Virtual FIQ.

HVC exceptions are always taken to EL2. All virtual interrupts are always taken to EL1, and can only be taken from EL1 or EL0.

Each of the virtual interrupts can be independently enabled using controls at EL2.

Each of the virtual interrupts has a corresponding physical interrupt. See [Virtual interrupts](#).

When a virtual interrupt is enabled, its corresponding physical exception is taken to EL2. For more information, see [Asynchronous exception behavior for exceptions taken from AArch32 state](#).

EL2 also:

- Provides controls that can be used to route some synchronous exceptions, taken from state, to EL2. For more information, see:
 - [Routing exceptions from EL0 to EL2](#).
 - [Routing debug exceptions to EL2 using AArch32](#).
 - [Routing of aborts taken to AArch32 state](#).
- Provides mechanisms to trap PE operations to EL2. See [EL2 configurable controls](#).
When an operation is trapped to EL2, the hypervisor typically either:
 - Emulates the required operation. The application running in the Guest RTOS is unaware of the trap.
 - Returns an error to the Guest RTOS.

D1.6.1.1 Virtual interrupts

The virtual interrupts have names that correspond to the physical interrupts, as shown in [Table D1-2](#).

Table D1-2 The virtual interrupts

Physical interrupt	Corresponding virtual interrupt
External SError	Virtual SError
IRQ	Virtual IRQ
FIQ	Virtual FIQ

Software executing at EL2 can use virtual interrupts to signal physical interrupts to EL1 and EL0. [Example D1-1](#) shows a usage model for virtual interrupts.

Example D1-1 Virtual interrupt usage model

A usage model is as follows:

1. Software executing at EL2 routes a physical interrupt to EL2.
2. When a physical interrupt of that type occurs, the exception handler executing in EL2 determines whether the interrupt can be handled in EL2 or requires routing to a Guest RTOS in EL1. If the interrupt requires routing to a Guest RTOS:
 - If the Guest RTOS is currently running, the hypervisor uses the appropriate virtual interrupt type to signal the physical interrupt to the Guest RTOS.
 - If the Guest RTOS is not currently running, the physical interrupt is marked as pending for the Guest RTOS. When the hypervisor next switches to the virtual machine that is running that Guest RTOS, the hypervisor uses the appropriate virtual interrupt type to signal the physical interrupt to the Guest RTOS.

EL1 and EL0 modes cannot distinguish a virtual interrupt from the corresponding physical interrupt.

For more information, see [Virtual exceptions](#).

D1.7 AArch32 state PE modes

Table D1-3 shows the PE modes defined by the Arm architecture, for execution in AArch32 state. In this table:

- The *PE mode* column gives the name of each mode and the abbreviation used, for example, in the general-purpose register name suffixes used in [AArch32 general-purpose registers, the PC, and the Special-purpose registers](#).
- The *Encoding* column gives the corresponding `PSTATE.M` field.
- The *Exception level* column gives the Exception level at which the mode is implemented, see [Exception levels](#).

Table D1-3 AArch32 PE modes

PE mode		Encoding	Exception level
User	usr	10000	EL0
FIQ	fiq	10001	EL1
IRQ	irq	10010	EL1
Supervisor	svc	10011	EL1
Abort	abt	10111	EL1
Hyp	hyp	11010	EL2
Undefined	und	11011	EL1
System	sys	11111	EL1

Mode changes can be made under software control, or can be caused by an external or internal exception.

D1.7.1 Notes on the AArch32 PE modes

PE modes are defined only in AArch32 state.

This section gives more information about each of the modes, when it is implemented.

User mode

Software executing in User mode executes at EL0. Execution in User mode is sometimes described as unprivileged execution. Application programs normally execute in User mode, and any program executed in User mode:

- Makes only unprivileged accesses to system resources, meaning it cannot access protected system resources.
- Makes only unprivileged access to memory.
- Cannot change mode except by causing an exception, see [Handling exceptions](#).

System mode

System mode is implemented at EL1.

System mode has the same registers available as User mode, and is not entered by any exception.

Supervisor mode

Supervisor mode is implemented at EL1.

Supervisor mode is the default mode to which a Supervisor Call exception is taken. Executing an `svc` (Supervisor Call) instruction generates a Supervisor Call exception.

Abort mode

Abort mode is implemented at EL1.

Abort mode is the default mode to which a Data Abort exception or Prefetch Abort exception is taken.

Undefined mode

Undefined mode is implemented at EL1.

Undefined mode is the default mode to which an instruction-related exception, including any attempt to execute an UNDEFINED instruction, is taken.

FIQ mode

FIQ mode is implemented at EL1.

FIQ mode is the default mode to which an FIQ interrupt is taken.

IRQ mode

IRQ mode is implemented at EL1.

IRQ mode is the default mode to which an IRQ interrupt is taken.

Hyp mode

Hyp mode is the EL2 mode.

Hyp mode is entered on taking an exception that must be taken to EL2.

The PE enters Hyp mode on reset.

The Hypervisor Call exception and Hyp Trap exception are implemented as part of EL2 and are always taken to Hyp mode when EL2 is using AArch32.

Executing an `HVC` (Hypervisor Call) instruction generates a Hypervisor Call exception. See [Hypervisor Call \(HVC\) exception](#).

For more information, see [Hyp mode](#).

D1.7.2 Hyp mode

Hyp mode is the EL2 mode. When EL2 is using AArch32, it provides the usual method of controlling the virtualization of execution at EL1 and EL0.

This section summarizes how Hyp mode differs from the other modes, and references where this part of the manual describes the features of Hyp mode in more detail:

- Software executing in Hyp mode executes at EL2.
- In Non-debug state, the only mechanisms for changing to Hyp mode are:
 - An exception taken from a EL1 or EL0 mode.
- In Hyp mode, the only exception return is execution of an `ERET` instruction, see `ERET`.
- In Hyp mode, the `CPACR` has no effect on the execution of:
 - System register access instructions.
 - Advanced SIMD and floating-point instructions.

The `HCPTTR` controls execution of these instructions in Hyp mode.

- If software running in Hyp mode executes an `SVC` instruction, the Supervisor Call exception generated by the instruction is taken to Hyp mode, see `SVC`.
- The instructions described in the following sections are UNDEFINED if executed in Hyp mode:
 - `SRS`. See [SRS](#), [SRSDA](#), [SRSDDB](#), [SRSIA](#), [SRSIB](#).
 - `RFE`. See [RFE](#), [RFEDA](#), [RFEDB](#), [RFEIA](#), [RFEIB](#).
 - [LDM \(exception return\)](#).
 - [LDM \(User registers\)](#).

- [STM \(User registers\)](#).
- The `SUBS PC, LR` forms of the instructions described in [SUB, SUBS \(immediate\)](#).

Note

In T32 state, `ERET` is encoded as `SUBS PC, LR, #0`, and therefore this is a valid instruction.

- The exception return form of the instructions described in [MOV, MOVS \(register\)](#).

In addition, deprecated forms of the A32 `ADCS`, `ADDS`, `ANDS`, `BICS`, `EORS`, `MOVS`, `MVNS`, `ORRS`, `RSBS`, `RSCS`, `SBCS`, and `SUBS` instructions with the PC as the destination register are UNDEFINED if executed in Hyp mode. The instruction descriptions identify these UNDEFINED cases.

- The Load unprivileged and Store unprivileged instructions `LDRT`, `LDRSHT`, `LDRHT`, `LDRBT`, `STRT`, `STRHT`, and `STRBT`, are CONSTRAINED UNPREDICTABLE if executed in Hyp mode.

If `HCR.HCD` is set to 1, the `HVC` instruction is UNDEFINED.

D1.7.3 Pseudocode description of mode operations

The `BadMode ()` function tests whether a 5-bit mode number corresponds to one of the permitted modes.

The `BadMode ()` function is defined in [R-profile Architecture Pseudocode](#).

D1.8 AArch32 general-purpose registers, the PC, and the Special-purpose registers

The [general-purpose registers, and the PC, in AArch32 state](#) describes the application level view of the general-purpose registers, and the PC. This view provides:

- The general-purpose registers R0-R14, of which:
 - The preferred name for R13 is SP (*stack pointer*).
 - The preferred name for R14 is LR (*link register*).
- The PC, which can be described as R15.

Figure D1-1 shows the full set of banked general-purpose registers, and the Special-purpose registers:

- The Program Status Registers [CPSR](#) and [SPSR](#).
- [ELR_hyp](#).

Note

The architecture uses system level register names, such as R0_usr, R8_usr, and R8_fiq, when it must identify a specific register. The application level names refer to the registers for the current mode, and usually are sufficient to identify a register.

		System level view							
		User	System	Hyp	Supervisor	Abort	Undefined	IRQ	FIQ
Application level view	R0	R0_usr							
	R1	R1_usr							
	R2	R2_usr							
	R3	R3_usr							
	R4	R4_usr							
	R5	R5_usr							
	R6	R6_usr							
	R7	R7_usr							
	R8	R8_usr							R8_fiq
	R9	R9_usr							R9_fiq
	R10	R10_usr							R10_fiq
	R11	R11_usr							R11_fiq
	R12	R12_usr							R12_fiq
	SP	SP_usr		SP_hyp	SP_svc	SP_abt	SP_und	SP_irq	SP_fiq
	LR	LR_usr			LR_svc	LR_abt	LR_und	LR_irq	LR_fiq
	PC	PC_usr							
	APSR	CPSR		SPSR_hyp	SPSR_svc	SPSR_abt	SPSR_und	SPSR_irq	SPSR_fiq

Cells with no entry indicate that the User mode register is used.

Figure D1-1 AArch32 general-purpose registers, PC, and Special-purpose registers, showing banking

As described in [PE mode for taking exceptions](#), on taking an exception the PE changes mode, unless it is already in the mode to which it must take the exception. Each mode that the PE might enter in this way has:

- A banked copy of the stack pointer, for example `SP_irq` and `SP_hyp`.
- A register that holds a preferred return address for the exception. This is:
 - For the EL2 mode, Hyp mode, the Special-purpose register `ELR_hyp`.
 - For the other privileged modes to which exceptions can be taken, a banked copy of the link register, for example `LR_und` and `LR_mon`.
- A saved copy of `PSTATE`, made on exception entry, for example `SPSR_irq` and `SPSR_hyp`.

In addition, FIQ mode has banked copies of the general-purpose registers R8 to R12.

User mode and System mode share the same general-purpose registers.

User mode, System mode, and Hyp mode share the same LR.

For more information about the application level view of the SP, LR, and PC, and the alternative descriptions of them as R13, R14 and R15, see [The general-purpose registers, and the PC, in AArch32 state](#).

In AArch32 state, the Special-purpose registers are:

- The `CPSR` and its view as the `APSR`.
- The `SPSR`, including the banked copies `SPSR_abt`, `SPSR_fiq`, `SPSR_hyp`, `SPSR_irq`, `SPSR_mon`, `SPSR_svc`, and `SPSR_und`.
- The `ELR_hyp`.

D1.8.1 Pseudocode description of general-purpose register and PC operations

The following pseudocode gives access to the general-purpose registers and the PC. These registers are an array, `_R`, indexed by parameter `n`.

`LookUpRIndex()` looks up the index value, `n`, for the specified register number and PE mode, using `RBankSelect()` to evaluate the result.

`_R` accesses the specified general-purpose register in the current PE mode, using `Rmode()` to access the register, accessing `_R` if necessary. `SP` accesses the stack pointer, `LR` accesses the link register, and `PC32` accesses the Program Counter. Each function has a non-assignment form for register reads and an assignment form for register writes, other than `PC32`, which has only a non-assignment form.

`BranchTo()` performs a branch to the specified address.

The `_R_PC`, `LR`, `PC32`, `SP`, `LookUpRIndex()`, `RBankSelect()`, `Rmode()`, and `BranchTo()` functions are defined in [R-profile Architecture Pseudocode](#).

D1.8.2 Saved Program Status Registers (SPSRs)

The Saved Program Status Registers (SPSRs) are used to save PE state on taking exceptions. In AArch32 state, there is an SPSR for every mode that an exception can be taken to, as shown in [Figure D1-1](#). For example, the SPSR for Hyp mode is called `SPSR_hyp`.

Note

Exceptions cannot be taken to EL0.

When the PE takes an exception, PE state is saved from `PSTATE` in the SPSR for the mode the exception is taken to. For example, if the PE takes an exception to Hyp mode, PE state is saved in `SPSR_hyp`. For more information on `PSTATE`, see [Process state, PSTATE](#).

Note

All `PSTATE` fields are saved, including those which have no direct read and write access.

Saving the `PSTATE` fields means the exception handler can:

- On return from the exception, restore the PE state to the values it had immediately before the exception was taken. When the PE returns from an exception, PE state is restored to the state stored in the SPSR of the mode the exception is returning from, if the exception return is made using one of:
 - ERET.
 - LDM.
 - The Exception return form of the instruction described in [MOV, MOVS \(register\)](#).
 - The Exception return form of the instruction described in [SUB, SUBS \(immediate\)](#).

For example, on returning from Hyp mode, PE state is restored to the state stored in [SPSR_mon](#). If the exception return is made using the RFE instruction, the PE restores the PE state from an SPSR valued read from memory.
- Examine the value that [PSTATE](#) had when the exception was taken, for example to determine the instruction set state and privilege level in which the instruction that caused an Undefined Instruction exception was executed.

The SPSRs are UNKNOWN on a Warm reset. Any operation in an EL1 or EL0 mode makes [SPSR_hyp](#) unknown.

SPSR bits that are defined as RES0 on an exception taken are ignored on any exception return.

For more information on SPSR, see [SPSR](#).

D1.8.2.1 Pseudocode description of SPSR operations

The following pseudocode gives access to the SPSRs.

The `SPSR_ELx []` function accesses the current SPSR.

The `SPSRWriteByInstr ()` function is used by the [MSR \(register\)](#) and [MSR \(immediate\)](#) instructions to update the current SPSR.

The `SPSR_ELx []` and `SPSRWriteByInstr ()` functions are defined in [R-profile Architecture Pseudocode](#).

D1.8.3 ELR_hyp

Hyp mode does not provide its own banked copy of LR. Instead, on taking an exception to Hyp mode, the preferred return address is stored in `ELR_hyp`, a 32-bit Special-purpose register implemented for this purpose.

`ELR_hyp` can be accessed explicitly only by executing:

- An MRS or MSR instruction that targets `ELR_hyp`, see:
 - [MRS \(Banked register\)](#).
 - [MSR \(Banked register\)](#).

The `ERET` instruction uses the value in `ELR_hyp` as the return address for the exception. For more information, see [ERET](#).

Software execution in any EL1 or EL0 mode makes `ELR_hyp` UNKNOWN.

D1.9 Process state, PSTATE

Process state or PSTATE is an abstraction of process state information. All of the instruction sets provide instructions that operate on elements of PSTATE.

PSTATE is defined in pseudocode as the PSTATE structure, of type ProcState. ProcState is defined in [A-profile Architecture Pseudocode](#).

The PSTATE fields that are meaningful in AArch32 state are:

The Condition flags

N	Negative Condition flag.
Z	Zero Condition flag.
C	Carry Condition flag.
V	Overflow Condition flag.

[Process state, PSTATE](#) gives more information about these.

The overflow or saturation flag

Q	See Process state, PSTATE .
---	---

The greater than or equal flags

GE[3:0]	See Process state, PSTATE .
---------	---

The PE state controls

J, T	Instruction set state. See PSTATE . J is RES0. On a Warm reset, T is set to an IMPLEMENTATION DEFINED value. On taking an exception to: - A PL1 mode, T is set to SCTLR.TE. - EL2, T is set to HSCTLR.TE.
IT[7:0]	IT block state bits. See Process state, PSTATE . On a Warm reset or taking an exception, these bits are set to 0.
E	Endianness of data accesses. See Process state, PSTATE . If an implementation provides both Big-endian and Little-endian support, then: - On a Warm reset this bit is set to the IMPLEMENTATION DEFINED reset value of HSCTLR.EE. - On taking an exception to: - A PL1 mode, this bit is set to SCTLR.EE. - EL2, this bit is set to HSCTLR.EE
IL	Illegal Execution state bit. See The Illegal Execution state exception . On a Warm reset or taking an exception to AArch32 state, this bit is set to 0.

For information on how the J, T, IT[7:0], E, and IL fields can be accessed, see [Accessing the PE state controls and the Execution state bit](#).

The asynchronous exception mask bits

A	SError mask bit.
I	IRQ interrupt mask bit.
F	FIQ interrupt mask bit.

For each bit, the values are:

- 0 Exception not masked.
- 1 Exception masked.

On a Warm reset, these bits are set to 1.

On taking an exception, one or more of these bits are set to 1.

For more information, see both:

- Asynchronous exception masking controls.
- PE state on exception entry.

The mode bits

- M[4:0]** Current mode of the PE. Table D1-3 lists the permitted values of this field. All other values are reserved. Illegal changes to PSTATE.M describes the effect of setting M[4:0] to a reserved value.
- M[4] is:
- M[4], RES1
- On a Warm reset, M[4:0] is set to 0b11010 meaning Hyp mode.
- On taking an exception, M[4:0] is set to the target mode for the exception type.
- For more information about the PE modes, see:
- AArch32 state PE modes.
 - PE state on exception entry.

D1.9.1 Accessing PSTATE fields

- The PSTATE fields can be accessed as described in the following subsections:
- The Current Program Status Register, CPSR.
 - Accessing the PE state controls, the Execution state bit, and the Undefined Instruction exception injection bit.
 - The CPS instruction.
 - The SETEND instruction.

D1.9.1.1 The Current Program Status Register, CPSR

Some PSTATE fields can be accessed using the Special-purpose Current Program Status Register (CPSR). The CPSR can be directly read using the MRS instruction, and directly written using the MSR (register) and MSR (immediate) instructions.

The CPSR bit assignments are:

- N, Z, C, V, bits [31:28]** The PSTATE Condition flags.
- Q, bit [27]** The PSTATE overflow or saturation flag.

Bits[26:20, 15:10, 5]

Reserved, RES0.

GE[3:0], bits [19:16]

The [PSTATE](#) greater than or equal flags.

E, bit [9] The [PSTATE](#) endianness bit.

A, I, F, bits [8:6]

The [PSTATE](#) asynchronous exception mask bits.

M[4:0], bits [4:0]

The [PSTATE](#) mode bits.

The other [PSTATE](#) fields cannot be accessed by using the CPSR. For information on how to access them, see [Accessing the PE state controls, the Execution state bit, and the Undefined Instruction exception injection bit](#).

The application level alias for the CPSR is the [APSR](#). The [APSR](#) is a subset of the CPSR. See [The Application Program Status Register, APSR](#).

Writes to the CPSR have side-effects on various aspects of PE operation. All of these side-effects, except side-effects on memory accesses associated with fetching instructions, are synchronous to the CPSR write. This means that they are guaranteed:

- Not to be visible to earlier instructions in the execution stream.
- To be visible to later instructions in the execution stream.

The privilege level and address space of memory accesses associated with fetching instructions depend on the current Exception level and Security state. Writes to [PSTATE.M](#) can change one or both of the Exception level and Security state. The effect, on memory accesses associated with fetching instructions, of a change of Exception level or Security state is:

- Synchronous to the change of Exception level or Security state, if that change is caused by an exception entry or exception return.
- Guaranteed not to be visible to any memory access caused by fetching an earlier instruction in the execution stream.
- Guaranteed to be visible to any memory access caused by fetching any instruction after the next [Context Synchronization event](#) in the execution stream.
- Might or might not affect memory accesses caused by fetching instructions between the mode change instruction and the point where the mode change is guaranteed to be visible.

See [Exception return](#) for the definition of exception return instructions.

D1.9.1.2 Accessing the PE state controls, the Execution state bit, and the Undefined Instruction exception injection bit

The PE state controls are the [PSTATE](#).{IL, IT[7:0], J, E, T} fields. Software can read or write these in an [SPSR](#).

In the [CPSR](#):

- The PE state controls, other than [PSTATE.E](#), are RAZ when read by an MRS instruction.
- Writes to the PE state controls, other than [PSTATE.E](#), by [MSR \(register\)](#) or [MSR \(immediate\)](#), are ignored in all modes.

Instructions other than MRS, [MSR \(register\)](#), or [MSR \(immediate\)](#) that access the PE state controls can read and write them in any mode.

Unlike the other [PSTATE](#) PE state controls, [PSTATE.E](#) can be read by an MRS instruction and might be written by [MSR \(register\)](#) or [MSR \(immediate\)](#). However, Arm deprecates [PSTATE.E](#) having a different value from the equivalent System register EE bit, see [Mixed-endian support in AArch32](#).

Note

To determine the current endianness, software can use an `LDR` instruction to load a word from memory with a known value that differs if the endianness is reversed. For example, using an `LDR` instruction to load a word whose four bytes are `0x01`, `0x00`, `0x00`, and `0x00` in ascending order of memory address loads the destination register with:

- `0x0000_0001` if the current endianness is little-endian.
 - `0x0100_0000` if the current endianness is big-endian.
-

The `PSTATE.M[4]` bit is the Execution state bit. When read by an `MRS` instruction in AArch32 state, this bit always reads as 1. When written by an `MSR (register)` instruction or `MSR (immediate)` instruction, writing a value other than 1 is an illegal change to the `PSTATE.M` field. See [Illegal changes to PSTATE.M](#).

D1.9.1.3 The CPS instruction

The T32 and A32 instruction sets both include an instruction to manipulate `PSTATE.{A, I, F}` and `PSTATE.M`:

`CPSIE <iflags> {, #<mode>}` Sets the specified `PSTATE.{A, I, F}` exception masks to 0, enabling the exception, and optionally changes to the specified mode.

`CPSID <iflags> {, #<mode>}` Sets the specified `PSTATE.{A, I, F}` exception masks to 1, disabling the exception, and optionally changes to the specified mode.

`CPS #<mode>` Changes to the specified mode without affecting the `PSTATE.{A, I, F}` exception masks.

The `CPS` instruction is unconditional. For more information, see [CPS](#), [CPSID](#), [CPSIE](#).

D1.9.1.4 The SETEND instruction

The T32 and A32 instruction sets both include an instruction to manipulate `PSTATE.E`:

`SETEND BE` Sets `PSTATE.E` to 1, for big-endian operation.

`SETEND LE` Sets `PSTATE.E` to 0, for little-endian operation.

The `SETEND` instruction is unconditional. For more information, see [SETEND](#). Arm deprecates use of the `SETEND` instruction.

D1.9.2 The Saved Program Status Registers (SPSRs)

On taking an exception, `PSTATE` is preserved in the SPSR of the mode to which the exception is taken. The SPSRs are described in [Saved Program Status Registers \(SPSRs\)](#).

D1.9.3 Illegal changes to PSTATE.M

In PE modes other than User mode, `MSR` and `CPS` instructions can explicitly change `PSTATE.M`. The following changes to `PSTATE.M` by `MSR` or `CPS` instructions are illegal:

- A change to an encoding that [Table D1-3](#) does not show.
- A change to a mode that is not implemented.
- A change to a mode that is not accessible from the context the `MRS` or `CPS` instruction is executed in, as follows:
 - A change to a mode that would cause entry to a higher Exception level.
 - A change to Hyp mode from any other mode.
 - A change from Hyp mode to any other mode.
 - When the value of `HCR.TGE` is 1, attempting to change from Hyp mode to a PL1 mode, see [Trapping of general exceptions to Hyp mode](#).

On executing an instruction that attempts an illegal change to `PSTATE.M`:

- `PSTATE.M` is unchanged, and the current mode remains unchanged.

- [PSTATE.IL](#) is set to 1.
- All other [PSTATE](#) fields are written to as normal.

———— **Note** ————

For the [PSTATE](#) fields that MSR and CPS instructions update, see the instruction descriptions:

- [MSR \(register\)](#).
 - [MSR \(immediate\)](#).
 - [CPS](#), [CPSID](#), [CPSIE](#).
-

When the value of [PSTATE.IL](#) is 1, any attempt to execute any instruction results in an Illegal Execution state exception. See [The Illegal Execution state exception](#).

———— **Note** ————

The PE ignores writes to [PSTATE.M](#) when executing at PL0.

D1.9.4 Pseudocode description of PSTATE operations

The [CPSRWriteByInstr\(\)](#) function is used by the [MSR \(register\)](#) and [MSR \(immediate\)](#) instructions to update [PSTATE](#).

The [SetPSTATEFromPSR\(\)](#) function updates [PSTATE](#) from a CPSR or SPSR.

[R-profile Architecture Pseudocode](#) defines these functions.

D1.10 Instruction set states

The instruction set states are described in [The AArch32 Application Level Memory Model](#) and application level operations on them are described there. This section supplies more information about how they interact with system level functionality, in the sections:

- [Exceptions and instruction set state.](#)
- [Unimplemented instruction sets.](#)

D1.10.1 Exceptions and instruction set state

If an exception is taken to an EL1 mode, the [SCTLR.TE](#) bit for the Security state the exception is taken to determines the instruction set state that handles the exception, and if necessary, the PE changes to this instruction set state on exception entry.

If the exception is taken to Hyp mode, the [HSCTLR.TE](#) bit determines the instruction set state that handles the exception, and if necessary, the PE changes to this instruction set state on exception entry.

On coming out of reset, the PE starts execution in Hyp mode, in the instruction set state determined by the reset value of [HSCTLR.TE](#).

For more information about exception entry, see [Overview of exception entry](#).

D1.10.2 Unimplemented instruction sets

The [PSTATE.T](#) bit defines the current instruction set state, see [Process state, PSTATE](#).

From the introduction of the Armv8 architecture, there is no support for the hardware acceleration of Java bytecodes, and the Jazelle Instruction set state is obsolete. Every AArch32 implementation must support the Trivial Jazelle implementation described in [Trivial implementation of the Jazelle extension](#).

Note

In previous versions of the Arm architecture, the [PSTATE.{J, T}](#) bits determined the Instruction set state. From the introduction of Armv8, [PSTATE.J](#) is RES0.

D1.10.2.1 Trivial implementation of the Jazelle extension

The implementation of AArch32 state is required to include the trivial Jazelle implementation.

In a trivial implementation of the Jazelle extension:

- At EL1 or EL2, if the Exception level is using AArch32:
 - The [JMCR](#) and [JOSCR](#) are RAZ/WI.
 - The [JIDR](#) is a RAZ read-only register.
- At EL0 when EL0 is using AArch32:
 - It is IMPLEMENTATION DEFINED whether the [JMCR](#) and [JOSCR](#) are RAZ/WI or UNDEFINED.
 - It is IMPLEMENTATION DEFINED whether [JIDR](#) is RAZ or UNDEFINED.
- The [BXJ](#) instruction behaves identically to the [BX](#) instruction in all circumstances.

Note

This is consistent with the [JMCR.JE](#) bit being RAZ, and means that the T32 and A32 instruction sets do not provide any mechanism for attempting to enter Jazelle state.

- Jazelle state, as defined in previous versions of the Arm architecture, is an unimplemented instruction set state.

These requirements ensure that operating systems that support an EJVM execute correctly.

A trivial implementation is not required to extend the PC to 32 bits, that is, it can implement PC[0] as RAZ/WI.

Note

This is because the only way that PC[0] is visible in A32 or T32 state is as a result of an exception occurring during Jazelle state execution, and Jazelle state execution cannot occur on a trivial implementation.

D1.11 Handling exceptions

An exception causes the PE to suspend program execution to handle an event, such as an externally generated interrupt or an attempt to execute an undefined instruction. Exceptions can be generated by internal and external sources.

Normally, when an exception is taken the PE state is preserved immediately, before handling the exception. This means that, when the event has been handled, the original state can be restored and program execution resumed from the point where the exception was taken.

More than one exception might be generated at the same time, and a new exception can be generated while the PE is handling an exception.

The following sections describe exception handling:

- [Exception vectors and the exception base address.](#)
- [Exception prioritization for exceptions taken to AArch32 state.](#)
- [Overview of exception entry.](#)
- [PE mode for taking exceptions.](#)
- [PE state on exception entry.](#)
- [Routing exceptions from EL0 to EL2.](#)
- [Routing debug exceptions to EL2 using AArch32.](#)

See also:

- [Routing of aborts taken to AArch32 state.](#)
- [Exception return to an Exception level using AArch32.](#)
- [Asynchronous exception behavior for exceptions taken from AArch32 state.](#)
- [AArch32 state exception descriptions.](#)

D1.11.1 Exception vectors and the exception base address

When an exception is taken, PE execution is forced to an address that corresponds to the type of exception. This address is called the *exception vector* for that exception. The vectors for the different types of exception form a *vector table*.

A set of exception vectors for an Exception level that is using AArch32 comprises eight consecutive word-aligned memory addresses, starting at an *exception base address*. These eight vectors form an AArch32 *vector table*.

The number of possible exception base addresses, and therefore the number of vector tables, depends on the implemented Exception levels, as follows:

EL1 vector tables

An implementation must include the following AArch32 vector table:

- An exception table for exceptions taken to EL1 modes other than System mode. This is the EL1 vector table, and is in the address space of the PL1&0 translation regime.

Note

Exceptions cannot be taken to System mode.

EL2 vector tables

An implementation that must include the following additional AArch32 vector table if EL2:

- An exception table for exceptions taken to Hyp mode. This is the Hyp vector table, and is in the address space of the PL2 translation regime.
For this vector table, [HVBAR](#) holds the exception base address.

The following subsections give more information:

- [The vector tables and exception offsets.](#)
- [Pseudocode determination of the exception base address.](#)

D1.11.1.1 The vector tables and exception offsets

Table D1-4 defines the AArch32 vector table entries. The *Hyp* column defines the vector table entries for exceptions taken to Hyp mode.

Exceptions cannot be taken to System mode or User mode.

For more information about determining the mode to which an exception is taken, see [PE mode for taking exceptions](#).

When EL2 is using AArch32, it provides a number of additional exceptions, some of which are not shown explicitly in the vector tables. For more information, see [Offsets of AArch32 exceptions provided by EL2](#).

Table D1-4 The AArch32 vector tables

Offset	Vector tables	
	EL2/Hyp	EL1
0x00	Not used	Not used
0x04	Undefined Instruction, from Hyp mode	Undefined Instruction
0x08	Hypervisor Call, from Hyp mode	Supervisor Call
0x0C	Prefetch Abort, from Hyp mode	Prefetch Abort
0x10	Data Abort, from Hyp mode	Data Abort
0x14	Hyp Trap, or Hyp mode entry ^a	Not used
0x18	IRQ interrupt	IRQ interrupt
0x1C	FIQ interrupt	FIQ interrupt

a. See [Use of offset 0x14 in the Hyp vector table](#).

Table D1-5 Modes for taking the exceptions shown in the vector table

Exception	Mode taken to
Undefined Instruction	Undefined
Supervisor Call	Supervisor
Prefetch Abort	Abort
Data Abort	Abort
IRQ interrupt	IRQ
FIQ interrupt	FIQ

For more information about use of the vector tables, see [Overview of exception entry](#).

D1.11.1.1.1 Offsets of AArch32 exceptions provided by EL2

EL2 provides the following exceptions. When EL2 is using AArch32, these exceptions are taken to Hyp mode, and the PE enters the handlers for these exceptions using the following vector table entries shown in [Table D1-4](#):

Hypervisor Call

If taken from Hyp mode, shown explicitly in the Hyp mode vector table. Otherwise, see [Use of offset 0x14 in the Hyp vector table](#).

Hyp Trap

Shown explicitly in the Hyp mode vector table.

Virtual Abort Entered through the Data Abort vector in the vector table.

Virtual IRQ Entered through the IRQ vector in the vector table.

Virtual FIQ Entered through the FIQ vector in the vector table.

Note

[Virtual exceptions when an implementation includes EL2](#) gives more information about the virtual exceptions.

D1.11.1.1.2 Use of offset 0×14 in the Hyp vector table

The vector at offset 0×14 in the Hyp vector table is used for all exceptions that cause entry to Hyp mode from EL0 and EL1, except for IRQ and FIQ exceptions.

Note

Virtual exceptions are never taken to Hyp mode.

D1.11.1.1.3 Pseudocode determination of the exception base address

For an exception taken to a PL1 mode, the `ExcVectorBase()` function determines the exception base address.

The `ExcVectorBase()` function is defined in [R-profile Architecture Pseudocode](#).

Note

The PL1 modes to which exceptions can be taken are Supervisor mode, Undefined mode, Abort mode, IRQ mode, and FIQ mode.

D1.11.2 Exception prioritization for exceptions taken to AArch32 state

The following sections describe the requirements for the prioritization of synchronous exceptions, and the limits on when asynchronous exceptions can be taken:

- [Synchronous exception prioritization for exceptions taken to AArch32 state](#).
- [Architectural requirements for taking asynchronous exceptions](#).

See also:

- [Debug state entry and debug event prioritization](#) for information about the relative prioritization of exceptions and the debug events that cause entry to Debug state.

D1.11.2.1 Synchronous exception prioritization for exceptions taken to AArch32 state

In principle, any single instruction can generate a number of different synchronous exceptions, between the fetching of the instruction, its decode, and eventual execution. This section describes the prioritization of such exceptions when they are taken to an Exception level that is using AArch32.

Exceptions are prioritized as follows, where 1 is the highest priority.

1-5 These priority numbers are used by AArch64 exceptions or debug events.

6 PC alignment fault exceptions. A PC alignment fault exception can only be taken to an Exception level that is using AArch32 as a result of:

- The CONSTRAINED UNPREDICTABLE handling of a branch to an unaligned address, see [Branching to an unaligned PC](#).
- Exiting from Debug state to AArch32 specifying an unaligned PC value, see [Exiting Debug state](#).

A PC alignment fault exception that is taken to an Exception level that is using AArch32 is reported as a Prefetch Abort exception, see [Prefetch Abort exception reporting a PC alignment fault exception](#).

- 7 Illegal Execution state exceptions. It is IMPLEMENTATION DEFINED whether this is prioritized here or at 12. See [The Illegal Execution state exception](#).
- 8 Prefetch Abort exceptions, that are not covered by priorities 9 or 11. See [Prefetch Abort exception](#) and [AArch32 state prioritization of synchronous aborts from a single stage of address translation](#).
- 9 If prioritized here, Prefetch Abort exceptions due to Synchronous External abort, not on translation table walk or hardware update of translation table.
- 10 Breakpoint exceptions or Address Matching Vector Catch exceptions. See:
 - [Breakpoint exceptions](#).
 - [Vector Catch exceptions](#).

Note

An Exception Trapping Vector Catch exception is generated on exception entry for an exception that has been prioritized as described in this section. This means that it does not have its own entry in this list.

- 11 The exceptions listed for priority 9, if they are prioritized as 11.
- 12 Illegal Execution state exceptions. It is IMPLEMENTATION DEFINED whether this is prioritized here or at 7. See [The Illegal Execution state exception](#).
- 13 This priority number is used by an AArch64 exception.
- 14 Software Breakpoint Exceptions caused by the execution of a BKPT Exception generating instruction.
- 15-18 These priority numbers are used by AArch64 exceptions.
- 19 Exceptions taken from EL1 to EL2 because of one of the following configuration settings:
 - [HSTR.Tn](#).
 - [HCR.TIDCP](#).
- 20 UNDEFINED Instruction exceptions that occur as a result of one or more of the following:
 - An attempt to execute an unallocated instruction encoding, including an encoding for an instruction that is not implemented in the PE implementation.
 - An attempt to execute an instruction that is defined never to be accessible at the current Exception level regardless of any enables or traps.
 - Debug state execution of an instruction encoding that is not accessible in Debug state.
 - Non-debug state execution of an instruction encoding that is not accessible in Non-debug state.
 - Execution of an HVC instruction when HVC instructions are disabled by [HCR.HCD](#).
 - Execution of an HLT instruction when HLT instructions are disabled by [EDSCR.HDE](#) or when halting is prohibited.
 - In Debug state:
 - Execution of a DCPS1 instruction in EL0 when [HCR.TGE](#) is 1.
 - Execution of a DCPS2 instruction in EL1 or EL0.
 - Execution of a DCPS3 instruction.
 - Execution of an instruction that is UNDEFINED as a result of any of:
 - Being in an IT block when [SCTLR.ITD](#) is 1, or when [HSCTLR.ITD](#) is 1.
 - Executing a SETEND instruction when [SCTLR.SED](#) is 1, or when [HSCTLR.SED](#) is 1.
 - Executing a CP15DMB, CP15DSB, or CP15ISB barrier instruction when [SCTLR.CP15BEN](#) is 0, or when [HSCTLR.CP15BEN](#) is 0.
 - Execution of an instruction that is UNDEFINED because at least one of [FPSCR](#).{Stride, Len} is nonzero, when programming these bits to nonzero values is supported. See [Floating-point exceptions and exception traps](#).
- 21 Reserved.
- 22 Exceptions taken to EL1, or taken to EL2 because the value of [HCR.TGE](#) is 1, that are generated because of configurable access to instructions, and that are not covered by any of priorities 6-20.

23	Exceptions taken from EL0 to EL2 because of one of the following configuration settings: • HSTR.Tn. • HCR.TIDCP.
24	Reserved.
25	Exceptions taken to EL2 because of configuration settings in the HCPTR .
26	Exceptions taken to EL2 because of one of the following configuration settings: • Any setting in HCR, other than the TIDCP bit. • Any setting in CNTHCTL. • Any setting in HDCR.
27	Exceptions taken to EL2 because of configurable access to instructions, and that are not covered by any of priorities 6-26.
28	Exceptions caused by the SMC instruction being UNDEFINED.
29	Exceptions caused by the execution of an Exception generating instruction, SVC, HVC, or SMC.
30-34	Reserved.
35-39	Reserved.
40	Trapped floating-point exceptions, if supported. See Floating-point exceptions and exception traps .
41-44	These priority numbers are used by debug events.
45	In descending priority order: a) Data Abort exceptions on address translations and memory protection region updates. b) Data Abort exceptions due to synchronous External aborts on address translations and memory protection region updates. c) Data Abort exceptions arising from an MPU fault not on a translation, that are not covered by priorities 46 or 48. See Data Abort exception and AArch32 state prioritization of synchronous aborts from a single stage of address translation.
46	Data Abort exceptions due to synchronous External aborts on the final physical address of the address translation process.
	Whether these are prioritized here or as priority 48 is IMPLEMENTATION DEFINED.
	See External aborts .
47	Watchpoint exceptions. See Watchpoint exceptions .
48	The exceptions listed for priority 46 if they are prioritized as 48.
49	Reserved.

For priorities 45-48, if an instruction results in more than one single-copy atomic memory access, the prioritization between synchronous exceptions generated on each of those different memory accesses is not defined by the architecture.

D1.11.2.2 Architectural requirements for taking asynchronous exceptions

The Arm architecture does not define when asynchronous exceptions are taken. The prioritization of asynchronous exceptions, including virtual asynchronous exceptions, is IMPLEMENTATION DEFINED.

An asynchronous exception that is pending before a [Context Synchronization event](#) in the following list, is taken before the first instruction after the context synchronization event, provided that the pending asynchronous event is not masked:

- Execution of an `ISB` instruction that does not fail its Condition code check.
- Exception entry.
- Exception return.
- Exit from Debug state.

Note

- If the first instruction after the context synchronization event generates a synchronous exception, then the architecture does not define the order in which that synchronous exception and the asynchronous exception are taken.
 - The `ISR` identifies any pending asynchronous exceptions.
 - Interrupts are masked when the PE is in Debug state, and therefore this list of context synchronization events does not include the `DCPS` and `DRPS` instructions.
-

In the absence of a specific requirement to take an asynchronous exception, the only requirement of the architecture is that an unmasked asynchronous exception is taken in finite time.

Note

The taking of an unmasked asynchronous exception in finite time must occur with all code sequences, including with a sequence that consists of unconditional loops.

If an unmasked interrupt was pending but is changed to not pending before it is taken, then the architecture permits the interrupt to be taken, but does not require this to happen. If the interrupt is taken, then it must be taken before the first [Context Synchronization event](#) after the interrupt was changed to not pending.

`PSTATE` includes a mask bit for each type of asynchronous exception. Setting one of these bits to 1 can prevent the corresponding asynchronous exception from being taken, although other controls can modify the effect of these bits. For more information, see [Asynchronous exception behavior for exceptions taken from AArch32 state](#).

Taking an exception sets an exception-dependent subset of these mask bits.

Note

In some contexts, the `PSTATE.{A, I, F}` bits mask the taking of asynchronous exceptions. The way these are set on exception entry, described in [PSTATE.{A, I, F, M} values on exception entry](#), can prevent an exception handler being interrupted by an asynchronous exception.

D1.11.3 Overview of exception entry

There are some significant differences between the handling of exceptions taken to Hyp mode and exceptions taken to other modes. Because Hyp mode is the EL2 mode, this means that the following descriptions sometimes distinguish between the *EL2 mode* and the *non-EL2 modes*.

On taking an exception to an Exception level that is using AArch32:

1. The hardware determines the mode to which the exception must be taken, see [PE mode for taking exceptions](#).
2. A link value, indicating the *preferred return address* for the exception, is saved. This is a possible return address for the exception handler, and depends on:
 - The exception type.
 - Whether the exception is taken to the EL2 mode or to a non-EL2 mode.
 - For some exceptions taken to non-EL2 modes, the instruction set state when the exception was taken.

Where the link value is saved depends on whether the exception is taken to the EL2 mode.

For more information, see [Link values saved on exception entry](#).

3. The value of `PSTATE` is saved in the `SPSR` for the mode to which the exception must be taken. The value saved in `SPSR.IT[7:0]` is always correct for the preferred return address.
4. `PSTATE` is updated with new context information for the exception handler. This includes:
 - Setting `PSTATE.M` to the PE mode to which the exception is taken.

- Setting the appropriate [PSTATE](#) mask bits. This can disable the corresponding exceptions, preventing uncontrolled nesting of exception handlers.
- Setting the instruction set state to the state required for exception entry.
- Setting the endianness to the required value for exception entry.
- Clearing the [PSTATE.IT\[7:0\]](#) bits to 0.

For more information, see [PE state on exception entry](#).

5. The appropriate exception vector is loaded into the PC, see [Exception vectors and the exception base address](#).
6. Execution continues from the address held in the PC.

For an exception taken to a non-EL2 mode, on exception entry, the exception handler can use the [SRS](#) instruction to store the return state onto the stack of any mode at the same Exception level and in the same Security state, and can use the [CPS](#) instruction to change mode. For more information about the instructions, see [SRS](#), [SRSDA](#), [SRSDB](#), [SRSIA](#), [SRSIB](#) and [CPS](#), [CPSID](#), [CPSIE](#).

Later sections of this chapter describe each of the possible exceptions, and each of these descriptions includes a pseudocode description of the PE state changes on taking that exception. [Table D1-6](#) gives an index to these descriptions:

Table D1-6 Pseudocode descriptions of exception entry for exceptions taken to AArch32 state

Exception	Description of exception entry
Reset	Pseudocode descriptions of reset
Undefined Instruction	Pseudocode description of taking the Undefined Instruction exception
Hyp Trap	Pseudocode description of taking the Hyp Trap exception
Supervisor Call	Pseudocode description of taking the Supervisor Call exception
Hypervisor Call	Pseudocode description of taking the Hypervisor Call exception
Prefetch Abort	Pseudocode description of taking the Prefetch Abort exception
Data Abort	Pseudocode description of taking the Data Abort exception
Virtual Abort	Pseudocode description of taking the Virtual SError interrupt exception
IRQ	Pseudocode description of taking the physical IRQ exception
Virtual IRQ	Pseudocode description of taking the Virtual IRQ exception
FIQ	Pseudocode description of taking the FIQ exception
Virtual FIQ	Pseudocode description of taking the Virtual FIQ exception

The following sections give more information about the PE state changes, for different architecture implementations. However, you must refer to the pseudocode for a full description of the state changes:

- [PE mode for taking exceptions](#).
- [PE state on exception entry](#).

D1.11.3.1 Link values saved on exception entry

On exception entry, a link value for use on return from the exception, is saved. This link value is based on the *preferred return address for the exception*, as shown in [Table D1-7](#):

Table D1-7 Exception return addresses for exceptions taken to AArch32 state

Exception	Preferred return address	Taken to a mode at
Undefined Instruction	Address of the UNDEFINED instruction	EL1 or EL2
Hyp Trap	Address of the trapped instruction	EL2 only
Supervisor Call	Address of the instruction after the SVC instruction	EL1 or EL2
Hypervisor Call	Address of the instruction after the HVC instruction	EL2 only
Prefetch Abort	Address of aborted instruction fetch	EL1 or EL2
Data Abort	Address of instruction that generated the abort	EL1 or EL2
Virtual Abort	Address of next instruction to execute	EL1
IRQ or FIQ	Address of next instruction to execute	EL1 or EL2
Virtual IRQ or Virtual FIQ	Address of next instruction to execute	EL1

———— **Note** ————

- Although Reset is described as an exception, it differs significantly from other exceptions. The architecture has no concept of a return from a Reset and therefore it is not listed in this section.
- For each exception, the preferred return address is not affected by the Exception level from which the exception was taken.

The link value saved, and where it is saved, depend on whether the exception is taken to a non-EL2 mode, or to an EL2 mode, as follows:

Exception taken to a non-EL2 mode

The link value is saved in the LR for the mode to which the exception is taken.

The saved link value is the preferred return address for the exception, plus an offset that depends on the instruction set state when the exception was taken, as [Table D1-8](#) shows:

Table D1-8 Offsets applied to Link value for exceptions taken to non-EL2 modes

Exception	Offset, for PE state of:	
	A32	T32
Undefined Instruction	+4	+2
Supervisor Call	None	None
Prefetch Abort	+4	+4
Data Abort	+8	+8
Virtual Abort	+8	+8
IRQ or FIQ	+4	+4
Virtual IRQ or Virtual FIQ	+4	+4

Exception taken to an EL2 mode

The link value is saved in the [ELR_hyp](#) Special-purpose register.

The saved link value is the preferred return address for the exception, as shown in [Table D1-7](#), with no offset.

D1.11.4 PE mode for taking exceptions

The following principles determine the Exception level to which an exception is taken, and if that Exception level is using AArch32, the PE mode to which the exception is taken:

- An exception cannot be taken to the EL0 mode.
- An exception is taken either:
 - To the Exception level at which the PE was executing when it took the exception.
 - To a higher Exception level.
- Configuration options and other features provided by EL2 can determine the mode to which some exceptions are taken, as follows:
 - If the exception is taken from Hyp mode, it is taken to Hyp mode.
 - Otherwise, the exception is either taken to Hyp mode, as described in [Exceptions taken to Hyp mode](#), or taken to the default mode for the exception.

[Table D1-5](#) shows the default mode to which each exception is taken.

[Asynchronous exception routing controls](#) describes the exception routing controls provided by EL2.

[Routing of aborts taken to AArch32 state](#) gives more information about the modes to which memory aborts are taken.

D1.11.4.1 Exceptions taken to Hyp mode

The following exceptions are taken to EL2:

- Any exception taken from Hyp mode is taken to Hyp mode.
- The following exceptions are taken to Hyp mode:
 - An abort that [Routing of aborts taken to AArch32 state](#) identifies as taken to Hyp mode.
 - A Hyp Trap exception, see [EL2 configurable controls](#).
 - A Hypervisor Call exception. This is generated by executing an HVC instruction.
 - An SError exception, IRQ exception or FIQ exception that is routed to Hyp mode, as described in [Asynchronous exception routing controls](#).
 - A synchronous External abort, Alignment fault, Undefined Instruction exception, or Supervisor Call exception taken from the EL0 mode and explicitly routed to Hyp mode, as described in [Routing exceptions from EL0 to EL2](#).
 - A debug exception that is explicitly routed to Hyp mode, as described in [Routing debug exceptions to EL2 using AArch32](#).

Note

The virtual exceptions cannot be taken to Hyp mode. They are always taken to an EL1 mode.

D1.11.4.2 The possible modes for taking each exception

Each of the exception descriptions in [AArch32 state exception descriptions](#) includes a subsection that describes the modes to which each exception can be taken. Those subsections are:

- [The PE mode to which the Undefined Instruction exception is taken.](#)
- [The PE mode to which the Hyp Trap exception is taken.](#)
- [The PE mode to which the Supervisor Call exception is taken.](#)
- [The PE mode to which the Hypervisor Call exception is taken.](#)
- [The PE mode to which the Prefetch Abort exception is taken.](#)
- [The PE mode to which the Data Abort exception is taken.](#)
- [The PE mode to which the Virtual SError interrupt exception is taken.](#)
- [The PE mode to which the physical IRQ exception is taken.](#)
- [The PE mode to which the Virtual IRQ exception is taken.](#)
- [The PE mode to which the physical FIQ exception is taken.](#)

- The PE mode to which the Virtual FIQ exception is taken.

These descriptions also show the vector offset for the exception entry for each mode.

For more information about:

- Vector offsets, see [Exception vectors and the exception base address](#).
- The routing of synchronous External aborts or SError, IRQ, and FIQ interrupt exceptions, and the virtual exceptions, see [Asynchronous exception routing controls](#).

D1.11.4.2.1 UNPREDICTABLE cases when the value of HCR.TGE is 1

When the value of HCR.TGE is 1, exceptions that would otherwise be taken to EL1 are, instead, routed to EL2, see [Routing exceptions from EL0 to EL2](#). Related to this, when the value of HCR.TGE is 1, execution in an EL1 mode is UNPREDICTABLE. The architecture does not constrain this UNPREDICTABLE behavior, but software that follows the Arm recommendations cannot get to this state. When following the Arm recommendations, any attempt to move to an EL1 mode when the value of HCR.TGE is 1 is either:

- An illegal exception return, see [Illegal return events from AArch32 state](#).
- An illegal PE mode change, see [Illegal changes to PSTATE.M](#).

D1.11.5 PE state on exception entry

The description of each exception includes a pseudocode description of entry to that exception, as [Table D1-6](#) shows. The following sections describe the PE state changes on entering an exception, for different implementations and operating states. However, you must always see the exception entry pseudocode for a full description of the state changes on exception entry:

- [Instruction set state on exception entry](#).
- [PSTATE.E value on exception entry](#).
- [PSTATE.{A, I, F, M} values on exception entry](#).

D1.11.5.1 Instruction set state on exception entry

Exception handlers can execute in either T32 state or A32 state. On exception entry, PSTATE.T is set to the required value, as determined by SCTLR.TE or HSCTLR.TE, depending on the mode the exception is taken to. [Table D1-9](#) shows this:

Table D1-9 PSTATE.T bit value on exception entry

Mode to which exception is taken	HSCTLR.TE	SCTLR.TE	PSTATE.T	Exception handler state
Not Hyp mode	x	0	0	A32
		1	1	T32
Hyp mode	0	x	0	A32
	1	x	1	T32

For an exception taken to a PE mode other than Hyp mode, the SCTLR.TE bit determines the instruction set state for the exception handler.

D1.11.5.2 PSTATE.E value on exception entry

PSTATE.E controls the load and store endianness for data handling. Table D1-10 show the value to which this bit is set on exception entry:

Table D1-10 PSTATE.E value on exception entry

Exception mode	HSCTLR.EE	SCTLR.EE	Endianness for data loads and stores	PSTATE.E
EL1	x	0	Little-endian	0
		1	Big-endian	1
Hyp	0	x	Little-endian	0
	1	x	Big-endian	1

For more information, see the bit description in [Saved Program Status Registers \(SPSRs\)](#).

D1.11.5.3 PSTATE.{A, I, F, M} values on exception entry

On exception entry, PSTATE.M is set to the value for the mode to which the exception is taken, as described in [PE mode for taking exceptions](#).

Table D1-11 shows the cases where PSTATE.{A, I, F} bits are set to 1 on an exception entry, and how this depends on the mode and Security state to which an exception is taken. If the table entry for a particular mode and Security state does not define a value for a PSTATE.{A, I, F} bit then that bit is unchanged by the exception entry.

In this table, the *PE mode exception is taken to* column is the mode to which the exception is taken.

Table D1-11 PSTATE.{A, I, F} values on exception entry

PE mode exception is taken to	
Hyp	PSTATE.A is set to 1 PSTATE.I is set to 1 PSTATE.F is set to 1
FIQ	PSTATE.A is set to 1 PSTATE.I is set to 1 PSTATE.F is set to 1
IRQ, Abort	PSTATE.A is set to 1 PSTATE.I is set to 1
Undefined, Supervisor	PSTATE.I is set to 1

[Asynchronous exception behavior for exceptions taken from AArch32 state](#) describes how, in some situations, the PSTATE.{A, I, F} bits mask the taking of SError exceptions, IRQ interrupts, and FIQ interrupts.

D1.11.6 Routing exceptions from EL0 to EL2

Note

The routing control described in this section permits a usage model where applications execute in User mode under a hypervisor, which executes in Hyp mode, without a Guest RTOS running at EL1. This control applies when the PE is executing in EL0 and the value of HCR.TGE is 1.

If the PE is in User mode, any exception that would otherwise be taken to EL1 is taken to EL2 if the value of [HCR.TGE](#) is 1.

In this case the exception is taken to Hyp mode, instead of to the default mode for handling the exception. For more information, see [Exception reporting when HCR.TGE routes an exception to EL2 using AArch32](#).

When the value of [HCR.TGE](#) is 1, meaning TGE routing from EL0 using AArch32 to EL2 using AArch32 applies:

- The [SCTLR.M](#) bit is treated as 0 for all purposes other than a direct read of the [SCTLR](#) register.
- Each of the [HCR](#).{FMO, IMO, AMO} bits is treated as 1 for all purposes other than a direct read of the [HCR](#) register.
- Each of the [HDCR](#).{TDE, TDA, TDRA, TDOSA} bits is treated as 1 for all purposes other than a direct read of the [HDCR](#) register.
- An exception return to EL1 is treated as an illegal exception return, see [Illegal return events from AArch32 state](#).
- All virtual interrupts, including any IMPLEMENTATION DEFINED mechanisms for signaling virtual interrupts, are disabled.

D1.11.6.1 Exception reporting when HCR.TGE routes an exception to EL2 using AArch32

The following sections give more information about the behavior of synchronous exceptions that are routed to Hyp mode because the value of [HCR.TGE](#) is 1:

- [Undefined Instruction exception, when the value of HCR.TGE is 1](#).
- [Supervisor Call exception, when the value of HCR.TGE is 1](#).
- [Abort exceptions, when the value of HCR.TGE is 1](#).
- [Reporting of exceptions routed to EL2 using AArch32 because the value of HCR.TGE is 1](#).

D1.11.6.1.1 Undefined Instruction exception, when the value of HCR.TGE is 1

When [HCR.TGE](#) is set to 1, if the PE is executing in User mode and attempts to execute an UNDEFINED instruction, it takes the Hyp Trap exception, instead of an Undefined Instruction exception. On taking the Hyp Trap exception, the [HSR](#) reports an unknown reason for the exception, using the EC value 0x00. For more information, see [Use of the HSR](#).

D1.11.6.1.2 Supervisor Call exception, when the value of HCR.TGE is 1

When [HCR.TGE](#) is set to 1, if the PE executes an SVC instruction in User mode, the Supervisor Call exception generated by the instruction is taken to Hyp mode.

The [HSR](#) reports that entry to Hyp mode was because of a Supervisor Call exception, and:

- If the SVC is unconditional, takes for the `imm16` value in the [HSR](#):
 - A zero-extended 8-bit immediate value for the T32 SVC instruction.

Note

The only T32 encoding for SVC is a 16-bit instruction encoding.

 - The bottom16 bits of the immediate value for the A32 SVC instruction.
- If the SVC is conditional, the `imm16` value in the [HSR](#) is UNKNOWN.

If the SVC is conditional, the PE takes the exception only if the instruction passes its Condition code check.

The [HSR](#) reports the exception as a Supervisor Call exception taken to Hyp mode, using the EC value 0x11. For more information, see [Use of the HSR](#).

Note

The effect of setting [HCR.TGE](#) to 1 is to route the Supervisor Call exception to Hyp mode, not to trap the execution of the SVC instruction. This means that the preferred return address for the exception, when routed to Hyp mode in this way, is the instruction after the SVC instruction.

D1.11.6.1.3 Abort exceptions, when the value of HCR.TGE is 1

When the value of [HCR.TGE](#) is 1, if the PE is executing in User mode then any abort exception generates an exception that is taken as a Hyp Trap exception. Where an attempt to execute an instruction causes an abort, on taking the Hyp Trap exception, the [HSR](#) indicates whether a Data Abort exception or a Prefetch Abort exception caused the Hyp Trap exception entry, and presents a valid syndrome in the [HSR](#).

An Error exception that is routed to Hyp mode because the value of [HCR.TGE](#) is 1 is reported as a Data Abort exception routed to Hyp mode.

The [HSR](#) reports the exception either:

- As a Prefetch Abort exception routed to Hyp mode, using the EC value `0x20`.
- As a Data Abort exception routed to Hyp mode, using the EC value `0x24`.

For more information about the exception reporting, see [Use of the HSR](#).

D1.11.6.1.4 Reporting of exceptions routed to EL2 using AArch32 because the value of HCR.TGE is 1

[PL1 configurable controls](#) describes controls that, when the value of [HCR.TGE](#) is 0, can generate exceptions that are taken from EL0 to EL1. When EL2 is using AArch32 and the value of [HCR.TGE](#) is 1, the exceptions generated by these controls are routed to Hyp mode. [Table D1-12](#) shows how these exceptions are then reported in the [HSR](#).

Table D1-12 Syndrome reporting in HSR from HCR.TGE routing of traps, disables, and enables

Control provided by PL1	Control type ^a	Syndrome reporting in HSR
SCTLR .{nTWE, nTWI}	T	Uses EC syndrome value <code>0x00</code> , Exception for an unknown reason
SCTLR .{SED, ITD}	D	Uses EC syndrome value <code>0x00</code> , Exception for an unknown reason
SCTLR .CP15BEN	E	Uses EC syndrome value <code>0x00</code> , Exception for an unknown reason
CPACR .TRCDIS	T	Uses EC syndrome value <code>0x00</code> , Exception for an unknown reason
CPACR .{cp11, cp10}	E	Uses EC syndrome value <code>0x00</code> , Exception for an unknown reason
FPEXC .EN	E	Uses EC syndrome value <code>0x00</code> , Exception for an unknown reason
CPACR .ASEDIS	D	Uses EC syndrome value <code>0x00</code> , Exception for an unknown reason
DBGDSCR ext.UDCCdis	T	Uses EC syndrome value <code>0x00</code> , Exception for an unknown reason
CNTKCTL .{PL0PTEN, PL0VTEN, PL0PCTEN, PL0VCTEN}	T	Uses EC syndrome value <code>0x00</code> , Exception for an unknown reason
PMUSERENR .{ER, CR, SW, EN}	T	Uses EC syndrome value <code>0x00</code> , Exception for an unknown reason

a. T indicates a trap control, E indicates an instruction enable, and D indicates an instruction disable. For the definition of these terms, see the list that begins with [Instruction enables and instruction disables](#).

D1.11.7 Routing debug exceptions to EL2 using AArch32

When the value of [HDCR.TDE](#) is 1, if the PE is executing in a mode other than Hyp mode, any Debug exception is routed to Hyp mode. This means it generates a Hyp Trap exception. This applies to:

- Debug exceptions associated with an instruction fetch, that would otherwise generate a Prefetch Abort exception. These are the Breakpoint, Breakpoint Instruction, and Vector Catch exception, see [AArch32 Self-hosted Debug](#).
- Watchpoint exceptions associated with data accesses, that would otherwise generate a Data Abort exception. See [Watchpoint exceptions](#).

When the value of [HDCR.TDE](#) is 1, each of the [HDCR](#).{TDRA, TDOSA, TDA} bits is treated as 1 for all purposes other than reading the [HDCR](#) register.

Note

- A Breakpoint or Watchpoint debug event that generates entry to Debug state cannot be trapped to Hyp mode. See [Breakpoint and Watchpoint debug events](#).
 - When [HDCR.TDE](#) is set to 1, the Hyp Trap exception is generated instead of the Prefetch Abort exception or Data Abort exception that is otherwise generated by the Debug exception.
 - Debug exceptions, other than Breakpoint Instruction exceptions, are never generated in Hyp mode.
-

When a Hyp Trap exception is generated because the value of [HDCR.TDE](#) is 1, The [HSR](#) reports the exception either:

- As a Prefetch Abort exception routed to Hyp mode, using the EC value `0x20`.
- As a Data Abort exception routed to Hyp mode, using the EC value `0x24`.

For more information, see [Use of the HSR](#).

D1.12 Routing of aborts

A memory abort is either a Data Abort exception or a Prefetch Abort exception. When executing, depending on the cause of the abort, and possibly on configuration settings, an abort is taken either:

- To the Exception level of the PE mode from which the abort is taken. In this case the abort is taken to AArch32 state.
- To a higher Exception level.

The mode to which a memory abort is taken depends on the reason for the exception, the mode the PE is in when it takes the exception, and configuration settings, as follows:

Memory aborts taken to Hyp mode

The following aborts are taken to EL2. This means they are taken to Hyp mode:

- Alignment faults taken:
 - When the PE is in Hyp mode.
 - When the PE is in a PL1 or EL0 mode and the exception is generated because the PL1&0 stage 2 translation identifies the target of an unaligned access as any type of Device memory.
 - When the PE is in User mode and [HCR.TGE](#) is set to 1. For more information, see [Abort exceptions, when the value of HCR.TGE is 1](#).
- When the PE is using the PL1&0 translation regime:
 - [MPU faults](#) from stage 2 translations, for which the stage 1 translation did not cause an MPU fault.
- When the PE is using EL2 translation regime, [MPU faults](#) from stage 1 translations.
- Debug exceptions, if [HDCR.TDE](#) is set to 1. For more information, see [Routing debug exceptions to EL2 using AArch32](#).

Memory aborts taken to Abort mode

All memory aborts that are taken to an Exception level that is using AArch32 are taken to Abort mode. The following aborts are taken to Abort mode:

- When the PE is in a PL1 or EL0 mode, Alignment faults taken for any of the following reasons:
 - [SCTLR.A](#) is set to 1.
 - An instruction that does not support unaligned accesses is committed for execution, and the instruction accesses an unaligned address.
 - The PL1&0 stage 1 translation identifies the target of an unaligned access as any type of Device memory.

These exceptions are taken to Abort mode only if the value of [HCR.TGE](#) is 0.

- When the PE is using the PL1&0 translation regime, an MPU fault from a stage 1 translation.
- External aborts, if the PE was executing in a PL1 or EL0 mode when it took the exception and the abort is not taken to EL2 for one of the reasons defined in [Memory aborts taken to Hyp mode](#).
- Virtual Aborts, see [Virtual exceptions when an implementation includes EL2](#).
- When the value of [HDCR.TDE](#) is 0, Debug exceptions. For more information, see [Routing debug exceptions to EL2 using AArch32](#).

Memory aborts with IMPLEMENTATION DEFINED behavior

In addition, a PE can generate an abort for an IMPLEMENTATION DEFINED reason associated with lockdown. Whether such an abort is taken to Abort mode or is taken to EL2 is IMPLEMENTATION DEFINED, and an implementation might include a mechanism to select whether the abort is routed to Abort mode or to EL2.

When the PE is in a mode other than Hyp mode, if multiple factors cause an Alignment fault, the abort is taken to Abort mode if any of the factors require the abort to be taken to Abort mode. For example, if the [SCTLR.A](#) bit is set to 1, and the access is an unaligned access to an address that the EL2 MPU marks as Device-nGnRnE, then the abort is taken to Abort mode.

For more information, see [Handling exceptions](#).

D1.13 Exception return to an Exception level using AArch32

In the Arm architecture, *exception return* to an Exception level that is using AArch32 requires the simultaneous restoration of the PC and **PSTATE** to values that are consistent with the desired state of execution on returning from the exception. Typically, exception return involves returning to one of:

- The instruction after the instruction boundary at which an asynchronous exception was taken.
- The instruction following an **SVC HVC** instruction, for an exception generated by one of those instructions.
- The instruction that caused the exception, after the reason for the exception has been removed.
- The subsequent instruction, if the instruction that caused the exception has been emulated in the exception handler.

The Arm architecture defines a *preferred return address* for each exception other than Reset, see [Link values saved on exception entry](#). The values of the **SPSR.IT**[7:0] bits generated on exception entry are always correct for this preferred return address, but might require adjustment by the exception handler if returning elsewhere.

In some cases, to calculate the appropriate preferred return address for a return to an Exception level that is using AArch32, a subtraction must be performed on the link value saved on taking the exception. The description of each exception includes any value that must be subtracted from the link value, and other information about the required exception return.

On an exception return, the **PSTATE** takes either:

- The value loaded by the **RFE** instruction.
- If the exception return is not performed by executing an **RFE** instruction, the value of the current **SPSR** at the time of the exception return.

[Illegal return events from AArch32 state](#) describes the behavior if the restored PE state would not be valid for the Exception level, PE mode, and Security state targeted by the exception return.

D1.13.1 Exception return instructions

The instructions that an exception handler can use to return from an exception depend on whether the exception was taken to an EL1 mode, or in an EL2 mode, see:

- [Return from an exception taken to a PE mode other than Hyp mode.](#)
- [Return from an exception taken to Hyp mode.](#)

D1.13.1.1 Return from an exception taken to a PE mode other than Hyp mode

For an exception taken to a PE mode other than Hyp mode, the Arm AArch32 architecture provides the following *exception return instructions*:

- From privileged modes other than System mode, the **ERET** instruction. After the exception return, execution resumes from the address held in the LR (R14) for the mode in which **ERET** is executed. See **ERET**.
- Data-processing instructions with the S bit set and the PC as a destination, see **MOV**, **MOVS (register)** and **SUB**, **SUBS (immediate)**.

Note

The A32 instruction set includes other instructions that can be used for an exception return, but Arm deprecates any use of those instructions.

Typically:

- A return where no subtraction is required uses **SUBS** with an operand of 0, or the equivalent **MOVS** instruction.
- A return requiring subtraction uses **SUBS** with a nonzero operand.
- The **RFE** instruction, see **RFE**, **RFEDA**, **RFEDB**, **RFEIA**, **RFEIB**. If a subtraction is required, typically it is performed before saving the LR value to memory. After the exception return, execution resumes from the address held in the memory location indicated by the base register specified by the **RFE** instruction.
- In A32 state, a form of the **LDM** instruction in which the PC is one of the registers loaded, see **LDM (exception return)**. If a subtraction is required, typically it is performed before saving the LR value to memory.

D1.13.1.2 Return from an exception taken to Hyp mode

For an exception taken to Hyp mode, the Arm architecture provides the `ERET` instruction, see `ERET`. An exception handler executing in Hyp mode must return using the `ERET` instruction.

Hyp mode is implemented only as part of EL2.

D1.13.2 Alignment of exception returns

The `T` bit of the value transferred to the `PSTATE` by an exception return controls the target instruction set of that return. The behavior of the hardware for exception returns for different values of the `T` bit is as follows:

- | | |
|---------------|---|
| T == 0 | The target instruction set state is A32 state. Bits[1:0] of the address transferred to the PC are ignored by the hardware. |
| T == 1 | The target instruction set state is T32 state: <ul style="list-style-type: none"> • Bit[0] of the address transferred to the PC is ignored by the hardware. • Bit[1] of the address transferred to the PC is part of the instruction address. |

Note

In previous versions of the Arm architecture, the `PSTATE.{J, T}` bits determined the Instruction set state. From the introduction of Armv8, `PSTATE.J` is `RES0`.

Arm deprecates any dependence on the requirements that the hardware ignores bits of the address. Arm recommends that the address transferred to the PC for an exception return is correctly aligned for the target instruction set.

After an exception entry other than Reset, the LR value has the correct alignment for the instruction set indicated by the `SPSR.T` bit. This means that if exception return instructions are used with the LR and `SPSR` values produced by such an exception entry, the only precaution software needs to take to ensure correct alignment is that any subtraction is of a multiple of four if returning to A32 state, or a multiple of two if returning to T32 state.

D1.13.3 Illegal return events from AArch32 state

Throughout this section:

- Return** In AArch32 state, refers to any of:
- Execution of any exception return instruction.
 - Execution of a `DRPS` instruction in Debug state.
 - Exit from Debug state.
- If an exception or debug return from an Exception level using AArch32 triggers an illegal exception return, then bit[1] of the PC is either:
- Zero.
 - The value of bit[1] of the return address for the exception or debug return.

The choice between these two alternatives is made by the implementation, and might differ from instance to instance of an illegal exception return.

Note

This means software must support both alternatives.

Saved process state value In AArch32 state, refers to any of:

- The value held in the `SPSR` for any exception return other than an exception return made by executing an `RFE` instruction.
- The value read from memory that is to be restored to `PSTATE` by the execution of an `RFE` instruction.
- The value held in the `SPSR` for the execution of a `DRPS` instruction in Debug state.

- The value held in the [DPSR](#) for a Debug state exit.

Link address In AArch32 state, refers to any of:

- The address held in the link register for any exception return other than an exception return made by executing an `ERET`, `LDM`, or `RFE` instruction.
- The address held in [ELR_hyp](#) for any exception return made by executing an `ERET` instruction.
- The address read from memory that is to be restored to the PC by the execution of an `LDM` or `RFE` instruction.
- The address held in the [DLR](#) for Debug state exit.

Configured from reset

Indicates the state determined on powerup or reset by a configuration input signal, or by another IMPLEMENTATION DEFINED mechanism.

The architecture has a generic mechanism for handling exception or debug returns to a mode or state that is illegal. In AArch32 state, this can occur as a result of any of the following situations:

- A return where the Exception level being returned to is higher than the current Exception level.
- A return to EL1 when the value of the [HCR.TGE](#) bit is 1.
- A return where the value of the saved process state `M[4:0]` field is not a valid AArch32 PE mode for the implementation. [Table D1-3](#) shows the valid `M[4:0]` values for AArch32 PE modes.

In these cases:

- [PSTATE.IL](#) is set to 1, to indicate an illegal return.
- [PSTATE.M](#) is unchanged. This means the PE mode does not change.
- The SS bit is handled in the same way as any other exception or debug return, see Software Step exceptions.
- The following [PSTATE](#) bits are restored from the saved process state value:
 - The N, Z, C, V Condition flags.
 - The Q Overflow or saturation flag.
 - The GE Greater than or Equal flags.
 - The E Endianness mapping bit.
 - The A, I, F exception mask bits.
- The [PSTATE.{IT, T}](#) bits are each either:
 - Set to 0.
 - Copied from the saved process state in the `SPSR` for the PE mode in which the exception is handled.

The choice between these two options is determined by an implementation, and might vary dynamically within an implementation. Correspondingly software must regard the value as being an UNKNOWN choice between the two values.
- The PC is restored from the link address, unless the illegal return is the execution of a `DRPS` instruction in Debug state.

When the value of the [PSTATE.IL](#) bit is 1, any attempt to execute any instruction results in an Illegal Execution state exception. See [The Illegal Execution state exception](#).

All aspects of the illegal return, other than the effects described in this section, are the same as for a legal return.

D1.13.4 Legal returns that set [PSTATE.IL](#) to 1

In this section, return, saved process state value, and link address have the meaning that is defined in [Illegal return events from AArch32 state](#).

If the IL bit in the saved process state value is 1, then it is copied to [PSTATE](#) meaning that [PSTATE.IL](#) is set to 1. In this case, the [PSTATE.{IT, T}](#) bits are each either:

- Set to 0.

- Copied from the SPSR, or loaded from memory if the exception return was performed by executing an RFE instruction.

The choice between these two options is determined by an implementation, and might vary dynamically within the implementation. This means software must regard each value as being an UNKNOWN choice between the two permitted values.

Because the return sets the [PSTATE.IL](#) bit to 1, any attempt to execute any instruction results in an Illegal Execution state exception. See [The Illegal Execution state exception](#).

D1.13.5 The Illegal Execution state exception

When the value of the [PSTATE.IL](#) bit is 1, any attempt to execute an instruction generates an Illegal Execution state exception. In AArch32 state, the [PSTATE.IL](#) bit can be set to 1 by one of the following:

- An illegal return, as described in [Illegal return events from AArch32 state](#).
- An illegal change to [PSTATE.M](#), as described in [Illegal changes to PSTATE.M](#).
- A legal return that sets [PSTATE.IL](#) to 1, as described in [Legal returns that set PSTATE.IL to 1](#).

An Illegal Execution state exception is taken in the same way as an Undefined Instruction exception in the current Exception level. If the current Exception level is EL2 using AArch32 state, the [HSR](#) provides additional syndrome information for the exception, see [Use of the HSR](#).

An Illegal Execution state exception has priority over any other Undefined Instruction exception that might arise from instruction execution.

Note

This section only describes the handling of an Illegal Execution state exception that is taken to an Exception level that is using AArch32 state.

On taking any exception to an Exception level that is using AArch32 state:

1. The value of the [PSTATE.IL](#) bit is 1 and this is copied to the SPSR.IL bit for the PE mode to which the exception is taken.
2. The [PSTATE.IL](#) bit is cleared to 0.

Note

This means that it is not possible for software to observe the value of [PSTATE.IL](#).

D1.13.5.1 Pseudocode description of exception return

The [AArch32_ExceptionReturn\(\)](#) function transfers the return address to the PC and restores [PSTATE](#) to its saved value.

This function uses the function [SetPSTATEFromPSR\(\)](#).

The [IllegalExceptionReturn\(\)](#) function checks for an Illegal Execution state exception.

[R-profile Architecture Pseudocode](#) includes the definitions of these functions.

D1.14 Asynchronous exception behavior for exceptions taken from AArch32 state

[PSTATE](#).{A, I, F} bits *mask* the asynchronous exceptions, meaning that when the value of one of these [PSTATE](#) bits is 1, the corresponding exception is not taken.

If a masked asynchronous exception remains signaled, then the exception remains pending unless the value of the [PSTATE](#) bit is changed to 0.

EL2 provides controls that affect:

- The routing of these exceptions, see [Asynchronous exception routing controls](#).
- Masking of these exceptions, see [Asynchronous exception masking controls](#).

The register control bits are provided in [HCR](#).

D1.14.1 Virtual exceptions when an implementation includes EL2

When implemented, EL2 provides the following virtual exceptions, which correspond to the physical asynchronous exceptions:

- Virtual SError, which corresponds to a physical external SError exception.
- Virtual IRQ, which corresponds to a physical IRQ.
- Virtual FIQ, which corresponds to a physical FIQ.

When the value of [HCR](#).TGE is 0 and the value of an [HCR](#).{AMO, IMO, FMO} routing control bit is 1, the corresponding virtual interrupt is enabled and a virtual exception is generated either:

- By setting the corresponding virtual interrupt pending bit, [HCR](#).{VA, VI, VF}, to 1.
- For a Virtual IRQ or Virtual FIQ, by an IMPLEMENTATION DEFINED mechanism. This might be a signal from an interrupt controller. See, for example, the *ARM Generic Interrupt Controller Architecture Specification*.

When the value of [HCR](#)._EL2.TGE is 1, all virtual interrupts are disabled.

When a virtual interrupt is disabled:

- It cannot be taken.
- It cannot be seen in the ISR.

In AArch32 state, a virtual exception is taken only from a EL1 or EL0 mode. In any other mode, if the exception is generated it is not taken.

A virtual exception is taken to the default mode for the corresponding physical exception. This means:

- A Virtual SError is taken to Abort mode.
- A Virtual IRQ is taken to IRQ mode.
- A Virtual FIQ is taken to FIQ mode.

[Table D1-13](#) summarizes the [HCR](#) bits that route asynchronous exceptions to EL2, and the bits that generate the virtual exceptions.

Table D1-13 HCR bits controlling asynchronous exceptions

Exception	Routing the physical exception to EL2	Generating the virtual exception
SError	HCR .AMO	HCR .VA

Exception	Routing the physical exception to EL2	Generating the virtual exception
IRQ	HCR.IMO	HCR.VI
FIQ	HCR.FMO	HCR.VF

The [HCR.{VA, VI, VF}](#) bits generate a virtual exception only if set to 1 when the value of the corresponding [HCR.{AMO, IMO, FMO}](#) is 1.

When the value of an [HCR.{AMO, IMO, FMO}](#) control bit is 1, the corresponding mask bit in [PSTATE](#):

- Does not mask the physical exception.
- Masks the virtual exception when the PE is executing in an EL1 or EL0 mode.

Taking a Virtual Abort exception clears [HCR.VA](#) to zero. Taking a Virtual IRQ exception or a Virtual FIQ exception does not affect the value of [HCR.VI](#) or [HCR.VF](#).

Note

This means that the exception handler for a Virtual IRQ exception or a Virtual FIQ exception must cause software that is executing at EL2 to update the [HCR](#) to clear the appropriate virtual exception bit to 0.

See [WFE wakeup events](#) and [Wait For Interrupt](#) for information about how virtual exceptions affect wake up from power-saving states.

Note

A hypervisor can use virtual exceptions to signal exceptions to the current Guest RTOS. The Guest RTOS takes a virtual exception exactly as it would take the corresponding physical exception, and is unaware of any distinction between virtual exception and the corresponding physical exception.

D1.14.1.1 Effects of the [HCR.{AMO, IMO, FMO}](#) bits

As described in this section, the [HCR.{AMO, IMO, FMO}](#) bits are part of the mechanism for enabling the virtual exceptions. In addition:

- As mentioned in this section, affect the routing of the exceptions. See [Asynchronous exception routing controls](#).
- Affect the masking of the exceptions. See [Asynchronous exception masking controls](#).

D1.14.2 Asynchronous exception routing controls

The following bits in the [HCR](#) route asynchronous exceptions to EL2 that are taken from an EL1 or EL0 mode.

- [HCR.AMO](#)** When the value of this bit is 1, an SError exception taken from an EL1 or EL0 mode is taken to EL2, instead of to Abort mode.
- [HCR.FMO](#)** When the value of this bit is 1, an FIQ exception taken from an EL1 or EL0 mode is taken to EL2, instead of to FIQ mode.
- [HCR.IMO](#)** When the value of this bit is 1, an IRQ exception taken from an EL1 or EL0 mode is taken to EL2, instead of to IRQ mode.

When the value of one of the [HCR.{AMO, FMO, IMO}](#) bits is 1, the exception is taken to Hyp mode.

Only software executing in Hyp mode can change the values of these bits.

The [HCR.{AMO, FMO, IMO}](#) bits also affect the masking of asynchronous exceptions, as described in [Asynchronous exception masking controls](#).

The [HCR.{AMO, FMO, IMO}](#) bits have no effect on the routing of Virtual Abort, Virtual FIQ, and Virtual IRQ exceptions.

Note

When the PE is in Hyp mode:

- Physical asynchronous exceptions are taken to Hyp mode.
 - Virtual exceptions are not signaled to the PE.
-

See also [Asynchronous exception behavior for exceptions taken from AArch32 state](#).

D1.14.3 Asynchronous exception masking controls

The [PSTATE](#).{A, I, F} bits can mask the taking of the corresponding exceptions from AArch32 state, as follows:

- [PSTATE](#).A can mask SError exceptions.
- [PSTATE](#).I can mask IRQ exceptions.
- [PSTATE](#).F can mask FIQ exceptions.

[HCR](#).{AMO, IMO, FMO} bits modify the masking of exceptions.

D1.14.3.1 Asynchronous exception masking in an implementation that includes EL2

The [HCR](#).{AMO, IMO, FMO} bits modify the effect of the [PSTATE](#).{A, I, F} bits. When the value of an [HCR](#).{AMO, IMO, FMO} mask override bit is 1, the value of the corresponding [PSTATE](#).{A, I, F} bit is ignored when the exception is taken from a mode other than Hyp mode.

D1.15 AArch32 state exception descriptions

[Handling exceptions that are taken to an Exception level using AArch32](#) gives general information about exception handling. This section describes each of the exceptions, in the following subsections:

- [Undefined Instruction exception.](#)
- [Hyp Trap exception.](#)
- [Supervisor Call \(SVC\) exception.](#)
- [Hypervisor Call \(HVC\) exception.](#)
- [Prefetch Abort exception.](#)
- [Data Abort exception.](#)
- [Virtual SError interrupt exception.](#)
- [IRQ exception.](#)
- [Virtual IRQ exception.](#)
- [FIQ exception.](#)
- [Virtual FIQ exception.](#)

[Additional pseudocode functions for exception handling](#) gives additional pseudocode that is used in the pseudocode descriptions of a number of the exceptions.

D1.15.1 Undefined Instruction exception

An Undefined Instruction exception might be caused by:

- A System register access, floating-point, or Advanced SIMD instruction that is not accessible because of the settings in one or more of the [CPACR](#), [NSACR](#), [HCPTR](#), and [DBGDSCRExt](#).
- A System register access, floating-point, or Advanced SIMD instruction that is not implemented.
- A System register access, floating-point, or Advanced SIMD instruction that causes an exception during execution. This includes:
 - Trapped floating-point exceptions that are taken to AArch32, if an implementation supports these traps. See [Floating-point exceptions and exception traps](#).
 - Execution of certain floating-point instructions when one or both of the [FPSCR](#).{Stride, Len} fields in nonzero, in an implementation in which those fields are RW. The description of [FPEXC](#) specifies the instructions to which this applies.
- An instruction that is UNDEFINED.

Note

The Undefined Instruction exception is taken using offset 0x04 in the Hyp vector table. See [The vector tables and exception offsets](#).

By default, an Undefined Instruction exception is taken to Undefined mode, but an Undefined Instruction exception can be taken to EL2, meaning it is taken to Hyp mode if EL2 is using AArch32, see [The PE mode to which the Undefined Instruction exception is taken](#).

The Undefined Instruction exception can provide:

- Signaling of an illegal instruction execution.
- *Lazy context switching* of System registers.

The preferred return address for an Undefined Instruction exception is the address of the instruction that generated the exception. For an exception taken to AArch32 state, this return is performed as follows:

- If returning from Undefined mode, the exception return uses the [SPSR](#) and LR_und values generated by the exception entry, as follows:

- If `SPSR.T` is 0, indicating that the exception occurred in A32 state, the return uses an exception return instruction with a subtraction of 4.
- If `SPSR.T` is 1, indicating that the exception occurred in T32 state, the return uses an exception return instruction with a subtraction of 2.
- If returning from Hyp mode, the exception return is performed by an `ERET` instruction, using the `SPSR` and `ELR_hyp` values generated by the exception entry.

For more information, see [Exception return to an Exception level using AArch32](#).

Note

If handling the Undefined Instruction exception requires instruction emulation, followed by return to the next instruction after the instruction that caused the exception, the instruction emulator must use the instruction length to calculate the correct return address, and to calculate the updated values of the IT bits if necessary.

D1.15.1.1 The PE mode to which the Undefined Instruction exception is taken

[Figure D1-2](#) shows how the implementation, state, and configuration options determine the PE mode to which an Undefined Instruction exception is taken, when the exception is taken to an Exception level that is using AArch32.

Figure D1-2 The PE mode an Undefined Instruction exception is taken to in AArch32 state

See also [UNPREDICTABLE cases when the value of HCR.TGE is 1](#).

D1.15.1.2 Pseudocode description of taking the Undefined Instruction exception

The `AArch32_Undefined()` pseudocode procedure determines whether the Undefined Instruction exception is taken to AArch32 state. If it is taken to AArch32 state, the `AArch32_TakeUndefInstrException()` pseudocode procedure describes how the PE takes the exception.

D1.15.1.3 Conditional execution of undefined instructions

The conditional execution rules described in [Conditional execution](#) apply to all instructions. This includes undefined instructions and other instructions that would cause entry to the Undefined Instruction exception.

If such an instruction fails its condition check, the behavior depends on the potential cause of entry to the Undefined Instruction exception, as follows:

- If the potential cause is the execution of the instruction itself and depends on data values used by the instruction, the instruction executes as a `NOP` and does not cause an Undefined Instruction exception.
- In the following cases, it is IMPLEMENTATION DEFINED whether the instruction executes as a `NOP` or causes an Undefined Instruction exception:
 - The potential cause is the execution of an earlier System register access instruction, floating-point instruction, or Advanced SIMD instruction.

- The potential cause is the execution of the instruction itself without dependence on the data values used by the instruction.

An implementation must handle all such cases in the same way.

D1.15.1.4 Interaction of UNDEFINED instruction behavior with UNPREDICTABLE or CONSTRAINED UNPREDICTABLE instruction behavior

If this manual describes an instruction as both:

- UNPREDICTABLE and UNDEFINED then the instruction is UNPREDICTABLE.
- CONSTRAINED UNPREDICTABLE and UNDEFINED then the instruction is CONSTRAINED UNPREDICTABLE.

Note

An example of this is where both:

- An instruction, or instruction class, is made UNDEFINED by some general principle, or by a configuration field.
 - A particular encoding of that instruction or instruction class is specified as CONSTRAINED UNPREDICTABLE.
-

D1.15.2 Hyp Trap exception

The Hyp Trap exception provides the standard mechanism for trapping Guest OS functions to the hypervisor.

The Hyp Trap exception is implemented only as part of EL2 and can be generated only if EL2 is using AArch32.

A Hyp Trap exception is generated if the PE is running in a mode other than Hyp mode, and commits for execution an instruction that is trapped to Hyp mode. Instruction traps are enabled by setting bits to 1 in the [HCR](#), [HCPTR](#), [HDCR](#), or [HSTR](#). For more information, see [EL2 configurable controls](#).

The preferred return address for a Hyp Trap exception is the address of the trapped instruction. The exception return is performed by an ERET instruction, using the [SPSR](#) and [ELR_hyp](#) values generated by the exception entry.

Note

The [SPSR](#) and [ELR_hyp](#) values generated on exception entry can be used, without modification, for an exception return to re-execute the trapped instruction. If the exception handler emulates the trapped instruction, and must return to the following instruction, the emulation of the instruction must include modifying [ELR_hyp](#), and possibly updating [SPSR_hyp](#).

When the PE enters the handler for a Hyp Trap exception, the [HSR](#) holds syndrome information for the exception. For more information, see [Use of the HSR](#).

D1.15.2.1 The PE mode to which the Hyp Trap exception is taken

A Hyp Trap exception is taken to Hyp mode, using a vector offset of 0×14 from the Hyp exception base address.

D1.15.2.2 Pseudocode description of taking the Hyp Trap exception

The [AArch32_TakeHypTrapException\(\)](#) pseudocode procedure describes how the PE takes the exception.

D1.15.3 Supervisor Call (SVC) exception

The Supervisor Call instruction, [SVC](#), requests a supervisor function, typically to request an operating system function. When EL1 is using AArch32, executing an [SVC](#) instruction causes the PE to enter Supervisor mode. For more information, see [SVC](#).

Note

In an implementation that includes EL2, when EL2 is using AArch32:

- When an `SVC` instruction is executed in Hyp mode, the Supervisor Call exception is taken to Hyp mode. For more information, see `SVC`.
- When the `HCR.TGE` bit is set to 1, the Supervisor Call exception generated by execution of an `SVC` instruction in User mode is routed to Hyp mode. For more information, see [Supervisor Call exception, when the value of `HCR.TGE` is 1](#).

By default, a Supervisor Call exception that is taken to AArch32 state is taken to Supervisor mode, but a Supervisor Call exception can be taken to EL2, meaning it is taken to Hyp mode if EL2 is using AArch32, see [The PE mode to which the Supervisor Call exception is taken](#).

The preferred return address for a Supervisor Call exception is the address of the next instruction after the `SVC` instruction. For an exception taken to AArch32 state, this return is performed as follows:

- If returning from Supervisor mode, the exception return uses the `SPSR` and `LR_svc` values generated by the exception entry, in an exception return instruction without subtraction.
- If returning from Hyp mode, the exception return is performed by an `ERET` instruction, using the `SPSR` and `ELR_hyp` values generated by the exception entry.

For more information, see [Exception return to an Exception level using AArch32](#).

D1.15.3.1 The PE mode to which the Supervisor Call exception is taken

[Figure D1-3](#) shows how the implementation, state, and configuration options determine the PE mode to which a Supervisor Call exception is taken, when the exception is taken to an Exception level that is using AArch32.

Figure D1-3 The PE mode the Supervisor Call exception is taken to in AArch32 state

See also [UNPREDICTABLE cases when the value of `HCR.TGE` is 1](#).

D1.15.3.2 Pseudocode description of taking the Supervisor Call exception

The `AArch32_CallSupervisor()` pseudocode procedure determines whether the Supervisor Call exception is taken to AArch32 state. If it is taken to AArch32 state, the `AArch32_TakeSVCException()` pseudocode procedure describes how the PE takes the exception.

D1.15.4 Hypervisor Call (HVC) exception

The Hypervisor Call exception is implemented only as part of EL2.

The Hypervisor Call instruction, `HVC`, requests a hypervisor function. When EL2 is using AArch32, executing an `HVC` instruction generates a Hypervisor Call exception that is taken to Hyp mode. For more information, see [HVC](#).

The preferred return address for a Hypervisor Call exception is the address of the next instruction after the `HVC` instruction. The exception return is performed by an `ERET` instruction, using the `SPSR` and `ELR_hyp` values generated by the exception entry.

For more information, see [Exception return to an Exception level using AArch32](#).

When EL2 is using AArch32, executing an `HVC` instruction transfers the immediate argument of the instruction to the `HSR`. The exception handler retrieves the argument from the `HSR`, and therefore does not have to access the original `HVC` instruction. For more information, see [Use of the HSR](#).

D1.15.4.1 The PE mode to which the Hypervisor Call exception is taken

The Hypervisor Call exception is supported only as part of EL2. When EL2 is using AArch32, a Hypervisor Call exception is taken to Hyp mode, using a vector offset that depends on the mode from which the exception is taken, as [Figure D1-4](#) shows. This offset is from the Hyp exception base address.

Figure D1-4 The PE mode the Hypervisor Call exception is taken to in AArch32 state

D1.15.4.2 Pseudocode description of taking the Hypervisor Call exception

The `AArch32_TakeHVCEXception()` pseudocode procedure describes how the PE takes a Hypervisor Call exception.

D1.15.5 Prefetch Abort exception

A Prefetch Abort exception can be generated by:

- A synchronous memory abort on an instruction fetch.

Note

Asynchronous External aborts on instruction fetches are reported as SError exceptions using the Data Abort exception, see [Data Abort exception](#).

A Prefetch Abort exception entry is synchronous to the instruction whose fetch aborted.

For more information about memory aborts see [MPU faults](#).

- A Breakpoint, Vector Catch or Breakpoint Instruction exception, see [AArch32 Self-hosted Debug](#).

Note

If an implementation fetches instructions speculatively, it must handle a synchronous abort on such an instruction fetch by:

- Generating a Prefetch Abort exception only if the instruction would be executed in a simple sequential execution of the program.
 - Ignoring the abort if the instruction would not be executed in a simple sequential execution of the program.
-

By default a Prefetch Abort exception is taken to Abort mode, but a Prefetch Abort exception can be taken to EL2, meaning it is taken to Hyp mode.

For more information:

- About cases where the Prefetch Abort exception is taken to an Exception level that is using AArch32, see [The PE mode to which the Prefetch Abort exception is taken](#).

The preferred return address for a Prefetch Abort exception is the address of the aborted instruction. For an exception taken to AArch32 state this return is performed as follows:

- If returning from a mode other than Hyp mode, using the [SPSR](#) and LR values generated by the exception entry, using an exception return instruction with a subtraction of 4. This means using:
 - [SPSR_abt](#) and [LR_abt](#) if returning from Abort mode.
- If returning from Hyp mode, using the [SPSR_hyp](#) and [ELR_hyp](#) values generated by the exception entry, using an [ERET](#) instruction.

For more information about the handling of Prefetch Abort exceptions in AArch32 state, see [Exception return to an Exception level using AArch32](#).

D1.15.5.1 Prefetch Abort exception reporting a PC alignment fault exception

A PC alignment fault exception that is taken to an Exception level that is using AArch32 is reported as a Prefetch Abort exception, and:

If the exception is taken to EL1

- The IFSR indicates the cause of the exception and [IFSR.STATUS](#) takes the value 0b100001.
- [IFAR](#) holds the value of the address that faulted, including the misaligned low order bit or bits.
- [R14_abt](#) holds the address that faulted, including the misaligned low order bit or bits, with the standard offset for a Prefetch Abort exception.

If the exception is taken to EL2

- [HSR.EC](#) takes the value 0b100010.
- [HSR.IL](#) is UNKNOWN.
- [HSR.ISS](#) is RES0.
- [HIFAR](#) and [ELR_hyp](#) each hold the value of the address that faulted, including the misaligned low order bit or bits.

For a PC alignment fault exception taken to an Exception level that is using AArch32:

- If the exception occurred because of the [CONSTRAINED UNPREDICTABLE](#) behavior of a branch to an unaligned PC value, as described in [Branching to an unaligned PC](#), then bit[0] of the faulting address is forced to zero, and therefore the misalignment is because the value of bit[1] of this address is 1.
- If the exception occurred on an exit from Debug state, as described in [Exiting Debug state](#), then it is [CONSTRAINED UNPREDICTABLE](#) whether bit[0] of the faulting address is forced to zero.

D1.15.5.2 The PE mode to which the Prefetch Abort exception is taken

Figure D1-5 shows how the implementation, state, and configuration options determine the PE mode to which a Prefetch Abort exception is taken, when the exception is taken to an Exception level that is using AArch32.

Figure D1-5 The PE mode the Prefetch Abort exception is taken to in AArch32 state

See also [UNPREDICTABLE cases when the value of HCR.TGE is 1](#).

D1.15.5.3 Pseudocode description of taking the Prefetch Abort exception

When the exception is taken in AArch32 state, the `AArch32_TakePrefetchAbortException()` pseudocode procedure describes how the PE takes the exception.

D1.15.6 Data Abort exception

In AArch32 state, a Data Abort exception can be generated by:

- A synchronous abort on a data read or write memory access. Exception entry is synchronous to the instruction that generated the memory access.
- An SError exception. The SError exception might be caused by an External abort on a memory access, which can be any of:
 - A data read or write access.
 - An instruction fetch.
 - In a PMSA memory system, an MPU translation.

Exception entry occurs asynchronously.

As described in [Asynchronous exception masking controls](#), SError exceptions can be masked. When this happens, a generated SError exception is not taken until it is not masked.

- A watchpoint, see [Watchpoint exceptions](#).

By default, when EL1 is using AArch32 a Data Abort exception is taken to Abort mode, but a Data Abort exception can be taken to EL2, meaning it is taken to Hyp mode.

For more information:

- About cases where the Data Abort exception is taken to an Exception level that is using AArch32, see [The PE mode to which the Data Abort exception is taken](#).
- About memory aborts in AArch32 state, see [External abort on a translation](#).

The preferred return address for a Data Abort exception is the address of the instruction that generated the aborting memory access, or the address of the instruction following the instruction boundary at which an SError exception was taken. For an exception taken to AArch32 state, this return is performed as follows:

- If returning from a mode other than Hyp mode, using the [SPSR](#) and LR values generated by the exception entry, using an exception return instruction with a subtraction of 8. This means using:
 - [SPSR_abt](#) and [LR_abt](#) if returning from Abort mode.
- If returning from Hyp mode, using the [SPSR_hyp](#) and [ELR_hyp](#) values generated by the exception entry, using an `ERET` instruction.

For more information about the handling of Data Abort exceptions in AArch32 state, see [Exception return to an Exception level using AArch32](#).

D1.15.6.1 The PE mode to which the Data Abort exception is taken

[Figure D1-6](#) shows the determination of the mode to which a Data Abort exception is taken when the exception is taken to an Exception level that is using AArch32.

Figure D1-6 The PE mode the Data Abort exception is taken to in AArch32 state

See also [UNPREDICTABLE cases when the value of HCR.TGE is 1](#).

D1.15.6.2 Pseudocode description of taking the Data Abort exception

When the exception is taken in AArch32 state, the [AArch32_TakeDataAbortException\(\)](#) pseudocode procedure describes how the PE takes the exception.

D1.15.6.3 Effects of data-aborted instructions

An instruction that accesses data memory can modify memory by storing one or more values. If the execution of such an instruction generates a Data Abort exception, or causes Debug state entry because of a watchpoint set on the location, the value of each memory location that the instruction stores to is:

- Unchanged for any location for which one of the following applies:
 - An Alignment fault is generated.
 - An [MPU fault](#) is generated.
 - A Watchpoint is generated.
 - An External abort is generated, if that External abort is taken synchronously.
- UNKNOWN for any location for which no exception and no debug event is generated.

If the access to a memory location generates an External abort that is taken asynchronously, it is outside the scope of the architecture to define the effect of the store on that memory location, because this depends on the system-specific nature of the External abort. However, in general, Arm recommends that such locations are unchanged.

For External aborts and Watchpoints, where in principle faulting could be identified at byte or halfword granularity, the size of a location in this definition is the size for which a memory access is single-copy atomic.

In AArch32 state, instructions that access data memory can modify registers in the following ways:

- By loading values into one or more of the general-purpose registers. The registers loaded can include the PC.
- By loading values into one or more of the registers in the Advanced SIMD and floating-point register file.
- By specifying *base register writeback*, in which the base register used in the address calculation has a modified value written to it. All instructions that support base register writeback have **CONSTRAINED UNPREDICTABLE** results if base register writeback is specified with the PC as the base register. Only general-purpose registers can be modified reliably in this way.
- By a direct transfer to or from the Debug Communication Channel (DCC) register, using the LDC and STC instructions. For more information, see [The Debug Communication Channel and Instruction Transfer Register](#). If the instruction that accesses the DCC System registers is an LDC or STC instruction, **UNKNOWN** values are left in the Data Transfer Register and DCC flow-control flags.
- By modifying **PSTATE**.

If the execution of such an instruction generates a synchronous Data Abort exception, the following rules determine the values left in these registers:

- On entry to the Data Abort exception handler:
 - The PC value is the Data Abort vector address, see [Exception vectors and the exception base address](#).
 - The LR_abt value is determined from the address of the aborted instruction.
 Neither value is affected by the results of any load specified by the instruction.
- The base register is restored to its original value if either:
 - The aborted instruction is a load and the list of registers to be loaded includes the base register.
 - The base register is being written back.
- If the instruction only loads one general-purpose register the value in that register is unchanged.
- If the instruction loads more than one general-purpose register, **UNKNOWN** values are left in destination registers other than the PC and the base register of the instruction.
- If the instruction affects any registers in the Advanced SIMD and floating-point register file, **UNKNOWN** values are left in the registers that are affected.
- **PSTATE** bits that are not defined as updated on exception entry retain their current value.
- If the instruction is a STREX, STREXB, STREXH, or STREXD, <Rd> is not updated.

After taking a Data Abort exception, the state of the Exclusives monitors is **UNKNOWN**. Therefore, Arm strongly recommends that the abort handler performs a CLREX instruction, or a dummy STREX instruction, to clear the Exclusives monitor state.

D1.15.6.4 The Arm abort model

The abort model used by an Arm PE is described as a *Base Restored Abort Model*. This means that if a synchronous Data Abort exception is generated by executing an instruction that specifies base register writeback, the value in the base register is unchanged.

The abort model applies uniformly across all instructions.

D1.15.7 Virtual SError interrupt exception

The Virtual SError interrupt exception is implemented only as part of EL2 is enabled in the current Security state.

A Virtual SError interrupt exception is generated in AArch32 state if all of the following apply:

- The PE is in a mode other than Hyp mode.

- The value of `PSTATE.A` is 0.
- EL2 is using AArch32 and the values of the `HCR`.{TGE, AMO, VA} bits are {0, 1, 1}.

The preferred return address for a Virtual SError interrupt exception is the address of the instruction immediately after the instruction boundary where the exception was taken. For an exception taken to AArch32 state, this return is performed using the `SPSR` and `LR_abt` values generated by the exception entry, using an exception return instruction without subtraction.

D1.15.7.1 The PE mode to which the Virtual SError interrupt exception is taken

The Virtual SError interrupt exception is taken using a vector offset of `0x10` from the exception base address.

The conditions for generating a Virtual SError interrupt exception in AArch32 state mean the exception is:

- Taken from a EL1 or EL0 mode.
- Taken to Abort mode .

For more information, see [Virtual exceptions when an implementation includes EL2](#).

Note

Because a Virtual SError interrupt exception taken to AArch32 state is always taken to Abort mode, on exception entry the preferred return address is always saved to `LR_abt`.

D1.15.7.2 Pseudocode description of taking the Virtual SError interrupt exception

The `AArch32_TakeVirtualSErrorException()` pseudocode procedure describes how the PE takes the exception.

D1.15.8 IRQ exception

The IRQ exception is generated by IMPLEMENTATION DEFINED means. Typically this is by asserting an IRQ interrupt request input to the PE.

When an IRQ exception is taken, exception entry is precise to an instruction boundary.

As described in [Asynchronous exception masking controls](#), IRQ exceptions can be masked. When this happens, a generated IRQ exception is not taken until it is not masked.

By default, an IRQ exception is taken to IRQ mode, but an IRQ exception can be taken to Hyp mode.

For more information, see [The PE mode to which the physical IRQ exception is taken](#)

The preferred return address for an IRQ exception is the address of the instruction following the instruction boundary at which the exception was taken. For an exception taken to AArch32 state this return is performed as follows:

- If returning from a mode other than Hyp mode, using the `SPSR` and `LR` values generated by the exception entry, using an exception return instruction with a subtraction of 4. This means using:
 - `SPSR_irq` and `LR_irq` if returning from IRQ mode.
- If returning from Hyp mode, using the `SPSR_hyp` and `ELR_hyp` values generated by the exception entry, using an `ERET` instruction.

For more information, see [Exception return to an Exception level using AArch32](#).

D1.15.8.1 The PE mode to which the physical IRQ exception is taken

[Figure D1-7](#) shows how the implementation, state, and configuration options determine the mode to which an IRQ exception is taken when the exception is taken to an Exception level that is using AArch32.

Figure D1-7 The PE mode the IRQ exception is taken to in AArch32 state

D1.15.8.2 Pseudocode description of taking the physical IRQ exception

The `AArch32_TakePhysicalIRQException()` pseudocode procedure describes how the PE takes the exception.

D1.15.9 Virtual IRQ exception

The Virtual IRQ exception is implemented only as part of EL2, if EL2 is enabled in the current Security state.

A Virtual IRQ exception is generated in AArch32 state if all of the following apply:

- The PE is in a mode other than Hyp mode.
- The value of `PSTATE.I` is 0.
- The value of `HCR.{TGE, IMO}` is {0, 1}.
- Either:
 - `HCR.VI` is 1.
 - A Virtual IRQ exception is generated by an IMPLEMENTATION DEFINED mechanism.

The preferred return address for a Virtual IRQ exception is the address of the instruction immediately after the instruction boundary where the exception was taken. For an exception taken to AArch32 state this return is performed using the `SPSR` and `LR_irq` values generated by the exception entry, using an exception return instruction with a subtraction of 4.

D1.15.9.1 The PE mode to which the Virtual IRQ exception is taken

The Virtual IRQ exception uses a vector offset of `0x18`.

The conditions for generating a Virtual IRQ exception in AArch32 state mean the exception is:

- Taken from an EL1 or EL0 mode.
- Taken to IRQ mode.

For more information, see [Virtual exceptions when an implementation includes EL2](#).

D1.15.9.2 Pseudocode description of taking the Virtual IRQ exception

The `AArch32_TakeVirtualIRQException()` pseudocode procedure describes how the PE takes the exception.

D1.15.10 FIQ exception

The FIQ exception is generated by IMPLEMENTATION DEFINED means. Typically this is by asserting an FIQ interrupt request input to the PE.

When an FIQ exception is taken, exception entry is precise to an instruction boundary.

As described in [Asynchronous exception masking controls](#), FIQ exceptions can be masked. When this happens, a generated FIQ exception is not taken until it is not masked.

By default, an FIQ exception is taken to FIQ mode, but an FIQ exception can be taken to EL2, that is Hyp mode.

For more information, see [The PE mode to which the physical FIQ exception is taken](#).

The preferred return address for an FIQ exception is the address of the instruction following the instruction boundary at which the exception was taken. For an exception taken to AArch32 state this return is performed as follows:

- If returning from a mode other than Hyp mode, using the [SPSR](#) and LR values generated by the exception entry, using an exception return instruction with a subtraction of 4. This means using:
 - [SPSR_fiq](#) and [LR_fiq](#) if returning from FIQ mode.
- If returning from Hyp mode, using the [SPSR_hyp](#) and [ELR_hyp](#) values generated by the exception entry, using an `ERET` instruction.

For more information, see [Exception return to an Exception level using AArch32](#).

D1.15.10.1 The PE mode to which the physical FIQ exception is taken

[Figure D1-8](#) shows how the implementation, state, and configuration options determine the PE mode to which an FIQ exception is taken when the exception is taken to an Exception level that is using AArch32.

Figure D1-8 The PE mode the FIQ exception is taken to in AArch32 state

D1.15.10.2 Pseudocode description of taking the FIQ exception

The [AArch32_TakePhysicalFIQException\(\)](#) pseudocode procedure describes how the PE takes the exception.

D1.15.11 Virtual FIQ exception

The Virtual FIQ exception is implemented only as part of EL2, if EL2 is enabled in the current Security state.

A Virtual FIQ exception is generated in AArch32 state if all of the following apply:

- The PE is in a mode other than Hyp mode.
- The value of [PSTATE.F](#) is 0.
- The value of [HCR](#).{TGE, FMO} is {0, 1}.

- Either:
 - The value of [HCR.VF](#) is 1.
 - A Virtual FIQ exception is generated by an IMPLEMENTATION DEFINED mechanism.

The preferred return address for a Virtual FIQ exception is the address of the instruction immediately after the instruction boundary where the exception was taken. For an exception taken to AArch32 state this return is performed using the [SPSR](#) and [LR_irq](#) values generated by the exception entry, using an exception return instruction with a subtraction of 4.

D1.15.11.1 The PE mode to which the Virtual FIQ exception is taken

The Virtual FIQ exception is taken using a vector offset of $0 \times 1C$.

The conditions for generating a Virtual FIQ exception in AArch32 state mean the exception is:

- Taken from EL1 or EL0.
- Taken to FIQ mode if EL1 is using AArch32.

For more information, see [Virtual exceptions when an implementation includes EL2](#).

D1.15.11.2 Pseudocode description of taking the Virtual FIQ exception

The [AArch32_TakeVirtualFIQException\(\)](#) pseudocode procedure describes how the PE takes the exception.

D1.15.12 Additional pseudocode functions for exception handling

The [AArch32_EnterHypMode\(\)](#) pseudocode function changes the PE mode to Hyp mode, with the required state changes.

The [AArch32_EnterMode\(\)](#) pseudocode function changes the PE mode to a PL1 mode, with the required state changes. It is used for all exceptions that are not routed to Hyp mode or Monitor mode.

The [AArch32_EnterHypMode\(\)](#), and [AArch32_EnterMode\(\)](#) functions are described in [R-profile Architecture Pseudocode](#).

D1.16 Reset into AArch32 state

Resets and power domains describes the Armv8 reset model, including the defined levels of reset.

When reset is deasserted, the PE starts executing instructions at EL2 in Hyp mode with interrupts disabled.

Reset returns some PE state to architecturally-defined or IMPLEMENTATION DEFINED values, and makes other state UNKNOWN, as described in [PE state on reset into AArch32 state](#).

For more information about behavior when resetting into an Exception level using AArch32, see:

- [Behavior of caches at reset](#).
- [Reset and debug](#).

When reset is deasserted execution starts from an IMPLEMENTATION DEFINED address.

Software might be able to identify the reset address by reading [RVBAR](#).

The Arm architecture does not define any way of returning to a previous Execution state from a reset.

D1.16.1 PE state on reset into AArch32 state

Immediately after a reset, much of the PE state is architecturally UNKNOWN. However, some of the PE state is defined, see the individual register descriptions for more information. The state that is reset to known values is sufficient to permit predictable initial execution at the highest Exception level, such that this execution is then capable of initializing the remaining state of the system where necessary before use.

If the PE resets using either a Cold or a Warm reset, the PE state that is defined is as follows:

- The global exclusive monitor and local exclusive monitor for the PE are UNKNOWN.
- The PE resets into Hyp mode and PSTATE.M resets to 0b1010.
- [PSTATE.IL](#) resets to 0.

D1.16.2 Pseudocode descriptions of reset

The [AArch32_TakeReset](#) () pseudocode procedure describes how the PE behaves when reset is deasserted.

The [AArch32_ResetGeneralRegisters](#) () pseudocode function resets the general-purpose registers.

The [AArch32_ResetSIMDFPRegisters](#) () pseudocode function resets the SIMD and floating-point registers.

The [AArch32_ResetSpecialRegisters](#) () pseudocode function resets the Special-purpose registers, and the debug System registers [DLR](#) and [DSPSR](#), which are used for handling Debug exceptions.

The [AArch32_ResetSystemRegisters](#) () pseudocode function resets all System registers in the (coproc == 0b111x) encoding space to their reset state as defined in the register descriptions in [AArch32 System Register Descriptions](#).

Note

The [AArch32_ResetSystemRegisters](#) () function only resets the System registers. It has no effect on memory-mapped registers.

The [ResetExternalDebugRegisters](#) () pseudocode function resets all external debug registers to their reset state as defined in the register descriptions in [External Debug Register Descriptions](#).

D1.17 Mechanisms for entering a low-power state

The following sections describe the architectural mechanisms that a PE can use to request entry to a low-power state:

- [Wait For Event and Send Event](#).
- [Wait For Interrupt](#).

D1.17.1 Wait For Event and Send Event

The Wait For Event (WFE) mechanism permits a PE to request entry to a low-power state, and, if the request succeeds, to remain in that state until an event is generated by a Send Event operation, or another WFE wakeup event occurs.

[Example D1-2](#) describes how a spinlock implementation might use this mechanism to save energy.

Example D1-2 Spinlock as an example of using Wait For Event and Send Event

A multiprocessor operating system requires locking mechanisms to protect data structures from being accessed simultaneously by multiple PEs. These mechanisms prevent the data structures becoming inconsistent or corrupted if different PEs try to make conflicting changes. If a lock is busy, because a data structure is being used by one PE, it might not be practical for another PE to do anything except wait for the lock to be released. For example, if a PE is handling an interrupt from a device it might need to add data received from the device to a queue. If another PE is removing data from the queue, it will have locked the memory area that holds the queue. The first PE cannot add the new data until the queue is in a consistent state and the lock has been released. It cannot return from the interrupt handler until the data has been added to the queue, so it must wait.

Typically, a spin-lock mechanism is used in these circumstances:

- A PE requiring access to the protected data attempts to obtain the lock using single-copy atomic synchronization primitives such as the Load-Exclusive and Store-Exclusive operations described in [Synchronization and semaphores](#).
- If the PE obtains the lock, it performs its memory operation and releases the lock.
- If the PE cannot obtain the lock, it reads the lock value repeatedly in a tight loop until the lock becomes available. At this point, it again attempts to obtain the lock.

A spin-lock mechanism is not ideal for all situations:

- In a low-power system, the tight read loop is undesirable because it uses energy to no effect.
- In a multithreaded implementation, the execution of spin-locks by waiting threads can significantly degrade overall performance.

Using the Wait For Event and Send Event mechanism can improve the energy efficiency of a spinlock. In this situation, a PE that fails to obtain a lock can execute a Wait For Event instruction, `WFE`, to request entry to a low-power state. When a PE releases a lock, it must execute a Send Event instruction, `SEV`, causing any waiting PEs to wake up. Then, these PEs can attempt to gain the lock again.

The execution of a `WFE` instruction can cause suspension of execution only if all of the following are true:

- The instruction does not cause any other exception.
- When the instruction is executed:
 - The Event Register is not set.
 - There is not a pending WFE wakeup event.

For more information about the trap to EL2, see `HCR.{WFI, WFE}`.

The architecture does not define the exact nature of the low power state entered as a result of executing a `WFE` instruction, but the execution of a `WFE` instruction must not cause a loss of memory coherency or architectural state.

Note

Although a complex operating system can contain thousands of distinct locks, the event sent by this mechanism does not indicate which lock has been released. If the event relates to a different lock, or if another PE acquires the lock more quickly, the PE fails to acquire the lock and can reenter the low-power state waiting for the next event.

The Wait For Event system relies on hardware and software working together to achieve energy saving:

- The hardware provides the mechanism to enter the Wait For Event low-power state.
- The operating system software is responsible for issuing:
 - A Wait For Event instruction, to request entry to the low-power state, used in the example when waiting for a spin-lock.
 - A Send Event instruction, required in the example when releasing a spin-lock.

The mechanism depends on the interaction of:

- WFE wakeup events, see [WFE wakeup events](#).
- The Event Register, see [The Event Register](#).
- The Send Event instructions, see [The Send Event instructions](#).
- The Wait For Event instruction, see [The Wait For Event instruction](#).

D1.17.1.1 The Event Register

The Event Register is a single bit register for each PE. When set, an event register indicates that an event has occurred, since the register was last cleared, that might require some action by the PE. Therefore, the PE must not suspend operation on issuing a WFE instruction.

The reset value of the Event Register is UNKNOWN.

The Event Register for a PE is set by:

- The execution of an SEV instruction on any PE in the multiprocessor system.
- The execution of an SEVL instruction by the PE.
- An exception return.
- An event from a Generic Timer event stream, see [Event streams](#).
- An event sent by some IMPLEMENTATION DEFINED mechanism.

As shown in this list, the Event Register might be set by IMPLEMENTATION DEFINED mechanisms.

The Event Register is cleared only by a Wait For Event instruction.

Software cannot read or write the value of the Event Register directly.

D1.17.1.2 The Wait For Event instruction

The action of the Wait For Event instruction depends on the state of the Event Register:

- If the Event Register is 1, the instruction clears the register and completes immediately. Normally, if this happens the software makes another attempt to claim the lock.
- If the Event Register is 0, the PE can suspend execution, and hardware might enter a low-power state. The PE can remain suspended until a WFE wakeup event or a reset occurs. When a WFE wakeup event occurs, or earlier if the implementation chooses, the WFE instruction completes.

The execution of a WFE instruction that would otherwise cause suspension of execution might be trapped, see:

- [SCTLR](#).{nTWE, nTWI}.
- [HCR](#).{TWE, TWI}.

The Wait For Event instruction, WFE, is available at all privilege levels, see WFE.

Software using the Wait For Event mechanism must tolerate spurious wakeup events, including multiple wake ups.

D1.17.1.3 WFE wakeup events

The following events are *WFE wakeup events*:

- The execution of an `SEV` instruction on any PE in the system.
- The execution of an `SEVL` instruction on the PE.
- A physical IRQ interrupt, unless masked by the `PSTATE.I` bit.
- A physical FIQ interrupt, unless masked by the `PSTATE.F` bit.
- A physical SError exception, unless masked by the `PSTATE.A` bit.
- In any mode other than Hyp mode:
 - When `HCR.IMO` is set to 1, a virtual IRQ interrupt, unless masked by the `PSTATE.I` bit.
 - When `HCR.FMO` is set to 1, a virtual FIQ interrupt, unless masked by the `PSTATE.F` bit.
 - When `HCR.AMO` is set to 1, a virtual SError exception, unless masked by the `PSTATE.A` bit.
- An asynchronous External Debug Request debug event, if halting is allowed. For the definition of *halting is allowed*, see [Halting allowed and halting prohibited](#).
See also [External Debug Request debug event](#).
- An event sent by the timer event stream, see Event streams.
- An event sent by some IMPLEMENTATION DEFINED mechanism.
- An event caused by the clearing of the global monitor associated with the PE.

In addition to the possible masking of WFE wakeup events shown in this list, when invasive debug is enabled and `EDSCR.HDE` is set to 1, `EDSCR.INTdis` can mask interrupts, including masking them acting as WFE wakeup events. See the register description for more information.

As shown in the list of wakeup events, an implementation can include IMPLEMENTATION DEFINED hardware mechanisms to generate wakeup events.

Note

For more information about `PSTATE` masking, see [Asynchronous exception masking controls](#). If the configuration of the masking controls provided by EL2 mean that a `PSTATE` mask bit cannot mask the corresponding exception, then the physical exception is a WFE wakeup event, regardless of the value of the `PSTATE` mask bit.

D1.17.1.4 The Send Event instructions

The Send Event instructions are:

SEV, Send Event This causes an event to be signaled to all PEs in the multiprocessor system.

SEVL, Send Event Local

This must set the local Event Register. It might signal an event to other PEs, but is not required to do so.

The mechanism that signals an event to other PEs is IMPLEMENTATION DEFINED. The PE is not required to guarantee the ordering of this event with respect to the completion of memory accesses by instructions before the `SEV` instruction. Therefore, Arm recommends that software includes a `DSB` instruction before any `SEV` instruction.

Note

A `DSB` instruction ensures that no instruction, including any `SEV` instruction, that appears in program order after the `DSB` instruction, can execute until the `DSB` instruction has completed. For more information, see [Data Synchronization Barrier](#).

