

Arm[®] Architecture Reference Manual

for R-profile AArch32 architecture

Document number	DDI 111353
Document quality	EAC
Document version	A.a
Document confidentiality	Non-Confidential
Date of issue	09 July 2026

Release information

The following releases of this document have been made.

Date	Version	Changes
09/Jul/2026	A.a	Initial release of Non-Confidential Arm Architecture Reference Manual for R-profile AArch32 architecture with ASLv1.0

Non-Confidential Proprietary Notice

This document is protected by copyright and other related rights and the use or implementation of the information contained in this document may be protected by one or more patents or pending patent applications. No part of this document may be reproduced in any form by any means without the express prior written permission of Arm Limited (“Arm”). **No license, express or implied, by estoppel or otherwise to any intellectual property rights is granted by this document unless specifically stated.**

Your access to the information in this document is conditional upon your acceptance that you will not use or permit others to use the information for the purposes of determining whether the subject matter of this document infringes any third party patents.

The content of this document is informational only. Any solutions presented herein are subject to changing conditions, information, scope, and data. This document was produced using reasonable efforts based on information available as of the date of issue of this document. The scope of information in this document may exceed that which Arm is required to provide, and such additional information is merely intended to further assist the recipient and does not represent Arm’s view of the scope of its obligations. You acknowledge and agree that you possess the necessary expertise in system security and functional safety and that you shall be solely responsible for compliance with all legal, regulatory, safety and security related requirements concerning your products, notwithstanding any information or support that may be provided by Arm herein. In addition, you are responsible for any applications which are used in conjunction with any Arm technology described in this document, and to minimize risks, adequate design and operating safeguards should be provided for by you.

This document may include technical inaccuracies or typographical errors. THIS DOCUMENT IS PROVIDED “AS IS”. ARM PROVIDES NO REPRESENTATIONS AND NO WARRANTIES, EXPRESS, IMPLIED OR STATUTORY, INCLUDING, WITHOUT LIMITATION, THE IMPLIED WARRANTIES OF MERCHANTABILITY, SATISFACTORY QUALITY, NON-INFRINGEMENT OR FITNESS FOR A PARTICULAR PURPOSE WITH RESPECT TO THE DOCUMENT. For the avoidance of doubt, Arm makes no representation with respect to, and has undertaken no analysis to identify or understand the scope and content of, any patents, copyrights, trade secrets, trademarks, or other rights.

TO THE EXTENT NOT PROHIBITED BY LAW, IN NO EVENT WILL ARM BE LIABLE FOR ANY DAMAGES, INCLUDING WITHOUT LIMITATION ANY DIRECT, INDIRECT, SPECIAL, INCIDENTAL, PUNITIVE, OR CONSEQUENTIAL DAMAGES, HOWEVER CAUSED AND REGARDLESS OF THE THEORY OF LIABILITY, ARISING OUT OF ANY USE OF THIS DOCUMENT, EVEN IF ARM HAS BEEN ADVISED OF THE POSSIBILITY OF SUCH DAMAGES.

Reference by Arm to any third party’s products or services within this document is not an express or implied approval or endorsement of the use thereof.

This document consists solely of commercial items. You shall be responsible for ensuring that any permitted use, duplication, or disclosure of this document complies fully with any relevant export laws and regulations to assure that this document or any portion thereof is not exported, directly or indirectly, in violation of such export laws. Use of the word “partner” in reference to Arm’s customers is not intended to create or refer to any partnership relationship with any other company. Arm may make changes to this document at any time and without notice.

This document may be translated into other languages for convenience, and you agree that if there is any conflict between the English version of this document and any translation, the terms of the English version of this document shall prevail.

The validity, construction and performance of this notice shall be governed by English Law.

PRE-20349

8 March 2024

Confidentiality Status

This document is Non-Confidential. The right to use, copy and disclose this document may be subject to license restrictions in accordance with the terms of the agreement entered into by Arm and the party that Arm delivered this document to.

Product Status

The information in this document is final, that is for a developed product.

The information in this manual is at EAC quality, which means that all features of the specification are described in the manual.

Arm[®] Architecture Reference Manual, for R-profile AArch32 architecture

Preface

About this Manual	14
Using this Manual.....	16
Conventions	20
Additional reading.....	23
Feedback	24

Part A Arm Architecture Introduction and Overview

Chapter A1 Introduction to the Arm Architecture

A1.1 About the Arm architecture	27
A1.2 Architecture profiles	28
A1.3 Arm architectural concepts.....	29
A1.4 Supported data types	32
A1.5 Floating-point support.....	40
A1.6 The Arm memory model.....	48

Chapter A2 R-profile Architecture Extensions

A2.1 About the Armv8-R AArch32 architecture extensions.....	50
A2.2 Armv8-R AArch32 architecture extensions	51

Part B The AArch32 Application Level Architecture

Chapter B1 The AArch32 Application Level Programmers' Model

B1.1 About the Application level programmers' model	57
B1.2 The Application level programmers' model in AArch32 state.....	58
B1.3 Advanced SIMD and floating-point instructions	69
B1.4 About the AArch32 System register interface	85
B1.5 Exceptions	86

Chapter B2 The AArch32 Application Level Memory Model

B2.1 About the Arm memory model	88
B2.2 Atomicity in the Arm architecture	90
B2.3 Definition of the memory model.....	94

B2.4	Ordering requirements defined by the formal concurrency model	95
B2.5	Additional ordering requirements outside of the scope of the formal concurrency model	126
B2.6	Endian support	133
B2.7	Caches and memory hierarchy	137
B2.8	Alignment support	142
B2.9	Memory types and attributes	144
B2.10	Mismatched memory attributes	154
B2.11	Synchronization and semaphores	157

Part C

The AArch32 Instruction Sets

Chapter C1

About the T32 and A32 Instruction Descriptions

C1.1	Format of instruction descriptions	168
C1.2	Standard assembler syntax fields	173
C1.3	Conditional execution	174
C1.4	Shifts applied to a register	176
C1.5	Memory accesses	178
C1.6	Encoding of lists of general-purpose registers and the PC	179
C1.7	General information about the T32 and A32 instruction descriptions	180
C1.8	Additional pseudocode support for instruction descriptions	194
C1.9	Additional information about Advanced SIMD and floating-point instructions	195

Chapter C2

The AArch32 Instruction Sets Overview

C2.1	Support for instructions in different versions of the Arm architecture	202
C2.2	Unified Assembler Language	203
C2.3	Branch instructions	205
C2.4	Data-processing instructions	206
C2.5	PSTATE and banked register access instructions	214
C2.6	Load/store instructions	215
C2.7	Load/store multiple instructions	217
C2.8	Miscellaneous instructions	218
C2.9	Exception-generating and exception-handling instructions	219
C2.10	System register access instructions	221
C2.11	Advanced SIMD and floating-point load/store instructions	222
C2.12	Advanced SIMD and floating-point register transfer instructions	224
C2.13	Advanced SIMD data-processing instructions	225
C2.14	Floating-point data-processing instructions	233

Chapter C3

T32 Instruction Set Encoding

C3.1	T32 instruction set encoding	235
C3.2	About the T32 Advanced SIMD and floating-point instructions and their encoding	307
Chapter C4	A32 Instruction Set Encoding	
C4.1	A32 instruction set encoding	309
C4.2	About the A32 Advanced SIMD and floating-point instructions and their encoding	372
Chapter C5	T32 and A32 Base Instruction Set Instruction Descriptions	
C5.1	Alphabetical list of T32 and A32 base instruction set instructions	374
C5.2	Encoding and use of banked register transfer instructions.....	1138
Chapter C6	T32 and A32 Advanced SIMD and Floating-point Instruction Descriptions	
C6.1	Alphabetical list of Advanced SIMD and floating-point instructions.....	1143
Part D	The AArch32 System Level Architecture	
Chapter D1	The AArch32 System Level Programmers' Model	
D1.1	About the AArch32 System level programmers' model	1890
D1.2	Exception levels.....	1891
D1.3	Exception terminology	1892
D1.4	Execution state.....	1894
D1.5	Instruction Set state	1895
D1.6	Virtualization	1896
D1.7	AArch32 state PE modes	1898
D1.8	AArch32 general-purpose registers, the PC, and the Special-purpose registers	1901
D1.9	Process state, PSTATE.....	1904
D1.10	Instruction set states	1909
D1.11	Handling exceptions.....	1911
D1.12	Routing of aborts	1925
D1.13	Exception return to an Exception level using AArch32	1926
D1.14	Asynchronous exception behavior for exceptions taken from AArch32 state.....	1930
D1.15	AArch32 state exception descriptions.....	1933
D1.16	Reset into AArch32 state.....	1947
D1.17	Mechanisms for entering a low-power state	1948
D1.18	The AArch32 System register interface	1953
D1.19	Advanced SIMD and floating-point support.....	1956
D1.20	Configurable instruction controls.....	1960
Chapter D2	AArch32 Self-hosted Debug	
D2.1	About self-hosted debug	1965

D2.2	Routing debug exceptions	1969
D2.3	The debug exception enable controls.....	1970
D2.4	The effect of powerdown on debug exceptions	1971
D2.5	Summary of permitted routing and enabling of debug exceptions.....	1972
D2.6	Pseudocode description of debug exceptions	1973
D2.7	Breakpoint Instruction exceptions	1974
D2.8	Breakpoint exceptions	1977
D2.9	Watchpoint exceptions.....	1996
D2.10	Vector Catch exceptions.....	2008
D2.11	Synchronization and debug exceptions	2013
Chapter D3	AArch32 Trace	
D3.1	About trace	2016
D3.2	Prohibited regions in self-hosted trace.....	2017
D3.3	Self-hosted trace timestamps	2018
D3.4	Synchronization in self-hosted trace	2019
Chapter D4	The AArch32 System Level Memory Model	
D4.1	About the memory system architecture.....	2021
D4.2	Address space	2022
D4.3	Mixed-endian support in AArch32	2023
D4.4	AArch32 cache and branch predictor support.....	2024
D4.5	System register support for IMPLEMENTATION DEFINED memory features	2044
D4.6	External aborts	2045
D4.7	Memory barrier instructions.....	2047
D4.8	Pseudocode description of general memory System instructions	2048
Chapter D5	The AArch32 Protected Memory System Architecture	
D5.1	About the AArch32 Protected Memory System Architecture	2052
D5.2	Memory protection units	2054
D5.3	Default memory maps and Background region checks.....	2057
D5.4	Protection region attributes and access permissions	2059
D5.5	PMSAv8-32 memory aborts	2063
D5.6	Exception reporting in a PMSAv8-32 implementation.....	2069
D5.7	PMSAv8-32 implications for caches.....	2080
Chapter D6	The Performance Monitors Extension	
D6.1	About the Performance Monitors	2082
D6.2	Accuracy of the Performance Monitors	2084
D6.3	Behavior on overflow.....	2086

D6.4	Attributability	2088
D6.5	Controlling the PMU counters	2089
D6.6	Multithreaded implementations.....	2092
D6.7	Event filtering	2093
D6.8	Performance Monitors and Debug state.....	2095
D6.9	Counter access	2096
D6.10	Performance Monitors Extension registers	2097
Chapter D7	PMU Event Descriptions	
D7.1	Definitions	2099
D7.2	The PMU event number space and common events	2108
D7.3	Common event numbers	2151
D7.4	Cycle event counting.....	2309
D7.5	Meaningful combinations of common events	2311
D7.6	Required events	2315
D7.7	IMPLEMENTATION DEFINED event numbers.....	2316
Chapter D8	The Generic Timer in AArch32 state	
D8.1	About the Generic Timer in AArch32 state.....	2318
D8.2	The AArch32 view of the Generic Timer.....	2322
Chapter D9	AArch32 System Register Encoding	
D9.1	The AArch32 System register encoding space	2328
D9.2	Organization of registers in the (<code>coproc == 0b1110</code>) encoding space.....	2329
D9.3	Organization of registers in the (<code>coproc == 0b1111</code>) encoding space.....	2332
Chapter D10	AArch32 System Register Descriptions	
D10.1	About the AArch32 System registers	2341
D10.2	General system control registers	2355
D10.3	Debug System registers.....	2776
D10.4	Performance Monitors registers.....	2861
D10.5	Generic Timer registers.....	2920
Part E	External Debug	
Chapter E1	About External Debug	
E1.1	Introduction to external debug.....	2962
E1.2	External debug	2963
E1.3	Required debug authentication.....	2964
Chapter E2	Debug State	

E2.1	About Debug state.....	2966
E2.2	Halting the PE on debug events	2967
E2.3	Entering Debug state	2973
E2.4	Behavior in Debug state	2976
E2.5	Exiting Debug state	2992
Chapter E3	Halting Debug Events	
E3.1	Introduction to Halting debug events	2995
E3.2	Halting Step debug events	2997
E3.3	Halt Instruction debug event	3006
E3.4	Exception Catch debug event	3007
E3.5	External Debug Request debug event	3010
E3.6	OS Unlock Catch debug event	3012
E3.7	Reset Catch debug events	3013
E3.8	Software Access debug event	3014
E3.9	Synchronization and Halting debug events	3015
Chapter E4	The Debug Communication Channel and Instruction Transfer Register	
E4.1	Introduction	3017
E4.2	DCC and ITR registers	3018
E4.3	DCC and ITR access modes	3022
E4.4	Flow control of the DCC and ITR registers	3026
E4.5	Synchronization of DCC and ITR accesses	3029
E4.6	Interrupt-driven use of the DCC	3034
E4.7	Pseudocode description of the operation of the DCC and ITR registers	3035
Chapter E5	The Embedded Cross-Trigger Interface	
E5.1	About the Embedded Cross-Trigger	3037
E5.2	Basic operation on the ECT	3039
E5.3	Cross-triggers on a PE in an Arm R-profile implementation	3043
E5.4	Description and allocation of CTI triggers	3044
E5.5	CTI registers programmers' model	3047
E5.6	Examples.....	3048
Chapter E6	Debug Reset and Powerdown Support	
E6.1	About Debug over powerdown	3052
E6.2	Power domains and debug	3053
E6.3	Core power domain power states	3054
E6.4	Powerup request mechanism	3056
E6.5	Emulating low-power states	3057

E6.6	Debug OS Save and Restore sequences	3059
E6.7	Reset and debug	3064
Chapter E7	The PC Sample-based Profiling Extension	
E7.1	About the PC Sample-based Profiling Extension	3067
Chapter E8	About the External Debug Registers	
E8.1	Relationship between external debug and System registers	3070
E8.2	Endianness and supported access sizes.....	3071
E8.3	Synchronization of changes to the external debug registers	3072
E8.4	Memory-mapped accesses to the external debug interface	3076
E8.5	External debug interface register access permissions.....	3078
E8.6	External debug interface registers.....	3081
E8.7	Cross-trigger interface registers	3086
E8.8	External debug register resets	3088
Chapter E9	External Debug Register Descriptions	
E9.1	About the external debug registers.....	3091
E9.2	External debug registers	3092
E9.3	External trace registers	3200
E9.4	Cross-Trigger Interface registers	3201
Part F	Memory-mapped Components of the Arm Architecture	
Chapter F1	Requirements for Memory-mapped Components	
F1.1	Supported access sizes and Endianness	3267
F1.2	Synchronization of memory-mapped registers	3269
F1.3	Access requirements for reserved and unallocated registers	3271
Chapter F2	System Level Implementation of the Generic Timer	
F2.1	About the Generic Timer specification	3273
F2.2	Memory-mapped counter module	3275
F2.3	Memory-mapped timer components	3279
Chapter F3	Recommended External Interface to the Performance Monitors	
F3.1	About the external interface to the Performance Monitors registers	3284
Chapter F4	External System Control Register Descriptions	
F4.1	About the external system control register descriptions	3289
F4.2	External Performance Monitors registers summary	3290
F4.3	Performance Monitors external register descriptions	3292

F4.4	Generic Timer memory-mapped registers overview.....	3360
F4.5	Generic Timer memory-mapped register descriptions	3361

Part G Architectural Pseudocode

Chapter G1 R-profile Architecture Pseudocode

G1.1	Pseudocode for AArch32 operation	3409
G1.2	Shared pseudocode.....	3491

Part H Appendixes

Appendix H1 Architectural Constraints on UNPREDICTABLE Behaviors

H1.1	AArch32 CONSTRAINED UNPREDICTABLE behaviors.....	3648
------	--	------

Appendix H2 Recommendations for Reporting Memory Attributes on an Interconnect

H2.1	Arm recommendations for reporting memory attributes on an interconnect	3666
------	--	------

Appendix H3 Legacy Instruction Syntax for AArch32 Instruction Sets

H3.1	Legacy Instruction Syntax.....	3668
------	--------------------------------	------

Appendix H4 Arm Pseudocode Definition

H4.1	About the Arm pseudocode.....	3675
H4.2	Pseudocode for instruction descriptions.....	3676

Appendix H5 Registers Index

H5.1	Alphabetical index of AArch32 registers and System instructions	3678
H5.2	Functional index of AArch32 registers and System instructions	3685
H5.3	Alphabetical index of memory-mapped registers	3692
H5.4	Functional index of memory-mapped registers.....	3699

Glossary

Preface

This preface introduces the *Arm Architecture Reference Manual, for R-profile AArch32 architecture*. It contains the following sections:

- [About this Manual.](#)
- [Using this Manual.](#)
- [Conventions.](#)
- [Additional reading.](#)
- [Feedback.](#)

About this Manual

This Manual describes the *Arm[®] architecture v8, Armv8 for R-profile AArch32 architecture*. It supersedes and replaces DDI0568 *Arm[®] Architecture Reference Manual Supplement - Armv8, for Armv8-R AArch32 architecture profile*. DDI0568 is deprecated.

This issue of the Manual contains many improvements and corrections.

The features implemented by the R-profile architecture are described in [R-profile Architecture Extensions](#). The following sections contain references to features that are not implemented in Armv8-R-compliant Processing Elements (PEs). These references can be ignored when interpreting the architecture for Armv8-R:

- The [Ordering requirements defined by the formal concurrency model](#). This is to ensure that the memory model is conformant with the [formal concurrency model](#).
- The [AArch32 System Register Descriptions](#).
- The [AArch32 Instruction Sets](#).
- The [PMU Event Descriptions](#).

Validation of this document has identified the following issues that Arm will address in future issues:

- Some diagrams in the register descriptions chapter have long field names that split over several lines. These are not wrong, and the descriptions list the field name correctly.
- [Arm Pseudocode Definition](#) requires further review and update. Since this appendix is informative, rather than being part of the architecture specification, this does not affect the quality status of this release.

The architecture describes the operation of an Armv8-R AArch32 architecture [Processing element \(PE\)](#), and this Manual includes descriptions of:

- The Execution state AArch32.
- The T32 and A32 instruction sets, which are compatible with earlier versions of the Arm architecture.
- The states that determine how a PE operates, including the current Exception level and Security state, and the PE mode.
- The Exception model.
- The memory model, that defines memory ordering and memory management. This Manual covers the Arm R-profile architecture profile that defines a *Protected Memory System Architecture* (PMSA).
- The programmers' model, and its interfaces to System registers that control most PE and memory system features, and provide status information.
- The Advanced SIMD and floating-point instructions, which provide high-performance:
 - Single-precision, half-precision, and double-precision floating-point operations.
 - Conversions between double-precision, single-precision, and half-precision floating-point values.
 - Integer, single-precision floating-point, and half-precision floating-point vector operations in all instruction sets.
- The Debug architecture, which provides software access to debug features.

This Manual gives the assembler syntax for the instructions it describes, meaning that it describes instructions in textual form. However, this Manual is not a tutorial for Arm assembler language, nor does it describe Arm assembler language, except at a basic level. To make effective use of Arm assembler language, read the documentation supplied with the assembler being used.

This Manual is organized into parts:

Part A Provides an introduction to the Arm architecture, and an overview of the AArch32 Execution state.

Part B Describes the application level view of the AArch32 Execution state, meaning the view from the EL0. It describes the application level view of the programmers' model and the memory model.

———— **Note** —————

In AArch32 state, execution at EL0 is execution in User mode.

Part C Describes the T32 and A32 instruction sets, which are available in the AArch32 Execution state. These instruction sets are backwards-compatible with earlier versions of the Arm architecture. This part describes the precise effects of each instruction when executed in User mode, described as *unprivileged* execution or execution at EL0, including any restrictions on its use, and how the effects of the instruction differ at higher Exception levels. This information is of primary importance to authors and users of compilers, assemblers, and other programs that generate Arm machine code.

Note

User mode is the only mode where software execution is unprivileged.

Part D Describes the system level view of the AArch32 Execution state, which is generally compatible with earlier versions of the Arm architecture. This part includes details of the System registers, most of which are not accessible from EL0, and the instruction interface to those registers. It also describes the system level view of the programmers' model and the memory model.

Part E Describes the Debug architecture for external debug. This provides configuration, breakpoint and watchpoint support, and a *Debug Communications Channel* (DCC) to a debug host.

Part F Describes additional features of the architecture that are not closely coupled to a PE, and therefore are accessed through memory-mapped interfaces. Some of these features are OPTIONAL.

Part G Provides pseudocode that describes various features of the Arm architecture.

Part H, Appendixes Provide additional information. Some appendixes give information that is not part of the A-profile architectural requirements. The cover page of each appendix indicates its status.

Glossary Defines terms used in this Manual that have a specialized meaning.

Note

Terms that are generally well understood in the microelectronics industry are not included in the Glossary.

Using this Manual

The information in this Manual is organized into parts, as described in this section.

Part A, Introduction and Architecture Overview

Part A gives an overview of the Armv8-R for AArch32 architecture profile. It introduces the terminology used to describe the architecture. It contains the following chapters:

Introduction to the Arm Architecture

Read this for an introduction to the Arm architecture.

R-profile AArch32 Architecture Extensions

Read this for an introduction to the R-profile AArch32 architecture extensions and features.

Part B, The AArch32 Application Level Architecture

Part B describes the AArch32 state application level view of the architecture. It contains the following chapters:

The AArch32 Application Level Programmers' Model

Read this for an application level description of the programmers' model for software executing in AArch32 state. It describes execution at EL0 when EL0 is using AArch32 state.

The AArch32 Application Level Memory Model

Read this for an application level description of the memory model for software executing in AArch32 state. It describes the memory model for execution in EL0 when EL0 is using AArch32 state. It includes information about Arm memory types, attributes, and memory access controls.

Part C, The AArch32 Instruction Sets

Part C describes the T32 and A32 instruction sets, which are used in AArch32 state. It contains the following chapters:

About the T32 and A32 Instruction Descriptions

Read this to understand the format of the T32 and A32 instruction descriptions.

The AArch32 Instruction Sets Overview

Read this for an overview of the T32 and A32 instruction sets.

T32 Instruction Set Encoding

Read this for a description of the T32 instruction set encoding. This includes the T32 encoding of the Advanced SIMD and floating-point instructions.

A32 Instruction Set Encoding

Read this for a description of the A32 instruction set encoding. This includes the A32 encoding of the Advanced SIMD and floating-point instructions.

T32 and A32 Base Instruction Set Instruction Descriptions

Read this for a description of each of the T32 and A32 base instructions.

T32 and A32 Advanced SIMD and Floating-point Instruction Descriptions

Read this for a description of each of the T32 and A32 Advanced SIMD and floating-point instructions.

Part D, The AArch32 System Level Architecture

Part D describes the AArch32 state system level view of the architecture. It contains the following chapters:

The AArch32 System Level Programmers' Model

Read this for a description of the AArch32 state system level view of the programmers' model for execution in an Exception level that is using AArch32.

AArch32 Self-hosted Debug

Read this for an introduction to, and a description of, self-hosted debug in AArch32 state.

AArch32 Self-hosted Trace

Read this for an introduction to, and a description of, self-hosted trace in AArch32 state.

The AArch32 System Level Memory Model

Read this for a system level view of the general features of the memory system.

The Generic Timer in AArch32 state

Read this for a description of the AArch32 view of an implementation of the Arm Generic Timer.

AArch32 System Register Encoding

Read this for a description of the encoding of the AArch32 System registers, including the System instructions that are part of the AArch32 System registers encoding space.

AArch32 System Register Descriptions

Read this for a description of each of the AArch32 System registers.

Part E, External Debug

Part E describes the architecture for external debug. It contains the following chapters:

About External Debug

Read this for an introduction to external debug, and a definition of the scope of this part of the Manual.

Debug State

Read this for a description of Debug state, which the PE might enter as the result of a Halting debug event.

Halting Debug Events

Read this for a description of the external debug events referred to as Halting debug events.

The Debug Communication Channel and Instruction Transfer Register

Read this for a description of the communication between a debugger and the PE debug logic using the Debug Communications Channel and the Instruction Transfer register.

The Embedded Cross-Trigger Interface

Read this for a description of the Embedded Cross-Trigger Interface.

Debug Reset and Powerdown Support

Read this for a description of reset and powerdown support in the Debug architecture.

The PC Sample-based Profiling Extension

Read this for a description of the PC Sample-based Profiling Extension that is an OPTIONAL extension.

About the External Debug Registers

Read this for some additional information about the external debug registers.

External Debug Register Descriptions

Read this for a description of each external debug register.

Part F, Memory-mapped Components of the Arm architecture

Part IF describes the memory-mapped components in the architecture. It contains the following chapters:

Requirements for Memory-mapped Components

Read this for descriptions of some general requirements for memory-mapped components within a system that complies with the Arm architecture.

System Level Implementation of the Generic Timer

Read this for a definition of a system level implementation of the Generic Timer.

Recommended External Interface to the Performance Monitors

Read this for a description of the recommended memory-mapped and external debug interfaces to the Performance Monitors.

External System Control Register Descriptions

Read this for a description of each memory-mapped system control register.

Part G, Architectural Pseudocode

Part G contains pseudocode that describes various features of the Arm architecture. It contains the following chapter:

R-profile Architecture Pseudocode

Read this for the pseudocode definitions that describe various features of the Arm architecture, for operation in AArch32 state.

Part H, Appendixes

Note

Some of the descriptions in the following appendixes are not part of the Arm architecture specification. They are included here as supplementary information, for the convenience of developers and users who might require this information.

This Manual contains the following appendixes:

Architectural Constraints on UNPREDICTABLE Behaviors

Read this for a description of the architecturally-required constraints on UNPREDICTABLE behaviors in the Arm architecture, including AArch32 behaviors that were UNPREDICTABLE in previous versions of the architecture.

Arm Pseudocode Definition

Read this for definitions of the Arm pseudocode.

Registers Index

Read this for an alphabetic and functional index of AArch32 registers, and memory-mapped registers.

Glossary

Defines terms used in this Manual that have a specialized meaning.

Note

Terms that are well understood in the microelectronics industry are not included in the Glossary.

Conventions

The following sections describe conventions that this book can use:

- [Typographic conventions.](#)
- [Rules-based writing.](#)
- [Signals.](#)
- [Numbers.](#)
- [Pseudocode descriptions.](#)
- [Assembler syntax descriptions.](#)

Typographic conventions

The typographical conventions are:

<i>italic</i>	Introduces special terminology, and denotes citations.
bold	Denotes signal names, and is used for terms in descriptive lists, where appropriate.
<code>monospace</code>	Used for assembler syntax descriptions, pseudocode, and source code examples. Also used in the main text for instruction mnemonics and for references to other items appearing in assembler syntax descriptions, pseudocode, and source code examples.

SMALL CAPITALS

Used in body text for a few terms that have specific technical meanings, and are defined in the [Glossary](#).

Colored text	Indicates a link. This can be: • A URL, for example https://developer.arm.com. • A link, to a chapter or appendix, or to a glossary entry, or to the section of the Manual that defines the colored term, for example Simple sequential execution or SCTLR.
---------------------	---

{ and }	Braces, { and }, have two distinct uses:
----------------	--

Optional items

In syntax descriptions braces enclose optional items. In the following example they indicate that the `<shift>` parameter is optional:

```
ADD <Wd|WSP>, <Wn|WSP>, #<imm>{, <shift>}
```

Similarly, they can be used in generalized field descriptions, for example `TCR_ELx.{I}PS` refers to a field in the `TCR_ELx` registers that is called either `IPS` or `PS`.

Sets of items

Braces can be used to enclose sets. For example, `HCR_EL2.{E2H, TGE}` refers to a set of two register fields, `HCR_EL2.E2H` and `HCR_EL2.TGE`.

Notes	Notes are formatted as:
--------------	-------------------------

Note

This is a Note.

In this Manual, Notes are used only to provide additional information, usually to help understanding of the text. While a Note might repeat architectural information given elsewhere in the Manual, a Note never provides any part of the definition of the architecture.

Rules-based writing

Some sections of this Manual use rules-based writing. Rules-based writing consists of a set of individual content items. A content item is classified as one of the following:

- Rule.
- Information.
- Software usage.
- Declaration.

Rules are normative statements. An implementation that is compliant with this specification must conform to all Rules in this Manual that apply to that implementation.

Rules must not be read in isolation. Where a particular feature is specified by multiple Rules, these are generally grouped into sections and subsections that provide context. Where appropriate, these sections begin with a short introduction.

Arm strongly recommends that implementers read all chapters and sections of this Manual to ensure that an implementation is compliant.

Content items other than Rules are informative statements. These are provided as an aid to understanding this Manual.

Content item identifiers

A content item may have an associated identifier which is unique among content items in this Manual. After content reaches beta status, a given content item has the same identifier across subsequent versions of this Manual.

Content item rendering

In this Manual, a content item is rendered with a token of the following format in the left margin: L_{iiii}. L is a label that indicates the content class of the content item. iiii is the identifier of the content item.

Content item classes

Each of the content item classes has a different function in this Manual.

Rule

A Rule is a statement that describes the behavior of a compliant implementation.

A Rule explains what happens in a particular situation.

A Rule does not define concepts or terminology.

A Rule is rendered with the label R.

Information

An Information statement provides information and guidance as an aid to understanding the Manual.

An Information statement is rendered with the label I.

Software usage

A Software usage statement provides guidance on how software can make use of the features defined by the specification.

A Software usage statement is rendered with the label S.

Declaration

A Declaration statement introduces concepts or terminology.

A Declaration does not describe behavior.

A Declaration is rendered with the label D.

Signals

In general this specification does not define hardware signals, but it does include some signal examples and recommendations. The signal conventions are:

- Signal level** The level of an asserted signal depends on whether the signal is active-HIGH or active-LOW. Asserted means:
- HIGH for active-HIGH signals.
 - LOW for active-LOW signals.
- Lowercase n** At the start or end of a signal name denotes an active-LOW signal.

Numbers

Numbers are normally written in decimal. Binary numbers are preceded by `0b`, and hexadecimal numbers by `0x`. In both cases, the prefix and the associated value are written in a `monospace` font, for example `0xFFFF_0000`. To improve readability, long numbers can be written with an underscore separator between every four characters, for example `0xFFFF_0000_0000_0000`. Ignore any underscores when interpreting the value of a number.

Pseudocode descriptions

This Manual uses a form of pseudocode to provide precise descriptions of the specified functionality. This pseudocode is written in `monospace` font, and is described in [Arm Pseudocode Definition](#).

Assembler syntax descriptions

This Manual contains numerous syntax descriptions for assembler instructions and for components of assembler instructions. These are shown in a `monospace` font, and use the conventions described in Structure of the A64 assembler language, and [Arm Pseudocode Definition](#).

Additional reading

This section lists relevant publications from Arm and third parties.

See Arm Developer, <https://developer.arm.com>, for access to Arm documentation.

Feedback

Arm welcomes feedback on its documentation.

Feedback on this Manual

If you have any comments or queries about this Manual, create a ticket at <https://support.developer.arm.com>.

As part of the ticket, include:

- The title, Arm® Architecture Reference Manual, for R-profile AArch32 architecture.
- The number, DDI 111353 A.a.
- The section name to which your comments refer.
- The page number(s) to which your comments refer.
- The rule identifier(s) to which your comments refer, if applicable.
- A concise explanation of your comments.

Arm also welcomes general suggestions for additions and improvements.

Note

Arm tests PDFs only in Adobe Acrobat and Acrobat Reader, and cannot guarantee the appearance or behavior of any document when viewed with any other PDF reader. Search performance may be significantly improved by increasing the Fast Find Maximum Cache Size under Search in Preferences.

If using Google Chrome™ or Microsoft Edge™, load time is significantly improved since the April 2025 release of these browsers.

Users may find, on some systems, that PDF viewers such as Okular or Foxit™ give good performance.

Inclusive terminology commitment

Arm values inclusive communities. Arm recognizes that we and our industry have used terms that can be offensive. Arm strives to lead the industry and create change.

Previous issues of this document included language that can be offensive. We have replaced this language. To report offensive language in this document, email terms@arm.com.

Part A **Arm Architecture Introduction and Overview**

Chapter A1

Introduction to the Arm Architecture

This chapter introduces the Arm architecture. It contains the following sections:

- [About the Arm architecture.](#)
- [Architecture profiles.](#)
- [Arm architectural concepts.](#)
- [Supported data types.](#)
- [Floating-point support.](#)
- [The Arm memory model.](#)

A1.1 About the Arm architecture

The Arm architecture described in this Architecture Reference Manual defines the behavior of an abstract machine, referred to as a *processing element*, often abbreviated to *PE*. Implementations compliant with the Arm architecture must conform to the described behavior of the processing element. It is not intended to describe how to build an implementation of the PE, nor to limit the scope of such implementations beyond the defined behaviors.

Except where the architecture specifies differently, the programmer-visible behavior of an implementation that is compliant with the Arm architecture must be the same as a simple sequential execution of the program on the processing element. The programmer-visible behavior does not include a specified execution time for any instruction but requires each instruction to execute in finite time, as long as another observer is not continually modifying any Location associated with a Memory Effect, other than an Explicit Memory Effect, that is architecturally required for execution of the instruction. In cases where another observer is continually modifying a Location associated with a Memory Effect, other than an Explicit Memory Effect, at least one of the observers must make forward progress in finite time. Unless otherwise specified, the architecturally defined effects of each instruction also complete in finite time.

The Arm Architecture Reference Manual also describes rules for software to use the PE.

The Arm architecture includes definitions of:

- An associated debug architecture, see:
 - [AArch32 Self-hosted Debug](#).
 - External Debug.
- Associated trace architectures that define trace units that implementers can implement with the associated processor hardware. For more information, see *The Arm® Embedded Trace Macrocell Architecture Specification, ETMv4* (ARM IHI 0064).

The Arm architecture is a *Reduced Instruction Set Computer* (RISC) architecture with the following RISC architecture features:

- A large uniform register file.
- A *load/store* architecture, where data-processing operations only operate on register contents, not directly on memory contents.
- Simple addressing modes, with all load/store addresses determined from register contents and instruction fields only.

The architecture defines the interaction of the PE with memory, including caches, and includes a memory translation system. It also describes how multiple PEs interact with each other and with other observers in a system.

This document defines version 8 of the R-profile AArch32 architecture.

See [Architecture profiles](#) for more information.

The Arm architecture supports implementations across a wide range of performance points. Implementation size, performance, and very low power consumption are key attributes of the Arm architecture.

An important feature of the Arm architecture is backward compatibility, combined with the freedom for optimal implementation in a wide range of standard and more specialized use cases.

The Arm architecture supports a 32-bit Execution state, AArch32, that is compatible with previous versions of the Arm architecture.

Features that are optional are explicitly defined as such in this Manual.

Note

The presence of an ID register field for a feature does not imply that the feature is optional.

The Arm architecture supports Scalar floating-point instructions that operate on registers in the SIMD&FP register file.

Note

See [Conventions](#) for information about conventions used in this Manual, including the use of SMALL CAPITALS for particular terms that have Arm-specific meanings that are defined in the Glossary.

A1.2 Architecture profiles

The Arm architecture has evolved significantly since its introduction, and Arm continues to develop it. Nine major versions of the architecture have been defined to date, denoted by the version numbers 1 to 9. The R-profile AArch32 architecture is based on the Armv8 architectural features.

The generic names AArch64 and AArch32 describe the 64-bit and 32-bit Execution states:

AArch64 Is the 64-bit Execution state, meaning addresses are held in 64-bit registers, and instructions in the base instruction set can use 64-bit registers for their processing. AArch64 state supports the A64 instruction set.

AArch32 Is the 32-bit Execution state, meaning addresses are held in 32-bit registers, and instructions in the base instruction sets use 32-bit registers for their processing. AArch32 state supports the T32 and A32 instruction sets.

Note
The *Base instruction set* comprises the supported instructions other than the floating-point instructions.

See sections [Execution state](#) and [The instruction sets](#) for more information.

Arm defines three architecture profiles:

- A** Application profile:
- Supports a *Virtual Memory System Architecture* (VMSA) based on a *Memory Management Unit* (MMU).
-
- Note**
An Armv8-A implementation can be called an AArchv8-A implementation and an Armv9-A implementation can be called an AArchv9-A implementation.
-
- Supports the A64, A32, and T32 instruction sets.
- R** Real-time profile, described in this Manual:
- Supports a *Protected Memory System Architecture* (PMSA) based on a *Memory Protection Unit* (MPU).
 - Supports an optional VMSA based on an MMU in the R-profile AArch64 architecture.
 - Supports the A64 instruction set if the R-profile AArch64 architecture is implemented, or the A32 and T32 instruction sets if the R-profile AArch32 architecture is implemented.
- M** Microcontroller profile:
- Implements a programmers' model designed for low-latency interrupt processing, with hardware stacking of registers and support for writing interrupt handlers in high-level languages.
 - Supports a PMSA based on an MPU.
 - Supports a variant of the T32 instruction set.

This Manual describes only Armv8-R AArch32. For information about the A, R AArch64 and M architecture profiles, and earlier Arm architecture versions, see:

- The *Arm[®] Architecture Reference Manual, for A-profile architecture*.
- The *Arm[®] Architecture Reference Manual, for Armv8-R AArch64 architecture profile*.
- The *ARM[®] Architecture Reference Manual ARMv7-A and ARMv7-R edition*.
- The *Armv8-M Architecture Reference Manual*.
- The *Armv7-M Architecture Reference Manual*.
- The *ARMv6-M Architecture Reference Manual*.

A1.3 Arm architectural concepts

This section introduces architectural concepts and the associated terminology.

The following subsections describe key architectural concepts. Each section introduces the corresponding terms that are used to describe the architecture:

- [Execution state](#).
- [The instruction sets](#).
- [System registers](#).
- [Arm Debug](#).

A1.3.1 Execution state

The Execution state defines the PE execution environment, including:

- The supported register widths.
- The supported instruction sets.
- Significant aspects of:
 - The Exception model.
 - The programmers' model.

The Execution state is:

- AArch32** The 32-bit Execution state. This Execution state:
- Provides 13 32-bit general-purpose registers, and a 32-bit PC, SP, and *Link Register* (LR). The LR is used as both an ELR and a procedure link register. Some of these registers have multiple *banked* instances for use in different PE *modes*.
 - Provides a single ELR, for exception returns from Hyp mode.
 - Provides 32 64-bit registers for Advanced SIMD vector and scalar floating-point support.
 - Provides two instruction sets, T32 and A32. For more information, see [The instruction sets](#).
 - Supports the Armv7-A Exception model, based on *PE modes*, and maps this onto the Armv8 Exception model, that is based on the Exception levels.
 - Provides support for 32-bit virtual addressing.
 - Defines a number of *Process state* (**PSTATE**) elements that hold PE state. The T32 and A32 instruction sets include instructions that operate directly on various **PSTATE** elements, and instructions that access **PSTATE** by using the *Application Program Status Register* (APSR) or the *Current Program Status Register* (CPSR).

A1.3.2 Security state

The architecture defines one *Security state*, Non-secure state.

A1.3.3 The instruction sets

The possible instruction sets depend on the Execution state:

- AArch32** AArch32 state supports the following instruction sets:
- | | |
|------------|---|
| A32 | This is a fixed-length instruction set that uses 32-bit instruction encodings. |
| T32 | This is a variable-length instruction set that uses both 16-bit and 32-bit instruction encodings. |

In previous documentation, these instruction sets were called the ARM and Thumb[®] instruction sets. Armv8 and Armv9 extend each of these instruction sets. In AArch32 state, the Instruction set state determines the instruction set that the PE executes.

For information on the T32 and A32 instruction sets, see [The AArch32 Instruction Sets Overview](#).

The instruction sets support SIMD and scalar floating-point instructions. See [Floating-point support](#).

A1.3.4 System registers

System registers provide control and status information of architected features.

The System registers use a standard naming format: <register_name>.<bit_field_name> to identify specific registers as well as control and status bits within a register.

Bits can also be described by their numerical position in the form <register_name>[x:y] or the generic form bits[x:y].

For information about Exception levels, see Exception levels.

The System registers comprise:

- The following registers that are described in this Manual:
 - General system control registers.
 - Debug registers.
 - Generic Timer registers.
 - Optionally, Performance Monitor registers.
- Optionally, one or more of the following groups of registers that are defined in other Arm architecture specifications:
 - Trace System registers, as defined in the *Arm[®] Embedded Trace Macrocell Architecture Specification, ETMv4*.
 - *Generic Interrupt Controller (GIC) System registers*, see [The Arm Generic Interrupt Controller System registers](#).

For information about the AArch32 System registers, see [AArch32 System Register Descriptions](#).

A1.3.4.1 The Arm Generic Interrupt Controller System registers

From version 3 of the Arm Generic Interrupt Controller architecture, GICv3, the GIC architecture specification defines a System register interface to some of its functionality. The System register summaries in this Manual include these registers, see:

- [About the GIC System registers](#), for more information about the AArch32 GIC System registers.

This section gives only short overviews of the GIC System registers. For more information, including descriptions of the registers, see the *Arm[®] Generic Interrupt Controller Architecture Specification, GIC architecture version 3 and version 4* (ARM IHI 0069).

Note

The programmers' model for earlier versions of the GIC architecture is wholly memory-mapped.

A1.3.5 Arm Debug

Armv8 and later architectures support the following:

Self-hosted debug

In this model, the PE generates *debug exceptions*. Debug exceptions are part of the Armv8 Exception model.

External debug

In this model, *debug events* cause the PE to enter *Debug state*. In Debug state, the PE is controlled by an external debugger.

All Armv8 and later implementations support both models. The model chosen by a particular user depends on the debug requirements during different stages of the design and development life cycle of the product. For example, external debug might be used during debugging of the hardware implementation and OS bring-up, and self-hosted debug might be used during application development.

For more information about self-hosted debug, see [AArch32 Self-hosted Debug](#).

For more information about external debug, see [External Debug](#).

A1.4 Supported data types

The Arm architecture supports the following integer data types:

Byte	8 bits.
Halfword	16 bits.
Word	32 bits.
Doubleword	64 bits.
Quadword	128 bits.

The architecture also supports the following floating-point data types:

- Half-precision. See [Half-precision floating-point formats](#).
- Single-precision. See [Single-precision floating-point format](#).
- Double-precision. See [Double-precision floating-point format](#).

It also supports vectors, where a register holds a vector of multiple elements, each the same size and data type. See [Advanced SIMD vector formats](#)

The architecture provides the following:

- A general-purpose register file.
- A SIMD&FP register file.

In AArch32 state:

- The general-purpose register file contains 32-bit registers:
 - Two 32-bit registers can support a doubleword.
 - Vector formatting is supported, see [Figure A1-3](#).
- The SIMD&FP register file contains 64-bit registers:
 - AArch32 state does not support quadword integer or floating-point data types.

Note

Two consecutive 64-bit registers can be used as a 128-bit register.

For more information on the register files in AArch32 state, see [The general-purpose registers, and the PC, in AArch32 state](#).

A1.4.1 Advanced SIMD vector formats

In an implementation that includes the Advanced SIMD instructions that operate on the SIMD&FP register file, a register can hold one or more packed elements, all of the same size and type. In AArch32 state, the combination of a register and a data type describes a vector of elements, where the number of elements in the vector is implied by the size of the data type and the size of the register.

Vector indices are in the range 0 to (number of elements - 1). An index of 0 refers to the least significant bits of the vector.

For more information on the Advanced SIMD and floating-point registers in AArch32 state, see [The SIMD and floating-point register file](#).

A1.4.1.1 Advanced SIMD vector formats in AArch32 state

Table A1-1 shows the available formats. Each instruction description specifies the data types that the instruction supports.

Table A1-1 Advanced SIMD data types in AArch32 state

Data type specifier	Meaning
.<size>	Any element of <size> bits
.F<size>	Floating-point number of <size> bits
.I<size>	Signed or unsigned integer of <size> bits
.P<size>	Polynomial over {0, 1} of degree less than <size>
.S<size>	Signed integer of <size> bits
.U<size>	Unsigned integer of <size> bits

Polynomial arithmetic over {0, 1} describes the polynomial data type.

The .F16 data type is the half-precision data type selected by the FPSCR.AHP bit, see [Half-precision floating-point formats](#).

The .F32 data type is the Arm standard single-precision floating-point data type, see [Single-precision floating-point format](#).

The instruction definitions use a data type specifier to define the data types appropriate to the operation. Figure A1-1 shows the hierarchy of the Advanced SIMD data types.

.8	.I8	.S8
		.U8
	.P8	
	-

	.P64 ‡	
	-	

† Output format only. See VMULL instruction description.

‡ Available only if the Cryptographic Extension is implemented. See VMULL instruction description.

Figure A1-1 Advanced SIMD data type hierarchy in AArch32 state

For example, a multiply instruction must distinguish between integer and floating-point data types.

An integer multiply instruction that generates a double-width (long) result must specify the input data types as signed or unsigned. However, some integer multiply instructions use modulo arithmetic, and therefore do not have to distinguish

between signed and unsigned inputs.

Figure A1-2 shows the Advanced SIMD vectors in AArch32 state.

Note

In AArch32 state, a pair of even and following odd numbered doubleword registers can be concatenated and treated as a single quadword register.

Figure A1-2 Advanced SIMD vectors in AArch32 state

The AArch32 general-purpose registers support vectors formats for use by the SIMD instructions in the Base instruction set. Figure A1-3 shows these formats, that means that a general-purpose register can be treated as either 2 halfwords or 4 bytes.

Figure A1-3 Vector formatting in AArch32 state

A1.4.2 Half-precision floating-point formats

The Arm architecture supports two half-precision floating-point formats:

- IEEE half-precision, as described in the IEEE 754-2008 standard.

- Arm *alternative half-precision* format.

Both formats can be used for conversions to and from other floating-point formats.

[FPSCR.AHP](#) controls the format in AArch32 state.

The description of IEEE half-precision includes Arm-specific details that are left open by the standard, and is only an introduction to the formats and to the values they can contain. For more information, especially on the handling of infinities, NaNs, and signed zeros, see the IEEE 754 standard.

For both half-precision floating-point formats, the layout of the 16-bit format is the same. The format is:

The interpretation of the format depends on the value of the exponent field, bits[14:10] and on which half-precision format is being used.

0 < exponent < 0x1F

The value is a normalized number and is equal to:

$$(-1)^S \times 2^{(\text{exponent}-15)} \times (1.\text{fraction})$$

The minimum positive normalized number is 2^{-14} , or approximately 6.104×10^{-5} .

The maximum positive normalized number is $(2 - 2^{-10}) \times 2^{15}$, or 65504.

Larger normalized numbers can be expressed using the alternative format when the exponent == 0x1F.

exponent == 0

The value is either a zero or a denormalized number, depending on the fraction bits:

fraction == 0

The value is a zero. There are two distinct zeros:

+0 when S==0.

-0 when S==1.

fraction != 0

The value is a denormalized number and is equal to:

$$(-1)^S \times 2^{-14} \times (0.\text{fraction})$$

The minimum positive denormalized number is 2^{-24} , or approximately 5.960×10^{-8} .

Half-precision denormalized numbers are not flushed to zero by default. For details, see [Flushing denormalized numbers to zero](#).

exponent == 0x1F

The value depends on which half-precision format is being used:

IEEE half-precision

The value is either an infinity or a Not a Number (NaN), depending on the fraction bits:

fraction == 0

The value is an infinity. There are two distinct infinities:

+infinity When $S=0$. This represents all positive numbers that are too big to be represented accurately as a normalized number.

-infinity When $S=-1$. This represents all negative numbers with an absolute value that is too big to be represented accurately as a normalized number.

fraction := 0

The value is a NaN, and is either a *quiet NaN* or a *signaling NaN*.

The two types of NaN are distinguished by their most significant fraction bit, bit[9]:

bit[9] == 0 The NaN is a signaling NaN. The sign bit can take any value, and the remaining fraction bits can take any value except all zeros.

bit[9] == 1 The NaN is a quiet NaN. The sign bit and remaining fraction bits can take any value.

Alternative half-precision

The value is a normalized number and is equal to:

$$-1^S \times 2^{16} \times (1.\text{fraction})$$

The maximum positive normalized number is $(2 \cdot 2^{-10}) \times 2^{16}$ or 131008.

A1.4.3 Single-precision floating-point format

The single-precision floating-point format is as defined by the IEEE 754 standard.

This description includes Arm-specific details that are left open by the standard. It is only intended as an introduction to the formats and to the values they can contain. For full details, especially of the handling of infinities, NaNs, and signed zeros, see the IEEE 754 standard.

A single-precision value is a 32-bit word with the format:

The interpretation of the format depends on the value of the exponent field, bits[30:23]:

$$0 < \text{exponent} < 0_{\text{xFF}}$$

The value is a normalized number and is equal to:

$$(-1)^S \times 2^{(\text{exponent} - 127)} \times (1.\text{fraction})$$

The minimum positive normalized number is 2^{-126} , or approximately 1.175×10^{-38} .

The maximum positive normalized number is $(2 - 2^{-23}) \times 2^{127}$, or approximately 3.403×10^{38} .

exponent == 0

The value is either a zero or a denormalized number, depending on the fraction bits:

fraction == 0

The value is a zero. There are two distinct zeros:

+0 When $S=0$.

-0 When $S=1$.

These usually behave identically. In particular, the result is *equal* if +0 and -0 are compared as floating-point numbers. However, they yield different results in some circumstances. For example, the sign of the infinity produced as the result of dividing by zero depends on the sign of the zero. The two zeros can be distinguished from each other by performing an integer comparison of the two words.

fraction != 0

The value is a denormalized number and is equal to:

$$(-1)^S \times 2^{-126} \times (0.\text{fraction})$$

The minimum positive denormalized number is 2^{-149} , or approximately 1.401×10^{-45} .

Denormalized numbers are always flushed to zero in Advanced SIMD processing in AArch32 state. are optionally flushed to zero in floating-point processing and in Advanced SIMD processing in AArch64 state. For details, see [Flushing denormalized numbers to zero](#).

exponent == 0xFF

The value is either an *infinity* or a *Not a Number* (NaN), depending on the fraction bits:

fraction == 0

The value is an infinity. There are two distinct infinities:

+infinity When $S=0$. This represents all positive numbers that are too big to be represented accurately as a normalized number.

-infinity When $S=1$. This represents all negative numbers with an absolute value that is too big to be represented accurately as a normalized number.

fraction != 0

The value is a NaN, and is either a *quiet NaN* or a *signaling NaN*.

The two types of NaN are distinguished by their most significant fraction bit, bit[22]:

bit[22] == 0

The NaN is a signaling NaN. The sign bit can take any value, and the remaining fraction bits can take any value except all zeros.

bit[22] == 1

The NaN is a quiet NaN. The sign bit and remaining fraction bits can take any value.

For details of the *default NaN*, see [Default NaN](#).

Note

NaNs with different sign or fraction bits are distinct NaNs, but this does not mean software can use floating-point comparison instructions to distinguish them. This is because the IEEE 754 standard specifies that a NaN compares as *unordered* with everything, including itself.

A1.4.4 Double-precision floating-point format

The double-precision floating-point format is as defined by the IEEE 754 standard.

Double-precision floating-point is supported only by floating-point instructions.

This description includes IMPLEMENTATION SPECIFIC details that are left open by the standard. It is only intended as an introduction to the formats and to the values they can contain. For full details, especially of the handling of infinities, NaNs, and signed zeros, see the IEEE 754 standard.

A double-precision value is a 64-bit doubleword, with the format:

Double-precision values represent numbers, infinities, and NaNs in a similar way to single-precision values, with the interpretation of the format depending on the value of the exponent:

$$0 < \text{exponent} < 0x7F$$

The value is a normalized number and is equal to:

$$(-1)^S \times 2^{(\text{exponent}-1023)} \times (1.\text{fraction})$$

The minimum positive normalized number is 2^{-1022} , or approximately 2.225×10^{-308} .

The maximum positive normalized number is $(2 - 2^{-52}) \times 2^{1023}$, or approximately 1.798×10^{308} .

exponent == 0

The value is either a zero or a denormalized number, depending on the fraction bits:

fraction == 0

The value is a zero. There are two distinct zeros that behave in the same way as the two single-precision zeros:

$$+0 \quad \text{when } S=0.$$

-0 when $S=1$.

fraction **!= 0**

The value is a denormalized number and is equal to:

$$(-1)^S \times 2^{-1022} \times (0.\text{fraction})$$

The minimum positive denormalized number is 2^{-1074} , or approximately 4.941×10^{-324} .

Optionally, denormalized numbers are flushed to zero in floating-point calculations. For details, see [Flushing denormalized numbers to zero](#).

```
exponent == 0x7FF
```

The value is either an infinity or a NaN, depending on the fraction bits:

fraction == 0

The value is an infinity. As for single-precision, there are two infinities:

+infinity When $S=0$.

-infinity When $S=1$.

fraction **!= 0**

The value is a NaN, and is either a *quiet NaN* or a *signaling NaN*.

The two types of NaN are distinguished by their most significant fraction bit, bit[51] of the doubleword:

bit[51] == 0

The NaN is a signaling NaN. The sign bit can take any value, and the remaining fraction bits can take any value except all zeros.

bit[51] == 1

The NaN is a quiet NaN. The sign bit and the remaining fraction bits can take any value.

For details of the *default NaN*, see [Default NaN](#).

Note

NaNs with different sign or fraction bits are distinct NaNs, but this does not mean software can use floating-point comparison instructions to distinguish them. This is because the IEEE 754 standard specifies that a NaN compares as *unordered* with everything, including itself.

A1.4.5 Conversion between floating-point and fixed-point values

The Arm architecture supports the conversion of a scalar floating-point value to or from a signed or unsigned fixed-point value in a general-purpose register. Conversion instructions take an argument, *#fbits*, that specifies the number of fraction bits in the fixed-point number. That is, *#fbits* indicates that the general-purpose register holds a fixed-point number with *fbits* bits after the binary point, where *fbits* is in the range 1 to 32 for a 32-bit general-purpose register:

- For a 32-bit register W_d or R_d :
 - The integer part is $W_d[31:\text{\#fbits}]$ or $R_d[31:\text{\#fbits}]$.
 - The fractional part is $W_d[(\text{\#fbits}-1):0]$ or $R_d[(\text{\#fbits}-1):0]$.

These instructions can cause the following floating-point exceptions:

Invalid Operation When the floating-point input is NaN or Infinity or when a numerical value cannot be represented within the destination register.

Inexact When the numeric result differs from the input value.

Input Denormal When flushing denormalized numbers to zero is enabled and the denormal input is replaced by a zero, see [Flushing denormalized numbers to zero](#) and Input Denormal exceptions.

Note

An out of range fixed-point result is saturated to the destination size.

For more information, see [Floating-point exceptions and exception traps](#).

A1.5 Floating-point support

The Armv8 architecture includes Scalar floating-point instructions that operate on the lowest numbered element of the SIMD&FP registers.

Armv8-R AArch32 also supports single-precision floating-point implementations without Advanced SIMD.

If an implementation supports only single-precision floating-point operations and does not support Advanced SIMD, then it must implement only 16 double-precision registers, D0-D15, that is, it must be a D16 implementation.

For more information about the permitted floating-point and Advanced SIMD support, see [MVFR0](#), [MVFR1](#) and [MVFR2](#).

The definitions of [HCPTR.TASE](#), [NSACR](#), and [CPACR](#) apply for all implementations, including D16.

The architecture can provide the following levels of floating-point support:

- No floating-point support. This option is licensed only for implementations targeting specialized markets.
- Floating-point support.

The architecture supports the IEEE 754 single-precision for scalar data processing. For many floating-point instructions, there are configurable behaviors, such as:

- Configurable rounding modes. See [Rounding](#).
- Configurable trapping of floating-point exceptions. See [Floating-point exceptions and exception traps](#).
- Configurable non-IEEE 754 *Default NaN* behavior. See [NaN handling and the Default NaN](#).
- Configurable non-IEEE 754 flushing to zero of denormalized numbers. See [Flushing denormalized numbers to zero](#).

Floating-point computation using AArch32 Advanced SIMD instructions remains unchanged from Armv7. T32 and A32 floating-point instructions always use Arm standard floating-point arithmetic and performs IEEE 754 floating-point arithmetic with the following restrictions:

- Denormalized numbers are flushed to zero, see [Flushing denormalized numbers to zero](#).
- Only default NaNs are supported, see [Default NaN](#).
- The Round to Nearest rounding mode is used.
- Untrapped floating-point exception handling is used for all floating-point exceptions.

If floating-point exception trapping is supported, then unless stated otherwise, when a floating-point exception is not trapped, that exception causes a cumulative status register bit to be set to 1 and the operation produces a default result.

For more information, see [Floating-point exceptions and exception traps](#).

There is a single Floating-Point Status and Control Register, [FPSCR](#).

The [FPSCR](#).{N,Z,C,V} condition flags are updated by floating-point comparison operations.

Note

For additional details of AArch32 state floating-point support, see [Advanced SIMD and floating-point support](#).

The remainder of this section contains:

- [Instruction support](#).
- [Floating-point standards, and terminology](#).
- [Arm standard floating-point input and output values](#).
- [Flushing denormalized numbers to zero](#).
- [NaN handling and the Default NaN](#).
- [Rounding](#).
- [Floating-point exceptions and exception traps](#).

A1.5.1 Instruction support

The floating-point instructions support:

- Load and store for single elements and vectors of multiple elements.

Note

Single elements are also referred to as scalar elements.

- Data processing on single and multiple elements.
- Complex number arithmetic.
- Floating-point conversion between different levels of precision.
- Conversion between floating-point and integer types.
- Floating-point rounding.
- Atomic floating-point in-memory operations.

For more information on floating-point instructions in AArch32 state, see [The AArch32 Instruction Sets Overview](#).

A1.5.2 Floating-point standards, and terminology

The Arm architecture includes support for all the required features of ANSI/IEEE Std 754-2008, *IEEE Standard for Binary Floating-Point Arithmetic*, referred to as IEEE 754-2008. However, some terms in this Manual are based on the 1985 version of this standard, referred to as IEEE 754-1985:

- Arm floating-point terminology generally uses the IEEE 754-1985 terms. This section summarizes how IEEE 754-2008 changes these terms.
- References to IEEE 754 that do not include the issue year apply to either issue of the standard.

[Table A1-2](#) shows how the terminology in this Manual differs from that used in IEEE 754-2008.

Table A1-2 Floating-point terminology

This manual	IEEE 754-2008
Normalized ^a	Normal
Denormal, or denormalized	Subnormal
Round towards Minus Infinity (RM)	roundTowardsNegative
Round towards Plus Infinity (RP)	roundTowardsPositive
Round towards Zero (RZ)	roundTowardZero
Round to Nearest (RN)	roundTiesToEven
Rounding mode	Rounding-direction attribute

a. *Normalized number* is used in preference to *normal number*, because of the other specific uses of *normal* in this Manual.

A1.5.3 Arm standard floating-point input and output values

The Arm architecture provides full IEEE 754 floating-point arithmetic support. In AArch32 state, floating-point operations performed using Advanced SIMD instructions are limited to *Arm standard floating-point operation*, regardless of the selected rounding mode in the [FPSCR](#).

Arm standard floating-point arithmetic supports the following input formats defined by the IEEE 754 floating-point standard:

- Zeros.
- Normalized numbers.
- Denormalized numbers are flushed to 0 before floating-point operations, see [Flushing denormalized numbers to zero](#).
- NaNs.
- Infinities.

Arm standard floating-point arithmetic supports the Round to Nearest (roundTiesToEven) rounding mode defined by the IEEE 754 standard.

Arm standard floating-point arithmetic supports the following output result formats defined by the IEEE 754 standard:

- Zeros.
- Normalized numbers.
- Results with an absolute value less than the minimum normalized number are flushed to zero, see [Flushing denormalized numbers to zero](#).
- NaNs produced in floating-point operations are always the default NaN, see [Default NaN](#).
- Infinities.

A1.5.4 Flushing denormalized numbers to zero

Calculations involving denormalized numbers and Underflow exceptions can reduce the performance of floating-point processing. For many algorithms, replacing the denormalized operands and intermediate results with zeros can recover this performance, without significantly affecting the accuracy of the final result. Arm floating-point implementations allow denormalized numbers to be flushed to zero to permit this optimization.

If a number `value` satisfies the condition $0 < \text{Abs}(\text{value}) < \text{MinNorm}$, it is treated as a denormalized number.

`MinNorm` is defined as follows:

- For half-precision numbers, `MinNorm` is 2^{-14} .
- For single-precision numbers, `MinNorm` is 2^{-126} .
- For double-precision numbers, `MinNorm` is 2^{-1022} .

Flushing denormals to zero is incompatible with the IEEE 754 standard, and must not be used when IEEE 754 compatibility is a requirement. Enabling flushing of denormals to zero must be done with care. Although it can improve performance on some algorithms, there are significant limitations on its use. These are application-dependent:

- On many algorithms, it has no noticeable effect, because the algorithm does not usually process denormalized numbers.
- On other algorithms, it can cause exceptions to occur and can seriously reduce the accuracy of the results of the algorithm.

A1.5.4.1 Flushing denormalized inputs to zero

If flushing denormalized inputs to zero is enabled for an instruction and a data type, and an input to that instruction is a denormalized number of that data type, the input operand is flushed to zero, and its sign bit is not changed.

If a floating-point operation has a denormalized input that is flushed to zero, for all purposes within the instruction other than calculating Input Denormal floating-point exceptions, all inputs that are denormalized numbers are treated as though they were zero with the same sign as the input.

If `FPSCR.FZ` == 0, for all inputs, `FPSCR.FZ` does not cause denormalized inputs to be flushed to zero, although other factors might cause denormalized inputs to be flushed to zero.

A1.5.4.2 Flushing denormalized outputs to zero

If a denormalized output is flushed to zero, the output is returned as zero with the same sign bit as the denormalized output value.

If a denormalized output is flushed to zero, the output is returned as zero with the same sign bit as the denormalized output value.

If $\text{FPSCR.FZ} = 0$, then unless otherwise specified, for all outputs, FPSCR.FZ does not cause denormalized outputs to be flushed to zero, although other factors might cause denormalized outputs to be flushed to zero.

If $\text{FPSCR.FZ} = 1$, for all outputs, denormalized outputs are flushed to zero.

A1.5.5 NaN handling and the default NaN

The IEEE 754 standard defines a NaN as a number with all exponent bits set to 1 and a nonzero number in the mantissa, and specifies that the sign bit of a NaN has no significance.

The Arm architecture additionally defines the following in [Table A1-3](#):

- A *default NaN*, compliant with the IEEE 754 standard.

For a quiet NaN output derived from a signaling NaN operand, the most significant fraction bit is set to 1.

A PE is forbidden to generate a NaN whose value is strongly correlated to the values of non-NaN inputs as a speculative result of a floating-point calculation not involving NaN inputs.

A1.5.5.1 Default NaN

A default NaN is encoded as described in [Table A1-3](#).

Table A1-3 Default NaN encodings

	Half-precision, IEEE Format	Single- precision	Double- precision
Exponent	0x1F	0xFF	0x7FF
Fraction	Bit[9] = '1', bits[8:0] = 0	Bit[22] = '1', bits[21:0] = 0	Bit[51] = '1', bits[50:0] = 0

When $\text{FPSCR.DN} = 1$, if any input to a floating-point operation is a NaN, the output is a default NaN.

Floating-point instructions that detect an Invalid Operation condition for a reason other than one of its inputs being a NaN, produce a default NaN as the result.

A1.5.5.2 NaN handling

The IEEE 754 standard does not specify which input NaN is used as the output NaN. Therefore, where the Arm architecture specifies which input NaN to use, this is an addition to the requirements in the IEEE 754 standard.

Depending on the operation, the exact value of a derived quiet NaN output might have both a different sign and different fraction bits from its source. See individual instruction descriptions for details.

A1.5.5.3 NaN propagation

If an output NaN is derived from one of the operands, how the input NaN propagates to the output depends on the instruction and the number of operands.

If an output NaN is derived from an input NaN and if the size of the output format is the same as the input format, then all of the following apply:

- If the input NaN is a quiet NaN, the output NaN is derived from the input NaN.

- If the input NaN is a signaling NaN, the output NaN is derived as follows:
 - If the handling of a signaling NaN by the instruction detects an Invalid Operation condition, the output NaN is derived from a quietened version of the input NaN.
 - If the handling of a signaling NaN by the instruction does not detect an Invalid Operation condition, the output NaN is derived from the input NaN.

If an output NaN is derived from an input NaN and if the size of the output format is larger than the input format, all of the following apply:

- If the input NaN is a quiet NaN, the output NaN is the same as the input NaN except that the mantissa is zero-extended in the low-order bit to fit the output format, and the exponent field is set to all ones.
- If the input NaN is a signaling NaN, the output NaN is the quietened version of the input NaN, except that the mantissa is zero-extended in the low-order bits and the exponent field is set to all ones.

If an output NaN is derived from an input NaN and if the size of the output format is smaller than the input format, all of the following apply:

- If the input NaN is a quiet NaN, the output NaN is the same as the input NaN except that the mantissa is truncated in the lower-order bits to fit the output format, and the exponent field is set to all ones.
- If the input NaN is a signaling NaN, the output NaN is the quietened version of the input NaN except that the mantissa is truncated in the lower-order bits to fit the output format, and the exponent field is set to all ones.

For the following descriptions, the term “first operand” and “second operand” relate to the left-to-right ordering of the arguments of the pseudocode function that describes the operation.

A1.5.6 Rounding

The rounding mode specifies how the exact result of a floating-point operation is rounded to a value in the destination format.

The rounding mode is either determined by the rounding mode control field `FPSCR.RMode` or by the instruction.

`FPSCR.RMode` can select one of:

- [Round to Nearest \(RN\) mode](#).
- [Round towards Plus Infinity \(RP\) mode](#).
- [Round towards Minus Infinity \(RM\) mode](#).
- [Round towards Zero \(RZ\) mode](#).

[Round to Nearest with Ties to Away](#) rounding behaviors are not selected by `FPSCR.RMode`, but are used by some instructions.

A1.5.6.1 Round to Nearest (RN) mode

Round to Nearest rounding mode rounds the exact result of a floating-point operation to a value that is representable in the destination format as follows:

- If the value before rounding has an absolute value that is too large to represent in the output format, the rounded value is an Infinity. The sign of the rounded value is the same as the sign of the value before rounding.
- If the value before rounding has an absolute value that is not too large to represent in the output format, the result is calculated as follows:
 - If the two nearest floating-point numbers bracketing the value before rounding are equally near, the result is the number with an even least significant digit.
 - If the two nearest floating-point numbers bracketing the value before rounding are not equally near, the result is the floating-point number nearest to the value before rounding.

A1.5.6.2 Round towards Plus Infinity (RP) mode

Round towards Plus Infinity rounding mode rounds the exact result of a floating-point operation to a value that is representable in the destination format. The result is the floating-point number in the output format that is closest to and not less than the value before rounding. The result can be plus infinity.

A1.5.6.3 Round towards Minus Infinity (RM) mode

Round towards Minus Infinity rounding mode rounds the exact result of a floating-point operation to a value that is representable in the destination format. The result is the number in the output format that is closest to and not greater than the value before rounding. The result can be minus infinity.

A1.5.6.4 Round towards Zero (RZ) mode

Round towards Zero rounding mode rounds the exact result of a floating-point operation to a value that is representable in the destination format. The result is the floating-point number in the output format that is closest to and not greater in absolute value than the value before rounding.

A1.5.6.5 Round to Nearest with Ties to Away

Round to Nearest with Ties to Away rounds the exact result of a floating-point operation to a value that is representable in the destination format. The result is calculated as follows:

- If the two nearest floating-point numbers bracketing the value before rounding are equally near, the result is the number with the largest absolute value.
- If the two nearest floating-point numbers bracketing the value before rounding are not equally near, the result is the floating-point number nearest to the value before rounding.

A1.5.7 Floating-point exceptions and exception traps

Execution of a floating-point instruction, or execution of an Advanced SIMD instruction that performs floating-point operations, can generate an exceptional condition, called a *floating-point exception*.

The architecture does not support asynchronous reporting of floating-point exceptions.

For each of the following floating-point exceptions, it is IMPLEMENTATION DEFINED whether an implementation includes synchronous exception generation:

- Input Denormal.
- Inexact.
- Underflow.
- Overflow.
- Divide by Zero.
- Invalid Operation.

If an implementation does not support synchronous exception generation from a floating-point exception, then that synchronous exception is never generated and all statements about synchronous exception generation from that floating-point exception do not apply to the implementation.

Synchronous exception generation by floating-point exceptions is enabled using the **FPSCR** as follows:

- For each floating-point exception that supports synchronous exception generation, the relevant control bit chosen from **FPSCR**. {IDE, IXE, UFE, OFE, DZE, IOE} is used to enable synchronous exception generation.
- For each floating-point exception that does not support synchronous exception generation, the relevant bit chosen from **FPSCR**. {IDE, IXE, UFE, OFE, DZE, IOE} is RAZ/WI.

A1.5.7.1 Inexact exceptions

The cumulative floating-point exception bit **FPSCR**.IXC and the trap enable bit **FPSCR**.IXE both relate to Inexact exceptions.

If a result is not flushed to zero, and the result does not equal the result calculated with unbounded exponent range and unbounded precision, then an Inexact exception is generated.

A1.5.7.2 Underflow exceptions

The cumulative floating-point exception bit `FPSCR.UFC`, and the trap enable bit `FPSCR.UFE` both relate to Underflow exceptions.

If the result of a floating-point operation is a denormalized number that is not flushed to zero, then:

- If the result is exact, an Underflow floating-point exception is generated only if `FPSCR.UFE` is 1.
- If the result is inexact, an Underflow floating-point exception is always generated.

If the result of a floating-point operation is a denormalized number that is flushed to zero, then the Underflow floating-point exception is generated, however this floating-point exception is not trapped regardless of the value of `FPSCR.UFE`.

A1.5.7.3 Overflow exceptions

The cumulative floating-point exception bit `FPSCR.OFC`, and the trap enable bit `FPSCR.OFE` both relate to Overflow exceptions.

If the output of an instruction rounded with an unbounded exponent is greater than the maximum normalized number for the output precision, an Overflow exception is generated.

If an untrapped Overflow exception is generated, the result is determined by the selected rounding behavior and the sign of the result before rounding, as follows:

- Round to Nearest carries all overflows to infinity with the sign of the result before rounding.
- Round towards Plus Infinity carries negative overflows to the most negative finite number of the output precision, and carries positive overflows to plus infinity.
- Round towards Minus Infinity carries positive overflows to the largest finite number of the output precision, and carries negative overflows to minus infinity.
- Round towards Zero carries all overflows to the output precision's largest finite number with the sign of the result before rounding.
- Round to Nearest Ties to Away carries all overflows to infinity with the sign of the result before rounding.
- Round to Odd, when used by convert instructions, carries all overflows to the output precision's largest finite number with the sign of the result before rounding.

A1.5.7.4 Divide by Zero exceptions

The cumulative floating-point exception bit `FPSCR.DZC`, and the trap enable bit `FPSCR.DZE` both relate to Divide by Zero exceptions.

If a floating-point operation divides a finite nonzero number by zero, a Divide by Zero exception is generated.

If a floating-point operation divides a finite nonzero number by zero, and the Divide by Zero exception is untrapped, the result is a correctly signed infinity.

A1.5.7.5 Invalid Operation exceptions

The cumulative floating-point exception bit `FPSCR.IOC`, and the trap enable bit `FPSCR.IOE` both relate to Invalid Operation exceptions.

For any floating-point instruction that performs a floating-point operation, if any of the following apply, the instruction generates an Invalid Operation exception:

- At least one operand is a signaling NaN.
- Subtracting two equal-magnitude infinities that are of the same sign.
- Multiplying a zero by an infinity.
- Dividing a zero by a zero.
- Dividing an infinity by an infinity.
- Taking the square root of an operand that is less than zero.

If the input is one of: a quiet NaN, an infinity, or a number that overflows the values that can be represented in the output format, and if another exception is not generated to signal the condition, then a conversion from floating-point to either integer or fixed-point format, generates an Invalid Operation exception.

A1.5.7.6 Handling floating-point exceptions

If an implementation supports synchronous exception generation for floating-point exceptions, the synchronous exceptions generated by the floating-point exception traps are taken to the lowest Exception level that can handle such an exception and that is not at a lower Exception level than where the exception was generated.

The `FPProcessException()` pseudocode function describes the handling of trapped floating-point exceptions generated in AArch32 state.

A1.5.7.7 Combinations of floating-point exceptions

More than one floating-point exception might occur on the same operation. The architecture permits only the following combinations of floating-point exceptions:

- Overflow with Inexact.
- Underflow with Inexact.

If two floating-point exceptions occur on the same operation, the Input Denormal exception is treated as highest priority and the Inexact exception is treated as lowest priority.

Some floating-point instructions specify more than one floating-point operation, this is indicated by the pseudocode descriptions of the instruction. In these cases, it is possible for one instruction to generate multiple exceptions. Multiple exceptions from one instruction are prioritized as follows:

- If an exception generating operation outputs a result that is used by a second exception generating operation, the exception generated by the operation that outputs the result is treated as higher priority than the exception generated by the second operation that uses the result.
- If exception generating operations do not use the outputs of other exception generating operations, it is **CONSTRAINED UNPREDICTABLE** which floating-point exception is treated as higher priority. The exception prioritized might differ between different instances of the same two floating-point exceptions being generated on the same operation during execution of the instruction.
- A trapped Underflow exception has priority over a trapped Inexact exception.

If none of the floating-point exceptions caused by an operation is trapped, any floating-point exception that occurs causes the associated cumulative exception flag bit in the `FPSCR` to be set to 1.

When `FPSCR.AHP` is 1, if the result of a floating-point operation is a denormalized number that is flushed to zero, both an untrapped Underflow floating-point exception and an Inexact floating-point exception are generated, which always sets the cumulative Underflow exception flag `FPSCR.UFC` to 1 regardless of whether the Inexact floating-point exception is trapped. Otherwise, when a trapped floating-point exception is taken, it is **IMPLEMENTATION DEFINED** whether the `FPSCR` is restored to the value it had immediately before the instruction that generated the trapped floating-point exception. If the **IMPLEMENTATION DEFINED** choice is that the `FPSCR` is not restored, it is **CONSTRAINED UNPREDICTABLE** which trapped floating-point exceptions, if any, are indicated by the corresponding `FPSCR` cumulative exception flag bits being set to 1.