The `SEVL` instruction appears to execute in program order relative to any subsequent `WFE` instruction executed on the same PE, without the need for any explicit insertion of barrier instructions.

Execution of the Send Event instruction sets the Event Register.

The Send Event instructions are available at all privilege levels.

D1.17.1.5 Pseudocode description of the Wait For Event mechanism

This section defines pseudocode functions that describe the operation of the Wait For Event mechanism.

The `ClearEventRegister()` pseudocode procedure clears the Event Register of the current PE.

The `IsEventRegisterSet()` pseudocode function returns TRUE if the Event Register of the current PE is 1 and FALSE if it is 0.

The `WaitForEvent()` pseudocode procedure optionally suspends execution until a WFE wakeup event or reset occurs, or until some earlier time if the implementation chooses. It is IMPLEMENTATION DEFINED whether restarting execution after the period of suspension causes a `ClearEventRegister()` to occur.

The `SendEvent()` pseudocode procedure sets the Event Register of every PE in the system.

D1.17.2 Wait For Interrupt

AArch32 state supports Wait For Interrupt through an instruction, `WFI`, which is provided in the T32 and A32 instruction sets. For more information, see `WFI`.

When a PE issues a `WFI` instruction, its execution can be suspended, and a low-power state can be entered.

The execution in AArch32 state of a `WFI` instruction that would otherwise cause suspension of execution might be trapped, see:

- `SCTLR.nTWI`.
- `HCR.WFI`.

The execution of a `WFI` instruction can cause suspension of execution only if both:

- The instruction does not cause any other exception.
- When the instruction is executed, there is not a pending WFI wakeup event.

D1.17.2.1 WFI wakeup events

The PE can remain suspended in its WFI state until it is reset, or one of the following *WFI wakeup events* occurs:

- A physical IRQ interrupt, regardless of the value of the `PSTATE.I` bit.
- A physical FIQ interrupt, regardless of the value of the `PSTATE.F` bit.
- A physical SError exception, regardless of the value of the `PSTATE.A` bit.
- In any mode other than Hyp mode:
 - When `HCR.IMO` is set to 1, a virtual IRQ interrupt, regardless of the value of the `PSTATE.I` bit.
 - When `HCR.FMO` is set to 1, a virtual FIQ interrupt, regardless of the value of the `PSTATE.F` bit.
 - When `HCR.AMO` is set to 1, a virtual SError exception, regardless of the value of the `PSTATE.A` bit.
- An asynchronous External Debug Request debug event, if halting is allowed. For the definition of *halting is allowed*, see [Halting allowed and halting prohibited](#).
See also [External Debug Request debug event](#).

An implementation can include other IMPLEMENTATION DEFINED hardware mechanisms to generate WFI wakeup events.

When a WFI wakeup event is detected, or earlier if the implementation chooses, the `WFI` instruction completes.

WFI wakeup events cannot be masked by the mask bits in the `PSTATE`.

The architecture does not define the exact nature of the low power state, except that:

- The execution of a `WFI` instruction must not cause a loss of memory coherency.
- If the system is configured such that the `WFI` instruction can be completed, then the `WFI` instruction must not cause a loss of architectural state.

Note

In some implementations, based on the configuration of system specific registers, WFI can be used as part of a powerdown sequence where no interrupts will cause WFI wakeup events, and restoration of power involves resetting of the PE. In those cases, the WFI is permitted to cause a loss of architectural state, as it is assumed that this state will have been saved by software as part of the powerdown sequence before the WFI.

Note

- Because debug events are WFI wakeup events, Arm strongly recommends that Wait For Interrupt is used as part of an idle loop rather than waiting for a single specific interrupt event to occur and then moving forward. This ensures the intervention of debug while waiting does not significantly change the function of the program being debugged.
 - In some previous implementations of Wait For Interrupt, the idle loop is followed by exit functions that must be executed before taking the interrupt. The operation of Wait For Interrupt remains consistent with this model, and therefore differs from the operation of Wait For Event.
 - Some implementations of Wait For Interrupt drain down any pending memory activity before suspending execution. The Arm architecture does not require this operation, and software must not rely on Wait For Interrupt operating in this way.
-

D1.17.2.2 Using WFI to indicate an idle state on bus interfaces

A common implementation practice is to complete any entry into powerdown routines with a `WFI` instruction. Typically, the `WFI` instruction:

1. Forces the completion of execution of any instructions that are in progress, and of all associated bus activity.
2. Suspends the execution of instructions by the PE.

The control logic required to do this tracks the activity of the bus interfaces used by the PE. This means it can signal to an external power controller when there is no ongoing bus activity.

However, memory-mapped and external debug interface accesses to debug registers must continue to be processed while the PE is in the WFI state. The indication of idle state to the system normally only applies to the non-debug functional interfaces used by the PE, not the debug interfaces.

If [FEAT_DoubleLock](#) is implemented and the value of `DBGOSDLR.DLK`, the OS Double Lock status bit, is set to 1, this idle state must not be signaled to the PE unless the system can guarantee, also, that the debug interface is idle.

Note

When separate Core and Debug power domains are implemented, the debug interface referred to in this section is the interface between the Core and Debug power domains, since the signal to the power controller indicates that the Core power domain is idle. For more information about the power domains, see [Power domains and debug](#).

The exact nature of this interface is IMPLEMENTATION DEFINED, but the use of Wait For Interrupt as the only architecturally-defined mechanism that completely suspends execution makes it very suitable as the preferred powerdown entry mechanism.

D1.17.2.3 Pseudocode description of Wait For Interrupt

The `WaitForInterrupt()` pseudocode function optionally suspends execution until a WFI wakeup event or reset occurs, or until some earlier time if the implementation chooses.

D1.18 The AArch32 System register interface

Most System registers are accessed using the instructions described in [System register access instructions](#). The System register interface provides access to those instructions, and:

- These registers are encoded using the parameters {coproc, opc1, CRn, CRm, opc2}, with permitted coproc values of 0b1110 and 0b1111.
- Some of these encodings provide the AArch32 System instructions.
- To maintain compatibility with previous versions of the Arm architecture, the access controls for the AArch32 System registers include the access controls for AArch32 Advanced SIMD and floating-point functionality.

Note

See [Background to the System register interface](#) for more information.

The following sections give more information about the AArch32 System register interface:

- [System registers in the coproc == 0b111x encoding space](#).
- [Access to System registers](#).
- [Access controls for Advanced SIMD and floating-point functionality](#).
- [Background to the System register interface](#).

D1.18.1 System registers in the coproc == 0b111x encoding space

In AArch32 state:

- The coproc == 0b1110 encoding space is reserved for the configuration and control of:
 - Debug features, see [Debug System registers](#).
 - Trace features, see the *Embedded Trace Macrocell Architecture Specification*.
 - Identification registers for the Trivial Jazelle implementation, see [Trivial implementation of the Jazelle extension](#).
- The coproc == 0b1111 encoding space is reserved for the control and configuration of the PE, including architecture and feature identification. This means these encodings provide access to the System registers that control and return status information for PE operation.

For more information, see [AArch32 System Register Descriptions](#).

D1.18.2 Access to System registers

Most System registers are accessible only from EL1 or higher. For possible accesses from EL0 the register descriptions in [AArch32 System Register Descriptions](#) indicate whether a register is accessible from EL0.

D1.18.3 Access controls for Advanced SIMD and floating-point functionality

The CPACR controls access to Advanced SIMD and floating-point functionality from software executing at PL1 or EL0 in AArch32 state:

- The {cp10, cp11} fields control access to all Advanced SIMD and floating-point functionality, and can:
 - Disable EL0 and PL1 access to this functionality.
 - Enable access to this functionality at PL1 only.
 - Enable access to this functionality at EL0 and PL1.
- The ASEDIS field controls access to Advanced SIMD instructions that are not also floating-point instructions.

Initially on powerup or reset into AArch32 state, all access to all Advanced SIMD and floating-point functionality from PL1 and EL0 is disabled.

Note

The [CPACR](#) has no effect on accesses from Hyp mode.

[HCPTR](#) provides additional controls on accesses to Advanced SIMD and floating-point functionality. For accesses that are otherwise permitted by the [CPACR](#) and [NSACR](#) settings, setting [HCPTR](#) bits to 1:

- Traps otherwise-permitted accesses from EL1 or EL0 to EL2. When EL2 is using AArch32, these accesses are trapped to Hyp mode.
- Makes accesses from EL2 mode UNDEFINED. When EL2 is using AArch32, this makes accesses from Hyp mode UNDEFINED.

In the [HCPTR](#):

- The {TCP10, TCP11} fields control access to all Advanced SIMD and floating-point functionality.
- The TASE field controls access to Advanced SIMD instructions that are not also floating-point instructions.
- The TCPAC field traps EL1 accesses to the [CPACR](#) to Hyp mode.

Note

Whenever a pair of fields control the access to the Advanced SIMD and floating-point functionality, the values of each field of the pair must be identical. If these settings are not identical the behavior of the Advanced SIMD and floating-point functionality is CONstrained UNPREDICTABLE, see [Handling of System register control fields for Advanced SIMD and floating-point operation](#).

For more information about Advanced SIMD and floating-point support, see [Advanced SIMD and floating-point support](#).

D1.18.4 Background to the System register interface

Note

This section is not part of the Architecture specification. It is included only to present the rationale of some aspects of the System register interface.

The interface to the System registers was originally defined as part of a generic *coprocessor* interface that gave access to 15 coprocessors, CP0 - CP15. Of these, CP8 - CP15 were reserved for use by Arm, while CP0 - CP7 were available for IMPLEMENTATION DEFINED coprocessors.

The coprocessors were accessed using coprocessor instructions. These instructions remain part of the T32 and A32 instruction sets, see [System register access instructions](#).

In the Arm coprocessor model, a coprocessor included both:

- Primary and secondary coprocessor registers, which form part of the coprocessor interface.
- A number of internal registers.

When accessing a 32-bit internal coprocessor register, using an MCR or MRC instruction, the instruction specified:

- The target coprocessor, specified by the `coproc` parameter and taking a value between p0 for CP0 and p15 for CP15.
- The primary coprocessor register, specified by the `CRn` parameter and taking a value between c0 and c15.
- The secondary coprocessor register, specified by the `CRm` parameter and taking a value between c0 and c15.
- Up to two additional parameters, `opc1` and `opc2`, taking values between 0 and 7.

Other instructions in the group described in [System register access instructions](#) take a subset of these parameters:

- MCRR and MRRC instructions take parameters {`coproc`, `opc1`, `CRm`}, where `CRm` is the primary coprocessor register.

To maintain backward compatibility, the arguments to an MCR or MRC instruction remain {coproc, opc1, CRn, CRm, opc2}. However:

- The naming of these parameters no longer has any particular significance.
- While the coproc field is a 4-bit field, opc1 is a 2-bit field.

Of the coprocessors reserved for use by Arm, in earlier versions of the architecture:

- CP15 provided access to the System registers relating to non-debug operation, and was originally called the System control coprocessor. From the introduction of Armv8, these registers are described as being in the coproc == 0b1111 encoding space.
- CP14 provided access to additional System registers, including those relating to debug and trace. From the introduction of Armv8, these registers are described as being in the coproc == 0b1110 encoding space.
- CP10 and CP11 were used for Advanced SIMD and floating-point control, and many coprocessor instruction encodings targeting CP10 and CP11 were used as floating-point instruction encodings:
 - Generally from the introduction of Armv8 the architecture does not relate these instructions to the coprocessor encoding space, but the naming of registers and register fields for Advanced SIMD and floating-point control reflects the historic coprocessor model.
 - Because the Advanced SIMD and floating-point functionality used both CP10 and CP11, some System register controls of this functionality have a pair of fields, for example NSACR.{cp10, cp11}. In these cases, both fields must be set to the same value. For more information, see [Access controls for Advanced SIMD and floating-point functionality](#).

From the introduction of Armv8:

- The AArch32 System registers include registers that were described as Special registers in Armv7 and earlier versions of the architecture. This means that the System registers include registers that are outside the earlier coprocessor model.
- The Armv7 AArch32 instruction encodings for LDC, STC, MCR, MRC, MCRR, and MRRC instructions with coproc field values other than {1010, 1011, 1110, 1111} are available for reuse. Armv8.2 re-uses some encodings in this way.

D1.19 Advanced SIMD and floating-point support

[Advanced SIMD and floating-point instructions](#) introduces:

- The scalar floating-point instructions in the T32 and A32 instruction sets.
- The Advanced SIMD integer and floating-point vector instructions in the T32 and A32 instruction sets.
- The SIMD and floating-point register file, which can be viewed as:
 - Singleword registers S0 - S31.
 - Doubleword registers D0 - D31.
 - Quadword registers Q0 - Q15.
- The *Floating-Point Status and Control Register (FPSCR)*.
- [Floating-point exceptions and exception traps](#).

For more information about the System registers for the Advanced SIMD and floating-point operation, see [Advanced SIMD and floating-point System registers](#). Software can interrogate these registers to discover the implemented Advanced SIMD and floating-point support.

[AArch32 implications of not including support for Advanced SIMD and floating-point](#) summarizes the effects of not supporting these instructions, and the following subsections give more information about the Advanced SIMD and Floating-point support:

- [Enabling Advanced SIMD and floating-point support](#).
- [Advanced SIMD and floating-point System registers](#).
- [Context switching when using Advanced SIMD and floating-point functionality](#).

D1.19.1 AArch32 implications of not including support for Advanced SIMD and floating-point

The architecture generally requires the inclusion of the Advanced SIMD and floating-point instructions in all instruction sets. However, for implementations targeting specialized markets, Arm might produce or license implementations that do not provide any support for Advanced SIMD and floating-point instructions. In such an implementation, in AArch32 state:

- The [CPACR](#).{ASEDIS, cp11, cp10} fields are RES0.
- The [NSACR](#).{NSASEDIS, cp11, cp10} fields are RES0.
- The [HCPTR](#).{TASE, TCP11, TCP10} fields are RES1.
- The [FPExc](#), [FPSCR](#), [FPSID](#), [MVFR0](#), [MVFR1](#), and [MVFR2](#) registers are not implemented and their encodings are UNDEFINED.
- Attempted accesses to Advanced SIMD and floating-point functionality are UNDEFINED. This means:
 - All Advanced SIMD and floating-point instructions are UNDEFINED.
 - Attempts to access the Advanced SIMD and floating-point System registers are UNDEFINED.

D1.19.2 Enabling Advanced SIMD and floating-point support

Software must ensure that the required access to the Advanced SIMD and floating-point features is enabled. Most of those controls are described in [Configurable instruction controls](#), and this section:

- Summarizes those controls.
- Provides additional information in the following subsections:
 - [FPExc control of access to Advanced SIMD and floating-point functionality](#).
 - [EL0 access to Advanced SIMD and floating-point functionality](#).

The controls of access to Advanced SIMD and floating-point functionality are:

General {cp10, cp11} or {TCP10, TCP11} controls

This relates to the [CPACR](#).{cp10, cp11}, [NSACR](#).{cp10, cp11}, and [HCPTR](#).{TCP10, TCP11} controls.

Note

[Background to the System register interface](#) explains the naming of these controls.

The {cp10, cp11} controls provide general control of the use of Advanced SIMD and floating-point functionality, as follows:

- [CPACR](#).{cp10, cp11} control access from PE modes other than Hyp mode. These fields have no effect on accesses to Advanced SIMD and floating-point functionality from Hyp mode.
- [HCPTR](#).{TCP10, TCP11} provides controls on accesses.

In each case, the {cp10, cp11} controls must be programmed to the same value, otherwise operation is CONSTRAINED UNPREDICTABLE. The CONSTRAINED UNPREDICTABLE behavior is that, for all purposes other than reading the value of the register field, behavior is as if the cp11 field has the same value as the cp10 field. For more information, see [Handling of System register control fields for Advanced SIMD and floating-point operation](#).

For more information about these controls, see:

- [FPEXC](#).
- [CPACR](#).
- [HCPTR](#).
- [NSACR](#).

Control of accesses to the CPACR from PL1 modes

As stated in [General {cp10, cp11} or {TCP10, TCP11} controls](#), the [CPACR](#) controls access to Advanced SIMD and floating-point functionality from PE modes other than Hyp mode. Accesses to the [CPACR](#) from PL1 modes can be trapped to EL2.

Additional controls of Advanced SIMD functionality

- If implemented as an RW field, [CPACR](#).ASEDIS can make all Advanced SIMD instructions UNDEFINED in all modes other than Hyp mode.
- In an implementation that includes EL2, when the [CPACR](#) and [NSACR](#) settings permit use of the Advanced SIMD instructions, if [HCPTR](#).TASE is implemented as an RW field it can make these instructions UNDEFINED in Hyp mode, and trap to Hyp mode any use of these instructions in a PL0 or PL1 mode.

[Pseudocode description of enabling SIMD and floating-point functionality](#) provides links to the pseudocode descriptions of all of these controls.

D1.19.2.1 FPEXC control of access to Advanced SIMD and floating-point functionality

In addition, [FPEXC](#).EN is an enable bit for most Advanced SIMD and floating-point operations. When [FPEXC](#).EN is 0, all Advanced SIMD and floating-point instructions are treated as UNDEFINED except for:

- A VMSR to the [FPEXC](#) or [FPSID](#) register.
- A VMRS from the [FPEXC](#), [FPSID](#), [MVFR0](#), [MVFR1](#), or [MVFR2](#) register.

These instructions can be executed only at EL1 or higher.

Note

- When the [FPSID](#) is accessible, any write access to the [FPSID](#) is ignored.
- When [FPEXC](#).EN is 0, these operations are treated as UNDEFINED :

- A VMSR to the [FPSCR](#).
 - A VMRS from the [FPSCR](#).
-

D1.19.2.2 EL0 access to Advanced SIMD and floating-point functionality

When the access controls summarized in this section permit EL0 access to the Advanced SIMD and floating-point functionality, this applies only to the subset of functionality that is available at EL0. In particular:

- Only Advanced SIMD and Floating-point System register that is accessible is the [FPSCR](#).
- The Advanced SIMD and floating-point instructions are available.

Execution at EL0 corresponds to the application level view of the Advanced SIMD and floating-point functionality, as described in [Advanced SIMD and floating-point System registers](#).

D1.19.3 Advanced SIMD and floating-point System registers

AArch32 state provides a common set of System registers for the Advanced SIMD and floating-point functionality. This section gives general information about this set of registers, and indicates where each register is described in detail. It contains the following subsections:

- [Register map of the Advanced SIMD and floating-point System registers](#).
- [Accessing the Advanced SIMD and floating-point System registers](#).

D1.19.3.1 Register map of the Advanced SIMD and floating-point System registers

[Table D1-14](#) shows the register map of the Advanced SIMD and Floating-point registers. Each register is 32 bits wide.

Table D1-14 Floating-point registers

Name	Permitted access
FPEXC	RW
FPSCR	RW
FPSID	RW ^a
MVFR0	RO
MVFR1	RO
MVFR2	RO

a. When [FPSID](#) is accessible, [VMSR](#) accesses to [FPSID](#) are ignored.

D1.19.3.2 Accessing the Advanced SIMD and floating-point System registers

Software accesses the Advanced SIMD and floating-point System registers using the [VMRS](#) and [VMSR](#) instructions, see:

- [VMRS](#).
- [VMSR](#).

For example:

```

VMRS <Rt>, FPSID    ; Read Floating-Point System ID Register
VMRS <Rt>, MVFR1     ; Read Media and VFP Feature Register 1
VMSR FPSCR, <Rt>    ; Write Floating-Point System Control Register

```

Software can access the Advanced SIMD and floating-point System registers only if the access controls permit the access, see [Enabling Advanced SIMD and floating-point support](#).

Note

All hardware ID information can be accessed only from EL1 or higher. This means:

The FPSID is accessible only from EL1 or higher.

This is a change introduced from VFPv3. Previously, the [FPSID](#) register can be accessed in all modes.

The MVFR registers are accessible only from EL1 or higher.

Unprivileged software must issue a system call to determine what features are supported.

D1.19.4 Context switching when using Advanced SIMD and floating-point functionality

When the Advanced SIMD and floating-point functionality is used by only a subset of processes, the operating system might implement lazy context switching of the Advanced SIMD and floating-point register file and System registers.

In the simplest lazy context switch implementation, the primary context switch software uses the [CPACR](#).{cp10, cp11} controls to disable access to the Advanced SIMD and floating-point functionality, see [Enabling Advanced SIMD and floating-point support](#). Subsequently, when a process or thread attempts to use an Advanced SIMD or floating-point instruction, it triggers an Undefined Instruction exception. The operating system responds by saving and restoring the Advanced SIMD and floating-point register file and System registers. Typically, it then re-executes the Advanced SIMD or floating-point instruction that generated the Undefined Instruction exception.

D1.20 Configurable instruction controls

This section describes the *Configurable instruction controls* provided by the AArch32 state.

Each control is categorized as an *instruction enable*, an *instruction disable*, or a *trap control*. The definitions of each type overlap, and in some cases are historical. Each configurable instruction control defines how an exception that is generated as a consequence of the configurable instruction control is handled or reported.

Instruction enables and instruction disables

Enable or disable the use of one or more particular instructions at a particular Privilege level and Security state.

When an instruction is disabled as a result of an instruction enable or disable, it is UNDEFINED.

The exception generated by attempting to execute an UNDEFINED instruction is:

- Taken to EL1 if the UNDEFINED instruction was executed at EL0, unless the instruction was executed at EL0 and is routed to EL2 by the control described in [Routing exceptions from EL0 to EL2](#).
When the exception is taken to EL1, it is taken to Undefined mode.
- Otherwise, taken to the Exception level at which the UNDEFINED instruction was executed:
 - If the instruction was executed in Hyp mode the exception is taken to Hyp mode.
 - Otherwise, the exception is taken to Undefined mode.

Trap controls

Control whether one or more instructions, when executed at a particular Privilege level, are *trapped*.

Trap controls are grouped as:

PL1

Trapped instructions generate Undefined Instruction exceptions that are taken to Undefined mode, unless the instruction was executed at EL0 and is routed to EL2 by the control described in [Routing exceptions from EL0 to EL2](#).

For more information about these traps, see [PL1 configurable controls](#).

Hyp mode (PL2)

Trapped instructions generate:

- Hyp Trap exceptions, taken to Hyp mode, if trapped from a mode other than Hyp mode.
- Undefined Instruction exceptions taken to Hyp mode, if trapped from Hyp mode.

For more information about these traps, see [EL2 configurable controls](#).

See also [Routing exceptions from EL0 to EL2](#).

An exception generated as a result of an instruction enable or disable, or a trap control, is only taken if the instruction does not also generate a higher priority exception. [Exception prioritization for exceptions taken to AArch32 state](#) defines the prioritization of different exceptions on the same instruction.

Exceptions generated as a result of these controls are synchronous exceptions.

For exceptions taken to an Exception level that is using AArch32, only exceptions that are taken to Hyp mode are reported in a syndrome register, the [HSR](#).

An implementation might provide additional controls, in IMPLEMENTATION DEFINED registers, to provide control of trapping of IMPLEMENTATION DEFINED features.

When a configurable instruction control causes an exception, the exception is taken and the instruction is not executed, and therefore all the following are true:

- The preferred exception return address of the exception is the instruction that generates the exception.

- There are no changes to the registers accessed by the instruction, including as a result of side-effects of a register access.

This section is organized as follows:

- [Instructions that fail their Condition code check.](#)
- [Instructions that are UNPREDICTABLE.](#)
- [Register access instructions.](#)
- [PL1 configurable controls.](#)
- [EL2 configurable controls.](#)
- [Pseudocode description of configurable instruction enables, disables, and traps.](#)

D1.20.1 Instructions that fail their Condition code check

When a configurable instruction control causes a conditional instruction to generate an exception in AArch32 state, it is IMPLEMENTATION DEFINED whether the exception applies to conditional AArch32 instructions that fail their condition code check.

For instructions that fail their Condition code check, see [Conditional execution of undefined instructions](#).

For an instruction that has a Hyp trap set that fails its Condition code check:

- Unless the trap description states otherwise, it is IMPLEMENTATION DEFINED whether the instruction:
 - Generates a Hyp Trap exception.
 - Executes as a NOP.

Any implementation must be consistent in its handling of instructions that fail their Condition code check. This means that:

- Whenever a Hyp trap is set on an instruction it must either:
 - Always generate a Hyp Trap exception.
 - Always treat the instruction as a NOP.
- The IMPLEMENTATION DEFINED part of the requirements of [Conditional execution of undefined instructions](#) must be consistent with the handling of Hyp traps on instructions that fail their Condition code check. [Table D1-15](#) shows this:

Table D1-15 Consistent handling of instructions that fail their Condition code check

Behavior of conditional undefined instruction ^a	Hyp trap on instruction that fails its Condition code check ^b
Executes as a NOP	Executes as a NOP
Generates an Undefined Instruction exception	Generates a Hyp Trap exception

a. As defined in [Conditional execution of undefined instructions](#). In EL0 and EL1 modes, this applies only if no Hyp trap is set for the instruction, otherwise see the behavior in the other column of the table.

b. For a trapped instruction executed in an EL1 or EL0 mode.

D1.20.2 Instructions that are UNPREDICTABLE

It is UNPREDICTABLE / CONSTRAINED UNPREDICTABLE whether configurable instruction controls generate an exception when the instruction is UNPREDICTABLE or CONSTRAINED UNPREDICTABLE in the PE state in which the instruction is executed, except in the following cases:

- If the instruction description explicitly states that the configurable instruction control is applied with higher priority than the CONSTRAINED UNPREDICTABLE behavior, then the configurable instruction control generates an exception.

- For an instruction where one of the CONSTRAINED UNPREDICTABLE behaviors is that a register value becomes UNKNOWN, then either:
 - The configurable instruction controls generate an exception.
 - The instruction executes with one of the CONSTRAINED UNPREDICTABLE behaviors that does not cause a register value to become UNKNOWN.

UNPREDICTABLE and CONSTRAINED UNPREDICTABLE instructions can generate exceptions as a result of configurable instruction controls, but the architecture does not require them to do so.

Note

UNPREDICTABLE and CONSTRAINED UNPREDICTABLE behavior must not perform any function that cannot be performed at the current or lower Exception level using instructions that are not UNPREDICTABLE and are not CONSTRAINED UNPREDICTABLE. This means that disabling or trapping an instruction changes the set of instructions that might be executed at EL1 or EL0, or in Hyp mode. This indirectly affects the permitted behavior of UNPREDICTABLE and CONSTRAINED UNPREDICTABLE instructions. Many CONSTRAINED UNPREDICTABLE behaviors for instructions include an allowance that the CONSTRAINED UNPREDICTABLE instruction behaves the same way as a closely related instruction that is not CONSTRAINED UNPREDICTABLE. In those cases, the instruction enable, disable, or trap control that causes an exception on the closely related instruction will cause the same exception on the CONSTRAINED UNPREDICTABLE instruction.

If no instructions are trapped, the attempted execution of an UNPREDICTABLE instruction in an EL1 or EL0 mode must not generate a Hyp Trap exception.

D1.20.3 Register access instructions

When an instruction is disabled or trapped, the exception is taken before execution of the instruction. This means that if the instruction is a register access instruction:

- No access is made before the exception is taken.
- Side-effects that are normally associated with the access do not occur before the exception is taken.

D1.20.4 PL1 configurable controls

Any exception that is generated because of an AArch32 PL1 control is taken to a PL1 mode.

Note

Any exception generated because of an AArch32 PL1 control is taken to AArch32 state.

[Table D1-16](#) shows the AArch32 System registers that contain these controls.

Table D1-16 PL1 System registers that contain configurable instruction controls

Register name	Register description
SCTLR	System Control Register
FPEXC	Floating-point Exception Control Register
CPACR	Architectural Feature Access Control Register
DBGDSCRExt	Monitor System Debug Control Register
PMUSERENR	Performance Monitors User Enable Register
CNTKCTL	Counter-timer Kernel Control Register

When generated in User mode, exceptions generated by these controls can be routed to EL2, as described in [Routing exceptions from EL0 to EL2](#).

D1.20.5 EL2 configurable controls

Table D1-17 shows the System registers that contain these controls.

Table D1-17 EL2 System registers that contain configurable instruction controls

Register name	Register description
FPEXC	Floating-point Exception Control Register
HCR	Hypervisor Configuration Register
HSTR	Hypervisor System Trap Register
HCPTR	Hyp Architectural Feature Trap Register
HDCR	Hyp Debug Control Register
HSCTLR	Hyp System Control Register
HCR2	Hypervisor Configuration Register 2
CNTHCTL	Counter-timer Hyp Control Register

D1.20.6 Pseudocode description of configurable instruction enables, disables, and traps

The pseudocode function [AArch32_CheckITEnabled\(\)](#) checks whether the T32 IT instruction is enabled.

The pseudocode function [AArch32_CheckSETENDEnabled\(\)](#) checks whether the SETEND instruction is disabled.

The pseudocode function for [AArch32_CheckForSMCUndefOrTrap\(\)](#) checks for traps on an SMC instruction.

The [AArch32_CheckForWFXTrap\(\)](#) pseudocode function checks for traps on WFE and WFI instructions:

D1.20.6.1 Pseudocode description of enabling SIMD and floating-point functionality

The [AArch32_CheckAdvSIMDOrFPEEnabled\(\)](#) and [AArch32_CheckFPAdvSIMDTrap\(\)](#) pseudocode functions take appropriate action if an SIMD or floating-point instruction is used when the SIMD and floating-point functionality is not enabled or is trapped.

The [CheckAdvSIMDOrVFPEEnabled\(\)](#), [CheckAdvSIMDEnabled\(\)](#), and [CheckVFPEEnabled\(\)](#) wrapper functions support the [AArch32_CheckAdvSIMDOrFPEEnabled\(\)](#) and [AArch32_CheckFPAdvSIMDTrap\(\)](#) functions.

The [AArch32_CheckAdvSIMDOrFPEEnabled\(\)](#), [AArch32_CheckFPAdvSIMDTrap\(\)](#), [CheckAdvSIMDOrVFPEEnabled\(\)](#), [CheckAdvSIMDEnabled\(\)](#), and [CheckVFPEEnabled\(\)](#) functions are described in [A-profile Architecture Pseudocode](#).

Chapter D2

AArch32 Self-hosted Debug

When the PE is using self-hosted debug, it generates *debug exceptions*. This chapter describes the AArch32 self-hosted debug Exception model. It is organized as follows:

- [About self-hosted debug](#)
- [Routing debug exceptions](#)
- [The debug exception enable controls](#)
- [The effect of powerdown on debug exceptions](#)
- [Summary of permitted routing and enabling of debug exceptions](#)
- [Pseudocode description of debug exceptions](#)
- [Breakpoint Instruction exceptions](#)
- [Breakpoint exceptions](#)
- [Watchpoint exceptions](#)
- [Vector Catch exceptions](#)
- [Synchronization and debug exceptions](#)

D2.1 About self-hosted debug

Self-hosted debug supports debugging through the generation and handling of *debug exceptions*, that are taken using the Exception model described in [The AArch32 System Level Programmers' Model](#).

This section introduces some terms used in describing self-hosted debug, and then introduces the debug exceptions. See:

- [Definition of a debugger in the context of self-hosted debug](#).
- [Context ID and Process ID](#).

D2.1.1 Definition of a debugger in the context of self-hosted debug

Within this chapter, *debugger* means that part of an operating system, or higher level of system software, that handles debug exceptions and programs the debug System registers. An operating system with rich application environments might provide debug services that support a debugger user interface executing at EL0. From the architectural perspective, the debug services are the debugger.

D2.1.2 Context ID and Process ID

The [CONTEXTIDR](#) identifies the current *Context ID*, that is used by:

- The debug logic, for breakpoint and watchpoint matching.
- Implemented trace logic, to identify the current process.

The [CONTEXTIDR](#) has a single field, PROCID, that is defined as the *Process Identifier* (Process ID).

D2.1.3 About debug exceptions

Debug exceptions occur during normal program flow if a debugger has programmed the PE to generate them. For example, a software developer might use a debugger contained in an operating system to debug an application. To do this, the debugger might enable one or more debug exceptions. The debug exceptions that can be generated in a stage 1 translation regime are:

- [Breakpoint Instruction exceptions](#).
- [Breakpoint exceptions](#), generated by hardware breakpoints.
- [Watchpoint exceptions](#), generated by hardware watchpoints.
- [Vector Catch exceptions](#).

Other than Breakpoint Instruction exceptions, the PE can generate a particular debug exception only if all of the following are true:

- The OS Lock is unlocked.
- `DoubleLockStatus()` == FALSE.
- Debug exceptions are not disabled from the current Exception level.
See [Enabling debug exceptions](#). Breakpoint Instruction exceptions are always enabled from the current Exception level.
- A debugger has not disabled that particular debug exception.
All of the debug exceptions except for Breakpoint Instruction exceptions have an enable control contained in the [DBGDSCRExt](#). See [The debug exception enable controls](#).

Breakpoint Instruction exceptions are always enabled.

Note

If *halting is allowed* and [EDSCR.HDE](#) is 1, hardware breakpoints and watchpoints cause entry to Debug state instead of causing debug exceptions. In Debug state, the PE is halted.
For the definition of halting is allowed, see [Halting allowed and halting prohibited](#).

When a debug exception is taken:

- If the debug exception is a Watchpoint exception, it is taken as a Data Abort exception.
- Otherwise, it is taken as a Prefetch Abort exception.

The following list summarizes each of the debug exceptions:

Breakpoint Instruction exceptions

Breakpoint instructions generate these. Breakpoint instructions are instructions that software developers can use to cause exceptions at particular points in the program flow.

The breakpoint instruction in the T32 and A32 instruction sets is `BKPT #<immediate>`. Whenever one of these is committed for execution, the PE takes a Breakpoint Instruction exception.

PE behavior

Breakpoint Instruction exceptions cannot be masked. The PE takes Breakpoint Instruction exceptions regardless of both of the following:

- The current Privilege level and AArch32 mode.
- The current Security state.

For more information, see [Breakpoint Instruction exceptions](#).

Breakpoint exceptions

The architecture provides 2-16 hardware breakpoints. These can be programmed to generate Breakpoint exceptions based on one or more of instruction addresses, accesses to any address in an instruction address range, or particular PE contexts.

For example, a software developer might program a hardware breakpoint to generate a Breakpoint exception whenever the instruction with address `0x1000` is committed for execution.

The architecture supports the following types of hardware breakpoint for use in stage 1 of an AArch32 translation regime:

- Address:
 - Address Match.
 - Address Mismatch.Comparisons are made with the virtual address of each instruction in the program flow.
- Context:
 - Context ID Match. Matches with the Context ID value held in the [CONTEXTIDR](#).
 - VMID Match. Matches with the VMID value held in the [VSCTLR](#).
 - Context ID and VMID Match. Matches with both the Context ID and the VMID value.

An Address breakpoint can link to a Context breakpoint, so that the Address breakpoint only generates a Breakpoint exception if the PE is in a particular context when the address match or mismatch occurs.

A breakpoint generates a Breakpoint exception whenever an instruction that causes a match is committed for execution.

PE behavior

If halting is allowed and [EDSCR.HDE](#) is 1, hardware breakpoints cause entry to Debug state. That is, they halt the PE. See [Debug State](#).

Otherwise:

- If debug exceptions are enabled, hardware breakpoints cause Breakpoint exceptions.
- If debug exceptions are disabled, hardware breakpoints are ignored.

For more information, see [Breakpoint exceptions](#).

Watchpoint exceptions

The architecture provides 2-16 hardware watchpoints. These can be programmed to generate Watchpoint exceptions based on accesses to particular data addresses, or based on accesses to any address in a data address range.

For example, a software developer might program a hardware watchpoint to generate a Watchpoint exception on an access to any address in the data address range $0 \times 1000 - 0 \times 101F$.

A hardware watchpoint can link to a hardware breakpoint if the hardware breakpoint is a Context matching breakpoint with linking enabled, or it can link to an address breakpoint. In this case, the watchpoint only generates a Watchpoint exception if the PE is in a particular context when the data address match occurs.

The smallest data address size that a watchpoint can be programmed to match on is a byte. A single watchpoint can be programmed to match on one or more bytes.

A watchpoint generates a Watchpoint exception whenever an instruction that initiates an access that causes a match is committed for execution.

PE behavior

If halting is allowed and `EDSCR.HDE` is 1, hardware watchpoints cause entry to Debug state. That is, they halt the PE. See [Debug State](#).

Otherwise:

- If debug exceptions are enabled, hardware watchpoints cause Watchpoint exceptions.
- If debug exceptions are disabled, hardware watchpoints are ignored.

For more information, see [Watchpoint exceptions](#).

Vector Catch exceptions

These are used to trap exceptions. The architecture provides two forms of vector catch, *address-matching* and *exception-trapping*. Only one form can be implemented.

Whichever form is implemented, a debugger must enable Vector Catch exceptions for one or more exception vectors by programming the `DBGVCR`. Generation of Vector Catch exceptions is then as follows:

- For the address-matching form, a Vector Catch exception is generated whenever the virtual address of an instruction matches a vector that Vector Catch exceptions are enabled for.
- For the Exception-trapping form, a Vector Catch exception is generated as part of exception entry for exception types that correspond to vectors that Vector Catch exceptions are enabled for.

PE behavior

If debug exceptions are:

- Enabled, Vector Catch exceptions can be generated.
- Disabled, vector catch is ignored.

For more information, see [Vector Catch exceptions](#).

[Table D2-1](#) summarizes PE behavior and shows the location of the pseudocode for each of the debug exceptions.

Table D2-1 PE behavior and pseudocode for each of the debug exceptions

Debug exception	PE behavior if debug exceptions are:		Pseudocode, see
	Enabled	Disabled	
Breakpoint Instruction exception	Takes Prefetch Abort exception	Takes Prefetch Abort exception	AArch32_SoftwareBreakpoint()
Breakpoint exception	Takes Prefetch Abort exception ^a	Ignored	Pseudocode description of Breakpoint exceptions taken from AArch32 state
Watchpoint exception	Takes Data Abort exception ^a	Ignored	Pseudocode description of Watchpoint exceptions taken from AArch32 state
Vector Catch exception	Takes Prefetch Abort exception	Ignored	Pseudocode description of Vector Catch exceptions

a. If halting is allowed and [EDSCR.HDE](#) is 1, hardware breakpoints and watchpoints cause the PE to enter Debug state instead of causing debug exceptions. See [Debug State](#).

D2.2 Routing debug exceptions

Debug exceptions are usually routed to Abort mode. However, the routing of debug exceptions depends on the [Effective values](#) of [HDCR.TDE](#) and [HCR.TGE](#):

If the [Effective value](#) of {[HDCR.TDE](#), [HCR.TGE](#)} is not {0, 0}

Debug exceptions are routed to Hyp mode.

Otherwise

Debug exceptions behave as follows:

- Debug exceptions taken from EL1 and EL0 are routed to Abort mode.
- Breakpoint Instruction exceptions taken from Hyp mode are routed to Hyp mode.
- All other debug exceptions are disabled from Hyp mode.

[Table D2-2](#) shows the routing of debug exceptions taken from an Exception level that is using AArch32 to an Exception level that is using AArch32. In these tables:

TDE Means the logical OR of [HDCR.TDE](#) and [HCR.TGE](#).

(Hyp mode) Means:

- All debug exceptions other than Breakpoint Instruction exceptions are disabled from this Privilege level.
- Breakpoint Instruction exceptions taken from this Privilege level are taken to Hyp mode.

Table D2-2 Routing of debug exceptions

TDE	Target AArch32 mode:		
	PL0	PL1	PL2
0	Abort mode	Abort mode	(Hyp mode)
1	Hyp mode	Hyp mode	(Hyp mode)

D2.2.1 Pseudocode description of routing debug exceptions

[DebugTarget\(\)](#) returns the current debug target Exception level. [DebugTargetFrom\(\)](#) returns the debug target Exception level for the specified Security state.

D2.3 The debug exception enable controls

The enable controls for each debug exception are as follows:

Breakpoint Instruction exceptions

None. Breakpoint Instruction exceptions are always enabled.

Breakpoint exceptions

`DBGDSCRExt.MDBGn`, plus an enable control for each breakpoint, `DBGBCR<n>.E`.

Watchpoint exceptions

`DBGDSCRExt.MDBGn`, plus an enable control for each watchpoint, `DBGWCR<n>.E`.

Vector Catch exceptions

`DBGDSCRExt.MDBGn`.

In addition, for all debug exceptions other than Breakpoint Instruction exceptions, software must configure the controls that enable debug exceptions from the current Exception level. See [Enabling debug exceptions](#).

The PE cannot take a debug exception if debug exceptions are disabled from either the current Exception level.

Breakpoint Instruction exceptions are always enabled from the current Exception level.

D2.3.1 Enabling debug exceptions

A debug exception can only be taken if all of the following are true:

- The OS Lock is unlocked.
- `DoubleLockStatus()` == FALSE.
- The debug exception is enabled from the current Privilege level.

[Table D2-3](#) shows when debug exceptions are enabled from the current Privilege level.

Table D2-3 Whether debug exceptions are enabled from the current Privilege level

Current Privilege level	Breakpoint Instruction exceptions	All other debug exceptions
PL2	Enabled	Disabled
PL1	Enabled	Enabled
PL0	Enabled	Enabled

D2.3.2 Pseudocode description of enabling debug exceptions

`AArch32.GenerateDebugExceptions()` determines whether debug exceptions are enabled from the current Exception level. `AArch32.GenerateDebugExceptionsFrom()` determines whether debug exceptions are enabled from the specified Exception level.

D2.4 The effect of powerdown on debug exceptions

[Debug OS Save and Restore sequences](#) describes the *powerdown save routine* and the *restore routine*.

When executing either routine, software must use the OS Lock to disable generation of all of the following:

- Breakpoint exceptions.
- Watchpoint exceptions.
- Vector Catch exceptions.

This is because the generation of these exceptions depends on the state of the debug registers, and the state of the debug registers might be lost over these routines.

Debug exceptions other than Breakpoint Instruction exceptions are enabled only if both the OS Lock is unlocked and `DoubleLockStatus() == FALSE`.

Breakpoint Instruction exceptions are enabled regardless of the state of the OS Lock and the OS Double Lock.

D2.5 Summary of permitted routing and enabling of debug exceptions

Behavior is as follows:

Breakpoint Instruction exceptions

These are always enabled, regardless of the current Privilege level. [Table D2-4](#) shows the routing of these.

Table D2-4 Routing of Breakpoint Instruction exceptions

HDCR.TDE ^a	Target when enabled from:		
	PL0	PL1	PL2
0	Abort mode	Abort mode	Hyp mode
1	Hyp mode	Hyp mode	Hyp mode

a. If the value of [HCR.TGE](#) is 1, [HDCR.TDE](#) is treated as being 1 other than for a direct read of [HDCR](#).

All other debug exceptions

The enabling and permitted routing is controlled by all of the following:

- [HDCR.TDE](#).
- The IMPLEMENTATION DEFINED authentication interface.

[Table D2-5](#) shows the valid combinations of the value of [HDCR.TDE](#). For each combination, the table shows where debug exceptions are enabled from and where they are taken to.

In the table, n/a means not applicable and a dash, -, means that debug exceptions are disabled from that Exception level.

Table D2-5 Breakpoint, Watchpoint, and Vector Catch exceptions

Debug state	Lock ^a	TDE ^b	Target AArch32 mode when enabled from:		
			PL0	PL1	PL2
Yes	X	X	-	-	-
No	TRUE	X	-	-	-
No	FALSE	0	Abort mode	Abort mode	-
No	FALSE	1	Hyp mode	Hyp mode	-

a. The value of `(OSLSR_EL1.OSLK == 1 || DoubleLockStatus())`.

b. If [HCR.TGE](#) is 1, this bit is treated as being 1 other than for a direct read of [HDCR](#). If EL2 is not implemented, behavior is as if TDE is 0.

D2.6 Pseudocode description of debug exceptions

The `AArch32_Abort()` function processes `FaultRecord()`, as described in [Abort exceptions](#), and generates:

- Data Abort exceptions for watchpoints.
- Prefetch Abort exceptions for all other debug exceptions.

D2.7 Breakpoint Instruction exceptions

This section describes Breakpoint Instruction exceptions in an AArch32 translation regime.

It contains the following subsections:

- [About Breakpoint Instruction exceptions.](#)
- [Breakpoint instruction in the T32 and A32 instruction sets.](#)
- [BKPT instructions as the first instruction in an IT block.](#)
- [Exception syndrome information and preferred return address for a BKPT instruction.](#)
- [Pseudocode description of Breakpoint Instruction exceptions.](#)

D2.7.1 About Breakpoint Instruction exceptions

A *breakpoint* is an event that results from the execution of an instruction, based on either:

- The instruction address, the PE context, or both. This type of breakpoint is called a *hardware breakpoint*.
- The instruction itself. That is, the instruction is a *breakpoint instruction*. These can be included in the program that the PE executes. This type of breakpoint is called a *software breakpoint*.

Breakpoint Instruction exceptions, that this section describes, are software breakpoints. [Breakpoint exceptions](#) describes hardware breakpoints.

There is no enable control for Breakpoint Instruction exceptions. They are always enabled, and cannot be masked.

A Breakpoint Instruction exception is generated whenever a breakpoint instruction is committed for execution, regardless of the current Exception level.

Note

- EL_D is the Exception level that debug exceptions are targeting. See [Enabling debug exceptions](#).
 - Debuggers using breakpoint instructions must be aware of the rules for concurrent modification and execution of instructions. See [Concurrent modification and execution of instructions](#).
-

D2.7.2 Breakpoint instruction in the T32 and A32 instruction sets

The breakpoint instruction, in both instruction sets, is:

- `BKPT #<immediate>`

For details of the instruction encoding, see [BKPT](#).

D2.7.2.1 About whether the BKPT instruction is conditional

In the T32 instruction set, BKPT instructions are always unconditional.

In the A32 instruction set:

- If the Condition code field is AL, the BKPT instruction is unconditional.
- If the Condition code field is anything other than AL, behavior is CONSTRAINED UNPREDICTABLE, and is one of the following:
 - The instruction is UNDEFINED.
 - The instruction is treated as a NOP instruction.
 - The instruction is executed unconditionally.
 - The instruction is executed conditionally.

D2.7.3 BKPT instructions as the first instruction in an IT block

If the first instruction in an IT block is a T32 BKPT instruction, then in an implementation that supports the ITD control, if ITD field that applies to the current Exception level is:

- | | |
|----------|--|
| 0 | The BKPT instruction generates a Breakpoint Instruction exception. |
| 1 | The combination of IT instruction and BKPT instruction is UNDEFINED. Either the IT instruction or the BKPT instruction generates an Undefined Instruction exception. |

In such an implementation, to ensure consistent behavior when making the first instruction in one or more IT blocks a BKPT instruction, the debugger must replace the IT instruction.

An implementation that does not support the ITD control behaves as if the value of the ITD field is 0.

The ITD control fields are:

HSCTLR.ITD Applies to execution at EL2 when EL2.

SCTLR.ITD Applies to execution at EL0 or EL1.

Note

T32 BKPT instructions are always unconditional.

D2.7.4 Exception syndrome information and preferred return address for a BKPT instruction

See the following:

- [Exception syndrome information for a Breakpoint Instruction exception.](#)
- [Preferred return address for a Breakpoint Instruction exception.](#)

Note

Usually, the term *exception syndrome* is used only for exceptions taken to Hyp mode. The referenced section uses the term more generally, to include exception information reported in the [IFSR](#).

D2.7.4.1 Exception syndrome information for a Breakpoint Instruction exception

The PE takes a Breakpoint Instruction exception as either:

- A Prefetch Abort exception if it is taken to PL1. In this case, it is taken to Abort mode.
- A Hyp Trap exception, if it is taken to PL2 because either [HCR.TGE](#) or [HDCR.TDE](#) is 1. In this case, it is taken to Hyp mode.

If the exception is taken to:

PL1 Abort mode

The PE sets all of the following:

- [DBGDSCRext.MOE](#) to 0b0011, to indicate a Breakpoint Instruction exception.
- [IFSR.FS](#) to the code for a debug, 0b00010.
- The [IFAR](#) with an UNKNOWN value.

PL2 Hyp mode

The PE does all of the following:

- Records information about the exception in the *Hypervisor Syndrome Register*, [HSR](#). See [Table D2-6](#).
- Sets [DBGDSCRext.MOE](#) to 0b0011, to indicate a Breakpoint Instruction exception.

- Sets the [HIFAR](#) to an unknown value.

Table D2-6 Information recorded in the HSR

HSR field	Information recorded
Exception Class, EC	The PE sets this to the code for a Prefetch Abort exception routed to Hyp mode, 0x20.
Instruction Length, IL	The PE sets this to: • 0 for a T32 BKPT instruction. • 1 for an A32 BKPT instruction.
Instruction Specific Syndrome, ISS	ISS[24:10]RES0. ISS[9]External Abort type (EA). The PE sets this to 0. ISS[8:6]RES0. ISS[5:0]Instruction Fault Status Code (IFSC). The PE sets this to the code for a debug exception, 0b100010.

Note
For information about how debug exceptions can be routed to PL2, see [Routing debug exceptions](#).

D2.7.4.2 Preferred return address for a Breakpoint Instruction exception

The preferred return address is the address of the breakpoint instruction, not the next instruction. This is different to the behavior of other exception-generating instructions, like `SVC`.

D2.7.5 Pseudocode description of Breakpoint Instruction exceptions

`AArch32_SoftwareBreakpoint()` generates a Prefetch Abort exception.

D2.8 Breakpoint exceptions

This section describes Breakpoint exceptions in stage 1 of a translation regime.

This section contains the following subsections:

- [About Breakpoint exceptions.](#)
- [Breakpoint types and linking of breakpoints.](#)
- [Execution conditions for which a breakpoint generates Breakpoint exceptions.](#)
- [Breakpoint instruction address comparisons.](#)
- [Breakpoint context comparisons.](#)
- [Using breakpoints.](#)
- [Exception syndrome information and preferred return address for a Breakpoint exception.](#)
- [Pseudocode description of Breakpoint exceptions taken from AArch32 state.](#)

D2.8.1 About Breakpoint exceptions

A *breakpoint* is an event that results from the execution of an instruction, based on either:

- The instruction address, the PE context, or both. This type of breakpoint is called a *hardware breakpoint*.
- The instruction itself. That is, the instruction is a *breakpoint instruction*. These can be included in the program that the PE executes. This type of breakpoint is called a *software breakpoint*.

Breakpoint exceptions are generated by *Breakpoint debug events*. Breakpoint debug events are generated by hardware breakpoints. Software breakpoints are described in [Breakpoint Instruction exceptions](#).

An implementation can include between 2-16 hardware breakpoints. [DBGDIDR.BRPs](#) shows how many are implemented.

To use an implemented hardware breakpoint, a debugger programs the following registers for the breakpoint:

- The *Breakpoint Control Register*, [DBGBCR<n>](#). This contains controls for the breakpoint, for example an enable control.
- The *Breakpoint Value Register*, [DBGBVR<n>](#). This holds a value used for breakpoint matching, that is one of:
 - An instruction virtual address.
 - A Context ID.
- The *Breakpoint Extended Value Register*, [DBGBXVR<n>](#), that holds a VMID value used for breakpoint matching.

These registers are numbered, so that:

- [DBGBCR1](#), [DBGBVR1](#), and [DBGBXVR1](#) are for breakpoint number one.
- [DBGBCR2](#), [DBGBVR2](#), and [DBGBXVR2](#) are for breakpoint number two.
- ...
- ...
- [DBGBCR<n>](#), [DBGBVR<n>](#), and [DBGBXVR<n>](#) are for breakpoint number <n>.

A debugger can link a breakpoint that is programmed with an address and a breakpoint that is programmed with anything other than an address together, so that a Breakpoint debug event is only generated if both breakpoints match.

For each instruction in the program flow, all of the breakpoints are tested. When a breakpoint is tested, it generates a Breakpoint debug event if all of the following are true:

- The breakpoint is enabled. That is, the breakpoint enable control for it, [DBGBCR<n>.E](#), is 1.
- The conditions specified in the [DBGBCR<n>](#) are met.
- The comparison with the value held in [DBGBVR<n>](#) is successful.

- If the breakpoint is linked to another breakpoint, the comparisons made by that other breakpoint are also successful.
- The instruction is committed for execution.

If all of these conditions are met, the breakpoint generates the Breakpoint debug event regardless of the following:

- Whether the instruction passes its Condition code check.
- The instruction type.

If halting is allowed and [EDSCR.HDE](#) is 1, Breakpoint debug events cause entry to Debug state.

Otherwise, if debug exceptions are

- Enabled, Breakpoint debug events generate Breakpoint exceptions
- Disabled, Breakpoint debug events are ignored.

Note

The remainder of this Breakpoint exceptions section, including all subsections, describes breakpoints as generating Breakpoint exceptions. However, the behavior described also applies if breakpoints are causing entry to Debug state.

[The debug exception enable controls](#) describes the enable controls for Breakpoint debug events.

D2.8.2 Breakpoint types and linking of breakpoints

Each implemented breakpoint is one of the following:

- A *context-aware* breakpoint. This is a breakpoint that can be programmed to generate a Breakpoint exception on any one of the following:
 - An instruction address match.
 - An instruction address mismatch.
 - A Context ID match, with the value held in the [CONTEXTIDR](#).
- A breakpoint that is not context-aware. These can only be programmed to generate a Breakpoint exception on an instruction address match or an instruction address mismatch.

[DBGDIDR.CTX_CMPs](#) shows how many of the implemented breakpoints are context-aware breakpoints. At least one implemented breakpoint must be context-aware. The context-aware breakpoints are the highest numbered breakpoints.

Any breakpoint that is programmed to generate a Breakpoint exception on an instruction address match or mismatch is categorized as an *Address breakpoint*. Breakpoints that are programmed to match on anything else are categorized as *Context breakpoints*.

When a debugger programs a breakpoint to be an Address or a Context breakpoint, it must also program that breakpoint so that it is either:

- Used in isolation. In this case, the breakpoint is called an *Unlinked breakpoint*.
- Enabled for linking to another breakpoint. In this case, the breakpoint is called a *Linked breakpoint*.

By linking an Address breakpoint and a Context breakpoint together, the debugger can create a breakpoint pair that only generates a Breakpoint exception if the PE is in a particular context when an instruction address match or mismatch occurs. For example, a debugger might:

1. Program breakpoint number one to be a *Linked Address Match breakpoint*.
2. Program breakpoint number five to be a *Linked Context ID Match breakpoint*.
3. Link these two breakpoints together. A Breakpoint exception is only generated if both the instruction address matches and the Context ID matches.

The *Breakpoint Type* field for a breakpoint, `DBGBCR<n>.BT`, controls the breakpoint type and whether the breakpoint is enabled for linking. If `BT[0]` is 1, the breakpoint is enabled for linking.

Address breakpoints can be programmed to generate Breakpoint exceptions on addresses that are halfword-aligned but not word-aligned. This makes it possible to breakpoint on T32 instructions. See [Specifying the halfword-aligned address that an Address breakpoint matches on](#).

D2.8.2.1 Rules for linking breakpoints

The rules for breakpoint linking are as follows:

- Only Linked breakpoint types can be linked.
- Any type of Linked Address breakpoint can link to any type of Linked Context breakpoint. The *Linked Breakpoint Number* field, `DBGBCR<n>.LBN`, for the Linked Address breakpoint specifies the particular Linked Context breakpoint that the Linked Address breakpoint links to, and:
 - `DBGBCR<n>.{HMC, PMC}` for the Linked Address breakpoint define the execution conditions that the breakpoint pair generates Breakpoint exceptions for. See [Execution conditions for which a breakpoint generates Breakpoint exceptions](#).
 - `DBGBCR<n>.{HMC, PMC}` for the Linked Context breakpoint are ignored.
- Linked Context breakpoint types can only be linked to. The LBN field for Context breakpoints is therefore ignored.
- Linked Address breakpoints cannot link to watchpoints. The LBN field can therefore only specify another breakpoint.
- If a Linked Address breakpoint links to a breakpoint that is not context-aware, the behavior of the Linked Address breakpoint is CONSTRAINED UNPREDICTABLE. See [Other usage constraints for Address breakpoints](#).
- If a Linked Address breakpoint links to an Unlinked Context breakpoint, the Linked Address breakpoint never generates any Breakpoint exceptions.
- Multiple Linked Address breakpoints can link to a single Linked Context breakpoint.

Note

Multiple Linked watchpoints can also link to a single Linked Context breakpoint. [Watchpoint exceptions](#) describes watchpoints.

These rules mean that a single Linked Context breakpoint might be linked to by all, or any combination of, the following:

- Multiple Linked Address Match breakpoints.
- Multiple Linked Address Mismatch breakpoints.
- Multiple Linked watchpoints.

It is also possible that a Linked Context breakpoint might have no breakpoints or watchpoints linked to it.

[Figure D2-1](#) shows an example of permitted breakpoint and watchpoint linking.

Figure D2-1 The role of linking in Breakpoint and Watchpoint exception generation

In [Figure D2-1](#), each Linked Address breakpoint can only generate a Breakpoint exception if the comparisons made by both it, and the Linked Context breakpoint that it links to, are successful.

D2.8.2.2 Breakpoint types defined by DBGBCRn.BT

The following list provides more detail about each breakpoint type:

0b0000, Unlinked Address Match breakpoint

Generation of a Breakpoint exception depends on both:

- [DBGBCR<n>.{HMC, PMC}](#). These define the execution conditions that the breakpoint generates Breakpoint exceptions for. See [Execution conditions for which a breakpoint generates Breakpoint exceptions](#).
- A successful address match, as described in [Breakpoint instruction address comparisons](#).

[DBGBCR<n>.LBN](#) for this breakpoint is ignored.

0b0001, Linked Address Match breakpoint

Generation of a Breakpoint exception depends on all of the following:

- [DBGBCR<n>.{HMC, PMC}](#) for this breakpoint. These define the execution conditions that the breakpoint generates Breakpoint exceptions for. See [Execution conditions for which a breakpoint generates Breakpoint exceptions](#).
- A successful address match defined by this breakpoint, as described in [Breakpoint instruction address comparisons](#).
- A successful context match defined by the Context breakpoint with linking enabled that this breakpoint links to.

[DBGBCR<n>.LBN](#) for this breakpoint selects the Context breakpoint with linking enabled that this breakpoint links to.

0b0010, Context ID Match breakpoint

BT = 0b0010 is a reserved value if the breakpoint is not a context-aware breakpoint.

For context-aware breakpoints, generation of a Breakpoint exception depends on both:

- [DBGBCR<n>.{HMC, PMC}](#). These define the execution conditions that the breakpoint generates Breakpoint exceptions for. See [Execution conditions for which a breakpoint generates Breakpoint exceptions](#).
- A successful Context ID match, as described in [Breakpoint context comparisons](#).

The value of [DBGBCR<n>.ContextID](#) is compared with the current Context ID.

[CONTEXTIDR](#) holds the current Context ID.

[DBGBCR<n>.{LBN, BAS}](#) for this breakpoint are ignored

0b0011, Context ID Match breakpoint with linking enabled

BT = 0b0011 is a reserved value if the breakpoint is not a context-aware breakpoint.

For context-aware breakpoints, either:

- This breakpoint does not generate any debug exceptions, if no Linked breakpoints or Linked watchpoints link to it.
- Generation of a Breakpoint exception depends on both:
 - A successful instruction address match, defined by a Linked Address breakpoint that links to this breakpoint, see [Breakpoint instruction address comparisons](#).
 - A successful Context ID match defined by this breakpoint, as described in [Breakpoint context comparisons](#).
- Generation of a Watchpoint exception depends on both:
 - A successful data address match, defined by a Linked watchpoint that links to this breakpoint, see [Watchpoint data address comparisons](#).
 - A successful Context ID match defined by this breakpoint, as described in [Breakpoint context comparisons](#).

The value of [DBGBCR<n>.ContextID](#) is compared with the current Context ID.

[CONTEXTIDR](#) holds the current Context ID.

[DBGBCR<n>.{LBN, HMC, BAS, PMC}](#) for this breakpoint are ignored.

0b0100, Unlinked Address Mismatch breakpoint

Generation of a Breakpoint exception depends on both:

- [DBGBCR<n>.{HMC, PMC}](#). These define the execution conditions that the breakpoint generates Breakpoint exceptions for. See [Execution conditions for which a breakpoint generates Breakpoint exceptions](#).
- A successful address mismatch, as described in [Breakpoint instruction address comparisons](#).

[DBGBCR<n>.LBN](#) for this breakpoint is ignored.

0b0101, Linked Address Mismatch breakpoint

Generation of a Breakpoint exception depends on all of the following:

- [DBGBCR<n>.{HMC, PMC}](#). These define the execution conditions that the breakpoint generates Breakpoint exceptions for. See [Execution conditions for which a breakpoint generates Breakpoint exceptions](#).
- A successful address mismatch defined by this breakpoint, as described in [Breakpoint instruction address comparisons](#).
- A successful context match defined by the Linked Context breakpoint that this breakpoint links to.

[DBGBCR<n>.](#)LBN for this breakpoint selects the Linked Context breakpoint that this breakpoint links to.

0b0110, CONTEXTIDR_EL1 Match breakpoint

BT = 0b0110 is a reserved value if the breakpoint is not a context-aware breakpoint.

For context-aware breakpoints, generation of a Breakpoint exception depends on both:

- [DBGBCR<n>.{HMC, PMC}](#). These define the execution conditions for which the breakpoint generates Breakpoint exceptions.
- A successful Context ID match defined by this breakpoint, as described in [Breakpoint context comparisons](#).

The Context ID check is made against the value in [CONTEXTIDR](#). The value of [DBGBVR<n>.](#)ContextID is compared with the Context ID value held in [CONTEXTIDR](#).

[DBGBCR<n>.{LBN, BAS}](#) for this breakpoint are ignored.

0b0111, CONTEXTIDR_EL1 Match breakpoint with linking enabled

BT = 0b0111 is a reserved value if the breakpoint is not a context-aware breakpoint.

For context-aware breakpoints, one of the following applies:

- If no Linked breakpoints or Linked watchpoints link to this breakpoint, then the breakpoint does not generate any debug exceptions.
- Generation of a Breakpoint exception depends on both:
 - A successful instruction address match, defined by a Linked Address match breakpoint that links to this breakpoint, see [Breakpoint instruction address comparisons](#).
 - A successful Context ID match defined by this breakpoint, as described in [Breakpoint context comparisons](#).
- Generation of a Watchpoint exception depends on both:
 - A successful data address match, defined by a Linked watchpoint that links to this breakpoint, see [Watchpoint data address comparisons](#).
 - A successful Context ID match defined by this breakpoint, as described in [Breakpoint context comparisons](#).

The Context ID check is made against the value in [CONTEXTIDR](#). The value of [DBGBVR<n>.](#)ContextID is compared with the Context ID value held in [CONTEXTIDR](#).

[DBGBCR<n>.{LBN, SSC, HMC, BAS, PMC}](#) for this breakpoint are ignored.

Note

See [Reserved DBGBCR<n>.BT values](#) for the behavior of breakpoints programmed with reserved BT values.

D2.8.3 Execution conditions for which a breakpoint generates Breakpoint exceptions

Each breakpoint can be programmed so that it only generates Breakpoint exceptions for certain execution conditions. For example, a breakpoint might be programmed to generate Breakpoint exceptions only when the PE is executing at PL0 in Secure state.

[DBGBCR<n>.{SSC, HMC, PMC}](#) define the execution conditions the breakpoint generates Breakpoint exceptions for, as follows:

Security State Control, SSC

The R-profile AArch32 architecture is always in Non-secure state, and therefore the Security state that the breakpoint targets is always Non-secure.

Higher Mode Control, HMC, and Privileged Mode Control, PMC

HMC and PMC together control which AArch32 modes the breakpoint generates Breakpoint exceptions in.

[Table D2-7](#) shows the valid combinations of the values of HMC, SSC, and PMC, and for each combination shows which Privilege levels breakpoints generate Breakpoint exceptions in.

In the table:

- Y** Means that a breakpoint programmed with the values of HMC, SSC and PMC shown in that row can generate Breakpoint exceptions in AArch32 modes at that Privilege level.
- Means that a breakpoint programmed with the values of HMC, SSC and PMC shown in that row cannot generate Breakpoint exceptions in AArch32 modes at that Privilege level.

A combination in [Table D2-7](#) might be reserved if an Exception level or Security state is not implemented. For information about which combinations of HMC, SSC and PMC are reserved if an Exception level or Security state are not implemented, see [Reserved DBGBCR<n>.{SSC, HMC, PMC} values](#).

Table D2-7 Summary of breakpoint HMC, SSC, and PMC encodings

HMC	SSC	PMC	PL2% ^a	PL1	PL0
0b0	0b00	0b00	-	Y% ^b	Y
0b0	0b00	0b01	-	Y	-
0b0	0b00	0b10	-	-	Y
0b0	0b00	0b11	-	Y	Y
0b1	0b00	0b01	Y	Y	Y
0b1	0b00	0b11	Y	Y	Y
0b1	0b11	0b00	Y	-	-

a. Debug exceptions are not generated at PL2. This means that these combinations of HMC and PMC are only relevant if breakpoints cause entry to Debug state. Self-hosted debuggers must avoid combinations of HMC and PMC that generate Breakpoint exceptions at PL2.

b. Only in User and System modes.

All combinations of HMC, SSC, and PMC that this table does not show are reserved. See [Table D2-10](#).

D2.8.4 Breakpoint instruction address comparisons

Address comparisons are made for each instruction in the program flow. The following subsections describe the criteria for a successful address comparison, for:

- [Address Match breakpoints.](#)
- [Address Mismatch breakpoints.](#)

D2.8.4.1 Address Match breakpoints

An address match comparison is successful if both:

- Bits [31:2] of the current instruction virtual address are equal to [DBGVCR<n>](#)[31:2].
 - The word or halfword selected by [DBGVCR<n>](#).BAS matches. That is, either:
 - [DBGVCR<n>](#).BAS is programmed with 0b0011 or 0b1111, and the instruction is at a word-aligned address.
 - [DBGVCR<n>](#).BAS is programmed with 0b1100, and the instruction is not at a word-aligned address.
- See [Specifying the halfword-aligned address that an Address breakpoint matches on.](#)

Note

[DBGVCR<n>](#)[1:0] are RES0 and are ignored.

D2.8.4.2 Address Mismatch breakpoints

An address mismatch comparison is successful if either:

- Bits [31:2] of the current instruction virtual address are not equal to [DBGVCR<n>](#)[31:2].
 - The word or halfword selected by [DBGVCR<n>](#).BAS does not match. That is, either:
 - [DBGVCR<n>](#).BAS is programmed with 0b0011 or 0b1111, and the instruction is not at a word-aligned address.
 - [DBGVCR<n>](#).BAS is programmed with 0b1100, and the instruction is at a word-aligned address.
- See [Specifying the halfword-aligned address that an Address breakpoint matches on.](#)

Note

- [DBGVCR<n>](#)[1:0] are RES0 and are ignored.
 - Address Mismatch breakpoints can be used to single-step through code. See [Using an Address Mismatch breakpoint to single-step an instruction.](#)
-

D2.8.4.3 Specifying the halfword-aligned address that an Address breakpoint matches on

For an Address breakpoint, a debugger can use the *Byte Address Selection* field, [DBGVCR<n>](#).BAS, so that the address comparison is successful on one of:

- The whole word starting at address [DBGVCR<n>](#)[31:2]:00.
- The halfword starting at address [DBGVCR<n>](#)[31:2]:00.
- The halfword starting at address (([DBGVCR<n>](#)[31:2]:00) + 2).

Note

The address programmed into the [DBGVCR<n>](#) must be word-aligned.

[DBGVCR<n>](#).BAS can be used in both Address Match breakpoints and Address Mismatch breakpoints, as follows:

- For an Address Match breakpoint, [DBGVCR<n>](#).BAS selects which halfword-aligned address the breakpoint must generate a Breakpoint exception for. This means that an address comparison is successful only if both of the following match:
 - The instruction address held in bits [31:2] of the [DBGVCR<n>](#).

— The halfword defined by the BAS field.

That is, a successful address comparison = `DBGBVR<n>[31:2]` match AND BAS match.

- For an Address Mismatch breakpoint, `DBGBCR<n>`.BAS selects which halfword-aligned address the breakpoint must not generate a Breakpoint exception for. This means that an address comparison is successful if either or both of the following do not match:

— The instruction address held in bits [31:2] of the `DBGBVR<n>`.

— The halfword defined by the BAS field.

That is, a successful address comparison = NOT (`DBGBVR<n>[31:2]` match AND BAS match).

The following subsections show the supported BAS values:

- [Using the BAS field in Address Match breakpoints.](#)
- [Using the BAS field in Address Mismatch breakpoints.](#)

For Context breakpoints, `DBGBCR<n>`.BAS is RES1 and is ignored.

D2.8.4.3.1 Using the BAS field in Address Match breakpoints

The supported BAS values are:

0b0000 This value is reserved. Behavior is a CONSTRAINED UNPREDICTABLE choice of:

- The breakpoint is disabled.
- The breakpoint behaves as if BAS is 0b0011, 0b1100, or 0b1111.

0b0011 The breakpoint generates a Breakpoint exception if an instruction with an address described as follows is committed for execution:

- Bits [31:2] of the address equals `DBGBVR<n>[31:2]`.
- Bits [1:0] of the address are 0b00.

This means that breakpoints programmed with this BAS value generate Breakpoint exceptions for all of the following:

- 32-bit T32 instructions at word-aligned addresses.
- 16-bit T32 instructions at word-aligned addresses.
- A32 instructions. These are always at word-aligned addresses.

However, Arm recommends that a debugger uses this BAS value only for T32 instructions.

It is CONSTRAINED UNPREDICTABLE whether a breakpoint programmed with this BAS value generates a Breakpoint exception on the second halfword of a 32-bit T32 instruction starting at the halfword-aligned address ((`DBGBVR<n>[31:2]`:00) - 2).

0b1100 The breakpoint generates a Breakpoint exception if an instruction with an address described as follows is committed for execution:

- Bits [31:2] of the address equals `DBGBVR<n>[31:2]`.
- Bits [1:0] of the address are 0b10.

This means that breakpoints programmed with this BAS value generate Breakpoint exceptions for both of the following:

- 32-bit T32 instructions at addresses that are halfword-aligned but not word-aligned.
- 16-bit T32 instructions at addresses that are halfword-aligned but not word-aligned.

It is CONSTRAINED UNPREDICTABLE whether a breakpoint programmed with this BAS value generates a Breakpoint exception on the second halfword of a 32-bit T32 or A32 instruction starting at a word-aligned address.

0b1111 The breakpoint generates a Breakpoint exception if an instruction with an address described as follows is committed for execution:

- Bits [31:2] of the address equals `DBGBVR<n>[31:2]`.
- Bits [1:0] of the address are `0b00`.

This means that breakpoints programmed with this BAS value generate Breakpoint exceptions for all of the following:

- 32-bit T32 instructions at word-aligned addresses.
- 16-bit T32 instructions at word-aligned addresses.
- A32 instructions. These are always at word-aligned addresses.

However, Arm recommends that a debugger uses this BAS value only for A32 instructions.

It is **CONSTRAINED UNPREDICTABLE** whether a breakpoint programmed with this BAS value generates a Breakpoint exception on the second halfword of a 32-bit T32 instruction starting at the halfword-aligned address $((\text{DBGBVR}\langle n \rangle[31:2]:00) - 2)$.

It is **CONSTRAINED UNPREDICTABLE** whether a breakpoint programmed with this BAS value generates a Breakpoint exception on a 32-bit T32 instruction or a 16-bit T32 instruction at the halfword-aligned address $((\text{DBGBVR}\langle n \rangle[31:2]:00) + 2)$.

All other BAS values are reserved. For these reserved other values, `DBGBCR<n>.BAS[3,1]` ignore writes and read the same values as `DBGBCR<n>[2,0]` respectively. This means that the smallest instruction size a debugger can program breakpoints to match on is a halfword.

Figure D2-2 shows a summary of when breakpoints programmed with particular BAS values generate Breakpoint exceptions.

The figure contains four parts:

- A column showing the row number, on the left.
- An instruction set and instruction size table.
- A location of instruction figure.
- A BAS field values table, on the right.

To use the figure, read across the rows. For example:

- Row 2 shows that a breakpoint with a BAS value of `0b1100` generates Breakpoint exceptions for 16-bit T32 instructions starting at the halfword-aligned address $((\text{DBGBVR}\langle n \rangle[31:2]:00) + 2)$.
- Row 6 shows that a breakpoint with a BAS value of either `0b0011` or `0b1111` generates Breakpoint exceptions for A32 instructions. A32 instructions are always at word-aligned addresses.

In the figure:

Yes	Means that the breakpoint generates a Breakpoint exception.
No	Means that the breakpoint does not generate a Breakpoint exception.
UNP	Means that it is CONSTRAINED UNPREDICTABLE whether the breakpoint generates a Breakpoint exception. See Other usage constraints for Address breakpoints .

	Instruction set	Size	Location of instruction ^a								BAS[3:0]		
			-2	-1	0	+1	+2	+3	+4	+5	0b0011	0b1100	0b1111
Row 1	T32	16-bit									Yes	No	Yes
Row 2		16-bit									No	Yes	UNP
Row 3	T32	32-bit									UNP	No	UNP
Row 4		32-bit									Yes	UNP	Yes
Row 5		32-bit									No	Yes	UNP
Row 6	A32	32-bit									Yes	UNP	Yes

a. 0 means the word-aligned address held in the DBGBVRn. The other locations are as follows:

- -2 means ((DBGBVRn[31:2]:00) - 2).
- -1 means ((DBGBVRn[31:2]:00) - 1).
- ...
- ...
- +5 means ((DBGBVRn[31:2]:00) + 5).

The solid areas show the location of the instruction.

Figure D2-2 Summary of BAS field meanings for Address Match breakpoints

D2.8.4.3.2 Using the BAS field in Address Mismatch breakpoints

An Address Mismatch breakpoint generates Breakpoint exceptions for all instructions committed for execution, except the instruction whose address the breakpoint is programmed to match.

The supported BAS values are:

- 0b0000 The breakpoint ignores the address held in the [DBGBVR<n>](#) and generates Breakpoint exceptions for all instruction addresses.
- 0b0011 The breakpoint does not generate a Breakpoint exception if an instruction with an address described as follows is committed for execution:
- Bits [31:2] of the address equals [DBGBVR<n>](#)[31:2].
 - Bits [1:0] of the address are 0b00.

This means that breakpoints programmed with this BAS value do not generate Breakpoint exceptions for any of the following:

- 32-bit T32 instructions at word-aligned addresses.
- 16-bit T32 instructions at word-aligned addresses.
- A32 instructions. These are always at word-aligned addresses.

However, Arm recommends that a debugger uses this BAS value only for T32 instructions.

It is **CONSTRAINED UNPREDICTABLE** whether a breakpoint programmed with this BAS value does not generate a Breakpoint exception on the second halfword of a 32-bit T32 instruction starting at the halfword-aligned address (([DBGBVR<n>](#)[31:2]:00) - 2).

- 0b1100 The breakpoint does not generate a Breakpoint exception if an instruction with an address described as follows is committed for execution:
- Bits [31:2] equals [DBGBVR<n>](#)[31:2].
 - Bits [1:0] of the address are 0b10.

This means that breakpoints programmed with this BAS value do not generate Breakpoint exceptions for either of the following:

- 32-bit T32 instructions at addresses that are halfword-aligned but not word-aligned.
- 16-bit T32 instructions at addresses that are halfword-aligned but not word-aligned.

It is **CONSTRAINED UNPREDICTABLE** whether a breakpoint programmed with this BAS value does not generate a Breakpoint exception on the second halfword of a 32-bit T32 or A32 instruction at a word-aligned address.

0b1111 The breakpoint does not generate a Breakpoint exception if an instruction with an address described as follows is committed for execution:

- Bits [31:2] of the address equals [DBGBVR<n>](#)[31:2].
- Bits [1:0] of the address are 0b00.

This means that breakpoints programmed with this BAS value do not generate Breakpoint exceptions for any of the following:

- 32-bit T32 instructions at word-aligned addresses.
- 16-bit T32 instructions at word-aligned addresses.
- A32 instructions. These are always at word-aligned addresses.

However, Arm recommends that a debugger uses this BAS value only for A32 instructions.

It is **CONSTRAINED UNPREDICTABLE** whether a breakpoint programmed with this BAS value does not generate a Breakpoint exception on the second halfword of a 32-bit T32 instruction starting at the halfword-aligned address (([DBGBVR<n>](#)[31:2]:00) - 2).

It is **CONSTRAINED UNPREDICTABLE** whether a breakpoint programmed with this BAS value does not generate a Breakpoint exception on a 32-bit T32 instruction or a 16-bit T32 instruction at the halfword-aligned address (([DBGBVR<n>](#)[31:2]:00) + 2).

All other BAS values are reserved. For these reserved other values, [DBGBCR<n>](#).BAS[3,1] ignore writes and read the same values as [DBGBCR<n>](#)[2,0] respectively. This means that the smallest instruction size that a breakpoint can never generate a Breakpoint exception for is a halfword.

[Figure D2-3](#) shows a summary of when breakpoints programmed with particular BAS values generate Breakpoint exceptions.

The figure contains four parts:

- A column showing the row number, on the left.
- An instruction set and instruction size table.
- A location of instruction figure.
- A BAS field values table, on the right.

To use the figure, read across the rows. For example:

- Row 1 shows that a breakpoint with a BAS value of 0b1100 generates Breakpoint exceptions for 16-bit T32 instructions starting at the word-aligned address held in the [DBGBVR<n>](#).
- Row 5 shows that a breakpoint with a BAS value of 0b0011 generates Breakpoint exceptions for 32-bit T32 instructions starting at the halfword-aligned address immediately after the word aligned address held in the [DBGBVR<n>](#).

In the figure:

Yes	Means that the breakpoint does generate a Breakpoint exception.
No	Means that the breakpoint does not generate a Breakpoint exception.
UNP	Means that it is CONSTRAINED UNPREDICTABLE whether the breakpoint generates a Breakpoint exception. See Other usage constraints for Address breakpoints .

			Location of instruction ^a							BAS[3:0]				
	Instruction set	Size	-2	-1	0	+1	+2	+3	+4	+5	0b0000	0b0011	0b1100	0b1111
Row 1	T32	16-bit									Yes	No	Yes	No
Row 2		16-bit									Yes	Yes	No	UNP
Row 3	T32	32-bit									Yes	UNP	Yes	UNP
Row 4		32-bit									Yes	No	UNP	No
Row 5		32-bit									Yes	Yes	No	UNP
Row 6	A32	32-bit									Yes	No	UNP	No

a. 0 means the word-aligned address held in the DBGVRn. The other locations are as follows:

- -2 means ((DBGVRn[31:2]:00) - 2).
- -1 means ((DBGVRn[31:2]:00) - 1).
- ...
- ...
- +5 means ((DBGVRn[31:2]:00) + 5).

The solid areas show the location of the instruction.

Figure D2-3 Summary of BAS field meanings for Address Mismatch breakpoints

D2.8.5 Breakpoint context comparisons

The breakpoint type defined by **DBGBCR<n>.BT** determines what context comparison is required, if any. [Table D2-8](#) shows the BT values that require a comparison, and the match required for the comparison to be successful.

Table D2-8 Breakpoint Context ID and VMID comparison tests

DBGBCR<n>.BT	Test required for successful context comparison
0b001x	CONTEXTIDR must match the DBGVR<n>.ContextID value.
0b011x	Reserved.
0b100x	VSCTLR.VMID must match the DBGXVR<n>.VMID value.
0b101x	CONTEXTIDR , must match the DBGVR<n>.ContextID value, and VSCTLR.VMID must match the DBGXVR<n>.VMID value.
0b111x	Reserved.

No context comparison is required for other valid **DBGBCR<n>.BT** values.

Context breakpoints do not generate Breakpoint exceptions when any of:

- The comparison uses the value of **CONTEXTIDR** and the PE is executing at EL2.

Note

- For all Context breakpoints, **DBGBCR<n>.BAS** is RES1 and is ignored.
- For Linked Context breakpoints, **DBGBCR<n>.{LBN, SSC, HMC, PMC}** are RES0 and are ignored.

D2.8.6 Using breakpoints

This section contains the following:

- [Using an Address Mismatch breakpoint to single-step an instruction.](#)

- [ITD control effects on address breakpoints on the first instruction in an IT block.](#)
- [Breakpoint usage constraints.](#)

D2.8.6.1 Using an Address Mismatch breakpoint to single-step an instruction

In execution conditions that an Address Mismatch breakpoint matches, defined by `DBGBCR<n>.{LBN, SSC, PMC}`, the breakpoint generates Breakpoint exceptions for all instructions committed for execution, except the instruction whose address the breakpoint is programmed with. [Figure D2-4](#) shows an example of Address Mismatch breakpoint operation, for an Address Mismatch breakpoint programmed with address `0x1014`.

Figure D2-4 Operation of an Address Mismatch breakpoint

This means that an Address Mismatch breakpoint can be used to single-step an instruction.

In the example shown in [Figure D2-4](#):

- If the target of a branch is an instruction other than the instruction at address `0x1014`, the breakpoint generates a Breakpoint exception when the instruction is committed for execution.
- If the target of a branch is the instruction at address `0x1014`, the PE executes the instruction at `0x1014` and the breakpoint does not generate a Breakpoint exception until the instruction at address `0x1018` is committed for execution. The instruction at address `0x1014` is therefore single-stepped.

However, if the instruction at `0x1014` generates a synchronous exception, or if the PE takes an asynchronous exception while the instruction is being stepped, the breakpoint is evaluated again after taking the exception. This means that behavior is as follows:

- If the exception handler executes in execution conditions that the breakpoint matches, the breakpoint generates a Breakpoint exception for the exception vector, because the exception vector is not address `0x1014`. This means that software execution steps into the exception.
- If the exception handler executes in execution conditions that the breakpoint does not match, the breakpoint does not generate any Breakpoint exceptions after the PE has taken the exception, until the exception handler completes and executes an exception return instruction. The effect is to step over the exception. Whether the instruction is stepped again depends on whether the target of the exception return instruction is the instruction at `0x1014` or the instruction at `0x1018`.

If the instruction at `0x1014` is single-stepped and branches to itself, it is **CONSTRAINED UNPREDICTABLE** whether the breakpoint generates a Breakpoint exception after the PE has executed the branch.

This means that an instruction is only single-stepped if it is the target of a branch instruction and its address matches the address the breakpoint is programmed for. In the example shown in [Figure D2-4](#), this is `0x1014`.

Usually this branch instruction is an exception return instruction that changes PE mode, branching from a PE mode in which the breakpoint does not generate a Breakpoint exception. A branch instruction that does not change PE mode would itself generate a Breakpoint exception. However, it might be a branch-to-self instruction as described above.

Note

The example shown in [Figure D2-4](#) assumes an A32 instruction.
The same behavior applies for both 32-bit and 16-bit T32 instructions.

D2.8.6.2 ITD control effects on address breakpoints on the first instruction in an IT block

In an implementation that supports the ITD control, if the value of the ITD field that applies to the current Exception level is 1, all of the following are true:

- An `IT` instruction can only be used to apply to one 16-bit T32 instruction.
- Only certain combinations of an `IT` instruction and second single 16-bit T32 instruction are permitted.
- For a permitted combination, it is IMPLEMENTATION DEFINED whether the implementation treats the combination as:
 - A pair of 16-bit instructions.
 - One 32-bit instruction.

If the implementation treats the combination as one 32-bit instruction, then as described in [Other usage constraints for Address breakpoints](#), an Address breakpoint might not generate a Breakpoint exception for an address match only on the second halfword of the instruction.

For this reason, if the ITD bit associated with the current Exception level is 1, Arm recommends that a debugger that wants to program a breakpoint to match on the second T32 instruction programs it to match on the `IT` instruction instead.

However, if returning from an exception whose preferred return address is the address of the second T32 instruction, then because the debugger is aware that the implementation has treated the combination as a pair of 16-bit instructions, the debugger is permitted to program the breakpoint to match on the second T32 instruction.

The ITD control fields are:

HSCTLR.ITD Applies to execution at EL2.

SCTLR.ITD Applies to execution at EL0 or EL1.

An implementation that does not support the ITD control behaves as if the value of the ITD field is 0, and therefore the information in this section does not apply to such an implementation.

Note

Programming the breakpoint to match on the second T32 instruction might be necessary when using an Address Mismatch breakpoint for single stepping.

D2.8.6.3 Breakpoint usage constraints

See the following sections:

- [Reserved DBGBCR<n>.BT values.](#)
- [Reserved DBGBCR<n>.{SSC, HMC, PMC} values.](#)
- [Reserved DBGBCR<n>.BAS values.](#)
- [Reserved DBGBCR<n>.LBN values.](#)
- [Other usage constraints for Address breakpoints.](#)
- [Other usage constraints for Context breakpoints.](#)

D2.8.6.3.1 Reserved DBGBCR<n>.BT values

[Table D2-9](#) shows when particular `DBGBCR<n>.BT` values are reserved.

Table D2-9 Reserved BT values

BT value	Breakpoint type	Reserved
0b001x	Context ID Match	If the breakpoint is not context-aware
0b010x	Address Mismatch	If EDSCR.HDE is 1 and halting is allowed
0b011x	•	Reserved
0b100x	Context ID Match and VMID Match	If the breakpoint is not context-aware
0b101x	•	Reserved
0b11xx	•	Reserved

If a breakpoint is programmed with one of these reserved BT values:

- The breakpoint must behave as if it is either:
 - Disabled.
 - Programmed with a BT value that is not reserved, other than for a direct or external read of [DBGBCR<n>](#).
- For a direct or external read of [DBGBCR<n>](#), if the reserved BT value:
 - Has no function for any execution conditions, the value read back is UNKNOWN.
 - Has a function for execution conditions other than the current execution conditions, the value read back is the value written. This permits software to save and restore the BT value so that the breakpoint functions for the other execution conditions.

The behavior of breakpoints with reserved BT values might change in future revisions of the architecture. For this reason, software must not rely on the behavior described here.

D2.8.6.3.2 Reserved [DBGBCR<n>](#).{SSC, HMC, PMC} values

[Table D2-10](#) shows when particular combinations of [DBGBCR<n>](#).{SSC, HMC, PMC} are reserved.

Table D2-10 Reserved HMC and PMC combinations

HMC, and PMC combination	Reserved
Combinations not included in Table D2-7 .	Always.

For all breakpoints except Linked Context breakpoints, if a breakpoint is programmed with one of these reserved combinations:

- If the reserved combination has a function for other execution conditions:
 - The breakpoint must behave as if it is disabled.
 - A direct or external read of [DBGBCR<n>](#).{SSC, HMC, PMC} returns the values written. This means that software can save and restore the combination so that the breakpoint can function for the other execution conditions.
- If the reserved combination does not have a function for other execution conditions:
 - It must behave either as if it is programmed with a combination that is not reserved or as if it is disabled.
 - A direct or external read of [DBGBCR<n>](#).{SSC, HMC, PMC} returns UNKNOWN values.

If the breakpoint is a Linked Context breakpoint, then:

- The values of HMC, SSC, and PMC are ignored.

- A direct or external read of `DBGBCR<n>.{SSC, HMC, PMC}` returns UNKNOWN values

The behavior of breakpoints with reserved combinations of HMC, SSC, and PMC might change in future revisions of the architecture. For this reason, software must not rely on the behavior described here.

D2.8.6.3.3 Reserved `DBGBCR<n>.BAS` values

For all Context breakpoints

`DBGBCR<n>.BAS` is RES1 and is ignored.

For all Address breakpoints

The supported values of the BAS field for the Address Match and Address Mismatch breakpoints are shown in [Specifying the halfword-aligned address that an Address breakpoint matches on](#).

If a breakpoint is programmed with a reserved BAS value:

- The breakpoint must behave as if it is either:
 - Disabled.
 - Programmed with a BAS value that is not reserved, other than for a direct or external read of `DBGBCR<n>`.
- A direct or external read of `DBGBCR<n>.BAS` returns an UNKNOWN value.

Software must not rely on these properties as the behavior of reserved values might change in a future revision of the architecture.

D2.8.6.3.4 Reserved `DBGBCR<n>.LBN` values

For all Context breakpoints

`DBGBCR<n>.LBN` reads UNKNOWN and its value is ignored.

For Linked Address breakpoints

A Linked Address breakpoint must link to a context-aware breakpoint. For a Linked Address breakpoint, any `DBGBCR<n>.LBN` value that is not for a context-aware breakpoint is reserved.

If a Linked Address breakpoint links to a breakpoint that is not implemented, or that is not context-aware, then reads of `DBGBCR<n>.LBN` return an unknown value and the behavior is CONSTRAINED UNPREDICTABLE. The Linked Address breakpoint behaves as if it is either:

- Disabled.
- Linked to an UNKNOWN context-aware breakpoint.

If a Linked Address breakpoint that links to a breakpoint that is implemented and that is context-aware, but that is either not enabled or not programmed as a Linked Context breakpoint, it behaves as if it is disabled.

For Unlinked Address breakpoints

`DBGBCR<n>.LBN` reads UNKNOWN and its value is ignored.

D2.8.6.3.5 Other usage constraints for Address breakpoints

For all Address breakpoints

- `DBGBVR<n>[1:0]` are RES0 and are ignored.
- The `DBGBXVR<n>` is ignored.

For Address Match breakpoints

- For 32-bit instructions, if a breakpoint matches on the address of the second halfword but not the address of the first halfword, it is CONSTRAINED UNPREDICTABLE whether the breakpoint generates a Breakpoint exception.

- If [DBGBCR<n>](#).BAS is 0b1111, it is CONSTRAINED UNPREDICTABLE whether the breakpoint generates a Breakpoint exception for a T32 instruction starting at address $((\text{DBGBVR}<n>[31:2]:00) + 2)$. For T32 instructions, Arm recommends that the debugger programs the BAS field with either 0b0011 or 0b1100.

For Address Mismatch breakpoints

The constraints are the same as those described in [For Address Match breakpoints](#), except that if two Address Mismatch breakpoints are programmed to match in the same Exception level and Security state, it is CONSTRAINED UNPREDICTABLE whether or not the instruction is stepped or a Breakpoint debug event is generated.

D2.8.6.3.6 Other usage constraints for Context breakpoints

For all Context breakpoints

Any bits of [DBGBVR<n>](#) and [DBGBXVR<n>](#) that are not used to specify Context ID or VMID are RES0 and are ignored.

Note

This means that for Context ID Match breakpoints, the [DBGBXVR<n>](#) is RES0 and is ignored, and for VMID Match breakpoints, the [DBGBVR<n>](#) is RES0 and is ignored.

For Linked Context breakpoints

If no Linked Address breakpoints or Linked Watchpoints link to a Linked Context breakpoint, the Linked Context breakpoint does not generate any Breakpoint exceptions.

D2.8.7 Exception syndrome information and preferred return address for a Breakpoint exception

See the following:

- [Exception syndrome information for a Breakpoint exception](#).
- [Preferred return address for a Breakpoint exception](#).

Note

Usually, the term *exception syndrome* is used only for exceptions taken to Hyp mode. The referenced section uses the term more generally, to include exception information reported in the [IFSR](#).

D2.8.7.1 Exception syndrome information for a Breakpoint exception

The PE takes a Breakpoint exception as either:

- A Prefetch Abort exception if it is taken to PL1. In this case, it is taken to Abort mode.
- A Hyp trap exception, if it is taken to PL2 because [HCR](#).TGE or [HDCR](#).TDE is 1. In this case, it is taken to Hyp mode.

If the exception is taken to:

Abort mode

The PE sets all of the following:

- [DBGDSCRExt](#).MOE to 0b0001, to indicate a Breakpoint exception.
- [IFSR](#).FS to the code for a debug exception, 0b00010.
- The [IFAR](#) with an UNKNOWN value.

Hyp mode

The PE does all of the following:

- Records information about the exception in the *Hypervisor Syndrome Register*, [HSR](#). See [Table D2-11](#).
- Sets [DBGDSCRext.MOE](#) to 0b0001, to indicate a Breakpoint exception.
- Sets the [HIFAR](#) to an unknown value.

Table D2-11 Information recorded in the HSR

HSR field	Information recorded	
Exception Class, EC	The PE sets this to the code for a Prefetch Abort exception routed to Hyp mode, 0x20.	
Instruction Length, IL	The PE sets this to 1.	
Instruction Specific Syndrome, ISS	ISS[24:10]	RES0.
	ISS[9]	External Abort type (EA). The PE sets this to 0.
	ISS[8:6]	RES0.
	ISS[5:0]	Instruction Fault Status Code (IFSC). The PE sets this to the code for a debug exception, 0b100010.

———— **Note** ————
For information about how debug exceptions can be routed to PL2, see [Routing debug exceptions](#).

D2.8.7.2 Preferred return address for a Breakpoint exception

The preferred return address of a Breakpoint exception is the address of the instruction that was not executed because the PE took the Breakpoint exception instead.

This means that the preferred return address is the address of the instruction that caused the exception.

D2.8.8 Pseudocode description of Breakpoint exceptions taken from AArch32 state

[AArch32_BreakpointValueMatch\(\)](#) returns a pair of results:

- A result for Address Match and Context breakpoints.
- A result for Address Mismatch breakpoints.

[AArch32_StateMatch\(\)](#) tests the values in [DBGBCR<n>.{SSC, HMC, PMC}](#) and, if the breakpoint links to a Linked Context breakpoint, also tests the Linked Context breakpoint.

[AArch32_BreakpointMatch\(\)](#) tests a committed instruction against all breakpoints.

[AArch32_CheckBreakpoint\(\)](#) generates a [FaultRecord](#). A Breakpoint exception is taken if all of the following are true:

- [DBGDSCRext.MDBGen](#) is 1.
- Debug exceptions are enabled from the current Exception level and Security state. See [Enabling debug exceptions](#).
- All of the conditions required for Breakpoint exception generation are met. See [About Breakpoint exceptions](#).

———— **Note** ————
[AArch32_CheckBreakpoint\(\)](#) might halt the PE and cause it to enter Debug state. External debug uses Debug state.

The [AArch32_Abort\(\)](#) function processes the [FaultRecord](#) object returned by [AArch32_CheckBreakpoint\(\)](#), as described in [Abort exceptions](#). When a Breakpoint exception is taken to AArch32 state, the [AArch32_Abort\(\)](#) function generates a Prefetch Abort exception.

D2.9 Watchpoint exceptions

This section describes Watchpoint exceptions in stage 1 of an AArch32 translation regime.

This section contains the following subsections:

- [About Watchpoint exceptions.](#)
- [Watchpoint types and linking of watchpoints.](#)
- [Execution conditions for which a watchpoint generates Watchpoint exceptions.](#)
- [Watchpoint data address comparisons.](#)
- [Watchpoint behavior for certain instruction classes.](#)
- [Watchpoint usage constraints.](#)
- [Exception syndrome information and preferred return address.](#)
- [Pseudocode description of Watchpoint exceptions taken from AArch32 state.](#)

D2.9.1 About Watchpoint exceptions

A *watchpoint* is an event that results from the execution of an instruction, based on a data address. Watchpoints are also known as *data breakpoints*.

A watchpoint operates as follows:

1. A debugger programs the watchpoint with a data address, or a data address range.
2. The watchpoint generates a *Watchpoint debug event* on an access to the address, or any address in the address range.

A watchpoint never generates a Watchpoint debug event on an instruction fetch.

An implementation can include between 2-16 watchpoints. In an implementation, [DBGDIDR](#).WRPs shows how many are implemented.

To use an implemented watchpoint, a debugger programs the following registers for the watchpoint:

- The *Watchpoint Control Register*, [DBGWCR<n>](#). This holds control information for the watchpoint, for example an enable control.
- The *Watchpoint Value Register*, [DBGWVR<n>](#). This holds the data virtual address used for watchpoint matching.

The registers are numbered, so that:

- DBGWCR1 and DBGWVR1 are for watchpoint number one.
- DBGWCR2 and DBGWVR2 are for watchpoint number two.
- ...
- ...
- DBGWCRn and DBGWVRn are for watchpoint number n.

A watchpoint can:

- Be programmed to generate Watchpoint debug events on read accesses only, on write accesses only, or on both types of access.
- Link to a *Linked Context breakpoint*, so that a Watchpoint debug event is only generated if the PE is in a particular context when the address match occurs.

A single watchpoint can be programmed to match on one or more address bytes. A watchpoint generates a Watchpoint debug event on an access to any byte that it is watching. The number of bytes a watchpoint is watching is either:

- One to eight bytes, provided that these bytes are contiguous and that they are all in the same naturally-aligned doubleword. A debugger uses the *Byte Address Select* field, `DBGWCR<n>.BAS`, to select the bytes. See [Programming a watchpoint with eight bytes or fewer](#).
- Eight bytes to 2GB, provided that both of the following are true:
 - The number of bytes is a power-of-two.
 - The range starts at an address that is aligned to the range size.
 A debugger uses the *MASK* field, `DBGWCR<n>.MASK`, to program a watchpoint with eight bytes to 2GB. See [Programming a watchpoint with eight or more bytes](#).

A debugger must use either the *BAS* field or the *MASK* field. If it uses both, whether the watchpoint generates Watchpoint exceptions is *CONSTRAINED UNPREDICTABLE*. See [Programming dependencies of the BAS and MASK fields](#).

For each memory access, all of the watchpoints are tested. When a watchpoint is tested, it generates a Watchpoint debug event if all of the following are true:

- The conditions specified in the `DBGWCR<n>` are met. This includes all of the following:
 - The watchpoint is enabled. See `DBGWCR<n>.E`.
 - The type of the access. See `DBGWCR<n>.LST`.
 - The Exception level and privilege of the access. See [Execution conditions for which a watchpoint generates Watchpoint exceptions](#).
 - If the watchpoint links to a breakpoint with linking enabled, the comparison or comparisons made by the breakpoint. See [Rules for linking watchpoints](#).
 Together, these define the *context* of the data access that the watchpoint matches.
- The comparison with the address held in the `DBGWVR<n>` is successful. See [Watchpoint data address comparisons](#).
- The instruction that initiates the memory access is committed for execution.
- The instruction that initiates the memory access passes its Condition code check.

If multiple watchpoints can generate a Watchpoint debug event for an access, then for all watchpoints that are enabled and match the context of the data access, the Boolean equality comparison results of all the watchpoints are OR'd together to generate a result.

If halting is allowed and `EDSCR.HDE` is 1, Watchpoint debug events cause entry to Debug state.

Otherwise, if debug exceptions are:

- Enabled, Watchpoint debug events generate Watchpoint exceptions.
- Disabled, Watchpoint debug events are ignored.

Note

The remainder of this Watchpoint Exceptions section, including all subsections, describes watchpoints as generating Watchpoint exceptions. However, the behavior described also applies if watchpoints are causing entry to Debug state.

[The debug exception enable controls](#) describes the enable controls for Watchpoint debug events.

D2.9.2 Watchpoint types and linking of watchpoints

When a debugger programs a watchpoint, it must program that watchpoint so that it is either:

- Used in isolation. In this case, the watchpoint is called an *Unlinked watchpoint*.
- Enabled for linking to a Linked Context breakpoint. In this case, the watchpoint is called a *Linked watchpoint*.

When a Linked watchpoint links to a Linked Context breakpoint, the Linked watchpoint only generates a Watchpoint exception if the PE is in a particular context when the data address match occurs. For example, a debugger might:

1. Program watchpoint number one with a data address.
2. Program breakpoint number five to be a *Linked Context Match breakpoint*.

3. Link the watchpoint and the breakpoint together. A Watchpoint exception is only generated if both the data address matches and the Context matches.

The *Watchpoint Type* field for a watchpoint, `DBGWCR<n>.WT`, controls whether the watchpoint is enabled for linking. If `DBGWCR<n>.WT` is 1, the watchpoint is enabled for linking.

D2.9.2.1 Rules for linking watchpoints

The rules for watchpoint linking are as follows:

- Only Linked watchpoints can be linked.
- A Linked watchpoint can link to any type of Linked Context breakpoint. The *Linked Breakpoint Number* field, `DBGWCR<n>.LBN`, for the Linked watchpoint specifies the particular Linked Context breakpoint that the Linked watchpoint links to, and:
 - `DBGWCR<n>.WT`. {SSC, HMC, PAC} for the Linked watchpoint define the execution conditions that the watchpoint generates Watchpoint exceptions for. See [Execution conditions for which a watchpoint generates Watchpoint exceptions](#).
 - `DBGBCR<n>.{SSC, HMC, PMC}` for the Linked Context breakpoint are ignored.
- A Linked watchpoint cannot link to another watchpoint. The LBN field can therefore only specify a breakpoint.
- If a Linked watchpoint links to a breakpoint that is not context-aware, the behavior of the Linked watchpoint is CONSTRAINED UNPREDICTABLE. See [Watchpoint usage constraints](#).
- If a Linked watchpoint links to an Unlinked Context breakpoint, the Linked watchpoint never generates any Watchpoint exceptions.
- Multiple Linked watchpoints can link to a single Linked Context breakpoint.

Note

Multiple Address breakpoints can also link to a single Linked Context breakpoint. [Breakpoint exceptions](#) describes breakpoints.

[Figure D2-1](#) shows an example of permitted watchpoint linking.

D2.9.3 Execution conditions for which a watchpoint generates Watchpoint exceptions

Each watchpoint can be programmed so that it only generates Watchpoint exceptions for certain execution conditions. For example, a watchpoint might be programmed to generate Watchpoint exceptions only when the PE is executing at EL2.

`DBGWCR<n>.{SSC, HMC, PAC}` define the execution conditions a watchpoint generates Watchpoint exceptions for, as follows:

Security State Control, SSC

Controls whether the watchpoint generates Watchpoint exceptions only in Secure state, only in Non-secure state, or in both Security states.

Note

This is determined by the Security state of the PE, not from the NS attribute returned by the translation of the virtual address on which the watchpoint is set.

Higher Mode Control, HMC, and Privileged Access Control, PAC

HMC and PAC together control which Exception levels and Privilege levels the watchpoint generates Watchpoint exceptions in.

The PAC control relates to the privilege of the memory access and Privilege level at which the access was made.

Example D2-1

PAC condition for generating a Watchpoint exception

This means that, if the PE executes a Load unprivileged or Store unprivileged instruction at PL1, the resulting data access triggers a watchpoint only if both:

- PAC is programmed to a value that generates watchpoints on PL0 accesses.
- All other conditions for generating the watchpoint are met.

Example A32/T32 Load unprivileged and Store unprivileged instructions are `LDRT` and `STRT`.

Table D2-12 shows the valid combinations of HMC, SSC, and PAC, and for each combination shows which Privilege levels watchpoints generate Watchpoint exceptions in.

In the table:

Y or -	Means that a watchpoint programmed with the values of HMC, SSC, and PAC shown in that row:
Y	Can generate Watchpoint exceptions at that Privilege level.
-	Cannot generate Watchpoint exceptions at that Privilege level.
Res	Means that the combination of HMC, SSC, and PAC is reserved. See Reserved DBGWCR<n>.{SSC, HMC, PAC} values .

Table D2-12 Summary of watchpoint HMC, SSC, and PAC encodings

HMC	SSC	PAC	PL2 ^a	PL1	Unprivileged
0b0	0b00	0b01	-	Y	-
0b0	0b00	0b10	-	-	Y
0b0	0b00	0b11	-	Y	Y
0b1	0b00	0b01	Y	Y	-
0b1	0b00	0b11	Y	Y	Y
0b1	0b11	0b00	Y	-	-

a. Debug exceptions are not generated at PL2 using AArch32. This means that these combinations of HMC, SSC, and PAC are only relevant if watchpoints cause entry to Debug state. Self-hosted debuggers must avoid combinations of HMC, SSC, and PAC that generate Watchpoint exceptions at PL2 using AArch32.

All combinations of HMC, SSC, and PAC that this table does not show are reserved. See [Reserved DBGWCR<n>.{SSC, HMC, PAC} values](#).

D2.9.4 Watchpoint data address comparisons

An address comparison is successful if bits [31:2] of the current data virtual address are equal to `DBGWVR<n>[31:2]`, taking into account all of the following:

- The size of the access. See [Size of the data access](#).
- The bytes selected by `DBGWVR<n>.BAS`. See [Programming a watchpoint with eight bytes or fewer](#).
- Any address ranges indicated by `DBGWVR<n>.MASK`. See [Programming a watchpoint with eight or more bytes](#).

Note

`DBGWVR<n>[1:0]` are `RES0` and are ignored.

D2.9.4.1 Size of the data access

Because watchpoints can be programmed to generate Watchpoint exceptions on individual bytes, the size of each access must be taken into account. See [Example D2-2](#).

Example D2-2

1. A debugger programs a watchpoint to generate Watchpoint exceptions only when the byte at address `0x1009` is accessed.
2. The PE accesses the unaligned doubleword starting at address `0x1003`.

In this scenario, the watchpoint must generate a Watchpoint exception.

The size of data accesses initiated by `DCIMVAC` instructions is an IMPLEMENTATION DEFINED size that is both:

- From the inclusive range between:
 - The size that `CTR.DminLine` defines.
 - 2KB.
- A power-of-two.

The lowest address accessed by a `DCIMVAC` instruction is the address supplied to the instruction, rounded down to the nearest multiple of the access size initiated by that instruction.

The highest address accessed is (size - 1) bytes above the lowest address accessed.

See also, [Watchpoint behavior on accesses by DCIMVAC instructions](#).

D2.9.4.2 Programming a watchpoint with eight bytes or fewer

The Byte Address Select field, `DBGWCR<n>.BAS`, selects which bytes in the doubleword starting at the address contained in the `DBGWVR<n>` the watchpoint generates Watchpoint exceptions for.

If the address programmed into the `DBGWVR<n>` is:

- Doubleword-aligned:
 - All eight bits of `DBGWCR<n>.BAS` are used, and the descriptions given in [Table D2-13](#) apply.
- Word-aligned but not doubleword-aligned:
 - Only `DBGWCR<n>.BAS[3:0]` are used, and the descriptions given in [Table D2-14](#) apply. In this case, `DBGWCR<n>.BAS[7:4]` are RES0.

Table D2-13 Supported BAS values when the DBGWVRn address alignment is doubleword

BAS value	Description
<code>BAS[0] == 1</code>	Byte at address <code>DBGWVR<n>[31:3]:000</code> selected.
<code>BAS[1] == 1</code>	Byte at address <code>DBGWVR<n>[31:3]:001</code> selected.
<code>BAS[2] == 1</code>	Byte at address <code>DBGWVR<n>[31:3]:010</code> selected.
<code>BAS[3] == 1</code>	Byte at address <code>DBGWVR<n>[31:3]:011</code> selected.
<code>BAS[4] == 1</code>	Byte at address <code>DBGWVR<n>[31:3]:100</code> selected.
<code>BAS[5] == 1</code>	Byte at address <code>DBGWVR<n>[31:3]:101</code> selected.
<code>BAS[6] == 1</code>	Byte at address <code>DBGWVR<n>[31:3]:110</code> selected.

BAS value	Description
BAS[7] == 1	Byte at address DBGWVR<n> [31:3]:111 selected.

Table D2-14 Supported BAS values when the DBGWVRn address alignment is word

BAS value ^a	Description
BAS[0] == 1	Byte at address DBGWVR<n> [31:2]:00 selected.
BAS[1] == 1	Byte at address DBGWVR<n> [31:2]:01 selected.
BAS[2] == 1	Byte at address DBGWVR<n> [31:2]:10 selected.
BAS[3] == 1	Byte at address DBGWVR<n> [31:2]:11 selected.

a. [DBGWCR<n>](#).BAS[7:4] are RES0.

If the BAS field selects more than one byte, the bytes it selects must be contiguous. For watchpoint behavior when its BAS field selects non-contiguous bytes, see [Other usage constraints](#).

When programming the BAS field with anything other than 0b11111111, a debugger must also program [DBGWCR<n>](#).MASK to be 0b000000. See [Programming dependencies of the BAS and MASK fields](#).

A watchpoint generates a Watchpoint exception whenever a watched byte is accessed, even if:

- The access size is smaller or larger than the address region being watched.
- The access is misaligned, and the base address of the access is not in the doubleword or word of memory addressed by the [DBGWVR<n>](#)[31:3]. See [Example D2-2](#).

The following are some example configurations of the BAS field:

- To program a watchpoint to generate a Watchpoint exception on the byte at address 0x1003, program:
 - [DBGWVR<n>](#) with 0x1000.
 - [DBGWCR<n>](#)._EL1.BAS to be 0b00001000.
- To program a watchpoint to generate a Watchpoint exception on the bytes at addresses 0x2003, 0x2004 and 0x2005, program:
 - [DBGWVR<n>](#) with 0x2000.
 - [DBGWCR<n>](#)._EL1.BAS to be 0b00111000.
- If the address programmed into the [DBGWVR<n>](#) is doubleword-aligned:
 - To generate a Watchpoint exception when any byte in the word starting at the doubleword-aligned address is accessed, program [DBGWCR<n>](#).BAS to be 0b00001111.
 - To generate a Watchpoint exception when any byte in the word starting at address [DBGWVR<n>](#)[31:3]:100 is accessed, program [DBGWCR<n>](#).BAS to be 0b11110000.

Note

Arm deprecates programming a [DBGWVR<n>](#) with an address that is not doubleword-aligned.

D2.9.4.3 Programming a watchpoint with eight or more bytes

A debugger can use the *MASK* field, [DBGWCR<n>](#).MASK, to program a single watchpoint with a data address range. The data address range must meet all of the following criteria:

- It is a size that is both:
 - A power-of-two.
 - A minimum of eight bytes.

- A maximum of 2GB.
- It starts at an address that is aligned to the size.

The MASK field specifies the number of least significant data address bits that must be masked. Up to 31 least significant bits can be masked.

If n least significant address bits are masked, the watchpoint generates a Watchpoint exception on all of the following:

- Address `DBGWVR<n>[31:n]:000...`
- Address `DBGWVR<n>[31:n]:111...`
- Any address between these two addresses.

For example, if the four least significant address bits are masked, Watchpoint exceptions are generated for all addresses between `DBGWVR<n>[31:4]:0000` and `DBGWVR<n>[31:4]:1111`, including these addresses.

Note

- The most significant bit cannot be masked. This means that the full address cannot be masked.
 - For watchpoint behavior when its MASK field is programmed with a reserved value, see [Reserved DBGWCR<n>.MASK values](#).
-

When masking address bits, a debugger must both:

- Program `DBGWCR<n>.BAS` to be `0b11111111`. See [Programming dependencies of the BAS and MASK fields](#).
- In the `DBGWVR<n>`, set the masked address bits to 0. For watchpoint behavior when any of the masked address bits are not 0, see [Other usage constraints](#).

D2.9.5 Watchpoint behavior for certain instruction classes

Under normal operating conditions, the following do not generate Watchpoint exceptions:

- Instruction cache maintenance instructions.
- Address translation instructions.
- TLB maintenance instructions.
- Prefetch instructions.
- All data cache maintenance instructions except `DCIMVAC`.

However, the debug architecture allows for IMPLEMENTATION DEFINED controls, such as those in ACTLR registers, to enable watchpoints on an IMPLEMENTATION DEFINED subset of these instructions. Whether a watchpoint treats the instruction as a load or a store, and the access size of instruction cache maintenance, address translation, and TLB maintenance instructions are IMPLEMENTATION DEFINED.

The access size of the IMPLEMENTATION DEFINED instruction cache maintenance, address translation, and TLB maintenance instructions that generate Watchpoint exceptions are IMPLEMENTATION DEFINED.

See also:

- [Watchpoint behavior on accesses by Store-Exclusive instructions](#).
- [Watchpoint behavior on accesses by DCIMVAC instructions](#).

D2.9.5.1 Watchpoint behavior on accesses by Store-Exclusive instructions

If a watchpoint matches on a data access caused by a Store-Exclusive instruction, then:

- If the store fails because an Exclusives monitor does not permit it, it is IMPLEMENTATION DEFINED whether the watchpoint generates a Watchpoint exception.
- Otherwise, the watchpoint generates a Watchpoint exception.

D2.9.5.2 Watchpoint behavior on accesses by DCIMVAC instructions

It is IMPLEMENTATION DEFINED whether DCIMVAC operations can generate Watchpoint exceptions. If they can, they are treated as data stores. This means that for a watchpoint to match on an access caused by a DCIMVAC instruction, the debugger must program DBGWCR<n>.LSC to be one of the following:

- 10 Match on data stores only.
- 11 Match on data stores and data loads.

Note

For the size of data accesses performed by DCIMVAC instructions, see [Watchpoint data address comparisons](#). The size of all data accesses must be considered because watchpoints can be programmed to match on individual bytes.

D2.9.6 Watchpoint usage constraints

See the following:

- [Reserved DBGWCR<n>.{SSC, HMC, PAC} values.](#)
- [Reserved DBGWCR<n>.LBN values.](#)
- [Programming dependencies of the BAS and MASK fields.](#)
- [Reserved DBGWCR<n>.BAS values.](#)
- [Reserved DBGWCR<n>.MASK values.](#)
- [Other usage constraints.](#)

D2.9.6.1 Reserved DBGWCR<n>.{SSC, HMC, PAC} values

[Table D2-15](#) shows when particular combinations of DBGWCR<n>.{SSC, HMC, PAC} are reserved.

Table D2-15 Reserved SSC, HMC, and PAC combinations

HMC, SSC, and PAC combination	Reserved
Combinations not included in Table D2-12 .	Always

If a watchpoint is programmed with one of these reserved combinations:

- The watchpoint must behave as if it is either:
 - Disabled.
 - Programmed with a combination that is not reserved, other than for a direct or external read of [DBGWCR<n>](#).
- For a direct or external read of [DBGWCR<n>](#), if the reserved combination:
 - Has no function for any execution conditions, the value read back for each of SSC, HMC, and PAC is UNKNOWN.
 - Has a function for execution conditions other than the current execution conditions, the value read back is the value written. This permits software to save and restore the combination so that the watchpoint functions for the other execution conditions.

The behavior of watchpoints with reserved combinations of SSC, HMC, and PAC might change in future revisions of the architecture. For this reason, software must not rely on the behavior described here.

D2.9.6.2 Reserved DBGWCR<n>.LBN values

For Linked watchpoints

A Linked watchpoint must link to a context-aware breakpoint. For a Linked watchpoint, any DBGWCR<n>.LBN value that is not for a context-aware breakpoint is reserved.

If a Linked watchpoint links to a breakpoint that is not implemented, or that is not context-aware, then reads of DBGWCR<n>.LBN return an UNKNOWN value and the behavior is CONSTRAINED UNPREDICTABLE. The Linked watchpoint behaves as if it is either:

- Disabled.
- Linked to an UNKNOWN context-aware breakpoint.

If a Linked watchpoint links to a breakpoint that is implemented and is context-aware, but that is either not enabled or not programmed as a Linked Context breakpoint, it behaves as if it is disabled.

For Unlinked watchpoints

For Unlinked watchpoints, DBGWCR<n>.LBN reads UNKNOWN and its value is ignored.

D2.9.6.3 Programming dependencies of the BAS and MASK fields

When programming a watchpoint, a debugger must use either:

- The MASK field, to program the watchpoint with an address range that can be eight bytes to 2GB.
- The BAS field, to select which bytes in the doubleword or word starting at the address contained in the DBGWVR<n> the watchpoint must generate Watchpoint exceptions for.

If the debugger uses the:

- MASK field, it must program BAS to be 0b11111111, so that all bytes in the doubleword or word are selected.
- BAS field, it must program MASK to be 0b000000, so that the MASK field does not indicate any address ranges.

If an enabled watchpoint has a MASK field that is nonzero and a BAS field that is not set to 0b11111111, then for each byte in the address range, it is CONSTRAINED UNPREDICTABLE whether or not a Watchpoint exception is generated.

D2.9.6.4 Reserved DBGWCR<n>.BAS values

The BAS field must be programmed with a value Zeros (8-n-m) : Ones (n) : Zeros (m), where:

- n is a nonzero positive integer less-than-or-equal-to 8.
- m is a positive integer less-than 8. m is permitted to be zero.
- n+m is less-than-or-equal-to 8.
- If DBGWVR<n>[2] is 1, then n+m is less-than-or-equal-to 4.

All other values are reserved.

Note

Zeros{0}() is an empty bitstring.

If DBGWVR<n>[2] is 1, DBGWCR<n>.BAS[7:4] are RES0.

If a watchpoint is programmed with a reserved BAS value:

- It is CONSTRAINED UNPREDICTABLE whether the watchpoint generates a Watchpoint exception for each byte in the doubleword or word of memory addressed by the DBGWVR<n>.
- A direct or external read of DBGWCR<n>.BAS returns an UNKNOWN value.

Software must not rely on these properties as the behavior of reserved values might change in a future revision of the architecture.

D2.9.6.5 Reserved DBGWCR<n>.MASK values

If a watchpoint is programmed with a reserved MASK value:

- The watchpoint must behave as if it is either:
 - Disabled.
 - Programmed with an UNKNOWN value that is not reserved, that might be 0b00000, other than for a direct or external read of DBGWCR<n>.
- A direct or external read of DBGWCR<n>.MASK returns an UNKNOWN value.

D2.9.6.6 Other usage constraints

For all watchpoints:

- DBGWVR<n>[1:0] are RES0 and are ignored.
- If DBGWCR<n>.MASK is nonzero, and any masked bits of DBGWVR<n> are not 0, it is CONSTRAINED UNPREDICTABLE whether the watchpoint generates a Watchpoint exception when the unmasked bits match.
- A watchpoint never generates any Watchpoint exceptions if DBGWCR<n>.LSC is 0b00.

D2.9.7 Exception syndrome information, fault address information, and preferred return address

See the following:

- [Exception syndrome information](#).
- [Fault address information](#).
- [Preferred return address](#).

D2.9.7.1 Exception syndrome information

The PE takes a Watchpoint exception as either:

- A Data Abort exception, if it is taken to PL1. In this case, it is taken to Abort mode.
- A Hyp trap exception, if it is taken to PL2 because HCR.TGE or HDCR.TDE is 1. In this case, it is taken to Hyp mode.

If the exception is taken to:

Abort mode

The PE sets all of the following:

- DBGDSCRExt.MOE to 0b1010, to indicate a Watchpoint exception.
- DFSR.CM to indicate whether a cache maintenance instruction caused the exception.
- DFSR.WnR to indicate whether the exception was generated on a read instruction or a write instruction.

Hyp mode

The PE does all of the following:

- Records information about the exception in the *Hypervisor Syndrome Register*, HSR. See [Table D2-16](#).
- Sets DBGDSCRExt.MOE to 0b1001, to indicate a Watchpoint exception.

Table D2-16 Information recorded in the HSR

HSR field	Information recorded	
<i>Exception Class</i> , EC	The PE sets this to the code for a Data Abort exception routed to Hyp mode, 0×24 .	
<i>Instruction Length</i> , IL	The PE sets this to 1.	
<i>Instruction Specific Syndrome</i> , ISS	ISV[24]	<i>Instruction Syndrome Valid</i> (ISV). The PE sets this to 0.
	ISS[23:10]	RES0.
	ISS[9]	<i>External Abort type</i> (EA). The PE sets this to 0.
	ISS[8]	<i>Cache Maintenance</i> (CM). The PE sets this to indicate whether a cache maintenance instruction caused the exception.
	ISS[7]	RES0 .
	ISS[6]	<i>Write not Read</i> (WnR). The PE sets this to indicate whether the exception was generated on a read instruction or a write instruction .
	ISS[5:0]	<i>Data Fault Status Code</i> (DFSC). The PE sets this to the code for a debug exception, $0b100010$.

Note

For information about how debug exceptions can be routed to PL2, see [Routing debug exceptions](#).

D2.9.7.2 Fault address information

On a Watchpoint exception, the PE records an address in a *Fault Address Register* that the debugger can use to determine the memory location that triggered the watchpoint.

The Fault Address Register (FAR) used is one of the following:

- For a Watchpoint taken as an exception to Abort mode, [DFAR](#).
- For a Watchpoint taken as an exception to Hyp mode, [EHDFAR](#).
- For a Watchpoint debug event that causes entry to Debug state, [EDWAR](#).

In cases where one instruction triggers multiple watchpoints, only one address is recorded.

Note

On entry into Debug state [EDWAR](#)[63:32] is UNKNOWN and must be ignored by the debugger.

In the following subsection, a *watchpointed address* is defined as any address for which at least one of the watchpoints generates a watchpoint match.

D2.9.7.2.1 Address recorded for Watchpoint exceptions generated by data cache maintenance instructions

For a watchpoint triggered by a Data Cache maintenance operation, the address recorded in [DFAR](#), [HDFAR](#), or [EDWAR](#) is both:

- Any address accessed by the instruction.
- Within a naturally-aligned block of memory.

D2.9.7.2.2 Address recorded for Watchpoint exceptions generated by instructions other than data cache maintenance instructions

The address recorded in [DFAR](#), [HDFAR](#), or [EDWAR](#) is both:

- From the inclusive range between:
 - The lowest address accessed by the memory access or set of contiguous memory accesses that triggered the watchpoint.
 - The highest watchpointed address accessed by the memory access or set of contiguous memory accesses that triggered the watchpoint.

- Within a naturally-aligned block of memory that is all of the following:
 - A power-of-two size.
 - No larger than the DC ZVA block size.
 - Contains a watchpointed address accessed by the memory access or set of contiguous memory accesses that triggered the watchpoint.

The size of the naturally-aligned block of memory is IMPLEMENTATION DEFINED. There is no architectural means of discovering the size.

Example D2-3 Address recorded for a watchpoint programmed on 0x8019

A debugger programs a watchpoint to generate a Watchpoint exception on any access to the byte 0x8019.

An A32 load multiple instruction then loads nine registers starting from address 0x8004 upwards. This triggers the watchpoint.

If the DC ZVA block size is:

- 32 bytes, the address that the PE records must be between 0x8004 and 0x8019 inclusive.
- 16 bytes, the address that the PE records must be between 0x8010 and 0x8019 inclusive.

D2.9.7.3 Preferred return address

The preferred return address of a Watchpoint exception is the address of the instruction that was not executed because the PE took the Watchpoint exception instead.

This means that the preferred return address is the address of the instruction that caused the exception.

D2.9.8 Pseudocode description of Watchpoint exceptions taken from AArch32 state

`AArch32_WatchpointByteMatch()` tests an individual byte accessed by an operation.

`AArch32_StateMatch()` tests the values in `DBGWCR<n>`. {HMC, SSC, PAC}, and if the watchpoint is Linked, also tests the Linked Context breakpoint that the watchpoint links to.

`AArch32_WatchpointMatch()` tests the value in `DBGWVR<n>`.

`AArch32_CheckWatchpoint()` generates a `FaultRecord`. A Watchpoint exception is taken if all of the following are true:

- `DBGDSCRext.MDBGen` is 1.
- Debug exceptions are enabled from the current Exception level and Security state. See [Enabling debug exceptions](#).
- All of the conditions required for Watchpoint exception generation are met. See [About Watchpoint exceptions](#).

Note

`AArch32_CheckWatchpoint` might halt the PE and cause it to enter Debug state. External debug uses Debug state.

The `AArch32_Abort()` function processes the `FaultRecord` object returned by `AArch32_CheckWatchpoint()`, as described in [Abort exceptions](#). If a Watchpoint exception is taken to AArch32 state, the `AArch32_Abort()` function generates a Data Abort exception.

D2.10 Vector Catch exceptions

Arm deprecates the use of vector catch.

This section describes Vector Catch exceptions in stage 1 of an AArch32 translation regime.

This section contains the following subsections:

- [About Vector Catch exceptions.](#)
- [Exception vectors that Vector Catch exceptions can be enabled for.](#)
- [Generation of Vector Catch exceptions.](#)
- [Usage constraints.](#)
- [Exception syndrome information and preferred return address for a Vector Catch exception.](#)
- [Pseudocode description of Vector Catch exceptions.](#)

D2.10.1 About Vector Catch exceptions

Whenever the PE takes an exception, execution is forced to an address that is the *exception vector* for that exception. Vector catch permits a debugger to trap exceptions based on the exception vector, or based on the exception type associated with the exception vector, as follows:

- If the *address-matching* form of vector catch is implemented, the debugger can trap exceptions based on the exception vector.
- If the *exception-trapping* form of vector catch is implemented, the debugger can trap exceptions based on the exception type associated with the exception vector.

The architecture supports only these two forms of vector catch. Only one form can be implemented, and which is implemented is IMPLEMENTATION DEFINED. The [DBGDEVID](#) indicates which form is implemented.

Regardless of the form of vector catch implemented, a debugger enables Vector Catch exceptions for exception vectors or types by programming the [DBGVCR](#). This register contains *vector catch enable bits*. Each of these bits corresponds to a different vector. When a debugger sets a vector catch enable bit to 1, Vector Catch exceptions are enabled for the corresponding exception vector or type.

When Vector Catch exceptions are enabled for an exception vector, this is called an *enabled vector catch*. The set of exception vectors that Vector Catch exceptions are enabled for is called the *enabled vector catch set*.

If the form of vector catch implemented is the:

Address-matching form:

The PE compares the virtual address of each instruction in the program flow with a subset of the enabled vector catch set.

If an address match occurs, a Vector Catch exception is generated when the instruction that caused the match is committed for execution.

Exception-trapping form

Whenever the PE takes an exception, if the vector the exception is taken to is included in a subset of the enabled vector catch set, a Vector Catch exception is generated.

The Vector Catch exception is generated as part of entry to the exception, and must be taken before the PE either executes any instructions or takes any further exceptions.

[Table D2-17](#) summarizes the differences between the address-matching and exception-trapping forms.

Table D2-17 Differences in behavior of the address-matching and exception-trapping forms of vector catch

Address-matching	Exception-trapping
An enabled vector catch generates a Vector Catch exception when an instruction that is fetched from the vector is committed for execution. This means that spurious Vector Catch exceptions might occur, where the Vector Catch exception does not result from an exception entry, but is instead caused by a branch to the vector. A branch to the vector might occur, for example, on a return from a nested exception or when simulating an exception entry.	An enabled vector catch generates a Vector Catch exception immediately after the PE takes the exception that is associated with the vector. This means that Vector Catch exceptions always result from exception entry, and not from branches to exception vectors.
A Vector Catch exception is generated as a result of an instruction fetch. This means that the Vector Catch exception has a priority relative to the other synchronous exceptions that result from an instruction fetch.	A Vector Catch exception is generated as a result of an exception entry. This means that the Vector Catch exception is part of the exception that caused the Vector Catch exception. Therefore, the Vector Catch exception has no priority associated with it.
A Vector Catch exception can be preempted by another exception. If this happens, the Vector Catch exception is generated again when the exception handler branches back to the vector.	Vector Catch exceptions must be taken before other exceptions.
A Vector Catch exception can be generated as a result of an instruction fetch executed in any AArch32 mode except Hyp mode, including User mode.	Because a Vector Catch exception is generated as the result of an exception entry, the Vector Catch exception is taken.
If HCR.TGE is 1, Vector Catch exceptions can be generated for User mode instruction fetches from PL1 vectors.	If HCR.TGE is 1, Vector Catch exceptions are never generated.

Depending on the implementation, some vector catch enable bits in the [DBGVCR](#) might be RES0.

See [Exception vectors that Vector Catch exceptions can be enabled for](#) for the vector catch enable bits that exist for different implementations.

[The debug exception enable controls](#) describes the enable controls for Vector Catch exceptions.

D2.10.2 Exception vectors that Vector Catch exceptions can be enabled for

When the PE takes an exception, the exception vector is contained in a *vector table* at the Privilege level the exception is taken to.

Depending on the Security state and AArch32 mode the exception is taken to, when the exception is taken, the vector table used is the table that contains one of:

- *Local exception vectors.*
- *Hyp exception vectors.*

The tables that follow show the vectors that Vector Catch exceptions can be enabled for, and their corresponding vector catch enable bits in the [DBGVCR](#):

- [Table D2-18](#) shows the Local exception vectors that Vector Catch exceptions can be enabled for.

The architecture does not provide vector catch enable bits for the Hyp exception vectors.

Table D2-18 Local exception vectors that Vector Catch exceptions can be enabled for

Vector catch enable bit	Exception type	Local exception vectors
Local exception vectors		
F	FIQ interrupt	$\text{VBAR} + 0 \times 0000001C$
I	IRQ interrupt	$\text{VBAR} + 0 \times 00000018$
D	Data Abort	$\text{VBAR} + 0 \times 00000010$
P	Prefetch Abort	$\text{VBAR} + 0 \times 0000000C$
S	Supervisor Call	$\text{VBAR} + 0 \times 00000008$
U	Undefined Instruction	$\text{VBAR} + 0 \times 00000004$

D2.10.3 Generation of Vector Catch exceptions

How Vector Catch exceptions are generated depends on which form is implemented:

- [Address-matching form.](#)
- [Exception-trapping form.](#)

D2.10.3.1 Address-matching form

The PE compares the virtual address of each instruction in the program flow is with some or all of the addresses in the enabled vector catch set, as follows:

The enabled vector catch set contains only Local exception vectors.

The PE compares the virtual address of each instruction in the program flow, including those executed at EL0, with all addresses in the enabled vector catch set.

For each instruction in the program flow, the PE tests for any possible Vector Catch exceptions before executing the instruction. If a match occurs, a Vector Catch exception is generated when the instruction is committed for execution, regardless of all of the following:

- Whether the instruction passes its Condition code check.
- Whether the instruction is executed as part of exception entry.
- What [HCR](#).{IMO, FMO, AMO} are set to.

D2.10.3.2 Exception-trapping form

When the PE takes an exception, it tests whether the exception is by branching to an exception vector in a subset of the enabled vector catch set, as follows:

The enabled vector catch set contains only Local exception vectors.

The PE tests whether the exception is by branching to any address in the enabled vector catch set.

If the exception is by branching to a vector in the subset, a Vector Catch exception is generated as part of exception entry. That is, a Vector Catch exception is generated instead of the exception handler executing its first instruction.

D2.10.4 Usage constraints

See the following subsections:

- [Usage constraints that apply to both forms of vector catch.](#)
- [Usage constraints that apply only to the address-matching form.](#)

D2.10.4.1 Usage constraints that apply to both forms of vector catch

For Vector Catch exceptions enabled for either the Prefetch Abort exception vector or the Data Abort exception vector, if one of these exception types is taken to the Exception level that debug exceptions are targeting, behavior is **CONSTRAINED UNPREDICTABLE**. Either:

- Vector catch is ignored, therefore a Vector Catch exception is not generated.
- Vector catch generates a Prefetch Abort debug exception. For Vector Catch exceptions enabled for the Prefetch Abort exception vector, the PE might enter a recursive loop of Prefetch Abort exceptions causing Vector Catch exceptions and Vector Catch exceptions causing Prefetch Abort exceptions.

Note

The Exception level that debug exceptions are targeting is called the *debug target Exception level*, EL_D . [Routing debug exceptions](#) describes how EL_D is derived.

D2.10.4.2 Usage constraints that apply only to the address-matching form

Exception vectors are at word-aligned addresses, and:

- It is **CONSTRAINED UNPREDICTABLE** whether an enabled vector catch generates a Vector Catch exception for a 32-bit T32 instruction starting at the halfword-aligned address immediately prior to the vector address.
- T32 instructions that start at the halfword-aligned address immediately after the exception vector do not generate Vector Catch exceptions.

For the address-matching form, Vector Catch exceptions have the same priority as Breakpoint exceptions. If a single instruction causes both a Vector Catch exception and a Breakpoint exception, it is **CONSTRAINED UNPREDICTABLE** which of these debug exceptions the PE takes.

D2.10.5 Exception syndrome information and preferred return address for a Vector Catch exception

See the following:

- [Exception syndrome information for a Vector Catch exception](#).
- [Preferred return address for a Vector Catch exception](#).

Note

Usually, the term *exception syndrome* is used only for exceptions taken to Hyp mode. The referenced section uses the term more generally, to include exception information reported in the [IFSR](#).

D2.10.5.1 Exception syndrome information for a Vector Catch exception

The PE takes a Vector Catch exception as either:

- A Prefetch Abort exception if it is taken to PL1. In this case, it is taken to Abort mode.
- A Hyp trap exception, if it is taken to PL2 because [HCR](#).TGE or [HDCR](#).TDE is 1. In this case, it is taken to Hyp mode.

If the exception is taken to:

PL1 Abort mode

The PE sets all of the following:

- [IFSR](#).FS to the code for a debug exception, 0b00010.
- [DBGDSCRExt](#).MOE to 0b0101, to indicate a Vector Catch exception.
- The [IFAR](#) with an UNKNOWN value.

PL2 Hyp mode

The PE does all of the following:

- Records information about the exception in the *Hypervisor Syndrome Register*, [HSR](#). See [Table D2-19](#).
- Sets [DBGDSCRExt.MOE](#) to 0b0101, to indicate a Vector Catch exception.
- Sets the [HIFAR](#) to an unknown value.

Table D2-19 Information recorded in the HSR

HSR field	Information recorded	
Exception Class, EC	The PE sets this to the code for a Prefetch Abort exception routed to Hyp mode, 0x20.	
Instruction Length, IL	The PE sets this to 1.	
Instruction Specific Syndrome, ISS	ISS[24:10]	RES0.
	ISS[9]	External Abort type (EA). The PE sets this to 0.
	ISS[8:6]	RES0.
	ISS[5:0]	Instruction Fault Status Code (IFSC). The PE sets this to the code for a debug exception, 0b100010.

Note
For information about how debug exceptions can be routed to PL2, see [Routing debug exceptions](#).

D2.10.5.2 Preferred return address for a Vector Catch exception

The preferred return address of a Vector Catch exceptions is the address of the instruction that was not executed because the PE took the Vector Catch exception instead.

This means that the preferred return address is the exception vector. This is true regardless of whether the address-matching form or the exception trapping form is implemented.

D2.10.6 Pseudocode description of Vector Catch exceptions

The `AArch32_VCRMatch()` pseudocode function checks whether the instruction at `address` generates a Vector Catch exception. It therefore shows the address-matching form of vector catch.

The `AArch32_CheckVectorCatch()` pseudocode function uses `AArch32_VCRMatch()` to test whether the instruction generates a Vector Catch exception, and if `AArch32_VCRMatch()` returns TRUE it generates that event.

The `AArch32_Abort()` function processes the `FaultRecord` object returned by `AArch32_CheckVectorCatch()`, as described in [Abort exceptions](#). If there is a Vector Catch exception, the `AArch32_Abort()` function generates a Prefetch Abort exception.

D2.11 Synchronization and debug exceptions

The behavior of debug depends on all of the following:

- The state of the external debug authentication interface.
- Indirect reads of:
 - External debug registers.
 - System registers, including system debug registers.
 - Special-purpose registers.

If a change is made to any of these, the effect of that change on debug exception generation cannot be relied on until after a [Context Synchronization event](#) has occurred.

For any instructions executed between the time when the change is made and the time when the next [Context Synchronization event](#) occurs, it is CONSTRAINED UNPREDICTABLE whether debug uses the state of the PE before the change, or the state of the PE after the change.

Example D2-4 Example of synchronization and Breakpoint exception generation

1. Software changes [DBGDSCRext.MDBGGen](#) from 0 to 1.
2. An instruction is executed, that would cause a Breakpoint exception if self-hosted debug uses the state of the PE after the change.
3. A [Context Synchronization event](#) occurs.

In this case, it is CONSTRAINED UNPREDICTABLE whether the instruction generates a Breakpoint exception.

Example D2-5 Example of synchronization and debug exceptions generation

1. Software unlocks the OS Lock.
2. The PE executes some instructions.
3. A [Context Synchronization event](#) occurs.

During the time when the PE is executing some instructions, step 2, it is CONSTRAINED UNPREDICTABLE whether debug exceptions other than Breakpoint Instruction exceptions can be generated.

Note

For more information, see:

- [Synchronization of changes to AArch32 System registers.](#)
 - [Accessing PSTATE fields.](#)
 - [Synchronization of changes to the external debug registers.](#)
-

D2.11.1 Mode changes without explicit Context Synchronization events

Most changes to the Exception level, happen as a result of operations that are an explicit [Context Synchronization event](#). This is because taking an exception and returning from an exception are both explicit [Context Synchronization events](#), and the Privilege level can only change as a result of taking or returning from an exception.

However, some AArch32 mode changes can happen because of operations that are not an explicit [Context Synchronization event](#).

These are AArch32 mode changes caused by MSR and CPS instructions.

A mode change might be to a mode at a lower Privilege level.

Chapter D3

AArch32 Trace

This chapter describes the AArch32 self-hosted trace:

- [About trace](#)
- [Prohibited regions in self-hosted trace](#)
- [Self-hosted trace timestamps](#)
- [Synchronization in self-hosted trace](#)

D3.1 About trace

A trace unit generates trace data to describe the program flow of the PE.

The trace unit can be an implementation of any of the following:

- In Armv8, a standard Arm Embedded Trace Macrocell (ETM). See *Arm® Embedded Trace Macrocell Architecture Specification, ETMv4*.
- An IMPLEMENTATION DEFINED trace function.

Self-hosted trace happens when the agent controlling the trace collection is part of the same software stack as the software being traced. The agent controls prohibited regions. The information collected by the agent is sent to a trace sink.

The trace unit and the PE must have the same view of the debug authentication interface.

`ExternalNoninvasiveDebugAllowed()` controls whether tracing is prohibited or allowed.

D3.1.1 Trace Sinks

The trace unit sends the trace data to a trace sink. A system might include multiple trace sinks, and allow software to configure which trace sink or sinks are used.

An example of an internal trace sink is an Embedded Trace Router (ETR), which allows software to define a buffer in memory. Trace data is written to this buffer.

D3.2 Prohibited regions in self-hosted trace

Trace is not generated in prohibited regions. The pseudocode function `TraceAllowed()` indicates whether tracing is allowed in the current Security state and Exception level.

The IMPLEMENTATION DEFINED debug authentication interface can allow an external agent to disable the self-hosted trace extension.

D3.3 Self-hosted trace timestamps

The trace timestamp is a value that represents the passage of time in real-time. It is calculated from a counter which increments all the time, when the PE is generating trace and when the PE is in a prohibited region.

While self-hosted trace is disabled, the external trace provides the trace timestamp. If the external trace is a standard CoreSight system, the relationship between CoreSight time and the Generic Timer counter is IMPLEMENTATION DEFINED.

When self-hosted trace is enabled, the trace time stamp is one of the following:

- Physical time, which is defined by the physical count value returned by `PhysicalCountInt()`.
- Virtual time, which is defined as the value of `PhysicalCountInt()` minus a virtual offset.
The virtual offset is always `CNTVOFF`, including when a read of `CNTVCT` at the current Exception level would treat the virtual offset as zero.

D3.4 Synchronization in self-hosted trace

The trace unit is an indirect observer of the trace control registers.

Chapter D4

The AArch32 System Level Memory Model

This chapter provides a system level view of the general features of the memory system. It contains the following sections:

- [About the memory system architecture](#)
- [Address space](#)
- [Mixed-endian support in AArch32](#)
- [AArch32 cache and branch predictor support](#)
- [System register support for IMPLEMENTATION DEFINED memory features](#)
- [External aborts](#)
- [Memory barrier instructions](#)
- [Pseudocode description of general memory System instructions](#)

D4.1 About the memory system architecture

The Arm architecture supports different implementation choices for the memory system microarchitecture and memory hierarchy, depending on the requirements of the system being implemented. In this respect, the memory system architecture describes a design space in which an implementation is made. The architecture does not prescribe a particular form for the memory systems. Key concepts are abstracted in a way that permits implementation choices to be made while enabling the development of common software routines that do not have to be specific to a particular microarchitectural form of the memory system. For more information about the concept of a hierarchical memory system, see [Memory hierarchy](#).

D4.1.1 Form of the memory system architecture

The Armv8 R-profile AArch32 architecture includes a *Protected Memory System Architecture* (PMSAv8-32). [The Protected Memory System Architecture](#) describes the PMSAv8-32.

D4.1.2 Memory attributes

[Memory types and attributes](#) describes the memory attributes, including how different memory types have different attributes. Each location in memory has a set of memory attributes, and the translation tables define the virtual memory locations, and the attributes for each location.

[Table D4-1](#) shows the memory attributes that are visible at the system level.

Table D4-1 Memory attribute summary

Memory type	Shareability	Cacheability
Device ^a	Outer Shareable.	Non-cacheable.
Normal	One of: - Non-shareable. - Inner Shareable. - Outer Shareable.	One of ^b : - Non-cacheable. - Write-Through Cacheable. - Write-Back Cacheable.

a. Takes additional attributes, see [Device memory](#).
b. See also [Cacheability](#), [cache allocation hints](#), and [cache transient hints](#).

For more information on Cacheability and Shareability, see [The Cacheability and Shareability memory attributes](#), [Non-shareable Normal memory](#), and [Caches and memory hierarchy](#).

D4.2 Address space

The architecture is designed to support a wide range of applications with different memory requirements. It supports a range of *Physical Address* (PA) sizes, and provides associated control and identification mechanisms. For more information, see [About PMSAv8-32](#).

D4.2.1 Address space overflow or underflow

This subsection describes address space overflow or underflow:

D4.2.1.1 Instruction address space overflow

When a PE performs a normal, sequential execution of instructions, it calculates:

$$\text{address_of_next_instruction} = \text{address_of_current_instruction} + \text{size_of_executed_instruction}$$

This calculation is performed after each instruction to determine which instruction to execute next.

If the address calculation performed after executing an A32 or T32 instruction overflows `0xFFFF_FFFF`, the Program Counter becomes UNKNOWN.

If the PE executes an instruction for which the instruction address, size, and alignment mean that it contains the bytes `0xFFFF_FFFF` and `0x0000_0000`, the bytes that apparently from `0x0000_0000` onwards come from an UNKNOWN address.

D4.2.1.2 Data address space overflow and underflow

If the PE executes a load or store instruction for which the calculated address, total access size, and alignment mean that it accesses bytes `0xFFFF_FFFF` and `0x0000_0000`, then the bytes that apparently come from `0x0000_0000` onwards come from UNKNOWN addresses.

D4.3 Mixed-endian support in AArch32

Table D4-2 shows the endianness of explicit data accesses and translations.

Table D4-2 Endianness support

Exception level	Explicit data accesses	Stage 1 translations	Stage 2 translations
EL0	PSTATE.E	SCTLR.EE	HSCTLR.EE
EL1	PSTATE.E	SCTLR.EE	HSCTLR.EE
EL2	PSTATE.E	HSCTLR.EE	n/a

The architecture provides the following options for endianness support:

- All Exception levels support mixed-endianness:
 - [SCTLR.EE](#), [HSCTLR.EE](#), and [PSTATE.E](#) are RW.
- Only EL0 supports mixed-endianness and EL1 and EL2 support only little-endianness:
 - [SCTLR.EE](#) and [HSCTLR.EE](#) are RES0. [PSTATE.E](#) is RW when in EL0 and RES0 when in EL1 or EL2. [SPSR.E](#) is also RES0 when not returning to EL0.
- Only EL0 supports mixed-endianness and EL1 and EL2 support only big-endianness:
 - [SCTLR.EE](#) and [HSCTLR.EE](#) are RES1. [PSTATE.E](#) is RW when in EL0 and RES1 when in EL1 or EL2. [SPSR.E](#) is also RES1 when not returning to EL0.
- All Exception levels support only little-endianness:
 - Each of [SCTLR.EE](#), [HSCTLR.EE](#), [PSTATE.E](#), and [SPSR.E](#) is RES0.
- All Exception levels support only big-endianness:
 - Each of [SCTLR.EE](#), [HSCTLR.EE](#), [PSTATE.E](#), and [SPSR.E](#) is RES1.

If mixed endian support is implemented for an Exception level, endianness is controlled by [PSTATE.E](#). For exception returns, [PSTATE.E](#) is copied from [SPSR.E](#). If the target Exception level supports only little-endian accesses, [SPSR.E](#) is RES0. If the target Exception level supports only big-endian accesses, [SPSR.E](#) is RES1.

———— Note ————

Arm deprecates [PSTATE.E](#) having a different value from the equivalent System register EE bit when in EL1 or EL2. The use of the `SETEND` instruction is also deprecated.

The `BigEndian()` function determines whether the current Exception level and Execution state is using big-endian data.

For more information about endianness in the Arm architecture, see [Endian support](#).

D4.4 AArch32 cache and branch predictor support

The following sections describe the support for caches and branch predictors in AArch32 state:

- [General behavior of the caches.](#)
- [Cache identification.](#)
- [Cacheability, cache allocation hints, and cache transient hints.](#)
- [Enabling and disabling the caching of memory accesses in AArch32 state.](#)
- [Behavior of caches at reset.](#)
- [About cache maintenance in AArch32 state.](#)
- [AArch32 cache and branch predictor maintenance instructions.](#)
- [Cache lockdown.](#)
- [System level caches.](#)

See also [The Protected Memory System Architecture](#), and in particular [PMSAv8-32 implications for caches](#).

Note

- Branch predictors typically use a form of cache to hold branch target data. Therefore, they are included in this section.
 - In the instruction mnemonics, MVA is a synonym for VA.
-

D4.4.1 General behavior of the caches

When a memory location is marked with a Normal Cacheable memory attribute, determining whether a copy of the memory location is held in a cache still depends on many aspects of the implementation. The following non-exhaustive list of factors might be involved:

- The size, line length, and associativity of the cache.
- The cache allocation algorithm.
- Activity by other elements of the system that can access the memory.
- Speculative instruction fetching algorithms.
- Speculative data fetching algorithms.
- Interrupt behaviors.

Given this range of factors, and the large variety of cache systems that might be implemented, the architecture cannot guarantee whether:

- A memory location present in the cache remains in the cache.
- A memory location not present in the cache is brought into the cache.

Instead, the following principles apply to the behavior of caches:

- The architecture has a concept of an entry locked down in the cache. How lockdown is achieved is IMPLEMENTATION DEFINED, and lockdown might not be supported by:
 - A particular implementation.
 - Some memory attributes.
- An unlocked entry in a cache might not remain in that cache. The architecture does not guarantee that an unlocked cache entry remains in the cache or remains incoherent with the rest of memory. Software must not assume that an unlocked item that remains in the cache remains dirty.
- A locked entry in a cache is guaranteed to remain in that cache. The architecture does not guarantee that a locked cache entry remains incoherent with the rest of memory, that is, it might not remain dirty.

Note

For more information, see [The interaction of cache lockdown with cache maintenance instructions](#).

- Any memory location that has a Normal Cacheable attribute at either the current Exception level or at a higher Exception level can be allocated to a cache at any time.
- It is guaranteed that no memory location that does not have a Normal Cacheable attribute is allocated into the cache.
- It is guaranteed that no memory location is allocated to the cache if it has a Normal Non-cacheable attribute or any type of Device memory attribute in both:
 - The translation regime at the current Exception level.
 - The translation regime at any higher Exception level.
- For data accesses, any memory location with a Normal Inner Shareable or Normal Outer Shareable attribute is guaranteed to be coherent with all Requesters in its Shareability domain.
- Any memory location is not guaranteed to remain incoherent with the rest of memory.
- The eviction of a cache entry from a cache level can overwrite memory that has been written by another observer only if the entry contains a memory location that has been written to by an observer in the Shareability domain of that memory location. The maximum size of the memory that can be overwritten is called the *Cache Write-back Granule*. In some implementations the [CTR](#) identifies the Cache Write-back Granule.
- The allocation of a memory location into a cache cannot cause the most recent value of that memory location to become invisible to an observer, if it was previously visible to that observer.

Note

The Cacheability attribute of an address is determined by the applicable translation table entry for that address, as modified by any applicable System register Cacheability controls, such as the [SCTLR](#).{I, C} controls.

For the purpose of these principles, a cache entry covers at least 16 bytes and no more than 2KB of contiguous address space, aligned to the size of the cache entry.

D4.4.2 Cache identification

The cache identification consists of a set of registers that describe the implemented caches that are affected by cache maintenance instructions executed on the PE. This includes cache maintenance instructions that:

- Affect the entire cache, for example [ICIALLUIS](#).
- Operate by VA, for example [ICIMVAU](#).
- Operate by set/way, for example [DCISW](#).

The cache identification registers are:

- A single Cache Type Register, [CTR](#), that defines:
 - The minimum line length of any of the instruction caches affected by the instruction cache maintenance instructions.
 - The minimum line length of any of the data or unified caches, affected by the data cache maintenance instructions.
 - The cache indexing and tagging policy of the Level 1 instruction cache.

Note

It is IMPLEMENTATION DEFINED whether caches beyond the PoC will be reported by this mechanism, and because of the possible existence of system caches some caches before the PoC might not be reported. For more information about system caches, see [System level caches](#).

- A single Cache Level ID Register, [CLIDR](#), that defines:
 - The type of cache that is implemented and can be maintained using the architected cache maintenance instructions that operate by set/way or operate on the entire cache at each cache level, up to the maximum of seven levels.

- The *Level of Unification Inner Shareable* (LoUIS), *Level of Coherence* (LoC) and the *Level of Unification* (LoU) for the caches. See [Terms used in describing the cache maintenance instructions](#) for a definition of these terms.
- An optional ICB field to indicate the boundary between the caches use for caching Inner Cacheable memory regions and those used only for caching Outer Cacheable regions.
- A single Cache Size Selection Register, [CSSELR](#), that selects the cache level and sort of cache (Instruction, Data/Unified/Tag) of the current Cache Size Identification Register.
- For each implemented cache that is identifiable by this mechanism, across all the levels of caching, a Cache Size Identification Register, that defines:
 - The number of sets, associativity, and line length of the cache. See [Terms used in describing the cache maintenance instructions](#) for a definition of these terms.

To determine the cache topology associated with a PE:

1. Read the Cache Type Register to find the indexing and tagging policy used for the Level 1 instruction cache. This register also provides the size of the smallest cache lines used for the instruction caches, and for the data and unified caches. These values are used in cache maintenance instructions.
2. Read the Cache Level ID Register to find what caches are implemented. The register includes seven Cache type fields, for cache levels 1 to 7. Scanning these fields, starting from Level 1, identifies the instruction, data or unified caches implemented at each level. This scan ends when it reaches a level at which no caches are defined. The Cache Level ID Register also specifies the Level of Unification (LoU) and the Level of Coherence (LoC) for the cache implementation.
3. For each cache identified at stage 2:
 - Write to the Cache Size Selection Register to select the required cache. A cache is identified by its level, and whether it is:
 - An instruction cache.
 - A data or unified cache.
 - Read the Cache Size Identification Register to find details of the cache.
 - There is a single 32-bit Cache Size Identification Register, [CCSIDR](#).
 - The length of the [CCSIDR](#).Assoc field is 10 bits. This limits the associativity of the currently selected cache to 2^{10} .
 - The length of the [CCSIDR](#).NumSets field is 15 bits. This limits the number of sets in the currently selected cache to 2^{15} .

D4.4.3 Cacheability, cache allocation hints, and cache transient hints

Cacheability applies only to Normal memory, and is defined independently for Inner and Outer cache locations. All types of Device memory are always treated as Non-cacheable.

As described in [Memory types and attributes](#), the memory attributes include a Cacheability attribute that is one of:

- Non-cacheable.
- Write-Through cacheable.
- Write-Back cacheable.

Cacheability attributes other than Non-cacheable can be complemented by a *cache allocation hint*. This is an indication to the memory system of whether allocating a value to a cache is likely to improve performance. In addition, it is IMPLEMENTATION DEFINED whether a *cache transient hint* is supported, see [Transient Cacheability hint](#).

The cache allocation hints are assigned independently for read and write accesses, and therefore when the Transient hint is supported the following cache allocation hints can be used:

For read accesses: Read-Allocate, Transient Read-Allocate, or No Read-Allocate.

For write accesses: Write-Allocate, Transient Write-Allocate, or No Write-Allocate.

Note

- A Cacheable location with both No Read-Allocate and No Write-Allocate hints is not the same as a Non-cacheable location. A Non-cacheable location has coherency guarantees for all observers within the system that do not apply for a location that is Cacheable, No Read-Allocate, No Write-Allocate.
 - Implementations can use the cache allocation hints to limit cache pollution to a part of a cache, such as to a subset of ways.
 - For translations, the appropriate ATTRindx fields define the memory attributes of the translation, including the Cacheability.
-

The architecture does not require an implementation to make any use of cache allocation hints. This means an implementation might not make any distinction between memory locations with attributes that differ only in their cache allocation hint.

D4.4.3.1 Transient Cacheability hint

It is IMPLEMENTATION DEFINED whether a Transient hint is supported for the translation scheme. In an implementation that supports the Transient hint, the Transient hint is a qualifier of the cache allocation hints, and indicates that the benefit of caching is for a relatively short period. It indicates that it might be better to restrict allocation of transient entries, to avoid possibly casting-out other, less transient, entries.

Note

The architecture does not specify what is meant by a *relatively short period*.

The description of the [MAIR0](#), [MAIR1](#), [HMAIR0](#), and [HMAIR1](#) registers includes the assignment of the Transient attribute in an implementation that supports this option. In this assignment:

- The Transient hint is defined independently for Inner Cacheable and Outer Cacheable memory regions.
- A single Transient hint applies to both read and write accesses to a memory region.

D4.4.4 Enabling and disabling the caching of memory accesses in AArch32 state

Cacheability control fields can force all memory locations with the Normal memory type to be treated as Non-cacheable, regardless of their assigned Cacheability attribute. Independent controls are provided for each stage of address translation, with separate controls for:

- Data accesses. These controls also apply to accesses to the translation tables.
- Instruction accesses.

Note

These Cacheability controls replace the cache enable controls provided in previous versions of the Arm architecture.

In AArch32 state, the Cacheability control fields and their effects are as follows:

For the PL1&0 translation regime

[SCTLR](#) holds the EL1 controls that affect Cacheability:

- When the value of [SCTLR.C](#) is 0:
 - All stage 1 translations for data accesses to Normal memory are Non-cacheable.
 - All accesses to the PL1&0 stage 1 translation tables are Non-cacheable.
- When the value of [SCTLR.I](#) is 0:
 - All stage 1 translations for instruction accesses to Normal memory are Non-cacheable.
- When the value of [HCR.DC](#) is 1, all stage 1 translations and all accesses to the EL1&0 stage 1 translation tables, are treated as accesses to Normal Non-shareable Inner Write-Back Cacheable Read-Allocate Write-Allocate, Outer Write-Back Cacheable Read-Allocate Write-Allocate memory, regardless of the value of [SCTLR.C](#). This applies to translations for both data and instruction accesses.

In addition, when the value of **SCTLR.M** is 0, indicating that the stage 1 translations are disabled for the translation regime, if the value of **HCR.DC** is 0 then:

- If the value of **SCTLR.I** is 0, instruction accesses to Normal memory from stage 1 of the translation regime are Outer Shareable, Inner Non-cacheable, Outer Non-cacheable.
- If the value of **SCTLR.I** is 1, instruction accesses to Normal memory from stage 1 of the translation regime are Outer Shareable, Inner Write-Through cacheable, Outer Write-Through cacheable.

Note

- The stage 1 and stage 2 Cacheability attributes are combined as described in Combining the Cacheability attribute.
 - **SCTLR.{C, I}** and **HCR.DC** fields have no effect on the EL2 translation regimes.
-

For the EL2 translation regime

- When the value of **HSCTLR.C** is 0:
 - All data accesses to Normal memory using the EL2 translation regime are Non-cacheable.
 - All accesses to the EL2 translation tables are Non-cacheable.
- When the value of **HSCTLR.I** is 0:
 - All instruction accesses to Normal memory using the EL2 translation regime are Non-cacheable.

In addition, when the value of **HSCTLR.M** is 0, indicating that stage 1 translations are disabled, then:

- If the value of **HSCTLR.I** is 0, instruction accesses to Normal memory from stage 1 of the translation regime are Outer Shareable, Inner Non-cacheable, Outer Non-cacheable.
- If the value of **HSCTLR.I** is 1, instruction accesses to Normal memory from stage 1 of the translation regime are Outer Shareable, Inner Write-Through cacheable, Outer Write-Through cacheable.

Note

- The **HSCTLR.{I, C, M}** fields have no effect on the PL1&0 translation regime.
-

The effect of the **SCTLR.C** or **HSCTLR.C** bits is reflected in the result of the address translation instructions in the PAR.

Note

- The requirements in this section mean the architecturally required effects of **SCTLR.I** and **HSCTLR.I** are limited to their effects on caching instruction accesses in unified caches.
 - This specification can give rise to different Cacheability attributes between instruction and data accesses to the same location. Where this occurs, the measures for mismatch memory attributes described in [Mismatched memory attributes](#) must be followed to manage the corresponding loss of coherency.
-

D4.4.5 Behavior of caches at reset

The following rules apply to caches at reset:

- All caches reset to IMPLEMENTATION DEFINED states that might be UNKNOWN.
- The Cacheability control fields described in [Enabling and disabling the caching of memory accesses in AArch32 state](#) reset to values that force all memory locations to be treated as Non-cacheable.

Note

This applies only to the controls that apply to the Translation regime that is used by the Exception level and PE mode entered on reset.

- An implementation can require the use of a specific cache initialization routine to invalidate its storage array before caching is enabled. The exact form of any required initialization routine is IMPLEMENTATION DEFINED, and the routine must be documented clearly as part of the documentation of the device.

- If an implementation permits cache hits when the Cacheability control fields force all memory locations to be treated as Non-cacheable then the cache initialization routine must:
 - Provide a mechanism to ensure the correct initialization of the caches.
 - Be documented clearly as part of the documentation of the device.

In particular, if an implementation permits cache hits when the Cacheability controls force all memory locations to be treated as Non-cacheable, and the cache contents are not invalidated at reset, the initialization routine must avoid any possibility of running from an uninitialized cache. It is acceptable for an initialization routine to require a fixed instruction sequence to be placed in a restricted range of memory.

- Arm recommends that whenever an invalidation routine is required, it is based on the cache maintenance instructions.

Similar rules apply to:

- Branch predictor behavior, see [Behavior of the branch predictors at reset](#).

D4.4.6 About cache maintenance in AArch32 state

The following sections give general information about cache maintenance:

- [Terms used in describing the cache maintenance instructions](#).
- [Abstraction of the cache hierarchy](#).

The following sections describe the AArch32 state cache maintenance instructions:

- [AArch32 instruction cache maintenance instructions \(IC*\)](#).
- [AArch32 data cache maintenance instructions \(DC*\)](#).

Note

Some descriptions of the cache maintenance instructions refer to the Cacheability of the address on which the instruction operates. The Cacheability of an address is determined by the applicable translation table entry for that address, as modified by any applicable System register Cacheability controls, such as the [SCTLR](#).{I, C} controls.

D4.4.6.1 Terms used in describing the cache maintenance instructions

Cache maintenance instructions are defined to act on particular memory locations. Instructions can be defined:

- By the virtual address of the memory location to be maintained, referred to as operating *by VA*.
- By a mechanism that describes the location in the hardware of the cache, referred to as operating *by set/way*.

In addition, for instruction caches and branch predictors, there are instructions that invalidate all entries.

The following subsections define the terms used in the descriptions of the cache maintenance instructions:

- [Terminology for cache maintenance instructions operating by set/way](#).
- [Terminology for Clean, Invalidate, and Clean and Invalidate instructions](#).

Note

There is no terminology specific to cache maintenance instructions that operate by VA. When all applicable stages of translation are disabled, the VA used is identical to the PA. For more information about memory system behavior when address translation is disabled, see [PMSAv8-32 implications for caches](#).

D4.4.6.1.1 Terminology for cache maintenance instructions operating by set/way

Cache maintenance instruction that operate by set/way refer to the particular structures in a cache. Three parameters describe the location in a cache hierarchy that an instruction works on. These parameters are:

Level	The cache level of the hierarchy. The number of levels of cache is IMPLEMENTATION DEFINED. The cache levels that can be managed using the architected cache maintenance instructions that operate by set/way can be determined from the CLIDR. In the Arm architecture, the lower numbered cache levels are those closest to the PE. See Memory hierarchy.
Set	Each level of a cache is split up into a number of <i>sets</i>. Each set is a set of locations in a cache level to which an address can be assigned. Usually, the set number is an IMPLEMENTATION DEFINED function of an address. In the Arm architecture, sets are numbered from 0.
Way	The associativity of a cache is the number of locations in a set to which a specific address can be assigned. The <i>way</i> number specifies one of these locations. In the Arm architecture, ways are numbered from 0.

Note

Because the allocation of a memory address to a cache location is entirely IMPLEMENTATION DEFINED, Arm expects that most portable software will use only the cache maintenance instructions by set/way as single steps in a routine to perform maintenance on the entire cache.

D4.4.6.1.2 Terminology for Clean, Invalidate, and Clean and Invalidate instructions

Caches introduce coherency problems in two possible directions:

1. An update to a memory location by a PE that accesses a cache might not be visible to other observers that can access memory. This can occur because new updates are still in the cache and are not visible yet to the other observers that do not access that cache.
2. Updates to memory locations by other observers that can access memory might not be visible to a PE that accesses a cache. This can occur when the cache contains an old, or *stale*, copy of the memory location that has been updated.

The *Clean* and *Invalidate* instructions address these two issues. The definitions of these instructions are:

Clean	A cache clean instruction ensures that updates made by an observer that controls the cache are made visible to other observers that can access memory at the point to which the instruction is performed. Once the Clean has completed, the new memory values are guaranteed to be visible to the point to which the instruction is performed, for example to the Point of Unification. The cleaning of a cache entry from a cache can overwrite memory that has been written by another observer only if the entry contains a location that has been written to by an observer in the Shareability domain of that memory location.
Invalidate	A cache invalidate instruction ensures that updates made visible by observers that access memory at the point to which the invalidate is defined, are made visible to an observer that controls the cache. This might result in the loss of updates to the locations affected by the invalidate instruction that have been written by observers that access the cache, if those updates have not been cleaned from the cache since they were made. If the address of an entry on which the invalidate instruction operates is Normal, Non-cacheable or any type of Device memory then an invalidate instruction also ensures that this address is not present in the cache.

Note

Entries for addresses that are Normal Cacheable can be allocated to the cache at any time, and so the cache invalidate instruction cannot ensure that the address is not present in a cache.

Clean and Invalidate

A cache *clean and invalidate* instruction behaves as the execution of a clean instruction followed immediately by an invalidate instruction. Both instructions are performed to the same location.

The points to which a cache maintenance instruction can be defined differ depending on whether the instruction operates by VA or by set/way:

- For instructions operating by set/way, the point is defined to be to the next level of caching. For the All operations, the point is defined as the Point of Unification for each location held in the cache.
- For instruction operating by VA, two conceptual points are defined:

Point of Coherency (PoC)

The point at which all observers in the Full System domain that can access a memory location are guaranteed to see the same copy of that memory location for accesses of any memory type or Cacheability attribute. In many cases this is effectively the main system memory, although the architecture does not prohibit the implementation of caches beyond the PoC that have no effect on the coherency between memory system agents.

Note

The presence of system caches can affect the determination of the Point of Coherency as described in [System level caches](#).

Point of Unification (PoU)

The PoU for a PE is the point by which the instruction and data caches and the translation table walks of that PE are guaranteed to see the same copy of a memory location. In many cases, the Point of Unification is the point in a uniprocessor memory system by which the instruction and data caches and the translation table walks have merged.

The PoU for an Inner Shareable Shareability domain is the point by which the instruction and data caches and the translation table walks of all the PEs in that Inner Shareable Shareability domain are guaranteed to see the same copy of a memory location. Defining this point permits self-modifying software to ensure future instruction fetches are associated with the modified version of the software by using the standard correctness policy of:

1. Clean data cache entry by address.
2. Invalidate instruction cache entry by address.

The following fields in the [CLIDR](#) relate to these conceptual points:

LoC, Level of Coherence

This field defines the last level of cache that must be cleaned or invalidated when cleaning or invalidating to the Point of Coherency. The LoC value is a cache level, so, for example, if LoC contains the value 3:

- A clean to the Point of Coherency operation requires the level 1, level 2 and level 3 caches to be cleaned.
- Level 4 cache is the first level that does not have to be maintained.

If the LoC field value is 0x0, this means that no levels of cache need to be cleaned or invalidated when cleaning or invalidating to the Point of Coherency.

If the LoC field value is a nonzero value that corresponds to a level that is not implemented, this indicates that all implemented caches are before the Point of Coherency.

LoUU, Level of Unification, uniprocessor

This field defines the last level of cache that must be cleaned or invalidated when cleaning or invalidating to the Point of Unification for the PE. As with LoC, the LoUU value is a cache level.

If the LoUU field value is 0x0, this means that no levels of cache need to be cleaned or invalidated when cleaning or invalidating to the Point of Unification.

If the LoUU field value is a nonzero value that corresponds to a level that is not implemented, this indicates that all implemented caches are before the Point of Unification.

LoUIS, Level of Unification, Inner Shareable

In any implementation:

- This field defines the last level of cache that must be cleaned or invalidated when cleaning or invalidating to the Point of Unification for the Inner Shareable Shareability domain. As with LoC, the LoUIS value is a cache level.

- If the LoUIS field value is 0x0, this means that no levels of cache need to be cleaned or invalidated when cleaning or invalidating to the Point of Unification for the Inner Shareable Shareability domain.
- If the LoUIS field value is a nonzero value that corresponds to a level that is not implemented, this indicates that all implemented caches are before the Point of Unification.

For more information, see the [CLIDR](#) description.

D4.4.6.2 Abstraction of the cache hierarchy

The following subsections describe the abstraction of the cache hierarchy:

- [Cache maintenance instructions that operate by VA.](#)
- [Cache maintenance instructions that operate by set/way.](#)

D4.4.6.2.1 Cache maintenance instructions that operate by VA

The VA-based cache maintenance instructions are described as operating by VA. Each of these instructions is always qualified as being either:

- Performed to the Point of Coherency.
- Performed to the Point of Unification.

See [Terms used in describing the cache maintenance instructions](#) for definitions of Point of Coherency and Point of Unification, and more information about possible meanings of VA.

[AArch32 cache and branch predictor maintenance instructions](#) lists the VA-based maintenance instructions.

The [CTR](#) holds minimum line length values for:

- The instruction caches.
- The data and unified caches.

These values support efficient invalidation of a range of addresses, because this value is the most efficient address stride to use to apply a sequence of VA-based maintenance instructions to a range of VAs.

For the Invalidate data or unified cache line by VA instruction, the Cache Write-back Granule field of the [CTR](#) defines the maximum granule that a single invalidate instruction can invalidate. This meaning of the Cache Write-back Granule is in addition to its defining the maximum size that can be written back.

D4.4.6.2.2 Cache maintenance instructions that operate by set/way

[AArch32 cache and branch predictor maintenance instructions](#) lists the set/way-based maintenance instructions. Some encodings of these instructions include a required field that specifies the cache level for the instruction:

- A clean instruction cleans from the level of cache specified through to at least the next level of cache, moving further from the PE.
- An invalidate instruction invalidates only at the level specified.

D4.4.7 AArch32 cache and branch predictor maintenance instructions

The instruction and data cache maintenance instructions have the same functionality in AArch32 state and in AArch64 state. [Table D4-3](#) shows the AArch32 System instructions. Instructions that take an argument include Rt in the instruction description.

The architecture does not define any branch predictor maintenance instructions for AArch32 state.

Note

- In [Table D4-3](#) the Point of Unification is the Point of Unification of the PE executing the cache maintenance instruction.
- In AArch32 state, all of the maintenance instructions are available from EL1 or higher.

Table D4-3 AArch32 System instructions for cache maintenance

Register	Instruction
Instruction cache maintenance instructions	
ICIALLUIS	Invalidate all to Point of Unification, Inner Shareable
ICIALLU	Invalidate all to Point of Unification
ICIMVAU , Rt	Invalidate by virtual address to Point of Unification
Data cache maintenance instructions	
DCIMVAC , Rt	Invalidate by virtual address to Point of Coherency
DCISW , Rt	Invalidate by set/way
DCCMVAC , Rt	Clean by virtual address to Point of Coherency
DCCSW , Rt	Clean by set/way
DCCMVAU , Rt	Clean by virtual address to Point of Unification
DCCIMVAC , Rt	Clean and invalidate by virtual address to Point of Coherency
DCCISW , Rt	Clean and invalidate by set/way
Branch prediction maintenance instructions	
BPIMVA , Rt	Invalidate the virtual address from the branch predictors
BPIALLIS , Rt	Invalidate all entries from branch predictors, Inner Shareable
BPIALL , Rt	Invalidate all entries from branch predictors

A DSB instruction intended to ensure the completion of cache or branch predictor maintenance instructions must have an access type of both loads and stores.

In an implementation where the branch predictors are architecturally invisible, the [BPIMVA](#), [BPIALLIS](#), and [BPIALL](#) instructions can execute as NOPs.

The following subsections give more information about these instructions:

- [AArch32 instruction cache maintenance instructions \(IC*\)](#).
- [AArch32 data cache maintenance instructions \(DC*\)](#).
- [Branch predictors](#).
- [General requirements for the scope of cache and branch predictor maintenance instructions](#).
- [Effects of instructions that operate by VA to the Point of Coherency](#).
- [Effects of instructions that operate by VA but not to the Point of Coherency](#).
- [Effects of All and set/way maintenance instructions](#).
- [Effects of virtualization and security on the AArch32 cache maintenance instructions](#).
- [Boundary conditions for cache maintenance instructions](#).
- [Ordering of cache and branch predictor maintenance instructions](#).
- [Performing cache maintenance instructions](#).

D4.4.7.1 AArch32 instruction cache maintenance instructions (IC*)

Where an address argument for these instructions is required, it takes the form of a 32-bit register that holds the virtual address argument. No alignment restrictions apply for this address.

Any cache maintenance instruction operating by VA includes as part of any required VA to PA translation:

- Whether the instruction was performed from Hyp mode, or at EL1.
- For an instruction executed at EL1, the VMID.

That VA to PA translation might fault. However for an instruction cache maintenance instruction that operates by VA:

- It is IMPLEMENTATION DEFINED whether the operation can generate a Data Abort exception for a [Translation fault](#).
- The operation cannot generate a Data Abort exception for a [Permission fault](#).

For more information about the possible faults on an instruction that operates by VA, see [Types of MPU faults](#).

An instruction cache maintenance instruction can complete at any time after it is executed, but is only guaranteed to be complete, and its effects visible to other observers, following a DSB instruction executed by the PE that executed the cache maintenance instruction. See also the completion requirements for cache and branch predictor maintenance instructions in [Completion and endpoint ordering](#).

See also [Ordering of cache and branch predictor maintenance instructions](#).

D4.4.7.2 AArch32 data cache maintenance instructions (DC*)

Data cache maintenance instructions that take a set/way/level argument take a 32-bit register.

If a data cache maintenance by set/way instruction specifies a set, way, or level argument that is larger than the value supported by the implementation then the instruction is CONSTRAINED UNPREDICTABLE, see [Out of range values of the Set/Way/Index fields in cache maintenance instructions](#) or the instruction description.

DCISW instructions executed at EL1 perform a clean and invalidate, meaning it performs the same maintenance as a DCCISW instruction, if the value of HCR.SWIO is 1.

Where an address argument for these instructions is required, it takes the form of a 32-bit register that holds the virtual address argument. No alignment restrictions apply for this address.

Any cache maintenance instruction operating by VA includes as part of any required VA to PA translation:

- Whether the instruction was performed from Hyp mode, or from EL1.
- For an instruction executed from EL1, the VMID.

That VA to PA translation might fault.

For more information about the possible faults on an instruction that operates by VA, see [Types of MPU faults](#).

DCIMVAC and DCISW instructions executed at EL1 perform a clean and invalidate, meaning they perform the same maintenance as a DCCIMVAC or DCCISW instruction respectively, if both of the following apply:

- PL1&0 stage two address translation is enabled.
- The value of HCR.VM is 1.

If a memory fault that sets FAR for the translation regime applicable for the cache maintenance instruction is generated from a data cache maintenance instruction, the FAR holds the address specified in the register argument of the instruction.

See also [Ordering of cache and branch predictor maintenance instructions](#).

D4.4.7.3 Branch predictors

In AArch32 state it is IMPLEMENTATION DEFINED whether branch prediction is architecturally visible. This means that under some circumstances software must perform branch predictor maintenance to avoid incorrect execution caused by out-of-date entries in the branch predictor. For example, to ensure correct operation it might be necessary to invalidate

branch predictor entries on a change to instruction memory, or a change of instruction address mapping. For more information, see [Specific requirements for branch predictor maintenance instructions](#).

In an implementation where the branch predictors are architecturally invisible, the branch predictor maintenance instructions can execute as `NOPS`.

An invalidate all operation on the branch predictor ensures that any location held in the branch predictor has no functional effect on execution. An invalidate branch predictor by VA instruction operates on the address of the branch instruction, but can affect other branch predictor entries.

Note

The architecture does not make visible the range of addresses in a branch predictor to which the invalidate operation applies. This means the address used in the invalidate by VA operation must be the address of the branch to be invalidated.

If branch prediction is architecturally visible, an instruction cache invalidate all operation also invalidates all branch predictors.

See also [Ordering of cache and branch predictor maintenance instructions](#).

D4.4.7.3.1 Specific requirements for branch predictor maintenance instructions

If, for a given translation regime and a given VMID as appropriate, the instructions at any virtual address change, then branch predictor maintenance instructions must be performed to invalidate entries in the branch predictor, to ensure that the change is visible to subsequent execution. This maintenance is required when writing new values to instruction locations. It can also be required as a result of any of the following situations that change the translation of a virtual address to a physical address, if, as a result of the change to the translation, the instructions at the virtual addresses change:

- For any translation regime other than the PL1&0 translation regime, enabling or disabling stage 1 translations.
- For the PL1&0 translation regime:
 - When stage 2 translations are enabled, enabling or disabling stage 1 translations unless accompanied by a change of VMID.
 - When stage 2 translations are disabled, enabling or disabling stage 1 translations.
 - Enabling or disabling stage 2 translations.
- Writing new mappings to the [PRBAR](#) or [PRLAR](#) registers unless accompanied by a change to the VMID.

Note

Invalidation is not required if the changes to the translations are such that the instructions associated with the non-faulting translations of a virtual address, for a given translation regime and a given VMID, as appropriate, remain unchanged throughout the sequence of changes to the translations. Examples of translation changes to which this applies are:

- Changing a valid translation to a translation that generates an [Types of MPU faults](#).
 - Changing a translation that generates an [MPU fault](#) to a valid translation.
-

Failure to invalidate entries might give `CONSTRAINED UNPREDICTABLE` results, caused by the execution of old branches. For more information, see [Ordering of cache and branch predictor maintenance instructions](#).

Note

- There is no requirement to use the branch predictor maintenance operations to invalidate the branch predictor after:
 - Changing the ContextID or VMID.
 - A cache maintenance instruction that is identified as also flushing the branch predictors, see [AArch32 cache and branch predictor maintenance instructions](#).
-

[Cache maintenance System instructions](#) shows the branch predictor maintenance operations in a PMSA implementation.

D4.4.7.3.2 Behavior of the branch predictors at reset

In AArch32 state:

- If branch predictors are not architecturally invisible:
 - The branch predictors reset to an IMPLEMENTATION DEFINED state that might be UNKNOWN.
 - The branch predictors are disabled at reset.
- An implementation can require the use of a specific branch predictor initialization routine to invalidate the branch predictor storage array before it is enabled. The exact form of any required initialization routine is IMPLEMENTATION DEFINED, but the routine must be documented clearly as part of the documentation of the device.
- Arm recommends that whenever an invalidation routine is required, it is based on the AArch32 branch predictor maintenance operations.

Similar rules apply to cache behavior, see [Behavior of caches at reset](#).

D4.4.7.4 General requirements for the scope of cache and branch predictor maintenance instructions

The specification of the cache maintenance and branch predictor instructions describes what each instruction is guaranteed to do in a system. It does not limit other behaviors that might occur, provided they are consistent with the requirements described in [General behavior of the caches](#), [Behavior of caches at reset](#), and [Prefetching into cache](#).

This means that as a side-effect of a cache maintenance instruction:

- Any location in the cache might be cleaned.
- Any unlocked location in the cache might be cleaned and invalidated.

As a side-effect of a branch predictor maintenance instruction, any entry in the branch predictor might be invalidated.

———— Note ————

Arm recommends that, for best performance, such side-effects are kept to a minimum.

D4.4.7.5 Effects of instructions that operate by VA to the Point of Coherency

For Normal memory that is not Inner Non-cacheable, Outer Non-cacheable, these instructions must affect the caches of other PEs in the Shareability domain described by the Shareability attributes of the VA supplied with the instruction.

For Device memory and Normal memory that is Inner Non-cacheable, Outer Non-cacheable, these instructions must affect the caches of all PEs in the Outer Shareable Shareability domain of the PE on which the instruction is operating.

In all cases, for any affected PE, these instructions affect all data and unified caches to the Point of Coherency.

Table D4-4 PEs affected by cache maintenance instructions to the Point of Coherency

Shareability	PEs affected	Effective to
Non-shareable	The PE performing the operation	The Point of Coherency of the entire system
Inner Shareable	All PEs in the same Inner Shareable Shareability domain as the PE performing the operation	The Point of Coherency of the entire system
Outer Shareable	All PEs in the same Outer Shareable Shareability domain as the PE performing the operation	The Point of Coherency of the entire system

D4.4.7.6 Effects of instructions that operate by VA but not to the Point of Coherency

The following instruction operate by VA but not to the Point of Coherency:

- Clean data or unified cache line by MVA to the Point of Unification, [DCCMVAU](#).
- Invalidate instruction cache line by MVA to Point of Unification, [ICIMVAU](#).

- Invalidate by MVA from branch predictors, [BPIMVA](#).

For these instructions, [Table D4-5](#) shows how, for a VA in a Normal or Device memory location, the Shareability attribute of the VA determines the minimum set of PEs affected, and the point to which the instruction must be effective.

Table D4-5 PEs affected by cache maintenance instructions to the Point of Unification

Shareability	PEs affected	Effective to
Non-shareable	The PE executing the instruction	The Point of Unification of instruction cache fills, data cache fills and write-backs, and translation table walks, on the PE executing the instruction
Inner Shareable or Outer Shareable	All PEs in the same Inner Shareable Shareability domain as the PE executing the instruction	The Point of Unification of instruction cache fills, data cache fills and write-backs, and translation table walks, of all PEs in the same Inner Shareable Shareability domain as the PE executing the instruction

Note

The set of PEs guaranteed to be affected is never greater than the PEs in the Inner Shareable Shareability domain containing the PE executing the instruction.

D4.4.7.7 Effects of All and set/way maintenance instructions

The [ICIALLU](#), [BPIALL](#) and DC* set/way instructions apply only to the caches and branch predictors of the PE that performs the instruction. If the branch predictors are architecturally-visible, [ICIALLU](#) also performs a [BPIALL](#) operation.

The [ICIALLUIS](#) and [BPIALLIS](#) instructions can affect the caches and branch predictors of all PEs in the same Inner Shareable Shareability domain as the PE that performs the instruction. If the branch predictors are architecturally-visible, [ICIALLUIS](#) also performs a [BPIALLIS](#) operation. These instructions have an effect to the Point of Unification of instruction cache fills, data cache fills, and write-backs, and translation table walks, of all PEs in the same Inner Shareable Shareability domain.

Note

The possible presence of system caches, as described in [System level caches](#), means architecture does not guarantee that all levels of cache can be maintained using set/way instructions. See [Example code for cache maintenance instructions](#) for more information.

D4.4.7.8 Effects of virtualization and security on the AArch32 cache maintenance instructions

Each Security state has its own physical address space, and therefore cache entries are associated with physical address space. In addition, cache maintenance and branch predictor instructions performed have to take account of:

- Whether the instruction was performed at EL1 or at EL2.
- For instructions that operate by VA, the current VMID.

[Table D4-6](#) shows the effects of virtualization and security on these maintenance instructions.

Table D4-6 Effects of virtualization and security on the AArch32 cache maintenance instructions

Cache maintenance instructions	Specified entry
Data or unified cache maintenance instructions	

Cache maintenance instructions	Specified entry
Invalidate, Clean, or Clean and Invalidate by VA: DCIMVAC , DCCMVAC , DCCMVAU , DCCIMVAC	All lines that hold the PA that, in the current translation regime, are mapped to by the combination of all of: - The specified VA. - For an instruction executed at EL1, the current VMID^a. - For an instruction executed at EL0
Invalidate, Clean, or Clean and Invalidate by set/way: DCISW , DCCSW , DCCISW	For an instruction, the line specified by set/way provided that the entry comes from the PA space.
Instruction cache maintenance instructions	
Invalidate by VA: ICIMVAU	All lines corresponding to the specified VA^b in the current translation regime and: For an instruction executed at EL1 or EL0, the current VMID^a.
Invalidate All: ICIALLU , ICIALUIS	Can invalidate any unlocked entry in the instruction cache, and are required to invalidate: - For an instruction executed at EL1, all instruction cache lines containing entries associated with the current VMID. - For an instruction executed at EL2, all instruction lines containing entries.
Branch predictor instructions ^c	
Invalidate by VA: BPIMVA	All lines that, in the current translation regime, are mapped to by the combination of all of: - The specified VA. - For an instruction executed at EL1 or EL0, the current VMID^a.
Invalidate all: BPIALL , BPIALLIS	Can invalidate any unlocked entry in the branch predictor, and are required to invalidate: - For an instruction executed at EL1, all lines containing entries associated with the current VMID. - For an instruction executed at EL2, all lines containing entries.

a. Dependencies on the VMID apply even when the value of [HCR.VM](#) is 0. However, if the PE resets, [VSCTLR.VMID](#) resets to a value that is architecturally UNKNOWN, and the [VSCTLR.VMID](#) field must be set to a known value, that might be zero, as part of the PE initialization sequence.

b. The type of instruction cache used affects the interpretation of the specified entries in this table such that:

- For a PIPT instruction cache, the cache maintenance applies to all entries whose physical address corresponds to the specified address.
- For a VIPT instruction cache, the cache maintenance applies to entries whose virtual index and physical tag corresponds to the specified address.

For information of types of instruction cache, see Instruction caches.

c. In an implementation where the branch predictors are architecturally invisible, these instructions can execute as NOPs.

For locked entries and entries that might be locked, the behavior of cache maintenance instructions described in [The interaction of cache lockdown with cache maintenance instructions](#) applies.

With an implementation that generates aborts if entries are locked or might be locked in the cache, when the use of lockdown aborts is enabled, these aborts can occur on any cache maintenance instructions.

In an implementation:

- The architecture does not require cache cleaning when switching between virtual machines. Cache invalidation by set/way must not present an opportunity for one virtual machine to corrupt state associated with a second

virtual machine. To ensure this requirement is met, EL1 invalidate by set/way instructions executed in at EL1 when HCR.VM is 1 and EL2 is enabled can, instead, perform a clean and invalidate by set/way.

- The Data cache invalidate instructions [DCIMVAC](#) and [DCISW](#) perform a cache clean as well as a cache invalidate, meaning [DCIMVAC](#) performs the same invalidation as a [DCCIMVAC](#) instruction, and [DCISW](#) performs the same invalidation as a [DCCISW](#) instruction, if the value of HCR.VM is 1, and the instruction is executed at EL1.
- The Data cache invalidate by set/way instruction [DCISW](#) performs a cache clean as well as a cache invalidate, meaning it performs the same invalidation as a [DCCISW](#) instruction, if the value of HCR.SWIO is 1, and the instruction is executed at EL1.

For more information about the cache maintenance instructions, see [About cache maintenance in AArch32 state](#), [AArch32 cache and branch predictor maintenance instructions](#), and [The Protected Memory System Architecture](#).

D4.4.7.9 Boundary conditions for cache maintenance instructions

Cache maintenance instructions operate on the caches regardless of whether the System register Cacheability controls force all memory accesses to be Non-cacheable.

For VA-based cache maintenance instructions, the instructions operate on the caches regardless of the memory type and Cacheability attributes marked for the memory address in the PMSA translation. This means that the effects of the cache maintenance instructions can apply regardless of:

- Whether the address accessed:
 - Is Normal memory or Device memory.
 - Has the Cacheable attribute or the Non-cacheable attribute.
- Any applicable domain control of the address accessed.
- The access permissions for the address accessed, other than the effect of the stage two write permission on data or unified cache invalidation instructions.

D4.4.7.10 Ordering of cache and branch predictor maintenance instructions

The following rules describe the effect of the memory order model on the cache and branch predictor maintenance instructions:

- All cache and branch predictor maintenance instructions that do not specify an address execute, relative to each other, in program order.
All cache and branch predictor instructions that specify an address:
 - Execute in program order relative to all cache and branch predictor operations that do not specify an address.
 - Execute in program order relative to all cache and branch predictor operations that specify the same address.
 - Can execute in any order relative to cache and branch predictor operations that specify a different address.
- Where a cache maintenance or branch predictor instruction appears in program order before a change to the memory protection regions, the architecture guarantees that the cache or branch predictor maintenance instruction uses the translations that were visible before the change to the memory protection regions.
- Where a change to the memory protection regions appears in program order before a cache maintenance or branch predictor instruction, synchronization is required before performing the cache or branch predictor maintenance instruction, to ensure that the maintenance operation uses the new translations. For more information see [PMSAv8-32 implications for caches](#).
- A [DMB](#) instruction causes the effect of all data or unified cache maintenance instructions appearing in program order before the [DMB](#) to be visible to all explicit memory read and write effects appearing in program order after the [DMB](#).
Also, a [DMB](#) instruction ensures that the effects of any data or unified cache maintenance instruction appearing in program order before the [DMB](#) are observable by any observer in the same required Shareability domain before any data or unified cache maintenance or explicit memory operations appearing in program order after the [DMB](#) are observed by the same observer. Completion of the [DMB](#) does not guarantee the visibility of all data to other observers. For example, all data might not be visible to instruction fetches.
- A [DSB](#) is required to guarantee the completion of all cache maintenance instruction that appear in program order before the [DSB](#) instruction.

- A [Context Synchronization event](#) is required to guarantee the effects of any branch predictor maintenance operation. This means a [Context Synchronization event](#) causes the effect of all completed branch predictor maintenance operations appearing in program order before the [Context Synchronization event](#) to be visible to all instructions after the [Context Synchronization event](#).
This means that, if a branch instruction appears after an invalidate branch predictor operation and before any [Context Synchronization event](#), it is CONSTRAINED UNPREDICTABLE whether the branch instruction is affected by the invalidate. Software must avoid this ordering of instructions, because it might cause CONSTRAINED UNPREDICTABLE behavior.
- Any data or unified cache maintenance instruction by VA must be executed in program order relative to any explicit memory read or write effect on the same PE to an address covered by the VA of the cache instruction if that load or store is to Normal Cacheable memory. The order of memory accesses that result from the cache maintenance instruction, relative to any other memory accesses to Normal Cacheable memory, are subject to the memory ordering rules. For more information, see [Definition of the memory model](#).
Any data or unified cache maintenance instruction by VA can be executed in any order relative to any explicit memory read or write effect on the same PE to an address covered by the VA of the cache maintenance instruction if that load or store is not to Normal Cacheable memory.
- There is no restriction on the ordering of data or unified cache maintenance instruction by VA relative to any explicit memory read or write effect on the same PE where the address of the explicit memory read or write effect is not covered by the VA of the cache instruction. Where the ordering must be restricted, a DMB instruction must be inserted to enforce ordering.
- There is no restriction on the ordering of a data or unified cache maintenance instruction by set/way relative to any explicit memory read or write effect on the same PE. Where the ordering must be restricted, a DMB instruction must be inserted to enforce ordering.
- Software must execute a [Context Synchronization event](#) after the completion of an instruction cache maintenance instruction, to guarantee that the effect of the maintenance instruction is visible to any instruction fetch.

A DSB instruction intended to ensure the completion of cache maintenance instructions or branch predictor instructions must have an access type of both loads and stores.

See also the completion requirements for cache and branch predictor maintenance instructions in [Completion and endpoint ordering](#).

The scope of instruction cache maintenance depends on the type of the instruction cache. For more information, see [Instruction caches](#).

Example D4-1 Cache cleaning operations for self-modifying code

The sequence of cache cleaning operations for a line of self-modifying code on a uniprocessor system is:

```
; Coherency example for data and instruction accesses within the same Inner Shareable domain.
; Enter this code with <Rt> containing a new 32-bit instruction,
; to be held in Cacheable space at a location pointed to by Rn. Use STRH in the first line
; instead of STR for a 16-bit instruction.
    STR Rt, [Rn]
    DCCMVAU Rn          ; Clean data cache by MVA to point of unification (PoU)
    DSB                 ; Ensure visibility of the data cleaned from cache
    ICIMVAU Rn          ; Invalidate instruction cache by MVA to PoU
    BPIMVA Rn           ; Invalidate branch predictor by MVA to PoU
    DSB                 ; Ensure completion of the invalidations
    ISB                 ; Synchronize the fetched instruction stream
```

D4.4.7.11 Performing cache maintenance instructions

To ensure all cache lines in a block of address space are maintained through all levels of cache Arm strongly recommends that software:

- For data or unified cache maintenance, uses the [CTR.DMinLine](#) value to determine the loop increment size for a loop of data cache maintenance by VA instructions.
- For instruction cache maintenance, uses the [CTR.IMinLine](#) value to determine the loop increment size for a loop of instruction cache maintenance by VA instructions.

D4.4.7.11.1 Example code for cache maintenance instructions

The cache maintenance instructions by set/way can be used to clean or invalidate, or both, the entirety of one or more levels of cache attached to a PE. However, unless all PEs attached to the caches regard all memory locations as Non-cacheable, it is not possible to prevent locations being allocated into the cache during such a sequence of the cache maintenance instructions.

Note

Because the set/way instructions operate only locally, there is no guarantee of the atomicity of cache maintenance between different PEs, even if those different PEs are each executing the same cache maintenance instructions at the same time. Because any cacheable line can be allocated into the cache at any time, it is possible for a cache line to migrate from an entry in the cache of one PE to the cache of a different PE in a way that means the cache line is not affected by set/way based cache maintenance. Therefore, Arm strongly discourages the use of set/way instructions to manage coherency in coherent systems. The expected use of the cache maintenance instructions that operate by set/way is limited to the cache maintenance associated with the powerdown and powerup of caches, if this is required by the implementation.

The limitations of cache maintenance by set/way mean maintenance by set/way does not happen on multiple PEs, and cannot be made to happen atomically for each address on each PE. Therefore in multiprocessor or multithreaded systems, the use of cache maintenance by set/way to clean, or clean and invalidate, the entire cache for coherency management with very large buffers or with buffers with unknown address can fail to provide the expected coherency results because of speculation by other PEs, or possibly by other threads. The only way that these instructions can be used in this way is to first ensure that all PEs that might cause speculative accesses to caches that need to be maintained are not capable of generating speculative accesses. This can be achieved by ensuring that those PEs have no memory locations with a Normal Cacheable attribute. Such an approach can have very large system performance effects, and Arm advises implementers to use hardware coherency mechanisms in systems where this will be an issue.

[System level caches](#) refers to other limitations of cache maintenance by set/way.

The following example code for cleaning a data or unified cache to the Point of Coherency illustrates a generic mechanism for cleaning the entire data or unified cache to the Point of Coherency. It assumes the current Cache Size Identification Register is in 32-bit format.

```

MRC p15, 1, R0, c0, c0, 1 ; Read CLIDR into R0
ANDS R3, R0, #0x07000000
MOV R3, R3, LSR #23 ; Cache level value (naturally aligned)
BEQ Finished
MOV R10, #0

Loop1
ADD R2, R10, R10, LSR #1 ; Work out 3 x cache level
MOV R1, R0, LSR R2 ; bottom 3 bits are the Cache type for this level
AND R1, R1, #7 ; get those 3 bits alone
CMP R1, #2
BLT Skip ; no cache or only instruction cache at this level
MCR p15, 2, R10, c0, c0, 0 ; write CSSELR from R10
ISB ; ISB to sync the change to the CCSIDR
MRC p15, 1, R1, c0, c0, 0 ; read current CCSIDR to R1
AND R2, R1, #7 ; extract the line length field
ADD R2, R2, #4 ; add 4 for the line length offset (log2 16 bytes)
MOV R4, #0x3FF
ANDS R4, R4, R1, LSR #3 ; R4 is the max number on the way size (right aligned)
CLZ R5, R4 ; R5 is the bit position of the way size increment
MOV R9, R4 ; R9 working copy of the max way size (right aligned)

Loop2
MOV R7, #0x00007FFF
ANDS R7, R7, R1, LSR #13 ; R7 is the max number of the index size (right aligned)

Loop3
ORR R11, R10, R9, LSL R5 ; factor in the way number and cache number into R11
ORR R11, R11, R7, LSL R2 ; factor in the index number
MCR p15, 0, R11, c7, c10, 2 ; DCCSW, clean by set/way
SUBS R7, R7, #1 ; decrement the index
BGE Loop3
SUBS R9, R9, #1 ; decrement the way number
BGE Loop2

Skip
ADD R10, R10, #2 ; increment the cache number
CMP R3, R10
DSB ; ensure completion of previous cache maintenance instruction

```

BGT Loop1
Finished

Similar approaches can be used for all cache maintenance instructions.

D4.4.8 Cache lockdown

The concept of an entry locked in a cache is allowed, but not architecturally defined. How lockdown is achieved is IMPLEMENTATION DEFINED and might not be supported by:

- An implementation.
- Some memory attributes.

An unlocked entry in a cache might not remain in that cache. The architecture does not guarantee that an unlocked cache entry remains in the cache or remains incoherent with the rest of memory. Software must not assume that an unlocked item that remains in the cache remains dirty.

A locked entry in a cache is guaranteed to remain in that cache. The architecture does not guarantee that a locked cache entry remains incoherent with the rest of memory, that is, it might not remain dirty.

D4.4.8.1 The interaction of cache lockdown with cache maintenance instructions

The interaction of cache lockdown and cache maintenance instructions is IMPLEMENTATION DEFINED. However, an architecturally-defined cache maintenance instruction on a locked cache line must comply with the following general rules:

- The effect of the following instructions on locked cache entries is IMPLEMENTATION DEFINED:
 - Cache clean by set/way, [DCCSW](#).
 - Cache invalidate by set/way, [DCISW](#).
 - Cache clean and invalidate by set/way, [DCISW](#).
 - Instruction cache invalidate all, [ICIALLU](#) and [ICIALUIS](#).

However, one of the following approaches must be adopted in all these cases:

1. If the instruction specified an invalidation, a locked entry is not invalidated from the cache.
2. If the instruction specified a clean it is IMPLEMENTATION DEFINED whether locked entries are cleaned.
3. If an entry is locked down, or could be locked down, an IMPLEMENTATION DEFINED Data Abort exception is generated, using the Fault status code defined for this purpose. See [Data Abort exception](#).

This permits a usage model for cache invalidate routines to operate on a large range of addresses by performing the required operation on the entire cache, without having to consider whether any cache entries are locked.

The effect of the following instructions is IMPLEMENTATION DEFINED:

- Cache clean by virtual address, [DCCMVAC](#) and [DCCMVAU](#).
- Cache invalidate by virtual address, [DCIMVAC](#).
- Cache clean and invalidate by virtual address, [DCCIMVAC](#).

However, one of the following approaches must be adopted in all these cases:

1. If the instruction specified an invalidation, a locked entry is invalidated from the cache. For the clean and invalidate instructions, the entry must be cleaned before it is invalidated.
2. If the instruction specified an invalidation, a locked entry is not invalidated from the cache. If the instruction specified a clean it is IMPLEMENTATION DEFINED whether locked entries are cleaned.
3. If an entry is locked down, or could be locked down, an IMPLEMENTATION DEFINED Data Abort exception is generated, using the Fault status code defined for this purpose. See [DFSR](#) or [HSR](#).

If [HCR.TIDCP](#) is set to 1, any exception relating to lockdown of an entry is routed to EL2.

Note

An implementation that uses an abort mechanism for entries that can be locked down but are not actually locked down must:

- Document the IMPLEMENTATION DEFINED instruction sequences that perform the required operations on entries that are not locked down.
- Implement one of the other permitted alternatives for the locked entries.

Arm recommends that, when possible, such IMPLEMENTATION DEFINED instruction sequences use architecturally-defined instructions. This minimizes the number of customized instructions required.

In addition, an implementation that uses an abort to handle cache maintenance instructions for entries that might be locked must provide a mechanism that ensures that no entries are locked in the cache.

The reset setting of the cache must be that no cache entries are locked.

D4.4.8.1.1 Additional cache functions for the implementation of lockdown

An implementation can add additional cache maintenance functions for the handling of lockdown in the IMPLEMENTATION DEFINED space.

D4.4.9 System level caches

The Arm Architecture defines a *system cache* as a cache that is not described in the PE Cache Identification registers, [CCSIDR](#), and [CLIDR](#), and for which the set/way cache maintenance instructions do not apply.

Conceptually, three classes of system cache can be envisaged:

1. System caches which lie before the point of coherency and cannot be managed by cache maintenance instructions. Such systems fundamentally undermine the concept of cache maintenance instructions operating to the point of coherency, as they imply the use of non-architecture mechanisms to manage coherency. The use of such systems in the Arm architecture is explicitly prohibited.
2. System caches which lie before the point of coherency and can be managed by cache maintenance by address instructions that apply to the point of coherency, but cannot be managed by cache maintenance by set/way instructions. Where maintenance of the entire system cache must be performed, as is the case for power management, it must be performed using non-architectural mechanisms.
3. System caches which lie beyond the point of coherency and so are invisible to software. The management of such caches is outside the scope of architecture.

D4.5 System register support for IMPLEMENTATION DEFINED memory features

The System register encoding space with $\{\text{coproc} == 0b1111, \text{CRn} == c15\}$ is reserved for IMPLEMENTATION DEFINED registers, and can provide additional registers for the memory system. For more information, see [Organization of registers in the \(coproc == 0b1111 \) encoding space](#).

D4.6 External aborts

The Arm architecture defines External aborts as errors that occur in the memory system, other than those that are detected by the MPU or Debug hardware. An External abort might signal a data corruption to the PE. For example, a memory location might have been corrupted, and this corruption is detected by hardware using a parity or error correction code (ECC). The error might have been propagated.

An External abort is one of:

- Synchronous.
- Precise asynchronous.
- Imprecise asynchronous.

For more information, see [Exception terminology](#).

The Arm architecture does not provide any method to distinguish between precise asynchronous and imprecise asynchronous External aborts.

PMSAv8-32 permits External aborts on data accesses, translation table walks, and instruction fetches to be either synchronous or asynchronous. The reported fault code identifies whether the External abort is synchronous or asynchronous.

It is IMPLEMENTATION DEFINED which External aborts, if any, are supported. Asynchronous External aborts generate SError exceptions.

In AArch32 state:

- SError exceptions are taken as asynchronous Data Abort exceptions.
- Synchronous External aborts:
 - On data accesses are taken as synchronous Data Abort exceptions.
 - On instruction fetches, or prefetches, are taken as synchronous Prefetch Abort exceptions.

Normally, External aborts are rare. An imprecise asynchronous External abort is likely to be fatal to the process that is running. Arm recommends that implementations make External aborts precise wherever possible.

The following subsections give more information about possible External aborts:

- [Provision for classification of External aborts](#).
- [Parity or ECC error reporting](#).

The section [Exception reporting in a PMSAv8-32 implementation](#) describes the reporting of External aborts.

D4.6.1 Provision for classification of External aborts

For an External abort taken to a privileged mode other than Hyp mode, an implementation can use the [DFSR.ExT](#) or [IFSR.ExT](#) bits to provide more information about the External abort:

- [DFSR.ExT](#) provides an IMPLEMENTATION DEFINED classification of External aborts on data accesses.
- [IFSR.ExT](#) provides an IMPLEMENTATION DEFINED classification of External aborts on instruction accesses.

For an External abort taken to Hyp mode, the [HSR.EA](#) bit, provides an IMPLEMENTATION DEFINED classification of External aborts.

For all aborts other than External aborts these bits return a value of 0.

D4.6.2 Parity or ECC error reporting

The Arm architecture supports the reporting of both synchronous and asynchronous parity or ECC errors from the cache systems. It is IMPLEMENTATION DEFINED what parity or ECC errors in the cache systems, if any, result in synchronous or asynchronous parity or ECC errors.

A fault code is defined for reporting parity or ECC errors, see [Exception reporting in a PMSAv8-32 implementation](#). However when parity or ECC error reporting is implemented it is IMPLEMENTATION DEFINED whether a parity or ECC error is reported using the assigned fault code, or using another appropriate encoding.

For all purposes other than the Fault status encoding, parity or ECC errors are treated as External aborts.

D4.7 Memory barrier instructions

[Memory barriers](#) describes the memory barrier instructions. This section describes the system level controls of those instructions.

D4.7.1 EL2 control of the maintenance scope of Data Synchronization Barrier instructions executed at EL0 or EL1

In an implementation that includes EL2 and that supports maintenance scope limitations on the [DSB](#) instructions, the [HCR.BSU](#) field can modify the required maintenance scope of an instruction that is executed at EL0 or EL1. [Table D4-7](#) shows the encoding of this field:

Table D4-7 EL2 control of DSB maintenance scope, for constraining both loads and stores executed at EL0 or EL1

HCR.BSU	Minimum maintenance scope of barrier instructions
00	No effect, maintenance scope is as specified by the instruction
01	Inner Shareable
10	Outer Shareable
11	Full system

For an instruction executed at EL0 or EL1, [Table D4-8](#) shows how the [HCR.BSU](#) is combined with the maintenance scope specified by the argument of the [DSB](#) to both loads and stores to give the scope of the instruction.

Table D4-8 Effect of the HCR.BSU on barrier instructions executed at Non-secure EL0 or EL1

Maintenance scope specified by the DSB argument	HCR.BSU	Resultant maintenance scope
Full system	Any	Full system
Outer Shareable	00, 01, or 10	Outer Shareable
	11, Full system	Full system
Inner Shareable	00 or 01	Inner Shareable
	10, Outer Shareable	Outer Shareable
	11, Full system	Full system
Non-shareable	00, No effect	Non-shareable
	01, Inner Shareable	Inner Shareable
	10, Outer Shareable	Outer Shareable
	11, Full system	Full system

D4.8 Pseudocode description of general memory System instructions

This section lists the pseudocode describing general memory operations:

- [Memory data type definitions.](#)
- [Basic memory access.](#)
- [Aligned memory access.](#)
- [Unaligned memory access.](#)
- [Exclusives monitors operations.](#)
- [Access permission checking.](#)
- [Abort exceptions.](#)
- [Memory barriers.](#)

D4.8.1 Memory data type definitions

This section lists the memory data types.

The memory data types are:

- Address descriptor, defined by the [AddressDescriptor](#) type.
- Full address, defined by the [FullAddress](#) type.
- Memory attributes, defined by the [MemoryAttributes](#) type.
- Memory type, defined by the [MemType](#) enumeration.
- Device memory type, defined by the [DeviceType](#) enumeration.
- Normal memory attributes, defined by the [MemAttrHints](#) type.
- Cacheability attributes, defined by the [MemAttr_NC](#), [MemAttr_WT](#), and [MemAttr_WB](#) constants.
- Allocation hints, defined by the [MemHint_No](#), [MemHint_WA](#), [MemHint_RA](#), and [MemHint_RWA](#) constants.
- Access permissions, defined by the [Permissions](#) type.

D4.8.2 Basic memory access

The [PhysMemRead\(\)](#) and [PhysMemWrite\(\)](#) functions perform single-copy atomic, aligned, little-endian memory accesses of `size` bytes to or from the underlying physical memory array of bytes.

The attributes in `memaddrdesc.memattrs` are used by the memory system to determine caching and ordering behaviors as described in [Memory types and attributes](#), [Definition of the memory model](#), and [Atomicity in the Arm architecture](#).

D4.8.3 Aligned memory access

The [AArch32_MemSingle\(\)](#) functions make atomic, little-endian accesses of `size` bytes.

D4.8.4 Unaligned memory access

See [Unaligned data access](#) for details of the [SCTLR.A](#) and [HSCTLR.A](#) controls on the generation of alignment faults. The [HSCTLR](#) control applies to Normal memory accesses from Hyp mode, and the [SCTLR](#) control applies to Normal memory accesses from all other modes.

The [Mem_with_type\(\)](#) functions make an access of the required type. If that access is naturally aligned, each form of the function performs an atomic access by making a single call to [AArch32_MemSingle\(\)](#). If that access is not aligned but passes the [IsAlignedSize\(\)](#) checks, each form of the function synthesizes the required access from multiple calls to [AArch32_MemSingle\(\)](#). It also reverses the byte order if the access is big-endian.

D4.8.5 Exclusives monitors operations

The `AArch32_SetExclusiveMonitors()` function sets the Exclusives monitors for a Load-Exclusive instruction, for a block of bytes. The size of the blocks is determined by `size`, at the VA address. The `AArch32_ExclusiveMonitorsPass()` function checks whether a Store-Exclusive instruction still has possession of the Exclusives monitors and therefore completes successfully.

The `AArch32_ExclusiveMonitorsPass()` function checks whether a Store-Exclusive instruction still has possession of the Exclusives monitors, by checking whether the Exclusives monitors are set to include the location of the memory block specified by `size`, at the virtual address defined by `address`. The atomic write that follows after the Exclusives monitors have been set must be to the same physical address. It is permitted, but not required, for this function to return FALSE if the virtual address is not the same as that used in the previous call to `AArch32_SetExclusiveMonitors()`.

The `ExclusiveMonitorsStatus()` function returns 0 if the previous atomic write was to the same physical memory locations selected by `AArch32_ExclusiveMonitorsPass()` and therefore succeeded. Otherwise the function returns 1, indicating that the address translation delivered a different physical address.

The `MarkExclusiveGlobal()` procedure takes as arguments a `FullAddress.address`, the PE identifier `processorid` and the size of the transfer. The procedure records that the PE `processorid` has requested exclusive access covering at least `size` bytes from address `address`. The size of the location marked as exclusive is IMPLEMENTATION DEFINED, up to a limit of 2KB and no smaller than two words, and aligned in the address space to the size of the location. It is CONSTRAINED UNPREDICTABLE whether this causes any previous request for exclusive access to any other address by the same PE to be cleared.

The `MarkExclusiveLocal()` procedure takes as arguments a `FullAddress.address`, the PE identifier `processorid` and the size of the transfer. The procedure records in a local record that PE `processorid` has requested exclusive access to an address covering at least `size` bytes from address `address`. The size of the location marked as exclusive is IMPLEMENTATION DEFINED, and can at its largest cover the whole of memory but is no smaller than two words, and is aligned in the address space to the size of the location. It is IMPLEMENTATION DEFINED whether this procedure also performs a `MarkExclusiveGlobal()` using the same parameters.

The `IsExclusiveGlobal()` function takes as arguments a `FullAddress.address`, the PE identifier `processorid` and the size of the transfer. The function returns TRUE if the PE `processorid` has marked in a global record an address range as exclusive access requested that covers at least `size` bytes from address `address`. It is IMPLEMENTATION DEFINED whether it returns TRUE or FALSE if a global record has marked a different address as exclusive access requested. If no address is marked in a global record as exclusive access, `IsExclusiveGlobal()` returns FALSE.

The `IsExclusiveLocal()` function takes as arguments a `FullAddress.address`, the PE identifier `processorid` and the size of the transfer. The function returns TRUE if the PE `processorid` has marked an address range as exclusive access requested that covers at least the `size` bytes from address `address`. It is IMPLEMENTATION DEFINED whether this function returns TRUE or FALSE if the address marked as exclusive access requested does not cover all of `size` bytes from address `address`. If no address is marked as exclusive access requested, then this function returns FALSE. It is IMPLEMENTATION DEFINED whether this result is ANDed with the result of `IsExclusiveGlobal()` with the same parameters.

The `ClearExclusiveByAddress()` procedure takes as arguments a `FullAddress.address`, the PE identifier `processorid` and the size of the transfer. The procedure clears the global records of all PEs, other than `processorid`, for which an address region including any of `size` bytes starting from `address` has had a request for an exclusive access. It is IMPLEMENTATION DEFINED whether the equivalent global record of the PE `processorid` is also cleared if any of `size` bytes starting from `address` has had a request for an exclusive access, or if any other address has had a request for an exclusive access.

The `ClearExclusiveLocal()` procedure takes as arguments the PE identifier `processorid`. The procedure clears the local record of PE `processorid` for which an address has had a request for an exclusive access. It is IMPLEMENTATION DEFINED whether this operation also clears the global record of PE `processorid` that an address has had a request for an exclusive access.

D4.8.6 Access permission checking

The `AArch32_S1CheckPermissions()` and `AArch32_S2CheckPermissions()` functions are used by the architecture to perform access permission checking based on attributes derived from the memory accesses presented to the MPUs.

The interpretation of access permission is shown in Memory access control.

D4.8.7 Abort exceptions

The function `AArch32_Abort()` generates a Data Abort exception or a Prefetch Abort exception by calling the `AArch32_TakeDataAbortException()` or `AArch32_TakePrefetchAbortException()` function.

The `FaultRecord` type describes a fault. Functions that check for faults return a record of this type appropriate to the type of fault.

The function `NoFault()` returns a null record that indicates no fault. The `IsFault()` function tests whether a `FaultRecord` contains a fault.

D4.8.8 Memory barriers

The definition for the memory barrier functions is given by the enumerations `MBMaintenanceScope` and `MBReqTypes`.

These enumerations define the required Shareability domains and required access types used as arguments for DMB and DSB instructions.

The procedures `DataMemoryBarrier()`, `DataSynchronizationBarrier()`, and `InstructionSynchronizationBarrier()` perform the memory barriers.

Chapter D5

The AArch32 Protected Memory System Architecture

This chapter provides a system-level view of the memory system architecture for an Armv8-R implementation, the *Protected Memory System Architecture* (PMSAv8-32). It contains the following sections:

- [About the AArch32 Protected Memory System Architecture](#)
- [Memory protection units](#)

D5.1 About the AArch32 Protected Memory System Architecture

IHXVHB	The Armv8-R AArch32 architecture supports the Protected Memory System Architecture (PMSAv8-32) at EL1 and EL2. PMSAv8-32 is not backwards-compatible with PMSAv7 or earlier Arm PMSAs. For general information about the Arm memory model, see: • The AArch32 Application Level Memory Model • The AArch32 System Level Memory Model
RCHCTW	The PMSAv8-32 uses a flat mapping between the <i>virtual address</i> (VA) accessed by the PE and the 32-bit <i>physical address</i> (PA) accessed in the memory system. That is, for all accesses, the VA is the same as the PA, see Address translation and translation regimes in PMSAv8-32.
RQKPHH	PMSAv8-32 only supports a unified memory protection scheme. It does not support separate instruction and data regions in the address map.

D5.1.1 Protection regions

RDZDNX	An MPU defines protection regions in the 4GB address map.
RTXYCY	The definition of a protection region specifies the start and the end of the region, the access permissions to the region, and the memory attributes for the region. An individual protection region is a contiguous memory region for which the MPU defines the memory attributes, for example the memory type and the access permissions. An individual protection region: • Is defined by a pair of a Base Address Register and a Limit Address Register, see Memory protection units (MPUs). • Has a minimum size of 64 bytes. • Has a maximum size of the entire address map, 4GB.
RJQBZH	When multiple protection regions are defined, the protection regions: • Must not overlap. • Do not need to be contiguous. For more information, see Memory protection.
RBWKMx	PMSAv8-32 defines two MPUs: EL1 MPU Defines the protection regions for accesses from EL1 and from EL0. EL2 MPU Defines the protection regions for accesses from EL2. When the value of HCR.VM is 1 and for accesses from EL1 and from EL0, the EL2 MPU uses these protection regions to modify the access permissions and memory attributes that are assigned by the EL1 MPU. For an address that does not match any defined protection region, PMSAv8-32 defines Background regions and default memory maps which are used by both the EL1 and EL2 MPU. For more information, see: • Memory protection units • Protection region attributes and access permissions. • Default memory maps and Background region checks.

D5.1.2 The Protected Memory System Architecture and Virtualization

RSTTXM	A PMSAv8-32 implementation can provide a virtualization scheme in which a single PE supports multiple guest environments under the control of a single hypervisor that executes at EL2, where executing at EL2 means executing in Hyp mode.
IQTNUM	Typically, a realtime operating system executing at EL1 programs the EL1 MPU to define the memory map for its own operation and for applications it runs at EL0. A hypervisor executing at EL2 programs the EL2 MPU to define the memory map for its own operation and to modify the access permission and memory attribute assignments that are performed by the EL1&0 stage 1 translation.

D5.2 Memory protection units

RFGXJQ An MPU checks whether the address used by a memory access matches a defined protection region. It uses the permissions and memory attributes that are defined for that region or for the Background region to determine whether the access is permitted and if it is permitted, how it must behave.

- The EL1 MPU is enabled when the value of **SCTLR.M** is 1.
- The EL2 MPU is enabled when the value of **HSCTLR.M** is 1.

RTKKKV Each MPU provides two mechanisms for accessing memory region attributes:

- Using indirect accesses, where:
 - **PRSEL**/**HPRSEL** is programmed to specify the required protection region.
 - **PRBAR**/**HPRBAR** and **PRLAR**/**HPRLAR** are programmed to specify the address range and attributes for that region.
- Directly specifying the address range and attributes for the first 32 regions using **PRBAR**<n>/**HPRBAR**<n> and **PRLAR**<n>/**HPRLAR**<n>.

For the EL2 protection regions, **HPREN** provides direct access to the region enable for regions 0-31.

D5.2.1 Effect of enabling one or both MPUs on attribute assignment and fault generation

RGQHFQ For accesses that fault:

- All MPU faults are treated as level 0 faults. For translation operations, PMSA contexts return the 64-bit PAR format. The PAR format discards the least significant bits but the translation query uses the entire input address. For more information, see the [Types of MPU faults](#). For fault status codes, see **DFSR**, **IFSR**, and **HSR**.
- If the value of **EDSCR.HDD** is 1, stage 2 faults in Debug state are reported as Debug events at EL1. For more information, see Behavior in Debug state.

RKTJZT For an access that does not fault:

When both the EL1 MPU and the EL2 MPU are enabled:

- For an EL2 access (an access from Hyp mode), the EL2 MPU configuration settings determine the access permissions and memory attributes.
- For EL1 and EL0 accesses, the EL1 MPU configuration settings determine the stage 1 access permissions and memory attributes. If the *Effective value* of **HCR.VM** is 1, those access permissions and memory attributes are then modified by the EL2 MPU, as described in [Combining attributes](#).

When the EL1 MPU is disabled and the EL2 MPU is enabled:

- For an EL2 access (an access from Hyp mode), the EL2 MPU configuration settings determine the access permissions and memory attributes.
- For an EL1 or EL0 access, the EL1 Background region settings determine the stage 1 access permissions and memory attributes. If the *Effective value* of **HCR.VM** is 1, those access permissions and memory attributes are then modified by the EL2 MPU, as described in [Combining attributes](#).

When the EL1 MPU is enabled but the EL2 MPU is disabled:

- For an EL2 access (an access from Hyp mode), the EL2 Background region settings determine the access permissions and memory attributes.
- For EL1 and EL0 accesses, the EL1 MPU configuration settings determine the access permissions and memory attributes. If the *Effective value* of **HCR.VM** is 1, those access permissions and memory attributes are then combined with the EL2 Background region settings, as described in [Combining attributes](#).

When both the EL1 MPU and the EL2 MPU are disabled:

- For an EL2 access (an access from Hyp mode), the EL2 Background region settings determine the stage 1 access permissions and memory attributes.
- For an EL1 or EL0 access, the EL1 Background region settings determine the access permissions and memory attributes. If the *Effective value* of **HCR.VM** is 1, those access permissions and memory attributes are then modified by the EL2 Background region settings, as described in [Combining attributes](#).

IPTVNN Combining attributes is trivial if the EL1 MPU check resulted in attributes from the EL1 Background region because the two Background regions are identical when both of them are enabled.

For more information on the fault checking sequence, see [The MPU fault-checking sequence](#).

D5.2.2 Address translation and translation regimes in PMSAv8-32

IJBGJ

In the Armv8-R AArch 32 architecture:

- Address translation describes the process of flat mapping the *virtual address* (VA) used by the PE to the *physical address* (PA) accessed in the memory system and determining the access permissions and memory attributes of the target PA.
- A *translation regime* maps a VA to a PA, using one or two stages of address translation to assign the access permissions and memory attributes of the target PA. When two translation stages are used, the intermediate address is treated as an *intermediate physical address* (IPA).

Note

These definitions provide consistency between the Armv8-A and Armv8-R descriptions of the memory model.

RVSJC

PMSAv8-32 defines the following translation regimes:

EL1&0 translation regime

This assigns the access permissions and memory attributes for any access from EL1 or EL0.

This translation regime has one or two stages of translation:

- All accesses from EL1 or EL0 are translated by the EL1 MPU if it is enabled. This translation is a stage 1 translation.
- When the value of [HCR.VM](#) is 1, the access is also translated by the EL2 MPU. This translation is a stage 2 translation, and can modify the access permissions and memory attributes that are assigned by the stage 1 translation.

For the EL1&0 stage 1 translation, ADDRESS is in protection region *n* if:

[PRBAR<n>.BASE::'000000'](#) <= ADDRESS <= [PRLAR<n>.LIMIT::'111111'](#)

EL2 translation regime

This assigns the access permissions and memory attributes for any access from EL2.

This translation regime has a single stage of translation, stage 1, that is performed by the EL2 MPU.

For the EL2 translation, ADDRESS is in protection region *n* if:

[HPRBAR<n>.BASE::'000000'](#) <= ADDRESS <= [HPRLAR<n>.LIMIT::'111111'](#)

RVFSXY

The attributes for a protection region are defined by the combination of:

- The values that are programmed into the Base Address Register and Limit Address Register pair that define the protection region.
- A Memory Attributes Indirection register that is indexed by those values.

[Figure D5-1](#) shows how memory accesses are handled when both MPUs are enabled.

Figure D5-1 PMSAv8-32 memory access permission and attribute control

For other scenarios, see [Effect of enabling one or both MPUs on attribute assignment and fault generation](#).

D5.3 Default memory maps and Background region checks

- RCYDZW** Each PMSAv8-32 MPU has an associated default memory map which is used when the MPU is not enabled.
- RKDMFP** When the MPU is enabled and Background region checking is enabled, privileged accesses that do not hit defined protection regions undergo a second check.
- For the EL1 MPU, Background region checking is enabled for privileged access when the value of **SCTLR.BR** is 1.
 - For the EL2 MPU, Background region checking is enabled for accesses from EL2 when the value of **HSCTLR.BR** is 1.
- For details, see [Effect of enabling one or both MPUs on attribute assignment and fault generation](#).

D5.3.1 EL1 MPU default memory map

- RTFFQW** [Table D5-1](#) and [Table D5-2](#) describe the default memory map defined for the EL1 MPU. When the value of **HCR.DC** is 0, Background region checking by the EL1 MPU also uses this memory map.

Table D5-1 Instruction accesses and EL1 Background region checks

Address range	SCTLR.I == 0	SCTLR.I == 1	XN
0x00000000 - 0x7FFFFFFF	Normal, Shareable, Non-cacheable	Normal, Non-shareable, Write-Through Cacheable	Execution permitted
0x80000000 - 0xFFFFFFFF	Not applicable	Not applicable	Execute-never

Table D5-2 Data accesses and EL1 Background region checks

Address range	SCTLR.C == 0	SCTLR.C == 1
0x00000000 - 0x3FFFFFFF	Normal, Shareable, Non-cacheable	Normal, Non-shareable, Write-Back, Write-Allocate Cacheable
0x40000000 - 0x5FFFFFFF	Normal, Shareable, Non-cacheable	Normal, Non-shareable, Write-Through Cacheable
0x60000000 - 0x7FFFFFFF	Normal, Shareable, Non-cacheable	Normal, Shareable, Non-cacheable
0x80000000 - 0xBFFFFFFF	Device-nGnRE	Device-nGnRE
0xC0000000 - 0xFFFFFFFF	Device-nGnRnE	Device-nGnRnE

- RZQKBH** When the value of **HCR.DC** is 1, the Background region and the Default memory map produce accesses with the following attributes:
- Normal memory.
 - Non-shareable.
 - Inner Write-Back Read-Allocate, Write-Allocate Cacheable.
 - Outer Write-Back Read-Allocate, Write-Allocate Cacheable.
 - Execution permitted.

D5.3.2 EL2 MPU default memory map

- RGZHVJ** [Table D5-3](#) and [Table D5-4](#) describe the default memory map defined for the EL2 MPU. Background region checking by the EL2 MPU also uses this memory map.

Table D5-3 Instruction accesses and EL2 Background region checks

Address range	HSCTLR.I == 0	HSCTLR.I == 1	XN
0x00000000 - 0x7FFFFFFF	Normal, Shareable, Non-cacheable	Normal, Non-shareable, Write-Through Cacheable	Execution permitted
0x80000000 - 0xFFFFFFFF	Not applicable	Not applicable	Execute-never

Table D5-4 Data accesses and EL2 Background region checks

Address range	HSCTLR.C == 1	HSCTLR.C == 1
0x00000000 - 0x3FFFFFFF	Normal, Shareable, Non-cacheable	Normal, Non-shareable, Write-Back, Write-Allocate Cacheable
0x40000000 - 0x5FFFFFFF	Normal, Shareable, Non-cacheable	Normal, Non-shareable, Write-Through Cacheable
0x60000000 - 0x7FFFFFFF	Normal, Shareable, Non-cacheable	Normal, Shareable, Non-cacheable
0x80000000 - 0xBFFFFFFF	Device-nGnRE	Device-nGnRE
0xC0000000 - 0xFFFFFFFF	Device-nGnRnE	Device-nGnRnE

D5.4 Protection region attributes and access permissions

IRKYYM	The protection region attribute fields control the memory type, Cacheability, and Shareability of the region. Armv8-R uses the same memory types and memory attributes as Armv8-A.
	Note The Armv8-R identification scheme is based on the scheme that is used by VMSAv8-32 when using the Long-descriptor translation table format.
RVLDLX	The scheme determines how the descriptions of the properties are grouped. The scheme is based on the following model: Access controls Determine whether the PE can access the output address that corresponds to the given input address. If not, an MPU fault is generated and there is no memory access. Attributes Are valid only for an output address that the PE, in its current state, can access. The attributes define aspects of the required behavior of accesses to the target memory region. The memory attributes and access permissions for a protection region are defined by entries in: • The PRBAR and PRLAR, or HPRBAR and HPRLAR, that define the region. • The MAIR<<i>m</i>>.Attr<<i>n</i>> or HMAIR<<i>m</i>>.Attr<<i>n</i>> field that is indexed by PRLAR.AttrIdx or HPRLAR.AttrIdx, respectively.
RJDLFX	If the memory attributes for an enabled protection region or the background region do not match the attributes defined by the memory access the relevant MPU generates a fault. See also Assignment model of memory attributes and access permissions.
RRMHGK	For the EL1&0 translation regime, when both MPUs are enabled and the value of HCR.VM is 1, the stage 1 memory attribute and access permission assignments are combined with the stage 2 assignments as described in Combining attributes.

D5.4.1 Assignment model of memory attributes and access permissions

IHBXLF	PRBAR.SH; HPRBAR.SH Defines the Shareability, for a Normal memory protection region. For any type of Device memory, and for Normal Inner Non-cacheable, Outer Non-cacheable memory, the value of the SH[1:0] field is IGNORED. PRBAR.AP[2:1]; HPRBAR.AP[2:1] Defines the Access permissions. For encoding information, see the register description. PRBAR.XN; HPRBAR.XN Defines the Execute-never attribute for the region. For encoding information, see the register description. XN == 1 The region is Execute-never. PMSAv8-32 makes no distinction between Privileged execute-never (PXN) and Unprivileged execute-never (UXN). PRLAR.AttrIdx; HPRLAR.AttrIdx Indexes an Attr<<i>n</i>> field in MAIR<<i>m</i>> or HMAIR<<i>m</i>>, as follows: • AttrIdx[2] indicates the MAIR register to be used: AttrIdx[2] == 0 Use MAIR0 or HMAIR0. AttrIdx[2] == 1 Use MAIR1 or HMAIR1. • AttrIdx[2:0] indicates the required Attr field, Attr<<i>n</i>>, where n = AttrIdx[2:0]. MAIR<<i>m</i>>.Attr<<i>n</i>>; HMAIR< <i>m</i>>.Attr<<i>n</i>> Defines: • The memory type, Normal memory, or a type of Device memory. • For Normal memory: — The Inner Cacheability and Outer Cacheability attributes, each of which is one of Non-cacheable, Write-Through Cacheable, or Write-Back Cacheable. — For Write-Through Cacheable and Write-Back Cacheable regions, the Read-Allocate and Write-Allocate policy hints, each of which is Allocate or Do not allocate.
--------	---

D5.4.2 Access permissions for instruction execution

RSICLL	Execute-never controls provide an additional level of control on memory accesses permitted by the access permissions settings. These controls are: XN, Execute-never PRBAR.XN and HPRBAR.XN, apply to execution at any Exception level to which the protection region applies. A value of 0 indicates that this control permits execution.
RQZKVB	Executing an instruction at ELx generates a Permission fault unless all of the following are true for the instruction address: - Any stage 1 execute-never control that applies to execution at ELx permits execution. - If the translation regime that applies to ELx has two stages of translations, the stage 2 execute-never control that applies to execution at ELx permits execution. - Read access is permitted.
IVZWDV	In addition, System register controls can enforce execute-never restrictions, regardless of the settings in the XN fields, see Preventing execution from writable locations.
RDTVJH	The execute-never controls apply also to speculative instruction fetching. This means a speculative instruction fetch from a memory region that is execute-never at the current level of privilege is prohibited. The execute-never controls means that, when the stage of address translation is enabled, the PE can fetch, or speculatively fetch, an instruction from a memory location only if all of the following apply: - In the Protection Region Base Address Register for the location the following apply: - The stage 1 execute-never control for the Exception level at which the instruction is executed permits execution. - For a translation regime with two stages of address translation, the stage 2 execute-never control that applies to the Exception level at which the instruction is executed permits execution. - The access permissions permit a read access from the current PE mode. - No other Prefetch Abort condition exists. - Although the XN control applies to speculative fetching, on a speculative instruction fetch from an XN location, no Permission fault is generated unless the PE attempts to execute the instruction that would have been fetched from that location. This means that, if a speculative fetch from an XN location is attempted, but there is no attempt to execute the corresponding instruction, a Permission fault is not generated. - The software that defines a protection region must mark any region of memory that is read-sensitive as XN, to avoid the possibility of a speculative fetch accessing the memory region. This means it must mark any memory region that corresponds to a read-sensitive peripheral as XN. Hardware does not prevent speculative accesses to a region of any Device memory type unless that region is also marked as execute-never for all Exception levels from which it can be accessed.
RXVPBN	When no stage of address translation for the translation regime is enabled, memory regions cannot have XN attributes assigned. Effect of enabling one or both MPUs on attribute assignment and fault generation describes how disabling all MPUs affects instruction fetching.

D5.4.2.1 Preventing execution from writable locations

RGFEND	The architecture provides control bits that, when the corresponding stage 1 address translation is enabled, force writable memory to be treated as XN, regardless of the value of the XN field. When the translation stages are controlled by an Exception level that is using AArch32: - For PL1&0 stage 1 translations, when SCTLR.WXN is set to 1, all regions that are writable at stage 1 of the address translation are treated as XN. - For PL1&0 stage 1 translations, when SCTLR.UWXN is set to 1, an instruction fetch is treated as accessing a PXN region if it accesses a region that software executing at EL0 can write to. - For EL2 stage 1 translations, when HSCCLR.WXN is set to 1, all regions that are writable at stage 1 of the address translation are treated as XN. Note - The SCTLR.WXN controls are intended to be used in systems with very high security requirements. - Setting a WXN or UWXN bit to 1 changes the interpretation of the attributes for the memory protection region, overriding a zero value of an XN field. It does not cause any change to the attributes for the memory protection region.
--------	--

ITJJWS For any given virtual machine, Arm expects WXN and UWXN to remain static in normal operation. A generic sequence to ensure synchronization of a change to these fields, when that change is made without a corresponding change of VMID, is:

```
Change the WXN or UWXN bit.  
  
ISB; // This ensures synchronization of the change.
```

For more information about address translation, see [Address translation and translation regimes in PMSAv8-32](#).

D5.4.3 Combining attributes

RFBPVX For the EL1&0 translation regime, when both MPUs are enabled and the value of HCR.VM is 1, the stage 1 and stage 2 attributes and access permissions are combined as follows:

- If the stage 1 access permissions indicate that an access is not permitted, a stage 1 Permission fault is generated regardless of the stage 2 permissions.
- If the stage 1 access permissions indicate that an access is permitted but the stage 2 access permissions indicate that it is not permitted, a stage 2 Permission fault is generated.
- If an access is permitted by both the stage 1 and the stage 2 access permissions, the memory attributes are combined as shown in [Table D5-5](#), [Table D5-6](#), and [Table D5-7](#).

Table D5-5 Combining the stage 1 and stage 2 memory type assignments

Rule	If the memory type assigned by either stage is:	The resultant memory type is:
Device has precedence over Normal	Any Device memory type	A Device memory type
non-Gathering has precedence over Gathering	A Device-nGxx memory type	A Device-nGxx memory type
non-Reordering has precedence over Reordering	A Device-nGnRx memory type	A Device-nGnRx memory type
No Early Write Acknowledgement has precedence over Early Write Acknowledgement	The Device-nGnRnE memory type	The Device-nGnRnE memory type

RFDGNX Regardless of any Shareability attribute that results from the combinations that are described in [Table D5-7](#):

- Any location for which the resultant memory type is any type of Device memory is always treated as Outer Shareable.
- Any location for which the resultant memory type is Normal Inner Non-cacheable, Outer Non-cacheable is always treated as Outer Shareable.

[Table D5-6](#) shows the assignments at each stage of translation are combined to create the resultant Cacheability attribute. These rules apply independently for the Inner Cacheability and Outer Cacheability attributes.

Table D5-6 Combining Cacheability assignments for Normal memory

Stage 1 assignment	Stage 2 assignment	Resultant Cacheability
Non-cacheable	Any	Non-cacheable
Any	Non-cacheable	Non-cacheable
Write-Through Cacheable	Write-Through or Write-Back Cacheable	Write-Through Cacheable

Stage 1 assignment	Stage 2 assignment	Resultant Cacheability
Write-Through or Write-Back Cacheable	Write-Through Cacheable	Write-Through Cacheable
Write-Back Cacheable	Write-Back Cacheable	Write-Back Cacheable

R_{HYQDR}

A protection region is treated as Outer Shareable, regardless of any Shareability assignments at either stage of translation if:

- The resultant memory type attribute, as described in [Table D5-5](#), is any type of Device memory.
- The resultant memory type attribute, as described in [Table D5-5](#), is Normal memory, and the resultant Cacheability, as described in [Table D5-6](#), is Inner Non-cacheable, Outer Non-cacheable.

For a protection region with a resultant memory type attribute of Normal that is not Inner Non-cacheable, Outer Non-cacheable, [Table D5-7](#) shows how the Shareability attribute is obtained from the assignment at each stage of translation.

Table D5-7 Combining Shareability assignments for Normal not Inner Non-cacheable, Outer Non-cacheable memory

Stage 1 assignment	Stage 2 assignment	Resultant Shareability
Outer Shareable	Any	Outer Shareable
Inner Shareable	Outer Shareable	Outer Shareable
Inner Shareable	Inner Shareable	Inner Shareable
Inner Shareable	Non-shareable	Inner Shareable
Non-shareable	Outer Shareable	Outer Shareable
Non-shareable	Inner Shareable	Inner Shareable
Non-shareable	Non-shareable	Non-shareable

D5.5 PMSAv8-32 memory aborts

IYPWPQ	In a PMSAv8-32 implementation, the following mechanisms cause a PE to take an exception on a failed memory access: Debug exception An exception caused by the debug configuration, see AArch32 Self-hosted Debug. Alignment fault An Alignment fault is generated if the address used for a memory access does not have the required alignment for the operation. For more information, see Unaligned data access and Alignment faults. MPU fault An MPU fault is a fault generated by the fault checking sequence for the current translation regime. See Types of MPU faults. External abort Any memory system fault other than a Debug exception, an Alignment fault, or an MPU fault. Collectively, these mechanisms are called <i>aborts</i>. AArch32 Self-hosted Debug and Halting Debug Events describe Debug exceptions, and the remainder of this section describes Alignment faults, MPU faults, and External aborts.
RNQXHQ	An access that causes an abort is said to be aborted, and uses the <i>Fault Address Registers</i> (FARs) and <i>Fault Status Registers</i> (FSRs) or <i>Exception Syndrome Registers</i> (ESRs) to record context information. The exception generated on a synchronous memory abort: - On an instruction fetch is called the Prefetch Abort exception. - On a data access is called the Data Abort exception. Note The Prefetch Abort exception applies to any synchronous memory abort on an instruction fetch. It is not restricted to speculative instruction fetches.
RNZWDF	The Exception level and PE mode that a PMSAv8-32 memory abort is taken to depends on the translation regime and stage that generate the abort. The fault context is dependent on whether: - The abort is reported as a Prefetch Abort or as a Data Abort. - The exception is taken from the same or a lower Exception level. For more information, see Routing of aborts taken to AArch32 state.
RXQPPG	External aborts can be reported synchronously or asynchronously. Asynchronous External aborts are reported using the SError exception. For more information, see External aborts.
RFTHTQD	In AArch32 state, asynchronous memory aborts are a type of External abort, and are treated as a type of Data Abort exception.
IKDMIQ	The following sections describe the abort mechanisms: Types of MPU faults. The MPU fault-checking sequence. Alignment faults. AArch32 state prioritization of synchronous aborts from a single stage of address translation. An access that causes an abort is said to be aborted. On an abort, System registers are used to record context information. For more information, see Exception reporting in a PMSAv8-32 implementation.