The architectural requirements for floating-point exception prioritization apply only to multiple floating-point exceptions generated on the same element of an Advanced SIMD operation. For trapped floating-point exceptions from Advanced SIMD the architecture does not define the floating-point exception prioritization between different elements of the instruction.

A1.6 The Arm memory model

The Arm memory model supports:

- Generating an exception on an unaligned memory access.
- Restricting access by applications to specified areas of memory.
- Translating *virtual addresses* (VAs) provided by executing instructions to *physical addresses* (PAs).
- Altering the interpretation of multi-byte data between big-endian and little-endian.
- Controlling the order of accesses to memory.
- Controlling caches and address translation structures.
- Synchronizing access to shared memory by multiple PEs.
- Barriers that control and prevent speculative access to memory.

AArch32 state VA supports 32-bit addressing, with the Protected Memory System Architecture defining protection regions arbitrated by Memory Protection Units at EL1 and EL2.

For more information, see:

For execution in AArch32 state

- [The AArch32 Application Level Memory Model.](#)
- [The AArch32 System Level Memory Model.](#)
- [The Protected Memory System Architecture.](#)

Chapter A2

R-profile Architecture Extensions

This chapter introduces the Arm R-profile architecture extensions. It contains the following sections:

- [About the Armv8-R AArch32 architecture extensions.](#)
- [Armv8-R AArch32 architecture extensions.](#)

A2.1 About the Armv8-R AArch32 architecture extensions

An architecture extension defines a set of features that, when implemented, may make an implementation compliant with the extension.

Each feature description includes:

- A feature name.
- A brief description of the feature.
- The Execution state the feature is supported in.
- Whether the implementation of the feature is mandatory or **OPTIONAL**.
- Dependencies on the implementation of other features if any.
- The register field that identifies the presence of the feature.

A2.2 Armv8-R AArch32 architecture extensions

A2.2.1 The Armv8.0 architecture extension

The original Armv8-R architecture is called Armv8.0. It contains mandatory and optional architectural features. Some features must be implemented together. An implementation is Armv8.0 compliant if it includes all of the Armv8.0 architectural features that are mandatory.

An Armv8.0 compliant implementation can additionally include:

- Armv8.0 features that are optional.
- Any arbitrary subset of the architectural features of Armv8.1, subject only to those constraints that require that certain features be implemented together.

FEAT_AA32, PE supports AArch32.

This feature is mandatory.

FEAT_AA32EL0, Support for AArch32 at EL0

This feature is mandatory.

FEAT_AA32EL1, Support for AArch32 at EL1

This feature is mandatory.

FEAT_AA32EL2, Support for AArch32 at EL2

This feature is mandatory.

FEAT_AES, Advanced SIMD AES instructions

FEAT_AES provides the AES* instructions to support AES encryption and decryption, AESD, AESE, AESMC, and AESIMC.

If FEAT_AES is implemented, then [FEAT_Crypto](#) is implemented.

FEAT_AdvSIMD, Advanced SIMD Extension

FEAT_AdvSIMD includes support for the SISD and SIMD operations. All Armv8-R systems that support standard operating systems with rich application environments also provide hardware support for Advanced SIMD instructions.

The following field identifies the presence of FEAT_AdvSIMD:

- [EDPFR](#).AdvSIMD.

For more information, see:

- [Supported data types](#).
- A64 Advanced SIMD and Floating-point Instruction Descriptions.
- [Advanced SIMD and floating-point instructions](#).
- [T32 and A32 Advanced SIMD and Floating-point Instruction Descriptions](#).

FEAT_BigEnd, Support for big-endian at EL1 and above

If FEAT_BigEnd is implemented, then [FEAT_BigEndEL0](#) is implemented.

If [FEAT_MixedEnd](#) is implemented, then FEAT_BigEnd is implemented.

FEAT_BigEndEL0, Support for big-endian at EL0

If [FEAT_MixedEndEL0](#) is implemented, then FEAT_BigEndEL0 is implemented.

FEAT_CRC32, CRC32 instructions

FEAT_CRC32 introduces the support for the CRC32* instructions that perform cyclic redundancy check calculations.

FEAT_CTI_PIDR, Support for CoreSight compliance for external CTI registers

FEAT_CTI_PIDR provides registers for compliance with the CoreSight architecture.

This feature is required for compliance with the CoreSight architecture.

FEAT_Crypto, Cryptographic Extension

The Arm Cryptographic Extension provides instructions for the acceleration of encryption and decryption. The presence of the Cryptographic Extension in an implementation is subject to export license controls.

The Cryptographic Extension is an extension of the SIMD support and operates on the vector register file. It also provides multiply instructions that operate on long polynomials.

In an implementation that supports both AArch64 state and AArch32 state, FEAT_AES, FEAT_PMULL, FEAT_SHA1 and FEAT_SHA256 provide the same functionality in both states.

If FEAT_Crypto is implemented, then [FEAT_AES](#) or [FEAT_SHA1](#) is implemented.

For more information, see:

- The Cryptographic Extension in AArch64 state.
- [The Cryptographic Extension in AArch32 state.](#)

FEAT_DoubleLock, Double Lock

FEAT_DoubleLock is the mnemonic used for the OS Double Lock.

The following field identifies the presence of FEAT_DoubleLock:

- [DBGDEVID](#).DoubleLock.

FEAT_ED_PIDR, Support for CoreSight compliance for External Debug registers

FEAT_ED_PIDR provides registers for compliance with the CoreSight architecture.

This feature is required for compliance with the CoreSight architecture.

For more information, see Management registers and CoreSight compliance.

FEAT_EL0, Support for execution at EL0

This feature is mandatory.

FEAT_EL1, Support for execution at EL1

This feature is mandatory.

FEAT_EL2, Support for execution at EL2

This feature is mandatory.

FEAT_ETMv4, Embedded Trace Macrocell version 4

FEAT_ETMv4 indicates support for the Embedded Trace Macrocell architecture ETMv4.

If FEAT_ETMv4 is implemented, then [FEAT_TRC_SR](#) or [FEAT_TRC_EXT](#) is implemented.

For more information, see the *Arm® Embedded Trace Macrocell Architecture Specification, ETMv4(ARM IHI 0064)*.

FEAT_FP, Floating Point extensions

FEAT_FP includes support for single-precision and double-precision floating-point types. All Armv8-R systems that support standard operating systems with rich application environments also provide hardware support for floating-point instructions.

The following field identifies the presence of FEAT_FP:

- [EDPFR.FP](#).

For more information, see:

- [Supported data types](#).
- [Floating-point support](#).
- [Advanced SIMD and floating-point instructions](#).
- [T32 and A32 Advanced SIMD and Floating-point Instruction Descriptions](#).

FEAT_IVIPT, The IVIPT Extension

FEAT_IVIPT describes any permitted instruction cache implementation. This includes *Virtual Index, Physical tag* (VIPT) cache policy and *Physical Index, Physical Tag* (PIPT) cache policy.

FEAT_LittleEnd, Support for little-endian at EL1 and above

If FEAT_LittleEnd is implemented, then [FEAT_LittleEndEL0](#) is implemented.

If [FEAT_MixedEnd](#) is implemented, then FEAT_LittleEnd is implemented.

FEAT_LittleEndEL0, Support for little-endian at EL0

If [FEAT_MixedEndEL0](#) is implemented, then FEAT_LittleEndEL0 is implemented.

FEAT_MixedEnd, Mixed-endian support

FEAT_MixedEnd provides support for mixed-endian configuration.

If FEAT_MixedEnd is implemented, then [FEAT_MixedEndEL0](#) is implemented.

For more information, see:

- [Mixed-endian support in AArch32](#).

FEAT_MixedEndEL0, Mixed-endian support at EL0

FEAT_MixedEndEL0 provides support for mixed-endian at EL0.

For more information, see:

- [Mixed-endian support in AArch32](#).

FEAT_PCSRv8, PC Sample-based Profiling extension

FEAT_PCSRv8 introduces support for PC Sample-based Profiling Extension that provides coarse-grained, non-invasive profiling by an external debugger.

For more information, see [About the PC Sample-based Profiling Extension](#).

FEAT_PMSAv32, Protected Memory System Architecture v8-32

For more information, see [The AArch32 Protected Memory System Architecture](#)

FEAT_PMULL, Advanced SIMD PMULL instructions

FEAT_PMULL provides the AES* instructions that support multiplication of 64-bit polynomials, PMULL, PMULL2.

If FEAT_PMULL is implemented, then [FEAT_AES](#) is implemented.

FEAT_PMU_PIDR, Support for CoreSight compliance for external PMU registers

FEAT_PMU_PIDR provides registers for compliance with the CoreSight architecture.

This feature is required for compliance with the CoreSight architecture.

If FEAT_PMU_PIDR is implemented, then [FEAT_PMUv3_EXT](#) is implemented.

For more information, see [Management registers and CoreSight compliance](#).

FEAT_PMUv3, Performance Monitors Extension, version 3

The Performance Monitors Extension, FEAT_PMUv3, is an optional non-invasive debug component.

The following fields identify the presence of FEAT_PMUv3:

- [ID_DFR0](#).PerfMon.
- [EDDFR](#).PMUVer.

For more information, see [The Performance Monitors Extension](#).

FEAT_PMUv3_EXT, External interface to the Performance Monitors

FEAT_PMUv3_EXT indicates support for external access to the FEAT_PMUv3 registers.

If FEAT_PMUv3_EXT is implemented, then [FEAT_PMUv3](#) is implemented.

If FEAT_PMUv3_EXT is implemented, then [FEAT_PMUv3_EXT32](#) is implemented.

FEAT_PMUv3_EXT32, 32-bit external interface to the Performance Monitors

FEAT_PMUv3_EXT32 indicates the external Performance Monitors and CoreSight registers are implemented as mostly 32-bit registers.

If FEAT_PMUv3_EXT32 is implemented, then [FEAT_PMUv3_EXT](#) is implemented.

If [FEAT_PMUv3_EXT](#) and [FEAT_PMUv3](#) are implemented, then FEAT_PMUv3_EXT32 is implemented.

For more information, see [Recommended External Interface to the Performance Monitors](#).

FEAT_SHA1, Advanced SIMD SHA1 instructions

FEAT_SHA1 implements the SHA1* instructions.

If FEAT_SHA1 is implemented, then [FEAT_Crypto](#) is implemented.

FEAT_SHA256, Advanced SIMD SHA256 instructions

FEAT_SHA256 implements the SHA256* instructions.

If FEAT_SHA256 is implemented, then [FEAT_SHA1](#) is implemented.

FEAT_TRC_EXT, Trace external registers

FEAT_TRC_EXT indicates support for external access to the ETMv4 registers.

If FEAT_TRC_EXT is implemented, then [FEAT_ETMv4](#) is implemented.

FEAT_TRC_SR, Trace System registers

FEAT_TRC_SR indicates support for System registers for ETMv4.

If FEAT_TRC_SR is implemented, then [FEAT_ETMv4](#) is implemented.

The following field identifies the presence of FEAT_TRC_SR:

- [ID_DFR0](#).CopTrc.

The AArch32 Application Level Architecture

Part B

Chapter B1

The AArch32 Application Level Programmers' Model

This chapter gives an Application level description of the programmers' model for software executing in AArch32 state. This means it describes execution in EL0. It contains the following sections:

- [About the Application level programmers' model](#)
- [The Application level programmers' model in AArch32 state](#)
- [Advanced SIMD and floating-point instructions](#)
- [About the AArch32 System register interface](#)
- [Exceptions](#)

B1.1 About the Application level programmers' model

This chapter contains the programmers' model information required for the development of applications that execute in AArch32 state.

The information in this chapter is distinct from the system information required to service and support application execution under an operating system, or higher level of system software. However, some knowledge of that system information is needed to put the Application level programmers' model into context.

Depending on the implementation, the architecture supports multiple levels of execution privilege. These privilege levels are indicated by different *Exception levels* that number upwards from EL0, where EL0 corresponds to the lowest privilege level and is often described as *unprivileged*. The Application level programmers' model is the programmers' model for software executing at EL0. For more information, see [Arm architectural concepts](#).

System software determines the Exception level, and therefore the level of privilege, at which application software runs. When an operating system supports execution at both EL1 and EL0, an application usually runs unprivileged. This has the following effects:

- It means that the operating system can allocate system resources to an application in a unique or shared manner.
- It provides a degree of protection from other processes, and so helps protect the operating system from malfunctioning software.

This chapter indicates where some System level understanding is helpful, and if appropriate it gives a reference to the System level description.

Application level software is generally unaware of any virtualization. For more information, see [The effect of implementing EL2 on the Exception model](#).

B1.2 The Application level programmers' model in AArch32 state

The following sections give more information about the application level programmers' model in AArch32 state:

- [Instruction sets, arithmetic operations, and register files.](#)
- [Core data types and arithmetic in AArch32 state.](#)
- [The general-purpose registers, and the PC, in AArch32 state.](#)
- [Process state, PSTATE.](#)
- [Jazelle support.](#)

B1.2.1 Instruction sets, arithmetic operations, and register files

The T32 and A32 instruction sets both provide a wide range of integer arithmetic and logical operations, that operate on a register file of sixteen 32-bit registers, that are comprised of the AArch32 general-purpose registers and the PC. As described in [The general-purpose registers, and the PC, in AArch32 state](#), these registers include the registers SP (R13) and LR (R14), which have specialized uses. [Core data types and arithmetic in AArch32 state](#) gives more information about these operations.

In addition, an implementation that implements the T32 and A32 instruction sets includes both:

- Scalar floating-point instructions.
- The Advanced SIMD vector instructions.

Floating-point and vector instructions operate on a separate common register file, described in [The SIMD and floating-point register file](#). [Advanced SIMD and floating-point instructions](#) gives more information about these instructions.

B1.2.2 Core data types and arithmetic in AArch32 state

When executing in AArch32 state, a PE supports the following data types in memory:

Byte	8 bits.
Halfword	16 bits.
Word	32 bits.
Doubleword	64 bits.

PE registers are 32 bits in size. The instruction sets provide instructions that use the following data types for data held in registers:

- 32-bit pointers.
- Unsigned or signed 32-bit integers.
- Unsigned 16-bit or 8-bit integers, held in zero-extended form.
- Signed 16-bit or 8-bit integers, held in sign-extended form.
- Two 16-bit integers packed into a register.
- Four 8-bit integers packed into a register.
- Unsigned or signed 64-bit integers held in two registers.

Load and store operations can transfer bytes, halfwords, or words to and from memory. Loads of bytes or halfwords zero-extend or sign-extend the data as it is loaded, as specified in the appropriate load instruction.

The instruction sets include load and store operations that transfer two or more words to and from memory. Software can load and store doublewords using these instructions.

Note

For information about the atomicity of memory accesses, see [Atomicity in the Arm architecture](#).

When any of the data types is described as *unsigned*, the N-bit data value represents a non-negative integer in the range 0 to 2^N-1 , using normal binary format.

When any of these types is described as *signed*, the N-bit data value represents an integer in the range $-2^{(N-1)}$ to $+2^{(N-1)}-1$, using two's complement format.

The instructions that operate on packed halfwords or bytes include some multiply instructions that use only one of two halfwords, and SIMD instructions that perform parallel addition or subtraction on all of the halfwords or bytes.

Note

These SIMD instructions operate on values held in the general-purpose registers, and must not be confused with the Advanced SIMD instructions that operate on a separate register file that provides registers of up to 128 bits.

Direct instruction support for 64-bit integers is limited, and most 64-bit operations require sequences of two or more instructions to synthesize them.

B1.2.2.1 Integer arithmetic

The instruction set provides a wide range of operations on the values in registers, including bitwise logical operations, shifts, additions, subtractions, multiplications, and divisions. The pseudocode defines these operations either using ASL stdlib code or using ASL functions described in the *Arm[®] Architecture Specification Language Reference (ARM DDI 0626)*.

B1.2.2.1.1 Shift and rotate operations

The following types of shift and rotate operations are used in instructions:

Logical Shift Left

The `LSL()` stdlib function moves each bit of a bitstring left by a specified number of bits. Zeros are shifted in at the right end of the bitstring. Bits that are shifted off the left end of the bitstring are discarded, except that the last such bit can be produced as a carry output.

Logical Shift Right

The `LSR()` stdlib function moves each bit of a bitstring right by a specified number of bits. Zeros are shifted in at the left end of the bitstring. Bits that are shifted off the right end of the bitstring are discarded, except that the last such bit can be produced as a carry output.

Arithmetic Shift Right

The `ASR()` stdlib function moves each bit of a bitstring right by a specified number of bits. Copies of the leftmost bit are shifted in at the left end of the bitstring. Bits that are shifted off the right end of the bitstring are discarded, except that the last such bit can be produced as a carry output.

Rotate Right The `ROR()` stdlib function moves each bit of a bitstring right by a specified number of bits. Each bit that is shifted off the right end of the bitstring is re-introduced at the left end. The last bit shifted off the right end of the bitstring can be produced as a carry output.

Rotate Right with Extend

The `RRX()` pseudocode function moves each bit of a bitstring right by one bit. A carry input is shifted in at the left end of the bitstring. The bit shifted off the right end of the bitstring can be produced as a carry output.

B1.2.2.1.2 Pseudocode description of addition and subtraction

In pseudocode, addition and subtraction can be performed on any combination of unbounded integers and bitstrings, provided that if they are performed on two bitstrings, the bitstrings must be identical in length. The result is another unbounded integer if both operands are unbounded integers, and a bitstring of the same length as the bitstring operand or operands otherwise.

The main addition and subtraction instructions can produce status information about both unsigned carry and signed overflow conditions. When necessary, multi-word additions and subtractions can be synthesized from this status information. In pseudocode, the `AddWithCarry()` function provides an addition with a carry input and a set of output Condition flags including carry output and overflow:

An important property of the `AddWithCarry()` function is that if:

```
(result, nzcvc) = AddWithCarry{N}(x, NOT( y), carry_in)
```

Then:

- If `carry_in == '1'`, then `result == x-y` with:
 - `nzcvc[0] == '1'` if signed overflow occurred during the subtraction.
 - `nzcvc[1] == '1'` if unsigned borrow did not occur during the subtraction, that is, if $x \geq y$.
- If `carry_in == '0'`, then `result == x-y-1` with:
 - `nzcvc[0] == '1'` if signed overflow occurred during the subtraction.
 - `nzcvc[1] == '1'` if unsigned borrow did not occur during the subtraction, that is, if $x \geq y$.

Taken together, this means that the `carry_in` and `nzcvc[1]` output in `AddWithCarry{N}()` calls can act as NOT borrow flags for subtractions as well as carry flags for additions.

B1.2.2.1.3 Pseudocode description of saturation

Some instructions perform *saturating arithmetic*, that is, if the result of the arithmetic overflows the destination signed or unsigned N-bit integer range, the result produced is the largest or smallest value in that range, rather than wrapping around modulo 2^N . This is supported in pseudocode by:

- The `SignedSatQ{N}()` and `UnsignedSatQ{N}()` functions when an operation requires, in addition to the saturated result, a Boolean argument that indicates whether saturation occurred.
- The `SignedSat{N}()` and `UnsignedSat{N}()` functions when only the saturated result is required.

`SatQ{N}(i, unsigned)` returns either `UnsignedSatQ{N}(i)` or `SignedSatQ{N}(i)` depending on the value of its third argument, and `Sat(i, N, unsigned)` returns either `UnsignedSat{N}(i)` or `SignedSat{N}(i)` depending on the value of its third argument.

B1.2.3 The general-purpose registers, and the PC, in AArch32 state

In the AArch32 Application level view, a PE has:

- Fifteen general-purpose 32-bit registers, R0 to R14, of which R13 and R14 have alternative names reflecting how they are, or can be, used:
 - R13 is usually identified as SP.
 - R14 is usually identified as LR.
- The PC (*Program Counter*), which can be described as R15.

The specialized uses of the SP (R13), LR (R14), and PC (R15) are:

SP, the stack pointer

The PE uses SP as a pointer to the active stack.

In the T32 instruction set, some instructions cannot access SP. Instructions that can access SP can use SP as a general-purpose register.

The A32 instruction set provides more general access to SP, and it can be used as a general-purpose register.

Note

Using SP for any purpose other than as a stack pointer might break the requirements of operating systems, debuggers, and other software systems, causing them to malfunction.

Software can refer to SP as R13.

LR, the link register

The link register can be used to hold return link information, and some cases described in this manual require this use of the LR. When software does not require the LR for linking, it can use it for other purposes. Software can refer to LR as R14.

PC, the Program Counter

- When executing an A32 instruction, PC reads as the address of the current instruction plus 8.
- When executing a T32 instruction, PC reads as the address of the current instruction plus 4.
- Writing an address to PC causes a branch to that address.

Most T32 instructions cannot access PC.

The A32 instruction set provides more general access to the PC, and many A32 instructions can use the PC as a general-purpose register. However, Arm deprecates the use of PC for any purpose other than as the Program Counter. See [Writing to the PC](#) for more information.

Software can refer to PC as R15.

See [AArch32 general-purpose registers, the PC, and the Special-purpose registers](#) for the system level view of these registers.

Note

In general, Arm strongly recommends using the names SP, LR, and PC instead of R13, R14, and R15. However, sometimes it is simpler to use the R13-R15 names when referring to a group of registers. For example, it is simpler to refer to *registers R8 to R15*, rather than to *registers R8 to R12, the SP, LR, and PC*. These two descriptions of the group of registers have the same meaning.

B1.2.3.1 Writing to the PC

In the T32 and A32 instruction sets, many data-processing instructions can write to the PC. Writes to the PC are handled as follows:

- In T32 state, the following 16-bit T32 instruction encodings branch to the value written to the PC:
 - Encoding T2 of [ADD, ADDS \(register\)](#).
 - Encoding T1 of [MOV, MOVS \(register\)](#).

The value written to the PC is forced to be halfword-aligned by ignoring its least significant bit, treating that bit as being 0.
- The B, BL, CBNZ, CBZ, TBB, and TBH instructions remain in the same instruction set state and branch to the value written to the PC.

The definition of each of these instructions ensures that the value written to the PC is correctly aligned for the current instruction set state.
- The BLX (immediate) instruction switches between T32 and A32 states and branches to the value written to the PC. Its definition ensures that the value written to the PC is correctly aligned for the new instruction set state.
- The following instructions write a value to the PC, treating that value as an interworking address to branch to, with low-order bits that determine the new instruction set state:
 - BLX (register), BX, and BXJ.
 - LDR instructions with <Rt> equal to the PC.
 - POP and all forms of LDM except LDM (exception return), when the register list includes the PC.
 - In A32 state only, ADC, ADD, ADR, AND, ASR (immediate), BIC, EOR, LSL (immediate), LSR (immediate), MOV, MVN, ORR, ROR (immediate), RRX, RSB, RSC, SBC, and SUB instructions with <Rd> equal to the PC and without flag-setting specified.

For details of how an interworking address specifies the new instruction set state and instruction address, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC](#).

Note

The register-shifted register instructions, which are available only in the A32 instruction set and are summarized in [Data-processing register \(register shift\)](#), are CONSTRAINED UNPREDICTABLE if they attempt to write to the PC, see [Using R15 by instruction](#).

- Some instructions are treated as exception return instructions, and write both the PC and the [CPSR](#). For more information, including which instructions are exception return instructions, see [Exception return](#).
- Some instructions cause an exception, and the exception handler address is written to the PC as part of the exception entry.

B1.2.3.2 Pseudocode description of operations on the AArch32 general-purpose registers and the PC

In pseudocode, the uses of the [R\(\)](#) accessor, with an index argument *n*, are:

- Reading or writing R0-R12, SP, and LR, using *n* = 0-12, 13, and 14 respectively.
- Reading the PC, using *n* = 15.

[Pseudocode description of general-purpose register and PC operations](#) describes accesses to these registers.

Descriptions of A32 store instructions that store the PC value use the [PCStoreValue\(\)](#) pseudocode function to specify the PC value stored by the instruction.

Writing an address to the PC causes either a simple branch to that address or an *interworking* branch that also selects the instruction set to execute after the branch. A simple branch is performed by the [BranchWritePC\(\)](#) function.

An interworking branch is performed by the [BXWritePC\(\)](#) function.

The [LoadWritePC\(\)](#) and [ALUWritePC\(\)](#) functions are used for two cases where the behavior was systematically modified between architecture versions.

B1.2.4 Process state, PSTATE

Process state or [PSTATE](#) is an abstraction of process state information. All of the instruction sets provide instructions that operate on elements of PSTATE.

Note

In this chapter, references to [PSTATE](#) link to the more appropriate of:

- The Application-level view of [PSTATE](#) given in this section.
 - The System-level description in [Process state, PSTATE](#).
-

The following [PSTATE](#) information is accessible at EL0:

The condition flags

Flag-setting instructions set these. They are:

N	Negative Condition flag. If the result of the instruction is regarded as a two's complement signed integer, the PE sets this to: • 1 if the result is negative. • 0 if the result is positive or zero.
Z	Zero Condition flag. Set to: • 1 if the result of the instruction is zero. • 0 otherwise. A result of zero often indicates an equal result from a comparison.
C	Carry Condition flag. Set to: • 1 if the instruction results in a carry condition, for example an unsigned overflow that is the result of an addition. • 0 otherwise.
V	Overflow Condition flag. Set to: • 1 if the instruction results in an overflow condition, for example a signed overflow that is the result of an addition. • 0 otherwise.

Conditional instructions test the N, Z, C, and V Condition flags, combining them with the *Condition code* for the instruction, to determine whether the instruction must be executed. In this way, execution of the instruction is conditional on the result of a previous operation. For more information about conditional execution, see [Conditional execution](#).

The overflow or saturation flag

Q	Some instructions can set this. For those instructions that can, the PE: • Sets it to 1 if the instruction indicates overflow or saturation. • Leaves it unchanged otherwise.
----------	--

For more information, see [Pseudocode description of saturation](#).

The greater than or equal flags

GE[3:0]	The instructions described in Parallel addition and subtraction instructions update these to indicate the results from individual bytes or halfwords of the operation. These flags can control a later <code>SEL</code> instruction. For more information, see SEL .
----------------	--

PSTATE also contains *PE state controls*. There is no direct access to these from application level instructions, but they can be changed by side-effects of application level instructions. They are:

Instruction set state

J, T The current instruction set state, as shown in [Table B1-1](#). The J bit is RES0, see the Note in this section.

Table B1-1 PSTATE.{J, T} encoding

J	T	Instruction set state
0	0	A32
0	1	T32

A32 The PE is executing the A32 instruction set, summarized in [A32 Instruction Set Encoding](#).

T32 The PE is executing the T32 instruction set, summarized in [T32 Instruction Set Encoding](#).

Note

Encoding with J==1 before Armv8, Jazelle, and T32EE states

In previous versions of the Arm architecture, the encoding {1, 0} selected Jazelle state, and encoding {1, 1} selected T32EE state. From the introduction of Armv8, the architecture does not support either of these states, and these are encodings for unimplemented instruction set states, see [Unimplemented instruction sets](#). AArch32 state requires a Trivial Jazelle implementation, see [Trivial implementation of the Jazelle extension](#).

The IT block state

IT[7:0] The If-Then controls for the T32 **IT** instruction, which applies to the *IT block* of instructions that immediately follow the **IT** instruction. See [IT](#) for a description of the **IT** instruction and its associated **IT** block.

For more information about the use of **PSTATE.IT**, see [Use of PSTATE.IT](#).

Endianness mapping

E For data accesses, controls the endianness:

0 Little-endian.

1 Big-endian.

If an implementation does not provide:

- Big-endian support for data accesses, this bit is RES0.
- Little-endian support for data accesses, this bit is RES1.

Instruction fetches are always little-endian, and ignore **PSTATE.E**.

B1.2.4.1 Accessing PSTATE fields at EL0

The following sections describe which **PSTATE** fields can be directly accessed at EL0, and how they can be accessed:

- [The Application Program Status Register, APSR](#).
- [The SETEND instruction](#).

B1.2.4.1.1 The Application Program Status Register, APSR

At EL0, some [PSTATE](#) fields can be accessed using the Special-purpose *Application Program Status Register* ([APSR](#)). The APSR can be directly read using the MRS instruction, and directly written using the [MSR \(register\)](#) and [MSR \(immediate\)](#) instructions.

The APSR bit assignments are:

N, Z, C, V, bits [31:28]

The [PSTATE](#) Condition flags.

Q, bit [27] The [PSTATE](#) overflow or saturation flag.

Bits[26:24] Reserved, RES0. Software can use MSR instructions that write the top byte of the [APSR](#) without using a read-modify-write sequence. If it does this, it must write zeros to bits[26:24].

Bits[23:20, 15:0]

Reserved bits that are allocated to system features, or are available for future expansion. Unprivileged execution ignores writes to fields that are accessible only at EL1 or higher. However, application level software that writes to the APSR must treat reserved bits as *Do-Not-Modify* (DNM) bits. For more information about the reserved bits, see [The Current Program Status Register, CPSR](#).

These bits are UNKNOWN on a Read, and it is permitted that, on a read of [APSR](#):

- Bit[22] returns the value of [PSTATE](#).PAN.
- Bit[9] returns the value of [PSTATE](#).E.
- Bits[8:6] return the value of [PSTATE](#).{A, I, F}, the mask bits.
- Bits[4:0] return the value of [PSTATE](#).M[4:0]. Bit[4] is RES1 indicating that the PE is in AArch32 state.

Note

This is an exception to the general rule that an UNKNOWN field must not return information that cannot be obtained, at the current Privilege level, by an architected mechanism.

GE[3:0], bits [19:16]

The [PSTATE](#) greater than or equal flags.

The other [PSTATE](#) fields cannot be accessed by using the APSR.

The system level alias for the APSR is the [CPSR](#). The [CPSR](#) is a superset of the APSR. See [The Current Program Status Register, CPSR](#).

Writes to the [PSTATE](#) fields have side-effects on various aspects of PE operation. All of these side-effects, except side-effects on memory accesses associated with fetching instructions, are synchronous to the APSR write. This means they are guaranteed:

- Not to be visible to earlier instructions in the Execution stream.
- To be visible to later instructions in the Execution stream.

B1.2.4.1.2 The SETEND instruction

The T32 and A32 instruction sets both include an instruction to manipulate [PSTATE.E](#):

SETEND BE Sets [PSTATE.E](#) to 1, for big-endian operation.

SETEND LE Sets [PSTATE.E](#) to 0, for little-endian operation.

The SETEND instruction is unconditional. For more information, see [SETEND](#). Arm deprecates use of the SETEND instruction.

B1.2.4.2 Use of PSTATE.IT

[PSTATE.IT](#) provides the If-Then controls for the T32 IT instruction, which applies to the *IT block* of instructions that immediately follow the IT instruction.

[PSTATE.IT](#) divides into two subfields:

- IT[7:5]** Holds the *base condition* for the current IT block. The base condition is the top three bits of the Condition code specified by the <firstcond> field of the IT instruction.
- IT[4:0]** Encodes:
- Implicitly, the size of the IT block. This is the number of instructions that are to be conditionally executed. The size of the block is indicated by the position of the least significant 1 in this field, as shown in [Table B1-2](#).
 - For each instruction in the IT block, the least significant bit of the Condition code. This is encoded in the IT block entries that [Table B1-2](#) shows as Nx.

Note

Changing the least significant bit of a Condition code from 0 to 1 has the effect of inverting the Condition code.

Both subfields are all zeros when no IT block is active.

When an IT instruction is executed, [PSTATE.IT](#) is set according to the <firstcond> field of the instruction and the *Then* and *Else* (T and E) parameters in the instruction, see [IT](#). This means that, on executing an IT instruction, the initial state of [PSTATE.IT](#) depends on the number of instructions in the IT block, as [Table B1-2](#) shows:

Table B1-2 Initial state of PSTATE.IT on executing an IT instruction

Number of instructions in IT block	PSTATE.IT bits ^a						Notes
	[7:5]	[4]	[3]	[2]	[1]	[0]	
4	cond_base	N1	N2	N3	N4	1	-
3	cond_base	N1	N2	N3	1	0	-
2	cond_base	N1	N2	1	0	0	-
1	cond_base	N1	1	0	0	0	-
Not executing an IT instruction	000	0	0	0	0	0	No IT block is active

a. Combinations of the IT bits not shown in this table are reserved.

In [Table B1-2](#), N1 refers to the first instruction in the IT block, and N2, N3, and N4 refer to the second, third, and fourth instructions in the IT block if they are present,

When permitted, an instruction in an IT block is conditional, see [Conditional instructions](#) and [Conditional execution](#). The Condition code used is the current value of IT[7:4]. When an instruction in an IT block completes its execution normally, [PSTATE.IT](#)[4:0] is left-shifted by one bit, so that [PSTATE](#)[4] always relates to the next instruction to be executed.

Table B1-3 shows how `PSTATE.IT` during the execution of an `IT` instruction with four instructions in the IT block.

Table B1-3 Updates to `PSTATE.IT` when executing an IT instruction with a four-instruction IT block

IT block instruction being executed	PSTATE.IT bits ^a						Notes
	[7:5]	[4]	[3]	[2]	[1]	[0]	
First	cond_base	N1	N2	N3	N4	1	-
Second	cond_base	N2	N3	N4	1	0	-
Third	cond_base	N3	N4	1	0	0	-
Fourth	cond_base	N4	1	0	0	0	-
Not executing an <code>IT</code> instruction	000	0	0	0	0	0	No IT block is active

a. Combinations of the IT bits not shown in this table are reserved.

A few instructions, for example `BKPT`, cannot be conditional and therefore are always executed ignoring the current value of `PSTATE.IT`.

For details of what happens if an instruction in an IT block takes an exception, see [Overview of exception entry](#).

An instruction that might complete its normal execution by branching is only permitted in an IT block as the last instruction in the block. This means that normal execution of the instruction always results in `PSTATE.IT` advancing to execution where no IT block is active.

Implementations can provide a set of ITD control fields, `SCTLR.ITD`, and `HSCTLR.ITD`, to disable use of IT for some instructions, making them `UNDEFINED`. When an implementation includes ITD control fields, [Changes to an ITD control by an instruction in an IT block](#) describes the permitted `CONSTRAINED UNPREDICTABLE` behaviors if an instruction in an IT block changes the value of an ITD control to disable the use of the `IT` instruction.

On a branch or an exception return, if `PSTATE.IT` is set to a value that is not consistent with the instruction stream being branched to or returned to, then instruction execution is `CONSTRAINED UNPREDICTABLE`.

`PSTATE.IT` affects instruction execution only in T32 state. In A32 state, `PSTATE.IT` must be `0b00000000`, otherwise the behavior is `CONSTRAINED UNPREDICTABLE`.

For more information, see [CONSTRAINED UNPREDICTABLE behavior associated with IT instructions and PSTATE.IT](#).

B1.2.4.2.1 Changes to an ITD control by an instruction in an IT block

In an implementation that includes `SCTLR.ITD`, and `HSCTLR.ITD` controls, if an instruction in an IT block changes an ITD control so that the `IT` instruction using the IT block would be disabled, then one of the following behaviors applies:

- The change to the ITD field, once synchronized, has no effect on the execution of instructions in the current IT block, but applies only to any subsequent execution of an `IT` instruction to which the control applies.
- Synchronizing the change to the ITD field guarantees that all bits of `PSTATE.IT` are cleared to 0.

In addition, after the change to the ITD field has been synchronized, any remaining instructions in the IT block that would be made `UNDEFINED` by the new value of ITD are either:

- Executed normally.
- Treated as `UNDEFINED`.

The choice between the options described in this section is determined by the implementation, and any choice can vary between different changes to an ITD control by an instruction in an IT block.

B1.2.4.3 Pseudocode description of PSTATE PE state fields

The pseudocode function `CurrentInstrSet()` returns the current instruction set. The pseudocode function `SelectInstrSet()` selects a new instruction set.

`PSTATE.IT` advances after normal execution of an IT block instruction. This is described by the `AArch32_ITAdvance()` pseudocode function.

The pseudocode function `InITBlock()` tests whether the current instruction is in an IT block. The pseudocode function `LastInITBlock()` tests whether the current instruction is the last instruction in an IT block.

The `BigEndian()` pseudocode function tests whether big-endian data memory accesses are currently selected.

B1.2.5 Jazelle support

The architecture requires AArch32 state to include a trivial implementation of the Jazelle Extension, as described in [Trivial implementation of the Jazelle extension](#).

B1.3 Advanced SIMD and floating-point instructions

The Armv8-R AArch32 architecture supports Advanced SIMD and floating-point operations. Armv8-R can optionally support single-precision floating-point operations without Advanced SIMD.

The Advanced SIMD instructions perform packed *Single Instruction Multiple Data* (SIMD) operations, on either integer or single-precision floating-point operands. The floating-point instructions perform single-precision or double-precision scalar floating-point operations.

These instructions permit *floating-point exceptions*, such as Overflow or Divide by Zero, to be handled without trapping. When handled in this way, a floating-point exception causes a cumulative status register bit to be set to 1 and a default result to be produced by the operation. The architecture also optionally supports the trapping of floating-point exceptions. For more information about floating-point exceptions, see [Floating-point exceptions and exception traps](#).

The Advanced SIMD and floating-point instructions also provide the following conversion functions:

- Between half-precision floating-point and single-precision floating-point, in both directions.
- From double-precision, floating-point to single-precision floating-point or integer.

Some Advanced SIMD instructions support polynomial arithmetic over $\{0, 1\}$, as described in Polynomial arithmetic over $\{0, 1\}$.

For system level information about the Advanced SIMD and floating-point implementation, see [Advanced SIMD and floating-point support](#).

The following sections give more information about the Advanced SIMD and floating-point instructions:

- [Floating-point standards, and terminology](#).
- [The SIMD and floating-point register file](#).
- [Data types supported by the Advanced SIMD implementation](#).
- [Advanced SIMD and floating-point System registers](#).
- [Floating-point data types and arithmetic](#).
- [Flushing denormalized numbers to zero](#).
- [Floating-point exceptions and exception traps](#).
- [Controls of Advanced SIMD operation that do not apply to floating-point operation](#).
- [Implications of not including Advanced SIMD and floating-point support](#).
- [Pseudocode description of floating-point operations](#).

B1.3.1 The SIMD and floating-point register file

The Advanced SIMD and floating-point instructions use the same register file, which comprises 32 registers. This is distinct from the register file that holds the general-purpose registers and the PC.

The Advanced SIMD and floating-point views of the register file are different. The following sections describe these different views. [Figure B1-1](#) shows the views of the register file, and the way the word, doubleword, and quadword registers overlap.

B1.3.1.1 Advanced SIMD views of the register file

Advanced SIMD can view this register file as:

- Sixteen 128-bit quadword registers, Q0–Q15.
- Thirty-two 64-bit doubleword registers, D0–D31.

These views can be used simultaneously. For example, a program might hold 64-bit vectors in D0 and D1 and a 128-bit vector in Q1.

B1.3.1.2 Floating-point views of the register file

The Advanced SIMD and floating-point register file consists of thirty-two doubleword registers, which can be viewed as:

- Thirty-two 64-bit doubleword registers, D0–D31. This view is also available to Advanced SIMD instructions.
- Thirty-two 32-bit single word registers, S0–S31. Only half of the set is accessible in this view.

Note
In AArch32 state, half-precision floating point values are always represented using the bottom 16 bits of a single word register, S0–S31. When a half-precision value is written to a single word register, the top 16 bits of that register are set to 0.

The two views can be used simultaneously.

B1.3.1.3 SIMD and Floating-point register file mapping onto registers

Figure B1-1 shows the different views of the SIMD and floating-point register file, and the relationship between them.

Figure B1-1 SIMD and floating-point register file, AArch32 operation

The mapping between the registers is as follows:

- S<2n> maps to the least significant half of D<n>.
- S<2n+1> maps to the most significant half of D<n>.
- D<2n> maps to the least significant half of Q<n>.
- D<2n+1> maps to the most significant half of Q<n>.

For example, software can access the least significant half of the elements of a vector in Q6 by referring to D12, and the most significant half of the elements by referring to D13.

B1.3.1.4 Pseudocode description of the SIMD and Floating-point register file

The array `_Dclone`, accessors `S()`, and `D()` provide the S0-S31, D0-D31, and Q0-Q15 views of the Advanced SIMD and floating-point registers. The array `_Dclone` is used to hold a copy of the Advanced SIMD and VFP registers.

The `Din()` function returns a doubleword register from the `_Dclone` copy of the SIMD and Floating-point register file, and the `Qin()` function returns a quadword register from that register file.

Note

The `CheckAdvSIMDEnabled()` function copies the `D()` register file to `_Dclone`, see [Pseudocode description of enabling SIMD and floating-point functionality](#).

B1.3.2 Data types supported by the Advanced SIMD implementation

Advanced SIMD instructions can operate on integer and floating-point data, and the implementation defines a set of data types that support the required data formats. [Advanced SIMD vector formats in AArch32 state](#) describes these formats.

B1.3.2.1 Advanced SIMD vectors

In an implementation that includes support for Advanced SIMD operation, a register can hold one or more packed elements, all of the same size and type. The combination of a register and a data type describes a vector of elements. The vector is considered to be an array of elements of the data type specified in the instruction. The number of elements in the vector is implied by the size of the data elements and the size of the register.

Vector indices are in the range 0 to (number of elements - 1). An index of 0 refers to the least significant end of the vector. In [Advanced SIMD vector formats in AArch32 state](#), [Figure A1-2](#) shows the Advanced SIMD vector formats.

B1.3.3 Advanced SIMD and floating-point System registers

The Advanced SIMD and floating-point instructions have a shared register space for System registers. The only register in this space that is accessible at the Application level is the [FPSCR](#).

Writes to the [FPSCR](#) can have side-effects on various aspects of PE operation. All of these side-effects are synchronous to the [FPSCR](#) write. This means they are guaranteed not to be visible to earlier instructions in the Execution stream, and they are guaranteed to be visible to later instructions in the Execution stream.

See [Advanced SIMD and floating-point System registers](#) for the system level view of the registers.

These registers can be described as the *SIMD and floating-point System registers*.

B1.3.4 Floating-point data types and arithmetic

The T32 and A32 floating-point instructions support single-precision (32-bit) and double-precision (64-bit) data types and arithmetic as defined by the IEEE 754 floating-point standard. They also support the half-precision (16-bit) floating-point data type for data storage, by supporting conversions between single-precision and half-precision data types.

Arm standard floating-point arithmetic means IEEE 754 floating-point arithmetic with the restrictions described in [Floating-point support](#), including supporting only the input and output values described in [Arm standard floating-point input and output values](#).

The following sections describe the Advanced SIMD and floating-point formats:

- [Half-precision floating-point formats](#).
- [Single-precision floating-point format](#).
- [Double-precision floating-point format](#).

The following sections describe features of Advanced SIMD and floating-point processing:

- [Flushing denormalized numbers to zero](#).
- [NaN handling and the default NaN](#).

B1.3.5 Flushing denormalized numbers to zero

Calculations involving denormalized numbers and Underflow exceptions can reduce the performance of floating-point processing. For many algorithms, replacing the denormalized operands and Intermediate results with zeros can recover this performance, without significantly affecting the accuracy of the final result. Arm floating-point implementations allow denormalized numbers to be flushed to zero to permit this optimization. If a number satisfies the condition $0 < \text{Abs}(\text{result}) < \text{MinNorm}$, it is treated as a denormalized number.

MinNorm is defined as follows:

- For half-precision numbers, MinNorm is 2^{-14} .
- For single-precision, MinNorm is 2^{-126} .
- For double-precision numbers, MinNorm is 2^{-1022} .

Flushing denormals to zero is incompatible with the IEEE 754 standard, and must not be used when IEEE 754 compatibility is a requirement. Enabling flushing of denormals to zero must be done with care. Although it can improve performance on some algorithms, there are significant limitations on its use. These are application-dependent:

- On many algorithms, it has no noticeable effect, because the algorithm does not usually process denormalized numbers.
- On other algorithms, it can cause exceptions to occur and can seriously reduce the accuracy of the results of the algorithm.

B1.3.5.1 Flushing denormalized inputs to zero

If flushing denormalized inputs to zero is enabled for an instruction and a data type, and an input to that instruction is a denormalized number of that data type, the input operand is flushed to zero, and its sign bit is not changed.

If a floating-point operation has an input denormalized number that is flushed to zero, for all purposes within the instruction other than calculating Input Denormal floating-point exceptions, all inputs that are denormalized numbers are treated as though they were zero with the same sign as the input.

For Advanced SIMD and scalar floating-point instructions that process single-precision, or double-precision inputs, flushing denormalized inputs to zero can be controlled as follows:

- If **FPSCR.FZ** is 0, flushing denormalized inputs to zero occurs as follows:
 - For Advanced SIMD floating-point instructions, all single-precision and double-precision inputs that are denormalized numbers are flushed to zero.
 - For scalar floating-point instructions, single-precision and double-precision inputs that are denormalized numbers are not flushed to zero.
- If **FPSCR.FZ** is 1, for all T32 and A32 instructions, single-precision and double-precision inputs that are denormalized numbers are flushed to zero.

B1.3.5.2 Flushing denormalized outputs to zero

If flushing denormalized outputs to zero is enabled for an instruction and a data type, and an output from that instruction is a denormalized number of that data type, the output operand is flushed to zero, and its sign bit is not changed.

If a floating-point operation has an output denormalized number that is flushed to zero, for all purposes within the instruction other than calculating floating-point exceptions, all outputs that are denormalized numbers are treated as though they were zero with the same sign as the output.

For Advanced SIMD and scalar floating-point instructions that process single-precision, or double-precision inputs, flushing denormalized outputs to zero can be controlled as follows:

- If **FPSCR.FZ** is 0, flushing denormalized outputs to zero occurs as follows:
 - For Advanced SIMD floating-point instructions, all single-precision and double-precision outputs that are denormalized numbers are flushed to zero.
 - For scalar floating-point instructions, single-precision and double-precision outputs that are denormalized numbers are not flushed to zero.
- If **FPSCR.FZ** is 1, for all T32 and A32 instructions, single-precision and double-precision outputs that are denormalized numbers are flushed to zero.

B1.3.6 NaN handling and the default NaN

The IEEE 754 standard defines a NaN as a number with all exponent bits set to 1 and a nonzero number in the mantissa, and specifies that the sign bit of a NaN has no significance.

The Arm architecture additionally defines a *default NaN*, compliant with the IEEE 754 standard, that follows the encoding in [Table B1-4](#)

For a quiet NaN output derived from a signaling NaN operand, the most significant fraction bit is set to 1.

A PE is forbidden to generate a NaN whose value is strongly correlated to the values of non-NaN inputs as a speculative result of a floating-point calculation not involving NaN inputs.

B1.3.6.1 The default NaN

The default NaN is encoded as described in [Table B1-4](#).

Table B1-4 Default NaN encoding

	Single-precision IEEE format	Double-precision
Sign bit	0	0
Exponent	0xFF	0x7FF
Fraction	Bit[22] == 1, bits[21:0] == 0	Bit[51] == 1, bits[50:0] == 0

If [FPSCR.DN](#) is 1, for Advanced SIMD and floating-point instructions if any input to a floating-point operation performed by the instruction is a NaN, the output of the floating-point operation is the default NaN.

If [FPSCR.DN](#) is 0, for floating-point processing the default NaN is not used for NaN propagation.

If a floating-point instruction performs a floating-point operation, and that instruction generates an untrapped Invalid Operation floating-point exception for a reason other than one of the inputs being a signaling NaN, the output is the default NaN.

B1.3.6.2 NaN handling

The IEEE 754 standard does not specify which input NaN is used as the output NaN. Therefore, where the Arm architecture specifies which input NaN to use, this is an addition to the requirements in the IEEE 754 standard.

Depending on the operation, the exact value of a derived quiet NaN output might have both a different sign and a different number of fraction bits from its source. See instruction descriptions for details.

B1.3.6.3 NaN propagation

If an output NaN is derived from one of the operands, how the input NaN propagates to the output depends on the instruction and the number of operands.

If an output NaN is derived from an input NaN and if the size of the output format is the same as the input format, then all of the following apply:

- If the input NaN is a quiet NaN, the output NaN is the same as the input NaN.
- If the input NaN is a signaling NaN, the output NaN is derived as follows:
 - If the handling of a signaling NaN by the instruction generates an Invalid Operation exception, the output NaN is the quieted version of the input NaN.
 - If the handling of a signaling NaN by the instruction does not generate an Invalid Operation exception, the output NaN is the same as the input NaN.

If an output NaN is derived from an input NaN and if the size of the output format is larger than the input format, all of the following apply:

- If the input NaN is a quiet NaN, the output NaN is the same as the input NaN except that the mantissa is zero-extended in the low-order bit to fit the output format, and the exponent field is set to all ones.
- If the input NaN is a signaling NaN, the output NaN is the quieted version of the input NaN, except that the mantissa is zero-extended in the low-order bits and the exponent field is set to all ones.

If an output NaN is derived from an input NaN and if the size of the output format is smaller than the input format, all of the following apply:

- If the input NaN is a quiet NaN, the output NaN is the same as the input NaN except that the mantissa is truncated in the lower-order bits to fit the output format, and the exponent field is set to all ones.
- If the input NaN is a signaling NaN, the output NaN is the quieted version of the input NaN except that the mantissa is truncated in the lower-order bits to fit the output format, and the exponent field is set to all ones.

For the following descriptions, when an operand is described as *first* this relates to the left-to-right ordering of the arguments of the pseudocode function that describes the operation.

If `FPSCR.DN` is 0, for Advanced SIMD or floating-point instructions that perform a floating-point operation, NaN outputs that derive from NaN inputs are derived as follows:

- If all of the following apply, an instruction outputs a quiet NaN derived from the first signaling NaN operand:
 - At least one operand is a signaling NaN.
 - The instruction is not trapped.
- If all of the following apply, an instruction outputs a quiet NaN derived from the first NaN operand:
 - At least one operand is a NaN, but none of the operands is a signaling NaN.
 - The instruction is not trapped.

B1.3.7 Rounding

The rounding mode specifies how the exact result of a floating-point operation is rounded to a value in the destination format.

The rounding mode is either determined by the rounding mode control field `FPSCR.RMode` or by the instruction.

The rounding mode control field `FPSCR.RMode` can select the following rounding modes:

- Round to Nearest (RN) mode.
- Round towards Plus Infinity (RP) mode.
- Round towards Minus Infinity (RM) mode.
- Round towards Zero (RZ) mode.

The following two additional rounding modes are not selected by `FPSCR.RMode`, but are used by some instructions:

- Round to Odd mode.
- Round to Nearest with ties to away mode.

B1.3.7.1 Round to Nearest mode

Round to Nearest rounding mode rounds the exact result of a floating-point operation to a value that is representable in the destination format as follows:

- If the value before rounding has an absolute value that is too large to represent in the output format, the rounded value is an Infinity. The sign of the rounded value is the same as the sign of the value before rounding.
- If the value before rounding has an absolute value that is not too large to represent in the output format, the result is calculated as follows:
 - If the two nearest floating-point numbers bracketing the value before rounding are equally near, the result is the number with an even least significant digit.
 - If the two nearest floating-point numbers bracketing the value before rounding are not equally near, the result is the floating-point number nearest to the value before rounding.

Advanced SIMD arithmetic always uses the Round to Nearest setting, regardless of the value of the `RMode` bits.

B1.3.7.2 Round towards Plus Infinity mode

Round towards Plus Infinity rounding mode rounds the exact result of a floating-point operation to a value that is representable in the destination format. The result is the floating-point number in the output format that is closest to and not less than the value before rounding. The result can be plus infinity.

B1.3.7.3 Round towards Minus Infinity mode

Round towards Minus Infinity rounding mode rounds the exact result of a floating-point operation to a value that is representable in the destination format. The result is the number in the output format that is closest to and not greater than the value before rounding. The result can be minus infinity.

B1.3.7.4 Round towards Zero mode

Round towards Zero rounding mode rounds the exact result of a floating-point operation to a value that is representable in the destination format. The result is the floating-point number in the output format that is closest to and not greater in absolute value than the value before rounding.

B1.3.7.5 Round to Nearest with Ties to Away

Round to Nearest with Ties to Away rounding mode is used by the [VCVTA \(Advanced SIMD\)](#), [VCVTA \(floating-point\)](#), [VRINTA \(Advanced SIMD\)](#), and [VRINTA \(floating-point\)](#) instructions.

Round to Nearest with Ties to Away rounding mode rounds the exact result of a floating-point operation to a value that is representable in the destination format as follows:

- If the value before rounding has an absolute value that is too large to represent in the output format, the rounded value is an Infinity, the sign of the rounded value is the same as the sign of the value before rounding.
- If the value before rounding has an absolute value that is not too large to represent in the output format, the result is calculated as follows:
 - If the two nearest floating-point numbers bracketing the value before rounding are equally near, the result is the larger number.
 - If the two nearest floating-point numbers bracketing the value before rounding are not equally near, the result is the floating-point number nearest to the value before rounding.

B1.3.7.6 Round to Odd mode

Round to Odd mode is not defined by IEEE 754.

B1.3.8 Floating-point exceptions and exception traps

Execution of a floating-point instruction, or execution of an Advanced SIMD instruction that performs floating-point operations, can generate an exceptional condition, called a *floating-point exception*.

Note

An Advanced SIMD instruction that operates on floating-point values can perform multiple floating-point operations. Therefore, this section describes the handling of a floating-point exception on an *operation*, rather than on an *instruction*.

The architecture does not support asynchronous reporting of floating-point exceptions.

For each of the following floating-point exceptions, it is IMPLEMENTATION DEFINED whether an implementation includes synchronous exception generation:

- Input Denormal.
- Inexact.
- Underflow.
- Overflow.
- Divide by Zero.
- Invalid Operation.

If an implementation does not support synchronous exception generation from a floating-point exception, then that synchronous exception is never generated, and all statements about synchronous exception generation from that floating-point exception do not apply to the implementation.

If an implementation supports synchronous exception generation for a floating-point exception, then the registers that are presented to the exception handler are consistent with the state of the PE immediately before the instruction that caused the exception.

On return from a synchronous floating-point exception, software might not restore the cumulative exception flags.

Trapped floating-point exceptions are taken to the following levels:

- If a trapped floating-point exception occurs at EL0, the exception is taken to EL1.
- If a trapped floating-point exception occurs at EL1, it is taken to EL1.
- If a trapped floating-point exception occurs at EL2, it is taken to EL2.

If the exception is taken, then it is taken as an Undefined Instruction exception, see [Undefined Instruction exception](#). The [FPEXC](#) identifies the floating-point exceptions that occurred since the corresponding status bits in that register were last set to 0.

B1.3.8.1 Input Denormal exceptions

The cumulative floating-point exception bit [FPSCR.IDC](#), and the trap enable bit [FPSCR.IDE](#) both relate to Input Denormal exceptions.

If a single-precision or double-precision floating-point input is flushed to zero, an Input Denormal exception is generated.

If a half-precision floating-point value is flushed to zero, an Input Denormal exception is not generated.

B1.3.8.2 Inexact exceptions

The cumulative floating-point exception bit [FPSCR.IXC](#), and the trap enable bit [FPSCR.IXE](#) both relate to Inexact exceptions.

If a denormalized output is flushed to zero, an Inexact exception is not generated.

If a result is not flushed to zero, and the result does not equal the result calculated with unbounded exponent range and unbounded precision, then an Inexact exception is generated.

B1.3.8.3 Underflow exceptions

The cumulative floating-point trap enable bit [FPSCR.UFE](#) relates to Underflow exceptions.

For the purpose of Underflow floating-point exception generation, a denormalized number is detected before rounding is applied.

If the result of a floating-point operation is a denormalized number that is not flushed to zero, then the Underflow exception is generated as follows:

- If the result is exact, an Underflow floating-point exception is generated only if [FPSCR.UFE](#) is 1.
- If the result is inexact, an Underflow floating-point exception is always generated.

If the result of a floating-point operation is a denormalized number that is flushed to zero, then the Underflow floating-point exception is generated. The Underflow exception is not trapped regardless of the value of [FPSCR.UFE](#).

B1.3.8.4 Overflow exceptions

The cumulative floating-point exception bit [FPSCR.OFC](#), and the trap enable bit [FPSCR.OFE](#) both relate to Overflow exceptions.

If the output of an instruction rounded with an unbounded exponent is greater than the maximum normalized number for the output precision, an Overflow exception is generated.

If an untrapped Overflow exception is generated, the result is determined by the rounding mode and the sign of the result before rounding as follows:

- Round to Nearest carries all overflows to infinity with the sign of the result before rounding.
- Round towards Plus Infinity carries negative overflows to the most negative finite number of the output precision, and carries positive overflows to plus infinity.
- Round towards Minus Infinity carries positive overflows to the largest finite number of the output precision, and carries negative overflows to minus infinity.
- Round towards Zero carries all overflows to the output precision's largest finite number with the sign of the result before rounding.

B1.3.8.5 Divide by Zero exceptions

The cumulative floating-point exception bit [FPSCR.DZC](#), and the trap enable bit [FPSCR.DZE](#) both relate to Divide by Zero exceptions.

If a floating-point operation divides a finite nonzero number by zero, a Divide by Zero exception is generated.

For the purpose of Divide by Zero exception generation, testing for zero occurs after flushing of denormalized numbers to zero.

A denormalized dividend that is flushed to zero is treated as zero and prevents Divide by Zero from occurring.

If the dividend is a finite nonzero, normalized number, and the divisor is a denormalized number, the divisor is treated as zero and causes Divide by Zero to occur.

For the reciprocal and reciprocal square root estimate functions, the dividend is assumed to be +1.0. This means that a zero or denormalized operand to these functions causes generation of a Divide by Zero floating-point exception.

If a floating-point operation divides a finite nonzero number by zero, and the Divide by Zero exception is untrapped, the result is a correctly signed infinity.

B1.3.8.6 Invalid Operation exceptions

The cumulative floating-point exception bit [FPSCR.IOC](#), and the trap enable bit [FPSCR.IOE](#) both relate to Invalid Operation exceptions.

For any floating-point instruction that performs a floating-point operation, if any of the following apply, the instruction generates an Invalid Operation exception:

- At least one operand is a signaling NaN.
- Subtracting two equal-magnitude infinities that are of the same sign.
- Multiplying a zero by an infinity.
- Dividing a zero by a zero.
- Dividing an infinity by an infinity.
- Taking the square root of an operand that is less than zero.

For the purpose of Invalid Operation Exception generation, testing for zero occurs after flushing of denormalized numbers to zero. So a denormalized input that is flushed to zero is treated as zero.

If the input is one of: a quiet NaN, an infinity, or a number that overflows the values that can be represented in the output format, and if another exception is not generated to signal the condition, then a conversion from floating-point to either integer or fixed-point format, generates an Invalid Operation exception.

B1.3.8.7 Floating-point exception traps

For Advanced SIMD instructions, and for floating-point instructions when floating-point exception trapping is not supported, these are non-trapping exceptions and the data-processing instructions do not generate any trapped exceptions.

For floating-point instructions when floating-point exception trapping is supported:

- The floating-point exceptions can be trapped, by setting trap enable bits in the [FPSCR](#), see [Floating-point exceptions and exception traps](#), and:
 - When a trap is not enabled the corresponding floating-point exception updates the corresponding [FPSCR](#) cumulative bit, but does not generate an exception.

- When a trap is enabled the corresponding floating-point exception does not update the [FPSCR](#), but generates an exception. In this case, bits in the [FPEXC](#) indicate which floating-point exceptions have occurred.
- The definition of the Underflow floating-point exception is different in the trapped and cumulative exception cases. In the trapped case, the definition is:
 - The trapped Underflow floating-point exception occurs if the absolute value of the result of an operation, produced before rounding, is less than the minimum positive normalized number for the destination precision, regardless of whether the rounded result is inexact.
- As with cumulative exceptions, higher priority trapped exceptions can prevent lower priority exceptions from occurring, as described in [Combinations of floating-point exceptions](#).
- For Invalid Operation floating-point exceptions, for details of which quiet NaN is produced as the default result, see [NaN handling and the default NaN](#).
- For Overflow floating-point exceptions, the sign bit of the default result is determined normally for the overflowing operation.
- For Divide by Zero floating-point exceptions, the sign bit of the default result is determined normally for a division. This means it is the exclusive-OR of the sign bits of the two operands.

[Table B1-5](#) shows the results of untrapped floating-point exceptions. That table uses the following abbreviations:

MaxNorm	The maximum normalized number of the destination precision.
RM	Round towards Minus Infinity mode, as defined in the IEEE 754 standard.
RN	Round to Nearest mode, as defined in the IEEE 754 standard.
RP	Round towards Plus Infinity mode, as defined in the IEEE 754 standard.
RZ	Round towards Zero mode, as defined in the IEEE 754 standard.

For more information about the IEEE 754 descriptions of the rounding modes, see [Floating-point standards, and terminology](#).

Table B1-5 Results of untrapped floating-point exceptions

Exception type	Default result for positive sign	Default result for negative sign
IOC, Invalid Operation	Quiet NaN	Quiet NaN
DZC, Divide by Zero	+infinity	-infinity
OFC, Overflow	RN, RP: RM, RZ: +infinity +MaxNorm	RN, RM: RP, RZ: -infinity -MaxNorm
UFC, Underflow	Normal rounded result	Normal rounded result
IXC, Inexact	Normal rounded result	Normal rounded result
IDC, Input Denormal	Normal rounded result	Normal rounded result

B1.3.8.8 Combinations of floating-point exceptions

Many pseudocode functions perform *floating-point operations*, including [FixedToFP\(\)](#), [FPAdd\(\)](#), [FPCompare\(\)](#), [FPCompareEQ\(\)](#), [FPCompareGE\(\)](#), [FPCompareGT\(\)](#), [FPDiv\(\)](#), [FPMax\(\)](#), [FPMin\(\)](#), [FPMul\(\)](#), [FPMulAdd\(\)](#), [FPRecipEstimate\(\)](#), [FPRecipStep\(\)](#), [FPRSqrtEstimate\(\)](#), [FPRSqrtStep\(\)](#), [FPSqrt\(\)](#), [FPSub\(\)](#), and [FPToFixed\(\)](#). All of these operations can generate floating-point exceptions.

Note

[FPAbs\(\)](#) and [FPNeg\(\)](#) are not classified as *floating-point operations* because:

- They cannot generate floating-point exceptions.
 - The floating-point operation behavior described in the following sections does not apply to them:
 - [Flushing denormalized numbers to zero.](#)
 - [NaN handling and the default NaN.](#)
-

More than one exception might occur on the same operation. The architecture permits only the following combinations of floating-point exceptions:

- Overflow with Inexact.
- Underflow with Inexact.
- Input Denormal with one or more of the other floating-point exception types.

The priority order of these floating-point exceptions is that the Inexact exception is treated as lowest priority, and the Input Denormal exception is treated as highest priority.

When none of the floating-point exceptions caused by an operation is trapped, any floating-point exception that occurs causes the associated cumulative bit in the [FPSCR](#) to be set.

When one or more floating-point exceptions caused by an operation is trapped, the behavior of the instruction depends on the priority of the exceptions:

- If the higher priority floating-point exception is trapped, its trap handler is called. It is IMPLEMENTATION DEFINED whether any information about the lower priority floating-point exception is provided.

Note

Information about the lower priority floating-point exception might be provided in the [FPEXC](#).

However, information might be provided in another IMPLEMENTATION DEFINED way, for example using an IMPLEMENTATION DEFINED register.

Apart from this, the lower priority floating-point exception is ignored in this case.

- If the higher priority floating-point exception is untrapped, its cumulative bit is set to 1 and its default result is evaluated. Then the lower priority floating-point exception is handled normally, using this default result.

Some floating-point instructions specify more than one floating-point operation, as indicated by the pseudocode descriptions of the instruction. In such cases, a floating-point exception on one operation is treated as higher priority than a floating-point exception on another operation if the occurrence of the second floating-point exception depends on the result of the first operation. Otherwise, it is CONstrained UNPREDICTABLE which floating-point exception is treated as higher priority.

For example, a `VMLA.F32` instruction specifies a floating-point multiplication followed by a floating-point addition. The addition can generate Overflow, Underflow and Inexact floating-point exceptions, all of which depend on both operands to the addition and so are treated as lower priority than any floating-point exception on the multiplication. The same applies to Invalid Operation floating-point exceptions on the addition caused by adding opposite-signed infinities. The addition can also generate an Input Denormal floating-point exception, caused by the addend being a denormalized number while in Flush-to-zero mode. It is CONstrained UNPREDICTABLE which of an Input Denormal floating-point exception on the addition and a floating-point exception on the multiplication is treated as higher priority, because the occurrence of the Input Denormal floating-point exception does not depend on the result of the multiplication. The same applies to an Invalid Operation floating-point exception on the addition caused by the addend being a signaling NaN.

Note

The `VFMA` instruction performs a vector addition and a vector multiplication as a single operation. The `VFMS` instruction performs a vector subtraction and a vector multiplication as a single operation.

B1.3.9 Controls of Advanced SIMD operation that do not apply to floating-point operation

Earlier architectures permitted implementation of either, both, or neither of the Advanced SIMD and floating-point additions to the base instruction set, and provided some controls that applied to the Advanced SIMD functionality but not to the floating-point functionality. From the introduction of Armv8, Advanced SIMD functionality cannot be separated from floating-point functionality, but in AArch32 state these controls function as they did in earlier architectures. This means they apply only to the following instructions and instruction encodings:

- All instructions with encodings defined in:
 - [Advanced SIMD data-processing](#), for the T32 instruction set.
 - [Advanced SIMD data-processing](#), for the A32 instruction set.
- All instructions with encodings defined in:
 - [Advanced SIMD element or structure load/store](#), for the T32 instruction set.
 - [Advanced SIMD element or structure load/store](#), for the A32 instruction set.
- The form of the `VDUP` instruction described in [VDUP \(general-purpose register\)](#).
- The byte and halfword forms of the `VMOV` instructions described in each of:
 - [VMOV \(general-purpose register to scalar\)](#).
 - [VMOV \(scalar to general-purpose register\)](#).

The optional control for this functionality is the `HCPTR.TASE` field.

If the `HCPTR.TASE` control is not supported then the `HCPTR.TASE` field is RAZ/WI. This means the `HCPTR` does not provide a control that can trap execution of Advanced SIMD instructions to Hyp mode.

B1.3.10 Implications of not including Advanced SIMD and floating-point support

In general, the architecture requires the inclusion of the Advanced SIMD and floating-point instructions in all instruction sets. Exceptionally, for implementation targeting specialized markets, Arm might produce or license an implementation that does not provide any support for Advanced SIMD and floating-point instructions. In such an implementation, in AArch32 state:

- Each of the `CPACR.{cp10, cp11}` fields is RES0.
- Each of the `HCPTR.{TASE, TCP10, TCP11}` fields is RES1.
- The `FPEXC` register is UNDEFINED.

B1.3.11 Pseudocode description of floating-point operations

The following subsections contain pseudocode definitions of the floating-point functionality supported by the architecture:

- [Generation of specific floating-point values.](#)
- [Floating-point negation and absolute value.](#)
- [Floating-point value unpacking.](#)
- [Floating-point exception and NaN handling.](#)
- [Floating-point rounding.](#)
- [Selection of Arm standard floating-point arithmetic.](#)
- [Floating-point comparisons.](#)
- [Floating-point maximum and minimum.](#)
- [Floating-point addition and subtraction.](#)
- [Floating-point multiplication and division.](#)
- [Floating-point fused multiply-add.](#)
- [Floating-point reciprocal estimate and step.](#)
- [Floating-point square root.](#)
- [Floating-point reciprocal square root estimate and step.](#)
- [Floating-point conversions.](#)

B1.3.11.1 Generation of specific floating-point values

The following pseudocode functions generate specific floating-point values. The `sign` argument is '0' for the positive version and '1' for the negative version:

- `FPInfinity()`.
- `FPMaxNormal()`.
- `FPZero()`.
- `FPTwo()`.
- `FPThree()`.
- `FPDefaultNaN()`.

B1.3.11.2 Floating-point negation and absolute value

The floating-point negation and absolute value operations affect only the sign bit. They do not treat NaN operands specially, nor denormalized number operands when flush-to-zero is selected.

The floating-point negation operation is described by the pseudocode function `FPNeg()`. The floating-point absolute value operation is described by the pseudocode function `FPAbs()`.

B1.3.11.3 Floating-point value unpacking

The `FPUnpack()` function determines the type of a floating-point number, defined by `FPType()`, and its numerical value. It also does flush-to-zero processing on input operands.

B1.3.11.4 Floating-point exception and NaN handling

The `FPProcessException()` procedure checks whether a floating-point exception is trapped, and handles it accordingly. The floating-point exception types are defined by `FPExc()`.

The `FPProcessNaN()` function processes a NaN operand, producing the correct result value and generating an Invalid Operation floating-point exception if necessary. The `FPProcessNaNs()` function performs the standard NaN processing for a two-operand operation. The `FPProcessNaNs3()` function performs the standard NaN processing for a three-operand operation.

B1.3.11.5 Floating-point rounding

The `FPRound()` function rounds and encodes a floating-point result to a specified destination format. This includes processing Overflow, Underflow and Inexact floating-point exceptions and performing flush-to-zero processing on result values.

B1.3.11.6 Selection of Arm standard floating-point arithmetic

The `StandardFPCR()` function returns the `FPSCR` value that selects Arm standard floating-point arithmetic. Most of the arithmetic functions have a Boolean `fpscr_controlled` argument that is `TRUE` for Floating-point operations and `FALSE` for Advanced SIMD operations, and that selects between using the real `FPSCR` value and this value.

B1.3.11.7 Floating-point comparisons

The `FPCompare()` function compares two floating-point numbers, producing a {N, Z, C, V} Condition flags result as shown in Table B1-6:

Table B1-6 Effect of a Floating-point comparison on the Condition flags

Comparison result	N	Z	C	V
Equal	0	1	1	0
Less than	1	0	0	0
Greater than	0	0	1	0

Comparison result	N	Z	C	V
Unordered	0	0	1	1

This result defines the operation of the `VCMP` floating-point instruction. The `VCMP` instruction writes these flag values in the `FPSCR`. After using a `VMRS` instruction to transfer them to the `APSR`, they can control conditional execution as shown in [Table C1-1](#).

The `FPCompareEQ()`, `FPCompareGE()`, and `FPCompareGT()` functions describe the operation of Advanced SIMD instructions that perform floating-point comparisons.

B1.3.11.8 Floating-point maximum and minimum

The `FPMAX()` function returns the maximum of two floating-point numbers. The `FPMIN()` function returns the minimum of two floating-point numbers.

B1.3.11.9 Floating-point addition and subtraction

The `FPMUL()` function adds two floating-point numbers. The `FPSUB()` function subtracts one floating-point number from another floating-point number.

B1.3.11.10 Floating-point multiplication and division

The `FPMUL()` function multiplies two floating-point numbers. The `FPDIV()` function divides one floating-point number by another floating-point number.

B1.3.11.11 Floating-point fused multiply-add

The `FPMULADD()` function performs a floating-point fused multiply-add.

B1.3.11.12 Floating-point reciprocal estimate and step

The Advanced SIMD implementation includes instructions that support Newton-Raphson calculation of the reciprocal of a number.

The `VRECPE` instruction produces the initial estimate of the reciprocal. It uses the pseudocode functions:

- `FPRecipEstimate()`.
- `UnsignedRecipEstimate()`.

[Table B1-7](#) shows the results where input values are out of range.

Table B1-7 VRECPE results for out of range inputs

Number type	Input <code>Vm[i]</code>	Result <code>Vd[i]</code>
Integer	$\leq 0x7FFF_FFFF$	<code>0xFFFF_FFFF</code>
Floating-point	NaN	Default NaN
Floating-point	± 0 or denormalized number	$\pm\text{infinity}^a$
Floating-point	$\pm\text{infinity}$	± 0
Floating-point	Absolute value $\geq 2^{126}$	± 0

a. `FPSCR.DZC` is set to 1

The Newton-Raphson iteration:

$$x_{n+1} = x_n(2 - dx_n)$$

converges to $(1/d)$ if x_0 is the result of `VRECPE` applied to d .

The `VRECPS` instruction performs a $(2 - \text{op1} \times \text{op2})$ calculation and can be used with a multiplication to perform a step of this iteration. The functionality of this instruction is defined by the `FPrecipStep()` pseudocode function.

Table B1-8 shows the results where input values are out of range.

Table B1-8 VRECPS results for out of range inputs

Input Vn[i]	Input Vm[i]	Result Vd[i]
Any NaN	-	Default NaN
-	Any NaN	Default NaN
± 0.0 or denormalized number	$\pm$ infinity	2.0
$\pm$ infinity	± 0.0 or denormalized number	2.0

B1.3.11.13 Floating-point square root

The `FPSqrt()` function returns the square root of a floating-point number.

B1.3.11.14 Floating-point reciprocal square root estimate and step

The Advanced SIMD implementation includes instructions that support Newton-Raphson calculation of the reciprocal of the square root of a number.

The `VRSQRTE` instruction produces the initial estimate of the reciprocal of the square root. It uses the pseudocode functions:

- `FPRSqrtEstimate()`.
- `UnsignedRSqrtEstimate()`.

Table B1-9 shows the results where input values are out of range.

Table B1-9 VRSQRTE results for out of range inputs

Number type	Input Vm[i]	Result Vd[i]
Integer	$\leq 0 \times 3FFF_FFFF$	$0 \times FFFF_FFFF$
Floating-point	NaN, -(normalized number), -infinity	Default NaN
Floating-point	-0 or -(denormalized number)	- infinity ^a
Floating-point	+0 or +(denormalized number)	+infinity ^a
Floating-point	+infinity	+0

a. `FPSCR.DZC` is set to 1.

The Newton-Raphson iteration:

$$x_{n+1} = x_n(3 - dx_n^2)/2$$

converges to $(1/\sqrt{d})$ if x_0 is the result of `VRSQRTE` applied to d .

The `VRSQRTS` instruction performs a $(3 - \text{op1} \times \text{op2})/2$ calculation and can be used with two multiplications to perform a step of this iteration. The functionality of this instruction is defined by the `FPRSqrtStep()` pseudocode function.

Table B1-10 shows the results where input values are out of range.

Table B1-10 VRSQRTS results for out of range inputs

Input Vn[i]	Input Vm[i]	Result Vd[i]
Any NaN	-	Default NaN
-	Any NaN	Default NaN
± 0.0 or denormalized number	$\pm \text{infinity}$	1.5
$\pm \text{infinity}$	± 0.0 or denormalized number	1.5

`FPRSqrtStep()` calls the `FPHalvedSub()` pseudocode function.

B1.3.11.15 Floating-point conversions

The `FPConvert()` pseudocode function performs conversions between half-precision, single-precision, and double-precision floating-point numbers.