D5.5.1 Types of MPU faults

ISJCRL	This section describes the faults that might be detected during one of the fault-checking sequences described in The MPU fault-checking sequence. MPU faults are always synchronous. When an MPU fault generates an abort for a region of memory, no memory access is made if that region is or could be marked as any type of Device memory. The MPU faults that might be detected during a fault checking sequence are: Permission fault. Translation fault.
--------	---

D5.5.1.1 Permission fault

IDWMXC	A Permission fault can be generated if the memory access does not meet the permissions defined for the Memory protection region. The access type can be Read, Write or Execute.
RMJFXD	Cache or branch predictor maintenance operations cannot cause a Permission fault.

D5.5.1.2 Translation fault

RWNSJK	A Translation fault is generated if the input address for a translation either does not map onto an address range of a Protection region , or the Protection region range that it maps onto is disabled. In these cases the fault is reported as a level 1 Translation fault on the translation stage at which the mapping to a region described by a Protection region failed.
RJTWYB	A data or unified cache maintenance by VA instruction can generate a Translation fault. However: • If the Point of Coherency is before any level of cache, it is IMPLEMENTATION DEFINED whether a data or unified cache maintenance by VA to the Point of Coherency instruction can generate a Translation fault. • If the Point of Unification is before any level of data cache, it is IMPLEMENTATION DEFINED whether a data or unified cache clean by VA to the Point of Unification instruction can generate a Translation fault. It is IMPLEMENTATION DEFINED whether an instruction cache invalidate by VA operation can generate a Translation fault. It is IMPLEMENTATION DEFINED whether a branch predictor maintenance operation can generate a Translation fault.

D5.5.2 The MPU fault-checking sequence

IMVKHL	This section describes the MPU checks made for the memory accesses required for instruction fetches and for explicit memory effects: • If an instruction fetch faults it generates a Prefetch Abort exception. • If an data memory access faults it generates a Data Abort exception. For more information about Prefetch Abort exceptions and Data Abort exceptions see Handling exceptions that are taken to an Exception level using AArch32.
RJQSLC	In PMSAv8-32, all memory accesses require VA to PA translation. Therefore, when a corresponding stage of address translation is enabled, each access requires a lookup of the attributes of the memory protection region for the accessed VA.
RBQZPH	MPU fault checking is performed for each stage of address translation.
IPQWBM	The fault-checking sequence shows a translation from an Input address to an Output address. For more information about this terminology, see Address translation and translation regimes in PMSAv8-32 .
IKWNJK	Types of MPU faults describes the faults that an MPU fault-checking sequence can report.
RKRLBY	Figure D5-2 shows the stage 1 translation for EL1 and EL0 accesses.

Note

[Figure D5-2](#) and [Figure D5-3](#) give an overview of the fault checking performed by the MPU. See [AArch32 state prioritization of synchronous aborts from a single stage of address translation](#) for the complete set of possible faults and their prioritization.

Figure D5-2 Stage 1 translation for EL1 and EL0 accesses

Figure D5-3 shows the stage 2 translation for EL1 and EL0 and stage 1 translation for EL2 accesses.

Figure D5-3 Stage 2 translation for EL1 and EL0, stage 1 translation for EL2 accesses

D5.5.2.1 EL1&0 Transaltion

R _{XXGXT}	When EL2 is operating in a PL1 or EL0 mode, any memory access goes through two stages of translation: • Stage 1, from VA to IPA. • Stage 2, from IPA to PA.
R _{DBFDD}	On performing a stage 1 translation, the input addresses must be translated from IPA to PA, using a stage 2 translation. This means that a memory access made as part of a stage 1 translation lookup might generate, on a stage 2 translation: • A Permission fault. • A synchronous External abort on the memory access. HSR.ISS[7] is set to 1, to indicate a stage 2 fault during a stage 1 translation, and the part of the ISS field that might contain details of the instruction is invalid. For more information, see Use of the HSR. Note On most systems, such a mapping to a Device memory type on the stage 2 translation is likely to indicate a Guest RTOS error, where the stage 1 translation is corrupted. Therefore, it is appropriate to trap this access to the hypervisor.
I _{JRZBY}	A cache maintenance instruction executed at PL1 can cause a stage 1 translation that might generate a stage 2 Permission fault, as described in this section. However: • If the Point of Coherency is before any level of cache, it is IMPLEMENTATION DEFINED whether a cache maintenance by VA instruction can generate a Permission fault in this way. • If the Point of Unification is before any level of data cache, it is IMPLEMENTATION DEFINED whether a data or unified cache clean by VA to the Point of Unification instruction can generate a Permission fault in this way. Note This is an exception to the general rule that a cache maintenance instruction cannot generate a Permission fault.

D5.5.3 Alignment faults

R _{PHJYP}	The Arm memory architecture requires support for strict alignment checking.
I _{XGSQB}	This checking is controlled by: • SCTLR.A, for accesses made from any PE mode other than Hyp mode. • HSCTLR.A, for accesses made from Hyp mode. In addition, some instructions do not support unaligned accesses, regardless of the value of SCTLR.A or HSCTLR.A.
I _{FDDCX}	Unaligned data access defines when Alignment faults are generated, for both values of SCTLR.A or HSCTLR.A .
R _{VZBNX}	An Alignment fault can occur on an access for which the stage of address translation is disabled.
R _{DSWST}	Any unaligned access to memory region with any Device memory type attribute generates an Alignment fault.
I _{HLKPM}	Routing of aborts taken to AArch32 state defines the mode to which an Alignment fault is taken. The prioritization of Alignment faults depends on whether the fault was generated because of an access to a Device memory type, or for another reason. For more information, see AArch32 state prioritization of synchronous aborts from a single stage of address translation.

D5.5.4 External abort on a translation

R _{XWGCJ}	An External abort on a translation can be either synchronous or asynchronous. For more information on External aborts, see External aborts.
R _{WBCCQ}	An External abort on a translation is reported: • If the External abort is synchronous, using: — A synchronous Prefetch Abort exception if the translation is for an instruction fetch.

- A synchronous Data Abort exception if the translation is for a data access.
- If the External abort is asynchronous, using an SError exception, which is taken as an asynchronous Data Abort exception.

If an implementation reports the error in the translation asynchronously from executing the instruction whose instruction fetch or memory access caused the translation, these aborts behave essentially as interrupts. The aborts are masked when [PSTATE.A](#) is set to 1, otherwise they are reported using the Data Abort exception.

D5.5.5 AArch32 state prioritization of synchronous aborts from a single stage of address translation

IDDPZN	Exception prioritization for exceptions taken to AArch32 state describes the prioritization of exceptions taken from an Exception level that is using AArch32. This section gives additional information about the prioritization of MPU faults from PMSAv8-32 translation regimes.
RLBYFH	If a single instruction generates aborts on more than one memory access, the architecture does not define any prioritization between those aborts.
RKGQZN	In general, the Arm architecture does not define when asynchronous events are taken, and therefore the prioritization of asynchronous events is IMPLEMENTATION DEFINED.
IFNFZC	The priority numbering in this list only shows the relative priorities of aborts from a single stage of address translation in a PMSAv8-32 translation regime. This numbering has no global significance.
IFJVWP	For a single stage of translation in a PMSAv8-32 translation regime, the following numbered list shows the priority of the possible memory management faults on a memory access. In this list: • For memory accesses that undergo two stages of translation, the <i>italic entries show where the faults from the stage 2 translation can occur</i>. A stage 2 fault within a stage 1 translation follows the same prioritization of faults. • For synchronous External aborts from translations see also Synchronous External abort errors from address translation caching structures. The priority order, from highest priority to lowest priority, is: 1. Alignment fault not caused by memory type. This is possible for a stage 1 translation only. 2. Permission fault due to the input address being out of the address range to be translated or requiring an AArch32 Protection region that is disabled. 3. <i>Second stage abort on a stage 1 translation. When stage 2 address translation is enabled this includes an Address size fault caused by the PA being out of the range implemented.</i> This is second stage abort during a first stage translation. 4. Synchronous parity or ECC error. 5. Synchronous External abort. 6. Translation fault on a level 1 translation. 7. Alignment fault caused by the memory type. 8. Permission fault. 9. <i>A fault from the stage 2 translation of the memory access. When stage 2 address translation is enabled this includes an Address size fault caused by the PA being out of the range implemented.</i> 10. Synchronous parity or ECC error on the memory access. 11. Synchronous External abort on the memory access.

Note

The prioritization of IMPLEMENTATION DEFINED [MPU faults](#) for a Load-Exclusive or Store-Exclusive to an unsupported memory type is IMPLEMENTATION DEFINED.

See also [The MPU fault-checking sequence](#).

D5.6 Exception reporting in a PMSAv8-32 implementation

This section describes exception reporting, in AArch32 state, in a PMSAv8-32 implementation. That is, it describes only the reporting of exceptions that are taken to an Exception level that is using AArch32. EL2 provides an enhanced reporting mechanism for exceptions taken to the EL2 mode, Hyp mode. This means that, for PMSAv8-32, the exception reporting depends on the mode to which the exception is taken.

[About exception reporting](#) introduces the general approach to exception reporting, and the following sections then describe exception reporting at different privilege levels:

- [Reporting exceptions taken to PL1 modes.](#)
- [Fault reporting in PL1 modes.](#)
- [Summary of register updates on faults taken to PL1 modes.](#)
- [Reporting exceptions taken to Hyp mode.](#)
- [Use of the HSR.](#)
- [Summary of register updates on exceptions taken to Hyp mode.](#)

Note

The registers used for exception reporting also report information about debug exceptions. For more information, see:

- [Data Abort exceptions, taken to a PL1 mode.](#)
 - [Prefetch Abort exceptions, taken to a PL1 mode.](#)
 - [Reporting exceptions taken to Hyp mode.](#)
-

D5.6.1 About exception reporting

I_{YNLND}

Exceptions can be taken to:

- Hyp mode.
- A PL1 mode.

Exception reporting in Hyp mode differs significantly from that in the other modes, but in general, exception reporting returns:

- Information about the exception:
 - On taking an exception to Hyp mode, the *Hyp Syndrome Register*, [HSR](#), returns syndrome information.
 - On taking an exception to any other mode, a *Fault Status Register* (FSR) returns status information.
- For synchronous exceptions, one or more addresses associated with the exceptions, returned in *Fault Address Registers* (FARs). For a permitted exception to this requirement see [Fault address reporting on synchronous External aborts](#).

In all modes, additional IMPLEMENTATION DEFINED registers can provide additional information about exceptions.

Note

- [PE mode for taking exceptions](#) describes how the mode to which an exception is taken is determined.
- EL2 provides:
 - Specific exception types, that can only be taken from PL1 and EL0 modes, and are always taken to Hyp mode.
 - Routing controls that can route some exceptions from PL1 and EL0 modes to Hyp mode.

These exceptions are reported using the same mechanism as the Hyp mode reporting of PMSAv8-32 memory aborts, as described in this section.

I_{LQFTF}

Memory system faults generate either a Data Abort exception or a Prefetch Abort exception, as summarized in:

- [Reporting exceptions taken to PL1 modes.](#)
- [Memory fault reporting in Hyp mode.](#)

On an access that might have multiple aborts, the [MPU fault](#) checking sequence and the prioritization of aborts determine which abort occurs. For more information, see [The MPU fault-checking sequence](#) and [AArch32 state prioritization of synchronous aborts from a single stage of address translation](#).

D5.6.1.1 Fault address reporting on synchronous External aborts

R_{TWYFP}

The general architectural requirement is that, on a synchronous abort, the faulting address is recorded in a *Fault Address Register* (FAR). This requirement is relaxed for the case of a synchronous External abort that is not a synchronous External abort on a translation. In this case only:

- It is IMPLEMENTATION DEFINED whether the faulting address is recorded in a FAR.
- A bit in a fault reporting register, the FnV bit, indicates whether a valid address is recorded.

The details of this reporting depend on whether the exception is taken to:

- A PL1 mode, as described in [Reporting exceptions taken to PL1 modes](#).
- Hyp mode, as described in [Reporting exceptions taken to Hyp mode](#).

D5.6.2 Reporting exceptions taken to PL1 modes

I_{WBXJS}

The following sections give general information about the reporting of exceptions when they are taken to a PL1 mode:

- [Registers used for reporting exceptions taken to PL1 modes](#).
- [Data Abort exceptions, taken to a PL1 mode](#).
- [Prefetch Abort exceptions, taken to a PL1 mode](#).

[Fault reporting in PL1 modes](#) then describes the fault reporting in these modes, including the encodings used for reporting the faults.

Note

Security state, Exception levels, and AArch32 execution privilege describes how the PL1 modes map onto the Exception levels.

D5.6.2.1 Registers used for reporting exceptions taken to PL1 modes

I_{PQQHX}

AArch32 state defines the following registers, and register encodings, for exceptions taken to PL1 modes:

- The [DFSR](#) holds information about a Data Abort exception.
- The [DFAR](#) holds the faulting address for some synchronous Data Abort exceptions.
- The [IFSR](#) holds information about a Prefetch Abort exception.
- The [IFAR](#) holds the faulting address for some synchronous Prefetch Abort exceptions.

In addition, if implemented, the optional ADFSR and AIFSR can provide additional fault information, see [Auxiliary Fault Status Registers](#).

D5.6.2.1.1 Auxiliary Fault Status Registers

I_{VGHVB}

AArch32 state defines the following Auxiliary Fault Status Registers:

- The Auxiliary Data Fault Status Register, [ADFSR](#).
- The Auxiliary Instruction Fault Status Register, [AIFSR](#).

The position of these registers is architecturally-defined, but the content and use of the registers is IMPLEMENTATION DEFINED. An implementation can use these registers to return additional fault status information. An example use of these registers is to return more information for diagnosing parity or ECC errors.

An implementation that does not need to report additional fault information must implement these registers as RES0. This ensures that an attempt to access these registers from software executing at PL1 does not cause an Undefined Instruction exception.

D5.6.2.2 Data Abort exceptions, taken to a PL1 mode

R_{KYSNC}

On taking a Data Abort exception to a PL1 mode:

- The [DFSR](#) is updated with details of the fault, including the appropriate Fault status code. If the Data Abort exception is synchronous, [DFSR.WnR](#) is updated to indicate whether the faulted instruction was a read or a write. However, if the fault is on a cache maintenance instruction, or on an address translation instruction, WnR is set to 1, to indicate a fault on a write instruction, and the CM bit is set to 1. If the Data Abort is external, then [DFSR](#) provides fields for additional classification of the abort, see [Provision for classification of External aborts](#). See the register description for more information about the returned fault information. See also [Data Abort on a Watchpoint exception](#). If the Data Abort exception is

- Synchronous, the [DFAR](#) is updated with the VA that caused the exception, but see [Fault address reporting on synchronous External aborts](#) for a permitted exception to this requirement.
- Asynchronous, the [DFAR](#) becomes UNKNOWN.

[DFSR.WnR](#) and [DFSR.CM](#) are UNKNOWN on an asynchronous Data Abort exception.

D5.6.2.2.1 Data Abort on an instruction cache or branch predictor maintenance instruction by VA

R_{CKYGN}

If an instruction cache invalidation by VA or branch predictor invalidation by VA operation generates a Data Abort exception that is taken to a PL1 mode, the [DFAR](#) is updated to hold the faulting VA.

The faulting is reported as follows:

- [DFSR.CM](#) is set to 1, to indicate a fault on a cache maintenance instruction.
- [DFSR.STATUS](#) indicates the cause of the fault, a Translation or Access flag fault.
- [DFSR.WnR](#) is set to 1.
- The [IFSR](#) is UNKNOWN.

D5.6.2.2.2 Data Abort on a Watchpoint exception

R_{HVTNX}

On taking a Data Abort exception caused by a watchpoint:

- [DFSR.FS](#) is updated to indicate a debug exception.
- [DFSR](#).{WnR, Domain} are UNKNOWN.
- [DFAR](#) is set to the address that generated the watchpoint.

Note

- [lr_ABT](#) indicates the address of the instruction that triggered the watchpoint.
-

R_{WZTWL}

A watchpointed address can be any byte-aligned address. The address reported in [DFAR](#) might not be the watchpointed address, and:

- For a watchpoint due to an operation other than a Data Cache maintenance instruction, can be any address between and including:
 - The lowest address accessed by the instruction that triggered the watchpoint.
 - The highest watchpointed address accessed by that instruction.

If multiple watchpoints are set in this range, there is no guarantee of which watchpoint is generated. The address must also be within a naturally-aligned block of memory of an IMPLEMENTATION DEFINED power-of-two size, containing a watchpoint address accessed by that location.

Note

In particular, there is no guarantee of generating the watchpoint with the lowest address in the range.

- For a watchpoint due to a Data Cache operation, the address is the address passed to the instruction. This might be an address that is above the watchpointed location.

D5.6.2.3 Prefetch Abort exceptions, taken to a PL1 mode

R_{WDQKK}

For a Prefetch Abort exception generated by an instruction fetch, the Prefetch Abort exception is taken synchronously with the instruction that the abort is reported on. This means:

- If the PE attempts to execute the instruction a Prefetch Abort exception is generated.
- If an instruction fetch is issued but the PE does not attempt to execute the prefetched instruction, no Prefetch Abort exception is generated for that instruction. For example, if the execution flow branches round a prefetched instruction, no Prefetch Abort exception is generated.

I_{NBBBM}

In addition, Breakpoint Instruction, Breakpoint, and Vector Catch exceptions, generate a Prefetch Abort exception, see the following for more information:

- [Exception syndrome information and preferred return address for a BKPT instruction.](#)
- [Exception syndrome information and preferred return address for a Breakpoint exception.](#)
- [Exception syndrome information and preferred return address for a Vector Catch exception.](#)

Note

Usually, the term *exception syndrome* is used only for exceptions taken to Hyp mode. The referenced sections use the term more generally, to include exception information reported in the [IFSR](#).

R_{PCNKL}

On taking a Prefetch Abort exception to a PL1 mode:

- The [IFSR](#) is updated with details of the fault, including the appropriate fault code. If appropriate, the fault code indicates that the exception was generated by a debug exception. See the register description for more information about the returned fault information.
- For a Prefetch Abort exception generated by an instruction fetch, the [IFAR](#) is updated with the VA that caused the exception, but see [Fault address reporting on synchronous External aborts](#) for a permitted exception to this requirement.
- For a Prefetch Abort exception generated by a debug exception, the [IFAR](#) is UNKNOWN.

D5.6.3 Fault reporting in PL1 modes

I_{GHVTT}

The FSRs provide fault information, including an indication of the fault that occurred. The following subsection describes fault reporting in PL1 modes for [PL1 fault reporting](#).

Reserved encoding in the IFSR and DFSR encodings tables gives some additional information about the encodings for both formats.

[Summary of register updates on faults taken to PL1 modes](#) shows which registers are updated on each of the reported faults.

D5.6.3.1 PL1 fault reporting

I_{LQYSC}

This subsection describes the fault reporting for a fault taken to a PL1 mode.

R_{CMTTH}

When the PE takes an exception, bit[9] of the FSR is set to 1 if the PE is using this FSR format.

The FSRs encode the fault in a 6-bit STATUS field, that comprises FSR[5:0]. In addition:

- For a fault taken to a PL1 mode, [Summary of register updates on faults taken to PL1 modes](#) shows whether the corresponding FAR is updated on the fault. That is:
 - For a fault reported in the [IFSR](#), whether the [IFAR](#) holds a valid address.
 - For a fault reported in the [DFSR](#), whether the [DFAR](#) holds a valid address.
- For a fault taken to the Hyp mode, [Summary of register updates on exceptions taken to Hyp mode](#) shows what registers are updated on the fault.

R_{ZNVVV}

The fault encodings reserve a single encoding for Cache faults. The details of these faults and any associated subsidiary registers are IMPLEMENTATION DEFINED.

D5.6.4 Summary of register updates on faults taken to PL1 modes

R_{JZVBX}

For faults that generate exceptions that are taken to a PL1 mode, [Table D5-8](#) shows the registers affected by each fault. In this table:

- Yes indicates that the register is updated.
- UNK indicates that the fault makes the register value UNKNOWN.
- A null entry, -, indicates that the fault does not affect the register.

Table D5-8 Effect of a fault taken to a PL1 mode on the reporting registers

Fault	IFSR	IFAR	DFSR	DFAR
Faults reported as Prefetch Abort exceptions:				

Fault	IFSR	IFAR	DFSR	DFAR
MPU fault , always synchronous	Yes	Yes	-	-
Synchronous External abort on translation	Yes	Yes	-	-
Synchronous parity or ECC error on translation	Yes	Yes	-	-
Synchronous External abort	Yes	IMP DEF ^a	-	-
Synchronous parity or ECC error on memory access	Yes	Yes	-	-
Fault reported as Data Abort exception:				
Alignment fault, always synchronous	-	-	Yes	Yes
MPU fault , always synchronous	-	-	Yes	Yes
Fault on instruction cache maintenance	UNK	-	Yes	Yes
Synchronous External abort	-	-	Yes	IMP DEF ^a
Synchronous parity or ECC error on memory access	-	-	Yes	Yes
SError exception	-	-	Yes	UNK
SError exception from a parity or ECC error on memory access	-	-	Yes	UNK
Debug exceptions:				
Breakpoint, Breakpoint Instruction, or Vector Catch ^b	Yes	UNK	-	-
Watchpoint ^c	-	-	Yes	Yes

a. IMPLEMENTATION DEFINED. The [IFSR.FnV](#) or [DFSR.FnV](#) bit indicates whether the register holds a valid address. See [Fault address reporting on synchronous External aborts](#).

b. Generates a Prefetch Abort exception.

c. Generates a Data Abort exception.

D5.6.5 Reporting exceptions taken to Hyp mode

I_{ZNTNS}

Hyp mode is the EL2 mode. It is entered by taking an exception to Hyp mode.

The following exceptions are taken to Hyp mode:

- SError exceptions, IRQ exceptions, and FIQ exceptions, from PL1 and EL0 modes, and if configured by the AMO, FMO or IMO bits. For more information, see [Asynchronous exception routing controls](#).
 - When [HCR.TGE](#) is set to 1, all exceptions that would be routed to PL1 modes. For more information, see [Routing exceptions from EL0 to EL2](#).
 - When [HDCR.TDE](#) is set to 1, any debug exception that would otherwise be taken to a PL1 mode, see [Routing debug exceptions to EL2 using AArch32](#).
 - The privilege rules for taking exceptions mean that any exception taken from Hyp mode, must be taken to Hyp mode.
 - An abort that [Routing of aborts taken to AArch32 state](#) identifies as taken to Hyp mode.
 - Hypervisor Call exceptions, and Hyp Trap exceptions, are always taken to Hyp mode. These exceptions are supported only as part of EL2.
- Various operations from PL1 and EL0 modes can be *trapped* to Hyp mode, using the Hyp Trap exception. For more information, see [EL2 configurable controls](#).

R_{HDC}CLH

Synchronous exceptions taken to Hyp mode provide syndrome information in the [HSR](#).

R_QRSWR

On an abort exception taken to Hyp mode, the syndrome information in the [HSR](#) includes the Fault status code otherwise provided by the fault status register, and extends the fault reporting compared to that available for an exception taken to a PL1 mode.

In addition, for a Debug exception taken to Hyp mode, [DBGDSCRint.MOE](#) or [DBGDSCRext.MOE](#) shows what caused the Debug exception. This field is valid regardless of whether the Debug exception was taken from Hyp mode or from another mode.

For more information, see the following subsections:

- [Registers used for reporting exceptions taken to Hyp mode.](#)
- [Memory fault reporting in Hyp mode.](#)
- [Use of the HSR](#)

D5.6.5.1 Registers used for reporting exceptions taken to Hyp mode

ICXTVC

The following registers are used for reporting exceptions taken to Hyp mode:

- The [HSR](#) holds syndrome information for the exception.
- The [HDFAR](#) holds the VA associated with a Data Abort exception.
- The [HIFAR](#) holds the VA associated with a Prefetch Abort exception.
- The [HPFAR](#) holds bits[39:12] of the IPA associated with some aborts on stage 2 address translations.

In addition, if implemented, the optional [HADFSR](#) and [HAIFSR](#) can provide additional fault information, see [Hyp Auxiliary Fault Syndrome Registers](#).

D5.6.5.1.1 Hyp Auxiliary Fault Syndrome Registers

IGYJPF

EL2 also defines encodings for the following Hyp Auxiliary Fault Syndrome Registers:

- The Hyp Auxiliary Data Fault Syndrome Register, [HADFSR](#).
- The Hyp Auxiliary Instruction Fault Syndrome Register, [HAIFSR](#).

An implementation can use these registers to return additional fault status information for aborts taken to Hyp mode. They are the Hyp mode equivalents of the registers described in [Auxiliary Fault Status Registers](#). An example use of these registers is to return more information for diagnosing parity or ECC errors.

ICJQZJ

The architectural requirements for the [HADFSR](#) and [HAIFSR](#) are:

- The position of these registers is architecturally-defined, but the content and use of the registers is IMPLEMENTATION DEFINED.
- An implementation with no requirement for additional fault reporting can implement these registers as RES0, but the architecture does not require it to do so.

D5.6.5.2 Memory fault reporting in Hyp mode

RWMVVZ

Prefetch Abort and Data Abort exceptions taken to Hyp mode report memory faults.

ILRNYS

For these aborts, the [HSR](#) contains the following fault status information:

- The [HSR](#).EC field indicates the type of abort, as [Table D5-9](#) shows.
- The [HSR](#).ISS field holds more information about the abort. In particular:
 - Bits[5:0] of this field hold the STATUS field for the abort, using the encodings defined in [PL1 fault reporting with the Long-descriptor translation table format](#).
 - Other subfields of the ISS give more information about the exception, equivalent to the information returned in the FSR for a memory fault reported at PL1.

See the descriptions of the ISS fields for the memory faults, referenced from the *Syndrome description* column of [Table D5-9](#), for information about the returned fault information.

Table D5-9 HSR.EC encodings for aborts taken to Hyp mode

HSR.EC	Abort	Syndrome description
0x20	Prefetch Abort taken from PL1 or EL0 mode	ISS encoding for exception from a Prefetch Abort
0x21	Prefetch Abort taken from Hyp mode	
0x24	Data Abort taken from PL1 or EL0 mode	ISS encoding for exception from a Data Abort
0x25	Data Abort taken from Hyp mode	

For more information, see [Use of the HSR](#).

RZVFML

A Prefetch Abort exception is taken synchronously with the instruction that the abort is reported on. This means:

- If the PE attempts to execute the instruction a Prefetch Abort exception is generated.
- If an instruction fetch is issued but the PE does not attempt to execute the prefetched instruction, no Prefetch Abort exception is generated for that instruction. For example, if the execution flow branches round a prefetched instruction that would abort if the PE attempted to execute it, no Prefetch Abort exception is generated.

D5.6.5.2.1 Register updates on exception reporting in Hyp mode

The use of the [HSR](#), and of the other registers listed in [Registers used for reporting exceptions taken to Hyp mode](#), depends on the cause of the Abort. In reporting these faults, in general:

- If the fault generates a synchronous Data Abort exception, the [HDFAR](#) holds the associated VA, but see [Fault address reporting on synchronous External aborts](#) for a permitted exception to this requirement.
- If the fault generates a Prefetch Abort exception, the [HIFAR](#) holds the associated VA, but see [Fault address reporting on synchronous External aborts](#) for a permitted exception to this requirement.
- In the following cases, the [HPFAR](#) holds the faulting IPA:
 - A Translation or Access flag fault on a stage 2 translation.
 - A Translation, Access flag, or Permission fault on the stage 2 translation of an address accessed in a stage 1 translation.
 - A stage 2 Address size fault.
 In all other cases, the [HPFAR](#) is UNKNOWN.
- On a Data Abort exception that is taken to Hyp mode, the [HIFAR](#) is UNKNOWN.
- On a Prefetch Abort exception that is taken to Hyp mode, the [HDFAR](#) is UNKNOWN.

In addition, the reporting of particular aborts is as follows:

Abort on the stage 1 translation for a memory access from Hyp mode

The [HDFAR](#) or [HIFAR](#) holds the VA that caused the fault. The STATUS subfield of [HSR](#).ISS indicates the type of fault, Translation, Address size, Access flag, or Permission. The [HPFAR](#) is UNKNOWN.

Abort on the stage 2 translation for a memory access from a PL1 or EL0 mode

This includes aborts on the stage 2 translation of a memory access made as part of a translation for a stage 1 translation. The [HDFAR](#) or [HIFAR](#) holds the VA that caused the fault. The STATUS subfield of [HSR](#).ISS indicates the type of fault, Translation, Address size, Access flag, or Permission.

For any Access flag fault or Translation fault, and also for any Permission fault on the stage 2 translation of a memory access made as part of a translation for a stage 1 translation, the [HPFAR](#) holds the IPA that caused the fault. Otherwise, the [HPFAR](#) is UNKNOWN.

Abort caused by a synchronous External abort, or synchronous parity or ECC error, and taken to Hyp mode

The [HDFAR](#) or [HIFAR](#) holds the VA that caused the fault, but see [Fault address reporting on synchronous External aborts](#) for a permitted exception to this requirement. The [HPFAR](#) is UNKNOWN.

Data Abort caused by a Watchpoint exception and routed to Hyp mode because HDCR.TDE is set to 1

When [HDCR](#).TDE is set to 1, a Watchpoint exception generated in a PL1 or EL0 mode, that would otherwise generate a Data Abort exception, is routed to Hyp mode and generates a Hyp Trap exception. [HDFAR](#) is set to the address that generated the watchpoint.

Note

[ELR_hyp](#) indicates the address of the instruction that triggered the watchpoint.

A watchpointed address can be any byte-aligned address. The address reported in [HDFAR](#) might not be the watchpointed address, and, for a watchpoint due to an operation other than a Data Cache maintenance instruction, can be any address between and including:

- The lowest address accessed by the instruction that triggered the watchpoint.
- The highest watchpointed address accessed by that instruction.

If multiple watchpoints are set in this range, there is no guarantee of which watchpoint is generated.

Note

In particular, there is no guarantee of generating the watchpoint with the lowest address in the range.

The address must also be within a naturally-aligned block of memory of an IMPLEMENTATION DEFINED power-of-two size, containing a watchpoint address accessed by that location.

See also [Watchpoint exceptions](#).

In all cases, [HPFAR](#) is UNKNOWN.

Prefetch Abort caused by a Breakpoint Instruction exception and taken to Hyp mode

This abort is generated if a BKPT instruction is executed in Hyp mode. The abort leaves the HIFAR and HPFAR UNKNOWN.

See also Breakpoint Instruction exceptions.

Prefetch Abort caused by a Breakpoint Instruction, Breakpoint, or Vector Catch exception, and routed to Hyp mode because HDCR.TDE is set to 1

When HDCR.TDE is set to 1, a debug exception, generated in a PL1 or EL0 mode, that would otherwise generate a Prefetch Abort exception, is routed to Hyp mode and generates a Hyp Trap exception.

The abort leaves the HIFAR and HPFAR UNKNOWN. This is identical to the reporting of a Prefetch Abort exception caused by a Debug exception on a BKPT instruction that is executed in Hyp mode.

Note

The difference between these two cases is:

- The Debug exception on a BKPT instruction executed in Hyp mode generates a Prefetch Abort exception, taken to Hyp mode, and reported in the HSR using EC value 0x21.
- Aborts generated because HDCR.TDE is set to 1 generate a Hyp Trap exception, and are reported in the HSR using EC value 0x20.

D5.6.5.3 Use of the HSR

I_{RY}SP

The HSR holds syndrome information for any synchronous exception taken to Hyp mode. Compared with the reporting of exceptions taken to PL1 modes, the HSR:

- Always provides details of the fault. The DFSR and IFSR are not used.
- Provides more extensive information, for a wider range of exceptions.

Note

IRQ and FIQ exceptions taken to Hyp mode do not report any syndrome information in the HSR.

I_{JX}VYP

The HSR comprises:

- A 6-bit Exception class field, EC, that indicates the cause of the exception.
- An instruction length bit, IL. When an exception is caused by trapping an instruction to Hyp mode, this bit indicates the length of the trapped instruction, as follows:
 - 0 16-bit instruction trapped.
 - 1 32-bit instruction trapped.

In other cases the IL field is not valid and is RES1.
- An instruction specific syndrome field, ISS. Architecturally, this field could be defined independently for each defined Exception class (EC), but in practice several ISS formats are common to more than one EC.

The format of the HSR depends on the value of the EC field, as follows:

$0b000000 < EC \leq 0b001100$

The ISS part of the returned value includes the CV and COND fields described in Encoding of ISS[24:20] when $0b000000 < EC \leq 0b001100$. Figure D5-4 shows the HSR format in this case.

Figure D5-4 HSR format when the ISS includes CV and COND fields

$EC = 0b000000$ or $EC = 0b001110$

There are no generic fields within the ISS. Figure D5-5 shows the HSR format in this case.

Figure D5-5 HSR format when the ISS does not include a COND field

D5.6.5.3.1 Encoding of ISS[24:20] when $0b000000 < EC \leq 0b001100$

I_{LRWPS}

For EC values that are nonzero and less than or equal to $0b001100$, ISS[24:20] provides the Condition code field for the trapped instruction, together with a valid flag for this field. The encoding of this part of the ISS field is:

CV, ISS[24] Condition code valid. Possible values of this bit are:

- 0** The COND field is not valid.
- 1** The COND field is valid.

COND, ISS[23:20]

The Condition code for the trapped instruction. This field is valid only when CV is set to 1.

If CV is set to 0, this field is RES0.

The full descriptions of the [HSR.ISS](#) formats give more information about the CV field.

———— Note ————

In some circumstances, it is IMPLEMENTATION DEFINED whether a conditional instruction that fails its Condition code check generates an Undefined Instruction exception, see [Conditional execution of undefined instructions](#).

D5.6.5.3.2 HSR exception classes

I_{YXQCP}

[Table D5-10](#) shows the encoding of the [HSR](#) exception class field, EC. Values of EC not shown in the table are reserved. For each EC value, the table references a subsection of the description of the [HSR](#) that describes the associated ISS format and gives information about the cause of the exception, for example the configuration required to enable the associated trap.

Table D5-10 HSR.EC field encoding

EC	Exception class	ISS description, or notes
0b000000	Unknown reason	ISS encoding for exceptions with an unknown reason.
0b000001	Trapped WFI or WFE instruction	ISS encoding for exception from a WFI or WFE instruction.
0b000011	Trapped MCR or MRC access with (coproc == 0b1111)	ISS encoding for exception from an MCR or MRC access.
0b000100	Trapped MCRR or MRRC access with (coproc == 0b1111)	ISS encoding for exception from an MCRR or MRRC access.
0b000101	Trapped MCR or MRC access with (coproc == 0b1110)	ISS encoding for exception from an MCR or MRC access.
0b000110	Trapped LDC or STC access	ISS encoding for exception from an LDC or STC instruction.
0b000111	Advanced SIMD or floating-point functionality trapped by a HCPTR . {TASE, TCP10} control	ISS encoding for exception from an access to SIMD or floating-point functionality, resulting from HCPTR.
0b001000	Trapped VMRS access, from ID group traps, that is not reported using EC 0b000111	ISS encoding for exception from an MCR or MRC access. This trap is not taken if the HCPTR settings trap the access.
0b001100	Trapped MRRC access with (coproc == 0b1110)	ISS encoding for exception from an MCRR or MRRC access.
0b001110	Illegal exception return to AArch32 state	ISS encoding for exception from an Illegal state or PC alignment fault.

EC	Exception class	ISS description, or notes
0b010001	Exception on SVC execution in AArch32 state routed to EL2	ISS encoding for exception from HVC or SVC instruction execution.
0b010010	HVC instruction execution in AArch32 state, when HVC is not disabled	
0b010011	Trapped execution of SMC instruction in AArch32 state	ISS encoding for exception from SMC instruction execution.
0b100000	Prefetch Abort from a lower Exception level	ISS encoding for exception from a Prefetch Abort.
0b100001	Prefetch Abort taken without a change in Exception level	
0b100010	PC alignment exception.	ISS encoding for exception from an Illegal state or PC alignment fault.
0b100100	Data Abort from a lower Exception level	ISS encoding for exception from a Data Abort.
0b100101	Data Abort taken without a change in Exception level	

All EC encodings not shown in [Table D5-9](#) are reserved by Arm.

D5.6.6 Summary of register updates on exceptions taken to Hyp mode

IC_{YMTK}

For memory system faults that generate exceptions that are taken to Hyp mode, [Table D5-11](#) shows the registers affected by each fault. In this table:

- Yes indicates that the register is updated.
- UNK indicates that the fault makes the register value UNKNOWN.
- A null entry, -, indicates that the fault does not affect the register.

Note

For a list of the [MPU faults](#), see [Types of MPU faults](#).

Table D5-11 Effect of an exception taken to Hyp mode on the reporting registers

Fault	HSR	HIFAR	HDFAR	HPFAR
Faults reported as Prefetch Abort exceptions:				
MPU fault ^a at stage 1.	Yes	Yes	UNK	UNK
Translation or Access flag MPU fault ^a at stage 2.	Yes	Yes	UNK	Yes
Other ^b MPU fault ^a at stage 2.	Yes	Yes	UNK	UNK
Stage 2 MPU fault ^a on a stage 1 translation.	Yes	Yes	UNK	Yes
Synchronous External abort on translation.	Yes	Yes	UNK	UNK
Synchronous parity or ECC error on translation.	Yes	Yes	UNK	UNK
Synchronous External abort.	Yes	IMP DEF ^c	UNK	UNK
Synchronous parity or ECC error on memory access.	Yes	Yes	UNK	UNK
Fault reported as Data Abort exception:				
MPU fault ^a at stage 1.	Yes	UNK	Yes	UNK
Translation or Access flag MPU fault ^a at stage 2.	Yes	UNK	Yes	Yes
Other ^b MPU fault ^a at stage 2.	Yes	UNK	Yes	UNK
Stage 2 MPU fault ^a on a stage 1 translation.	Yes	UNK	Yes	Yes

Fault	HSR	HIFAR	HDFAR	HPFAR
Synchronous External abort on translation.	Yes	UNK	Yes	UNK
Synchronous parity or ECC error on translation.	Yes	UNK	Yes	UNK
Synchronous External abort.	Yes	UNK	IMP DEF ^c	UNK
Synchronous parity or ECC error on memory access.	Yes	UNK	Yes	UNK
SError exception.	Yes	UNK	UNK	UNK
SError exception from a parity or ECC error on memory access.	Yes	UNK	UNK	UNK
Debug exception:				
Breakpoint Instruction ^d , generates a Prefetch Abort exception.	Yes	UNK	-	UNK
Debug exception routed to Hyp mode because HDCR.TDE is set to 1. Generates a Hyp Trap exception.				
Breakpoint Instruction or Vector Catch.	Yes	UNK	-	UNK
Watchpoint.	Yes	-	Yes	UNK

- a. For more information, see [Classification of MPU faults taken to Hyp mode](#)
b. [MPU fault](#) other than a Translation fault or an Access flag fault.
c. IMPLEMENTATION DEFINED. The FnV bit in the HSR.ISS field indicates whether the register holds a valid address. See [Fault address reporting on synchronous External aborts](#).
d. All other debug exceptions are not permitted in Hyp mode.

Note

Unlike [Table D5-8](#), the Hyp mode fault reporting table does not include an entry for a fault on an instruction cache maintenance instruction. That is because, when the fault is taken to Hyp mode, the reporting indicates the cause of the fault, for example a Translation fault, and ISS.CM is set to 1 to indicate that the fault was on a cache maintenance instruction, see [ISS encoding for exception from a Data Abort](#).

D5.6.6.1 Classification of MPU faults taken to Hyp mode

This subsection gives more information about the [MPU faults](#) shown in [Table D5-11](#).

Note

All [MPU faults](#) are synchronous.

IVBTXM

The table uses the following descriptions for [MPU faults](#) taken to Hyp mode:

MPU fault at stage 1

This is an [MPU fault](#) generated on a stage 1 translation performed in the EL2 translation regime.

MPU fault at stage 2

This is an [MPU fault](#) generated on a stage 2 translation performed in the PL1&0 translation regime.

As the table shows, for the faults in this group:

- Translation and Access flag faults update the [HPFAR](#).
- Permission faults leave the [HPFAR](#) UNKNOWN.

MPU stage 2 fault on a stage 1 translation

This is an [MPU fault](#) generated on the stage 2 translation of an address accessed in a stage 1 translation performed in the PL1&0 translation regime. For more information about these faults see [Stage 2 fault on a stage 1 translation](#).

[Figure D5-1](#) shows the different translation regimes and associated stages of translation.

D5.7 PMSAv8-32 implications for caches

RQXCyx

Enabling or reconfiguring the MPU, or reprogramming any protection regions, can result in new and different memory attributes for a previously accessed or speculatively accessed address. In this situation, the rules for [Mismatched memory attributes](#) apply.

D5.7.1 Cache line length

A PMSAv8-32 MPU permits the definition of protection regions that might be smaller than a cache line in the implementation. Therefore, the following rules apply:

- If the MPU is configured such that multiple differing attributes apply to a single cache line, then for any access to that cache line the rules for mismatched memory attributes apply. For more information, see Memory region attributes.
- Marking any part of a cache line as Write-Back permits the entire line to be treated as Write-Back.

Chapter D6

The Performance Monitors Extension

This chapter describes the implementation of the Arm Performance Monitors, which are an optional non-invasive debug component. It describes version 3 of the *Performance Monitor Unit* (PMU) architecture, [FEAT_PMUv3](#). It contains the following sections:

- [About the Performance Monitors](#)
- [Accuracy of the Performance Monitors](#)
- [Behavior on overflow](#)
- [Attributability](#)
- [Controlling the PMU counters](#)
- [Multithreaded implementations](#)
- [Event filtering](#)
- [Performance Monitors and Debug state](#)
- [Counter access](#)
- [Performance Monitors Extension registers](#)

D6.1 About the Performance Monitors

The Performance Monitors Extension is an OPTIONAL feature of an implementation, but Arm strongly recommends that implementations include version 3 of the Performance Monitors Extension, [FEAT_PMUv3](#).

Note

No previous versions of the Performance Monitors Extension can be implemented in architectures from Armv8.0.

The Performance Monitors Extension provides:

- The 64-bit cycle counter, [PMCCNTR](#). The cycle counter is always implemented.
- The event counters, [PMEVCNTR<n>](#). The number of event counters is an IMPLEMENTATION DEFINED parameter, [NUM_PMU_COUNTERS](#), between 0 and 31.
The event counters are 32 bit counters.
- Controls for:
 - Enabling counters. See [Enabling PMU counters](#).
 - Resetting counters. [Resetting counters](#).
 - Flagging overflows. See [Behavior on overflow](#).
 - Enabling interrupts on overflow. See [Generating overflow interrupt requests](#).
 - Prohibiting counting. See [Prohibiting counting](#).
 - Partitioning the implemented event counters into ranges. See [Event counter ranges](#).

The PMU architecture uses event numbers to identify an event. It:

- Defines event numbers for common events, for use across many architectures and microarchitectures. See [Common event numbers](#).

Note

Implementations that include [FEAT_PMUv3](#) must, as a minimum requirement, implement a subset of the common events. See [Common event numbers](#).

- Reserves a large event number space for IMPLEMENTATION DEFINED events. See [IMPLEMENTATION DEFINED event numbers](#).

The full set of events for an implementation is IMPLEMENTATION DEFINED. Arm recommends that implementations include all of the events that are appropriate to the architecture profile and microarchitecture of the implementation. For more information, see [PMU Event Descriptions](#).

When an implementation includes the Performance Monitors Extension, the architecture defines the following possible interfaces to the Performance Monitors Extension registers:

- A System register interface. This interface is mandatory.

Note

In AArch32 state, the interface is in the (`coproc == 0b1111`) encoding space.

- An external debug interface which optionally supports memory-mapped accesses. Implementation of this interface is OPTIONAL. See [Recommended External Interface to the Performance Monitors](#).

An operating system can use the System registers to access the counters.

Also, if required, the operating system can enable application software to access the counters. This enables an application to monitor its own performance with fine-grain control without requiring operating system support. For example, an application might implement per-function performance monitoring.

To enable interaction with external monitoring, an implementation might consider additional enhancements, such as providing:

- A set of events, from which a selection can be exported onto a bus for use as external events.
- The ability to count external events. This enhancement requires the implementation to include a set of external event input signals.

D6.1.1 Event counter ranges

I _{STBND}	If any of the following apply, then the behavior is CONSTRAINED UNPREDICTABLE: • HDCR.HPMN is 0. • HDCR.HPMN is greater-than NUM_PMU_COUNTERS. See: • The Performance Monitors Extension when accessing the Performance Monitors Extension in AArch32 state.
I _{SBQGI}	When EL2 is enabled in the current Security state, self-hosted software executing at EL1 and, if enabled by PMUSERENR, EL0 only has access through System registers to event counters in the first range, the cycle counter PMCCNTR. This software is not able to directly determine that event counters in the second range are implemented. Self-hosted software executing at EL2 additionally has access through System registers to event counters in the second range.
R _{NNBYQ}	If all of the following are true, then direct reads of PMCR.N return the Effective value of HDCR.HPMN: • PE is executing at EL0 or EL1. • The access does not generate an exception.

D6.1.2 Interaction with EL2

I _{FZHQW}	Software executing at EL2 can program HDCR.HPMN to partition the event counters into a first range and a second range. See Event counter ranges.
I _{BPVYL}	Software executing at EL2 can: • Trap an access at EL0 or EL1 to the PMU. This means the hypervisor can identify which Guest OSs are using the PMU and intelligently employ switching of the PMU state. There is a separate trap for the PMCR register. When EL2 is implemented, software executing at EL1 and, if enabled by PMUSERENR, EL0: • Will read the value of HDCR.HPMN for PMCR.N. • Cannot access the event counters in the second range, or the controls associated with them.
I _{MVYJY}	For more information, see: • Enabling PMU counters. • Counter access. • Controlling the PMU counters. • Multithreaded implementations.

D6.1.3 Interaction with trace

When [FEAT_ETMv4](#) is implemented, it is IMPLEMENTATION DEFINED whether the implementation exports PMU events to the ETM trace unit, and the form of any exporting is also IMPLEMENTATION DEFINED. If implemented, this exporting is controlled by [PMCR.X](#).

For more information about when the trace unit is permitted to observe PMU events, see Controls to prohibit trace at Exception levels and External inputs.

D6.2 Accuracy of the Performance Monitors

The Performance Monitors:

- Are a non-invasive debug component. See [Non-invasive behavior](#).
- Must provide broadly accurate and statistically useful count information.

However, the Performance Monitors allow for:

- A reasonable degree of inaccuracy in the counts to keep the implementation and validation cost low. See [A reasonable degree of inaccuracy](#).
- IMPLEMENTATION DEFINED controls, such as those in ACTLR registers, that software must configure before using certain PMU events. For example, to configure how the PE generates PMU events for components such as external caches and external memory.
- Other IMPLEMENTATION DEFINED controls, such as those in ACTLR registers, to optionally put the PE in an operating state that might do one or both of the following:
 - Change the level of non-invasiveness of the Performance Monitors so that enabling an event counter can impact the performance or behavior of the PE.
 - Allow inaccurate counts. This includes, but is not limited to, cycle counts.

D6.2.1 Non-invasive behavior

The Performance Monitors are a non-invasive debug feature. A non-invasive debug feature permits the observation of data and program flow. Performance Monitors, PC Sample-based Profiling and Trace are non-invasive debug features.

Non-invasive debug components do not guarantee that they do not make any changes to the behavior or performance of the processor. Any changes that do occur must not be severe however, as this will reduce the usefulness of event counters for performance measurement and profiling. This does not include any change to program behavior that results from the same program being instrumented to use the Performance Monitors, or from some other performance monitoring process being run concurrently with the process being profiled in a multitasking operating system. As such, a reasonable variation in performance is permissible.

Note

Power consumption is one measure of performance. Therefore, a reasonable variation in power consumption is permissible.

Arm does not define a *reasonable variation in performance*, but recommends that such a variation is kept within 5% of normal operating performance, when averaged across a suite of code that is representative of the application workload.

For some common architectural events, this requirement to be non-invasive can conflict with the requirement to present an accurate value of the count under normal operating conditions. Should an implementation require more performance-invasive techniques to accurately count an event, there are the following options:

- If the event is optional, define an alternative IMPLEMENTATION DEFINED event that accurately counts the event and document the impact on performance of enabling the event.
- Provide an IMPLEMENTATION DEFINED control that disables accurate counting of the event to restore broadly accurate performance, and document the impact on performance of accurate counting.

Note

The IMPLEMENTATION DEFINED invasiveness might include the PE disabling one or more performance optimizations such as multi-issue, out-of-order execution, and pipelining.

A software implication is that the performance invasiveness is proportional to the sampling interval. This can disproportionately affect profiling of rare events, because the population is smaller and therefore the interval will tend to be smaller.

D6.2.2 A reasonable degree of inaccuracy

The Performance Monitors provide broadly accurate and statistically useful count information. To keep the implementation, validation, and performance overhead costs low, a reasonable degree of inaccuracy in the counts and the detection of overflow is acceptable. Arm does not define a *reasonable degree of inaccuracy* but recommends the following guidelines:

- Under normal operating conditions, the counters must present an accurate value of the count.
- In exceptional circumstances, such as enabling or disabling the counter, entry to and exit from Debug state, a change in Security state, taking an exception, executing an exception return, or other boundary condition, it is acceptable for the count to be inaccurate, unless otherwise stated.
- Under very unusual, non-repeating pathological cases, the counts can be inaccurate. These cases are likely to occur as a result of asynchronous exceptions, such as interrupts, where the chance of a systematic error in the count is very unlikely.

Note

- An implementation must not introduce inaccuracies that can be triggered systematically by the execution of normal pieces of software. For example, it is not reasonable for the count of branch behavior to be inaccurate when caused by a systematic error generated by the loop structure producing a dropping in branch count. However, dropping a single branch count as the result of a rare interaction with an interrupt is acceptable.
 - To limit inaccuracy caused by entering Debug state, an implementation can, for example, promptly disable the counters during the Debug state entry sequence.
-

The architecture does not permit these behaviors for events that specifically count architectural exceptional circumstances, such as a change in Exception level, for example, [EXC_TAKEN](#).

The permitted inaccuracy limits the possible uses of the Performance Monitors. In particular, the architecture does not define the point in a pipeline where the event counter is incremented, relative to the point where a read of the event counters is made. This means that pipelining effects can cause some imprecision, and can affect which events are counted.

This applies to both architectural and microarchitectural events, and can apply differently to different events. Arm recommends that is applied consistently between counters. For example, any boundary condition effects that apply to an event counter counting the [CPU_CYCLES](#) event should apply in the same way to the cycle counter PMCCNTR_EL0. However, this is not required.

Inaccuracies around exceptional events, such as enabling or disabling the counter, should be such that the inaccuracy is reduced by lengthening the sampling period.

Where a direct write to a Performance Monitors control register disables a counter, and is followed by a [Context Synchronization event](#), any subsequent indirect read of the control register by the Performance Monitors to determine whether the counter is enabled will return the updated value. Any subsequent direct read of the counter or counter overflow status flags will return the value at the point the counter was disabled.

Note

The imprecision means that the counter might have counted an event around the time the counter was disabled, but does not allow the event to be observed as counted after the counter was disabled.

An implementation must document any particular scenarios where significant inaccuracies are expected.

D6.3 Behavior on overflow

IYVWXN	The event counters, PMEVCNTR<n> are 32-bit unsigned counters that overflow if incrementing PMEVCNTR<n> causes an unsigned overflow of an event counter, the PE sets PMOVSCLR_EL0[n] to 1. The cycle counter, PMCCNTR , is a 64-bit unsigned counter, if incrementing PMCCNTR causes an unsigned overflow of bits [31:0] of the cycle counter, the PE sets PMOVSCLR_EL0[31] to 1.
RHTPDY	The update of PMOVSCLR_EL0 occurs synchronously with the update of the counter.
IHRJFC	A PMU overflow can generate an interrupt request. For more information, see Generating overflow interrupt requests .
IPVBJQ	A PMU overflow can be used as an input trigger event to the <i>Cross Trigger Interface</i> (CTI) for the PE. For more information, see Performance Monitors overflow trigger event .

D6.3.1 Generating overflow interrupt requests

Software can program the Performance Monitors so that an overflow interrupt request is generated when a counter overflows. See [PMINTENSET](#) and [PMINTENCLR](#).

-
- Note**
- The mechanism by which an interrupt request from the Performance Monitors generates an FIQ or IRQ exception is IMPLEMENTATION DEFINED.
 - Arm recommends that the overflow interrupt requests:
 - Translate into a [PMUIRQ](#) signal, so that they are observable to external devices.
 - Connect to inputs on an IMPLEMENTATION DEFINED Generic Interrupt Controller as a *Private Peripheral Interrupt* (PPI) for the originating processor. See the *ARM Generic Interrupt Controller Architecture Specification* for information about PPIs.
 - Connect to a CTI, see [The Embedded Cross-Trigger Interface](#).
 - Arm strongly discourages implementations from connecting overflow interrupt requests from multiple PEs to the same *System Peripheral Interrupt* (SPI) identifier.
 - From GICv3, the *ARM® Generic Interrupt Controller Architecture Specification* recommends that the *Private Peripheral Interrupt* (PPI) with ID 23 is used for overflow interrupt requests.
-

Software can write to the counters to control the frequency at which interrupt requests occur. For example, software might set a 32-bit counter to `0xFFFF_0000`, to generate another counter overflow after 65 536 increments, and reset it to this value every time an overflow interrupt occurs.

-
- Note**
- If an event can occur multiple times in a single clock cycle, then counter overflow can occur without the counter registering a value of zero.
-

The overflow interrupt request is a level-sensitive request. The PE signals a request for:

- Any implemented [PMEVCNTR<n>](#) counter, when the [global enable control](#) for the event counter is 1, the value of [PMOVSSET.P<n>](#) is 1, and the value of [PMINTENSET.P<n>](#) is 1.
- The cycle counter, when the values of [PMCR.E](#), [PMOVSSET.C](#) and [PMINTENSET.C](#) are all 1.
- The instruction counter, when the values of [PMCR.E](#), [PMOVSSET_EL0.F0](#), and [PMINTENSET_EL1.F0](#), are all 1.

The overflow interrupt request is active in all Security states.

The interrupt handler for the counter overflow request must cancel the interrupt request, for example, by writing 1 to [PMOVSCLR_EL0.P<n>](#) to clear the overflow bit to 0.

D6.3.1.1 Pseudocode description of overflow interrupt requests

See [R-profile Architecture Pseudocode](#) for a pseudocode description of overflow interrupt requests. The [CheckForPMUOverflow\(\)](#) pseudocode function signal PMU overflow interrupt requests to an interrupt controller and PMU overflow trigger events to the cross-trigger interface.

D6.4 Attributability

An event caused by the PE counting the event is *Attributable*. If an agent other than the PE that is counting the events causes an event, these events are Unattributable.

An event is defined as being either Attributable or Unattributable. If the event is Attributable, it is further defined whether it is Attributable to:

- The current Exception level of the PE.
- When the PE is in Debug state, operations issued to the PE by the debugger through the external debug interface.

In a multithreaded implementation, an event might be generated by another PE with the same values for affinity level 1 and higher. This event is further defined as Attributable to:

- The current Exception level of that PE.
- When that PE is in Debug state, operations issued to that PE by the debugger through the external debug interface.

See [Multithreaded implementations](#) for information about enabling and restricting counting events in a multithreaded implementation.

Note

An implementation is described as multithreaded when the lowest level of affinity, as reported by [MPIDR](#) {Aff3, Aff2, Aff1, Aff0}, consists of logical PEs that are implemented using a multithreading type approach. In this section, when referring to a multithreaded implementation, *thread* is used to mean processing elements with:

- [MPIDR](#).MT set to 1,
 - Different values for affinity level 0.
 - The same values for affinity level 1 and higher.
-

An event can be defined as the combination of multiple subevents, which can be either Attributable or Unattributable.

All architecturally defined events are [Attributable](#), unless otherwise stated.

Unattributable events might be counted when Attributable events are not counted. For more information see, [Event filtering](#) and [Performance Monitors and Debug state](#).

D6.5 Controlling the PMU counters

This section describes the mechanisms available for controlling the PMU event and cycle counters. The following sections describe those mechanisms:

- [Enabling PMU counters.](#)
- [Prohibiting counting.](#)

D6.5.1 Enabling PMU counters

ICFQVP Counters are enabled by a combination of the *global enable control* for the counter and a counter enable control, [PMCNTENSET](#), as described in the following sections.

D6.5.1.1 Enabling the event counters

RKYBQW The global enable controls for PMU event counters are defined as follows:

- The [global enable control](#) for PMU event counters in the second range is [HDCR](#).HPME.
- The [global enable control](#) for PMU event counters in the first range is [PMCR](#).E.

ISTZYQ [PMCNTENSET](#).P<n> is the counter enable control for event counter *n*.

IVQXCB The [global enable control](#) is used, with other controls, for all of the following:

- Enabling counting of events by [PMEVCNTR](#)<n>.
- Generation of the PMU overflow interrupt request, [PMUIRQ](#), by [PMOVSLR_EL0](#)[n].
- Generation of the CTI overflow interrupt trigger by [PMOVSLR_EL0](#)[n].

The global enable control for the other range do not affect whether the event counter [PMEVCNTR](#)<n> generates any of these.

IQKDTZ The effect of [HDCR](#).{HPME, HPMN} on the counter enables applies at all Exception levels and in all Security states.

D6.5.1.2 Enabling the cycle counter

IBTGDI For the cycle counter, [PMCCNTR](#), the [global enable control](#) is [PMCR](#).E.
For the cycle counter, the counter enable control is [PMCNTENSET](#).C.
[PMCR](#).DP controls whether the cycle counter is disabled when event counting is prohibited, as described in [Prohibiting counting](#).

D6.5.2 Resetting counters

Software can reset all the event counters and/or the cycle counter in a single operation by writing 1 to [PMCR](#).C and/or [PMCR](#).P.

D6.5.3 Prohibiting counting

DJHDZC In this section:

- *Context* means the Exception level, and Debug state.
- Whether event counting for a context is allowed or prohibited by a PE counting an event is defined by the rules in this section.

[Attributability](#) defines how an event is [Attributable](#) to a context.

RQRRHL When all of the following apply:

- An event is to be counted by event counter <n>.
- The [Effective value](#) of [PMEVTYPER](#)<n>.MT is 0 and the event is [Attributable](#) to the PE counting the event.
- The PE counting the event is executing in a context **A**.
- The event is [Attributable](#) to context **B**.

Then, it is IMPLEMENTATION SPECIFIC which of context **A** or context **B** the PE counting the event uses to determine whether the event is allowed to be counted or is not counted.

Regardless of whether the event is allowed to be counted or not, if event filtering or any other controls disable counting the event, then the event is not counted.

It is IMPLEMENTATION SPECIFIC whether event filtering uses context **A** or context **B**.

R_{XBZL}

When all of the following apply:

- An event is to be counted by event counter <n>.
- The Effective value of `PMEVTYPEPER<n>.MT` is 0 and the event is [Attributable](#) to the PE counting the event.
- The PE counting the event is executing in a context **A**.
- The event is [Attributable](#) to context **B**.

Then all of the following apply:

- If both context **A** event counting and context **B** event counting are allowed by the PE counting the event, then the event is allowed to be counted.
- If context **A** event counting is prohibited by the PE counting the event and context **B** event counting is allowed by the PE counting the event, then it is IMPLEMENTATION SPECIFIC whether the event is allowed to be counted or not counted.
- If context **B** event counting is prohibited by the PE counting the event, then the event is not counted, regardless of whether context **A** event counting is allowed or prohibited by the PE counting the event.

Whether event counting for any context is prohibited by the PE the event is [Attributable](#) to has no effect on this rule.

Regardless of whether the event is allowed to be counted or not, if event filtering or any other controls disable counting the event, then the event is not counted. It is IMPLEMENTATION SPECIFIC which of context **A** or context **B** event filtering uses.

R_{RTMLK}

When all the following apply:

- An event is to be counted by event counter <n>.
- The Effective value of `PMEVTYPEPER<n>.MT` is 0 and the event is [Attributable](#) to a PE other than the PE counting the event.

Then the event is not counted. For more information, see [Multithreaded implementations](#).

I_{SLTTL}

[R_{QRRHL}](#) and [R_{XBZL}](#) allow events in a single-threaded implementation to be attributed to the current context when they are counted, rather than requiring the PE to keep track of precisely which context an event was generated in. This is acceptable because the current context changes rarely, meaning such an implementation exhibits [a reasonable degree of inaccuracy](#).

This would not be acceptable for multithreaded implementations where an event might be generated by a different PE from the PE counting the events. However, these rules permit an implementation to keep track of which PE generated the event and attribute the event to the current context of the PE counting the event. It is also not expected that the controls for prohibiting events in a given context will be set differently on different PEs in a multithreaded implementation that is making use of the PMU multithreading extensions.

R_{MMZLZ}

EL2 event counting is prohibited at EL2 unless any of the following is true:

- `FEAT_PMUV3p1` is not implemented.
- `HDCCR.HPMD` is 0.
- The event is being counted by an event counter <n> in the second range.

R_{TDGMF}

The accessibility of Performance Monitors registers is unaffected by whether event counting is enabled or prohibited.

R_{SGDTN}

The cycle counter, `PMCCNTR`, counts even when counting is prohibited, unless `PMCR.DP` is set to 1 or the PE is in Debug state.

R_{PTKLW}

Other counters can be enabled or disabled by using `PMCR.E` and `PMCNTENSET.C`.

I_{FZPQV}

The `CountPMUEvents(n)` function returns TRUE if any of the following apply:

- `PMEVCNTR<n>` counts events at the current Exception level and state.
- `n` is 31 and the cycle counter counts cycles at the current Exception level and state.
- Otherwise, the function returns FALSE.

However, this function does not completely describe the behavior for Unattributable events and events Attributable to a Security state that is not the current Security state, an Exception level that is not the current Exception level, or both. For more information, see [CountPMUEvents\(\)](#) in .

I_{BT}VLD

The Performance Monitors are intended to be broadly accurate and statistically useful, see [Accuracy of the Performance Monitors](#). Some inaccuracy is permitted at the point of changing between a state where counting is prohibited and a state where counting is allowed, however. To avoid the leaking of information, the permitted inaccuracy is that transactions that are not prohibited can be uncounted. Where possible, prohibited transactions must not be counted, but if they are counted, then that counting must not degrade security.

D6.6 Multithreaded implementations

If an implementation is multithreaded and the [Effective value](#) of `PMEVTYPER<n>.MT` is 1, then, unless otherwise stated, the counter counts the sum of all events across all PEs with the same level 1 Affinity. A pair of PEs have the same level 1 Affinity if they have the same values for all fields in `MPIDR_EL1` or `MPIDR` except the `Aff0` field.

See also [Cycle event counting in multithreaded implementations](#) for additional requirements for events that count cycles.

Events on other PEs are not counted when the [Effective value](#) of `PMEVTYPER<n>.MT` is 0.

If the CPU implements multithreading, it is IMPLEMENTATION DEFINED whether `PMEVTYPER<n>.MT` is implemented as `RW` or `RES0`.

See Time as measured by the Performance Monitors cycle counter.

D6.7 Event filtering

The PMU can filter events by various combinations of Exception level. This gives software the flexibility to count events across multiple processes.

D6.7.1 Filtering by Exception level

For an event that is [Attributable](#) to an Exception level, in a multithreaded implementation:

- When the [Effective value](#) of `PMEVTYPER<n>.MT` is 1, the specified filtering is evaluated using the current Exception level and Security state of the thread to which the event is [Attributable](#). See [Example D6-1](#).
- When the [Effective value](#) of `PMEVTYPER<n>.MT` is 0, the event is only counted if it is [Attributable](#) to the counting thread, and the filtering is evaluated using the Exception level and Security state of the counting thread.

Example D6-1

Example of the effect of the `PMEVTYPER<n>_EL0.MT` control

In a multithreaded implementation, if the [Effective value](#) of `PMEVTYPER<n>.MT` is 1 and the value of `PMEVTYPER<n>.U` is 1 on the counting thread, then event counter *n* does not count events [Attributable](#) to EL0 on another thread, even if the counting thread is not executing at EL0.

For each Unattributable event, it is IMPLEMENTATION DEFINED whether the filtering applies. In a multithreaded implementation, if the filtering applies to an Unattributable event, then the filtering is evaluated using the Exception level and Security state of the counting thread.

In AArch32 state, the filtering controls are provided by the `PMEVTYPER<n>` and `PMCCFILTR` registers.

For more information, see the individual register descriptions and [Multithreaded implementations](#).

D6.7.2 Accuracy of event filtering

For most events, it is acceptable that, during a transition between states, events generated by instructions executed in one state are counted in the other state. The following sections describe the cases where event counts must not be counted in the wrong state:

- [Exception-related events](#).
- [Software increment events](#).

D6.7.2.1 Exception-related events

The PMU must filter events related to exceptions and exception handling according to the Exception level in which the event occurred. These events are:

- `EXC_TAKEN`, Exception taken.
- `EXC_RETURN`, Instruction architecturally executed, Condition code check pass, exception return.
- `CID_WRITE_RETIRED`, Instruction architecturally executed, Condition code check pass, write to `CONTEXTIDR`.
- `TTBR_WRITE_RETIRED`, Instruction architecturally executed, Condition code check pass, write to translation table base.
- `EXC_UNDEF`, Exception taken, other synchronous.
- `EXC_SVC`, Exception taken, Supervisor Call.
- `EXC_PABORT`, Exception taken, Instruction Abort.
- `EXC_DABORT`, Exception taken, Data Abort or SError.
- `EXC_IRQ`, Exception taken, IRQ.
- `EXC_FIQ`, Exception taken, FIQ.
- `EXC_SMC`, Exception taken, Secure Monitor Call.

- [EXC_HVC](#), Exception taken, Hypervisor Call.
- [EXC_TRAP_PABORT](#), Exception taken, Instruction Abort not [Taken locally](#).
- [EXC_TRAP_DABORT](#), Exception taken, Data Abort or SError not [Taken locally](#).
- [EXC_TRAP_OTHER](#), Exception taken, other traps not [Taken locally](#).
- [EXC_TRAP_IRQ](#), Exception taken, IRQ not [Taken locally](#).

The PMU must not count an exception after it has been taken because this could systematically report a result of zero exceptions at EL0. Similarly, it is not acceptable for the PMU to count exception returns or writes to [CONTEXTIDR](#) after the return from the exception.

D6.7.2.2 Software increment events

The PMU must filter software increment events according to the Exception level in which the software increment occurred. Software increment counting must also be precise, meaning the PMU must count every architecturally executed software increment event, and must not count any [Speculatively executed](#) software increment.

If the PE performs two architecturally executed writes to the PMSWINC_EL0 or [PMSWINC](#) register without an intervening [Context Synchronization event](#), then the counter is incremented twice.

For more information, see [SW_INCR](#).

D6.7.3 Pseudocode description of event filtering

See [CountPMUEvents\(\)](#) in [R-profile Architecture Pseudocode](#) for a pseudocode description of event filtering. However, this function does not completely describe the behavior for Unattributable events.

D6.8 Performance Monitors and Debug state

Events that count cycles are not counted in Debug state.

Events [Attributable](#) to the operations issued by the debugger through the external debug interface are not counted in Debug state.

In an implementation that supports multithreading, when the [Effective value](#) of PMEVTYPER<n>_EL0.MT is 1, if an event is Attributable to an operation issued by the debugger through the external debug interface to another thread that is in Debug state, then the event is not counted, and it is IMPLEMENTATION DEFINED whether the event is counted when the counting thread is in Debug state.

For all other events, it is IMPLEMENTATION SPECIFIC whether it is counted when the counting PE is in Debug state. If the event might be counted, then the rules in [Filtering by Exception level](#) apply for the current Security state in Debug state.

D6.9 Counter access

- I_{VYCGK}** All implemented event counters are accessible in EL2. If EL2 is implemented the hypervisor uses [HDCR.HPMN](#) to reserve an event counter, with the effect that if EL2 is enabled in the current Security state, software cannot access that counter and its associated state from EL0 or EL1.
- I_{SDHCP}** Whether software can access an event counter at an Exception level does not affect whether the counter counts events at that Exception level. For more information, see [Controlling the PMU counters](#) and [Enabling PMU counters](#).

D6.9.1 PMEVCNTR<n> event counters

- D_{YBKKV}** [Table D6-1](#) shows how the [counter range](#) affects the behavior of permitted accesses to the event counter registers.

Table D6-1 Result of event counter System register access

Counter range	Access at Exception level		
	EL2	EL1	EL0
First range	Succeeds	Succeeds	Succeeds
Second range	Succeeds	No access	No access
Counter not implemented	No access	No access	No access

- I_{MWZHC}** Where [Table D6-1](#) shows access succeeds for an event counter *n*, the access might be UNDEFINED or generate a trap exception. See the descriptions of [PMEVCNTR<n>](#) and [PMXEVCNTR](#) for details.
- I_{DXWRB}** Where [Table D6-1](#) shows no access for an event counter *n*, all of the following apply:
- When [PMSELR.SEL](#) is *n*, the PE prevents direct reads and direct writes of [PMXEVTYPER](#) or [PMXEVCNTR](#).
 - The PE prevents direct reads and direct writes of [PMEVTYPER<n>](#) and [PMEVCNTR<n>](#).
 - Direct reads and direct writes of the following register bits are RAZ/WI:
 - [PMOVSLR_EL0\[n\]](#).
 - [PMOVSSET\[n\]](#).
 - [PMCNTENSET\[n\]](#).
 - [PMCNTENCLR\[n\]](#).
 - [PMINTENSET\[n\]](#).
 - [PMINTENCLR\[n\]](#).
 - [PMOVSLR_EL0\[n\]](#).
 - [PMOVSSET\[n\]](#).
 - [PMCNTENSET\[n\]](#).
 - [PMCNTENCLR\[n\]](#).
 - Direct writes to [PMSWINC\[n\]](#) are ignored.
 - A direct write of 1 to [PMCR.P](#) does not reset [PMEVCNTR<n>](#).

D6.9.2 Cycle and instruction counters

The PMU does not provide any control that a hypervisor can use to reserve the cycle counter for its own use. However, access to the PMU registers are subject to the access permissions described in Configurable instruction controls.

D6.9.3 EL0 access controls

- I_{HNKZY}** [PMUSERENR](#) controls EL0 access to the Performance Monitors.

D6.10 Performance Monitors Extension registers

Further information on the Performance Monitors Extension Registers can be found in the following sections:

- [Performance monitors System registers](#) summarizes the Performance Monitors Extension System registers in AArch32 state.
- [Memory-mapped Performance monitors registers](#) summarizes the memory-mapped Performance Monitors Extension registers.

Chapter D7

PMU Event Descriptions

This chapter describes the PMU events that can be counted, their associated event numbers, and the mnemonics for the events. It contains the following sections:

- [Definitions](#)
- [The PMU event number space and common events](#)
- [Common event numbers](#)
- [Cycle event counting](#)
- [Meaningful combinations of common events](#)
- [Required events](#)
- [IMPLEMENTATION DEFINED event numbers](#)

D7.1 Definitions

The following subsections give more information about terms used in the event definitions:

- [Definition of terms.](#)
- [Levels of caches.](#)
- [Counting events from shared components.](#)
- [Counting exceptions taken locally or not taken locally.](#)

D7.1.1 Definition of terms

This section describes terms used by PMU events as they relate to the implementation of the PMU. For more definitions, see [Glossary](#).

Architectural event

An architectural event is an event which gives the same result for the same program on any implementation of the Arm architecture, subject to the program having the same inputs, including asynchronous events triggered by the system, any IMPLEMENTATION DEFINED or UNPREDICTABLE variation permitted by the event definition, and the reasonable degree of inaccuracy described in [A reasonable degree of inaccuracy](#). `INST_RETIRED` is an example of an architectural event.

An architectural event should not be confused with an event defined by the architecture, which is referred to as a Common event.

Note: Do not confuse Architectural events and Common events. An Architectural event can be either Common or IMPLEMENTATION DEFINED. See also Common event and IMPLEMENTATION DEFINED event.

At-retirement event

An at-retirement event is generated by an [Architecturally executed](#) instruction that does not generate an exception, unless specified otherwise. This includes SVC, HVC, and SMC exceptions.

For cache and TLB events:

- The event counts each architecturally-executed instruction that generates the event.
- The event is only counted once, by the first instruction that causes it. This might not be the first instruction in program order.

Note

Consider two loads that execute out of order that access the same cache line granule which is not in the cache. The second instruction in program order causes the miss, and the first instruction fetches data from the same cache miss result. Only the second instruction counts the cache miss event. Also, the second instruction might be speculative and the first instruction retired, meaning the cache miss is not counted at all.

- The population counts for the events are the architecturally-executed instruction counts.

Common event

An event that is defined by the Performance Monitors Extension. For more information, see Common event numbers.

Note: Do not confuse Common events and Architectural events. A Common event can be either Architectural or Microarchitectural. See also Architectural event and Microarchitectural event.

CSIZE

Container size, in bits, that corresponds to the largest non-overlapping Advanced SIMD vector element size or scalar register size that is encoded in the instruction opcode.

Event in progress

Some events count when another event or condition is *in progress*. This might mean that the event counts the occupancy of a queue or other microarchitectural structure tracking the event. It is usually IMPLEMENTATION DEFINED when an event is in progress.

For example, the [MEM_ACCESS_RD_PERCYC](#) event counts when the [MEM_ACCESS_RD](#) event is in progress, meaning on each [Processor cycle](#), the counter increments by the number of Memory-read operations that are in progress.

These events can be used to calculate the average number of events in progress. In the case of the [MEM_ACCESS_RD_PERCYC](#) event, this is also the average read latency. However, the definition of *in progress* might not include all parts of the operation.

Example D7-1

Stages of an operation not included in the definition of event in progress

In an example implementation, a Memory-read operation generated by a load instruction occupies three pipeline stages in the PE before generating a [MEM_ACCESS_RD](#) event when the PE starts to access memory. The event is then considered to be *in progress* until the data is returned to the PE. In the case of a Normal Cacheable access, the PE first looks in the Level 1 data cache, and if the address is cached, returns data in two cycles. Once the data is returned, it is another cycle before the result can be forwarded to any other instruction.

In this example, if all loads hit in the Level 1 cache, the average read latency calculated using the [MEM_ACCESS_RD_PERCYC](#) and [MEM_ACCESS_RD](#) events might be two cycles. Although this value is correct for the IMPLEMENTATION SPECIFIC definition of this event, it has to be adjusted by a constant four additional cycles to match the more commonly understood definition of Level 1 cache access latency, which for this example would be quoted as six cycles.

Instruction architecturally executed

An instruction that is part of the [Execution stream](#). See also [Architecturally executed](#).

A [reasonable degree of inaccuracy](#) allows for counts to be inaccurate in exceptional circumstances. For an event that counts instructions architecturally executed, this allows an implementation to count instructions that do not form part of the Execution stream because of an exceptional event, such as if the instruction generates a synchronous exception or entry to Debug state.

Instructions that have no visible effect on the architectural state of the PE are architecturally executed and counted even if they form part of the [Execution stream](#).

Examples of instructions that have no visible effect are:

- A NOP.
- A conditional instruction that fails its Condition code check.
- A Compare and Branch on Zero, CBZ, instruction that does not branch.
- A Compare and Branch on Nonzero, CBNZ, instruction that does not branch.

However, for events that count only the execution of instructions that update System registers, such as [CID_WRITE_RETIRED](#), if such an instruction is executed twice without an intervening [Context Synchronization event](#), it is constrained unpredictable whether the first instruction is counted.

If FEAT_PMUv3p9 is implemented, then architecturally-executed MOVPRFX instructions are counted.

Otherwise, it is IMPLEMENTATION DEFINED whether architecturally-executed MOVPRFX instructions are counted. This can vary dynamically between MOVPRFX instructions and for each execution of the same MOVPRFX instruction.

Instruction architecturally executed, Condition code check pass

Instruction architecturally executed, Condition code check pass is a class of events that explicitly do not occur for:

- A conditional instruction that fails its Condition code check.
- A Compare and Branch on Zero, CBZ, instruction that does not branch.
- A Compare and Branch on Nonzero, CBNZ, instruction that does not branch.
- A Test and Branch on Zero, TBZ, instruction that does not branch.
- A Test and Branch on Nonzero, TBNZ, instruction that does not branch.

- A Store-Exclusive instruction that does not write to memory.

Otherwise, the definition of architecturally executed is the same as for [Instruction architecturally executed](#).

A branch that is architecturally executed, with condition code check pass is also described as a branch taken.

Instruction memory access

A PE acquires instructions for execution through instruction fetches. Instruction fetches might be due to:

- Fetching instructions that are architecturally executed.
- The result of the execution of an instruction prefetch instruction, `PLI`.
- Speculation that a particular instruction might be executed in the future.

The relationship between the fetch of an individual instruction and an instruction memory access is `IMPLEMENTATION DEFINED`. For example, an implementation might fetch many instructions including a non-integer number of instructions in a single instruction memory access.

IMPLEMENTATION DEFINED event

An event that is defined by the implementation. For more information, see `IMPLEMENTATION DEFINED` event numbers.

Note: Do not confuse `IMPLEMENTATION DEFINED` events and Microarchitectural events. An `IMPLEMENTATION DEFINED` event can be either Architectural or Microarchitectural. See also Architectural event and Microarchitectural event.

Memory-write operations

Memory-write operations might be due to:

- The result of an architecturally executed [Memory-writing instructions](#).
- The result of a [Speculatively executed Memory-writing instructions](#).
- A hardware update of a translation table entry.

Note

[Speculatively executed](#) Memory-writing instructions that do not become architecturally executed must not alter the architecturally defined view of memory. They can, however, generate a Memory-write operation that is later undone in some `IMPLEMENTATION SPECIFIC` way.

For levels of cache hierarchy beyond the Level 1 caches, Memory-write operations also include accesses made as part of a write-back from another cache closer to the PE. Such write-backs might be due to:

- Evicting a dirty line from the cache, to allocate a cache line for a cache refill, see Memory-read operations.
- The execution of a cache maintenance instruction.

Note

A cache maintenance instruction is not in itself an access to that cache. However, it might generate write-backs which are then treated as Memory-write operations beyond that cache.

- The result of a coherency request from another PE.

This list is not exhaustive.

`DC ZVA` is counted as a Memory-write operation.

The relationship between Memory-writing instructions and Memory-write operations is `IMPLEMENTATION DEFINED`. For example, for some implementations an `STP` instruction that writes two 64-bit registers might generate one Memory-write operation if the address is quadword-aligned, but for other addresses it generates two or more Memory-write operations. In some implementations, the result of two `STR` instructions that write to adjacent memory might be merged into a single Memory-write operation.

Note

The data written back from a cache that is shared with other PEs might not be data that was written by the PE that performs the operation that leads to the write-back. Nevertheless, the event is counted as a write-back event for that PE.

Memory-writing instructions

Are instructions with explicit Memory write effects. Stores and atomic instructions are counted as Memory-writing instructions.

Unless otherwise specified, this includes instructions that can have a Memory write effect, even if the instruction does not actually write to memory for some other reason. For example, a CAS or Store-exclusive that does not update memory, or a store that generates an MPU fault.

DC ZVA is counted as Memory-writing instructions.

Microarchitectural event

A microarchitectural event is any event which is not architectural. That is, it will give different results for the same program on two different implementations of the Arm architecture, due to microarchitectural differences in the implementations. [L1D_CACHE_REFILL](#) is an example of a microarchitectural event.

A microarchitectural event should not be confused with an event defined by the implementation, which is referred to as an IMPLEMENTATION DEFINED event.

Note: Do not confuse Microarchitectural events and IMPLEMENTATION DEFINED events. A Microarchitectural event can be either Common or IMPLEMENTATION DEFINED. See also Common event and IMPLEMENTATION DEFINED event.

MSIZE

Memory element access size, in bits, that corresponds to a load or store instruction mnemonic suffix, where B=8, H=16, W=32 and D=64. When an instruction mnemonic does not end with B, H, W or D, the memory access size is implied by the scalar transfer register size or SIMD transfer register element size.

Operation

An event that counts operations counts an IMPLEMENTATION DEFINED choice between:

- Architectural instructions.
- IMPLEMENTATION SPECIFIC microarchitectural operations (micro-ops).

An architectural instruction might create one or more microarchitectural operations (micro-ops) at any point in the execution pipeline. Depending on the event definition, the micro-ops might be counted instead of instructions. The definition of a micro-op is IMPLEMENTATION SPECIFIC. An architecture instruction might create more than one micro-op for each instruction. A micro-op might also be removed or merged with another micro-op in the execution stream, so an architecture instruction might create no micro-ops for an instruction. Any arbitrary translation of instructions to an equivalent sequence of micro-ops is permitted.

Microarchitectural operations might have different characteristics from the architectural instructions they are created from. For events defined with reference to a particular instruction or type of instruction, the PE counts events appropriate to the micro-op.

This means the relationship between a micro-op and an architecturally executed instruction is IMPLEMENTATION DEFINED, and an architecture instruction of one type might be counted as one or more micro-ops of a different type.

However, in order for the profile information to be meaningful to the user of the counter information, Arm recommends that the micro-op is counted as a type appropriate to the instruction when this is appropriate and feasible.

Example D7-2 Counting micro-ops

If an architectural load instruction is split into an address generation micro-op and a load micro-op, and the PMU counts micro-ops, then when counting the operations:

- The instruction is counted as two operations.
- The address generation micro-op is counted as a data-processing operation.
- The load micro-op is counted as a Memory-reading operation.

Example D7-3 Counting SIMD micro-ops

If the PMU counts micro-ops as operations, then a micro-op generated by an SIMD SVE instruction might be counted as an Advanced SIMD operation when all of the following are true:

- The effective vector length for the micro-op is 128 bits.
- The operation is not predicated, and does not have a predicate register as an input or output.
- The operation has an equivalent Advanced SIMD operation.

Operation speculatively executed

An [Operation](#) that is [Speculatively executed](#).

There is no architecturally guaranteed relationship between a [Speculatively executed](#) micro-op and an architecturally executed instruction.

The results of such an operation can also be discarded, if it transpires that the operation was not required, such as following a mispredicted branch. Therefore, the architecture defines these events as *operations speculatively executed*, where appropriate.

Many PMU events count operations that are speculatively executed. This means that the PMU can observe and record the behavior of operations executed under the effects of speculation.

For example:

- An address that is not permitted to be used by the operation might be inferred by whether it is present in a cache.
- A condition code that is not permitted to be used by the operation can be inferred by whether a branch was taken or not taken.

Note

In some events, operation has a more specific meaning described in the event.

Processor cycle

For a non-multithreaded implementation, this means a cycle of the processor. For a multithreaded implementation, processor cycle means each cycle of the multithreaded processor, not just those cycles for which the PE counting the event is active.

Slot

An implementation of a PE might be able to execute multiple micro-ops in a single processor cycle. The maximum number of micro-ops that can be executed might vary at different points in the execution pipeline.

To allow profiling of the utilization of the resource of the PE, an IMPLEMENTATION SPECIFIC point in the execution pipeline is chosen where the maximum number of micro-ops that can be executed is an IMPLEMENTATION DEFINED fixed value.

Each possible micro-op that can be executed at that point in a cycle is called a Slot. The maximum number of micro-ops that can be executed is defined by PMMIR.SLOTS.

Software change of the PC

All of the following are treated as a software change of the PC:

- Branch instructions.
- Memory-reading instructions that explicitly write to the PC.
- Data-processing instructions that explicitly write to the PC.
- Exception return instructions.

It is IMPLEMENTATION DEFINED whether any or all of the following are treated as software changes of the PC:

- BRK and BKPT instructions.
- An exception generated because an instruction is UNDEFINED.
- The exception-generating instructions, SVC.
- Context synchronization barrier ISB instructions.

Speculatively executed

An instruction or operation that is counted by an event when it might be [Speculative](#).

An operation or instruction might be [Speculative](#), meaning it will be discarded if the operation was incorrectly speculatively executed. For example, following a mispredicted branch. Otherwise, a [Speculative](#) operation or instruction is later retired and becomes [Architecturally executed](#).

The architecture does not define the point in a pipeline where an event is counted. For some events, the event can be counted before the operation or instruction that caused the event is retired. In some cases, this means events might be counted for [Speculative](#) operations or instructions which are later discarded. In other cases, the [Speculative](#) operation or instruction might be discarded before the event is counted, meaning such operations or events are not counted.

Different groups of events might be counted at different points in the pipeline and so can have different IMPLEMENTATION DEFINED definitions of speculatively executed. Such groups share a common base type, which the event name denotes. Each of the events in the previous example is of the base type, operation speculatively executed.

For groups of events with a common base type, speculatively executed operations are all counted on the same basis, which normally means at the same point in the pipeline. It is possible to compare the counts and make meaningful observations about the program being profiled.

Taken locally

Taken locally is a qualifier that determines which instances of an exception are counted by particular PMU events. See [Counting exceptions taken locally or not taken locally](#).

In this context, an exception that is *Taken locally* means an exception that is one of:

- Taken to the current Exception level.

Note

This is not possible when the current Exception level is EL0.

- Taken from EL0 to EL1.
- Taken from EL0 to EL2 because the [Effective value](#) of HCR.TGE is 1.

D7.1.2 Levels of caches

The mapping of levels of cache and TLB to the PMU events is IMPLEMENTATION DEFINED. Although [CLIDR](#) defines the implemented levels of cache, these are not required to correspond with the levels of cache defined for PMU events. The architecture does not provide any way of determining implemented levels of TLB. Also, many implementations include structures that provide some caching at a higher level than the level 1 caches or TLBs. Typically, these structures, that might be called Level 0 caches, or mini caches, or microcaches, are invisible to software. The IMPLEMENTATION SPECIFIC nature of cache and TLB implementations mean that, in general, PMU event counts cannot be used reliably to make direct comparisons between different implementations, and Arm recommends the following implementation guidelines:

- If L3D_CACHE events are implemented, then L2D_CACHE and if applicable L2I_CACHE events should be implemented.
- If L2D_CACHE events are implemented, then L1D_CACHE and if applicable L1I_CACHE events should be implemented.
- If L2I_CACHE events are implemented, then L1I_CACHE events should be implemented.
- Where the Last Level of cache is also the Level 3 or Level 2 unified cache, the LL_CACHE events should be implemented in preference to the L3D_CACHE or L2D_CACHE events as applicable.
- For the Level <n> cache, where <n> = 1 or <n> = 2:
 - If the Level <n> cache is unified, but the cache can disambiguate between Data and Instruction accesses to the cache, then both the L<n>D_CACHE and L<n>I_CACHE events should be implemented.
 - If the cache is unified and the cache cannot disambiguate between Data and Instruction accesses, then only the L<n>D_CACHE should be implemented, counting all accesses.

This final property is IMPLEMENTATION DEFINED.

N1_*, N2_*, N3_*, and N4_* events are defined for identifying the *non-uniform memory access* (NUMA) distance for data returned directly from caches and memory, with support for:

- Up to four NUMA distance levels.
- Up to three cache types at each level.
- Up to three memory types at each level.
- Cache snoop responses at each level.

The NUMA distance indicates the relative distance that the return data has traveled. The NUMA distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have different levels of hierarchy. The interpretation of NUMA distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system.

The mapping of NUMA distance values to LOCAL and REMOTE events is IMPLEMENTATION DEFINED.

The definition of memory types in the system is IMPLEMENTATION DEFINED, but must be broadly similar for all devices in the system.

D7.1.3 Counting events from shared components

There is no architectural concept of a *shared* component. However, when a cache, a bus, or any other system component that might generate countable events is implemented, and:

- The extent of the first-order effects due to an event from that component are only applicable to a single PE, then the event is not shared.
- Otherwise, the event is shared.

Second-order effects are not considered when determining if an event is shared.

If the cache is shared and the Effective value of `PMEVTYPER<n>.MT` for the counter is `0b0`, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the cache is shared by PEs other than the PEs in the multithreaded processor and the Effective value of `PMEVTYPER<n>.MT` for the counter is `0b1`, the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted and might depend on the Effective value of `PMEVTYPER<n>.MT`.

Example D7-4 First and second order effects of a cache miss in a multiple-PE implementation

In an implementation that consists of two PEs, each with its own L1 cache, a cache miss by one of the PEs is a first-order effect of an access to its cache. Any snoop that is performed on the L1 cache of the other PE in the implementation as a result of that cache miss is a second order effect.

Note

Shared events are inherently linked to microarchitectures and so the implementer must make an informed decision about how such events are implemented.

D7.1.4 Counting exceptions taken locally or not taken locally

Table D7-1 shows the events for exceptions taken to an Exception level using AArch32.

Table D7-1 Events for exceptions taken to an Exception level using AArch32

HSR.EC	Description	Event number and classification for exceptions	
		Taken locally	Not Taken locally
0x00	Unknown or uncategorized	0x0081, EXC_UNDEF	0x008D, EXC_TRAP_OTHER
0x01	WF* traps	0x0081, EXC_UNDEF	0x008D, EXC_TRAP_OTHER
0x03	AArch32 MCR/MRC traps on (coproc == 0b1111) accesses	0x0081, EXC_UNDEF	0x008D, EXC_TRAP_OTHER
0x04	AArch32 MCRR/MRRC traps on (coproc == 0b1111) accesses	0x0081, EXC_UNDEF	0x008D, EXC_TRAP_OTHER
0x05	AArch32 MCR/MRC traps on (coproc == 0b1110) accesses	0x0081, EXC_UNDEF	0x008D, EXC_TRAP_OTHER
0x06	AArch32 LDC/STC traps on (coproc == 0b1110) accesses	0x0081, EXC_UNDEF	0x008D, EXC_TRAP_OTHER
0x07	Advanced SIMD or FP traps	0x0081, EXC_UNDEF	0x008D, EXC_TRAP_OTHER
0x08	AArch32 MVFR* and FPSID traps	-	0x008D, EXC_TRAP_OTHER
0x0C	AArch32 MCRR/MRRC traps on (coproc == 0b1110) accesses	0x0081, EXC_UNDEF	0x008D, EXC_TRAP_OTHER
0x0E	Illegal instruction set state	0x0081, EXC_UNDEF	0x008D, EXC_TRAP_OTHER
0x11	AArch32 SVC	0x0082, EXC_SVC	0x008D, EXC_TRAP_OTHER
0x12	AArch32 HVC that is not disabled	-	0x008A, EXC_HVC
0x13	AArch32 SMC that is not disabled to EL2	-	0x008D, EXC_TRAP_OTHER
0x20	Instruction Abort from below	0x0083, EXC_PABORT	0x008B, EXC_TRAP_PABORT
0x21	Instruction Abort from current Exception level	0x0083, EXC_PABORT	-
0x22	PC alignment	0x0083, EXC_PABORT	0x008B, EXC_TRAP_PABORT
0x24	Data Abort from below	0x0084, EXC_DABORT	0x008C, EXC_TRAP_DABORT
0x25	Data Abort from current Exception level	0x0084, EXC_DABORT	-
0x28	AArch32 FP exception	0x0081, EXC_UNDEF	0x008D, EXC_TRAP_OTHER
0x30	Breakpoint from below	0x0083, EXC_PABORT	0x008B, EXC_TRAP_PABORT
0x31	Breakpoint from current Exception level	0x0083, EXC_PABORT	-

HSR.EC	Description	Event number and classification for exceptions	
		Taken locally	Not Taken locally
0x34	Watchpoint from below	0x0084, EXC_DABORT	0x008C, EXC_TRAP_DABORT
0x35	Watchpoint from current Exception level	0x0084, EXC_DABORT	-
0x38	AArch32 BKPT instruction	0x0083, EXC_PABORT	0x008B, EXC_TRAP_PABORT
0x3A	AArch32 Vector Catch debug event	0x0083, EXC_PABORT	0x008B, EXC_TRAP_PABORT
-	IRQ interrupt	0x0086, EXC_IRQ	0x008E, EXC_TRAP_FIQ
-	FIQ interrupt	0x0087, EXC_FIQ	0x008F, EXC_TRAP_FIQ
All other values	All other exceptions	0x0081, EXC_UNDEF	0x008D, EXC_TRAP_OTHER

Note

The [Glossary](#) defines the term [Taken locally](#), that is used in event definitions in [Common microarchitectural events](#). See also Exception levels for more information.

D7.2 The PMU event number space and common events

The event number space is 10 bits. For more information about the entries in the [Allocation](#) column see the text that follows this table:

Table D7-2 Allocation of the PMU event number space

Event numbers	Allocation
0x0000 - 0x003F	Common architectural and microarchitectural events.
0x0040 - 0x00BF	Arm-recommended common architectural and microarchitectural events
0x00C0 - 0x03FF	IMPLEMENTATION DEFINED events.

See PMEVTYPEPER<n>.evtCount for details of the PE behavior when an event number for a reserved or unimplemented PMU event is written to evtCount.

[Table D7-3](#) lists the number, mnemonic, and description of PMU events.

Table D7-3 Event index

Number	Mnemonic	Description
0x0000	SW_INCR	Instruction architecturally executed, Condition code check pass, software increment.
0x0001	L1I_CACHE_REFILL	Level 1 instruction cache refill.
0x0002	L1I_TLB_REFILL	Level 1 instruction TLB refill.
0x0003	L1D_CACHE_REFILL	Level 1 data cache refill.
0x0004	L1D_CACHE	Level 1 data cache access.
0x0005	L1D_TLB_REFILL	Level 1 data TLB refill.
0x0006	LD_RETIRED	Instruction architecturally executed, Condition code check pass, load.
0x0007	ST_RETIRED	Instruction architecturally executed, Condition code check pass, store.
0x0008	INST_RETIRED	Instruction architecturally executed.
0x0009	EXC_TAKEN	Exception taken.
0x000A	EXC_RETURN	Instruction architecturally executed, Condition code check pass, exception return.
0x000B	CID_WRITE_RETIRED	Instruction architecturally executed, Condition code check pass, write to CONTEXTIDR.
0x000C	PC_WRITE_RETIRED	Instruction architecturally executed, Condition code check pass, Software change of the PC.
0x000D	BR_IMMED_RETIRED	Branch instruction architecturally executed, immediate.

Number	Mnemonic	Description
0x000E	BR_RETURN_RETIRED	Branch instruction architecturally executed, procedure return, taken.
0x000F	UNALIGNED_LDST_RETIRED	Instruction architecturally executed, Condition code check pass, unaligned load or store.
0x0010	BR_MIS_PRED	Branch instruction speculatively executed, mispredicted or not predicted.
0x0011	CPU_CYCLES	Cycle.
0x0012	BR_PRED	Predictable branch instruction speculatively executed.
0x0013	MEM_ACCESS	Data memory access.
0x0014	L1I_CACHE	Level 1 instruction cache access.
0x0015	L1D_CACHE_WB	Level 1 data cache write-back.
0x0016	L2D_CACHE	Level 2 data cache access.
0x0017	L2D_CACHE_REFILL	Level 2 data cache refill.
0x0018	L2D_CACHE_WB	Level 2 data cache write-back.
0x0019	BUS_ACCESS	Bus access.
0x001A	MEMORY_ERROR	Local memory error.
0x001B	INST_SPEC	Operation speculatively executed.
0x001C	TTBR_WRITE_RETIRED	Instruction architecturally executed, Condition code check pass, write to TTBR.
0x001D	BUS_CYCLES	Bus cycle.
0x001E	CHAIN	Chain a pair of event counters.
0x001F	L1D_CACHE_ALLOCATE	Level 1 data cache allocation without refill.
0x0020	L2D_CACHE_ALLOCATE	Level 2 data cache allocation without refill.
0x0021	BR_RETIRED	Instruction architecturally executed, branch.
0x0022	BR_MIS_PRED_RETIRED	Branch instruction architecturally executed, mispredicted.
0x0023	STALL_FRONTEND	No operation sent for execution due to the frontend.
0x0024	STALL_BACKEND	No operation sent for execution due to the backend.
0x0025	L1D_TLB	Level 1 data TLB access.
0x0026	L1I_TLB	Level 1 instruction TLB access.
0x0027	L2I_CACHE	Level 2 instruction cache access.
0x0028	L2I_CACHE_REFILL	Level 2 instruction cache refill.
0x0029	L3D_CACHE_ALLOCATE	Level 3 data cache allocation without refill.
0x002A	L3D_CACHE_REFILL	Level 3 data cache refill.
0x002B	L3D_CACHE	Level 3 data cache access.

Number	Mnemonic	Description
0x002C	L3D_CACHE_WB	Level 3 data cache write-back.
0x002D	L2D_TLB_REFILL	Level 2 data TLB refill.
0x002E	L2I_TLB_REFILL	Level 2 instruction TLB refill.
0x002F	L2D_TLB	Level 2 data TLB access.
0x0030	L2I_TLB	Level 2 instruction TLB access.
0x0031	REMOTE_ACCESS	Access to a remote device.
0x0032	LL_CACHE	Last level cache access.
0x0033	LL_CACHE_MISS	Last level cache miss.
0x0034	DTLB_WALK	Data TLB access with at least one translation table walk.
0x0035	ITLB_WALK	Instruction TLB access with at least one translation table walk.
0x0036	LL_CACHE_RD	Last level cache access, read.
0x0037	LL_CACHE_MISS_RD	Last level cache miss, read.
0x0038	REMOTE_ACCESS_RD	Access to a remote device, read.
0x0039	L1D_CACHE_LMISS_RD	Level 1 data cache long-latency read miss.
0x003A	OP_RETIRED	Micro-operation architecturally executed.
0x003B	OP_SPEC	Micro-operation speculatively executed.
0x003C	STALL	No operation sent for execution.
0x003D	STALL_SLOT_BACKEND	No operation sent for execution on a Slot due to the backend.
0x003E	STALL_SLOT_FRONTEND	No operation sent for execution on a Slot due to the frontend.
0x003F	STALL_SLOT	No operation sent for execution on a Slot.
0x0040	L1D_CACHE_RD	Level 1 data cache access, read.
0x0041	L1D_CACHE_WR	Level 1 data cache access, write.
0x0042	L1D_CACHE_REFILL_RD	Level 1 data cache refill, read.
0x0043	L1D_CACHE_REFILL_WR	Level 1 data cache refill, write.
0x0044	L1D_CACHE_REFILL_INNER	Level 1 data cache refill, inner.
0x0045	L1D_CACHE_REFILL_OUTER	Level 1 data cache refill, outer.
0x0046	L1D_CACHE_WB_VICTIM	Level 1 data cache write-back, victim.
0x0047	L1D_CACHE_WB_CLEAN	Level 1 data cache write-back, cleaning and coherency.
0x0048	L1D_CACHE_INVALID	Level 1 data cache invalidate.
0x004C	L1D_TLB_REFILL_RD	Level 1 data TLB refill, read.
0x004D	L1D_TLB_REFILL_WR	Level 1 data TLB refill, write.
0x004E	L1D_TLB_RD	Level 1 data TLB access, read.
0x004F	L1D_TLB_WR	Level 1 data TLB access, write.
0x0050	L2D_CACHE_RD	Level 2 data cache access, read.

Number	Mnemonic	Description
0x0051	L2D_CACHE_WR	Level 2 data cache access, write.
0x0052	L2D_CACHE_REFILL_RD	Level 2 data cache refill, read.
0x0053	L2D_CACHE_REFILL_WR	Level 2 data cache refill, write.
0x0056	L2D_CACHE_WB_VICTIM	Level 2 data cache write-back, victim.
0x0057	L2D_CACHE_WB_CLEAN	Level 2 data cache write-back, cleaning and coherency.
0x0058	L2D_CACHE_INVALID	Level 2 data cache invalidate.
0x005C	L2D_TLB_REFILL_RD	Level 2 data TLB refill, read.
0x005D	L2D_TLB_REFILL_WR	Level 2 data TLB refill, write.
0x005E	L2D_TLB_RD	Level 2 data TLB access, read.
0x005F	L2D_TLB_WR	Level 2 data TLB access, write.
0x0060	BUS_ACCESS_RD	Bus access, read.
0x0061	BUS_ACCESS_WR	Bus access, write.
0x0062	BUS_ACCESS_SHARED	Bus access, Normal, Cacheable, Shareable.
0x0063	BUS_ACCESS_NOT_SHARED	Bus access, not Normal, Cacheable, Shareable.
0x0064	BUS_ACCESS_NORMAL	Bus access, normal.
0x0065	BUS_ACCESS_PERIPH	Bus access, peripheral.
0x0066	MEM_ACCESS_RD	Data memory access, read.
0x0067	MEM_ACCESS_WR	Data memory access, write.
0x0068	UNALIGNED_LD_SPEC	Unaligned access, read.
0x0069	UNALIGNED_ST_SPEC	Unaligned access, write.
0x006A	UNALIGNED_LDST_SPEC	Unaligned access.
0x006C	LDREX_SPEC	Exclusive operation speculatively executed, Load-Exclusive.
0x006D	STREX_PASS_SPEC	Exclusive operation speculatively executed, Store-Exclusive pass.
0x006E	STREX_FAIL_SPEC	Exclusive operation speculatively executed, Store-Exclusive fail.
0x006F	STREX_SPEC	Exclusive operation speculatively executed, Store-Exclusive.
0x0070	LD_SPEC	Operation speculatively executed, load.
0x0071	ST_SPEC	Operation speculatively executed, store.
0x0072	LDST_SPEC	Operation speculatively executed, load or store.
0x0073	DP_SPEC	Operation speculatively executed, integer data processing.
0x0074	ASE_SPEC	Operation speculatively executed, Advanced SIMD data processing.
0x0075	VFP_SPEC	Operation speculatively executed, scalar floating-point data processing.

Number	Mnemonic	Description
0x0076	PC_WRITE_SPEC	Operation speculatively executed, Software change of the PC.
0x0077	CRYPTO_SPEC	Operation speculatively executed, cryptographic data processing.
0x0078	BR_IMMED_SPEC	Branch speculatively executed, immediate branch.
0x0079	BR_RETURN_SPEC	Branch speculatively executed, procedure return.
0x007A	BR_INDIRECT_SPEC	Branch speculatively executed, indirect branch.
0x007C	ISB_SPEC	Barrier speculatively executed, ISB.
0x007D	DSB_SPEC	Barrier speculatively executed, DSB.
0x007E	DMB_SPEC	Barrier speculatively executed, DMB.
0x007F	CSDB_SPEC	Barrier speculatively executed, CSDB.
0x0081	EXC_UNDEF	Exception taken, other synchronous.
0x0082	EXC_SVC	Exception taken, Supervisor Call.
0x0083	EXC_PABORT	Exception taken, Instruction Abort.
0x0084	EXC_DABORT	Exception taken, Data Abort or SError.
0x0086	EXC_IRQ	Exception taken, IRQ.
0x0087	EXC_FIQ	Exception taken, FIQ.
0x0088	EXC_SMC	Exception taken, Secure Monitor Call.
0x008A	EXC_HVC	Exception taken, Hypervisor Call.
0x008B	EXC_TRAP_PABORT	Exception taken, Instruction Abort not Taken locally.
0x008C	EXC_TRAP_DABORT	Exception taken, Data Abort or SError not Taken locally.
0x008D	EXC_TRAP_OTHER	Exception taken, other traps not Taken locally.
0x008E	EXC_TRAP_IRQ	Exception taken, IRQ not Taken locally.
0x008F	EXC_TRAP_FIQ	Exception taken, FIQ not Taken locally.
0x0090	RC_LD_SPEC	Release consistency operation speculatively executed, Load-Acquire.
0x0091	RC_ST_SPEC	Release consistency operation speculatively executed, Store-Release.
0x00A0	L3D_CACHE_RD	Level 3 data cache access, read.
0x00A1	L3D_CACHE_WR	Level 3 data cache access, write.
0x00A2	L3D_CACHE_REFILL_RD	Level 3 data cache refill, read.
0x00A3	L3D_CACHE_REFILL_WR	Level 3 data cache refill, write.
0x00A6	L3D_CACHE_WB_VICTIM	Level 3 data cache write-back, victim.

Number	Mnemonic	Description
0x00A7	L3D_CACHE_WB_CLEAN	Level 3 data cache write-back, cleaning and coherency.
0x00A8	L3D_CACHE_INVALID	Level 3 data cache invalidate.
	ASE_FP_ADDSUB_SPEC	Floating-point operation speculatively executed, Advanced SIMD add or subtract.
	ASE_FP_BF16_MIN_SPEC	Advanced SIMD data processing operation speculatively executed, smallest type is BFloat16 floating-point.
	ASE_FP_CVT_SPEC	Floating-point operation speculatively executed, Advanced SIMD convert.
	ASE_FP_DIV_SPEC	Floating-point operation speculatively executed, Advanced SIMD divide.
	ASE_FP_DOT_SPEC	Floating-point operation speculatively executed, Advanced SIMD dot-product.
	ASE_FP_DP_SPEC	Floating-point operation speculatively executed, Advanced SIMD double-precision, data-processing.
	ASE_FP_FMA_SPEC	Floating-point operation speculatively executed, Advanced SIMD FMA.
	ASE_FP_FP8_MIN_SPEC	Advanced SIMD data processing operation speculatively executed, smallest type is 8-bit floating-point.
	ASE_FP_HP_MIN_SPEC	Advanced SIMD data processing operation speculatively executed, smallest type is half-precision floating-point.
	ASE_FP_HP_SPEC	Floating-point operation speculatively executed, Advanced SIMD half-precision, data-processing.
	ASE_FP_MMLA_SPEC	Floating-point operation speculatively executed, Advanced SIMD matrix multiply.
	ASE_FP_MUL_SPEC	Floating-point operation speculatively executed, Advanced SIMD multiply.
	ASE_FP_PREDUCE_SPEC	Floating-point operation speculatively executed, Advanced SIMD pairwise add step or pairwise reduce step.
	ASE_FP_RECPE_SPEC	Floating-point operation speculatively executed, Advanced SIMD reciprocal estimate.
	ASE_FP_SPEC	Floating-point operation speculatively executed, Advanced SIMD.
	ASE_FP_SP_MIN_SPEC	Advanced SIMD data processing operation speculatively executed, smallest type is single-precision floating-point.

Number	Mnemonic	Description
	ASE_FP_SP_SPEC	Floating-point operation speculatively executed, Advanced SIMD single-precision, data-processing.
	ASE_FP_SQRT_SPEC	Floating-point operation speculatively executed, Advanced SIMD square root.
	ASE_FP_VREDUCE_SPEC	Floating-point operation speculatively executed, Advanced SIMD pairwise or reduction.
	ASE_INST_RETIRED	Instruction architecturally executed, Advanced SIMD.
	ASE_INST_SPEC	Operation speculatively executed, Advanced SIMD.
	ASE_INT16_SPEC	Integer operation speculatively executed, Advanced SIMD 16-bit.
	ASE_INT32_SPEC	Integer operation speculatively executed, Advanced SIMD 32-bit.
	ASE_INT64_SPEC	Integer operation speculatively executed, Advanced SIMD 64-bit.
	ASE_INT8_SPEC	Integer operation speculatively executed, Advanced SIMD 8-bit.
	ASE_INT_DOT_SPEC	Operation speculatively executed, Advanced SIMD integer dot-product.
	ASE_INT_MMLA_SPEC	Integer operation speculatively executed, Advanced SIMD matrix multiply.
	ASE_INT_MUL_SPEC	Integer operation speculatively executed, Advanced SIMD multiply.
	ASE_INT_SPEC	Integer operation speculatively executed, Advanced SIMD.
	ASE_INT_VREDUCE_SPEC	Integer operation speculatively executed, Advanced SIMD reduction.
	ASE_LUT_SPEC	Lookup table operation speculatively executed, Advanced SIMD data processing.
	ASE_NONFP_SPEC	Non-floating-point operation speculatively executed, Advanced SIMD.
	ASE_RETIRED	Instruction architecturally executed, Advanced SIMD data processing.
	ASE_SVE_FP_ADDSUB_SPEC	Floating-point operation speculatively executed, Advanced SIMD or SVE add or subtract .
	ASE_SVE_FP_BF16_MIN_SPEC	Advanced SIMD data processing or SVE data processing operation speculatively executed, smallest type is BFloat16 floating-point.
	ASE_SVE_FP_BF16_SPEC	Floating-point operation speculatively executed, SVE or Advanced SIMD BFloat16, data-processing.

Number	Mnemonic	Description
	ASE_SVE_FP_CVT_SPEC	Floating-point operation speculatively executed, Advanced SIMD or SVE convert.
	ASE_SVE_FP_DIV_SPEC	Floating-point operation speculatively executed, Advanced SIMD or SVE divide.
	ASE_SVE_FP_DOT_SPEC	Floating-point operation speculatively executed, Advanced SIMD or SVE dot-product.
	ASE_SVE_FP_DP_SPEC	Floating-point operation speculatively executed, Advanced SIMD or SVE double-precision, data-processing.
	ASE_SVE_FP_FMA_SPEC	Floating-point operation speculatively executed, Advanced SIMD or SVE FMA.
	ASE_SVE_FP_FP8_MIN_SPEC	Advanced SIMD data processing or SVE data processing operation speculatively executed, smallest type is 8-bit floating-point.
	ASE_SVE_FP_HP_MIN_SPEC	Advanced SIMD data processing or SVE data processing operation speculatively executed, smallest type is half-precision floating-point.
	ASE_SVE_FP_HP_SPEC	Floating-point operation speculatively executed, Advanced SIMD or SVE half-precision.
	ASE_SVE_FP_MMLA_SPEC	Floating-point operation speculatively executed, Advanced SIMD or SVE matrix multiply.
	ASE_SVE_FP_MUL_SPEC	Floating-point operation speculatively executed, Advanced SIMD or SVE multiply.
	ASE_SVE_FP_RECPE_SPEC	Floating-point operation speculatively executed, Advanced SIMD or SVE reciprocal estimate.
	ASE_SVE_FP_SPEC	Floating-point operation speculatively executed, Advanced SIMD or SVE.
	ASE_SVE_FP_SP_MIN_SPEC	Advanced SIMD data processing or SVE data processing operation speculatively executed, smallest type is single-precision floating-point.
	ASE_SVE_FP_SP_SPEC	Floating-point operation speculatively executed, Advanced SIMD or SVE single-precision, data-processing.
	ASE_SVE_FP_SQRT_SPEC	Floating-point operation speculatively executed, Advanced SIMD or SVE square-root.
	ASE_SVE_FP_VREDUCE_SPEC	Floating-point operation speculatively executed, Advanced SIMD or SVE vector reduction.
	ASE_SVE_INST_RETIRED	Instruction architecturally executed, Advanced SIMD or SVE.

Number	Mnemonic	Description
	ASE_SVE_INST_SPEC	Operation speculatively executed, Advanced SIMD or SVE.
	ASE_SVE_INT16_SPEC	Integer operation speculatively executed, Advanced SIMD or SVE 16-bit.
	ASE_SVE_INT32_SPEC	Integer operation speculatively executed, Advanced SIMD or SVE 32-bit.
	ASE_SVE_INT64_SPEC	Integer operation speculatively executed, Advanced SIMD or SVE 64-bit.
	ASE_SVE_INT8_SPEC	Integer operation speculatively executed, Advanced SIMD or SVE 8-bit.
	ASE_SVE_INT_DOT_SPEC	Integer operation speculatively executed, Advanced SIMD or SVE dot-product.
	ASE_SVE_INT_MMLA_SPEC	Integer operation speculatively executed, Advanced SIMD or SVE matrix multiply.
	ASE_SVE_INT_MUL_SPEC	Integer operation speculatively executed, Advanced SIMD or SVE multiply.
	ASE_SVE_INT_SPEC	Integer operation speculatively executed, Advanced SIMD or SVE.
	ASE_SVE_INT_VREDUCE_SPEC	Integer operation speculatively executed, Advanced SIMD or SVE reduction.
	ASE_SVE_LDST_MULTI_SPEC	Operation speculatively executed, Advanced SIMD or SVE contiguous load or store multiple vector.
	ASE_SVE_LDST_SPEC	Operation speculatively executed, Advanced SIMD or SVE load or store.
	ASE_SVE_LD_MULTI_SPEC	Operation speculatively executed, Advanced SIMD or SVE contiguous load multiple vector.
	ASE_SVE_LD_SPEC	Operation speculatively executed, Advanced SIMD or SVE load.
	ASE_SVE_NONFP_SPEC	Non-floating-point operation speculatively executed, Advanced SIMD or SVE.
	ASE_SVE_RETIRED	Instruction architecturally executed, Advanced SIMD data processing or SVE data processing.
	ASE_SVE_SPEC	Operation speculatively executed, Advanced SIMD data processing or SVE data processing.
	ASE_SVE_ST_MULTI_SPEC	Operation speculatively executed, Advanced SIMD or SVE contiguous store multiple vector.

Number	Mnemonic	Description
	ASE_SVE_ST_SPEC	Operation speculatively executed, Advanced SIMD or SVE store.
	ASE_SVE_UNALIGNED_CONTIG_LDST_SPEC	Advanced SIMD or SVE unaligned contiguous access.
	ASE_SVE_UNALIGNED_CONTIG_LD_SPEC	Advanced SIMD or SVE unaligned contiguous read.
	ASE_SVE_UNALIGNED_CONTIG_ST_SPEC	Advanced SIMD or SVE unaligned contiguous write.
	ASE_SVE_UNALIGNED_LDST_SPEC	Advanced SIMD or SVE unaligned access.
	ASE_SVE_UNALIGNED_LD_SPEC	Advanced SIMD or SVE unaligned read.
	ASE_SVE_UNALIGNED_ST_SPEC	Advanced SIMD or SVE unaligned write.
	ASE_SVE_UOP_SPEC	Microarchitectural operation speculatively executed, Advanced SIMD or SVE.
	ASE_UOP_SPEC	Microarchitectural operation speculatively executed, Advanced SIMD.
	BASE_LDST_REG_SPEC	Operation speculatively executed, general-purpose register load, store, or prefetch.
	BASE_LD_REG_SPEC	Operation speculatively executed, general-purpose register load.
	BASE_PRF_SPEC	Operation speculatively executed, general-purpose register prefetch.
	BASE_ST_REG_SPEC	Operation speculatively executed, general-purpose register store.
	BL_IMMED_TAKEN_RETIRED	Branch instruction architecturally executed, direct branch with link, taken.
	BL_IND_TAKEN_RETIRED	Branch instruction architecturally executed, indirect branch with link, taken.
	BL_TAKEN_RETIRED	Branch instruction architecturally executed, branch with link, taken.
	BRB_FILTRATE	Branch Record captured.
	BRNL_IMMED_TAKEN_RETIRED	Branch instruction architecturally executed, direct branch without link, taken.
	BRNL_INDNR_TAKEN_RETIRED	Branch instruction architecturally executed, indirect branch without link excluding procedure return, taken.
	BRNL_IND_TAKEN_RETIRED	Branch instruction architecturally executed, indirect branch without link, taken.
	BRNL_TAKEN_RETIRED	Branch instruction architecturally executed, branch without link, taken.

Number	Mnemonic	Description
	BR_COND_RETIRE	Branch instruction architecturally executed, conditional branch.
	BR_COND_TAKEN_RETIRE	Branch instruction architecturally executed, conditional branch, taken.
	BR_IMMED_MIS_PRED_RETIRE	Branch instruction architecturally executed, mispredicted immediate.
	BR_IMMED_PRED_RETIRE	Branch instruction architecturally executed, predicted immediate.
	BR_IMMED_SKIP_RETIRE	Branch instruction architecturally executed, immediate, not taken.
	BR_IMMED_TAKEN_RETIRE	Branch instruction architecturally executed, immediate, taken.
	BR_INDNR_MIS_PRED_RETIRE	Branch instruction architecturally executed, mispredicted indirect excluding procedure return.
	BR_INDNR_PRED_RETIRE	Branch instruction architecturally executed, predicted indirect excluding procedure return.
	BR_INDNR_RETIRE	Branch instruction architecturally executed, indirect excluding procedure return.
	BR_INDNR_SKIP_RETIRE	Branch instruction architecturally executed, indirect excluding procedure return, not taken.
	BR_INDNR_TAKEN_RETIRE	Branch instruction architecturally executed, indirect excluding procedure return, taken.
	BR_IND_MIS_PRED_RETIRE	Branch instruction architecturally executed, mispredicted indirect.
	BR_IND_PRED_RETIRE	Branch instruction architecturally executed, predicted indirect.
	BR_IND_RETIRE	Instruction architecturally executed, indirect branch.
	BR_IND_SKIP_RETIRE	Branch instruction architecturally executed, indirect, not taken.
	BR_IND_TAKEN_RETIRE	Branch instruction architecturally executed, indirect, taken.
	BR_PRED_RETIRE	Branch instruction architecturally executed, predicted branch.
	BR_RETURN_ANY_RETIRE	Branch instruction architecturally executed, procedure return.
	BR_RETURN_MIS_PRED_RETIRE	Branch instruction architecturally executed, mispredicted procedure return.
	BR_RETURN_PRED_RETIRE	Branch instruction architecturally executed, predicted procedure return.
	BR_RETURN_SKIP_RETIRE	Branch instruction architecturally executed, procedure return, not taken.

Number	Mnemonic	Description
	BR_SKIP_MIS_PRED_RETIRED	Branch instruction architecturally executed, mispredicted branch, not taken.
	BR_SKIP_PRED_RETIRED	Branch instruction architecturally executed, predicted branch, not taken.
	BR_SKIP_RETIRED	Branch instruction architecturally executed, not taken.
	BR_TAKEN_MIS_PRED_RETIRED	Branch instruction architecturally executed, mispredicted branch, taken.
	BR_TAKEN_PRED_RETIRED	Branch instruction architecturally executed, predicted branch, taken.
	BR_UNCOND_RETIRED	Branch instruction architecturally executed, unconditional branch.
	BUS_REQ	Bus request.
	BUS_REQ_RD	Bus request, read.
	BUS_REQ_RD_PERCYC	Bus read transactions in progress.
	BUS_REQ_WR	Bus request, write.
	BUS_REQ_WR_PERCYC	Bus write transactions in progress.
	CNT_CYCLES	Constant frequency cycles.
	CRYPTO_RETIRED	Instruction architecturally executed, cryptographic data processing.
	CTI_TRIGOUT4	Cross-trigger Interface output trigger 4.
	CTI_TRIGOUT5	Cross-trigger Interface output trigger 5.
	CTI_TRIGOUT6	Cross-trigger Interface output trigger 6.
	CTI_TRIGOUT7	Cross-trigger Interface output trigger 7.
	DP_RETIRED	Instruction architecturally executed, integer data processing.
	DSNP_HIT	Snoop hit, data.
	DSNP_HITM_FAR_LDST_RETIRED	Load or store instruction architecturally executed, snoop hit in far cache.
	DSNP_HITM_FAR_LD_RETIRED	Load instruction architecturally executed, snoop hit in far cache.
	DSNP_HITM_FAR_RD	Snoop hit in far local cache, demand data read, modified.
	DSNP_HITM_FAR_RW	Snoop hit in far local cache, demand data access, modified.
	DSNP_HITM_FAR_ST_RETIRED	Store instruction architecturally executed, snoop hit in far cache.
	DSNP_HITM_FAR_WR	Snoop hit in far local cache, demand data write, modified.
	DSNP_HITM_LDST_RETIRED	Load or store instruction architecturally executed, snoop hit.

Number	Mnemonic	Description
	DSNP_HITM_LD_RETIRED	Load instruction architecturally executed, snoop hit.
	DSNP_HITM_N1_RD	Snoop hit in cache at distance 1, demand data read, modified.
	DSNP_HITM_N1_RW	Snoop hit in cache at distance 1, demand data access, modified.
	DSNP_HITM_N1_WR	Snoop hit in cache at distance 1, demand data write, modified.
	DSNP_HITM_N2_RD	Snoop hit in cache at distance 2, demand data read, modified.
	DSNP_HITM_N2_RW	Snoop hit in cache at distance 2, demand data access, modified.
	DSNP_HITM_N2_WR	Snoop hit in cache at distance 2, demand data write, modified.
	DSNP_HITM_N3_RD	Snoop hit in cache at distance 3, demand data read, modified.
	DSNP_HITM_N3_RW	Snoop hit in cache at distance 3, demand data access, modified.
	DSNP_HITM_N3_WR	Snoop hit in cache at distance 3, demand data write, modified.
	DSNP_HITM_N4_RD	Snoop hit in cache at distance 4, demand data read, modified.
	DSNP_HITM_N4_RW	Snoop hit in cache at distance 4, demand data access, modified.
	DSNP_HITM_N4_WR	Snoop hit in cache at distance 4, demand data write, modified.
	DSNP_HITM_NEAR_LDST_RETIRED	Load or store instruction architecturally executed, snoop hit in near cache.
	DSNP_HITM_NEAR_LD_RETIRED	Load instruction architecturally executed, snoop hit in near cache.
	DSNP_HITM_NEAR_RD	Snoop hit in near local cache, demand data read, modified.
	DSNP_HITM_NEAR_RW	Snoop hit in near local cache, demand data access, modified.
	DSNP_HITM_NEAR_ST_RETIRED	Store instruction architecturally executed, snoop hit in near cache.
	DSNP_HITM_NEAR_WR	Snoop hit in near local cache, demand data write, modified.
	DSNP_HITM_RD	Snoop hit, demand data read, modified.
	DSNP_HITM_REMOTE_LDST_RETIRED	Load or store instruction architecturally executed, snoop hit in remote cache.
	DSNP_HITM_REMOTE_LD_RETIRED	Load instruction architecturally executed, snoop hit in remote cache.
	DSNP_HITM_REMOTE_RD	Snoop hit in remote cache, demand data read, modified.

Number	Mnemonic	Description
	DSNP_HITM_REMOTE_RW	Snoop hit in remote cache, demand data access, modified.
	DSNP_HITM_REMOTE_ST_RETIRED	Store instruction architecturally executed, snoop hit in remote cache.
	DSNP_HITM_REMOTE_WR	Snoop hit in remote cache, demand data write, modified.
	DSNP_HITM_RW	Snoop hit, demand data access, modified.
	DSNP_HITM_ST_RETIRED	Store instruction architecturally executed, snoop hit.
	DSNP_HITM_WR	Snoop hit, demand data write, modified.
	DSNP_HIT_FAR	Snoop hit in far local cache, data access.
	DSNP_HIT_FAR_HWPRF	Snoop hit in far local cache, hardware data prefetch.
	DSNP_HIT_FAR_LDST_RETIRED	Load or store instruction architecturally executed, snoop hit in far cache.
	DSNP_HIT_FAR_LD_RETIRED	Load instruction architecturally executed, snoop hit in far cache.
	DSNP_HIT_FAR_PRF	Snoop hit in far local cache, data prefetch.
	DSNP_HIT_FAR_PRFM	Snoop hit in far local cache, software data prefetch.
	DSNP_HIT_FAR_RD	Snoop hit in far local cache, demand data read.
	DSNP_HIT_FAR_RW	Snoop hit in far local cache, demand data access.
	DSNP_HIT_FAR_ST_RETIRED	Store instruction architecturally executed, snoop hit in far cache.
	DSNP_HIT_FAR_WR	Snoop hit in far local cache, demand data write.
	DSNP_HIT_HWPRF	Snoop hit, hardware data prefetch.
	DSNP_HIT_LDST_RETIRED	Load or store instruction architecturally executed, snoop hit.
	DSNP_HIT_LD_RETIRED	Load instruction architecturally executed, snoop hit.
	DSNP_HIT_N1	Snoop hit in cache at distance 1, data access.
	DSNP_HIT_N1_HWPRF	Snoop hit in cache at distance 1, hardware data prefetch.
	DSNP_HIT_N1_PRF	Snoop hit in cache at distance 1, data prefetch.
	DSNP_HIT_N1_PRFM	Snoop hit in cache at distance 1, software data prefetch.
	DSNP_HIT_N1_RD	Snoop hit in cache at distance 1, demand data read.

Number	Mnemonic	Description
	DSNP_HIT_N1_RW	Snoop hit in cache at distance 1, demand data access.
	DSNP_HIT_N1_WR	Snoop hit in cache at distance 1, demand data write.
	DSNP_HIT_N2	Snoop hit in cache at distance 2, data access.
	DSNP_HIT_N2_HWPRF	Snoop hit in cache at distance 2, hardware data prefetch.
	DSNP_HIT_N2_PRF	Snoop hit in cache at distance 2, data prefetch.
	DSNP_HIT_N2_PRFM	Snoop hit in cache at distance 2, software data prefetch.
	DSNP_HIT_N2_RD	Snoop hit in cache at distance 2, demand data read.
	DSNP_HIT_N2_RW	Snoop hit in cache at distance 2, demand data access.
	DSNP_HIT_N2_WR	Snoop hit in cache at distance 2, demand data write.
	DSNP_HIT_N3	Snoop hit in cache at distance 3, data access.
	DSNP_HIT_N3_HWPRF	Snoop hit in cache at distance 3, hardware data prefetch.
	DSNP_HIT_N3_PRF	Snoop hit in cache at distance 3, data prefetch.
	DSNP_HIT_N3_PRFM	Snoop hit in cache at distance 3, software data prefetch.
	DSNP_HIT_N3_RD	Snoop hit in cache at distance 3, demand data read.
	DSNP_HIT_N3_RW	Snoop hit in cache at distance 3, demand data access.
	DSNP_HIT_N3_WR	Snoop hit in cache at distance 3, demand data write.
	DSNP_HIT_N4	Snoop hit in cache at distance 4, data access.
	DSNP_HIT_N4_HWPRF	Snoop hit in cache at distance 4, hardware data prefetch.
	DSNP_HIT_N4_PRF	Snoop hit in cache at distance 4, data prefetch.
	DSNP_HIT_N4_PRFM	Snoop hit in cache at distance 4, software data prefetch.
	DSNP_HIT_N4_RD	Snoop hit in cache at distance 4, demand data read.
	DSNP_HIT_N4_RW	Snoop hit in cache at distance 4, demand data access.
	DSNP_HIT_N4_WR	Snoop hit in cache at distance 4, demand data write.
	DSNP_HIT_NEAR	Snoop hit in near local cache, data access.

Number	Mnemonic	Description
	DSNP_HIT_NEAR_HWPRF	Snoop hit in near local cache, hardware data prefetch.
	DSNP_HIT_NEAR_LDST_RETIRED	Load or store instruction architecturally executed, snoop hit in near cache.
	DSNP_HIT_NEAR_LD_RETIRED	Load instruction architecturally executed, snoop hit in near cache.
	DSNP_HIT_NEAR_PRF	Snoop hit in near local cache, data prefetch.
	DSNP_HIT_NEAR_PRFM	Snoop hit in near local cache, software data prefetch.
	DSNP_HIT_NEAR_RD	Snoop hit in near local cache, demand data read.
	DSNP_HIT_NEAR_RW	Snoop hit in near local cache, demand data access.
	DSNP_HIT_NEAR_ST_RETIRED	Store instruction architecturally executed, snoop hit in near cache.
	DSNP_HIT_NEAR_WR	Snoop hit in near local cache, demand data write.
	DSNP_HIT_PRF	Snoop hit, data prefetch.
	DSNP_HIT_PRFM	Snoop hit, software data prefetch.
	DSNP_HIT_RD	Snoop hit, demand data read.
	DSNP_HIT_REMOTE	Snoop hit in remote cache, data access.
	DSNP_HIT_REMOTE_HWPRF	Snoop hit in remote cache, hardware data prefetch.
	DSNP_HIT_REMOTE_LDST_RETIRED	Load or store instruction architecturally executed, snoop hit in remote cache.
	DSNP_HIT_REMOTE_LD_RETIRED	Load instruction architecturally executed, snoop hit in remote cache.
	DSNP_HIT_REMOTE_PRF	Snoop hit in remote cache, data prefetch.
	DSNP_HIT_REMOTE_PRFM	Snoop hit in remote cache, software data prefetch.
	DSNP_HIT_REMOTE_RD	Snoop hit in remote cache, demand data read.
	DSNP_HIT_REMOTE_RW	Snoop hit in remote cache, demand data access.
	DSNP_HIT_REMOTE_ST_RETIRED	Store instruction architecturally executed, snoop hit in remote cache.
	DSNP_HIT_REMOTE_WR	Snoop hit in remote cache, demand data write.
	DSNP_HIT_RW	Snoop hit, demand data access.
	DSNP_HIT_ST_RETIRED	Store instruction architecturally executed, snoop hit.
	DSNP_HIT_WR	Snoop hit, demand data write.

Number	Mnemonic	Description
	DTLB_HIT_LDST_RETIRED	Load or store instruction architecturally executed, no translation table walk.
	DTLB_HIT_LD_RETIRED	Load instruction architecturally executed, no translation table walk.
	DTLB_HIT_ST_RETIRED	Store instruction architecturally executed, no translation table walk.
	DTLB_WALK_HWPRF	Data TLB hardware prefetch, with at least one translation table walk.
	DTLB_WALK_LDST_RETIRED	Load or store instruction architecturally executed, at least one translation table walk.
	DTLB_WALK_LD_RETIRED	Load instruction architecturally executed, at least one translation table walk.
	DTLB_WALK_PERCYC	Data translation table walks in progress.
	DTLB_WALK_PRF	Data TLB prefetch, with at least one translation table walk.
	DTLB_WALK_PRFM	Data TLB software prefetch, with at least one translation table walk.
	DTLB_WALK_RW	Data TLB demand access, with at least one translation table walk.
	DTLB_WALK_ST_RETIRED	Store instruction architecturally executed, at least one translation table walk.
	FPASE_LDST_REG_SPEC	Operation speculatively executed, SIMD&FP register load or store.
	FPASE_LD_REG_SPEC	Operation speculatively executed, SIMD&FP register load.
	FPASE_ST_REG_SPEC	Operation speculatively executed, SIMD&FP register store.
	FP_ADDSUB_SPEC	Floating-point operation speculatively executed, add or subtract.
	FP_BF16_FIXED_MIN_OPS_SPEC	Non-scalable element arithmetic operations speculatively executed, smallest type is BFloat16 floating-point.
	FP_BF16_FIXED_OPS_SPEC	Non-scalable element arithmetic operations speculatively executed, largest type is BFloat16 floating-point.
	FP_BF16_MIN_SPEC	Floating-point operation speculatively executed, smallest type is BFloat16 floating-point.
	FP_CVT_SPEC	Floating-point operation speculatively executed, convert.
	FP_DIV_SPEC	Floating-point operation speculatively executed, divide.

Number	Mnemonic	Description
	FP_DP_FIXED_OPS_SPEC	Non-scalable element arithmetic operations speculatively executed, largest type is double-precision floating-point.
	FP_DP_SPEC	Floating-point operation speculatively executed, double-precision, data-processing.
	FP_FIXED_OPS_SPEC	Non-scalable element arithmetic operations speculatively executed, floating-point.
	FP_FMA_SPEC	Floating-point operation speculatively executed, FMA.
	FP_FP8_FIXED_MIN_OPS_SPEC	Non-scalable element arithmetic operations speculatively executed, smallest type is 8-bit floating-point.
	FP_FP8_MIN_SPEC	Floating-point operation speculatively executed, smallest type is 8-bit floating-point.
	FP_HP_FIXED_MIN_OPS_SPEC	Non-scalable element arithmetic operations speculatively executed, smallest type is half-precision floating-point.
	FP_HP_FIXED_OPS_SPEC	Non-scalable element arithmetic operations speculatively executed, largest type is half-precision floating-point.
	FP_HP_MIN_SPEC	Floating-point operation speculatively executed, smallest type is half-precision floating-point.
	FP_HP_SPEC	Floating-point operation speculatively executed, half-precision.
	FP_MUL_SPEC	Floating-point operation speculatively executed, multiply.
	FP_RECPE_SPEC	Floating-point operation speculatively executed, reciprocal estimate.
	FP_SPEC	Floating-point operation speculatively executed, including SIMD.
	FP_SP_FIXED_MIN_OPS_SPEC	Non-scalable element arithmetic operations speculatively executed, smallest type is single-precision floating-point.
	FP_SP_FIXED_OPS_SPEC	Non-scalable element arithmetic operations speculatively executed, largest type is single-precision floating-point.
	FP_SP_MIN_SPEC	Floating-point operation speculatively executed, smallest type is single-precision floating-point.
	FP_SP_SPEC	Floating-point operation speculatively executed, single-precision.
	FP_SQRT_SPEC	Floating-point operation speculatively executed, square root.

Number	Mnemonic	Description
	GCSTLB_WALK	GCS TLB access with at least one translation table walk.
	GCSTLB_WALK_PERCYC	Translation table walks in progress.
	GCSTLB_WALK_RW	GCS TLB demand access with at least one translation table walk.
	GCSTLB_WALK_STEP	GCS TLB translation table walk, step.
	INST_FETCH	Instruction memory access.
	INST_FETCH_PERCYC	Instruction fetches in progress.
	INST_FETCH_PRFM	Instruction memory access, software prefetch.
	INST_FETCH_RD	Instruction memory access, demand fetch.
	INT_DIV64_SPEC	Integer operation speculatively executed, 64-bit divide.
	INT_DIV_SPEC	Integer operation speculatively executed, divide.
	INT_FIXED_OPS_SPEC	Non-scalable element arithmetic operations speculatively executed, integer.
	INT_MUL64_SPEC	Integer operation speculatively executed, 64×64 multiply.
	INT_MULH64_SPEC	Integer operation speculatively executed, 64×64 multiply returning high part.
	INT_MUL_SPEC	Integer operation speculatively executed, multiply.
	INT_SPEC	Integer operation speculatively executed.
	ISNP_HIT	Snoop hit, instruction.
	ISNP_HIT_FAR	Snoop hit in far local cache, instruction access.
	ISNP_HIT_FAR_HWPRF	Snoop hit in far local cache, hardware instruction prefetch.
	ISNP_HIT_FAR_PRF	Snoop hit in far local cache, instruction prefetch.
	ISNP_HIT_FAR_PRFM	Snoop hit in far local cache, software instruction prefetch.
	ISNP_HIT_FAR_RD	Snoop hit in far local cache, demand instruction fetch.
	ISNP_HIT_FAR_RETIRED	Instruction architecturally executed, instruction fetch snoop hit in far cache.
	ISNP_HIT_HWPRF	Snoop hit, hardware instruction prefetch.
	ISNP_HIT_N1	Snoop hit in cache at distance 1, instruction access.
	ISNP_HIT_N1_HWPRF	Snoop hit in cache at distance 1, hardware instruction prefetch.

Number	Mnemonic	Description
	ISNP_HIT_N1_PRF	Snoop hit in cache at distance 1, instruction prefetch.
	ISNP_HIT_N1_PRFM	Snoop hit in cache at distance 1, software instruction prefetch.
	ISNP_HIT_N1_RD	Snoop hit in cache at distance 1, demand instruction fetch.
	ISNP_HIT_N2	Snoop hit in cache at distance 2, instruction access.
	ISNP_HIT_N2_HWPRF	Snoop hit in cache at distance 2, hardware instruction prefetch.
	ISNP_HIT_N2_PRF	Snoop hit in cache at distance 2, instruction prefetch.
	ISNP_HIT_N2_PRFM	Snoop hit in cache at distance 2, software instruction prefetch.
	ISNP_HIT_N2_RD	Snoop hit in cache at distance 2, demand instruction fetch.
	ISNP_HIT_N3	Snoop hit in cache at distance 3, instruction access.
	ISNP_HIT_N3_HWPRF	Snoop hit in cache at distance 3, hardware instruction prefetch.
	ISNP_HIT_N3_PRF	Snoop hit in cache at distance 3, instruction prefetch.
	ISNP_HIT_N3_PRFM	Snoop hit in cache at distance 3, software instruction prefetch.
	ISNP_HIT_N3_RD	Snoop hit in cache at distance 3, demand instruction fetch.
	ISNP_HIT_N4	Snoop hit in cache at distance 4, instruction access.
	ISNP_HIT_N4_HWPRF	Snoop hit in cache at distance 4, hardware instruction prefetch.
	ISNP_HIT_N4_PRF	Snoop hit in cache at distance 4, instruction prefetch.
	ISNP_HIT_N4_PRFM	Snoop hit in cache at distance 4, software instruction prefetch.
	ISNP_HIT_N4_RD	Snoop hit in cache at distance 4, demand instruction fetch.
	ISNP_HIT_NEAR	Snoop hit in near local cache, instruction access.
	ISNP_HIT_NEAR_HWPRF	Snoop hit in near local cache, hardware instruction prefetch.
	ISNP_HIT_NEAR_PRF	Snoop hit in near local cache, instruction prefetch.
	ISNP_HIT_NEAR_PRFM	Snoop hit in near local cache, software instruction prefetch.
	ISNP_HIT_NEAR_RD	Snoop hit in near local cache, demand instruction fetch.
	ISNP_HIT_NEAR_RETIRED	Instruction architecturally executed, instruction fetch snoop hit in near cache.

Number	Mnemonic	Description
	ISNP_HIT_PRF	Snoop hit, instruction prefetch.
	ISNP_HIT_PRFM	Snoop hit, software instruction prefetch.
	ISNP_HIT_RD	Snoop hit, demand instruction fetch.
	ISNP_HIT_REMOTE	Snoop hit in remote cache, instruction access.
	ISNP_HIT_REMOTE_HWPRF	Snoop hit in remote cache, hardware instruction prefetch.
	ISNP_HIT_REMOTE_PRF	Snoop hit in remote cache, instruction prefetch.
	ISNP_HIT_REMOTE_PRFM	Snoop hit in remote cache, software instruction prefetch.
	ISNP_HIT_REMOTE_RD	Snoop hit in remote cache, demand instruction fetch.
	ISNP_HIT_REMOTE_RETIRED	Instruction architecturally executed, instruction fetch snoop hit in remote cache.
	ISNP_HIT_RETIRED	Instruction architecturally executed, instruction fetch snoop hit.
	ITLB_HIT_RETIRED	Instruction architecturally executed, no translation table walk.
	ITLB_WALK_HWPRF	Instruction TLB hardware prefetch, with at least one translation table walk.
	ITLB_WALK_PERCYC	Instruction translation table walks in progress.
	ITLB_WALK_PRF	Instruction TLB prefetch, with at least one translation table walk.
	ITLB_WALK_PRFM	Instruction TLB software prefetch, with at least one translation table walk.
	ITLB_WALK_RD	Instruction TLB demand access, with at least one translation table walk.
	ITLB_WALK_RETIRED	Instruction architecturally executed, at least one translation table walk.
	L1D_CACHE_HIT	Level 1 data cache hit.
	L1D_CACHE_HITM_LDST_RETIRED	Load or store instruction architecturally executed, hit modified data in Level 1 data cache.
	L1D_CACHE_HITM_LD_RETIRED	Load instruction architecturally executed, hit modified data in Level 1 data cache.
	L1D_CACHE_HITM_RD	Level 1 data cache demand access hit modified, read.
	L1D_CACHE_HITM_RW	Level 1 data cache demand access hit modified.
	L1D_CACHE_HITM_ST_RETIRED	Store instruction architecturally executed, hit modified data in Level 1 data cache.

Number	Mnemonic	Description
	L1D_CACHE_HITM_WR	Level 1 data cache demand access hit modified, write.
	L1D_CACHE_HIT_LDST_RETIRED	Load or store instruction architecturally executed, hit in Level 1 data cache.
	L1D_CACHE_HIT_LD_RETIRED	Load instruction architecturally executed, hit in Level 1 data cache.
	L1D_CACHE_HIT_PRFM	Level 1 data cache software prefetch hit.
	L1D_CACHE_HIT_RD	Level 1 data cache demand access hit, read.
	L1D_CACHE_HIT_RD_FHWPRF	Level 1 data cache demand access first hit, read, fetched by hardware prefetcher.
	L1D_CACHE_HIT_RD_FPRF	Level 1 data cache demand access first hit, read, fetched by prefetch.
	L1D_CACHE_HIT_RD_FPRFM	Level 1 data cache demand access first hit, read, fetched by software prefetch.
	L1D_CACHE_HIT_RW	Level 1 data cache demand access hit.
	L1D_CACHE_HIT_RW_FHWPRF	Level 1 data cache demand access first hit, fetched by hardware prefetcher.
	L1D_CACHE_HIT_RW_FPRF	Level 1 data cache demand access first hit, fetched by prefetch.
	L1D_CACHE_HIT_RW_FPRFM	Level 1 data cache demand access first hit, fetched by software prefetch.
	L1D_CACHE_HIT_ST_RETIRED	Store instruction architecturally executed, hit in Level 1 data cache.
	L1D_CACHE_HIT_WR	Level 1 data cache demand access hit, write.
	L1D_CACHE_HIT_WR_FHWPRF	Level 1 data cache demand access first hit, write, fetched by hardware prefetcher.
	L1D_CACHE_HIT_WR_FPRF	Level 1 data cache demand access first hit, write, fetched by prefetch.
	L1D_CACHE_HIT_WR_FPRFM	Level 1 data cache demand access first hit, write, fetched by software prefetch.
	L1D_CACHE_HWPRF	Level 1 data cache hardware prefetch.
	L1D_CACHE_MISS	Level 1 data cache demand access miss.
	L1D_CACHE_MISS_LDST_RETIRED	Load or store instruction architecturally executed, miss in Level 1 data cache.
	L1D_CACHE_MISS_LD_RETIRED	Load instruction architecturally executed, miss in Level 1 data cache.
	L1D_CACHE_MISS_ST_RETIRED	Store instruction architecturally executed, miss in Level 1 data cache.

Number	Mnemonic	Description
	L1D_CACHE_PRF	Level 1 data cache, prefetch hit.
	L1D_CACHE_PRFM	Level 1 data cache software prefetch.
	L1D_CACHE_REFILL_HWPRF	Level 1 data cache refill, hardware prefetch.
	L1D_CACHE_REFILL_PERCYC	Level 1 data or unified cache refills in progress.
	L1D_CACHE_REFILL_PRF	Level 1 data cache refill, prefetch hit.
	L1D_CACHE_REFILL_PRFM	Level 1 data cache refill, software prefetch.
	L1D_CACHE_RW	Level 1 data cache demand access.
	L1D_LFB_HIT_LDST_RETIRED	Load or store instruction architecturally executed, line-fill buffer hit in Level 1 data cache.
	L1D_LFB_HIT_LD_RETIRED	Load instruction architecturally executed, line-fill buffer hit in Level 1 data cache.
	L1D_LFB_HIT_RD	Level 1 data cache demand access line-fill buffer hit, read.
	L1D_LFB_HIT_RD_FHWPRF	Level 1 data cache demand access line-fill buffer first hit, read, recently fetched by hardware prefetcher.
	L1D_LFB_HIT_RD_FPRF	Level 1 data cache demand access line-fill buffer first hit, read, recently fetched by prefetch.
	L1D_LFB_HIT_RD_FPRFM	Level 1 data cache demand access line-fill buffer first hit, read, recently fetched by software prefetch.
	L1D_LFB_HIT_RW	Level 1 data cache demand access line-fill buffer hit.
	L1D_LFB_HIT_RW_FHWPRF	Level 1 data cache demand access line-fill buffer first hit, recently fetched by hardware prefetcher.
	L1D_LFB_HIT_RW_FPRF	Level 1 data cache demand access line-fill buffer first hit, recently fetched by prefetch.
	L1D_LFB_HIT_RW_FPRFM	Level 1 data cache demand access line-fill buffer first hit, recently fetched by software prefetch.
	L1D_LFB_HIT_ST_RETIRED	Store instruction architecturally executed, line-fill buffer hit in Level 1 data cache.
	L1D_LFB_HIT_WR	Level 1 data cache demand access line-fill buffer hit, write.
	L1D_LFB_HIT_WR_FHWPRF	Level 1 data cache demand access line-fill buffer first hit, write, recently fetched by hardware prefetcher.
	L1D_LFB_HIT_WR_FPRF	Level 1 data cache demand access line-fill buffer first hit, write, recently fetched by prefetch.

Number	Mnemonic	Description
	L1D_LFB_HIT_WR_FPRFM	Level 1 data cache demand access line-fill buffer first hit, write, recently fetched by software prefetch.
	L1D_TLB_HWPRF	Level 1 data TLB access, hardware prefetch.
	L1D_TLB_PRF	Level 1 data TLB access, prefetch.
	L1D_TLB_PRFM	Level 1 data TLB access, software prefetch.
	L1D_TLB_RW	Level 1 data TLB access, demand access.
	L1GCS_CACHE	Level 1 GCS cache access.
	L1GCS_CACHE_HIT_RW	Level 1 GCS cache demand access hit.
	L1GCS_CACHE_HIT_RW_FHWPRF	Level 1 GCS cache demand access first hit, fetched by GCS hardware prefetcher.
	L1GCS_CACHE_HWPRF	Level 1 GCS cache hardware prefetch.
	L1GCS_CACHE_INVALID	Level 1 GCS cache invalidate.
	L1GCS_CACHE_MISS	Level 1 GCS cache demand access miss.
	L1GCS_CACHE_MISS_RD	Level 1 GCS cache demand access read miss.
	L1GCS_CACHE_REFILL	Level 1 GCS cache refill.
	L1GCS_CACHE_REFILL_HWPRF	Level 1 GCS cache refill, hardware prefetch.
	L1GCS_CACHE_REFILL_PERCYC	Level 1 GCS cache refills in progress.
	L1GCS_CACHE_RW	Level 1 GCS cache demand access.
	L1GCS_LFB_HIT_RW	Level 1 GCS cache demand access line-fill buffer hit.
	L1GCS_LFB_HIT_RW_FHWPRF	Level 1 GCS cache demand access line-fill buffer first hit, recently fetched by GCS hardware prefetcher.
	L1GCS_TLB	Level 1 GCS TLB access.
	L1GCS_TLB_HWPRF	Level 1 GCS demand TLB access, GCS hardware prefetch.
	L1GCS_TLB_RW	Level 1 GCS demand TLB access.
	L1I_CACHE_HIT	Level 1 instruction cache hit.
	L1I_CACHE_HIT_PRFM	Level 1 instruction cache software prefetch hit.
	L1I_CACHE_HIT_RD	Level 1 instruction cache demand fetch hit.
	L1I_CACHE_HIT_RD_FHWPRF	Level 1 instruction cache demand fetch first hit, fetched by hardware prefetcher.
	L1I_CACHE_HIT_RD_FPRF	Level 1 instruction cache demand fetch first hit, fetched by prefetch.

Number	Mnemonic	Description
	L1I_CACHE_HIT_RD_FPRFM	Level 1 instruction cache demand fetch first hit, fetched by software prefetch.
	L1I_CACHE_HIT_RETIRED	Instruction architecturally executed, hit in Level 1 instruction cache.
	L1I_CACHE_HWPRF	Level 1 instruction cache hardware prefetch.
	L1I_CACHE_LMISS	Level 1 instruction cache long-latency miss.
	L1I_CACHE_MISS_RETIRED	Instruction architecturally executed, miss in Level 1 instruction cache.
	L1I_CACHE_PRF	Level 1 instruction cache, prefetch hit.
	L1I_CACHE_PRFM	Level 1 instruction cache software prefetch.
	L1I_CACHE_RD	Level 1 instruction cache demand fetch.
	L1I_CACHE_REFILL_HWPRF	Level 1 instruction cache refill, hardware prefetch.
	L1I_CACHE_REFILL_PERCYC	Level 1 instruction or unified cache refills in progress.
	L1I_CACHE_REFILL_PRF	Level 1 instruction cache refill, prefetch hit.
	L1I_CACHE_REFILL_PRFM	Level 1 instruction cache refill, software prefetch.
	L1I_LFB_HIT_RD	Level 1 instruction cache demand fetch line-fill buffer hit.
	L1I_LFB_HIT_RD_FHWPRF	Level 1 instruction cache demand fetch line-fill buffer first hit, recently fetched by hardware prefetcher.
	L1I_LFB_HIT_RD_FPRF	Level 1 instruction cache demand fetch line-fill buffer first hit, recently fetched by prefetch.
	L1I_LFB_HIT_RD_FPRFM	Level 1 instruction cache demand fetch line-fill buffer first hit, recently fetched by software prefetch.
	L1I_LFB_HIT_RETIRED	Instruction architecturally executed, line-fill buffer hit in Level 1 instruction cache.
	L1I_TLB_HWPRF	Level 1 instruction TLB access, hardware prefetch.
	L1I_TLB_PRF	Level 1 instruction TLB access, prefetch.
	L1I_TLB_PRFM	Level 1 instruction TLB access, software prefetch.
	L1I_TLB_RD	Level 1 instruction TLB access, demand access.
	L2D_CACHE_HIT	Level 2 data cache hit.

Number	Mnemonic	Description
	L2D_CACHE_HITM_LDST_RETIRED	Load or store instruction architecturally executed, hit modified data in Level 2 data cache.
	L2D_CACHE_HITM_LD_RETIRED	Load instruction architecturally executed, hit modified data in Level 2 data cache.
	L2D_CACHE_HITM_RD	Level 2 data cache demand access hit modified, read.
	L2D_CACHE_HITM_RW	Level 2 data cache demand access hit modified.
	L2D_CACHE_HITM_ST_RETIRED	Store instruction architecturally executed, hit modified data in Level 2 data cache.
	L2D_CACHE_HITM_WR	Level 2 data cache demand access hit modified, write.
	L2D_CACHE_HIT_LDST_RETIRED	Load or store instruction architecturally executed, hit in Level 2 data cache.
	L2D_CACHE_HIT_LD_RETIRED	Load instruction architecturally executed, hit in Level 2 data cache.
	L2D_CACHE_HIT_PRFM	Level 2 data cache software prefetch hit.
	L2D_CACHE_HIT_RD	Level 2 data cache demand access hit, read.
	L2D_CACHE_HIT_RD_FHWPRF	Level 2 data cache demand access first hit, read, fetched by hardware prefetcher.
	L2D_CACHE_HIT_RD_FPRF	Level 2 data cache demand access first hit, read, fetched by prefetch.
	L2D_CACHE_HIT_RD_FPRFM	Level 2 data cache demand access first hit, read, fetched by software prefetch.
	L2D_CACHE_HIT_RW	Level 2 data cache demand access hit.
	L2D_CACHE_HIT_RW_FHWPRF	Level 2 data cache demand access first hit, fetched by hardware prefetcher.
	L2D_CACHE_HIT_RW_FPRF	Level 2 data cache demand access first hit, fetched by prefetch.
	L2D_CACHE_HIT_RW_FPRFM	Level 2 data cache demand access first hit, fetched by software prefetch.
	L2D_CACHE_HIT_ST_RETIRED	Store instruction architecturally executed, hit in Level 2 data cache.
	L2D_CACHE_HIT_WR	Level 2 data cache demand access hit, write.
	L2D_CACHE_HIT_WR_FHWPRF	Level 2 data cache demand access first hit, write, fetched by hardware prefetcher.
	L2D_CACHE_HIT_WR_FPRF	Level 2 data cache demand access first hit, write, fetched by prefetch.

Number	Mnemonic	Description
	L2D_CACHE_HIT_WR_FPRFM	Level 2 data cache demand access first hit, write, fetched by software prefetch.
	L2D_CACHE_HWPRF	Level 2 data cache hardware prefetch.
	L2D_CACHE_LMISS_RD	Level 2 data cache long-latency read miss.
	L2D_CACHE_MISS	Level 2 data cache demand access miss.
	L2D_CACHE_MISS_LDST_RETIRED	Load or store instruction architecturally executed, miss in Level 2 data cache.
	L2D_CACHE_MISS_LD_RETIRED	Load instruction architecturally executed, miss in Level 2 data cache.
	L2D_CACHE_MISS_ST_RETIRED	Store instruction architecturally executed, miss in Level 2 data cache.
	L2D_CACHE_PRF	Level 2 data cache, prefetch hit.
	L2D_CACHE_PRFM	Level 2 data cache software prefetch.
	L2D_CACHE_REFILL_HWPRF	Level 2 data cache refill, hardware prefetch.
	L2D_CACHE_REFILL_PERCYC	Level 2 data or unified cache refills in progress.
	L2D_CACHE_REFILL_PRF	Level 2 data cache refill, prefetch hit.
	L2D_CACHE_REFILL_PRFM	Level 2 data cache refill, software prefetch.
	L2D_CACHE_RW	Level 2 data cache demand access.
	L2D_LFB_HIT_LDST_RETIRED	Load or store instruction architecturally executed, line-fill buffer hit in Level 2 data cache.
	L2D_LFB_HIT_LD_RETIRED	Load instruction architecturally executed, line-fill buffer hit in Level 2 data cache.
	L2D_LFB_HIT_RD	Level 2 data cache demand access line-fill buffer hit, read.
	L2D_LFB_HIT_RD_FHWPRF	Level 2 data cache demand access line-fill buffer first hit, read, recently fetched by hardware prefetcher.
	L2D_LFB_HIT_RD_FPRF	Level 2 data cache demand access line-fill buffer first hit, read, recently fetched by prefetch.
	L2D_LFB_HIT_RD_FPRFM	Level 2 data cache demand access line-fill buffer first hit, read, recently fetched by software prefetch.
	L2D_LFB_HIT_RW	Level 2 data cache demand access line-fill buffer hit.
	L2D_LFB_HIT_RW_FHWPRF	Level 2 data cache demand access line-fill buffer first hit, recently fetched by hardware prefetcher.

Number	Mnemonic	Description
	L2D_LFB_HIT_RW_FPRF	Level 2 data cache demand access line-fill buffer first hit, recently fetched by prefetch.
	L2D_LFB_HIT_RW_FPRFM	Level 2 data cache demand access line-fill buffer first hit, recently fetched by software prefetch.
	L2D_LFB_HIT_ST_RETIRED	Store instruction architecturally executed, line-fill buffer hit in Level 2 data cache.
	L2D_LFB_HIT_WR	Level 2 data cache demand access line-fill buffer hit, write.
	L2D_LFB_HIT_WR_FHWPRF	Level 2 data cache demand access line-fill buffer first hit, write, recently fetched by hardware prefetcher.
	L2D_LFB_HIT_WR_FPRF	Level 2 data cache demand access line-fill buffer first hit, write, recently fetched by prefetch.
	L2D_LFB_HIT_WR_FPRFM	Level 2 data cache demand access line-fill buffer first hit, write, recently fetched by software prefetch.
	L2I_CACHE_HIT	Level 2 instruction cache hit.
	L2I_CACHE_HIT_PRFM	Level 2 instruction cache software prefetch hit.
	L2I_CACHE_HIT_RD	Level 2 instruction cache demand fetch hit.
	L2I_CACHE_HIT_RD_FHWPRF	Level 2 instruction cache demand fetch first hit, fetched by hardware prefetcher.
	L2I_CACHE_HIT_RD_FPRF	Level 2 instruction cache demand fetch first hit, fetched by prefetch.
	L2I_CACHE_HIT_RD_FPRFM	Level 2 instruction cache demand fetch first hit, fetched by software prefetch.
	L2I_CACHE_HIT_RETIRED	Instruction architecturally executed, hit in Level 2 instruction cache.
	L2I_CACHE_HWPRF	Level 2 instruction cache hardware prefetch.
	L2I_CACHE_LMISS	Level 2 instruction cache long-latency miss.
	L2I_CACHE_MISS_RETIRED	Instruction architecturally executed, miss in Level 2 instruction cache.
	L2I_CACHE_PRF	Level 2 instruction cache, prefetch hit.
	L2I_CACHE_PRFM	Level 2 instruction cache software prefetch.
	L2I_CACHE_RD	Level 2 instruction cache demand fetch.
	L2I_CACHE_REFILL_HWPRF	Level 2 instruction cache refill, hardware prefetch.
	L2I_CACHE_REFILL_PERCYC	Level 2 instruction or unified cache refills in progress.

Number	Mnemonic	Description
	L2I_CACHE_REFILL_PRF	Level 2 instruction cache refill, prefetch hit.
	L2I_CACHE_REFILL_PRFM	Level 2 instruction cache refill, software prefetch.
	L2I_LFB_HIT_RD	Level 2 instruction cache demand fetch line-fill buffer hit.
	L2I_LFB_HIT_RD_FHWPRF	Level 2 instruction cache demand fetch line-fill buffer first hit, recently fetched by hardware prefetcher.
	L2I_LFB_HIT_RD_FPRF	Level 2 instruction cache demand fetch line-fill buffer first hit, recently fetched by prefetch.
	L2I_LFB_HIT_RD_FPRFM	Level 2 instruction cache demand fetch line-fill buffer first hit, recently fetched by software prefetch.
	L2I_LFB_HIT_RETIRED	Instruction architecturally executed, line-fill buffer hit in Level 2 instruction cache.
	L3D_CACHE_HIT	Level 3 data cache hit.
	L3D_CACHE_HITM_LDST_RETIRED	Load or store instruction architecturally executed, hit modified data in Level 3 data cache.
	L3D_CACHE_HITM_LD_RETIRED	Load instruction architecturally executed, hit modified data in Level 3 data cache.
	L3D_CACHE_HITM_RD	Level 3 data cache demand access hit modified, read.
	L3D_CACHE_HITM_RW	Level 3 data cache demand access hit modified.
	L3D_CACHE_HITM_ST_RETIRED	Store instruction architecturally executed, hit modified data in Level 3 data cache.
	L3D_CACHE_HITM_WR	Level 3 data cache demand access hit modified, write.
	L3D_CACHE_HIT_LDST_RETIRED	Load or store instruction architecturally executed, hit in Level 3 data cache.
	L3D_CACHE_HIT_LD_RETIRED	Load instruction architecturally executed, hit in Level 3 data cache.
	L3D_CACHE_HIT_PRFM	Level 3 data cache software prefetch hit.
	L3D_CACHE_HIT_RD	Level 3 data cache demand access hit, read.
	L3D_CACHE_HIT_RD_FHWPRF	Level 3 data cache demand access first hit, read, fetched by hardware prefetcher.
	L3D_CACHE_HIT_RD_FPRF	Level 3 data cache demand access first hit, read, fetched by prefetch.

Number	Mnemonic	Description
	L3D_CACHE_HIT_RD_FPRFM	Level 3 data cache demand access first hit, read, fetched by software prefetch.
	L3D_CACHE_HIT_RW	Level 3 data cache demand access hit.
	L3D_CACHE_HIT_RW_FHWPRF	Level 3 data cache demand access first hit, fetched by hardware prefetcher.
	L3D_CACHE_HIT_RW_FPRF	Level 3 data cache demand access first hit, fetched by prefetch.
	L3D_CACHE_HIT_RW_FPRFM	Level 3 data cache demand access first hit, fetched by software prefetch.
	L3D_CACHE_HIT_ST_RETIRED	Store instruction architecturally executed, hit in Level 3 data cache.
	L3D_CACHE_HIT_WR	Level 3 data cache demand access hit, write.
	L3D_CACHE_HIT_WR_FHWPRF	Level 3 data cache demand access first hit, write, fetched by hardware prefetcher.
	L3D_CACHE_HIT_WR_FPRF	Level 3 data cache demand access first hit, write, fetched by prefetch.
	L3D_CACHE_HIT_WR_FPRFM	Level 3 data cache demand access first hit, write, fetched by software prefetch.
	L3D_CACHE_HWPRF	Level 3 data cache hardware prefetch.
	L3D_CACHE_LMISS_RD	Level 3 data cache long-latency read miss.
	L3D_CACHE_MISS	Level 3 data cache demand access miss.
	L3D_CACHE_MISS_LDST_RETIRED	Load or store instruction architecturally executed, miss in Level 3 data cache.
	L3D_CACHE_MISS_LD_RETIRED	Load instruction architecturally executed, miss in Level 3 data cache.
	L3D_CACHE_MISS_ST_RETIRED	Store instruction architecturally executed, miss in Level 3 data cache.
	L3D_CACHE_PRF	Level 3 data cache, prefetch hit.
	L3D_CACHE_PRFM	Level 3 data cache software prefetch.
	L3D_CACHE_REFILL_HWPRF	Level 3 data cache refill, hardware prefetch.
	L3D_CACHE_REFILL_PERCYC	Level 3 data or unified cache refills in progress.
	L3D_CACHE_REFILL_PRF	Level 3 data cache refill, prefetch hit.
	L3D_CACHE_REFILL_PRFM	Level 3 data cache refill, software prefetch.
	L3D_CACHE_RW	Level 3 data cache demand access.
	L3D_LFB_HIT_LDST_RETIRED	Load or store instruction architecturally executed, line-fill buffer hit in Level 3 data cache.

Number	Mnemonic	Description
	L3D_LFB_HIT_LD_RETIRED	Load instruction architecturally executed, line-fill buffer hit in Level 3 data cache.
	L3D_LFB_HIT_RD	Level 3 data cache demand access line-fill buffer hit, read.
	L3D_LFB_HIT_RD_FHWPRF	Level 3 data cache demand access line-fill buffer first hit, read, recently fetched by hardware prefetcher.
	L3D_LFB_HIT_RD_FPRF	Level 3 data cache demand access line-fill buffer first hit, read, recently fetched by prefetch.
	L3D_LFB_HIT_RD_FPRFM	Level 3 data cache demand access line-fill buffer first hit, read, recently fetched by software prefetch.
	L3D_LFB_HIT_RW	Level 3 data cache demand access line-fill buffer hit.
	L3D_LFB_HIT_RW_FHWPRF	Level 3 data cache demand access line-fill buffer first hit, recently fetched by hardware prefetcher.
	L3D_LFB_HIT_RW_FPRF	Level 3 data cache demand access line-fill buffer first hit, recently fetched by prefetch.
	L3D_LFB_HIT_RW_FPRFM	Level 3 data cache demand access line-fill buffer first hit, recently fetched by software prefetch.
	L3D_LFB_HIT_ST_RETIRED	Store instruction architecturally executed, line-fill buffer hit in Level 3 data cache.
	L3D_LFB_HIT_WR	Level 3 data cache demand access line-fill buffer hit, write.
	L3D_LFB_HIT_WR_FHWPRF	Level 3 data cache demand access line-fill buffer first hit, write, recently fetched by hardware prefetcher.
	L3D_LFB_HIT_WR_FPRF	Level 3 data cache demand access line-fill buffer first hit, write, recently fetched by prefetch.
	L3D_LFB_HIT_WR_FPRFM	Level 3 data cache demand access line-fill buffer first hit, write, recently fetched by software prefetch.
	LDST_ALIGN_LAT	Access with additional latency from alignment.
	LDST_ANY_RETIRED	Instruction architecturally executed, load or store.
	LDST_FIXED_BYTES_SPEC	Non-scalable load and store bytes speculatively executed.
	LDST_FIXED_OPS_SPEC	Non-scalable load or store element operations speculatively executed.
	LD_ALIGN_LAT	Load with additional latency from alignment.
	LD_ANY_RETIRED	Instruction architecturally executed, load.

Number	Mnemonic	Description
	LD_FIXED_BYTES_SPEC	Non-scalable load bytes speculatively executed.
	LD_FIXED_OPS_SPEC	Non-scalable load element operations speculatively executed.
	LL_CACHE_HIT	Last level cache hit.
	LL_CACHE_HITM_LDST_RETIRED	Load or store instruction architecturally executed, hit modified data in Last level cache.
	LL_CACHE_HITM_LD_RETIRED	Load instruction architecturally executed, hit modified data in Last level cache.
	LL_CACHE_HITM_RD	Last level cache demand access hit modified, read.
	LL_CACHE_HITM_RW	Last level cache demand access hit modified.
	LL_CACHE_HITM_ST_RETIRED	Store instruction architecturally executed, hit modified data in Last level cache.
	LL_CACHE_HITM_WR	Last level cache demand access hit modified, write.
	LL_CACHE_HIT_LDST_RETIRED	Load or store instruction architecturally executed, hit in Last level cache.
	LL_CACHE_HIT_LD_RETIRED	Load instruction architecturally executed, hit in Last level cache.
	LL_CACHE_HIT_PRFM	Last level cache software prefetch hit.
	LL_CACHE_HIT_RD	Last level cache demand access hit, read.
	LL_CACHE_HIT_RD_FHWPRF	Last level cache demand access first hit, read, fetched by hardware prefetcher.
	LL_CACHE_HIT_RD_FPRF	Last level cache demand access first hit, read, fetched by prefetch.
	LL_CACHE_HIT_RD_FPRFM	Last level cache demand access first hit, read, fetched by software prefetch.
	LL_CACHE_HIT_RW	Last level cache demand access hit.
	LL_CACHE_HIT_RW_FHWPRF	Last level cache demand access first hit, fetched by hardware prefetcher.
	LL_CACHE_HIT_RW_FPRF	Last level cache demand access first hit, fetched by prefetch.
	LL_CACHE_HIT_RW_FPRFM	Last level cache demand access first hit, fetched by software prefetch.
	LL_CACHE_HIT_ST_RETIRED	Store instruction architecturally executed, hit in Last level cache.
	LL_CACHE_HIT_WR	Last level cache demand access hit, write.
	LL_CACHE_HIT_WR_FHWPRF	Last level cache demand access first hit, write, fetched by hardware prefetcher.

Number	Mnemonic	Description
	LL_CACHE_HIT_WR_FPRF	Last level cache demand access first hit, write, fetched by prefetch.
	LL_CACHE_HIT_WR_FPRFM	Last level cache demand access first hit, write, fetched by software prefetch.
	LL_CACHE_HWPRF	Last level cache hardware prefetch.
	LL_CACHE_MISS_LDST_RETIRED	Load or store instruction architecturally executed, miss in Last level cache.
	LL_CACHE_MISS_LD_RETIRED	Load instruction architecturally executed, miss in Last level cache.
	LL_CACHE_MISS_ST_RETIRED	Store instruction architecturally executed, miss in Last level cache.
	LL_CACHE_PRF	Last level cache, prefetch hit.
	LL_CACHE_PRFM	Last level cache software prefetch.
	LL_CACHE_REFILL	Last level cache refill.
	LL_CACHE_REFILL_HWPRF	Last level cache refill, hardware prefetch.
	LL_CACHE_REFILL_PRF	Last level cache refill, prefetch hit.
	LL_CACHE_REFILL_PRFM	Last level cache refill, software prefetch.
	LL_CACHE_REFILL_WR	Last level cache refill, write.
	LL_CACHE_RW	Last level cache demand access.
	LL_CACHE_WB	Last level cache write-back.
	LL_CACHE_WR	Last level cache access, write.
	LL_LFB_HIT_LDST_RETIRED	Load or store instruction architecturally executed, line-fill buffer hit in Last level cache.
	LL_LFB_HIT_LD_RETIRED	Load instruction architecturally executed, line-fill buffer hit in Last level cache.
	LL_LFB_HIT_RD	Last level cache demand access line-fill buffer hit, read.
	LL_LFB_HIT_RD_FHWPRF	Last level cache demand access line-fill buffer first hit, read, recently fetched by hardware prefetcher.
	LL_LFB_HIT_RD_FPRF	Last level cache demand access line-fill buffer first hit, read, recently fetched by prefetch.
	LL_LFB_HIT_RD_FPRFM	Last level cache demand access line-fill buffer first hit, read, recently fetched by software prefetch.
	LL_LFB_HIT_RW	Last level cache demand access line-fill buffer hit.
	LL_LFB_HIT_RW_FHWPRF	Last level cache demand access line-fill buffer first hit, recently fetched by hardware prefetcher.

Number	Mnemonic	Description
	LL_LFB_HIT_RW_FPRF	Last level cache demand access line-fill buffer first hit, recently fetched by prefetch.
	LL_LFB_HIT_RW_FPRFM	Last level cache demand access line-fill buffer first hit, recently fetched by software prefetch.
	LL_LFB_HIT_ST_RETIRED	Store instruction architecturally executed, line-fill buffer hit in Last level cache.
	LL_LFB_HIT_WR	Last level cache demand access line-fill buffer hit, write.
	LL_LFB_HIT_WR_FHWPRF	Last level cache demand access line-fill buffer first hit, write, recently fetched by hardware prefetcher.
	LL_LFB_HIT_WR_FPRF	Last level cache demand access line-fill buffer first hit, write, recently fetched by prefetch.
	LL_LFB_HIT_WR_FPRFM	Last level cache demand access line-fill buffer first hit, write, recently fetched by software prefetch.
	LOCAL_MEM	Access to memory attached to this device.
	LOCAL_MEM_LDST_RETIRED	Load or store instruction architecturally executed, access to memory attached to this device.
	LOCAL_MEM_LD_RETIRED	Load instruction architecturally executed, access to memory attached to this device.
	LOCAL_MEM_PRFM	Access to memory attached to this device, software prefetch.
	LOCAL_MEM_RD	Access to memory attached to this device, demand access, read.
	LOCAL_MEM_RW	Access to memory attached to this device, demand access.
	LOCAL_MEM_ST_RETIRED	Store instruction architecturally executed, access to memory attached to this device.
	LOCAL_MEM_WR	Access to memory attached to this device, demand access, write.
	MEM_ACCESS_PRFM	Data memory access, software prefetch.
	MEM_ACCESS_RD_PERCYC	Data memory reads in progress.
	MEM_ACCESS_RW	Data memory access, demand access.
	N1_CACHE1_HITM_RD	Cache type 1 at distance 1 demand access hit modified, read.
	N1_CACHE1_HIT_PRFM	Cache type 1 at distance 1 software prefetch hit.
	N1_CACHE1_HIT_RD	Cache type 1 at distance 1 demand access hit, read.

Number	Mnemonic	Description
	N1_CACHE2_HITM_RD	Cache type 2 at distance 1 demand access hit modified, read.
	N1_CACHE2_HIT_PRFM	Cache type 2 at distance 1 software prefetch hit.
	N1_CACHE2_HIT_RD	Cache type 2 at distance 1 demand access hit, read.
	N1_CACHE3_HITM_RD	Cache type 3 at distance 1 demand access hit modified, read.
	N1_CACHE3_HIT_PRFM	Cache type 3 at distance 1 software prefetch hit.
	N1_CACHE3_HIT_RD	Cache type 3 at distance 1 demand access hit, read.
	N1_CACHE_HITM_RD	Cache at distance 1, demand access hit modified, read.
	N1_CACHE_HIT_PRFM	Cache at distance 1, software prefetch hit.
	N1_CACHE_HIT_RD	Cache at distance 1, demand access hit, read.
	N1_LFB1_HIT_RD	Cache type 1 at distance 1 demand access line-fill buffer hit, read.
	N1_LFB2_HIT_RD	Cache type 2 at distance 1 demand access line-fill buffer hit, read.
	N1_LFB3_HIT_RD	Cache type 3 at distance 1 demand access line-fill buffer hit, read.
	N1_LFB_HIT_RD	Cache at distance 1 demand access line-fill buffer hit, read.
	N1_MEM1_PRFM	Access to type 1 memory at distance 1, software prefetch.
	N1_MEM1_RD	Access to type 1 memory at distance 1, demand access, read.
	N1_MEM2_PRFM	Access to type 2 memory at distance 1, software prefetch.
	N1_MEM2_RD	Access to type 2 memory at distance 1, demand access, read.
	N1_MEM3_PRFM	Access to type 3 memory at distance 1, software prefetch.
	N1_MEM3_RD	Access to type 3 memory at distance 1, demand access, read.
	N1_MEM_PRFM	Access to memory at distance 1, software prefetch.
	N1_MEM_RD	Access to memory at distance 1, demand access, read.
	N2_CACHE1_HITM_RD	Cache type 1 at distance 2 demand access hit modified, read.
	N2_CACHE1_HIT_PRFM	Cache type 1 at distance 2 software prefetch hit.
	N2_CACHE1_HIT_RD	Cache type 1 at distance 2 demand access hit, read.

Number	Mnemonic	Description
	N2_CACHE2_HITM_RD	Cache type 2 at distance 2 demand access hit modified, read.
	N2_CACHE2_HIT_PRFM	Cache type 2 at distance 2 software prefetch hit.
	N2_CACHE2_HIT_RD	Cache type 2 at distance 2 demand access hit, read.
	N2_CACHE3_HITM_RD	Cache type 3 at distance 2 demand access hit modified, read.
	N2_CACHE3_HIT_PRFM	Cache type 3 at distance 2 software prefetch hit.
	N2_CACHE3_HIT_RD	Cache type 3 at distance 2 demand access hit, read.
	N2_CACHE_HITM_RD	Cache at distance 2, demand access hit modified, read.
	N2_CACHE_HIT_PRFM	Cache at distance 2, software prefetch hit.
	N2_CACHE_HIT_RD	Cache at distance 2, demand access hit, read.
	N2_LFB1_HIT_RD	Cache type 1 at distance 2 demand access line-fill buffer hit, read.
	N2_LFB2_HIT_RD	Cache type 2 at distance 2 demand access line-fill buffer hit, read.
	N2_LFB3_HIT_RD	Cache type 3 at distance 2 demand access line-fill buffer hit, read.
	N2_LFB_HIT_RD	Cache at distance 2 demand access line-fill buffer hit, read.
	N2_MEM1_PRFM	Access to type 1 memory at distance 2, software prefetch.
	N2_MEM1_RD	Access to type 1 memory at distance 2, demand access, read.
	N2_MEM2_PRFM	Access to type 2 memory at distance 2, software prefetch.
	N2_MEM2_RD	Access to type 2 memory at distance 2, demand access, read.
	N2_MEM3_PRFM	Access to type 3 memory at distance 2, software prefetch.
	N2_MEM3_RD	Access to type 3 memory at distance 2, demand access, read.
	N2_MEM_PRFM	Access to memory at distance 2, software prefetch.
	N2_MEM_RD	Access to memory at distance 2, demand access, read.
	N3_CACHE1_HITM_RD	Cache type 1 at distance 3 demand access hit modified, read.
	N3_CACHE1_HIT_PRFM	Cache type 1 at distance 3 software prefetch hit.
	N3_CACHE1_HIT_RD	Cache type 1 at distance 3 demand access hit, read.

Number	Mnemonic	Description
	N3_CACHE2_HITM_RD	Cache type 2 at distance 3 demand access hit modified, read.
	N3_CACHE2_HIT_PRFM	Cache type 2 at distance 3 software prefetch hit.
	N3_CACHE2_HIT_RD	Cache type 2 at distance 3 demand access hit, read.
	N3_CACHE3_HITM_RD	Cache type 3 at distance 3 demand access hit modified, read.
	N3_CACHE3_HIT_PRFM	Cache type 3 at distance 3 software prefetch hit.
	N3_CACHE3_HIT_RD	Cache type 3 at distance 3 demand access hit, read.
	N3_CACHE_HITM_RD	Cache at distance 3, demand access hit modified, read.
	N3_CACHE_HIT_PRFM	Cache at distance 3, software prefetch hit.
	N3_CACHE_HIT_RD	Cache at distance 3, demand access hit, read.
	N3_LFB1_HIT_RD	Cache type 1 at distance 3 demand access line-fill buffer hit, read.
	N3_LFB2_HIT_RD	Cache type 2 at distance 3 demand access line-fill buffer hit, read.
	N3_LFB3_HIT_RD	Cache type 3 at distance 3 demand access line-fill buffer hit, read.
	N3_LFB_HIT_RD	Cache at distance 3 demand access line-fill buffer hit, read.
	N3_MEM1_PRFM	Access to type 1 memory at distance 3, software prefetch.
	N3_MEM1_RD	Access to type 1 memory at distance 3, demand access, read.
	N3_MEM2_PRFM	Access to type 2 memory at distance 3, software prefetch.
	N3_MEM2_RD	Access to type 2 memory at distance 3, demand access, read.
	N3_MEM3_PRFM	Access to type 3 memory at distance 3, software prefetch.
	N3_MEM3_RD	Access to type 3 memory at distance 3, demand access, read.
	N3_MEM_PRFM	Access to memory at distance 3, software prefetch.
	N3_MEM_RD	Access to memory at distance 3, demand access, read.
	N4_CACHE1_HITM_RD	Cache type 1 at distance 4 demand access hit modified, read.
	N4_CACHE1_HIT_PRFM	Cache type 1 at distance 4 software prefetch hit.
	N4_CACHE1_HIT_RD	Cache type 1 at distance 4 demand access hit, read.

Number	Mnemonic	Description
	N4_CACHE2_HITM_RD	Cache type 2 at distance 4 demand access hit modified, read.
	N4_CACHE2_HIT_PRFM	Cache type 2 at distance 4 software prefetch hit.
	N4_CACHE2_HIT_RD	Cache type 2 at distance 4 demand access hit, read.
	N4_CACHE3_HITM_RD	Cache type 3 at distance 4 demand access hit modified, read.
	N4_CACHE3_HIT_PRFM	Cache type 3 at distance 4 software prefetch hit.
	N4_CACHE3_HIT_RD	Cache type 3 at distance 4 demand access hit, read.
	N4_CACHE_HITM_RD	Cache at distance 4, demand access hit modified, read.
	N4_CACHE_HIT_PRFM	Cache at distance 4, software prefetch hit.
	N4_CACHE_HIT_RD	Cache at distance 4, demand access hit, read.
	N4_LFB1_HIT_RD	Cache type 1 at distance 4 demand access line-fill buffer hit, read.
	N4_LFB2_HIT_RD	Cache type 2 at distance 4 demand access line-fill buffer hit, read.
	N4_LFB3_HIT_RD	Cache type 3 at distance 4 demand access line-fill buffer hit, read.
	N4_LFB_HIT_RD	Cache at distance 4 demand access line-fill buffer hit, read.
	N4_MEM1_PRFM	Access to type 1 memory at distance 4, software prefetch.
	N4_MEM1_RD	Access to type 1 memory at distance 4, demand access, read.
	N4_MEM2_PRFM	Access to type 2 memory at distance 4, software prefetch.
	N4_MEM2_RD	Access to type 2 memory at distance 4, demand access, read.
	N4_MEM3_PRFM	Access to type 3 memory at distance 4, software prefetch.
	N4_MEM3_RD	Access to type 3 memory at distance 4, demand access, read.
	N4_MEM_PRFM	Access to memory at distance 4, software prefetch.
	N4_MEM_RD	Access to memory at distance 4, demand access, read.
	NONFP_SPEC	Non-floating-point operation speculatively executed.
	PMU_SNAPSHOT	Successful PMU capture event.
	PRF_RETIRED	Instruction architecturally executed, prefetch.

Number	Mnemonic	Description
	PRF_SPEC	Operation speculatively executed, prefetch.
	REMOTE_ACCESS_WR	Access to a remote device, write.
	REMOTE_CACHE_HITM_RD	Remote cache demand access hit modified, read.
	REMOTE_CACHE_HIT_PRFM	Remote cache software prefetch hit.
	REMOTE_CACHE_HIT_RD	Remote cache demand access hit, read.
	REMOTE_LFB_HIT_RD	Remote cache demand access line-fill buffer hit, read.
	REMOTE_MEM	Access to memory attached to a remote device.
	REMOTE_MEM_LDST_RETIRED	Load or store instruction architecturally executed, access to memory attached to a remote device.
	REMOTE_MEM_LD_RETIRED	Load instruction architecturally executed, access to memory attached to a remote device.
	REMOTE_MEM_PRFM	Access to memory attached to a remote device, software prefetch.
	REMOTE_MEM_RD	Access to memory attached to a remote device, demand access, read.
	REMOTE_MEM_RW	Access to memory attached to a remote device, demand access.
	REMOTE_MEM_ST_RETIRED	Store instruction architecturally executed, access to memory attached to a remote device.
	REMOTE_MEM_WR	Access to memory attached to a remote device, demand access, write.
	SAMPLE_BUFFER_FULL	Profiling Buffer full.
	SAMPLE_COLLISION	Statistical Profiling sample collided with previous sample.
	SAMPLE_FEED	Statistical Profiling sample taken.
	SAMPLE_FEED_DS	Statistical Profiling sample taken, selected Data Source.
	SAMPLE_FILTRATE	Statistical Profiling sample taken and not removed by filtering.
	SAMPLE_POP	Statistical Profiling sample population.
	SE_FP_ADDSUB_SPEC	Operation speculatively executed, Advanced SIMD, SVE, or SME SIMD floating-point addition or subtraction.
	SE_FP_BF16_MIN_SPEC	Advanced SIMD, SVE, or SME data processing operation speculatively executed, smallest type is BFloat16 floating-point.

Number	Mnemonic	Description
	SE_FP_BF16_SPEC	Operation speculatively executed, Advanced SIMD, SVE, or SME SIMD BFloat16 floating-point, data-processing.
	SE_FP_DOT_SPEC	Operation speculatively executed, Advanced SIMD, SVE, or SME SIMD floating-point dot product.
	SE_FP_DP_SPEC	Operation speculatively executed, Advanced SIMD, SVE, or SME SIMD double-precision floating-point, data-processing.
	SE_FP_FMA_SPEC	Operation speculatively executed, Advanced SIMD, SVE, or SME SIMD floating-point multiply-add or multiply-subtract.
	SE_FP_FP8_MIN_SPEC	Advanced SIMD, SVE, or SME data processing operation speculatively executed, smallest type is 8-bit floating-point.
	SE_FP_HP_MIN_SPEC	Advanced SIMD, SVE, or SME data processing operation speculatively executed, smallest type is half-precision floating-point.
	SE_FP_HP_SPEC	Operation speculatively executed, Advanced SIMD, SVE, or SME SIMD half-precision floating-point, data-processing.
	SE_FP_SPEC	Operation speculatively executed, Advanced SIMD, SVE, or SME SIMD floating-point, data-processing.
	SE_FP_SP_MIN_SPEC	Advanced SIMD, SVE, or SME data processing operation speculatively executed, smallest type is single-precision floating-point.
	SE_FP_SP_SPEC	Operation speculatively executed, Advanced SIMD, SVE, or SME SIMD single-precision floating-point, data-processing.
	SE_INST_RETIRED	Instruction architecturally executed, Advanced SIMD, SVE, or SME.
	SE_INST_SPEC	Operation speculatively executed, Advanced SIMD, SVE, or SME.
	SE_INT16_SPEC	Operation speculatively executed, Advanced SIMD, SVE, or SME SIMD 16-bit integer, data-processing.
	SE_INT32_SPEC	Operation speculatively executed, Advanced SIMD, SVE, or SME SIMD 32-bit integer, data-processing.
	SE_INT64_SPEC	Operation speculatively executed, Advanced SIMD, SVE, or SME SIMD 64-bit integer, data-processing.

Number	Mnemonic	Description
	SE_INT8_SPEC	Operation speculatively executed, Advanced SIMD, SVE, or SME SIMD 8-bit integer, data-processing.
	SE_INT_DOT_SPEC	Operation speculatively executed, Advanced SIMD, SVE, or SME SIMD integer dot product.
	SE_INT_MUL_SPEC	Operation speculatively executed, Advanced SIMD, SVE, or SME SIMD integer multiply or multiply-accumulate.
	SE_INT_SPEC	Operation speculatively executed, Advanced SIMD, SVE, or SME SIMD integer, data-processing.
	SE_LUT_SPEC	Lookup table operation speculatively executed, Advanced SIMD, SVE, or SME data processing.
	SE_RETIRED	Instruction architecturally executed, Advanced SIMD, SVE, or SME data processing.
	SE_SPEC	Operation speculatively executed, Advanced SIMD, SVE, or SME data processing.
	SIMD_INST_RETIRED	Instruction architecturally executed, SIMD.
	SIMD_INST_SPEC	Operation speculatively executed, SIMD.
	SIMD_UOP_SPEC	Microarchitectural operation speculatively executed, SIMD.
	SME_FP_BF16_MIN_SPEC	SME data processing operation speculatively executed, smallest type is BFloat16 floating-point.
	SME_FP_FP8_MIN_SPEC	SME data processing operation speculatively executed, smallest type is 8-bit floating-point.
	SME_FP_HP_MIN_SPEC	SME data processing operation speculatively executed, smallest type is half-precision floating-point.
	SME_FP_SP_MIN_SPEC	SME data processing operation speculatively executed, smallest type is single-precision floating-point.
	STALL_BACKEND_BUSY	Backend stall cycles, backend busy.
	STALL_BACKEND_CPUBOUND	Backend stall cycles, processor bound.
	STALL_BACKEND_GCSTLB	Backend stall cycles, GCS TLB.
	STALL_BACKEND_ILOCK	Backend stall cycles, input dependency.
	STALL_BACKEND_L1D	Backend stall cycles, level 1 data cache.
	STALL_BACKEND_L1GCS	Backend stall cycles, Level 1 GCS cache.

Number	Mnemonic	Description
	STALL_BACKEND_L2D	Backend stall cycles, level 2 data cache.
	STALL_BACKEND_MEM	Memory stall cycles.
	STALL_BACKEND_MEMBOUND	Backend stall cycles, memory bound.
	STALL_BACKEND_RENAME	Backend stall cycles, rename full.
	STALL_BACKEND_ST	Backend stall cycles, store.
	STALL_BACKEND_TLB	Backend stall cycles, TLB.
	STALL_FRONTEND_CPUBOUND	Frontend stall cycles, processor bound.
	STALL_FRONTEND_FLOW	Frontend stall cycles, flow control.
	STALL_FRONTEND_FLUSH	Frontend stall cycles, flush recovery.
	STALL_FRONTEND_L1I	Frontend stall cycles, level 1 instruction cache.
	STALL_FRONTEND_L2I	Frontend stall cycles, level 2 instruction cache.
	STALL_FRONTEND_MEM	Frontend stall cycles, last level PE cache or memory.
	STALL_FRONTEND_MEMBOUND	Frontend stall cycles, memory bound.
	STALL_FRONTEND_RENAME	Frontend stall cycles, rename full.
	STALL_FRONTEND_TLB	Frontend stall cycles, TLB.
	ST_ALIGN_LAT	Store with additional latency from alignment.
	ST_ANY_RETIRED	Instruction architecturally executed, store.
	ST_FIXED_BYTES_SPEC	Non-scalable store bytes speculatively executed.
	ST_FIXED_OPS_SPEC	Non-scalable store element operations speculatively executed.
	SVE_FP_BF16_MIN_SPEC	SVE data processing operation speculatively executed, smallest type is BFloat16 floating-point.
	SVE_FP_FP8_MIN_SPEC	SVE data processing operation speculatively executed, smallest type is 8-bit floating-point.
	SVE_FP_HP_MIN_SPEC	SVE data processing operation speculatively executed, smallest type is half-precision floating-point.
	SVE_FP_PREDUCE_SPEC	Floating-point operation speculatively executed, SVE pairwise add step or pairwise reduce step.
	SVE_FP_SP_MIN_SPEC	SVE data processing operation speculatively executed, smallest type is single-precision floating-point.
	SVE_LUT_SPEC	Lookup table operation speculatively executed, SVE data processing.
	SVE_SPEC	Operation speculatively executed, SVE data processing.

Number	Mnemonic	Description
	TRB_TRIG	Trace buffer Trigger Event.
	TRB_WRAP	Trace buffer current write pointer wrapped.
	TRCEXTOUT0	Trace unit external output 0.
	TRCEXTOUT1	Trace unit external output 1.
	TRCEXTOUT2	Trace unit external output 2.
	TRCEXTOUT3	Trace unit external output 3.
	UOP_RETIRED	Micro-operation architecturally executed.
	UOP_SPEC	Microarchitectural operation speculatively executed.
	VFP_RETIRED	Instruction architecturally executed, scalar floating-point data processing.
	ZA_ACTIVE	CPU cycles, ZA enabled.

D7.3 Common event numbers

The event numbers of the common architectural and microarchitectural events are reserved for the specified events. Each of these event numbers must either:

- Be used for its assigned event.
- Not be used.

However, see [Required events](#).

When an implementation supports monitoring of an event that is assigned a common architectural or microarchitectural event number, Arm strongly recommends that it uses that number for the event. However, software might encounter implementations where an event assigned a number in this range is monitored using an event number from an IMPLEMENTATION DEFINED range.

Note

Arm might define other common architectural and microarchitectural event numbers. This is one reason why software must not assume that an event with an assigned common architectural or microarchitectural event number is never monitored using an event number from the IMPLEMENTATION DEFINED range.

It is IMPLEMENTATION DEFINED which events, including Common events, are generated by IMPLEMENTATION DEFINED extensions to the architecture, including accesses to IMPLEMENTATION DEFINED System registers and IMPLEMENTATION DEFINED System instructions. However, the functionality of the IMPLEMENTATION DEFINED extension must be appropriate for the generated events.

The common events are described in the following sections:

- [Common architectural events](#).
- [Common microarchitectural events](#).

The supported common architectural and microarchitectural events in the range 0x0000-0x003F are discoverable to software through the [PMCEID0](#) or [PMCEID1](#) register.

Arm recommends that the value of 0 is used for the [PMCEID0](#) or [PMCEID1](#) bit corresponding to any event that an implementation never generates, even if the implementation is considered to support but never count the event.

For example, if an implementation never generates the L1D_CACHE_ALLOCATE event, event 31, Arm recommends that [PMCEID0](#) [31] is RAZ.

However, for some implementations, an event in the common events range might be generated by the system, meaning behavior can vary between systems. In such a case, the corresponding [PMCEID \$n\$](#) bit might be RAO.

Event numbers that [Table D7-2](#) shows as allocated for common architectural and microarchitectural events that are not described in [Common architectural events](#) and [Common microarchitectural events](#) are reserved. Future revisions of this Manual, or of the architecture, might assign these reserved values to additional common events. Events that do not require additional features in the PMU can be implemented retrospectively, meaning an implementation of a particular version of the PMU specification might support common events that are first defined in a later version of the PMU specification.

Note

The requirement that an event that is implemented retrospectively *does not require additional features in the PMU* means that it must be possible to represent the event n in the [PMEVTYPER< \$n\$ >.evtCount](#) field. This means, for example, that an implementation with a 10-bit [PMEVTYPER< \$n\$ >.evtCount](#) field can only implement events with event numbers 0x0000-0x03FF.

D7.3.1 Common architectural events

The Common architectural events are:

0x0000, **SW_INCR**, Instruction architecturally executed, Condition code check pass, software increment

The counter counts each write to the PMSWINC_EL0 and **PMSWINC** register, for each implemented event counter <n>:

- In AArch64 state, if **PMEVTYPER**<n>_EL0.evtCount is 0x0000 then the counter counts each MSR write to PMSWINC_EL0 with bit [n] set to 1.
- In AArch32 state, if **PMEVTYPER**<n>_EL0.evtCount is 0x0000 then the counter counts each MCR write to **PMSWINC** with bit [n] set to 1.

If the PE performs two architecturally executed writes to the PMSWINC_EL0 or **PMSWINC** register without an intervening **Context synchronization event**, then the counter is incremented twice.

Note

In a multithreaded implementation, if the Effective value of **PMEVTYPER**<n>_EL0.MT is 1, then the counter counts writes by all PEs that have the same affinity at level 1 and above.

PMCEID0_EL0[0] reads as 1 if this event is implemented and 0 otherwise.

0x0006, **LD_RETIRED**, Instruction architecturally executed, Condition code check pass, load

The counter counts each architecturally-executed memory-reading instruction counted by **INST_RETIRED**.

It is IMPLEMENTATION DEFINED whether the prefetch instructions counted by **PRF_RETIRED** are counted as Memory-reading instructions:

- If the prefetch instructions are counted as Memory-reading instructions, then they are counted by **LD_RETIRED** and **LD_ANY_RETIRED**.
- Otherwise, if the prefetch instructions are not counted as Memory-reading instructions by **LD_RETIRED**, then it is further IMPLEMENTATION DEFINED which one of the following applies:
 - They are counted as data-processing instructions.
 - They are counted by **LDST_ANY_RETIRED**.

Arm recommends that if a prefetch instruction is not implemented as a NOP and the **PRF_RETIRED** event is not implemented, then the instruction is counted as a Memory-reading instruction.

PMCEID0_EL0[6] reads as 1 if this event is implemented and 0 otherwise.

0x0007, **ST_RETIRED**, Instruction architecturally executed, Condition code check pass, store

The counter counts each architecturally-executed **memory-writing instruction** counted by **INST_RETIRED**.

The counter does not count a Store-Exclusive instruction that fails.

PMCEID0_EL0[7] reads as 1 if this event is implemented and 0 otherwise.

0x0008, **INST_RETIRED**, Instruction architecturally executed

The counter counts each architecturally-executed instruction.

PMCEID0_EL0[8] reads as 1 if this event is implemented and 0 otherwise.

0x0009, **EXC_TAKEN**, Exception taken

The counter counts each exception taken.

It is IMPLEMENTATION SPECIFIC whether the counter counts each entry to Debug state.

Note

The counter counts the PE exceptions described in:

- For exceptions taken to an Exception level using AArch64, Exception entry.
- For exceptions taken to an Exception level using AArch32, [AArch32 state exception descriptions](#).

PMCEID0_EL0[9] reads as 1 if this event is implemented and 0 otherwise.

0x000A, **EXC_RETURN**, Instruction architecturally executed, Condition code check pass, exception return

The counter counts each architecturally-executed exception return instruction.

Instructions defined in the following sections are counted as exception return instructions:

- For an exception return from an Exception level using AArch64, Exception return.
- For an exception return from an Exception level using AArch32, [Exception return instructions](#).

It is IMPLEMENTATION SPECIFIC whether the execution of an exception return instruction is counted if any of the following apply:

- Execution of the instruction is, itself, CONSTRAINED UNPREDICTABLE.
- Execution of an exception return instruction that generates an exception.
- Execution of the instruction sets PSTATE.IL and does not generate an exception return.
- Exit from Debug state.

Note

- Examples of when an exception return instruction is CONSTRAINED UNPREDICTABLE are if the instruction is executed in AArch32 state at EL0 or in System mode.
- A particular consequence of this CONSTRAINED UNPREDICTABLE behavior is that an implementation that does not support AArch32 state at EL1 or higher does not have to count AArch32 `MOVS PC, LR`, and related instructions, as exception return instructions.

PMCEID0_EL0[10] reads as 1 if this event is implemented and 0 otherwise.

0x000B, **CID_WRITE_RETIRED**, Instruction architecturally executed, Condition code check pass, write to CONTEXTIDR

The counter counts each MSR write to CONTEXTIDR_EL1 and MCR write to [CONTEXTIDR](#).

If the PE performs two architecturally-executed writes to CONTEXTIDR without an intervening [Context synchronization event](#), it is CONSTRAINED UNPREDICTABLE whether the first write is counted.

PMCEID0_EL0[11] reads as 1 if this event is implemented and 0 otherwise.

0x000C, **PC_WRITE_RETIRED**, Instruction architecturally executed, Condition code check pass, Software change of the PC

The counter counts each architecturally-executed [Software change of the PC](#) that is taken.

This includes all:

- Branch instructions.
- ‘Memory-reading instructions’ that explicitly write to the PC.
- Data-processing instructions that explicitly write to the PC.
- Exception return instructions.

Note

Conditional branches are only counted if the branch is taken.

It is IMPLEMENTATION DEFINED whether the following instructions are included as a [Software change of the PC](#):

- A BRK or BKPT instruction.
- An UNDEFINED instruction that generates an exception.
- An exception-generating instruction, SVC, HVC, and SMC, that generates an exception.
- A Context synchronization barrier instruction, ISB.

The counter does not increment for exceptions other than those explicitly identified in these lists.

PMCEID0_EL0[12] reads as 1 if this event is implemented and 0 otherwise.

0x000D, **BR_IMMED_RETIRED**, Branch instruction architecturally executed, immediate

The counter counts each architecturally-executed immediate branch instruction.

The following instructions are counted as immediate branch instructions:

- For AArch32 state, the following instructions:
 - B{<c>} <label>.
 - BL{<c>} <label>.
 - BLX{<c>} <label>.
 - CBZ <Rn>, <label>.
 - CBNZ <label>.
- For AArch64 state, the following instructions:
 - B <label>.
 - B.cond <label>.
 - BL <label>.
 - CBZ <Rn>, <label>.
 - CBNZ <Rn>, <label>.
 - TBZ <Rn>, <label>.
 - TBNZ <Rn>, <label>.

Note

Conditional branches are always counted, regardless of whether the branch is taken or not taken.

If the Context synchronization barrier instruction ISB is counted as a [Software change of the PC](#) instruction by [PC_WRITE_RETIRED](#), then it is IMPLEMENTATION DEFINED whether ISB is counted as an immediate branch instruction.

PMCEID0_EL0[13] reads as 1 if this event is implemented and 0 otherwise.

0x000E, **BR_RETURN_RETIRED**, Branch instruction architecturally executed, procedure return, taken

The counter counts each [architecturally executed](#) procedure return instruction.

The following instructions are counted as procedure return instructions:

- For AArch32 state, the following instructions:
 - BX R14.
 - MOV PC, LR.
 - POP {..., PC}.
 - LDR PC, [SP], #offset.
- For AArch64 state, the following instructions:
 - RET.

Note

The counter counts only the listed instructions as procedure returns. For example, it does not count the following AArch32 instructions as procedure return instructions:

- BX R0, because Rm != R14.
 - MOV PC, R0, because Rm != R14.
 - LDM SP, {..., PC}, because writeback is not specified.
 - LDR PC, [SP, #offset], because this specifies the wrong addressing mode.
-

PMCEID0_EL0[14] reads as 1 if this event is implemented and 0 otherwise.

0x000F, **UNALIGNED_LDST_RETIRED**, Instruction architecturally executed, Condition code check pass, unaligned load or store

The counter counts each memory-reading instruction or [memory-writing instruction](#) access that would generate an Alignment fault when Alignment fault checking is enabled.

The counter does not count accesses that would generate an SP alignment fault exception if the applicable stack pointer alignment check is enabled, unless that access would also generate an Alignment fault Data Abort exception if Alignment fault checking is enabled.

It is IMPLEMENTATION DEFINED and might be UNPREDICTABLE whether this event counts accesses that generate an exception, including accesses that do generate Alignment fault Data Abort exceptions.

PMCEID0_EL0[15] reads as 1 if this event is implemented and 0 otherwise.

0x001C, **TTBR_WRITE_RETIRED**, Instruction architecturally executed, Condition code check pass, write to TTBR

The counter counts each MSR write to TTBR0_EL1 and TTBR1_EL1 in AArch64 state and MCR and MCRR write to TTBR0 and TTBR1 in AArch32 state.

The counter counts MSR writes to TTBR0_EL1 and TTBR1_EL1 in AArch64 state and MCR and MCRR writes to TTBR0 and TTBR1 in AArch32 state.

If the PE executes two writes to the same TTBR, without an intervening [Context synchronization event](#), it is CONSTRAINED UNPREDICTABLE whether the first write to the TTBR, is counted.

The counter counts only writes to these registers by name. For example:

- If EL3 is implemented, the counter does not count writes using the register name TTBR0_EL3. However, when EL3 is using AArch32, the counter counts writes to either banked copy of TTBR0 and TTBR1.
- If EL2 is implemented, the counter does not count writes using the register names TTBR0_EL2, VTTBR_EL2, HTTBR, and VTTBR.

PMCEID0_EL0[28] reads as 1 if this event is implemented and 0 otherwise.

0x001E, **CHAIN**, Chain a pair of event counters

Even-numbered counters never increment as a result of this event.

For an odd-numbered counter <n+1>, the counter increments when an event increments the preceding even-numbered counter <n> on the same PE causing unsigned overflow of bits [31:0] of the event counter <n>.

This means the [CHAIN](#) event can be used to link the odd-numbered counter with the preceding even-numbered counter to provide a 64-bit counter.

If EL2 is implemented and <n+1> is equal to the Effective value of HDCR.HPMN, then it is UNPREDICTABLE whether the counter counts.

Note

- The **CHAIN** event allows software to use the N event counters as N 32-bit counters, N÷2 64-bit counters, or a mixture of 32-bit counters and 64-bit counters.
 - The **CHAIN** event only counts overflows from the preceding even-numbered counter on the same PE. This means it ignores the Effective value of PMEVTYPEPER<n>_EL0.MT.
 - The architecture does not provide atomic access to a pair of counters.
-

To filter the Exception levels and Security states in which the event is counted, software:

- Programs PMEVTYPEPER<n>_EL0 to count the event in the required conditions.
- Programs PMEVTYPEPER<n+1>_EL0 to count the **CHAIN** event in all Exception levels and states.

The PE might ignore the filter settings for the **CHAIN** event and behave as if they are set to count in all Exception levels and states. If software does not program the event in this way, the count becomes UNPREDICTABLE.

The architecture does not define the latency between the low counter overflowing and the high counter incrementing the **CHAIN** event. There is no requirement for updates to occur synchronously, but software reading or enabling the counter pair by reading the low counter first and the high counter second, with an intervening Context synchronization event, will not observe the low counter incrementing and overflowing for the event and the high counter not incrementing for the resulting **CHAIN** event. This means that the ISB executed after reading the low counter ensures the completion of the update of the high counter by the **CHAIN** event.

PMCEID0_EL0[30] reads as 1 if this event is implemented and 0 otherwise.

0x0021, **BR_RETIRED**, Instruction architecturally executed, branch

The counter counts each branch instruction on the architecturally executed path that would incur cost if mispredicted.

It is IMPLEMENTATION DEFINED whether the counter increments for any or all of:

- Unconditional direct branch instructions.
- Exception-generating instructions.
- Exception return instructions.
- Context synchronization instructions.

The counter counts all other branch instructions, memory-reading instructions and data-processing instructions that explicitly write to the PC, at retirement.

Note

Conditional branches are always counted, regardless of whether the branch is taken.

Arm recommends that **BR_RETIRED** counts Unconditional direct branch instructions and Exception return instructions.

PMCEID1_EL0[1] reads as 1 if this event is implemented and 0 otherwise.

0x0081, **EXC_UNDEF**, Exception taken, other synchronous

The counter counts each exception counted by **EXC_TAKEN** that is **Taken locally** and is not counted as any of the following:

- Exception taken, Supervisor Call (EXC_SVC).
- Exception taken, Secure Monitor Call (EXC_SMC).
- Exception taken, Hypervisor Call (EXC_HVC).
- Exception taken, IRQ (EXC_IRQ).
- Exception taken, FIQ (EXC_FIQ).

It is IMPLEMENTATION SPECIFIC whether the counter counts each entry to Debug state not counted by either of the following:

- Exception taken, Instruction Abort (EXC_PABORT).
- Exception taken, Data Abort or SError (EXC_DABORT).

0x0082, **EXC_SVC, Exception taken, Supervisor Call**

The counter counts each Supervisor Call exception counted by [EXC_TAKEN](#) that is [Taken locally](#).

0x0083, **EXC_PABORT, Exception taken, Instruction Abort**

The counter counts each Instruction Abort exception counted by [EXC_TAKEN](#) that is [Taken locally](#).

It is IMPLEMENTATION SPECIFIC whether the counter counts each entry to Debug state due to a Breakpoint debug event.

0x0084, **EXC_DABORT, Exception taken, Data Abort or SError**

The counter counts each Data Abort, SError interrupt, or virtual SError interrupt exception counted by [EXC_TAKEN](#) that is [Taken locally](#).

It is IMPLEMENTATION SPECIFIC whether the counter counts each entry to Debug state due to a Watchpoint debug event.

0x0086, **EXC_IRQ, Exception taken, IRQ**

The counter counts each IRQ or virtual IRQ exception counted by [EXC_TAKEN](#) that is [Taken locally](#).

0x0087, **EXC_FIQ, Exception taken, FIQ**

The counter counts each FIQ or virtual FIQ exception counted by [EXC_TAKEN](#) that is [Taken locally](#).

0x0088, **EXC_SMC, Exception taken, Secure Monitor Call**

The counter counts each Secure Monitor Call exception counted by [EXC_TAKEN](#).

The counter does not count SMC instructions that generate other exceptions, including Trap exceptions and Undefined Instruction exceptions.

0x008A, **EXC_HVC, Exception taken, Hypervisor Call**

The counter counts each Hypervisor Call exception counted by [EXC_TAKEN](#).

The counter does not count HVC instructions that are UNDEFINED.

0x008B, **EXC_TRAP_PABORT, Exception taken, Instruction Abort not Taken locally**

The counter counts each Instruction Abort exception counted by [EXC_TAKEN](#) that is not [Taken locally](#).

0x008C, **EXC_TRAP_DABORT, Exception taken, Data Abort or SError not Taken locally**

The counter counts each Data Abort, SError interrupt, or virtual SError interrupt exception counted by [EXC_TAKEN](#), that is not [Taken locally](#).

0x008D, **EXC_TRAP_OTHER**, Exception taken, other traps not Taken locally

The counter counts each exception counted by [EXC_TAKEN](#) that is not [Taken locally](#) and not counted as any of the following:

- Exception taken, Secure Monitor Call (EXC_SMC).
- Exception taken, Hypervisor Call (EXC_HVC).
- Exception taken, Instruction Abort not [Taken locally](#) (EXC_TRAP_PABORT).
- Exception taken, Data Abort or SError not [Taken locally](#) (EXC_TRAP_DABORT).
- Exception taken, IRQ not [Taken locally](#) (EXC_TRAP_IRQ).
- Exception taken, FIQ not [Taken locally](#) (EXC_TRAP_FIQ).

0x008E, **EXC_TRAP_IRQ**, Exception taken, IRQ not Taken locally

The counter counts each IRQ or virtual IRQ exception counted by [EXC_TAKEN](#) that is not [Taken locally](#).

0x008F, **EXC_TRAP_FIQ**, Exception taken, FIQ not Taken locally

The counter counts each FIQ or virtual FIQ exception counted by [EXC_TAKEN](#) that is not [Taken locally](#).

ASE_INST_RETIRED, Instruction architecturally executed, Advanced SIMD

The counter counts each [architecturally executed](#) instruction counted by [ASE_SVE_INST_RETIRED](#) that is classified as an Advanced SIMD instruction.

The following instructions are counted as Advanced SIMD instructions:

- For AArch64 state:
 - The SIMD operations listed in Data processing - SIMD and floating-point.
 - If [FEAT_Crypto](#) is implemented, the Advanced SIMD Cryptographic instructions. See The Cryptographic Extension in AArch64 state.
 - Advanced SIMD loads and stores.
- For AArch32 state:
 - Instructions from [Advanced SIMD data-processing instructions](#).
 - If [FEAT_Crypto](#) is implemented, the `VMULL` (P64 variant) instruction. See [The Cryptographic Extension in AArch32 state](#).

This includes all instructions that operate on the SIMD&FP registers, except those that are counted as one of the following:

- Integer data-processing instructions.
- Scalar floating-point data-processing instructions.

It is IMPLEMENTATION DEFINED whether Advanced SIMD scalar instructions are counted as Advanced SIMD instructions. This includes Advanced SIMD scalar instructions which operate on floating-point values.

ASE_RETIRED, Instruction architecturally executed, Advanced SIMD data processing

The counter counts each [architecturally executed](#) instruction counted by [ASE_SVE_RETIRED](#) that is classified as an Advanced SIMD data-processing instruction.

The following instructions are counted as Advanced SIMD data-processing instructions:

- For AArch64 state:
 - The SIMD operations listed in Data processing - SIMD and floating-point.
 - Advanced SIMD scalar instructions, including those which operate on floating-point values.
 - If [FEAT_Crypto](#) is implemented, the Advanced SIMD `PMULL` and `PMULL2` (1Q variants) instructions. See The Cryptographic Extension in AArch64 state.
- For AArch32 state:

- Instructions from [Advanced SIMD data-processing instructions](#).
- If [FEAT_Crypto](#) is implemented, the `VMULL` (P64 variant) instruction. See [The Cryptographic Extension in AArch32 state](#).

This includes all instructions that operate on the SIMD&FP registers, except those that are counted as one of the following:

- Integer data-processing instructions.
- Scalar floating-point data-processing instructions.
- Load or store instructions.
- Cryptographic data-processing instructions counted by `CRYPTO_RETIRED`. `CRYPTO_RETIRED` does not count the Cryptographic data-processing instructions included above.

ASE_SVE_INST_RETIRED, Instruction architecturally executed, Advanced SIMD or SVE

The counter counts each [architecturally executed](#) instruction counted by `SE_INST_RETIRED` that is classified as an Advanced SIMD instruction or an SVE instruction.

See [ASE_INST_RETIRED](#) and `SVE_INST_RETIRED` for these classifications.

ASE_SVE_RETIRED, Instruction architecturally executed, Advanced SIMD data processing or SVE data processing

The counter counts each [architecturally executed](#) instruction counted by `INST_RETIRED` that is classified as an Advanced SIMD data-processing instruction or an SVE data-processing instruction.

See [ASE_RETIRED](#) and `SVE_RETIRED` for these classifications.

BL_IMMED_TAKEN_RETIRED, Branch instruction architecturally executed, direct branch with link, taken

The counter counts each branch counted by both [BL_TAKEN_RETIRED](#) and [BR_IMMED_TAKEN_RETIRED](#).

These are all direct branch with link instructions on the architecturally executed path, where the branch is taken.

BL_IND_TAKEN_RETIRED, Branch instruction architecturally executed, indirect branch with link, taken

The counter counts each branch counted by both [BL_TAKEN_RETIRED](#) and [BR_IND_TAKEN_RETIRED](#).

These are all indirect branch with link instructions on the architecturally executed path, where the branch is taken.

BL_TAKEN_RETIRED, Branch instruction architecturally executed, branch with link, taken

The counter counts each [Software change of the PC](#) counted by [PC_WRITE_RETIRED](#) that calls a subroutine and sets LR to return address.

These are all branch with link instructions on the architecturally executed path, where the branch is taken.

BRB_FILTRATE, Branch Record captured

The counter counts each valid Branch record captured in the branch record buffer.

Branch records that are not captured because they are removed by filtering are not counted.

When [BRB_FILTRATE](#) is generated for an exception or an exception return, it is an Exception-related event.

It is `CONSTRAINED UNPREDICTABLE` whether the counter counts Branch records injected by a BRB INJ instruction.

If counting this event causes unsigned overflow of the event counter counting the event and this in turn causes a BRBE freeze event then:

- The Branch record for the operation that generated the event will be generated and captured in the Branch record buffer.

- It is CONSTRAINED UNPREDICTABLE whether the Branch Record Buffer Extension generates Branch records for other operations in program order after the operation that generated the event that would otherwise be generated when generation of Branch records is not Paused.

Arm recommends that implementations minimize capture of additional branches.

BRNL_IMMED_TAKEN_RETIRED, Branch instruction architecturally executed, direct branch without link, taken

The counter counts each branch counted by both [BRNL_TAKEN_RETIRED](#) and [BR_IMMED_TAKEN_RETIRED](#).

These are all direct branch without link instructions on the architecturally executed path, where the branch is taken.

BRNL_INDNR_TAKEN_RETIRED, Branch instruction architecturally executed, indirect branch without link excluding procedure return, taken

The counter counts each branch counted by [BRNL_IND_TAKEN_RETIRED](#) that is not counted by [BR_RETURN_RETIRED](#).

These are all indirect branch without link excluding procedure return instructions on the architecturally executed path, where the branch is taken.

BRNL_IND_TAKEN_RETIRED, Branch instruction architecturally executed, indirect branch without link, taken

The counter counts each branch counted by both [BRNL_TAKEN_RETIRED](#) and [BR_IND_TAKEN_RETIRED](#).

These are all indirect branch without link instructions on the architecturally executed path, where the branch is taken.

BRNL_TAKEN_RETIRED, Branch instruction architecturally executed, branch without link, taken

The counter counts each [Software change of the PC](#) counted by [PC_WRITE_RETIRED](#) that is not counted by [BL_TAKEN_RETIRED](#).

These are all branch without link instructions on the architecturally executed path, where the branch is taken.

BR_COND_RETIRED, Branch instruction architecturally executed, conditional branch

The counter counts each [Software change of the PC](#) counted by [BR_RETIRED](#) that is a conditional branch.

These are all conditional branch instructions on the architecturally executed path.

In the A64 instruction set, conditional branches are:

- B.cond, CBNZ, CBZ, TBNZ, and TBZ.

This includes conditional branch instructions with the AL or NV condition code.

In the A32 instruction set, conditional branches are [Software change of the PC](#) instructions that have bits [31:29] of the instruction opcode not equal to 0b111.

In the T32 instruction set, conditional branches are B<c>, B<c>.W, [Software change of the PC](#) instructions executed in an IT block, CBNZ, and CBZ. Branch instruction encodings, including B{<c>} and B{<c>}.W, where <c> is either omitted or AL are only considered conditional branches when they are the last instruction in an IT block.

BR_COND_TAKEN_RETIRED, Branch instruction architecturally executed, conditional branch, taken

The counter counts each [Software change of the PC](#) counted by both [BR_COND_RETIRED](#) and [PC_WRITE_RETIRED](#).

These are all conditional branch instructions on the architecturally executed path, where the branch is taken.

BR_IMMED_SKIP_RETIRE, Branch instruction architecturally executed, immediate, not taken

The counter counts each instruction counted by both [BR_IMMED_RETIRE](#) and [BR_SKIP_RETIRE](#).

These are all direct branch instructions on the architecturally executed path, where the branch is not taken.

BR_IMMED_TAKEN_RETIRE, Branch instruction architecturally executed, immediate, taken

The counter counts each instruction counted by both [BR_IMMED_RETIRE](#) and [PC_WRITE_RETIRE](#).

These are all direct branch instructions on the architecturally executed path, where the branch is taken.

BR_INDNR_RETIRE, Branch instruction architecturally executed, indirect excluding procedure return

The counter counts each instruction counted by [BR_IND_RETIRE](#) that is not counted by [BR_RETURN_ANY_RETIRE](#).

These are all indirect branch instructions, excluding return instructions, on the architecturally executed path.

BR_INDNR_SKIP_RETIRE, Branch instruction architecturally executed, indirect excluding procedure return, not taken

The counter counts each instruction counted by both [BR_INDNR_RETIRE](#) and [BR_SKIP_RETIRE](#).

These are all indirect branch instructions, excluding return instructions, on the architecturally executed path, where the branch is not taken.

BR_INDNR_TAKEN_RETIRE, Branch instruction architecturally executed, indirect excluding procedure return, taken

The counter counts each instruction counted by both [BR_IND_RETIRE](#) and [PC_WRITE_RETIRE](#), that is not counted by [BR_RETURN_RETIRE](#).

These are all indirect branch instructions, excluding return instructions, on the architecturally executed path, where the branch is taken.

BR_IND_RETIRE, Instruction architecturally executed, indirect branch

The counter counts each [architecturally executed](#) indirect branch instruction.

Indirect branch instructions are [Software change of the PC](#) instructions other than exception-generating instructions and immediate branch instructions. [Software change of the PC](#) has the same definition as for the [PC_WRITE_RETIRE](#) and [BR_SKIP_RETIRE](#) events. Immediate branch instructions are defined by the [BR_IMMED_RETIRE](#) event.

Note

Conditional branches are always counted, regardless of whether the branch is taken.

BR_IND_SKIP_RETIRE, Branch instruction architecturally executed, indirect, not taken

The counter counts each instruction counted by both [BR_IND_RETIRE](#) and [BR_SKIP_RETIRE](#).

These are all indirect branch instructions, including return instructions, on the architecturally executed path, where the branch is not taken.

BR_IND_TAKEN_RETIRE, Branch instruction architecturally executed, indirect, taken

The counter counts each instruction counted by both [BR_IND_RETIRE](#) and [PC_WRITE_RETIRE](#).

These are all indirect branch instructions, including return instructions, on the architecturally executed path, where the branch is taken.

BR_RETURN_ANY_RETIRED, Branch instruction architecturally executed, procedure return

The counter counts each instruction counted by [BR_IND_RETIRED](#) where if taken, the branch would be counted by [BR_RETURN_RETIRED](#).

These are all return instructions on the architecturally executed path.

BR_RETURN_SKIP_RETIRED, Branch instruction architecturally executed, procedure return, not taken

The counter counts each instruction counted by both [BR_RETURN_ANY_RETIRED](#) and [BR_SKIP_RETIRED](#).

These are all return instructions on the architecturally executed path, where the branch is not taken.

BR_SKIP_RETIRED, Branch instruction architecturally executed, not taken

The counter counts each conditional [Software change of the PC](#) instruction that is not taken.

This includes all:

- Conditional branch instructions.
- Conditional memory-reading instructions that explicitly write to the PC.
- Conditional data-processing instructions that explicitly write to the PC.
- Conditional exception return instructions.

These are the same instructions which, if unconditional, or conditional and taken, are counted by the [PC_WRITE_RETIRED](#) event.

It is IMPLEMENTATION DEFINED whether the following instructions are included as a [Software change of the PC](#), which the counter increments for:

- A conditional UNDEFINED instruction that does not generate an exception.
- A conditional exception-generating instruction, SVC, HVC, or SMC, that does not generate an exception.
- A conditional Context synchronization barrier instruction, ISB, that fails its condition code check.

Note

Many of these instructions can only be conditional in the AArch32 instruction sets.

The counter does not increment for exceptions other than those explicitly identified in these lists.

BR_UNCOND_RETIRED, Branch instruction architecturally executed, unconditional branch

The counter counts each [Software change of the PC](#) counted by [BR_RETIRED](#) that is not counted by [BR_COND_RETIRED](#).

These are all unconditional branch instructions on the architecturally executed path.

CRYPTO_RETIRED, Instruction architecturally executed, cryptographic data processing

The counter counts each [architecturally executed](#) instruction counted by [INST_RETIRED](#) that is classified as a cryptographic instruction.

The following instructions are counted as cryptographic data-processing instructions:

- In AArch64 state, instructions from The Cryptographic Extension in AArch64 state other than the include Advanced SIMD `PMULL` and `PMULL2` (1Q variants) instructions.
- In AArch32 state, instructions from [The Cryptographic Extension in AArch32 state](#) other than `VMULL` (P64 variant).

DP_RETIRE, Instruction architecturally executed, integer data processing

The counter counts each [architecturally executed](#) instruction counted by [INST_RETIRE](#) that is classified as an integer data-processing instruction.

An integer data-processing instruction is any instruction that is not counted as any of the following:

- A load or store instruction, counted by [LD_RETIRE](#) or [ST_RETIRE](#).
- A Software change of PC instruction, counted by [PC_WRITE_RETIRE](#).
- A scalar floating-point data processing instruction, counted by [VFP_RETIRE](#).
- An Advanced SIMD or SVE data processing instruction, counted by [ASE_SVE_RETIRE](#).
- A cryptographic instruction, counted by [CRYPTO_RETIRE](#).

That is, the following instructions are counted as integer data-processing instructions:

- In AArch64 state:
 - Instructions from Data processing - immediate.
 - Instructions from Data processing - register.
 - Instructions from System register instructions.
 - Instructions from ‘Instructions with register argument’.
 - Instructions from System instructions other than ‘Memory-writing instructions’.
 - Instructions from Hint instructions.
 - Instructions from Floating-point move (register) that transfer data between a general-purpose register and a SIMD&FP register without conversion: [FMOV](#) (general).
 - Instructions from SIMD move that transfer data between a general-purpose register and an element or elements in a SIMD&FP register: [DUP](#) (general), [SMOV](#), [UMOV](#), and [INS](#) (general). This includes the aliases [MOV](#) (from general) and [MOV](#) (to general).
- In AArch32 state:
 - Instructions from [Data-processing instructions](#).
 - Instructions from [PSTATE and banked register access instructions](#).
 - Instructions from [Banked register access instructions](#).
 - Instructions from [Miscellaneous instructions](#) other than [ISB](#) and prefetches.
 - Instructions from [System register access instructions](#) other than [LDC](#) and [STC](#) instructions.
 - [VDUP](#) (general-purpose register).
 - All [VMOV](#) instructions that transfer data between a general-purpose register and a SIMD&FP register.
 - [VMRS](#) and [VMSR](#).

LDST_ANY_RETIRE, Instruction architecturally executed, load or store

The counter counts each [architecturally executed](#) instruction counted by [INST_RETIRE](#) that is classified as a Memory-reading instruction or a [Memory-writing instruction](#).

See [LD_ANY_RETIRE](#) and [ST_ANY_RETIRE](#) for these classifications.

If the [PRF_RETIRE](#) event is implemented and the prefetch instructions counted by [PRF_RETIRE](#) are not counted as Memory-reading instructions by [LD_RETIRE](#) and [LD_ANY_RETIRE](#), then it is IMPLEMENTATION DEFINED whether these instructions are counted by [LDST_ANY_RETIRE](#). Arm recommends that these instructions are counted by [LDST_ANY_RETIRE](#).

LD_ANY_RETIRE, Instruction architecturally executed, load

The counter counts each [architecturally executed](#) instruction counted by [LDST_ANY_RETIRE](#) that is classified as a Memory-reading instruction.

It is IMPLEMENTATION DEFINED whether the prefetch instructions counted by [PRF_RETIRE](#) are counted as Memory-reading instructions:

- If the prefetch instructions are counted as Memory-reading instructions, then they are counted by [LD_RETIRE](#) and [LD_ANY_RETIRE](#).
- Otherwise, if the prefetch instructions are not counted as Memory-reading instructions by [LD_ANY_RETIRE](#), then it is further IMPLEMENTATION DEFINED which one of the following applies:
 - They are counted as data-processing instructions.

- They are counted by [LDST_ANY_RETIRED](#).

Arm recommends that if a prefetch instruction is not implemented as a NOP and the [PRF_RETIRED](#) event is not implemented, then the instruction is counted as a Memory-reading instruction.

PRF_RETIRED, Instruction architecturally executed, prefetch

The counter counts each [architecturally executed](#) prefetch instruction counted by [INST_RETIRED](#).

SE_INST_RETIRED, Instruction architecturally executed, Advanced SIMD, SVE, or SME

The counter counts each [architecturally executed](#) instruction counted by [INST_RETIRED](#) that is classified as an Advanced SIMD, SVE, or SME instruction.

See [ASE_SVE_INST_RETIRED](#) and [SME_INST_RETIRED](#) for these classifications.

SE_RETIRED, Instruction architecturally executed, Advanced SIMD, SVE, or SME data processing

The counter counts each [architecturally executed](#) instruction counted by [INST_RETIRED](#) that is classified as an Advanced SIMD, SVE, or SME data-processing instruction.

See [ASE_SVE_RETIRED](#) and [SME_RETIRED](#) for these classifications.

SIMD_INST_RETIRED, Instruction architecturally executed, SIMD

The counter counts each [architecturally executed](#) SIMD instruction counted by [INST_RETIRED](#) due to any of:

- An Advanced SIMD data-processing instruction. Advanced SIMD scalar data-processing instructions are not counted.
- An SVE SIMD data-processing instruction. SVE non-SIMD data-processing instructions are not counted.
- A structure load/store of one or more SIMD&FP registers.
- A load and replicate to one or more SIMD&FP registers.
- A scalar load/store of a SIMD&FP Q register or pair of Q registers.
- An SVE load/store.

It is IMPLEMENTATION DEFINED which [architecturally executed](#) SIMD instructions are counted in AArch32 state.

It is IMPLEMENTATION DEFINED whether scalar loads and stores to SIMD&FP registers other than those listed above are counted.

ST_ANY_RETIRED, Instruction architecturally executed, store

The counter counts each [architecturally executed](#) instruction counted by [LDST_ANY_RETIRED](#) that is classified as a [Memory-writing instruction](#).

TRB_TRIG, Trace buffer Trigger Event

The counter counts each trace buffer Trigger Event.

It is IMPLEMENTATION DEFINED whether this event can be counted by the PMU.

PMCEID0_EL0[46] reads as 1 if this event is implemented and can be counted by the PMU, and 0 otherwise.

TRB_WRAP, Trace buffer current write pointer wrapped

The counter counts each write made by the Trace Buffer Unit to the trace buffer that causes the trace buffer current write pointer to wrap to the trace buffer base pointer.

PMCEID0_EL0[44] reads as 1 if this event is implemented and 0 otherwise.

VFP_RETIRE, Instruction architecturally executed, scalar floating-point data processing

The counter counts each [architecturally executed](#) instruction counted by [INST_RETIRE](#) that is classified as a scalar floating-point instruction.

The following instructions are counted as scalar floating-point data-processing instructions:

- In AArch64 state:
 - The scalar floating-point instructions from Data processing - SIMD and floating-point. Only the scalar instructions are counted. SIMD floating-point instructions are not counted.
 - Instructions that take both an integer register and a floating-point register argument and perform a type conversion (to/from integer or to/from fixed-point): `FCVT{<mode>}`, `UCVTF`, and `SCVTF`.
- In AArch32 state:
 - Instructions from [Floating-point data-processing instructions](#).
 - Instructions that take both an integer register and a floating-point register argument and perform a type conversion (to/from integer or to/from fixed-point): `VCVT<mode>` (floating-point), `VCVT`, `VCVTT`, and `VCVTB`.

This includes all scalar instructions that operate on the SIMD&FP registers as floating-point values, except those that are counted as one of the following:

- SIMD scalar instructions.
- Integer data-processing instructions.
- Load or store instructions.

D7.3.2 Common microarchitectural events

The Common microarchitectural events are:

0x0001, L1I_CACHE_REFILL, Level 1 instruction cache refill

The counter counts each access counted by [L1I_CACHE](#) that causes a refill of the Level 1 instruction or unified cache from outside of the Level 1 instruction or unified cache.

A refill includes any access that causes data to be fetched from outside of the Level 1 caches, even if the data is ultimately not allocated into the Level 1 instruction cache. For example, data might be fetched into a buffer but then discarded, rather than being allocated into a cache. These buffers are treated as part of the cache.

For example, the counter counts accesses to the Level 1 instruction cache that cause a refill that is satisfied by fetching data from memory, a Level 2 cache, or a Level 1 cache of another PE.

The counter does not count accesses that miss in the cache but are satisfied by the refill of a previous miss and do not cause a new refill, even if that previous refill is not complete at the time of the miss.

It is IMPLEMENTATION DEFINED whether accesses that result from cache maintenance instructions are counted.

If the cache is shared and the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the cache is shared by PEs other than the PEs in the multithreaded processor and the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of `PMEVTYPER<n>_EL0.MT`.

`PMCEID0_EL0[1]` reads as 1 if this event is implemented and 0 otherwise.

0x0002, L1I_TLB_REFILL, Level 1 instruction TLB refill

The counter counts each [Instruction memory access](#) counted by [L1I_TLB](#) that causes a TLB refill of the Level 1 instruction TLB.

This includes each [Instruction memory access](#) that causes a memory access due to a translation table walk or an access to another level of TLB caching.

The counter does not count the access if any of the following are true:

- The access is due to a TLB maintenance instruction.
- The access generates a Translation fault because the applicable `TCR_ELx.EPDy` bit is 1.

It is IMPLEMENTATION DEFINED whether the counter counts the access if any of the following are true:

- The access misses in the TLB and generates a translation table walk, but the result is not allocated into the TLB for any reason other than a Translation fault.
- The access generates a Translation fault for any other reason.

If the TLB is shared and the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of `PMEVTYPER<n>_EL0.MT`.

`PMCEID0_EL0[2]` reads as 1 if this event is implemented and 0 otherwise.

0x0003, L1D_CACHE_REFILL, Level 1 data cache refill

The counter counts each access counted by [L1D_CACHE](#) that causes a refill of the Level 1 data or unified cache from outside of the Level 1 data or unified cache.

A refill includes any access that causes data to be fetched from outside of the Level 1 caches, even if the data is ultimately not allocated into the Level 1 data cache. For example, data might be fetched into a buffer but then discarded, rather than being allocated into a cache. These buffers are treated as part of the cache.

For example, the counter counts accesses to the Level 1 data cache that cause a refill that is satisfied by fetching data from memory, a Level 2 cache, or a Level 1 cache of another PE.

The counter does not count accesses that:

- Miss in the cache but are satisfied by the refill of a previous miss and do not cause a new refill, even if that previous refill is not complete at the time of the miss.
- Miss in the cache but do not generate a refill, such as a write through the cache.

It is IMPLEMENTATION DEFINED whether accesses that result from cache maintenance instructions are counted.

If the cache is shared and the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the cache is shared by PEs other than the PEs in the multithreaded processor and the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of `PMEVTYPER<n>_EL0.MT`.

`PMCEID0_EL0[3]` reads as 1 if this event is implemented and 0 otherwise.

0x0004, **L1D_CACHE, Level 1 data cache access**

The counter counts each ‘Memory-read operation’ or [Memory-write operation](#) that causes a cache access to at least the Level 1 data or unified cache.

Each access to a cache line is counted including the multiple accesses caused by single instructions such as `LDM` or `STM`. Each access to other Level 1 data or unified memory structures, for example refill buffers, write buffers, and write-back buffers, is also counted.

It is IMPLEMENTATION DEFINED whether accesses that result from cache maintenance instructions are counted.

It is IMPLEMENTATION DEFINED whether accesses that only update the cache status information for a cache entry without accessing the content of the cache entry are counted. For example, whether the cached data is held in an exclusive or shared state.

When the [L1D_CACHE_RW](#) event is implemented:

- If the [L1D_CACHE_PRFM](#) event is implemented, accesses to the Level 1 data cache due to a prefetch instruction are counted. Otherwise, these accesses are not counted.
- If the [L1D_CACHE_HWPRF](#) event is implemented, accesses to the Level 1 data cache due to a hardware prefetcher are counted. Otherwise these accesses are not counted.

When the [L1D_CACHE_RW](#) event is not implemented, it IMPLEMENTATION DEFINED whether accesses to the Level 1 data cache due to prefetch instructions or due to a hardware prefetcher are counted.

If the cache is shared and the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the cache is shared by PEs other than the PEs in the multithreaded processor and the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of `PMEVTYPER<n>_EL0.MT`.

`PMCEID0_EL0[4]` reads as 1 if this event is implemented and 0 otherwise.

0x0005, **L1D_TLB_REFILL, Level 1 data TLB refill**

The counter counts each access counted by [L1D_TLB](#) that causes a TLB refill of the Level 1 data or unified TLB.

This includes each access that causes a memory access due to a translation table walk or an access to another level of TLB caching.

The counter does not count the access if any of the following are true:

- The access is due to a TLB maintenance instruction.
- The access generates a Translation fault because the applicable TCR_ELx.EPDy bit is 1.

It is IMPLEMENTATION DEFINED whether the counter counts the access if any of the following are true:

- The access misses in the TLB and generates a translation table walk, but the result is not allocated into the TLB for any reason other than a Translation fault.
- The access generates a Translation fault for any other reason.

If the TLB is shared and the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of `PMEVTYPER<n>_EL0.MT`.

`PMCEID0_EL0[5]` reads as 1 if this event is implemented and 0 otherwise.

0x0010, **BR_MIS_PRED**, Branch instruction speculatively executed, mispredicted or not predicted

The counter counts each correction to the predicted program flow that occurs because of a misprediction from, or no prediction from, the branch prediction resources and that relates to instructions that the branch prediction resources are capable of predicting.

If no program-flow prediction resources are implemented, Arm recommends that the counter counts all branches that are not taken.

`PMCEID0_EL0[16]` reads as 1 if this event is implemented and 0 otherwise.

0x0011, **CPU_CYCLES**, Cycle

The counter increments on every cycle when the PE is not in `WFI` or `WFE` state.

When the PE is in `WFI` or `WFE` state, it is IMPLEMENTATION SPECIFIC whether the counter counts.

Note

Unlike `PMCCNTR` or `PMCCNTR_EL0`, this count is not affected by the cycle counter controls:

- The counter is not incremented in prohibited regions, so is not affected by `PMCR.DP` or `PMCR_EL0.DP`.
 - The counter increments on every cycle, regardless of the value of `PMCR.D` or `PMCR_EL0.D`.
 - The counter is reset when event counters are reset by `PMCR.P` and `PMCR_EL0.P`, never by `PMCR.C` or `PMCR_EL0.C`.
-

In a multithreaded implementation:

- If the Effective value of `PMEVTYPER<n>_EL0.MT` for the event counter is 0, then the counter counts each [Processor cycle](#) when the counting PE is active.
- If the Effective value of `PMEVTYPER<n>_EL0.MT` for the event counter is 1, then the counter counts each [Processor cycle](#).

`PMCEID0_EL0[17]` reads as 1 if this event is implemented and 0 otherwise.

0x0012, **BR_PRED**, Predictable branch instruction speculatively executed

The counter counts each branch or other change in the program flow that the branch prediction resources are capable of predicting.

If all branches are subject to prediction, for example a BTB or BTAC, then all branches are predictable branches.

If branches are decoded before the predictor, so that the branch prediction logic dynamically predicts only some branches, for example conditional and indirect branches, then it is IMPLEMENTATION DEFINED whether other branches are counted as predictable branches. Arm recommends that all branches are counted.

An implementation might include other structures that predict branches, such as a loop buffer that predicts short backwards direct branches as taken. Each execution of such a branch is a predictable branch. Terminating the loop might generate a misprediction event that is counted by [BR_MIS_PRED](#).

If no program-flow prediction resources are implemented, this event is optional, but Arm recommends that [BR_PRED](#) counts all branches.

It is IMPLEMENTATION DEFINED when the branch is counted. Arm recommends that it is counted when the branch is resolved, that is, at the same point in the instruction pipeline as when the [BR_MIS_PRED](#) event would be counted if the branch resolves as mispredicted.