The `FPToFixed()` and `FixedToFP()` functions perform conversions between floating-point numbers and integers or fixed-point numbers.

B1.4 About the AArch32 System register interface

AArch32 state provides a System register encoding space, which is indexed by the parameter set {coproc, opc1, CRn, CRm, opc2}, and a set of System register access instructions. This encoding space is used for:

- System registers.
- System instructions, for:
 - Cache and branch predictor maintenance.
 - Address translation.

This encoding space uses only the coproc values 0b111x.

Note

The encoding space with coproc values 0b101x is redefined to provide Advanced SIMD and floating-point functionality.

The coproc encodings provide access to System register encoding space as follows:

- The (coproc==0b1111) encodings provide system control functionality, by providing access to System registers and System instructions. This includes architecture and feature identification, as well as control, status information and configuration support.
The following section gives a general description of these encodings: [Organization of registers in the \(coproc == 0b1111 \) encoding space](#).
These encodings also provide:
 - The Performance Monitor System registers. For more information, see [The Performance Monitors Extension](#).
- The (coproc==0b1110) encodings provide access to additional registers, which support:
 - Debug, see [AArch32 Self-hosted Debug](#).
 - The Jazelle identification registers, see [Jazelle support](#).

[UNPREDICTABLE, CONSTRAINED UNPREDICTABLE, and UNDEFINED behavior for AArch32 System register accesses](#) gives more information about permitted accesses to the System registers in AArch32 state.

Most functionality in the (coproc==0b111x) encoding space cannot be accessed by software executing at EL0. This manual clearly identifies those functions that can be accessed at EL0.

For more information:

- About this encoding space, including the naming of the parameters that index the space, see [The AArch32 System register interface](#).
- About the System interface access instructions, see [System register access instructions](#).

B1.5 Exceptions

The Arm architecture uses the following terms to describe various types of exceptional condition:

Exceptions In the Arm architecture, an *exception* causes entry to EL1 or EL2. On entry to the Exception level that the exception is taken to, it also causes entry to the PE mode in which the exception must be taken. Exception levels in the Armv8-R AArch32 architecture are based on PE modes. A software handler for the exception is then executed.

Note

The term *floating-point exception* does not use this meaning of *exception*. This term is described later in this list.

Exceptions include:

- Reset.
- Interrupts.
- Memory system aborts.
- Undefined instructions.
- Supervisor calls (SVCs), and Hypervisor calls (HVCs).
- Debug exceptions.

Most details of exception handling are not visible to application level software, and are described in [Handling exceptions that are taken to an Exception level using AArch32](#). In an implementation that includes all the Exception levels, aspects that are visible to application level software are:

- The `SVC` instruction causes a Supervisor Call exception. This provides a mechanism for unprivileged software to make a call to the operating system, or other system component that is accessible only at EL1.
- The `SMC` instruction is UNDEFINED.
- The `HVC` instruction causes a Hypervisor Call exception, but only if software execution is at EL1 or higher. Unprivileged software can only cause a Hypervisor Call exception by methods defined by the hypervisor, or by another component of the software system that executes at EL1 or higher.
- The `BKPT` instruction causes a Breakpoint Instruction exception, which is taken as a Prefetch Abort exception. This provides a mechanism for a debugger to insert breakpoints into unprivileged software, or for unprivileged software to make a call into a debugger that is accessible at EL1.
- The `WFI` (Wait for Interrupt) instruction provides a hint that nothing needs to be done until an interrupt or another WFI wakeup event occurs, see [Wait For Interrupt](#). This means the hardware might enter a low-power state until the wakeup event occurs.
- The `WFE` (Wait for Event) instruction provides a hint that nothing needs to be done until either an `SEV` instruction generates an event, or another WFE wakeup event occurs, see [Wait For Event and Send Event](#). This means the hardware might enter a low-power state until the wakeup event occurs.

Floating-point exceptions

These relate to exceptional conditions encountered during floating-point arithmetic, such as Divide by Zero or Overflow. For more information, see:

- [Floating-point exceptions and exception traps](#).
- The `FPEXC` and `FPSCR` register descriptions.
- ANSI/IEEE Std. 754, *IEEE Standard for Binary Floating-Point Arithmetic*.

Chapter B2

The AArch32 Application Level Memory Model

This chapter gives an application level description of the memory model for software executing in AArch32 state. This means it describes the memory model for execution in EL0 in the following sections:

- [About the Arm memory model](#)
- [Atomicity in the Arm architecture](#)
- [Definition of the memory model](#)
- [Ordering requirements defined by the formal concurrency model](#)
- [Additional ordering requirements outside of the scope of the formal concurrency model](#)
- [Endian support](#)
- [Caches and memory hierarchy](#)
- [Alignment support](#)
- [Memory types and attributes](#)
- [Mismatched memory attributes](#)
- [Synchronization and semaphores](#)

Note

In this chapter, System register names usually link to the description of the register in [AArch32 System Register Descriptions](#), for example [SCTLR](#).

Note

In the [Definition of the memory model](#) there is mention of Features and states that are not achievable in the Armv8-R AArch32 architecture in order to maintain concurrence with [formal concurrency model](#). The Memory Model should be interpreted in accordance with the Features and limitations of the architecture described in [Armv8-R AArch32 architecture extensions](#).

B2.1 About the Arm memory model

The Arm architecture is a weakly ordered memory architecture that permits the observation and completion of memory accesses in a different order from the program order. The following sections of this chapter provide the complete definition of the memory model, this introduction is not intended to contradict the definition found in those sections. In general, the basic principles of the memory model are:

- To provide a memory model that has similar weaknesses to those found in the memory models used by high-level programming languages such as C or Java. For example, by permitting independent memory accesses to be reordered as seen by other observers.
- To avoid the requirement for multi-copy atomicity in the majority of memory types.
- The provision of instructions and memory barriers to compensate for the lack of multi-copy atomicity in the cases where it would be needed.
- The use of address, data, and control dependencies in the creation of order so as to avoid having excessive numbers of barriers or other explicit instructions in common situations where some order is required by the programmer or the compiler.

This section contains:

- [Address space](#).
- [Memory type overview](#).

B2.1.1 Address space

Address calculations are performed using 32-bit registers. Supervisory software determines the valid address range.

Attempting to access an address that is not valid generates an [MPU fault](#).

Address calculations are performed modulo 2^{32} .

The result of an address calculation is UNKNOWN if it overflows or underflows the 32-bit address range A[31:0].

Memory accesses use the [MemA{size}\(\)](#), [MemO{size}\(\)](#), [MemU{size}\(\)](#), and [MemU_unpriv{size}\(\)](#) pseudocode accessors:

- The [MemA{size}\(\)](#) accessor makes an aligned access of the required type.
- The [MemO{size}\(\)](#) accessor makes an ordered access of the required type.
- The [MemU{size}\(\)](#) accessor makes an unaligned access of the required type
- The [MemU_unpriv{size}\(\)](#) accessor makes an unaligned, unprivileged access of the required type.

Each of these accessors calls the [Mem_with_type{size}\(\)](#) accessor, which specifies the required access. This calls [AArch32_MemSingle{size}\(\)](#), which performs an atomic, little-endian read.

The [AccessDescriptor](#) type defines the different access types and attributes.

Note

- The [AArch32 System Level Memory Model](#) includes descriptions of memory system features that are transparent to the application, including memory access, address translation, memory maintenance instructions, and alignment checking and the associated fault handling. These chapters also reference pseudocode descriptions of these operations.
 - For references to the pseudocode that relates to memory accesses, see [Basic memory access](#), [Unaligned memory access](#), and [Aligned memory access](#).
-

B2.1.2 Memory type overview

The architecture provides the following mutually-exclusive memory types:

Normal	This is generally used for the majority of memory operations, both read/write and read-only operations.
---------------	---

- Device** The Arm architecture forbids speculative reads of any type of Device memory. This means Device memory types are suitable attributes for read-sensitive locations.
- Locations of the memory map that are assigned to peripherals are usually assigned the Device memory attribute.
- Device memory has additional attributes that have the following effects:
- They prevent aggregation of reads and writes, maintaining the number and size of the specified memory accesses. See [Gathering](#).
 - They preserve the access order and synchronization requirements, both for accesses to a single peripheral and where there is a synchronization requirement on the observability of one or more memory write and read accesses. See [Reordering](#)
 - They indicate whether a write can be acknowledged other than at the end point. See [Early Write Acknowledgement](#).

For more information on Normal memory and Device memory, see [Memory types and attributes](#).

Note

Earlier versions of the Arm architecture defined a single Device memory type and a Strongly-ordered memory type. A Note in [Device memory](#) describes how these memory types map onto the memory types used from the introduction of Armv8.

B2.2 Atomicity in the Arm architecture

Atomicity is a feature of memory accesses, described as *atomic* accesses. The Arm architecture description refers to two types of atomicity, *single-copy atomicity* and *multi-copy atomicity*. The atomicity requirements for memory accesses depend on the memory type, and whether the access is explicit or implicit. For more information, see:

- [Requirements for single-copy atomicity.](#)
- [Properties of single-copy atomic accesses.](#)
- [Multi-copy atomicity.](#)
- [Requirements for multi-copy atomicity.](#)
- [Concurrent modification and execution of instructions.](#)

For more information about the memory types, see [Memory type overview](#).

B2.2.1 Requirements for single-copy atomicity

In AArch32 state, the single-copy atomic PE accesses are:

- All byte accesses.
- All halfword accesses to halfword-aligned locations.
- All word accesses to word-aligned locations.
- Memory accesses caused by `LDREXD` and `STREXD` instructions to doubleword-aligned locations.

`LDM`, `LDC`, `LDRD`, `STM`, `STC`, `STRD`, `PUSH`, `POP`, `RFE`, `SRS`, `VLDM`, `VLDR`, `VSTM`, and `VSTR` instructions are executed as a sequence of word-aligned word accesses. Each 32-bit word access is guaranteed to be single-copy atomic. The architecture does not require subsequences of two or more word accesses from the sequence to be single-copy atomic.

`LDRD` and `STRD` accesses to 64-bit aligned locations are 64-bit single-copy atomic as seen by accesses.

Note

This requirement has been added to avoid the need for complex measures to avoid atomicity issues when changing memory protection regions, without creating a requirement that all locations in the memory system are 64-bit single-copy atomic. This addition means:

- The system designer must ensure that all writable memory locations that might be used to hold translations, such as bulk SDRAM, can be accessed with 64-bit single-copy atomicity.
- Software must ensure that memory protection region attributes are not held in memory locations that cannot meet this atomicity requirement, such as peripherals that are typically accessed using a narrow bus.

This requirement places no burden on read-only memory locations for which reads have no side effects, since it is impossible to detect the size of memory accesses to such locations.

Advanced SIMD element and structure loads and stores are executed as a sequence of accesses of the element or structure size. The architecture requires the element accesses to be single-copy atomic if and only if both:

- The element size is 32 bits, or smaller.
- The elements are naturally-aligned.

Accesses to 64-bit elements or structures that are 32-bit aligned are executed as a sequence of 32-bit accesses, each of which is single-copy atomic. The architecture does not require subsequences of two or more 32-bit accesses from the sequence to be single-copy atomic.

When an access is not single-copy atomic by the rules described in this section, it is executed as a sequence of one or more accesses that aggregate to the size of the original access. Each of the accesses in this sequence is single-copy atomic, at least at the byte level.

Note

In this section, the terms *before the write operation* and *after the write operation* mean before or after the write operation has had its effect on the coherence order of the bytes of the memory location accessed by the write operation.

If, according to these rules, an instruction is executed as a sequence of accesses, a synchronous Data Abort exception or Debug state entry can be taken during that sequence. This causes execution of the instruction to be abandoned.

See [Data Abort exception](#)

If the synchronous Data Abort exception is returned from using the preferred return address, the instruction that generated the sequence of accesses is re-executed and so any access that was performed before the exception was taken is repeated. This also applies to an exit from Debug state.

Note

The exception behavior for these multiple access instructions means they are not suitable for use for writes to memory for the purpose of software synchronization.

For implicit accesses:

- Cache linefills and evictions have no effect on the single-copy atomicity of explicit transactions or instruction fetches.
- Instruction fetches are single-copy atomic:
 - At 32-bit granularity in A32 state.
 - At 16-bit granularity in T32 state.[Concurrent modification and execution of instructions](#) describes additional constraints on the behavior of instruction fetches.
- Translations which are performed using accesses that are single-copy atomic at 64-bit granularity when using the Long-descriptor format.

B2.2.2 Properties of single-copy atomic accesses

A memory access instruction that is single-copy atomic has the following properties:

1. For a pair of overlapping single-copy atomic store instructions, all of the overlapping writes generated by one of the stores are Coherence-after the corresponding overlapping writes generated by the other store.
2. For a single-copy atomic load instruction L_1 that overlaps a single-copy atomic store instruction S_2 , if one of the overlapping reads generated by L_1 Reads-from-memory one of the overlapping writes generated by S_2 , then none of the overlapping writes generated by S_2 are Coherence-after the corresponding overlapping reads generated by L_1 .

For more information, see [Definition of the memory model](#).

B2.2.3 Multi-copy atomicity

In a multiprocessing system, writes to a memory location are *multi-copy atomic* if the following conditions are both true:

- All writes to the same location are *serialized*, meaning they are observed in the same order by all observers, although some observers might not observe all of the writes.
- A read of a location does not return the value of a write until all observers observe that write.

Note

Writes that are not coherent are not multi-copy atomic.

B2.2.4 Requirements for multi-copy atomicity

For Normal memory, writes are not required to be multi-copy atomic.

For Device memory, writes are not required to be multi-copy atomic.

The memory model is Other-multi-copy-atomic. For more information, see [External visibility requirement](#).

B2.2.5 Concurrent modification and execution of instructions

The architecture limits the set of instructions that can be executed by one thread of execution as they are being modified by another thread of execution without requiring explicit synchronization.

Concurrent modification and execution of instructions can lead to the resulting instruction performing any behavior that can be achieved by executing any sequence of instructions that can be executed from the same Exception level, except where the instruction before modification and the instruction after modification are:

- When executing the A32 instruction set, a B, BKPT, BL, HVC, ISB, NOP, SMC, or SVC instruction.
- When executing the T32 instruction set, a 16-bit B, BKPT, BLX, BX, NOP, or SVC instruction.

In addition, for the 32-bit T32 instructions, for which [Instruction encodings](#) describes the meaning of {hw1, hw2}:

- hw1 of a 32-bit BL (immediate) instruction can be concurrently modified to hw1 of another BL (immediate) instruction:
 - This means that some of the most significant bits of the immediate value can be modified.
- hw1 of a 32-bit BLX (immediate) instruction can be concurrently modified to hw1 of another BLX immediate instruction:
 - This means that some of the most significant bits of the immediate value can be modified.
- hw1 of a 32-bit BL (immediate) or BLX (immediate) instruction can be concurrently modified to a T32 16-bit B, BX, BLX, BKPT, or SVC instruction. This modification also works in reverse.
- hw2 of a 32-bit BL (immediate) instruction can be concurrently modified to hw2 of another BL (immediate) instruction with a different immediate:
 - This means that some bits of the immediate value, including the least significant bits, can be modified.
- hw2 of a 32-bit BLX (immediate) instruction can be concurrently modified to hw2 of another BLX (immediate) instruction with a different immediate:
 - This means that some bits of the immediate value, including the least significant bits, can be modified.
- hw2 of a 32-bit B (immediate) instruction with a condition field can be concurrently modified to hw2 of another 32-bit B (immediate) instruction with a condition field with a different immediate:
 - This means that some bits of the immediate value, including the least significant bits, can be modified.
- hw2 of a 32-bit B (immediate) instruction without a condition field can be concurrently modified to hw2 of another 32-bit B (immediate) instruction without a condition field:
 - This means that some bits of the immediate value, including the least significant bits, can be modified.

Note

- In the T32 instruction set:
 - The only encodings of BKPT and SVC are 16-bit.
 - The only encoding of BL is 32-bit.
 - The ISB instruction can be concurrently modified and executed in the A32 and A64 instruction sets, but not in the T32 instruction set.
-

For the instructions explicitly identified in this section, the architecture guarantees that, after modification of the instruction, behavior is consistent with execution of either:

- The instruction originally fetched.
- A fetch of the modified instruction.

The instructions to which this applies are the B, BL, NOP, BKPT, SVC, HVC, and SMC instructions.

For both instruction sets, if one thread of execution changes a conditional branch instruction to another conditional branch instruction, and the change affects both the condition field and the branch target, execution of the changed instruction by another thread of execution before the change is synchronized can lead to either:

- The old condition being associated with the new target address.

- The new condition being associated with the old target address.

These possibilities apply regardless of whether the condition, either before or after the change to the branch instruction, is the *always* condition.

For all other instructions, to avoid UNPREDICTABLE or CONSTRAINED UNPREDICTABLE behavior, instruction modifications must be explicitly synchronized before they are executed. The required synchronization is as follows:

1. No PE must be executing an instruction when another PE is modifying that instruction.
2. To ensure that the modified instructions are observable, a PE that is writing the instructions must issue the following sequence of instructions and operations:

```
; Coherency example for self-modifying code
; Enter this code with <Rt> containing a new 32-bit instruction,
; to be held in Cacheable space at a location pointed to by Rn. Use STRH in the first
; line instead of STR for a 16-bit instruction.
STR <Rt>, [Rn]
DCCMVAU Rn                ; Clean data cache by MVA to point of unification (PoU)
DSB                        ; Ensure visibility of the data stored
ICIMVAU Rn                ; Invalidate instruction cache by VA to PoU
BPIMVA Rn                  ; Invalidate branch predictor by MVA to PoU
DSB
```

Note

- The DCCMVAU operation is not required if the area of memory is either Non-cacheable or Write-Through Cacheable.
 - If the contents of physical memory differ between the mappings, changing the mapping of VAs to PAs can cause the instructions to be concurrently modified by one PE and executed by another PE. If the modifications affect instructions other than those listed as being acceptable for modification, synchronization must be used to avoid UNPREDICTABLE or CONSTRAINED UNPREDICTABLE behavior.
-
3. In a multiprocessor system, the ICIMVAU and BPIMVA are broadcast to all PEs within the Inner Shareable domain of the PE running this sequence. However, once the modified instructions are observable, each PE that is executing the modified instructions must issue the following instruction to ensure execution of the modified instructions:

```
ISB                        ; Synchronize fetched instruction stream
```

For more information about the required synchronization operation, see [Synchronization and coherency issues between data and instruction accesses](#).

For information about the Memory Effects generated by instruction fetches, see [External visibility requirement](#).

B2.3 Definition of the memory model

This section describes observation and ordering in the memory model. It contains the following subsections:

- [Basic definitions.](#)
- [Intrinsic Dependency relations.](#)
- [Fetch-intrinsically-before.](#)
- [Dependency relations.](#)
- [Ordering relations.](#)
- [Observation relations.](#)
- [Definition of an Architecturally Allowed Execution.](#)
- [Alternative formulations of the External visibility requirement for Explicit Memory Effects.](#)
- [Ordering of instruction fetches.](#)
- [Memory barriers.](#)

For more information on endpoint ordering of memory accesses, see [Reordering](#).

In the memory model, the Shareability memory attribute indicates the degree to which hardware must ensure memory coherency between a set of observers, see [Memory types and attributes](#).

The architecture defines additional memory attributes and associated behaviors, which are defined in the system level section of this manual. See: [The AArch32 System Level Memory Model](#).

See also [Mismatched memory attributes](#).

B2.4 Ordering requirements defined by the formal concurrency model

The material presented in the current section corresponds to what is described in the [formal concurrency model](#). The definitions of relations, including but not limited to Dependency-ordered-before, Barrier-ordered-before, or Atomic-ordered-before, are automatically transliterated from the formal concurrency model.

The Arm memory model introduces a number of relations which are as follows:

- *Intrinsic relations*; For example, Intrinsic Data Dependencies, Intrinsic Control Dependencies, Intrinsic Order Dependencies and Translation-intrinsically-before are hardware requirements which stem from the instruction semantics.
- *After relations*; For example, Coherence-after and TLBI-after are relations which happen to be oriented that way in a specific execution, but could be oriented the other way in a different execution.
- *Observation relations*; For example, Explicit-Observed-by and TLBI-Observed-by build on *After relations* to describe an execution.
- *Ordered relations*; For example, Ordered-before and TLBI-ordered-before are architectural requirements which must be respected by hardware in all executions.

This section describes observation and ordering in the Arm memory model. It contains the following subsections:

- [Basic definitions.](#)
- [Intrinsic Dependency relations.](#)
- [Tag-check-intrinsically-before.](#)
- [Translation-intrinsically-before.](#)
- [Fetch-intrinsically-before.](#)
- [Dependency relations.](#)
- [Ordering relations.](#)
- [Observation relations.](#)
- [Definition of an Architecturally Allowed Execution.](#)
- [Alternative formulations of the External visibility requirement for Explicit Memory Effects.](#)

For more information about endpoint ordering of memory accesses, see Reordering.

In the Arm memory model, the Shareability memory attribute indicates the degree to which hardware must ensure memory coherency between a set of observers. See Memory types and attributes.

The Arm architecture defines additional memory attributes and associated behaviors, which are defined in the system level section of this manual. See:

- The AArch64 System Level Memory Model.
- The AArch64 Virtual Memory System Architecture.

See also Mismatched memory attributes.

The formal memory model described in this section covers much, but not all, of the memory system functionality. In particular the following are in scope:

- Ordering requirements for instructions that explicitly access memory (for example: LDR, STR, SWP, etc.).
 - This includes the ordering requirements between any two Explicit Memory Effects where:
 - The Explicit Memory Effects are to the same Location either from the same or different PEs.
 - One or both of the Explicit Memory Effects are generated by an atomic instruction.
 - A barrier instruction is in program order between the Explicit Memory Effects.
 - There is a dependency between the Explicit Memory Effects.
 - And excludes cases where:
 - At least one of the Explicit Memory Effects is generated by SVE instructions.
 - At least one of the Explicit Memory Effects is generated by SME instructions.
 - At least one of the Explicit Memory Effects is generated by instructions added by FEAT_MOPS.

- Ordering requirements relating to the Virtual Memory System Architecture:
 - This includes:
 - Implicit TTD Memory Read Effects.
 - Implicit TTD Memory Write Effects when FEAT_HAF or FEAT_HAFDBS is implemented.
 - MMU Fault Effects that cause Data Abort exceptions.
 - This excludes:
 - Any Effects relating to address translation instructions.
 - Any Effects relating to address translation for instruction fetch.
 - The ordering requirements between Implicit TTD Memory Effects that belong to different levels or stages of translation.
 - The ordering requirements relating to FEAT_HDBSS.
 - The ordering requirements relating to FEAT_HACDBS.
- Ordering requirements relating to tag checks when FEAT_MTE2 is implemented. This includes:
 - Implicit Tag Memory Read Effects generated by tag checked instructions.
 - Explicit Tag Memory Effects generated by tag load, tag store, tag and data store, and bulk allocation tag access instructions.
 - TagCheck Fault Effects generated by tag checked instructions.
- Ordering requirements relating to instruction fetch. This includes:
 - Implicit Instruction Memory Read Effects generated as a result of instruction fetch.
 - DC CVAU Effects.
 - IC Effects.
 - Undefined Instruction Fault Effects.

Note

Arm is in the process of formalizing many features of the memory system architecture, but this work is not complete at this time. The following items are not in scope:

- Ordering requirements relating to the Event Register.
- Ordering requirements relating to the Exclusives monitor.
- Endpoint arrival of memory accesses.
- Interactions between memory accesses and peripherals.
- Ordering requirements relating to asynchronous exceptions and error exceptions.
- Ordering requirements relating to the generic interrupt controller.
- Ordering requirements for direct and indirect System register reads and writes.
- Ordering requirements relating to FEAT_GCS.
- Ordering requirements relating to FEAT_SPE.
- Ordering requirements relating to FEAT_TRBE.
- Ordering requirements relating to FEAT_RME.
- Ordering requirements relating to RAS PE architecture.
- Ordering requirements of DC Effects generated by DC instructions other than the DC CVAU, `xt` instruction.

These will be addressed progressively in future versions of the Arm architecture, but until then, the required behaviors are described less formally in the prose and pseudocode of the Arm ARM.

For the purposes of the memory model, all Effects generated due to execution of an instruction are considered to be generated by the PE on which the instruction is executed. The list of all Effects of an instruction in the scope of the Arm Memory Model is further presented in [Effects](#).

In this section [Ordering requirements defined by the formal concurrency model](#), all of the following are assumed:

- One of the following applies:

- All PEs are part of the same Inner Shareable domain and all Memory Effects are to Inner Shareable or Outer Shareable memory as long as no TLB invalidations nor their corresponding DSB specify the Non-shareable domain.
- All PEs are part of the same Outer Shareable domain and all Memory Effects are to Outer Shareable memory as long as no TLB invalidations nor their corresponding DSB specify the Non-shareable domain or the Inner Shareable domain.
- All PEs are part of the Full System domain and all Memory Effects are to Normal, Inner Non-cacheable, Outer Non-cacheable memory or all Memory Effects are to Normal, Inner Write-Through, Outer Write-Through memory or all Memory Effects are to Device memory as long as all barriers specify the Full System domain and there are no TLB invalidations.
- All Memory Effects are to Normal, Inner Write-Back, Outer Write-Back memory. Behaviors in [Ordering requirements defined by the formal concurrency model](#) also apply to Memory Effects to memory with attributes other than Normal, Inner Write-Back, Outer Write-Back (for example, Device or Inner Write-Through, Outer Write-Through) as long as the behavior of the instruction which generated the Memory Effect is guaranteed for the memory type. For example, atomic instructions are only guaranteed to be atomic for Normal, Inner Write-Back, Outer Write-Back, Shareable memory. Memory Effects to memory with attributes other than Normal, Inner Write-Back, Outer Write-Back may require additional ordering behaviors than specified in [Ordering requirements defined by the formal concurrency model](#). Such additional behaviors are described in Memory types and attributes.
- All Memory Effects to a given Location are not using mismatched memory attributes as described in Mismatched memory attributes.

B2.4.1 Basic definitions

The Arm memory model provides a set of definitions that are used to construct conditions on the permitted sequences of accesses to memory.

Location

A *Location* is a Memory Location or a Tag Location. A *Memory Location* is a byte of data that is associated with an address in the physical address space. A *Tag Location* is a 4-bit MTE Allocation Tag that is associated with an address in the physical address space.

Effects

The *Effects* of an instruction can be:

- Register Effects.
- Memory Effects.
- Explicit Memory Effects.
- Implicit TTD Memory Effects.
- Hardware Update Effects.
- Tag Memory Effects.
- Implicit Instruction Memory Read Effects.
- Barrier Effects.
- Instruction Fetch Barrier Effects.
- Conditional Branching, and Intrinsic Branching Effects.
- Fault Effects, Exception Entry, and Exception Return Effects.
- TLBI Effects, Completed TLBI Effects and Invalidation Scopes.
- TLBUncacheable Effects.
- DC CVAU Effects.
- IC Effects, Completed IC Effects.
- Empty Effects.

Program order

An Effect E_1 of an instruction I_1 appears in program order before an Effect E_2 of an instruction I_2 if and only if I_1 occurs before I_2 in the order specified by the program. Each Effect generated by an instruction has a unique Effect identifier that characterizes it among the Effects generated by the same instruction.

Register Effects

The *Register Effects* of an instruction are register reads or register writes of that instruction. Register Effects only pertain to:

- General purpose registers from R0 to R30, excluding the zero register.
- SVE registers.
- SIMD/FP registers.
- PSTATE.NZCV.
- Direct reads from System registers that are readable.
- Direct writes to System registers that are writable.
- Direct reads from Special-purpose registers that are readable.
- Direct writes to Special-purpose registers that are writable.

For an instruction that accesses registers, a *Register Read Effect* is generated for each register read by the instruction and a *Register Write Effect* is generated for each register written by the instruction. An instruction may generate both Register Read and Write Effects.

Memory Effects

The *Memory Effects* of an instruction are the Read or Write Effects from memory of that instruction. For an instruction that accesses memory, a *Memory Read Effect* is generated for each [Location](#) read from by the instruction and a *Memory Write Effect* is generated for each [Location](#) written to by the instruction. An instruction can generate both Memory Read and Write Effects.

Explicit Memory Effects

An *Explicit Memory Effect* is a Memory Read or Memory Write Effect that is generated by one of the following:

- A load instruction, store instruction, atomic instruction, Tag and Data store instruction, DC ZVA, DC GZVA, or STZGM; to access the Memory Location(s) addressed by any of the following from the instruction:
 - The X_n | SP operand, plus any applicable offset.
 - The PC plus the offset specified by the <label> argument.
- A Tag load instruction, Tag store instruction, Tag and Data store instruction, Bulk Allocation tag access instruction, DC GZVA, or DC GVA; to access the Tag Location(s) addressed by the X_n | SP operand, plus any applicable offset, of the instruction.
- A Memory Copy or Memory Set instruction; to access the Memory Location(s) addressed by the X_s or X_d operand of the instruction, including all of the bytes within the range specified by the X_n operand of the instruction.
- A Memory Set with tag setting instruction; to access the Tag Location(s) addressed by the X_s or X_d operand of the instruction, including all of the Allocation tags within the range specified by the X_n operand of the instruction.
- An MRS or MSR instruction that is transformed into a Memory Effect due to FEAT_NV2; to access the Memory Locations addressed by VNCR_EL2 plus the offset for the specified register.

Note

Prefetch memory instructions do not generate any Explicit Memory Effects.

Implicit TTD Memory Effects

Implicit Translation Table Descriptor Memory Effects (Implicit TTD Memory Effects) are Memory Read or Write Effects to translation table descriptors caused by address translation, including the hardware updates for the Access Flag or the Dirty State of a TTD.

Hardware Update Effects

Hardware Update Effects are Implicit TTD Memory Write Effects that correspond to writes modifying the Access Flag or the Dirty State of a TTD.

For more information on Hardware Updates of the Access Flag or Dirty State, see Hardware management of the Access flag and Hardware management of the dirty state.

Note

A Hardware Update Effect for the Access Flag may occur even in the absence of corresponding architecturally executed instructions, in which case the Hardware Update Effect is considered autonomous. Autonomous Hardware Update Effects are not constrained by the ordering relations that apply to the Hardware Update Effects of architecturally executed instructions.

Tag Memory Effects

Tag Memory Effects are a subset of Memory Effects. A Tag Memory Effect refers to a Memory Read or Write Effect to a [Tag Location](#). For example:

- LDG and LDGM instructions generate an Explicit Tag Memory Read Effect for their read from a [Tag Location](#).
- STG, STGM, STGP, DC GZVA, and DC GVA instructions generate an Explicit Tag Memory Write Effect for their write to a [Tag Location](#).
- A Tag Checked memory access generates an Implicit Tag Memory Read Effect for its read of a [Tag Location](#), as well as an Explicit Data Memory Effect.

Implicit Instruction Memory Read Effects

An *Implicit Instruction Memory Read Effect* refers to a Memory Read Effect generated as a result of an instruction fetch.

Barrier Effects

Barrier instructions generate *Barrier Effects*. In this chapter, the resulting Effect is named after the instruction. Therefore, an ISB instruction generates an ISB Effect, a DMB instruction generates a DMB Effect, and a DSB instruction generates a DSB Effect.

The following conventions are used when referring to DMB Effects:

- A DMB FULL Effect is generated by a DMB instruction with neither a LD nor ST qualifier.
- A DMB LD Effect is generated by a DMB instruction with the LD qualifier.
- A DMB ST Effect is generated by a DMB instruction with the ST qualifier.

The following conventions are used when referring to DSB Effects:

- A DSB FULL Effect is generated by a DSB instruction with neither a LD nor ST qualifier.
- A DSB LD Effect is generated by a DSB instruction with the LD qualifier.
- A DSB ST Effect is generated by a DSB instruction with the ST qualifier.

Instruction Fetch Barrier Effects

An *Instruction Fetch Barrier Effect* (IFBE) is generated by any of the following:

- A [Context Synchronization event](#).
- An exception entry to ELx, regardless of the value of SCTLR_ELx.EIS, due to an exception generated for any reason other than any of the following:
 - SVC instruction execution that is not trapped.
 - HVC instruction execution that is not disabled.
 - SMC instruction execution that is not trapped or disabled.
 - [BKPT](#) instruction execution.
 - BRK instruction execution.

Note

- If FEAT_ExS is not implemented, or if FEAT_ExS is implemented and the SCTLR_ELx.EOS field is 1, an Exception Return effect is an IFBE due to it being a [Context Synchronization event](#).
 - If FEAT_ExS is not implemented, or if FEAT_ExS is implemented and the SCTLR_ELx.EIS field is 1, the Exception entry effects due to the exceptions excluded above are IFBEs due to being [Context Synchronization events](#).
-

Conditional Branching, and Intrinsic Branching Effects

Branching Effects are generated when a choice is made between two possible paths in the execution flow. Branching Effects represent such decision points.

Conditional Branching Effects are generated by Conditional branch instructions, when as a consequence of evaluating a condition a choice potentially affecting the execution flow of other subsequent instructions is made.

Intrinsic Branching Effects due to a translation occur when, as a consequence of reading a TTD, a choice is made between raising a fault (for example, if the descriptor is invalid) or performing a physical access. *Intrinsic Branching Effects* represent such decision points.

Intrinsic Branching Effects due to tag checking occur when, as a consequence of reading a tag, a choice is made between raising a fault (that is, due to a failed tag check) or performing a physical access. *Intrinsic Branching Effects* represent such decision points.

Intrinsic Branching Effects due to instruction fetch occur when, as a consequence of reading and decoding an instruction, a choice is made between raising a fault (for example, as a result of fetching an illegal instruction) or proceeding to execute the valid instruction. *Intrinsic Branching Effects* represent such decision points.

Note

Conditional Selection instructions and Compare-and-Swap instructions generate *Intrinsic Branching Effects*.

Fault Effects, Exception Entry, and Exception Return Effects

An instruction that encounters a [fault](#) generates a Fault Effect. An instruction that encounters a fault leading to a synchronous exception generates a Fault Effect that is also an *Exception Entry Effect*, for example as a result of reading an invalid TTD or fetching an illegal instruction.

An ERET instruction generates an *Exception Return Effect*.

A Fault Effect generated by the MMU is called an *MMU Fault Effect*. See MMU fault types for a full list of faults generated by the MMU.

A Fault Effect generated by a failed Tag Check is called a *TagCheck Fault Effect*.

Note

- An instruction that encounters an asynchronous Tag Check Fault generates a TagCheck Fault Effect that is not an Exception Entry Effect.
 - An instruction that encounters a synchronous Tag Check Fault generates a TagCheck Fault Effect that is also an Exception Entry Effect.
-

TLBI Effects, Completed TLBI Effects and Invalidation Scopes

TLBI Effects are generated by TLBI instructions.

A TLBI Effect E_1 is a *Completed TLBI Effect* if E_1 appears in program order before a DSB FULL Effect.

The *Invalidation scope* of a TLBI Effect is a set Memory Effects. For a Virtual Address x , a Memory Read or Write Effect to the TTD of x is in the Invalidation Scope of a TLBI Effect if x is in the scope of the TLBI instruction. For the full description of the scope of TLBI instructions, see TLB maintenance instruction scope.

TLBUncacheable Effects

An MMU Fault Effect is TLBUncacheable if it is one of:

- A Translation Fault Effect.
- An Access Flag Fault Effect.
- An Address Size Fault Effect.
- A synchronous External Abort on translation table walk, such that it cannot be determined whether the TTD would otherwise generate a Translation Fault, Access Flag Fault, or Address Size Fault effect.

Note

A Permission Fault Effect is not TLBUncacheable.

DC CVAU Effects

DC CVAU Effects are generated by DC CVAU instructions.

IC Effects, Completed IC Effects

IC Effects are generated by IC IALLUIS, IC IALLU or IC IVAU instructions. An IC Effect E_1 is a *Completed IC Effect* if E_1 appears in program order before a DSB FULL Effect.

Empty Effects

Empty Effects are generated by instructions where a decision point, represented by a Branching Effect, leads to no further action resulting from that decision. For example, when FEAT_MTE_ASYNC is implemented and Tag Check Faults are reported asynchronously, a successful tag comparison generates an Empty Effect instead of a TagCheck Fault Effect.

Low-order Bits

The Low-order Bits of an address are the bits that remain unchanged in the translation process of an input address to an output address. The number of low-order bits that remain unchanged depends on the translation granule size.

Same Low-order Bits

Two Effects E_1 and E_2 have the Same Low-order Bits if the Low-order Bits of the address of E_1 and the Low-order Bits of the address of E_2 match.

Note

The address associated with an MMU Fault Effect is the faulting address as indicated in FAR_ELx.

Effects with a valid Physical Address

An Effect E_1 is an Effect with a valid Physical Address if one of the following applies:

- E_1 is a Memory Effect.
- E_1 is a DC Effect.
- E_1 is an IC Effect.

Note

In situations where accessing a Physical Address generates an MMU fault, the PE does not generate the corresponding Memory Effect or DC Effect or IC Effect.

Same Location

An Effect E_1 and an Effect E_2 are to the *Same Location* if one of the following applies:

- All of the following apply:
 - E_1 is an Effect with a valid Physical Address.
 - It is not the case that E_1 is a Tag Memory Effect.
 - E_1 and E_2 are to the same Physical Address.
 - E_2 is an Effect with a valid Physical Address.
 - It is not the case that E_2 is a Tag Memory Effect.
- All of the following apply:
 - E_1 is a Tag Memory Effect.
 - E_1 and E_2 are to the same Physical Address.
 - E_2 is a Tag Memory Effect.

Same Cache Line

An Effect E_1 and an Effect E_2 are to the *Same Cache Line* if:

- E_1 and E_2 are Memory Effects or DC CVAU Effects or IC Effects.
- E_1 and E_2 are to PAs that are on the Same Cache Line as follows from section Cache identification.

Successful Read-Modify-Write pair

Two Effects E_1 and E_2 form a *Successful Read-Modify-Write* pair if all of the following apply:

- E_1 is a Memory Read Effect.
- E_2 is a Memory Write Effect.
- E_1 and E_2 are to the Same Location.
- One of the following applies:
 - E_1 and E_2 are generated by the same atomic instruction.
 - E_1 and E_2 are generated by the same successful Load-Exclusive/Store-Exclusive instruction pair.

Reads-from-memory

The *Reads-from-memory* relation couples Memory Read and Write Effects to the same [Location](#) so that each Memory Read Effect is paired with exactly one Memory Write Effect in the execution of a program. A Memory Read Effect E_2 Reads-from-memory a Memory Write Effect E_1 , if and only if E_1 and E_2 are to the same location and E_2 takes its data from E_1 .

For two Effects E_1 and E_2 if all of the following apply:

- E_1 is an Explicit Memory Read Effect.
- E_2 is an Explicit Memory Write Effect.
- E_1 appears in program order before E_2 .
- E_1 and E_2 are to the Same Location.

then it is not the case that E_1 Reads-from-memory E_2 .

For two Effects E_1 and E_2 if all of the following apply:

- E_1 is an Explicit Memory Read Effect.
- E_2 is an Explicit Memory Write Effect.
- E_1 and E_2 form a successful Read-Modify-Write pair.

then it is not the case that E_1 Reads-from-memory E_2 .

For two Effects E_1 and E_2 if all of the following apply:

- E_1 is an Implicit Tag Memory Read Effect.
- E_2 is an Explicit Memory Write Effect.
- E_1 appears in program order before E_2 .
- E_1 and E_2 are to the Same Location.

then it is not the case that E_1 Reads-from-memory E_2 .

Coherence order

There is a per-location *Coherence order* relation that provides a total order over all Memory Write Effects to that Location, starting with a notional Memory Write Effect of the initial value. The Coherence order of a [Location](#) represents the order in which Memory Write Effects to the [Location](#) arrive at memory.

Local register read successor

An Effect E_2 is a *Local register read successor* of an Effect E_1 if all of the following apply:

- E_1 is a Register Write Effect.
- E_1 appears in program order before E_2 .
- E_1 and E_2 are to the same Register.
- It is not the case that all of the following apply:
 - E_1 appears in program order before E_3 .

- E_1 and E_3 are to the same Register.
- E_3 is a Register Write Effect.
- E_3 appears in program order before E_2 .
- E_3 and E_2 are to the same Register.
- E_2 is a Register Read Effect.

Local memory read successor

An Effect E_2 is a *Local memory read successor* of an Effect E_1 if all of the following apply:

- E_1 is a Memory Write Effect.
- E_1 appears in program order before E_2 .
- E_1 and E_2 are to the Same Location.
- E_2 is a Memory Read Effect.
- There is no Memory Write Effect E_3 to the Same Location as E_1 such that E_1 appears in program order before E_3 and E_3 appears in program order before E_2 .

Local memory write successor

An Effect E_2 is a *Local memory write successor* of an Effect E_1 if one of the following applies:

- All of the following apply:
 - One of the following applies:
 - E_1 is an Explicit Memory Effect.
 - E_1 is an Implicit Tag Memory Read Effect.
 - E_1 appears in program order before E_2 .
 - E_1 and E_2 are to the Same Location.
 - E_2 is an Explicit Memory Write Effect.
- All of the following apply:
 - E_1 is an Implicit TTD Memory Read Effect.
 - E_1 appears in program order before E_2 .
 - E_1 and E_2 are to the Same Location.
 - One of the following applies:
 - E_2 is an Explicit Memory Write Effect.
 - E_2 is a Hardware Update Effect.

Coherence-before, Coherence-after

A Memory Write Effect E_1 is *Coherence-before* a Memory Write Effect E_2 to the same [Location](#) if E_1 is sequenced before E_2 in the Coherence order for the [Location](#).

A Memory Read Effect E_1 is *Coherence-before* a Memory Write Effect E_2 to the same [Location](#) if E_1 Reads-from-memory a Memory Write Effect E_3 and E_3 is Coherence-before E_2 .

An Effect E_2 is *Coherence-after* an Effect E_1 if E_1 is *Coherence-before* E_2 .

For two Effects E_1 and E_2 if all of the following apply:

- E_1 is an Explicit Memory Write Effect.
- E_2 is an Explicit Memory Write Effect.
- E_1 appears in program order before E_2 .
- E_1 and E_2 are to the Same Location.

then it is not the case that E_2 is Coherence-before E_1 .

For two Effects E_1 and E_2 if all of the following apply:

- E_1 is an Explicit Memory Write Effect.
- E_2 is an Explicit Memory Read Effect.
- E_1 appears in program order before E_2 .
- E_1 and E_2 are to the Same Location.

then it is not the case that E_2 is Coherence-before E_1 .

For two Effects E_1 and E_2 if all of the following apply:

- E_1 is an Explicit Memory Write Effect.
- E_2 is an Implicit Tag Memory Read Effect.
- E_1 appears in program order before E_2 .
- E_1 and E_2 are to the Same Location.

then it is not the case that E_2 is Coherence-before E_1 .

TLBI-before, TLBI-after

For two Effects E_1 and E_2 , if and only if all of the following applies:

- E_1 is a Completed TLBI Effect.
- E_2 is an Implicit TTD Memory Read Effect.
- E_2 is in the Invalidation Scope of E_1 .

then one and only one of the following applies:

- E_1 is *TLBI-after* E_2 (equivalently E_2 is *TLBI-before* E_1), or
- E_2 is *TLBI-after* E_1 (equivalently E_1 is *TLBI-before* E_2).

Note

The TLBI-after relation enumerates all possible pairs (E_1, E_2) where E_1 is a TLBI Effect and E_2 is an Implicit TTD Memory Read Effect such that E_2 is in the Invalidation Scope of E_1 , and the TLBI-after relation is asymmetric.

DC-before, DC-after

For two Effects E_1 and E_2 , if all of the following applies:

- E_1 is a DC CVAU Effect.
- E_2 is an Explicit Memory Write Effect.
- E_1 and E_2 are to the Same Cache Line.

then one of the following applies:

- E_1 is *DC-after* E_2 (equivalently E_2 is *DC-before* E_1), or
- E_2 is *DC-after* E_1 (equivalently E_1 is *DC-before* E_2).

Note

The DC-after relation enumerates all possible pairs (E_1, E_2) where E_1 is a DC CVAU Effect and E_2 is an Explicit Memory Write Effect such that E_1 and E_2 are to the Same Cache Line, and the relation DC-after is asymmetric.

IC-before, IC-after

For two Effects E_1 and E_2 , if and only if all of the following applies:

- E_1 is a completed IC Effect.
- E_2 is an Implicit Instruction Memory Read Effect.
- E_1 and E_2 are to the Same Cache Line.

then one and only one of the following applies:

- E_1 is *IC-after* E_2 (equivalently E_2 is *IC-before* E_1), or
- E_2 is *IC-after* E_1 (equivalently E_1 is *IC-before* E_2).

Note

The IC-after relation enumerates all possible pairs (E_1, E_2) where E_1 is a completed IC Effect and E_2 is an Implicit Instruction Memory Read Effect such that E_1 and E_2 are to the Same Cache Line, and the relation IC-after is asymmetric.

Single-copy-atomic grouping

A *single-copy-atomic grouping* gathers Explicit Memory Effects generated by the same instruction when the architecture requires the Explicit Memory Effects to be single-copy atomic as defined in Requirements for single-copy atomicity. For example, an aligned STRH instruction generates two Explicit Memory Write Effects that are in the same single-copy-atomic grouping.

Atomicity of Successful Read-Modify-Write pair

For two Effects E_1 and E_2 if all of the following apply:

- E_1 and E_2 form a successful Read-Modify-Write pair.
- There is an Explicit Memory Write Effect E_3 .
- It is not the case that all of the following apply:
 - E_1 is an Explicit Memory Effect.
 - E_1 and E_3 are from the same Processing Element.
 - E_2 is an Explicit Memory Effect.
 - E_2 and E_3 are from the same Processing Element.

then it is not the case that E_1 is Coherence-before E_3 and E_3 is Coherence-before E_2 .

B2.4.2 Intrinsic Dependency relations

Intrinsic Dependencies are as follows:

Intrinsic Data Dependency

There is an *Intrinsic Data Dependency* from an Effect E_1 to an Effect E_2 if and only if all the following apply:

- It is not the case that E_1 is an Intrinsic Branching Effect.
- E_1 and E_2 are generated by the same instruction $\mathbb{I}$.
- The instruction semantics for that instruction $\mathbb{I}$ indicate that the value produced by E_1 is consumed by E_2 .

Note

This applies even in cases where the Intrinsic Data Dependency might be perceived to be a false dependency.

Intrinsic Control Dependency

There is an *Intrinsic Control Dependency* from an Effect E_1 to an Effect E_2 if and only if all the following apply:

- E_1 is an Intrinsic Branching Effect.
- E_1 and E_2 are generated by the same instruction $\mathbb{I}$.
- The instruction semantics for that instruction $\mathbb{I}$ indicate that the generation of E_2 is conditional and based on the determination of E_1 .

Intrinsic Order Dependency

There is an *Intrinsic Order Dependency* from an Effect E_1 to an Effect E_2 if and only if all the following apply:

- E_1 is a Memory Effect.
- E_1 and E_2 are generated by the same instruction $\mathbb{I}$.
- The instruction semantics for that instruction $\mathbb{I}$ indicate that E_1 is generated before E_2 .
- It is not the case that there is an Intrinsic Data Dependency from E_1 to E_2 .
- It is not the case that there is an Intrinsic Control Dependency from E_1 to E_2 .
- E_2 is a Memory Effect.

In the following, instructions whose Intrinsic dependencies are special cases that arose during the formalization of the memory model are listed. This does not preclude the existence of other special cases in the future.

B2.4.2.1 Conditional Selection instructions

The following applies to the Effects generated by `CSEL Xd,Xn,Xm, cond`

When the condition `cond` is true all of the following apply:

- Dt_1 : There is an Intrinsic Data Dependency from the Register Read Effect of `PSTATE.NZCV` to the Intrinsic Branching Effect corresponding to the condition `cond`.
- Ct_1 : There is an Intrinsic Control Dependency from the Intrinsic Branching Effect which checks the condition `cond` to the Register Read Effect of X_n .
- Dt_2 : There is an Intrinsic Data Dependency from the Register Read Effect of X_n to the Register Write Effect of X_d .

When the condition `cond` is false all of the following apply:

- Df_1 : There is an Intrinsic Data Dependency from the Register Read Effect of `PSTATE.NZCV` to the Intrinsic Branching Effect corresponding to the condition `cond`.
- Cf_1 : There is an Intrinsic Control Dependency from the Intrinsic Branching Effect corresponding to the condition `cond` to the Register Read Effect of X_m .
- Df_1 : There is an Intrinsic Data Dependency from the Register Read Effect of X_m to the Register Write Effect of X_d .

B2.4.2.2 Compare-and-Swap instructions

The following apply to the Effects generated by `CAS Xs,Xt,[Xn]`:

When the value of the Memory Location x addressed by X_n is not equal to the value of X_s one of the following applies:

- D_1 : There is an Intrinsic Data Dependency from the Register Read Effect of X_n to the Explicit Memory Read Effect of the Memory Location x addressed by X_n .
- D_2 : There is an Intrinsic Data Dependency from the Explicit Memory Read Effect of the Memory Location x addressed by X_n to the Intrinsic Branching Effect which checks whether the contents of the Memory Location x are equal to the contents of the Register X_s .
- D_3 : There is an Intrinsic Data Dependency from the Register Read Effect of X_s to the Intrinsic Branching Effect which checks whether the contents of the Memory Location x are equal to the contents of the Register X_s .
- Df_1 : There is an Intrinsic Data Dependency from the Explicit Memory Read Effect of the Memory Location x addressed by X_n to the Register Write Effect of X_s .

When the value of the Memory Location x addressed by X_n is equal to the value of X_s one of the following applies:

- All of the following apply:
 - D_1 : There is an Intrinsic Data Dependency from the Register Read Effect of X_n to the Explicit Memory Read Effect of the Memory Location x addressed by X_n .
 - D_2 : There is an Intrinsic Data Dependency from the Explicit Memory Read Effect of the Memory Location x addressed by X_n to the Intrinsic Branching Effect which checks whether the contents of the Memory Location x are equal to the contents of the Register X_s .
 - D_3 : There is an Intrinsic Data Dependency from the Register Read Effect of X_s to the Intrinsic Branching Effect which checks whether the contents of the Memory Location x are equal to the contents of the Register X_s .
 - DS_1 : There is an Intrinsic Data Dependency from the Register Read Effect of X_n to the Explicit Memory Write Effect of the Memory Location x addressed by X_n .
 - DS_2 : There is an Intrinsic Data Dependency from Register Read Effect X_t to the Explicit Memory Write Effect of the Memory Location x addressed by X_n .
 - CS_1 : There is an Intrinsic Control Dependency from the Intrinsic Branching Effect which checks whether the contents of the Memory Location x are equal to the contents of the Register X_s to the Explicit Memory Write Effect of the Memory Location x addressed by X_n .
 - DS_{31} : There is an Intrinsic Data Dependency from the Explicit Memory Read Effect of the Memory Location x addressed by X_n to the Register Write Effect of X_s .
- All of the following apply:

- D_1 : There is an Intrinsic Data Dependency from the Register Read Effect of X_n to the Explicit Memory Read Effect of the Memory Location x addressed by X_n .
- D_2 : There is an Intrinsic Data Dependency from the Explicit Memory Read Effect of the Memory Location x addressed by X_n to the Intrinsic Branching Effect which checks whether the contents of the Memory Location x are equal to the contents of the Register X_s .
- D_3 : There is an Intrinsic Data Dependency from the Register Read Effect of X_s to the Intrinsic Branching Effect which checks whether the contents of the Memory Location x are equal to the contents of the Register X_s .
- DS_1 : There is an Intrinsic Data Dependency from the Register Read Effect of X_n to the Explicit Memory Write Effect of the Memory Location x addressed by X_n .
- DS_2 : There is an Intrinsic Data Dependency from the Register Read Effect of X_t to the Explicit Memory Write Effect of the Memory Location x addressed by X_n .
- CS_1 : There is an Intrinsic Control Dependency from the Intrinsic Branching Effect which checks whether the contents of the Memory Location x are equal to the contents of the Register X_s to the Explicit Memory Write Effect of the Memory Location x addressed by X_n .
- DS_3 : There is an Intrinsic Data Dependency from Register Read Effect X_s to the Register Write Effect of X_s .
- CS_2 : There is an Intrinsic Control Dependency from the Intrinsic Branching Effect which checks whether the contents of the Memory Location x are equal to the contents of the Register X_s to the Register Write Effect of X_s .

B2.4.2.3 Swap instructions

All of the following apply to the Effects generated by the `SWP  $X_s, X_t, [X_n]$` instruction:

- D_1 : There is an Intrinsic Data Dependency from the Register Read Effect of X_n to the Explicit Memory Read Effect of the Memory Location x addressed by X_n .
- D_2 : There is an Intrinsic Data Dependency from the Register Read Effect of X_n to the Explicit Memory Write Effect of the Memory Location x addressed by X_n .
- O_1 : There is an Intrinsic Order Dependency from the Explicit Memory Read Effect of the Memory Location x addressed by X_n to the Explicit Memory Write Effect of the Memory Location x addressed by X_n .
- D_3 : There is an Intrinsic Data Dependency from the Explicit Memory Read Effect of the Memory Location x addressed by X_n to the Register Write Effect of X_t .
- D_4 : There is an Intrinsic Data Dependency from the Register Read Effect of X_s , to the Explicit Memory Write Effect of the Memory Location x addressed by X_n .

B2.4.2.4 Branch with Link to Register instructions

All of the following apply to the Effects generated by the `BLR  $X_n$` instruction:

- D_1 : There is an Intrinsic Data Dependency from the Register Read Effect of X_n to the Branching Effect of the instruction.

B2.4.3 Fetch-intrinsically-before

An Effect E_1 is *Fetch-intrinsically-before* an Effect E_2 if all of the following apply:

- E_1 is an Implicit Instruction Memory Read Effect.
- There is an Intrinsic Data Dependency from E_1 to E_3 .
- E_3 is a Branching Effect.
- One of the following applies:
 - There is an Intrinsic Control Dependency from E_3 to E_2 .
 - All of the following apply:
 - There is an Intrinsic Control Dependency from E_3 to E_4 .
 - There is an Intrinsic Data Dependency from E_4 to E_2 .

B2.4.4 Dependency relations

Dependency through registers and memory

There is a *Dependency through registers and memory* from an Effect E_1 to an Effect E_2 if one of the following applies:

- All of the following apply:
 - It is not the case that E_1 is generated by a Store-Exclusive instruction as part of a successful Load-Exclusive/Store-Exclusive pair.
 - E_2 is a Local register read successor of E_1 .
- E_2 is a Local memory read successor of E_1 .
- There is an Intrinsic Data Dependency from E_1 to E_2 .
- All of the following apply:
 - There is a Dependency through registers and memory from E_1 to E_3 .
 - There is a Dependency through registers and memory from E_3 to E_2 .

Data dependency

There is a *Data dependency* from an Effect E_1 to an Effect E_2 if all of the following apply:

- E_1 is an Explicit Memory Read Effect.
- There is a Dependency through registers and memory from E_1 to E_3 .
- E_1 appears in program order before E_3 .
- E_3 is a Register Read Effect.
- There is an Intrinsic Data Dependency from E_3 to E_2 .
- The semantics of the instruction that generates E_3 and E_2 indicate that the value produced by E_3 is consumed in the calculation of the data value written by E_2 .
- E_2 is an Explicit Memory Write Effect.

Address dependency

There is an *Address dependency* from an Effect E_1 to an Effect E_2 if all of the following apply:

- E_1 is an Explicit Memory Read Effect.
- There is a Dependency through registers and memory from E_1 to E_3 .
- E_1 appears in program order before E_3 .
- E_3 is a Register Read Effect.
- There is an Intrinsic Data Dependency from E_3 to E_2 .
- The semantics of the instruction that generates E_3 and E_2 indicate that the value produced by E_3 is consumed in the calculation of the address of the Location of E_2 .
- One of the following applies:
 - E_2 is an Explicit Memory Effect.
 - E_2 is an Implicit Tag Memory Read Effect.
 - E_2 is an Implicit TTD Memory Read Effect.
 - E_2 is a Hardware Update Effect.
 - E_2 is a TLBI Effect.
 - E_2 is a DC CVAU Effect.
 - E_2 is an IC IVAU Effect.

Control dependency

There is a *Control dependency* from an Effect E_1 to an Effect E_2 if all of the following apply:

- E_1 is an Explicit Memory Read Effect.
- There is a Dependency through registers and memory from E_1 to E_3 .
- E_1 appears in program order before E_3 .
- E_3 is a Register Read Effect.
- There is an Intrinsic Data Dependency from E_3 to E_4 .
- E_4 is a Conditional Branching Effect.
- E_4 appears in program order before E_2 .

Pick dependency through registers and memory

There is a *Pick dependency through registers and memory* from an Effect E_1 to an Effect E_2 if one of the following applies:

- There is a Dependency through registers and memory from E_1 to E_2 .
- There is an Intrinsic Control Dependency from E_1 to E_2 .
- All of the following apply:
 - There is a Pick dependency through registers and memory from E_1 to E_3 .
 - There is a Pick dependency through registers and memory from E_3 to E_2 .

Pick Basic dependency

There is a *Pick Basic dependency* from an Effect E_1 to an Effect E_2 if all of the following apply:

- E_1 is an Explicit Memory Read Effect.
- There is a Pick dependency through registers and memory from E_1 to E_2 .

Pick Data dependency

There is a *Pick Data dependency* from an Effect E_1 to an Effect E_2 if all of the following apply:

- E_1 is an Explicit Memory Read Effect.
- There is a Pick dependency through registers and memory from E_1 to E_3 .
- E_1 appears in program order before E_3 .
- E_3 is a Register Read Effect.
- One of the following applies:
 - There is an Intrinsic Data Dependency from E_3 to E_2 .
 - All of the following apply:
 - There is an Intrinsic Data Dependency from E_3 to E_4 .
 - There is an Intrinsic Control Dependency from E_4 to E_2 .
- The semantics of the instruction that generates E_3 and E_2 indicate that the value produced by E_3 is consumed in the calculation of the data value written by E_2 .
- E_2 is an Explicit Memory Write Effect.

Pick Address dependency

There is a *Pick Address dependency* from an Effect E_1 to an Effect E_2 if all of the following apply:

- E_1 is an Explicit Memory Read Effect.
- There is a Pick dependency through registers and memory from E_1 to E_3 .
- E_1 appears in program order before E_3 .
- E_3 is a Register Read Effect.
- There is an Intrinsic Data Dependency from E_3 to E_2 .
- The semantics of the instruction that generates E_3 and E_2 indicate that the value produced by E_3 is consumed in the calculation of the address of the Location of E_2 .
- One of the following applies:
 - E_2 is an Explicit Memory Effect.
 - E_2 is an Implicit Tag Memory Read Effect.
 - E_2 is an Implicit TTD Memory Read Effect.
 - E_2 is a Hardware Update Effect.
 - E_2 is a TLBI Effect.
 - E_2 is a DC CVAU Effect.
 - E_2 is an IC IVAU Effect.

Pick Control dependency

There is a *Pick Control dependency* from an Effect E_1 to an Effect E_2 if all of the following apply:

- E_1 is an Explicit Memory Read Effect.
- There is a Pick dependency through registers and memory from E_1 to E_3 .

- E_1 appears in program order before E_3 .
- E_3 is a Register Read Effect.
- There is an Intrinsic Data Dependency from E_3 to E_4 .
- E_4 is a Conditional Branching Effect.
- E_4 appears in program order before E_2 .

Pick dependency

There is a *Pick dependency* from an Effect E_1 to an Effect E_2 if all of the following apply:

- One of the following applies:
 - There is a Pick Basic dependency from E_1 to E_2 .
 - There is a Pick Address dependency from E_1 to E_2 .
 - There is a Pick Data dependency from E_1 to E_2 .
 - There is a Pick Control dependency from E_1 to E_2 .
- It is not the case that E_1 and E_2 are generated by the same instruction.

B2.4.5 Ordering relations

Explicit-hazard-ordered-before

An Effect E_1 is *Explicit-hazard-ordered-before* an Effect E_2 if all of the following apply:

- E_1 is an Explicit Memory Read Effect.
- E_1 appears in program order before E_3 .
- E_1 and E_3 are to the Same Location.
- E_3 is an Explicit Memory Read Effect.
- One of the following applies:
 - E_3 belongs to the same single-copy-atomic grouping as E_4 .
 - E_3 and E_4 are the same Effect.
- E_4 is an Explicit Memory Read Effect.
- E_4 is Coherence-before E_5 .
- E_4 and E_5 are from different Processing Elements.
- One of the following applies:
 - E_5 is an Explicit Memory Write Effect.
 - E_5 is a Hardware Update Effect.
- One of the following applies:
 - E_5 belongs to the same single-copy-atomic grouping as E_2 .
 - E_5 and E_2 are the same Effect.
- One of the following applies:
 - E_2 is an Explicit Memory Write Effect.
 - E_2 is a Hardware Update Effect.

Note

The Explicit-hazard-ordered-before relation does not apply when either E_1 or E_2 or both are generated by SVE instructions.

TTD-read-ordered-before

An Effect E_1 is *TTD-read-ordered-before* an Effect E_2 if one of the following applies:

- All of the following apply:
 - E_1 is TLBI-before E_3 .
 - E_3 is a TLBI Effect.
 - E_3 is DSB-ordered-before E_2 .
- All of the following apply:
 - E_1 is TLBI-before E_3 .

- E_3 is a TLBI Effect.
- E_3 is Instruction-fetch-barrier-ordered-before E_2 .

TLBI-ordered-before

An Effect E_1 is *TLBI-ordered-before* an Effect E_2 if one of the following applies:

- E_1 is TTD-read-ordered-before E_2 .
- All of the following apply:
 - E_3 is Translation-intrinsically-before E_1 .
 - E_3 is TTD-read-ordered-before E_2 .
 - E_3 and E_2 are from different Processing Elements.
- All of the following apply:
 - E_1 is an Implicit TTD Memory Read Effect.
 - E_1 is Translation-intrinsically-before E_4 .
 - E_4 and E_5 have the Same Low-order Bits.
 - E_4 appears in program order before E_5 .
 - E_3 is Translation-intrinsically-before E_5 .
 - E_3 is an Implicit TTD Memory Read Effect.
 - E_1 and E_3 are generated in the same translation context.
 - E_3 is TTD-read-ordered-before E_2 .
 - E_3 and E_2 are from different Processing Elements.

Note

The clause of TLBI-ordered-before which refers to “Same Low-order Bits” applies in cases where an instruction I_1 which generates E_1 and E_4 appears in program order before an instruction I_2 which generates E_3 and E_5 , and I_1 and I_2 access overlapping bytes in memory.

Instruction-read-ordered-before

An Effect E_1 is *Instruction-read-ordered-before* an Effect E_2 if one of the following applies:

- All of the following apply:
 - E_1 is IC-before E_3 .
 - E_3 is an IC Effect.
 - E_3 is DSB-ordered-before E_2 .
- All of the following apply:
 - E_1 is IC-before E_3 .
 - E_3 is an IC Effect.
 - E_3 is Instruction-fetch-barrier-ordered-before E_2 .
- All of the following apply:
 - The [Effective value](#) of CTR_EL0.DIC is 1.
 - E_1 is Coherence-before E_2 .

IC-ordered-before

An Effect E_1 is *IC-ordered-before* an Effect E_2 if all of the following apply:

- E_1 is an Implicit Instruction Memory Read Effect.
- E_1 appears in program order before E_3 .
- E_3 is an Implicit Instruction Memory Read Effect.
- E_3 is Instruction-read-ordered-before E_2 .

Hazard-ordered-before

An Effect E_1 is *Hazard-ordered-before* an Effect E_2 if one of the following applies:

- E_1 is Explicit-hazard-ordered-before E_2 .
- E_1 is TLBI-ordered-before E_2 .
- E_1 is IC-ordered-before E_2 .

ETS-ordered-before

An Effect E_1 is *ETS-ordered-before* an Effect E_2 if one of the following applies:

- All of the following apply:
 - FEAT_ETSS2 is implemented.
 - E_1 is an Explicit Memory Effect.
 - E_1 appears in program order before E_3 .
 - E_3 is a TLBUncacheable Fault Effect.
 - E_2 is Translation-intrinsically-before E_3 .
 - E_2 is an Implicit TTD Memory Read Effect.
- All of the following apply:
 - FEAT_ETSS3 is implemented.
 - E_1 is an Explicit Memory Effect.
 - E_1 appears in program order before E_3 .
 - E_3 is an MMU Fault Effect.
 - E_2 is Translation-intrinsically-before E_3 .
 - E_2 is an Implicit TTD Memory Read Effect.
- All of the following apply:
 - FEAT_ETSS3 is implemented.
 - E_1 is an Explicit Memory Effect.
 - E_1 appears in program order before E_3 .
 - E_3 is a TagCheck Fault Effect that generates a synchronous exception.
 - E_2 is Tag-check-intrinsically-before E_3 .
 - E_2 is an Implicit Tag Memory Read Effect.

Note

The ETS-ordered-before relation does not apply when E_1 is generated by an Advanced SIMD, floating-point, SVE, or SME instruction. It also does not apply when E_2 is an Implicit TTD Memory Read Effect generated for an instruction fetch.

Fetch-ordered-before

An Effect E_1 is *Fetch-ordered-before* an Effect E_2 if all of the following apply:

- E_1 is an Implicit Instruction Memory Read Effect.
- E_1 appears in program order before E_2 .
- It is not the case that E_2 is an Implicit Instruction Memory Read Effect.

Same-Cache-Line-ordered-before

An Effect E_1 is *Same-Cache-Line-ordered-before* an Effect E_2 if one of the following applies:

- All of the following apply:
 - E_1 is an Explicit Memory Effect.
 - E_1 appears in program order before E_2 .
 - E_1 and E_2 are to the Same Cache Line.
 - E_2 is a DC CVAU Effect.
- All of the following apply:
 - E_1 is a DC CVAU Effect.
 - E_1 appears in program order before E_2 .
 - E_1 and E_2 are to the Same Cache Line.
 - E_2 is an Explicit Memory Effect.
- All of the following apply:
 - E_1 is a DC CVAU Effect.
 - E_1 appears in program order before E_2 .
 - E_1 and E_2 are to the Same Cache Line.
 - E_2 is a DC CVAU Effect.

DSB-ordered-before

An Effect E_1 is *DSB-ordered-before* an Effect E_2 if one of the following applies:

- All of the following apply:
 - One of the following applies:
 - E_1 is a Memory Effect.
 - E_1 is a DC CVAU Effect.
 - E_1 is an IC Effect.
 - E_1 is a TLBI Effect.
 - E_1 appears in program order before E_3 .
 - E_3 is a DSB FULL Effect.
 - E_3 appears in program order before E_2 .
 - It is not the case that one of the following applies:
 - E_2 is an Implicit TTD Memory Effect.
 - E_2 is an Implicit Instruction Memory Read Effect.
- All of the following apply:
 - FEAT_ETS2 is implemented.
 - One of the following applies:
 - E_1 is a Memory Effect.
 - E_1 is a DC CVAU Effect.
 - E_1 is an IC Effect.
 - E_1 is a TLBI Effect.
 - E_1 appears in program order before E_3 .
 - E_3 is a DSB FULL Effect.
 - E_3 appears in program order before E_2 .
 - E_2 is an Implicit TTD Memory Effect.
- All of the following apply:
 - One of the following applies:
 - All of the following apply:
 - E_1 is an Explicit Memory Read Effect.
 - It is not the case that E_1 is generated by an atomic instruction whose destination register is WZR or XZR.
 - E_1 is an Implicit Tag Memory Read Effect.
 - E_1 appears in program order before E_3 .
 - E_3 is a DSB LD Effect.
 - E_3 appears in program order before E_2 .
 - It is not the case that one of the following applies:
 - E_2 is an Implicit TTD Memory Effect.
 - E_2 is an Implicit Instruction Memory Read Effect.
- All of the following apply:
 - FEAT_ETS2 is implemented.
 - E_1 is an Explicit Memory Read Effect.
 - It is not the case that E_1 is generated by an atomic instruction whose destination register is WZR or XZR.
 - E_1 appears in program order before E_3 .
 - E_3 is a DSB LD Effect.
 - E_3 appears in program order before E_2 .
 - E_2 is an Implicit TTD Memory Effect.
- All of the following apply:
 - E_1 is an Explicit Memory Write Effect.
 - E_1 appears in program order before E_3 .
 - E_3 is a DSB ST Effect.
 - E_3 appears in program order before E_2 .
 - It is not the case that one of the following applies:

- E_2 is an Implicit TTD Memory Effect.
- E_2 is an Implicit Instruction Memory Read Effect.
- All of the following apply:
 - FEAT_ETS2 is implemented.
 - E_1 is an Explicit Memory Write Effect.
 - E_1 appears in program order before E_3 .
 - E_3 is a DSB ST Effect.
 - E_3 appears in program order before E_2 .
 - E_2 is an Implicit TTD Memory Effect.

Note

Regardless of whether FEAT_ETS2 is implemented, the DSB-ordered-before relation does not apply when E_2 is an Implicit TTD Memory Read Effect generated for an instruction fetch.

Instruction-fetch-barrier-ordered-before

An Effect E_1 is *Instruction-fetch-barrier-ordered-before* an Effect E_2 if one of the following applies:

- All of the following apply:
 - E_1 is an Explicit Memory Read Effect.
 - There is a Control dependency from E_1 to E_3 .
 - E_3 is an Instruction Fetch Barrier Effect.
 - E_3 appears in program order before E_2 .
- All of the following apply:
 - E_1 is an Explicit Memory Read Effect.
 - There is a Pick Control dependency from E_1 to E_3 .
 - E_3 is an Instruction Fetch Barrier Effect.
 - E_3 appears in program order before E_2 .
- All of the following apply:
 - E_1 is an Explicit Memory Read Effect.
 - There is an Address dependency from E_1 to E_3 .
 - E_3 is an Explicit Memory Effect.
 - E_3 appears in program order before E_4 .
 - E_4 is an Instruction Fetch Barrier Effect.
 - E_4 appears in program order before E_2 .
- All of the following apply:
 - E_1 is an Explicit Memory Read Effect.
 - There is a Pick Address dependency from E_1 to E_3 .
 - E_3 is an Explicit Memory Effect.
 - E_3 appears in program order before E_4 .
 - E_4 is an Instruction Fetch Barrier Effect.
 - E_4 appears in program order before E_2 .
- All of the following apply:
 - E_1 is an Explicit Memory Read Effect.
 - There is a Pick Address dependency from E_1 to E_3 .
 - One of the following applies:
 - E_3 is Tag-check-intrinsically-before E_4 .
 - E_3 is Translation-intrinsically-before E_4 .
 - E_4 is an Instruction Fetch Barrier Effect.
 - E_4 appears in program order before E_2 .
- All of the following apply:
 - E_1 is DSB-ordered-before E_3 .
 - E_3 is an Instruction Fetch Barrier Effect.
 - E_3 appears in program order before E_2 .
- All of the following apply:

- E_1 is an Implicit TTD Memory Read Effect.
- E_1 is Translation-intrinsically-before E_3 .
- E_3 is an Instruction Fetch Barrier Effect.
- E_3 appears in program order before E_2 .
- All of the following apply:
 - E_1 is an Implicit Tag Memory Read Effect.
 - E_1 is Tag-check-intrinsically-before E_3 .
 - E_3 is an Instruction Fetch Barrier Effect.
 - E_3 appears in program order before E_2 .
- All of the following apply:
 - E_1 is an Implicit TTD Memory Read Effect.
 - E_1 is Translation-intrinsically-before E_3 .
 - E_3 is an Explicit Memory Effect.
 - E_3 appears in program order before E_4 .
 - E_4 is an Instruction Fetch Barrier Effect.
 - E_4 appears in program order before E_2 .
- All of the following apply:
 - E_1 is an Implicit Tag Memory Read Effect.
 - E_1 is Tag-check-before E_3 .
 - E_3 is an Explicit Memory Effect.
 - E_3 appears in program order before E_4 .
 - E_4 is an Instruction Fetch Barrier Effect.
 - E_4 appears in program order before E_2 .

Dependency-ordered-before

An Effect E_1 is *Dependency-ordered-before* an Effect E_2 if one of the following applies:

- There is an Address dependency from E_1 to E_2 .
- There is a Data dependency from E_1 to E_2 .
- All of the following apply:
 - There is a Control dependency from E_1 to E_2 .
 - One of the following applies:
 - E_2 is an Explicit Memory Write Effect.
 - E_2 is a Hardware Update Effect.
 - E_2 is a TLBI Effect.
 - E_2 is a DC CVAU Effect.
 - E_2 is an IC Effect.
- All of the following apply:
 - There is an Address dependency from E_1 to E_3 .
 - E_3 is an Explicit Memory Effect.
 - E_3 appears in program order before E_2 .
 - One of the following applies:
 - E_2 is an Explicit Memory Write Effect.
 - E_2 is a Hardware Update Effect.
- All of the following apply:
 - There is an Address dependency from E_1 to E_3 .
 - E_3 is an Explicit Memory Effect.
 - E_2 is a Local memory read successor of E_3 .
 - One of the following applies:
 - E_2 is an Explicit Memory Read Effect.
 - E_2 is an Implicit Tag Memory Read Effect.
- All of the following apply:
 - There is a Data dependency from E_1 to E_3 .
 - E_3 is an Explicit Memory Effect.

- E_2 is a Local memory read successor of E_3 .
- One of the following applies:
 - E_2 is an Explicit Memory Read Effect.
 - E_2 is an Implicit Tag Memory Read Effect.
- All of the following apply:
 - E_1 is an Implicit TTD Memory Read Effect.
 - E_1 is Translation-intrinsically-before E_3 .
 - E_3 is an Explicit Memory Effect.
 - E_3 appears in program order before E_2 .
 - One of the following applies:
 - E_2 is an Explicit Memory Write Effect.
 - E_2 is a Hardware Update Effect.
- All of the following apply:
 - E_1 is an Implicit Tag Memory Read Effect.
 - E_1 is Tag-check-before E_3 .
 - E_3 is an Explicit Memory Effect.
 - E_3 appears in program order before E_2 .
 - One of the following applies:
 - E_2 is an Explicit Memory Write Effect.
 - E_2 is a Hardware Update Effect.

Intrinsically-ordered-before

An Effect E_1 is *Intrinsically-ordered-before* an Effect E_2 if one of the following applies:

- E_1 is Tag-check-intrinsically-before E_2 .
- E_1 is Translation-intrinsically-before E_2 .
- E_1 is Fetch-intrinsically-before E_2 .
- All of the following apply:
 - E_1 is an Explicit Memory Effect.
 - There is an Intrinsic Order Dependency from E_1 to E_2 .
 - E_2 is an Explicit Memory Effect.