PMCEID0_EL0[18] reads as 1 if this event is implemented and 0 otherwise.

0x0013, **MEM_ACCESS**, Data memory access

The counter counts each ‘Memory-read operation’ or [Memory-write operation](#) that the PE makes.

The counter increments whether the access results in an access to a Level 1 data or unified cache, a Level 2 data or unified cache, or neither of these.

The number of accesses generated by each instruction is IMPLEMENTATION DEFINED.

The counter does not count:

- [Instruction memory accesses](#).
- Translation table walks.
- Write-back from any cache.
- Refilling of any cache.

It is IMPLEMENTATION DEFINED whether accesses that result from cache maintenance instructions are counted.

PMCEID0_EL0[19] reads as 1 if this event is implemented and 0 otherwise.

0x0014, **L1I_CACHE**, Level 1 instruction cache access

The counter counts each [Instruction memory access](#) to at least the Level 1 instruction or unified cache.

Each [Instruction memory access](#) to other Level 1 instruction or unified memory structures, such as refill buffers, is also counted.

It is IMPLEMENTATION DEFINED whether accesses that result from cache maintenance instructions are counted.

It is IMPLEMENTATION DEFINED whether accesses that only update the cache status information for a cache entry without accessing the content of the cache entry are counted. For example, whether the cached data is held in an exclusive or shared state.

When the [L1I_CACHE_RD](#) event is implemented:

- If the [L1I_CACHE_PRFM](#) event is implemented, accesses to the Level 1 instruction cache due to a prefetch instruction are counted. Otherwise, these are not counted.
- If the [L1I_CACHE_HWPRF](#) event is implemented, accesses to the Level 1 instruction cache due to a hardware prefetcher are counted. Otherwise these events are not counted.

When the [L1I_CACHE_RD](#) event is not implemented, it IMPLEMENTATION DEFINED whether accesses to the Level 1 instruction cache due to prefetch instructions or due to a hardware prefetcher are counted.

If the cache is shared and the Effective value of PMEVTYPEPER<n>_EL0.MT for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the cache is shared by PEs other than the PEs in the multithreaded processor and the Effective value of PMEVTYPEPER<n>_EL0.MT for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of PMEVTYPEPER<n>_EL0.MT.

PMCEID0_EL0[20] reads as 1 if this event is implemented and 0 otherwise.

0x0015, **L1D_CACHE_WB, Level 1 data cache write-back**

The counter counts each write-back of data from the Level 1 data or unified cache to outside of the Level 1 caches.

For example:

- A write-back of a cache line to a Level 2 cache or memory.
- A write-back of a recently fetched cache line that has not been allocated to the Level 1 data cache.

Each write-back is counted once, even if multiple accesses are required to complete the write-back.

It is IMPLEMENTATION DEFINED whether the counter counts:

- A transfer of a dirty cache line from the Level 1 data cache to outside of Level 1 caches made as a result of a coherency request.
- Write-backs made as a result of cache maintenance instructions.

The counter does not count:

- The invalidation of a cache line without any write-back to outside of the Level 1 caches or memory.
- Writes that write through the Level 1 data cache to outside of the Level 1 caches.

A write-back is attributable to one of the following, and it is IMPLEMENTATION DEFINED which:

- The PE or other agent that generated the request that caused the write-back. This might not be the same agent that caused the data to be allocated into the cache.
- If the cache is shared, the PE or other agent that caused the data to be allocated into the cache.
- If the cache is shared, the PE or other agent that last accessed the data when it was in the cache. If the data has not been accessed since being allocated, then the PE or other agent that caused the data to be allocated into the cache.

If the cache is shared, then the write-back event is counted only if it is attributable to the PE counting the event.

If the cache is not shared, then the event is counted by the PE that the cache is attached to, even if the write-back is not attributable to that PE. For example, a requestor outside of the PE made a coherency request that resulted in write-back.

It is IMPLEMENTATION DEFINED whether a write of a whole cache line that is not the result of the eviction of a line from the cache, is counted. For example, this applies when the PE determines software is streaming writes to memory and does not allocate lines to the cache, or by a DC ZVA operation.

PMCEID0_EL0[21] reads as 1 if this event is implemented and 0 otherwise.

0x0016, **L2D_CACHE, Level 2 data cache access**

The counter counts each ‘Memory-read operation’ or [Memory-write operation](#) that causes a cache access to at least the Level 2 data or unified cache.

Each access to a cache line is counted including refills of and write-backs from other caches. Each access to other Level 2 data or unified memory structures, for example refill buffers, write buffers, and write-back buffers, is also counted.

It is IMPLEMENTATION DEFINED whether accesses that result from cache maintenance instructions are counted.

It is IMPLEMENTATION DEFINED whether accesses that only update the cache status information for a cache entry without accessing the content of the cache entry are counted. For example, whether the cached data is held in an exclusive or shared state.

When the [L2D_CACHE_RW](#) event is implemented:

- If the [L2D_CACHE_PRFM](#) event is implemented, accesses to the Level 2 data cache due to a prefetch instruction are counted. Otherwise, these accesses are not counted.
- If the [L2D_CACHE_HWPRF](#) event is implemented, accesses to the Level 2 data cache due to a hardware prefetcher are counted. Otherwise these accesses are not counted.

When the [L2D_CACHE_RW](#) event is not implemented, it IMPLEMENTATION DEFINED whether accesses to the Level 2 data cache due to prefetch instructions or due to a hardware prefetcher are counted.

If the cache is shared and the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the cache is shared by PEs other than the PEs in the multithreaded processor and the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of `PMEVTYPER<n>_EL0.MT`.

`PMCEID0_EL0[22]` reads as 1 if this event is implemented and 0 otherwise.

0x0017, **L2D_CACHE_REFILL, Level 2 data cache refill**

The counter counts each access counted by **L2D_CACHE** that causes a refill of the Level 2 data or unified cache, or any Level 1 data, instruction, or unified cache of this PE, from outside of those caches.

A refill includes any access that causes data to be fetched from outside of the Level 1 and Level 2 caches, even if the data is ultimately not allocated into the Level 2 data cache. For example, data might be fetched into a buffer but then discarded, rather than being allocated into a cache. These buffers are treated as part of the cache.

For example, the counter counts:

- Accesses to the Level 2 data cache that cause a refill that is satisfied by fetching data from memory, a Level 3 cache, or a Level 2 cache of another PE.
- Refills of and write-backs from any Level 1 data, instruction, or unified cache of this PE that cause a refill from outside of the Level 1 and Level 2 caches of this PE.
- Accesses to the Level 2 data cache that cause a refill of a Level 1 cache of this PE from outside of the Level 1 and Level 2 caches of this PE, even if there is no refill of the Level 2 data cache.

The counter does not count accesses that:

- Miss in the cache but are satisfied by the refill of a previous miss and do not cause a new refill, even if that previous refill is not complete at the time of the miss.
- Miss in the cache but do not generate a refill, such as a write through the cache.

It is IMPLEMENTATION DEFINED whether accesses that result from cache maintenance instructions are counted.

If the cache is shared and the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the cache is shared by PEs other than the PEs in the multithreaded processor and the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of `PMEVTYPER<n>_EL0.MT`.

`PMCEID0_EL0[23]` reads as 1 if this event is implemented and 0 otherwise.

0x0018, **L2D_CACHE_WB, Level 2 data cache write-back**

The counter counts each write-back of data from the Level 2 data or unified cache to outside of the Level 1 and Level 2 caches.

For example:

- A write-back of a cache line to a Level 3 cache or memory.
- A write-back of a recently fetched cache line that has not been allocated to the Level 2 data cache.

Each write-back is counted once, even if multiple accesses are required to complete the write-back.

It is IMPLEMENTATION DEFINED whether the counter counts:

- A transfer of a dirty cache line from the Level 2 data cache to outside of Level 1 and Level 2 caches made as a result of a coherency request.
- Write-backs made as a result of cache maintenance instructions.

The counter does not count:

- The invalidation of a cache line without any write-back to outside of the Level 1 and Level 2 caches or memory.
- Writes that write through the Level 2 data cache to outside of the Level 1 and Level 2 caches.
- Transfers of data from the Level 2 data cache to a Level 1 cache to satisfy a refill of the other cache.

A write-back is attributable to one of the following, and it is IMPLEMENTATION DEFINED which:

- The PE or other agent that generated the request that caused the write-back. This might not be the same agent that caused the data to be allocated into the cache.
- If the cache is shared, the PE or other agent that caused the data to be allocated into the cache.
- If the cache is shared, the PE or other agent that last accessed the data when it was in the cache. If the data has not been accessed since being allocated, then the PE or other agent that caused the data to be allocated into the cache.

If the cache is shared, then the write-back event is counted only if it is attributable to the PE counting the event.

If the cache is not shared, then the event is counted by the PE that the cache is attached to, even if the write-back is not attributable to that PE. For example, a requestor outside of the PE made a coherency request that resulted in write-back.

It is IMPLEMENTATION DEFINED whether a write of a whole cache line that is not the result of the eviction of a line from the cache, is counted. For example, this applies when the PE determines software is streaming writes to memory and does not allocate lines to the cache, or by a DC ZVA operation.

PMCEID0_EL0[24] reads as 1 if this event is implemented and 0 otherwise.

0x0019, **BUS_ACCESS**, Bus access

The counter counts each ‘Memory-read operation’ or [Memory-write operation](#) that accesses outside of the boundary of the PE and its closely-coupled caches.

Where this boundary lies with respect to any implemented caches is IMPLEMENTATION DEFINED. Where an implementation has multiple buses at this boundary, this event counts the sum of accesses across all buses.

A bus access is part of a bus transaction. The exact nature of a bus transaction is IMPLEMENTATION DEFINED, but for the purposes of event monitoring consists of a single access comprising one or more cycles, or beats, when the transaction occupies the bus. The [BUS_ACCESS](#) event counts each beat of each transaction. That is, each bus cycle counted by [BUS_CYCLES](#) for which the bus is active.

Bus transactions include refills of and write-backs from data, instruction, and unified caches. Whether bus transactions include operations that use the bus but do not explicitly transfer data is IMPLEMENTATION DEFINED.

An Unattributable bus transaction occurs when a requester outside the PE makes a request that results in a bus access, for example, a coherency request.

If a bus supports multiple accesses per cycle, for example through multiple channels, the counter increments once for each channel that is active on a cycle, and so it might increment by more than one in any given cycle.

The maximum increment in any given cycle is IMPLEMENTATION DEFINED.

PMCEID0_EL0[25] reads as 1 if this event is implemented and 0 otherwise.

0x001A, **MEMORY_ERROR**, Local memory error

The counter counts each occurrence of a memory error signaled by a memory closely coupled to this PE.

The definition of local memories is IMPLEMENTATION DEFINED but includes caches, tightly-coupled memories, and TLB arrays.

Memory error refers to a physical error detected by the hardware, such as a parity or ECC error. It includes errors that are correctable and those that are not. It does not include errors as defined in the architecture, such as MMU faults.

PMCEID0_EL0[26] reads as 1 if this event is implemented and 0 otherwise.

0x001B, **INST_SPEC**, Operation speculatively executed

The counter counts each [speculatively executed](#) operation.

This includes operations that are subsequently not architecturally executed.

PMCEID0_EL0[27] reads as 1 if this event is implemented and 0 otherwise.

0x001D, **BUS_CYCLES, Bus cycle**

The counter increments on every cycle of the interface at the boundary of the PE and its closely-coupled caches. Where this boundary lies with respect to any implemented caches is IMPLEMENTATION DEFINED.

Note

If the implementation clocks the external memory interface at the same rate as the processor hardware, then the counter counts every cycle.

PMCEID0_EL0[29] reads as 1 if this event is implemented and 0 otherwise.

0x001F, **L1D_CACHE_ALLOCATE, Level 1 data cache allocation without refill**

The counter counts each [Memory-write operation](#) that writes an entire line into the Level 1 data or unified cache without fetching data from outside the Level 1 data or unified cache.

These are allocations of cache lines in the Level 1 data or unified cache that are not refills counted by [L1D_CACHE_REFILL](#). For example:

- A write of an entire cache line from a coalescing write buffer.
- An operation such as `DC ZVA`.

The counter counts only [Memory-write operations](#) Attributable to the PE counting the event, and, if the Effective value of `PMEVTPER<n>_EL0.MT` for the counter is 1, other PEs in the multithreaded implementation.

PMCEID0_EL0[31] reads as 1 if this event is implemented and 0 otherwise.

0x0020, **L2D_CACHE_ALLOCATE, Level 2 data cache allocation without refill**

The counter counts each [Memory-write operation](#) that writes an entire line into the Level 2 data or unified cache without fetching data from outside the Level 2 data or unified cache.

These are allocations of cache lines in the Level 2 data or unified cache that are not refills counted by [L2D_CACHE_REFILL](#). For example:

- A write-back of an entire cache line from a Level 1 cache to the Level 2 data cache.
- A write of an entire cache line from a coalescing write buffer.
- An operation such as `DC ZVA`.

The counter counts only [Memory-write operations](#) Attributable to the PE counting the event, and, if the Effective value of `PMEVTPER<n>_EL0.MT` for the counter is 1, other PEs in the multithreaded implementation.

PMCEID1_EL0[0] reads as 1 if this event is implemented and 0 otherwise.

0x0022, **BR_MIS_PRED_RETIRED, Branch instruction architecturally executed, mispredicted**

The counter counts each branch instruction counted by [BR_RETIRED](#) that was not correctly predicted.

If no program-flow prediction resources are implemented, this event counts all retired not-taken branches.

PMCEID1_EL0[2] reads as 1 if this event is implemented and 0 otherwise.

0x0023, **STALL_FRONTEND, No operation sent for execution due to the frontend**

The counter counts each cycle counted by [CPU_CYCLES](#) where no Attributable instruction or operation was sent for execution and there was no Attributable instruction or operation available to dispatch for the PE from the frontend.

The division between frontend and backend is IMPLEMENTATION DEFINED. All [STALL](#) events are counted at the same point in the pipeline.

For a multithreaded processor implementation, if the Effective value of `PMEVTYPER<n>_EL0.MT` is 1, then the counter counts only if the stall condition is true for all the PEs in the multithreaded processor.

Note

- For a simplified pipeline model of Fetch-Decode-Issue-Execute-Retire, Arm recommends that the events are counted when instructions are dispatched from Decode to Issue.
 - In a single cycle, both the [STALL_BACKEND](#) and [STALL_FRONTEND](#) events might be counted, if both the backend is unable to accept any operations and there are no operations available to issue from the frontend.
-

`PMCEID1_EL0[3]` reads as 1 if this event is implemented and 0 otherwise.

0x0024, **STALL_BACKEND**, No operation sent for execution due to the backend

The counter counts each cycle counted by [CPU_CYCLES](#) where Attributable instructions or operations for the PE are available to dispatch from the frontend to the backend, but no Attributable instruction or operation is sent for execution because the backend is unable to accept any of the instructions or operations available for the PE.

For example, the backend might be unable to accept operations because of a resource conflict or non-availability.

It is IMPLEMENTATION DEFINED whether the counter also counts each cycle counted by [CPU_CYCLES](#) where no Attributable instructions or operations for the PE are available to dispatch from the frontend and the backend is unable to accept any instructions or operations for the PE.

The division between frontend and backend is IMPLEMENTATION DEFINED. For more information, see [STALL_FRONTEND](#). All [STALL](#) events are counted at the same point in the pipeline.

For a multithreaded processor implementation, if the Effective value of `PMEVTYPER<n>_EL0.MT` is 1, then the counter counts only if the stall condition is true for all the PEs in the multithreaded processor.

Note

In a single cycle, both the [STALL_BACKEND](#) and [STALL_FRONTEND](#) events might be counted, if both the backend is unable to accept any operations and there are no operations available to issue from the frontend.

`PMCEID1_EL0[4]` reads as 1 if this event is implemented and 0 otherwise.

0x0025, **L1D_TLB**, Level 1 data TLB access

The counter counts each ‘Memory-read operation’ or [Memory-write operation](#) that causes a TLB access to at least the Level 1 data or unified TLB.

Each access to a TLB entry is counted including multiple accesses caused by single instructions such as LDM or STM.

The counter does not count the access if the access is due to a TLB maintenance instruction.

If the TLB is shared and the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of `PMEVTYPER<n>_EL0.MT`.

`PMCEID1_EL0[5]` reads as 1 if this event is implemented and 0 otherwise.

0x0026, **L1I_TLB**, Level 1 instruction TLB access

The counter counts each [Instruction memory access](#) that causes a TLB access to at least the Level 1 instruction TLB.

The counter does not count the access if the access is due to a TLB maintenance instruction.

If the TLB is shared and the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of `PMEVTYPER<n>_EL0.MT`

for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of `PMEVTYPER<n>_EL0.MT`.

`PMCEID1_EL0[6]` reads as 1 if this event is implemented and 0 otherwise.

0x0027, **L2I_CACHE**, Level 2 instruction cache access

The counter counts each [Instruction memory access](#) to at least the Level 2 instruction or unified cache.

Each [Instruction memory access](#) to other Level 2 instruction or unified memory structures, such as refill buffers, is also counted.

It is IMPLEMENTATION DEFINED whether accesses that result from cache maintenance instructions are counted.

It is IMPLEMENTATION DEFINED whether accesses that only update the cache status information for a cache entry without accessing the content of the cache entry are counted. For example, whether the cached data is held in an exclusive or shared state.

When the [L2I_CACHE_RD](#) event is implemented:

- If the [L2I_CACHE_PRFM](#) event is implemented, accesses to the Level 2 instruction cache due to a prefetch instruction are counted. Otherwise, these are not counted.
- If the [L2I_CACHE_HWPRF](#) event is implemented, accesses to the Level 2 instruction cache due to a hardware prefetcher are counted. Otherwise these events are not counted.

When the [L2I_CACHE_RD](#) event is not implemented, it IMPLEMENTATION DEFINED whether accesses to the Level 2 instruction cache due to prefetch instructions or due to a hardware prefetcher are counted.

If the cache is shared and the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the cache is shared by PEs other than the PEs in the multithreaded processor and the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of `PMEVTYPER<n>_EL0.MT`.

`PMCEID1_EL0[7]` reads as 1 if this event is implemented and 0 otherwise.

0x0028, **L2I_CACHE_REFILL**, Level 2 instruction cache refill

The counter counts each access counted by [L2I_CACHE](#) that causes a refill of the Level 2 instruction or unified cache, or any Level 1 data, instruction, or unified cache of this PE, from outside of those caches.

A refill includes any access that causes data to be fetched from outside of the Level 1 and Level 2 caches, even if the data is ultimately not allocated into the Level 2 instruction cache. For example, data might be fetched into a buffer but then discarded, rather than being allocated into a cache. These buffers are treated as part of the cache.

For example, the counter counts:

- Accesses to the Level 2 instruction cache that cause a refill that is satisfied by fetching data from memory, a Level 3 cache, or a Level 2 cache of another PE.
- Refills of any Level 1 instruction or unified cache of this PE that cause a refill from outside of the Level 1 and Level 2 caches of this PE.
- Accesses to the Level 2 instruction cache that cause a refill of a Level 1 cache of this PE from outside of the Level 1 and Level 2 caches of this PE, even if there is no refill of the Level 2 instruction cache.

The counter does not count accesses that miss in the cache but are satisfied by the refill of a previous miss and do not cause a new refill, even if that previous refill is not complete at the time of the miss.

It is IMPLEMENTATION DEFINED whether accesses that result from cache maintenance instructions are counted.

If the cache is shared and the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the cache is shared by PEs other than the PEs in the multithreaded processor and the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other

cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of `PMEVTYPER<n>_EL0.MT`.

`PMCEID1_EL0[8]` reads as 1 if this event is implemented and 0 otherwise.

0x0029, **L3D_CACHE_ALLOCATE, Level 3 data cache allocation without refill**

The counter counts each [Memory-write operation](#) that writes an entire line into the Level 3 data or unified cache without fetching data from outside the Level 3 data or unified cache.

These are allocations of cache lines in the Level 3 data or unified cache that are not refills counted by [L3D_CACHE_REFILL](#). For example:

- A write-back of an entire cache line from a Level 2 cache to the Level 3 data cache.
- A write of an entire cache line from a coalescing write buffer.
- An operation such as `DC ZVA`.

The counter counts only [Memory-write operations](#) Attributable to the PE counting the event, and, if the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 1, other PEs in the multithreaded implementation.

`PMCEID1_EL0[9]` reads as 1 if this event is implemented and 0 otherwise.

0x002A, **L3D_CACHE_REFILL, Level 3 data cache refill**

The counter counts each access counted by [L3D_CACHE](#) that causes a refill of the Level 3 data or unified cache, or any Level 1 or Level 2 data, instruction, or unified cache of this PE, from outside of those caches.

A refill includes any access that causes data to be fetched from outside of the Level 1 to Level 3 caches, even if the data is ultimately not allocated into the Level 3 data cache. For example, data might be fetched into a buffer but then discarded, rather than being allocated into a cache. These buffers are treated as part of the cache.

For example, the counter counts:

- Accesses to the Level 3 data cache that cause a refill that is satisfied by fetching data from memory, a lower level cache, or a Level 3 cache of another PE.
- Refills of and write-backs from any Level 1 or Level 2 data, instruction, or unified caches of this PE that cause a refill from outside of the Level 1 to Level 3 caches of this PE.
- Accesses to the Level 3 data cache that cause a refill of a Level 2 cache of this PE from outside of the Level 1 to Level 3 caches of this PE, even if there is no refill of the Level 3 data cache.

The counter does not count accesses that:

- Miss in the cache but are satisfied by the refill of a previous miss and do not cause a new refill, even if that previous refill is not complete at the time of the miss.
- Miss in the cache but do not generate a refill, such as a write through the cache.

It is IMPLEMENTATION DEFINED whether accesses that result from cache maintenance instructions are counted.

If the cache is shared and the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the cache is shared by PEs other than the PEs in the multithreaded processor and the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of `PMEVTYPER<n>_EL0.MT`.

`PMCEID1_EL0[10]` reads as 1 if this event is implemented and 0 otherwise.

0x002B, **L3D_CACHE, Level 3 data cache access**

The counter counts each ‘Memory-read operation’ or [Memory-write operation](#) that causes a cache access to at least the Level 3 data or unified cache.

Each access to a cache line is counted including refills of and write-backs from other caches. Each access to other Level 3 data or unified memory structures, for example refill buffers, write buffers, and write-back buffers, is also counted.

It is IMPLEMENTATION DEFINED whether accesses that result from cache maintenance instructions are counted.

It is IMPLEMENTATION DEFINED whether accesses that only update the cache status information for a cache entry without accessing the content of the cache entry are counted. For example, whether the cached data is held in an exclusive or shared state.

When the **L3D_CACHE_RW** event is implemented:

- If the **L3D_CACHE_PRFM** event is implemented, accesses to the Level 3 data cache due to a prefetch instruction are counted. Otherwise, these accesses are not counted.
- If the **L3D_CACHE_HWPRF** event is implemented, accesses to the Level 3 data cache due to a hardware prefetcher are counted. Otherwise these accesses are not counted.

When the **L3D_CACHE_RW** event is not implemented, it IMPLEMENTATION DEFINED whether accesses to the Level 3 data cache due to prefetch instructions or due to a hardware prefetcher are counted.

If the cache is shared and the Effective value of **PMEVTYPER<n>_EL0.MT** for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the cache is shared by PEs other than the PEs in the multithreaded processor and the Effective value of **PMEVTYPER<n>_EL0.MT** for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of **PMEVTYPER<n>_EL0.MT**.

PMCEID1_EL0[11] reads as 1 if this event is implemented and 0 otherwise.

0x002C, **L3D_CACHE_WB, Level 3 data cache write-back**

The counter counts each write-back of data from the Level 3 data or unified cache to outside of the Level 1 to Level 3 caches.

For example:

- A write-back of a cache line to a lower level cache or memory.
- A write-back of a recently fetched cache line that has not been allocated to the Level 3 data cache.

Each write-back is counted once, even if multiple accesses are required to complete the write-back.

It is IMPLEMENTATION DEFINED whether the counter counts:

- A transfer of a dirty cache line from the Level 3 data cache to outside of Level 1 to Level 3 caches made as a result of a coherency request.
- Write-backs made as a result of cache maintenance instructions.

The counter does not count:

- The invalidation of a cache line without any write-back to outside of the Level 1 to Level 3 caches or memory.
- Writes that write through the Level 3 data cache to outside of the Level 1 to Level 3 caches.
- Transfers of data from the Level 3 data cache to a Level 1 or Level 2 cache to satisfy a refill of the other cache.

A write-back is attributable to one of the following, and it is IMPLEMENTATION DEFINED which:

- The PE or other agent that generated the request that caused the write-back. This might not be the same agent that caused the data to be allocated into the cache.
- If the cache is shared, the PE or other agent that caused the data to be allocated into the cache.
- If the cache is shared, the PE or other agent that last accessed the data when it was in the cache. If the data has not been accessed since being allocated, then the PE or other agent that caused the data to be allocated into the cache.

If the cache is shared, then the write-back event is counted only if it is attributable to the PE counting the event.

If the cache is not shared, then the event is counted by the PE that the cache is attached to, even if the write-back is not attributable to that PE. For example, a requestor outside of the PE made a coherency request that resulted in write-back.

It is IMPLEMENTATION DEFINED whether a write of a whole cache line that is not the result of the eviction of a line from the cache, is counted. For example, this applies when the PE determines software is streaming writes to memory and does not allocate lines to the cache, or by a DC ZVA operation.

PMCEID1_EL0[12] reads as 1 if this event is implemented and 0 otherwise.

0x002D, L2D_TLB_REFILL, Level 2 data TLB refill

The counter counts each access counted by L2D_TLB that causes a TLB refill of the Level 2 data or unified TLB, or any Level 1 data, instruction, or unified TLBs of this PE.

This includes each access that causes a memory access due to a translation table walk or an access to another level of TLB caching.

The counter does not count the access if any of the following are true:

- The access is due to a TLB maintenance instruction.
- The access generates a Translation fault because the applicable TCR_ELx.EPDy bit is 1.

It is IMPLEMENTATION DEFINED whether the counter counts the access if any of the following are true:

- The access misses in the TLB and generates a translation table walk, but the result is not allocated into the TLB for any reason other than a Translation fault.
- The access generates a Translation fault for any other reason.

If the TLB is shared and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of PMEVTYPER<n>_EL0.MT.

PMCEID1_EL0[13] reads as 1 if this event is implemented and 0 otherwise.

0x002E, L2I_TLB_REFILL, Level 2 instruction TLB refill

The counter counts each Instruction memory access counted by L2I_TLB that causes a TLB refill of the Level 2 instruction TLB, or any Level 1 data, instruction, or unified TLBs of this PE.

This includes each Instruction memory access that causes a memory access due to a translation table walk or an access to another level of TLB caching.

The counter does not count the access if any of the following are true:

- The access is due to a TLB maintenance instruction.
- The access generates a Translation fault because the applicable TCR_ELx.EPDy bit is 1.

It is IMPLEMENTATION DEFINED whether the counter counts the access if any of the following are true:

- The access misses in the TLB and generates a translation table walk, but the result is not allocated into the TLB for any reason other than a Translation fault.
- The access generates a Translation fault for any other reason.

If the TLB is shared and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of PMEVTYPER<n>_EL0.MT.

PMCEID1_EL0[14] reads as 1 if this event is implemented and 0 otherwise.

0x002F, **L2D_TLB, Level 2 data TLB access**

The counter counts each ‘Memory-read operation’ or [Memory-write operation](#) that causes a TLB access to at least the Level 2 data or unified TLB.

Each access to a TLB entry is counted including refills of Level 1 TLBs.

The counter does not count the access if the access is due to a TLB maintenance instruction.

If the TLB is shared and the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of `PMEVTYPER<n>_EL0.MT`.

`PMCEID1_EL0[15]` reads as 1 if this event is implemented and 0 otherwise.

0x0030, **L2I_TLB, Level 2 instruction TLB access**

The counter counts each [Instruction memory access](#) that causes a TLB access to at least the Level 2 instruction TLB.

Each access to a TLB entry is counted including refills of Level 1 TLBs.

The counter does not count the access if the access is due to a TLB maintenance instruction.

If the TLB is shared and the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of `PMEVTYPER<n>_EL0.MT`.

`PMCEID1_EL0[16]` reads as 1 if this event is implemented and 0 otherwise.

0x0031, **REMOTE_ACCESS, Access to a remote device**

The counter counts each ‘Memory-read operation’ or [Memory-write operation](#) that causes an access to a remote device.

That is, a socket that does not contain the PE.

System topology is IMPLEMENTATION DEFINED. This means that it is IMPLEMENTATION DEFINED which systems are defined as multi-socket systems, and, in systems defined as multi-socket systems, which components are defined as being in the same or different sockets. Arm recommends that devices where an access through that device incurs a significant latency penalty compared to other accesses are treated as being in a different socket.

For example, in a system comprising multiple integrated circuits in a multi-chip module, an access to a different integrated circuit in the same module might be treated as an access to another socket, even though the multi-chip module is physically connected to a single socket at the motherboard. However, in another system with many such multi-chip modules, an access to a different integrated system in the same module might be treated as an access to the same socket because an access to an integrated circuit on a different module has much higher latency.

It is IMPLEMENTATION DEFINED whether an access that causes a snoop into a different socket but does not return data from or pass data to the remote socket is counted.

`PMCEID1_EL0[17]` reads as 1 if this event is implemented and 0 otherwise.

0x0032, **LL_CACHE, Last level cache access**

The counter counts each ‘Memory-read operation’ or [Memory-write operation](#) that causes a cache access to at least the Last level cache.

Each access to a cache line is counted including refills of and write-backs from other caches. Each access to other Last level data or unified memory structures, for example refill buffers, write buffers, and write-back buffers, is also counted.

It is IMPLEMENTATION DEFINED whether accesses that result from cache maintenance instructions are counted.

It is IMPLEMENTATION DEFINED whether accesses that only update the cache status information for a cache entry without accessing the content of the cache entry are counted. For example, whether the cached data is held in an exclusive or shared state.

When the [LL_CACHE_RW](#) event is implemented:

- If the [LL_CACHE_PRFM](#) event is implemented, accesses to the Last level cache due to a prefetch instruction are counted. Otherwise, these accesses are not counted.
- If the [LL_CACHE_HWPRF](#) event is implemented, accesses to the Last level cache due to a hardware prefetcher are counted. Otherwise these accesses are not counted.

When the [LL_CACHE_RW](#) event is not implemented, it IMPLEMENTATION DEFINED whether accesses to the Last level cache due to prefetch instructions or due to a hardware prefetcher are counted.

If the cache is shared and the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the cache is shared by PEs other than the PEs in the multithreaded processor and the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of `PMEVTYPER<n>_EL0.MT`.

`PMCEID1_EL0[18]` reads as 1 if this event is implemented and 0 otherwise.

0x0033, [LL_CACHE_MISS](#), Last level cache miss

If the [LL_CACHE_RW](#) event is implemented, the counter counts each access counted by [LL_CACHE_RW](#) that is not completed by the Last level cache.

If the [LL_CACHE_RW](#) event is not implemented, the counter counts each access counted by [LL_CACHE](#) that is not completed by the Last level cache.

That is, the access is one of the following:

- A ‘Memory-read operation’ that does not return data from the Last level cache.
- A [Memory-write operation](#) that does not update the Last level cache.

The counter does not count operations that are completed by a cache above the Last level cache.

It is IMPLEMENTATION DEFINED whether accesses that result from cache maintenance instructions are counted.

If the cache is shared and the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the cache is shared by PEs other than the PEs in the multithreaded processor and the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of `PMEVTYPER<n>_EL0.MT`.

`PMCEID1_EL0[19]` reads as 1 if this event is implemented and 0 otherwise.

0x0034, [DTLB_WALK](#), Data TLB access with at least one translation table walk

The counter counts each access counted by [L1D_TLB](#) that causes a refill of a data or unified TLB involving at least one translation table walk access.

This includes each complete or partial translation table walk that causes an access to memory, including to data or translation table walk caches.

It is IMPLEMENTATION DEFINED whether accesses that cause an update of an existing TLB entry involving at least one translation table walk access are counted.

The counter does not count the access if any of the following are true:

- The access is due to a TLB maintenance instruction.
- The access generates a Translation fault because the applicable `TCR_ELx.EPDy` bit is 1.

It is IMPLEMENTATION DEFINED whether the counter counts the access if the access generates a Translation fault for any other reason.

If the TLB is shared and the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of `PMEVTYPER<n>_EL0.MT`.

`PMCEID1_EL0[20]` reads as 1 if this event is implemented and 0 otherwise.

0x0035, **ITLB_WALK**, Instruction TLB access with at least one translation table walk

The counter counts each access counted by `L1I_TLB` that causes a refill of an instruction TLB involving at least one translation table walk access.

This includes each complete or partial translation table walk that causes an access to memory, including to data or translation table walk caches.

It is IMPLEMENTATION DEFINED whether accesses that cause an update of an existing TLB entry involving at least one translation table walk access are counted.

The counter does not count the access if any of the following are true:

- The access is due to a TLB maintenance instruction.
- The access generates a Translation fault because the applicable `TCR_ELx.EPDy` bit is 1.

It is IMPLEMENTATION DEFINED whether the counter counts the access if the access generates a Translation fault for any other reason.

If the TLB is shared and the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of `PMEVTYPER<n>_EL0.MT`.

`PMCEID1_EL0[21]` reads as 1 if this event is implemented and 0 otherwise.

0x0036, **LL_CACHE_RD**, Last level cache access, read

If the `LL_CACHE_RW` event is implemented, the counter counts each access counted by `LL_CACHE_RW` that is a ‘Memory-read operation’.

If the `LL_CACHE_RW` event is not implemented, the counter counts each access counted by `LL_CACHE` that is a ‘Memory-read operation’.

If the cache is shared and the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the cache is shared by PEs other than the PEs in the multithreaded processor and the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of `PMEVTYPER<n>_EL0.MT`.

`PMCEID1_EL0[22]` reads as 1 if this event is implemented and 0 otherwise.

0x0037, **LL_CACHE_MISS_RD**, Last level cache miss, read

The counter counts each access counted by both `LL_CACHE_MISS` and `LL_CACHE_RD`.

That is, every miss of the Last level cache counted by `LL_CACHE_MISS` that is caused by a ‘Memory-read operation’.

If the cache is shared and the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the cache is

shared by PEs other than the PEs in the multithreaded processor and the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of `PMEVTYPER<n>_EL0.MT`.

`PMCEID1_EL0[23]` reads as 1 if this event is implemented and 0 otherwise.

0x0038, **REMOTE_ACCESS_RD, Access to a remote device, read**

The counter counts each access counted by `REMOTE_ACCESS` that is a 'Memory-read operation'.

`PMCEID1_EL0[24]` reads as 1 if this event is implemented and 0 otherwise.

0x0039, **L1D_CACHE_LMISS_RD, Level 1 data cache long-latency read miss**

The counter counts each 'Memory-read operation' to the Level 1 data or unified cache counted by `L1D_CACHE_RD` that incurs additional latency because it returns data from outside of the Level 1 data or unified cache of this PE.

The event indicates to software that the access missed in the Level 1 data or unified cache and might have a significant performance impact due to the additional latency compared to the latency of an access that hits in the Level 1 data or unified cache.

The counter does not count:

- Accesses where the additional latency is unlikely to be significantly performance-impacting. For example, if the access hits in another cache in the same local cluster, and the additional latency is small when compared to a miss in all Level 1 caches that the access looks up in and results in an access being made to a Level 2 cache or elsewhere beyond the Level 1 data or unified cache.
- A miss that does not cause a new cache refill but is satisfied from a previous miss.

An implementation is not required to measure the latency, nor to track the access to determine whether the additional latency caused a performance impact. An implementation can extend the definition of this event with additional scenarios where an access might have a significant performance impact due to additional latency for the access.

It is IMPLEMENTATION DEFINED whether accesses that result from cache maintenance operations are counted.

If the cache is shared and the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the cache is shared by PEs other than the PEs in the multithreaded processor and the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of `PMEVTYPER<n>_EL0.MT`.

`PMCEID1_EL0[25]` reads as 1 if this event is implemented and 0 otherwise.

0x003A, **OP_RETIRED, Micro-operation architecturally executed**

The counter counts each operation counted by `OP_SPEC` that would be executed in a Simple sequential execution of the program.

`PMCEID1_EL0[26]` reads as 1 if this event is implemented and 0 otherwise.

0x003B, **OP_SPEC, Micro-operation speculatively executed**

The counter counts each operation `speculatively executed` executed by the PE.

This includes operations that would not be executed in a Simple sequential execution of the program.

`PMCEID1_EL0[27]` reads as 1 if this event is implemented and 0 otherwise.

0x003C, **STALL, No operation sent for execution**

The counter counts each cycle counted by [CPU_CYCLES](#) where no operation was sent for execution.

On a multithreaded implementation:

- If the Effective value of `PMEVTPER<n>_EL0.MT` is 0, then the counter counts cycles when the PE is active and no operation for the PE is sent for execution, even if operations Attributable to other PEs in the multithreaded implementation are sent for execution in that cycle. The counter does not count cycles when the PE is not active.
- If the Effective value of `PMEVTPER<n>_EL0.MT` is 1, then the counter counts all cycles when no instructions or operations for any PE in the multithreaded implementation were sent for execution.

All [STALL](#) events are counted at the same point in the pipeline.

`PMCEID1_EL0[28]` reads as 1 if this event is implemented and 0 otherwise.

0x003D, **STALL_SLOT_BACKEND, No operation sent for execution on a Slot due to the backend**

The counter counts each Slot counted by [STALL_SLOT](#) where an Attributable instruction or operation for the PE is available on the Slot to dispatch from the frontend to the backend, but is not sent for execution because the backend is unable to accept the available instruction or operation for the PE.

It is IMPLEMENTATION DEFINED whether the counter also counts each Slot counted by [STALL_SLOT](#) where no Attributable instruction or operation for the PE is available on the Slot to dispatch from the frontend and the backend is unable to accept any instruction or operation for the PE.

The division between frontend and backend is IMPLEMENTATION DEFINED. For more information, see [STALL_FRONTEND](#). All [STALL](#) events are counted at the same point in the pipeline. The maximum value by which [STALL_SLOT_BACKEND](#) can count in a single cycle is an IMPLEMENTATION DEFINED fixed value, `slots`. For more information, see [STALL_SLOT](#).

Note

In a single cycle, the sum of values counted by [STALL_SLOT_BACKEND](#) and [STALL_SLOT_FRONTEND](#) might be greater-than `slots`, if both the backend is unable to accept some operations and there are fewer-than `slots` operations available to dispatch from the frontend.

`PMCEID1_EL0[29]` reads as 1 if this event is implemented and 0 otherwise.

0x003E, **STALL_SLOT_FRONTEND, No operation sent for execution on a Slot due to the frontend**

The counter counts each Slot counted by [STALL_SLOT](#) where no Attributable instruction or operation was sent for execution and there was no Attributable instruction or operation available to dispatch for the PE from the frontend for the Slot.

The division between frontend and backend is IMPLEMENTATION DEFINED. For more information, see [STALL_FRONTEND](#). All [STALL](#) events are counted at the same point in the pipeline. The maximum value by which [STALL_SLOT_FRONTEND](#) can count in a single cycle is an IMPLEMENTATION DEFINED fixed value, `slots`. For more information, see [STALL_SLOT](#).

Note

In a single cycle, the sum of values counted by [STALL_SLOT_BACKEND](#) and [STALL_SLOT_FRONTEND](#) might be greater-than `slots`, if both the backend is unable to accept some operations and there are fewer-than `slots` operations available to dispatch from the frontend.

`PMCEID1_EL0[30]` reads as 1 if this event is implemented and 0 otherwise.

0x003F, **STALL_SLOT, No operation sent for execution on a Slot**

The counter increments by the number of instruction or operation Slots that were not occupied by an instruction or operation Attributable to the PE on each cycle.

All **STALL** events are counted at the same point in the pipeline. The maximum value by which **STALL_SLOT** can count in a single cycle is an IMPLEMENTATION DEFINED fixed value, `slots`. The definition of a Slot is IMPLEMENTATION DEFINED. The formula $\text{STALL_SLOT} \div (\text{CPU_CYCLES} \times \text{slots})$ gives the utilization of the Slots of the processor by Attributable instruction or operations of this PE. Each Slot holds at most one instruction or operation each cycle.

On a multithreaded implementation:

- If the Effective value of **PMEVTYPER**<n>_EL0.MT is 0, then the counter counts Slots occupied by an instruction or operation Attributable to other PEs of the multithreaded implementation only when the PE was active in that cycle. The counter does not count Slots on cycles when the PE was not active.
- If the Effective value of **PMEVTYPER**<n>_EL0.MT is 1, then, for every cycle, the counter counts all Slots not occupied by any instruction or operation for any PE of the multithreaded implementation.

PMCEID1_EL0[31] reads as 1 if this event is implemented and 0 otherwise.

0x0040, **L1D_CACHE_RD, Level 1 data cache access, read**

If the **L1D_CACHE_RW** event is implemented, the counter counts each access counted by **L1D_CACHE_RW** that is a ‘Memory-read operation’.

If the **L1D_CACHE_RW** event is not implemented, the counter counts each access counted by **L1D_CACHE** that is a ‘Memory-read operation’.

If the cache is shared and the Effective value of **PMEVTYPER**<n>_EL0.MT for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the cache is shared by PEs other than the PEs in the multithreaded processor and the Effective value of **PMEVTYPER**<n>_EL0.MT for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of **PMEVTYPER**<n>_EL0.MT.

0x0041, **L1D_CACHE_WR, Level 1 data cache access, write**

If the **L1D_CACHE_RW** event is implemented, the counter counts each access counted by **L1D_CACHE_RW** that is a Memory-write operation.

If the **L1D_CACHE_RW** event is not implemented, the counter counts each access counted by **L1D_CACHE** that is a Memory-write operation.

If the cache is shared and the Effective value of **PMEVTYPER**<n>_EL0.MT for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the cache is shared by PEs other than the PEs in the multithreaded processor and the Effective value of **PMEVTYPER**<n>_EL0.MT for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of **PMEVTYPER**<n>_EL0.MT.

0x0042, **L1D_CACHE_REFILL_RD, Level 1 data cache refill, read**

The counter counts each access counted by both **L1D_CACHE_RD** and **L1D_CACHE_REFILL**.

That is, every refill of the Level 1 data or unified cache counted by **L1D_CACHE_REFILL** that is caused by a ‘Memory-read operation’.

If the cache is shared and the Effective value of **PMEVTYPER**<n>_EL0.MT for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the cache is shared by PEs other than the PEs in the multithreaded processor and the Effective value of **PMEVTYPER**<n>_EL0.MT for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of **PMEVTYPER**<n>_EL0.MT.

0x0043, **L1D_CACHE_REFILL_WR, Level 1 data cache refill, write**

The counter counts each access counted by both **L1D_CACHE_REFILL** and **L1D_CACHE_WR**.

That is, every refill of the Level 1 data or unified cache counted by [L1D_CACHE_REFILL](#) that is caused by a [Memory-write operation](#).

If the cache is shared and the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the cache is shared by PEs other than the PEs in the multithreaded processor and the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of `PMEVTYPER<n>_EL0.MT`.

0x0044, **L1D_CACHE_REFILL_INNER, Level 1 data cache refill, inner**

The counter counts each access counted by [L1D_CACHE_REFILL](#) that generates a refill satisfied by transfer from another cache inside of the immediate cluster.

Note

The boundary between inner and outer is IMPLEMENTATION DEFINED, and it is not necessarily linked to other similar boundaries, such as the boundary between Inner Cacheable and Outer Cacheable or the boundary between Inner Shareable and Outer Shareable.

If the cache is shared and the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the cache is shared by PEs other than the PEs in the multithreaded processor and the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of `PMEVTYPER<n>_EL0.MT`.

0x0045, **L1D_CACHE_REFILL_OUTER, Level 1 data cache refill, outer**

The counter counts each access counted by [L1D_CACHE_REFILL](#) that generates a refill satisfied by transfer from outside of the immediate cluster.

Note

The boundary between inner and outer is IMPLEMENTATION DEFINED, and it is not necessarily linked to other similar boundaries, such as the boundary between Inner Cacheable and Outer Cacheable or the boundary between Inner Shareable and Outer Shareable.

If the cache is shared and the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the cache is shared by PEs other than the PEs in the multithreaded processor and the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of `PMEVTYPER<n>_EL0.MT`.

0x0046, **L1D_CACHE_WB_VICTIM, Level 1 data cache write-back, victim**

The counter counts each write-back counted by [L1D_CACHE_WB](#) that occurs because of a capacity eviction due to a line being allocated into the cache..

It is IMPLEMENTATION DEFINED whether this includes capacity evictions due to an agent other the PE counting the event. For example, a stashing request from outside of the PE, or an allocation due to another PE that shares the cache.

In all cases, the event is counted only if the eviction is also an [L1D_CACHE_WB](#) event. This means that, if the cache is shared, the eviction is counted only if it is attributable to the PE counting the event, as defined by [L1D_CACHE_WB](#).

0x0047, **L1D_CACHE_WB_CLEAN, Level 1 data cache write-back, cleaning and coherency**

The counter counts each write-back counted by [L1D_CACHE_WB](#) that occurs because of a coherency operation made by another PE or, optionally, the execution of a cache maintenance instruction..

It is IMPLEMENTATION DEFINED whether the transfer of a dirty cache line from the Level 1 data cache of this PE to the data cache of another PE due to a hardware coherency operation is counted when the dirty cache line is not also written back to a Level 2 cache or memory.

In all cases, the event is counted only if the write-back is also an [L1D_CACHE_WB](#) event. This means that, if the cache is shared, the write-back is counted only if it is attributable to the PE counting the event, as defined by [L1D_CACHE_WB](#).

0x0048, **L1D_CACHE_INVALID, Level 1 data cache invalidate**

The counter counts each invalidation of a cache line in the Level 1 data or unified cache. For example:

- Invalidation of a cache line because of a cache maintenance operation.
- Transfer of ownership of a cache line to another cache because of a coherency or refill request.

The counter does not count events if a cache refill of the Level 1 data or unified cache invalidates a line in the Level 1 data or unified cache.

The counter does not count locally-executed cache maintenance instructions that operate by set/way.

Note

Software that uses this event must know whether the Level 1 data cache is shared with other PEs. This event does not follow the general rule of Level 1 data cache events of only counting Attributable events.

0x004C, **L1D_TLB_REFILL_RD, Level 1 data TLB refill, read**

The counter counts each access counted by both [L1D_TLB_RD](#) and [L1D_TLB_REFILL](#).

The counter does not count the access if any of the following are true:

- The access generates a Translation fault because the applicable TCR_ELx.EPDy bit is 1.

It is IMPLEMENTATION DEFINED whether the counter counts the access if the access generates a Translation fault for any other reason.

If the TLB is shared and the Effective value of PMEVTYPEPER<n>_EL0.MT for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of PMEVTYPEPER<n>_EL0.MT for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of PMEVTYPEPER<n>_EL0.MT.

0x004D, **L1D_TLB_REFILL_WR, Level 1 data TLB refill, write**

The counter counts each access counted by both [L1D_TLB_REFILL](#) and [L1D_TLB_WR](#).

The counter does not count the access if any of the following are true:

- The access generates a Translation fault because the applicable TCR_ELx.EPDy bit is 1.

It is IMPLEMENTATION DEFINED whether the counter counts the access if the access generates a Translation fault for any other reason.

If the TLB is shared and the Effective value of PMEVTYPEPER<n>_EL0.MT for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of PMEVTYPEPER<n>_EL0.MT for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of PMEVTYPEPER<n>_EL0.MT.

0x004E, L1D_TLB_RD, Level 1 data TLB access, read

If the [L1D_TLB_RW](#) event is implemented, the counter counts each access counted by [L1D_TLB_RW](#) that is due to a demand 'Memory-read operation'.

If the [L1D_TLB_RW](#) event is not implemented, the counter counts each access counted by [L1D_TLB](#) that is due to a 'Memory-read operation'.

If the TLB is shared and the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of `PMEVTYPER<n>_EL0.MT`.

0x004F, L1D_TLB_WR, Level 1 data TLB access, write

If the [L1D_TLB_RW](#) event is implemented, the counter counts each access counted by [L1D_TLB_RW](#) that is due to a demand [Memory-write operation](#).

If the [L1D_TLB_RW](#) event is not implemented, the counter counts each access counted by [L1D_TLB](#) that is due to a [Memory-write operation](#).

If the TLB is shared and the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of `PMEVTYPER<n>_EL0.MT`.

0x0050, L2D_CACHE_RD, Level 2 data cache access, read

If the [L2D_CACHE_RW](#) event is implemented, the counter counts each access counted by [L2D_CACHE_RW](#) that is a 'Memory-read operation'.

If the [L2D_CACHE_RW](#) event is not implemented, the counter counts each access counted by [L2D_CACHE](#) that is a 'Memory-read operation'.

If the cache is shared and the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the cache is shared by PEs other than the PEs in the multithreaded processor and the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of `PMEVTYPER<n>_EL0.MT`.

0x0051, L2D_CACHE_WR, Level 2 data cache access, write

If the [L2D_CACHE_RW](#) event is implemented, the counter counts each access counted by [L2D_CACHE_RW](#) that is a [Memory-write operation](#).

If the [L2D_CACHE_RW](#) event is not implemented, the counter counts each access counted by [L2D_CACHE](#) that is a [Memory-write operation](#).

If the cache is shared and the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the cache is shared by PEs other than the PEs in the multithreaded processor and the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of `PMEVTYPER<n>_EL0.MT`.

0x0052, L2D_CACHE_REFILL_RD, Level 2 data cache refill, read

The counter counts each access counted by both [L2D_CACHE_RD](#) and [L2D_CACHE_REFILL](#).

That is, every refill of the Level 2 data or unified cache counted by [L2D_CACHE_REFILL](#) that is caused by a ‘Memory-read operation’.

If the cache is shared and the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the cache is shared by PEs other than the PEs in the multithreaded processor and the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of `PMEVTYPER<n>_EL0.MT`.

0x0053, [L2D_CACHE_REFILL_WR](#), Level 2 data cache refill, write

The counter counts each access counted by both [L2D_CACHE_REFILL](#) and [L2D_CACHE_WR](#).

That is, every refill of the Level 2 data or unified cache counted by [L2D_CACHE_REFILL](#) that is caused by a [Memory-write operation](#).

If the cache is shared and the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the cache is shared by PEs other than the PEs in the multithreaded processor and the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of `PMEVTYPER<n>_EL0.MT`.

0x0056, [L2D_CACHE_WB_VICTIM](#), Level 2 data cache write-back, victim

The counter counts each write-back counted by [L2D_CACHE_WB](#) that occurs because of a capacity eviction due to a line being allocated into the cache..

It is IMPLEMENTATION DEFINED whether this includes capacity evictions due to an agent other the PE counting the event. For example, a stashing request from outside of the PE, or an allocation due to another PE that shares the cache.

In all cases, the event is counted only if the eviction is also an [L2D_CACHE_WB](#) event. This means that, if the cache is shared, the eviction is counted only if it is attributable to the PE counting the event, as defined by [L2D_CACHE_WB](#).

0x0057, [L2D_CACHE_WB_CLEAN](#), Level 2 data cache write-back, cleaning and coherency

The counter counts each write-back counted by [L2D_CACHE_WB](#) that occurs because of a coherency operation made by another PE or, optionally, the execution of a cache maintenance instruction..

It is IMPLEMENTATION DEFINED whether the transfer of a dirty cache line from the Level 1 data cache of this PE to the data cache of another PE due to a hardware coherency operation is counted when the dirty cache line is not also written back to a Level 2 cache or memory.

In all cases, the event is counted only if the write-back is also an [L2D_CACHE_WB](#) event. This means that, if the cache is shared, the write-back is counted only if it is attributable to the PE counting the event, as defined by [L2D_CACHE_WB](#).

0x0058, [L2D_CACHE_INVAL](#), Level 2 data cache invalidate

The counter counts each invalidation of a cache line in the Level 2 data or unified cache. For example:

- Invalidation of a cache line because of a cache maintenance operation.
- Transfer of ownership of a cache line to another cache because of a coherency or refill request.

The counter does not count events if a cache refill of the Level 2 data or unified cache invalidates a line in the Level 2 data or unified cache.

The counter does not count locally-executed cache maintenance instructions that operate by set/way.

Note

Software that uses this event must know whether the Level 2 data cache is shared with other PEs. This event does not follow the general rule of Level 2 data cache events of only counting Attributable events.

0x005C, L2D_TLB_REFILL_RD, Level 2 data TLB refill, read

The counter counts each access counted by both [L2D_TLB_RD](#) and [L2D_TLB_REFILL](#).

The counter does not count the access if any of the following are true:

- The access generates a Translation fault because the applicable TCR_ELx.EPDy bit is 1.

It is IMPLEMENTATION DEFINED whether the counter counts the access if the access generates a Translation fault for any other reason.

If the TLB is shared and the Effective value of PMEVTYPEPER<n>_EL0.MT for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of PMEVTYPEPER<n>_EL0.MT for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of PMEVTYPEPER<n>_EL0.MT.

0x005D, L2D_TLB_REFILL_WR, Level 2 data TLB refill, write

The counter counts each access counted by both [L2D_TLB_REFILL](#) and [L2D_TLB_WR](#).

The counter does not count the access if any of the following are true:

- The access generates a Translation fault because the applicable TCR_ELx.EPDy bit is 1.

It is IMPLEMENTATION DEFINED whether the counter counts the access if the access generates a Translation fault for any other reason.

If the TLB is shared and the Effective value of PMEVTYPEPER<n>_EL0.MT for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of PMEVTYPEPER<n>_EL0.MT for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of PMEVTYPEPER<n>_EL0.MT.

0x005E, L2D_TLB_RD, Level 2 data TLB access, read

If the L2D_TLB_RW event is implemented, the counter counts each access counted by L2D_TLB_RW that is due to a demand 'Memory-read operation'.

If the L2D_TLB_RW event is not implemented, the counter counts each access counted by [L2D_TLB](#) that is due to a 'Memory-read operation'.

If the TLB is shared and the Effective value of PMEVTYPEPER<n>_EL0.MT for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of PMEVTYPEPER<n>_EL0.MT for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of PMEVTYPEPER<n>_EL0.MT.

0x005F, L2D_TLB_WR, Level 2 data TLB access, write

If the L2D_TLB_RW event is implemented, the counter counts each access counted by L2D_TLB_RW that is due to a demand [Memory-write operation](#).

If the L2D_TLB_RW event is not implemented, the counter counts each access counted by [L2D_TLB](#) that is due to a [Memory-write operation](#).

If the TLB is shared and the Effective value of PMEVTYPEPER<n>_EL0.MT for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of PMEVTYPEPER<n>_EL0.MT for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other

cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of PMEVTYPER<n>_EL0.MT.

0x0060, **BUS_ACCESS_RD, Bus access, read**

The counter counts each access counted by [BUS_ACCESS](#) that is a ‘Memory-read operation’.

0x0061, **BUS_ACCESS_WR, Bus access, write**

The counter counts each access counted by [BUS_ACCESS](#) that is a [Memory-write operation](#).

0x0062, **BUS_ACCESS_SHARED, Bus access, Normal, Cacheable, Shareable**

The counter counts each access counted by [BUS_ACCESS](#) that is Normal, Cacheable, Shareable.

Note

It is IMPLEMENTATION DEFINED how the PE translates the attributes from the translation table entry for a region to the attributes on the bus.

In particular, a region of memory designated as Normal, Cacheable, Inner Shareable, Not Outer Shareable by a translation table entry, might be marked as either shareable or Non-shareable at the boundary of the PE and its closely-coupled caches. This depends on where the IMPLEMENTATION DEFINED boundary lies, between Inner and Outer Shareable.

If the Inner Shareable extends beyond the PE boundary, and the bus indicates the distinction between Inner and Outer Shareable, then either is counted as shareable for the purposes of defining this event.

0x0063, **BUS_ACCESS_NOT_SHARED, Bus access, not Normal, Cacheable, Shareable**

The counter counts each access counted by [BUS_ACCESS](#) that is not counted by [BUS_ACCESS_SHARED](#).

For example, the counter counts accesses marked as:

- Normal, Cacheable, Non-shareable.
- Normal, Non-cacheable.
- Device.

Note

It is IMPLEMENTATION DEFINED, how the PE translates the attributes from the translation table entries for a region to the attributes on the bus.

In particular, a region of memory designated as Normal, Cacheable, Inner Shareable, Not Outer Shareable by a translation table entry, might be marked as either shareable or Non-shareable at the boundary of the PE and its closely-coupled caches. This depends on where the IMPLEMENTATION DEFINED boundary lies, between Inner and Outer Shareable.

If the Inner Shareable extends beyond the PE boundary, and the bus indicates the distinction between Inner and Outer Shareable, then either is counted as shareable for the purposes of defining this event.

0x0064, **BUS_ACCESS_NORMAL, Bus access, normal**

The counter counts each access counted by [BUS_ACCESS](#) that is to Normal or bulk memory.

For example, the counter counts Normal, Cacheable and Normal, Non-cacheable accesses but does not count Device accesses.

0x0065, **BUS_ACCESS_PERIPH, Bus access, peripheral**

The counter counts each access counted by [BUS_ACCESS](#) that is not counted by [BUS_ACCESS_NORMAL](#).

For example, the counter counts accesses to Device memory.

0x0066, **MEM_ACCESS_RD, Data memory access, read**

If the [MEM_ACCESS_RW](#) event is implemented, the counter counts each access counted by [MEM_ACCESS_RW](#) that is a ‘Memory-read operation’.

If the [MEM_ACCESS_RW](#) event is not implemented, the counter counts each access counted by [MEM_ACCESS](#) that is a ‘Memory-read operation’.

0x0067, **MEM_ACCESS_WR, Data memory access, write**

If the [MEM_ACCESS_RW](#) event is implemented, the counter counts each access counted by [MEM_ACCESS_RW](#) that is a [Memory-write operation](#).

If the [MEM_ACCESS_RW](#) event is not implemented, the counter counts each access counted by [MEM_ACCESS](#) that is a [Memory-write operation](#).

0x0068, **UNALIGNED_LD_SPEC, Unaligned access, read**

The counter counts each unaligned access counted by [UNALIGNED_LDST_SPEC](#) that is a ‘Memory-read operation’.

The unaligned access is counted even if it is subsequently transformed into multiple aligned accesses.

0x0069, **UNALIGNED_ST_SPEC, Unaligned access, write**

The counter counts each unaligned access counted by [UNALIGNED_LDST_SPEC](#) that is a [Memory-write operation](#).

The unaligned access is counted even if it is subsequently transformed into multiple aligned accesses.

0x006A, **UNALIGNED_LDST_SPEC, Unaligned access**

The counter counts each access counted by [MEM_ACCESS](#) that is an unaligned ‘Memory-read operation’ or unaligned [Memory-write operation](#).

The unaligned access is counted even if it is subsequently transformed into multiple aligned accesses.

0x006C, **LDREX_SPEC, Exclusive operation speculatively executed, Load-Exclusive**

The counter counts each [speculatively executed](#) Load-Exclusive instruction.

The definition of [speculatively executed](#) is IMPLEMENTATION DEFINED but must be the same as for the [STREX_SPEC](#) event.

0x006D, **STREX_PASS_SPEC, Exclusive operation speculatively executed, Store-Exclusive pass**

The counter counts each [speculatively executed](#) Store-Exclusive instruction counted by [STREX_SPEC](#) that completed a write.

0x006E, **STREX_FAIL_SPEC, Exclusive operation speculatively executed, Store-Exclusive fail**

The counter counts each [speculatively executed](#) Store-Exclusive instruction counted by [STREX_SPEC](#) that fails to complete a write.

It is within the IMPLEMENTATION DEFINED definition of [speculatively executed](#) whether this includes conditional instructions that fail the condition code check.

0x006F, **STREX_SPEC, Exclusive operation speculatively executed, Store-Exclusive**

The counter counts each [speculatively executed](#) Store-Exclusive instruction.

The definition of [speculatively executed](#) is IMPLEMENTATION DEFINED but it must be the same as for the [LDREX_SPEC](#) event.

Arm recommends that this event is implemented if it is not possible to implement the exclusive operation [speculatively executed](#), Store-Exclusive pass, and exclusive operation [speculatively executed](#), Store-Exclusive fail, events with the same degree of speculation as the [LDREX_SPEC](#) event.

0x0070, **LD_SPEC, Operation speculatively executed, load**

The counter counts each operation counted by [LDST_SPEC](#) that is a load operation.

Operations due to 'Memory-reading instructions' are counted as load operations.

It is IMPLEMENTATION DEFINED whether operations due to the prefetch instructions counted by [PRF_SPEC](#) are counted as load operations:

- If operations due to the prefetch instructions are counted as load operations, then they are counted by [LD_SPEC](#).
- Otherwise, if operations due to the prefetch instructions are not counted as load operations by [LD_SPEC](#), then it is further IMPLEMENTATION DEFINED which one of the following applies:
 - They are counted as data-processing operations.
 - They are counted by [LDST_SPEC](#).

Arm recommends that if a prefetch operation is not implemented as a NOP and the [PRF_SPEC](#) event is not implemented, then the operation is counted as a load operation.

0x0071, **ST_SPEC, Operation speculatively executed, store**

The counter counts each operation counted by [LDST_SPEC](#) that is a store operation.

Operations due to 'Memory-writing instructions' are counted as store operations.

0x0072, **LDST_SPEC, Operation speculatively executed, load or store**

The counter counts each operation counted by [INST_SPEC](#) that is a load operation or a store operation.

See [LD_SPEC](#) and [ST_SPEC](#) for these classifications.

If the [PRF_SPEC](#) event is implemented and operations due to the prefetch instructions counted by [PRF_SPEC](#) are not counted as load operations by [LD_SPEC](#), then it is IMPLEMENTATION DEFINED whether these operations are counted by [LDST_SPEC](#). Arm recommends that these operations are counted by [LDST_SPEC](#).

0x0073, **DP_SPEC, Operation speculatively executed, integer data processing**

The counter counts each operation counted by [INST_SPEC](#) that is an integer data-processing operation.

An integer data-processing operation is any operation that is not counted as any of the following:

- A load or store operation, counted by [LDST_SPEC](#).
- A Software change of PC operation, counted by [PC_WRITE_SPEC](#).
- A scalar floating-point data processing operation, counted by [VFP_SPEC](#).
- An Advanced SIMD or SVE data processing operation, counted by [ASE_SVE_SPEC](#).
- A cryptographic operation, counted by [CRYPTO_SPEC](#).

That is, operations due to the following instructions are counted as integer data-processing operations:

- In AArch64 state instructions from the following sections:
 - Data processing - immediate.
 - Data processing - register.
 - System register instructions.

- ‘Instructions with register argument’.
- System instructions other than ‘Memory-writing instructions’.
- Hint instructions.
- In AArch32 state instructions from the following sections:
 - [Data-processing instructions](#).
 - [PSTATE and banked register access instructions](#).
 - [Banked register access instructions](#).
 - [Miscellaneous instructions](#) other than `ISB` and prefetches.
 - [System register access instructions](#) other than `LDC` and `STC` instructions.

0x0074, **ASE_SPEC, Operation speculatively executed, Advanced SIMD data processing**

The counter counts each operation counted by [INST_SPEC](#) that is an Advanced SIMD data-processing operation.

Operations due to the following instructions are counted as Advanced SIMD data-processing operations:

- For AArch64 state:
 - The SIMD operations listed in Data processing - SIMD and floating-point.
 - Advanced SIMD scalar instructions, including those which operate on floating-point values.
 - If [FEAT_Crypto](#) is implemented, the Advanced SIMD `PMULL` and `PMULL2` (1Q variants) instructions. See [The Cryptographic Extension in AArch64 state](#).
- For AArch32 state:
 - Instructions from [Advanced SIMD data-processing instructions](#).
 - If [FEAT_Crypto](#) is implemented, the `VMULL` (P64 variant) instruction. See [The Cryptographic Extension in AArch32 state](#).

This includes all operations that operate on the SIMD&FP registers, except those that are counted as one of the following:

- Integer data-processing operations.
- Scalar floating-point data-processing operations.
- Load or store operations.
- Cryptographic data-processing operations counted by [CRYPTO_SPEC](#). [CRYPTO_SPEC](#) does not count the Cryptographic data-processing operations included above.

0x0075, **VFP_SPEC, Operation speculatively executed, scalar floating-point data processing**

The counter counts each operation counted by [INST_SPEC](#) that is a scalar floating-point operation.

Operations due to the following instructions are counted as scalar floating-point data-processing operations:

- In AArch64 state:
 - The scalar floating-point operations from Data processing - SIMD and floating-point. Only the scalar operations are counted. SIMD floating-point operations are not counted.
 - Operations that take both an integer register and a floating-point register argument and perform a type conversion (to/from integer or to/from fixed-point): `FCVT{<mode>}`, `UCVTF`, and `SCVTF`.
- In AArch32 state:
 - Instructions from [Floating-point data-processing instructions](#).
 - Operations that take both an integer register and a floating-point register argument and perform a type conversion (to/from integer or to/from fixed-point): `VCVT<mode>` (floating-point), `VCVT`, `VCVTT`, and `VCVTB`.

This includes all scalar operations that operate on the SIMD&FP registers as floating-point values, except those that are counted as one of the following:

- SIMD scalar operations.
- Integer data-processing operations.
- Load or store operations.

0x0076, **PC_WRITE_SPEC**, Operation speculatively executed, Software change of the PC

The counter counts each operation counted by [INST_SPEC](#) that is a [Software change of the PC](#).

[Software change of the PC](#) operations are defined by the [PC_WRITE_RETIRED](#) event.

It is IMPLEMENTATION DEFINED whether the counter counts the operation when the branch is not taken.

0x0077, **CRYPTO_SPEC**, Operation speculatively executed, cryptographic data processing

The counter counts each operation counted by [INST_SPEC](#) that is a cryptographic operation.

Operations due to the following instructions are counted as cryptographic data-processing operations:

- In AArch64 state, instructions from The Cryptographic Extension in AArch64 state other than the include Advanced SIMD [PMULL](#) and [PMULL2](#) (1Q variants) instructions.
- In AArch32 state, instructions from [The Cryptographic Extension in AArch32 state](#) other than [VMULL](#) (P64 variant).

0x0078, **BR_IMMED_SPEC**, Branch speculatively executed, immediate branch

The counter counts each [speculatively executed](#) immediate branch instruction.

Operations due to the following instructions are counted as [speculatively executed](#) immediate branch instructions:

- For AArch32 state, the following instructions:
 - B{<c>} <label>.
 - BL{<c>} <label>.
 - BLX{<c>} <label>.
 - CBZ <Rn>, <label>.
 - CBNZ <label>.
- For AArch64 state, the following instructions:
 - B <label>.
 - B.cond <label>.
 - BL <label>.
 - CBZ <Rn>, <label>.
 - CBNZ <Rn>, <label>.
 - TBZ <Rn>, <label>.
 - TBNZ <Rn>, <label>.

Note

Conditional branches are always counted, regardless of whether the branch is taken or not taken.

If the Context synchronization barrier instruction ISB is counted as a [Software change of the PC](#) instruction by [PC_WRITE_SPEC](#), then it is IMPLEMENTATION DEFINED whether ISB is counted as a [speculatively executed](#) immediate branch instruction.

0x0079, **BR_RETURN_SPEC**, Branch speculatively executed, procedure return

The counter counts each [speculatively executed](#) procedure return instruction.

Operations due to the following instructions are counted as [speculatively executed](#) procedure return instructions:

- For AArch32 state, the following instructions:
 - BX R14.
 - MOV PC, LR.
 - POP {..., PC}.
 - LDR PC, [SP], #offset.
- For AArch64 state, the following instructions:
 - RET.

Note

The counter counts only the listed instructions as procedure returns. For example, it does not count the following AArch32 instructions as procedure return instructions:

- BX R0, because Rm != R14.
 - MOV PC, R0, because Rm != R14.
 - LDM SP, {..., PC}, because writeback is not specified.
 - LDR PC, [SP, #offset], because this specifies the wrong addressing mode.
-

0x007A, **BR_INDIRECT_SPEC, Branch speculatively executed, indirect branch**

The counter counts each [speculatively executed](#) indirect branch instruction.

Indirect branch instructions are [Software change of the PC](#) instructions other than exception-generating instructions and immediate branch instructions. [Software change of the PC](#) has the same definition as for the [PC_WRITE_SPEC](#) event. Immediate branch instructions are defined by the [BR_IMMED_SPEC](#) event.

0x007C, **ISB_SPEC, Barrier speculatively executed, ISB**

The counter counts each [speculatively executed](#) Instruction Synchronization Barrier instruction.

This includes the CP15ISB instruction.

0x007D, **DSB_SPEC, Barrier speculatively executed, DSB**

The counter counts each [speculatively executed](#) data synchronization and speculative load barrier instruction.

This includes the CP15DSB instruction.

0x007E, **DMB_SPEC, Barrier speculatively executed, DMB**

The counter counts each [speculatively executed](#) data memory barrier instruction.

This includes the CP15DSB instruction.

This does not include the implied barrier operations of load/store operations with release consistency semantics.

0x007F, **CSDB_SPEC, Barrier speculatively executed, CSDB**

The counter counts each [speculatively executed](#) control speculation barrier instruction.

0x0090, **RC_LD_SPEC, Release consistency operation speculatively executed, Load-Acquire**

The counter counts each [speculatively executed](#) ‘Memory-read operation’ with acquire or acquirepc semantics.

0x0091, **RC_ST_SPEC, Release consistency operation speculatively executed, Store-Release**

The counter counts each [speculatively executed Memory-write operation](#) with release semantics.

0x00A0, **L3D_CACHE_RD, Level 3 data cache access, read**

If the [L3D_CACHE_RW](#) event is implemented, the counter counts each access counted by [L3D_CACHE_RW](#) that is a ‘Memory-read operation’.

If the [L3D_CACHE_RW](#) event is not implemented, the counter counts each access counted by [L3D_CACHE](#) that is a ‘Memory-read operation’.

If the cache is shared and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the cache is

shared by PEs other than the PEs in the multithreaded processor and the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of `PMEVTYPER<n>_EL0.MT`.

0x00A1, **L3D_CACHE_WR, Level 3 data cache access, write**

If the `L3D_CACHE_RW` event is implemented, the counter counts each access counted by `L3D_CACHE_RW` that is a Memory-write operation.

If the `L3D_CACHE_RW` event is not implemented, the counter counts each access counted by `L3D_CACHE` that is a Memory-write operation.

If the cache is shared and the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the cache is shared by PEs other than the PEs in the multithreaded processor and the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of `PMEVTYPER<n>_EL0.MT`.

0x00A2, **L3D_CACHE_REFILL_RD, Level 3 data cache refill, read**

The counter counts each access counted by both `L3D_CACHE_RD` and `L3D_CACHE_REFILL`.

That is, every refill of the Level 3 data or unified cache counted by `L3D_CACHE_REFILL` that is caused by a 'Memory-read operation'.

If the cache is shared and the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the cache is shared by PEs other than the PEs in the multithreaded processor and the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of `PMEVTYPER<n>_EL0.MT`.

0x00A3, **L3D_CACHE_REFILL_WR, Level 3 data cache refill, write**

The counter counts each access counted by both `L3D_CACHE_REFILL` and `L3D_CACHE_WR`.

That is, every refill of the Level 3 data or unified cache counted by `L3D_CACHE_REFILL` that is caused by a Memory-write operation.

If the cache is shared and the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the cache is shared by PEs other than the PEs in the multithreaded processor and the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of `PMEVTYPER<n>_EL0.MT`.

0x00A6, **L3D_CACHE_WB_VICTIM, Level 3 data cache write-back, victim**

The counter counts each write-back counted by `L3D_CACHE_WB` that occurs because of a capacity eviction due to a line being allocated into the cache..

It is IMPLEMENTATION DEFINED whether this includes capacity evictions due to an agent other the PE counting the event. For example, a stashing request from outside of the PE, or an allocation due to another PE that shares the cache.

In all cases, the event is counted only if the eviction is also an `L3D_CACHE_WB` event. This means that, if the cache is shared, the eviction is counted only if it is attributable to the PE counting the event, as defined by `L3D_CACHE_WB`.

0x00A7, **L3D_CACHE_WB_CLEAN, Level 3 data cache write-back, cleaning and coherency**

The counter counts each write-back counted by [L3D_CACHE_WB](#) that occurs because of a coherency operation made by another PE or, optionally, the execution of a cache maintenance instruction..

It is IMPLEMENTATION DEFINED whether the transfer of a dirty cache line from the Level 1 data cache of this PE to the data cache of another PE due to a hardware coherency operation is counted when the dirty cache line is not also written back to a Level 2 cache or memory.

In all cases, the event is counted only if the write-back is also an [L3D_CACHE_WB](#) event. This means that, if the cache is shared, the write-back is counted only if it is attributable to the PE counting the event, as defined by [L3D_CACHE_WB](#).

0x00A8, **L3D_CACHE_INVALID, Level 3 data cache invalidate**

The counter counts each invalidation of a cache line in the Level 3 data or unified cache. For example:

- Invalidation of a cache line because of a cache maintenance operation.
- Transfer of ownership of a cache line to another cache because of a coherency or refill request.

The counter does not count events if a cache refill of the Level 3 data or unified cache invalidates a line in the Level 3 data or unified cache.

The counter does not count locally-executed cache maintenance instructions that operate by set/way.

Note

Software that uses this event must know whether the Level 3 data cache is shared with other PEs. This event does not follow the general rule of Level 3 data cache events of only counting Attributable events.

ASE_FP_ADDSUB_SPEC, Floating-point operation speculatively executed, Advanced SIMD add or subtract

The counter counts each [speculatively executed](#) floating-point add or subtract operation counted by [ASE_SVE_FP_ADDSUB_SPEC](#) due to any of the following A64 instructions:

- Advanced SIMD: FABD, FADD, or FSUB.

It is IMPLEMENTATION DEFINED which floating-point add or subtract operations are counted in AArch32 state.

ASE_FP_BF16_MIN_SPEC, Advanced SIMD data processing operation speculatively executed, smallest type is BFloat16 floating-point

The counter counts each Advanced SIMD data-processing operation counted by [ASE_SVE_FP_BF16_MIN_SPEC](#) due to an instruction where the smallest type was BFloat16 floating-point.

ASE_FP_CVT_SPEC, Floating-point operation speculatively executed, Advanced SIMD convert

The counter counts each [speculatively executed](#) floating-point convert operation counted by [ASE_SVE_FP_CVT_SPEC](#) due to an A64 Advanced SIMD instruction.

It is IMPLEMENTATION DEFINED which Advanced SIMD floating-point convert operations are counted in AArch32 state.

ASE_FP_DIV_SPEC, Floating-point operation speculatively executed, Advanced SIMD divide

The counter counts each [speculatively executed](#) floating-point divide operation counted by [ASE_SVE_FP_DIV_SPEC](#) due to any of the following A64 instructions:

- Advanced SIMD: FDIV.

It is IMPLEMENTATION DEFINED which floating-point divide operations are counted in AArch32 state.

ASE_FP_DOT_SPEC, Floating-point operation speculatively executed, Advanced SIMD dot-product

The counter counts each dot-product operation counted by [ASE_SVE_FP_DOT_SPEC](#) due to any of the following A64 instructions:

It is IMPLEMENTATION DEFINED which dot-product operations are counted in AArch32 state.

ASE_FP_DP_SPEC, Floating-point operation speculatively executed, Advanced SIMD double-precision, data-processing

The counter counts each [speculatively executed](#) double-precision floating-point data-processing operation counted by [ASE_SVE_FP_DP_SPEC](#) due to an Advanced SIMD instruction.

ASE_FP_FMA_SPEC, Floating-point operation speculatively executed, Advanced SIMD FMA

The counter counts each [speculatively executed](#) floating-point fused multiply-add or multiply-subtract operation counted by [ASE_SVE_FP_FMA_SPEC](#) due to any of the following A64 instructions:

- Advanced SIMD: FMLA or FMLS.

It is IMPLEMENTATION DEFINED which floating-point fused multiply-add or multiply-subtract operations are counted in AArch32 state.

ASE_FP_FP8_MIN_SPEC, Advanced SIMD data processing operation speculatively executed, smallest type is 8-bit floating-point

The counter counts each Advanced SIMD data-processing operation counted by [ASE_SVE_FP_FP8_MIN_SPEC](#) due to an instruction where the smallest type was 8-bit floating-point.

ASE_FP_HP_MIN_SPEC, Advanced SIMD data processing operation speculatively executed, smallest type is half-precision floating-point

The counter counts each Advanced SIMD data-processing operation counted by [ASE_SVE_FP_HP_MIN_SPEC](#) due to an instruction where the smallest type was half-precision floating-point.

ASE_FP_HP_SPEC, Floating-point operation speculatively executed, Advanced SIMD half-precision, data-processing

The counter counts each [speculatively executed](#) half-precision floating-point data-processing operation counted by [ASE_SVE_FP_HP_SPEC](#) due to an Advanced SIMD instruction.

ASE_FP_MMLA_SPEC, Floating-point operation speculatively executed, Advanced SIMD matrix multiply

The counter counts each floating-point matrix multiply operation counted by [ASE_SVE_FP_MMLA_SPEC](#) due to any of the following A64 instructions:

It is IMPLEMENTATION DEFINED which floating-point matrix multiply operations are counted in AArch32 state.

ASE_FP_MUL_SPEC, Floating-point operation speculatively executed, Advanced SIMD multiply

The counter counts each [speculatively executed](#) floating-point multiply operation counted by [ASE_SVE_FP_MUL_SPEC](#) due to any of the following A64 instructions:

- Advanced SIMD: FMUL or FMULX.

It is IMPLEMENTATION DEFINED which floating-point multiply operations are counted in AArch32 state.

ASE_FP_PREDUCE_SPEC, Floating-point operation speculatively executed, Advanced SIMD pairwise add step or pairwise reduce step

The counter counts each [speculatively executed](#) floating-point pairwise add step or pairwise reduce step operation counted by [ASE_FP_VREDUCE_SPEC](#) due to any of the following A64 instructions:

- Advanced SIMD: FADDP, FMAXNMP, FMAXP, FMINNMP, or FMINP.

It is IMPLEMENTATION DEFINED which floating-point pairwise add step or pairwise reduce step operations are counted in AArch32 state.

ASE_FP_RECPE_SPEC, Floating-point operation speculatively executed, Advanced SIMD reciprocal estimate

The counter counts each [speculatively executed](#) floating-point reciprocal estimate operation counted by [ASE_SVE_FP_RECPE_SPEC](#) due to any of the following A64 instructions:

- Advanced SIMD: FRECPPE or FRSQRTE.

It is IMPLEMENTATION DEFINED which floating-point reciprocal estimate operations are counted in AArch32 state.

ASE_FP_SPEC, Floating-point operation speculatively executed, Advanced SIMD

The counter counts each [speculatively executed](#) floating-point operation counted by [ASE_SVE_FP_SPEC](#) due to an A64 Advanced SIMD instruction.

It is IMPLEMENTATION DEFINED which Advanced SIMD floating-point operations are counted in AArch32 state.

ASE_FP_SP_MIN_SPEC, Advanced SIMD data processing operation speculatively executed, smallest type is single-precision floating-point

The counter counts each Advanced SIMD data-processing operation counted by [ASE_SVE_FP_SP_MIN_SPEC](#) due to an instruction where the smallest type was single-precision floating-point.

ASE_FP_SP_SPEC, Floating-point operation speculatively executed, Advanced SIMD single-precision, data-processing

The counter counts each [speculatively executed](#) single-precision floating-point data-processing operation counted by [ASE_SVE_FP_SP_SPEC](#) due to an Advanced SIMD instruction.

ASE_FP_SQRT_SPEC, Floating-point operation speculatively executed, Advanced SIMD square root

The counter counts each [speculatively executed](#) floating-point square-root operation counted by [ASE_SVE_FP_SQRT_SPEC](#) due to any of the following A64 instructions:

- Advanced SIMD: FSQRT.

It is IMPLEMENTATION DEFINED which floating-point square-root operations are counted in AArch32 state.

ASE_FP_VREDUCE_SPEC, Floating-point operation speculatively executed, Advanced SIMD pairwise or reduction

The counter counts each [speculatively executed](#) floating-point pairwise reduction or pairwise operation counted by [ASE_SVE_FP_VREDUCE_SPEC](#) due to any of the following A64 instructions:

- Advanced SIMD: FADDP, FMAXNMP, FMAXNMV, FMAXP, FMAXV, FMINNMP, FMINNMV, FMINP, or FMINV.

Note

Treewise reduction instructions might be executed and counted as multiple pairwise operations.

ASE_INST_SPEC, Operation speculatively executed, Advanced SIMD

The counter counts each [speculatively executed](#) operation counted by [ASE_SVE_INST_SPEC](#) that is classified as an Advanced SIMD operation.

Operations due to the following instructions are counted as Advanced SIMD operations:

- For AArch64 state:
 - The SIMD operations listed in Data processing - SIMD and floating-point.
 - If [FEAT_Crypto](#) is implemented, the Advanced SIMD Cryptographic instructions. See The Cryptographic Extension in AArch64 state.
 - Advanced SIMD loads and stores.
- For AArch32 state:
 - Instructions from [Advanced SIMD data-processing instructions](#).
 - If [FEAT_Crypto](#) is implemented, the `VMULL` (P64 variant) instruction. See [The Cryptographic Extension in AArch32 state](#).

This includes all operations that operate on the SIMD&FP registers, except those that are counted as one of the following:

- Integer data-processing operations.
- Scalar floating-point data-processing operations.

It is IMPLEMENTATION DEFINED whether Advanced SIMD scalar operations are counted as Advanced SIMD operations. This includes Advanced SIMD scalar instructions which operate on floating-point values.

ASE_INT16_SPEC, Integer operation speculatively executed, Advanced SIMD 16-bit

The counter counts each operation counted by [ASE_SVE_INT16_SPEC](#) that is an Advanced SIMD operation.

ASE_INT32_SPEC, Integer operation speculatively executed, Advanced SIMD 32-bit

The counter counts each operation counted by [ASE_SVE_INT32_SPEC](#) that is an Advanced SIMD operation.

ASE_INT64_SPEC, Integer operation speculatively executed, Advanced SIMD 64-bit

The counter counts each operation counted by [ASE_SVE_INT64_SPEC](#) that is an Advanced SIMD operation.

ASE_INT8_SPEC, Integer operation speculatively executed, Advanced SIMD 8-bit

The counter counts each operation counted by [ASE_SVE_INT8_SPEC](#) that is an Advanced SIMD operation.

ASE_INT_DOT_SPEC, Operation speculatively executed, Advanced SIMD integer dot-product

The counter counts each integer dot product operation counted by [ASE_SVE_INT_DOT_SPEC](#) due to any of the following A64 instructions:

It is IMPLEMENTATION DEFINED which integer dot product operations are counted in AArch32 state.

ASE_INT_MMLA_SPEC, Integer operation speculatively executed, Advanced SIMD matrix multiply

The counter counts each integer matrix multiply operation counted by [ASE_SVE_INT_MMLA_SPEC](#) due to any of the following A64 instructions:

It is IMPLEMENTATION DEFINED which integer matrix multiply operations are counted in AArch32 state.

ASE_INT_MUL_SPEC, Integer operation speculatively executed, Advanced SIMD multiply

The counter counts each [speculatively executed](#) integer multiply or multiply-accumulate operation counted by [ASE_SVE_INT_MUL_SPEC](#) due to any of the following A64 instructions:

- Advanced SIMD: MLA, MLS, MUL, PMUL, PMULL, PMULL2, SMLAL, SMLAL2, SMLSL, SMLSL2, SMULL, SMULL2, SQDMLAL, SQDMLAL2, SQDMLSL, SQDMLSL2, SQDMULH, SQDMULL, SQDMULL2, SQRDMULH, UMLAL, UMLAL2, UMLSL, UMLSL2, UMULL, or UMULL2.

It is IMPLEMENTATION DEFINED which integer multiply or multiply-accumulate operations are counted in AArch32 state.

ASE_INT_SPEC, Integer operation speculatively executed, Advanced SIMD

The counter counts each [speculatively executed](#) integer operation counted by [ASE_SVE_INT_SPEC](#) due to an A64 Advanced SIMD instruction.

It is IMPLEMENTATION DEFINED which Advanced SIMD integer operations are counted in AArch32 state.

ASE_INT_VREDUCE_SPEC, Integer operation speculatively executed, Advanced SIMD reduction

The counter counts each [speculatively executed](#) across-vector and pairwise integer reduction operation counted by [ASE_SVE_INT_VREDUCE_SPEC](#) due to any of the following A64 instructions:

- Advanced SIMD: ADDP, ADDV, SADALP, SADDLP, SADDLV, SMAXP, SMAXV, SMINP, SMINV, UADALP, UADDLP, UADDLV, UMAXP, UMAXV, UMINP, or UMINV.

It is IMPLEMENTATION DEFINED which across-vector and pairwise integer reduction operations are counted in AArch32 state.

ASE_LUT_SPEC, Lookup table operation speculatively executed, Advanced SIMD data processing

The counter counts each [speculatively executed](#) LUT operation counted by [SE_LUT_SPEC](#) that returns a value from a lookup table made up of a V register which is indexed by values from a V register.

ASE_NONFP_SPEC, Non-floating-point operation speculatively executed, Advanced SIMD

The counter counts each [speculatively executed](#) non-floating-point operation counted by [ASE_SVE_NONFP_SPEC](#) due to an A64 Advanced SIMD instruction.

It is IMPLEMENTATION DEFINED which Advanced SIMD non-floating-point data-processing operations are counted in AArch32 state.

ASE_SVE_FP_ADDSUB_SPEC, Floating-point operation speculatively executed, Advanced SIMD or SVE add or subtract

The counter counts each [speculatively executed](#) floating-point add or subtract operation counted by [FP_ADDSUB_SPEC](#) due to any of the following A64 instructions:

- Advanced SIMD: FABD, FADD, or FSUB.

It is IMPLEMENTATION DEFINED which floating-point add or subtract operations are counted in AArch32 state.

ASE_SVE_FP_BF16_MIN_SPEC, Advanced SIMD data processing or SVE data processing operation speculatively executed, smallest type is BFloat16 floating-point

The counter counts each Advanced SIMD or SVE data-processing operation counted by [SE_FP_BF16_MIN_SPEC](#) due to an instruction where the smallest type was BFloat16 floating-point.

ASE_SVE_FP_BF16_SPEC, Floating-point operation speculatively executed, SVE or Advanced SIMD BFloat16, data-processing

The counter counts each [speculatively executed](#) BFloat16 floating-point data-processing operation counted by FP_BF16_SPEC due to an Advanced SIMD.

ASE_SVE_FP_CVT_SPEC, Floating-point operation speculatively executed, Advanced SIMD or SVE convert

The counter counts each [speculatively executed](#) floating-point convert operation counted by FP_CVT_SPEC due to an A64 Advanced SIMD instruction.

It is IMPLEMENTATION DEFINED which Advanced SIMD floating-point convert operations are counted in AArch32 state.

ASE_SVE_FP_DIV_SPEC, Floating-point operation speculatively executed, Advanced SIMD or SVE divide

The counter counts each [speculatively executed](#) floating-point divide operation counted by FP_DIV_SPEC due to any of the following A64 instructions:

- Advanced SIMD: FDIV.

It is IMPLEMENTATION DEFINED which floating-point divide operations are counted in AArch32 state.

ASE_SVE_FP_DOT_SPEC, Floating-point operation speculatively executed, Advanced SIMD or SVE dot-product

The counter counts each dot-product operation counted by FP_SPEC due to any of the following A64 instructions:

It is IMPLEMENTATION DEFINED which dot-product operations are counted in AArch32 state.

ASE_SVE_FP_DP_SPEC, Floating-point operation speculatively executed, Advanced SIMD or SVE double-precision, data-processing

The counter counts each [speculatively executed](#) double-precision floating-point data-processing operation due to an Advanced SIMD.

ASE_SVE_FP_FMA_SPEC, Floating-point operation speculatively executed, Advanced SIMD or SVE FMA

The counter counts each [speculatively executed](#) floating-point fused multiply-add or multiply-subtract operation counted by FP_FMA_SPEC due to any of the following A64 instructions:

- Advanced SIMD: FMLA or FMLS.

It is IMPLEMENTATION DEFINED which floating-point fused multiply-add or multiply-subtract operations are counted in AArch32 state.

ASE_SVE_FP_FP8_MIN_SPEC, Advanced SIMD data processing or SVE data processing operation speculatively executed, smallest type is 8-bit floating-point

The counter counts each Advanced SIMD or SVE data-processing operation counted by SE_FP_FP8_MIN_SPEC due to an instruction where the smallest type was 8-bit floating-point.

ASE_SVE_FP_HP_MIN_SPEC, Advanced SIMD data processing or SVE data processing operation speculatively executed, smallest type is half-precision floating-point

The counter counts each Advanced SIMD or SVE data-processing operation counted by SE_FP_HP_MIN_SPEC due to an instruction where the smallest type was half-precision floating-point.

ASE_SVE_FP_HP_SPEC, Floating-point operation speculatively executed, Advanced SIMD or SVE half-precision

The counter counts each [speculatively executed](#) half-precision floating-point operation counted by [FP_HP_SPEC](#) due to an Advanced SIMD.

ASE_SVE_FP_MMLA_SPEC, Floating-point operation speculatively executed, Advanced SIMD or SVE matrix multiply

The counter counts each floating-point matrix multiply operation counted by [FP_SPEC](#) due to any of the following A64 instructions:

It is IMPLEMENTATION DEFINED which floating-point matrix multiply operations are counted in AArch32 state.

ASE_SVE_FP_MUL_SPEC, Floating-point operation speculatively executed, Advanced SIMD or SVE multiply

The counter counts each [speculatively executed](#) floating-point fused multiply-add or multiply-subtract operation counted by [FP_MUL_SPEC](#) due to any of the following A64 instructions:

- Advanced SIMD: FMUL or FMULX.

It is IMPLEMENTATION DEFINED which floating-point fused multiply-add or multiply-subtract operations are counted in AArch32 state.

ASE_SVE_FP_RECPE_SPEC, Floating-point operation speculatively executed, Advanced SIMD or SVE reciprocal estimate

The counter counts each [speculatively executed](#) floating-point reciprocal estimate operation counted by [FP_RECPE_SPEC](#) due to any of the following A64 instructions:

- Advanced SIMD: FRECPE or FRSQRTE.

It is IMPLEMENTATION DEFINED which floating-point reciprocal estimate operations are counted in AArch32 state.

ASE_SVE_FP_SPEC, Floating-point operation speculatively executed, Advanced SIMD or SVE

The counter counts each [speculatively executed](#) floating-point operation counted by [SE_FP_SPEC](#) due to an A64 Advanced SIMD instruction.

It is IMPLEMENTATION DEFINED which Advanced SIMD floating-point operations are counted in AArch32 state.

ASE_SVE_FP_SP_MIN_SPEC, Advanced SIMD data processing or SVE data processing operation speculatively executed, smallest type is single-precision floating-point

The counter counts each Advanced SIMD or SVE data-processing operation counted by [SE_FP_SP_MIN_SPEC](#) due to an instruction where the smallest type was single-precision floating-point.

ASE_SVE_FP_SP_SPEC, Floating-point operation speculatively executed, Advanced SIMD or SVE single-precision, data-processing

The counter counts each [speculatively executed](#) single-precision floating-point data-processing operation counted by [FP_SP_SPEC](#) due to an Advanced SIMD.

ASE_SVE_FP_SQRT_SPEC, Floating-point operation speculatively executed, Advanced SIMD or SVE square-root

The counter counts each [speculatively executed](#) floating-point square-root operation counted by [FP_SQRT_SPEC](#) due to any of the following A64 instructions:

- Advanced SIMD: FSQRT.

It is IMPLEMENTATION DEFINED which floating-point square-root operations are counted in AArch32 state.

ASE_SVE_FP_VREDUCE_SPEC, Floating-point operation speculatively executed, Advanced SIMD or SVE vector reduction

The counter counts each [speculatively executed](#) floating-point reduction operation counted by [ASE_SVE_FP_SPEC](#) due to any of the following A64 instructions:

- Advanced SIMD: FADDP, FMAXNMP, FMAXNMV, FMAXP, FMAXV, FMINNMP, FMINNMPV, FMINP, or FMINV.

It is IMPLEMENTATION DEFINED which floating-point reduction operations are counted in AArch32 state.

ASE_SVE_INST_SPEC, Operation speculatively executed, Advanced SIMD or SVE

The counter counts each [speculatively executed](#) operation counted by [SE_INST_SPEC](#) that is classified as an Advanced SIMD operation or an SVE operation.

See [ASE_INST_SPEC](#) and [SVE_INST_SPEC](#) for these classifications.

ASE_SVE_INT16_SPEC, Integer operation speculatively executed, Advanced SIMD or SVE 16-bit

The counter counts each operation counted by [ASE_SVE_INT_SPEC](#) where the largest type is 16-bit integer.

ASE_SVE_INT32_SPEC, Integer operation speculatively executed, Advanced SIMD or SVE 32-bit

The counter counts each operation counted by [ASE_SVE_INT_SPEC](#) where the largest type is 32-bit integer.

ASE_SVE_INT64_SPEC, Integer operation speculatively executed, Advanced SIMD or SVE 64-bit

The counter counts each operation counted by [ASE_SVE_INT_SPEC](#) where the largest type is 64-bit integer.

ASE_SVE_INT8_SPEC, Integer operation speculatively executed, Advanced SIMD or SVE 8-bit

The counter counts each operation counted by [ASE_SVE_INT_SPEC](#) where the largest type is 8-bit integer.

ASE_SVE_INT_DOT_SPEC, Integer operation speculatively executed, Advanced SIMD or SVE dot-product

The counter counts each integer dot product operation counted by [INT_SPEC](#) due to any of the following A64 instructions:

It is IMPLEMENTATION DEFINED which integer dot product operations are counted in AArch32 state.

ASE_SVE_INT_MMLA_SPEC, Integer operation speculatively executed, Advanced SIMD or SVE matrix multiply

The counter counts each integer matrix multiply operation counted by [INT_SPEC](#) due to any of the following A64 instructions:

It is IMPLEMENTATION DEFINED which integer matrix multiply operations are counted in AArch32 state.

ASE_SVE_INT_MUL_SPEC, Integer operation speculatively executed, Advanced SIMD or SVE multiply

The counter counts each [speculatively executed](#) integer multiply or multiply-accumulate operation counted by [INT_MUL_SPEC](#) due to any of the following A64 instructions:

- Advanced SIMD: MLA, MLS, MUL, PMUL, PMULL, PMULL2, SMLAL, SMLAL2, SMLSL, SMLSL2, SMULL, SMULL2, SQDMLAL, SQDMLAL2, SQDMLSL, SQDMLSL2, SQDMULH, SQDMULL, SQDMULL2, SQRDMULH, UMLAL, UMLAL2, UMLSL, UMLSL2, UMULL, or UMULL2.

It is IMPLEMENTATION DEFINED which integer multiply or multiply-accumulate operations are counted in AArch32 state.

ASE_SVE_INT_SPEC, Integer operation speculatively executed, Advanced SIMD or SVE

The counter counts each [speculatively executed](#) integer arithmetic operation counted by [SE_INT_SPEC](#) due to an A64 Advanced SIMD.

It is IMPLEMENTATION DEFINED which Advanced SIMD integer operations are counted in AArch32 state.

ASE_SVE_INT_VREDUCE_SPEC, Integer operation speculatively executed, Advanced SIMD or SVE reduction

The counter counts each [speculatively executed](#) across-vector and pairwise integer reduction operation counted by [INT_SPEC](#) due to any of the following A64 instructions:

- Advanced SIMD: ADDP, ADDV, SADALP, SADDLP, SADDLV, SMAXP, SMAXV, SMINP, SMINV, UADALP, UADDLP, UADDLV, UMAXP, UMAXV, UMINP, or UMINV.

It is IMPLEMENTATION DEFINED which across-vector and pairwise integer reduction operations are counted in AArch32 state.

ASE_SVE_LDST_MULTI_SPEC, Operation speculatively executed, Advanced SIMD or SVE contiguous load or store multiple vector

The counter counts each [speculatively executed](#) operation due to an A64 Advanced SIMD multiple vector contiguous structure load or store instruction.

It is IMPLEMENTATION DEFINED which Advanced SIMD contiguous structure load or store operations are counted in AArch32 state.

ASE_SVE_LDST_SPEC, Operation speculatively executed, Advanced SIMD or SVE load or store

The counter counts each [speculatively executed](#) operation that reads from or writes to memory due to an A64 Advanced SIMD load, store, or prefetch instruction.

It is IMPLEMENTATION DEFINED which Advanced SIMD load or store operations are counted in AArch32 state.

ASE_SVE_LD_MULTI_SPEC, Operation speculatively executed, Advanced SIMD or SVE contiguous load multiple vector

The counter counts each [speculatively executed](#) operation that reads from memory counted by [ASE_SVE_LDST_MULTI_SPEC](#) due to an A64 Advanced SIMD multiple vector contiguous structure load instruction.

It is IMPLEMENTATION DEFINED which Advanced SIMD contiguous structure load operations are counted in AArch32 state.

ASE_SVE_LD_SPEC, Operation speculatively executed, Advanced SIMD or SVE load

The counter counts each [speculatively executed](#) operation that reads from memory counted by [ASE_SVE_LDST_SPEC](#) due to an A64 Advanced SIMD load instruction.

It is IMPLEMENTATION DEFINED which Advanced SIMD load operations are counted in AArch32 state.

ASE_SVE_NONFP_SPEC, Non-floating-point operation speculatively executed, Advanced SIMD or SVE

The counter counts each [speculatively executed](#) non-floating-point operation counted by [NONFP_SPEC](#) due to an A64 Advanced SIMD instruction.

It is IMPLEMENTATION DEFINED which Advanced SIMD non-floating-point data-processing operations are counted in AArch32 state.

ASE_SVE_SPEC, Operation speculatively executed, Advanced SIMD data processing or SVE data processing

The counter counts each operation counted by [INST_SPEC](#) that is an Advanced SIMD data-processing operation or an SVE data-processing operation.

See [ASE_SPEC](#) and [SVE_SPEC](#) for these classifications.

ASE_SVE_ST_MULTI_SPEC, Operation speculatively executed, Advanced SIMD or SVE contiguous store multiple vector

The counter counts each [speculatively executed](#) operation that writes to memory counted by [ASE_SVE_LDST_MULTI_SPEC](#) due to an A64 Advanced SIMD multiple vector contiguous structure store instruction.

It is IMPLEMENTATION DEFINED which Advanced SIMD contiguous structure store operations are counted in AArch32 state.

ASE_SVE_ST_SPEC, Operation speculatively executed, Advanced SIMD or SVE store

The counter counts each [speculatively executed](#) operation that writes to memory counted by [ASE_SVE_LDST_SPEC](#) due to an A64 Advanced SIMD store instruction.

It is IMPLEMENTATION DEFINED which Advanced SIMD store operations are counted in AArch32 state.

ASE_SVE_UNALIGNED_CONTIG_LDST_SPEC, Advanced SIMD or SVE unaligned contiguous access

The counter counts each [speculatively executed](#) Advanced SIMD contiguous load or store operation where the address is not aligned to the minimum of the in-memory size of the vector and the cache line size, in bytes.

The unaligned access is counted even if it is subsequently converted into multiple aligned accesses.

It is IMPLEMENTATION DEFINED which unaligned contiguous Advanced SIMD load or store operations are counted in AArch32 state.

ASE_SVE_UNALIGNED_CONTIG_LD_SPEC, Advanced SIMD or SVE unaligned contiguous read

The counter counts each unaligned memory access counted by [ASE_SVE_UNALIGNED_CONTIG_LDST_SPEC](#) due to an A64 Advanced SIMD load instruction.

The unaligned access is counted even if it is subsequently converted into multiple aligned accesses.

It is IMPLEMENTATION DEFINED which unaligned contiguous Advanced SIMD load operations are counted in AArch32 state.

ASE_SVE_UNALIGNED_CONTIG_ST_SPEC, Advanced SIMD or SVE unaligned contiguous write

The counter counts each unaligned memory access counted by [ASE_SVE_UNALIGNED_CONTIG_LDST_SPEC](#) due to a A64 Advanced SIMD store instruction.

The unaligned access is counted even if it is subsequently converted into multiple aligned accesses.

It is IMPLEMENTATION DEFINED which unaligned contiguous Advanced SIMD store operations are counted in AArch32 state.

ASE_SVE_UNALIGNED_LDST_SPEC, Advanced SIMD or SVE unaligned access

The counter counts each [speculatively executed](#) A64 Advanced SIMD load or store instruction where either:

- A contiguous vector address is not aligned to the minimum of the in-memory size of the vector and the cache line size, in bytes.
- A gather, scatter, or single element address is not aligned to the memory element access size, in bytes.

The unaligned access is counted even if it is subsequently converted into multiple aligned accesses.

It is IMPLEMENTATION DEFINED which unaligned Advanced SIMD load or store operations are counted in AArch32 state.

ASE_SVE_UNALIGNED_LD_SPEC, Advanced SIMD or SVE unaligned read

The counter counts each unaligned memory access counted by [ASE_SVE_UNALIGNED_LDST_SPEC](#) due to an A64 Advanced SIMD load instruction.

The unaligned access is counted even if it is subsequently converted into multiple aligned accesses.

It is IMPLEMENTATION DEFINED which unaligned Advanced SIMD load operations are counted in AArch32 state.

ASE_SVE_UNALIGNED_ST_SPEC, Advanced SIMD or SVE unaligned write

The counter counts each unaligned memory access counted by [ASE_SVE_UNALIGNED_LDST_SPEC](#) due to an A64 Advanced SIMD store instruction.

The unaligned access is counted even if it is subsequently converted into multiple aligned accesses.

It is IMPLEMENTATION DEFINED which unaligned Advanced SIMD store operations are counted in AArch32 state.

ASE_SVE_UOP_SPEC, Microarchitectural operation speculatively executed, Advanced SIMD or SVE

The counter counts each [speculatively executed](#) microarchitectural operation counted by [UOP_SPEC](#) due to an A64 Advanced SIMD instruction.

It is IMPLEMENTATION DEFINED whether the counter counts microarchitectural operations due to Advanced SIMD scalar instructions.

It is IMPLEMENTATION DEFINED which Advanced SIMD microarchitectural operations are counted in AArch32 state.

ASE_UOP_SPEC, Microarchitectural operation speculatively executed, Advanced SIMD

The counter counts each [speculatively executed](#) microarchitectural operation counted by [ASE_SVE_UOP_SPEC](#) due to an A64 Advanced SIMD instruction.

It is IMPLEMENTATION DEFINED whether the counter counts microarchitectural operations due to Advanced SIMD scalar instructions.

It is IMPLEMENTATION DEFINED which Advanced SIMD microarchitectural operations are counted in AArch32 state.

BASE_LDST_REG_SPEC, Operation speculatively executed, general-purpose register load, store, or prefetch

The counter counts each [speculatively executed](#) operation that reads from or writes to memory due to a general-purpose register load, store, or prefetch instruction.

It is IMPLEMENTATION DEFINED which load, store, and prefetch operations are counted in AArch32 state.

BASE_LD_REG_SPEC, Operation speculatively executed, general-purpose register load

The counter counts each [speculatively executed](#) operation that reads from memory counted by [BASE_LDST_REG_SPEC](#) due to a general-purpose register load instruction.

It is IMPLEMENTATION DEFINED which load operations are counted in AArch32 state.

BASE_PRF_SPEC, Operation speculatively executed, general-purpose register prefetch

The counter counts each [speculatively executed](#) prefetch operation counted by [BASE_LDST_REG_SPEC](#) due to any of the following A64 instructions:

- Scalar: PRFM, PRFUM, or RPRFM.

It is IMPLEMENTATION DEFINED which prefetch operations are counted in AArch32 state.

BASE_ST_REG_SPEC, Operation speculatively executed, general-purpose register store

The counter counts each [speculatively executed](#) operation that writes to memory counted by [BASE_LDST_REG_SPEC](#) due to a general-purpose register store instruction.

It is IMPLEMENTATION DEFINED whether the counter counts operations due to DC ZVA instructions.

It is IMPLEMENTATION DEFINED which store operations are counted in AArch32 state.

BR_IMMED_MIS_PRED_RETIRE, Branch instruction architecturally executed, mispredicted immediate

The counter counts each instruction counted by both [BR_IMMED_RETIRE](#) and [BR_MIS_PRED_RETIRE](#).

These are all direct branch instructions on the architecturally executed path, where the branch is mispredicted.

BR_IMMED_PRED_RETIRE, Branch instruction architecturally executed, predicted immediate

The counter counts each instruction counted by both [BR_IMMED_RETIRE](#) and [BR_PRED_RETIRE](#).

These are all direct branch instructions on the architecturally executed path, where the branch is correctly predicted.

BR_INDNR_MIS_PRED_RETIRE, Branch instruction architecturally executed, mispredicted indirect excluding procedure return

The counter counts each instruction counted by [BR_IND_MIS_PRED_RETIRE](#) where if taken, the branch would not be counted by [BR_RETURN_RETIRE](#).

These are all indirect branch instructions, excluding return instructions, on the architecturally executed path, where the branch is mispredicted.

BR_INDNR_PRED_RETIRE, Branch instruction architecturally executed, predicted indirect excluding procedure return

The counter counts each instruction counted by [BR_IND_PRED_RETIRE](#) where if taken, the branch would not be counted by [BR_RETURN_RETIRE](#).

These are all indirect branch instructions, excluding return instructions, on the architecturally executed path, where the branch is correctly predicted.

BR_IND_MIS_PRED_RETIRE, Branch instruction architecturally executed, mispredicted indirect

The counter counts each instruction counted by both [BR_IND_RETIRE](#) and [BR_MIS_PRED_RETIRE](#).

These are all indirect branch instructions, including return instructions, on the architecturally executed path, where the branch is mispredicted.

BR_IND_PRED_RETIRE, Branch instruction architecturally executed, predicted indirect

The counter counts each instruction counted by both [BR_IND_RETIRE](#) and [BR_PRED_RETIRE](#).

These are all indirect branch instructions, including return instructions, on the architecturally executed path, where the branch is correctly predicted.

BR_PRED_RETIRE, Branch instruction architecturally executed, predicted branch

The counter counts each instruction counted by [BR_RETIRE](#) that is not counted by [BR_MIS_PRED_RETIRE](#).

These are all branch instructions on the architecturally executed path, where the branch is correctly predicted.

BR_RETURN_MIS_PRED_RETIRE, Branch instruction architecturally executed, mispredicted procedure return

The counter counts each instruction counted by [BR_IND_MIS_PRED_RETIRE](#) where if taken, the branch would also be counted by [BR_RETURN_RETIRE](#).

These are all return instructions on the architecturally executed path, where the branch is mispredicted.

BR_RETURN_PRED_RETIRE, Branch instruction architecturally executed, predicted procedure return

The counter counts each instruction counted by [BR_IND_PRED_RETIRE](#) where if taken, the branch would be counted by [BR_RETURN_RETIRE](#).

These are all return instructions on the architecturally executed path, where the branch is correctly predicted.

BR_SKIP_MIS_PRED_RETIRE, Branch instruction architecturally executed, mispredicted branch, not taken

The counter counts each instruction counted by both [BR_MIS_PRED_RETIRE](#) and [BR_SKIP_RETIRE](#).

These are all branch instructions on the architecturally executed path, where the branch is mispredicted and not taken.

BR_SKIP_PRED_RETIRE, Branch instruction architecturally executed, predicted branch, not taken

The counter counts each instruction counted by both [BR_PRED_RETIRE](#) and [BR_SKIP_RETIRE](#).

These are all branch instructions on the architecturally executed path, where the branch is correctly predicted and not taken.

BR_TAKEN_MIS_PRED_RETIRE, Branch instruction architecturally executed, mispredicted branch, taken

The counter counts each instruction counted by both [BR_MIS_PRED_RETIRE](#) and [PC_WRITE_RETIRE](#).

These are all branch instructions on the architecturally executed path, where the branch is mispredicted and taken.

BR_TAKEN_PRED_RETIRE, Branch instruction architecturally executed, predicted branch, taken

The counter counts each instruction counted by both [BR_PRED_RETIRE](#) and [PC_WRITE_RETIRE](#).

These are all branch instructions on the architecturally executed path, where the branch is correctly predicted and taken.

BUS_REQ, Bus request

The counter counts each request generated by a 'Memory-read operation' or [Memory-write operation](#) that accesses outside of the boundary of the PE and its closely-coupled caches.

Where this boundary lies with respect to any implemented caches is IMPLEMENTATION DEFINED. Where an implementation has multiple buses at this boundary, this event counts the sum of requests across all buses.

A bus request is the start of a bus transaction. The exact nature of a bus transaction is IMPLEMENTATION DEFINED, but for the purposes of event monitoring consists of a single access comprising one or more cycles, or beats, when the transaction occupies the bus. The [BUS_REQ](#) event therefore counts the number of transactions. The [BUS_ACCESS](#) event counts the occupancy of the transaction on the bus.

Bus transactions include refills of and write-backs from data, instruction, and unified caches. Whether bus transactions include operations that use the bus but do not explicitly transfer data is IMPLEMENTATION DEFINED. This must be the same for the [BUS_REQ](#) and [BUS_ACCESS](#) events.

An Unattributable bus transaction occurs when a requester outside the PE makes a request that results in a bus transaction, for example, a coherency request.

The maximum increment in any given cycle is IMPLEMENTATION DEFINED.

If the bus is shared and the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the bus is shared by PEs other than the PEs in the multithreaded processor and the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of `PMEVTYPER<n>_EL0.MT`.

BUS_REQ_RD, Bus request, read

The counter counts each transaction counted by `BUS_REQ` that is a ‘Memory-read operation’.

BUS_REQ_RD_PERCYC, Bus read transactions in progress

The counter increments by the number of bus read transactions counted by `BUS_REQ_RD` in progress on each `Processor cycle`.

The ratio $\text{BUS_REQ_RD_PERCYC} \div \text{BUS_REQ_RD}$ is the mean duration of bus read transactions in `Processor cycles`.

A bus read transaction is in progress between the transaction starting and it completing. This includes cycles when the transaction is not occupying the bus.

If the bus is shared and the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the bus is shared by PEs other than the PEs in the multithreaded processor and the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of `PMEVTYPER<n>_EL0.MT`.

BUS_REQ_WR, Bus request, write

The counter counts each transaction counted by `BUS_REQ` that is a `Memory-write operation`.

BUS_REQ_WR_PERCYC, Bus write transactions in progress

The counter increments by the number of bus write transactions counted by `BUS_REQ_WR` in progress on each `Processor cycle`.

The ratio $\text{BUS_REQ_WR_PERCYC} \div \text{BUS_REQ_WR}$ is the mean duration of bus write transactions in `Processor cycles`.

A bus write transaction is in progress between the transaction starting and it completing. This includes cycles when the transaction is not occupying the bus.

A mean duration value calculated using this event only measures the latency from the perspective of the bus. This is not necessarily the same as the latency for the write to be Complete, as the write might be completed on the bus before reaching its endpoint.

For some bus implementations, writes are posted, meaning that, from the perspective of the bus, the write completes immediately. There is no response when the write reaches its Completion endpoint. This event is not included for such implementations.

If the bus is shared and the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the bus is shared by PEs other than the PEs in the multithreaded processor and the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of `PMEVTYPER<n>_EL0.MT`.

CNT_CYCLES, Constant frequency cycles

The counter increments at a constant frequency when the PE is not in `WFI` or `WFE` state, equal to the rate of increment of the System Counter, `CNTPCT_EL0`.

When the PE is in `WFI` or `WFE` state, it is IMPLEMENTATION SPECIFIC whether the counter counts.

`PMCEID0_EL0[36]` reads as 1 if this event is implemented and 0 otherwise.

CTI_TRIGOUT4, Cross-trigger Interface output trigger 4

The counter counts each event signaled on CTI output trigger 4.

Note

CTI output triggers are input events to the PMU and trace unit.

`PMCEID0_EL0[56]` reads as 1 if this event is implemented and 0 otherwise.

CTI_TRIGOUT5, Cross-trigger Interface output trigger 5

The counter counts each event signaled on CTI output trigger 5.

Note

CTI output triggers are input events to the PMU and trace unit.

`PMCEID0_EL0[57]` reads as 1 if this event is implemented and 0 otherwise.

CTI_TRIGOUT6, Cross-trigger Interface output trigger 6

The counter counts each event signaled on CTI output trigger 6.

Note

CTI output triggers are input events to the PMU and trace unit.

`PMCEID0_EL0[58]` reads as 1 if this event is implemented and 0 otherwise.

CTI_TRIGOUT7, Cross-trigger Interface output trigger 7

The counter counts each event signaled on CTI output trigger 7.

Note

CTI output triggers are input events to the PMU and trace unit.

`PMCEID0_EL0[59]` reads as 1 if this event is implemented and 0 otherwise.

DSNP_HIT, Snoop hit, data

The counter counts each snoop that hits in a cache outside of the cache hierarchy of this PE.

The event is counted by the PE generating the snoop, not the PE being snooped.

DSNP_HITM_FAR_LDST_RETIRED, Load or store instruction architecturally executed, snoop hit in far cache

The counter counts each [architecturally executed](#) Memory-reading instruction or [Memory-writing instruction](#) counted by `DSNP_HITM_LDST_RETIRED` that hit modified data outside the local PE cluster on the same device.

DSNP_HITM_FAR_LD_RETIRED, Load instruction architecturally executed, snoop hit in far cache

The counter counts each [architecturally executed](#) instruction counted by [DSNP_HITM_FAR_LDST_RETIRED](#) that is a Memory-reading instruction.

DSNP_HITM_FAR_RD, Snoop hit in far local cache, demand data read, modified

The counter counts each snoop generated by the PE in response to a demand ‘Memory-read operation’ counted by [DSNP_HIT_FAR_RD](#) that accesses a previously modified cache location.

DSNP_HITM_FAR_RW, Snoop hit in far local cache, demand data access, modified

The counter counts each snoop generated by the PE in response to a demand ‘Memory-read operation’ or demand [Memory-write operation](#) counted by [DSNP_HIT_FAR_RW](#) that accesses a previously modified cache location.

DSNP_HITM_FAR_ST_RETIRED, Store instruction architecturally executed, snoop hit in far cache

The counter counts each [architecturally executed](#) instruction counted by [DSNP_HITM_FAR_LDST_RETIRED](#) that is a [Memory-writing instruction](#).

DSNP_HITM_FAR_WR, Snoop hit in far local cache, demand data write, modified

The counter counts each snoop generated by the PE in response to a demand [Memory-write operation](#) counted by [DSNP_HIT_FAR_WR](#) that accesses a previously modified cache location.

DSNP_HITM_LDST_RETIRED, Load or store instruction architecturally executed, snoop hit

The counter counts each [architecturally executed](#) Memory-reading instruction or [Memory-writing instruction](#) counted by [LDST_ANY_RETIRED](#) that hit modified data in a data cache outside the cache hierarchy of this PE.

DSNP_HITM_LD_RETIRED, Load instruction architecturally executed, snoop hit

The counter counts each [architecturally executed](#) instruction counted by [DSNP_HITM_LDST_RETIRED](#) that is a Memory-reading instruction.

DSNP_HITM_N1_RD, Snoop hit in cache at distance 1, demand data read, modified

The counter counts each snoop generated by the PE in response to a demand ‘Memory-read operation’ counted by [DSNP_HIT_N1_RD](#) that accesses a previously modified cache location.

DSNP_HITM_N1_RW, Snoop hit in cache at distance 1, demand data access, modified

The counter counts each snoop generated by the PE in response to a demand ‘Memory-read operation’ or demand [Memory-write operation](#) counted by [DSNP_HIT_N1_RW](#) that accesses a previously modified cache location.

DSNP_HITM_N1_WR, Snoop hit in cache at distance 1, demand data write, modified

The counter counts each snoop generated by the PE in response to a demand [Memory-write operation](#) counted by [DSNP_HIT_N1_WR](#) that accesses a previously modified cache location.

DSNP_HITM_N2_RD, Snoop hit in cache at distance 2, demand data read, modified

The counter counts each snoop generated by the PE in response to a demand ‘Memory-read operation’ counted by [DSNP_HIT_N2_RD](#) that accesses a previously modified cache location.

DSNP_HITM_N2_RW, Snoop hit in cache at distance 2, demand data access, modified

The counter counts each snoop generated by the PE in response to a demand ‘Memory-read operation’ or demand [Memory-write operation](#) counted by [DSNP_HIT_N2_RW](#) that accesses a previously modified cache location.

DSNP_HITM_N2_WR, Snoop hit in cache at distance 2, demand data write, modified

The counter counts each snoop generated by the PE in response to a demand [Memory-write operation](#) counted by [DSNP_HIT_N2_WR](#) that accesses a previously modified cache location.

DSNP_HITM_N3_RD, Snoop hit in cache at distance 3, demand data read, modified

The counter counts each snoop generated by the PE in response to a demand ‘Memory-read operation’ counted by [DSNP_HIT_N3_RD](#) that accesses a previously modified cache location.

DSNP_HITM_N3_RW, Snoop hit in cache at distance 3, demand data access, modified

The counter counts each snoop generated by the PE in response to a demand ‘Memory-read operation’ or demand [Memory-write operation](#) counted by [DSNP_HIT_N3_RW](#) that accesses a previously modified cache location.

DSNP_HITM_N3_WR, Snoop hit in cache at distance 3, demand data write, modified

The counter counts each snoop generated by the PE in response to a demand [Memory-write operation](#) counted by [DSNP_HIT_N3_WR](#) that accesses a previously modified cache location.

DSNP_HITM_N4_RD, Snoop hit in cache at distance 4, demand data read, modified

The counter counts each snoop generated by the PE in response to a demand ‘Memory-read operation’ counted by [DSNP_HIT_N4_RD](#) that accesses a previously modified cache location.

DSNP_HITM_N4_RW, Snoop hit in cache at distance 4, demand data access, modified

The counter counts each snoop generated by the PE in response to a demand ‘Memory-read operation’ or demand [Memory-write operation](#) counted by [DSNP_HIT_N4_RW](#) that accesses a previously modified cache location.

DSNP_HITM_N4_WR, Snoop hit in cache at distance 4, demand data write, modified

The counter counts each snoop generated by the PE in response to a demand [Memory-write operation](#) counted by [DSNP_HIT_N4_WR](#) that accesses a previously modified cache location.

DSNP_HITM_NEAR_LDST_RETIRED, Load or store instruction architecturally executed, snoop hit in near cache

The counter counts each [architecturally executed](#) Memory-reading instruction or [Memory-writing instruction](#) counted by [DSNP_HITM_NEAR_LDST_RETIRED](#) that hit modified data outside of the cache hierarchy of this PE in the local PE cluster.

DSNP_HITM_NEAR_LD_RETIRED, Load instruction architecturally executed, snoop hit in near cache

The counter counts each [architecturally executed](#) instruction counted by [DSNP_HITM_NEAR_LDST_RETIRED](#) that is a Memory-reading instruction.

DSNP_HITM_NEAR_RD, Snoop hit in near local cache, demand data read, modified

The counter counts each snoop generated by the PE in response to a demand ‘Memory-read operation’ counted by [DSNP_HIT_NEAR_RD](#) that accesses a previously modified cache location.

DSNP_HITM_NEAR_RW, Snoop hit in near local cache, demand data access, modified

The counter counts each snoop generated by the PE in response to a demand ‘Memory-read operation’ or demand [Memory-write operation](#) counted by [DSNP_HIT_NEAR_RW](#) that accesses a previously modified cache location.

DSNP_HITM_NEAR_ST_RETIRED, Store instruction architecturally executed, snoop hit in near cache

The counter counts each [architecturally executed](#) instruction counted by [DSNP_HITM_NEAR_LDST_RETIRED](#) that is a [Memory-writing instruction](#).

DSNP_HITM_NEAR_WR, Snoop hit in near local cache, demand data write, modified

The counter counts each snoop generated by the PE in response to a demand [Memory-write operation](#) counted by [DSNP_HIT_NEAR_WR](#) that accesses a previously modified cache location.

DSNP_HITM_RD, Snoop hit, demand data read, modified

The counter counts each snoop generated by the PE in response to a demand ‘Memory-read operation’ counted by [DSNP_HIT_RD](#) that accesses a previously modified cache location.

DSNP_HITM_REMOTE_LDST_RETIRED, Load or store instruction architecturally executed, snoop hit in remote cache

The counter counts each [architecturally executed](#) Memory-reading instruction or [Memory-writing instruction](#) counted by [DSNP_HITM_LDST_RETIRED](#) that hit modified data on a remote device.

DSNP_HITM_REMOTE_LD_RETIRED, Load instruction architecturally executed, snoop hit in remote cache

The counter counts each [architecturally executed](#) instruction counted by [DSNP_HITM_REMOTE_LDST_RETIRED](#) that is a Memory-reading instruction.

DSNP_HITM_REMOTE_RD, Snoop hit in remote cache, demand data read, modified

The counter counts each snoop generated by the PE in response to a demand ‘Memory-read operation’ counted by [DSNP_HIT_REMOTE_RD](#) that accesses a previously modified cache location.

DSNP_HITM_REMOTE_RW, Snoop hit in remote cache, demand data access, modified

The counter counts each snoop generated by the PE in response to a demand ‘Memory-read operation’ or demand [Memory-write operation](#) counted by [DSNP_HIT_REMOTE_RW](#) that accesses a previously modified cache location.

DSNP_HITM_REMOTE_ST_RETIRED, Store instruction architecturally executed, snoop hit in remote cache

The counter counts each [architecturally executed](#) instruction counted by [DSNP_HITM_REMOTE_LDST_RETIRED](#) that is a [Memory-writing instruction](#).

DSNP_HITM_REMOTE_WR, Snoop hit in remote cache, demand data write, modified

The counter counts each snoop generated by the PE in response to a demand [Memory-write operation](#) counted by [DSNP_HIT_REMOTE_WR](#) that accesses a previously modified cache location.

DSNP_HITM_RW, Snoop hit, demand data access, modified

The counter counts each snoop generated by the PE in response to a demand ‘Memory-read operation’ or demand [Memory-write operation](#) counted by [DSNP_HIT_RW](#) that accesses a previously modified cache location.

DSNP_HITM_ST_RETIRED, Store instruction architecturally executed, snoop hit

The counter counts each [architecturally executed](#) instruction counted by [DSNP_HITM_LDST_RETIRED](#) that is a [Memory-writing instruction](#).

DSNP_HITM_WR, Snoop hit, demand data write, modified

The counter counts each snoop generated by the PE in response to a demand [Memory-write operation](#) counted by [DSNP_HIT_WR](#) that accesses a previously modified cache location.

DSNP_HIT_FAR, Snoop hit in far local cache, data access

The counter counts each snoop counted by [DSNP_HIT](#) that hits in a cache outside the local PE cluster on the same device.

The event is counted by the PE generating the snoop, not the PE being snooped.

DSNP_HIT_FAR_HWPRF, Snoop hit in far local cache, hardware data prefetch

The counter counts each snoop generated by a data hardware prefetch counted by [DSNP_HIT_HWPRF](#) that hits in a cache outside the local PE cluster on the same device.

The event is counted by the PE generating the snoop, not the PE being snooped.

DSNP_HIT_FAR_LDST_RETIRED, Load or store instruction architecturally executed, snoop hit in far cache

The counter counts each [architecturally executed](#) Memory-reading instruction or [Memory-writing instruction](#) counted by [DSNP_HIT_LDST_RETIRED](#) that hit outside the local PE cluster on the same device.

DSNP_HIT_FAR_LD_RETIRED, Load instruction architecturally executed, snoop hit in far cache

The counter counts each [architecturally executed](#) instruction counted by [DSNP_HIT_FAR_LDST_RETIRED](#) that is a Memory-reading instruction.

DSNP_HIT_FAR_PRF, Snoop hit in far local cache, data prefetch

The counter counts each snoop generated by the PE in response to a data prefetch instruction, or by a data hardware prefetch counted by [DSNP_HIT_PRF](#) that hits in a cache outside the local PE cluster on the same device.

The event is counted by the PE generating the snoop, not the PE being snooped.

DSNP_HIT_FAR_PRFM, Snoop hit in far local cache, software data prefetch

The counter counts each snoop generated by the PE in response to a data prefetch instruction counted by [DSNP_HIT_PRFM](#) that hits in a cache outside the local PE cluster on the same device.

The event is counted by the PE generating the snoop, not the PE being snooped.

DSNP_HIT_FAR_RD, Snoop hit in far local cache, demand data read

The counter counts each snoop generated by the PE in response to a demand ‘Memory-read operation’ counted by [DSNP_HIT_RD](#) that hits in a cache outside the local PE cluster on the same device.

The event is counted by the PE generating the snoop, not the PE being snooped.

DSNP_HIT_FAR_RW, Snoop hit in far local cache, demand data access

The counter counts each snoop generated by the PE in response to a demand ‘Memory-read operation’ or demand [Memory-write operation](#) counted by [DSNP_HIT_RW](#) that hits in a cache outside the local PE cluster on the same device.

The event is counted by the PE generating the snoop, not the PE being snooped.

DSNP_HIT_FAR_ST_RETIRED, Store instruction architecturally executed, snoop hit in far cache

The counter counts each [architecturally executed](#) instruction counted by [DSNP_HIT_FAR_LDST_RETIRED](#) that is a [Memory-writing instruction](#).

DSNP_HIT_FAR_WR, Snoop hit in far local cache, demand data write

The counter counts each snoop generated by the PE in response to a demand [Memory-write operation](#) counted by [DSNP_HIT_WR](#) that hits in a cache outside the local PE cluster on the same device.

The event is counted by the PE generating the snoop, not the PE being snooped.

DSNP_HIT_HWPRF, Snoop hit, hardware data prefetch

The counter counts each snoop generated by a data hardware prefetch counted by [DSNP_HIT_PRF](#) that hits in a cache outside of the cache hierarchy of this PE.

The event is counted by the PE generating the snoop, not the PE being snooped.

DSNP_HIT_LDST_RETIRED, Load or store instruction architecturally executed, snoop hit

The counter counts each [architecturally executed](#) Memory-reading instruction or [Memory-writing instruction](#) counted by [LDST_ANY_RETIRED](#) that hit in a data cache outside the cache hierarchy of this PE.

DSNP_HIT_LD_RETIRED, Load instruction architecturally executed, snoop hit

The counter counts each [architecturally executed](#) instruction counted by [DSNP_HIT_LDST_RETIRED](#) that is a Memory-reading instruction.

DSNP_HIT_N1, Snoop hit in cache at distance 1, data access

The counter counts each snoop counted by [DSNP_HIT](#) that hits in a cache at distance 1.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

DSNP_HIT_N1_HWPRF, Snoop hit in cache at distance 1, hardware data prefetch

The counter counts each snoop generated by a data hardware prefetch counted by [DSNP_HIT_HWPRF](#) that hits in a cache at distance 1.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

DSNP_HIT_N1_PRF, Snoop hit in cache at distance 1, data prefetch

The counter counts each snoop generated by the PE in response to a data prefetch instruction, or by a data hardware prefetch counted by [DSNP_HIT_PRF](#) that hits in a cache at distance 1.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

DSNP_HIT_N1_PRFM, Snoop hit in cache at distance 1, software data prefetch

The counter counts each snoop generated by the PE in response to a data prefetch instruction counted by [DSNP_HIT_PRFM](#) that hits in a cache at distance 1.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

DSNP_HIT_N1_RD, Snoop hit in cache at distance 1, demand data read

The counter counts each snoop generated by the PE in response to a demand 'Memory-read operation' counted by [DSNP_HIT_RD](#) that hits in a cache at distance 1.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

DSNP_HIT_N1_RW, Snoop hit in cache at distance 1, demand data access

The counter counts each snoop generated by the PE in response to a demand 'Memory-read operation' or demand [Memory-write operation](#) counted by [DSNP_HIT_RW](#) that hits in a cache at distance 1.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

DSNP_HIT_N1_WR, Snoop hit in cache at distance 1, demand data write

The counter counts each snoop generated by the PE in response to a demand [Memory-write operation](#) counted by [DSNP_HIT_WR](#) that hits in a cache at distance 1.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

DSNP_HIT_N2, Snoop hit in cache at distance 2, data access

The counter counts each snoop counted by [DSNP_HIT](#) that hits in a cache at distance 2.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

DSNP_HIT_N2_HWPRF, Snoop hit in cache at distance 2, hardware data prefetch

The counter counts each snoop generated by a data hardware prefetch counted by [DSNP_HIT_HWPRF](#) that hits in a cache at distance 2.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

DSNP_HIT_N2_PRF, Snoop hit in cache at distance 2, data prefetch

The counter counts each snoop generated by the PE in response to a data prefetch instruction, or by a data hardware prefetch counted by [DSNP_HIT_PRF](#) that hits in a cache at distance 2.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

DSNP_HIT_N2_PRFM, Snoop hit in cache at distance 2, software data prefetch

The counter counts each snoop generated by the PE in response to a data prefetch instruction counted by [DSNP_HIT_PRFM](#) that hits in a cache at distance 2.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

DSNP_HIT_N2_RD, Snoop hit in cache at distance 2, demand data read

The counter counts each snoop generated by the PE in response to a demand 'Memory-read operation' counted by [DSNP_HIT_RD](#) that hits in a cache at distance 2.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

DSNP_HIT_N2_RW, Snoop hit in cache at distance 2, demand data access

The counter counts each snoop generated by the PE in response to a demand ‘Memory-read operation’ or demand [Memory-write operation](#) counted by [DSNP_HIT_RW](#) that hits in a cache at distance 2.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

DSNP_HIT_N2_WR, Snoop hit in cache at distance 2, demand data write

The counter counts each snoop generated by the PE in response to a demand [Memory-write operation](#) counted by [DSNP_HIT_WR](#) that hits in a cache at distance 2.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

DSNP_HIT_N3, Snoop hit in cache at distance 3, data access

The counter counts each snoop counted by [DSNP_HIT](#) that hits in a cache at distance 3.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

DSNP_HIT_N3_HWPRF, Snoop hit in cache at distance 3, hardware data prefetch

The counter counts each snoop generated by a data hardware prefetch counted by [DSNP_HIT_HWPRF](#) that hits in a cache at distance 3.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

DSNP_HIT_N3_PRF, Snoop hit in cache at distance 3, data prefetch

The counter counts each snoop generated by the PE in response to a data prefetch instruction, or by a data hardware prefetch counted by [DSNP_HIT_PRF](#) that hits in a cache at distance 3.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

DSNP_HIT_N3_PRFM, Snoop hit in cache at distance 3, software data prefetch

The counter counts each snoop generated by the PE in response to a data prefetch instruction counted by [DSNP_HIT_PRFM](#) that hits in a cache at distance 3.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

DSNP_HIT_N3_RD, Snoop hit in cache at distance 3, demand data read

The counter counts each snoop generated by the PE in response to a demand ‘Memory-read operation’ counted by [DSNP_HIT_RD](#) that hits in a cache at distance 3.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

DSNP_HIT_N3_RW, Snoop hit in cache at distance 3, demand data access

The counter counts each snoop generated by the PE in response to a demand ‘Memory-read operation’ or demand [Memory-write operation](#) counted by [DSNP_HIT_RW](#) that hits in a cache at distance 3.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

DSNP_HIT_N3_WR, Snoop hit in cache at distance 3, demand data write

The counter counts each snoop generated by the PE in response to a demand [Memory-write operation](#) counted by [DSNP_HIT_WR](#) that hits in a cache at distance 3.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

DSNP_HIT_N4, Snoop hit in cache at distance 4, data access

The counter counts each snoop counted by [DSNP_HIT](#) that hits in a cache at distance 4.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

DSNP_HIT_N4_HWPRF, Snoop hit in cache at distance 4, hardware data prefetch

The counter counts each snoop generated by a data hardware prefetch counted by [DSNP_HIT_HWPRF](#) that hits in a cache at distance 4.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

DSNP_HIT_N4_PRF, Snoop hit in cache at distance 4, data prefetch

The counter counts each snoop generated by the PE in response to a data prefetch instruction, or by a data hardware prefetch counted by [DSNP_HIT_PRF](#) that hits in a cache at distance 4.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

DSNP_HIT_N4_PRFM, Snoop hit in cache at distance 4, software data prefetch

The counter counts each snoop generated by the PE in response to a data prefetch instruction counted by [DSNP_HIT_PRFM](#) that hits in a cache at distance 4.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

DSNP_HIT_N4_RD, Snoop hit in cache at distance 4, demand data read

The counter counts each snoop generated by the PE in response to a demand 'Memory-read operation' counted by [DSNP_HIT_RD](#) that hits in a cache at distance 4.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

DSNP_HIT_N4_RW, Snoop hit in cache at distance 4, demand data access

The counter counts each snoop generated by the PE in response to a demand 'Memory-read operation' or demand [Memory-write operation](#) counted by [DSNP_HIT_RW](#) that hits in a cache at distance 4.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

DSNP_HIT_N4_WR, Snoop hit in cache at distance 4, demand data write

The counter counts each snoop generated by the PE in response to a demand [Memory-write operation](#) counted by [DSNP_HIT_WR](#) that hits in a cache at distance 4.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

DSNP_HIT_NEAR, Snoop hit in near local cache, data access

The counter counts each snoop counted by [DSNP_HIT](#) that hits in a cache outside of the cache hierarchy of this PE in the local PE cluster.

The event is counted by the PE generating the snoop, not the PE being snooped.

DSNP_HIT_NEAR_HWPRF, Snoop hit in near local cache, hardware data prefetch

The counter counts each snoop generated by a data hardware prefetch counted by [DSNP_HIT_HWPRF](#) that hits in a cache outside of the cache hierarchy of this PE in the local PE cluster.

The event is counted by the PE generating the snoop, not the PE being snooped.

DSNP_HIT_NEAR_LDST_RETIRED, Load or store instruction architecturally executed, snoop hit in near cache

The counter counts each [architecturally executed](#) Memory-reading instruction or [Memory-writing instruction](#) counted by [DSNP_HIT_LDST_RETIRED](#) that hit outside of the cache hierarchy of this PE in the local PE cluster.

DSNP_HIT_NEAR_LD_RETIRED, Load instruction architecturally executed, snoop hit in near cache

The counter counts each [architecturally executed](#) instruction counted by [DSNP_HIT_NEAR_LDST_RETIRED](#) that is a Memory-reading instruction.

DSNP_HIT_NEAR_PRF, Snoop hit in near local cache, data prefetch

The counter counts each snoop generated by the PE in response to a data prefetch instruction, or by a data hardware prefetch counted by [DSNP_HIT_PRF](#) that hits in a cache outside of the cache hierarchy of this PE in the local PE cluster.

The event is counted by the PE generating the snoop, not the PE being snooped.

DSNP_HIT_NEAR_PRFM, Snoop hit in near local cache, software data prefetch

The counter counts each snoop generated by the PE in response to a data prefetch instruction counted by [DSNP_HIT_PRFM](#) that hits in a cache outside of the cache hierarchy of this PE in the local PE cluster.

The event is counted by the PE generating the snoop, not the PE being snooped.

DSNP_HIT_NEAR_RD, Snoop hit in near local cache, demand data read

The counter counts each snoop generated by the PE in response to a demand 'Memory-read operation' counted by [DSNP_HIT_RD](#) that hits in a cache outside of the cache hierarchy of this PE in the local PE cluster.

The event is counted by the PE generating the snoop, not the PE being snooped.

DSNP_HIT_NEAR_RW, Snoop hit in near local cache, demand data access

The counter counts each snoop generated by the PE in response to a demand ‘Memory-read operation’ or demand [Memory-write operation](#) counted by [DSNP_HIT_RW](#) that hits in a cache outside of the cache hierarchy of this PE in the local PE cluster.

The event is counted by the PE generating the snoop, not the PE being snooped.

DSNP_HIT_NEAR_ST_RETIRED, Store instruction architecturally executed, snoop hit in near cache

The counter counts each [architecturally executed](#) instruction counted by [DSNP_HIT_NEAR_LDST_RETIRED](#) that is a [Memory-writing instruction](#).

DSNP_HIT_NEAR_WR, Snoop hit in near local cache, demand data write

The counter counts each snoop generated by the PE in response to a demand [Memory-write operation](#) counted by [DSNP_HIT_WR](#) that hits in a cache outside of the cache hierarchy of this PE in the local PE cluster.

The event is counted by the PE generating the snoop, not the PE being snooped.

DSNP_HIT_PRF, Snoop hit, data prefetch

The counter counts each snoop generated by the PE in response to a data prefetch instruction, or by a data hardware prefetch that hits in a cache outside of the cache hierarchy of this PE.

The event is counted by the PE generating the snoop, not the PE being snooped.

DSNP_HIT_PRFM, Snoop hit, software data prefetch

The counter counts each snoop generated by the PE in response to a data prefetch instruction counted by [DSNP_HIT_PRF](#) that hits in a cache outside of the cache hierarchy of this PE.

The event is counted by the PE generating the snoop, not the PE being snooped.

DSNP_HIT_RD, Snoop hit, demand data read

The counter counts each snoop generated by the PE in response to a demand ‘Memory-read operation’ counted by [DSNP_HIT_RW](#) that hits in a cache outside of the cache hierarchy of this PE.

The event is counted by the PE generating the snoop, not the PE being snooped.

DSNP_HIT_REMOTE, Snoop hit in remote cache, data access

The counter counts each snoop counted by [DSNP_HIT](#) that hits in a cache on a remote device.

The event is counted by the PE generating the snoop, not the PE being snooped.

DSNP_HIT_REMOTE_HWPRF, Snoop hit in remote cache, hardware data prefetch

The counter counts each snoop generated by a data hardware prefetch counted by [DSNP_HIT_HWPRF](#) that hits in a cache on a remote device.

The event is counted by the PE generating the snoop, not the PE being snooped.

DSNP_HIT_REMOTE_LDST_RETIRED, Load or store instruction architecturally executed, snoop hit in remote cache

The counter counts each [architecturally executed](#) Memory-reading instruction or [Memory-writing instruction](#) counted by [DSNP_HIT_LDST_RETIRED](#) that hit on a remote device.

DSNP_HIT_REMOTE_LD_RETIRED, Load instruction architecturally executed, snoop hit in remote cache

The counter counts each [architecturally executed](#) instruction counted by [DSNP_HIT_REMOTE_LDST_RETIRED](#) that is a Memory-reading instruction.

DSNP_HIT_REMOTE_PRF, Snoop hit in remote cache, data prefetch

The counter counts each snoop generated by the PE in response to a data prefetch instruction, or by a data hardware prefetch counted by [DSNP_HIT_PRF](#) that hits in a cache on a remote device.

The event is counted by the PE generating the snoop, not the PE being snooped.

DSNP_HIT_REMOTE_PRFM, Snoop hit in remote cache, software data prefetch

The counter counts each snoop generated by the PE in response to a data prefetch instruction counted by [DSNP_HIT_PRFM](#) that hits in a cache on a remote device.

The event is counted by the PE generating the snoop, not the PE being snooped.

DSNP_HIT_REMOTE_RD, Snoop hit in remote cache, demand data read

The counter counts each snoop generated by the PE in response to a demand ‘Memory-read operation’ counted by [DSNP_HIT_RD](#) that hits in a cache on a remote device.

The event is counted by the PE generating the snoop, not the PE being snooped.

DSNP_HIT_REMOTE_RW, Snoop hit in remote cache, demand data access

The counter counts each snoop generated by the PE in response to a demand ‘Memory-read operation’ or demand [Memory-write operation](#) counted by [DSNP_HIT_RW](#) that hits in a cache on a remote device.

The event is counted by the PE generating the snoop, not the PE being snooped.

DSNP_HIT_REMOTE_ST_RETIRED, Store instruction architecturally executed, snoop hit in remote cache

The counter counts each [architecturally executed](#) instruction counted by [DSNP_HIT_REMOTE_LDST_RETIRED](#) that is a [Memory-writing instruction](#).

DSNP_HIT_REMOTE_WR, Snoop hit in remote cache, demand data write

The counter counts each snoop generated by the PE in response to a demand [Memory-write operation](#) counted by [DSNP_HIT_WR](#) that hits in a cache on a remote device.

The event is counted by the PE generating the snoop, not the PE being snooped.

DSNP_HIT_RW, Snoop hit, demand data access

The counter counts each snoop generated by the PE in response to a demand ‘Memory-read operation’ or demand [Memory-write operation](#) that hits in a cache outside of the cache hierarchy of this PE.

The event is counted by the PE generating the snoop, not the PE being snooped.

DSNP_HIT_ST_RETIRED, Store instruction architecturally executed, snoop hit

The counter counts each [architecturally executed](#) instruction counted by [DSNP_HIT_LDST_RETIRED](#) that is a [Memory-writing instruction](#).

DSNP_HIT_WR, Snoop hit, demand data write

The counter counts each snoop generated by the PE in response to a demand [Memory-write operation](#) counted by [DSNP_HIT_RW](#) that hits in a cache outside of the cache hierarchy of this PE.

The event is counted by the PE generating the snoop, not the PE being snooped.

DTLB_HIT_LDST_RETIRED, Load or store instruction architecturally executed, no translation table walk

The counter counts each Memory-reading instruction or [Memory-writing instruction architecturally executed](#) counted by [LDST_ANY_RETIRED](#) that did not cause a refill of a data TLB involving at least one translation table walk access.

DTLB_HIT_LD_RETIRED, Load instruction architecturally executed, no translation table walk

The counter counts each Memory-reading instruction [architecturally executed](#) counted by [DTLB_HIT_LDST_RETIRED](#) that did not cause a refill of a data TLB involving at least one translation table walk access.

DTLB_HIT_ST_RETIRED, Store instruction architecturally executed, no translation table walk

The counter counts each [Memory-writing instruction architecturally executed](#) counted by [DTLB_HIT_LDST_RETIRED](#) that did not cause a refill of a data TLB involving at least one translation table walk access.

DTLB_WALK_HWPRF, Data TLB hardware prefetch, with at least one translation table walk

The counter counts each hardware prefetch access counted by [L1D_TLB_HWPRF](#) that causes a refill or update of a data or unified TLB involving at least one translation table walk access.

The counter does not count the hardware prefetch access if any of the following are true:

- The access is due to a TLB maintenance instruction.
- The access generates a Translation fault because the applicable TCR_ELx.EPDy bit is 1.

It is IMPLEMENTATION DEFINED whether the counter counts the hardware prefetch access if the access generates a Translation fault for any other reason.

If the TLB is shared and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of PMEVTYPER<n>_EL0.MT.

DTLB_WALK_LDST_RETIRED, Load or store instruction architecturally executed, at least one translation table walk

The counter counts each Memory-reading instruction or [Memory-writing instruction architecturally executed](#) counted by [LDST_ANY_RETIRED](#) that caused a refill of a data TLB involving at least one translation table walk access.

The counter does not count the Memory-reading instruction or [Memory-writing instruction architecturally executed](#) if any of the following are true:

- The access generates a Translation fault because the applicable TCR_ELx.EPDy bit is 1.

It is IMPLEMENTATION DEFINED whether the counter counts the Memory-reading instruction or [Memory-writing instruction architecturally executed](#) if the access generates a Translation fault for any other reason.

DTLB_WALK_LD_RETIRED, Load instruction architecturally executed, at least one translation table walk

The counter counts each Memory-reading instruction [architecturally executed](#) counted by [DTLB_WALK_LDST_RETIRED](#) that caused a refill of a data TLB involving at least one translation table walk access.

The counter does not count the Memory-reading instruction [architecturally executed](#) if any of the following are true:

- The access generates a Translation fault because the applicable TCR_ELx.EPDy bit is 1.

It is IMPLEMENTATION DEFINED whether the counter counts the Memory-reading instruction [architecturally executed](#) if the access generates a Translation fault for any other reason.

DTLB_WALK_PERCYC, Data translation table walks in progress

The counter increments by the number of data translation table walks counted by [DTLB_WALK](#) in progress on each [Processor cycle](#).

The ratio $\text{DTLB_WALK_PERCYC} \div \text{DTLB_WALK}$ is the mean duration of data translation table walks in [Processor cycles](#).

If the TLB is shared and the Effective value of PMEVTYPERS<n>_EL0.MT for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of PMEVTYPERS<n>_EL0.MT for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of PMEVTYPERS<n>_EL0.MT.

DTLB_WALK_PRF, Data TLB prefetch, with at least one translation table walk

The counter counts each software prefetch or hardware prefetch access counted by [L1D_TLB_PRF](#) that causes a refill or update of a data or unified TLB involving at least one translation table walk access.

The counter does not count the software prefetch or hardware prefetch access if any of the following are true:

- The access is due to a TLB maintenance instruction.
- The access generates a Translation fault because the applicable TCR_ELx.EPDy bit is 1.

It is IMPLEMENTATION DEFINED whether the counter counts the software prefetch or hardware prefetch access if the access generates a Translation fault for any other reason.

If the TLB is shared and the Effective value of PMEVTYPERS<n>_EL0.MT for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of PMEVTYPERS<n>_EL0.MT for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of PMEVTYPERS<n>_EL0.MT.

DTLB_WALK_PRFM, Data TLB software prefetch, with at least one translation table walk

The counter counts each software prefetch access counted by [L1D_TLB_PRFM](#) that causes a refill or update of a data or unified TLB involving at least one translation table walk access.

The counter does not count the software prefetch access if any of the following are true:

- The access is due to a TLB maintenance instruction.
- The access generates a Translation fault because the applicable TCR_ELx.EPDy bit is 1.

It is IMPLEMENTATION DEFINED whether the counter counts the software prefetch access if the access generates a Translation fault for any other reason.

If the TLB is shared and the Effective value of PMEVTYPERS<n>_EL0.MT for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of PMEVTYPERS<n>_EL0.MT

for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of PMEVTYPEPER<n>_EL0.MT.

DTLB_WALK_RW, Data TLB demand access, with at least one translation table walk

The counter counts each demand access counted by [L1D_TLB_RW](#) that causes a refill or update of a data or unified TLB involving at least one translation table walk access.

The counter does not count the demand access if any of the following are true:

- The access is due to a TLB maintenance instruction.
- The access generates a Translation fault because the applicable TCR_ELx.EPDy bit is 1.

It is IMPLEMENTATION DEFINED whether the counter counts the demand access if the access generates a Translation fault for any other reason.

If the TLB is shared and the Effective value of PMEVTYPEPER<n>_EL0.MT for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of PMEVTYPEPER<n>_EL0.MT for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of PMEVTYPEPER<n>_EL0.MT.

DTLB_WALK_ST_RETIRED, Store instruction architecturally executed, at least one translation table walk

The counter counts each [Memory-writing instruction architecturally executed](#) counted by [DTLB_WALK_LDST_RETIRED](#) that caused a refill of a data TLB involving at least one translation table walk access.

The counter does not count the [Memory-writing instruction architecturally executed](#) if any of the following are true:

- The access generates a Translation fault because the applicable TCR_ELx.EPDy bit is 1.

It is IMPLEMENTATION DEFINED whether the counter counts the [Memory-writing instruction architecturally executed](#) if the access generates a Translation fault for any other reason.

FPASE_LDST_REG_SPEC, Operation speculatively executed, SIMD&FP register load or store

The counter counts each [speculatively executed](#) operation that reads from or writes to memory due to any of the following A64 instructions:

- Scalar: LDP (SIMD&FP), LDR (SIMD&FP), STP (SIMD&FP), or STR (SIMD&FP).
- Advanced SIMD: LD1, LD1R, LDNP, LDP, LDR, LDUR, ST1, STNP, STP, STR, or STUR.

It is IMPLEMENTATION DEFINED which load and store operations are counted in AArch32 state.

FPASE_LD_REG_SPEC, Operation speculatively executed, SIMD&FP register load

The counter counts each [speculatively executed](#) operation that reads from memory counted by [FPASE_LDST_REG_SPEC](#) due to any of the following A64 instructions:

- Scalar: LDP (SIMD&FP) or LDR (SIMD&FP).
- Advanced SIMD: LD1, LD1R, LDNP, LDP, LDR, or LDUR.

It is IMPLEMENTATION DEFINED which load operations are counted in AArch32 state.

FPASE_ST_REG_SPEC, Operation speculatively executed, SIMD&FP register store

The counter counts each [speculatively executed](#) operation that writes to memory counted by [FPASE_LDST_REG_SPEC](#) due to any of the following A64 instructions:

- Scalar: STP (SIMD&FP) or STR (SIMD&FP).
- Advanced SIMD: ST1, STNP, STP, STR, or STUR.

It is IMPLEMENTATION DEFINED which store operations are counted in AArch32 state.

FP_ADDSUB_SPEC, Floating-point operation speculatively executed, add or subtract

The counter counts each [speculatively executed](#) floating-point add or subtract operation counted by [FP_SPEC](#) due to any of the following A64 instructions:

- Scalar: FADD or FSUB.
- Advanced SIMD: FABD, FADD, or FSUB.

It is IMPLEMENTATION DEFINED which floating-point add or subtract operations are counted in AArch32 state.

FP_BF16_FIXED_MIN_OPS_SPEC, Non-scalable element arithmetic operations speculatively executed, smallest type is BFloat16 floating-point

The counter increments by v for each [speculatively executed](#) non-scalable element arithmetic operation, due to an instruction where the smallest type was BFloat16 floating-point.

Where v is the number of arithmetic operations carried out by the operation or instruction which causes the counter to increment.

The counter does not count operations that are counted by [FP_SCALE_OPS_SPEC](#).

FP_BF16_FIXED_OPS_SPEC, Non-scalable element arithmetic operations speculatively executed, largest type is BFloat16 floating-point

The counter increments by v for each [speculatively executed](#) non-scalable element arithmetic operation, due to an instruction where the largest type was BFloat16 floating-point.

Where v is the number of arithmetic operations carried out by the operation or instruction which causes the counter to increment.

The counter does not count operations that are counted by [FP_SCALE_OPS_SPEC](#).

FP_BF16_MIN_SPEC, Floating-point operation speculatively executed, smallest type is BFloat16 floating-point

The counter counts each floating-point operation counted by [FP_SPEC](#) due to an instruction where the smallest type was BFloat16 floating-point.

FP_CVT_SPEC, Floating-point operation speculatively executed, convert

The counter counts each [speculatively executed](#) floating-point convert operation due to any of:

- An A64 scalar floating-point conversion instruction.
- An Advanced SIMD floating-point conversion instruction.
- An SVE floating-point conversion instruction.

This includes both conversions between floating-point types, and conversions between integer and floating-point types.

It is IMPLEMENTATION DEFINED which floating-point convert operations are counted in AArch32 state.

FP_DIV_SPEC, Floating-point operation speculatively executed, divide

The counter counts each [speculatively executed](#) floating-point divide operation counted by [FP_SPEC](#) due to any of the following A64 instructions:

- Scalar: FDIV.
- Advanced SIMD: FDIV.

It is IMPLEMENTATION DEFINED which floating-point divide operations are counted in AArch32 state.

FP_DP_FIXED_OPS_SPEC, Non-scalable element arithmetic operations speculatively executed, largest type is double-precision floating-point

The counter increments by v for each [speculatively executed](#) non-scalable element arithmetic operation, due to an instruction where the largest type was double-precision floating-point.

Where v is the number of arithmetic operations carried out by the operation or instruction which causes the counter to increment.

The counter does not count operations that are counted by FP_SCALE_OPS_SPEC.

FP_DP_SPEC, Floating-point operation speculatively executed, double-precision, data-processing

The counter counts each [speculatively executed](#) floating-point data-processing operation counted by [FP_SPEC](#) where the largest type is double-precision.

FP_FIXED_OPS_SPEC, Non-scalable element arithmetic operations speculatively executed, floating-point

The counter increments by v for each [speculatively executed](#) non-scalable element arithmetic operation, due to an instruction where the type was floating-point.

Where v is the number of arithmetic operations carried out by the operation or instruction which causes the counter to increment.

The counter does not count operations that are counted by FP_SCALE_OPS_SPEC.

FP_FMA_SPEC, Floating-point operation speculatively executed, FMA

The counter counts each [speculatively executed](#) floating-point fused multiply-add or multiply-subtract operation counted by [FP_SPEC](#) due to any of the following A64 instructions:

- Scalar: FMADD, FMSUB, FNMADD, or FNMSUB.
- Advanced SIMD: FMLA or FMLS.

It is IMPLEMENTATION DEFINED which floating-point fused multiply-add or multiply-subtract operations are counted in AArch32 state.

FP_FP8_FIXED_MIN_OPS_SPEC, Non-scalable element arithmetic operations speculatively executed, smallest type is 8-bit floating-point

The counter increments by v for each [speculatively executed](#) non-scalable element arithmetic operation, due to an instruction where the smallest type was 8-bit floating-point.

Where v is the number of arithmetic operations carried out by the operation or instruction which causes the counter to increment.

The counter does not count operations that are counted by FP_SCALE_OPS_SPEC.

FP_FP8_MIN_SPEC, Floating-point operation speculatively executed, smallest type is 8-bit floating-point

The counter counts each floating-point operation counted by [FP_SPEC](#) due to an instruction where the smallest type was 8-bit floating-point.

FP_HP_FIXED_MIN_OPS_SPEC, Non-scalable element arithmetic operations speculatively executed, smallest type is half-precision floating-point

The counter increments by v for each [speculatively executed](#) non-scalable element arithmetic operation, due to an instruction where the smallest type was half-precision floating-point.

Where v is the number of arithmetic operations carried out by the operation or instruction which causes the counter to increment.

The counter does not count operations that are counted by [FP_SCALE_OPS_SPEC](#).

FP_HP_FIXED_OPS_SPEC, Non-scalable element arithmetic operations speculatively executed, largest type is half-precision floating-point

The counter increments by v for each [speculatively executed](#) non-scalable element arithmetic operation, due to an instruction where the largest type was half-precision floating-point.

Where v is the number of arithmetic operations carried out by the operation or instruction which causes the counter to increment.

The counter does not count operations that are counted by [FP_SCALE_OPS_SPEC](#).

FP_HP_MIN_SPEC, Floating-point operation speculatively executed, smallest type is half-precision floating-point

The counter counts each floating-point operation counted by [FP_SPEC](#) due to an instruction where the smallest type was half-precision floating-point.

FP_HP_SPEC, Floating-point operation speculatively executed, half-precision

The counter counts each [speculatively executed](#) floating-point operation counted by [FP_SPEC](#) where the largest type is half-precision.

FP_MUL_SPEC, Floating-point operation speculatively executed, multiply

The counter counts each [speculatively executed](#) floating-point multiply operation counted by [FP_SPEC](#) due to any of the following A64 instructions:

- Scalar: FMUL or FMULX.
- Advanced SIMD: FMUL or FMULX.

It is IMPLEMENTATION DEFINED which floating-point multiply operations are counted in AArch32 state.

FP_RECPE_SPEC, Floating-point operation speculatively executed, reciprocal estimate

The counter counts each [speculatively executed](#) floating-point reciprocal estimate operation counted by [FP_SPEC](#) due to any of the following A64 instructions:

- Advanced SIMD: FRECPE or FRSQRTE.

It is IMPLEMENTATION DEFINED which floating-point reciprocal estimate operations are counted in AArch32 state.

FP_SPEC, Floating-point operation speculatively executed, including SIMD

The counter counts each [speculatively executed](#) floating-point data-processing operation due to any of:

- An A64 scalar instruction.
- An A64 Advanced SIMD instruction.

It is IMPLEMENTATION DEFINED whether the counter counts any operation due to the following instructions:

- Scalar: `FABS`, or `FNEG` (scalar).
- Advanced SIMD: `FABS`, `FNEG` (vector), `FRECPE`, or `FRSQRT`.
- Data movement instructions which move data without carrying out any operations on the data. This includes identity data-processing operations.
- Conditional select instructions.
- Floating-point conversion instructions.

Any operation counted by [INT_SPEC](#) is not counted.

It is IMPLEMENTATION DEFINED which floating-point data-processing operations are counted in AArch32 state.

Arm recommends that if [FP_CVT_SPEC](#) is implemented, [FP_SPEC](#) counts operations due to convert instructions.

Note

This event differs from the [VFP_SPEC](#) event which does not count SIMD operations.

FP_SP_FIXED_MIN_OPS_SPEC, Non-scalable element arithmetic operations speculatively executed, smallest type is single-precision floating-point

The counter increments by v for each [speculatively executed](#) non-scalable element arithmetic operation, due to an instruction where the smallest type was single-precision floating-point.

Where v is the number of arithmetic operations carried out by the operation or instruction which causes the counter to increment.

The counter does not count operations that are counted by [FP_SCALE_OPS_SPEC](#).

FP_SP_FIXED_OPS_SPEC, Non-scalable element arithmetic operations speculatively executed, largest type is single-precision floating-point

The counter increments by v for each [speculatively executed](#) non-scalable element arithmetic operation, due to an instruction where the largest type was single-precision floating-point.

Where v is the number of arithmetic operations carried out by the operation or instruction which causes the counter to increment.

The counter does not count operations that are counted by [FP_SCALE_OPS_SPEC](#).

FP_SP_MIN_SPEC, Floating-point operation speculatively executed, smallest type is single-precision floating-point

The counter counts each floating-point operation counted by [FP_SPEC](#) due to an instruction where the smallest type was single-precision floating-point.

FP_SP_SPEC, Floating-point operation speculatively executed, single-precision

The counter counts each [speculatively executed](#) floating-point operation counted by [FP_SPEC](#) where the largest type is single-precision.

FP_SQRT_SPEC, Floating-point operation speculatively executed, square root

The counter counts each [speculatively executed](#) floating-point square-root operation counted by [FP_SPEC](#) due to any of the following A64 instructions:

- Scalar: FSQRT.
- Advanced SIMD: FSQRT.

It is IMPLEMENTATION DEFINED which floating-point square-root operations are counted in AArch32 state.

GCSTLB_WALK, GCS TLB access with at least one translation table walk

The counter counts each access counted by [LIGCS_TLB](#) that causes a refill of a TLB involving at least one translation table walk access.

This includes each complete or partial translation table walk that causes an access to memory, including to data or translation table walk caches.

Accesses that cause an update of an existing TLB entry involving at least one translation table walk access are counted.

The counter does not count the access if any of the following are true:

- FEAT_E0PD is implemented and the access is an unprivileged access that generates a Translation fault because the applicable TCR_ELx.E0PDy bit is 1.
- The access generates a Translation fault because the applicable TCR_ELx.EPDy bit is 1.
- The access is due to a TLB maintenance instruction.

It is IMPLEMENTATION DEFINED whether the counter counts the access if the access generates a Translation fault for any other reason.

The counter does not count the access if any of the following are true:

- The access generates a Translation fault because the applicable TCR_ELx.EPDy bit is 1.

It is IMPLEMENTATION DEFINED whether the counter counts the access if the access generates a Translation fault for any other reason.

If the TLB is shared and the Effective value of PMEVTYPERS<n>_EL0.MT for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of PMEVTYPERS<n>_EL0.MT for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of PMEVTYPERS<n>_EL0.MT.

GCSTLB_WALK_PERCYC, Translation table walks in progress

The counter increments by the number of translation table walks counted by [GCSTLB_WALK](#) in progress on each [Processor cycle](#).

The ratio $\text{GCSTLB_WALK_PERCYC} \div \text{GCSTLB_WALK}$ is the mean duration of translation table walks in [Processor cycles](#).

If the TLB is shared and the Effective value of PMEVTYPERS<n>_EL0.MT for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of PMEVTYPERS<n>_EL0.MT for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of PMEVTYPERS<n>_EL0.MT.

GCSTLB_WALK_RW, GCS TLB demand access with at least one translation table walk

The counter counts each demand access counted by both [GCSTLB_WALK](#) and [LIGCS_TLB_RW](#).

If the TLB is shared and the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of `PMEVTYPER<n>_EL0.MT`.

GCSTLB_WALK_STEP, GCS TLB translation table walk, step

The counter counts each translation table walk access due to a refill of a TLB.

The translation table walk must be due to either GCS data read operation or GCS data write operation.

The event is Attributable to the access that missed in the TLB and caused the walk, not to the owner of the translation tables being accessed. For example, this means that if an EL0 access causes a translation table walk consisting of accesses to both stage 1 and stage 2 translation tables, all accesses are counted if event counting is allowed at EL0, regardless of whether event counting is allowed at EL1 and/or EL2.

The counter does not count the event if any of the following are true:

- The access causing the refill generates a Translation fault because the applicable `TCR_ELx.EPDy` bit is 1.
- The access causing the refill is an unprivileged access that generates a Translation fault because the applicable `TCR_ELx.EOPDy` bit is 1.

It is IMPLEMENTATION DEFINED whether the counter counts the event if the access causing the refill generates a Translation fault for any other reason.

Implementation of this optional event requires that `FEAT_EOPD` is implemented.

If the TLB is shared and the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of `PMEVTYPER<n>_EL0.MT`.

INST_FETCH, Instruction memory access

The counter counts each [Instruction memory access](#).

The counter increments whether the access results in an access to a Level 1 instruction cache, a Level 2 instruction, data or unified cache, or none of these.

The counter does not increment as a result of:

- Data memory accesses.
- Translation table walks.
- Refilling of any cache.
- Accesses that result from cache maintenance instructions.

INST_FETCH_PERCYC, Instruction fetches in progress

The counter increments by the number of instruction fetches counted by [INST_FETCH](#) in progress on each [Processor cycle](#).

The ratio $\text{INST_FETCH_PERCYC} \div \text{INST_FETCH}$ is the mean duration of instruction fetches in [Processor cycles](#).

INST_FETCH_PRFM, Instruction memory access, software prefetch

The counter counts each fetch counted by [INST_FETCH](#) that is due to a prefetch instruction.

INST_FETCH_RD, Instruction memory access, demand fetch

The counter counts each fetch counted by `INST_FETCH` that is a demand [Instruction memory access](#).

This includes any fetch made for a speculative instruction.

INT_DIV64_SPEC, Integer operation speculatively executed, 64-bit divide

The counter counts each [speculatively executed](#) integer divide operation counted by `INT_SPEC` due to any of the following A64 instructions:

- Scalar: SDIV or UDIV.

The counter only counts operations with 64-bit operands or vector elements.

INT_DIV_SPEC, Integer operation speculatively executed, divide

The counter counts each [speculatively executed](#) integer divide operation counted by `INT_SPEC` due to any of the following A64 instructions:

- Scalar: SDIV or UDIV.

It is IMPLEMENTATION DEFINED which integer divide operations are counted in AArch32 state.

INT_FIXED_OPS_SPEC, Non-scalable element arithmetic operations speculatively executed, integer

The counter increments by v for each [speculatively executed](#) non-scalable element arithmetic operation, due to an instruction where the type was integer.

Where v is the number of arithmetic operations carried out by the operation or instruction which causes the counter to increment.

The counter does not count operations that are counted by `FP_SCALE_OPS_SPEC`.

INT_MUL64_SPEC, Integer operation speculatively executed, 64×64 multiply

The counter counts each [speculatively executed](#) 64×64 integer multiply operation counted by `INT_SPEC` due to any of the following A64 instructions:

- Scalar: MADD, MSUB, MUL, SMULH, or UMULH.

The counter only counts operations that perform a $64\text{-bit} \times 64\text{-bit}$ integer multiply operations.

INT_MULH64_SPEC, Integer operation speculatively executed, 64×64 multiply returning high part

The counter counts each [speculatively executed](#) widening 64×64 integer multiply operation counted by `INT_SPEC` due to any of the following A64 instructions:

- Scalar: SMULH or UMULH.

These instructions perform $64\text{-bit} \times 64\text{-bit}$ integer multiply operations.

INT_MUL_SPEC, Integer operation speculatively executed, multiply

The counter counts each [speculatively executed](#) integer multiply or multiply-accumulate operation counted by [INT_SPEC](#) due to any of the following A64 instructions:

- Scalar: MADD, MSUB, MUL, SMADDL, SMULH, UMADDL, or UMULH.
- Advanced SIMD: MLA, MLS, MUL, PMUL, PMULL, PMULL2, SMLAL, SMLAL2, SMLSL, SMLSL2, SMULL, SMULL2, SQDMLAL, SQDMLAL2, SQDMLSL, SQDMLSL2, SQDMULH, SQDMULL, SQDMULL2, SQRDMULH, UMLAL, UMLAL2, UMLSL, UMLSL2, UMULL, or UMULL2.

It is IMPLEMENTATION DEFINED which integer multiply or multiply-accumulate operations are counted in AArch32 state.

INT_SPEC, Integer operation speculatively executed

The counter counts each [speculatively executed](#) integer arithmetic operation due to any of:

- An A64 scalar data-processing instruction.
- An Advanced SIMD instruction.
- An SVE data-processing instruction.

It is IMPLEMENTATION DEFINED whether the counter counts any operation due to the following instructions:

- Scalar: FABS, FNEG (scalar).
- Advanced SIMD: FABS, FNEG (vector), FRECPE, FRSQRTE.
- Data movement instructions which move data without carrying out any operations on the data. This includes identity data-processing operations.
- Conditional select instructions.
- Floating-point conversion instructions.

Any operation counted by [FP_SPEC](#) is not counted.

It is IMPLEMENTATION DEFINED which integer arithmetic operations are counted in AArch32 state.

ISNP_HIT, Snoop hit, instruction

The counter counts each snoop that hits in a cache outside of the cache hierarchy of this PE.

The event is counted by the PE generating the snoop, not the PE being snooped.

ISNP_HIT_FAR, Snoop hit in far local cache, instruction access

The counter counts each snoop counted by [ISNP_HIT](#) that hits in a cache outside the local PE cluster on the same device.

The event is counted by the PE generating the snoop, not the PE being snooped.

ISNP_HIT_FAR_HWPRF, Snoop hit in far local cache, hardware instruction prefetch

The counter counts each snoop generated by an instruction hardware prefetch counted by [ISNP_HIT_HWPRF](#) that hits in a cache outside the local PE cluster on the same device.

The event is counted by the PE generating the snoop, not the PE being snooped.

ISNP_HIT_FAR_PRF, Snoop hit in far local cache, instruction prefetch

The counter counts each snoop generated by the PE in response to an instruction prefetch instruction, or by an instruction hardware prefetch counted by [ISNP_HIT_PRF](#) that hits in a cache outside the local PE cluster on the same device.

The event is counted by the PE generating the snoop, not the PE being snooped.

ISNP_HIT_FAR_PRFM, Snoop hit in far local cache, software instruction prefetch

The counter counts each snoop generated by the PE in response to an instruction prefetch instruction counted by [ISNP_HIT_PRFM](#) that hits in a cache outside the local PE cluster on the same device.

The event is counted by the PE generating the snoop, not the PE being snooped.

ISNP_HIT_FAR_RD, Snoop hit in far local cache, demand instruction fetch

The counter counts each snoop generated by the PE in response to a demand [Instruction memory access](#) counted by [ISNP_HIT_RD](#) that hits in a cache outside the local PE cluster on the same device.

The event is counted by the PE generating the snoop, not the PE being snooped.

ISNP_HIT_FAR_RETIRED, Instruction architecturally executed, instruction fetch snoop hit in far cache

The counter counts each [instruction architecturally executed](#) counted by [ISNP_HIT_RETIRED](#) that hit outside the local PE cluster on the same device when fetched.

ISNP_HIT_HWPRF, Snoop hit, hardware instruction prefetch

The counter counts each snoop generated by an instruction hardware prefetch counted by [ISNP_HIT_PRF](#) that hits in a cache outside of the cache hierarchy of this PE.

The event is counted by the PE generating the snoop, not the PE being snooped.

ISNP_HIT_N1, Snoop hit in cache at distance 1, instruction access

The counter counts each snoop counted by [ISNP_HIT](#) that hits in a cache at distance 1.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

ISNP_HIT_N1_HWPRF, Snoop hit in cache at distance 1, hardware instruction prefetch

The counter counts each snoop generated by an instruction hardware prefetch counted by [ISNP_HIT_HWPRF](#) that hits in a cache at distance 1.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

ISNP_HIT_N1_PRF, Snoop hit in cache at distance 1, instruction prefetch

The counter counts each snoop generated by the PE in response to an instruction prefetch instruction, or by an instruction hardware prefetch counted by [ISNP_HIT_PRF](#) that hits in a cache at distance 1.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

ISNP_HIT_N1_PRFM, Snoop hit in cache at distance 1, software instruction prefetch

The counter counts each snoop generated by the PE in response to an instruction prefetch instruction counted by [ISNP_HIT_PRFM](#) that hits in a cache at distance 1.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

ISNP_HIT_N1_RD, Snoop hit in cache at distance 1, demand instruction fetch

The counter counts each snoop generated by the PE in response to a demand [Instruction memory access](#) counted by [ISNP_HIT_RD](#) that hits in a cache at distance 1.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

ISNP_HIT_N2, Snoop hit in cache at distance 2, instruction access

The counter counts each snoop counted by [ISNP_HIT](#) that hits in a cache at distance 2.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

ISNP_HIT_N2_HWPRF, Snoop hit in cache at distance 2, hardware instruction prefetch

The counter counts each snoop generated by an instruction hardware prefetch counted by [ISNP_HIT_HWPRF](#) that hits in a cache at distance 2.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

ISNP_HIT_N2_PRF, Snoop hit in cache at distance 2, instruction prefetch

The counter counts each snoop generated by the PE in response to an instruction prefetch instruction, or by an instruction hardware prefetch counted by [ISNP_HIT_PRF](#) that hits in a cache at distance 2.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

ISNP_HIT_N2_PRFM, Snoop hit in cache at distance 2, software instruction prefetch

The counter counts each snoop generated by the PE in response to an instruction prefetch instruction counted by [ISNP_HIT_PRFM](#) that hits in a cache at distance 2.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

ISNP_HIT_N2_RD, Snoop hit in cache at distance 2, demand instruction fetch

The counter counts each snoop generated by the PE in response to a demand [Instruction memory access](#) counted by [ISNP_HIT_RD](#) that hits in a cache at distance 2.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

ISNP_HIT_N3, Snoop hit in cache at distance 3, instruction access

The counter counts each snoop counted by [ISNP_HIT](#) that hits in a cache at distance 3.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

ISNP_HIT_N3_HWPRF, Snoop hit in cache at distance 3, hardware instruction prefetch

The counter counts each snoop generated by an instruction hardware prefetch counted by [ISNP_HIT_HWPRF](#) that hits in a cache at distance 3.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

ISNP_HIT_N3_PRF, Snoop hit in cache at distance 3, instruction prefetch

The counter counts each snoop generated by the PE in response to an instruction prefetch instruction, or by an instruction hardware prefetch counted by [ISNP_HIT_PRF](#) that hits in a cache at distance 3.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

ISNP_HIT_N3_PRFM, Snoop hit in cache at distance 3, software instruction prefetch

The counter counts each snoop generated by the PE in response to an instruction prefetch instruction counted by [ISNP_HIT_PRFM](#) that hits in a cache at distance 3.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

ISNP_HIT_N3_RD, Snoop hit in cache at distance 3, demand instruction fetch

The counter counts each snoop generated by the PE in response to a demand [Instruction memory access](#) counted by [ISNP_HIT_RD](#) that hits in a cache at distance 3.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

ISNP_HIT_N4, Snoop hit in cache at distance 4, instruction access

The counter counts each snoop counted by [ISNP_HIT](#) that hits in a cache at distance 4.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

ISNP_HIT_N4_HWPRF, Snoop hit in cache at distance 4, hardware instruction prefetch

The counter counts each snoop generated by an instruction hardware prefetch counted by [ISNP_HIT_HWPRF](#) that hits in a cache at distance 4.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

ISNP_HIT_N4_PRF, Snoop hit in cache at distance 4, instruction prefetch

The counter counts each snoop generated by the PE in response to an instruction prefetch instruction, or by an instruction hardware prefetch counted by [ISNP_HIT_PRF](#) that hits in a cache at distance 4.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

ISNP_HIT_N4_PRFM, Snoop hit in cache at distance 4, software instruction prefetch

The counter counts each snoop generated by the PE in response to an instruction prefetch instruction counted by [ISNP_HIT_PRFM](#) that hits in a cache at distance 4.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

ISNP_HIT_N4_RD, Snoop hit in cache at distance 4, demand instruction fetch

The counter counts each snoop generated by the PE in response to a demand [Instruction memory access](#) counted by [ISNP_HIT_RD](#) that hits in a cache at distance 4.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

ISNP_HIT_NEAR, Snoop hit in near local cache, instruction access

The counter counts each snoop counted by [ISNP_HIT](#) that hits in a cache outside of the cache hierarchy of this PE in the local PE cluster.

The event is counted by the PE generating the snoop, not the PE being snooped.

ISNP_HIT_NEAR_HWPRF, Snoop hit in near local cache, hardware instruction prefetch

The counter counts each snoop generated by an instruction hardware prefetch counted by [ISNP_HIT_HWPRF](#) that hits in a cache outside of the cache hierarchy of this PE in the local PE cluster.

The event is counted by the PE generating the snoop, not the PE being snooped.

ISNP_HIT_NEAR_PRF, Snoop hit in near local cache, instruction prefetch

The counter counts each snoop generated by the PE in response to an instruction prefetch instruction, or by an instruction hardware prefetch counted by [ISNP_HIT_PRF](#) that hits in a cache outside of the cache hierarchy of this PE in the local PE cluster.

The event is counted by the PE generating the snoop, not the PE being snooped.

ISNP_HIT_NEAR_PRFM, Snoop hit in near local cache, software instruction prefetch

The counter counts each snoop generated by the PE in response to an instruction prefetch instruction counted by [ISNP_HIT_PRFM](#) that hits in a cache outside of the cache hierarchy of this PE in the local PE cluster.

The event is counted by the PE generating the snoop, not the PE being snooped.

ISNP_HIT_NEAR_RD, Snoop hit in near local cache, demand instruction fetch

The counter counts each snoop generated by the PE in response to a demand [Instruction memory access](#) counted by [ISNP_HIT_RD](#) that hits in a cache outside of the cache hierarchy of this PE in the local PE cluster.

The event is counted by the PE generating the snoop, not the PE being snooped.

ISNP_HIT_NEAR_RETIRED, Instruction architecturally executed, instruction fetch snoop hit in near cache

The counter counts each [instruction architecturally executed](#) counted by [ISNP_HIT_RETIRED](#) that hit outside of the cache hierarchy of this PE in the local PE cluster when fetched.

ISNP_HIT_PRF, Snoop hit, instruction prefetch

The counter counts each snoop generated by the PE in response to an instruction prefetch instruction, or by an instruction hardware prefetch that hits in a cache outside of the cache hierarchy of this PE.

The event is counted by the PE generating the snoop, not the PE being snooped.

ISNP_HIT_PRFM, Snoop hit, software instruction prefetch

The counter counts each snoop generated by the PE in response to an instruction prefetch instruction counted by [ISNP_HIT_PRF](#) that hits in a cache outside of the cache hierarchy of this PE.

The event is counted by the PE generating the snoop, not the PE being snooped.

ISNP_HIT_RD, Snoop hit, demand instruction fetch

The counter counts each snoop generated by the PE in response to a demand [Instruction memory access](#) that hits in a cache outside of the cache hierarchy of this PE.

The event is counted by the PE generating the snoop, not the PE being snooped.

ISNP_HIT_REMOTE, Snoop hit in remote cache, instruction access

The counter counts each snoop counted by [ISNP_HIT](#) that hits in a cache on a remote device.

The event is counted by the PE generating the snoop, not the PE being snooped.

ISNP_HIT_REMOTE_HWPRF, Snoop hit in remote cache, hardware instruction prefetch

The counter counts each snoop generated by an instruction hardware prefetch counted by [ISNP_HIT_HWPRF](#) that hits in a cache on a remote device.

The event is counted by the PE generating the snoop, not the PE being snooped.

ISNP_HIT_REMOTE_PRF, Snoop hit in remote cache, instruction prefetch

The counter counts each snoop generated by the PE in response to an instruction prefetch instruction, or by an instruction hardware prefetch counted by [ISNP_HIT_PRF](#) that hits in a cache on a remote device.

The event is counted by the PE generating the snoop, not the PE being snooped.

ISNP_HIT_REMOTE_PRFM, Snoop hit in remote cache, software instruction prefetch

The counter counts each snoop generated by the PE in response to an instruction prefetch instruction counted by [ISNP_HIT_PRFM](#) that hits in a cache on a remote device.

The event is counted by the PE generating the snoop, not the PE being snooped.

ISNP_HIT_REMOTE_RD, Snoop hit in remote cache, demand instruction fetch

The counter counts each snoop generated by the PE in response to a demand [Instruction memory access](#) counted by [ISNP_HIT_RD](#) that hits in a cache on a remote device.

The event is counted by the PE generating the snoop, not the PE being snooped.

ISNP_HIT_REMOTE_RETIRED, Instruction architecturally executed, instruction fetch snoop hit in remote cache

The counter counts each [instruction architecturally executed](#) counted by [ISNP_HIT_RETIRED](#) that hit on a remote device when fetched.

ISNP_HIT_RETIRED, Instruction architecturally executed, instruction fetch snoop hit

The counter counts each [instruction architecturally executed](#) counted by [INST_RETIRED](#) that hit in an instruction cache outside the cache hierarchy of this PE when fetched.

ITLB_HIT_RETIRED, Instruction architecturally executed, no translation table walk

The counter counts each instruction which was [architecturally executed](#) counted by [INST_RETIRED](#) that did not cause a refill of an instruction TLB involving at least one translation table walk access.

The counter does not count the instruction which was [architecturally executed](#) if any of the following are true:

- The access generates a Translation fault because the applicable TCR_ELx.EPDy bit is 1.

It is IMPLEMENTATION DEFINED whether the counter counts the instruction which was [architecturally executed](#) if the access generates a Translation fault for any other reason.

ITLB_WALK_HWPRF, Instruction TLB hardware prefetch, with at least one translation table walk

The counter counts each hardware prefetch access counted by [L1I_TLB_HWPRF](#) that causes a refill or update of an instruction TLB involving at least one translation table walk access.

The counter does not count the hardware prefetch access if any of the following are true:

- The access is due to a TLB maintenance instruction.
- The access generates a Translation fault because the applicable TCR_ELx.EPDy bit is 1.

It is IMPLEMENTATION DEFINED whether the counter counts the hardware prefetch access if the access generates a Translation fault for any other reason.

If the TLB is shared and the Effective value of PMEVTYPEPER<n>_EL0.MT for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of PMEVTYPEPER<n>_EL0.MT for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of PMEVTYPEPER<n>_EL0.MT.

ITLB_WALK_PERCYC, Instruction translation table walks in progress

The counter increments by the number of instruction translation table walks counted by [ITLB_WALK](#) in progress on each [Processor cycle](#).

The ratio $\text{ITLB_WALK_PERCYC} \div \text{ITLB_WALK}$ is the mean duration of instruction translation table walks in [Processor cycles](#).

If the TLB is shared and the Effective value of PMEVTYPEPER<n>_EL0.MT for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of PMEVTYPEPER<n>_EL0.MT for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of PMEVTYPEPER<n>_EL0.MT.

ITLB_WALK_PRF, Instruction TLB prefetch, with at least one translation table walk

The counter counts each software prefetch or hardware prefetch access counted by [L1I_TLB_PRF](#) that causes a refill or update of an instruction TLB involving at least one translation table walk access.

The counter does not count the software prefetch or hardware prefetch access if any of the following are true:

- The access is due to a TLB maintenance instruction.
- The access generates a Translation fault because the applicable TCR_ELx.EPDy bit is 1.

It is IMPLEMENTATION DEFINED whether the counter counts the software prefetch or hardware prefetch access if the access generates a Translation fault for any other reason.

If the TLB is shared and the Effective value of PMEVTYPERS<n>_EL0.MT for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of PMEVTYPERS<n>_EL0.MT for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of PMEVTYPERS<n>_EL0.MT.

ITLB_WALK_PRFM, Instruction TLB software prefetch, with at least one translation table walk

The counter counts each software prefetch access counted by [L1I_TLB_PRFM](#) that causes a refill or update of an instruction TLB involving at least one translation table walk access.

The counter does not count the software prefetch access if any of the following are true:

- The access is due to a TLB maintenance instruction.
- The access generates a Translation fault because the applicable TCR_ELx.EPDy bit is 1.

It is IMPLEMENTATION DEFINED whether the counter counts the software prefetch access if the access generates a Translation fault for any other reason.

If the TLB is shared and the Effective value of PMEVTYPERS<n>_EL0.MT for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of PMEVTYPERS<n>_EL0.MT for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of PMEVTYPERS<n>_EL0.MT.

ITLB_WALK_RD, Instruction TLB demand access, with at least one translation table walk

The counter counts each demand access counted by [L1I_TLB_RD](#) that causes a refill or update of an instruction TLB involving at least one translation table walk access.

The counter does not count the demand access if any of the following are true:

- The access is due to a TLB maintenance instruction.
- The access generates a Translation fault because the applicable TCR_ELx.EPDy bit is 1.

It is IMPLEMENTATION DEFINED whether the counter counts the demand access if the access generates a Translation fault for any other reason.

If the TLB is shared and the Effective value of PMEVTYPERS<n>_EL0.MT for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of PMEVTYPERS<n>_EL0.MT for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of PMEVTYPERS<n>_EL0.MT.

ITLB_WALK_RETIRED, Instruction architecturally executed, at least one translation table walk

The counter counts each instruction which was [architecturally executed](#) counted by [INST_RETIRED](#) that caused a refill of an instruction TLB involving at least one translation table walk access.

The counter does not count the instruction which was [architecturally executed](#) if any of the following are true:

- The access generates a Translation fault because the applicable TCR_ELx.EPDy bit is 1.

It is IMPLEMENTATION DEFINED whether the counter counts the instruction which was [architecturally executed](#) if the access generates a Translation fault for any other reason.

L1D_CACHE_HIT, Level 1 data cache hit

The counter counts each access counted by [L1D_CACHE](#) that hits in the Level 1 data or unified cache.

L1D_CACHE_HITM_LDST_RETIRED, Load or store instruction architecturally executed, hit modified data in Level 1 data cache

The counter counts each [architecturally executed](#) Memory-reading instruction or [Memory-writing instruction](#) counted by [L1D_CACHE_HIT_LDST_RETIRED](#) that hit modified data in Level 1 data or unified cache.

L1D_CACHE_HITM_LD_RETIRED, Load instruction architecturally executed, hit modified data in Level 1 data cache

The counter counts each [architecturally executed](#) instruction counted by [L1D_CACHE_HITM_LDST_RETIRED](#) that is a Memory-reading instruction.

L1D_CACHE_HITM_RD, Level 1 data cache demand access hit modified, read

The counter counts each cache access counted by [L1D_CACHE_HIT_RD](#) that accesses a previously modified cache location.

L1D_CACHE_HITM_RW, Level 1 data cache demand access hit modified

The counter counts each cache access counted by [L1D_CACHE_HIT_RW](#) that accesses a previously modified cache location.

L1D_CACHE_HITM_ST_RETIRED, Store instruction architecturally executed, hit modified data in Level 1 data cache

The counter counts each [architecturally executed](#) instruction counted by [L1D_CACHE_HITM_LDST_RETIRED](#) that is a [Memory-writing instruction](#).

L1D_CACHE_HITM_WR, Level 1 data cache demand access hit modified, write

The counter counts each cache access counted by [L1D_CACHE_HIT_WR](#) that accesses a previously modified cache location.

L1D_CACHE_HIT_LDST_RETIRED, Load or store instruction architecturally executed, hit in Level 1 data cache

The counter counts each [architecturally executed](#) Memory-reading instruction or [Memory-writing instruction](#) counted by [LDST_ANY_RETIRED](#) that hit in Level 1 data or unified cache.

L1D_CACHE_HIT_LD_RETIRED, Load instruction architecturally executed, hit in Level 1 data cache

The counter counts each [architecturally executed](#) instruction counted by [L1D_CACHE_HIT_LDST_RETIRED](#) that is a Memory-reading instruction.

L1D_CACHE_HIT_PRFM, Level 1 data cache software prefetch hit

The counter counts each software prefetch counted by [L1D_CACHE_PRFM](#) that hits in the Level 1 data or unified cache.

L1D_CACHE_HIT_RD, Level 1 data cache demand access hit, read

The counter counts each demand read counted by [L1D_CACHE_RD](#) that hits in the Level 1 data or unified cache.

L1D_CACHE_HIT_RD_FHWPRF, Level 1 data cache demand access first hit, read, fetched by hardware prefetcher

The counter counts each first hit counted by [L1D_CACHE_HIT_RW_FHWPRF](#) that is due to a demand ‘Memory-read operation’.

L1D_CACHE_HIT_RD_FPRF, Level 1 data cache demand access first hit, read, fetched by prefetch

The counter counts each first hit counted by [L1D_CACHE_HIT_RW_FPRF](#) that is due to a demand ‘Memory-read operation’.

L1D_CACHE_HIT_RD_FPRFM, Level 1 data cache demand access first hit, read, fetched by software prefetch

The counter counts each first hit counted by [L1D_CACHE_HIT_RW_FPRFM](#) that is due to a demand ‘Memory-read operation’.

L1D_CACHE_HIT_RW, Level 1 data cache demand access hit

The counter counts each demand access counted by [L1D_CACHE_RW](#) that hits in the Level 1 data or unified cache.

L1D_CACHE_HIT_RW_FHWPRF, Level 1 data cache demand access first hit, fetched by hardware prefetcher

The counter counts each demand access first hit counted by [L1D_CACHE_HIT_RW_FPRF](#) where the cache line was fetched by a hardware prefetcher.

That is, the [L1D_CACHE_REFILL_HWPRF](#) event was generated when the cache line was fetched into the cache.

Only the first hit by a demand access is counted. After this event is generated for a cache line, the event is not generated again for the same cache line while it remains in the cache.

L1D_CACHE_HIT_RW_FPRF, Level 1 data cache demand access first hit, fetched by prefetch

The counter counts each demand access first hit counted by [L1D_CACHE_HIT_RW](#) where the cache line was fetched in response to a prefetch instruction or by a hardware prefetcher.

That is, the [L1D_CACHE_REFILL_PRF](#) event was generated when the cache line was fetched into the cache.

Only the first hit by a demand access is counted. After this event is generated for a cache line, the event is not generated again for the same cache line while it remains in the cache.

L1D_CACHE_HIT_RW_FPRFM, Level 1 data cache demand access first hit, fetched by software prefetch

The counter counts each demand access first hit counted by [L1D_CACHE_HIT_RW_FPRF](#) where the cache line was fetched in response to a prefetch instruction.

That is, the [L1D_CACHE_REFILL_PRFM](#) event was generated when the cache line was fetched into the cache.

Only the first hit by a demand access is counted. After this event is generated for a cache line, the event is not generated again for the same cache line while it remains in the cache.

L1D_CACHE_HIT_ST_RETIRED, Store instruction architecturally executed, hit in Level 1 data cache

The counter counts each [architecturally executed](#) instruction counted by [L1D_CACHE_HIT_LDST_RETIRED](#) that is a [Memory-writing instruction](#).

L1D_CACHE_HIT_WR, Level 1 data cache demand access hit, write

The counter counts each demand write counted by [L1D_CACHE_WR](#) that hits in the Level 1 data or unified cache.

L1D_CACHE_HIT_WR_FHWPRF, Level 1 data cache demand access first hit, write, fetched by hardware prefetcher

The counter counts each first hit counted by [L1D_CACHE_HIT_RW_FHWPRF](#) that is due to a demand [Memory-write operation](#).

L1D_CACHE_HIT_WR_FPRF, Level 1 data cache demand access first hit, write, fetched by prefetch

The counter counts each first hit counted by [L1D_CACHE_HIT_RW_FPRF](#) that is due to a demand [Memory-write operation](#).

L1D_CACHE_HIT_WR_FPRFM, Level 1 data cache demand access first hit, write, fetched by software prefetch

The counter counts each first hit counted by [L1D_CACHE_HIT_RW_FPRFM](#) that is due to a demand [Memory-write operation](#).

L1D_CACHE_HWPRF, Level 1 data cache hardware prefetch

The counter counts each access counted by [L1D_CACHE_PRF](#) that is due to a hardware prefetch.

The hardware prefetch is generated by a hardware prefetcher at the Level 1 data or unified cache.

L1D_CACHE_MISS, Level 1 data cache demand access miss

The counter counts each demand access counted by [L1D_CACHE_RW](#) that misses in the Level 1 data or unified cache, causing an access to outside of the Level 1 caches of this PE.

L1D_CACHE_MISS_LDST_RETIRED, Load or store instruction architecturally executed, miss in Level 1 data cache

The counter counts each [architecturally executed](#) Memory-reading instruction or [Memory-writing instruction](#) counted by [LDST_ANY_RETIRED](#) that missed in Level 1 data or unified cache.

L1D_CACHE_MISS_LD_RETIRED, Load instruction architecturally executed, miss in Level 1 data cache

The counter counts each [architecturally executed](#) instruction counted by [L1D_CACHE_MISS_LDST_RETIRED](#) that is a Memory-reading instruction.

L1D_CACHE_MISS_ST_RETIRED, Store instruction architecturally executed, miss in Level 1 data cache

The counter counts each [architecturally executed](#) instruction counted by [L1D_CACHE_MISS_LDST_RETIRED](#) that is a [Memory-writing instruction](#).

L1D_CACHE_PRF, Level 1 data cache, prefetch hit

The counter counts each access counted by [L1D_CACHE](#) that is due to a prefetch instruction, or hardware prefetch.

L1D_CACHE_PRFM, Level 1 data cache software prefetch

The counter counts each access counted by [L1D_CACHE_PRF](#) that is due to a prefetch instruction.

Arm recommends that this event is implemented if event [L1D_CACHE_RW](#) is implemented.

L1D_CACHE_REFILL_HWPRF, Level 1 data cache refill, hardware prefetch

The counter counts each hardware prefetch counted by [L1D_CACHE_HWPRF](#) that causes a refill of the Level 1 data or unified cache from outside of the Level 1 data or unified cache.

L1D_CACHE_REFILL_PERCYC, Level 1 data or unified cache refills in progress

The counter increments by the number of Level 1 data or unified cache refills counted by [L1D_CACHE_REFILL](#) in progress on each [Processor cycle](#).

The ratio $\text{L1D_CACHE_REFILL_PERCYC} \div \text{L1D_CACHE_REFILL}$ is the mean duration of Level 1 data or unified cache refills in [Processor cycles](#).

L1D_CACHE_REFILL_PRF, Level 1 data cache refill, prefetch hit

The counter counts each access counted by [L1D_CACHE_PRF](#) that causes a refill of the Level 1 data or unified cache from outside of the Level 1 data or unified cache.

L1D_CACHE_REFILL_PRFM, Level 1 data cache refill, software prefetch

The counter counts each access counted by [L1D_CACHE_PRFM](#) that causes a refill of the Level 1 data or unified cache from outside of the Level 1 data or unified cache.

L1D_CACHE_RW, Level 1 data cache demand access

The counter counts each access counted by [L1D_CACHE](#) that is due to a demand ‘Memory-read operation’ or demand [Memory-write operation](#).

This includes accesses made by [speculatively executed](#) instructions.

Arm recommends that this event is implemented if any of the following are true:

- Event [L1D_CACHE_PRFM](#) is implemented.
- Event [L1D_CACHE_HWPRF](#) is implemented.

L1D_LFB_HIT_LDST_RETIRED, Load or store instruction architecturally executed, line-fill buffer hit in Level 1 data cache

The counter counts each [architecturally executed](#) Memory-reading instruction or [Memory-writing instruction](#) counted by [L1D_CACHE_HIT_LDST_RETIRED](#) that hit a recently fetched line in Level 1 data or unified cache.

L1D_LFB_HIT_LD_RETIRED, Load instruction architecturally executed, line-fill buffer hit in Level 1 data cache

The counter counts each [architecturally executed](#) instruction counted by [L1D_LFB_HIT_LDST_RETIRED](#) that is a Memory-reading instruction.

L1D_LFB_HIT_RD, Level 1 data cache demand access line-fill buffer hit, read

The counter counts each demand access counted by [L1D_CACHE_HIT_RD](#) that hits a recently fetched line in the Level 1 data or unified cache.

That is, the access hits a cache line that is in the process of being loaded into the Level 1 data or unified cache, and so does not generate a new refill, but has to wait for the previous refill to complete.

L1D_LFB_HIT_RD_FHWPRF, Level 1 data cache demand access line-fill buffer first hit, read, recently fetched by hardware prefetcher

The counter counts each line-fill buffer first hit counted by [L1D_LFB_HIT_RW_FHWPRF](#) that is due to a demand ‘Memory-read operation’.

L1D_LFB_HIT_RD_FPRF, Level 1 data cache demand access line-fill buffer first hit, read, recently fetched by prefetch

The counter counts each line-fill buffer first hit counted by [L1D_LFB_HIT_RW_FPRF](#) that is due to a demand ‘Memory-read operation’.

L1D_LFB_HIT_RD_FPRFM, Level 1 data cache demand access line-fill buffer first hit, read, recently fetched by software prefetch

The counter counts each line-fill buffer first hit counted by [L1D_LFB_HIT_RW_FPRFM](#) that is due to a demand ‘Memory-read operation’.

L1D_LFB_HIT_RW, Level 1 data cache demand access line-fill buffer hit

The counter counts each demand access counted by [L1D_CACHE_HIT_RW](#) that hits a recently fetched line in the Level 1 data or unified cache.

That is, the access hits a cache line that is in the process of being loaded into the Level 1 data or unified cache, and so does not generate a new refill, but has to wait for the previous refill to complete.

L1D_LFB_HIT_RW_FHWPRF, Level 1 data cache demand access line-fill buffer first hit, recently fetched by hardware prefetcher

The counter counts each demand access line-fill buffer first hit counted by [L1D_LFB_HIT_RW_FPRF](#) where the cache line was fetched by a hardware prefetcher.

That is, the access hits a cache line that is in the process of being loaded into the Level 1 data or unified cache, and so does not generate a new refill, but has to wait for the previous refill to complete, and the [L1D_CACHE_REFILL_HWPRF](#) event was generated when the cache line was fetched into the cache.

Only the first hit by a demand access is counted. After this event is generated for a cache line, the event is not generated again for the same cache line while it remains in the cache.

L1D_LFB_HIT_RW_FPRF, Level 1 data cache demand access line-fill buffer first hit, recently fetched by prefetch

The counter counts each demand access line-fill buffer first hit counted by [L1D_LFB_HIT_RW](#) where the cache line was fetched in response to a prefetch instruction or by a hardware prefetcher.

That is, the access hits a cache line that is in the process of being loaded into the Level 1 data or unified cache, and so does not generate a new refill, but has to wait for the previous refill to complete, and the [L1D_CACHE_REFILL_PRF](#) event was generated when the cache line was fetched into the cache.

Only the first hit by a demand access is counted. After this event is generated for a cache line, the event is not generated again for the same cache line while it remains in the cache.

L1D_LFB_HIT_RW_FPRFM, Level 1 data cache demand access line-fill buffer first hit, recently fetched by software prefetch

The counter counts each demand access line-fill buffer first hit counted by [L1D_LFB_HIT_RW_FPRF](#) where the cache line was fetched in response to a prefetch instruction.

That is, the access hits a cache line that is in the process of being loaded into the Level 1 data or unified cache, and so does not generate a new refill, but has to wait for the previous refill to complete, and the [L1D_CACHE_REFILL_PRFM](#) event was generated when the cache line was fetched into the cache.

Only the first hit by a demand access is counted. After this event is generated for a cache line, the event is not generated again for the same cache line while it remains in the cache.

L1D_LFB_HIT_ST_RETIRED, Store instruction architecturally executed, line-fill buffer hit in Level 1 data cache

The counter counts each [architecturally executed](#) instruction counted by [L1D_LFB_HIT_LDST_RETIRED](#) that is a [Memory-writing instruction](#).

L1D_LFB_HIT_WR, Level 1 data cache demand access line-fill buffer hit, write

The counter counts each demand access counted by [L1D_CACHE_HIT_WR](#) that hits a recently fetched line in the Level 1 data or unified cache.

That is, the access hits a cache line that is in the process of being loaded into the Level 1 data or unified cache, and so does not generate a new refill, but has to wait for the previous refill to complete.

L1D_LFB_HIT_WR_FHWPRF, Level 1 data cache demand access line-fill buffer first hit, write, recently fetched by hardware prefetcher

The counter counts each line-fill buffer first hit counted by [L1D_LFB_HIT_RW_FHWPRF](#) that is due to a demand [Memory-write operation](#).

L1D_LFB_HIT_WR_FPRF, Level 1 data cache demand access line-fill buffer first hit, write, recently fetched by prefetch

The counter counts each line-fill buffer first hit counted by [L1D_LFB_HIT_RW_FPRF](#) that is due to a demand [Memory-write operation](#).

L1D_LFB_HIT_WR_FPRFM, Level 1 data cache demand access line-fill buffer first hit, write, recently fetched by software prefetch

The counter counts each line-fill buffer first hit counted by [L1D_LFB_HIT_RW_FPRFM](#) that is due to a demand [Memory-write operation](#).

L1D_TLB_HWPRF, Level 1 data TLB access, hardware prefetch

The counter counts each access counted by [L1D_TLB_PRF](#) that is due to a hardware prefetch.

If the TLB is shared and the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of `PMEVTYPER<n>_EL0.MT`.

L1D_TLB_PRF, Level 1 data TLB access, prefetch

The counter counts each access counted by [L1D_TLB](#) that is due to a prefetch instruction or hardware prefetch.

If the TLB is shared and the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of `PMEVTYPER<n>_EL0.MT`.

L1D_TLB_PRFM, Level 1 data TLB access, software prefetch

The counter counts each access counted by [L1D_TLB_PRF](#) that is due to a prefetch instruction.

If the TLB is shared and the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of `PMEVTYPER<n>_EL0.MT`.

Arm recommends that this event is implemented if event [L1D_TLB_RW](#) is implemented.

L1D_TLB_RW, Level 1 data TLB access, demand access

The counter counts each access counted by [L1D_TLB](#) that is due to a demand ‘Memory-read operation’ or demand [Memory-write operation](#).

If the TLB is shared and the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of `PMEVTYPER<n>_EL0.MT`.

Arm recommends that this event is implemented if event [L1D_TLB_PRFM](#) is implemented.

L1GCS_CACHE, Level 1 GCS cache access

The counter counts each GCS data read operation or GCS data write operation that causes a cache access to at least a Level 1 cache.

Each access to a cache line is counted including the multiple accesses caused by single instructions such as `GCSPUSHX` or `GCSPOPX`. Each access to other Level 1 memory structures, for example refill buffers, write buffers, and write-back buffers, is also counted.

Accesses to a Level 1 cache due to a GCS hardware prefetcher as well are counted.

When there are separate GCS caching structures implemented:

- It is IMPLEMENTATION DEFINED whether accesses that result from cache maintenance instructions are counted.
- Accesses that only update the cache status information for a cache entry without accessing the content of the cache entry are not counted.

L1GCS_CACHE_HIT_RW, Level 1 GCS cache demand access hit

The counter counts each access counted by [L1GCS_CACHE_RW](#) that hits in a Level 1 cache.

L1GCS_CACHE_HIT_RW_FHWPRF, Level 1 GCS cache demand access first hit, fetched by GCS hardware prefetcher

The counter counts each demand access first hit counted by [L1GCS_CACHE_HIT_RW](#) where the cache line was fetched by a GCS hardware prefetcher.

That is, the [L1GCS_CACHE_REFILL_HWPRF](#) event was generated when the cache line was fetched into the cache.

Only the first hit by a demand access is counted. After this event is generated for a cache line, the event is not generated again for the same cache line while it remains in the cache.

L1GCS_CACHE_HWPRF, Level 1 GCS cache hardware prefetch

The counter counts each access counted by [L1GCS_CACHE](#) that is due to a GCS hardware prefetcher.

L1GCS_CACHE_INVALID, Level 1 GCS cache invalidate

The counter counts each invalidation of a cache line in a Level 1 GCS cache.

For example:

- Invalidation of a cache line because of a GCSB effect.
- Transfer of ownership of a cache line to another cache because of a coherency or refill request.

The counter does not count events if a cache refill of the Level 1 cache invalidates a line in the Level 1 cache.

Note

Software that uses this event must know whether the Level 1 cache is shared with other PEs. This event does not follow the general rule of Level 1 cache events of only counting Attributable events.

L1GCS_CACHE_MISS, Level 1 GCS cache demand access miss

The counter counts each access counted by [L1GCS_CACHE_RW](#) that misses in the Level 1 caches causing an access to outside of the Level 1 caches of this PE.

L1GCS_CACHE_MISS_RD, Level 1 GCS cache demand access read miss

The counter counts each access counted by [L1GCS_CACHE_MISS](#) that is also a Memory-read operation.

It is IMPLEMENTATION DEFINED whether accesses that result from cache maintenance instructions are counted.

If the cache is shared and the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the cache is shared by PEs other than the PEs in the multithreaded processor and the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of `PMEVTYPER<n>_EL0.MT`.

Arm recommends that this event is implemented if event [L1GCS_CACHE](#) is implemented.

L1GCS_CACHE_REFILL, Level 1 GCS cache refill

The counter counts each access counted by [L1GCS_CACHE](#) that causes a refill of a Level 1 cache from outside of the Level 1 cache.

A refill includes any access that causes data to be fetched from outside of the Level 1 caches, even if the data is ultimately not allocated into the Level 1 cache. For example, data might be fetched into a buffer but then discarded, rather than being allocated into a cache. These buffers are treated as part of the cache.

For example, the counter counts accesses to the Level 1 cache that cause a refill that is satisfied by fetching data from memory, a Level 2 cache, or a Level 1 cache of another PE.

The counter does not count accesses that:

- Miss in the cache but are satisfied by the refill of a previous miss and do not cause a new refill, even if that previous refill is not complete at the time of the miss.
- Miss in the cache but do not generate a refill, such as a write through the cache.

If the cache is shared and the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the cache is shared by PEs other than the PEs in the multithreaded processor and the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of `PMEVTYPER<n>_EL0.MT`.

L1GCS_CACHE_REFILL_HWPRF, Level 1 GCS cache refill, hardware prefetch

The counter counts each hardware prefetch counted by [L1GCS_CACHE_HWPRF](#) that causes a refill of a Level 1 cache from outside of the Level 1 cache.

L1GCS_CACHE_REFILL_PERCYC, Level 1 GCS cache refills in progress

The counter increments by the number of Level 1 GCS cache refills counted by [L1GCS_CACHE_REFILL](#) in progress on each [Processor cycle](#).

The ratio $\text{L1GCS_CACHE_REFILL_PERCYC} \div \text{L1GCS_CACHE_REFILL}$ is the mean duration of Level 1 GCS cache refills in [Processor cycles](#).

L1GCS_CACHE_RW, Level 1 GCS cache demand access

The counter counts each access counted by [L1GCS_CACHE](#) that is due to a demand Memory-read operation or demand Memory-write operation.

This includes accesses made by Speculatively executed instructions.

Arm recommends that this event is implemented if event [L1GCS_CACHE_HWPRF](#) is implemented.

L1GCS_LFB_HIT_RW, Level 1 GCS cache demand access line-fill buffer hit

The counter counts each demand access counted by [L1GCS_CACHE_HIT_RW](#) that hits a recently fetched line in a Level 1 cache.

That is, the access hits a cache line that is in the process of being loaded into the Level 1 cache, and so does not generate a new refill, but has to wait for the previous refill to complete.

L1GCS_LFB_HIT_RW_FHWPRF, Level 1 GCS cache demand access line-fill buffer first hit, recently fetched by GCS hardware prefetcher

The counter counts each demand access line-fill buffer first hit counted by [L1GCS_LFB_HIT_RW](#) where the cache line was fetched by a GCS hardware prefetcher.

That is, the access hits a cache line that is in the process of being loaded into the Level 1 cache, and so does not generate a new refill, but has to wait for the previous refill to complete, and the [L1GCS_CACHE_REFILL_HWPRF](#) event was generated when the cache line was fetched into the cache.

L1GCS_TLB, Level 1 GCS TLB access

The counter counts each GCS data read operation or GCS data write operation that causes a TLB access to at least a Level 1 TLB.

Each access to a TLB entry is counted including multiple accesses caused by single instructions such as [GCSPUSHX](#) or [GCSPOPX](#).

The counter does not count the access if the access is due to a TLB maintenance instruction.

If the TLB is shared and the Effective value of [PMEVTYPER<n>_EL0.MT](#) for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of [PMEVTYPER<n>_EL0.MT](#) for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of [PMEVTYPER<n>_EL0.MT](#).

L1GCS_TLB_HWPRF, Level 1 GCS demand TLB access, GCS hardware prefetch

The counter counts each access counted by [L1GCS_TLB](#) that is due to a GCS hardware prefetch.

If the TLB is shared and the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of `PMEVTYPER<n>_EL0.MT`.

L1GCS_TLB_RW, Level 1 GCS demand TLB access

The counter counts each access counted by [L1GCS_TLB](#) that is due to a demand Memory-read operation or demand Memory-write operation.

If the TLB is shared and the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of `PMEVTYPER<n>_EL0.MT`.

L1I_CACHE_HIT, Level 1 instruction cache hit

The counter counts each access counted by [L1I_CACHE](#) that hits in the Level 1 instruction or unified cache.

L1I_CACHE_HIT_PRFM, Level 1 instruction cache software prefetch hit

The counter counts each software prefetch counted by [L1I_CACHE_PRFM](#) that hits in the Level 1 instruction or unified cache.

L1I_CACHE_HIT_RD, Level 1 instruction cache demand fetch hit

The counter counts each demand fetch counted by [L1I_CACHE_RD](#) that hits in the Level 1 instruction or unified cache.

L1I_CACHE_HIT_RD_FHWPRF, Level 1 instruction cache demand fetch first hit, fetched by hardware prefetcher

The counter counts each demand fetch first hit counted by [L1I_CACHE_HIT_RD_FPRF](#) where the cache line was fetched by a hardware prefetcher.

That is, the [L1I_CACHE_REFILL_HWPRF](#) event was generated when the cache line was fetched into the cache.

Only the first hit by a demand access is counted. After this event is generated for a cache line, the event is not generated again for the same cache line while it remains in the cache.

L1I_CACHE_HIT_RD_FPRF, Level 1 instruction cache demand fetch first hit, fetched by prefetch

The counter counts each demand fetch first hit counted by [L1I_CACHE_HIT_RD](#) where the cache line was fetched in response to a prefetch instruction or by a hardware prefetcher.

That is, the [L1I_CACHE_REFILL_PRF](#) event was generated when the cache line was fetched into the cache.

Only the first hit by a demand access is counted. After this event is generated for a cache line, the event is not generated again for the same cache line while it remains in the cache.

L1I_CACHE_HIT_RD_FPRFM, Level 1 instruction cache demand fetch first hit, fetched by software prefetch

The counter counts each demand fetch first hit counted by [L1I_CACHE_HIT_RD_FPRF](#) where the cache line was fetched in response to a prefetch instruction.

That is, the [L1I_CACHE_REFILL_PRFM](#) event was generated when the cache line was fetched into the cache.

Only the first hit by a demand access is counted. After this event is generated for a cache line, the event is not generated again for the same cache line while it remains in the cache.

L1I_CACHE_HIT_RETIRED, Instruction architecturally executed, hit in Level 1 instruction cache

The counter counts each [instruction architecturally executed](#) counted by [INST_RETIRED](#) that hit in Level 1 instruction or unified cache when fetched.

L1I_CACHE_HWPRF, Level 1 instruction cache hardware prefetch

The counter counts each access counted by [L1I_CACHE_PRF](#) that is due to a hardware prefetch.

The hardware prefetch is generated by a hardware prefetcher at the Level 1 instruction or unified cache.

The PE might prefetch instructions as part of instruction pipelining, and might do so for [speculatively executed](#) instruction paths. PE instruction prefetching is not counted as hardware prefetching. Unlike PE instruction prefetching, a hardware prefetch only allocates instructions into the cache.

L1I_CACHE_LMISS, Level 1 instruction cache long-latency miss

If the [L1I_CACHE_RD](#) event is implemented, the counter counts each access to the Level 1 instruction or unified cache counted by [L1I_CACHE_RD](#) that incurs additional latency because it returns instructions from outside of the Level 1 instruction or unified cache of this PE.

If the [L1I_CACHE_RD](#) event is not implemented, the counter counts each access to the Level 1 instruction or unified cache counted by [L1I_CACHE](#) that incurs additional latency because it returns instructions from outside of the Level 1 instruction or unified cache of this PE.

The event indicates to software that the access missed in the Level 1 instruction or unified cache and might have a significant performance impact due to the additional latency compared to the latency of an access that hits in the Level 1 instruction or unified cache.

The counter does not count:

- Accesses where the additional latency is unlikely to be significantly performance-impacting. For example, if the access hits in another cache in the same local cluster, and the additional latency is small when compared to a miss in all Level 1 caches that the access looks up in and results in instructions being returned from a Level 2 cache or elsewhere beyond the Level 1 instruction or unified cache.
- A miss that does not cause a new cache refill but is satisfied from a previous miss.

An implementation is not required to measure the latency, nor to track the access to determine whether the additional latency caused a performance impact. An implementation can extend the definition of this event with additional scenarios where an access might have a significant performance impact due to additional latency for the access.

It is IMPLEMENTATION DEFINED whether accesses that result from cache maintenance operations are counted.

If the cache is shared and the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the cache is shared by PEs other than the PEs in the multithreaded processor and the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of `PMEVTYPER<n>_EL0.MT`.

`PMCEID0_EL0[38]` reads as 1 if this event is implemented and 0 otherwise.

L1I_CACHE_MISS_RETIRED, Instruction architecturally executed, miss in Level 1 instruction cache

The counter counts each [instruction architecturally executed](#) counted by [INST_RETIRED](#) that missed in Level 1 instruction or unified cache when fetched.

L1I_CACHE_PRF, Level 1 instruction cache, prefetch hit

The counter counts each access counted by [L1I_CACHE](#) that is due to a prefetch instruction, or hardware prefetch.

L1I_CACHE_PRFM, Level 1 instruction cache software prefetch

The counter counts each access counted by [L1I_CACHE_PRF](#) that is due to a prefetch instruction.

Arm recommends that this event is implemented if event [L1I_CACHE_RD](#) is implemented.

L1I_CACHE_RD, Level 1 instruction cache demand fetch

The counter counts each access counted by [L1I_CACHE](#) that is due to a demand [Instruction memory access](#).

This includes instruction prefetches made by the PE for [speculatively executed](#) instructions.

Arm recommends that this event is implemented if any of the following are true:

- Event [L1I_CACHE_PRFM](#) is implemented.
- Event [L1I_CACHE_HWPRF](#) is implemented.

L1I_CACHE_REFILL_HWPRF, Level 1 instruction cache refill, hardware prefetch

The counter counts each hardware prefetch counted by [L1I_CACHE_HWPRF](#) that causes a refill of the Level 1 instruction or unified cache from outside of the Level 1 instruction or unified cache.

L1I_CACHE_REFILL_PERCYC, Level 1 instruction or unified cache refills in progress

The counter increments by the number of Level 1 instruction or unified cache refills counted by [L1I_CACHE_REFILL](#) in progress on each [Processor cycle](#).

The ratio $\text{L1I_CACHE_REFILL_PERCYC} \div \text{L1I_CACHE_REFILL}$ is the mean duration of Level 1 instruction or unified cache refills in [Processor cycles](#).

L1I_CACHE_REFILL_PRF, Level 1 instruction cache refill, prefetch hit

The counter counts each access counted by [L1I_CACHE_PRF](#) that causes a refill of the Level 1 instruction or unified cache from outside of the Level 1 instruction or unified cache.

L1I_CACHE_REFILL_PRFM, Level 1 instruction cache refill, software prefetch

The counter counts each access counted by [L1I_CACHE_PRFM](#) that causes a refill of the Level 1 instruction or unified cache from outside of the Level 1 instruction or unified cache.

L1I_LFB_HIT_RD, Level 1 instruction cache demand fetch line-fill buffer hit

The counter counts each demand access counted by [L1I_CACHE_HIT_RD](#) that hits a recently fetched line in the Level 1 instruction or unified cache.

That is, the access hits a cache line that is in the process of being loaded into the Level 1 instruction or unified cache, and so does not generate a new refill, but has to wait for the previous refill to complete.

L1I_LFB_HIT_RD_FHWPFRF, Level 1 instruction cache demand fetch line-fill buffer first hit, recently fetched by hardware prefetcher

The counter counts each demand fetch line-fill buffer first hit counted by [L1I_LFB_HIT_RD_FPRF](#) where the cache line was fetched by a hardware prefetcher.

That is, the fetch hits a cache line that is in the process of being loaded into the Level 1 instruction or unified cache, and so does not generate a new refill, but has to wait for the previous refill to complete, and the [L1I_CACHE_REFILL_HWPFRF](#) event was generated when the cache line was fetched into the cache.

Only the first hit by a demand access is counted. After this event is generated for a cache line, the event is not generated again for the same cache line while it remains in the cache.

L1I_LFB_HIT_RD_FPRF, Level 1 instruction cache demand fetch line-fill buffer first hit, recently fetched by prefetch

The counter counts each demand fetch line-fill buffer first hit counted by [L1I_LFB_HIT_RD](#) where the cache line was fetched in response to a prefetch instruction or by a hardware prefetcher.

That is, the fetch hits a cache line that is in the process of being loaded into the Level 1 instruction or unified cache, and so does not generate a new refill, but has to wait for the previous refill to complete, and the [L1I_CACHE_REFILL_PRF](#) event was generated when the cache line was fetched into the cache.

Only the first hit by a demand access is counted. After this event is generated for a cache line, the event is not generated again for the same cache line while it remains in the cache.

L1I_LFB_HIT_RD_FPRFM, Level 1 instruction cache demand fetch line-fill buffer first hit, recently fetched by software prefetch

The counter counts each demand fetch line-fill buffer first hit counted by [L1I_LFB_HIT_RD_FPRF](#) where the cache line was fetched in response to a prefetch instruction.

That is, the fetch hits a cache line that is in the process of being loaded into the Level 1 instruction or unified cache, and so does not generate a new refill, but has to wait for the previous refill to complete, and the [L1I_CACHE_REFILL_PRFM](#) event was generated when the cache line was fetched into the cache.

Only the first hit by a demand access is counted. After this event is generated for a cache line, the event is not generated again for the same cache line while it remains in the cache.

L1I_LFB_HIT_RETIRED, Instruction architecturally executed, line-fill buffer hit in Level 1 instruction cache

The counter counts each [instruction architecturally executed](#) counted by [L1I_CACHE_HIT_RETIRED](#) that hit a recently fetched line in Level 1 instruction or unified cache when fetched.

L1I_TLB_HWPFRF, Level 1 instruction TLB access, hardware prefetch

The counter counts each access counted by [L1I_TLB_PRF](#) that is due to a hardware prefetch.

If the TLB is shared and the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of `PMEVTYPER<n>_EL0.MT`.

L1I_TLB_PRF, Level 1 instruction TLB access, prefetch

The counter counts each access counted by [L1I_TLB](#) that is due to a prefetch instruction or hardware prefetch.

If the TLB is shared and the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other

cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of `PMEVTYPER<n>_EL0.MT`.

L1I_TLB_PRFM, Level 1 instruction TLB access, software prefetch

The counter counts each access counted by `L1I_TLB_PRF` that is due to a prefetch instruction.

If the TLB is shared and the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of `PMEVTYPER<n>_EL0.MT`.

Arm recommends that this event is implemented if event `L1I_TLB_RD` is implemented.

L1I_TLB_RD, Level 1 instruction TLB access, demand access

The counter counts each access counted by `L1I_TLB` that is due to a demand [Instruction memory access](#).

If the TLB is shared and the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of `PMEVTYPER<n>_EL0.MT`.

Arm recommends that this event is implemented if event `L1I_TLB_PRFM` is implemented.

L2D_CACHE_HIT, Level 2 data cache hit

The counter counts each access counted by `L2D_CACHE` that hits in the Level 2 data or unified cache.

L2D_CACHE_HITM_LDST_RETIRED, Load or store instruction architecturally executed, hit modified data in Level 2 data cache

The counter counts each [architecturally executed](#) Memory-reading instruction or [Memory-writing instruction](#) counted by `L2D_CACHE_HIT_LDST_RETIRED` that hit modified data in Level 2 data or unified cache.

L2D_CACHE_HITM_LD_RETIRED, Load instruction architecturally executed, hit modified data in Level 2 data cache

The counter counts each [architecturally executed](#) instruction counted by `L2D_CACHE_HITM_LDST_RETIRED` that is a Memory-reading instruction.

L2D_CACHE_HITM_RD, Level 2 data cache demand access hit modified, read

The counter counts each cache access counted by `L2D_CACHE_HIT_RD` that accesses a previously modified cache location.

L2D_CACHE_HITM_RW, Level 2 data cache demand access hit modified

The counter counts each cache access counted by `L2D_CACHE_HIT_RW` that accesses a previously modified cache location.

L2D_CACHE_HITM_ST_RETIRED, Store instruction architecturally executed, hit modified data in Level 2 data cache

The counter counts each [architecturally executed](#) instruction counted by `L2D_CACHE_HITM_LDST_RETIRED` that is a [Memory-writing instruction](#).

L2D_CACHE_HITM_WR, Level 2 data cache demand access hit modified, write

The counter counts each cache access counted by [L2D_CACHE_HIT_WR](#) that accesses a previously modified cache location.

L2D_CACHE_HIT_LDST_RETIRED, Load or store instruction architecturally executed, hit in Level 2 data cache

The counter counts each [architecturally executed](#) Memory-reading instruction or [Memory-writing instruction](#) counted by [LDST_ANY_RETIRED](#) that hit in Level 2 data or unified cache.

L2D_CACHE_HIT_LD_RETIRED, Load instruction architecturally executed, hit in Level 2 data cache

The counter counts each [architecturally executed](#) instruction counted by [L2D_CACHE_HIT_LDST_RETIRED](#) that is a Memory-reading instruction.

L2D_CACHE_HIT_PRFM, Level 2 data cache software prefetch hit

The counter counts each software prefetch counted by [L2D_CACHE_PRFM](#) that hits in the Level 2 data or unified cache.

L2D_CACHE_HIT_RD, Level 2 data cache demand access hit, read

The counter counts each demand read counted by [L2D_CACHE_RD](#) that hits in the Level 2 data or unified cache.

L2D_CACHE_HIT_RD_FHWPRF, Level 2 data cache demand access first hit, read, fetched by hardware prefetcher

The counter counts each first hit counted by [L2D_CACHE_HIT_RW_FHWPRF](#) that is due to a demand ‘Memory-read operation’.

L2D_CACHE_HIT_RD_FPRF, Level 2 data cache demand access first hit, read, fetched by prefetch

The counter counts each first hit counted by [L2D_CACHE_HIT_RW_FPRF](#) that is due to a demand ‘Memory-read operation’.

L2D_CACHE_HIT_RD_FPRFM, Level 2 data cache demand access first hit, read, fetched by software prefetch

The counter counts each first hit counted by [L2D_CACHE_HIT_RW_FPRFM](#) that is due to a demand ‘Memory-read operation’.

L2D_CACHE_HIT_RW, Level 2 data cache demand access hit

The counter counts each demand access counted by [L2D_CACHE_RW](#) that hits in the Level 2 data or unified cache.

L2D_CACHE_HIT_RW_FHWPRF, Level 2 data cache demand access first hit, fetched by hardware prefetcher

The counter counts each demand access first hit counted by [L2D_CACHE_HIT_RW_FPRF](#) where the cache line was fetched by a hardware prefetcher.

That is, the [L2D_CACHE_REFILL_HWPRF](#) event was generated when the cache line was fetched into the cache.

Only the first hit by a demand access is counted. After this event is generated for a cache line, the event is not generated again for the same cache line while it remains in the cache.

L2D_CACHE_HIT_RW_FPRF, Level 2 data cache demand access first hit, fetched by prefetch

The counter counts each demand access first hit counted by [L2D_CACHE_HIT_RW](#) where the cache line was fetched in response to a prefetch instruction or by a hardware prefetcher.

That is, the [L2D_CACHE_REFILL_PRF](#) event was generated when the cache line was fetched into the cache.

Only the first hit by a demand access is counted. After this event is generated for a cache line, the event is not generated again for the same cache line while it remains in the cache.

L2D_CACHE_HIT_RW_FPRFM, Level 2 data cache demand access first hit, fetched by software prefetch

The counter counts each demand access first hit counted by [L2D_CACHE_HIT_RW_FPRF](#) where the cache line was fetched in response to a prefetch instruction.

That is, the [L2D_CACHE_REFILL_PRFM](#) event was generated when the cache line was fetched into the cache.

Only the first hit by a demand access is counted. After this event is generated for a cache line, the event is not generated again for the same cache line while it remains in the cache.

L2D_CACHE_HIT_ST_RETIRED, Store instruction architecturally executed, hit in Level 2 data cache

The counter counts each [architecturally executed](#) instruction counted by [L2D_CACHE_HIT_LDST_RETIRED](#) that is a [Memory-writing instruction](#).

L2D_CACHE_HIT_WR, Level 2 data cache demand access hit, write

The counter counts each demand write counted by [L2D_CACHE_WR](#) that hits in the Level 2 data or unified cache.

L2D_CACHE_HIT_WR_FHWPRF, Level 2 data cache demand access first hit, write, fetched by hardware prefetcher

The counter counts each first hit counted by [L2D_CACHE_HIT_RW_FHWPRF](#) that is due to a demand [Memory-write operation](#).

L2D_CACHE_HIT_WR_FPRF, Level 2 data cache demand access first hit, write, fetched by prefetch

The counter counts each first hit counted by [L2D_CACHE_HIT_RW_FPRF](#) that is due to a demand [Memory-write operation](#).

L2D_CACHE_HIT_WR_FPRFM, Level 2 data cache demand access first hit, write, fetched by software prefetch

The counter counts each first hit counted by [L2D_CACHE_HIT_RW_FPRFM](#) that is due to a demand [Memory-write operation](#).

L2D_CACHE_HWPRF, Level 2 data cache hardware prefetch

The counter counts each access counted by [L2D_CACHE_PRF](#) that is due to a hardware prefetch.

The hardware prefetch is generated by a hardware prefetcher at the Level 2 data or unified cache.

L2D_CACHE_LMISS_RD, Level 2 data cache long-latency read miss

The counter counts each ‘Memory-read operation’ to the Level 2 data or unified cache counted by [L2D_CACHE_RD](#) that incurs additional latency because it returns data from outside of the Level 1 and Level 2 data or unified caches of this PE.

The event indicates to software that the access missed in the Level 2 data or unified cache and might have a significant performance impact due to the additional latency compared to the latency of an access that hits in the Level 2 data or unified cache.

The counter does not count:

- Accesses where the additional latency is unlikely to be significantly performance-impacting. For example, if the access hits in another cache in the same local cluster, and the additional latency is small when compared to a miss in all Level 2 caches that the access looks up in and results in an access being made to a Level 3 cache or elsewhere beyond the Level 2 data or unified cache. This might be counted as a Level 1 cache miss.
- A miss that does not cause a new cache refill but is satisfied from a previous miss.

An implementation is not required to measure the latency, nor to track the access to determine whether the additional latency caused a performance impact. An implementation can extend the definition of this event with additional scenarios where an access might have a significant performance impact due to additional latency for the access.

It is IMPLEMENTATION DEFINED whether accesses that result from cache maintenance operations are counted.

If the cache is shared and the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the cache is shared by PEs other than the PEs in the multithreaded processor and the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of `PMEVTYPER<n>_EL0.MT`.

`PMCEID0_EL0[41]` reads as 1 if this event is implemented and 0 otherwise.

L2D_CACHE_MISS, Level 2 data cache demand access miss

The counter counts each demand access counted by [L2D_CACHE_RW](#) that misses in the Level 1 and Level 2 data or unified caches, causing an access to outside of the Level 1 and Level 2 caches of this PE.

L2D_CACHE_MISS_LDST_RETIRED, Load or store instruction architecturally executed, miss in Level 2 data cache

The counter counts each [architecturally executed](#) Memory-reading instruction or [Memory-writing instruction](#) counted by [LDST_ANY_RETIRED](#) that missed in Level 2 data or unified cache.

L2D_CACHE_MISS_LD_RETIRED, Load instruction architecturally executed, miss in Level 2 data cache

The counter counts each [architecturally executed](#) instruction counted by [L2D_CACHE_MISS_LDST_RETIRED](#) that is a Memory-reading instruction.

L2D_CACHE_MISS_ST_RETIRED, Store instruction architecturally executed, miss in Level 2 data cache

The counter counts each [architecturally executed](#) instruction counted by [L2D_CACHE_MISS_LDST_RETIRED](#) that is a [Memory-writing instruction](#).

L2D_CACHE_PRF, Level 2 data cache, prefetch hit

The counter counts each access counted by [L2D_CACHE](#) that is due to a prefetch instruction, or hardware prefetch.

This includes accesses to the Level 2 data or unified cache due to a refill of another cache caused by a prefetch instruction, or hardware prefetch.

L2D_CACHE_PRFM, Level 2 data cache software prefetch

The counter counts each access counted by [L2D_CACHE_PRF](#) that is due to a prefetch instruction.

This includes accesses to the Level 2 data or unified cache due to a refill of another cache caused by a prefetch instruction.

Arm recommends that this event is implemented if event [L2D_CACHE_RW](#) is implemented.

L2D_CACHE_REFILL_HWPRF, Level 2 data cache refill, hardware prefetch

The counter counts each hardware prefetch counted by [L2D_CACHE_HWPRF](#) that causes a refill of the Level 2 data or unified cache, or any Level 1 data, instruction, or unified cache of this PE, from outside of those caches.

L2D_CACHE_REFILL_PERCYC, Level 2 data or unified cache refills in progress

The counter increments by the number of Level 2 data or unified cache refills counted by [L2D_CACHE_REFILL](#) in progress on each [Processor cycle](#).

The ratio $\text{L2D_CACHE_REFILL_PERCYC} \div \text{L2D_CACHE_REFILL}$ is the mean duration of Level 2 data or unified cache refills in [Processor cycles](#).

L2D_CACHE_REFILL_PRF, Level 2 data cache refill, prefetch hit

The counter counts each access counted by [L2D_CACHE_PRF](#) that causes a refill of the Level 2 data or unified cache, or any Level 1 data, instruction, or unified cache of this PE, from outside of those caches.

L2D_CACHE_REFILL_PRFM, Level 2 data cache refill, software prefetch

The counter counts each access counted by [L2D_CACHE_PRFM](#) that causes a refill of the Level 2 data or unified cache, or any Level 1 data, instruction, or unified cache of this PE, from outside of those caches.

L2D_CACHE_RW, Level 2 data cache demand access

The counter counts each access counted by [L2D_CACHE](#) that is due to a demand ‘Memory-read operation’ or demand [Memory-write operation](#).

This includes:

- Accesses made by [speculatively executed](#) instructions.
- Accesses to the Level 2 data or unified cache due to a refill of another cache caused by a demand ‘Memory-read operation’ or demand [Memory-write operation](#).

Arm recommends that this event is implemented if any of the following are true:

- Event [L2D_CACHE_PRFM](#) is implemented.
- Event [L2D_CACHE_HWPFR](#) is implemented.

L2D_LFB_HIT_LDST_RETIRED, Load or store instruction architecturally executed, line-fill buffer hit in Level 2 data cache

The counter counts each [architecturally executed](#) Memory-reading instruction or [Memory-writing instruction](#) counted by [L2D_CACHE_HIT_LDST_RETIRED](#) that hit a recently fetched line in Level 2 data or unified cache.

L2D_LFB_HIT_LD_RETIRED, Load instruction architecturally executed, line-fill buffer hit in Level 2 data cache

The counter counts each [architecturally executed](#) instruction counted by [L2D_LFB_HIT_LDST_RETIRED](#) that is a Memory-reading instruction.

L2D_LFB_HIT_RD, Level 2 data cache demand access line-fill buffer hit, read

The counter counts each demand access counted by [L2D_CACHE_HIT_RD](#) that hits a recently fetched line in the Level 2 data or unified cache.

That is, the access hits a cache line that is in the process of being loaded into the Level 2 data or unified cache, and so does not generate a new refill, but has to wait for the previous refill to complete.

L2D_LFB_HIT_RD_FHWPFR, Level 2 data cache demand access line-fill buffer first hit, read, recently fetched by hardware prefetcher

The counter counts each line-fill buffer first hit counted by [L2D_LFB_HIT_RW_FHWPFR](#) that is due to a demand ‘Memory-read operation’.

L2D_LFB_HIT_RD_FPRF, Level 2 data cache demand access line-fill buffer first hit, read, recently fetched by prefetch

The counter counts each line-fill buffer first hit counted by [L2D_LFB_HIT_RW_FPRF](#) that is due to a demand ‘Memory-read operation’.

L2D_LFB_HIT_RD_FPRFM, Level 2 data cache demand access line-fill buffer first hit, read, recently fetched by software prefetch

The counter counts each line-fill buffer first hit counted by [L2D_LFB_HIT_RW_FPRFM](#) that is due to a demand ‘Memory-read operation’.

L2D_LFB_HIT_RW, Level 2 data cache demand access line-fill buffer hit

The counter counts each demand access counted by [L2D_CACHE_HIT_RW](#) that hits a recently fetched line in the Level 2 data or unified cache.

That is, the access hits a cache line that is in the process of being loaded into the Level 2 data or unified cache, and so does not generate a new refill, but has to wait for the previous refill to complete.

L2D_LFB_HIT_RW_FHWPRF, Level 2 data cache demand access line-fill buffer first hit, recently fetched by hardware prefetcher

The counter counts each demand access line-fill buffer first hit counted by [L2D_LFB_HIT_RW_FPRF](#) where the cache line was fetched by a hardware prefetcher.

That is, the access hits a cache line that is in the process of being loaded into the Level 2 data or unified cache, and so does not generate a new refill, but has to wait for the previous refill to complete, and the [L2D_CACHE_REFILL_HWPRF](#) event was generated when the cache line was fetched into the cache.

Only the first hit by a demand access is counted. After this event is generated for a cache line, the event is not generated again for the same cache line while it remains in the cache.

L2D_LFB_HIT_RW_FPRF, Level 2 data cache demand access line-fill buffer first hit, recently fetched by prefetch

The counter counts each demand access line-fill buffer first hit counted by [L2D_LFB_HIT_RW](#) where the cache line was fetched in response to a prefetch instruction or by a hardware prefetcher.

That is, the access hits a cache line that is in the process of being loaded into the Level 2 data or unified cache, and so does not generate a new refill, but has to wait for the previous refill to complete, and the [L2D_CACHE_REFILL_PRF](#) event was generated when the cache line was fetched into the cache.

Only the first hit by a demand access is counted. After this event is generated for a cache line, the event is not generated again for the same cache line while it remains in the cache.

L2D_LFB_HIT_RW_FPRFM, Level 2 data cache demand access line-fill buffer first hit, recently fetched by software prefetch

The counter counts each demand access line-fill buffer first hit counted by [L2D_LFB_HIT_RW_FPRF](#) where the cache line was fetched in response to a prefetch instruction.

That is, the access hits a cache line that is in the process of being loaded into the Level 2 data or unified cache, and so does not generate a new refill, but has to wait for the previous refill to complete, and the [L2D_CACHE_REFILL_PRFM](#) event was generated when the cache line was fetched into the cache.

Only the first hit by a demand access is counted. After this event is generated for a cache line, the event is not generated again for the same cache line while it remains in the cache.

L2D_LFB_HIT_ST_RETIRED, Store instruction architecturally executed, line-fill buffer hit in Level 2 data cache

The counter counts each [architecturally executed](#) instruction counted by [L2D_LFB_HIT_LDST_RETIRED](#) that is a [Memory-writing instruction](#).

L2D_LFB_HIT_WR, Level 2 data cache demand access line-fill buffer hit, write

The counter counts each demand access counted by [L2D_CACHE_HIT_WR](#) that hits a recently fetched line in the Level 2 data or unified cache.

That is, the access hits a cache line that is in the process of being loaded into the Level 2 data or unified cache, and so does not generate a new refill, but has to wait for the previous refill to complete.

L2D_LFB_HIT_WR_FHWPRF, Level 2 data cache demand access line-fill buffer first hit, write, recently fetched by hardware prefetcher

The counter counts each line-fill buffer first hit counted by [L2D_LFB_HIT_RW_FHWPRF](#) that is due to a demand [Memory-write operation](#).

L2D_LFB_HIT_WR_FPRF, Level 2 data cache demand access line-fill buffer first hit, write, recently fetched by prefetch

The counter counts each line-fill buffer first hit counted by [L2D_LFB_HIT_RW_FPRF](#) that is due to a demand [Memory-write operation](#).

L2D_LFB_HIT_WR_FPRFM, Level 2 data cache demand access line-fill buffer first hit, write, recently fetched by software prefetch

The counter counts each line-fill buffer first hit counted by [L2D_LFB_HIT_RW_FPRFM](#) that is due to a demand [Memory-write operation](#).

L2I_CACHE_HIT, Level 2 instruction cache hit

The counter counts each access counted by [L2I_CACHE](#) that hits in the Level 2 instruction or unified cache.

L2I_CACHE_HIT_PRFM, Level 2 instruction cache software prefetch hit

The counter counts each software prefetch counted by [L2I_CACHE_PRFM](#) that hits in the Level 2 instruction or unified cache.