Pick-ordered-before

An Effect E_1 is *Pick-ordered-before* an Effect E_2 if one of the following applies:

- All of the following apply:
 - There is a Pick Address dependency from E_1 to E_2 .
 - One of the following applies:
 - E_2 is an Explicit Memory Write Effect.
 - E_2 is a Hardware Update Effect.
 - E_2 is a TLBI Effect.
 - E_2 is a DC CVAU Effect.
 - E_2 is an IC Effect.
- There is a Pick Data dependency from E_1 to E_2 .
- All of the following apply:
 - There is a Pick Control dependency from E_1 to E_2 .
 - One of the following applies:
 - E_2 is an Explicit Memory Write Effect.
 - E_2 is a Hardware Update Effect.
 - E_2 is a TLBI Effect.
 - E_2 is a DC CVAU Effect.
 - E_2 is an IC Effect.
- All of the following apply:
 - There is a Pick Address dependency from E_1 to E_3 .
 - E_3 is an Explicit Memory Effect.

- E_3 appears in program order before E_2 .
- One of the following applies:
 - E_2 is an Explicit Memory Write Effect.
 - E_2 is a Hardware Update Effect.

Atomic-ordered-before

E_1 and E_2 form a successful Read-Modify-Write pair if and only if E_1 and E_2 are generated by the same atomic instruction or the same successful Load-Exclusive/Store-Exclusive instruction pair to the Same Location.

An Effect E_1 is *Atomic-ordered-before* an Effect E_2 if one of the following applies:

- All of the following apply:
 - E_1 is an Explicit Memory Effect.
 - E_1 and E_2 form a successful Read-Modify-Write pair.
 - E_2 is an Explicit Memory Effect.
- All of the following apply:
 - E_1 is an Explicit Memory Effect.
 - E_1 and E_3 form a successful Read-Modify-Write pair.
 - E_2 is a Local memory read successor of E_3 .
 - One of the following applies:
 - E_2 is an Explicit Memory Read Effect with Acquire semantics.
 - E_2 is an Explicit Memory Read Effect with AcquirePC semantics.
- All of the following apply:
 - E_1 is an Implicit TTD Memory Read Effect.
 - E_1 and E_2 form a successful Read-Modify-Write pair.
 - E_2 is a Hardware Update Effect.

Barrier-ordered-before

An Effect E_1 is *Barrier-ordered-before* an Effect E_2 if one of the following applies:

- All of the following apply:
 - One of the following applies:
 - E_1 is an Explicit Memory Effect.
 - E_1 is an Implicit Tag Memory Read Effect.
 - E_1 appears in program order before E_3 .
 - E_3 is a DMB FULL Effect.
 - E_3 appears in program order before E_2 .
 - One of the following applies:
 - E_2 is an Explicit Memory Effect.
 - E_2 is an Implicit Tag Memory Read Effect.
 - E_2 is an MMU Fault Effect.
- All of the following apply:
 - E_1 is an Explicit Memory Effect.
 - E_1 appears in program order before E_3 .
 - E_3 is a DMB FULL Effect.
 - E_3 appears in program order before E_2 .
 - E_2 is a DC CVAU Effect.
- All of the following apply:
 - E_1 is a DC CVAU Effect.
 - E_1 appears in program order before E_3 .
 - E_3 is a DMB FULL Effect.
 - E_3 appears in program order before E_2 .
 - E_2 is an Explicit Memory Effect.
- All of the following apply:
 - E_1 is a DC CVAU Effect.

- E_1 appears in program order before E_3 .
- E_3 is a DMB FULL Effect.
- E_3 appears in program order before E_2 .
- E_2 is a DC CVAU Effect.
- All of the following apply:
 - One of the following applies:
 - All of the following apply:
 - E_1 is an Explicit Effect.
 - E_1 is a Memory Read Effect.
 - It is not the case that E_1 is generated by an atomic instruction whose destination register is WZR or XZR.
 - E_1 is an Implicit Tag Memory Read Effect.
 - E_1 appears in program order before E_3 .
 - E_3 is a DMB LD Effect.
 - E_3 appears in program order before E_2 .
 - One of the following applies:
 - E_2 is an Explicit Memory Effect.
 - E_2 is an Implicit Tag Memory Read Effect.
 - E_2 is an MMU Fault Effect.
- All of the following apply:
 - E_1 is an Explicit Memory Write Effect.
 - E_1 appears in program order before E_3 .
 - E_3 is a DMB ST Effect.
 - E_3 appears in program order before E_2 .
 - One of the following applies:
 - E_2 is an Explicit Memory Write Effect.
 - E_2 is an MMU Fault Effect.
- All of the following apply:
 - E_1 is an Explicit Memory Write Effect with Release semantics.
 - E_3 and E_1 are generated by an atomic instruction.
 - E_3 is an Explicit Memory Read Effect with Acquire semantics.
 - E_1 appears in program order before E_2 .
 - One of the following applies:
 - E_2 is an Explicit Memory Effect.
 - E_2 is an Implicit Tag Memory Read Effect.
 - E_2 is an MMU Fault Effect.
- All of the following apply:
 - E_1 is an Explicit Memory Write Effect with Release semantics.
 - E_1 appears in program order before E_2 .
 - E_2 is an Explicit Memory Read Effect with Acquire semantics.
- All of the following apply:
 - One of the following applies:
 - E_1 is an Explicit Memory Read Effect with Acquire semantics.
 - E_1 is an Explicit Memory Read Effect with AcquirePC semantics.
 - E_1 appears in program order before E_2 .
 - One of the following applies:
 - E_2 is an Explicit Memory Effect.
 - E_2 is an Implicit Tag Memory Read Effect.
 - E_2 is an MMU Fault Effect.
- All of the following apply:
 - One of the following applies:
 - E_1 is an Explicit Memory Effect.
 - E_1 is an Implicit Tag Memory Read Effect.
 - E_1 appears in program order before E_2 .

— E_2 is an Explicit Memory Write Effect with Release semantics.

Locally-ordered-before

An Effect E_1 is *Locally-ordered-before* an Effect E_2 if one of the following applies:

- E_1 is Intrinsically-ordered-before E_2 .
- E_1 is ETS-ordered-before E_2 .
- E_1 is Fetch-ordered-before E_2 .
- E_1 is Same-Cache-Line-ordered-before E_2 .
- E_1 is DSB-ordered-before E_2 .
- E_1 is Instruction-fetch-barrier-ordered-before E_2 .
- E_2 is a Local memory write successor of E_1 .
- All of the following apply:
 - E_3 is a Local memory write successor of E_1 .
 - E_3 belongs to the same single-copy-atomic grouping as E_2 .
- E_1 is Dependency-ordered-before E_2 .
- E_1 is Pick-ordered-before E_2 .
- E_1 is Atomic-ordered-before E_2 .
- E_1 is Barrier-ordered-before E_2 .
- All of the following apply:
 - E_1 is Locally-ordered-before E_3 .
 - E_3 is Locally-ordered-before E_2 .

Pick-locally-ordered-before

An Effect E_1 is *Pick-locally-ordered-before* an Effect E_2 if all of the following apply:

- There is a Pick dependency from E_1 to E_3 .
- E_3 is Locally-ordered-before E_2 .
- E_2 is an Explicit Memory Write Effect.

Locally-hardware-required-ordered-before

An Effect E_1 is *Locally-hardware-required-ordered-before* an Effect E_2 if one of the following applies:

- E_1 is Locally-ordered-before E_2 .
- E_1 is Pick-locally-ordered-before E_2 .
- All of the following apply:
 - E_1 is Locally-hardware-required-ordered-before E_3 .
 - E_3 is Locally-hardware-required-ordered-before E_2 .

Hardware-required-ordered-before

An Effect E_1 is *Hardware-required-ordered-before* an Effect E_2 if one of the following applies:

- E_1 is Locally-hardware-required-ordered-before E_2 .
- E_1 is Hazard-ordered-before E_2 .

B2.4.6 Observation relations

Explicit-Observed-by

An Effect E_1 is *Explicit-Observed-by* an Effect E_2 if one of the following applies:

- All of the following apply:
 - E_1 is an Explicit Memory Effect.
 - E_2 Reads-from-memory E_1 .
 - E_1 and E_2 are from different Processing Elements.
 - E_2 is an Explicit Memory Effect.

- All of the following apply:
 - E_1 is an Explicit Memory Effect.
 - E_1 is Coherence-before E_2 .
 - E_1 and E_2 are from different Processing Elements.
 - E_2 is an Explicit Memory Effect.

Tag-Observed-by

An Effect E_1 is *Tag-Observed-by* an Effect E_2 if one of the following applies:

- All of the following apply:
 - E_1 is an Explicit Memory Write Effect.
 - E_2 Reads-from-memory E_1 .
 - E_1 and E_2 are from different Processing Elements.
 - E_2 is an Implicit Tag Memory Read Effect.
- All of the following apply:
 - E_1 is an Implicit Tag Memory Read Effect.
 - E_1 is Coherence-before E_2 .
 - E_1 and E_2 are from different Processing Elements.
 - E_2 is an Explicit Memory Write Effect.

TLBUncacheable-coherence-before

An Effect E_1 is *TLBUncacheable-coherence-before* an Effect E_2 if all of the following apply:

- E_1 is an Implicit TTD Memory Read Effect.
- E_1 is Translation-intrinsically-before E_3 .
- E_3 is a TLBUncacheable Fault Effect.
- E_1 is Coherence-before E_2 .
- One of the following applies:
 - E_2 is an Explicit Memory Write Effect.
 - E_2 is a Hardware Update Effect.

Hardware-Update-coherence-before

An Effect E_1 is *Hardware-Update-coherence-before* an Effect E_2 if all of the following apply:

- E_1 is an Explicit Memory Read Effect.
- E_1 is Coherence-before E_2 .
- E_2 is a Hardware Update Effect.

TLBI-coherence-before

An Effect E_1 is *TLBI-coherence-before* an Effect E_2 if all of the following apply:

- E_1 is a TLBI Effect.
- E_1 is TLBI-before E_3 .
- E_3 is an Implicit TTD Memory Read Effect.
- E_3 is Coherence-before E_2 .
- E_2 is a Memory Write Effect.

TTD-Observed-by

An Effect E_1 is *TTD-Observed-by* an Effect E_2 if one of the following applies:

- All of the following apply:
 - E_1 is an Implicit TTD Memory Effect.
 - E_2 Reads-from-memory E_1 .
- All of the following apply:
 - E_2 Reads-from-memory E_1 .
 - E_2 is an Implicit TTD Memory Effect.

- E_1 is TLBUncacheable-coherence-before E_2 .
- E_1 is Hardware-Update-coherence-before E_2 .
- All of the following apply:
 - E_1 is a Hardware Update Effect.
 - E_1 is Coherence-before E_2 .
 - E_2 is a Memory Write Effect.
- All of the following apply:
 - E_1 is a Memory Write Effect.
 - E_1 is Coherence-before E_2 .
 - E_2 is a Hardware Update Effect.
- E_1 is TLBI-coherence-before E_2 .

IC-Coherence-before

An Effect E_1 is *IC-coherence-before* an Effect E_2 if one of the following applies:

- All of the following apply:
 - The **Effective value** of CTR_EL0.DIC is 0.
 - The **Effective value** of CTR_EL0.IDC is 0.
 - E_1 is an IC Effect.
 - E_1 is IC-before E_3 .
 - E_3 is an Implicit Instruction Memory Read Effect.
 - E_3 is Coherence-before E_4 .
 - E_4 is a Memory Write Effect.
 - E_4 is DC-before E_2 .
 - E_2 is a DC CVAU Effect.
- All of the following apply:
 - The **Effective value** of CTR_EL0.DIC is 0.
 - The **Effective value** of CTR_EL0.IDC is 1.
 - E_1 is an IC Effect.
 - E_1 is IC-before E_3 .
 - E_3 is an Implicit Instruction Memory Read Effect.
 - E_3 is Coherence-before E_2 .
 - E_2 is a Memory Write Effect.
- All of the following apply:
 - The **Effective value** of CTR_EL0.DIC is 1.
 - The **Effective value** of CTR_EL0.IDC is 1.
 - E_1 is an Implicit Instruction Memory Read Effect.
 - E_1 is Coherence-before E_2 .
 - E_2 is a Memory Write Effect.

Instruction-Observed-by

An Effect E_1 is *Instruction-Observed-by* an Effect E_2 if one of the following applies:

- All of the following apply:
 - E_2 Reads-from-memory E_1 .
 - E_2 is an Implicit Instruction Memory Read Effect.
- E_1 is IC-before E_2 .
- All of the following apply:
 - E_1 is a DC CVAU Effect.
 - E_1 is DC-before E_2 .
 - E_2 is a Memory Write Effect.
- All of the following apply:
 - E_1 is a Memory Write Effect.
 - E_1 is DC-before E_2 .
 - E_2 is a DC CVAU Effect.

- E_1 is IC-coherence-before E_2 .

Observed-by

An Effect E_1 is *Observed-by* an Effect E_2 if one of the following applies:

- E_1 is Explicit-Observed-by either E_2 or an Effect which belongs to the same single-copy-atomic grouping as E_2 .
- E_1 is Tag-Observed-by either E_2 or an Effect which belongs to the same single-copy-atomic grouping as E_2 .
- E_1 is TTD-Observed-by E_2 .
- E_1 is Instruction-Observed-by E_2 .

B2.4.7 Definition of an Architecturally Allowed Execution

An Architecturally Allowed Execution must satisfy the *External visibility requirement*, which is formulated in terms of an ordering relation called *Ordered-before*. An execution that does not satisfy the external visibility requirement is an Architecturally Forbidden Execution.

Ordered-before

An Effect E_1 is *Ordered-before* an Effect E_2 if one of the following applies:

- E_1 is Hardware-required-ordered-before E_2 .
- E_1 is Observed-by E_2 .
- All of the following apply:
 - E_1 is Ordered-before E_3 .
 - E_3 is Ordered-before E_2 .

External visibility requirement

The external visibility requirement is defined as follows: an Architecturally Allowed Execution must not exhibit a cycle in the Ordered-before relation.

In particular, for an Effect E_1 that is Ordered-before an Effect E_2 , the External visibility requirement requires that E_2 is not Observed-by E_1 .

B2.4.8 Alternative formulations of the External visibility requirement for Explicit Memory Effects

B2.4.8.1 Additional ordering relations

Single-copy-atomic-ordered-before

A Memory Read Effect E_1 is *single-copy-atomic-ordered-before* another Memory Read Effect E_2 if all the following apply:

- E_1 belongs to the same single-copy-atomic grouping as E_2 .
- E_1 Reads-from-memory a Memory Write Effect E_3 .
- E_1 and E_3 are from different Processing Elements.
- E_2 Reads-from-memory a Memory Write Effect E_4 .
- E_2 and E_4 are from the same Processing Element.

B2.4.8.2 External completion requirement for Explicit Memory Effects

The *External completion requirement for Explicit Memory Effects* is an alternative way of formulating the External visibility requirement, in the context of Explicit Memory Effects only.

The Completes-before order is a total order that corresponds to the order in which Memory Effects complete within the system. Effects E_1 and E_2 constitute a single entry in the Completes-before order, if any of the following applies:

- All of the following apply:
 - E_1 is a Memory Write Effect.

- E_2 is a Memory Write Effect.
- E_1 belongs to the same single-copy-atomic grouping as E_2 .
- All of the following apply:
 - E_1 is a Memory Read Effect.
 - E_2 is a Memory Read Effect.
 - E_1 belongs to the same single-copy-atomic grouping as E_2 .
 - E_1 Reads-from-memory a Memory Write Effect E_3 .
 - E_1 and E_3 are from different Processing Elements.
 - E_2 Reads-from-memory a Memory Write Effect E_4 .
 - E_2 and E_4 are from different Processing Elements.
- All of the following apply:
 - E_1 is a Memory Read Effect.
 - E_2 is a Memory Read Effect.
 - E_1 belongs to the same single-copy-atomic grouping as E_2 .
 - E_1 Reads-from-memory a Memory Write Effect E_3 .
 - E_1 and E_3 are from the same Processing Element.
 - E_2 Reads-from-memory a Memory Write Effect E_4 .
 - E_2 and E_4 are from the same Processing Element.
 - E_3 belongs to the same single-copy-atomic grouping as E_4 .

All other Memory Read Effects constitute distinct entries in the Completes-before order.

Completes-before

A Memory Read or Write Effect E_1 completes-before a Memory Read or Write Effect E_2 if E_1 appears in the *Completes-before* order before E_2 .

Deriving Reads-from-memory and Coherence order from the Completes-before order

The Reads-from-memory relation can be derived from the Completes-before order by specifying which Memory Write Effect every Memory Read Effect gets its value from. Specifically, for a Memory Read Effect E_1 one of the following must apply:

- If all of the following apply:
 - There is a Memory Write Effect E_2 .
 - E_1 is a Local memory read successor of E_2 .
 - E_1 Completes-before E_2 .
 - There is no Memory Write Effect E_3 to the Same Location in the Completes-before order between E_2 and an Explicit Memory Read Effect E_4 to the Same Location that appears in program order before E_1 .
then it must be that E_1 Reads-from-memory E_2 .
- If all of the following apply:
 - There is a Memory Write Effect E_2 (possibly representing the writing of the initial value to the Location).
 - E_2 and E_1 are to the Same Location.
 - E_2 Completes-before E_1 .
 - It is not the case that E_2 Completes-before a Memory Write Effect E_3 and E_1 is the Local memory read successor of E_3 .
 - There is no Memory Write Effect E_4 to the Same Location in the Completes-before order between E_2 and E_1 .
 - There is no Memory Write Effect E_5 to the Same Location in the Completes-before order between E_2 and a Memory Read Effect E_6 to the Same Location that appears in program order before E_1 .
then it must be that E_1 Reads-from-memory E_2 .

The Coherence order can be derived from the Completes-before order by letting the Coherence order of Memory Write Effects to a memory location be the order in which those Memory Write Effects appear in the Completes-before order. The final value of each memory location is therefore determined by the

final Memory Write Effect to each Location in the Completes-before order. If no such Memory Write Effect exists for a given Location, the final value is the initial value of that Location.

External completion requirement for Explicit Memory Effects

The External completion requirement for Explicit Memory Effects requires that an Memory Effect E_1 Completes-before a Memory Effect E_2 if any of the following statements are true:

- E_1 is Locally-hardware-required-ordered-before E_2 .
- E_1 is a Memory Read Effect, E_2 is a Memory Read Effect, and E_1 is single-copy-atomic-ordered-before E_2 .

B2.4.8.3 External global completion requirement for Explicit Memory Effects

The *External global completion requirement for Explicit Memory Effects* is an alternative way of formulating the External visibility requirement, in the context of Explicit Memory Effects only.

The Globally-completes-before order is a total order that corresponds to the order in which Memory Effects complete within the system. Effects E_1 and E_2 constitute a single entry in the Globally-completes-before order, if any of the following applies:

- All of the following apply:
 - E_1 is a Memory Write Effect.
 - E_2 is a Memory Write Effect.
 - E_1 belongs to the same single-copy-atomic grouping as E_2 .
- All of the following apply:
 - E_1 is a Memory Read Effect.
 - E_2 is a Memory Read Effect.
 - E_1 belongs to the same single-copy-atomic grouping as E_2 .
 - E_1 Reads-from-memory a Memory Write Effect E_3 .
 - E_1 and E_3 are from different Processing Elements.
 - E_2 Reads-from-memory a Memory Write Effect E_4 .
 - E_2 and E_4 are from different Processing Elements.
- All of the following apply:
 - E_1 is a Memory Read Effect.
 - E_2 is a Memory Read Effect.
 - E_1 belongs to the same single-copy-atomic grouping as E_2 .
 - E_1 Reads-from-memory a Memory Write Effect E_3 .
 - E_1 and E_3 are from the same Processing Element.
 - E_2 Reads-from-memory a Memory Write Effect E_4 .
 - E_2 and E_4 are from the same Processing Element.
 - E_3 belongs to the same single-copy-atomic grouping as E_4 .

All other Memory Read Effects constitute distinct entries in the Globally-completes-before order.

Globally-completes-before

A Memory Read or Write Effect E_1 *Globally-completes-before* a Memory Read or Write Effect E_2 if E_1 appears in the Globally-completes-before order before E_2 .

Deriving Reads-from-memory and Coherence order from the Globally-completes-before order

The Reads-from-memory relation can be derived from the Globally-completes-before order by specifying which Memory Write Effect every Memory Read Effect gets its value from. Specifically, for a Memory Read Effect E_1 it must be that if all of the following applies:

- There is Memory Write Effect E_2 (possibly representing the writing of the initial value to the Location).
- E_2 Globally-completes-before E_1 .
- E_1 and E_2 are to the Same Location.

- There is no Memory Write Effect E_3 to the Same Location in the Globally-completes-before order between E_2 and E_1 .
- There is no Memory Write Effect E_4 to the Same Location in the Globally-completes-before order between E_2 and an Explicit Memory Read Effect E_5 to the Same Location that appears in program order before E_1 .

then it must be that E_1 Reads-from-memory E_2 .

The Coherence order can be derived from the Globally-completes-before order by letting the Coherence order of Memory Write Effects to a memory location be the order in which those Memory Write Effects appear in the Globally-completes-before order. The final value of each memory location is therefore determined by the final Memory Write Effect to each Location in the Globally-completes-before order. If no such Memory Write Effect exists for a given Location, the final value is the initial value of that Location.

External global completion requirement

The External global completion requirement requires that a Memory Effect E_1 Globally-completes-before a Memory Effect E_2 if any of the following statements are true:

- E_1 is Locally-hardware-required-ordered-before E_2 and one of the following applies:
 - E_1 is a Memory Write Effect.
 - E_1 is a Memory Read Effect, and one of the following applies:
 - E_1 Reads-from-memory a Memory Write Effect E_3 , and E_1 and E_3 are from different Processing Elements, or.
 - E_1 Reads-from-memory a Memory Write Effect E_3 , E_1 , and E_3 are from the same Processing Element, and E_3 is Locally-hardware-required-ordered-before E_2 .
- E_1 is a Memory Read Effect, E_2 is a Memory Read Effect, and E_1 is single-copy-atomic-ordered before E_2 .

B2.5 Additional ordering requirements outside of the scope of the formal concurrency model

The following sections present ordering rules which have been architected but not yet formalized. As a consequence they do not appear in the [formal concurrency model](#), nor in the corresponding transliteration in [Ordering requirements defined by the formal concurrency model](#). They will be integrated into [Ordering requirements defined by the formal concurrency model](#) in due course.

B2.5.1 Completion and endpoint ordering

For all memory, the completion rules are defined as:

- A Memory Read effect E_1 to a [Location](#) is complete for a shareability domain when all of the following are true:
 - Any Memory Write Effect to the same [Location](#) by an observer within the shareability domain will be Coherence-after E_1 .
 - All Implicit TTD Memory Read Effects associated with E_1 are complete for that shareability domain.
- A Memory Write effect E_1 to a [Location](#) is complete for a shareability domain when all of the following are true:
 - Any Memory Write Effect to the same [Location](#) by an observer within the shareability domain will be Coherence-after E_1 .
 - Any Memory Read Effect to the same [Location](#) by an observer within the shareability domain will be such that either [Reads-from](#) E_1 or [Reads-from](#) a Memory Write effect that is Coherence-after E_1 .
 - All Implicit TTD Memory Read Effects associated with E_1 are complete for that shareability domain.
- An Implicit TTD Memory Read Effect is complete for a shareability domain when the memory accesses associated with the Implicit TTD Memory Read Effect, including Hardware Update Effects, are complete for that shareability domain, and the TLB is updated.
- A cache maintenance instruction is complete for a shareability domain when the memory effects of the instruction are complete for that shareability domain, and Implicit TTD Memory Read Effects that arise from the instruction are complete for that shareability domain.
- A TLB invalidate instruction is complete when all memory accesses using the TLB entries that have been invalidated are complete.

The completion of any cache or TLB maintenance instruction includes its completion on all PEs that are affected by both the instruction and the DSB operation that is required to guarantee visibility of the maintenance instruction.

Additionally, for Device-nGnRnE memory, a read or write of a [Location](#) in a [Memory-mapped peripheral](#) that exhibits side effects is complete only when the read or write both:

- Can begin to affect the state of the [Memory-mapped peripheral](#).
- Can trigger all associated side effects, whether they affect other peripheral devices, PEs, or memory.

Interaction between observers in a system is not restricted to communication through shared variables in coherent memory. For example, an observer could configure an interrupt controller to raise an interrupt on another observer as a form of message passing. These interactions typically involve an additional agent, which defines the instruction sequence that is required to establish communication links between different observers. When these forms of interaction are used in conjunction with shared variables, a DSB instruction can be used to enforce ordering between them.

Note

This requirement for Device-nGnRnE memory is consistent with the memory access having reached the peripheral endpoint.

Note

These completion rules mean that, for example, a cache maintenance instruction that operates by VA to the PoC completes only after memory at the PoC has been updated.

B2.5.1.1 Peripherals

This section defines a Memory-mapped peripheral and the total order of reads and writes to a peripheral which is defined as the [Peripheral arrival order](#):

Memory-mapped peripheral

A *Memory-mapped peripheral* occupies a memory region of IMPLEMENTATION DEFINED size and can be accessed using load and store instructions. [Memory effects](#) to a Memory-mapped peripheral can have side effects, such as causing the peripheral to perform an action. Values that are read from addresses within a Memory-mapped peripheral might not correspond to the last data value written to those addresses. As such, [Memory effects](#) to a Memory-mapped peripheral might not appear in the [Reads-from](#) or [Coherence order](#) relations.

Peripheral arrival order

The *Peripheral arrival order* of a [Memory-mapped peripheral](#) is a total order on all Memory Read Effects and Memory Write Effects to that peripheral.

A [Memory effect](#) E_1 is inserted in the Peripheral arrival order for a peripheral before a [Memory effect](#) E_2 , if E_1 and E_2 are to the same peripheral and any of the following applies:

- All of the following apply:
 - E_1 is to Device memory with the non-Reordering attribute.
 - E_2 is to Device memory with the non-Reordering attribute.
 - E_1 appears in program order before E_2 .
- All of the following apply:
 - E_1 is to Device memory with the non-Gathering attribute.
 - E_2 is to Device memory with the non-Gathering attribute.
 - E_1 is Ordered-before E_2 .
- All of the following apply:
 - Any of the following applies:
 - E_1 is to Device memory.
 - E_1 is to Non-cacheable Normal memory.
 - Any of the following applies:
 - E_2 is to Device memory.
 - E_2 is to Non-cacheable Normal memory.
 - E_1 is Barrier-ordered-before E_2 .

Otherwise, exactly one of the following applies:

- E_1 and E_2 are gathered into a single transaction and appear as one Effect in the Peripheral arrival order for the peripheral.
- E_1 is inserted in the Peripheral arrival order for the peripheral before E_2 .
- E_2 is inserted in the Peripheral arrival order for the peripheral before E_1 .

Gathering is permitted, but not required if none of the following apply:

- E_1 is to Device memory with the non-Gathering attribute.
- All of the following apply:
 - E_1 appears in program order before E_2 .
 - E_2 is a [Memory Write Effect](#).
- E_2 is to Device memory with the non-Gathering attribute.

Out-of-band-ordered-before

An Effect E_1 is *Out-of-band-ordered-before* an Effect E_2 if and only if all of the following apply:

- E_1 is a Memory Effect.
- Any of the following applies:
 - E_1 is DSB-ordered-before E_3 .
 - E_1 is Instruction-fetch-barrier-ordered-before E_3 .
- There is an IMPLEMENTATION DEFINED instruction sequence beginning with E_3 indirectly leading to the generation of E_2 .
- E_2 is a Memory Effect.

If an Effect E_1 is Out-of-band-ordered-before an Effect E_2 , then E_1 is Ordered-before E_2 .

Note

Arm expects that, in most systems with early acknowledgments, those acknowledgments will come from a point at or after the point that establishes global visibility. This is expected in such systems to enable the acknowledgments to be used as part of the mechanisms to implement the ordering requirements of the Arm memory model.

B2.5.2 Metadata Dependencies**I_{YRHC}**

The execution of the following instructions create ordering relations for the purposes of the Arm memory model:

- PACDA.
- PACDB.
- AUTDA.
- AUTDB

R_{MSWTM}

If FEAT_PAAuth is implemented, the execution of a PACDA Xd, Xn instruction creates:

- A [Dependency through registers and memory](#) from the Register Read Effect of Xd to Register Write Effect of Xd.
- If authentication using the APDAKey_EL1 key is enabled, a [Dependency through registers and memory](#) from the Register Read Effect of Xn to Register Write Effect of Xd.

R_{JMNSC}

If FEAT_FPAC is implemented, the execution of a PACDB Xd, Xn instruction creates:

- A [Dependency through registers and memory](#) from the Register Read Effect of Xd to Register Write Effect of Xd.
- If authentication using the APDBKey_EL1 key is enabled, a [Dependency through registers and memory](#) from the Register Read Effect of Xn to Register Write Effect of Xd.

R_{XYRJT}

If FEAT_FPAC is implemented, the execution of an AUTDA Xd, Xn instruction creates:

- If authentication using the APDAKey_EL1 key is enabled, a [Pick dependency through registers and memory](#) from the Register Read Effect of Xn to Register Write Effect of Xd.
- A [Dependency through registers and memory](#) from the Register Read Effect of Xd to Register Write Effect of Xd.

R_{SPBZX}

If FEAT_FPAC is implemented, the execution of an AUTDB Xd, Xn instruction creates:

- If authentication using the APDBKey_EL1 key is enabled, a [Pick dependency through registers and memory](#) from the Register Read Effect of Xn to Register Write Effect of Xd.
- A [Dependency through registers and memory](#) from the Register Read Effect of Xd to Register Write Effect of Xd.

B2.5.3 Limited ordering regions

FEAT_LOR introduces *limited ordering regions* (LORegions), which allow large systems to perform special load-acquire and store-release instructions that provide order between the memory accesses to a region of the PA map as observed by a set of observers.

LORegions are defined in the Non-secure physical address space. LORegions cannot be defined in the Secure, Realm, or Root physical address spaces.

This feature is supported in AArch64 state only.

B2.5.4 Ordering of instruction fetches

For two memory locations A and B, if A has been written to with an updated value and been made coherent with the instruction fetches of the shareability domain before B has been written to with an updated value by an observer in the same shareability domain, then where, for an observer in the shareability domain, an instruction read from B appears in program order before an instruction fetched from A, if the instruction read from B contains the updated value of B then the instruction read from A appearing later in program order will contain the updated value of A.

A write has been made coherent with an instruction fetch of a shareability domain when:

CTR.{DIC, IDC} = {0, 0} The location written to has been cleaned to the [Point of unification \(PoU\)](#) from the data cache, and that clean is complete for the shareability domain. Subsequently the location has been invalidated to the [Point of unification \(PoU\)](#) from the instruction cache, and that invalidation is complete for the shareability domain.

CTR.{DIC, IDC} = {0, 1} The write is complete for the shareability domain. Subsequently the location has been invalidated to the [Point of unification \(PoU\)](#) from the instruction cache, and that invalidation is complete for the shareability domain.

CTR.{DIC, IDC} = {1, 1} The write is complete for the shareability domain.

Note

Microarchitecturally, this means that these situations cannot both be true in an implementation:

- After delays in fetching from memory, the instruction queue can have entries written into it out of order.
 - For an implementation:
 - When **CTR.DIC** = 0, if there is an outstanding entry in the instruction queue, then later entries in the instruction queue are not impacted by the [ICIMVAU](#) instructions of a different core.
 - When **CTR.DIC** = 1, if there is a write to the location that is held in the queue when there is an outstanding entry in the instruction queue for an older entry, then the instruction queue does not have entries invalidated from it.
-

B2.5.5 Memory barriers

The Arm architecture is a weakly ordered memory architecture that supports out of order completion. *Memory barrier* is the general term applied to an instruction, or sequence of instructions, that forces synchronization events by a PE with respect to retiring load/store instructions. The memory barriers defined by the architecture provide a range of functionality, including:

- Ordering of load/store instructions.
- Completion of load/store instructions.
- Context synchronization.

The Armv8-R AArch32 architecture redefines **DMB** and **DSB**, and defines a new instruction, **DFB**.

Armv8-R relaxes the ordering requirements for **DMB** and **DSB** by enforcing ordering only in terms of certain Exception level criteria:

- Accesses from EL1 and EL0 are ordered only with respect to accesses using the same VMID.
- Accesses from EL2 are ordered only with respect to other accesses from EL2.

All other memory barrier requirements are unchanged.

The following subsections describe the memory barrier instructions:

- [Instruction Synchronization Barrier](#).
- [Data Memory Barrier](#).
- [Data Synchronization Barrier](#).
- [Load-Acquire, Store-Release](#).

Note

Depending on the required synchronization, a program might use memory barriers on their own, or it might use them in conjunction with cache maintenance and memory management instructions that in general are available only when software execution is at EL1 or higher.

The DMB and DSB memory barriers affect reads and writes to the memory system generated by load/store instructions and data or unified cache maintenance instructions being executed by the PE.

AArch32 state also supports the legacy barrier instructions [CP15DMB](#), [CP15DSB](#), and [CP15ISB](#). These instructions are executed as MCRs using the appropriate encoding, and are accessible from EL0. However, for performance reasons Arm deprecates any use of these operations, and strongly recommends that software uses the [DMB](#), [DSB](#), and [ISB](#) instructions described in this section instead. Optionally, an implementation can support a CP15BEN control that supervisory software can use to disable use of these instructions, meaning the corresponding MCR encodings are UNDEFINED. When the CP15BEN control is supported, setting one of the following CP15BEN fields to 0 makes execution of [CP15DMB](#), [CP15DSB](#), and [CP15ISB](#) UNDEFINED:

- [SCTLR](#).CP15BEN, for execution of these instructions at EL0 or EL1 when EL1 is using AArch32.
- [HSTCLR](#).CP15BEN, for execution of these instructions at EL2 when EL2 is using AArch32.

B2.5.5.1 Instruction Synchronization Barrier

An [ISB](#) instruction ensures that all instructions that come after the [ISB](#) instruction in program order are fetched from the cache or memory after the [ISB](#) instruction has completed. Using an [ISB](#) ensures that the effects of context-changing operations executed before the [ISB](#) are visible to the instructions fetched after the [ISB](#) instruction. Examples of context-changing operations that require the insertion of an [ISB](#) instruction to ensure the effects of the operation are visible to instructions fetched after the [ISB](#) instruction are:

- Completed cache and TLB maintenance instructions.
- Changes to System registers.

Any context-changing operations appearing in program order after the [ISB](#) instruction take effect only after the [ISB](#) has been executed.

The pseudocode function for the operation of an [ISB](#) is [InstructionSynchronizationBarrier\(\)](#).

See also [Memory barriers](#).

B2.5.5.2 Data Memory Barrier

The [DMB](#) instruction is a memory barrier instruction that ensures the relative order of memory accesses before the barrier with memory accesses after the barrier. The [DMB](#) instruction does not ensure the completion of any of the memory accesses for which it ensures relative order.

The full definition of the [DMB](#) instruction is covered formally in the [Definition of the memory model](#) and this introduction to the [DMB](#) instruction is not intended to contradict that section.

The basic principle of a [DMB](#) instruction is to introduce order between memory accesses that are specified to be affected by the [DMB](#) options supplied as arguments to the [DMB](#) instruction. The [DMB](#) instruction ensures that all affected memory accesses by the PE executing the [DMB](#) instruction that appear in program order before the [DMB](#) instruction and those which originate from a different PE, to the extent required by the [DMB](#) options, which have been Observed-by the PE before the [DMB](#) instruction is executed, are Observed-by each PE, to the extent required by the [DMB](#) options, before any affected memory accesses that appear in program order after the [DMB](#) instruction are Observed-by that PE.

The use of a [DMB](#) instruction creates order between the Memory effects of instructions as described in the definition of Barrier-ordered-before.

The pseudocode function for the operation of a [DMB](#) instruction is [DataMemoryBarrier\(\)](#).

B2.5.5.3 Data Synchronization Barrier

A [DSB](#) instruction is a memory barrier that ensures that memory accesses that occur before the [DSB](#) instruction have completed before the completion of the [DSB](#) instruction. In doing this, it acts as a stronger barrier than a [DMB](#) and all ordering that is created by a [DMB](#) with specific options is also generated by a [DSB](#) with the same options.

Execution of a [DSB](#) at EL2 ensures that any memory accesses caused by speculative accesses from the PL1&0 translation regime have been observed.

A [DSB](#) executed by a PE, PEe, completes when all of the following apply:

- All explicit memory effects of the required access types appearing in program order before the [DSB](#) are complete for the set of observers in the required shareability domain.

- If the required access types of the DSB is reads and writes, the following instructions issued by PEE before the DSB are complete for the required shareability domain:
 - All cache maintenance instructions.
 - All PSB instructions.

In addition, no instruction that appears in program order after the DSB instruction can alter any state of the system or perform any part of its functionality until the DSB completes, other than:

- Being fetched from memory and decoded, or any change to architectural or microarchitectural state resulting from being fetched or decoded.
- Indirectly or directly reading any of the following, so long as the reading of these resources does not cause a change in architectural state:
 - General-purpose registers
 - SIMD&FP registers
 - The Stack Pointer register
 - The Program Counter
 - Special-purpose registers

The pseudocode function for the operation of a DSB is `DataSynchronizationBarrier()`.

See also [Memory barrier instructions](#) and [Memory barriers](#).

B2.5.5.3.1 Maintenance scope of the data synchronization barrier operations

A DSB instruction that applies to both reads and writes takes an argument that specifies its maintenance scope. The maintenance scope indicates the subset of TLB invalidate (TLBI) instructions, TLB invalidate pair (TLBIP) instructions, and Instruction cache maintenance (IC) instructions that are covered by this DSB, for one of:

- Outer Shareable domain.
- Inner Shareable domain.
- Non-shareable domain.

When a DSB instruction that applies to both reads and writes is used to ensure completion of TLB maintenance instructions or Instruction cache maintenance (IC) instructions, all of the following apply:

- A DSB_{NSH} is sufficient to ensure completion of TLB maintenance instructions or Instruction cache maintenance (IC) instructions that apply to a single PE.
- A DSB_{ISH} is sufficient to ensure completion of TLB maintenance instructions or Instruction cache maintenance (IC) instructions that apply to PEs in the same Inner Shareable domain.
- A DSB_{OSH} is sufficient to ensure completion of TLB maintenance instructions that apply to PEs in the same Outer Shareable domain.

B2.5.5.4 Load-Acquire, Store-Release

The architecture provides a set of instructions with Acquire semantics for loads, and Release semantics for stores.

The full definition of the Load-Acquire instruction is covered formally in the [Definition of the memory model](#) and this introduction to the Load-Acquire instruction is not intended to contradict that section.

The basic principle of a Load-Acquire instruction is to introduce order between the memory access generated by the Load-Acquire instruction and the memory accesses appearing in program order after the Load-Acquire instruction, such that the memory access generated by the Load-Acquire instruction is Observed-by each PE, to the extent that PE is required to observe the access coherently, before any of the memory accesses appearing in program order after the Load-Acquire instruction are Observed-by that PE, to the extent that the PE is required to observe the accesses coherently.

The use of a Load-Acquire instruction creates order between the Memory effects of instructions as described in the definition of Barrier-ordered-before.

The full definition of the Store-Release instruction is covered formally in the [Definition of the memory model](#) and this introduction to the Store-Release instruction is not intended to contradict that section.

The basic principle of a Store-Release instruction is to introduce order between the memory accesses generated by the PEE executing the Store-Release instruction, together with those which originate from a different PE, to the extent that the PEE is required to observe them coherently, Observed-by the PEE before executing the Store-release.

The use of a Store-Release instruction creates order between the Memory effects of instructions as described in the definition of Barrier-ordered-before.

In addition, the use of a Load-Acquire or a Store-Release instruction on accesses to a Memory-mapped peripheral introduces order between the Memory effects of the instructions that access that peripheral, as described in the definition of Peripheral arrival order.

Load-Acquire and Store-Release, other than LDAEXD and STLEXD, access only a single data element. This access is single-copy atomic. The address of the data object must be aligned to the size of the data element being accessed, otherwise the access generates an Alignment fault.

LDAEXD and STLEXD access two data elements. The address supplied to the instructions must be doubleword-aligned, otherwise the access generates an Alignment fault.

A Store-Release Exclusive instruction has the release semantics only if the store is successful.

Note

- Each Load-Acquire Exclusive and Store-Release Exclusive instruction is essentially a variant of the equivalent Load-Exclusive or Store-Exclusive instruction. All usage restrictions and single-copy atomicity properties:
 - That apply to the Load-Exclusive instructions also apply to the Load-Acquire Exclusive instructions.
 - That apply to the Store-Exclusive instructions also apply to the Store-Release Exclusive instructions.
 - The Load-Acquire/Store-Release instructions can remove the requirement to use the explicit DMB memory barrier instruction.
-

Table B2-1 summarizes the Load-Acquire/Store-release instructions.

Table B2-1 Load-Acquire/Store-Release instructions

Data type	Load-Acquire	Store-Release	Load-Acquire Exclusive	Store-Release Exclusive
32-bit word	LDA	STL	LDAEX	STLEX
16-bit halfword	LDAH	STLH	LDAEXH	STLEXH
8-bit byte	LDAB	STLB	LDAEXB	STLEXB
64-bit doubleword	-	-	LDAEXD	STLEXD

B2.6 Endian support

[General description of endianness in the Arm architecture](#) describes the relationship between endianness and memory addressing in the Arm architecture.

The following subsections then describe the endianness schemes supported by the architecture:

- [Instruction endianness.](#)
- [Data endianness.](#)
- [Endianness of memory-mapped peripherals.](#)

B2.6.1 General description of endianness in the Arm architecture

This section only describes memory addressing and the effects of endianness for data elements up to doubleword of 64 bits. However, this description can be extended to apply to larger data elements.

For an address A, [Figure B2-1](#) shows, for big-endian and little-endian memory systems, the relationship between:

- The doubleword at address A.
- The words at addresses A and A+4.
- The halfwords at addresses A, A+2, A+4, and A+6.
- The bytes at addresses A, A+1, A+2, A+3, A+4, A+5, A+6, and A+7.

The terms in [Figure B2-1](#) have the following definitions:

MSByte Most significant byte.

LSByte Least significant byte.

Big-endian memory system

Little-endian memory system

In this figure, *Byte, A+1* is an abbreviation for *Byte at address A+1*

Figure B2-1 Endianness relationships in AArch32 state

B2.6.2 Instruction endianness

The mapping of instruction memory is always little-endian.

B2.6.3 Data endianness

The size of the data value that is loaded or stored is the size that is used for the purpose of endian conversion for floating-point, Advanced SIMD, and general-purpose register loads and stores.

Table B2-2 shows the element sizes of all the load/store instructions, for all instruction sets.

Table B2-2 Element size of load/store instructions

Instructions	Element size
LDRB, LDREXB, LDRBT, LDRSB, LDRSBT, STRB, STREXB, STRBT, TBB	Byte
LDRH, LDREXH, LDRHT, LDRSH, LDRSHT, STRH, STREXH, STRHT, TBH	Halfword
LDR, LDRT, LDREX, STR, STRT, STREX	Word
LDRD, LDREXD, STRD, STREXD	Word
All forms of LDM, PUSH, POP, RFE, SRS, all forms of STM,	Word
LDC, STC	Word

Instructions	Element size
Forms of VLDM, VLDR, VPOP, VPUSH, VSTM, VSTR that transfer 32-bit S registers	Word
Forms of VLDM, VLDR, VPOP, VPUSH, VSTM, VSTR that transfer 64-bit D registers	Doubleword
VLD1, VLD2, VLD3, VLD4, VST1, VST2, VST3, VST4	Element size of the Advanced SIMD access

[CPSR.E](#) determines the data endianness.

The data size used for endianness conversions:

- Is the size of the data value that is loaded or stored for Advanced SIMD and floating-point register and general-purpose register loads and stores.
- Is the size of the data element that is loaded or stored for Advanced SIMD element and data structure loads and stores. For more information, see [Endianness in Advanced SIMD](#).

B2.6.3.1 Instructions to reverse bytes in registers

An application or device driver might have to interface to memory-mapped peripheral registers or shared memory structures that are not the same endianness as the internal data structures. Similarly, the endianness of the operating system might not match that of the peripheral registers or shared memory. In these cases, the PE requires an efficient method to transform explicitly the endianness of the data.

[Table B2-3](#) shows the instructions that provide this functionality in the T32 and A32 instruction sets.

Table B2-3 Byte reversal instructions

Function	T32/A32 instruction	Notes
Reverse bytes in whole register	REV	For use with general purpose registers
Reverse bytes in 16-bit halfwords	REV16	For use with general purpose registers
Reverse bytes in halfword and sign-extend	REVSH	For use with general purpose registers
Reverse elements in doublewords, vector	VREV64	For use with registers in the SIMD and floating-point register file
Reverse elements in words, vector	VREV32	For use with registers in the SIMD and floating-point register file
Reverse elements in halfwords, vector	VREV16	For use with registers in the SIMD and floating-point register file

B2.6.3.2 Endianness in Advanced SIMD

Advanced SIMD element load/store instructions transfer vectors of elements between memory and the SIMD and floating-point register file. An instruction specifies both the length of the transfer and the size of the data elements being transferred. This information is used by the PE to load and store data correctly in both big-endian and little-endian systems.

Consider, for example, the A32 or T32 instruction:

```
VLD1.16 {D0}, [R1]
```

This loads a 64-bit register with four 16-bit values. The four elements appear in the register in array order, with the lowest indexed element fetched from the lowest address. The order of bytes in the elements depends on the endianness configuration, as shown in [Figure B2-2](#). Therefore, the order of the elements in the registers is the same regardless of the endianness configuration.

Figure B2-2 Advanced SIMD byte order example for AArch32 state

For information about the alignment of Advanced SIMD instructions, see [Alignment support](#).

The `BigEndian()` pseudocode function determines the current endianness of the data.

The `BigEndianReverse()` pseudocode function reverses the endianness of a bitstring.

The `BigEndian()` and `BigEndianReverse()` functions are defined in [A-profile Architecture Pseudocode](#).

B2.6.4 Endianness of memory-mapped peripherals

All memory-mapped peripherals defined in the Arm architecture must be little-endian.

Peripherals to which this requirement applies include:

- Memory-mapped register interfaces to a debugger, or to a Cross Trigger Interface, see [About the External Debug Registers](#).
- The memory-mapped register interface to the system level implementation of the Generic Timer, see [System Level Implementation of the Generic Timer](#).
- A memory-mapped register interface to the Performance Monitors, see [Recommended External Interface to the Performance Monitors](#).
- Memory-mapped register interfaces to an Arm Generic Interface Controller, see the *ARM[®] Generic Interrupt Controller Architecture Specification, GIC architecture version 3 and version 4*.
- The memory-mapped register interface to an Arm trace component. See, for example, the *Arm[®] Embedded Trace Macrocell Architecture Specification, ETMv4*.

B2.7 Caches and memory hierarchy

The implementation of a memory system depends heavily on the microarchitecture and therefore many details of the memory system are IMPLEMENTATION DEFINED. The architecture defines the application level interface to the memory system, including a hierarchical memory system with multiple levels of cache. This section describes an application level view of this system. It contains the subsections:

- [Introduction to caches.](#)
- [Memory hierarchy.](#)
- [Implication of caches for the application programmer.](#)
- [Prefetching into cache.](#)

B2.7.1 Introduction to caches

A cache is a block of high-speed memory that contains a number of entries, each consisting of:

- Main memory address information, commonly known as a *tag*.
- The associated data.

Caches increase the average speed of a memory access and take account of two principles of locality:

Spatial locality

An access to one location is likely to be followed by accesses to adjacent locations. Examples of this principle are:

- Sequential instruction execution.
- Accessing a data structure.

Temporal locality

An access to an area of memory is likely to be repeated in a short time period. An example of this principle is the execution of a software loop.

To minimize the quantity of control information stored, the spatial locality property groups several locations together under the same tag. This logical block is commonly known as a *cache line*. When data is loaded into a cache, access times for subsequent loads and stores are reduced, resulting in overall performance benefits. An access to information already in a cache is known as a *cache hit*, and other accesses are called *cache misses*.

Normally, caches are self-managing, with the updates occurring automatically. Whenever the PE accesses a cacheable memory location, the cache is checked. If the access is a cache hit, the access occurs in the cache. Otherwise, the access is made to memory. Typically, when making this access, a cache location is allocated and the cache line loaded from memory. The architecture permits different cache topologies and access policies, provided they comply with the memory coherency model described in this manual.

Caches introduce a number of potential problems, mainly because:

- Memory accesses can occur at times other than when the programmer would expect them.
- A data item can be held in multiple physical locations.

B2.7.2 Memory hierarchy

Typically memory close to a PE has very low latency, but is limited in size and expensive to implement. Further from the PE it is common to implement larger blocks of memory but these have increased latency. To optimize overall performance, a memory system can include multiple levels of cache in a hierarchical memory system that exploits this trade-off between size and latency. [Figure B2-3](#) shows an example of such a system in a system that supports virtual addressing.

Figure B2-3 Multiple levels of cache in a memory hierarchy

Note

In this manual, in a hierarchical memory system, Level 1 refers to the level closest to the PE, as shown in [Figure B2-3](#).

Instructions and data can be held in separate caches or in a unified cache. A cache hierarchy can have one or more levels of separate instruction and data caches, with one or more unified caches located at the levels closest to the main memory. Memory coherency for cache topologies can be defined using the conceptual points Point of Unification (PoU) and Point of Coherency (PoC). For more information, including the definitions of PoU and PoC, see [About cache maintenance in AArch32 state](#).

B2.7.2.1 The Cacheability and Shareability memory attributes

Cacheability and Shareability are two attributes that describe the memory hierarchy in a multiprocessing system:

- Cacheability** This term defines whether memory locations are allowed to be allocated into a cache or not. Cacheability is defined independently for Inner and Outer Cacheability locations.
- Shareability** This term defines whether memory locations are shareable between different agents in a system. Marking a memory location as shareable for a particular domain requires hardware to ensure that the location is coherent for all agents in that domain. Shareability is defined independently for Inner and Outer Shareability domains.

For more information about the Cacheability and Shareability attributes, see [Memory types and attributes](#).

B2.7.3 Implication of caches for the application programmer

In normal operation, the caches are largely invisible to the application programmer. However they can become visible when there is a breakdown in the coherency of the caches. Such a breakdown can occur:

- When memory locations are updated by other agents in the system that do not use hardware management of coherency.
- When memory updates made from the application software must be made visible to other agents in the system, without the use of hardware management of coherency.

For example:

- In the absence of hardware management of coherency of DMA accesses, in a system with a DMA controller that reads memory locations that are held in the data cache of a PE, a breakdown of coherency occurs when the PE has written new data in the data cache, but the DMA controller reads the old data held in memory.

- In a Harvard cache implementation, where there are separate instruction and data caches, a breakdown of coherency occurs when new instruction data has been written into the data cache, but the instruction cache still contains the old instruction data.

B2.7.3.1 Data coherency issues

Software can ensure the data coherency of caches in the following ways:

- By not using the caches in situations where coherency issues can arise. This can be achieved by:
 - Using Non-cacheable or, in some cases, Write-Through Cacheable memory.
 - Not enabling caches in the system.
- By using system calls to functions using cache maintenance instructions that execute at a higher Exception level.
- By using hardware coherency mechanisms to ensure the coherency of data accesses to memory for cacheable locations by observers within the different shareability domains, see [Non-shareable Normal memory](#) and [Shareable, Inner Shareable, and Outer Shareable Normal memory](#).

Note

The performance of these hardware coherency mechanisms is highly IMPLEMENTATION SPECIFIC. In some implementations the mechanism suppresses the ability to cache shareable locations. In other implementations, cache coherency hardware can hold data in caches while managing coherency between observers within the shareability domains.

B2.7.3.2 Synchronization and coherency issues between data and instruction accesses

How far ahead of the current point of execution instructions are fetched from is IMPLEMENTATION DEFINED. Such prefetching can be either a fixed or a dynamically varying number of instructions, and can follow any or all possible future execution paths. For all types of memory:

- The PE might have fetched the instructions from memory at any time since the last [Context Synchronization event](#) on that PE.
- Any instructions fetched in this way might be executed multiple times, if this is required by the execution of the program, without being re-fetched from memory.

The Arm architecture does not require the hardware to ensure coherency between instruction caches and memory, even for locations of shared memory.

If software requires coherency between instruction execution and memory, it must manage this coherency using [Context Synchronization events](#) and cache maintenance instructions. These can be accessed only from an Exception level that is higher than EL0, and therefore require a system call, see [Exception-generating and exception-handling instructions](#). The following code sequence can be used for this purpose:

```
; Coherency example for data and instruction accesses within the same Inner Shareable domain.
; Enter this code with <Rt> containing a new 32-bit instruction,
; to be held in Cacheable space at a location pointed to by Rn. Use STRH in the first line
; instead of STR for a 16-bit instruction.
STR Rt, [Rn]
DCCMVAU Rn      ; Clean data cache by MVA to point of unification (PoU)
DSB             ; Ensure visibility of the data cleaned from cache
ICIMVAU Rn      ; Invalidate instruction cache by MVA to PoU
BPIMVA Rn       ; Invalidate branch predictor by MVA to PoU
DSB             ; Ensure completion of the invalidations
ISB             ; Synchronize the fetched instruction stream
```

A write has been made coherent with an instruction fetch of a shareability domain when:

CTR.{DIC, IDC} = {0, 0} The location written to has been cleaned to the [Point of unification \(PoU\)](#) from the data cache, and that clean is complete for the shareability domain. Subsequently the location has been invalidated to the [Point of unification \(PoU\)](#) from the instruction cache, and that invalidation is complete for the shareability domain.

CTR.{DIC, IDC} = {0, 1} The write is complete for the shareability domain. Subsequently the location has been invalidated to the [Point of unification \(PoU\)](#) from the instruction cache, and that invalidation is complete for the shareability domain.

CTR.{DIC, IDC} = {1, 1} The write is complete for the shareability domain.

Note

- For accesses that are Non-cacheable or Write-Through, the clean data cache instruction is not required. For accesses that are Non-cacheable, the invalidate instruction cache is not required, because in AArch32 state these accesses are not permitted to be held in an instruction cache.
 - This code can be used when the thread of execution modifying the code is the same thread of execution that is executing the code. The architecture limits the set of instructions that can be executed by one thread of execution as they are being modified by another thread of execution without requiring explicit synchronization. See [Concurrent modification and execution of instructions](#).
-

B2.7.4 Prefetching into cache

The Arm architecture provides the memory system hints `PLD` (Preload Data), `PLDW` (Preload Data With Intent To Write) and `PLI` (Preload Instruction) that software can use to communicate the expected use of memory locations to the hardware. The memory system can respond by taking actions that are expected to speed up the memory accesses if they occur. The effect of these memory system hints is IMPLEMENTATION DEFINED. Typically, implementations use this information to bring data or instruction locations into caches.

The prefetch instructions are hints, and so implementations can treat them as `NOPS` without affecting the functional behavior of the device. The instructions cannot generate synchronous Data Abort exceptions, but the resulting memory system operations might, under exceptional circumstances, generate an asynchronous External abort, which is reported using an `SError` exception and taken using an asynchronous Data Abort exception. For more information, see [Data Abort exception](#).

A `PLD`, `PLDW`, or `PLI` instruction can only cause allocation to software-visible caching structures such as caches or TLBs for memory locations that can be accessed, according to the permissions defined by the current translation regime or a translation regime for a higher Exception level in the current Security state, by any of:

- Reads.
- Writes.
- Instruction fetches.

A `PLD`, `PLDW`, or `PLI` instruction can access any memory location in Normal memory that can be accessed, according to the permissions defined by the current translation regime or a translation regime for a higher Exception level in the current Security state, by any of:

- Reads.
- Writes.
- Instruction fetches.

Note

In each case, the entire list applies to each of `PLD`, `PLDW`, and `PLI`.

A `PLD`, `PLDW`, or `PLI` instruction is guaranteed not to access any type of Device memory.

A `PLI` instruction must not perform any access that cannot be performed by a speculative instruction fetch by the processor.

The pseudocode enumeration [PrefetchHint](#) defines the prefetch hint types.

The `Hint_Prefetch()` pseudocode function signals to the memory system that memory accesses of the type `hint` to or from the specified `address` are likely to occur in the near future. The memory system might take some action to speed up the memory accesses when they do occur, such as prefetching the specified address into one or more caches as indicated by the innermost cache level `target` and non-temporal hint `stream`.

For more information on `PLD`, `PLI`, and `PLDW`, see:

- [PLD, PLDW \(immediate\)](#).

- PLD (literal).
- PLD, PLDW (register).
- PLI (immediate, literal).
- PLI (register).

B2.8 Alignment support

This section describes alignment support. It contains the following subsections:

- [Instruction alignment.](#)
- [Unaligned data access.](#)
- [Cases where unaligned accesses are CONSTRAINED UNPREDICTABLE.](#)
- [Unaligned data access restrictions.](#)

For more information about Alignment faults, see [Alignment faults](#).

B2.8.1 Instruction alignment

A32 instructions are word-aligned.

T32 instructions are halfword-aligned.

B2.8.2 Unaligned data access

An R-profile implementation must support unaligned data accesses to Normal memory by some load and store instructions. As [Table B2-4](#) shows, software can control whether a misaligned access to Normal memory by one of these instructions causes an Alignment fault Data Abort exception:

- By setting [SCTLR.A](#), for unaligned accesses from any mode other than Hyp mode.
- By setting [HSCTLR.A](#), for unaligned accesses from Hyp mode.

Table B2-4 Alignment requirements of load/store instructions

Instructions	Alignment check	Result if check fails when:	
		SCTLR.A or HSCTLR.A is 0	SCTLR.A or HSCTLR.A is 1
LDRB, LDREXB, LDRBT, LDRSB, LDRSBT, STRB, STREXB, STRBT, TBB	None	-	-
LDRH, LDRHT, LDRSH, LDRSHT, STRH, STRHT, TBH	Halfword	Unaligned access	Alignment fault
LDREXH, STREXH, LDAH, STLH, LDAEXH, STLEXH	Halfword	Alignment fault	Alignment fault
LDR, LDRT, STR, STRT PUSH, encodings T3 and A2 only POP, encodings T3 and A2 only	Word	Unaligned access	Alignment fault
LDREX, STREX, LDA, STL, LDAEX, STLEX	Word	Alignment fault	Alignment fault
LDREXD, STREXD, LDAEXD, STLEXD	Doubleword	Alignment fault	Alignment fault
All forms of LDM and STM, LDRD, RFE, SRS, STRD	Word	Alignment fault	Alignment fault
LDC, STC	Word	Alignment fault	Alignment fault
VLDM, VPOP, VPUSH, VSTM	Word	Alignment fault	Alignment fault
VLDR, VSTR - single-precision scalar and double-precision scalar	Word	Alignment fault	Alignment fault
VLD1, VLD2, VLD3, VLD4, VST1, VST2, VST3, VST4, all with standard alignment	Element size	Unaligned access	Alignment fault
VLD1, VLD2, VLD3, VLD4, VST1, VST2, VST3, VST4, all with :<align> specified ^a	As specified by :<align>	Alignment fault	Alignment fault

a. Previous versions of this manual used @<align> to specify alignment. Both forms are supported, see [T32 and A32 Advanced SIMD and Floating-point Instruction Descriptions](#) for more information.

Note

Any unaligned access to any type of Device memory generates an Alignment fault, see [Alignment faults](#).

B2.8.3 Cases where unaligned accesses are CONSTRAINED UNPREDICTABLE

Any load instruction that is not faulted by the alignment restrictions shown in [Table B2-4](#) and that loads the PC has CONSTRAINED UNPREDICTABLE behavior if the address it loads from is not word-aligned, see [Loads and Stores to unaligned locations](#). This overrides any permitted load/store behavior shown in [Table B2-4](#).

B2.8.4 Unaligned data access restrictions

The following points apply to unaligned data accesses:

- Accesses are not guaranteed to be single-copy atomic except at the byte access level, see [Atomicity in the Arm architecture](#).
- Unaligned accesses typically take a number of additional cycles to complete compared to a naturally-aligned access.
- An operation that performs an unaligned access can abort on any memory access that it makes, and can abort on more than one access. This means that an unaligned access that occurs across a page boundary can generate an abort on either side of the boundary.

B2.8.5 Endianness of memory-mapped peripherals

All memory-mapped peripherals defined in the Arm architecture must be little-endian.

Peripherals to which this requirement applies include:

- Memory-mapped register interfaces to a debugger, or to a cross-trigger interface, see [About the External Debug Registers](#).
- The memory-mapped register interface to the system level implementation of the Generic Timer, see [System Level Implementation of the Generic Timer](#).
- A memory-mapped register interface to the Performance Monitors, see [Recommended External Interface to the Performance Monitors](#).
- Memory-mapped register interfaces to an Arm Generic Interface Controller, see the *ARM[®] Generic Interrupt Controller Architecture Specification, GIC architecture version 3 and version 4*.
- The memory-mapped register interface to an Arm trace component. See, for example, the *Arm[®] Embedded Trace Macrocell Architecture Specification, ETMv4*.

B2.9 Memory types and attributes

The ordering of accesses for addresses in memory, referred to as the memory order model, is defined by the memory attributes. The following sections describe this model:

- [Normal memory](#).
- [Device memory](#).
- [Memory access restrictions](#).

B2.9.1 Normal memory

The Normal memory type attribute applies to most memory in a system. It indicates that the hardware is permitted by the architecture to perform [Speculative](#) data read accesses to these locations, regardless of the access permissions for these locations.

The Normal memory type has the following properties:

- An Explicit Memory Write Effect to a memory location with the Normal attribute completes in finite time.
- Explicit Memory Write Effects to a memory location with the Normal memory type that is either Non-cacheable or Write-Through cacheable for both the Inner and Outer Cacheability must reach the endpoint for that location in the memory system in finite time. Two writes to the same location, where at least one is using the Normal memory type, might be merged before they reach the endpoint unless there is an ordered-before relationship between the two writes. For the purposes of this requirement, the endpoint for a location in [Conventional memory](#) is the PoC.
- Unaligned memory accesses can access Normal memory if the system is configured to generate such accesses.
- There is no requirement for the memory system beyond the PE to be able to identify the elements accessed by multi-register load/store instructions. See [Multi-register loads and stores that access Normal memory](#).

Note

- The Normal memory attribute is appropriate for locations of memory that are idempotent, meaning that they exhibit all of the following properties:
 - Read accesses can be repeated with no side-effects.
 - Repeated read accesses return the last value written to the resource being read.
 - Read accesses can fetch additional memory locations with no side-effects.
 - Write accesses can be repeated with no side-effects if the contents of the location accessed are unchanged between the repeated writes or as the result of an exception, as described in this section.
 - Unaligned accesses can be supported.
 - Accesses can be merged before accessing the target memory system.
- Normal memory allows speculative reads and may be affected by intermediate buffering and forwarding of data. If non-idempotent memory locations are mapped as Normal memory, the following may occur:
 - Memory accesses return UNKNOWN values.
 - UNPREDICTABLE effects on memory-mapped peripherals.
- An instruction that generates a sequence of accesses as described in [Atomicity in the Arm architecture](#) might be abandoned as a result of an exception being taken during the sequence of accesses. On return from the exception the instruction is restarted, and therefore one or more of the memory locations might be accessed multiple times. This can result in repeated write accesses to a location that has been changed between the write accesses.

The following sections describe the other attributes for Normal memory:

- [Shareable Normal memory](#).
- [Non-shareable Normal memory](#).
- [Cacheability attributes for Normal memory](#).

See also:

- [Multi-register loads and stores that access Normal memory.](#)
- [Atomicity in the Arm architecture.](#)
- [Memory barriers.](#) For accesses to Normal memory, a DMB instruction is required to ensure the required ordering.
- [Concurrent modification and execution of instructions.](#)

B2.9.1.1 Shareable Normal memory

A Normal memory location has a Shareability attribute that is defined as one of:

- Inner Shareable.
- Outer Shareable.
- Non-shareable.

The shareability attributes define the data coherency requirements of the location, which hardware must enforce. They do not affect the coherency requirements of instruction fetches, see [Synchronization and coherency issues between data and instruction accesses](#).

Note

- System designers can use the Shareability attribute to specify the locations in Normal memory for which coherency must be maintained. However, software developers must not assume that specifying a memory location as Non-shareable permits software to make assumptions about the incoherency of the location between different PEs in a shared memory system. Such assumptions are not portable between different multiprocessing implementations that might use the Shareability attribute. Any multiprocessing implementation might implement caches that are shared, inherently, between different PEs.
 - This architecture assumes that all PEs that use the same operating system or hypervisor are in the same Inner Shareable shareability domain.
-

B2.9.1.1.1 Shareable, Inner Shareable, and Outer Shareable Normal memory

The Arm architecture abstracts the system as a series of Inner and Outer Shareability domains.

Each Inner Shareability domain contains a set of observers that are data coherent for each member of that set for data accesses with the Inner Shareable attribute made by any member of that set.

Each Outer Shareability domain contains a set of observers that are data coherent for each member of that set for data accesses with the Outer Shareable attribute made by any member of that set.

The following properties also hold:

- Each observer is only a member of a single Inner Shareability domain.
- Each observer is only a member of a single Outer Shareability domain.
- All observers in an Inner Shareability domain are always members of the same Outer Shareability domain. This means that an Inner Shareability domain is a subset of an Outer Shareability domain, although it is not required to be a proper subset.

Note

- Because all data accesses to Non-cacheable locations are data coherent to all observers, Non-cacheable locations are always treated as Outer Shareable.
 - The Inner Shareable domain is expected to be the set of PEs controlled by a single hypervisor or operating system.
-

The details of the use of the Shareability attributes are system-specific. [Example B2-1](#) shows how they might be used.

Example B2-1 Use of shareability attributes

In an implementation, a particular subsystem with two clusters of PEs has the requirement that:

- In each cluster, the data caches or unified caches of the PEs in the cluster are transparent for all data accesses to memory locations with the Inner Shareable attribute.
- However, between the two clusters, the caches:
 - Are not required to be coherent for data accesses that have only the Inner Shareable attribute.
 - Are coherent for data accesses that have the Outer Shareable attribute.

In this system, each cluster is in a different Shareability domain for the Inner Shareable attribute, but all components of the subsystem are in the same Shareability domain for the Outer Shareable attribute.

A system might implement two such subsystems. If the data caches or unified caches of one subsystem are not transparent to the accesses from the other subsystem, this system has two Outer Shareable Shareability domains.

Having two levels of shareability means system designers can reduce the performance and power overhead for shared memory locations that do not need to be part of the Outer Shareable Shareability domain.

For Shareable Normal memory, the Load-Exclusive and Store-Exclusive synchronization primitives take account of the possibility of accesses by more than one observer in the same Shareability domain.

B2.9.1.2 Non-shareable Normal memory

For Normal memory locations, the Non-shareable attribute identifies Normal memory that is likely to be accessed only by a single PE.

A location in Normal memory with the Non-shareable attribute does not require the hardware to make data accesses by different observers coherent, unless the memory is Non-cacheable. For a Non-shareable location, if other observers share the memory system, software must use cache maintenance instructions, if the presence of caches might lead to coherency issues when communicating between the observers. This cache maintenance requirement is in addition to the barrier operations that are required to ensure memory ordering.

For Non-shareable Normal memory, it is IMPLEMENTATION DEFINED whether the Load-Exclusive and Store-Exclusive synchronization primitives take account of the possibility of accesses by more than one observer.

B2.9.1.3 Cacheability attributes for Normal memory

In addition to being Outer Shareable, Inner Shareable or Non-shareable, each region of Normal memory is assigned a Cacheability attribute that is one of:

- Write-Back Cacheable.
- Write-Through.
- Non-cacheable.

Also, for Write-Back Cacheable and Write-Through Normal memory regions:

- A region might be assigned cache allocation hints for read and write accesses.
- It is IMPLEMENTATION DEFINED whether the cache allocation hints can have an additional attribute of Transient or Non-transient.

For more information, see [Cacheability, cache allocation hints, and cache transient hints](#).

A memory location can be marked as having different cacheability attributes, for example when using aliases in a VA to PA mapping:

- If the attributes differ only in the cache allocation hint this does not affect the behavior of accesses to that location.
- For other cases, see [Mismatched memory attributes](#).

The cacheability attributes provide a mechanism of coherency control with observers that lie outside the Shareability domain of a region of memory. In some cases, the use of Write-Through or Non-cacheable regions of memory might provide a better mechanism for controlling coherency than the use of hardware coherency mechanisms or the use of cache maintenance routines. For this reason, the architecture requires the following properties for Non-cacheable or Write-Through memory:

- A completed write to a memory location that is Non-cacheable or Write-Through for a level of cache made by an observer accessing the memory system inside the level of cache is visible to all observers accessing the memory system outside the level of cache without the need of explicit cache maintenance.
- A completed write to a memory location that is Non-cacheable or Write-Through for a level of cache made by an observer accessing the memory system outside the level of cache is visible to all observers accessing the memory system inside the level of cache without the need of explicit cache maintenance.
- For accesses to Normal memory that is Non-cacheable or Write-Through, a DMB instruction introduces a Barrier-ordered-before relation on all accesses to a single peripheral or block of memory that is of IMPLEMENTATION DEFINED size. For more information, see Ordering relations and constraints.

Note

Implementations can use the cache allocation hints to indicate a probable performance benefit of caching. For example, a programmer might know that a piece of memory is not going to be accessed again and would be better treated as Non-cacheable. The distinction between memory regions with attributes that differ only in the cache allocation hints exists only as a hint for performance.

For Normal memory, the Arm architecture provides cacheability attributes that are defined independently for each of two conceptual levels of cache, the *inner* and the *outer* cache. The relationship between these conceptual levels of cache and the implemented physical levels of cache is IMPLEMENTATION DEFINED, and can differ from the boundaries between the Inner and Outer Shareability domains. However:

- Inner refers to the innermost caches, meaning the caches that are closest to the PE, and always includes the lowest level of cache.
- No cache that is controlled by the Inner Cacheability attributes can lie outside a cache that is controlled by the Outer Cacheability attributes.
- An implementation might not have any outer cache.

[Example B2-2](#), [Example B2-3](#), and [Example B2-4](#) describe the possible ways of implementing a system with three levels of cache, *level 1* (L1) to *level 3* (L3).

Note

- L1 cache is the level closest to the PE, see [Memory hierarchy](#).
 - When managing coherency, system designs must consider both the Inner and Outer Cacheability attributes, as well as the Shareability attributes. This is because hardware might have to manage the coherency of caches at one conceptual level, even when another conceptual level has the Non-cacheable attribute.
-

Example B2-2 Implementation with two inner and one outer cache levels

Implement the three levels of cache in the system, L1 to L3, with:

- The Inner Cacheability attribute applied to L1 and L2 cache.
- The Outer Cacheability attribute applied to L3 cache.

Example B2-3 Implementation with three inner and no outer cache levels

Implement the three levels of cache in the system, L1 to L3, with the Inner Cacheability attribute applied to L1, L2, and L3 cache. Do not use the Outer Cacheability attribute.

Example B2-4 Implementation with one inner and two outer cache levels

Implement the three levels of cache in the system, L1 to L3, with:

- The Inner Cacheability attribute applied to L1 cache.
- The Outer Cacheability attribute applied to L2 and L3 cache.

B2.9.1.4 Multi-register loads and stores that access Normal memory

For all instructions that load or store more than one general-purpose register from an Exception level there is no requirement for the memory system beyond the PE to be able to identify the size of the elements accessed by these load or store instructions.

For all instructions that load or store more than one general-purpose register from an Exception level the order in which the registers are accessed is not defined by the architecture.

For all instructions that load or store one or more registers from the SIMD and floating-point register file from an Exception level there is no requirement for the memory system beyond the PE to be able to identify the size of the element accessed by these load or store instructions.

B2.9.2 Device memory

The Device memory type attributes define memory locations where an access to the location can cause side-effects, or where the value returned for a load can vary depending on the number of loads performed. Typically, the Device memory attributes are used for memory-mapped peripherals and similar locations.

The attributes for Device memory are:

Gathering Identified as G or nG, see [Gathering](#).

Reordering Identified as R or nR, see [Reordering](#).

Early Write Acknowledgement

Identified as E or nE, see [Early Write Acknowledgement](#).

The Device memory types are:

Device-nGnRnE Device non-Gathering, non-Reordering, No Early Write Acknowledgement.

Equivalent to the Strongly-ordered memory type in earlier versions of the architecture.

Device-nGnRE Device non-Gathering, non-Reordering, Early Write Acknowledgement.

Equivalent to the Device memory type in earlier versions of the architecture.

Device-nGRE Device non-Gathering, Reordering, Early Write Acknowledgement.

ArmV8 added this memory type to the translation table formats found in earlier versions of the architecture. The use of barriers is required to order accesses to Device-nGRE memory.

The Device-nGRE memory type is introduced into the AArch32 translation table formats when the PE is using the Long Descriptor Translation Table format.

Device-GRE Device Gathering, Reordering, Early Write Acknowledgement.

ArmV8 added this memory type to the translation table formats found in earlier versions of the architecture. Device-GRE memory has the fewest constraints. It behaves similar to Normal memory, with the restriction that speculative accesses to Device-GRE memory is forbidden.

The Device-GRE memory type is introduced into the AArch32 translation table formats when the PE is using the Long Descriptor Translation Table format.

Collectively these are referred to as *any Device memory type*. Going down the list, the memory types are described as getting *weaker*; conversely the going up the list the memory types are described as getting *stronger*.

Note

- As the list of types shows, these additional attributes are hierarchical. For example, a memory location that permits Gathering must also permit Reordering and Early Write Acknowledgement.
 - The architecture does not require an implementation to distinguish between each of these memory types and Arm recognizes that not all implementations will do so. The subsection that describes each of the attributes, describes the implementation rules for the attribute.
 - Earlier versions of the Arm architecture defined the following memory types:
 - Strongly-ordered memory. This is the equivalent of the Device-nGnRnE memory type.
 - Device memory. This is the equivalent of the Device-nGnRE memory type.
-

All of these memory types have the following properties:

- Speculative data accesses are not permitted to any memory location with any Device memory attribute. This means that each memory access to any Device memory type must be one that would be generated by a simple sequential execution of the program.

An exception to this applies:

- Reads generated by the Advanced SIMD and floating-point instructions can access bytes that are not explicitly accessed by the instruction if the bytes accessed are in a 16-byte window, aligned to 16-bytes, that contains at least one byte that is explicitly accessed by the instruction.

Note

- An instruction that generates a sequence of accesses as described in [Atomicity in the Arm architecture](#) might be abandoned as a result of an exception being taken during the sequence of accesses. On return from the exception the instruction is restarted, and therefore one or more of the memory locations might be accessed multiple times. This can result in repeated accesses to a location where the program defines only a single access. For this reason, Arm strongly recommends that no accesses to Device memory are performed from a single instruction that spans the boundary of a translation granule or which in some other way could lead to some of the accesses being aborted.
 - Write speculation that is visible to other observers is prohibited for all memory types.
-

- An Explicit Memory Write Effect to a memory location with any Device memory type completes in finite time.
- If a value that would be returned from a read of a memory location with the Device memory type changes without an explicit memory write effect by an observer, this change must also be globally observed for all observers in the system in finite time. Such a change might occur in a peripheral location that holds status information.
- Data accesses to memory locations are coherent for all observers in the system, and correspondingly are treated as being Outer Shareable.
- A memory location with any Device memory attribute cannot be allocated into a cache.
- Explicit Memory Write Effects to a memory location with any Device memory attribute must reach the endpoint for that address in the memory system in finite time. Two Explicit Memory Write Effects of Device memory type to the same location might be merged before they reach the endpoint, unless both Explicit Memory Write Effects have the non-Gathering attribute or there is an ordered-before relationship between the two Explicit Memory Write Effects.
- If a memory location is not capable of supporting unaligned memory accesses, then an unaligned access to that memory location generates an Alignment fault at the first stage of translation that defined the location as being Device.
- If a memory location is capable of supporting unaligned memory accesses, and such a memory location is marked as Device, then it is IMPLEMENTATION DEFINED whether an unaligned access to that memory location generates an Alignment fault at the first stage of translation that defined the location as being Device.
- Hardware does not prevent speculative instruction fetches from a memory location with any of the Device memory attributes unless the memory location is also marked as execute-never for all Exception levels.

Note

This means that to prevent speculative instruction fetches from memory locations with Device memory attributes, any location that is assigned any Device memory type must also be marked as execute-never for all Exception levels. Failure to mark a memory location with any Device memory attribute as execute-never for all Exception levels is a programming error.

Note

In the PL1&0 translation regime in systems where [HCR.TGE](#) == 1 and [HCR.DC](#) == 0, any Alignment fault that results from the fact that all locations are treated as Device is a fault at the first stage of translation. This causes the value of [HSR.ISS.\[24\]](#) to be 0.

See also [Memory access restrictions](#).

The memory types for translation table walks cannot be defined as any Device memory type within the TCR. For the EL1&0 translation regime, the memory accesses made during a stage 1 translation table walk are subject to a stage 2 translation, and as a result of this second stage of translation, the accesses from the first stage translation table walk might be made to memory locations with any Device memory type. These accesses might be made speculatively. When the value of the [HCR.PTW](#) bit is 1, a stage 2 Permission fault is generated if a first stage translation table walk is made to any Device memory type.

For an instruction fetch from a memory location with the Device attribute that is not marked as execute-never for the current Exception level, an implementation can either:

- Treat the instruction fetch as if it were to a memory location with the Normal Non-cacheable attribute.
- Take a Permission fault.

B2.9.2.1 Gathering

In the Device memory attribute:

G Indicates that the location has the Gathering attribute.

nG Indicates that the location does not have the Gathering attribute, meaning it is non-Gathering.

The Gathering attribute determines whether it is permissible for either:

- Multiple memory accesses of the same type, read or write, to the same memory location to be merged into a single transaction.
- Multiple memory accesses of the same type, read or write, to different memory locations to be merged into a single memory transaction on an interconnect.

For memory types with the Gathering attribute, either of these behaviors is permitted, provided that the ordering and coherency rules of the memory location are followed.

For memory types with the non-Gathering attribute, neither of these behaviors is permitted. As a result:

- The number of memory accesses that are made corresponds to the number that would be generated by a simple sequential execution of the program.
- All access occur at their programmed size, except that there is no requirement for the memory system beyond the PE to be able to identify the elements accessed by multi-register load/store instructions. See [Multi-register loads and stores that access Device memory](#).

Gathering between memory accesses separated by a memory barrier that affects those memory accesses is not permitted.

Gathering between two memory accesses generated by a Load-Acquire/Store-Release is not permitted.

A read from a memory location with the non-Gathering attribute cannot come from a cache or a buffer, but must come from the endpoint for that address in the memory system. Typically this is a peripheral or physical memory.

Note

- A read from a memory location with the Gathering attribute can come from intermediate buffering of a previous write, provided that:
 - The accesses are not separated by a DMB or DSB barrier that affects both of the accesses.
 - The accesses are not separated by other ordering constructions that require that the accesses are in order. Such a construction might be a combination of Load-Acquire and Store-Release.
 - The accesses are not generated by a Store-Release instruction.
 - The Arm architecture defines only programmer visible behavior. Therefore, gathering can be performed if a programmer cannot tell whether gathering has occurred.
-

An implementation is permitted to perform an access with the Gathering attribute in a manner consistent with the requirements specified by the non-Gathering attribute.

An implementation is not permitted to perform an access with the non-Gathering attribute in a manner consistent with the relaxations allowed by the Gathering attribute.

B2.9.2.2 Reordering

In the Device memory attribute:

R Indicates that the location has the Reordering attribute.

nR Indicates that the location does not have the Reordering attribute, meaning it is non-Reordering.

For all memory types with the non-Reordering attribute, the order of memory accesses arriving at a single peripheral of IMPLEMENTATION DEFINED size, as defined by the peripheral, must be the same order that occurs in a simple sequential execution of the program. That is, the accesses appear in program order. This ordering applies to all accesses using any of the memory types with the non-Reordering attribute. As a result, if there is a mixture of Device-nGnRE and Device-nGnRnE accesses to the same peripheral, these occur in program order. If the memory accesses are not to a peripheral, then this attribute imposes no restrictions.

Note

- The IMPLEMENTATION DEFINED size of the single peripheral is the same as applies for the ordering guarantee provided by the DMB instruction.
 - The Arm architecture defines only programmer visible behavior. Therefore, reordering can be performed if a programmer cannot tell whether reordering has occurred.
-

An implementation is permitted to perform an access with the Reordering attribute in a manner consistent with the requirements specified by the non-Reordering attribute.

An additional relaxation is that an implementation is not permitted to perform an access with the non-Reordering attribute in a manner consistent with the relaxations allowed by the Reordering attribute.

The non-Reordering attribute does not require any additional ordering, other than that which applies to Normal memory, between:

- Accesses to one physical address with the non-Reordering attribute and accesses to a different physical address with the Reordering attribute.
- Access to one physical address with the non-Reordering attribute and access to a different physical address to Normal memory.
- Accesses with the non-Reordering attribute and accesses to different peripherals of IMPLEMENTATION DEFINED size.

B2.9.2.3 Early Write Acknowledgement

In the Device memory attribute:

E Indicates that the location has the Early Write Acknowledgement attribute.

nE Indicates that the location has the No Early Write Acknowledgement attribute.

If the No Early Write Acknowledgement attribute is assigned for a Device memory location:

- For memory system endpoints where the system architecture in which the PE is operating requires that acknowledgment of a write comes from the endpoint, it is guaranteed that:
 - Only the endpoint of the write access returns a write acknowledgment of the access.
 - No earlier point in the memory system returns a write acknowledgment.
- For memory system endpoints where the system architecture in which the PE is operating does not require that acknowledgment of a write comes from the endpoint, the acknowledgment of a write is not required to come from the endpoint.

Note

A write with the No Early Write Acknowledgement attribute assigned for a Device memory location is not expected to generate an abort in any situation where the equivalent write to the same location without the No Early Write Acknowledgement attribute assigned does not generate an abort.

This means that a `DSB` barrier instruction, executed by the PE that performed the write to the No Early Write Acknowledgement Location, completes only after the write has reached its endpoint in the memory system if that is required by the system architecture.

Peripherals are an example of system endpoints that require that the acknowledgment of a write comes from the endpoint.

Note

- The Early Write Acknowledgement attribute affects only where the endpoint acknowledgment is returned from, and does not affect the ordering of arrival at the endpoint between accesses, which is determined by either the Device Reordering attribute, or the use of barriers to create order.
 - The areas of the physical memory map for which write acknowledgment from the endpoint is required is outside the scope of the Arm Architecture definition and must be defined as part of the system architecture in which the PE is operating. In particular, regions of memory handled as PCIe configuration writes are expected to support write acknowledgment from the endpoint.
 - Arm recognizes that not all areas of a physical memory map will be capable of supporting write acknowledgment from the endpoint. In particular, Arm expects that regions of memory handled as posted writes under PCIe will not support write acknowledgment from the endpoint.
 - For maximum software compatibility, Arm strongly recommends that all peripherals for which standard software drivers expect that the use of a `DSB` instruction will determine that a write has reached its endpoint are placed in areas of the physical memory map that support write acknowledgment from the endpoint.
-

B2.9.2.4 Multi-register loads and stores that access Device memory

For all instructions that load or store more than one general-purpose register there is no requirement for the memory system beyond the PE to be able to identify the size of the elements accessed by these load and store instructions.

For all instructions that load or store one or more registers from the SIMD and floating-point register file there is no requirement for the memory system beyond the PE to be able to identify the size of the element accessed by these load and store instructions.

The architecture permits that the non-speculative execution of an instruction that loads or stores more than one general-purpose or SIMD and floating-point register might result in repeated accesses to the same address, even if the resulting accesses are to any type of Device memory.

For an `LDRD`, `STRD`, or `LDM` instruction with a register list that includes the PC, or an `STM` instruction with a register list that includes the PC, the order in which the registers are accessed is not defined by the architecture.

For a load or store of an Advanced SIMD element or structure, the order in which the registers are accessed is not defined by the architecture.

For a `VLDM` and `VSTM` instruction with a register list that does not include the PC, all registers are accessed in ascending address order for accesses to Device memory with the non-Reordering attribute.

For a LDM or STM instruction with a register list that does not include the PC, all registers are accessed in ascending address order for accesses to Device memory with the non-Reordering attribute.

B2.9.3 Memory access restrictions

The following restrictions apply to memory accesses:

- For two explicit memory read effects to any two adjacent bytes in memory, p and $p+1$, generated by the same instruction, and for two explicit memory write effects to any two adjacent bytes in memory, p and $p+1$, that are generated by the same instruction:
 - The bytes p and $p+1$ must have the same memory type and Shareability attributes. otherwise the results are CONSTRAINED UNPREDICTABLE. For example, an LDC, LDM, LDRD STC, STM or STRD instruction, or an unaligned load or store that spans the boundary between Normal memory and Device memory is CONSTRAINED UNPREDICTABLE.
 - Except for possible differences in the cache allocation hints, Arm deprecates having different cacheability attributes for bytes p and $p+1$.

For the permitted CONSTRAINED UNPREDICTABLE behavior, see [Crossing a page boundary with different memory types or Shareability attributes](#).

- If the accesses of an instruction that causes multiple accesses to any type of Device memory cross a 4KB address boundary then behavior is CONSTRAINED UNPREDICTABLE and [Crossing a 4KB boundary with a Device access](#) describes the permitted behaviors.

Note

- The boundary referred to is between two Device memory regions that are both of 4KB and aligned to 4KB.
 - This restriction means it is important that an access to a volatile memory device is not made using a single instruction that crosses a 4KB address boundary.
 - Arm expects this restriction to constrain the placing of volatile memory devices in the system memory map, rather than expecting a compiler to be aware of the alignment of memory accesses.
-

B2.10 Mismatched memory attributes

Mismatched memory attributes are controlled by privileged software.

Physical memory Locations are accessed with *mismatched attributes* if all accesses to the Location do not use a common definition of all of the following attributes of that Location:

- Memory type: Device-nGnRnE, Device-nGnRE, Device-nGRE, Device-GRE or Normal.
- Shareability.
- Cacheability, for the same level of the inner or outer cache, but excluding any cache allocation hints.

Collectively these are referred to as memory attributes.

Note

In this document, the terms *location* and *memory location* refer to any byte within the current coherency granule and are used interchangeably.

When a memory Location is accessed with mismatched attributes, the only software visible effects are one or more of the following:

- Uniprocessor semantics for reads and writes to that memory Location might be lost. This means:
 - A read of the memory Location by one agent might not return the value most recently written to that memory Location by the same agent.
 - Multiple writes to the memory Location by one agent with different memory attributes might not be ordered in program order.
- There might be a loss of coherency when multiple agents attempt to access a memory Location.
- There might be a loss of properties derived from the memory type, as described in later bullets in this section.
- If all Load-Exclusive/Store-Exclusive instructions executed across all threads to access a given memory Location do not use consistent memory attributes, the Exclusives monitor state becomes UNKNOWN.
- Bytes written without the Write-Back cacheable attribute within the same Write-Back granule as bytes written with the Write-Back cacheable attribute might have their values reverted to the old values as a result of cache Write-Back.

The loss of properties associated with mismatched memory type attributes refers only to the following properties of Device memory that are additional to the properties of Normal memory:

- Prohibition of speculative read accesses.
- Prohibition on Gathering.
- Prohibition on Reordering.

For the following situations, when a physical memory Location is accessed with mismatched attributes, a more restrictive set of behaviors applies. The description of each situation also describes the behaviors that apply:

1. Any agent that reads that memory Location using the same common definition of the Memory type, Shareability and Cacheability attributes is guaranteed to access it coherently, to the extent required by that common definition of the memory attributes, only if all the following conditions are met:
 - All writes are performed to an alias of the memory Location that uses the same definition of the Memory type, Shareability and Cacheability attributes.
 - Either:
 - All writes are performed to an alias of the memory Location that has Inner Cacheability and Outer Cacheability attributes both as Non-cacheable or Write-Through.
 - All aliases to a memory Location use a definition of the Shareability attributes that encompasses all the agents with permission to access the Location.
2. The possible software-visible effects caused by mismatched attributes for a memory Location are defined more precisely if all of the mismatched attributes define the memory Location as one of:
 - Any Device memory type.
 - Any Normal, Inner Non-cacheable or Write-Through, Outer Non-cacheable or Write-Through memory.

In these cases, the only permitted software-visible effects of the mismatched attributes are one or more of the following:

- Possible loss of properties derived from the memory type when multiple agents attempt to access the memory Location.
- Possible reordering of memory transactions to the same memory Location with different memory attributes, potentially leading to a loss of coherency or uniprocessor semantics. Any possible loss of coherency or uniprocessor semantics can be avoided by inserting DMB barrier instructions between accesses to the same memory Location that might use different attributes.

Where there is a loss of the uniprocessor semantics, ordering, or coherency, the following approaches can be used:

1. If the mismatched attributes for a memory Location all assign the same Shareability attribute to a Location that has a cacheable attribute, any loss of uniprocessor semantics, ordering, or coherency within a Shareability domain can be avoided by use of software cache management. To do so, software must use the techniques that are required for the software management of the ordering or coherency of cacheable Locations between agents in different shareability domains. This means:
 - Before writing to a cacheable Location not using the Write-Back attribute, software must invalidate, or clean, a Location from the caches if any agent might have written to the Location with the Write-Back attribute. This avoids the possibility of overwriting the Location with stale data.
 - After writing to a cacheable Location with the Write-Back attribute, software must clean the Location from the caches, to make the write visible to external memory.
 - Before reading the Location with a cacheable attribute, software must invalidate, or clean and invalidate, the Location from the caches, to ensure that any value held in the caches reflects the last value made visible in external memory.
 - Executing a DMB barrier instruction between any accesses to the same cacheable Location that use different attributes.

Note

In AArch32 state, cache maintenance instructions can be accessed only from an Exception level that is higher than EL0, and therefore require a system call. For information on system calls, see [Exception-generating and exception-handling instructions](#). For information about the AArch32 cache maintenance instructions, see [AArch32 cache and branch predictor support](#).

In all cases:

- Location refers to any byte within the current coherency granule.
- A clean and invalidate instruction can be used instead of a clean instruction, or instead of an invalidate instruction.
- In the sequences outlined in this section, all cache maintenance instructions and memory transactions must be completed, or ordered by the use of barrier operations, if they are not naturally ordered by the use of a common address, see [Ordering of cache and branch predictor maintenance instructions](#).

Note

With software management of coherency, race conditions can cause loss of data. A race condition occurs when different agents write simultaneously to bytes that are in the same Location, and the invalidate, write, clean sequence of one agent overlaps with the equivalent sequence of another agent. A race condition also occurs if the first operation of either sequence is a clean, rather than an invalidate.

2. If the mismatched attributes for a Location mean that multiple cacheable accesses to the Location might be made with different Shareability attributes, then ordering and coherency are guaranteed only if:
 - Software running on a PE cleans and invalidates a Location from cache before and after each read or write to that Location by that PE.
 - A DMB barrier is placed between any accesses to the same memory Location that use different attributes.

Note

The Note in rule 1 of this list, about possible race conditions, also applies to this rule.

In addition, if multiple agents attempt to use Load-Exclusive or Store-Exclusive instructions to access a Location, and the accesses from the different agents have different memory attributes associated with the Location, the Exclusives monitor state becomes UNKNOWN.

Arm strongly recommends that software does not use mismatched attributes for aliases of the same Location. An implementation might not optimize the performance of a system that uses mismatched aliases.

Note

As described in Non-cacheable accesses and instruction caches, a non-cacheable access is permitted to be cached in an instruction cache, despite the fact that a non-cacheable access is not permitted to be cached in a unified cache. Despite this, when cacheable and non-cacheable aliases exist for memory which is executable, these must be treated as mismatched aliases to avoid coherency issues from the data or unified caches that might hold entries that will be brought into the instruction caches.

B2.11 Synchronization and semaphores

The architecture provides non-blocking synchronization of shared memory, using *synchronization primitives*. The information in this section about memory accesses by synchronization primitives applies to accesses to both Normal and Device memory.

Note

Use of the synchronization primitives scales for multiprocessing system designs.

Table B2-5 shows the synchronization primitives and the associated CLREX instruction.

Table B2-5 Synchronization primitives and associated instruction, T32 and A32 instruction sets

Transaction size	Additional semantics	Load-Exclusive ^a	Store-Exclusive ^a	Other ^a
Byte	-	LDREXB	STREXB	-
	Load-Acquire/Store-Release	LDAEXB	STLEXB	-
Halfword	-	LDREXH	STREXH	-
	Load-Acquire/Store-Release	LDAEXH	STLEXH	-
Word	-	LDREX	STREX	-
	Load-Acquire/Store-Release	LDAEX	STLEX	-
Doubleword	-	LDREXD	STREXD	-
	Load-Acquire/Store-Release	LDAEXD	STLEXD	-
None	Clear-Exclusive	-	-	CLREX

a. Instruction in the T32 and A32 instruction sets.

Except for the row showing the CLREX instruction, the two instructions in a single row are a Load-Exclusive/Store-Exclusive instruction pair. The model for the use of a Load-Exclusive/Store-Exclusive instruction pair accessing a non-aborting memory address x is:

- The Load-Exclusive instruction reads a value from memory address x .
- The corresponding Store-Exclusive instruction succeeds in writing back to memory address x only if no other observer, process, or thread has performed a more recent store to address x . The Store-Exclusive instruction returns a status bit that indicates whether the memory write succeeded.

A Load-Exclusive instruction marks a small block of memory for exclusive access. The size of the marked block is IMPLEMENTATION DEFINED, see [Marking and the size of the marked memory block](#). A Store-Exclusive instruction to any address in the marked block clears the marking.

Note

In this section, the term PE includes any observer that can generate a Load-Exclusive or a Store-Exclusive instruction.

The following sections give more information:

- [Exclusive access instructions and Non-shareable memory locations](#).
- [Exclusive access instructions and shareable memory locations](#).
- [Marking and the size of the marked memory block](#).
- [Context switch support](#).
- [Load-Exclusive and Store-Exclusive instruction usage restrictions](#).
- [Use of WFE and SEV instructions by spin-locks](#).

B2.11.1 Exclusive access instructions and Non-shareable memory locations

For memory locations for which the Shareability attribute is Non-shareable, the exclusive access instructions rely on a *local Exclusives monitor*, or *local monitor*, that marks any address from which the PE executes a Load-Exclusive instruction. Any non-aborted attempt by the same PE to use a Store-Exclusive instruction to modify any address is guaranteed to clear the marking.

A Load-Exclusive instruction performs a load from memory, and:

- The executing PE marks the physical memory address for exclusive access.
- The local monitor of the executing PE transitions to the Exclusive Access state.

A Store-Exclusive instruction performs a conditional store to memory that depends on the state of the local monitor:

If the local monitor is in the Exclusive Access state

- If the address of the Store-Exclusive instruction is the same as the address that has been marked in the monitor by an earlier Load-Exclusive instruction, then the store occurs. Otherwise, it is IMPLEMENTATION DEFINED whether the store occurs.
- A status value is returned to a register:
 - If the store took place the status value is 0.
 - Otherwise, the status value is 1.
- The local monitor of the executing PE transitions to the Open Access state.

When an Exclusives monitor is in the Exclusive Access state the monitor is *set*.

If the local monitor is in the Open Access state

- No store takes place.
- A status value of 1 is returned to a register.
- The local monitor remains in the Open Access state.

When an Exclusives monitor is in the Exclusive Access state the monitor is *clear*:

The Store-Exclusive instruction defines the register to which the status value is returned.

When a PE writes using any instruction other than a Store-Exclusive instruction:

- If the write is to a PA that is not marked as Exclusive Access by its local monitor and that local monitor is in the Exclusive Access state it is IMPLEMENTATION DEFINED whether the write affects the state of the local monitor.
- If the write is to a PA that is marked as Exclusive Access by its local monitor it is IMPLEMENTATION DEFINED whether the write affects the state of the local monitor.

It is IMPLEMENTATION DEFINED whether a store to a marked PA causes a mark in the local monitor to be cleared if that store is by an observer other than the one that caused the PA to be marked.

[Figure B2-4](#) shows the state machine for the local monitor and the effect of each of the operations shown in the figure.

Operations marked * are possible alternative IMPLEMENTATION DEFINED options.

In the diagram: `LoadExcl` represents any Load-Exclusive instruction

`StoreExcl` represents any Store-Exclusive instruction

`Store` represents any other store instruction.

Any `LoadExcl` operation updates the marked address to the most significant bits of the address `x` used for the operation.

Figure B2-4 Local monitor state machine diagram

For more information about marking, see [Marking and the size of the marked memory block](#).

Note

For the local monitor state machine, as shown in [Figure B2-4](#):

- The IMPLEMENTATION DEFINED options for the local monitor are consistent with the local monitor being constructed so that it does not hold any PA, but instead treats any access as matching the address of the previous Load-Exclusive instruction.
- A local monitor implementation can be unaware of Load-Exclusive and Store-Exclusive instructions from other PEs.
- The architecture does not require a load instruction, by another PE, that is not a Load-Exclusive instruction, to have any effect on the local monitor.
- It is IMPLEMENTATION DEFINED whether the transition from Exclusive Access to Open Access state occurs when the `Store` or `StoreExcl` is from another observer.

B2.11.1.1 Changes to the local monitor state resulting from speculative execution

The architecture permits a local monitor to transition to the Open Access state as a result of speculation, or from some other cause. This is in addition to the transitions to Open Access state caused by the architectural execution of an operation shown in [Figure B2-4](#).

An implementation must ensure that:

- The local monitor cannot be seen to transition to the Exclusive Access state except as a result of the architectural execution of one of the operations shown in [Figure B2-4](#).
- Any transition of the local monitor to the Open Access state not caused by the architectural execution of an operation shown in [Figure B2-4](#) must not indefinitely delay forward progress of execution.

B2.11.2 Exclusive access instructions and shareable memory locations

In the context of this section, a shareable memory location is a memory location that has, or is treated as if it has, a Shareability attribute of Inner Shareable or Outer Shareable.

For shareable memory locations, exclusive access instructions rely on:

- A *local monitor* for each PE in the system, which marks any address from which the PE executes a Load-Exclusive. The local monitor operates as described in [Exclusive access instructions and Non-shareable](#)

[memory locations](#), except that for shareable memory any Store-Exclusive is then subject to checking by the global monitor if it is described in that section as doing at least one of the following:

- Updating memory.
- Returning a status value of 0.

The local monitor can ignore accesses from other PEs in the system.

- A *global monitor* that marks a PA as exclusive access for a particular PE. This marking is used later to determine whether a Store-Exclusive to that address that has not been failed by the local monitor can occur. Any successful write to the marked block by any other observer in the Shareability domain of the memory location is guaranteed to clear the marking. For each PE in the system, the global monitor:
 - Can hold at least one marked block.
 - Maintains a state machine for each marked block it can hold.

Note

For each PE, the architecture only requires global monitor support for a single marked address. Any situation that might benefit from the use of multiple marked addresses on a single PE is CONSTRAINED UNPREDICTABLE, see [Load-Exclusive and Store-Exclusive instruction usage restrictions](#).

Note

The global monitor can either reside in a block that is part of the hardware on which the PE executes or exist as a secondary monitor at the memory interfaces. The IMPLEMENTATION DEFINED aspects of the monitors mean that the global monitor and local monitor can be combined into a single unit, provided that the unit performs the global monitor and local monitor functions defined in this manual.

For shareable memory locations, in some implementations and for some memory types, the properties of the global monitor require functionality outside the PE. Some system implementations might not implement this functionality for all locations of memory. In particular, this can apply to:

- Any type of memory in the system implementation that does not support hardware cache coherency.
- Non-cacheable memory, or memory treated as Non-cacheable, in an implementation that does support hardware cache coherency.

In such a system, it is defined by the system:

- Whether the global monitor is implemented.
- If the global monitor is implemented, which address ranges or memory types it monitors.

Note

To support the use of the Load-Exclusive/Store-Exclusive mechanism when address translation is disabled, a system might define at least one location of memory, of at least the size of the translation granule, in the system memory map to support the global monitor for all PEs within a common Inner Shareable domain. However, this is not an architectural requirement. Therefore, architecturally-compliant software that requires mutual exclusion must not rely on using the Load-Exclusive/Store-Exclusive mechanism, and must instead use a software algorithm such as Lamport's Bakery algorithm to achieve mutual exclusion.

Because implementations can choose which memory types are treated as Non-cacheable, the only memory types for which it is architecturally guaranteed that a global Exclusives monitor is implemented are:

- Inner Shareable, Inner Write-Back, Outer Write-Back Normal memory.
- Outer Shareable, Inner Write-Back, Outer Write-Back Normal memory.

If the global monitor is not implemented for an address range or memory type, then performing a Load-Exclusive/Store-Exclusive instruction to such a location has one or more of the following effects:

- The instruction generates an External abort.
- The instruction generates an IMPLEMENTATION DEFINED [MPU fault](#). This is reported using the Fault status code of:

- **DFSR.STATUS** = 0b110101. The fault can also be reported in the **HSR.ISS**[5:0] field for exceptions to Hyp mode.

If the IMPLEMENTATION DEFINED **MPU fault** is generated for the PL1&0 translation regime then:

- If the fault is generated because of the memory type defined in the first stage of translation, or if the second stage of translation is disabled, then this is a first stage fault and the exception is taken to EL1.
- Otherwise, the fault is a second stage fault and the exception is taken to EL2.

The priority of this fault is IMPLEMENTATION DEFINED.

- The instruction is treated as a **NOP**.
- The Load-Exclusive instruction is treated as if it were accessing a Non-shareable location, but the state of the local monitor becomes **UNKNOWN**.
- The Store-Exclusive instruction is treated as if it were accessing a Non-shareable location, but the state of the local monitor becomes **UNKNOWN**.
- The value held in the result register of the Store-Exclusive instruction becomes **UNKNOWN**.

In addition, for write transactions generated by non-PE observers that do not implement exclusive accesses or other atomic access mechanisms, the effect that writes have on the global and local monitors used by an Arm PE is IMPLEMENTATION DEFINED. The writes might not clear the global monitors of other PEs for:

- Some address ranges.
- Some memory types.

B2.11.2.1 Operation of the global Exclusives monitor

A Load-Exclusive instruction from shareable memory performs a load from memory, and causes the PA of the access to be marked as exclusive access for the requesting PE. This access can also cause the exclusive access mark to be removed from any other PA that has been marked by the requesting PE.

Note

The global monitor only supports a single outstanding exclusive access to shareable memory for each PE.

A Load-Exclusive instruction by one PE has no effect on the global monitor state for any other PE.

A Store-Exclusive instruction performs a conditional store to memory:

- The store is guaranteed to succeed only if the PA accessed is marked as exclusive access for the requesting PE and both the local monitor and the global monitor state machines for the requesting PE are in the Exclusive Access state. In this case:
 - A status value of 0 is returned to a register to acknowledge the successful store.
 - The final state of the global monitor state machine for the requesting PE is IMPLEMENTATION DEFINED.
 - If the address accessed is marked for exclusive access in the global monitor state machine for any other PE then that state machine transitions to Open Access state.
- If no address is marked as exclusive access for the requesting PE, the store does not succeed:
 - A status value of 1 is returned to a register to indicate that the store failed.
 - The global monitor is not affected and remains in Open Access state for the requesting PE.
- If a different PA is marked as exclusive access for the requesting PE, it is IMPLEMENTATION DEFINED whether the store succeeds or not:
 - If the store succeeds a status value of 0 is returned to a register, otherwise a value of 1 is returned.
 - If the global monitor state machine for the PE was in the Exclusive Access state before the Store-Exclusive instruction it is IMPLEMENTATION DEFINED whether that state machine transitions to the Open Access state.

The Store-Exclusive instruction defines the register to which the status value is returned.

In a shared memory system, the global monitor implements a separate state machine for each PE in the system. The state machine for accesses to shareable memory by PE(n) can respond to all the shareable memory accesses visible to it. This means it responds to:

- Accesses generated by PE(n).

- Accesses generated by the other observers in the Shareability domain of the memory location. These accesses are identified as (!n).

In a shared memory system, the global monitor implements a separate state machine for each observer that can generate a Load-Exclusive or a Store-Exclusive instruction in the system.

A global monitor:

- In the Exclusive Access state is *set*.
- In the Open Access state is *clear*.

B2.11.2.1.1 Clear global monitor event

Whenever the global monitor state for a PE changes from Exclusive access to Open access, an event is generated and held in the Event register for that PE. This register is used by the Wait for Event mechanism, see [Wait For Event and Send Event](#).

Figure B2-5 shows the state machine for PE(n) in a global monitor.

‡StoreExcl(Marked_address, !n) clears the monitor only if the StoreExcl updates memory

Operations marked * are possible alternative IMPLEMENTATION DEFINED options.

In the diagram: LoadExcl represents any Load-Exclusive instruction

StoreExcl represents any Store-Exclusive instruction

Store represents any other store instruction.

Any LoadExcl operation updates the marked address to the most significant bits of the address x used for the operation.

Figure B2-5 Global monitor state machine diagram for PE(n) in a multiprocessor system

For more information about marking, see [Marking and the size of the marked memory block](#).

Note

For the global monitor state machine, as shown in [Figure B2-5](#):

- The architecture does not require a load instruction by another PE, that is not a Load-Exclusive instruction, to have any effect on the global monitor.
 - Whether a Store-Exclusive instruction successfully updates memory or not depends on whether the address accessed matches the marked shareable memory address for the PE issuing the Store-Exclusive instruction, and whether the local and global monitors are in the exclusive state. For this reason, [Figure B2-5](#) shows only how the operations by (!n) cause state transitions of the state machine for PE(n).
 - A Load-Exclusive instruction can update only the marked shareable memory address for the PE issuing the Load-Exclusive instruction.
 - When the global monitor is in the Exclusive Access state, it is IMPLEMENTATION DEFINED whether a CLREX instruction causes the global monitor to transition from Exclusive Access to Open Access state.
 - It is IMPLEMENTATION DEFINED:
 - Whether a modification to a Non-shareable memory location can cause a global monitor to transition from Exclusive Access to Open Access state.
 - Whether a Load-Exclusive instruction to a Non-shareable memory location can cause a global monitor to transition from Open Access to Exclusive Access state.
-

B2.11.3 Marking and the size of the marked memory block

When a Load-Exclusive instruction is executed, the resulting marked block ignores the least significant bits of the 64-bit memory address.

When a Load-Exclusive instruction is executed, a marked block of size 2^a bytes is created by ignoring the least significant bits of the memory address. A marked address is any address within this marked block. The size of the marked memory block is called the *Exclusives reservation granule*. The Exclusives reservation granule is IMPLEMENTATION DEFINED in the range 4 - 512 words.

Note

This definition means that the Exclusives reservation granule is:

- 4 words in an implementation where a is 4.
- 512 words in an implementation where a is 11.

For example, in an implementation where a is 4, a successful LDREXB of address $0 \times 341B4$ defines a marked block using bits[47:4] of the address. This means that the four words of memory from $0 \times 341B0$ to $0 \times 341BF$ are marked for exclusive access.

In some implementations the CTR identifies the Exclusives reservation granule, see [CTR](#). Otherwise, software must assume that the maximum Exclusives reservation granule, 512 words, is implemented.

B2.11.4 Context switch support

An exception return clears the local monitor. As a result, performing a CLREX instruction as part of a context switch is not required in most situations.

Note

Context switching is not an application level operation. However, this information is included here to complete the description of the exclusive operations.

B2.11.5 Load-Exclusive and Store-Exclusive instruction usage restrictions

The Load-Exclusive and Store-Exclusive instructions are intended to work together as a pair, for example a LDREX/STREX pair or a LDREXB/STREXB pair, executed as part of a loop that contains only a single Load-Exclusive and

Store-Exclusive pair. To support different implementations of these functions, software must follow the notes and restrictions given in this subsection.

The following notes describe use of a Load-Exclusive/ Store-Exclusive instruction pair, `LoadExcl/StoreExcl`, to indicate the use of any of the Load-Exclusive/Store-Exclusive instruction pairs shown in Table B2-5. In this context, a `LoadExcl/StoreExcl` pair comprises two instructions in the same thread of execution:

- The exclusives support a single outstanding exclusive access for each PE thread that is executed. The architecture makes use of this by not requiring an address or size check as part of the `IsExclusiveLocal()` function. If the target VA of a `StoreExcl` is different from the VA of the preceding `LoadExcl` instruction in the same thread of execution, behavior can be CONSTRAINED UNPREDICTABLE with the following behavior:
 - The `StoreExcl` either passes or fails, the status value returned by the `StoreExcl` is UNKNOWN, and the states of the local and global monitors for that PE are UNKNOWN.

———— **Note** ————

This means the `StoreExcl` might pass for some instances of a `LoadExcl/StoreExcl` pair with mismatched addresses, and fail for other instances of a `LoadExcl/StoreExcl` pair with mismatched addresses.

- The data at the address accessed by the `LoadExcl`, and at the address accessed by the `StoreExcl`, is UNKNOWN.

This means software can rely on a `LoadExcl/StoreExcl` pair to eventually succeed only if the `LoadExcl` and the `StoreExcl` are executed with the same VA.

- An implementation of the Load-Exclusive and Store-Exclusive instructions can require that, in any thread of execution, the transaction size of a `StoreExcl` instruction is the same as the transaction size of the preceding `LoadExcl` instruction executed in that thread. If the transaction size of a `StoreExcl` instruction is different from the preceding `LoadExcl` instruction in the same thread of execution, behavior can be CONSTRAINED UNPREDICTABLE with the following behavior:
 - The `StoreExcl` either passes or fails, and the status value returned by the `StoreExcl` is UNKNOWN.

———— **Note** ————

This means the `StoreExcl` might pass for some instances of a `LoadExcl/StoreExcl` pair with mismatched transaction sizes, and fail for other instances of a `LoadExcl/StoreExcl` pair with mismatched transaction sizes.

- The block of data of the size of the larger of the transaction sizes used by the `LoadExcl/StoreExcl` pair at the address accessed by the `LoadExcl/StoreExcl` pair, is UNKNOWN.

This means software can rely on a `LoadExcl/StoreExcl` pair to eventually succeed only if the `LoadExcl` and the `StoreExcl` have the same transaction size.

- `LoadExcl/StoreExcl` loops are guaranteed to make forward progress only if, for any `LoadExcl/StoreExcl` loop within a single thread of execution, the software meets all of the following conditions.
- Implementations can benefit from keeping the `LoadExcl` and `StoreExcl` operations close together in a single thread of execution. This minimizes the likelihood of the Exclusives monitor state being cleared between the `LoadExcl` instruction and the `StoreExcl` instruction. Therefore, for best performance, Arm strongly recommends a limit of 128 bytes between `LoadExcl` and `StoreExcl` instructions in a single thread of execution.
- The architecture sets an upper limit of 2048 bytes on the Exclusives reservation granule that can be marked as exclusive. For performance reasons, Arm recommends that objects that are accessed by exclusive accesses are separated by the size of the Exclusives reservation granule. This is a performance guideline rather than a functional requirement.
- After taking a Data Abort exception, the state of the Exclusives monitors is UNKNOWN.
- For the memory location accessed by a `LoadExcl/StoreExcl` pair, if the memory attributes for a `StoreExcl` instruction are different from the memory attributes for the preceding `LoadExcl` instruction in the same thread of execution, behavior is CONSTRAINED UNPREDICTABLE. Where this occurs because the translation of the accessed address changes between the `LoadExcl` instruction and the `StoreExcl` instruction, the CONSTRAINED UNPREDICTABLE behavior is as follows:
 - The `StoreExcl` either passes or fails, and the status value returned by the `StoreExcl` is UNKNOWN.

———— **Note** ————

This means the `StoreExcl` might pass for some instances of a `LoadExcl/StoreExcl` pair with changed memory attributes, and fail for other instances of a `LoadExcl/StoreExcl` pair with changed memory attributes.

- The data at the address accessed by the `StoreExcl` is UNKNOWN.

Note

Another bullet point in this list covers the case where the memory attributes of a `LoadExcl/StoreExcl` pair differ as a result of using different VAs with different attributes that point to the same PA.

- The effect of a data or unified cache invalidate, clean, or clean and invalidate instruction on a local or global Exclusives monitor that is in the Exclusive Access state is CONSTRAINED UNPREDICTABLE, and the instruction might clear the monitor, or it might leave it in the Exclusive Access state. For address-based maintenance instructions, this also applies to the monitors of other PEs in the same Shareability domain as the PE executing the cache maintenance instruction, as determined by the Shareability domain of the address being maintained.
- If the mapping of the VA to PA is changed between the `LoadExcl` instruction and the `StoreExcl` instruction, and the change is performed using a break-before-make sequence as described in [Using break-before-make when updating translation table entries](#), if the `StoreExcl` is performed after another write to the same PA as the `StoreExcl`, and that other write was performed after the old translation was properly invalidated and that invalidation was properly synchronized, then the `StoreExcl` will not pass its monitor check.

Note

Arm expects that, in many implementations, either:

- The TLB invalidation will clear either the local or global monitor.
 - The PA will be checked between the `LoadExcl` and `StoreExcl`.
-

- The Exclusive Access state for an address accessed by a PE can be lost as a result of a `PLDW` instruction to the same PA executed by another PE. This means that a very high rate of repeated `PLDW` accesses to a memory location might impede the forward progress of another PE.

Note

In the event of repeatedly-contending `LoadExcl/StoreExcl` instruction sequences from multiple PEs, an implementation must ensure that forward progress is made by at least one PE.

B2.11.6 Use of WFE and SEV instructions by spin-locks

The architecture provides Wait For Event, Send Event, and Send Event Local instructions, `WFE`, `SEV`, `SEVL`, that can assist with reducing power consumption and bus contention caused by PEs repeatedly attempting to obtain a spin-lock. These instructions can be used at the application level, but a complete understanding of what they do depends on a system level understanding of exceptions. They are described in [Wait For Event and Send Event](#). However, when the global monitor for a PE changes from Exclusive Access state to Open Access state, an event is generated.

Note

This is equivalent to issuing an `SEVL` instruction on the PE for which the monitor state has changed. It removes the need for spinlock code to include an `SEV` instruction after clearing a spinlock.

Part C The AArch32 Instruction Sets

Chapter C1

About the T32 and A32 Instruction Descriptions

This chapter describes each instruction. It contains the following sections:

- [Format of instruction descriptions](#)
- [Standard assembler syntax fields](#)
- [Conditional execution](#)
- [Shifts applied to a register](#)
- [Memory accesses](#)
- [Encoding of lists of general-purpose registers and the PC](#)
- [General information about the T32 and A32 instruction descriptions](#)
- [Additional pseudocode support for instruction descriptions](#)
- [Additional information about Advanced SIMD and floating-point instructions](#)

C1.1 Format of instruction descriptions

The instruction descriptions in [T32 and A32 Base Instruction Set Instruction Descriptions](#) and [T32 and A32 Advanced SIMD and Floating-point Instruction Descriptions](#) normally use the following format:

- Instruction section title.
- Introduction to the instruction.
- A description of each encoding of the instruction.
- Assembler syntax.
- Pseudocode describing how the instruction operates.
- Notes, if applicable.

Each of these items is described in more detail in the following subsections.

C1.1.1 Instruction section title

The instruction section title gives the base mnemonic for the instruction or instructions described in the section. When one mnemonic has multiple forms described in separate instruction sections, this is followed by a short description of the form in parentheses. The most common use of this is to distinguish between forms of an instruction in which one of the operands is an immediate value and forms in which it is a register.

C1.1.2 Introduction to the instruction

The introduction to the instruction briefly describes the main features of the instruction. This description is not necessarily complete and is not definitive. If there is any conflict between it and the more detailed information that follows, the latter takes priority.

C1.1.3 Instruction encodings

This is a list of one or more instruction encodings. Each instruction encoding is labeled as:

- A1, A2, A3 . . . for the first, second, third, and any additional A32 encodings.
- T1, T2, T3 . . . for the first, second, third, and any additional T32 encodings.

Each instruction encoding description consists of:

- An assembly syntax that ensures that the assembler selects the encoding in preference to any other encoding. Sometimes, multiple syntax variants are given. These are written in a `typewriter` font using the conventions described in [Assembler syntax prototype line conventions](#). The correct one to use can be indicated by:
 - A subheading that identifies the encodings that correspond to the syntax. See, for example, the subheading *Flag setting, rotate right with extend variant* in the description of the A1 encoding of the ADC, ADCS (register) instructions in [A1](#).
 - An annotation to the syntax, such as *Inside IT block* or *Outside IT block*. See, for example, the syntax descriptions of the T1 encoding of the ADC, ADCS (register) instructions in [T1](#).

In other cases, the correct one to use can be determined by looking at the assembler syntax description and using it to determine which syntax corresponds to the instruction being disassembled.

There is usually more than one syntax variant that ensures re-assembly to any particular encoding, and the exact set of syntaxes that do so usually depends on the register numbers, immediate constants, and other operands to the instruction. For example, when assembling to the T32 instruction set, the syntax `AND R0, R0, R8` ensures selection of a 32-bit encoding but `AND R0, R0, R1` selects a 16-bit encoding.

For each instruction encoding belonging to a target instruction set, an assembler can use this information to determine whether it can use that encoding to encode the instruction requested by the UAL source. If multiple encodings can encode the instruction, then:

- If both a 16-bit encoding and a 32-bit encoding can encode the instruction, the architecture *prefers* the 16-bit encoding. This means the assembler must use the 16-bit encoding rather than the 32-bit encoding. Software can use the `.W` and `.N` qualifiers to specify the required encoding width, see [Standard assembler syntax fields](#).

- If multiple encodings of the same length can encode the instruction, the *Assembler syntax* subsection says which encoding is preferred, and how software can, instead, select the other encodings. Each encoding also documents UAL syntax that selects it in preference to any other encoding.

If no encodings of the target instruction set can encode the instruction requested by the UAL source, normally the assembler generates an error saying that the instruction is not available in that instruction set.

Note

In some cases, an instruction is available in one instruction set but not in another. The *Assembler syntax* subsection identifies many of these cases. For example, the A32 instructions with bits<31:28> == 0b1111 described in [Branch, branch with link, and block data transfer](#), [System register access](#), [Advanced SIMD, floating-point, and Supervisor call](#), and [Unconditional instructions](#) cannot have a Condition code, but the equivalent T32 instructions often can, and this usually appears in the *Assembler syntax* subsection as a statement that the A32 instruction cannot be conditional.

However, some such cases are too complex to describe in the available space, so the definitive test of whether an instruction is available in a given instruction set is whether there is an available encoding for it in that instruction set.

The assembly syntax given for an encoding is therefore a suitable one for a disassembler to disassemble that encoding to. However, disassemblers might use simpler syntaxes when they are suitable for the operand combination, to produce more readable disassembled code.

- An encoding diagram, where:
 - For a 32-bit A32 encoding diagram, the bits are numbered from 31-0.
 - For a 16-bit T32 encoding diagram, the bits are numbered from 15-0. This halfword can be described as *hw1* of the instruction.
 - For a 32-bit T32 encoding diagram, the bits are numbered from 15-0 for each halfword, as a reminder that a 32-bit T32 instruction consists of two consecutive halfwords rather than a word. In this case, the left-hand halfword in the diagram is identified as *hw1*, and the right-hand halfword is identified as *hw2*.

Where instructions are stored using the standard little-endian instruction endianness:

- The encoding diagram for an A32 instruction at address *A* shows, from left to right, the bytes at addresses *A+3*, *A+2*, *A+1*, *A*.
- The encoding diagram for a 32-bit T32 instruction shows bytes in the order *A+1*, *A* for *hw1*, followed by bytes *A+3*, *A+2* for *hw2*.
- Encoding-specific pseudocode. This is pseudocode that translates the encoding-specific instruction fields into inputs to the encoding-independent pseudocode in the *Operation* subsection, and that picks out any special cases in the encoding. For a detailed description of the pseudocode used and of the relationship between the encoding diagram, the encoding-specific pseudocode and the encoding-independent pseudocode, see [Arm Pseudocode Definition](#).

C1.1.4 Assembler symbols

The *Assembly symbols* describe the standard UAL syntax for the instruction.

Each syntax description consists of the following elements:

- Descriptions of all variable or optional fields of the syntax.

Some syntax fields are standardized across all or most instructions. [Standard assembler syntax fields](#) describes these fields.

By default, syntax fields that specify registers, such as <*Rd*>, <*Rn*>, or <*Rt*>, can be any of R0-R12 or LR in T32 instructions, and any of R0-R12, SP, or LR in A32 instructions. These require that the encoding-specific pseudocode set the corresponding integer variable (such as *d*, *n*, or *t*) to the corresponding register number, using 0-12 for R0-R12, 13 for SP, or 14 for LR:

 - Normally, software can do this by setting the corresponding field in the instruction, typically named *Rd*, *Rn*, *Rt*, to the binary encoding of that number.
 - In the case of 16-bit T32 encodings, the field is normally of length 3, and so the encoding is available only when the assembler syntax specifies one of R0-R7. Such encodings often use a register field name like *Rdn*. This indicates that the encoding is available only if <*Rd*> and <*Rn*> specify the same register, and that the register number of that register is encoded in the field if they do.

The description of a syntax field that specifies a register sometimes extends or restricts the permitted range of registers or documents other differences from the default rules for such fields. Examples of extensions are permitting the use of the SP in a T32 instruction, or permitting the use of the PC, identified using register number 15.

- Where appropriate, text that briefly describes changes from the pre-UAL assembler syntax. Where present, this usually consists of an alternative pre-UAL form of the assembler mnemonic. The pre-UAL assembler syntax does not conflict with UAL. Arm recommends that it is supported, as an optional extension to UAL, so that pre-UAL assembler source files can be assembled.

C1.1.4.1 Assembler syntax prototype line conventions

The following conventions are used in assembler syntax prototype lines and their subfields:

< > Any item bracketed by < and > is a short description of a type of value to be supplied by the user in that position. A longer description of the item is normally supplied by subsequent text. Such items often correspond to a similarly named field in an encoding diagram for an instruction. When the correspondence requires only the binary encoding of an integer value or register number to be substituted into the instruction encoding, it is not described explicitly. For example, if the assembler syntax for an instruction contains an item <Rn> and the instruction encoding diagram contains a 4-bit field named Rn, the number of the register specified in the assembler syntax is encoded in binary in the instruction field.

If the correspondence between the assembler syntax item and the instruction encoding is more complex than simple binary encoding of an integer or register number, the item description indicates how it is encoded. This is often done by specifying a required output from the encoding-specific pseudocode, such as `add = TRUE`. The assembler must use only encodings that produce that output.

{ } Any item bracketed by { and } is optional. A description of the item and of how its presence or absence is encoded in the instruction is normally supplied by subsequent text.

Many instructions have an optional destination register. Unless otherwise stated, if such a destination register is omitted, it is the same as the immediately following source register in the instruction syntax.

In the assembler syntax, numeric constants are normally preceded by a #. Some UAL instruction syntax descriptions explicitly show this # as optional. Any UAL assembler:

- Must treat the # as optional where an instruction syntax description shows it as optional.
- Can treat the # either as mandatory or as optional where an instruction syntax description does not show it as optional.

Note

Arm recommends that UAL assemblers treat all uses of # shown in this manual as optional.

spaces Single spaces are used for clarity, to separate items. When a space is obligatory in the assembler syntax, two or more consecutive spaces are used.

+/- This indicates an optional + or - sign. If neither is coded, + is assumed.

All other characters must be encoded precisely as they appear in the assembler syntax. Apart from { and }, the special characters described above do not appear in the basic forms of assembler instructions documented in this manual. In a few places, the { and } characters must be encoded as part of a variable item. When this happens, the long description of the variable item indicates how they must be used.

C1.1.5 Pseudocode describing how the instruction operates

The *Operation for all classes* subsection contains encoding-independent pseudocode that describes the main operation of the instruction.

C1.1.5.1 Limitations of the instruction pseudocode

The pseudocode descriptions of instruction functionality have a number of limitations. These are mainly due to the fact that, for clarity and brevity, the pseudocode is a sequential and mostly deterministic language.

These limitations include:

- Pseudocode does not describe the ordering requirements when an instruction generates multiple memory accesses. For a description of the ordering requirements on memory accesses, see [External visibility requirement](#).
- Pseudocode does not describe the exact rules when an instruction that generates any of the following fails its condition code check:
 - UNDEFINED instruction.
 - Hyp trap.

In such cases, the `Undefined()` pseudocode statement or call to the applicable trap function lies inside the `if ConditionPassed() then ...` structure, either directly or in the `EncodingSpecificOperations()` function call, and so the pseudocode indicates that the instruction executes as a NOP. For the exact rules, see:

- [Conditional execution of undefined instructions](#).
- [EL2 configurable controls](#).
- Pseudocode does not describe the exact ordering requirements when a single floating-point instruction generates more than one floating-point exception and one or more of those floating-point exceptions is trapped. [Combinations of floating-point exceptions](#) describes the exact rules.

Note

There is no limitation in the case where all the floating-point exceptions are untrapped, because the pseudocode specifies the same behavior as the cross-referenced section.

- An exception can be taken during execution of the pseudocode for an instruction, either explicitly as a result of the execution of a pseudocode function such as `Abort()`, or implicitly, for example if an interrupt is taken during execution of an LDM instruction. If this happens, the pseudocode does not describe the extent to which the normal behavior of the instruction occurs.

C1.1.5.2 Instruction encoding diagrams and instruction pseudocode

This is a list of one or more instruction encodings. Each instruction encoding is labeled as:

- A1, A2, A3 ... for the first, second, third, and any additional A32 encodings.
- T1, T2, T3 ... for the first, second, third, and any additional T32 encodings.

Each instruction encoding description consists of:

- An assembly syntax that ensures that the assembler selects the encoding in preference to any other encoding. Sometimes, multiple syntax variants are given. These are written in a *typewriter* font using the conventions described in [Assembler syntax prototype line conventions](#). The correct one to use can be indicated by:
 - A subheading that identifies the encodings that correspond to the syntax. See, for example, the subheading *Flag setting, rotate right with extend variant* in the description of the A1 encoding of the ADC, ADCS (register) instructions in [A1](#).
 - An annotation to the syntax, such as *Inside IT block* or *Outside IT block*. See, for example, the syntax descriptions of the T1 encoding of the ADC, ADCS (register) instructions in [T1](#).

In other cases, the correct one to use can be determined by looking at the assembler syntax description and using it to determine which syntax corresponds to the instruction being disassembled.

There is usually more than one syntax variant that ensures re-assembly to any particular encoding, and the exact set of syntaxes that do so usually depends on the register numbers, immediate constants, and other operands to the instruction. For example, when assembling to the T32 instruction set, the syntax `AND R0, R0, R8` ensures selection of a 32-bit encoding but `AND R0, R0, R1` selects a 16-bit encoding.

For each instruction encoding belonging to a target instruction set, an assembler can use this information to determine whether it can use that encoding to encode the instruction requested by the UAL source. If multiple encodings can encode the instruction, then:

- If both a 16-bit encoding and a 32-bit encoding can encode the instruction, the architecture *prefers* the 16-bit encoding. This means the assembler must use the 16-bit encoding rather than the 32-bit encoding. Software can use the `.W` and `.N` qualifiers to specify the required encoding width, see [Standard assembler syntax fields](#).
- If multiple encodings of the same length can encode the instruction, the *Assembler syntax* subsection says which encoding is preferred, and how software can, instead, select the other encodings. Each encoding also documents UAL syntax that selects it in preference to any other encoding.

If no encodings of the target instruction set can encode the instruction requested by the UAL source, normally the assembler generates an error saying that the instruction is not available in that instruction set.

Note

In some cases, an instruction is available in one instruction set but not in another. The *Assembler syntax* subsection identifies many of these cases. For example, the A32 instructions with bits<31:28> == 0b1111 described in [Branch, branch with link, and block data transfer](#), [System register access](#), [Advanced SIMD, floating-point, and Supervisor call](#), and [Unconditional instructions](#) cannot have a Condition code, but the equivalent T32 instructions often can, and this usually appears in the *Assembler syntax* subsection as a statement that the A32 instruction cannot be conditional.

However, some such cases are too complex to describe in the available space, so the definitive test of whether an instruction is available in a given instruction set is whether there is an available encoding for it in that instruction set.

The assembly syntax given for an encoding is therefore a suitable one for a disassembler to disassemble that encoding to. However, disassemblers might use simpler syntaxes when they are suitable for the operand combination, to produce more readable disassembled code.

- An encoding diagram, where:
 - For a 32-bit A32 encoding diagram, the bits are numbered from 31-0.
 - For a 16-bit T32 encoding diagram, the bits are numbered from 15-0.
This halfword can be described as `hw1` of the instruction.
 - For a 32-bit T32 encoding diagram, the bits are numbered from 15-0 for each halfword, as a reminder that a 32-bit T32 instruction consists of two consecutive halfwords rather than a word.
In this case, the left-hand halfword in the diagram is identified as `hw1`, and the right-hand halfword is identified as `hw2`.

Where instructions are stored using the standard little-endian instruction endianness:

- The encoding diagram for an A32 instruction at address `A` shows, from left to right, the bytes at addresses `A+3`, `A+2`, `A+1`, `A`.
- The encoding diagram for a 32-bit T32 instruction shows bytes in the order `A+1`, `A` for `hw1`, followed by bytes `A+3`, `A+2` for `hw2`.
- Encoding-specific pseudocode. This is pseudocode that translates the encoding-specific instruction fields into inputs to the encoding-independent pseudocode in the *Operation* subsection, and that picks out any special cases in the encoding. For a detailed description of the pseudocode used and of the relationship between the encoding diagram, the encoding-specific pseudocode and the encoding-independent pseudocode, see [Instruction encoding diagrams and instruction pseudocode](#).

C1.2 Standard assembler syntax fields

The following assembler syntax fields are standard across all or most instructions:

<c> Is an optional field. It specifies the condition under which the instruction is executed. See [Conditional execution](#) for the range of available conditions and their encoding. If <c> is omitted, it defaults to *always* (AL).

<q> Specifies optional assembler qualifiers on the instruction. The following qualifiers are defined:

.N Meaning narrow, specifies that the assembler must select a 16-bit encoding for the instruction. If this is not possible, an assembler error is produced.

.W Meaning wide, specifies that the assembler must select a 32-bit encoding for the instruction. If this is not possible, an assembler error is produced.

If neither .W nor .N is specified, the assembler can select either 16-bit or 32-bit encodings. If both are available, it must select a 16-bit encoding. In a few cases, more than one encoding of the same length can be available for an instruction. The rules for selecting between such encodings are instruction-specific and are part of the instruction description. The assembler syntax includes a mandatory .W qualifier, along with a note describing the cases in which it applies, where this qualifier is required to select a particular encoding for an instruction. Additional assembler syntax will describe the syntax when the conditions are not met.

Note

When assembling to the A32 instruction set, the .N qualifier produces an assembler error and the .W qualifier has no effect.

C1.3 Conditional execution

Most T32 and A32 instructions can be executed conditionally, based on the values of the APSR Condition flags. [Table C1-1](#) lists the available conditions.

Table C1-1 Condition codes

cond	Mnemonic extension	Meaning (integer)	Meaning (floating-point) ^a	Condition flags
0000	EQ	Equal	Equal	Z == 1
0001	NE	Not equal	Not equal, or unordered	Z == 0
0010	CS ^b	Carry set	Greater than, equal, or unordered	C == 1
0011	CC ^c	Carry clear	Less than	C == 0
0100	MI	Minus, negative	Less than	N == 1
0101	PL	Plus, positive or zero	Greater than, equal, or unordered	N == 0
0110	VS	Overflow	Unordered	V == 1
0111	VC	No overflow	Not unordered	V == 0
1000	HI	Unsigned higher	Greater than, or unordered	C == 1 and Z == 0
1001	LS	Unsigned lower or same	Less than or equal	C == 0 or Z == 1
1010	GE	Signed greater than or equal	Greater than or equal	N == V
1011	LT	Signed less than	Less than, or unordered	N != V
1100	GT	Signed greater than	Greater than	Z == 0 and N == V
1101	LE	Signed less than or equal	Less than, equal, or unordered	Z == 1 or N != V
1110	None (AL) ^d	Always (unconditional)	Always (unconditional)	Any

a. Unordered means at least one NaN operand.

b. HS (unsigned higher or same) is a synonym for CS.

c. LO (unsigned lower) is a synonym for CC.

d. AL is an optional mnemonic extension for always, except in IT instructions. For details, see IT.

In T32 instructions, the condition, if it is not AL, is normally encoded in a preceding IT instruction. For more information, see [Conditional instructions](#) and [IT](#). Some conditional branch instructions do not require a preceding IT instruction, because they include a Condition code in their encoding.

Implementations can provide a set of ITD control fields, [SCTLR.ITD](#) and [HSCTLR.ITD](#), to disable use of IT for some instructions, making them UNDEFINED.

In A32 instructions, bits[31:28] of the instruction contain either:

- The Condition code, see [The Condition code field in A32 instruction encodings](#).
- 0b1111 for some A32 instructions that can only be executed unconditionally.

C1.3.1 The Condition code field in A32 instruction encodings

Every conditional A32 instruction contains a 4-bit Condition code field, the cond field, in bits 31-28:

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond																															

This field contains one of the values 0b0000-0b1110, as shown in [Table C1-1](#). Most instruction mnemonics can be extended with the letters defined in the [Mnemonic extension](#) column of that table.

If the *always* (AL) condition is specified, the instruction is executed irrespective of the value of the Condition flags. The absence of a Condition code on an instruction mnemonic implies the AL Condition code.

C1.3.2 Pseudocode description of conditional execution

The `CurrentCond()` function returns a 4-bit condition specifier as follows:

- For A32 instructions, it returns bits[31:28] of the instruction.
- For the T1 and T3 encodings of the Branch instruction (see [B](#)), it returns the 4-bit `cond` field of the encoding.
- For all other T32 instructions:
 - If `PSTATE.IT<3:0> != '0000'` it returns `PSTATE.IT<7:4>`.
 - If `PSTATE.IT<7:0> == '00000000'` it returns `'1110'`.
 - Otherwise, execution of the instruction is `CONSTRAINED UNPREDICTABLE`.

For more information, see [Process state, PSTATE](#).

The `ConditionPassed()` function uses this condition specifier and the Condition flags to determine whether the instruction must be executed, by calling the `ConditionHolds()` function.

[A-profile Architecture Pseudocode](#) includes the definitions of these functions.

[Undefined Instruction exception](#) describes the handling of conditional instructions that are `UNDEFINED`, `UNPREDICTABLE`, or `CONSTRAINED UNPREDICTABLE`. The pseudocode in the manual, as a sequential description of the instructions, has limitations in this respect. For more information, see [Limitations of the instruction pseudocode](#).

C1.4 Shifts applied to a register

A32 register offset load/store word and unsigned byte instructions can apply a wide range of different constant shifts to the offset register. Both T32 and A32 data-processing instructions can apply the same range of different constant shifts to the second operand register. For details, see [Constant shifts](#).

A32 data-processing instructions can apply a register-controlled shift to the second operand register.

C1.4.1 Constant shifts

These are the same in T32 and A32 instructions, except that the input bits come from different positions.

`<shift>` is an optional shift to be applied to `<Rm>`. It can be any one of:

(omitted)	No shift.
LSL #<n>	Logical shift left <n> bits. $1 \leq \text{<n>} \leq 31$.
LSR #<n>	Logical shift right <n> bits. $1 \leq \text{<n>} \leq 32$.
ASR #<n>	Arithmetic shift right <n> bits. $1 \leq \text{<n>} \leq 32$.
ROR #<n>	Rotate right <n> bits. $1 \leq \text{<n>} \leq 31$.
RRX	Rotate right one bit, with extend. Bit[0] is written to <code>shifter_carry_out</code> , bits[31:1] are shifted right one bit, and the Carry flag is shifted into bit[31].

Note

Assemblers can permit the use of some or all of ASR #0, LSL #0, LSR #0, and ROR #0 to specify that no shift is to be performed. This is not standard UAL, and the encoding selected for T32 instructions might vary between UAL assemblers if it is used. To ensure disassembled code assembles to the original instructions, disassemblers must omit the shift specifier when the instruction specifies no shift.

Similarly, assemblers can permit the use of #0 in the immediate forms of ASR, LSL, LSR, and ROR instructions to specify that no shift is to be performed, that is, that a MOV (register) instruction is wanted. Again, this is not standard UAL, and the encoding selected for T32 instructions might vary between UAL assemblers if it is used. To ensure disassembled code assembles to the original instructions, disassemblers must use the MOV (register) syntax when the instruction specifies no shift.

C1.4.1.1 Encoding

The assembler encodes `<shift>` into two type bits and five immediate bits, as follows:

(omitted)	type = 0b00, immediate = 0.
LSL #<n>	type = 0b00, immediate = <n>.
LSR #<n>	type = 0b01. If <n> < 32, immediate = <n>. If <n> == 32, immediate = 0.
ASR #<n>	type = 0b10. If <n> < 32, immediate = <n>. If <n> == 32, immediate = 0.
ROR #<n>	type = 0b11, immediate = <n>.
RRX	type = 0b11, immediate = 0.

C1.4.2 Register controlled shifts

These are available only in A32 instructions.

<type> is the type of shift to apply to the value read from <Rm>. It must be one of:

ASR	Arithmetic shift right, encoded as type = 0b10.
LSL	Logical shift left, encoded as type = 0b00.
LSR	Logical shift right, encoded as type = 0b01.
ROR	Rotate right, encoded as type = 0b11.

The bottom byte of <Rs> contains the shift amount.

C1.4.3 Pseudocode description of instruction-specified shifts and rotates

The pseudocode enumeration `SRType` { } defines the shift types. Shift and rotate instruction decode is described by the pseudocode function:

- `DecodeImmShift` () for a constant shift.
- `DecodeRegShift` () for a register controlled shift.

Shift and rotate operations are made by the pseudocode function `Shift` () .

C1.5 Memory accesses

Commonly, the following addressing modes are permitted for memory access instructions:

Offset addressing

The offset value is applied to an address obtained from the base register. The result is used as the address for the memory access. The value of the base register is unchanged.

The assembly language syntax for this mode is:

[<Rn>, <offset>]

Pre-indexed addressing

The offset value is applied to an address obtained from the base register. The result is used as the address for the memory access, and written back into the base register.

The assembly language syntax for this mode is:

[<Rn>, <offset>]!

Post-indexed addressing

The address obtained from the base register is used, unchanged, as the address for the memory access. The offset value is applied to the address, and written back into the base register.

The assembly language syntax for this mode is:

[<Rn>], <offset>

In each case, <Rn> is the base register. <offset> can be:

- An immediate constant, such as <imm8> or <imm12>.
- An index register, <Rm>.
- A shifted index register, such as <Rm>, LSL #<shift>.

For information about unaligned access, endianness, and exclusive access, see:

- [Alignment support](#).
- [Endian support](#).
- [Synchronization and semaphores](#).

C1.6 Encoding of lists of general-purpose registers and the PC

A number of instructions operate on lists of general-purpose registers. For some load instructions, the list of registers to be loaded can include the PC. For these instructions, the assembler syntax includes a `<registers>` field, which provides a list of the registers to be operated on, with list entries separated by commas.

The registers list is encoded in the instruction encoding. Most often, this is done using an 8-bit, 13-bit, or 16-bit `register_list` field. This section gives more information about these and other possible register list encodings.

In a `register_list` field, each bit corresponds to a single register, and if the `<registers>` field of the assembler instruction includes `Rt` then `register_list<t>` is set to 1, otherwise it is set to 0.

The full rules for the encoding of lists of general-purpose registers, and possibly the PC, are:

- Except for the cases listed here, 16-bit T32 encodings use an 8-bit register list, and can access only registers R0-R7.
The exceptions to this rule are:
 - The T1 encoding of `POP` uses an 8-bit register list, and an additional bit, `P`, that corresponds to the PC. This means it can access any of R0-R7 and the PC.
 - The T1 encoding of `PUSH` uses an 8-bit register list, and an additional bit, `M`, that corresponds to the LR. This means it can access any of R0-R7 and the LR.
- 32-bit T32 encodings of load operations use a 13-bit register list, and two additional bits, `M`, corresponding to the LR, and `P`, corresponding to the PC. This means these instructions can access any of R0-R12 and the LR and PC.
- 32-bit T32 encodings of store operations use a 13-bit register list, and one additional bit, `M`, corresponding to the LR. This means these instructions can access any of R0-R12 and the LR.
- Except for the case listed here, A32 encodings use a 16-bit register list. This means these instructions can access any of R0-R12 and the SP, LR, and PC.
The exception to this rule is:
 - The System instructions `LDM` (exception return) and `LDM` (User registers) use a 15-bit register list. This means these instructions can access any of R0-R12 and the SP and LR.
- The T3 and A2 encodings of `POP`, and the T3 and A2 encodings of `PUSH`, access a single register from the set of registers {R0-R12, LR, PC} and encode the register number in the `Rt` field.

Note

`POP` is a load operation, and `PUSH` is a store operation.

In every case, the encoding-specific pseudocode converts the register list into a 32-bit variable, `registers`, with a bit corresponding to each of the registers R0-R12, SP, LR, and PC.

Note

Some Advanced SIMD and floating-point instructions operate on lists of SIMD and floating-point registers. The assembler syntax of these instructions includes a `<list>` field that specifies the registers to be operated on, and the description of the instruction in [Alphabetical list of T32 and A32 base instruction set instructions](#) defines the use and encoding of this field.

C1.7 General information about the T32 and A32 instruction descriptions

[T32 Instruction Set Encoding](#) describes the T32 instruction encodings, and [A32 Instruction Set Encoding](#) describes the A32 instruction encodings. The following subsections give more information about the descriptions of these instructions and their encodings:

- [Execution of instructions in debug state.](#)
- [Fixed values in AArch32 instruction and System register descriptions.](#)
- [UNDEFINED, UNPREDICTABLE, and CONSTRAINED UNPREDICTABLE instruction set space.](#)
- [T32 and A32 Advanced SIMD and floating-point instruction encodings.](#)
- [The PC and the use of 0b1111 as a register specifier in T32 and A32 instructions.](#)
- [The SP and the use of 0b1101 as a register specifier in T32 and A32 instructions.](#)
- [Modified immediate constants in T32 and A32 instructions.](#)

C1.7.1 Execution of instructions in debug state

In general, except for the instructions described in [Debug state](#), the T32 instruction descriptions do not indicate any differences in the behavior of the instruction if it is executed in Debug state. For this information, see [Executing instructions in Debug state](#).

-
- Note**
- A32 instructions cannot be executed in Debug state.
 - For many T32 instructions, execution is unchanged in Debug state. [Executing instructions in Debug state](#) identifies these instructions.
-

C1.7.2 Fixed values in AArch32 instruction and System register descriptions

This section summarizes the terms used to describe fixed values in AArch64 register and instruction descriptions. The [Glossary](#) gives full descriptions of these terms, and each entry in this section includes a link to the corresponding [Glossary](#) entry.

-
- Note**
- In register descriptions, the meaning of some bits depends on the PE state. This affects the definitions of RES0 and RES1, as shown in the [Glossary](#).
-

The following terms are used to describe bits or fields with fixed values:

RAZ Read-As-Zero. See [Read-As-Zero \(RAZ\)](#).

In diagrams, a RAZ bit can be shown as 0.

(0), RES0 Reserved, [Should-Be-Zero \(SBZ\)](#) or RES0.

In instruction encoding diagrams, and sometimes in other descriptions, (0) indicates an SBZ bit. If the bit is set to 1, behavior is CONSTRAINED UNPREDICTABLE, and must be one of the following:

- The instruction is UNDEFINED.
- The instruction is treated as a NOP.
- The instruction executes as if the value of the bit was 0.
- Any destination registers of the instruction become UNKNOWN.

This notation can be expanded for fields, so a three-bit field can be shown as either (0) (0) (0) or as (000).

In register diagrams, but not in the A64 encoding and instruction descriptions, bits or fields can be shown as RES0. For more information, see the [Glossary](#) definition of RES0.

Note

Some of the System instruction descriptions in this chapter are based on the *field description* of the input value for the instruction. These are register descriptions and therefore can include RES0 fields,

The (0) and RES0 descriptions can be applied to bits or bit fields that are read-only, or are write-only. The [Glossary](#) definitions cover these cases.

RAO Read-As-One. See [Read-As-One \(RAO\)](#).

In diagrams, a RAO bit can be shown as 1.

(1), RES1 Reserved, [Should-Be-One \(SBO\)](#) or [RES1](#).

In instruction encoding diagrams, and sometimes in other descriptions, (1) indicates an SBO bit. If the bit is set to 0, behavior is CONSTRAINED UNPREDICTABLE, and must be one of the following:

- The instruction is UNDEFINED.
- The instruction is treated as a NOP.
- The instruction executes as if the value of the bit was 1.
- Any destination registers of the instruction become UNKNOWN.

This notation can be expanded for fields, so a three-bit field can be shown as either (1) (1) (1) or as (111).

In register diagrams, but not in the A64 encoding and instruction descriptions, bits or fields can be shown as RES1. For more information, see the [Glossary](#) definition of [RES1](#).

Note

Some of the System instruction descriptions in this chapter are based on the *field description* of the input value for the instruction. These are register descriptions and therefore can include RES1 fields.

The (1) and RES1 descriptions can be applied to bits or bit fields that are read-only, or are write-only. The [Glossary](#) definitions cover these cases.

Note

In register diagrams, (0) is a synonym for RES0, and (1) is a synonym for RES1, where RES0 and RES1 are defined in the [Glossary](#). However, when used in an instruction encoding diagram, (0) and (1) have the narrower definition that behavior is UNPREDICTABLE or CONSTRAINED UNPREDICTABLE if either:

- A bit marked as (0) has the value 1.
 - A bit marked as (1) has the value 0.
-

C1.7.3 UNDEFINED, UNPREDICTABLE, and CONSTRAINED UNPREDICTABLE instruction set space

An attempt to execute an unallocated instruction results in either:

- Unpredictable behavior. The instruction is described as UNPREDICTABLE or CONSTRAINED UNPREDICTABLE. From the introduction of Armv8-R, the architecturally UNPREDICTABLE behavior in AArch32 state is greatly reduced. Most cases that earlier versions of the architecture describe as UNPREDICTABLE become either:
 - CONSTRAINED UNPREDICTABLE, meaning the architecture defines a limited range of permitted behaviors.
 - Fully predictable.
 For more information, see [Architectural Constraints on UNPREDICTABLE Behaviors](#).
- An Undefined Instruction exception. The instruction is described as UNDEFINED.

An instruction is UNDEFINED if it is declared as UNDEFINED in an instruction description, or in [T32 Instruction Set Encoding](#) or [A32 Instruction Set Encoding](#).

An instruction is UNPREDICTABLE only if:

- It is declared as UNPREDICTABLE in an instruction description or in [T32 Instruction Set Encoding](#) or [A32 Instruction Set Encoding](#), and [Architectural Constraints on UNPREDICTABLE Behaviors](#) does not redefine the behavior as CONSTRAINED UNPREDICTABLE.
- The pseudocode for that encoding does not indicate that a different special case applies, and a bit marked (0) or (1) in the encoding diagram of an instruction is not 0 or 1 respectively. In most cases, Armv8 makes these cases CONSTRAINED UNPREDICTABLE, as described in [SBZ or SBO fields T32 and A32 in instructions](#).

Unless otherwise specified, T32 and A32 instructions provided as part of an architectural extension, or by an optional feature of the architecture, are UNDEFINED in an implementation that does not include that extension or feature.

Note

Examples of where this rule applies are:

- The instructions provided by the Cryptographic Extension.
 - The System instructions that provide access to the System registers of the OPTIONAL Performance Monitors Extension.
 - The Advanced SIMD and floating-point instructions.
-

For more information about UNDEFINED, UNPREDICTABLE, and CONSTRAINED UNPREDICTABLE instruction behavior, see [Undefined Instruction exception](#).

C1.7.4 T32 and A32 Advanced SIMD and floating-point instruction encodings

The T32 and A32 encodings of Advanced SIMD and floating-point instructions that are described in [T32 Instruction Set Encoding](#) and in [A32 Instruction Set Encoding](#) are common to the T32 and A32 instruction sets. This means:

- The instruction groups, and the set of instructions in each group, are identical for T32 and A32.
- For each instruction:
 - Each T32 encoding is exactly equivalent to an A32 encoding.
 - There is no T32 encoding without an equivalent A32 encoding, and no A32 encoding without an equivalent T32 encoding.

Note

- In the T32 instruction sets, the Advanced SIMD and floating-point instructions have 32-bit encodings.
 - In the base instruction sets, some instructions are common to the T32 and A32 instruction sets, whereas other instructions have equivalent but not identical functionality in the two instruction sets.
-

32-bit T32 encodings are described as two contiguous halfwords, {hw1:hw2}, as described in [Instruction encodings](#). In general:

- hw1 of a T32 encoding maps onto bits[31:16] of an equivalent A32 encoding.
- hw2 of a T32 encoding maps onto bits[15:0] of an equivalent A32 encoding.

However, the different structures of the T32 instruction encoding space and the A32 instruction encoding space mean that:

- For a given Advanced SIMD and floating-point instruction group:
 - The positions of the fields that identify the instruction, or instruction encoding, within the instruction group might differ between the T32 encodings and the A32 encodings.
 - However, the field values that identify the instruction of instruction encoding are identical for the T32 encoding and the A32 encoding.