L2I_CACHE_HIT_RD, Level 2 instruction cache demand fetch hit

The counter counts each demand fetch counted by [L2I_CACHE_RD](#) that hits in the Level 2 instruction or unified cache.

L2I_CACHE_HIT_RD_FHWPRF, Level 2 instruction cache demand fetch first hit, fetched by hardware prefetcher

The counter counts each demand fetch first hit counted by [L2I_CACHE_HIT_RD_FPRF](#) where the cache line was fetched by a hardware prefetcher.

That is, the [L2I_CACHE_REFILL_HWPFRF](#) event was generated when the cache line was fetched into the cache.

Only the first hit by a demand access is counted. After this event is generated for a cache line, the event is not generated again for the same cache line while it remains in the cache.

L2I_CACHE_HIT_RD_FPRF, Level 2 instruction cache demand fetch first hit, fetched by prefetch

The counter counts each demand fetch first hit counted by [L2I_CACHE_HIT_RD](#) where the cache line was fetched in response to a prefetch instruction or by a hardware prefetcher.

That is, the [L2I_CACHE_REFILL_PRF](#) event was generated when the cache line was fetched into the cache.

Only the first hit by a demand access is counted. After this event is generated for a cache line, the event is not generated again for the same cache line while it remains in the cache.

L2I_CACHE_HIT_RD_FPRFM, Level 2 instruction cache demand fetch first hit, fetched by software prefetch

The counter counts each demand fetch first hit counted by [L2I_CACHE_HIT_RD_FPRF](#) where the cache line was fetched in response to a prefetch instruction.

That is, the [L2I_CACHE_REFILL_PRFM](#) event was generated when the cache line was fetched into the cache.

Only the first hit by a demand access is counted. After this event is generated for a cache line, the event is not generated again for the same cache line while it remains in the cache.

L2I_CACHE_HIT_RETIRED, Instruction architecturally executed, hit in Level 2 instruction cache

The counter counts each [instruction architecturally executed](#) counted by [INST_RETIRED](#) that hit in Level 2 instruction or unified cache when fetched.

L2I_CACHE_HWPRF, Level 2 instruction cache hardware prefetch

The counter counts each access counted by [L2I_CACHE_PRF](#) that is due to a hardware prefetch.

The hardware prefetch is generated by a hardware prefetcher at the Level 2 instruction or unified cache.

L2I_CACHE_LMISS, Level 2 instruction cache long-latency miss

If the [L2I_CACHE_RD](#) event is implemented, the counter counts each access to the Level 2 instruction or unified cache counted by [L2I_CACHE_RD](#) that incurs additional latency because it returns instructions from outside of the Level 1 and Level 2 instruction or unified caches of this PE.

If the [L2I_CACHE_RD](#) event is not implemented, the counter counts each access to the Level 2 instruction or unified cache counted by [L2I_CACHE](#) that incurs additional latency because it returns instructions from outside of the Level 1 and Level 2 instruction or unified caches of this PE.

The event indicates to software that the access missed in the Level 2 instruction or unified cache and might have a significant performance impact due to the additional latency compared to the latency of an access that hits in the Level 2 instruction or unified cache.

The counter does not count:

- Accesses where the additional latency is unlikely to be significantly performance-impacting. For example, if the access hits in another cache in the same local cluster, and the additional latency is small when compared to a miss in all Level 2 caches that the access looks up in and results in instructions being returned from a Level 3 cache or elsewhere beyond the Level 2 instruction or unified cache. This might be counted as a Level 1 cache miss.
- A miss that does not cause a new cache refill but is satisfied from a previous miss.

An implementation is not required to measure the latency, nor to track the access to determine whether the additional latency caused a performance impact. An implementation can extend the definition of this event with additional scenarios where an access might have a significant performance impact due to additional latency for the access.

It is IMPLEMENTATION DEFINED whether accesses that result from cache maintenance operations are counted.

If the cache is shared and the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the cache is shared by PEs other than the PEs in the multithreaded processor and the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of `PMEVTYPER<n>_EL0.MT`.

`PMCEID0_EL0[42]` reads as 1 if this event is implemented and 0 otherwise.

L2I_CACHE_MISS_RETIRED, Instruction architecturally executed, miss in Level 2 instruction cache

The counter counts each [instruction architecturally executed](#) counted by [INST_RETIRED](#) that missed in Level 2 instruction or unified cache when fetched.

L2I_CACHE_PRF, Level 2 instruction cache, prefetch hit

The counter counts each access counted by [L2I_CACHE](#) that is due to a prefetch instruction, or hardware prefetch.

This includes accesses to the Level 2 instruction or unified cache due to a refill of another cache caused by a prefetch instruction, or hardware prefetch.

L2I_CACHE_PRFM, Level 2 instruction cache software prefetch

The counter counts each access counted by [L2I_CACHE_PRF](#) that is due to a prefetch instruction.

This includes accesses to the Level 2 instruction or unified cache due to a refill of another cache caused by a prefetch instruction.

Arm recommends that this event is implemented if event [L2I_CACHE_RD](#) is implemented.

L2I_CACHE_RD, Level 2 instruction cache demand fetch

The counter counts each access counted by [L2I_CACHE](#) that is due to a demand [Instruction memory access](#).

This includes:

- Instruction prefetches made by the PE for [speculatively executed](#) instructions.
- Accesses to the Level 2 instruction or unified cache due to a refill of another cache caused by a demand [Instruction memory access](#).

Arm recommends that this event is implemented if any of the following are true:

- Event [L2I_CACHE_PRFM](#) is implemented.
- Event [L2I_CACHE_HWPRF](#) is implemented.

L2I_CACHE_REFILL_HWPRF, Level 2 instruction cache refill, hardware prefetch

The counter counts each hardware prefetch counted by [L2I_CACHE_HWPRF](#) that causes a refill of the Level 2 instruction or unified cache, or any Level 1 data, instruction, or unified cache of this PE, from outside of those caches.

L2I_CACHE_REFILL_PERCYC, Level 2 instruction or unified cache refills in progress

The counter increments by the number of Level 2 instruction or unified cache refills counted by [L2I_CACHE_REFILL](#) in progress on each [Processor cycle](#).

The ratio $\text{L2I_CACHE_REFILL_PERCYC} \div \text{L2I_CACHE_REFILL}$ is the mean duration of Level 2 instruction or unified cache refills in [Processor cycles](#).

L2I_CACHE_REFILL_PRF, Level 2 instruction cache refill, prefetch hit

The counter counts each access counted by [L2I_CACHE_PRF](#) that causes a refill of the Level 2 instruction or unified cache, or any Level 1 data, instruction, or unified cache of this PE, from outside of those caches.

L2I_CACHE_REFILL_PRFM, Level 2 instruction cache refill, software prefetch

The counter counts each access counted by [L2I_CACHE_PRFM](#) that causes a refill of the Level 2 instruction or unified cache, or any Level 1 data, instruction, or unified cache of this PE, from outside of those caches.

L2I_LFB_HIT_RD, Level 2 instruction cache demand fetch line-fill buffer hit

The counter counts each demand access counted by [L2I_CACHE_HIT_RD](#) that hits a recently fetched line in the Level 2 instruction or unified cache.

That is, the access hits a cache line that is in the process of being loaded into the Level 2 instruction or unified cache, and so does not generate a new refill, but has to wait for the previous refill to complete.

L2I_LFB_HIT_RD_FHWPRF, Level 2 instruction cache demand fetch line-fill buffer first hit, recently fetched by hardware prefetcher

The counter counts each demand fetch line-fill buffer first hit counted by [L2I_LFB_HIT_RD_FPRF](#) where the cache line was fetched by a hardware prefetcher.

That is, the fetch hits a cache line that is in the process of being loaded into the Level 2 instruction or unified cache, and so does not generate a new refill, but has to wait for the previous refill to complete, and the [L2I_CACHE_REFILL_HWPFRF](#) event was generated when the cache line was fetched into the cache.

Only the first hit by a demand access is counted. After this event is generated for a cache line, the event is not generated again for the same cache line while it remains in the cache.

L2I_LFB_HIT_RD_FPRF, Level 2 instruction cache demand fetch line-fill buffer first hit, recently fetched by prefetch

The counter counts each demand fetch line-fill buffer first hit counted by [L2I_LFB_HIT_RD](#) where the cache line was fetched in response to a prefetch instruction or by a hardware prefetcher.

That is, the fetch hits a cache line that is in the process of being loaded into the Level 2 instruction or unified cache, and so does not generate a new refill, but has to wait for the previous refill to complete, and the [L2I_CACHE_REFILL_PRFRF](#) event was generated when the cache line was fetched into the cache.

Only the first hit by a demand access is counted. After this event is generated for a cache line, the event is not generated again for the same cache line while it remains in the cache.

L2I_LFB_HIT_RD_FPRFM, Level 2 instruction cache demand fetch line-fill buffer first hit, recently fetched by software prefetch

The counter counts each demand fetch line-fill buffer first hit counted by [L2I_LFB_HIT_RD_FPRF](#) where the cache line was fetched in response to a prefetch instruction.

That is, the fetch hits a cache line that is in the process of being loaded into the Level 2 instruction or unified cache, and so does not generate a new refill, but has to wait for the previous refill to complete, and the [L2I_CACHE_REFILL_PRFRM](#) event was generated when the cache line was fetched into the cache.

Only the first hit by a demand access is counted. After this event is generated for a cache line, the event is not generated again for the same cache line while it remains in the cache.

L2I_LFB_HIT_RETIRED, Instruction architecturally executed, line-fill buffer hit in Level 2 instruction cache

The counter counts each [instruction architecturally executed](#) counted by [L2I_CACHE_HIT_RETIRED](#) that hit a recently fetched line in Level 2 instruction or unified cache when fetched.

L3D_CACHE_HIT, Level 3 data cache hit

The counter counts each access counted by [L3D_CACHE](#) that hits in the Level 3 data or unified cache.

L3D_CACHE_HITM_LDST_RETIRED, Load or store instruction architecturally executed, hit modified data in Level 3 data cache

The counter counts each [architecturally executed](#) Memory-reading instruction or [Memory-writing instruction](#) counted by [L3D_CACHE_HIT_LDST_RETIRED](#) that hit modified data in Level 3 data or unified cache.

L3D_CACHE_HITM_LD_RETIRED, Load instruction architecturally executed, hit modified data in Level 3 data cache

The counter counts each [architecturally executed](#) instruction counted by [L3D_CACHE_HITM_LDST_RETIRED](#) that is a Memory-reading instruction.

L3D_CACHE_HITM_RD, Level 3 data cache demand access hit modified, read

The counter counts each cache access counted by [L3D_CACHE_HIT_RD](#) that accesses a previously modified cache location.

L3D_CACHE_HITM_RW, Level 3 data cache demand access hit modified

The counter counts each cache access counted by [L3D_CACHE_HIT_RW](#) that accesses a previously modified cache location.

L3D_CACHE_HITM_ST_RETIRED, Store instruction architecturally executed, hit modified data in Level 3 data cache

The counter counts each [architecturally executed](#) instruction counted by [L3D_CACHE_HITM_LDST_RETIRED](#) that is a [Memory-writing instruction](#).

L3D_CACHE_HITM_WR, Level 3 data cache demand access hit modified, write

The counter counts each cache access counted by [L3D_CACHE_HIT_WR](#) that accesses a previously modified cache location.

L3D_CACHE_HIT_LDST_RETIRED, Load or store instruction architecturally executed, hit in Level 3 data cache

The counter counts each [architecturally executed](#) Memory-reading instruction or [Memory-writing instruction](#) counted by [LDST_ANY_RETIRED](#) that hit in Level 3 data or unified cache.

L3D_CACHE_HIT_LD_RETIRED, Load instruction architecturally executed, hit in Level 3 data cache

The counter counts each [architecturally executed](#) instruction counted by [L3D_CACHE_HIT_LDST_RETIRED](#) that is a Memory-reading instruction.

L3D_CACHE_HIT_PRFM, Level 3 data cache software prefetch hit

The counter counts each software prefetch counted by [L3D_CACHE_PRFM](#) that hits in the Level 3 data or unified cache.

L3D_CACHE_HIT_RD, Level 3 data cache demand access hit, read

The counter counts each demand read counted by [L3D_CACHE_RD](#) that hits in the Level 3 data or unified cache.

L3D_CACHE_HIT_RD_FHWPRF, Level 3 data cache demand access first hit, read, fetched by hardware prefetcher

The counter counts each first hit counted by [L3D_CACHE_HIT_RW_FHWPRF](#) that is due to a demand ‘Memory-read operation’.

L3D_CACHE_HIT_RD_FPRF, Level 3 data cache demand access first hit, read, fetched by prefetch

The counter counts each first hit counted by [L3D_CACHE_HIT_RW_FPRF](#) that is due to a demand ‘Memory-read operation’.

L3D_CACHE_HIT_RD_FPRFM, Level 3 data cache demand access first hit, read, fetched by software prefetch

The counter counts each first hit counted by [L3D_CACHE_HIT_RW_FPRFM](#) that is due to a demand ‘Memory-read operation’.

L3D_CACHE_HIT_RW, Level 3 data cache demand access hit

The counter counts each demand access counted by [L3D_CACHE_RW](#) that hits in the Level 3 data or unified cache.

L3D_CACHE_HIT_RW_FHWPRF, Level 3 data cache demand access first hit, fetched by hardware prefetcher

The counter counts each demand access first hit counted by [L3D_CACHE_HIT_RW_FPRF](#) where the cache line was fetched by a hardware prefetcher.

That is, the [L3D_CACHE_REFILL_HWPFRF](#) event was generated when the cache line was fetched into the cache.

Only the first hit by a demand access is counted. After this event is generated for a cache line, the event is not generated again for the same cache line while it remains in the cache.

L3D_CACHE_HIT_RW_FPRF, Level 3 data cache demand access first hit, fetched by prefetch

The counter counts each demand access first hit counted by [L3D_CACHE_HIT_RW](#) where the cache line was fetched in response to a prefetch instruction or by a hardware prefetcher.

That is, the [L3D_CACHE_REFILL_PRF](#) event was generated when the cache line was fetched into the cache.

Only the first hit by a demand access is counted. After this event is generated for a cache line, the event is not generated again for the same cache line while it remains in the cache.

L3D_CACHE_HIT_RW_FPRFM, Level 3 data cache demand access first hit, fetched by software prefetch

The counter counts each demand access first hit counted by [L3D_CACHE_HIT_RW_FPRF](#) where the cache line was fetched in response to a prefetch instruction.

That is, the [L3D_CACHE_REFILL_PRFM](#) event was generated when the cache line was fetched into the cache.

Only the first hit by a demand access is counted. After this event is generated for a cache line, the event is not generated again for the same cache line while it remains in the cache.

L3D_CACHE_HIT_ST_RETIRED, Store instruction architecturally executed, hit in Level 3 data cache

The counter counts each [architecturally executed](#) instruction counted by [L3D_CACHE_HIT_LDST_RETIRED](#) that is a [Memory-writing instruction](#).

L3D_CACHE_HIT_WR, Level 3 data cache demand access hit, write

The counter counts each demand write counted by [L3D_CACHE_WR](#) that hits in the Level 3 data or unified cache.

L3D_CACHE_HIT_WR_FHWPRF, Level 3 data cache demand access first hit, write, fetched by hardware prefetcher

The counter counts each first hit counted by [L3D_CACHE_HIT_RW_FHWPRF](#) that is due to a demand [Memory-write operation](#).

L3D_CACHE_HIT_WR_FPRF, Level 3 data cache demand access first hit, write, fetched by prefetch

The counter counts each first hit counted by [L3D_CACHE_HIT_RW_FPRF](#) that is due to a demand [Memory-write operation](#).

L3D_CACHE_HIT_WR_FPRFM, Level 3 data cache demand access first hit, write, fetched by software prefetch

The counter counts each first hit counted by [L3D_CACHE_HIT_RW_FPRFM](#) that is due to a demand [Memory-write operation](#).

L3D_CACHE_HWPRF, Level 3 data cache hardware prefetch

The counter counts each access counted by [L3D_CACHE_PRF](#) that is due to a hardware prefetch.

The hardware prefetch is generated by a hardware prefetcher at the Level 3 data or unified cache.

L3D_CACHE_LMISS_RD, Level 3 data cache long-latency read miss

The counter counts each ‘Memory-read operation’ to the Level 3 data or unified cache counted by [L3D_CACHE_RD](#) that incurs additional latency because it returns data from outside of the Level 1 to Level 3 data or unified caches of this PE.

The event indicates to software that the access missed in the Level 3 data or unified cache and might have a significant performance impact due to the additional latency compared to the latency of an access that hits in the Level 3 data or unified cache.

The counter does not count:

- Accesses where the additional latency is unlikely to be significantly performance-impacting. For example, if the access hits in another cache in the same local cluster, and the additional latency is small when compared to a miss in all Level 3 caches that the access looks up in and results in an access being made to a lower level cache or elsewhere beyond the Level 3 data or unified cache. This might be counted as a Level 2 cache miss.
- A miss that does not cause a new cache refill but is satisfied from a previous miss.

An implementation is not required to measure the latency, nor to track the access to determine whether the additional latency caused a performance impact. An implementation can extend the definition of this event with additional scenarios where an access might have a significant performance impact due to additional latency for the access.

It is IMPLEMENTATION DEFINED whether accesses that result from cache maintenance operations are counted.

If the cache is shared and the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the cache is shared by PEs other than the PEs in the multithreaded processor and the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of `PMEVTYPER<n>_EL0.MT`.

`PMCEID0_EL0[43]` reads as 1 if this event is implemented and 0 otherwise.

L3D_CACHE_MISS, Level 3 data cache demand access miss

The counter counts each demand access counted by [L3D_CACHE_RW](#) that misses in the Level 1 to Level 3 data or unified caches, causing an access to outside of the Level 1 to Level 3 caches of this PE.

L3D_CACHE_MISS_LDST_RETIRED, Load or store instruction architecturally executed, miss in Level 3 data cache

The counter counts each [architecturally executed](#) Memory-reading instruction or [Memory-writing instruction](#) counted by [LDST_ANY_RETIRED](#) that missed in Level 3 data or unified cache.

L3D_CACHE_MISS_LD_RETIRED, Load instruction architecturally executed, miss in Level 3 data cache

The counter counts each [architecturally executed](#) instruction counted by [L3D_CACHE_MISS_LDST_RETIRED](#) that is a Memory-reading instruction.

L3D_CACHE_MISS_ST_RETIRED, Store instruction architecturally executed, miss in Level 3 data cache

The counter counts each [architecturally executed](#) instruction counted by [L3D_CACHE_MISS_LDST_RETIRED](#) that is a [Memory-writing instruction](#).

L3D_CACHE_PRF, Level 3 data cache, prefetch hit

The counter counts each access counted by [L3D_CACHE](#) that is due to a prefetch instruction, or hardware prefetch.

This includes accesses to the Level 3 data or unified cache due to a refill of another cache caused by a prefetch instruction, or hardware prefetch.

L3D_CACHE_PRFM, Level 3 data cache software prefetch

The counter counts each access counted by [L3D_CACHE_PRF](#) that is due to a prefetch instruction.

This includes accesses to the Level 3 data or unified cache due to a refill of another cache caused by a prefetch instruction.

Arm recommends that this event is implemented if event [L3D_CACHE_RW](#) is implemented.

L3D_CACHE_REFILL_HWPRF, Level 3 data cache refill, hardware prefetch

The counter counts each hardware prefetch counted by [L3D_CACHE_HWPRF](#) that causes a refill of the Level 3 data or unified cache, or any Level 1 or Level 2 data, instruction, or unified cache of this PE, from outside of those caches.

L3D_CACHE_REFILL_PERCYC, Level 3 data or unified cache refills in progress

The counter increments by the number of Level 3 data or unified cache refills counted by [L3D_CACHE_REFILL](#) in progress on each [Processor cycle](#).

The ratio $\text{L3D_CACHE_REFILL_PERCYC} \div \text{L3D_CACHE_REFILL}$ is the mean duration of Level 3 data or unified cache refills in [Processor cycles](#).

L3D_CACHE_REFILL_PRF, Level 3 data cache refill, prefetch hit

The counter counts each access counted by [L3D_CACHE_PRF](#) that causes a refill of the Level 3 data or unified cache, or any Level 1 or Level 2 data, instruction, or unified cache of this PE, from outside of those caches.

L3D_CACHE_REFILL_PRFM, Level 3 data cache refill, software prefetch

The counter counts each access counted by [L3D_CACHE_PRFM](#) that causes a refill of the Level 3 data or unified cache, or any Level 1 or Level 2 data, instruction, or unified cache of this PE, from outside of those caches.

L3D_CACHE_RW, Level 3 data cache demand access

The counter counts each access counted by [L3D_CACHE](#) that is due to a demand ‘Memory-read operation’ or demand [Memory-write operation](#).

This includes:

- Accesses made by [speculatively executed](#) instructions.
- Accesses to the Level 3 data or unified cache due to a refill of another cache caused by a demand ‘Memory-read operation’ or demand [Memory-write operation](#).

Arm recommends that this event is implemented if any of the following are true:

- Event [L3D_CACHE_PRFM](#) is implemented.
- Event [L3D_CACHE_HWPRF](#) is implemented.

L3D_LFB_HIT_LDST_RETIRED, Load or store instruction architecturally executed, line-fill buffer hit in Level 3 data cache

The counter counts each [architecturally executed](#) Memory-reading instruction or [Memory-writing instruction](#) counted by [L3D_CACHE_HIT_LDST_RETIRED](#) that hit a recently fetched line in Level 3 data or unified cache.

L3D_LFB_HIT_LD_RETIRED, Load instruction architecturally executed, line-fill buffer hit in Level 3 data cache

The counter counts each [architecturally executed](#) instruction counted by [L3D_LFB_HIT_LDST_RETIRED](#) that is a Memory-reading instruction.

L3D_LFB_HIT_RD, Level 3 data cache demand access line-fill buffer hit, read

The counter counts each demand access counted by [L3D_CACHE_HIT_RD](#) that hits a recently fetched line in the Level 3 data or unified cache.

That is, the access hits a cache line that is in the process of being loaded into the Level 3 data or unified cache, and so does not generate a new refill, but has to wait for the previous refill to complete.

L3D_LFB_HIT_RD_FHWPRF, Level 3 data cache demand access line-fill buffer first hit, read, recently fetched by hardware prefetcher

The counter counts each line-fill buffer first hit counted by [L3D_LFB_HIT_RW_FHWPRF](#) that is due to a demand 'Memory-read operation'.

L3D_LFB_HIT_RD_FPRF, Level 3 data cache demand access line-fill buffer first hit, read, recently fetched by prefetch

The counter counts each line-fill buffer first hit counted by [L3D_LFB_HIT_RW_FPRF](#) that is due to a demand 'Memory-read operation'.

L3D_LFB_HIT_RD_FPRFM, Level 3 data cache demand access line-fill buffer first hit, read, recently fetched by software prefetch

The counter counts each line-fill buffer first hit counted by [L3D_LFB_HIT_RW_FPRFM](#) that is due to a demand 'Memory-read operation'.

L3D_LFB_HIT_RW, Level 3 data cache demand access line-fill buffer hit

The counter counts each demand access counted by [L3D_CACHE_HIT_RW](#) that hits a recently fetched line in the Level 3 data or unified cache.

That is, the access hits a cache line that is in the process of being loaded into the Level 3 data or unified cache, and so does not generate a new refill, but has to wait for the previous refill to complete.

L3D_LFB_HIT_RW_FHWPRF, Level 3 data cache demand access line-fill buffer first hit, recently fetched by hardware prefetcher

The counter counts each demand access line-fill buffer first hit counted by [L3D_LFB_HIT_RW_FPRF](#) where the cache line was fetched by a hardware prefetcher.

That is, the access hits a cache line that is in the process of being loaded into the Level 3 data or unified cache, and so does not generate a new refill, but has to wait for the previous refill to complete, and the [L3D_CACHE_REFILL_HWPFRF](#) event was generated when the cache line was fetched into the cache.

Only the first hit by a demand access is counted. After this event is generated for a cache line, the event is not generated again for the same cache line while it remains in the cache.

L3D_LFB_HIT_RW_FPRF, Level 3 data cache demand access line-fill buffer first hit, recently fetched by prefetch

The counter counts each demand access line-fill buffer first hit counted by [L3D_LFB_HIT_RW](#) where the cache line was fetched in response to a prefetch instruction or by a hardware prefetcher.

That is, the access hits a cache line that is in the process of being loaded into the Level 3 data or unified cache, and so does not generate a new refill, but has to wait for the previous refill to complete, and the [L3D_CACHE_REFILL_PRF](#) event was generated when the cache line was fetched into the cache.

Only the first hit by a demand access is counted. After this event is generated for a cache line, the event is not generated again for the same cache line while it remains in the cache.

L3D_LFB_HIT_RW_FPRFM, Level 3 data cache demand access line-fill buffer first hit, recently fetched by software prefetch

The counter counts each demand access line-fill buffer first hit counted by [L3D_LFB_HIT_RW_FPRF](#) where the cache line was fetched in response to a prefetch instruction.

That is, the access hits a cache line that is in the process of being loaded into the Level 3 data or unified cache, and so does not generate a new refill, but has to wait for the previous refill to complete, and the [L3D_CACHE_REFILL_PRFM](#) event was generated when the cache line was fetched into the cache.

Only the first hit by a demand access is counted. After this event is generated for a cache line, the event is not generated again for the same cache line while it remains in the cache.

L3D_LFB_HIT_ST_RETIRED, Store instruction architecturally executed, line-fill buffer hit in Level 3 data cache

The counter counts each [architecturally executed](#) instruction counted by [L3D_LFB_HIT_LDST_RETIRED](#) that is a [Memory-writing instruction](#).

L3D_LFB_HIT_WR, Level 3 data cache demand access line-fill buffer hit, write

The counter counts each demand access counted by [L3D_CACHE_HIT_WR](#) that hits a recently fetched line in the Level 3 data or unified cache.

That is, the access hits a cache line that is in the process of being loaded into the Level 3 data or unified cache, and so does not generate a new refill, but has to wait for the previous refill to complete.

L3D_LFB_HIT_WR_FHWPRF, Level 3 data cache demand access line-fill buffer first hit, write, recently fetched by hardware prefetcher

The counter counts each line-fill buffer first hit counted by [L3D_LFB_HIT_RW_FHWPRF](#) that is due to a demand [Memory-write operation](#).

L3D_LFB_HIT_WR_FPRF, Level 3 data cache demand access line-fill buffer first hit, write, recently fetched by prefetch

The counter counts each line-fill buffer first hit counted by [L3D_LFB_HIT_RW_FPRF](#) that is due to a demand [Memory-write operation](#).

L3D_LFB_HIT_WR_FPRFM, Level 3 data cache demand access line-fill buffer first hit, write, recently fetched by software prefetch

The counter counts each line-fill buffer first hit counted by [L3D_LFB_HIT_RW_FPRFM](#) that is due to a demand [Memory-write operation](#).

LDST_ALIGN_LAT, Access with additional latency from alignment

The counter counts each access counted by [MEM_ACCESS](#) that incurred additional latency due to the alignment of the address and size of data being accessed.

PMCEID1_EL0[32] reads as 1 if this event is implemented and 0 otherwise.

LDST_FIXED_BYTES_SPEC, Non-scalable load and store bytes speculatively executed

The counter counts each byte speculatively read or written due to any of:

- Any load, store, or atomic operation, other than loads and stores of the SVE P and Z registers.
- Any SVE non-vector load or store operation.
- An SVE load and replicate instruction, including: LD1R, LD1RB, LD1RD, LD1RH, LD1RQ, LD1RQB, LD1RQD, LD1RQH, LD1RQW, LD1RSB, LD1RSH, or LD1RSW.

For each instruction, the counter is incremented by the number of bytes transferred per register multiplied by the number of registers transferred multiplied by the number of transfers made per register. For example, the counter counts bytes as follows:

- Non-SVE load and store of a single register instructions increment the counter by $(MSIZE \div 8)$. This includes loads and stores of Sx, Dx, and Qx SIMD&FP registers.
- Non-SVE load and store of a pair of registers instructions increment the counter by $2 \times (MSIZE \div 8)$. This includes loads and stores of Sx, Dx, and Qx SIMD&FP registers.
- AArch32 load and store multiple registers instructions increment the counter by the number of registers transferred multiplied by $(MSIZE \div 8)$.
- Atomic store instructions increment the counter by $(MSIZE \div 8)$. These are instructions that atomically update a value in memory without returning a value to a register.
- Atomic load, compare and swap of a single register, and swap instructions increment the counter by $2 \times (MSIZE \div 8)$. Atomic load instructions are instructions that atomically update a value in memory, returning a value to a register.
- Compare and swap of a pair of registers increment the counter by $4 \times (MSIZE \div 8)$.
- Advanced SIMD LD1R instructions increment the counter by $(MSIZE \div 8)$.
- Advanced SIMD LD[1-4] and ST[1-4] instructions increment the counter by the number of registers transferred multiplied by the number of bytes being transferred per register.
- DC ZVA instructions increment by the counter by $2^{(DCZID_EL0.BS)}$.

LDST_FIXED_OPS_SPEC, Non-scalable load or store element operations speculatively executed

The counter counts each [speculatively executed](#) ‘Memory-read operation’ or [Memory-write operation](#) due to any of:

- Any load, store, or atomic operation, other than loads and stores of the SVE P and Z registers.
- Any SVE non-vector load or store operation.
- An SVE load and replicate instruction, including: LD1R, LD1RB, LD1RD, LD1RH, LD1RQ, LD1RQB, LD1RQD, LD1RQH, LD1RQW, LD1RSB, LD1RSH, or LD1RSW.

For each instruction, the counter is incremented by the number of operations specified by the instruction. For example, the counter counts operations as follows:

- Non-SVE load and store of a single register instructions increment the counter by 1. This includes loads and stores of Sx, Dx, and Qx SIMD&FP registers.
- Non-SVE load and store of a pair of registers instructions increment the counter by 2. This includes loads and stores of Sx, Dx, and Qx SIMD&FP registers.
- AArch32 load and store multiple registers instructions increment the counter by the number of registers transferred.
- Atomic store instructions increment the counter by 1. These are instructions that atomically update a value in memory without returning a value to a register.
- Atomic load, compare and swap of a single register, and swap instructions increment the counter by 2. Atomic load instructions are instructions that atomically update a value in memory, returning a value to a register.
- Compare and swap of a pair of registers increment the counter by 4.
- Advanced SIMD LD1R instructions increment the counter by 1.
- Advanced SIMD LD[1-4] and ST[1-4] instructions increment the counter by the number of elements transferred per vector multiplied by the number of transferred registers.
- DC ZVA and DC GZVA instructions increment by an IMPLEMENTATION DEFINED amount.

Note

When a replicating load instruction loads data of the same size as the vector length, which causes no replication to occur, the instruction is counted.

LD_ALIGN_LAT, Load with additional latency from alignment

The counter counts each ‘Memory-read operation’ counted by [LDST_ALIGN_LAT](#).

PMCEID1_EL0[33] reads as 1 if this event is implemented and 0 otherwise.

LD_FIXED_BYTES_SPEC, Non-scalable load bytes speculatively executed

The counter counts each speculatively read byte counted by [LDST_FIXED_BYTES_SPEC](#).

For each instruction, the counter is incremented by the number of bytes transferred per register multiplied by the number of registers transferred. That is, the counter is incremented by:

- Half the value that the [LDST_FIXED_BYTES_SPEC](#) event counts if the operation is a load atomic, compare and swap, or swap operation.
- The same as for [LDST_FIXED_BYTES_SPEC](#) if the operation is any other load operation.

LD_FIXED_OPS_SPEC, Non-scalable load element operations speculatively executed

The counter counts each [speculatively executed](#) ‘Memory-read operation’ counted by [LDST_FIXED_OPS_SPEC](#).

For each instruction, the counter is incremented by the number of operations specified by the instruction. That is, the counter is incremented by:

- Half the value that the [LDST_FIXED_OPS_SPEC](#) event counts if the operation is a load atomic, compare and swap, or swap operation.
- The same as for [LDST_FIXED_OPS_SPEC](#) if the operation is any other load operation.

LL_CACHE_HIT, Last level cache hit

The counter counts each access counted by [LL_CACHE](#) that hits in the Last level cache.

LL_CACHE_HITM_LDST_RETIRED, Load or store instruction architecturally executed, hit modified data in Last level cache

The counter counts each [architecturally executed](#) Memory-reading instruction or [Memory-writing instruction](#) counted by [LL_CACHE_HIT_LDST_RETIRED](#) that hit modified data in Last level cache.

LL_CACHE_HITM_LD_RETIRED, Load instruction architecturally executed, hit modified data in Last level cache

The counter counts each [architecturally executed](#) instruction counted by [LL_CACHE_HITM_LDST_RETIRED](#) that is a Memory-reading instruction.

LL_CACHE_HITM_RD, Last level cache demand access hit modified, read

The counter counts each cache access counted by [LL_CACHE_HIT_RD](#) that accesses a previously modified cache location.

LL_CACHE_HITM_RW, Last level cache demand access hit modified

The counter counts each cache access counted by [LL_CACHE_HIT_RW](#) that accesses a previously modified cache location.

LL_CACHE_HITM_ST_RETIRED, Store instruction architecturally executed, hit modified data in Last level cache

The counter counts each [architecturally executed](#) instruction counted by [LL_CACHE_HITM_LDST_RETIRED](#) that is a [Memory-writing instruction](#).

LL_CACHE_HITM_WR, Last level cache demand access hit modified, write

The counter counts each cache access counted by [LL_CACHE_HIT_WR](#) that accesses a previously modified cache location.

LL_CACHE_HIT_LDST_RETIRED, Load or store instruction architecturally executed, hit in Last level cache

The counter counts each [architecturally executed](#) Memory-reading instruction or [Memory-writing instruction](#) counted by [LDST_ANY_RETIRED](#) that hit in Last level cache.

LL_CACHE_HIT_LD_RETIRED, Load instruction architecturally executed, hit in Last level cache

The counter counts each [architecturally executed](#) instruction counted by [LL_CACHE_HIT_LDST_RETIRED](#) that is a Memory-reading instruction.

LL_CACHE_HIT_PRFM, Last level cache software prefetch hit

The counter counts each software prefetch counted by [LL_CACHE_PRFM](#) that hits in the Last level cache.

LL_CACHE_HIT_RD, Last level cache demand access hit, read

The counter counts each demand read counted by [LL_CACHE_RD](#) that hits in the Last level cache.

LL_CACHE_HIT_RD_FHWPRF, Last level cache demand access first hit, read, fetched by hardware prefetcher

The counter counts each first hit counted by [LL_CACHE_HIT_RW_FHWPRF](#) that is due to a demand ‘Memory-read operation’.

LL_CACHE_HIT_RD_FPRF, Last level cache demand access first hit, read, fetched by prefetch

The counter counts each first hit counted by [LL_CACHE_HIT_RW_FPRF](#) that is due to a demand ‘Memory-read operation’.

LL_CACHE_HIT_RD_FPRFM, Last level cache demand access first hit, read, fetched by software prefetch

The counter counts each first hit counted by [LL_CACHE_HIT_RW_FPRFM](#) that is due to a demand ‘Memory-read operation’.

LL_CACHE_HIT_RW, Last level cache demand access hit

The counter counts each demand access counted by [LL_CACHE_RW](#) that hits in the Last level cache.

LL_CACHE_HIT_RW_FHWPRF, Last level cache demand access first hit, fetched by hardware prefetcher

The counter counts each demand access first hit counted by [LL_CACHE_HIT_RW_FPRF](#) where the cache line was fetched by a hardware prefetcher.

That is, the [LL_CACHE_REFILL_HWPRF](#) event was generated when the cache line was fetched into the cache.

Only the first hit by a demand access is counted. After this event is generated for a cache line, the event is not generated again for the same cache line while it remains in the cache.

LL_CACHE_HIT_RW_FPRF, Last level cache demand access first hit, fetched by prefetch

The counter counts each demand access first hit counted by [LL_CACHE_HIT_RW](#) where the cache line was fetched in response to a prefetch instruction or by a hardware prefetcher.

That is, the [LL_CACHE_REFILL_PRF](#) event was generated when the cache line was fetched into the cache.

Only the first hit by a demand access is counted. After this event is generated for a cache line, the event is not generated again for the same cache line while it remains in the cache.

LL_CACHE_HIT_RW_FPRFM, Last level cache demand access first hit, fetched by software prefetch

The counter counts each demand access first hit counted by [LL_CACHE_HIT_RW_FPRF](#) where the cache line was fetched in response to a prefetch instruction.

That is, the [LL_CACHE_REFILL_PRFM](#) event was generated when the cache line was fetched into the cache.

Only the first hit by a demand access is counted. After this event is generated for a cache line, the event is not generated again for the same cache line while it remains in the cache.

LL_CACHE_HIT_ST_RETIRED, Store instruction architecturally executed, hit in Last level cache

The counter counts each [architecturally executed](#) instruction counted by [LL_CACHE_HIT_LDST_RETIRED](#) that is a [Memory-writing instruction](#).

LL_CACHE_HIT_WR, Last level cache demand access hit, write

The counter counts each demand write counted by [LL_CACHE_WR](#) that hits in the Last level cache.

LL_CACHE_HIT_WR_FHWPRF, Last level cache demand access first hit, write, fetched by hardware prefetcher

The counter counts each first hit counted by [LL_CACHE_HIT_RW_FHWPRF](#) that is due to a demand [Memory-write operation](#).

LL_CACHE_HIT_WR_FPRF, Last level cache demand access first hit, write, fetched by prefetch

The counter counts each first hit counted by [LL_CACHE_HIT_RW_FPRF](#) that is due to a demand [Memory-write operation](#).

LL_CACHE_HIT_WR_FPRFM, Last level cache demand access first hit, write, fetched by software prefetch

The counter counts each first hit counted by [LL_CACHE_HIT_RW_FPRFM](#) that is due to a demand [Memory-write operation](#).

LL_CACHE_HWPRF, Last level cache hardware prefetch

The counter counts each access counted by [LL_CACHE_PRF](#) that is due to a hardware prefetch.

The hardware prefetch is generated by a hardware prefetcher at the Last level cache.

LL_CACHE_MISS_LDST_RETIRED, Load or store instruction architecturally executed, miss in Last level cache

The counter counts each [architecturally executed](#) Memory-reading instruction or [Memory-writing instruction](#) counted by [LDST_ANY_RETIRED](#) that missed in Last level cache.

LL_CACHE_MISS_LD_RETIRED, Load instruction architecturally executed, miss in Last level cache

The counter counts each [architecturally executed](#) instruction counted by [LL_CACHE_MISS_LDST_RETIRED](#) that is a Memory-reading instruction.

LL_CACHE_MISS_ST_RETIRED, Store instruction architecturally executed, miss in Last level cache

The counter counts each [architecturally executed](#) instruction counted by [LL_CACHE_MISS_LDST_RETIRED](#) that is a [Memory-writing instruction](#).

LL_CACHE_PRF, Last level cache, prefetch hit

The counter counts each access counted by [LL_CACHE](#) that is due to a prefetch instruction, or hardware prefetch.

This includes accesses to the Last level cache due to a refill of another cache caused by a prefetch instruction, or hardware prefetch.

LL_CACHE_PRFM, Last level cache software prefetch

The counter counts each access counted by [LL_CACHE_PRF](#) that is due to a prefetch instruction.

This includes accesses to the Last level cache due to a refill of another cache caused by a prefetch instruction.

Arm recommends that this event is implemented if event [LL_CACHE_RW](#) is implemented.

LL_CACHE_REFILL, Last level cache refill

The counter counts each access counted by [LL_CACHE](#) that causes a refill of the Last level cache, or any other data, instruction, or unified cache of this PE, from outside of those caches.

A refill includes any access that causes data to be fetched from outside of the Level 1 to Last level caches, even if the data is ultimately not allocated into the Last level cache. For example, data might be fetched into a buffer but then discarded, rather than being allocated into a cache. These buffers are treated as part of the cache.

For example, the counter counts:

- Accesses to the Last level cache that cause a refill that is satisfied by fetching data from memory, or a Last level cache of another PE.
- Refills of and write-backs from any other data, instruction, or unified caches of this PE that cause a refill from outside of the Level 1 to Last level caches of this PE.
- Accesses to the Last level cache that cause a refill of a higher level cache of this PE from outside of the Level 1 to Last level caches of this PE, even if there is no refill of the Last level cache.

The counter does not count accesses that:

- Miss in the cache but are satisfied by the refill of a previous miss and do not cause a new refill, even if that previous refill is not complete at the time of the miss.
- Miss in the cache but do not generate a refill, such as a write through the cache.

It is IMPLEMENTATION DEFINED whether accesses that result from cache maintenance instructions are counted.

If the cache is shared and the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the cache is shared by PEs other than the PEs in the multithreaded processor and the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of `PMEVTYPER<n>_EL0.MT`.

LL_CACHE_REFILL_HWPRF, Last level cache refill, hardware prefetch

The counter counts each hardware prefetch counted by [LL_CACHE_HWPRF](#) that causes a refill of the Last level cache, or any other data, instruction, or unified cache of this PE, from outside of those caches.

LL_CACHE_REFILL_PRF, Last level cache refill, prefetch hit

The counter counts each access counted by [LL_CACHE_PRF](#) that causes a refill of the Last level cache, or any other data, instruction, or unified cache of this PE, from outside of those caches.

LL_CACHE_REFILL_PRFM, Last level cache refill, software prefetch

The counter counts each access counted by [LL_CACHE_PRFM](#) that causes a refill of the Last level cache, or any other data, instruction, or unified cache of this PE, from outside of those caches.

LL_CACHE_REFILL_WR, Last level cache refill, write

The counter counts each access counted by both [LL_CACHE_REFILL](#) and [LL_CACHE_WR](#).

That is, every refill of the Last level cache counted by [LL_CACHE_REFILL](#) that is caused by a [Memory-write operation](#).

If the cache is shared and the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the cache is shared by PEs other than the PEs in the multithreaded processor and the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of `PMEVTYPER<n>_EL0.MT`.

LL_CACHE_RW, Last level cache demand access

The counter counts each access counted by [LL_CACHE](#) that is due to a demand ‘Memory-read operation’ or demand [Memory-write operation](#).

This includes:

- Accesses made by [speculatively executed](#) instructions.
- Accesses to the Last level cache due to a refill of another cache caused by a demand ‘Memory-read operation’ or demand [Memory-write operation](#).

Arm recommends that this event is implemented if any of the following are true:

- Event [LL_CACHE_PRFM](#) is implemented.
- Event [LL_CACHE_HWPRF](#) is implemented.

LL_CACHE_WB, Last level cache write-back

The counter counts each write-back of data from the Last level cache to outside of the Level 1 to Last level caches.

For example:

- A write-back of a cache line to memory.
- A write-back of a recently fetched cache line that has not been allocated to the Last level cache.

Each write-back is counted once, even if multiple accesses are required to complete the write-back.

It is IMPLEMENTATION DEFINED whether the counter counts:

- A transfer of a dirty cache line from the Last level cache to outside of Level 1 to Last level caches made as a result of a coherency request.
- Write-backs made as a result of cache maintenance instructions.

The counter does not count:

- The invalidation of a cache line without any write-back to outside of the Level 1 to Last level caches or memory.
- Writes that write through the Last level cache to outside of the Level 1 to Last level caches.
- Transfers of data from the Last level cache to another cache to satisfy a refill of the other cache.

A write-back is attributable to one of the following, and it is IMPLEMENTATION DEFINED which:

- The PE or other agent that generated the request that caused the write-back. This might not be the same agent that caused the data to be allocated into the cache.

- If the cache is shared, the PE or other agent that caused the data to be allocated into the cache.
- If the cache is shared, the PE or other agent that last accessed the data when it was in the cache. If the data has not been accessed since being allocated, then the PE or other agent that caused the data to be allocated into the cache.

If the cache is shared, then the write-back event is counted only if it is attributable to the PE counting the event.

If the cache is not shared, then the event is counted by the PE that the cache is attached to, even if the write-back is not attributable to that PE. For example, a requestor outside of the PE made a coherency request that resulted in write-back.

It is IMPLEMENTATION DEFINED whether a write of a whole cache line that is not the result of the eviction of a line from the cache, is counted. For example, this applies when the PE determines software is streaming writes to memory and does not allocate lines to the cache, or by a DC ZVA operation.

LL_CACHE_WR, Last level cache access, write

If the [LL_CACHE_RW](#) event is implemented, the counter counts each access counted by [LL_CACHE_RW](#) that is a [Memory-write operation](#).

If the [LL_CACHE_RW](#) event is not implemented, the counter counts each access counted by [LL_CACHE](#) that is a [Memory-write operation](#).

If the cache is shared and the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the cache is shared by PEs other than the PEs in the multithreaded processor and the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of `PMEVTYPER<n>_EL0.MT`.

LL_LFB_HIT_LDST_RETIRED, Load or store instruction architecturally executed, line-fill buffer hit in Last level cache

The counter counts each [architecturally executed](#) Memory-reading instruction or [Memory-writing instruction](#) counted by [LL_CACHE_HIT_LDST_RETIRED](#) that hit a recently fetched line in Last level cache.

LL_LFB_HIT_LD_RETIRED, Load instruction architecturally executed, line-fill buffer hit in Last level cache

The counter counts each [architecturally executed](#) instruction counted by [LL_LFB_HIT_LDST_RETIRED](#) that is a Memory-reading instruction.

LL_LFB_HIT_RD, Last level cache demand access line-fill buffer hit, read

The counter counts each demand access counted by [LL_CACHE_HIT_RD](#) that hits a recently fetched line in the Last level cache.

That is, the access hits a cache line that is in the process of being loaded into the Last level cache, and so does not generate a new refill, but has to wait for the previous refill to complete.

LL_LFB_HIT_RD_FHWPRF, Last level cache demand access line-fill buffer first hit, read, recently fetched by hardware prefetcher

The counter counts each line-fill buffer first hit counted by [LL_LFB_HIT_RW_FHWPRF](#) that is due to a demand 'Memory-read operation'.

LL_LFB_HIT_RD_FPRF, Last level cache demand access line-fill buffer first hit, read, recently fetched by prefetch

The counter counts each line-fill buffer first hit counted by [LL_LFB_HIT_RW_FPRF](#) that is due to a demand 'Memory-read operation'.

LL_LFB_HIT_RD_FPRFM, Last level cache demand access line-fill buffer first hit, read, recently fetched by software prefetch

The counter counts each line-fill buffer first hit counted by [LL_LFB_HIT_RW_FPRFM](#) that is due to a demand ‘Memory-read operation’.

LL_LFB_HIT_RW, Last level cache demand access line-fill buffer hit

The counter counts each demand access counted by [LL_CACHE_HIT_RW](#) that hits a recently fetched line in the Last level cache.

That is, the access hits a cache line that is in the process of being loaded into the Last level cache, and so does not generate a new refill, but has to wait for the previous refill to complete.

LL_LFB_HIT_RW_FHWPRF, Last level cache demand access line-fill buffer first hit, recently fetched by hardware prefetcher

The counter counts each demand access line-fill buffer first hit counted by [LL_LFB_HIT_RW_FPRF](#) where the cache line was fetched by a hardware prefetcher.

That is, the access hits a cache line that is in the process of being loaded into the Last level cache, and so does not generate a new refill, but has to wait for the previous refill to complete, and the [LL_CACHE_REFILL_HWPRF](#) event was generated when the cache line was fetched into the cache.

Only the first hit by a demand access is counted. After this event is generated for a cache line, the event is not generated again for the same cache line while it remains in the cache.

LL_LFB_HIT_RW_FPRF, Last level cache demand access line-fill buffer first hit, recently fetched by prefetch

The counter counts each demand access line-fill buffer first hit counted by [LL_LFB_HIT_RW](#) where the cache line was fetched in response to a prefetch instruction or by a hardware prefetcher.

That is, the access hits a cache line that is in the process of being loaded into the Last level cache, and so does not generate a new refill, but has to wait for the previous refill to complete, and the [LL_CACHE_REFILL_PRF](#) event was generated when the cache line was fetched into the cache.

Only the first hit by a demand access is counted. After this event is generated for a cache line, the event is not generated again for the same cache line while it remains in the cache.

LL_LFB_HIT_RW_FPRFM, Last level cache demand access line-fill buffer first hit, recently fetched by software prefetch

The counter counts each demand access line-fill buffer first hit counted by [LL_LFB_HIT_RW_FPRF](#) where the cache line was fetched in response to a prefetch instruction.

That is, the access hits a cache line that is in the process of being loaded into the Last level cache, and so does not generate a new refill, but has to wait for the previous refill to complete, and the [LL_CACHE_REFILL_PRFM](#) event was generated when the cache line was fetched into the cache.

Only the first hit by a demand access is counted. After this event is generated for a cache line, the event is not generated again for the same cache line while it remains in the cache.

LL_LFB_HIT_ST_RETIRED, Store instruction architecturally executed, line-fill buffer hit in Last level cache

The counter counts each [architecturally executed](#) instruction counted by [LL_LFB_HIT_LDST_RETIRED](#) that is a [Memory-writing instruction](#).

LL_LFB_HIT_WR, Last level cache demand access line-fill buffer hit, write

The counter counts each demand access counted by [LL_CACHE_HIT_WR](#) that hits a recently fetched line in the Last level cache.

That is, the access hits a cache line that is in the process of being loaded into the Last level cache, and so does not generate a new refill, but has to wait for the previous refill to complete.

LL_LFB_HIT_WR_FHWPRF, Last level cache demand access line-fill buffer first hit, write, recently fetched by hardware prefetcher

The counter counts each line-fill buffer first hit counted by [LL_LFB_HIT_RW_FHWPRF](#) that is due to a demand [Memory-write operation](#).

LL_LFB_HIT_WR_FPRF, Last level cache demand access line-fill buffer first hit, write, recently fetched by prefetch

The counter counts each line-fill buffer first hit counted by [LL_LFB_HIT_RW_FPRF](#) that is due to a demand [Memory-write operation](#).

LL_LFB_HIT_WR_FPRFM, Last level cache demand access line-fill buffer first hit, write, recently fetched by software prefetch

The counter counts each line-fill buffer first hit counted by [LL_LFB_HIT_RW_FPRFM](#) that is due to a demand [Memory-write operation](#).

LOCAL_MEM, Access to memory attached to this device

The counter counts each ‘Memory-read operation’ or [Memory-write operation](#) access to external memory attached to this device.

In a multi-socket system this means attached to the socket that contains the PE. For more information, see [REMOTE_ACCESS](#).

In systems where there multiple types of memory attached to this device with different performance characteristics, it is IMPLEMENTATION DEFINED whether accesses to all external memory types are counted by this event, or are classified as remote accesses and counted by [REMOTE_MEM](#).

For example, in a system with an expansion memory connected to the device that has significantly higher latency than the main system memory, accesses to the main system memory might be counted by this event and accesses to the expansion memory by [REMOTE_MEM](#).

LOCAL_MEM_LDST_RETIRED, Load or store instruction architecturally executed, access to memory attached to this device

The counter counts each Memory-reading instruction or [Memory-writing instruction architecturally executed](#) counted by [LDST_ANY_RETIRED](#) that accessed external memory attached to this device.

LOCAL_MEM_LD_RETIRED, Load instruction architecturally executed, access to memory attached to this device

The counter counts each [architecturally executed](#) instruction counted by [LOCAL_MEM_LDST_RETIRED](#) that is a Memory-reading instruction.

LOCAL_MEM_PRFM, Access to memory attached to this device, software prefetch

The counter counts each access counted by [LOCAL_MEM](#) that is due to a prefetch instruction.

It is IMPLEMENTATION DEFINED whether an access to external memory due to a prefetch to a cache is counted by [LOCAL_MEM_RW](#) or [LOCAL_MEM_PRFM](#).

LOCAL_MEM_RD, Access to memory attached to this device, demand access, read

The counter counts each access counted by [LOCAL_MEM_RW](#) that is a demand ‘Memory-read operation’.

LOCAL_MEM_RW, Access to memory attached to this device, demand access

The counter counts each access counted by [LOCAL_MEM](#) that is a demand ‘Memory-read operation’ or demand [Memory-write operation](#).

It is IMPLEMENTATION DEFINED whether an access to external memory due to a prefetch to a cache is counted by [LOCAL_MEM_RW](#) or [LOCAL_MEM_PRFM](#).

LOCAL_MEM_ST_RETIRED, Store instruction architecturally executed, access to memory attached to this device

The counter counts each [architecturally executed](#) instruction counted by [LOCAL_MEM_LDST_RETIRED](#) that is a [Memory-writing instruction](#).

LOCAL_MEM_WR, Access to memory attached to this device, demand access, write

The counter counts each access counted by [LOCAL_MEM_RW](#) that is a demand [Memory-write operation](#).

MEM_ACCESS_PRFM, Data memory access, software prefetch

The counter counts each access counted by [MEM_ACCESS](#) that is due to a prefetch instruction.

MEM_ACCESS_RD_PERCYC, Data memory reads in progress

The counter increments by the number of data memory reads counted by [MEM_ACCESS_RD](#) in progress on each [Processor cycle](#).

The ratio $\text{MEM_ACCESS_RD_PERCYC} \div \text{MEM_ACCESS_RD}$ is the mean duration of data memory reads in [Processor cycles](#).

MEM_ACCESS_RW, Data memory access, demand access

The counter counts each access counted by [MEM_ACCESS](#) that is a demand ‘Memory-read operation’ or demand [Memory-write operation](#).

This includes accesses made by speculative instructions.

N1_CACHE1_HITM_RD, Cache type 1 at distance 1 demand access hit modified, read

The counter counts each demand read counted by [N1_CACHE_HITM_RD](#) that accesses a previously modified location in a first cache type at distance 1.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

N1_CACHE1_HIT_PRFM, Cache type 1 at distance 1 software prefetch hit

The counter counts each software prefetch counted by [N1_CACHE_HIT_PRFM](#) due to a software prefetch accessing a first cache type at distance 1.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

N1_CACHE1_HIT_RD, Cache type 1 at distance 1 demand access hit, read

The counter counts each demand read counted by [N1_CACHE_HIT_RD](#) due to a demand read accessing a first cache type at distance 1.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

N1_CACHE2_HITM_RD, Cache type 2 at distance 1 demand access hit modified, read

The counter counts each demand read counted by [N1_CACHE_HITM_RD](#) that accesses a previously modified location in a second cache type at distance 1.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

N1_CACHE2_HIT_PRFM, Cache type 2 at distance 1 software prefetch hit

The counter counts each software prefetch counted by [N1_CACHE_HIT_PRFM](#) due to a software prefetch accessing a second cache type at distance 1.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

N1_CACHE2_HIT_RD, Cache type 2 at distance 1 demand access hit, read

The counter counts each demand read counted by [N1_CACHE_HIT_RD](#) due to a demand read accessing a second cache type at distance 1.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

N1_CACHE3_HITM_RD, Cache type 3 at distance 1 demand access hit modified, read

The counter counts each demand read counted by [N1_CACHE_HITM_RD](#) that accesses a previously modified location in a third cache type at distance 1.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

N1_CACHE3_HIT_PRFM, Cache type 3 at distance 1 software prefetch hit

The counter counts each software prefetch counted by [N1_CACHE_HIT_PRFM](#) due to a software prefetch accessing a third cache type at distance 1.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

N1_CACHE3_HIT_RD, Cache type 3 at distance 1 demand access hit, read

The counter counts each demand read counted by [N1_CACHE_HIT_RD](#) due to a demand read accessing a third cache type at distance 1.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

N1_CACHE_HITM_RD, Cache at distance 1, demand access hit modified, read

The counter counts each demand read counted by [N1_CACHE_HIT_RD](#) that accesses a previously modified location in a cache at distance 1.

N1_CACHE_HIT_PRFM, Cache at distance 1, software prefetch hit

The counter counts each cache hit at distance 1 due to a software prefetch.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

N1_CACHE_HIT_RD, Cache at distance 1, demand access hit, read

The counter counts each cache hit at distance 1 due to a demand read.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

N1_LFB1_HIT_RD, Cache type 1 at distance 1 demand access line-fill buffer hit, read

The counter counts each demand read counted by [N1_LFB_HIT_RD](#) that hits a recently fetched line in a first cache type at distance 1.

That is, the read hits a cache line that is in the process of being loaded into the cache at distance 1, and so does not generate a new refill, but has to wait for the previous refill to complete.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

N1_LFB2_HIT_RD, Cache type 2 at distance 1 demand access line-fill buffer hit, read

The counter counts each demand read counted by [N1_LFB_HIT_RD](#) that hits a recently fetched line in a second cache type at distance 1.

That is, the read hits a cache line that is in the process of being loaded into the cache at distance 1, and so does not generate a new refill, but has to wait for the previous refill to complete.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

N1_LFB3_HIT_RD, Cache type 3 at distance 1 demand access line-fill buffer hit, read

The counter counts each demand read counted by [N1_LFB_HIT_RD](#) that hits a recently fetched line in a third cache type at distance 1.

That is, the read hits a cache line that is in the process of being loaded into the cache at distance 1, and so does not generate a new refill, but has to wait for the previous refill to complete.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

N1_LFB_HIT_RD, Cache at distance 1 demand access line-fill buffer hit, read

The counter counts each demand read counted by [N1_CACHE_HIT_RD](#) that hits a recently fetched line in a cache at distance 1.

That is, the read hits a cache line that is in the process of being loaded into the cache at distance 1, and so does not generate a new refill, but has to wait for the previous refill to complete.

N1_MEM1_PRFM, Access to type 1 memory at distance 1, software prefetch

The counter counts each software prefetch counted by [N1_MEM_PRFM](#) to a first memory type at distance 1.

The definition of memory types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

N1_MEM1_RD, Access to type 1 memory at distance 1, demand access, read

The counter counts each demand read counted by [N1_MEM_RD](#) to a first memory type at distance 1.

The definition of memory types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system. See also [N1_MEM1_RD](#).

For example, the first memory type might be commodity DRAM connected to a device. However, this must be the same for all devices in the system, such that, for example, [N1_MEM1_RD](#) refers to commodity DRAM for a PE at distance 1

from the memory, regardless of which device the PE is located on, and [N4_MEM1_RD](#) refers to the same memory for any PE located at distance 4. This means that when a process counting the [N1_MEM1_RD](#) event migrates between PEs on different devices, its relative view of the first memory type remains unchanged, even if the distance changes.

N1_MEM2_PRFM, Access to type 2 memory at distance 1, software prefetch

The counter counts each software prefetch counted by [N1_MEM_PRFM](#) to a second memory type at distance 1.

The definition of memory types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

N1_MEM2_RD, Access to type 2 memory at distance 1, demand access, read

The counter counts each demand read counted by [N1_MEM_RD](#) to a second memory type at distance 1.

The definition of memory types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system. See also [N1_MEM2_RD](#).

For example, the second memory type might be bulk expansion memory connected to a device. However, this must be the same for all devices in the system, such that, for example, [N1_MEM2_RD](#) refers to bulk expansion memory for a PE at distance 1 from the memory, regardless of which device the PE is located on, and [N4_MEM2_RD](#) refers to the same memory for any PE located at distance 4. This means that when a process counting the [N1_MEM2_RD](#) event migrates between PEs on different devices, its relative view of the second memory type remains unchanged, even if the distance changes.

N1_MEM3_PRFM, Access to type 3 memory at distance 1, software prefetch

The counter counts each software prefetch counted by [N1_MEM_PRFM](#) to a third memory type at distance 1.

The definition of memory types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

N1_MEM3_RD, Access to type 3 memory at distance 1, demand access, read

The counter counts each demand read counted by [N1_MEM_RD](#) to a third memory type at distance 1.

The definition of memory types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system. See also [N1_MEM3_RD](#).

For example, the third memory type might be high-bandwidth memory connected to a device. However, this must be the same for all devices in the system, such that, for example, [N1_MEM3_RD](#) refers to high-bandwidth memory for a PE at distance 1 from the memory, regardless of which device the PE is located on, and [N4_MEM3_RD](#) refers to the same memory for any PE located at distance 4. This means that when a process counting the [N1_MEM3_RD](#) event migrates between PEs on different devices, its relative view of the third memory type remains unchanged, even if the distance changes.

N1_MEM_PRFM, Access to memory at distance 1, software prefetch

The counter counts each software prefetch to memory at distance 1.

The memory distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

N1_MEM_RD, Access to memory at distance 1, demand access, read

The counter counts each demand read to memory at distance 1.

The memory distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

N2_CACHE1_HITM_RD, Cache type 1 at distance 2 demand access hit modified, read

The counter counts each demand read counted by [N2_CACHE_HITM_RD](#) that accesses a previously modified location in a first cache type at distance 2.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

N2_CACHE1_HIT_PRFM, Cache type 1 at distance 2 software prefetch hit

The counter counts each software prefetch counted by [N2_CACHE_HIT_PRFM](#) due to a software prefetch accessing a first cache type at distance 2.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

N2_CACHE1_HIT_RD, Cache type 1 at distance 2 demand access hit, read

The counter counts each demand read counted by [N2_CACHE_HIT_RD](#) due to a demand read accessing a first cache type at distance 2.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

N2_CACHE2_HITM_RD, Cache type 2 at distance 2 demand access hit modified, read

The counter counts each demand read counted by [N2_CACHE_HITM_RD](#) that accesses a previously modified location in a second cache type at distance 2.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

N2_CACHE2_HIT_PRFM, Cache type 2 at distance 2 software prefetch hit

The counter counts each software prefetch counted by [N2_CACHE_HIT_PRFM](#) due to a software prefetch accessing a second cache type at distance 2.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

N2_CACHE2_HIT_RD, Cache type 2 at distance 2 demand access hit, read

The counter counts each demand read counted by [N2_CACHE_HIT_RD](#) due to a demand read accessing a second cache type at distance 2.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

N2_CACHE3_HITM_RD, Cache type 3 at distance 2 demand access hit modified, read

The counter counts each demand read counted by [N2_CACHE_HITM_RD](#) that accesses a previously modified location in a third cache type at distance 2.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

N2_CACHE3_HIT_PRFM, Cache type 3 at distance 2 software prefetch hit

The counter counts each software prefetch counted by [N2_CACHE_HIT_PRFM](#) due to a software prefetch accessing a third cache type at distance 2.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

N2_CACHE3_HIT_RD, Cache type 3 at distance 2 demand access hit, read

The counter counts each demand read counted by [N2_CACHE_HIT_RD](#) due to a demand read accessing a third cache type at distance 2.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

N2_CACHE_HITM_RD, Cache at distance 2, demand access hit modified, read

The counter counts each demand read counted by [N2_CACHE_HIT_RD](#) that accesses a previously modified location in a cache at distance 2.

N2_CACHE_HIT_PRFM, Cache at distance 2, software prefetch hit

The counter counts each cache hit at distance 2 due to a software prefetch.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

Cache distance 2 represents a further distance of travel than cache distance 1.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

N2_CACHE_HIT_RD, Cache at distance 2, demand access hit, read

The counter counts each cache hit at distance 2 due to a demand read.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

Cache distance 2 represents a further distance of travel than cache distance 1.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

N2_LFB1_HIT_RD, Cache type 1 at distance 2 demand access line-fill buffer hit, read

The counter counts each demand read counted by [N2_LFB_HIT_RD](#) that hits a recently fetched line in a first cache type at distance 2.

That is, the read hits a cache line that is in the process of being loaded into the cache at distance 2, and so does not generate a new refill, but has to wait for the previous refill to complete.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

N2_LFB2_HIT_RD, Cache type 2 at distance 2 demand access line-fill buffer hit, read

The counter counts each demand read counted by [N2_LFB_HIT_RD](#) that hits a recently fetched line in a second cache type at distance 2.

That is, the read hits a cache line that is in the process of being loaded into the cache at distance 2, and so does not generate a new refill, but has to wait for the previous refill to complete.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

N2_LFB3_HIT_RD, Cache type 3 at distance 2 demand access line-fill buffer hit, read

The counter counts each demand read counted by [N2_LFB_HIT_RD](#) that hits a recently fetched line in a third cache type at distance 2.

That is, the read hits a cache line that is in the process of being loaded into the cache at distance 2, and so does not generate a new refill, but has to wait for the previous refill to complete.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

N2_LFB_HIT_RD, Cache at distance 2 demand access line-fill buffer hit, read

The counter counts each demand read counted by [N2_CACHE_HIT_RD](#) that hits a recently fetched line in a cache at distance 2.

That is, the read hits a cache line that is in the process of being loaded into the cache at distance 2, and so does not generate a new refill, but has to wait for the previous refill to complete.

N2_MEM1_PRFM, Access to type 1 memory at distance 2, software prefetch

The counter counts each software prefetch counted by [N2_MEM_PRFM](#) to a first memory type at distance 2.

The definition of memory types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

N2_MEM1_RD, Access to type 1 memory at distance 2, demand access, read

The counter counts each demand read counted by [N2_MEM_RD](#) to a first memory type at distance 2.

The definition of memory types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system. See also [N1_MEM1_RD](#).

N2_MEM2_PRFM, Access to type 2 memory at distance 2, software prefetch

The counter counts each software prefetch counted by [N2_MEM_PRFM](#) to a second memory type at distance 2.

The definition of memory types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

N2_MEM2_RD, Access to type 2 memory at distance 2, demand access, read

The counter counts each demand read counted by [N2_MEM_RD](#) to a second memory type at distance 2.

The definition of memory types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system. See also [N1_MEM2_RD](#).

N2_MEM3_PRFM, Access to type 3 memory at distance 2, software prefetch

The counter counts each software prefetch counted by [N2_MEM_PRFM](#) to a third memory type at distance 2.

The definition of memory types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

N2_MEM3_RD, Access to type 3 memory at distance 2, demand access, read

The counter counts each demand read counted by [N2_MEM_RD](#) to a third memory type at distance 2.

The definition of memory types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system. See also [N1_MEM3_RD](#).

N2_MEM_PRFM, Access to memory at distance 2, software prefetch

The counter counts each software prefetch to memory at distance 2.

The memory distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

Distance 2 represents a further distance of travel than distance 1.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

N2_MEM_RD, Access to memory at distance 2, demand access, read

The counter counts each demand read to memory at distance 2.

The memory distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

Distance 2 represents a further distance of travel than distance 1.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

N3_CACHE1_HITM_RD, Cache type 1 at distance 3 demand access hit modified, read

The counter counts each demand read counted by [N3_CACHE_HITM_RD](#) that accesses a previously modified location in a first cache type at distance 3.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

N3_CACHE1_HIT_PRFM, Cache type 1 at distance 3 software prefetch hit

The counter counts each software prefetch counted by [N3_CACHE_HIT_PRFM](#) due to a software prefetch accessing a first cache type at distance 3.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

N3_CACHE1_HIT_RD, Cache type 1 at distance 3 demand access hit, read

The counter counts each demand read counted by [N3_CACHE_HIT_RD](#) due to a demand read accessing a first cache type at distance 3.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

N3_CACHE2_HITM_RD, Cache type 2 at distance 3 demand access hit modified, read

The counter counts each demand read counted by [N3_CACHE_HITM_RD](#) that accesses a previously modified location in a second cache type at distance 3.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

N3_CACHE2_HIT_PRFM, Cache type 2 at distance 3 software prefetch hit

The counter counts each software prefetch counted by [N3_CACHE_HIT_PRFM](#) due to a software prefetch accessing a second cache type at distance 3.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

N3_CACHE2_HIT_RD, Cache type 2 at distance 3 demand access hit, read

The counter counts each demand read counted by [N3_CACHE_HIT_RD](#) due to a demand read accessing a second cache type at distance 3.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

N3_CACHE3_HITM_RD, Cache type 3 at distance 3 demand access hit modified, read

The counter counts each demand read counted by [N3_CACHE_HITM_RD](#) that accesses a previously modified location in a third cache type at distance 3.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

N3_CACHE3_HIT_PRFM, Cache type 3 at distance 3 software prefetch hit

The counter counts each software prefetch counted by [N3_CACHE_HIT_PRFM](#) due to a software prefetch accessing a third cache type at distance 3.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

N3_CACHE3_HIT_RD, Cache type 3 at distance 3 demand access hit, read

The counter counts each demand read counted by [N3_CACHE_HIT_RD](#) due to a demand read accessing a third cache type at distance 3.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

N3_CACHE_HITM_RD, Cache at distance 3, demand access hit modified, read

The counter counts each demand read counted by [N3_CACHE_HIT_RD](#) that accesses a previously modified location in a cache at distance 3.

N3_CACHE_HIT_PRFM, Cache at distance 3, software prefetch hit

The counter counts each cache hit at distance 3 due to a software prefetch.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

Cache distance 3 represents a further distance of travel than cache distance 2.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

N3_CACHE_HIT_RD, Cache at distance 3, demand access hit, read

The counter counts each cache hit at distance 3 due to a demand read.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

Cache distance 3 represents a further distance of travel than cache distance 2.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

N3_LFB1_HIT_RD, Cache type 1 at distance 3 demand access line-fill buffer hit, read

The counter counts each demand read counted by [N3_LFB_HIT_RD](#) that hits a recently fetched line in a first cache type at distance 3.

That is, the read hits a cache line that is in the process of being loaded into the cache at distance 3, and so does not generate a new refill, but has to wait for the previous refill to complete.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

N3_LFB2_HIT_RD, Cache type 2 at distance 3 demand access line-fill buffer hit, read

The counter counts each demand read counted by [N3_LFB_HIT_RD](#) that hits a recently fetched line in a second cache type at distance 3.

That is, the read hits a cache line that is in the process of being loaded into the cache at distance 3, and so does not generate a new refill, but has to wait for the previous refill to complete.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

N3_LFB3_HIT_RD, Cache type 3 at distance 3 demand access line-fill buffer hit, read

The counter counts each demand read counted by [N3_LFB_HIT_RD](#) that hits a recently fetched line in a third cache type at distance 3.

That is, the read hits a cache line that is in the process of being loaded into the cache at distance 3, and so does not generate a new refill, but has to wait for the previous refill to complete.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

N3_LFB_HIT_RD, Cache at distance 3 demand access line-fill buffer hit, read

The counter counts each demand read counted by [N3_CACHE_HIT_RD](#) that hits a recently fetched line in a cache at distance 3.

That is, the read hits a cache line that is in the process of being loaded into the cache at distance 3, and so does not generate a new refill, but has to wait for the previous refill to complete.

N3_MEM1_PRFM, Access to type 1 memory at distance 3, software prefetch

The counter counts each software prefetch counted by [N3_MEM_PRFM](#) to a first memory type at distance 3.

The definition of memory types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

N3_MEM1_RD, Access to type 1 memory at distance 3, demand access, read

The counter counts each demand read counted by [N3_MEM_RD](#) to a first memory type at distance 3.

The definition of memory types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system. See also [N1_MEM1_RD](#).

N3_MEM2_PRFM, Access to type 2 memory at distance 3, software prefetch

The counter counts each software prefetch counted by [N3_MEM_PRFM](#) to a second memory type at distance 3.

The definition of memory types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

N3_MEM2_RD, Access to type 2 memory at distance 3, demand access, read

The counter counts each demand read counted by [N3_MEM_RD](#) to a second memory type at distance 3.

The definition of memory types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system. See also [N1_MEM2_RD](#).

N3_MEM3_PRFM, Access to type 3 memory at distance 3, software prefetch

The counter counts each software prefetch counted by [N3_MEM_PRFM](#) to a third memory type at distance 3.

The definition of memory types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

N3_MEM3_RD, Access to type 3 memory at distance 3, demand access, read

The counter counts each demand read counted by [N3_MEM_RD](#) to a third memory type at distance 3.

The definition of memory types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system. See also [N1_MEM3_RD](#).

N3_MEM_PRFM, Access to memory at distance 3, software prefetch

The counter counts each software prefetch to memory at distance 3.

The memory distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

Distance 3 represents a further distance of travel than distance 2.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

N3_MEM_RD, Access to memory at distance 3, demand access, read

The counter counts each demand read to memory at distance 3.

The memory distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

Distance 3 represents a further distance of travel than distance 2.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

N4_CACHE1_HITM_RD, Cache type 1 at distance 4 demand access hit modified, read

The counter counts each demand read counted by [N4_CACHE_HITM_RD](#) that accesses a previously modified location in a first cache type at distance 4.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

N4_CACHE1_HIT_PRFM, Cache type 1 at distance 4 software prefetch hit

The counter counts each software prefetch counted by [N4_CACHE_HIT_PRFM](#) due to a software prefetch accessing a first cache type at distance 4.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

N4_CACHE1_HIT_RD, Cache type 1 at distance 4 demand access hit, read

The counter counts each demand read counted by [N4_CACHE_HIT_RD](#) due to a demand read accessing a first cache type at distance 4.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

N4_CACHE2_HITM_RD, Cache type 2 at distance 4 demand access hit modified, read

The counter counts each demand read counted by [N4_CACHE_HITM_RD](#) that accesses a previously modified location in a second cache type at distance 4.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

N4_CACHE2_HIT_PRFM, Cache type 2 at distance 4 software prefetch hit

The counter counts each software prefetch counted by [N4_CACHE_HIT_PRFM](#) due to a software prefetch accessing a second cache type at distance 4.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

N4_CACHE2_HIT_RD, Cache type 2 at distance 4 demand access hit, read

The counter counts each demand read counted by [N4_CACHE_HIT_RD](#) due to a demand read accessing a second cache type at distance 4.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

N4_CACHE3_HITM_RD, Cache type 3 at distance 4 demand access hit modified, read

The counter counts each demand read counted by [N4_CACHE_HITM_RD](#) that accesses a previously modified location in a third cache type at distance 4.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

N4_CACHE3_HIT_PRFM, Cache type 3 at distance 4 software prefetch hit

The counter counts each software prefetch counted by [N4_CACHE_HIT_PRFM](#) due to a software prefetch accessing a third cache type at distance 4.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

N4_CACHE3_HIT_RD, Cache type 3 at distance 4 demand access hit, read

The counter counts each demand read counted by [N4_CACHE_HIT_RD](#) due to a demand read accessing a third cache type at distance 4.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

N4_CACHE_HITM_RD, Cache at distance 4, demand access hit modified, read

The counter counts each demand read counted by [N4_CACHE_HIT_RD](#) that accesses a previously modified location in a cache at distance 4.

N4_CACHE_HIT_PRFM, Cache at distance 4, software prefetch hit

The counter counts each cache hit at distance 4 due to a software prefetch.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

Cache distance 4 represents a further distance of travel than cache distance 3.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

N4_CACHE_HIT_RD, Cache at distance 4, demand access hit, read

The counter counts each cache hit at distance 4 due to a demand read.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

Cache distance 4 represents a further distance of travel than cache distance 3.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

N4_LFB1_HIT_RD, Cache type 1 at distance 4 demand access line-fill buffer hit, read

The counter counts each demand read counted by [N4_LFB_HIT_RD](#) that hits a recently fetched line in a first cache type at distance 4.

That is, the read hits a cache line that is in the process of being loaded into the cache at distance 4, and so does not generate a new refill, but has to wait for the previous refill to complete.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

N4_LFB2_HIT_RD, Cache type 2 at distance 4 demand access line-fill buffer hit, read

The counter counts each demand read counted by [N4_LFB_HIT_RD](#) that hits a recently fetched line in a second cache type at distance 4.

That is, the read hits a cache line that is in the process of being loaded into the cache at distance 4, and so does not generate a new refill, but has to wait for the previous refill to complete.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

N4_LFB3_HIT_RD, Cache type 3 at distance 4 demand access line-fill buffer hit, read

The counter counts each demand read counted by [N4_LFB_HIT_RD](#) that hits a recently fetched line in a third cache type at distance 4.

That is, the read hits a cache line that is in the process of being loaded into the cache at distance 4, and so does not generate a new refill, but has to wait for the previous refill to complete.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

N4_LFB_HIT_RD, Cache at distance 4 demand access line-fill buffer hit, read

The counter counts each demand read counted by [N4_CACHE_HIT_RD](#) that hits a recently fetched line in a cache at distance 4.

That is, the read hits a cache line that is in the process of being loaded into the cache at distance 4, and so does not generate a new refill, but has to wait for the previous refill to complete.

N4_MEM1_PRFM, Access to type 1 memory at distance 4, software prefetch

The counter counts each software prefetch counted by [N4_MEM_PRFM](#) to a first memory type at distance 4.

The definition of memory types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

N4_MEM1_RD, Access to type 1 memory at distance 4, demand access, read

The counter counts each demand read counted by [N4_MEM_RD](#) to a first memory type at distance 4.

The definition of memory types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system. See also [N1_MEM1_RD](#).

N4_MEM2_PRFM, Access to type 2 memory at distance 4, software prefetch

The counter counts each software prefetch counted by [N4_MEM_PRFM](#) to a second memory type at distance 4.

The definition of memory types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

N4_MEM2_RD, Access to type 2 memory at distance 4, demand access, read

The counter counts each demand read counted by [N4_MEM_RD](#) to a second memory type at distance 4.

The definition of memory types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system. See also [N1_MEM2_RD](#).

N4_MEM3_PRFM, Access to type 3 memory at distance 4, software prefetch

The counter counts each software prefetch counted by [N4_MEM_PRFM](#) to a third memory type at distance 4.

The definition of memory types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

N4_MEM3_RD, Access to type 3 memory at distance 4, demand access, read

The counter counts each demand read counted by [N4_MEM_RD](#) to a third memory type at distance 4.

The definition of memory types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system. See also [N1_MEM3_RD](#).

N4_MEM_PRFM, Access to memory at distance 4, software prefetch

The counter counts each software prefetch to memory at distance 4.

The memory distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

Distance 4 represents a further distance of travel than distance 3.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

N4_MEM_RD, Access to memory at distance 4, demand access, read

The counter counts each demand read to memory at distance 4.

The memory distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

Distance 4 represents a further distance of travel than distance 3.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

NONFP_SPEC, Non-floating-point operation speculatively executed

The counter counts each [speculatively executed](#) data-processing operation due to any of:

- A scalar instruction that would be counted by the [DP_SPEC](#) event.
- An A64 Advanced SIMD data processing instruction defined in the section Data processing - SIMD and floating-point that would not be counted by [FP_SPEC](#).
- An SVE instruction with vector source or destination registers that would not be counted by [FP_SPEC](#).

It is IMPLEMENTATION DEFINED which non-floating-point data-processing operations are counted in AArch32 state.

PMU_SNAPSHOT, Successful PMU capture event

The counter counts each PMU snapshot Capture event that was successful, that is, PMSSCR_EL1.NC is set to 0.

It is CONSTRAINED UNPREDICTABLE whether the counter counts successful Capture events when the PE is in Debug state.

PRF_SPEC, Operation speculatively executed, prefetch

The counter counts each [speculatively executed](#) prefetch operation due to any of the following A64 instructions:

- Scalar: PRFM, PRFUM, or RPRFM.

It is IMPLEMENTATION DEFINED which prefetch operations are counted in AArch32 state.

REMOTE_ACCESS_WR, Access to a remote device, write

The counter counts each access counted by [REMOTE_ACCESS](#) that is a [Memory-write operation](#).

REMOTE_CACHE_HITM_RD, Remote cache demand access hit modified, read

The counter counts each cache hit on a remote device counted by [REMOTE_CACHE_HIT_RD](#) that accesses a previously modified location.

REMOTE_CACHE_HIT_PRFM, Remote cache software prefetch hit

The counter counts each cache hit on a remote device due to a software prefetch.

REMOTE_CACHE_HIT_RD, Remote cache demand access hit, read

The counter counts each cache hit on a remote device due to a demand read.

REMOTE_LFB_HIT_RD, Remote cache demand access line-fill buffer hit, read

The counter counts each cache hit on a remote device counted by [REMOTE_CACHE_HIT_RD](#) that hits a recently fetched line.

That is, the read hits a cache line that is in the process of being loaded into the cache attached to a remote device, and so does not generate a new refill, but has to wait for the previous refill to complete.

REMOTE_MEM, Access to memory attached to a remote device

The counter counts each ‘Memory-read operation’ or [Memory-write operation](#) access counted by [REMOTE_ACCESS](#) to external memory attached to a remote device.

The counter also counts any accesses to external memory that are not counted by [LOCAL_MEM](#) because the implementation classifies them as remote accesses. For example, accesses to expansion memory connected to the device that has significantly higher latency than the main system memory might be classified as remote accesses. For more information, see [LOCAL_MEM](#).

REMOTE_MEM_LDST_RETIRED, Load or store instruction architecturally executed, access to memory attached to a remote device

The counter counts each Memory-reading instruction or [Memory-writing instruction architecturally executed](#) counted by [LDST_ANY_RETIRED](#) that accessed external memory attached to a remote device.

REMOTE_MEM_LD_RETIRED, Load instruction architecturally executed, access to memory attached to a remote device

The counter counts each [architecturally executed](#) instruction counted by [REMOTE_MEM_LDST_RETIRED](#) that is a Memory-reading instruction.

REMOTE_MEM_PRFM, Access to memory attached to a remote device, software prefetch

The counter counts each access counted by [REMOTE_MEM](#) that is due to a prefetch instruction.

REMOTE_MEM_RD, Access to memory attached to a remote device, demand access, read

The counter counts each access counted by [REMOTE_MEM_RW](#) that is a demand ‘Memory-read operation’.

REMOTE_MEM_RW, Access to memory attached to a remote device, demand access

The counter counts each access counted by [REMOTE_MEM](#) that is a demand ‘Memory-read operation’ or demand [Memory-write operation](#).

REMOTE_MEM_ST_RETIRED, Store instruction architecturally executed, access to memory attached to a remote device

The counter counts each [architecturally executed](#) instruction counted by [REMOTE_MEM_LDST_RETIRED](#) that is a [Memory-writing instruction](#).

REMOTE_MEM_WR, Access to memory attached to a remote device, demand access, write

The counter counts each access counted by [REMOTE_MEM_RW](#) that is a demand [Memory-write operation](#).

SAMPLE_BUFFER_FULL, Profiling Buffer full

The counter counts each Profiling Buffer full management event.

SAMPLE_COLLISION, Statistical Profiling sample collided with previous sample

The counter counts each time the sample interval counter reaches zero and is reloaded, and the sample collides with a previous sample.

For more information, see ‘Sample collisions’.

PMCEID0_EL0[35] reads as 1 if this event is implemented and 0 otherwise.

SAMPLE_FEED, Statistical Profiling sample taken

The counter counts each time the sample interval counter reaches zero and is reloaded, and the sample does not collide with the previous sample.

Samples that are removed by filtering, or discarded, and not written to the Profiling Buffer are counted.

PMCEID0_EL0[33] reads as 1 if this event is implemented and 0 otherwise.

SAMPLE_FEED_DS, Statistical Profiling sample taken, selected Data Source

The counter counts each SPE sample that is a load operations where PMSDSFR_EL1[s] is 1 and s is bits [5:0] of the sampled Data Source.

The values of PMSFCR_EL1.FDS are ignored when generating this event.

Samples that are removed by filtering, or discarded, and not written to the Profiling Buffer are counted.

SAMPLE_FILTRATE, Statistical Profiling sample taken and not removed by filtering

The counter counts each sample counted by [SAMPLE_FEED](#) that is not removed by filtering.

Sample records that are not removed by filtering, but are discarded before being written to the Profiling Buffer because of a Profiling Buffer management event, are counted.

PMCEID0_EL0[34] reads as 1 if this event is implemented and 0 otherwise.

SAMPLE_POP, Statistical Profiling sample population

The counter counts each operation that might be sampled, whether or not the operation was sampled.

The counter does not count when profiling is disabled.

PMCEID0_EL0[32] reads as 1 if this event is implemented and 0 otherwise.

SE_FP_ADDSUB_SPEC, Operation speculatively executed, Advanced SIMD, SVE, or SME SIMD floating-point addition or subtraction

The counter counts each [speculatively executed](#) floating-point addition or subtraction operation counted by [SE_FP_SPEC](#) due to an A64 Advanced SIMD, SVE, or SME operation.

That is, each operation counted by [ASE_FP_ADDSUB_SPEC](#), [SVE_FP_ADDSUB_SPEC](#), or [SME_FP_ADDSUB_SPEC](#).

SE_FP_BF16_MIN_SPEC, Advanced SIMD, SVE, or SME data processing operation speculatively executed, smallest type is BFloat16 floating-point

The counter counts each Advanced SIMD, SVE, or SME data processing operation counted by [FP_BF16_MIN_SPEC](#) due to an instruction where the smallest type was BFloat16 floating-point.

SE_FP_BF16_SPEC, Operation speculatively executed, Advanced SIMD, SVE, or SME SIMD BFloat16 floating-point, data-processing

The counter counts each [speculatively executed](#) BFloat16 floating-point data-processing operation counted by [SE_FP_SPEC](#) due to an A64 Advanced SIMD, SVE, or SME operation.

That is, each operation counted by [SVE_FP_BF16_SPEC](#), or [SME_FP_BF16_SPEC](#).

SE_FP_DOT_SPEC, Operation speculatively executed, Advanced SIMD, SVE, or SME SIMD floating-point dot product

The counter counts each [speculatively executed](#) floating-point dot product operation counted by [SE_FP_SPEC](#) due to any of the following A64 instructions:

That is, each operation counted by [ASE_FP_DOT_SPEC](#), [SVE_FP_DOT_SPEC](#), or [SME_FP_DOT_SPEC](#).

SE_FP_DP_SPEC, Operation speculatively executed, Advanced SIMD, SVE, or SME SIMD double-precision floating-point, data-processing

The counter counts each [speculatively executed](#) double-precision floating-point data-processing operation counted by [SE_FP_SPEC](#) due to an A64 Advanced SIMD, SVE, or SME operation.

That is, each operation counted by [ASE_FP_DP_SPEC](#), [SVE_FP_DP_SPEC](#), or [SME_FP_DP_SPEC](#).

It is IMPLEMENTATION DEFINED which double-precision floating-point data-processing operations are counted in AArch32 state.

SE_FP_FMA_SPEC, Operation speculatively executed, Advanced SIMD, SVE, or SME SIMD floating-point multiply-add or multiply-subtract

The counter counts each [speculatively executed](#) floating-point multiply-add, multiply-add long, multiply-subtract, or multiply-subtract long operation counted by [SE_FP_SPEC](#) due to an A64 Advanced SIMD, SVE, or SME operation.

That is, each operation counted by [ASE_FP_FMA_SPEC](#), [SVE_FP_FMA_SPEC](#), or [SME_FP_FMA_SPEC](#).

SE_FP_FP8_MIN_SPEC, Advanced SIMD, SVE, or SME data processing operation speculatively executed, smallest type is 8-bit floating-point

The counter counts each Advanced SIMD, SVE, or SME data processing operation counted by [FP_FP8_MIN_SPEC](#) due to an instruction where the smallest type was 8-bit floating-point.

SE_FP_HP_MIN_SPEC, Advanced SIMD, SVE, or SME data processing operation speculatively executed, smallest type is half-precision floating-point

The counter counts each Advanced SIMD, SVE, or SME data processing operation counted by [FP_HP_MIN_SPEC](#) due to an instruction where the smallest type was half-precision floating-point.

SE_FP_HP_SPEC, Operation speculatively executed, Advanced SIMD, SVE, or SME SIMD half-precision floating-point, data-processing

The counter counts each [speculatively executed](#) half-precision floating-point data-processing operation counted by [SE_FP_SPEC](#) due to an A64 Advanced SIMD, SVE, or SME operation.

That is, each operation counted by [ASE_FP_HP_SPEC](#), [SVE_FP_HP_SPEC](#), or [SME_FP_HP_SPEC](#).

It is IMPLEMENTATION DEFINED which half-precision floating-point data-processing operations are counted in AArch32 state.

SE_FP_SPEC, Operation speculatively executed, Advanced SIMD, SVE, or SME SIMD floating-point, data-processing

The counter counts each [speculatively executed](#) floating-point data-processing operation counted by [FP_SPEC](#) due to an A64 Advanced SIMD, SVE, or SME operation.

That is, each operation counted by [ASE_FP_SPEC](#), [SVE_FP_SPEC](#), or [SME_FP_SPEC](#).

It is IMPLEMENTATION DEFINED which floating-point data-processing operations are counted in AArch32 state.

SE_FP_SP_MIN_SPEC, Advanced SIMD, SVE, or SME data processing operation speculatively executed, smallest type is single-precision floating-point

The counter counts each Advanced SIMD, SVE, or SME data processing operation counted by [FP_SP_MIN_SPEC](#) due to an instruction where the smallest type was single-precision floating-point.

SE_FP_SP_SPEC, Operation speculatively executed, Advanced SIMD, SVE, or SME SIMD single-precision floating-point, data-processing

The counter counts each [speculatively executed](#) single-precision floating-point data-processing operation counted by [SE_FP_SPEC](#) due to an A64 Advanced SIMD, SVE, or SME operation.

That is, each operation counted by [ASE_FP_SP_SPEC](#), [SVE_FP_SP_SPEC](#), or [SME_FP_SP_SPEC](#).

It is IMPLEMENTATION DEFINED which single-precision floating-point data-processing operations are counted in AArch32 state.

SE_INST_SPEC, Operation speculatively executed, Advanced SIMD, SVE, or SME

The counter counts each [speculatively executed](#) operation counted by [INST_SPEC](#) that is classified as an Advanced SIMD, SVE, or SME operation.

See [ASE_SVE_INST_SPEC](#) and [SME_INST_SPEC](#) for these classifications.

SE_INT16_SPEC, Operation speculatively executed, Advanced SIMD, SVE, or SME SIMD 16-bit integer, data-processing

The counter counts each [speculatively executed](#) 16-bit integer data-processing operation counted by [SE_INT_SPEC](#) due to an A64 Advanced SIMD, SVE, or SME operation.

That is, each operation counted by [ASE_INT16_SPEC](#), [SVE_INT16_SPEC](#), or [SME_INT16_SPEC](#).

It is IMPLEMENTATION DEFINED which 16-bit integer data-processing operations are counted in AArch32 state.

SE_INT32_SPEC, Operation speculatively executed, Advanced SIMD, SVE, or SME SIMD 32-bit integer, data-processing

The counter counts each [speculatively executed](#) 32-bit integer data-processing operation counted by [SE_INT_SPEC](#) due to an A64 Advanced SIMD, SVE, or SME operation.

That is, each operation counted by [ASE_INT32_SPEC](#), [SVE_INT32_SPEC](#), or [SME_INT32_SPEC](#).

It is IMPLEMENTATION DEFINED which 32-bit integer data-processing operations are counted in AArch32 state.

SE_INT64_SPEC, Operation speculatively executed, Advanced SIMD, SVE, or SME SIMD 64-bit integer, data-processing

The counter counts each [speculatively executed](#) 64-bit integer data-processing operation counted by [SE_INT_SPEC](#) due to an A64 Advanced SIMD, SVE, or SME operation.

That is, each operation counted by [ASE_INT64_SPEC](#), [SVE_INT64_SPEC](#), or [SME_INT64_SPEC](#).

It is IMPLEMENTATION DEFINED which 64-bit integer data-processing operations are counted in AArch32 state.

SE_INT8_SPEC, Operation speculatively executed, Advanced SIMD, SVE, or SME SIMD 8-bit integer, data-processing

The counter counts each [speculatively executed](#) 8-bit integer data-processing operation counted by [SE_INT_SPEC](#) due to an A64 Advanced SIMD, SVE, or SME operation.

That is, each operation counted by [ASE_INT8_SPEC](#), [SVE_INT8_SPEC](#), or [SME_INT8_SPEC](#).

It is IMPLEMENTATION DEFINED which 8-bit integer data-processing operations are counted in AArch32 state.

SE_INT_DOT_SPEC, Operation speculatively executed, Advanced SIMD, SVE, or SME SIMD integer dot product

The counter counts each [speculatively executed](#) integer dot product operation counted by [SE_INT_SPEC](#) due to any of the following A64 instructions:

That is, each operation counted by [ASE_INT_DOT_SPEC](#), [SVE_INT_DOT_SPEC](#), or [SME_INT_DOT_SPEC](#).

SE_INT_MUL_SPEC, Operation speculatively executed, Advanced SIMD, SVE, or SME SIMD integer multiply or multiply-accumulate

The counter counts each [speculatively executed](#) integer multiply, multiply-add, or multiply-subtract operation counted by [SE_INT_SPEC](#) due to an A64 Advanced SIMD, SVE, or SME operation.

That is, each operation counted by [ASE_INT_MUL_SPEC](#), [SVE_INT_MUL_SPEC](#), or [SME_INT_MUL_SPEC](#).

SE_INT_SPEC, Operation speculatively executed, Advanced SIMD, SVE, or SME SIMD integer, data-processing

The counter counts each [speculatively executed](#) integer data-processing operation counted by [INT_SPEC](#) due to an A64 Advanced SIMD, SVE, or SME operation.

That is, each operation counted by [ASE_INT_SPEC](#), [SVE_INT_SPEC](#), or [SME_INT_SPEC](#).

It is IMPLEMENTATION DEFINED which integer data-processing operations are counted in AArch32 state.

SE_LUT_SPEC, Lookup table operation speculatively executed, Advanced SIMD, SVE, or SME data processing

The counter counts each [speculatively executed](#) LUT operation counted by [SE_INST_SPEC](#) that returns a value from a lookup table made up of a ZT register, Z or V register which is indexed by values from a Z or V register.

SE_SPEC, Operation speculatively executed, Advanced SIMD, SVE, or SME data processing

The counter counts each operation counted by [INST_SPEC](#) that is an Advanced SIMD, SVE, or SME data-processing operation.

See [ASE_SVE_SPEC](#) and [SME_SPEC](#) for these classifications.

SIMD_INST_SPEC, Operation speculatively executed, SIMD

The counter counts each [speculatively executed](#) operation due to any of:

- An Advanced SIMD data-processing operation. Advanced SIMD scalar data-processing operations are not counted.
- An SVE SIMD data-processing operation. SVE non-SIMD data-processing operations are not counted.
- A structure load/store of one or more SIMD&FP registers.
- A load and replicate to one or more SIMD&FP registers.
- A scalar load/store of a SIMD&FP Q register or pair of Q registers.
- An SVE load/store.

It is IMPLEMENTATION DEFINED which Advanced SIMD operations are counted in AArch32 state.

It is IMPLEMENTATION DEFINED whether scalar loads and stores to SIMD&FP registers other than those listed above are counted.

SIMD_UOP_SPEC, Microarchitectural operation speculatively executed, SIMD

The counter counts each [speculatively executed](#) microarchitectural operation counted by [UOP_SPEC](#) due to any of:

- An SVE instruction other than non-SIMD SVE instructions.
- An A64 Advanced SIMD instruction other than an Advanced SIMD scalar instruction.

It is IMPLEMENTATION DEFINED which Advanced SIMD microarchitectural operations are counted in AArch32 state.

SME_FP_BF16_MIN_SPEC, SME data processing operation speculatively executed, smallest type is BFloat16 floating-point

The counter counts each SME data-processing operation counted by [SE_FP_BF16_MIN_SPEC](#) due to an instruction where the smallest type was BFloat16 floating-point.

SME_FP_FP8_MIN_SPEC, SME data processing operation speculatively executed, smallest type is 8-bit floating-point

The counter counts each SME data-processing operation counted by [SE_FP_FP8_MIN_SPEC](#) due to an instruction where the smallest type was 8-bit floating-point.

SME_FP_HP_MIN_SPEC, SME data processing operation speculatively executed, smallest type is half-precision floating-point

The counter counts each SME data-processing operation counted by [SE_FP_HP_MIN_SPEC](#) due to an instruction where the smallest type was half-precision floating-point.

SME_FP_SP_MIN_SPEC, SME data processing operation speculatively executed, smallest type is single-precision floating-point

The counter counts each SME data-processing operation counted by [SE_FP_SP_MIN_SPEC](#) due to an instruction where the smallest type was single-precision floating-point.

STALL_BACKEND_BUSY, Backend stall cycles, backend busy

The counter counts each cycle counted by [STALL_BACKEND](#) when operations are available from the frontend but the backend is not able to accept an operation because an execution unit is busy.

For example a complex operation unit such as a divider is executing a previous operation and cannot accept a new operation.

For a multithreaded processor implementation, if the Effective value of `PMEVTYPER<n>_EL0.MT` is 1, then the counter counts when operations are available from the frontend but the backend is not able to accept an operation because an execution unit is busy for any PE in the multithreaded processor.

STALL_BACKEND_CPUBOUND, Backend stall cycles, processor bound

The counter counts each cycle counted by [STALL_BACKEND](#) when the backend is stalled on a processor resource, not including memory.

The counter counts each stall that occurs when a backend processor resource is busy. This includes the stalls counted by [STALL_BACKEND_RENAME](#), and any other IMPLEMENTATION DEFINED processor resource stalls.

It does not include stalls that are counted by [STALL_BACKEND_MEMBOUND](#), although both events might count on the same cycle counted by [STALL_BACKEND](#) if there are both memory and processor-resource stall conditions active.

For a multithreaded processor implementation, if the Effective value of `PMEVTYPER<n>_EL0.MT` is 1, then the counter counts when the backend is stalled on a processor resource, not including memory for any PE in the multithreaded processor.

STALL_BACKEND_GCSTLB, Backend stall cycles, GCS TLB

The counter counts each cycle counted by [STALL_BACKEND_MEMBOUND](#) when there is a demand data miss in a TLB.

The demand data miss must be due to translation of a GCS data read operation or GCS data write operation.

Implementation of this optional event requires implementing [LIGCS_TLB](#) event.

For a multithreaded processor implementation, if the Effective value of $\text{PMEVTYPER}_{<n>_EL0.MT}$ is 1, then the counter counts when there is a demand data miss in a TLB for any PE in the multithreaded processor.

STALL_BACKEND_ILOCK, Backend stall cycles, input dependency

The counter counts each cycle counted by [STALL_BACKEND](#) when operations are available from the frontend but at least one is not ready to be sent to the backend because of an input dependency.

For a multithreaded processor implementation, if the Effective value of $\text{PMEVTYPER}_{<n>_EL0.MT}$ is 1, then the counter counts when operations are available from the frontend but at least one is not ready to be sent to the backend because of an input dependency for any PE in the multithreaded processor.

STALL_BACKEND_L1D, Backend stall cycles, level 1 data cache

The counter counts each cycle counted by [STALL_BACKEND_MEMBOUND](#) when there is a demand data miss in the first level of data or unified cache.

For a multithreaded processor implementation, if the Effective value of $\text{PMEVTYPER}_{<n>_EL0.MT}$ is 1, then the counter counts when there is a demand data miss in the first level of data or unified cache for any PE in the multithreaded processor.

The counter does not count the cycle if any of the following are true:

- The [STALL_BACKEND_L2D](#) event is implemented and there is a demand data miss in the second level of data or unified cache, meaning the [STALL_BACKEND_L2D](#) event counts the cycle.
- There is a demand data miss in the last level of data or unified cache within the PE clock domain, meaning the [STALL_BACKEND_MEM](#) event counts the cycle.

STALL_BACKEND_L1GCS, Backend stall cycles, Level 1 GCS cache

The counter counts each cycle counted by [STALL_BACKEND_MEMBOUND](#) when there is a demand data miss in a first level cache.

The demand data miss must be due to either GCS data read operation or GCS data write operation.

The counter does not count the cycle if any of the following are true:

- The [STALL_BACKEND_L2D](#) event is implemented and there is a demand data miss in the second level of data or unified cache, meaning the [STALL_BACKEND_L2D](#) event counts the cycle.
- There is a demand data miss in the last level of data or unified cache within the PE clock domain, meaning the [STALL_BACKEND_MEM](#) event counts the cycle.

Implementation of this optional event requires that the first level cache is implemented within the PE clock domain and is not the last level cache within the PE clock domain.

Implementation of this optional event requires implementing [LIGCS_CACHE](#) event.

For a multithreaded processor implementation, if the Effective value of $\text{PMEVTYPER}_{<n>_EL0.MT}$ is 1, then the counter counts when there is a demand data miss in a first level cache for any PE in the multithreaded processor.

Note

It is possible that both the events [STALL_BACKEND_LIGCS](#) and [STALL_BACKEND_L1D](#) events may be counted on a same cycle.

STALL_BACKEND_L2D, Backend stall cycles, level 2 data cache

The counter counts each cycle counted by [STALL_BACKEND_MEMBOUND](#) when there is a demand data miss in the second level of data or unified cache.

For a multithreaded processor implementation, if the Effective value of `PMEVTYPER<n>_EL0.MT` is 1, then the counter counts when there is a demand data miss in the second level of data or unified cache for any PE in the multithreaded processor.

The counter does not count the cycle if there is a demand data miss in the last level of data or unified cache within the PE clock domain, meaning the [STALL_BACKEND_MEM](#) event counts the cycle.

STALL_BACKEND_MEM, Memory stall cycles

The counter counts each cycle counted by [STALL_BACKEND_MEMBOUND](#) when there is a demand data miss in the last level of data or unified cache within the PE clock domain.

It is IMPLEMENTATION DEFINED whether the counter counts backend stall cycles when a non-cacheable data access is in progress.

For a multithreaded processor implementation, if the Effective value of `PMEVTYPER<n>_EL0.MT` is 1, then the counter counts when there is a demand data miss in the last level of data or unified cache within the PE clock domain for any PE in the multithreaded processor.

`PMCEID0_EL0[37]` reads as 1 if this event is implemented and 0 otherwise.

STALL_BACKEND_MEMBOUND, Backend stall cycles, memory bound

The counter counts each cycle counted by [STALL_BACKEND](#) when the backend is waiting for a memory access to complete.

The counter counts each stall that occurs when the backend interface to memory is busy or stalled.

This includes the stalls counted by: [STALL_BACKEND_L1D](#), [STALL_BACKEND_L2D](#), [STALL_BACKEND_MEM](#), [STALL_BACKEND_ST](#), [STALL_BACKEND_TLB](#), and any other IMPLEMENTATION DEFINED memory stall events.

It does not include stalls that are counted by [STALL_BACKEND_CPUBOUND](#), although both events might count on the same cycle counted by [STALL_BACKEND](#) if there are both memory and processor-resource stall conditions active.

For a multithreaded processor implementation, if the Effective value of `PMEVTYPER<n>_EL0.MT` is 1, then the counter counts when the backend is waiting for a memory access to complete for any PE in the multithreaded processor.

STALL_BACKEND_RENAME, Backend stall cycles, rename full

The counter counts each cycle counted by [STALL_BACKEND_CPUBOUND](#) when operations are available from the frontend but at least one is not ready to be sent to the backend because no rename register is available.

If this event is implemented and counts such stalls then the [STALL_FRONTEND_RENAME](#) event counts as zero.

For a multithreaded processor implementation, if the Effective value of `PMEVTYPER<n>_EL0.MT` is 1, then the counter counts when operations are available from the frontend but at least one is not ready to be sent to the backend because no rename register is available for any PE in the multithreaded processor.

STALL_BACKEND_ST, Backend stall cycles, store

The counter counts each cycle counted by [STALL_BACKEND_MEMBOUND](#) when the backend is stalled waiting for a store.

For a multithreaded processor implementation, if the Effective value of `PMEVTYPER<n>_EL0.MT` is 1, then the counter counts when the backend is stalled waiting for a store for any PE in the multithreaded processor.

STALL_BACKEND_TLB, Backend stall cycles, TLB

The counter counts each cycle counted by [STALL_BACKEND_MEMBOUND](#) when there is a demand data miss in the data or unified TLB.

For a multithreaded processor implementation, if the Effective value of `PMEVTYPER<n>_EL0.MT` is 1, then the counter counts when there is a demand data miss in the data or unified TLB for any PE in the multithreaded processor.

STALL_FRONTEND_CPUBOUND, Frontend stall cycles, processor bound

The counter counts each cycle counted by [STALL_FRONTEND](#) when the frontend is stalled on a frontend processor resource, not including memory.

The counter counts each stall that occurs when a frontend processor resource is busy.

This includes the stalls counted by [STALL_FRONTEND_FLOW](#), [STALL_FRONTEND_FLUSH](#), and [STALL_FRONTEND_RENAME](#), and any other IMPLEMENTATION DEFINED processor resource stalls.

It does not include stalls that are counted by [STALL_FRONTEND_MEMBOUND](#). However both events will count the same cycle counted by [STALL_FRONTEND](#) if there are both memory and processor-resource stall conditions active.

For a multithreaded processor implementation, if the Effective value of `PMEVTYPER<n>_EL0.MT` is 1, then the counter counts when the frontend is stalled on a frontend processor resource, not including memory for any PE in the multithreaded processor.

STALL_FRONTEND_FLOW, Frontend stall cycles, flow control

The counter counts each cycle counted by [STALL_FRONTEND_CPUBOUND](#) when the frontend is stalled on unavailability of prediction flow resources.

For a multithreaded processor implementation, if the Effective value of `PMEVTYPER<n>_EL0.MT` is 1, then the counter counts when the frontend is stalled on unavailability of prediction flow resources for any PE in the multithreaded processor.

Note

This event is not counting stalls due to mispredictions, but rather stalls when the frontend is unable to make a prediction.

STALL_FRONTEND_FLUSH, Frontend stall cycles, flush recovery

The counter counts each cycle counted by [STALL_FRONTEND_CPUBOUND](#) when the frontend is recovering from a pipeline flush.

The situations where the frontend is flushed are IMPLEMENTATION DEFINED. For example, the frontend might be flushed on a branch misprediction or on a Context synchronization event.

For a multithreaded processor implementation, if the Effective value of `PMEVTYPER<n>_EL0.MT` is 1, then the counter counts when the frontend is recovering from a pipeline flush for any PE in the multithreaded processor.

STALL_FRONTEND_L1I, Frontend stall cycles, level 1 instruction cache

The counter counts each cycle counted by [STALL_FRONTEND_MEMBOUND](#) when there is a demand instruction miss in the first level of instruction cache.

For a multithreaded processor implementation, if the Effective value of `PMEVTYPER<n>_EL0.MT` is 1, then the counter counts when there is a demand instruction miss in the first level of instruction cache for any PE in the multithreaded processor.

The counter does not count the cycle if any of the following are true:

- The [STALL_FRONTEND_L2I](#) event is implemented and there is a demand instruction miss in the second level of instruction cache, meaning the [STALL_FRONTEND_L2I](#) event counts the cycle.
- There is a demand instruction miss in the last level of instruction cache within the PE clock domain, meaning the [STALL_FRONTEND_MEM](#) event counts the cycle.

STALL_FRONTEND_L2I, Frontend stall cycles, level 2 instruction cache

The counter counts each cycle counted by [STALL_FRONTEND_MEMBOUND](#) when there is a demand instruction miss in the second level of instruction or unified cache.

For a multithreaded processor implementation, if the Effective value of `PMEVTYPER<n>_EL0.MT` is 1, then the counter counts when there is a demand instruction miss in the second level of instruction or unified cache for any PE in the multithreaded processor.

The counter does not count the cycle if there is a demand instruction miss in the last level of instruction cache within the PE clock domain, meaning the [STALL_FRONTEND_MEM](#) event counts the cycle.

STALL_FRONTEND_MEM, Frontend stall cycles, last level PE cache or memory

The counter counts each cycle counted by [STALL_FRONTEND_MEMBOUND](#) when there is a demand instruction miss in the last level of instruction or unified cache within the PE clock domain or a non-cacheable instruction fetch in progress.

For a multithreaded processor implementation, if the Effective value of `PMEVTYPER<n>_EL0.MT` is 1, then the counter counts when there is a demand instruction miss in the last level of instruction or unified cache within the PE clock domain or a non-cacheable instruction fetch in progress for any PE in the multithreaded processor.

STALL_FRONTEND_MEMBOUND, Frontend stall cycles, memory bound

The counter counts each cycle counted by [STALL_FRONTEND](#) when no instructions are delivered from the memory system.

The counter counts each stall that occurs when the frontend interface to memory is busy or stalled.

This includes the stalls counted by [STALL_FRONTEND_L1I](#), [STALL_FRONTEND_L2I](#), [STALL_FRONTEND_MEM](#), and [STALL_FRONTEND_TLB](#), and any other IMPLEMENTATION DEFINED memory stalls.

It does not include stalls that are counted by [STALL_FRONTEND_CPUBOUND](#). However both events will count the same cycle counted by [STALL_FRONTEND](#) if there are both memory and processor-resource stall conditions active.

For a multithreaded processor implementation, if the Effective value of `PMEVTYPER<n>_EL0.MT` is 1, then the counter counts when no instructions are delivered from the memory system for any PE in the multithreaded processor.

STALL_FRONTEND_RENAME, Frontend stall cycles, rename full

The counter counts each cycle counted by [STALL_FRONTEND_CPUBOUND](#) when operations are available from the frontend but at least one is not ready to be sent to the backend because no rename register is available.

If this event is implemented and counts such stalls then the [STALL_BACKEND_RENAME](#) event counts as zero.

For a multithreaded processor implementation, if the Effective value of `PMEVTYPER<n>_EL0.MT` is 1, then the counter counts when operations are available from the frontend but at least one is not ready to be sent to the backend because no rename register is available for any PE in the multithreaded processor.

STALL_FRONTEND_TLB, Frontend stall cycles, TLB

The counter counts each cycle counted by [STALL_FRONTEND_MEMBOUND](#) when there is a demand instruction miss in the instruction or unified TLB.

For a multithreaded processor implementation, if the Effective value of `PMEVTYPER<n>_EL0.MT` is 1, then the counter counts when there is a demand instruction miss in the instruction or unified TLB for any PE in the multithreaded processor.

ST_ALIGN_LAT, Store with additional latency from alignment

The counter counts each [Memory-write operation](#) counted by [LDST_ALIGN_LAT](#).

`PMCEID1_EL0[34]` reads as 1 if this event is implemented and 0 otherwise.

ST_FIXED_BYTES_SPEC, Non-scalable store bytes speculatively executed

The counter counts each speculatively written byte counted by [LDST_FIXED_BYTES_SPEC](#).

For each instruction, the counter is incremented by the number of bytes transferred per register multiplied by the number of registers transferred. That is, the counter is incremented by:

- Half the value that the [LDST_FIXED_BYTES_SPEC](#) event counts if the operation is a swap, or compare and swap operation.
- The same as for [LDST_FIXED_BYTES_SPEC](#) if the operation is any other store operation, including an atomic store operation.

ST_FIXED_OPS_SPEC, Non-scalable store element operations speculatively executed

The counter counts each [Memory-write operation](#) counted by [LDST_FIXED_OPS_SPEC](#).

For each instruction, the counter is incremented by the number of operations specified by the instruction. That is, the counter is incremented by:

- Half the value that the [LDST_FIXED_OPS_SPEC](#) event counts if the operation is a store atomic, compare and swap, or swap operation.
- The same as for [LDST_FIXED_OPS_SPEC](#) if the operation is any other store operation.

SVE_FP_BF16_MIN_SPEC, SVE data processing operation speculatively executed, smallest type is BFloat16 floating-point

The counter counts each SVE data-processing operation counted by [ASE_SVE_FP_BF16_MIN_SPEC](#) due to an instruction where the smallest type was BFloat16 floating-point.

SVE_FP_FP8_MIN_SPEC, SVE data processing operation speculatively executed, smallest type is 8-bit floating-point

The counter counts each SVE data-processing operation counted by [ASE_SVE_FP_FP8_MIN_SPEC](#) due to an instruction where the smallest type was 8-bit floating-point.

SVE_FP_HP_MIN_SPEC, SVE data processing operation speculatively executed, smallest type is half-precision floating-point

The counter counts each SVE data-processing operation counted by [ASE_SVE_FP_HP_MIN_SPEC](#) due to an instruction where the smallest type was half-precision floating-point.

SVE_FP_PREDUCE_SPEC, Floating-point operation speculatively executed, SVE pairwise add step or pairwise reduce step

The counter counts each [speculatively executed](#) floating-point pairwise add step or pairwise reduce step operation counted by [SVE_FP_VREDUCE_SPEC](#) due to any of the following instructions:

SVE_FP_SP_MIN_SPEC, SVE data processing operation speculatively executed, smallest type is single-precision floating-point

The counter counts each SVE data-processing operation counted by [ASE_SVE_FP_SP_MIN_SPEC](#) due to an instruction where the smallest type was single-precision floating-point.

SVE_LUT_SPEC, Lookup table operation speculatively executed, SVE data processing

The counter counts each [speculatively executed](#) LUT operation counted by [SE_LUT_SPEC](#) that returns a value from a lookup table made up of a Z register which is indexed by values from a Z register.

That is, due to any of the following instructions:

SVE_SPEC, Operation speculatively executed, SVE data processing

The counter counts each operation counted by [ASE_SVE_SPEC](#) that is an SVE data-processing operation.

An SVE data-processing operation is any operation due to an instruction that operates on the SVE scalable vector and predicate registers that is not any of the following:

- A load or store operation. These are counted by [SVE_INST_SPEC](#).
- If the Cryptographic Extension is implemented, an operation counted by [CRYPTO_SPEC](#) as a Cryptographic data-processing operation.

If the Cryptographic Extension and FEAT_SVE2 are implemented, operations due to the SVE [PMULLB](#) and [PMULLT](#) (Q variants) instructions are not counted by [CRYPTO_SPEC](#) and are counted as SVE data-processing operations.

TRCEXTOUT0, Trace unit external output 0

The counter counts each event signaled by the trace unit on external event 0.

It is IMPLEMENTATION DEFINED whether this event is available as an external input to the ETE.

PMCEID0_EL0[48] reads as 1 if this event is implemented and 0 otherwise.

TRCEXTOUT1, Trace unit external output 1

The counter counts each event signaled by the trace unit on external event 1.

It is IMPLEMENTATION DEFINED whether this event is available as an external input to the ETE.

PMCEID0_EL0[49] reads as 1 if this event is implemented and 0 otherwise.

TRCEXTOUT2, Trace unit external output 2

The counter counts each event signaled by the trace unit on external event 2.

It is IMPLEMENTATION DEFINED whether this event is available as an external input to the ETE.

PMCEID0_EL0[50] reads as 1 if this event is implemented and 0 otherwise.

TRCEXTOUT3, Trace unit external output 3

The counter counts each event signaled by the trace unit on external event 3.

It is IMPLEMENTATION DEFINED whether this event is available as an external input to the ETE.

PMCEID0_EL0[51] reads as 1 if this event is implemented and 0 otherwise.

UOP_RETIRED, Micro-operation architecturally executed

The counter counts each micro-operation that would be executed in a Simple sequential execution of the program.

Unlike [OP_RETIRED](#), this event is not linked to the definition of [OP_SPEC](#), meaning it counts micro-operations that are created from other operations after those operations are counted by [OP_SPEC](#).

UOP_SPEC, Microarchitectural operation speculatively executed

The counter counts each [speculatively executed](#) microarchitectural operation.

ZA_ACTIVE, CPU cycles, ZA enabled

The counter counts each cycle counted by [CPU_CYCLES](#) when PSTATE.ZA is 1.

D7.4 Cycle event counting

The `CPU_CYCLES` event and the cycle counter, `PMCCNTR`, count cycles. The duration of a cycle is subject to any changes in clock frequency, including clock stopping caused by the WFI and WFE instructions.

It is IMPLEMENTATION SPECIFIC whether `CPU_CYCLES` and `PMCCNTR` count when the PE is in WFI or WFE state, even if the clocks are not stopped.

In addition, events such as `STALL`, `STALL_FRONTEND` and `STALL_BACKEND` that are defined to only count cycles that are counted by the `CPU_CYCLES` event have the same limitation.

D7.4.1 Cycle event counting in multithreaded implementations

Multithreaded implementations can have various forms, some examples of these are:

- *Simultaneous Multithreading* (SMT), where every PE thread is active on every `Processor cycle`.
- *Fine-grained Multithreading* (FGMT), also known as a Barrel processor, where one PE thread is active on each `Processor cycle`, and this changes regularly.
- *Switch on Event Multithreading* (SoEMT), also known as *Coarse-grained Multithreading* (CGMT), where high latency events cause the processor to switch the active PE thread.

In the above examples, active means that the PE might execute the instructions. A PE can be active but not executing instructions when no instruction is available or because of limited execution resources.

It is IMPLEMENTATION SPECIFIC whether a thread is active when the thread is in WFE or WFI state. This applies for all forms of multithreaded implementation.

When the PMU implementation supports multithreading, the `Effective value` of `PMEVTYPER<n>.MT` bit is 0, and the thread is not in WFE or WFI state, the `CPU_CYCLES` event only counts `Processor cycles` when the thread is active. For the example multithreaded implementations, this means that, if the event counter is enabled, event counting is not prohibited, and the thread is not in WFE or WFI state:

- For an SMT implementation, the `CPU_CYCLES` event counts every `Processor cycle`.
- For a particular FGMT implementation, that alternates between two threads on each `Processor cycle`, the `CPU_CYCLES` event counts every other `Processor cycle`.