The remainder of this section describes the equivalence of the T32 and A32 encodings for each of the Advanced SIMD and floating-point instruction groups.

C1.7.4.1 Advanced SIMD data-processing

The T32 encoding of the Advanced SIMD data-processing group is:

The A32 encoding of the Advanced SIMD data-processing group is:

The encodings in this group are identified by:

- hw1[15:13] of the T32 encoding is equivalent to bits[27:25] of the A32 encoding, and:
 - Has the value 0b111 in the T32 encoding.
 - Has the value 0b001 in the A32 encoding.
- hw1[11:8] of the T32 encoding is equivalent to bits[31:28] of the A32 encoding, and has the value 0b111.

This table shows the equivalence of the fields that identify the instructions, or instruction encodings, within this group:

T32 encoding	A32 encoding	Field size
op0:op1	op0	2 bits
op2	op1	15 bits
op3	op2	1 bit
op4	op3	1 bit

C1.7.4.2 Advanced SIMD element or structure load/store

The T32 encoding of the Advanced SIMD element or structure load/store group is:

The A32 encoding of the Advanced SIMD element or structure load/store group is:

The encodings in this group are identified by:

- hw1[15:12] of the T32 encoding is equivalent to bits[31:28] of the A32 encoding, and has the value 0b1111.
- hw1[11:8] of the T32 encoding is equivalent to bits[27:24] of the A32 encoding, and:
 - Has the value 0b1001 in the T32 encoding.
 - Has the value 0b0100 in the A32 encoding.
- hw1[4] of the T32 encoding is equivalent to bit[20] of the A32 encoding, and has the value 0b0.

op0, op1, and op2 are the fields that identify the instructions, or instruction encodings, within this group, and they are in equivalent positions in the T32 and A32 encodings.

C1.7.4.3 Advanced SIMD and floating-point load/store and 64-bit register moves

The T32 encoding of the Advanced SIMD and floating-point load/store and 64-bit register moves group is:

The A32 encoding of the Advanced SIMD and floating-point load/store and 64-bit register moves group is:

The encodings in the group are identified by:

- hw1[15:12] of the T32 encoding is equivalent to bits[31:28] of the A32 encoding, and:
 - Has the value 0b1110 in the T32 encoding.
 - Can have any value other than 0b1111 in the A32 encoding.
This range of values is required because A32 instructions in this group can be executed conditionally, see [Conditional execution](#).
- hw1[11:9] of the T32 encoding is equivalent to bits[27:25] of the A32 encoding, and has the value 0b110.
- hw2[11:9] of the T32 encoding is equivalent to bits[11:9] of the A32 encoding, and has the value 0b101.

op0 is the field that identifies the instructions, or instruction encodings, within this group, and is in equivalent positions in the T32 and A32 encodings.

C1.7.4.4 Advanced SIMD and floating-point 32-bit register moves

The T32 encoding of the Advanced SIMD and floating-point 32-bit register moves group is:

The A32 encoding of the Advanced SIMD 32-bit register moves group is:

The encodings in this group are identified by:

- hw1[15:12] of the T32 encoding is equivalent to bits[31:28] of the A32 encoding, and:
 - Has the value 0b1110 in the T32 encoding.
 - Can have any value other than 0b1111 in the A32 encoding.
This range of values is required because A32 instructions in this group can be executed conditionally, see [Conditional execution](#).
- hw1[11:8] of the T32 encoding is equivalent to bits[27:24] of the A32 encoding, and has the value 0b1110.
- hw2[11:9] of the T32 encoding is equivalent to bits[11:9] of the A32 encoding, and has the value 0b101.
- hw2[4] of the T32 encoding is equivalent to bit[4] of the A32 encoding, and has the value 0b1.

op0 is the field that identifies the instructions, or instruction encodings, within this group, and is in equivalent positions in the T32 and A32 encodings.

C1.7.4.5 Floating-point data-processing

The T32 encoding of the Floating-point data-processing group is:

The A32 encoding of the Floating-point data-processing group is:

The encodings in this group are identified by:

- `hw1[15:12]` of the T32 encoding is equivalent to bits[31:28] of the A32 encoding, and:
 - In the T32 encoding, `hw1[15:13]` has the value `0b1111`, and `hw1[12]` is the `op0` parameter used in identifying instruction encodings within this group.
 - In the A32 encoding, is the `cond` field and also implies the value of bit[28] of some A32 instruction encodings within this group, as the following table shows:

cond	Significance of bit[28] in A32 encodings
<code>!= 0b1111</code>	Part of the <code>cond</code> field.
<code>0b1111</code>	Has fixed value of 1.

The range of `cond` values other than `0b1111` is required because A32 instructions in this group can be executed conditionally, see [Conditional execution](#).

- `hw1[11:8]` of the T32 encoding is equivalent to bits[27:24] of the A32 encoding, and has the value `0b1110`.
- `hw2[11:9]` of the T32 encoding is equivalent to bits[11:9] of the A32 encoding, and has the value `0b101`.
- `hw2[4]` of the T32 encoding is equivalent to bit[4] of the A32 encoding, and has the value `0b0`.

This table shows the equivalence of the fields that identify the instructions, or instruction encodings, within this group:

T32 encoding	A32 encoding
<code>op0</code>	Bit[28] of the instruction encoding is 1 when <code>cond</code> is <code>0b1111</code> .
<code>op1</code>	<code>op0</code>
<code>op2</code>	<code>op1</code>
<code>op3</code>	<code>op2</code>

C1.7.5 The PC and the use of `0b1111` as a register specifier in T32 and A32 instructions

Restrictions on the use of PC or `0b1111` as a register specifier differ between the T32 and the A32 instruction sets, as described in:

- [T32 restrictions on the use of the PC, and use of `0b1111` as a register specifier.](#)
- [A32 restrictions on the use of PC or `0b1111` as a register specifier.](#)

C1.7.5.1 T32 restrictions on the use of the PC, and use of 0b1111 as a register specifier

The use of 0b1111 as a register specifier is not normally permitted in T32 instructions. When a value of 0b1111 is permitted, various meanings are possible. For register reads, these meanings include:

- Read the PC value, that is, the address of the current instruction + 4. The base register of the table branch instructions *TBB* and *TBH* can be the PC. This means branch tables can be placed in memory immediately after the instruction.

Note

Arm deprecates use of the PC as the base register in the *STC* instruction.

- Read the word-aligned PC value, that is, the address of the current instruction + 4, with bits[1:0] forced to zero. The base register of *LDC*, *LDR*, *LDRB*, *LDRD* (pre-indexed, no writeback), *LDRH*, *LDRSB*, and *LDRSH* instructions can be the word-aligned PC. This provides PC-relative data addressing. In addition, some encodings of the *ADD* and *SUB* instructions permit their source registers to be 0b1111 for the same purpose.
- Read zero. This is done in some cases when one instruction is a special case of another, more general instruction, but with one operand zero. In these cases, the instructions are listed on separate pages, with a special case in the pseudocode for the more general instruction cross-referencing the other page.

For register writes, these meanings include:

- The PC can be specified as the destination register of an *LDR* instruction. This is done by encoding *Rt* as 0b1111. The loaded value is treated as an address, and the effect of execution is a branch to that address. Bit[0] of the loaded value selects whether to execute A32 or T32 instructions after the branch.
- Some other instructions write the PC in similar ways. An instruction can specify that the PC is written:
 - Implicitly, for example, branch instructions.
 - Explicitly by a register specifier of 0b1111, for example 16-bit *MOV* (register) instructions.
 - Explicitly by using a register mask, for example *LDM* instructions.

The address to branch to can be:

- A loaded value, for example, *RFE*.
- A register value, for example, *BX*.
- The result of a calculation, for example, *TBB* or *TBH*.

The method of choosing the instruction set used after the branch can be:

- Similar to the *LDR* case, for example, *LDM* or *BX*.
- A fixed instruction set other than the one currently being used, for example, the immediate form of *BLX*.
- Unchanged, for example, branch instructions or 16-bit *MOV* (register) instructions.
- Set from the *SPSR.T* bit, for *RFE* and *SUBS PC, LR, #imm8*.

- Discard the result of a calculation. This is done in some cases when one instruction is a special case of another, more general instruction, but with the result discarded. In these cases, the instructions are listed on separate pages, with a special case in the pseudocode for the more general instruction cross-referencing the other page.
- If the destination register specifier of an *LDRB*, *LDRH*, *LDRSB*, or *LDRSH* instruction is 0b1111, the instruction is a memory hint instead of a load operation.
- If the destination register specifier of an *MRC* instruction is 0b1111, bits[31:28] of the value transferred from the System register are written to the *N*, *Z*, *C*, and *V* condition flags in the *APSR*, and bits[27:0] are discarded.

C1.7.5.2 A32 restrictions on the use of PC or 0b1111 as a register specifier

In A32 instructions, the use of 0b1111 as a register specifier specifies the PC.

Many instructions are *CONSTRAINED UNPREDICTABLE* if they use 0b1111 as a register specifier. This is specified by pseudocode in the instruction description. Armv8-R constrains the resulting *CONSTRAINED UNPREDICTABLE* behavior, see [Using R15 by instruction](#).

Note

Arm deprecates use of the PC as the base register in any store instruction.

C1.7.6 The SP and the use of 0b1101 as a register specifier in T32 and A32 instructions

In the T32 and A32 instruction sets, Arm recommends that the use of 0b1101 as a register specifier specifies the SP.

Note

- The recommendation that the register specifier 0b1101 is used only to specify the SP applies to both the T32 and the A32 instruction sets.
- Despite this recommendation, T32 instructions that can access R13, or the SP, behave predictably from the introduction of Armv8.

C1.7.7 Modified immediate constants in T32 and A32 instructions

The following sections describe the encoding of modified immediate constants:

- [Modified immediate constants in T32 instructions.](#)
- [Modified immediate constants in A32 instructions.](#)
- [Modified immediate constants in T32 and A32 Advanced SIMD instructions.](#)
- [Modified immediate constants in T32 and A32 floating-point instructions.](#)

C1.7.7.1 Modified immediate constants in T32 instructions

The encoding of a modified immediate constant in a 32-bit T32 instruction is:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
					i												imm3							a	b	c	d	e	f	g	h

[Table C1-5](#) shows the range of modified immediate constants available in T32 data-processing instructions, and their encoding in the a, b, c, d, e, f, g, h, and i bits, and the imm3 field, in the instruction.

Table C1-5 Encoding of modified immediates in T32 data-processing instructions

i:imm3:a	<const> ^a
0000x	00000000 00000000 00000000 abcdefgh
0001x	00000000 abcdefgh 00000000 abcdefgh ^b
0010x	abcdefgh 00000000 abcdefgh 00000000 ^b
0011x	abcdefgh abcdefgh abcdefgh abcdefgh ^b
01000	1bcdefgh 00000000 00000000 00000000
01001	01bcdefg h0000000 00000000 00000000 ^c
01010	001bcdef gh000000 00000000 00000000
01011	0001bcde fgh00000 00000000 00000000 ^c
.	.
.	.
.	.
11101	00000000 00000000 000001bc defgh000 ^c
11110	00000000 00000000 0000001b cdefgh00
11111	00000000 00000000 00000001 bcdefgh0 ^c

- a. This table shows the immediate constant value in binary form, to relate `abcdefgh` to the encoding diagram. In assembly syntax, the immediate value is specified in the usual way (a decimal number by default).
- b. Arm deprecates using a modified immediate with `abcdefgh == 00000000`, and these cases are **CONSTRAINED UNPREDICTABLE**, see [UNPREDICTABLE cases in immediate constants in T32 data-processing instructions](#).
- c. Not available in A32 instructions if `h == 1`.

Note

As the footnotes to [Table C1-5](#) show, the range of values available in T32 modified immediate constants is slightly different from the range of values available in A32 instructions. See [Modified immediate constants in A32 instructions](#) for the A32 values.

C1.7.7.1.1 Carry out

A logical instruction with `i::imm3::a == '00xxx'` does not affect the Carry flag. Otherwise, a logical flag-setting instruction sets the Carry flag to the value of `bit[31]` of the modified immediate constant.

C1.7.7.1.2 Operation of modified immediate constants, T32 instructions

For a T32 data-processing instruction, the `T32ExpandImm()` pseudocode function returns the value of the 32-bit immediate constant, calling `T32ExpandImm_C()` to evaluate the constant.

C1.7.7.2 Modified immediate constants in A32 instructions

The encoding of a modified immediate constant in an A32 instruction is:

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
																					rotation		a	b	c	d	e	f	g	h	

Table C1-6 shows the range of modified immediate constants available in A32 data-processing instructions, and their encoding in the a, b, c, d, e, f, g, and h bits and the rotation field in the instruction.

Table C1-6 Encoding of modified immediates in A32 processing instructions

rotation	<const> ^a
0000	00000000 00000000 00000000 abcdefgh
0001	gh000000 00000000 00000000 00abcdef
0010	efgh0000 00000000 00000000 0000abcd
0011	cdefgh00 00000000 00000000 000000ab
0100	abcdefgh 00000000 00000000 00000000
.	.
.	.
.	.
1001	00000000 00abcdef gh000000 00000000
.	.
.	.
.	.
1110	00000000 00000000 0000abcd efgh0000
1111	00000000 00000000 000000ab cdefgh00

a. This table shows the immediate constant value in binary form, to relate abcdefgh to the encoding diagram. In assembly syntax, the immediate value is specified in the usual way (a decimal number by default).

Note

The range of values available in A32 modified immediate constants is slightly different from the range of values available in 32-bit T32 instructions. See [Modified immediate constants in T32 instructions](#).

C1.7.7.2.1 Carry out

A logical instruction with the rotation field set to 0b0000 does not affect APSR.C. Otherwise, a logical flag-setting instruction sets APSR.C to the value of bit[31] of the modified immediate constant.

C1.7.7.2.2 Constants with multiple encodings

Some constant values have multiple possible encodings. In this case, a UAL assembler must select the encoding with the lowest unsigned value of the rotation field. This is the encoding that appears first in Table C1-6. For example, the constant #3 must be encoded with (rotation, abcdefgh) = (0b0000, 0b00000011), not (0b0001, 0b00001100), (0b0010, 0b00110000), or (0b0011, 0b11000000).

In particular, this means that all constants in the range 0-255 are encoded with rotation == 0b0000, and permitted constants outside that range are encoded with rotation != 0b0000. A flag-setting logical instruction with a modified immediate constant therefore leaves APSR.C unchanged if the constant is in the range 0-255 and sets it to the most significant bit of the constant otherwise. This matches the behavior of T32 modified immediate constants for all constants that are permitted in both the T32 and A32 instruction sets.

An alternative syntax is available for a modified immediate constant that permits the programmer to specify the encoding directly. In this syntax, #<const> is instead written as #<byte>, #<rot>, where:

<byte> Is the numeric value of abcdefgh, in the range 0-255.

<rot> Is twice the numeric value of rotation, an even number in the range 0-30.

This syntax permits all A32 data-processing instructions with modified immediate constants to be disassembled to assembler syntax that assembles to the original instruction.

This syntax also makes it possible to write variants of some flag-setting logical instructions that have different effects on APSR.C to those obtained with the normal #<const> syntax. For example, `ANDS R1, R2, #12, #2` has the same behavior as `ANDS R1, R2, #3` except that it sets APSR.C to 0 instead of leaving it unchanged. Such variants of flag-setting logical instructions do not have equivalents in the T32 instruction set, and Arm deprecates their use.

C1.7.7.2.3 Operation of modified immediate constants, A32 instructions

For an A32 data-processing instruction, the `A32ExpandImm()` pseudocode function returns the value of the 32-bit immediate constant, calling `A32ExpandImm_C()` to evaluate the constant.

C1.7.7.3 Modified immediate constants in T32 and A32 Advanced SIMD instructions

Table C1-7 shows the modified immediate constants available with Advanced SIMD instructions, and how they are encoded.

Table C1-7 Modified immediate values for Advanced SIMD instructions

op	cmode	Constant ^a	<dt> ^b	Notes

		00000000		

op	cmode	Constant ^a	<dt> ^b	Notes
1	1110	aaaaaaaa bbbbbbbb cccccccc dddddddd eeeeeeee ffffffff gggggggg hhhhhhhh	I64	f
	1111	UNDEFINED	-	-

a. In this table, the immediate value is shown in binary form, to relate abcdefgh to the encoding diagram. In assembler syntax, the constant is specified by a data type and a value of that type. That value is specified in the normal way (a decimal number by default) and is replicated enough times to fill the 64-bit immediate. For example, a data type of I32 and a value of 10 specify the 64-bit constant 0x0000000A0000000A.

b. This specifies the data type used when the instruction is disassembled. On assembly, the data type must be matched in the table if possible. Other data types are permitted as pseudo-instructions when a program is assembled, provided the 64-bit constant specified by the data type and value is available for the instruction. If a constant is available in more than one way, the first entry in this table that can produce it is used. For example, `VMOV.I64 D0, #0x8000000080000000` does not specify a 64-bit constant that is available from the I64 line of the table, but does specify one that is available from the fourth I32 line or the F32 line. It is assembled to the first of these, and therefore is disassembled as `VMOV.I32 D0, #0x80000000`.

c. This constant is available for the VBIC, VMOV, VMVN, and VORR instructions.

d. CONSTRAINED UNPREDICTABLE if `abcdefgh == 0b00000000`, see [UNPREDICTABLE cases in immediate constants in Advanced SIMD instructions](#). The required behavior is that these encodings produce an immediate constant of zero.

e. This constant is available for the VMOV and VMVN instructions only.

f. This constant is available for the VMOV instruction only.

g. In this entry, $B = \text{NOT}(b)$. The bit pattern represents the floating-point number $(-1)^S \times 2^{\text{exp}} \times \text{mantissa}$, where $S = \text{UInt}(a)$, $\text{exp} = \text{UInt}(\text{NOT}(b) : c : d) - 3$ and $\text{mantissa} = (16 + \text{UInt}(e : f : g : h)) / 16$.

C1.7.7.3.1 Operation of modified immediate constants, Advanced SIMD instructions

For a T32 or A32 Advanced SIMD instruction that uses a modified immediate constant, the operation described by the [AdvSIMDExpandImm\(\)](#) pseudocode function returns the value of the 64-bit immediate constant.

C1.7.7.4 Modified immediate constants in T32 and A32 floating-point instructions

[Table C1-8](#) shows the immediate constants available in the `VMOV` (immediate) floating-point instruction, and [Table C1-9](#) shows the resulting floating-point values.

Table C1-8 Floating-point modified immediate constants

Data type	imm4H	imm4L	Constant ^a
F16	abcd	efgh	aBbbcd ef gh000000
F32	abcd	efgh	aBbbbbbc defgh000 00000000 00000000
F64	abcd	efgh	aBbbbbbb bbcdefgh 00000000 00000000 00000000 00000000 00000000

a. In this column, B = NOT(b). The bit pattern represents the floating-point number $(-1)^S \times 2^{\text{exp}} \times \text{mantissa}$, where $S = \text{UInt}(a)$, $\text{exp} = \text{UInt}(\text{NOT}(b) : c : d) - 3$ and $\text{mantissa} = (\text{UInt}(e : f : g : h)) / 16$.

Table C1-9 Floating-point constant values

efgh	bcd							
	000	001	010	011	100	101	110	111
0000	2.0	4.0	8.0	16.0	0.125	0.25	0.5	1.0

1111	3.875	7.75	15.5	31.0	0.2421875	0.484375	0.96875	1.9375

C1.7.7.4.1 Operation of modified immediate constants, floating-point instructions

For a T32 or A32 floating-point instruction that uses a modified immediate constant, the operation described by the [VFPEExpandImm\(\)](#) pseudocode function returns the value of the immediate constant.

C1.8 Additional pseudocode support for instruction descriptions

Earlier sections of this chapter include pseudocode that describes features of the execution of T32 and A32 instructions, see:

- [Pseudocode description of conditional execution.](#)
- [Pseudocode description of instruction-specified shifts and rotates](#)

The following subsection gives additional pseudocode support functions for some of the instructions described in [Alphabetical list of T32 and A32 base instruction set instructions](#). See also [Pseudocode support for the banked register transfer instructions](#).

C1.8.1 Pseudocode description of operations for System register access instructions

The `AArch32_SysRegRead()` function obtains the word for an MRC instruction from the System register.

The `AArch32_SysRegRead64()` function obtains the two words for an MRRC instruction from the System register.

Note

The relative significance of the two words returned is IMPLEMENTATION DEFINED, but all uses within this manual present the two words in the order (most significant, least significant).

The `AArch32_SysRegWrite()` procedure sends the word for an MCR instruction to the System register.

The `AArch32_SysRegWrite64()` procedure sends the two words for an MCRR instruction to the System register.

Note

The relative significance of `word2` and `word1` is IMPLEMENTATION DEFINED, but all uses within this manual treat `word2` as more significant than `word1`.

C1.8.2 Pseudocode details of system calls

The `AArch32_CallSupervisor()` pseudocode function generates a Supervisor Call exception. Valid execution of the SVC instruction calls this function.

The `AArch32_CallHypervisor()` pseudocode function generates an HVC exception. Valid execution of the HVC instruction calls this function.

C1.9 Additional information about Advanced SIMD and floating-point instructions

The following subsections give additional information about the Advanced SIMD and floating-point instructions:

- [Advanced SIMD and floating-point instruction syntax.](#)
- [The Advanced SIMD addressing mode.](#)
- [Advanced SIMD instruction modifiers.](#)
- [Advanced SIMD operand shapes.](#)
- [Data type specifiers.](#)
- [Register specifiers.](#)
- [Register lists.](#)
- [Register encoding.](#)
- [Advanced SIMD scalars.](#)

Note

The Advanced SIMD architecture, its associated implementations, and supporting software, are commonly referred to as NEON™ technology.

C1.9.1 Advanced SIMD and floating-point instruction syntax

Advanced SIMD and floating-point instructions use the general conventions of the T32 and A32 instruction sets.

Advanced SIMD and floating-point data-processing instructions use the following general format:

```
V{<modifier>}<operation>{<shape>}{<c>}{<q>}{<dt>} {<dest>}, {<src1>}, {<src2>}
```

All Advanced SIMD and floating-point instructions begin with a `v`. This distinguishes Advanced SIMD vector and floating-point instructions from scalar instructions.

The main operation is specified in the `<operation>` field. It is usually a three letter mnemonic the same as or similar to the corresponding scalar integer instruction.

The `<c>` and `<q>` fields are standard assembler syntax fields. For details, see [Standard assembler syntax fields](#).

C1.9.2 The Advanced SIMD addressing mode

All the element and structure load/store instructions use this addressing mode. There is a choice of three formats:

`[<Rn>{:<align>}]` The address is contained in general-purpose register `Rn`.

`Rn` is not updated by this instruction.

Encoded as `Rm = 0b1111`.

If `Rn` is encoded as `0b1111`, the instruction is CONSTRAINED UNPREDICTABLE.

`[<Rn>{:<align>}]!` The address is contained in general-purpose register `Rn`.

`Rn` is updated by this instruction: `Rn = Rn + transfer_size`

Encoded as `Rm = 0b1101`.

`transfer_size` is the number of bytes transferred by the instruction. This means that, after the instruction is executed, `Rn` points to the address in memory immediately following the last address loaded from or stored to.

If `Rn` is encoded as `0b1111`, the instruction is CONSTRAINED UNPREDICTABLE.

This addressing mode can also be written as:

`[<Rn>{:<align>}], #<transfer_size>`

However, disassembly produces the `[<Rn>{:<align>}]!` form.

[<Rn>{:<align>}], <Rm>

The address is contained in general-purpose register <Rn>.

Rn is updated by this instruction: $Rn = Rn + Rm$

Encoded as Rm = Rm. Rm must not be encoded as 0b1111 or 0b1101, the PC or the SP.

If Rn is encoded as 0b1111, the instruction is CONSTRAINED UNPREDICTABLE.

The CONSTRAINED UNPREDICTABLE behavior of encodings where Rn is 0b1111 is described in the section: [Using R15 by instruction](#).

In all cases, <align> specifies an alignment, as specified by the individual instruction descriptions.

Previous versions of the manual used the @ character for alignment. So, for example, the first format in this section was shown as [<Rn>{@<align>}]. Both @ and : are supported. However, to ensure portability of code to assemblers that treat @ as a comment character, : is preferred.

C1.9.3 Advanced SIMD instruction modifiers

The <modifier> field provides additional variants of some instructions. [Table C1-10](#) provides definitions of the modifiers. Modifiers are not available for every instruction.

Table C1-10 Advanced SIMD instruction modifiers

<modifier>	Meaning
Q	The operation uses saturating arithmetic.
R	The operation performs rounding.
D	The operation doubles the result (before accumulation, if any).
H	The operation halves the result.

C1.9.4 Advanced SIMD operand shapes

The <shape> field provides additional variants of some instructions. [Table C1-11](#) provides definitions of the shapes. Operand shapes are not available for every instruction.

Table C1-11 Advanced SIMD operand shapes

<shape>	Meaning	Typical register shape
(none)	The operands and result are all the same width.	Dd, Dn, Dm Qd, Qn, Qm
L	Long operation - result is twice the width of both operands	Qd, Dn, Dm
N	Narrow operation - result is half the width of both operands	Dd, Qn, Qm
W	Wide operation - result and first operand are twice the width of the second operand	Qd, Qn, Dm

Note

- Some assemblers support a Q shape specifier, which requires all operands to be Q registers. An example of using this specifier is `VADDQ.S32 q0, q1, q2`. This is not standard UAL, and Arm recommends that programmers do not use a Q shape specifier.
- A disassembler must not generate any shape specifier not shown in [Table C1-11](#).

C1.9.5 Data type specifiers

The <dt> field normally contains one data type specifier. Unless the assembler syntax description for the instruction indicates otherwise, this indicates the data type contained in:

- The second operand, if any.
- The operand, if there is no second operand.
- The result, if there are no operand registers.

The data types of the other operand and result are implied by the <dt> field combined with the instruction shape. For information about data type formats, see [Data types supported by the Advanced SIMD implementation](#).

In the instruction syntax descriptions in [About the T32 and A32 Instruction Descriptions](#), the <dt> field is usually specified as a single field. However, where more convenient, it is sometimes specified as a concatenation of two fields, <type><size>.

C1.9.5.1 Syntax flexibility

There is some flexibility in the data type specifier syntax:

- Software can specify three data types, specifying the result and both operand data types. For example:
VSUBW.I16.I16.S8 Q3, Q5, D0 instead of VSUBW.S8 Q3, Q5, D0
- Software can specify two data types, specifying the data types of the two operands. The data type of the result is implied by the instruction shape. For example:
VSUBW.I16.S8 Q3, Q5, D0 instead of VSUBW.S8 Q3, Q5, D0
- Software can specify two data types, specifying the data types of the single operand and the result. For example:
VMOVN.I16.I32 D0, Q1 instead of VMOVN.I32 D0, Q1
- Where an instruction requires a less specific data type, software can instead specify a more specific type, as shown in [Table C1-12](#).
- Where an instruction does not require a data type, software can provide one.
- The F32 data type can be abbreviated to F.
- The F64 data type can be abbreviated to D.

In all cases, if software provides additional information, the additional information must match the instruction shape. Disassembly does not regenerate this additional information.

Table C1-12 Data type specification flexibility

Specified data type	Permitted more specific data types				
None	Any				
.I<size>	-	.S<size>	.U<size>	-	-
.8	.I8	.S8	.U8	.P8	-
.16	.I16	.S16	.U16	.P16	.F16
.32	.I32	.S32	.U32	-	.F32 or .F
.64	.I64	.S64	.U64	-	.F64 or .D

C1.9.6 Register specifiers

The `<dest>`, `<src1>`, and `<src2>` fields contain register specifiers, or in some cases scalar specifiers or register lists. [Table C1-13](#) shows the register and scalar specifier formats that appear in the instruction descriptions.

If `<dest>` is omitted, it is the same as `<src1>`.

Table C1-13 Advanced SIMD and floating-point register specifier formats

<specifier>	Usual meaning^a	Used in
<code><Qd></code>	A quadword destination register for the result vector.	Advanced SIMD
<code><Qn></code>	A quadword source register for the first operand vector.	Advanced SIMD
<code><Qm></code>	A quadword source register for the second operand vector.	Advanced SIMD
<code><Dd></code>	A doubleword destination register for the result vector.	Both
<code><Dn></code>	A doubleword source register for the first operand vector.	Both
<code><Dm></code>	A doubleword source register for the second operand vector.	Both
<code><Sd></code>	A singleword destination register for the result vector.	Floating-point
<code><Sn></code>	A singleword source register for the first operand vector.	Floating-point
<code><Sm></code>	A singleword source register for the second operand vector.	Floating-point
<code><Dd[x]></code>	A destination scalar for the result. Element x of vector <code><Dd></code> .	Advanced SIMD
<code><Dn[x]></code>	A source scalar for the first operand. Element x of vector <code><Dn></code> .	Both ^b
<code><Dm[x]></code>	A source scalar for the second operand. Element x of vector <code><Dm></code> .	Advanced SIMD
<code><Rt></code>	A general-purpose register, used for a source or destination address.	Both
<code><Rt2></code>	A general-purpose register, used for a source or destination address.	Both
<code><Rn></code>	A general-purpose register, used as a load or store base address.	Both
<code><Rm></code>	A general-purpose register, used as a post-indexed address source.	Both

a. In some instructions the roles of registers are different.

b. In the floating-point instructions, `<Dn[x]>` is used only in `VMOV` (scalar to general-purpose register), see [VMOV \(scalar to general-purpose register\)](#).

C1.9.7 Register lists

A register list is a list of register specifiers separated by commas and enclosed in brackets { and }. There are restrictions on what registers can appear in a register list. These restrictions are described in the individual instruction descriptions. [Table C1-14](#) shows some register list formats, with examples of actual register lists corresponding to those formats.

Note

Register lists must not wrap around the end of the register bank.

C1.9.7.1 Syntax flexibility

There is some flexibility in the register list syntax:

- Where a register list contains consecutive registers, they can be specified as a range, instead of listing every register, for example {D0–D3} instead of {D0, D1, D2, D3}.
- Where a register list contains an even number of consecutive doubleword registers starting with an even-numbered register, it can be written as a list of quadword registers instead, for example {Q1, Q2} instead of {D2–D5}.
- Where a register list contains only one register, the enclosing braces can be omitted, for example VLD1.8 D0, [R0] instead of VLD1.8 {D0}, [R0].

Table C1-14 Example register lists

Format	Example	Alternative
{<Dd>}	{D3}	D3
{<Dd>, <Dd+1>, <Dd+2>}	{D3, D4, D5}	{D3–D5}
{<Dd[x]>, <Dd+2[x]>}	{D0[3], D2[3]}	-
{<Dd[]>}	{D7[]}	D7[]

C1.9.8 Register encoding

An Advanced SIMD register is either:

- Quadword*, meaning it is 128 bits wide.
- Doubleword*, meaning it is 64 bits wide.

Some instructions have options for either doubleword or quadword registers. This is normally encoded in Q, bit[6], as Q = 0 for doubleword operations, or Q = 1 for quadword operations.

A floating-point register is either:

- Double-precision, meaning it is 64 bits wide.
- Single-precision, meaning it is 32 bits wide.

This is encoded in the sz field, bit[8], as sz = 1 for double-precision operations, or sz = 0 for single-precision operations.

The T32 instruction encoding of Advanced SIMD or floating-point registers is:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0			
									D				Vn						Vd						sz	N	Q	M				Vm		

The A32 instruction encoding of Advanced SIMD or floating-point registers is:

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
									D				Vn			Vd						sz	N	Q	M				Vm		

Some instructions use only one or two registers, and use the unused register fields as additional opcode bits.

Table C1-15 shows the encodings for the registers.

Table C1-15 Encoding of register numbers

Register mnemonic	Usual usage	Register number encoded in ^a	Notes ^a	Used in
<Qd>	Destination (quadword)	D, Vd (bits[22, 15:13])	bit[12] == 0 ^b	Advanced SIMD
<Qn>	First operand (quadword)	N, Vn (bits[7, 19:17])	bit[16] == 0 ^b	Advanced SIMD
<Qm>	Second operand (quadword)	M, Vm (bits[5, 3:1])	bit[0] == 0 ^b	Advanced SIMD
<Dd>	Destination (doubleword)	D, Vd (bits[22, 15:12])	-	Both
<Dn>	First operand (doubleword)	N, Vn (bits[7, 19:16])	-	Both
<Dm>	Second operand (doubleword)	M, Vm (bits[5, 3:0])	-	Both
<Sd>	Destination (single-precision)	Vd, D (bits[15:12, 22])	-	Floating-point
<Sn>	First operand (single-precision)	Vn, N (bits[19:16, 7])	-	Floating-point
<Sm>	Second operand (single-precision)	Vm, M (bits[3:0, 5])	-	Floating-point

a. Bit numbers given for the A32 instruction encoding. See the figures in this section for the equivalent bits in the T32 encoding.

b. If this bit is 1, the instruction is UNDEFINED.

C1.9.9 Advanced SIMD scalars

Advanced SIMD scalars can be 8-bit, 16-bit, 32-bit, or 64-bit. Instructions other than multiply instructions can access any element in the register set. The instruction syntax refers to the scalars using an index into a doubleword vector. The descriptions of the individual instructions contain details of the encodings.

Table C1-16 shows the form of encoding for scalars used in multiply instructions. These instructions cannot access scalars in some registers. The descriptions of the individual instructions contain cross references to this section where appropriate.

32-bit Advanced SIMD scalars, when used as single-precision floating-point numbers, are equivalent to Floating-point single-precision registers. That is, $D_m[x]$ in a 32-bit context ($0 \leq m \leq 15, 0 \leq x \leq 1$) is equivalent to $S[2m + x]$.

Table C1-16 Encoding of scalars in multiply instructions

Scalar mnemonic	Usual usage	Scalar size	Register specifier	Index specifier	Accessible registers
<Dm [x]>	Second operand	16-bit	Vm[2:0]	M, Vm[3]	D0-D7
		32-bit	Vm[3:0]	M	D0-D15

Chapter C2

The AArch32 Instruction Sets Overview

This chapter describes the T32 and A32 instruction sets. It contains the following sections:

- [Support for instructions in different versions of the Arm architecture](#)
- [Unified Assembler Language](#)
- [Branch instructions](#)
- [Data-processing instructions](#)
- [PSTATE and banked register access instructions](#)
- [Load/store instructions](#)
- [Load/store multiple instructions](#)
- [Miscellaneous instructions](#)
- [Exception-generating and exception-handling instructions](#)
- [System register access instructions](#)
- [Advanced SIMD and floating-point load/store instructions](#)
- [Advanced SIMD and floating-point register transfer instructions](#)
- [Advanced SIMD data-processing instructions](#)
- [Floating-point data-processing instructions](#)

C2.1 Support for instructions in different versions of the Arm architecture

This manual describes the T32 and A32 instruction sets for the architecture. Therefore, it indicates how any options or extensions in the architecture affect the available instructions.

C2.2 Unified Assembler Language

This manual uses the Arm *Unified Assembler Language* (UAL). This assembly language syntax provides a canonical form for all T32 and A32 instructions.

UAL describes the syntax for the mnemonic and the operands of each instruction. In addition, it assumes that instructions and data items can be given labels. It does not specify the syntax to be used for labels, nor what assembler directives and options are available. See your assembler documentation for these details.

Most earlier Arm assembly language mnemonics are still supported as synonyms, as described in the instruction details.

Note

Most earlier T32 assembly language mnemonics are *not* supported.

UAL includes *instruction selection* rules that specify which instruction encoding is selected when more than one can provide the required functionality. For example, both 16-bit and 32-bit encodings exist for an `ADD R0, R1, R2` instruction. The most common instruction selection rule is that when both a 16-bit encoding and a 32-bit encoding are available, the 16-bit encoding is selected, to optimize code density.

Syntax options exist to override the normal instruction selection rules and ensure that a particular encoding is selected. These are useful when disassembling code, to ensure that subsequent assembly produces the original code, and in some other situations.

C2.2.1 Conditional instructions

For maximum portability of UAL assembly language between the T32 and A32 instruction sets, Arm recommends that:

- `IT` instructions are written before conditional instructions in the correct way for the T32 instruction set.
- When assembling to the A32 instruction set, assemblers check that any `IT` instructions are correct, but do not generate any code for them.

Although other T32 instructions are unconditional, all instructions that are made conditional by an `IT` instruction must be written with a condition. These conditions must match the conditions imposed by the `IT` instruction. For example, an `ITTEE EQ` instruction imposes the `EQ` condition on the first two following instructions, and the `NE` condition on the next two. Those four instructions must be written with `EQ`, `EQ`, `NE` and `NE` conditions respectively.

Some instructions cannot be made conditional by an `IT` instruction. Some instructions can be conditional if they are the last instruction in the `IT` block, but not otherwise.

The branch instruction encodings that include a condition code field cannot be made conditional by an `IT` instruction. If the assembler syntax indicates a conditional branch that correctly matches a preceding `IT` instruction, it is assembled using a branch instruction encoding that does not include a condition code field.

C2.2.2 Use of labels in UAL instruction syntax

The UAL syntax for some instructions includes the label of an instruction or a literal data item that is at a fixed offset from the instruction being specified. The assembler must:

1. Calculate the `PC` or `Align(PC, 4)` value of the instruction. The `PC` value of an instruction is its address plus 4 for a T32 instruction, or plus 8 for an A32 instruction. The `Align(PC, 4)` value of an instruction is its `PC` value ANDed with `0xFFFFFEC` to force it to be word-aligned. There is no difference between the `PC` and `Align(PC, 4)` values for an A32 instruction, but there can be for a T32 instruction.
2. Calculate the offset from the `PC` or `Align(PC, 4)` value of the instruction to the address of the labeled instruction or literal data item.
3. Assemble a *PC-relative* encoding of the instruction, that is, one that reads its `PC` or `Align(PC, 4)` value and adds the calculated offset to form the required address.

Note

For instructions that can encode a subtraction operation, if the instruction cannot encode the calculated offset but can encode minus the calculated offset, the instruction encoding specifies a subtraction of minus the calculated offset.

The syntax of the following instructions includes a label:

- **B, BL, and BLX (immediate).** The assembler syntax for these instructions always specifies the label of the instruction that they branch to. Their encodings specify a sign-extended immediate offset that is added to the PC value of the instruction to form the target address of the branch.
- **CBNZ and CBZ.** The assembler syntax for these instructions always specifies the label of the instruction that they branch to. Their encodings specify a zero-extended immediate offset that is added to the PC value of the instruction to form the target address of the branch. They do not support backward branches.
- **LDR, LDRB, LDRD, LDRH, LDRSB, LDRSH, PLD, PLDW, PLI, and VLDR.** The normal assembler syntax of these load instructions can specify the label of a literal data item that is to be loaded. The encodings of these instructions specify a zero-extended immediate offset that is either added to or subtracted from the `Align(PC, 4)` value of the instruction to form the address of the data item. A few such encodings perform a fixed addition or a fixed subtraction and must only be used when that operation is required, but most contain a bit that specifies whether the offset is to be added or subtracted.

When the assembler calculates an offset of 0 for the normal syntax of these instructions, it must assemble an encoding that adds 0 to the `Align(PC, 4)` value of the instruction. Encodings that subtract 0 from the `Align(PC, 4)` value cannot be specified by the normal syntax.

There is an alternative syntax for these instructions that specifies the addition or subtraction and the immediate offset explicitly. In this syntax, the label is replaced by `[PC, #+/-<imm>]`, where:

`+/-` Is + or omitted to specify that the immediate offset is to be added to the `Align(PC, 4)` value, or - if it is to be subtracted.

`<imm>` Is the immediate offset.

This alternative syntax makes it possible to assemble the encodings that subtract 0 from the `Align(PC, 4)` value, and to disassemble them to a syntax that can be re-assembled correctly.

- **ADR.** The normal assembler syntax for this instruction can specify the label of an instruction or literal data item whose address is to be calculated. Its encoding specifies a zero-extended immediate offset that is either added to or subtracted from the `Align(PC, 4)` value of the instruction to form the address of the data item, and some opcode bits that determine whether it is an addition or subtraction.

When the assembler calculates an offset of 0 for the normal syntax of this instruction, it must assemble the encoding that adds 0 to the `Align(PC, 4)` value of the instruction. The encoding that subtracts 0 from the `Align(PC, 4)` value cannot be specified by the normal syntax.

There is an alternative syntax for this instruction that specifies the addition or subtraction and the immediate value explicitly, by writing them as additions `ADD <Rd>, PC, #<imm>` or subtractions `SUB <Rd>, PC, #<imm>`. This alternative syntax makes it possible to assemble the encoding that subtracts 0 from the `Align(PC, 4)` value, and to disassemble it to a syntax that can be re-assembled correctly.

Note

Arm recommends that where possible, software avoids using:

- The alternative syntax for the **ADR, LDC, LDR, LDRB, LDRD, LDRH, LDRSB, LDRSH, PLD, PLI, PLDW, and VLDR** instructions.
 - The encodings of these instructions that subtract 0 from the `Align(PC, 4)` value.
-

C2.3 Branch instructions

[Table C2-1](#) summarizes the branch instructions in the T32 and A32 instruction sets. In addition to providing for changes in the flow of execution, some branch instructions can change instruction set.

Table C2-1 Branch instructions

Instruction	See	Range, T32	Range, A32
Branch to target address	B	±16MB	±32MB
Compare and Branch on Nonzero Compare and Branch on Zero	CBNZ, CBZ	0-126 bytes	-
Call a subroutine Call a subroutine, change instruction set ^a	BL, BLX (immediate)	±16MB ±16MB	±32MB ±32MB
Call a subroutine, optionally change instruction set	BLX (register)	Any	Any
Branch to target address, change instruction set	BX	Any	Any
Change to Jazelle state	BXJ	-	-
Table Branch (byte offsets) Table Branch (halfword offsets)	TBB, TBH	0-510 bytes 0-131070 bytes	-

a. The range is determined by the instruction set of the BLX instruction, not of the instruction it branches to.

Branches to loaded and calculated addresses can be performed by `LDR`, `LDM` and data-processing instructions. For details, see [Load/store instructions](#), [Load/store multiple instructions](#), [Standard data-processing instructions](#), and [Shift instructions](#).

In addition to the branch instructions shown in [Table C2-1](#):

- In the A32 instruction set, a data-processing instruction that targets the PC behaves as a branch instruction. For more information, see [Data-processing instructions](#).
- In the T32 and A32 instruction sets, a load instruction that targets the PC behaves as a branch instruction. For more information, see [Load/store instructions](#).

C2.4 Data-processing instructions

Core data-processing instructions belong to one of the following groups:

- [Standard data-processing instructions.](#)
- [Shift instructions.](#)
- [Multiply instructions.](#)
- [Saturating instructions.](#)
- [Saturating addition and subtraction instructions.](#)
- [Packing and unpacking instructions.](#)
- [Parallel addition and subtraction instructions.](#)
- [Divide instructions.](#)
- [Miscellaneous data-processing instructions.](#)

For related Advanced SIMD and floating-point instructions see [Advanced SIMD data-processing instructions](#) and [Floating-point data-processing instructions](#).

C2.4.1 Standard data-processing instructions

These instructions perform basic data-processing operations, and share a common format with some variations.

These instructions generally have a destination register Rd, a first operand register Rn, and a second operand. The second operand can be another register Rm, or an immediate constant.

If the second operand is an immediate constant, it can be:

- Encoded directly in the instruction.
- A *modified immediate constant* that uses 12 bits of the instruction to encode a range of constants. T32 and A32 instructions have slightly different ranges of modified immediate constants. For more information, see [Modified immediate constants in T32 instructions](#) and [Modified immediate constants in A32 instructions](#).

If the second operand is another register, it can optionally be shifted in any of the following ways:

LSL	Logical Shift Left by 1-31 bits.
LSR	Logical Shift Right by 1-32 bits.
ASR	Arithmetic Shift Right by 1-32 bits.
ROR	Rotate Right by 1-31 bits.
RRX	Rotate Right with Extend. For details, see Shift and rotate operations .

In T32 code, the amount to shift by is always a constant encoded in the instruction. In A32 code, the amount to shift by is either a constant encoded in the instruction, or the value of a register, Rs.

For instructions other than CMN, CMP, TEQ, and TST, the result of the data-processing operation is placed in the destination register. In the A32 instruction set, the destination register can be the PC, causing the result to be treated as a branch address. In the T32 instruction set, this is only permitted for some 16-bit forms of the ADD and MOV instructions.

These instructions can optionally set the Condition flags, according to the result of the operation. If they do not set the flags, existing flag settings from a previous instruction are preserved.

[Table C2-2](#) summarizes the main data-processing instructions in the T32 and A32 instruction sets. Generally, each of these instructions is described in three sections in [About the T32 and A32 Instruction Descriptions](#), one section for each of the following:

- INSTRUCTION (immediate) where the second operand is a modified immediate constant.
- INSTRUCTION (register) where the second operand is a register, or a register shifted by a constant.
- INSTRUCTION (register-shifted register) where the second operand is a register shifted by a value obtained from another register. These are only available in the A32 instruction set.

Table C2-2 Standard data-processing instructions

Instruction	Mnemonic	Notes
Add with Carry	ADC	-
Add	ADD	T32 instruction set permits use of a modified immediate constant or a zero-extended 12-bit immediate constant.
Form PC-relative Address	ADR	First operand is the PC. Second operand is an immediate constant. T32 instruction set uses a zero-extended 12-bit immediate constant. Operation is an addition or a subtraction.
Bitwise AND	AND	-
Bitwise Bit Clear	BIC	-
Compare Negative	CMN	Sets flags. Like ADD but with no destination register.
Compare	CMP	Sets flags. Like SUB but with no destination register.
Bitwise Exclusive OR	EOR	-
Copy operand to destination	MOV	Has only one operand, with the same options as the second operand in most of these instructions. If the operand is a shifted register, the instruction is an LSL, LSR, ASR, or ROR instruction instead. For details, see Shift instructions . The T32 and A32 instruction sets permit use of a modified immediate constant or a zero-extended 16-bit immediate constant.
Bitwise NOT	MVN	Has only one operand, with the same options as the second operand in most of these instructions.
Bitwise OR NOT	ORN	Not available in the A32 instruction set.
Bitwise OR	ORR	-
Reverse Subtract	RSB	Subtracts first operand from second operand. This permits subtraction from constants and shifted registers.
Reverse Subtract with Carry	RSC	Not available in the T32 instruction set.
Subtract with Carry	SBC	-
Subtract	SUB	T32 instruction set permits use of a modified immediate constant or a zero-extended 12-bit immediate constant.
Test Equivalence	TEQ	Sets flags. Like EOR but with no destination register.
Test	TST	Sets flags. Like AND but with no destination register.

C2.4.2 Shift instructions

[Table C2-3](#) lists the shift instructions in the T32 and A32 instruction sets.

Table C2-3 Shift instructions

Instruction	See
Arithmetic Shift Right	ASR (immediate) ASR (register) ASRS (immediate) ASRS (register)

Instruction	See
Logical Shift Left	LSL (immediate) LSL (register) LSLS (immediate) LSLS (register)
Logical Shift Right	LSR (immediate) LSR (register) LSRS (immediate) LSRS (register)
Rotate Right	ROR (immediate) ROR (register) RORS (immediate) RORS (register)
Rotate Right with Extend	RRX RRXS

In the A32 instruction set only, the destination register of these instructions can be the PC, causing the result to be treated as an address to branch to.

C2.4.3 Multiply instructions

These instructions can operate on signed or unsigned quantities. In some types of operation, the results are the same whether the operands are signed or unsigned.

- [Table C2-4](#) summarizes the multiply instructions where there is no distinction between signed and unsigned quantities.
The least significant 32 bits of the result are used. More significant bits are discarded.
- [Table C2-5](#) summarizes the signed multiply instructions.
- [Table C2-6](#) summarizes the unsigned multiply instructions.

Table C2-4 General multiply instructions

Instruction	See	Operation (number of bits)
Multiply Accumulate	MLA , MLAS	$32 = 32 + 32 \times 32$
Multiply and Subtract	MLS	$32 = 32 - 32 \times 32$
Multiply	MUL , MULS	$32 = 32 \times 32$

Table C2-5 Signed multiply instructions

Instruction	See	Operation (number of bits)
Signed Multiply Accumulate (halfwords)	SMLABB , SMLABT , SMLATB , SMLATT	$32 = 32 + 16 \times 16$
Signed Multiply Accumulate Dual	SMLAD , SMLADX	$32 = 32 + 16 \times 16 + 16 \times 16$
Signed Multiply Accumulate Long	SMLAL , SMLALS	$64 = 64 + 32 \times 32$

Instruction	See	Operation (number of bits)
Signed Multiply Accumulate Long (halfwords)	SMLALBB , SMLALBT , SMLALTB , SMLALTT	$64 = 64 + 16 \times 16$
Signed Multiply Accumulate Long Dual	SMLALD , SMLALDX	$64 = 64 + 16 \times 16 + 16 \times 16$
Signed Multiply Accumulate (word by halfword)	SMLAWB , SMLAWT	$32 = 32 + 32 \times 16^a$
Signed Multiply Subtract Dual	SMLSD , SMLSXD	$32 = 32 + 16 \times 16 - 16 \times 16$
Signed Multiply Subtract Long Dual	SMLSLD , SMLSLDX	$64 = 64 + 16 \times 16 - 16 \times 16$
Signed Most Significant Word Multiply Accumulate	SMMLA , SMMLAR	$32 = 32 + 32 \times 32^b$
Signed Most Significant Word Multiply Subtract	SMMLS , SMMLSR	$32 = 32 - 32 \times 32^b$
Signed Most Significant Word Multiply	SMMUL , SMMULR	$32 = 32 \times 32^b$
Signed Dual Multiply Add	SMUAD , SMUADX	$32 = 16 \times 16 + 16 \times 16$
Signed Multiply (halfwords)	SMULBB , SMULBT , SMULTB , SMULTT	$32 = 16 \times 16$
Signed Multiply Long	SMULL , SMULLS	$64 = 32 \times 32$
Signed Multiply (word by halfword)	SMULWB , SMULWT	$32 = 32 \times 16^a$
Signed Dual Multiply Subtract	SMUSD , SMUSDX	$32 = 16 \times 16 - 16 \times 16$

a. The most significant 32 bits of the 48-bit product are used. Less significant bits are discarded.

b. The most significant 32 bits of the 64-bit product are used. Less significant bits are discarded.

Table C2-6 Unsigned multiply instructions

Instruction	See	Operation (number of bits)
Unsigned Multiply Accumulate Accumulate Long	UMAAL	$64 = 32 + 32 + 32 \times 32$
Unsigned Multiply Accumulate Long	UMLAL , UMLALS	$64 = 64 + 32 \times 32$
Unsigned Multiply Long	UMULL , UMULLS	$64 = 32 \times 32$

C2.4.4 Saturating instructions

[Table C2-7](#) lists the saturating instructions in the T32 and A32 instruction sets. For more information, see [Pseudocode description of saturation](#).

Table C2-7 Saturating instructions

Instruction	See	Operation
Signed Saturate	SSAT	Saturates optionally shifted 32-bit value to selected range
Signed Saturate 16	SSAT16	Saturates two 16-bit values to selected range
Unsigned Saturate	USAT	Saturates optionally shifted 32-bit value to selected range
Unsigned Saturate 16	USAT16	Saturates two 16-bit values to selected range

C2.4.5 Saturating addition and subtraction instructions

[Table C2-8](#) lists the saturating addition and subtraction instructions in the T32 and A32 instruction sets. For more information, see [Pseudocode description of saturation](#).

Table C2-8 Saturating addition and subtraction instructions

Instruction	See	Operation
Saturating Add	QADD	Add, saturating result to the 32-bit signed integer range
Saturating Subtract	QSUB	Subtract, saturating result to the 32-bit signed integer range
Saturating Double and Add	QADD	Doubles one value and adds a second value, saturating the doubling and the addition to the 32-bit signed integer range
Saturating Double and Subtract	QDSUB	Doubles one value and subtracts the result from a second value, saturating the doubling and the subtraction to the 32-bit signed integer range

C2.4.6 Packing and unpacking instructions

[Table C2-9](#) lists the packing and unpacking instructions in the T32 and A32 instruction sets.

Table C2-9 Packing and unpacking instructions

Instruction	See	Operation
Pack Halfword	PKHBT , PKHTB	Combine halfwords
Signed Extend and Add Byte	SXTAB	Extend 8 bits to 32 and add
Signed Extend and Add Byte 16	SXTAB16	Dual extend 8 bits to 16 and add
Signed Extend and Add Halfword	SXTAH	Extend 16 bits to 32 and add
Signed Extend Byte	SXTB	Extend 8 bits to 32

Instruction	See	Operation
Signed Extend Byte 16	SXTB16	Dual extend 8 bits to 16
Signed Extend Halfword	SXTH	Extend 16 bits to 32
Unsigned Extend and Add Byte	UXTAB	Extend 8 bits to 32 and add
Unsigned Extend and Add Byte 16	UXTAB16	Dual extend 8 bits to 16 and add
Unsigned Extend and Add Halfword	UXTAH	Extend 16 bits to 32 and add
Unsigned Extend Byte	UXTB	Extend 8 bits to 32
Unsigned Extend Byte 16	UXTB16	Dual extend 8 bits to 16
Unsigned Extend Halfword	UXTH	Extend 16 bits to 32

C2.4.7 Parallel addition and subtraction instructions

These instructions perform additions and subtractions on the values of two registers and write the result to a destination register, treating the register values as sets of two halfwords or four bytes. That is, they perform SIMD additions or subtractions on the general-purpose registers.

These instructions consist of a prefix followed by a main instruction mnemonic. The prefixes are as follows:

S	Signed arithmetic modulo 2^8 or 2^{16} .
Q	Signed saturating arithmetic.
SH	Signed arithmetic, halving the results.
U	Unsigned arithmetic modulo 2^8 or 2^{16} .
UQ	Unsigned saturating arithmetic.
UH	Unsigned arithmetic, halving the results.

The main instruction mnemonics are as follows:

ADD16	Adds the top halfwords of two operands to form the top halfword of the result, and the bottom halfwords of the same two operands to form the bottom halfword of the result.
ASX	Exchanges halfwords of the second operand, and then adds top halfwords and subtracts bottom halfwords.
SAX	Exchanges halfwords of the second operand, and then subtracts top halfwords and adds bottom halfwords.
SUB16	Subtracts each halfword of the second operand from the corresponding halfword of the first operand to form the corresponding halfword of the result.
ADD8	Adds each byte of the second operand to the corresponding byte of the first operand to form the corresponding byte of the result.
SUB8	Subtracts each byte of the second operand from the corresponding byte of the first operand to form the corresponding byte of the result.

The instruction set permits all 36 combinations of prefix and main instruction operand, as [Table C2-10](#) shows.

See also [Advanced SIMD parallel addition and subtraction](#).

Table C2-10 Parallel addition and subtraction instructions

Main instruction	Signed	Saturating	Signed halving	Unsigned	Unsigned saturating	Unsigned halving
ADD16, add, two halfwords	SADD16	QADD16	SHADD16	UADD16	UQADD16	UHADD16
ASX, add and subtract with exchange	SASX	QASX	SHASX	UASX	UQASX	UHASX
SAX, subtract and add with exchange	SSAX	QSAX	SHSAX	USAX	UQSAX	UHSAX
SUB16, subtract, two halfwords	SSUB16	QSUB16	SHSUB16	USUB16	UQSUB16	UHSUB16
ADD8, add, four bytes	SADD8	QADD8	SHADD8	UADD8	UQADD8	UHADD8
SUB8, subtract, four bytes	SSUB8	QSUB8	SHSUB8	USUB8	UQSUB8	UHSUB8

C2.4.8 Divide instructions

Signed and unsigned integer divide instructions are included in both the T32 instruction set and the A32 instruction set.

For descriptions of the instructions see:

- SDIV.
- UDIV.

For the SDIV and UDIV

instructions, division by zero always returns a zero result.

The ID_ISAR0.Divide_instrs field indicates the level of support for these instructions. The field value of 0b0010 indicates they are implemented in both the T32 and A32 instruction sets.

C2.4.9 Miscellaneous data-processing instructions

Table C2-11 lists the miscellaneous data-processing instructions in the T32 and A32 instruction sets. Immediate values in these instructions are simple binary numbers.

Table C2-11 Miscellaneous data-processing instructions

Instruction	See	Notes
BitField Clear	BFC	-
BitField Insert	BFI	-
Count Leading Zeros	CLZ	-
Move Top	MOVT	Moves 16-bit immediate value to top halfword. Bottom halfword unchanged.
Reverse Bits	RBIT	-
Byte-Reverse Word	REV	-
Byte-Reverse Packed Halfword	REV16	-
Byte-Reverse Signed Halfword	REVSH	-
Signed BitField Extract	SBFX	-
Select Bytes using GE flags	SEL	-
Unsigned BitField Extract	UBFX	-
Unsigned Sum of Absolute Differences	USAD8	-
Unsigned Sum of Absolute Differences and Accumulate	USADA8	-

C2.5 PSTATE and banked register access instructions

These instructions transfer PE state information to or from a general-purpose register.

C2.5.1 PSTATE access instructions

PSTATE holds process state information, see [Process state, PSTATE](#). In AArch32 state:

- At EL1 or higher, [PSTATE](#) is accessible using the *Current Program Status Register (CPSR)*.
- At EL0, a subset of the [CPSR](#) is accessible as the *Application Program Status Register (APSR)*.
- On taking an exception, the contents of the [CPSR](#) are copied to the *Saved Program Status Register (SPSR)* of the mode from which the exception is taken.

The [MRS](#) and [MSR](#) instructions move the contents of the [CPSR](#), [APSR](#), or the [SPSR](#) of the current mode to or from a general-purpose register, see:

- [MRS](#).
- [MSR \(immediate\)](#).
- [MSR \(register\)](#).

When executed at EL0, [MRS](#) and [MSR](#) instructions can only access the [APSR](#).

The [PSTATE](#) Condition flags, [PSTATE](#).{N, Z, C, V} are set by the execution of data-processing instructions, and can control the execution of conditional instructions. However, software can set the Condition flags explicitly using the [MSR](#) instruction, and can read the current state of the Condition flags explicitly using the [MRS](#) instruction.

In addition, at EL1 or higher, software can use the [CPS](#) instruction to change the [PSTATE](#).M field and the [PSTATE](#).{A, I, F} interrupt mask bits, see [CPS](#), [CPSID](#), [CPSIE](#).

C2.5.2 Banked register access instructions

At EL1 or higher, the [MRS](#) (banked register) and [MSR](#) (banked register) instructions move the contents of a banked general-purpose register, the [SPSR](#), or the [ELR_hyp](#), to or from a general-purpose register. See:

- [MRS \(Banked register\)](#).
- [MSR \(Banked register\)](#).

C2.6 Load/store instructions

Table C2-12 summarizes the general-purpose register load/store instructions in the T32 and A32 instruction sets. Some of these instructions can also operate on the PC. See also:

- [Load/store multiple instructions](#).
- [Synchronization and semaphores](#), for more information about the Load-Exclusive and Store-Exclusive instructions.
- [Load-Acquire, Store-Release](#), for more information about the Load-Acquire/Store-Release and Load-Acquire Exclusive/Store-Release Exclusive instructions.
- [Advanced SIMD and floating-point load/store instructions](#).

Load/store instructions have several options for addressing memory. For more information, see [Addressing modes](#).

Table C2-12 Load/store instructions

Data type	Load	Store	Unprivileged		Exclusive		Load-Acquire	Store-Release	Exclusive Load-Acquire	Store-Release
			Load	Store	Load	Store				
32-bit word	LDR	STR	LDRT	STRT	LDREX	STREX	LDA	STL	LDAEX	STLEX
16-bit halfword	-	STRH	-	STRHT	-	STREXH	LDAH	STLH	LDAEXH	STLEXH
16-bit unsigned halfword	LDRH	-	LDRHT	-	LDREXH	-	-	-	-	-
16-bit signed halfword	LDRSH	-	LDRSHT	-	-	-	-	-	-	-
8-bit byte	-	STRB	-	STRBT	-	STREXB	LDAB	STLB	LDAEXB	STLEXB
8-bit unsigned byte	LDRB	-	LDRBT	-	LDREXB	-	-	-	-	-
8-bit signed byte	LDRSB	-	LDRSBT	-	-	-	-	-	-	-
Two 32-bit words	LDRD	STRD	-	-	-	-	-	-	-	-
64-bit doubleword	-	-	-	-	LDREXD	STREXD	-	-	LDAEXD	STLEXD

C2.6.1 Loads to the PC

The LDR instruction can load a value into the PC. The value loaded is treated as an interworking address, as described by the `LoadWritePC()` pseudocode function in [Pseudocode description of operations on the AArch32 general-purpose registers and the PC](#).

C2.6.2 Halfword and byte loads and stores

Halfword and byte stores store the least significant halfword or byte from the register, to 16 or 8 bits of memory respectively. There is no distinction between signed and unsigned stores.

Halfword and byte loads load 16 or 8 bits from memory into the least significant halfword or byte of a register. Unsigned loads zero-extend the loaded value to 32 bits, and signed loads sign-extend the value to 32 bits.

C2.6.3 Load unprivileged and Store unprivileged

When executing at EL0, a Load unprivileged or Store unprivileged instruction operates in the same way as the corresponding ordinary load or store instruction. For example, an LDRT instruction executes in exactly the same way as the equivalent LDR instruction. When executed at PL1, Load unprivileged and Store unprivileged instructions behave as

they would if they were executed at EL0. For example, an `LDRT` instruction executes in exactly the way that the equivalent `LDR` instruction would execute at EL0. In particular, the instructions make unprivileged memory accesses.

The Load unprivileged and Store unprivileged instructions are **CONSTRAINED UNPREDICTABLE** if executed at EL2.

For more information about execution privilege, see [Access permissions for instruction execution](#).

C2.6.4 Load-Exclusive and Store-Exclusive

Load-Exclusive and Store-Exclusive instructions provide shared memory synchronization. For more information, see [Synchronization and semaphores](#).

C2.6.5 Load-Acquire and Store-Release

Load-Acquire and Store-Release instructions provide memory barriers. Load-Acquire Exclusive and Store-Release Exclusive instructions provide memory barriers with shared memory synchronization. For more information, see [Load-Acquire, Store-Release](#).

C2.6.6 Addressing modes

The address for a load or store is formed from two parts: a value from a base register, and an offset.

The base register can be any one of the general-purpose registers R0-R12, SP, or LR.

For loads, the base register can be the PC. This provides PC-relative addressing for position-independent code. Instructions marked (literal) in their title in [About the T32 and A32 Instruction Descriptions](#) are PC-relative loads.

The offset takes one of three formats:

- | | |
|------------------------|---|
| Immediate | The offset is an unsigned number that can be added to or subtracted from the base register value. Immediate offset addressing is useful for accessing data elements that are a fixed distance from the start of the data object, such as structure fields, stack offsets, and input/output registers. |
| Register | The offset is a value from a general-purpose register. The value can be added to, or subtracted from, the base register value. Register offsets are useful for accessing arrays or blocks of data. |
| Scaled register | The offset is a general-purpose register, shifted by an immediate value, then added to or subtracted from the base register. This means an array index can be scaled by the size of each array element. |

The offset and base register can be used in three different ways to form the memory address. The addressing modes are described as follows:

- | | |
|---------------------|--|
| Offset | The offset is added to or subtracted from the base register to form the memory address. |
| Pre-indexed | The offset is added to or subtracted from the base register to form the memory address. The base register is then updated with this new address, to permit automatic indexing through an array or memory block. |
| Post-indexed | The value of the base register alone is used as the memory address. The offset is then added to or subtracted from the base register. The result is stored back in the base register, to permit automatic indexing through an array or memory block. |

Note

Not every variant is available for every instruction, and the range of permitted immediate values and the options for scaled registers vary from instruction to instruction. See [About the T32 and A32 Instruction Descriptions](#) for full details for each instruction.

C2.7 Load/store multiple instructions

Load Multiple instructions load from memory a subset, or possibly all, of the general-purpose registers and the PC.

Store Multiple instructions store to memory a subset, or possibly all, of the general-purpose registers.

The memory locations are consecutive word-aligned words. The addresses used are obtained from a base register, and can be either above or below the value in the base register. The base register can optionally be updated by the total size of the data transferred.

[Table C2-13](#) summarizes the load/store multiple instructions in the T32 and A32 instruction sets.

Table C2-13 Load/store multiple instructions

Instruction	See
Load Multiple, Increment After or Full Descending	LDM, LDMIA, LDMFD
Load Multiple, Decrement After or Full Ascending ^a	LDMDA, LDMFA
Load Multiple, Decrement Before or Empty Ascending	LDMDB, LDMEA
Load Multiple, Increment Before or Empty Descending ^a	LDMIB, LDMED
Pop multiple registers off the stack ^b	POP
Push multiple registers onto the stack ^c	PUSH
Store Multiple, Increment After or Empty Ascending	STM, STMIA, STMEA
Store Multiple, Decrement After or Empty Descending ^a	STMDA, STMED
Store Multiple, Decrement Before or Full Descending	STMDB, STMFD
Store Multiple, Increment Before or Full Ascending ^a	STMIB, STMFA

a. Not available in the T32 instruction set.

b. This instruction is equivalent to an `LDM` instruction with the `SP` as base register, and base register updating.

c. This instruction is equivalent to an `STMDB` instruction with the `SP` as base register, and base register updating.

When executing at EL1, variants of the `LDM` and `STM` instructions load and store User mode registers. Another system level variant of the `LDM` instruction performs an exception return.

C2.7.1 Loads to the PC

The `LDM`, `LDMDA`, `LDMDB`, `LDMIB`, and `POP` instructions can load a value into the PC. The value loaded is treated as an interworking address, as described by the `LoadWritePC()` pseudocode function in [Pseudocode description of operations on the AArch32 general-purpose registers and the PC](#).

C2.8 Miscellaneous instructions

Table C2-14 summarizes the miscellaneous instructions in the T32 and A32 instruction sets.

Table C2-14 Miscellaneous instructions

Instruction	See
Clear-Exclusive	CLREX
Data Memory Barrier	DMB
Data Synchronization Barrier	DSB
Instruction Synchronization Barrier	ISB
If-Then	IT
No Operation	NOP
Preload Data	PLD, PLDW (immediate) PLD (literal) PLD, PLDW (register)
Preload Instruction	PLI (immediate, literal) PLI (register)
Set Endianness	SETEND ^a
Send Event	SEV
Send Event Local	SEVL
Wait For Event	WFE
Wait For Interrupt	WFI
Yield	YIELD ^b

a. Arm deprecates any use of the SETEND instruction.

b. See also [The Yield instruction](#).

———— Note ————

Previous versions of the architecture defined the DBG instruction, that could provide a hint to the debug system, in this group. From the introduction of Armv8, this instruction executes as a NOP. Arm deprecates any use of the DBG instruction.

C2.8.1 The Yield instruction

In a *Symmetric Multithreading* (SMT) design, a thread can use the YIELD instruction to give a hint to the PE that it is running on. The YIELD hint indicates that whatever the thread is currently doing is of low importance, and so could yield. For example, the thread might be sitting in a spin-lock. A similar use might be in modifying the arbitration priority of the snoop bus in a multiprocessor (MP) system. Defining such an instruction permits binary compatibility between SMT and SMP systems.

AArch32 state defines a YIELD instruction as a specific NOP (No Operation) hint instruction.

The YIELD instruction has no effect in a single-threaded system, but developers of such systems can use the instruction to flag its intended use on migration to a multiprocessor or multithreading system. Operating systems can use YIELD in places where a yield hint is wanted, knowing that it will be treated as a NOP if there is no implementation benefit.

C2.9 Exception-generating and exception-handling instructions

The following instructions are intended specifically to cause a synchronous exception to occur:

- The `SVC` instruction generates a Supervisor Call exception. For more information, see [Supervisor Call \(SVC\) exception](#).
- The Breakpoint instruction `BKPT` provides software breakpoints. For more information, see [Breakpoint Instruction exceptions](#).
- In an implementation that includes EL2 the `HVC` instruction generates a Hypervisor Call exception. For more information, see [Hypervisor Call \(HVC\) exception](#).

[Debug state](#) summarizes the Debug state instructions.

For an exception taken to an EL1 mode:

- The system level variants of the `SUBS` and `LDM` instructions can perform a return from an exception.

Note

The variants of `SUBS` include `MOVS`. See the references to [Subtract \(exception return\)](#), [Move \(exception return\)](#), and [Load Multiple \(exception return\)](#) in [Table C2-15](#) for more information.

- The `SRS` instruction can be used near the start of the handler, to store return information. The `RFE` instruction can then perform a return from the exception using the stored return information.

In an implementation that includes EL2, the `ERET` instruction performs a return from an exception taken to Hyp mode.

For more information, see [Exception return to an Exception level using AArch32](#).

[Table C2-15](#) summarizes the instructions, in the T32 and A32 instruction sets, for generating or handling an exception. Except for `BKPT` and `SVC`, these are system level instructions.

Table C2-15 Exception-generating and exception-handling instructions

Instruction	See
Supervisor Call	<code>SVC</code>
Breakpoint	<code>BKPT</code>
Return From Exception	<code>RFE</code> , <code>RFEDA</code> , <code>RFEDB</code> , <code>RFEIA</code> , <code>RFEIB</code>
Subtract (exception return) ^a	<code>SUB</code> , <code>SUBS</code> (immediate) ^a
Move (exception return) ^a	<code>MOV</code> , <code>MOVS</code> (register) ^a
Hypervisor Call	<code>HVC</code>
Exception Return	<code>ERET</code>
Load Multiple (exception return)	<code>LDM</code> (exception return)
Store Return State	<code>SRS</code> , <code>SRSDA</code> , <code>SRSDB</code> , <code>SRSIA</code> , <code>SRSIB</code>

a. The A32 instruction set includes other instruction forms that can be used for an exception return, that have previously been described as variants of `SUBS` `PC`, `LR`. Arm deprecates any use of these instruction forms.

C2.9.1 Debug state

[Table C2-16](#) shows the Debug state instructions that are implemented in the T32 instruction set:

Table C2-16 T32 Debug state instructions

Mnemonic	Instruction	See	Note
DCPS _n	Debug switch to EL _n	DCPS1 DCPS2	-
ERET	Debug restore PE state (DRPS)	ERET	When executed in Debug state, the T1 encoding of ERET performs the DRPS operation

C2.10 System register access instructions

The System register encoding space is indexed using the parameters {coproc, opc1, CRn, CRm, opc2}, see [The AArch32 System register interface](#). This encoding space provides System registers and System instructions. The only permitted values of coproc are 0b1110 and 0b1111, and the following instructions give access to this encoding space:

- Instructions that transfer data between general-purpose registers and System registers. See:
 - [MCR](#).
 - [MCRR](#).
 - [MRC](#).
 - [MRRC](#).
- Instructions that load or store from memory to a System register. See:
 - [LDC \(immediate\)](#).
 - [LDC \(literal\)](#).
 - [STC](#).

Note

The System register encoding space with coproc == 0b101x is redefined to provide some of the Advanced SIMD and floating-point functionality. That is, to:

- Initiate a floating-point data-processing operation, see [Floating-point data-processing instructions](#).
 - Transfer data between general-purpose registers and the Advanced SIMD and floating-point registers, see [Advanced SIMD and floating-point register transfer instructions](#).
 - Load or store data to the Advanced SIMD and floating-point registers, see [Advanced SIMD and floating-point load/store instructions](#).
-

System register access instructions are part of the instruction stream executed by the PE, and therefore any System register access instruction that cannot be executed by the implementation causes an Undefined Instruction exception. In the A-profile and the R-profile architectures, the instruction encodings in the System register access instruction encoding space are unallocated, and generate Undefined Instruction exceptions, except for:

- The instructions summarized in this section that access the coproc == 0b111x encoding space.
- The instructions in the coproc == 0b101x encoding space that are redefined to provide Advanced SIMD and floating-point functionality, as summarized in the Note in this section.

C2.11 Advanced SIMD and floating-point load/store instructions

Table C2-17 summarizes the SIMD and floating-point register file load/store instructions in the Advanced SIMD and floating-point instruction sets.

Advanced SIMD also provides instructions for loading and storing multiple elements, or structures of elements, see [Element and structure load/store instructions](#).

Table C2-17 SIMD and floating-point register file load/store instructions

Instruction	See	Operation
Vector Load Multiple	VLDM , VLDMDB , VLDMIA	Load 1-16 consecutive 64-bit registers, Advanced SIMD and floating-point. Load 1-32 consecutive 32-bit registers, floating-point only.
Vector Load Register	VLDR (immediate) VLDR (literal)	Load one 64-bit register, Advanced SIMD and floating-point. Load one 32-bit register, floating-point only.
Vector Store Multiple	VSTM , VSTMDB , VSTMIA	Store 1-16 consecutive 64-bit registers, Advanced SIMD and floating-point. Store 1-32 consecutive 32-bit registers, floating-point only.
Vector Store Register	VSTR	Store one 64-bit register, Advanced SIMD and floating-point. Store one 32-bit register, floating-point only.

C2.11.1 Element and structure load/store instructions

Table C2-18 shows the element and structure load/store instructions available in the Advanced SIMD instruction set. Loading and storing structures of more than one element automatically de-interleaves or interleaves the elements, see [Figure C2-1](#) for an example of de-interleaving. Interleaving is the inverse process.

Table C2-18 Element and structure load/store instructions

Instruction	See
Load single element	
Multiple elements	VLD1 (multiple single elements)
To one lane	VLD1 (single element to one lane)
To all lanes	VLD1 (single element to all lanes)
Load 2-element structure	
Multiple structures	VLD2 (multiple 2-element structures)
To one lane	VLD2 (single 2-element structure to one lane)
To all lanes	VLD2 (single 2-element structure to all lanes)
Load 3-element structure	
Multiple structures	VLD3 (multiple 3-element structures)
To one lane	VLD3 (single 3-element structure to one lane)
To all lanes	VLD3 (single 3-element structure to all lanes)

Instruction	See
Load 4-element structure	
Multiple structures	VLD4 (multiple 4-element structures)
To one lane	VLD4 (single 4-element structure to one lane)
To all lanes	VLD4 (single 4-element structure to all lanes)
Store single element	
Multiple elements	VST1 (multiple single elements)
From one lane	VST1 (single element from one lane)
Store 2-element structure	
Multiple structures	VST2 (multiple 2-element structures)
From one lane	VST2 (single 2-element structure from one lane)
Store 3-element structure	
Multiple structures	VST3 (multiple 3-element structures)
From one lane	VST3 (single 3-element structure from one lane)
Store 4-element structure	
Multiple structures	VST4 (multiple 4-element structures)
From one lane	VST4 (single 4-element structure from one lane)

Figure C2-1 shows the de-interleaving of a VLD3 . 16 (multiple 3-element structures) instruction:

Figure C2-1 De-interleaving an array of 3-element structures

Figure C2-1 shows the VLD3 . 16 instruction operating to three 64-bit registers that comprise four 16-bit elements:

- Different instructions in this group would produce similar figures, but operate on different numbers of registers. For example, VLD4 and VST4 instructions operate on four registers.
- Different element sizes would produce similar figures but with 8-bit or 32-bit elements.
- These instructions operate only on doubleword (64-bit) registers.

C2.12 Advanced SIMD and floating-point register transfer instructions

[Table C2-19](#) summarizes the SIMD and floating-point register file transfer instructions in the Advanced SIMD and floating-point instruction sets. These instructions transfer data between the general-purpose registers and the registers in the SIMD and floating-point register file.

Advanced SIMD vectors, and single-precision and double-precision floating-point registers, are all views of the same register file. For details, see [The SIMD and floating-point register file](#).

Table C2-19 SIMD and floating-point register file transfer instructions

Instruction	See
Copy element from general-purpose register to every element of an Advanced SIMD vector	VDUP (general-purpose register)
Copy byte, halfword, or word from general-purpose register to a register in the SIMD and floating-point register file	VMOV (general-purpose register to scalar)
Copy byte, halfword, or word from a register in the SIMD and floating-point register file to a general-purpose register	VMOV (scalar to general-purpose register)
Copy from single-precision floating-point register to general-purpose register, or from general-purpose register to single-precision floating-point register	VMOV (between general-purpose register and single-precision)
Copy two words from general-purpose registers to consecutive single-precision floating-point registers, or from consecutive single-precision floating-point registers to general-purpose registers	VMOV (between two general-purpose registers and two single-precision registers)
Copy two words from general-purpose registers to a doubleword register in the SIMD and floating-point register file, or from a doubleword register in the SIMD and floating-point register file to general-purpose registers	VMOV (between two general-purpose registers and a doubleword floating-point register)
Copy from an Advanced SIMD and floating-point System Register to a general-purpose register	VMRS
Copy from a general-purpose register to an Advanced SIMD and floating-point System Register	VMSR

C2.13 Advanced SIMD data-processing instructions

Advanced SIMD data-processing instructions process registers containing vectors of elements of the same type packed together, enabling the same operation to be performed on multiple items in parallel.

Instructions operate on vectors held in 64-bit or 128-bit registers. [Figure C2-2](#) shows an operation on two 64-bit operand vectors, generating a 64-bit vector result.

Note

[Figure C2-2](#) and other similar figures show 64-bit vectors that consist of four 16-bit elements, and 128-bit vectors that consist of four 32-bit elements. Other element sizes produce similar figures, but with 1, 2, 8, or 16 operations performed in parallel instead of 4.

Figure C2-2 Advanced SIMD instruction operating on 64-bit registers

Many Advanced SIMD instructions have variants that produce vectors of elements double the size of the inputs. In this case, the number of elements in the result vector is the same as the number of elements in the operand vectors, but each element, and the whole vector, is double the size.

[Figure C2-3](#) shows an example of an Advanced SIMD instruction operating on 64-bit registers, and generating a 128-bit result.

Figure C2-3 Advanced SIMD instruction producing wider result

There are also Advanced SIMD instructions that have variants that produce vectors containing elements half the size of the inputs. [Figure C2-4](#) shows an example of an Advanced SIMD instruction operating on one 128-bit register, and generating a 64-bit result.

Figure C2-4 Advanced SIMD instruction producing narrower result

Some Advanced SIMD instructions do not conform to these standard patterns. Their operation patterns are described in the individual instruction descriptions.

Advanced SIMD instructions that perform floating-point arithmetic use the Arm standard floating-point arithmetic defined in [Floating-point support](#).

The following sections summarize the Advanced SIMD data-processing instructions:

- [Advanced SIMD parallel addition and subtraction](#).
- [Bitwise Advanced SIMD data-processing instructions](#).
- [Advanced SIMD comparison instructions](#).
- [Advanced SIMD shift instructions](#).
- [Advanced SIMD multiply instructions](#).
- [Miscellaneous Advanced SIMD data-processing instructions](#).
- [The Cryptographic Extension in AArch32 state](#).

C2.13.1 Advanced SIMD parallel addition and subtraction

Table C2-20 shows the Advanced SIMD parallel add and subtract instructions.

Table C2-20 Advanced SIMD parallel add and subtract instructions

Vector Shift Left Long	VSHLL
Vector Shift Right	VSHR
Vector Shift Right and Narrow	VSHRN
Vector Shift Left and Insert	VSLI
Vector Shift Right and Accumulate	VSRA
Vector Shift Right and Insert	VSRI

C2.13.5 Advanced SIMD multiply instructions

Table C2-24 shows the Advanced SIMD multiply instructions.

Table C2-24 Advanced SIMD multiply instructions

Instruction	See
Vector Multiply Accumulate	VMLA (integer) VMLA (floating-point) VMLA (by scalar)
Vector Multiply Accumulate Long	VMLAL (integer) VMLAL (by scalar)
Vector Multiply Subtract	VMLS (integer) VMLS (floating-point) VMLS (by scalar)
Vector Multiply Subtract Long	VMLSL (integer) VMLSL (by scalar)
Vector Multiply	VMUL (integer and polynomial) VMUL (floating-point) VMUL (by scalar)
Vector Multiply Long	VMULL (integer and polynomial) VMULL (by scalar)
Vector Fused Multiply Accumulate	VFMA
Vector Fused Multiply Subtract	VFMS
Vector Saturating Doubling Multiply Accumulate Long	VQDMLAL
Vector Saturating Doubling Multiply Subtract Long	VQDMLSL
Vector Saturating Doubling Multiply Returning High Half	VQDMULH
Vector Saturating Doubling Multiply Long	VQDMULL
Vector Saturating Rounding Doubling Multiply Returning High Half	VQRDMULH

Advanced SIMD multiply instructions can operate on vectors of:

- 8-bit, 16-bit, or 32-bit unsigned integers.
- 8-bit, 16-bit, or 32-bit signed integers.
- 8-bit polynomials over $\{0, 1\}$. VMUL and VMULL are the only instructions that operate on polynomials. VMULL produces a 16-bit polynomial over $\{0, 1\}$.
- Single-precision (32-bit) floating-point numbers.

They can also act on one vector and one scalar.

Long instructions have doubleword (64-bit) operands, and produce quadword (128-bit) results. Other Advanced SIMD multiply instructions can have either doubleword or quadword operands, and produce results of the same size.

Floating-point multiply instructions can operate on:

- Single-precision (32-bit) floating-point numbers.
- Double-precision (64-bit) floating-point numbers.

C2.13.6 Miscellaneous Advanced SIMD data-processing instructions

Table C2-25 shows miscellaneous Advanced SIMD data-processing instructions.

Chapter C3

T32 Instruction Set Encoding

This chapter describes the encoding of the T32 instruction set. It contains the following sections:

- [T32 instruction set encoding](#)
- [About the T32 Advanced SIMD and floating-point instructions and their encoding](#)

In this chapter:

- In the decode tables, an entry of $\times$ for a field value means the value of the field does not affect the decoding.
- In the decode diagrams, a shaded field indicates that the bits in that field are not used in that level of decode.

C3.1 T32 instruction set encoding

The T32 instruction stream is a sequence of halfword-aligned halfwords. Each T32 instruction is either a single 16-bit halfword in that stream, or a 32-bit instruction consisting of two consecutive halfwords in that stream.

If the value of bits[15:11] of the halfword being decoded is one of the following, the halfword is the first halfword of a 32-bit instruction:

- 0b11101.
- 0b11110.
- 0b11111.

Otherwise, the halfword is a 16-bit instruction.

The T32 instruction encoding is:

Table C3-1 Main encoding table for the T32 instruction set

Decode fields		Decode group or instruction page
op0	op1	
!= 111	xx	16-bit
111	00	B - T2 variant
111	!= 00	32-bit

C3.1.1 16-bit

This section describes the encoding of the 16-bit group. The encodings in this section are decoded from [T32 instruction set encoding](#).

This decode also imposes the constraint:

- op0<5:3> != 111.

Table C3-2 Encoding table for the 16-bit group

Decode fields	Decode group or instruction page
op0	
00xxxx	Shift (immediate), add, subtract, move, and compare
010000	Data-processing (two low registers)
010001	Special data instructions and branch and exchange
01001x	LDR (literal) - T1 variant
0101xx	Load/store (register offset)
011xxx	Load/store word/byte (immediate offset)
1000xx	Load/store halfword (immediate offset)
1001xx	Load/store (SP-relative)
1010xx	Add PC/SP (immediate)
1011xx	Miscellaneous 16-bit instructions
1100xx	Load/store multiple
1101xx	Conditional branch, and Supervisor Call

C3.1.1.1 Data-processing (two low registers)

This section describes the encoding of the Data-processing (two low registers) instruction class. The encodings in this section are decoded from 16-bit.

Table C3-3

Decode fields	Instruction page
op	
0000	AND, ANDS (register)
0001	EOR, EORS (register)
0010	MOV, MOVS (register-shifted register) - Logical shift left variant
0011	MOV, MOVS (register-shifted register) - Logical shift right variant
0100	MOV, MOVS (register-shifted register) - Arithmetic shift right variant
0101	ADC, ADCS (register)
0110	SBC, SBCS (register)
0111	MOV, MOVS (register-shifted register) - Rotate right variant
1000	TST (register)
1001	RSB, RSBS (immediate)

Decode fields	Instruction page
op	
1010	CMP (register)
1011	CMN (register)
1100	ORR, ORRS (register)
1101	MUL, MULS
1110	BIC, BICS (register)
1111	MVN, MVNS (register)

C3.1.1.2 Load/store (register offset)

This section describes the encoding of the Load/store (register offset) instruction class. The encodings in this section are decoded from 16-bit.

Table C3-4

Decode fields			Instruction page
L	B	H	
0	0	0	STR (register)
0	0	1	STRH (register)
0	1	0	STRB (register)
0	1	1	LDRSB (register)
1	0	0	LDR (register)
1	0	1	LDRH (register)
1	1	0	LDRB (register)
1	1	1	LDRSH (register)

C3.1.1.3 Load/store word/byte (immediate offset)

This section describes the encoding of the Load/store word/byte (immediate offset) instruction class. The encodings in this section are decoded from 16-bit.

Table C3-5

Decode fields		Instruction page
B	L	
0	0	STR (immediate)
0	1	LDR (immediate)
1	0	STRB (immediate)
1	1	LDRB (immediate)

C3.1.1.4 Load/store halfword (immediate offset)

This section describes the encoding of the Load/store halfword (immediate offset) instruction class. The encodings in this section are decoded from 16-bit.

15	14	13	12	11	10		6	5		3	2	0
1	0	0	0	L		imm5			Rn			Rt

Table C3-6

Decode fields	Instruction page
L	
0	STRH (immediate)
1	LDRH (immediate)

C3.1.1.5 Load/store (SP-relative)

This section describes the encoding of the Load/store (SP-relative) instruction class. The encodings in this section are decoded from 16-bit.

15	14	13	12	11	10	8	7				0
1	0	0	1	L		Rt				imm8	

Table C3-7

Decode fields	Instruction page
L	
0	STR (immediate)
1	LDR (immediate)

C3.1.1.6 Add PC/SP (immediate)

This section describes the encoding of the Add PC/SP (immediate) instruction class. The encodings in this section are decoded from 16-bit.

Table C3-8

Decode fields	Instruction page
SP	
0	ADR
1	ADD, ADDS (SP plus immediate)

C3.1.1.7 Load/store multiple

This section describes the encoding of the Load/store multiple instruction class. The encodings in this section are decoded from 16-bit.

Table C3-9

Decode fields	Instruction page
L	
0	STM, STMIA, STMEA
1	LDM, LDMIA, LDMFD

C3.1.2 Shift (immediate), add, subtract, move, and compare

This section describes the encoding of the Shift (immediate), add, subtract, move, and compare group. The encodings in this section are decoded from 16-bit.

Table C3-10 Encoding table for the Shift (immediate), add, subtract, move, and compare group

Decode fields			Decode group or instruction page
op0	op1	op2	
0	11	0	Add, subtract (three low registers)
0	11	1	Add, subtract (two low registers and immediate)
0	!= 11	x	MOV, MOVS (register) - T2 variant
1	xx	x	Add, subtract, compare, move (one low register and immediate)

C3.1.2.1 Add, subtract (three low registers)

This section describes the encoding of the Add, subtract (three low registers) instruction class. The encodings in this section are decoded from Shift (immediate), add, subtract, move, and compare.

Table C3-11

Decode fields	Instruction page
S	
0	ADD, ADDS (register)
1	SUB, SUBS (register)

C3.1.2.2 Add, subtract (two low registers and immediate)

This section describes the encoding of the Add, subtract (two low registers and immediate) instruction class. The encodings in this section are decoded from Shift (immediate), add, subtract, move, and compare.

Table C3-12

Decode fields	Instruction page
S	
0	ADD, ADDS (immediate)
1	SUB, SUBS (immediate)

C3.1.2.3 Add, subtract, compare, move (one low register and immediate)

This section describes the encoding of the Add, subtract, compare, move (one low register and immediate) instruction class. The encodings in this section are decoded from [Shift \(immediate\)](#), [add](#), [subtract](#), [move](#), and [compare](#).

Table C3-13

Decode fields	Instruction page
op	
00	MOV, MOVS (immediate)
01	CMP (immediate)
10	ADD, ADDS (immediate)
11	SUB, SUBS (immediate)

C3.1.3 Special data instructions and branch and exchange

This section describes the encoding of the Special data instructions and branch and exchange group. The encodings in this section are decoded from [16-bit](#).

Table C3-14 Encoding table for the Special data instructions and branch and exchange group

Decode fields	Decode group or instruction page
op0	
11	Branch and exchange
!= 11	Add, subtract, compare, move (two high registers)

C3.1.3.1 Branch and exchange

This section describes the encoding of the Branch and exchange instruction class. The encodings in this section are decoded from Special data instructions and branch and exchange.

Table C3-15

Decode fields	Instruction page
L	
0	BX
1	BLX (register)

C3.1.3.2 Add, subtract, compare, move (two high registers)

This section describes the encoding of the Add, subtract, compare, move (two high registers) instruction class. The encodings in this section are decoded from Special data instructions and branch and exchange.

Table C3-16

Decode fields			Instruction page
op	D:Rd	Rs	
00	!= 1101	!= 1101	ADD, ADDS (register)
00	xxxx	1101	ADD, ADDS (SP plus register) - T1
00	1101	!= 1101	ADD, ADDS (SP plus register) - T2
01	xxxx	xxxx	CMP (register)
10	xxxx	xxxx	MOV, MOVS (register)

C3.1.4 Miscellaneous 16-bit instructions

This section describes the encoding of the Miscellaneous 16-bit instructions group. The encodings in this section are decoded from [16-bit](#).

Table C3-17 Encoding table for the Miscellaneous 16-bit instructions group

Decode fields				Decode group or instruction page
op0	op1	op2	op3	
0000	xx	x	xxxx	Adjust SP (immediate)
0010	xx	x	xxxx	Extend
0110	! =01	x	xxxx	Unallocated.
0110	01	x	xxxx	Change Processor State
1010	10	x	xxxx	HLT
1010	!= 10	x	xxxx	Reverse bytes
1110	xx	x	xxxx	BKPT
1111	xx	x	0000	Hints
1111	xx	x	!= 0000	IT
x0x1	xx	x	xxxx	CBNZ, CBZ
x10x	xx	x	xxxx	Push and Pop

C3.1.4.1 Adjust SP (immediate)

This section describes the encoding of the Adjust SP (immediate) instruction class. The encodings in this section are decoded from [Miscellaneous 16-bit instructions](#).

Table C3-18

Decode fields	Instruction page
S	
0	ADD, ADDS (SP plus immediate)
1	SUB, SUBS (SP minus immediate)

C3.1.4.2 Extend

This section describes the encoding of the Extend instruction class. The encodings in this section are decoded from [Miscellaneous 16-bit instructions](#).

Table C3-19

Decode fields		Instruction page
U	B	
0	0	SXTH
0	1	SXTB
1	0	UXTH
1	1	UXTB

C3.1.4.3 Change Processor State

This section describes the encoding of the Change Processor State instruction class. The encodings in this section are decoded from [Miscellaneous 16-bit instructions](#).

Table C3-20

Decode fields		Instruction page
op	flags	
0	xxxxx	SETEND
1	0xxxx	CPS, CPSID, CPSIE - Interrupt enable variant
1	1xxxx	CPS, CPSID, CPSIE - Interrupt disable variant

C3.1.4.4 Reverse bytes

This section describes the encoding of the Reverse bytes instruction class. The encodings in this section are decoded from Miscellaneous 16-bit instructions.

Table C3-21

Decode fields		Instruction page
op		
00		REV
01		REV16
11		REVSH

C3.1.4.5 Hints

This section describes the encoding of the Hints instruction class. The encodings in this section are decoded from Miscellaneous 16-bit instructions.

Table C3-22

Decode fields	Instruction page
hint	
0000	NOP
0001	YIELD
0010	WFE
0011	WFI
0100	SEV
0101	SEVL
011x	Reserved hint, behaves as NOP.
1xxx	Reserved hint, behaves as NOP.

C3.1.4.6 Push and Pop

This section describes the encoding of the Push and Pop instruction class. The encodings in this section are decoded from [Miscellaneous 16-bit instructions](#).

Table C3-23

Decode fields	Instruction page
L	
0	PUSH
1	POP

C3.1.5 Conditional branch, and Supervisor Call

This section describes the encoding of the Conditional branch, and Supervisor Call group. The encodings in this section are decoded from [16-bit](#).

Table C3-24 Encoding table for the Conditional branch, and Supervisor Call group

Decode fields	Decode group or instruction page
op0	
111x	Exception generation
!= 111x	B - T1 variant

C3.1.5.1 Exception generation

This section describes the encoding of the Exception generation instruction class. The encodings in this section are decoded from Conditional branch, and Supervisor Call.

Table C3-25

Decode fields	Instruction page
S	
0	UDF
1	SVC

C3.1.6 32-bit

This section describes the encoding of the 32-bit group. The encodings in this section are decoded from T32 instruction set encoding.

This decode also imposes the constraint:

- op0<3:2> != 00.

Table C3-26 Encoding table for the 32-bit group

Decode fields			Decode group or instruction page
op0	op1	op3	
x11x	xxxxx	x	System register access, Advanced SIMD, and floating-point
0100	xx0xx	x	Load/store multiple
0100	xx1xx	x	Load/store dual, load/store exclusive, load-acquire/store-release, and table branch
0101	xxxxx	x	Data-processing (shifted register)
10xx	xxxxx	1	Branches and miscellaneous control
10x0	xxxxx	0	Data-processing (modified immediate)
10x1	xxxx0	0	Data-processing (plain binary immediate)
10x1	xxxx1	0	Unallocated.
1100	1xxx0	x	Advanced SIMD element or structure load/store
1100	!= 1xxx0	x	Load/store single
1101	0xxxx	x	Data-processing (register)
1101	10xxx	x	Multiply, multiply accumulate, and absolute difference
1101	11xxx	x	Long multiply and divide

C3.1.6.1 Load/store multiple

This section describes the encoding of the Load/store multiple instruction class. The encodings in this section are decoded from 32-bit.

C3.1.7 System register access, Advanced SIMD, and floating-point

This section describes the encoding of the System register access, Advanced SIMD, and floating-point group. The encodings in this section are decoded from 32-bit.

Table C3-31 Encoding table for the System register access, Advanced SIMD, and floating-point group

Decode fields				Decode group or instruction page
op0	op1	op2	op3	
x	0x	0x	x	Unallocated.
x	10	0x	x	Unallocated.
x	11	xx	x	Advanced SIMD data-processing
0	0x	1x	x	Advanced SIMD and System register load/store and 64-bit move
0	10	1x	1	Advanced SIMD and System register 32-bit move
0	10	10	0	Floating-point data-processing
0	10	11	0	Unallocated.
1	!= 11	1x	x	Additional Advanced SIMD and floating-point instructions

C3.1.8 Advanced SIMD data-processing

This section describes the encoding of the Advanced SIMD data-processing group. The encodings in this section are decoded from [System register access, Advanced SIMD, and floating-point](#).

This group has encodings in both the T32 and A32 instruction sets. For information about mappings between the encodings of this group, see [About the T32 Advanced SIMD and floating-point instructions and their encoding](#)

Table C3-32 Encoding table for the Advanced SIMD data-processing group

Decode fields		Decode group or instruction page

C3.1.11 Advanced SIMD and System register load/store and 64-bit move

This section describes the encoding of the Advanced SIMD and System register load/store and 64-bit move group. The encodings in this section are decoded from [System register access](#), [Advanced SIMD](#), and [floating-point](#).

This group has encodings in both the T32 and A32 instruction sets. For information about mappings between the encodings of this group, see [About the T32 Advanced SIMD and floating-point instructions and their encoding](#)

Table C3-43

Decode fields					Instruction page
D	op	size	opc2	o3	
0	x	xx	xx	x	Unallocated.
1	x	xx	xx	0	Unallocated.
1	x	0x	00	1	Unallocated.
1	x	xx	01	x	Unallocated.
1	0	10	00	1	VMOV (between two general-purpose registers and two single-precision registers) - From general-purpose registers variant
1	0	11	00	1	VMOV (between two general-purpose registers and a doubleword floating-point register) - From general-purpose registers variant
1	x	xx	1x	x	Unallocated.
1	1	10	00	1	VMOV (between two general-purpose registers and two single-precision registers) - To general-purpose registers variant
1	1	11	00	1	VMOV (between two general-purpose registers and a doubleword floating-point register) - To general-purpose registers variant

C3.1.11.2 System register 64-bit move

This section describes the encoding of the System register 64-bit move instruction class. The encodings in this section are decoded from [Advanced SIMD and System register load/store and 64-bit move](#).

Table C3-44

Decode fields		Instruction page
D	L	
0	x	Unallocated.
1	0	MCRR
1	1	MRRC

C3.1.11.3 Advanced SIMD and floating-point load/store

This section describes the encoding of the Advanced SIMD and floating-point load/store instruction class. The encodings in this section are decoded from Advanced SIMD and System register load/store and 64-bit move.

Table C3-45

Decode fields							Instruction page
P	U	W	L	Rn	size	imm8	
0	0	1	x	xxxx	xx	xxxxxxxx	Unallocated.
x	1	x	x	xxxx	0x	xxxxxxxx	Unallocated.
0	1	x	0	xxxx	10	xxxxxxxx	VSTM, VSTMDB, VSTMIA - Increment After variant
0	1	x	0	xxxx	11	xxxxxxxx0	VSTM, VSTMDB, VSTMIA - Increment After variant
0	1	x	0	xxxx	11	xxxxxxxx1	FSTMDBX, FSTMIAX - Increment After variant
0	1	x	1	xxxx	10	xxxxxxxx	VLDM, VLDMDB, VLDMIA - Increment After variant
0	1	x	1	xxxx	11	xxxxxxxx0	VLDM, VLDMDB, VLDMIA - Increment After variant
0	1	x	1	xxxx	11	xxxxxxxx1	FLDM*X (FLDMDBX, FLDMIAX) - Increment After variant
1	x	0	0	xxxx	10	xxxxxxxx	VSTR - Single-precision scalar variant

Decode fields						Instruction page	
P	U	W	L	Rn	size	imm8	
1	x	0	0	xxxx	11	xxxxxxxx	VSTR - Double-precision scalar variant
1	x	0	1	!= 1111	01	xxxxxxxx	VLDR (immediate) - Half-precision scalar variant
1	x	0	1	!= 1111	10	xxxxxxxx	VLDR (immediate) - Single-precision scalar variant

xxx	10x	Unallocated.
xxx	11x	System register 32-bit move

C3.1.12.1 Floating-point move special register

This section describes the encoding of the Floating-point move special register instruction class. The encodings in this section are decoded from [Advanced SIMD and System register 32-bit move](#).

Table C3-48

Decode fields	Instruction page
L	
0	VMSR
1	VMRS

C3.1.12.2 Advanced SIMD 8/16/32-bit element move/duplicate

This section describes the encoding of the Advanced SIMD 8/16/32-bit element move/duplicate instruction class. The encodings in this section are decoded from [Advanced SIMD and System register 32-bit move](#).

Table C3-49

Decode fields			Instruction page
opc1	L	opc2	
0xx	0	xx	VMOV (general-purpose register to scalar)
xxx	1	xx	VMOV (scalar to general-purpose register)
1xx	0	0x	VDUP (general-purpose register)
1xx	0	1x	Unallocated.

C3.1.12.3 System register 32-bit move

This section describes the encoding of the System register 32-bit move instruction class. The encodings in this section are decoded from [Advanced SIMD and System register 32-bit move](#).

Table C3-50

Decode fields	Instruction page
L	
0	MCR
1	MRC

C3.1.13 Floating-point data-processing

This section describes the encoding of the Floating-point data-processing group. The encodings in this section are decoded from System register access, Advanced SIMD, and floating-point.
This group has encodings in both the T32 and A32 instruction sets. For information about mappings between the encodings of this group, see About the T32 Advanced SIMD and floating-point instructions and their encoding

Table C3-51 Encoding table for the Floating-point data-processing group

Decode fields	Decode group or instruction page
op0	op1
1x11	1 Floating-point data-processing (two registers)
1x11	0 Floating-point move immediate
!= 1x11	x Floating-point data-processing (three registers)

C3.1.13.1 Floating-point data-processing (two registers)

This section describes the encoding of the Floating-point data-processing (two registers) instruction class. The encodings in this section are decoded from Floating-point data-processing.

110	11	0	VFMA - Double-precision scalar variant
110	11	1	VFMS - Double-precision scalar variant

C3.1.14 Additional Advanced SIMD and floating-point instructions

This section describes the encoding of the Additional Advanced SIMD and floating-point instructions group. The encodings in this section are decoded from [System register access, Advanced SIMD, and floating-point](#).

This decode also imposes the constraint:

- $op0<2:1> \neq 11$.

Table C3-55 Encoding table for the Additional Advanced SIMD and floating-point instructions group

Decode fields						Decode group or instruction page
op0	op1	op2	op3	op4	op5	
0xx	xxxxxxx	x	0x	x	x	Unallocated.
100	xxxxxxx	0	!= 00	0	0	Floating-point conditional select
101	00xxxxx	0	!= 00	x	0	Floating-point minNum/maxNum
101	110000	0	!= 00	1	0	Unallocated.
101	111xxx	0	!= 00	1	0	Floating-point directed convert to integer
10x	xxxxxxx	0	0x	x	x	Unallocated.

C3.1.14.1 Floating-point conditional select

This section describes the encoding of the Floating-point conditional select instruction class. The encodings in this section are decoded from [Additional Advanced SIMD and floating-point instructions](#).

Table C3-56

Decode fields size	Instruction page
01	Unallocated.
10	VSELEQ, VSELGE, VSELGT, VSELVS - Greater than, single-precision scalar variant
11	VSELEQ, VSELGE, VSELGT, VSELVS - Greater than, double-precision scalar variant

C3.1.14.2 Floating-point minNum/maxNum

This section describes the encoding of the Floating-point minNum/maxNum instruction class. The encodings in this section are decoded from [Additional Advanced SIMD and floating-point instructions](#).

Table C3-57

Decode fields size	op	Instruction page
01	0	Unallocated.
10	0	VMAXNM - Single-precision scalar variant
10	1	VMINNM - Single-precision scalar variant
11	0	VMAXNM - Double-precision scalar variant
11	1	VMINNM - Double-precision scalar variant

C3.1.14.3 Floating-point directed convert to integer

This section describes the encoding of the Floating-point directed convert to integer instruction class. The encodings in this section are decoded from [Additional Advanced SIMD and floating-point instructions](#).

Table C3-58

Decode fields				Instruction page
o1	RM	size	op	
0	xx	!= 00	1	Unallocated.
0	xx	01	0	Unallocated.
0	00	10	0	VRINTA (floating-point) - Single-precision scalar variant
0	00	11	0	VRINTA (floating-point) - Double-precision scalar variant
0	01	10	0	VRINTN (floating-point) - Single-precision scalar variant
0	01	11	0	VRINTN (floating-point) - Double-precision scalar variant
0	10	10	0	VRINTP (floating-point) - Single-precision scalar variant
0	10	11	0	VRINTP (floating-point) - Double-precision scalar variant
0	11	10	0	VRINTM (floating-point) - Single-precision scalar variant
0	11	11	0	VRINTM (floating-point) - Double-precision scalar variant
1	00	10	x	VCVTA (floating-point) - Single-precision scalar variant
1	00	11	x	VCVTA (floating-point) - Double-precision scalar variant
1	01	10	x	VCVTN (floating-point) - Single-precision scalar variant
1	01	11	x	VCVTN (floating-point) - Double-precision scalar variant
1	10	10	x	VCVTP (floating-point) - Single-precision scalar variant
1	10	11	x	VCVTP (floating-point) - Double-precision scalar variant
1	11	10	x	VCVTM (floating-point) - Single-precision scalar variant
1	11	11	x	VCVTM (floating-point) - Double-precision scalar variant

C3.1.15 Load/store dual, load/store exclusive, load-acquire/store-release, and table branch

This section describes the encoding of the Load/store dual, load/store exclusive, load-acquire/store-release, and table branch group. The encodings in this section are decoded from 32-bit.

This decode also imposes the constraint:

- op0<1> == 1.

Table C3-59 Encoding table for the Load/store dual, load/store exclusive, load-acquire/store-release, and table branch group

Decode fields				Decode group or instruction page
op0	op1	op2	op3	
0010	x	xxxx	xxx	Load/store exclusive
0110	0	xxxx	000	Unallocated.
0110	1	xxxx	000	TBB, TBH

C3.1.16 Branches and miscellaneous control

This section describes the encoding of the Branches and miscellaneous control group. The encodings in this section are decoded from 32-bit.

Table C3-66 Encoding table for the Branches and miscellaneous control group

Decode fields						Decode group or instruction page
op0	op1	op2	op3	op4	op5	
0	1110	0x	0x0	xxx	0	MSR (register)
0	1110	0x	0x0	xxx	1	MSR (Banked register)

Decode fields						Decode group or instruction page
op0	op1	op2	op3	op4	op5	
0	1110	10	0x0	000	x	Hints
0	1110	10	0x0	!= 000	x	Change processor state
0	1110	11	0x0	xxx	x	Miscellaneous system
0	1111	00	0x0	xxx	x	BXJ
0	1111	01	0x0	xxx	x	Exception return
0	1111	1x	0x0	xxx	0	MRS
0	1111	1x	0x0	xxx	1	MRS (Banked register)
1	1110	00	000	xxx	x	DCPS
1	1110	00	010	xxx	x	Unallocated.
1	1110	!= 00	0x0	xxx	x	Unallocated.
1	1111	0x	0x0	xxx	x	Unallocated.
1	1111	1x	0x0	xxx	x	Exception generation
x	!= 111x	x	0x0	xxx	x	B - T3 variant
x	xxxx	x	0x1	xxx	x	B - T4 variant
x	xxxx	x	1x0	xxx	x	BL, BLX (immediate) - T2 variant
x	xxxx	x	1x1	xxx	x	BL, BLX (immediate) - T1 variant

C3.1.16.1 Hints

This section describes the encoding of the Hints instruction class. The encodings in this section are decoded from [Branches and miscellaneous control](#).

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7		4	3		0
1	1	1	1	0	0	1	1	1	0	1	0	(1)	(1)	(1)	(1)	1	0	(0)	0	(0)	0	0	0		hint		option		

Table C3-67

Decode fields		Instruction page
hint	option	
x100	xxxx	Reserved hint, behaves as NOP.
x101	xxxx	Reserved hint, behaves as NOP.
0x1x	xxxx	Reserved hint, behaves as NOP.
0000	0000	NOP
0000	0001	YIELD
0000	0010	WFE
0000	0011	WFI

Decode fields		Instruction page
hint	option	
0000	0100	SEV
0000	0101	SEVL
0000	011x	Reserved hint, behaves as NOP.
0000	1xxx	Reserved hint, behaves as NOP.
0001	xxxx	Reserved hint, behaves as NOP.
10xx	xxxx	Reserved hint, behaves as NOP.
1110	xxxx	Reserved hint, behaves as NOP.
1111	xxxx	DBG

C3.1.16.2 Change processor state

This section describes the encoding of the Change processor state instruction class. The encodings in this section are decoded from [Branches and miscellaneous control](#).

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	0
1	1	1	1	0	0	1	1	1	0	1	0	(1)	(1)	(1)	(1)	1	0	(0)	0	(0)	imod	M	A	I	F	mode		

Table C3-68

Decode fields		Instruction page
imod	M	
00	1	CPS, CPSID, CPSIE - Change mode variant
01	x	Unallocated.
10	x	CPS, CPSID, CPSIE - Interrupt enable and change mode variant
11	x	CPS, CPSID, CPSIE - Interrupt disable and change mode variant

C3.1.16.3 Miscellaneous system

This section describes the encoding of the Miscellaneous system instruction class. The encodings in this section are decoded from [Branches and miscellaneous control](#).

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7		4	3		0
1	1	1	1	0	0	1	1	1	0	1	1	(1)	(1)	(1)	(1)	1	0	(0)	0	(1)	(1)	(1)	(1)	opc		option			

Table C3-69

Decode fields		Instruction page
opc	option	
000x	xxxx	Unallocated.
0010	xxxx	CLREX
0011	xxxx	Unallocated.
0100	!= 0x00	DSB
0100	0000	Unallocated.
0100	0100	Unallocated.
0101	xxxx	DMB
0110	xxxx	ISB
0111	xxxx	Unallocated.
1xxx	xxxx	Unallocated.

C3.1.16.4 Exception return

This section describes the encoding of the Exception return instruction class. The encodings in this section are decoded from [Branches and miscellaneous control](#).

15 14 13 12 11 10 9 8 7 6 5 4 3	0	15 14 13 12 11 10 9 8 7	0
1 1 1 1 0 0 1 1 1 1 0 1	Rn	1 0 (0) 0 (1)(1)(1)(1)	imm8

Table C3-70

Decode fields	Instruction page
Rn:imm8	
!= 111000000000	SUB, SUBS (immediate)
111000000000	ERET

C3.1.16.5 DCPS

This section describes the encoding of the DCPS instruction class. The encodings in this section are decoded from [Branches and miscellaneous control](#).

15 14 13 12 11 10 9 8 7 6 5 4 3	0	15 14 13 12 11		2 1 0
1 1 1 1 0 1 1 1 1 0 0 0	imm4	1 0 0 0	imm10	opt

Table C3-71

Decode fields			Instruction page
imm4	imm10	opt	
!= 1111	xxxxxxxxxx	xx	Unallocated.
1111	!= 0000000000	xx	Unallocated.
1111	0000000000	00	Unallocated.

1111	0000000000	10	DCPS2
1111	0000000000	11	DCPS3

C3.1.16.6 Exception generation

This section describes the encoding of the Exception generation instruction class. The encodings in this section are decoded from [Branches and miscellaneous control](#).

Table C3-72

Decode fields		Instruction page
o1	o2	
0	0	HVC
0	1	Unallocated.
1	0	SMC
1	1	UDF

C3.1.17 Data-processing (plain binary immediate)

This section describes the encoding of the Data-processing (plain binary immediate) group. The encodings in this section are decoded from [32-bit](#).

Table C3-73 Encoding table for the Data-processing (plain binary immediate) group

Decode fields		Decode group or instruction page
op0	op1	
0	0x	Data-processing (simple immediate)
0	10	Move Wide (16-bit immediate)
0	11	Unallocated.
1	xx	Saturate, Bitfield

C3.1.17.1 Data-processing (simple immediate)

This section describes the encoding of the Data-processing (simple immediate) instruction class. The encodings in this section are decoded from [Data-processing \(plain binary immediate\)](#).

15	14	13	12	11	10	9	8	7	6	5	4	3	0	15	14	12	11	8	7	0
1	1	1	1	0	i	1	0	o1	0	o2	0	Rn	0	imm3	Rd	imm8				

Table C3-74

Decode fields			Instruction page
o1	o2	Rn	
0	0	!= 11x1	ADD, ADDS (immediate)
0	0	1101	ADD, ADDS (SP plus immediate)
0	0	1111	ADR - T3
0	1	xxxx	Unallocated.
1	0	xxxx	Unallocated.
1	1	!= 11x1	SUB, SUBS (immediate)
1	1	1101	SUB, SUBS (SP minus immediate)
1	1	1111	ADR - T2

C3.1.17.2 Move Wide (16-bit immediate)

This section describes the encoding of the Move Wide (16-bit immediate) instruction class. The encodings in this section are decoded from [Data-processing \(plain binary immediate\)](#).

15	14	13	12	11	10	9	8	7	6	5	4	3	0	15	14	12	11	8	7	0
1	1	1	1	0	i	1	0	o1	1	0	0	imm4	0	imm3	Rd	imm8				

Table C3-75

Decode fields	Instruction page
o1	
0	MOV, MOVS (immediate)
1	MOVT

C3.1.17.3 Saturate, Bitfield

This section describes the encoding of the Saturate, Bitfield instruction class. The encodings in this section are decoded from [Data-processing \(plain binary immediate\)](#).

15	14	13	12	11	10	9	8	7	5	4	3	0	15	14	12	11	8	7	6	5	4	0
1	1	1	1	0	(0)	1	1	op1	0	Rn	0	imm3	Rd	imm2	(0)	widthm1						

Table C3-76

Decode fields			Instruction page
op1	Rn	imm3:imm2	
000	xxxx	xxxxxx	SSAT - Logical shift left variant
001	xxxx	!= 00000	SSAT - Arithmetic shift right variant
001	xxxx	00000	SSAT16
010	xxxx	xxxxxx	SBFX
011	!= 1111	xxxxxx	BFI
011	1111	xxxxxx	BFC
100	xxxx	xxxxxx	USAT - Logical shift left variant
101	xxxx	!= 00000	USAT - Arithmetic shift right variant
101	xxxx	00000	USAT16
110	xxxx	xxxxxx	UBFX
111	xxxx	xxxxxx	Unallocated.

C3.1.18 Advanced SIMD element or structure load/store

This section describes the encoding of the Advanced SIMD element or structure load/store group. The encodings in this section are decoded from [32-bit](#).

This group has encodings in both the T32 and A32 instruction sets. For information about mappings between the encodings of this group, see [About the T32 Advanced SIMD and floating-point instructions and their encoding](#)

Table C3-77 Encoding table for the Advanced SIMD element or structure load/store group

Decode fields		Decode group or instruction page
op0	op1	
0	xx	Advanced SIMD load/store multiple structures
1	11	Advanced SIMD load single structure to all lanes
1	!= 11	Advanced SIMD load/store single structure to one lane

C3.1.18.1 Advanced SIMD load/store multiple structures

This section describes the encoding of the Advanced SIMD load/store multiple structures instruction class. The encodings in this section are decoded from Advanced SIMD element or structure load/store.

Table C3-78

Decode fields			Instruction page
L	itype	Rm	
0	000x	!= 11x1	VST4 (multiple 4-element structures)

C3.2 About the T32 Advanced SIMD and floating-point instructions and their encoding

The Advanced SIMD and floating-point instructions are common to the T32 and A32 instruction sets. These instructions perform Advanced SIMD and floating-point operations on a common register file, the SIMD&FP register file. This means:

- In general, the instructions that load or store registers in this file, or move data between general-purpose registers and this register file, are common to the Advanced SIMD and floating-point instructions.
- There are distinct Advanced SIMD data-processing instructions and floating-point data-processing instructions.

All T32 Advanced SIMD and floating-point instructions have 32-bit encodings. Different groups of these instructions are decoded from different points in the 32-bit T32 instruction decode structure. [Table C3-102](#) shows these instruction groups, and where each group is decoded from the overall T32 decode structure:

Table C3-102 Advanced SIMD and floating-point instructions in the T32 decode structure

Advanced SIMD and floating-point instruction group	T32 decode is from
Advanced SIMD and System register load/store and 64-bit move	System register access, Advanced SIMD, and floating-point
Floating-point data-processing	System register access, Advanced SIMD, and floating-point
Advanced SIMD and System register 32-bit move	System register access, Advanced SIMD, and floating-point
Advanced SIMD data-processing	System register access, Advanced SIMD, and floating-point
Advanced SIMD element or structure load/store	32-bit

Chapter C4

A32 Instruction Set Encoding

This chapter describes the encoding of the A32 instruction set. It contains the following sections:

- [A32 instruction set encoding](#)
- [About the A32 Advanced SIMD and floating-point instructions and their encoding](#)

In this chapter:

- In the decode tables, an entry of $\times$ for a field value means the value of the field does not affect the decoding.
- In the decode diagrams, a shaded field indicates that the bits in that field are not used in that level of decode.

C4.1 A32 instruction set encoding

The A32 instruction stream is a sequence of 32-bit word-aligned words. Each instruction is a single word in the stream.

Most A32 instructions can be conditional, with a condition determined by bits[31:28] of the instruction, the `cond` field. For more information see [The Condition code field in A32 instruction encodings](#). This applies to all instructions except those with the `cond` field equal to `0b1111`.

The behavior of an attempt to execute an unallocated instruction is described in [UNDEFINED, UNPREDICTABLE, and CONSTRAINED UNPREDICTABLE instruction set space](#).

For more information on A32 instruction encodings see [About the T32 and A32 Instruction Descriptions](#).

The A32 instruction encoding is:

Table C4-1 Main encoding table for the A32 instruction set

Decode fields			Decode group or instruction page
cond	op0	op1	
!= 1111	00x	x	Data-processing and miscellaneous instructions

Table C4-81

Decode fields			Instruction page
D	o2	imm5:styp	
0	0	xxxxxxxx	Reserved hint, behaves as NOP.
0	1	!= 0000011	PLI (register) - Shift or rotate by value variant
0	1	0000011	PLI (register) - Rotate right with extend variant
1	0	!= 0000011	PLD, PLDW (register) - Preload write, optional shift or rotate variant
1	0	0000011	PLD, PLDW (register) - Preload write, rotate right with extend variant
1	1	!= 0000011	PLD, PLDW (register) - Preload read, optional shift or rotate variant
1	1	0000011	PLD, PLDW (register) - Preload read, rotate right with extend variant

C4.1.24 Advanced SIMD element or structure load/store

This section describes the encoding of the Advanced SIMD element or structure load/store group. The encodings in this section are decoded from [Unconditional instructions](#).

This group has encodings in both the T32 and A32 instruction sets. For information about mappings between the encodings of this group, see [About the A32 Advanced SIMD and floating-point instructions and their encoding](#)

Table C4-82 Encoding table for the Advanced SIMD element or structure load/store group

Decode fields		Decode group or instruction page
op0	op1	
0	xx	Advanced SIMD load/store multiple structures
1	11	Advanced SIMD load single structure to all lanes
1	!= 11	Advanced SIMD load/store single structure to one lane

C4.1.24.1 Advanced SIMD load/store multiple structures

This section describes the encoding of the Advanced SIMD load/store multiple structures instruction class. The encodings in this section are decoded from [Advanced SIMD element or structure load/store](#).

Table C4-83

Decode fields			Instruction page
L	itype	Rm	
0	000x	!= 11x1	VST4 (multiple 4-element structures)

C4.2 About the A32 Advanced SIMD and floating-point instructions and their encoding

The Advanced SIMD and floating-point instructions are common to the T32 and A32 instruction sets. These instructions perform Advanced SIMD and floating-point operations on a common register file, the SIMD&FP register file. This means:

- In general, the instructions that load or store registers in this file, or move data between general-purpose registers and this register file, are common to the Advanced SIMD and floating-point instructions.
- There are distinct Advanced SIMD data-processing instructions and floating-point data-processing instructions.

All A32 Advanced SIMD and floating-point instructions have 32-bit encodings. Different groups of these instructions are decoded from different points in the 32-bit A32 instruction decode structure. [Table C4-86](#) shows these instruction groups, and where each group is decoded from the overall A32 decode structure:

Table C4-86 Advanced SIMD and floating-point instructions in the A32 decode structure

Advanced SIMD and floating-point instruction group	A32 decode is from
Advanced SIMD and System register load/store and 64-bit move	System register access, Advanced SIMD, floating-point, and Supervisor call
Floating-point data-processing	System register access, Advanced SIMD, floating-point, and Supervisor call
Advanced SIMD and System register 32-bit move	System register access, Advanced SIMD, floating-point, and Supervisor call
Advanced SIMD data-processing	Unconditional instructions
Advanced SIMD element or structure load/store	Unconditional instructions

Chapter C5

T32 and A32 Base Instruction Set Instruction Descriptions

This chapter describes each instruction. It contains the following sections:

- [Alphabetical list of T32 and A32 base instruction set instructions](#)
- [Encoding and use of banked register transfer instructions](#)

C5.1 Alphabetical list of T32 and A32 base instruction set instructions

This section lists every instruction in the T32 and A32 base instruction sets. For details of the format used see [Format of instruction descriptions](#).

This section is formatted so that each instruction description starts on a new page.

C5.1.1 ADC, ADCS (immediate)

Add with Carry (immediate) adds an immediate value and the Carry flag value to a register value, and writes the result to the destination register.

If the destination register is not the PC, the ADCS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. Arm deprecates any use of these encodings. However, when the destination register is the PC:

- The ADC variant of the instruction is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC](#).
- The ADCS variant of the instruction performs an exception return without the use of the stack. In this case:
 - The PE branches to the address written to the PC, and restores **PSTATE** from SPSR_<current_mode>.
 - The PE checks SPSR_<current_mode> for an illegal return event. See [Illegal return events from AArch32 state](#).
 - The instruction is UNDEFINED in Hyp mode.
 - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding for the ADC variant

Applies when (S == 0)

```
ADC{<c>}{<q>} {<Rd>, }<Rn>, #<const>
```

Encoding for the ADCS variant

Applies when (S == 1)

```
ADCS{<c>}{<q>} {<Rd>, }<Rn>, #<const>
```

Decode for all variants of this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let setflags : boolean = (S == '1');
let imm32 : bits(32) = A32ExpandImm(imm12);
```

T1

Encoding for the ADC variant

Applies when (S == 0)

```
ADC{<c>}{<q>} {<Rd>, }<Rn>, #<const>
```

Encoding for the ADCS variant

Applies when (S == 1)

```
ADCS{<c>}{<q>} {<Rd>, }<Rn>, #<const>
```

Decode for all variants of this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let setflags : boolean = (S == '1');
let imm32 : bits(32) = T32ExpandImm(i::imm3::imm8);
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 || n == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rd>

For the “A1 ADC” and “A1 ADCS” variants: is the general-purpose destination register, encoded in the “Rd” field. If omitted, this register is the same as <Rn>. Arm deprecates using the PC as the destination register, but if the PC is used:

- For the ADC variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC](#).
- For the ADCS variant, the instruction performs an exception return, that restores [PSTATE](#) from SPSR_<current_mode>.

For the “T1 ADC” and “T1 ADCS” variants: is the general-purpose destination register, encoded in the “Rd” field. If omitted, this register is the same as <Rn>.

<Rn>

For the “A1 ADC” and “A1 ADCS” variants: is the general-purpose source register, encoded in the “Rn” field. The PC can be used, but this is deprecated.

For the “T1 ADC” and “T1 ADCS” variants: is the general-purpose source register, encoded in the “Rn” field.

<const>

For the “A1 ADC” and “A1 ADCS” variants: an immediate value. See [Modified immediate constants in A32 instructions](#) for the range of values.

For the “T1 ADC” and “T1 ADCS” variants: an immediate value. See [Modified immediate constants in T32 instructions](#) for the range of values.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let (result, nzcvc) : (bits(32), bits(4)) = AddWithCarry{32}(R(n), imm32, PSTATE.C);
    if d == 15 then          // Can only occur for A32 encoding
        if setflags then
            ALUEXCEPTIONReturn(result);
        else
            ALUWritePC(result);
        end;
    else
        R(d) = result;
        if setflags then
            PSTATE.[N,Z,C,V] = nzcvc;
        end;
    end;
end;
```

C5.1.2 ADC, ADCS (register)

Add with Carry (register) adds a register value, the Carry flag value, and an optionally-shifted register value, and writes the result to the destination register.

If the destination register is not the PC, the ADCS variant of the instruction updates the condition flags based on the result.

The field descriptions for <RD> identify the encodings where the PC is permitted as the destination register. Arm deprecates any use of these encodings. However, when the destination register is the PC:

- The ADC variant of the instruction is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC](#).
- The ADCS variant of the instruction performs an exception return without the use of the stack. In this case:
 - The PE branches to the address written to the PC, and restores **PSTATE** from SPSR_<current_mode>.
 - The PE checks SPSR_<current_mode> for an illegal return event. See [Illegal return events from AArch32 state](#).
 - The instruction is UNDEFINED in Hyp mode.
 - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#) and [T2](#)).

A1

Encoding for the ADC, rotate right with extend variant

Applies when (S == 0 && imm5 == 00000 && stype == 11)

ADC{<c>}{<q>}{<Rd>}{<Rn>}{<Rm>}{RRX}

Encoding for the ADC, shift or rotate by value variant

Applies when (S == 0 && !(imm5 == 00000 && stype == 11))

```
ADC{<c>}{<q>}{<Rd>,<Rn>,<Rm>,<shift>#<amount>}
```

Encoding for the ADCS, rotate right with extend variant

Applies when (S == 1 && imm5 == 00000 && stype == 11)

ADCS { <c> } { <q> } { <Rd>, } <Rn>, <Rm>, RRX

Encoding for the ADCS, shift or rotate by value variant

Applies when (S == 1 && !(imm5 == 00000 && stype == 11))

ADCS{<c>}{<q>}{<Rd>,<Rn>,<Rm>{,<shift>#<amount>}

Decode for all variants of this encoding

```

let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);

let setflags : boolean = (S == '1');

let (shift t, shift n) : (SRTyp, integer) = DecodeImmShift(stype, imm5);

```

T1

Encoding

```
ADC<c>{<q>} {<Rdn>, }<Rdn>, <Rm> // (InITBlock())
```

ADCS{<q>} {<Rdn>, }<Rdn>, <Rm> // (Outside IT block)

Decode for this encoding

```
let d : integer = UInt(Rdn);
let n : integer = UInt(Rdn);
let m : integer = UInt(Rm);
let setflags : boolean = !InITBlock();
let shift_t : SRTYPE = SRTYPE_LSL;
let shift_n : integer = 0;
```

T2

Encoding for the ADC, rotate right with extend variant

Applies when (S == 0 && imm3 == 000 && imm2 == 00 && stype == 11)

ADC {<c>} {<q>} {<Rd>, }<Rn>, <Rm>, RRX

Encoding for the ADC, shift or rotate by value variant

Applies when (S == 0 && !(imm3 == 000 && imm2 == 00 && stype == 11))

```
ADC{<c>}{<q>}{<Rd>, }<Rn>, <Rm> {, <shift> #<amount>}
```

ADC<c>.W {<Rd>, }<Rn>, <Rm> // (Inside IT block, and <Rd>, <Rn>, <Rm> can be represented in T1)

Encoding for the ADCS, rotate right with extend variant

Applies when (S == 1 && imm3 == 000 && imm2 == 00 && stype == 11)

ADCS {<c>} {<q>} {<Rd>, }<Rn>, <Rm>, RRX

Encoding for the ADCS, shift or rotate by value variant

Applies when (S == 1 && !(imm3 == 000 && imm2 == 00 && stype == 11))

ADCS{<c>}{<q>}{<Rd>,<Rn>,<Rm>{,<shift>#<amount>}

ADCS.W {<Rd>, }<Rn>, <Rm> // (Outside IT block, and <Rd>, <Rn>, <Rm> can be represented in T1)

Decode for all variants of this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let setflags : boolean = (S == '1');
let (shift_t, shift_n) : (SRTYPE, integer) = DecodeImmShift(stype, imm3::imm2);
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rd>

For the “A1 ADC, rotate right with extend”, “A1 ADC, shift or rotate by value”, “A1 ADCS, rotate right with extend”, and “A1 ADCS, shift or rotate by value” variants: is the general-purpose destination register, encoded in the “Rd” field. If omitted, this register is the same as <Rn>. Arm deprecates using the PC as the destination register, but if the PC is used:

- For the ADC variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC](#).
- For the ADCS variant, the instruction performs an exception return, that restores [PSTATE](#) from `SPSR_<current_mode>`.

For the “T2 ADC, rotate right with extend”, “T2 ADC, shift or rotate by value”, “T2 ADCS, rotate right with extend”, and “T2 ADCS, shift or rotate by value” variants: is the general-purpose destination register, encoded in the “Rd” field. If omitted, this register is the same as <Rn>.

<Rn>

For the “A1 ADC, rotate right with extend”, “A1 ADC, shift or rotate by value”, “A1 ADCS, rotate right with extend”, and “A1 ADCS, shift or rotate by value” variants: is the first general-purpose source register, encoded in the “Rn” field. The PC can be used, but this is deprecated.

For the “T2 ADC, rotate right with extend”, “T2 ADC, shift or rotate by value”, “T2 ADCS, rotate right with extend”, and “T2 ADCS, shift or rotate by value” variants: is the first general-purpose source register, encoded in the “Rn” field.

<Rm>

For the “A1 ADC, rotate right with extend”, “A1 ADC, shift or rotate by value”, “A1 ADCS, rotate right with extend”, and “A1 ADCS, shift or rotate by value” variants: is the second general-purpose source register, encoded in the “Rm” field. The PC can be used, but this is deprecated.

For the “T1”, “T2 ADC, rotate right with extend”, “T2 ADC, shift or rotate by value”, “T2 ADCS, rotate right with extend”, and “T2 ADCS, shift or rotate by value” variants: is the second general-purpose source register, encoded in the “Rm” field.

<shift>

Is the type of shift to be applied to the second source register, encoded in “stype”:

type	<shift>
00	LSL
01	LSR
10	ASR
11	ROR

<amount>

For the “A1 ADC, shift or rotate by value” and “A1 ADCS, shift or rotate by value” variants: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the “imm5” field as <amount> modulo 32.

For the “T2 ADC, shift or rotate by value” and “T2 ADCS, shift or rotate by value” variants: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR), encoded in the “imm3:imm2” field as <amount> modulo 32.

<Rdn>

Is the first general-purpose source register and the destination register, encoded in the “Rdn” field.

In T32 assembly:

- Outside an IT block, if ADCS <Rd>, <Rn>, <Rd> has <Rd> and <Rn> both in the range R0-R7, it is assembled using encoding T1 as though ADCS <Rd>, <Rn> had been written.
- Inside an IT block, if ADC<c> <Rd>, <Rn>, <Rd> has <Rd> and <Rn> both in the range R0-R7, it is assembled using encoding T1 as though ADC<c> <Rd>, <Rn> had been written.

To prevent either of these happening, use the .W qualifier.

Operation

```

if ConditionPassed() then
    EncodingSpecificOperations();
    let shifted : bits(32) = Shift{}(R(m), shift_t, shift_n, PSTATE.C);
    let (result, nzcv) : (bits(32), bits(4)) = AddWithCarry{32}(R(n), shifted, PSTATE.C);
    if d == 15 then          // Can only occur for A32 encoding
        if setflags then
            ALUExceptionReturn(result);
        else
            ALUWritePC(result);
        end;
    else
        R(d) = result;
        if setflags then
            PSTATE.[N,Z,C,V] = nzcv;
        end;
    end;
end;
end;

```

C5.1.3 ADC, ADCS (register-shifted register)

Add with Carry (register-shifted register) adds a register value, the Carry flag value, and a register-shifted register value. It writes the result to the destination register, and can optionally update the condition flags based on the result.

Encoding for the Flag setting variant

Applies when (S == 1)

ADCS{<c>}{<q>}{<Rd>, }<Rn>, <Rm>, <shift> <Rs>

Encoding for the Not flag setting variant

Applies when (S == 0)

```
ADC{<c>}{<q>}{<Rd>,<Rn>,<Rm>,<shift><Rs>}
```

Decode for all variants of this encoding

```

let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let s : integer = UInt(Rs);
let setflags : boolean = (S == '1');
let shift_t : SRTYPE = DecodeRegShift(stype);
if d == 15 || n == 15 || m == 15 || s == 15 then UnpredictableProcedure(); end;

```

For more information about the CONSTRAINED UNPREDICTABLE behavior, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

 $\langle q \rangle$

See [Standard assembler syntax fields](#).

<Rd>

Is the general-purpose destination register, encoded in the “Rd” field.

 $\langle R_n \rangle$

Is the first general-purpose source register, encoded in the “Rn” field.

<Rm>

Is the second general-purpose source register, encoded in the “Rm” field.

<shift>

Is the type of shift to be applied to the second source register, encoded in “stype”:

stype	<shift>
00	LSL
01	LSR
10	ASR
11	ROR

<Rs>

Is the third general-purpose source register holding a shift amount in its bottom 8 bits, encoded in the “Rs” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let shift_n : integer = UInt(R(s)[7:0]);
    let shifted : bits(32) = Shift{}(R(m), shift_t, shift_n, PSTATE.C);
    let (result, nzcvc) : (bits(32), bits(4)) = AddWithCarry{32}(R(n), shifted, PSTATE.C);
    R(d) = result;
    if setflags then
        PSTATE.[N,Z,C,V] = nzcvc;
    end;
end;
```

C5.1.4 ADD (immediate, to PC)

Add to PC adds an immediate value to the Align(PC, 4) value to form a PC-relative address, and writes the result to the destination register. Arm recommends that, where possible, software avoids using this alias.

This is a pseudo-instruction of [ADR](#). This means:

- The encodings in this description are named to match the encodings of [ADR](#).
- The assembler syntax is used only for assembly, and is not used on disassembly.
- The description of [ADR](#) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#) and [T3](#)).

A1

Encoding for the A1 variant

ADD{<c>}{<q>} <Rd>, PC, #<const>

is equivalent to

ADR{<c>}{<q>} <Rd>, <label>

T1

Encoding for the T1 variant

ADD{<c>}{<q>} <Rd>, PC, #<imm8>

is equivalent to

ADR{<c>}{<q>} <Rd>, <label>

T3

Encoding for the T3 variant

ADD{<c>}{<q>} <Rd>, PC, #<imm12>

ADDW{<c>}{<q>} <Rd>, PC, #<imm12> // (UInt(Rd) < 8 && UInt(i :: imm3 :: imm8) < 256)

is equivalent to

ADR{<c>}{<q>} <Rd>, <label>

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rd>

For the “A1” variant: is the general-purpose destination register, encoded in the “Rd” field. If the PC is used, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC](#).

For the “T1” and “T3” variants: is the general-purpose destination register, encoded in the “Rd” field.

<const>

An immediate value. See [Modified immediate constants in A32 instructions](#) for the range of values.

<imm8>

Is an unsigned immediate, a multiple of 4, in the range 0 to 1020, encoded in the “imm8” field as <imm8>/4.

<imm12>

Is a 12-bit unsigned immediate, in the range 0 to 4095, encoded in the “i:imm3:imm8” field.

Operation

The description of [ADR](#) gives the operational pseudocode for this instruction.

C5.1.5 ADD, ADDS (immediate)

Add (immediate) adds an immediate value to a register value, and writes the result to the destination register.

If the destination register is not the PC, the ADDS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. If the destination register is the PC:

- The ADD variant of the instruction is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC](#).
- The ADDS variant of the instruction performs an exception return without the use of the stack. Arm deprecates use of this instruction. However, in this case:
 - The PE branches to the address written to the PC, and restores **PSTATE** from SPSR_<current_mode>.
 - The PE checks SPSR_<current_mode> for an illegal return event. See [Illegal return events from AArch32 state](#).
 - The instruction is UNDEFINED in Hyp mode.
 - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#), [T2](#), [T3](#), and [T4](#)).

A1

Encoding for the ADD variant

Applies when (S == 0 && Rn != 11x1)

ADD{<c>}{<q>} {<Rd>, }<Rn>, #<const>

Encoding for the ADDS variant

Applies when (S == 1 && Rn != 1101)

ADDS{<c>}{<q>} {<Rd>, }<Rn>, #<const>

Decode for all variants of this encoding

```

if Rn == '1111' && S == '0' then See("ADR"); end;
if Rn == '1101' then See("ADD (SP plus immediate)"); end;
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let setflags : boolean = (S == '1');
let imm32 : bits(32) = A32ExpandImm(imm12);

```

T1

Encoding

```
ADD<c>{<q>} <Rd>, <Rn>, #<imm3> // (InITBlock())
```

```
ADDS{<q>} <Rd>, <Rn>, #<imm3> // (Outside IT block)
```

Decode for this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let setflags : boolean = !InITBlock();
let imm32 : bits(32) = ZeroExtend{}(imm3);
```

T2

Encoding

```
ADD<c>{<q>} <Rdn>, #<imm8> // (InITBlock() && UInt(imm8) < 8)
```

```
ADD<c>{<q>} {<Rdn>, }<Rdn>, #<imm8> // (Inside IT block, and <Rdn>, <imm8> cannot be represented in T1)
```

```
ADDS{<q>} <Rdn>, #<imm8> // (Outside IT block, and <Rdn>, <imm8> can be represented in T1)
```

```
ADDS{<q>} {<Rdn>, }<Rdn>, #<imm8> // (Outside IT block, and <Rdn>, <imm8> cannot be represented in T1)
```

Decode for this encoding

```
let d : integer = UInt(Rdn);
let n : integer = UInt(Rdn);
let setflags : boolean = !InITBlock();
let imm32 : bits(32) = ZeroExtend{}(imm8);
```

T3

Encoding for the ADD variant

Applies when (S == 0)

```
ADD{<c>}{<q>} {<Rd>, }<Rn>, #<const>
```

```
ADD<c>.W {<Rd>, }<Rn>, #<const> // (Inside IT block, and <Rd>, <Rn>, <const> can be represented in T1
↳ or T2)
```

Encoding for the ADDS variant

Applies when (S == 1 && Rd != 1111)

ADDS{<c>}{<q>} {<Rd>, }<Rn>, #<const>

ADDS.W {<Rd>, }<Rn>, #<const> // (Outside IT block, and <Rd>, <Rn>, <const> can be represented in T1 or
↪T2)

Decode for all variants of this encoding

```
if Rd == '1111' && S == '1' then See("CMN (immediate)"); end;
if Rn == '1101' then See("ADD (SP plus immediate)"); end;
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let setflags : boolean = (S == '1');
let imm32 : bits(32) = T32ExpandImm(i::imm3::imm8);
// Armv8-A removes UNPREDICTABLE for R13
if (d == 15 && !setflags) || n == 15 then UnpredictableProcedure(); end;
```

T4

Encoding

ADD{<c>}{<q>} {<Rd>, }<Rn>, #<imm12> // (<imm12> cannot be represented in T1, T2, or T3)

ADDW{<c>}{<q>} {<Rd>, }<Rn>, #<imm12> // (<imm12> can be represented in T1, T2, or T3)

Decode for this encoding

```
if Rn == '1111' then See("ADR"); end;
if Rn == '1101' then See("ADD (SP plus immediate)"); end;
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let setflags : boolean = FALSE;
let imm32 : bits(32) = ZeroExtend{i::imm3::imm8};
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rd>

For the “A1 ADD” and “A1 ADDS” variants: is the general-purpose destination register, encoded in the “Rd” field. If omitted, this register is the same as <Rn>. If the PC is used:

- For the ADD variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC](#).
- For the ADDS variant, the instruction performs an exception return, that restores `PSTATE` from `SPSR_<current_mode>`. Arm deprecates use of this instruction.

For the “T1”, “T3 ADD”, “T3 ADDS”, and “T4” variants: is the general-purpose destination register, encoded in the “Rd” field. If omitted, this register is the same as `<Rn>`.

<Rn>

For the “A1 ADD”, “A1 ADDS”, and “T4” variants: is the general-purpose source register, encoded in the “Rn” field. If the SP is used, see [ADD \(SP plus immediate\)](#). If the PC is used, see [ADR](#).

For the “T1” variant: is the general-purpose source register, encoded in the “Rn” field.

For the “T3 ADD” and “T3 ADDS” variants: is the general-purpose source register, encoded in the “Rn” field. If the SP is used, see [ADD \(SP plus immediate\)](#).

<const>

For the “A1 ADD” and “A1 ADDS” variants: an immediate value. See [Modified immediate constants in A32 instructions](#) for the range of values.

For the “T3 ADD” and “T3 ADDS” variants: an immediate value. See [Modified immediate constants in T32 instructions](#) for the range of values.

<imm3>

Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the “imm3” field.

<Rdn>

Is the general-purpose source and destination register, encoded in the “Rdn” field.

<imm8>

Is a 8-bit unsigned immediate, in the range 0 to 255, encoded in the “imm8” field.

<imm12>

Is a 12-bit unsigned immediate, in the range 0 to 4095, encoded in the “i:imm3:imm8” field.

When multiple encodings of the same length are available for an instruction, encoding T3 is preferred to encoding T4 (if encoding T4 is required, use the `ADDW` syntax). Encoding T1 is preferred to encoding T2 if `<Rd>` is specified and encoding T2 is preferred to encoding T1 if `<Rd>` is omitted.

Operation

```
if CurrentInstrSet() == InstrSet_A32 then
    if ConditionPassed() then
        EncodingSpecificOperations();
        let (result, nzcvt) : (bits(32), bits(4)) = AddWithCarry{32}(R(n), imm32, '0');
        if d == 15 then           // Can only occur for A32 encoding
            if setflags then
                ALUEXCEPTIONReturn(result);
            else
                ALUWritePC(result);
            end;
        else
            R(d) = result;
            if setflags then
                PSTATE.[N,Z,C,V] = nzcvt;
            end;
        end;
    end;
end;
else
```

```
    if ConditionPassed() then
        EncodingSpecificOperations();
        let (result, nzcvc) : (bits(32), bits(4)) = AddWithCarry{32}(R(n), imm32, '0');
        R(d) = result;
        if setflags then
            PSTATE.[N,Z,C,V] = nzcvc;
        end;
    end;
end;
```

C5.1.6 ADD, ADDS (register)

Add (register) adds a register value and an optionally-shifted register value, and writes the result to the destination register.

If the destination register is not the PC, the ADDS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. If the destination register is the PC:

- The ADD variant of the instruction is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC](#).
- The ADDS variant of the instruction performs an exception return without the use of the stack. Arm deprecates use of this instruction. However, in this case:
 - The PE branches to the address written to the PC, and restores **PSTATE** from SPSR_<current_mode>.
 - The PE checks SPSR_<current_mode> for an illegal return event. See [Illegal return events from AArch32 state](#).
 - The instruction is UNDEFINED in Hyp mode.
 - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#), [T2](#), and [T3](#)).

A1

Encoding for the ADD, rotate right with extend variant

Applies when (S == 0 && imm5 == 00000 && stype == 11)

ADD{<c>}{<q>} {<Rd>, }<Rn>, <Rm>, RRX

Encoding for the ADD, shift or rotate by value variant

Applies when (S == 0 && !(imm5 == 00000 && stype == 11))

ADD{<c>}{<q>} {<Rd>, }<Rn>, <Rm> {, <shift> #<amount>}

Encoding for the ADDS, rotate right with extend variant

Applies when (S == 1 && imm5 == 00000 && stype == 11)

ADDS{<c>}{<q>} {<Rd>, }<Rn>, <Rm>, RRX

Encoding for the ADDS, shift or rotate by value variant

Applies when (S == 1 && !(imm5 == 00000 && stype == 11))

ADDS{<c>}{<q>} {<Rd>, }<Rn>, <Rm> {, <shift> #<amount>}

Decode for all variants of this encoding

```

if Rn == '1101' then See("ADD (SP plus register)"); end;
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let setflags : boolean = (S == '1');
let (shift_t, shift_n) : (SRTType, integer) = DecodeImmShift(stype, imm5);
    
```

T1

Encoding

ADD<c>{<q>} <Rd>, <Rn>, <Rm> // (InITBlock())

ADDS{<q>} {<Rd>, }<Rn>, <Rm> // (Outside IT block)

Decode for this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let setflags : boolean = !InITBlock();
let shift_t : SRTYPE = SRTYPE_LSL;
let shift_n : integer = 0;
```

T2

Encoding

Applies when (!(DN == '1' && Rdn == '101'))

ADD{<c>}{<q>} {<Rdn>, }<Rdn>, <Rm>

ADD<c>{<q>} <Rdn>, <Rm> // (Preferred syntax, Inside IT block)

Decode for this encoding

```
if (DN::Rdn == '1101' || Rm == '1101' then See("ADD (SP plus register)"); end;
let d : integer = UInt(DN::Rdn);
let n : integer = d;
let m : integer = UInt(Rm);
let setflags : boolean = FALSE;
let shift_t : SRTYPE = SRTYPE_LSL;
let shift_n : integer = 0;
if n == 15 && m == 15 then UnpredictableProcedure(); end;
if d == 15 && InITBlock() && !LastInITBlock() then UnpredictableProcedure(); end;
```

T3

Encoding for the ADD, rotate right with extend variant

Applies when (S == 0 && imm3 == 000 && imm2 == 00 && stype == 11)

ADD{<c>}{<q>} {<Rd>, }<Rn>, <Rm>, RRX

Encoding for the ADD, shift or rotate by value variant

Applies when (S == 0 && !(imm3 == 000 && imm2 == 00 && stype == 11))

ADD{<c>}{<q>} {<Rd>, }<Rn>, <Rm> {, <shift> #<amount>}

ADD<c>.W {<Rd>, }<Rn>, <Rm> // (Inside IT block, and <Rd>, <Rn>, <Rm> can be represented in T1)

ADD{<c>}.W {<Rd>, }<Rn>, <Rm> // (<Rd> == <Rn>, and <Rd>, <Rn>, <Rm> can be represented in T2)

Encoding for the ADDS, rotate right with extend variant

Applies when (S == 1 && imm3 == 000 && Rd != 1111 && imm2 == 00 && stype == 11)

ADDS{<c>}{<q>} {<Rd>, }<Rn>, <Rm>, RRX

Encoding for the ADDS, shift or rotate by value variant

Applies when (S == 1 && Rd != 1111 && !(imm3 == 000 && imm2 == 00 && stype == 11))

ADDS{<c>}{<q>} {<Rd>, }<Rn>, <Rm> {, <shift> #<amount>}

ADDS.W {<Rd>, }<Rn>, <Rm> // (Outside IT block, and <Rd>, <Rn>, <Rm> can be represented in T1 or T2)

Decode for all variants of this encoding

```

if Rd == '1111' && S == '1' then See("CMN (register)"); end;
if Rn == '1101' then See("ADD (SP plus register)"); end;
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let setflags : boolean = (S == '1');
let (shift_t, shift_n) : (SRTYPE, integer) = DecodeImmShift(stype, imm3::imm2);
// Armv8-A removes UNPREDICTABLE for R13
if (d == 15 && !setflags) || n == 15 || m == 15 then UnpredictableProcedure(); end;

```

For more information about the CONSTRAINED UNPREDICTABLE behavior, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rd>

For the “A1 ADD, rotate right with extend”, “A1 ADD, shift or rotate by value”, “A1 ADDS, rotate right with extend”, and “A1 ADDS, shift or rotate by value” variants: is the general-purpose destination register, encoded in the “Rd” field. If omitted, this register is the same as <Rn>. If the PC is used:

- For the ADD variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC](#).
- For the ADDS variant, the instruction performs an exception return, that restores [PSTATE](#) from `SPSR_<current_mode>`. Arm deprecates use of this instruction.

For the “T1” variant: is the general-purpose destination register, encoded in the “Rd” field.

When used inside an IT block, <Rd> must be specified. When used outside an IT block, <Rd> is optional, and:

- If omitted, this register is the same as <Rn>.
- If present, encoding T1 is preferred to encoding T2.

For the “T3 ADD, rotate right with extend”, “T3 ADD, shift or rotate by value”, “T3 ADDS, rotate right with extend”, and “T3 ADDS, shift or rotate by value” variants: is the general-purpose destination register, encoded in the “Rd” field. If omitted, this register is the same as <Rn>.

<Rn>

For the “A1 ADD, rotate right with extend”, “A1 ADD, shift or rotate by value”, “A1 ADDS, rotate right with extend”, and “A1 ADDS, shift or rotate by value” variants: is the first general-purpose source register, encoded in the “Rn” field. The PC can be used. If the SP is used, see [ADD \(SP plus register\)](#).

For the “T1” variant: is the first general-purpose source register, encoded in the “Rn” field.

For the “T3 ADD, rotate right with extend”, “T3 ADD, shift or rotate by value”, “T3 ADDS, rotate right with extend”, and “T3 ADDS, shift or rotate by value” variants: is the first general-purpose source register, encoded in the “Rn” field. If the SP is used, see [ADD \(SP plus register\)](#).

<Rm>

For the “A1 ADD, rotate right with extend”, “A1 ADD, shift or rotate by value”, “A1 ADDS, rotate right with extend”, and “A1 ADDS, shift or rotate by value” variants: is the second general-purpose source register, encoded in the “Rm” field. The PC can be used, but this is deprecated.

For the “T1”, “T3 ADD, rotate right with extend”, “T3 ADD, shift or rotate by value”, “T3 ADDS, rotate right with extend”, and “T3 ADDS, shift or rotate by value” variants: is the second general-purpose source register, encoded in the “Rm” field.

For the “T2” variant: is the second general-purpose source register, encoded in the “Rm” field. The PC can be used.

<shift>

Is the type of shift to be applied to the second source register, encoded in “stype”:

stype	<shift>
00	LSL
01	LSR
10	ASR
11	ROR

<amount>

For the “A1 ADD, shift or rotate by value” and “A1 ADDS, shift or rotate by value” variants: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the “imm5” field as <amount> modulo 32.

For the “T3 ADD, shift or rotate by value” and “T3 ADDS, shift or rotate by value” variants: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR), encoded in the “imm3:imm2” field as <amount> modulo 32.

<Rdn>

Is the general-purpose source and destination register, encoded in the “DN:Rdn” field. If the PC is used, the instruction is a branch to the address calculated by the operation. This is a simple branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC](#).

The assembler language allows <Rdn> to be specified once or twice in the assembler syntax. When used inside an IT block, and <Rdn> and <Rm> are in the range R0 to R7, <Rdn> must be specified once so that encoding T2 is preferred to encoding T1. In all other cases there is no difference in behavior when <Rdn> is specified once or twice.

Inside an IT block, if ADD<c> <Rd>, <Rn>, <Rd> cannot be assembled using encoding T1, it is assembled using encoding T2 as though ADD<c> <Rd>, <Rn> had been written. To prevent this happening, use the .w qualifier.

Operation

```

if ConditionPassed() then
    EncodingSpecificOperations();
    let shifted : bits(32) = Shift{}(R(m), shift_t, shift_n, PSTATE.C);
    let (result, nzcvc) : (bits(32), bits(4)) = AddWithCarry{32}(R(n), shifted, '0');
    if d == 15 then
        if setflags then
            ALUEXCEPTIONReturn(result);
        else
            ALUWritePC(result);
        end;
    else
        R(d) = result;
        if setflags then
            PSTATE.[N,Z,C,V] = nzcvc;
        end;
    end;
end;
end;

```

C5.1.7 ADD, ADDS (register-shifted register)

Add (register-shifted register) adds a register value and a register-shifted register value. It writes the result to the destination register, and can optionally update the condition flags based on the result.

Encoding for the Flag setting variant

Applies when (S == 1)

ADDS{<c>}{<q>} {<Rd>, }<Rn>, <Rm>, <shift> <Rs>

Encoding for the Not flag setting variant

Applies when (S == 0)

ADD{<c>}{<q>} {<Rd>, }<Rn>, <Rm>, <shift> <Rs>

Decode for all variants of this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let s : integer = UInt(Rs);
let setflags : boolean = (S == '1');
let shift_t : SRTYPE = DecodeRegShift(stype);
if d == 15 || n == 15 || m == 15 || s == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rd>

Is the general-purpose destination register, encoded in the “Rd” field.

<Rn>

Is the first general-purpose source register, encoded in the “Rn” field.

<Rm>

Is the second general-purpose source register, encoded in the “Rm” field.

<shift>

Is the type of shift to be applied to the second source register, encoded in “stype”:

stype	<shift>
00	LSL
01	LSR
10	ASR
11	ROR

<Rs>

Is the third general-purpose source register holding a shift amount in its bottom 8 bits, encoded in the “Rs” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let shift_n : integer = UInt(R(s)[7:0]);
    let shifted : bits(32) = Shift{}(R(m), shift_t, shift_n, PSTATE.C);
    let (result, nzcvc) : (bits(32), bits(4)) = AddWithCarry{32}(R(n), shifted, '0');
    R(d) = result;
    if setflags then
        PSTATE.[N,Z,C,V] = nzcvc;
    end;
end;
```

C5.1.8 ADD, ADDS (SP plus immediate)

Add to SP (immediate) adds an immediate value to the SP value, and writes the result to the destination register.

If the destination register is not the PC, the ADDS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. However, when the destination register is the PC:

- The ADD variant of the instruction is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC](#).
- The ADDS variant of the instruction performs an exception return without the use of the stack. Arm deprecates use of this instruction. However, in this case:
 - The PE branches to the address written to the PC, and restores `PSTATE` from `SPSR_<current_mode>`.
 - The PE checks `SPSR_<current_mode>` for an illegal return event. See [Illegal return events from AArch32 state](#).
 - The instruction is UNDEFINED in Hyp mode.
 - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#), [T2](#), [T3](#), and [T4](#)).

A1

Encoding for the ADD variant

Applies when (S == 0)

```
ADD{<c>}{<q>} {<Rd>, }SP, #<const>
```

Encoding for the ADDS variant

Applies when (S == 1)

```
ADDS{<c>}{<q>} {<Rd>, }SP, #<const>
```

Decode for all variants of this encoding

```
let d : integer = UInt(Rd);
let setflags : boolean = (S == '1');
let imm32 : bits(32) = A32ExpandImm(imm12);
```

T1

Encoding

```
ADD{<c>}{<q>} <Rd>, SP, #<imm8>
```

Decode for this encoding

```
let d : integer = UInt(Rd);
let setflags : boolean = FALSE;
let imm32 : bits(32) = ZeroExtend{}(imm8::'00');
```

T2

Encoding

```
ADD{<c>}{<q>} {SP, }SP, #<imm7>
```

Decode for this encoding

```
let d : integer = 13;
let setflags : boolean = FALSE;
let imm32 : bits(32) = ZeroExtend{}(imm7::'00');
```

T3

Encoding for the ADD variant

Applies when (S == 0)

```
ADD{<c>}{<q>} {<Rd>, }SP, #<const>
```

```
ADD{<c>}.W {<Rd>, }SP, #<const> // (<Rd>, <const> can be represented in T1 or T2)
```

Encoding for the ADDS variant

Applies when (S == 1 && Rd != 1111)

```
ADDS{<c>}{<q>} {<Rd>, }SP, #<const>
```

Decode for all variants of this encoding

```
if Rd == '1111' && S == '1' then See("CMN (immediate)"); end;
let d : integer = UInt(Rd);
let setflags : boolean = (S == '1');
let imm32 : bits(32) = T32ExpandImm(i::imm3::imm8);
if d == 15 && !setflags then UnpredictableProcedure(); end;
```

T4

Encoding

ADD{<c>}{<q>} {<Rd>, }SP, #<imm12> // (<imm12> cannot be represented in T1, T2, or T3)

ADDW{<c>}{<q>} {<Rd>, }SP, #<imm12> // (<imm12> can be represented in T1, T2, or T3)

Decode for this encoding

```
let d : integer = UInt(Rd);
let setflags : boolean = FALSE;
let imm32 : bits(32) = ZeroExtend{(i::imm3::imm8)};
if d == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rd>

For the “A1 ADD” and “A1 ADDS” variants: is the general-purpose destination register, encoded in the “Rd” field. If omitted, this register is the SP. Arm deprecates using the PC as the destination register, but if the PC is used:

- For the ADD variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC](#).
- For the ADDS variant, the instruction performs an exception return, that restores `PSTATE` from `SPSR_<current_mode>`.

For the “T1” variant: is the general-purpose destination register, encoded in the “Rd” field.

For the “T3 ADD”, “T3 ADDS”, and “T4” variants: is the general-purpose destination register, encoded in the “Rd” field. If omitted, this register is the SP.

<const>

For the “A1 ADD” and “A1 ADDS” variants: an immediate value. See [Modified immediate constants in A32 instructions](#) for the range of values.

For the “T3 ADD” and “T3 ADDS” variants: an immediate value. See [Modified immediate constants in T32 instructions](#) for the range of values.

<imm8>

Is an unsigned immediate, a multiple of 4, in the range 0 to 1020, encoded in the “imm8” field as <imm8>/4.

SP

Is the stack pointer.

<imm7>

Is the unsigned immediate, a multiple of 4, in the range 0 to 508, encoded in the “imm7” field as <imm7>/4.

<imm12>

Is a 12-bit unsigned immediate, in the range 0 to 4095, encoded in the “i:imm3:imm8” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let (result, nzcvc) : (bits(32), bits(4)) = AddWithCarry{32}(R(13), imm32, '0');
    if d == 15 then                // Can only occur for A32 encoding
        if setflags then
            ALUExceptionReturn(result);
        else
            ALUWritePC(result);
        end;
    else
        R(d) = result;
        if setflags then
            PSTATE.[N,Z,C,V] = nzcvc;
        end;
    end;
end;
```

C5.1.9 ADD, ADDS (SP plus register)

Add to SP (register) adds an optionally-shifted register value to the SP value, and writes the result to the destination register.

If the destination register is not the PC, the ADDS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. Arm deprecates any use of these encodings. However, when the destination register is the PC:

- The ADD variant of the instruction is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC](#).
- The ADDS variant of the instruction performs an exception return without the use of the stack. In this case:
 - The PE branches to the address written to the PC, and restores [PSTATE](#) from `SPSR_<current_mode>`.
 - The PE checks `SPSR_<current_mode>` for an illegal return event. See [Illegal return events from AArch32 state](#).
 - The instruction is UNDEFINED in Hyp mode.
 - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1, T2, and T3).

A1

Encoding for the ADD, rotate right with extend variant

Applies when (S == 0 && imm5 == 00000 && stype == 11)

ADD {<c>} {<q>} {<Rd>}, SP, <Rm>, RRX

Encoding for the ADD, shift or rotate by value variant

Applies when (S == 0 && !(imm5 == 00000 && stype == 11))

ADD{<c>}{<q>}{<Rd>,<Rm>,<shift>#<amount>}

Encoding for the ADDS, rotate right with extend variant

Applies when (S == 1 && imm5 == 00000 && stype == 11)

ADDS {<c>} {<q>} {<Rd>}, SP, <Rm>, RRX

Encoding for the ADDS, shift or rotate by value variant

Applies when (S == 1 && !(imm5 == 00000 && stype == 11))

ADDS{<c>}{<q>}{<Rd>, }SP, <Rm> {, <shift> #<amount>}

Decode for all variants of this encoding

```
let d : integer = UInt(Rd);
let m : integer = UInt(Rm);
let setflags : boolean = (S == '1');
let (shift t, shift n) : (SRTType, integer) = DecodeImmShift(stype, imm5);
```

T1

Encoding

ADD{<c>}{<q>} {<Rdm>, }SP, <Rdm>

Decode for this encoding

```

let d : integer = UInt(DM::Rdm);
let m : integer = UInt(DM::Rdm);
let setflags : boolean = FALSE;
let shift_t : SRTYPE = SRTYPE_LSL;
let shift_n : integer = 0;
if d == 15 && InITBlock() && !LastInITBlock() then UnpredictableProcedure(); end;

```

T2

Encoding

ADD{<c>}{<q>} {SP, }SP, <Rm>

Decode for this encoding

```

if Rm == '1101' then See("encoding T1"); end;
let d : integer = 13;
let m : integer = UInt(Rm);
let setflags : boolean = FALSE;
let shift_t : SRTYPE = SRTYPE_LSL;
let shift_n : integer = 0;

```

T3

Encoding for the ADD, rotate right with extend variant

Applies when (S == 0 && imm3 == 000 && imm2 == 00 && stype == 11)

ADD{<c>}{<q>} {<Rd>, }SP, <Rm>, RRX

Encoding for the ADD, shift or rotate by value variant

Applies when (S == 0 && !(imm3 == 000 && imm2 == 00 && stype == 11))

```
ADD{<c>}{<q>} {<Rd>, }SP, <Rm> {, <shift> #<amount>}
```

```
ADD{<c>}.W {<Rd>, }SP, <Rm> // (<Rd>, <Rm> can be represented in T1 or T2)
```

Encoding for the ADDS, rotate right with extend variant

Applies when (S == 1 && imm3 == 000 && Rd != 1111 && imm2 == 00 && stype == 11)

```
ADDS{<c>}{<q>} {<Rd>, }SP, <Rm>, RRX
```

Encoding for the ADDS, shift or rotate by value variant

Applies when (S == 1 && Rd != 1111 && !(imm3 == 000 && imm2 == 00 && stype == 11))

```
ADDS{<c>}{<q>} {<Rd>, }SP, <Rm> {, <shift> #<amount>}
```

Decode for all variants of this encoding

```
if Rd == '1111' && S == '1' then See("CMN (register)"); end;
let d : integer = UInt(Rd);
let m : integer = UInt(Rm);
let setflags : boolean = (S == '1');
let (shift_t, shift_n) : (SRTType, integer) = DecodeImmShift(stype, imm3::imm2);
// Armv8-A removes UNPREDICTABLE for R13
if (d == 15 && !setflags) || m == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rd>

For the “A1 ADD, rotate right with extend”, “A1 ADD, shift or rotate by value”, “A1 ADDS, rotate right with extend”, and “A1 ADDS, shift or rotate by value” variants: is the general-purpose destination register, encoded in the “Rd” field. If omitted, this register is the SP. Arm deprecates using the PC as the destination register, but if the PC is used:

- For the ADD variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC](#).
- For the ADDS variant, the instruction performs an exception return, that restores [PSTATE](#) from `SPSR_<current_mode>`.

For the “T3 ADD, rotate right with extend”, “T3 ADD, shift or rotate by value”, “T3 ADDS, rotate right with extend”, and “T3 ADDS, shift or rotate by value” variants: is the general-purpose destination register, encoded in the “Rd” field. If omitted, this register is the SP.

<Rm>

For the “A1 ADD, rotate right with extend”, “A1 ADD, shift or rotate by value”, “A1 ADDS, rotate right with extend”, “A1 ADDS, shift or rotate by value”, and “T2” variants: is the second general-purpose source register, encoded in the “Rm” field. The PC can be used, but this is deprecated.

For the “T3 ADD, rotate right with extend”, “T3 ADD, shift or rotate by value”, “T3 ADDS, rotate right with extend”, and “T3 ADDS, shift or rotate by value” variants: is the second general-purpose source register, encoded in the “Rm” field.

<shift>

Is the type of shift to be applied to the second source register, encoded in “stype”:

stype	<shift>
00	LSL
01	LSR
10	ASR
11	ROR

<amount>

For the “A1 ADD, shift or rotate by value” and “A1 ADDS, shift or rotate by value” variants: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the “imm5” field as <amount> modulo 32.

For the “T3 ADD, shift or rotate by value” and “T3 ADDS, shift or rotate by value” variants: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR), encoded in the “imm3:imm2” field as <amount> modulo 32.

<Rdm>

Is the general-purpose destination and second source register, encoded in the “Rdm” field. If omitted, this register is the SP. Arm deprecates using the PC as the destination register, but if the PC is used, the instruction is a branch to the address calculated by the operation. This is a simple branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC](#).

SP

Is the stack pointer.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let shifted : bits(32) = Shift{(R(m), shift_t, shift_n, PSTATE.C);
    let (result, nzcvc) : (bits(32), bits(4)) = AddWithCarry{32}(R(13), shifted, '0');
    if d == 15 then
        if setflags then
            ALUExceptionReturn(result);
        else
            ALUWritePC(result);
        end;
    else
        R(d) = result;
        if setflags then
            PSTATE.[N,Z,C,V] = nzcvc;
        end;
    end;
end;
```

C5.1.10 ADR

Form PC-relative address adds an immediate value to the PC value to form a PC-relative address, and writes the result to the destination register.

This instruction is used by the alias [SUB \(immediate, from PC\)](#).

This instruction is used by the pseudo-instruction [ADD \(immediate, to PC\)](#).

It has encodings from the following instruction sets: A32 ([A1](#) and [A2](#)) and T32 ([T1](#), [T2](#), and [T3](#)).

A1

Encoding

ADR{<c>}{<q>} <Rd>, <label>

Decode for this encoding

```
let d : integer = UInt(Rd);
let imm32 : bits(32) = A32ExpandImm(imm12);
let add : boolean = TRUE;
```

A2

Encoding

ADR{<c>}{<q>} <Rd>, <label>

Decode for this encoding

```
let d : integer = UInt(Rd);
let imm32 : bits(32) = A32ExpandImm(imm12);
let add : boolean = FALSE;
```

T1

Encoding

ADR{<c>}{<q>} <Rd>, <label>

Decode for this encoding

```
let d : integer = UInt(Rd);
let imm32 : bits(32) = ZeroExtend{}(imm8::'00');
let add : boolean = TRUE;
```

T2

Encoding

ADR{<c>}{<q>} <Rd>, <label>

Decode for this encoding

```
let d : integer = UInt(Rd);
let imm32 : bits(32) = ZeroExtend{}(i::imm3::imm8);
let add : boolean = FALSE;
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 then UnpredictableProcedure(); end;
```

T3

Encoding

ADR{<c>}{<q>} <Rd>, <label>

ADR{<c>}.W <Rd>, <label> // (<Rd>, <label> can be presented in T1)

Decode for this encoding

```
let d : integer = UInt(Rd);  
let imm32 : bits(32) = ZeroExtend{(i::imm3::imm8)};  
let add : boolean = TRUE;  
// Armv8-A removes UNPREDICTABLE for R13  
if d == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rd>

For the “A1” and “A2” variants: is the general-purpose destination register, encoded in the “Rd” field. If the PC is used, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC](#).

For the “T1”, “T2”, and “T3” variants: is the general-purpose destination register, encoded in the “Rd” field.

<label>

For the “A1” and “A2” variants: the label of an instruction or literal data item whose address is to be loaded into <Rd>. The assembler calculates the required value of the offset from the `Align(PC, 4)` value of the ADR instruction to this label.

If the offset is zero or positive, encoding A1 is used, with `imm32` equal to the offset.

If the offset is negative, encoding A2 is used, with `imm32` equal to the size of the offset. That is, the use of encoding A2 indicates that the required offset is minus the value of `imm32`.

Permitted values of the size of the offset are any of the constants described in [Modified immediate constants in A32 instructions](#).

For the “T1” variant: the label of an instruction or literal data item whose address is to be loaded into <Rd>. The assembler calculates the required value of the offset from the `Align(PC, 4)` value of the ADR instruction to this label. Permitted values of the size of the offset are multiples of 4 in the range 0 to 1020.

For the “T2” and “T3” variants: the label of an instruction or literal data item whose address is to be loaded into <Rd>. The assembler calculates the required value of the offset from the `Align(PC, 4)` value of the ADR instruction to this label.

If the offset is zero or positive, encoding T3 is used, with `imm32` equal to the offset.

If the offset is negative, encoding T2 is used, with `imm32` equal to the size of the offset. That is, the use of encoding T2 indicates that the required offset is minus the value of `imm32`.

Permitted values of the size of the offset are 0–4095.

The instruction aliases permit the addition or subtraction of the offset and the immediate offset to be specified separately, including permitting a subtraction of 0 that cannot be specified using the normal syntax. For more information, see [Use of labels in UAL instruction syntax](#).

Alias Conditions

Alias	Of variant	Is preferred when
ADD (immediate, to PC)		Never
SUB (immediate, from PC)	A2	imm12 == '000000000000'
SUB (immediate, from PC)	T2	i : imm3 : imm8 == '000000000000'

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let result : bits(32) = (if add then (AlignDownSize(PC32(),4) + imm32)
                             else (AlignDownSize(PC32(),4) - imm32));
    if d == 15 then          // Can only occur for A32 encodings
        ALUWritePC(result);
    else
        R(d) = result;
    end;
end;
```

C5.1.11 AND, ANDS (immediate)

Bitwise AND (immediate) performs a bitwise AND of a register value and an immediate value, and writes the result to the destination register.

If the destination register is not the PC, the ANDS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. Arm deprecates any use of these encodings. However, when the destination register is the PC:

- The AND variant of the instruction is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC](#).
- The ANDS variant of the instruction performs an exception return without the use of the stack. In this case:
 - The PE branches to the address written to the PC, and restores **PSTATE** from SPSR_<current_mode>.
 - The PE checks SPSR_<current_mode> for an illegal return event. See [Illegal return events from AArch32 state](#).
 - The instruction is UNDEFINED in Hyp mode.
 - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding for the AND variant

Applies when (S == 0)

AND{<c>}{<q>} {<Rd>, }<Rn>, #<const>

Encoding for the ANDS variant

Applies when (S == 1)

ANDS{<c>}{<q>} {<Rd>, }<Rn>, #<const>

Decode for all variants of this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let setflags : boolean = (S == '1');
let a32 : boolean = TRUE;
let imm : bits(12) = imm12;
```

T1

Encoding for the AND variant

Applies when (S == 0)

AND{<c>}{<q>} {<Rd>, }<Rn>, #<const>

Encoding for the ANDS variant

Applies when (S == 1 && Rd != 1111)

ANDS{<c>}{<q>} {<Rd>, }<Rn>, #<const>

Decode for all variants of this encoding

```
if Rd == '1111' && S == '1' then See("TST (immediate)"); end;
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let setflags : boolean = (S == '1');
let a32 : boolean = FALSE;
let imm : bits(12) = i::imm3::imm8;
// Armv8-A removes UNPREDICTABLE for R13
if (d == 15 && !setflags) || n == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rd>

For the “A1 AND” and “A1 ANDS” variants: is the general-purpose destination register, encoded in the “Rd” field. If omitted, this register is the same as <Rn>. Arm deprecates using the PC as the destination register, but if the PC is used:

- For the AND variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC](#).
- For the ANDS variant, the instruction performs an exception return, that restores [PSTATE](#) from SPSR_<current_mode>.

For the “T1 AND” and “T1 ANDS” variants: is the general-purpose destination register, encoded in the “Rd” field. If omitted, this register is the same as <Rn>.

<Rn>

For the “A1 AND” and “A1 ANDS” variants: is the general-purpose source register, encoded in the “Rn” field. The PC can be used, but this is deprecated.

For the “T1 AND” and “T1 ANDS” variants: is the general-purpose source register, encoded in the “Rn” field.

<const>

For the “A1 AND” and “A1 ANDS” variants: an immediate value. See [Modified immediate constants in A32 instructions](#) for the range of values.

For the “T1 AND” and “T1 ANDS” variants: an immediate value. See [Modified immediate constants in T32 instructions](#) for the range of values.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let (imm32, carry) : (bits(32), bit) = (if a32 then A32ExpandImm_C(imm, PSTATE.C)
                                             else T32ExpandImm_C(imm, PSTATE.C));

    let result : bits(32) = R(n) AND imm32;
    if d == 15 then                // Can only occur for A32 encoding
        if setflags then
            ALUExceptionReturn(result);
        else
            ALUWritePC(result);
        end;
    else
        R(d) = result;
        if setflags then
            PSTATE.N = result[31];
            PSTATE.Z = IsZeroBit{32}(result);
            PSTATE.C = carry;
            // PSTATE.V unchanged
        end;
    end;
end;
```

C5.1.12 AND, ANDS (register)

Bitwise AND (register) performs a bitwise AND of a register value and an optionally-shifted register value, and writes the result to the destination register.

If the destination register is not the PC, the ANDS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. Arm deprecates any use of these encodings. However, when the destination register is the PC:

- The AND variant of the instruction is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC](#).
- The ANDS variant of the instruction performs an exception return without the use of the stack. In this case:
 - The PE branches to the address written to the PC, and restores **PSTATE** from SPSR_<current_mode>.
 - The PE checks SPSR_<current_mode> for an illegal return event. See [Illegal return events from AArch32 state](#).
 - The instruction is UNDEFINED in Hyp mode.
 - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#) and [T2](#)).

A1

Encoding for the AND, rotate right with extend variant

Applies when (S == 0 && imm5 == 00000 && stype == 11)

AND {<c>} {<q>} {<Rd>, }<Rn>, <Rm>, RRX

Encoding for the AND, shift or rotate by value variant

Applies when (S == 0 && !(imm5 == 00000 && stype == 11))

AND{<c>}{<q>}{<Rd>,<Rn>,<Rm>,<shift>#<amount>}

Encoding for the ANDS, rotate right with extend variant

Applies when (S == 1 && imm5 == 00000 && stype == 11)

ANDS {<c>} {<q>} {<Rd>, }<Rn>, <Rm>, RRX

Encoding for the ANDS, shift or rotate by value variant

Applies when (S == 1 && !(imm5 == 00000 && stype == 11))

ANDS{<c>}{<q>}{<Rd>,<Rn>,<Rm>{,<shift>#<amount>}

Decode for all variants of this encoding

```

let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);

let setflags : boolean = (S == '1');

let (shift t, shift n) : (SRTyp, integer) = DecodeImmShift(stype, imm5);

```

T1

Encoding

AND<c>{<q>} {<Rdn>, }<Rdn>, <Rm> // (InITBlock())

ANDS{<q>} {<Rdn>, }<Rdn>, <Rm> // (Outside IT block)

Decode for this encoding

```
let d : integer = UInt(Rdn);
let n : integer = UInt(Rdn);
let m : integer = UInt(Rm);
let setflags : boolean = !InITBlock();
let shift_t : SRTYPE = SRTYPE_LSL;
let shift_n : integer = 0;
```

T2

Encoding for the AND, rotate right with extend variant

Applies when (S == 0 && imm3 == 000 && imm2 == 00 && stype == 11)

AND{<c>}{<q>} {<Rd>, }<Rn>, <Rm>, RRX

Encoding for the AND, shift or rotate by value variant

Applies when (S == 0 && !(imm3 == 000 && imm2 == 00 && stype == 11))

AND{<c>}{<q>} {<Rd>, }<Rn>, <Rm> {, <shift> #<amount>}

AND<c>.W {<Rd>, }<Rn>, <Rm> // (Inside IT block, and <Rd>, <Rn>, <Rm> can be represented in T1)

Encoding for the ANDS, rotate right with extend variant

Applies when (S == 1 && imm3 == 000 && Rd != 1111 && imm2 == 00 && stype == 11)

ANDS{<c>}{<q>} {<Rd>, }<Rn>, <Rm>, RRX

Encoding for the ANDS, shift or rotate by value variant

Applies when (S == 1 && Rd != 1111 && !(imm3 == 000 && imm2 == 00 && stype == 11))

ANDS{<c>}{<q>} {<Rd>, }<Rn>, <Rm> {, <shift> #<amount>}

ANDS.W {<Rd>, }<Rn>, <Rm> // (Outside IT block, and <Rd>, <Rn>, <Rm> can be represented in T1)

Decode for all variants of this encoding

```
if Rd == '1111' && S == '1' then See("TST (register)"); end;
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let setflags : boolean = (S == '1');
let (shift_t, shift_n) : (SRTType, integer) = DecodeImmShift(stype, imm3::imm2);
// Armv8-A removes UNPREDICTABLE for R13
if (d == 15 && !setflags) || n == 15 || m == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rd>

For the “A1 AND, rotate right with extend”, “A1 AND, shift or rotate by value”, “A1 ANDS, rotate right with extend”, and “A1 ANDS, shift or rotate by value” variants: is the general-purpose destination register, encoded in the “Rd” field. If omitted, this register is the same as <Rn>. Arm deprecates using the PC as the destination register, but if the PC is used:

- For the AND variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC](#).
- For the ANDS variant, the instruction performs an exception return, that restores [PSTATE](#) from `SPSR_<current_mode>`.

For the “T2 AND, rotate right with extend”, “T2 AND, shift or rotate by value”, “T2 ANDS, rotate right with extend”, and “T2 ANDS, shift or rotate by value” variants: is the general-purpose destination register, encoded in the “Rd” field. If omitted, this register is the same as <Rn>.

<Rn>

For the “A1 AND, rotate right with extend”, “A1 AND, shift or rotate by value”, “A1 ANDS, rotate right with extend”, and “A1 ANDS, shift or rotate by value” variants: is the first general-purpose source register, encoded in the “Rn” field. The PC can be used, but this is deprecated.

For the “T2 AND, rotate right with extend”, “T2 AND, shift or rotate by value”, “T2 ANDS, rotate right with extend”, and “T2 ANDS, shift or rotate by value” variants: is the first general-purpose source register, encoded in the “Rn” field.

<Rm>

For the “A1 AND, rotate right with extend”, “A1 AND, shift or rotate by value”, “A1 ANDS, rotate right with extend”, and “A1 ANDS, shift or rotate by value” variants: is the second general-purpose source register, encoded in the “Rm” field. The PC can be used, but this is deprecated.

For the “T1”, “T2 AND, rotate right with extend”, “T2 AND, shift or rotate by value”, “T2 ANDS, rotate right with extend”, and “T2 ANDS, shift or rotate by value” variants: is the second general-purpose source register, encoded in the “Rm” field.

<shift>

Is the type of shift to be applied to the second source register, encoded in “stype”:

type	<shift>
00	LSL
01	LSR
10	ASR
11	ROR

<amount>

For the “A1 AND, shift or rotate by value” and “A1 ANDS, shift or rotate by value” variants: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the “imm5” field as <amount> modulo 32.

For the “T2 AND, shift or rotate by value” and “T2 ANDS, shift or rotate by value” variants: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR), encoded in the “imm3:imm2” field as <amount> modulo 32.

<Rdn>

Is the first general-purpose source register and the destination register, encoded in the “Rdn” field.

In T32 assembly:

- Outside an IT block, if ANDS <Rd>, <Rn>, <Rd> has <Rd> and <Rn> both in the range R0-R7, it is assembled using encoding T1 as though ANDS <Rd>, <Rn> had been written.
- Inside an IT block, if AND<c> <Rd>, <Rn>, <Rd> has <Rd> and <Rn> both in the range R0-R7, it is assembled using encoding T1 as though AND<c> <Rd>, <Rn> had been written.

To prevent either of these happening, use the .w qualifier.

Operation

```

if ConditionPassed() then
    EncodingSpecificOperations();
    let (shifted, carry) : (bits(32), bit) = Shift_C{32}(R(m), shift_t, shift_n, PSTATE.C);
    let result : bits(32) = R(n) AND shifted;
    if d == 15 then          // Can only occur for A32 encoding
        if setflags then
            ALUEXCEPTIONReturn(result);
        else
            ALUWritePC(result);
        end;
    else
        R(d) = result;
        if setflags then
            PSTATE.N = result[31];
            PSTATE.Z = IsZeroBit{32}(result);
            PSTATE.C = carry;
            // PSTATE.V unchanged
        end;
    end;
end;
end;

```

C5.1.13 AND, ANDS (register-shifted register)

Bitwise AND (register-shifted register) performs a bitwise AND of a register value and a register-shifted register value. It writes the result to the destination register, and can optionally update the condition flags based on the result.

Encoding for the Flag setting variant

Applies when (S == 1)

ANDS{<c>}{<q>} {<Rd>, }<Rn>, <Rm>, <shift> <Rs>

Encoding for the Not flag setting variant

Applies when (S == 0)

AND{<c>}{<q>} {<Rd>, }<Rn>, <Rm>, <shift> <Rs>

Decode for all variants of this encoding

```

let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let s : integer = UInt(Rs);
let setflags : boolean = (S == '1');
let shift_t : SRTYPE = DecodeRegShift(stype);
if d == 15 || n == 15 || m == 15 || s == 15 then UnpredictableProcedure(); end;

```

For more information about the CONSTRAINED UNPREDICTABLE behavior, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rd>

Is the general-purpose destination register, encoded in the “Rd” field.

<Rn>

Is the first general-purpose source register, encoded in the “Rn” field.

<Rm>

Is the second general-purpose source register, encoded in the “Rm” field.

<shift>

Is the type of shift to be applied to the second source register, encoded in “stype”:

stype	<shift>
00	LSL
01	LSR
10	ASR
11	ROR

<Rs>

Is the third general-purpose source register holding a shift amount in its bottom 8 bits, encoded in the “Rs” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let shift_n : integer = UInt(R(s)[7:0]);
    let (shifted, carry) : (bits(32), bit) = Shift_C{32}(R(m), shift_t, shift_n, PSTATE.C);
    let result : bits(32) = R(n) AND shifted;
    R(d) = result;
    if setflags then
        PSTATE.N = result[31];
        PSTATE.Z = IsZeroBit{32}(result);
        PSTATE.C = carry;
        // PSTATE.V unchanged
    end;
end;
```

C5.1.14 ASR (immediate)

Arithmetic Shift Right (immediate) shifts a register value right by an immediate number of bits, shifting in copies of its sign bit, and writes the result to the destination register.

This is an alias of [MOV, MOVS \(register\)](#). This means:

- The encodings in this description are named to match the encodings of [MOV, MOVS \(register\)](#).
- The description of [MOV, MOVS \(register\)](#) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T2](#) and [T3](#)).

A1

Encoding for the MOV, shift or rotate by value variant

ASR{<c>}{<q>} {<Rd>, }<Rm>, #<imm>

is equivalent to

MOV{<c>}{<q>} <Rd>, <Rm>, ASR #<imm>

and is always the preferred disassembly.

T2

Encoding for the T2 variant

ASR<c>{<q>} {<Rd>, }<Rm>, #<imm>

is equivalent to

MOV<c>{<q>} <Rd>, <Rm>, ASR #<imm>

and is the preferred disassembly when `InITBlock()`.

T3

Encoding for the MOV, shift or rotate by value variant

```
ASR{<c>}{<q>} {<Rd>, }<Rm>, #<imm>
```

```
ASR<c>.W {<Rd>, }<Rm>, #<imm> // (!InITBlock() && UInt(Rd) < 8 && UInt(Rm) < 8)
```

is equivalent to

```
MOV{<c>}{<q>} <Rd>, <Rm>, ASR #<imm>
```

and is always the preferred disassembly.

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rd>

For the “A1 MOV, shift or rotate by value” variant: is the general-purpose destination register, encoded in the “Rd” field. Arm deprecates using the PC as the destination register, but if the PC is used, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC](#).

For the “T2” and “T3 MOV, shift or rotate by value” variants: is the general-purpose destination register, encoded in the “Rd” field.

<Rm>

For the “A1 MOV, shift or rotate by value” variant: is the general-purpose source register, encoded in the “Rm” field. The PC can be used, but this is deprecated.

For the “T2” and “T3 MOV, shift or rotate by value” variants: is the general-purpose source register, encoded in the “Rm” field.

<imm>

For the “A1 MOV, shift or rotate by value” and “T2” variants: is the shift amount, in the range 1 to 32, encoded in the “imm5” field as <imm> modulo 32.

For the “T3 MOV, shift or rotate by value” variant: is the shift amount, in the range 1 to 32, encoded in the “imm3:imm2” field as <imm> modulo 32.

Operation

The description of [MOV, MOVS \(register\)](#) gives the operational pseudocode for this instruction.

C5.1.15 ASR (register)

Arithmetic Shift Right (register) shifts a register value right by a variable number of bits, shifting in copies of its sign bit, and writes the result to the destination register. The variable number of bits is read from the bottom byte of a register.

This is an alias of [MOV, MOVS \(register-shifted register\)](#). This means:

- The encodings in this description are named to match the encodings of [MOV, MOVS \(register-shifted register\)](#).
- The description of [MOV, MOVS \(register-shifted register\)](#) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#) and [T2](#)).

A1

Encoding for the Not flag setting variant

ASR{<c>}{<q>} {<Rd>, }<Rm>, <Rs>

is equivalent to

MOV{<c>}{<q>} <Rd>, <Rm>, ASR <Rs>

and is always the preferred disassembly.

T1

Encoding for the Arithmetic shift right variant

ASR<c>{<q>} {<Rdm>, }<Rdm>, <Rs>

is equivalent to

MOV<c>{<q>} <Rdm>, <Rdm>, ASR <Rs>

and is the preferred disassembly when `InITBlock()`.

T2

Encoding for the Not flag setting variant

```
ASR{<c>}{<q>}{<Rd>, }<Rm>, <Rs>
```

```
ASR<c>.W {<Rd>, }<Rm>, <Rs> // (InITBlock() && (UInt(Rd) < 8 && Rd == Rm && UInt(Rs) < 8))
```

is equivalent to

```
MOV{<c>}{<q>}{<Rd>, <Rm>, ASR <Rs>}
```

and is always the preferred disassembly.

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rd>

Is the general-purpose destination register, encoded in the “Rd” field.

<Rm>

Is the first general-purpose source register, encoded in the “Rm” field.

<Rs>

Is the second general-purpose source register holding a shift amount in its bottom 8 bits, encoded in the “Rs” field.

<Rdm>

Is the first general-purpose source register and the destination register, encoded in the “Rdm” field.

Operation

The description of [MOV, MOVS \(register-shifted register\)](#) gives the operational pseudocode for this instruction.

C5.1.16 ASRS (immediate)

Arithmetic Shift Right, setting flags (immediate) shifts a register value right by an immediate number of bits, shifting in copies of its sign bit, and writes the result to the destination register.

If the destination register is not the PC, this instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. Arm deprecates any use of these encodings. However, when the destination register is the PC:

- The PE branches to the address written to the PC, and restores [PSTATE](#) from SPSR_<current_mode>.
- The PE checks SPSR_<current_mode> for an illegal return event. See [Illegal return events from AArch32 state](#).
- The instruction is UNDEFINED in Hyp mode.
- The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

This is an alias of [MOV, MOVS \(register\)](#). This means:

- The encodings in this description are named to match the encodings of [MOV, MOVS \(register\)](#).
- The description of [MOV, MOVS \(register\)](#) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T2](#) and [T3](#)).

A1

Encoding for the MOVs, shift or rotate by value variant

ASRS{<c>}{<q>} {<Rd>, }<Rm>, #<imm>

is equivalent to

MOVS{<c>}{<q>} <Rd>, <Rm>, ASR #<imm>

and is always the preferred disassembly.

T2

Encoding for the T2 variant

ASRS{<q>} {<Rd>, }<Rm>, #<imm>

is equivalent to

MOVS<c>{<q>} <Rd>, <Rm>, ASR #<imm>

and is the preferred disassembly when !InITBlock().

T3

Encoding for the MOVs, shift or rotate by value variant

```
ASRS{<c>}{<q>} {<Rd>, }<Rm>, #<imm>
```

```
ASRS.W {<Rd>, }<Rm>, #<imm> // (!InITBlock() && UInt(Rd) < 8 && UInt(Rm) < 8)
```

is equivalent to

```
MOVS{<c>}{<q>} <Rd>, <Rm>, ASR #<imm>
```

and is always the preferred disassembly.

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rd>

For the “A1 MOVs, shift or rotate by value” variant: is the general-purpose destination register, encoded in the “Rd” field. Arm deprecates using the PC as the destination register, but if the PC is used, the instruction performs an exception return, that restores [PSTATE](#) from SPSR_<current_mode>.

For the “T2” and “T3 MOVs, shift or rotate by value” variants: is the general-purpose destination register, encoded in the “Rd” field.

<Rm>

For the “A1 MOVs, shift or rotate by value” variant: is the general-purpose source register, encoded in the “Rm” field. The PC can be used, but this is deprecated.

For the “T2” and “T3 MOVs, shift or rotate by value” variants: is the general-purpose source register, encoded in the “Rm” field.

<imm>

For the “A1 MOVs, shift or rotate by value” and “T2” variants: is the shift amount, in the range 1 to 32, encoded in the “imm5” field as <imm> modulo 32.

For the “T3 MOVs, shift or rotate by value” variant: is the shift amount, in the range 1 to 32, encoded in the “imm3:imm2” field as <imm> modulo 32.

Operation

The description of [MOV](#), [MOVS \(register\)](#) gives the operational pseudocode for this instruction.

C5.1.17 ASRS (register)

Arithmetic Shift Right, setting flags (register) shifts a register value right by a variable number of bits, shifting in copies of its sign bit, writes the result to the destination register, and updates the condition flags based on the result. The variable number of bits is read from the bottom byte of a register.

This is an alias of [MOV, MOVS \(register-shifted register\)](#). This means:

- The encodings in this description are named to match the encodings of [MOV, MOVS \(register-shifted register\)](#).
- The description of [MOV, MOVS \(register-shifted register\)](#) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#) and [T2](#)).

A1

Encoding for the Flag setting variant

ASRS{<c>}{<q>} {<Rd>, }<Rm>, <Rs>

is equivalent to

MOVS{<c>}{<q>} <Rd>, <Rm>, ASR <Rs>

and is always the preferred disassembly.

T1

Encoding for the Arithmetic shift right variant

ASRS{<q>} {<Rdm>, }<Rdm>, <Rs>

is equivalent to

MOVS{<q>} <Rdm>, <Rdm>, ASR <Rs>

and is the preferred disassembly when !InITBlock().

T2

Encoding for the Flag setting variant

ASRS{<c>}{<q>}{<Rd>,<Rm>,<Rs>}

```
ASRS.W {<Rd>, }<Rm>, <Rs> // (!InITBlock() && (UInt(Rd) < 8 && Rd == Rm && UInt(Rs) < 8))
```

is equivalent to

```
MOVS{<c>}{<q>} <Rd>, <Rm>, ASR <Rs>
```

and is always the preferred disassembly.

Assembler Symbols

 $\langle c \rangle$

See [Standard assembler syntax fields](#).

 $\langle q \rangle$

See [Standard assembler syntax fields](#).

<Rd>

Is the general-purpose destination register, encoded in the “Rd” field.

<Rm>

Is the first general-purpose source register, encoded in the “Rm” field.

 $\langle R_s \rangle$

Is the second general-purpose source register holding a shift amount in its bottom 8 bits, encoded in the “Rs” field.

<Rdm>

Is the first general-purpose source register and the destination register, encoded in the “Rdm” field.

Operation

The description of [MOV, MOVS \(register-shifted register\)](#) gives the operational pseudocode for this instruction.

C5.1.18 B

Branch causes a branch to a target address.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1, T2, T3, and T4).

A1

Encoding

$$B\{\langle c \rangle\} \{\langle q \rangle\} \quad \langle \text{label} \rangle$$

Decode for this encoding

```
let imm32 : bits(32) = SignExtend{}(imm24::'00');
```

T1

Encoding

B<c>{<g>} <label> // (Not permitted in IT block)

Decode for this encoding

```

if cond == 'l110' then See("UDF"); end;
if cond == 'l111' then See("SVC"); end;
let imm32 : bits(32) = SignExtend{(imm8::'0')};
if InITBlock() then UnpredictableProcedure(); end;

```

T2

Encoding

```
B{<c>}{<q>} <label> // (Outside or last in IT block)
```

Decode for this encoding

```
let imm32 : bits(32) = SignExtend{{imm11::'0'}};
if InITBlock() && !LastInITBlock() then UnpredictableProcedure(); end;
```

T3

Encoding

B<c>.W <label> // (Not permitted in IT block, and <label> can be represented in T1)

B<c>{<q>} <label> // (Not permitted in IT block)

Decode for this encoding

```
if cond[3:1] == '111' then See("Related encodings"); end;
let imm32 : bits(32) = SignExtend{(S::J2::J1::imm6::imm11::'0')};
if InITBlock() then UnpredictableProcedure(); end;
```

T4

Encoding

$$B\{\langle c \rangle\} \{\langle q \rangle\} \quad \langle \text{label} \rangle$$

```
B{<c>}.W <label> // (<label> can be represented in T2)
```

Decode for this encoding

```

let I1 : bit = NOT(J1 XOR S);
let I2 : bit = NOT(J2 XOR S);
let imm32 : bits(32) = SignExtend{(S::I1::I2::imm10::imm11::'0')};
if InITBlock() && !LastInITBlock() then UnpredictableProcedure(); end;

```

For more information about the CONSTRAINED UNPREDICTABLE behavior, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Related encodings: [Branches and miscellaneous control](#).

Assembler Symbols

<c>

For the “A1”, “T2”, and “T4” variants: see [Standard assembler syntax fields](#).

For the “T1” and “T3” variants: see [Standard assembler syntax fields](#). Must not be `AL` or omitted.

<q>

See [Standard assembler syntax fields](#).

<label>

For the “A1” variant: the label of the instruction that is to be branched to. The assembler calculates the required value of the offset from the PC value of the `B` instruction to this label, then selects an encoding that sets `imm32` to that offset.

Permitted offsets are multiples of 4 in the range -33554432 to 33554428 .

For the “T1” variant: the label of the instruction that is to be branched to. The assembler calculates the required value of the offset from the PC value of the `B` instruction to this label, then selects an encoding that sets `imm32` to that offset. Permitted offsets are even numbers in the range -256 to 254 .

For the “T2” variant: the label of the instruction that is to be branched to. The assembler calculates the required value of the offset from the PC value of the `B` instruction to this label, then selects an encoding that sets `imm32` to that offset. Permitted offsets are even numbers in the range -2048 to 2046 .

For the “T3” variant: the label of the instruction that is to be branched to. The assembler calculates the required value of the offset from the PC value of the `B` instruction to this label, then selects an encoding that sets `imm32` to that offset.

Permitted offsets are even numbers in the range -1048576 to 1048574 .

For the “T4” variant: the label of the instruction that is to be branched to. The assembler calculates the required value of the offset from the PC value of the `B` instruction to this label, then selects an encoding that sets `imm32` to that offset.

Permitted offsets are even numbers in the range -16777216 to 16777214 .

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    BranchWritePC(PC32() + imm32, BranchType_DIR);
end;
```

C5.1.19 BFC

Bit Field Clear clears any number of adjacent bits at any position in a register, without affecting the other bits in the register.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

BFC{<c>}{<q>} <Rd>, #<lsb>, #<width>

Decode for this encoding

```
let d : integer = UInt(Rd);
let msbit : integer{} = UInt(msb);
let lsbit : integer{} = UInt(lsb);
if d == 15 then UnpredictableProcedure(); end;
if msbit < lsbit then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If $msbit < lsbit$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The value in the destination register is UNKNOWN.

T1

Encoding

BFC{<c>}{<q>} <Rd>, #<lsb>, #<width>

Decode for this encoding

```
let d : integer = UInt(Rd);
let msbit : integer{} = UInt(msb);
let lsbit : integer{} = UInt(imm3::imm2);
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 then UnpredictableProcedure(); end;
if msbit < lsbit then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `msbit < lsbit`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The value in the destination register is UNKNOWN.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rd>

Is the general-purpose destination register, encoded in the “Rd” field.

<lsb>

For the “A1” variant: is the least significant bit to be cleared, in the range 0 to 31, encoded in the “lsb” field.

For the “T1” variant: is the least significant bit that is to be cleared, in the range 0 to 31, encoded in the “imm3:imm2” field.

<width>

Is the number of bits to be cleared, in the range 1 to 32-`<lsb>`, encoded in the “msb” field as `<lsb>+<width>-1`.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    R(d)[msbit:lsbit] = Replicate{(msbit-lsbit)+1}('0');
    // Other bits of R[d] are unchanged
end;
```

C5.1.20 BFI

Bit Field Insert copies any number of low order bits from a register into the same number of adjacent bits at any position in the destination register.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

BFI{<c>}{<q>} <Rd>, <Rn>, #<lsb>, #<width>

Decode for this encoding

```

if Rn == '1111' then See("BFC"); end;
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let msbit : integer{} = UInt(msb);
let lsbit : integer{} = UInt(lsb);
if d == 15 then UnpredictableProcedure(); end;
if msbit < lsbit then UnpredictableProcedure(); end;

```

CONSTRAINED UNPREDICTABLE behavior

If `msbit < lsbit`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The value in the destination register is UNKNOWN.

T1

Encoding

BFI{<c>}{<q>} <Rd>, <Rn>, #<lsb>, #<width>

Decode for this encoding

```

if Rn == '1111' then See("BFC"); end;
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let msbit : integer{} = UInt(msb);
let lsbit : integer{} = UInt(imm3::imm2);
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 then UnpredictableProcedure(); end;
if msbit < lsbit then UnpredictableProcedure(); end;

```

CONSTRAINED UNPREDICTABLE behavior

If `msbit < lsbit`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The value in the destination register is UNKNOWN.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rd>

Is the general-purpose destination register, encoded in the “Rd” field.

<Rn>

Is the general-purpose source register, encoded in the “Rn” field.

<lsb>

For the “A1” variant: is the least significant destination bit, in the range 0 to 31, encoded in the “lsb” field.

For the “T1” variant: is the least significant destination bit, in the range 0 to 31, encoded in the “imm3:imm2” field.

<width>

Is the number of bits to be copied, in the range 1 to 32-`<lsb>`, encoded in the “msb” field as `<lsb>+<width>-1`.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    R(d)[msbit:lsbit] = R(n)[(msbit-lsbit):0];
    // Other bits of R[d] are unchanged
end;
```

C5.1.21 BIC, BICS (immediate)

Bitwise Bit Clear (immediate) performs a bitwise AND of a register value and the complement of an immediate value, and writes the result to the destination register.

If the destination register is not the PC, the BICS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. Arm deprecates any use of these encodings. However, when the destination register is the PC:

- The BIC variant of the instruction is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC](#).
- The BICS variant of the instruction performs an exception return without the use of the stack. In this case:
 - The PE branches to the address written to the PC, and restores **PSTATE** from SPSR_<current_mode>.
 - The PE checks SPSR_<current_mode> for an illegal return event. See [Illegal return events from AArch32 state](#).
 - The instruction is UNDEFINED in Hyp mode.
 - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding for the BIC variant

Applies when (S == 0)

BIC{<c>}{<q>} {<Rd>, }<Rn>, #<const>

Encoding for the BICS variant

Applies when (S == 1)

BICS{<c>}{<q>} {<Rd>, }<Rn>, #<const>

Decode for all variants of this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let setflags : boolean = (S == '1');
let a32 : boolean = TRUE;
let imm : bits(12) = imm12;
```

T1

Encoding for the BIC variant

Applies when (S == 0)

BIC{<c>}{<q>} {<Rd>, }<Rn>, #<const>

Encoding for the BICS variant

Applies when (S == 1)

BICS{<c>}{<q>} {<Rd>, }<Rn>, #<const>

Decode for all variants of this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let setflags : boolean = (S == '1');
let a32 : boolean = FALSE;
let imm : bits(12) = i::imm3::imm8;
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 || n == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rd>

For the “A1 BIC” and “A1 BICS” variants: is the general-purpose destination register, encoded in the “Rd” field. If omitted, this register is the same as <Rn>. Arm deprecates using the PC as the destination register, but if the PC is used:

- For the BIC variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC](#).
- For the BICS variant, the instruction performs an exception return, that restores [PSTATE](#) from `SPSR_<current_mode>`.

For the “T1 BIC” and “T1 BICS” variants: is the general-purpose destination register, encoded in the “Rd” field. If omitted, this register is the same as <Rn>.

<Rn>

For the “A1 BIC” and “A1 BICS” variants: is the general-purpose source register, encoded in the “Rn” field. The PC can be used, but this is deprecated.

For the “T1 BIC” and “T1 BICS” variants: is the general-purpose source register, encoded in the “Rn” field.

<const>

For the “A1 BIC” and “A1 BICS” variants: an immediate value. See [Modified immediate constants in A32 instructions](#) for the range of values.

For the “T1 BIC” and “T1 BICS” variants: an immediate value. See [Modified immediate constants in T32 instructions](#) for the range of values.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let (imm32, carry) : (bits(32), bit) = (if a32 then A32ExpandImm_C(imm, PSTATE.C)
                                              else T32ExpandImm_C(imm, PSTATE.C));

    let result : bits(32) = R(n) AND NOT(imm32);
    if d == 15 then                // Can only occur for A32 encoding
        if setflags then
            ALUExceptionReturn(result);
        else
            ALUWritePC(result);
        end;
    else
        R(d) = result;
        if setflags then
            PSTATE.N = result[31];
            PSTATE.Z = IsZeroBit{32}(result);
            PSTATE.C = carry;
            // PSTATE.V unchanged
        end;
    end;
end;
```

C5.1.22 BIC, BICS (register)

Bitwise Bit Clear (register) performs a bitwise AND of a register value and the complement of an optionally-shifted register value, and writes the result to the destination register.

If the destination register is not the PC, the BICS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. Arm deprecates any use of these encodings. However, when the destination register is the PC:

- The BIC variant of the instruction is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC](#).
- The BICS variant of the instruction performs an exception return without the use of the stack. In this case:
 - The PE branches to the address written to the PC, and restores **PSTATE** from SPSR_<current_mode>.
 - The PE checks SPSR_<current_mode> for an illegal return event. See [Illegal return events from AArch32 state](#).
 - The instruction is UNDEFINED in Hyp mode.
 - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#) and [T2](#)).

A1

Encoding for the BIC, rotate right with extend variant

Applies when (S == 0 && imm5 == 00000 && stype == 11)

BIC{<c>}{<q>} {<Rd>, }<Rn>, <Rm>, RRX

Encoding for the BIC, shift or rotate by value variant

Applies when (S == 0 && !(imm5 == 00000 && stype == 11))

BIC{<c>}{<q>} {<Rd>, }<Rn>, <Rm> {, <shift> #<amount>}

Encoding for the BICS, rotate right with extend variant

Applies when (S == 1 && imm5 == 00000 && stype == 11)

BICS{<c>}{<q>} {<Rd>, }<Rn>, <Rm>, RRX

Encoding for the BICS, shift or rotate by value variant

Applies when (S == 1 && !(imm5 == 00000 && stype == 11))

BICS{<c>}{<q>} {<Rd>, }<Rn>, <Rm> {, <shift> #<amount>}

Decode for all variants of this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let setflags : boolean = (S == '1');
let (shift_t, shift_n) : (SRTYPE, integer) = DecodeImmShift(stype, imm5);
```

T1

Encoding

BIC<c>{<q>} {<Rdn>, }<Rdn>, <Rm> // (InITBlock())

BICS{<q>} {<Rdn>, }<Rdn>, <Rm> // (Outside IT block)

Decode for this encoding

```
let d : integer = UInt(Rdn);
let n : integer = UInt(Rdn);
let m : integer = UInt(Rm);
let setflags : boolean = !InITBlock();
let shift_t : SRTYPE = SRTYPE_LSL;
let shift_n : integer = 0;
```

T2

Encoding for the BIC, rotate right with extend variant

Applies when (S == 0 && imm3 == 000 && imm2 == 00 && stype == 11)

BIC{<c>}{<q>} {<Rd>, }<Rn>, <Rm>, RRX

Encoding for the BIC, shift or rotate by value variant

Applies when (S == 0 && !(imm3 == 000 && imm2 == 00 && stype == 11))

BIC{<c>}{<q>} {<Rd>, }<Rn>, <Rm> {, <shift> #<amount>}

BIC<c>.W {<Rd>, }<Rn>, <Rm> // (Inside IT block, and <Rd>, <Rn>, <Rm> can be represented in T1)

Encoding for the BICS, rotate right with extend variant

Applies when (S == 1 && imm3 == 000 && imm2 == 00 && stype == 11)

BICS{<c>}{<q>} {<Rd>, }<Rn>, <Rm>, RRX

Encoding for the BICS, shift or rotate by value variant

Applies when (S == 1 && !(imm3 == 000 && imm2 == 00 && stype == 11))

BICS{<c>}{<q>} {<Rd>, }<Rn>, <Rm> {, <shift> #<amount>}

BICS.W {<Rd>, }<Rn>, <Rm> // (Outside IT block, and <Rd>, <Rn>, <Rm> can be represented in T1)

Decode for all variants of this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let setflags : boolean = (S == '1');
let (shift_t, shift_n) : (SRTYPE, integer) = DecodeImmShift(stype, imm3::imm2);
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rd>

For the “A1 BIC, rotate right with extend”, “A1 BIC, shift or rotate by value”, “A1 BICS, rotate right with extend”, and “A1 BICS, shift or rotate by value” variants: is the general-purpose destination register, encoded in the “Rd” field. If omitted, this register is the same as <Rn>. Arm deprecates using the PC as the destination register, but if the PC is used:

- For the BIC variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC](#).
- For the BICS variant, the instruction performs an exception return, that restores [PSTATE](#) from `SPSR_<current_mode>`.

For the “T2 BIC, rotate right with extend”, “T2 BIC, shift or rotate by value”, “T2 BICS, rotate right with extend”, and “T2 BICS, shift or rotate by value” variants: is the general-purpose destination register, encoded in the “Rd” field. If omitted, this register is the same as <Rn>.

<Rn>

For the “A1 BIC, rotate right with extend”, “A1 BIC, shift or rotate by value”, “A1 BICS, rotate right with extend”, and “A1 BICS, shift or rotate by value” variants: is the first general-purpose source register, encoded in the “Rn” field. The PC can be used, but this is deprecated.

For the “T2 BIC, rotate right with extend”, “T2 BIC, shift or rotate by value”, “T2 BICS, rotate right with extend”, and “T2 BICS, shift or rotate by value” variants: is the first general-purpose source register, encoded in the “Rn” field.

<Rm>

For the “A1 BIC, rotate right with extend”, “A1 BIC, shift or rotate by value”, “A1 BICS, rotate right with extend”, and “A1 BICS, shift or rotate by value” variants: is the second general-purpose source register, encoded in the “Rm” field. The PC can be used, but this is deprecated.

For the “T1”, “T2 BIC, rotate right with extend”, “T2 BIC, shift or rotate by value”, “T2 BICS, rotate right with extend”, and “T2 BICS, shift or rotate by value” variants: is the second general-purpose source register, encoded in the “Rm” field.

<shift>

Is the type of shift to be applied to the second source register, encoded in “stype”:

stype	<shift>
00	LSL
01	LSR
10	ASR
11	ROR

<amount>

For the “A1 BIC, shift or rotate by value” and “A1 BICS, shift or rotate by value” variants: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR), encoded in the “imm5” field as <amount> modulo 32.

For the “T2 BIC, shift or rotate by value” and “T2 BICS, shift or rotate by value” variants: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR), encoded in the “imm3:imm2” field as <amount> modulo 32.

<Rdn>

Is the first general-purpose source register and the destination register, encoded in the “Rdn” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let (shifted, carry) : (bits(32), bit) = Shift_C{32}(R(m), shift_t, shift_n, PSTATE.C);
    let result : bits(32) = R(n) AND NOT(shifted);
    if d == 15 then // Can only occur for A32 encoding
        if setflags then
            ALUEXCEPTIONReturn(result);
        else
            ALUWritePC(result);
        end;
    else
        R(d) = result;
        if setflags then
            PSTATE.N = result[31];
            PSTATE.Z = IsZeroBit{32}(result);
            PSTATE.C = carry;
            // PSTATE.V unchanged
        end;
    end;
end;
end;
```

C5.1.23 BIC, BICS (register-shifted register)

Bitwise Bit Clear (register-shifted register) performs a bitwise AND of a register value and the complement of a register-shifted register value. It writes the result to the destination register, and can optionally update the condition flags based on the result.

Encoding for the Flag setting variant

Applies when (S == 1)

BICS{<c>}{<q>} {<Rd>, }<Rn>, <Rm>, <shift> <Rs>

Encoding for the Not flag setting variant

Applies when (S == 0)

BIC{<c>}{<q>} {<Rd>, }<Rn>, <Rm>, <shift> <Rs>

Decode for all variants of this encoding

```

let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let s : integer = UInt(Rs);
let setflags : boolean = (S == '1');
let shift_t : SType = DecodeRegShift(stype);
if d == 15 || n == 15 || m == 15 || s == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rd>

Is the general-purpose destination register, encoded in the “Rd” field.

<Rn>

Is the first general-purpose source register, encoded in the “Rn” field.

<Rm>

Is the second general-purpose source register, encoded in the “Rm” field.

<shift>

Is the type of shift to be applied to the second source register, encoded in “stype”:

stype	<shift>
00	LSL
01	LSR
10	ASR
11	ROR

<Rs>

Is the general-purpose source register holding a shift amount in its bottom 8 bits, encoded in the “Rs” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let shift_n : integer = UInt(R(s)[7:0]);
    let (shifted, carry) : (bits(32), bit) = Shift_C{32}(R(m), shift_t, shift_n, PSTATE.C);
    let result : bits(32) = R(n) AND NOT(shifted);
    R(d) = result;
    if setflags then
        PSTATE.N = result[31];
        PSTATE.Z = IsZeroBit{32}(result);
        PSTATE.C = carry;
        // PSTATE.V unchanged
    end;
end;
```

C5.1.24 BKPT

Breakpoint causes a Breakpoint Instruction exception.

Breakpoint is always unconditional, even when inside an IT block.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

BKPT{<q>} {#}<imm>

Decode for this encoding

```
let imm16 : bits(16) = imm12::imm4;
if cond != '1110' then UnpredictableProcedure(); end; // BKPT must be encoded with AL condition
```

CONSTRAINED UNPREDICTABLE behavior

If cond != '1110', then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes unconditionally.
- The instruction executes conditionally.

T1

Encoding

BKPT{<q>} {#}<imm>

Decode for this encoding

```
let imm16 : bits(16) = ZeroExtend{}(imm8);
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<q>

See [Standard assembler syntax fields](#). A BKPT instruction must be unconditional.

<imm>

For the “A1” variant: is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the “imm12:imm4” field. This value:

- Is recorded in the Comment field of ESR_ELx.ISS if the Software Breakpoint Instruction exception is taken to an exception level that is using AArch64.
- Is ignored otherwise.

For the “T1” variant: is a 8-bit unsigned immediate, in the range 0 to 255, encoded in the “imm8” field. This value:

- Is recorded in the Comment field of ESR_ELx.ISS if the Software Breakpoint Instruction exception is taken to an exception level that is using AArch64.
- Is ignored otherwise.

Operation

```
EncodingSpecificOperations();  
AArch32\_SoftwareBreakpoint(imm16);
```

C5.1.25 BL, BLX (immediate)

Branch with Link and optional Exchange (immediate)

Branch with Link calls a subroutine at a PC-relative address, and setting LR to the return address.

Branch with Link and Exchange Instruction Sets (immediate) calls a subroutine at a PC-relative address, setting LR to the return address, and changes the instruction set from A32 to T32, or from T32 to A32.

It has encodings from the following instruction sets: A32 ([A1](#) and [A2](#)) and T32 ([T1](#) and [T2](#)).

A1

Encoding

```
BL{<c>} {<q>}    <label>
```

Decode for this encoding

```
let imm32 : bits(32) = SignExtend{}(imm24::'00');
let targetInstrSet : InstrSet = InstrSet_A32;
```

A2

Encoding

```
BLX{<c>}{<q>}  <label>
```

Decode for this encoding

```
let imm32 : bits(32) = SignExtend{}(imm24::H::'0');
let targetInstrSet : InstrSet = InstrSet T32;
```

T1

Encoding

$$\text{BL}\{\langle c \rangle\} \{\langle q \rangle\} \quad \langle \text{label} \rangle$$

Decode for this encoding

```
let I1 : bit = NOT(J1 XOR S);
let I2 : bit = NOT(J2 XOR S);
let imm32 : bits(32) = SignExtend{(S::I1::I2::imm10::imm11::'0')};
let targetInstrSet : InstrSet = InstrSet_T32;
if InITBlock() && !LastInITBlock() then UnpredictableProcedure(); end;
```

T2

15	13	12	11	10	9											0	15	14	13	12	11	10											1	0
1	1	1	1	0	S	imm10H										1	1	J1	0	J2	imm10L										H			

Encoding

```
BLX{<c>}{<q>} <label>
```

Decode for this encoding

```
if H == '1' then Undefined(); end;
let I1 : bit = NOT(J1 XOR S);
let I2 : bit = NOT(J2 XOR S);
let imm32 : bits(32) = SignExtend{(S::I1::I2::imm10H::imm10L::'00')};
let targetInstrSet : InstrSet = InstrSet_A32;
if InITBlock() && !LastInITBlock() then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

For the “A1”, “T1”, and “T2” variants: see [Standard assembler syntax fields](#).
For the “A2” variant: see [Standard assembler syntax fields](#). <c> must be AL or omitted.

<q>

See [Standard assembler syntax fields](#).

<label>

For the “A1” variant: the label of the instruction that is to be branched to. The assembler calculates the required value of the offset from the PC value of the BL instruction to this label, then selects an encoding that sets imm32 to that offset.

Permitted offsets are multiples of 4 in the range –33554432 to 33554428.

For the “A2” variant: the label of the instruction that is to be branched to. The assembler calculates the required value of the offset from the PC value of the BLX instruction to this label, then selects an encoding with imm32 set to that offset.

Permitted offsets are even numbers in the range –33554432 to 33554430.

For the “T1” variant: the label of the instruction that is to be branched to.

The assembler calculates the required value of the offset from the PC value of the BL instruction to this label, then selects an encoding with imm32 set to that offset.

Permitted offsets are even numbers in the range –16777216 to 16777214.

For the “T2” variant: the label of the instruction that is to be branched to.

The assembler calculates the required value of the offset from the `Align(PC, 4)` value of the BLX instruction to this label, then selects an encoding with `imm32` set to that offset.

Permitted offsets are multiples of 4 in the range -16777216 to 16777212 .

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    if CurrentInstrSet() == InstrSet_A32 then
        LR() = PC32() - 4;
    else
        LR() = PC32()[31:1] :: '1';
    end;
    var targetAddress : bits(32);
    if targetInstrSet == InstrSet_A32 then
        targetAddress = AlignDownSize(PC32(), 4) + imm32;
    else
        targetAddress = PC32() + imm32;
    end;
    SelectInstrSet(targetInstrSet);
    BranchWritePC(targetAddress, BranchType_DIRCALL);
end;
```

C5.1.26 BLX (register)

Branch with Link and Exchange (register) calls a subroutine at an address specified in the register, and if necessary changes to the instruction set indicated by bit[0] of the register value. If the value in bit[0] is 0, the instruction set after the branch will be A32. If the value in bit[0] is 1, the instruction set after the branch will be T32.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

$$\text{BLX}\{\langle c \rangle\} \{\langle q \rangle\} \quad \langle \text{Rm} \rangle$$

Decode for this encoding

```
let m : integer = UInt(Rm);
if m == 15 then UnpredictableProcedure(); end;
```

T1

Encoding

$$\text{BLX}\{\langle c \rangle\} \{\langle q \rangle\} \quad \langle \text{Rm} \rangle$$

Decode for this encoding

```
let m : integer = UInt(Rm);
if m == 15 then UnpredictableProcedure(); end;
if InITBlock() && !LastInITBlock() then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

 $\langle q \rangle$

See [Standard assembler syntax fields](#).

 $\langle R_m \rangle$

Is the general-purpose register holding the address to be branched to, encoded in the “Rm” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let target : bits(32) = R(m);
    var next_instr_addr : bits(32);
    if CurrentInstrSet() == InstrSet_A32 then
        next_instr_addr = PC32() - 4;
        LR() = next_instr_addr;
    else
        next_instr_addr = PC32() - 2;
        LR() = next_instr_addr[31:1] :: '1';
    end;
    BXWritePC(target, BranchType_INDCALL);
end;
```

C5.1.27 BX

Branch and Exchange causes a branch to an address and instruction set specified by a register.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1).

A1

Encoding

BX{<c>}{<q>}<Rm>

Decode for this encoding

let m : integer = UInt(Rm);

T1

Encoding

BX{<c>}{<q>}<Rm>

Decode for this encoding

let m : integer = UInt(Rm);
if InITBlock() && !LastInITBlock() then UnpredictableProcedure(); end;

For more information about the CONSTRAINED UNPREDICTABLE behavior, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rm>

For the “A1” variant: is the general-purpose register holding the address to be branched to, encoded in the “Rm” field. The PC can be used.

For the “T1” variant: is the general-purpose register holding the address to be branched to, encoded in the “Rm” field. The PC can be used.

Note

If <Rm> is the PC at a non word-aligned address, it results in UNPREDICTABLE behavior because the address passed to the `BXWritePC()` pseudocode function has bits<1:0> = '10'.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    BXWritePC(R(m), BranchType_INDIR);
end;
```

C5.1.28 BXJ

Branch and Exchange, previously Branch and Exchange Jazelle.

BXJ behaves as a **BX** instruction, see **BX**. This means it causes a branch to an address and instruction set specified by a register.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

$$\text{BXJ}\{\langle c \rangle\}\{\langle q \rangle\} \quad \langle \text{Rm} \rangle$$

Decode for this encoding

```
let m : integer = UInt(Rm);
if m == 15 then UnpredictableProcedure(); end;
```

T1

Encoding

$$\text{BXJ}\{\langle c \rangle\}\{\langle q \rangle\} \quad \langle \text{Rm} \rangle$$

Decode for this encoding

```
let m : integer = UInt(Rm);
// Armv8-A removes UNPREDICTABLE for R13
if m == 15 then UnpredictableProcedure(); end;
if InITBlock() && !LastInITBlock() then UnpredictableProcedure(); end;
```

For more information about the `CONSTRAINED UNPREDICTABLE` behavior, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

 $\langle q \rangle$

See [Standard assembler syntax fields](#).

<Rm>

Is the general-purpose register holding the address to be branched to, encoded in the “Rm” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    BXWritePC(R(m), BranchType_INDIR);
end;
```

C5.1.29 CBNZ, CBZ

Compare and Branch on Nonzero or Zero

Compare and Branch on Nonzero and Compare and Branch on Zero compare the value in a register with zero, and conditionally branch forward a constant value. They do not affect the condition flags.

15	12	11	10	9	8	7	3	2	0
1	0	1	1	op	0	i	1	imm5	Rn

Encoding for the CBNZ variant

Applies when (op == 1)

CBNZ{<q>} <Rn>, <label>

Encoding for the CBZ variant

Applies when (op == 0)

CBZ{<q>} <Rn>, <label>

Decode for all variants of this encoding

```
let n : integer = UInt(Rn);
let imm32 : bits(32) = ZeroExtend{(i::imm5::'0')};
let nonzero : boolean = (op == '1');
if InITBlock() then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<q>

See [Standard assembler syntax fields](#).

<Rn>

Is the general-purpose register to be tested, encoded in the “Rn” field.

<label>

Is the program label to be conditionally branched to. Its offset from the PC, a multiple of 2 and in the range 0 to 126, is encoded as “i:imm5” times 2.

Operation

```
EncodingSpecificOperations();
if nonzero != IsZero(R(n)) then
    CBWritePC(PC32() + imm32);
end;
```

C5.1.30 CLREX

Clear-Exclusive clears the local monitor of the executing PE.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

31	28	27	26	25	21	20	19	8	7	4	3	0	
1	1	1	1	0	1	0	1	(1)(1)(1)(1)(1)(1)(1)(1)(0)(0)(0)(0)	0	0	0	1	(1)(1)(1)(1)
opcode										option			

Encoding

CLREX{<c>}{<q>}

Decode for this encoding

// No additional decoding required

T1

opc																option						

Encoding

CLREX{<c>}{<q>}

Decode for this encoding

// No additional decoding required

For more information about the CONSTRAINED UNPREDICTABLE behavior, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

For the “A1” variant: see [Standard assembler syntax fields](#). Must be AL or omitted.

For the “T1” variant: see [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    ClearExclusiveLocal(ProcessorID());
end;
```

C5.1.31 CLZ

Count Leading Zeros returns the number of binary zero bits before the first binary one bit in a value.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

CLZ{<c>}{<q>} <Rd>, <Rm>

Decode for this encoding

```
let d : integer = UInt(Rd);
let m : integer = UInt(Rm);
if d == 15 || m == 15 then UnpredictableProcedure(); end;
```

T1

Encoding

CLZ{<c>}{<q>} <Rd>, <Rm>

Decode for this encoding

```

let d : integer = UInt(Rd);
let m : integer = UInt(Rm);
let n : integer = UInt(Rn);
// Armv8-A removes UNPREDICTABLE for R13
if m != n || d == 15 || m == 15 then UnpredictableProcedure(); end;

```

CONSTRAINED UNPREDICTABLE behavior

If $m \neq n$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes as described, with no change to its behavior and no additional side effects.
- The instruction executes with the additional decode: $m = \text{UInt}(R_n)$.
- The value in the destination register is UNKNOWN.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rd>

Is the general-purpose destination register, encoded in the “Rd” field.

<Rm>

For the “A1” variant: is the general-purpose source register, encoded in the “Rm” field.

For the “T1” variant: is the general-purpose source register, encoded in the “Rm” field. It must be encoded with an identical value in the “Rn” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let result : integer = CountLeadingZeroBits(R(m));
    R(d) = result[31:0];
end;
```

C5.1.32 CMN (immediate)

Compare Negative (immediate) adds a register value and an immediate value. It updates the condition flags based on the result, and discards the result.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

CMN{<c>}{<q>} <Rn>, #<const>

Decode for this encoding

```
let n : integer = UInt(Rn);
let imm32 : bits(32) = A32ExpandImm(imm12);
```

T1

Encoding

CMN{<c>}{<q>} <Rn>, #<const>

Decode for this encoding

```
let n : integer = UInt(Rn);
let imm32 : bits(32) = T32ExpandImm(i::imm3::imm8);
if n == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rn>

For the “A1” variant: is the general-purpose source register, encoded in the “Rn” field. The PC can be used, but this is deprecated.

For the “T1” variant: is the general-purpose source register, encoded in the “Rn” field.

<const>

For the “A1” variant: an immediate value. See [Modified immediate constants in A32 instructions](#) for the range of values.

For the “T1” variant: an immediate value. See [Modified immediate constants in T32 instructions](#) for the range of values.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
let (result, nzcvc) : (bits(32), bits(4)) = AddWithCarry{32}(R(n), imm32, '0');
PSTATE.[N,Z,C,V] = nzcvc;
end;
```

C5.1.33 CMN (register)

Compare Negative (register) adds a register value and an optionally-shifted register value. It updates the condition flags based on the result, and discards the result.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#) and [T2](#)).

A1

Encoding for the Rotate right with extend variant

Applies when (imm5 == 00000 && stype == 11)

CMN{<c>}{<q>} <Rn>, <Rm>, RRX

Encoding for the Shift or rotate by value variant

Applies when (!(imm5 == 00000 && stype == 11))

CMN{<c>}{<q>} <Rn>, <Rm> {, <shift> #<amount>}

Decode for all variants of this encoding

```
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let (shift_t, shift_n) : (SRTYPE, integer) = DecodeImmShift(stype, imm5);
```

T1

Encoding

CMN{<c>}{<q>} <Rn>, <Rm>

Decode for this encoding

```
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let shift_t : SRTYPE = SRTYPE_LSL;
let shift_n : integer = 0;
```

T2

Encoding for the Rotate right with extend variant

Applies when (imm3 == 000 && imm2 == 00 && stype == 11)

CMN { <c> } { <q> } <Rn>, <Rm>, RRX

Encoding for the Shift or rotate by value variant

Applies when `(!(imm3 == 000 && imm2 == 00 && stype == 11))`

CMN{<c>}{<q>} <Rn>, <Rm> {, <shift> #<amount>}

CMN{<c>}.W <Rn>, <Rm> // (<Rn>, <Rm> can be represented in T1)

Decode for all variants of this encoding

```

let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let (shift_t, shift_n) : (SRTType, integer) = DecodeImmShift(stype, imm3::imm2);
// Armv8-A removes UNPREDICTABLE for R13
if n == 15 || m == 15 then UnpredictableProcedure(); end;

```

For more information about the `CONSTRAINED UNPREDICTABLE` behavior, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

 $\langle q \rangle$

See [Standard assembler syntax fields](#).

 $\langle R_n \rangle$

For the “A1 Rotate right with extend” and “A1 Shift or rotate by value” variants: is the first general-purpose source register, encoded in the “Rn” field. The PC can be used, but this is deprecated.

For the “T1”, “T2 Rotate right with extend”, and “T2 Shift or rotate by value” variants: is the first general-purpose source register, encoded in the “Rn” field.

<Rm>

For the “A1 Rotate right with extend” and “A1 Shift or rotate by value” variants: is the second general-purpose source register, encoded in the “Rm” field. The PC can be used, but this is deprecated.

For the “T1”, “T2 Rotate right with extend”, and “T2 Shift or rotate by value” variants: is the second general-purpose source register, encoded in the “Rm” field.

<shift>

Is the type of shift to be applied to the second source register, encoded in “stype”:

stype	<shift>
00	LSL
01	LSR
10	ASR
11	ROR

<amount>

For the “A1 Shift or rotate by value” variant: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the “imm5” field as <amount> modulo 32.

For the “T2 Shift or rotate by value” variant: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR), encoded in the “imm3:imm2” field as <amount> modulo 32.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let shifted : bits(32) = Shift{}(R(m), shift_t, shift_n, PSTATE.C);
    let (result, nzcvc) : (bits(32), bits(4)) = AddWithCarry{32}(R(n), shifted, '0');
    PSTATE.[N,Z,C,V] = nzcvc;
end;
```

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let shift_n : integer = UInt(R(s)[7:0]);
    let shifted : bits(32) = Shift{}(R(m), shift_t, shift_n, PSTATE.C);
    let (result, nzcv) : (bits(32), bits(4)) = AddWithCarry{32}(R(n), shifted, '0');
    PSTATE.[N,Z,C,V] = nzcv;
end;
```

C5.1.35 CMP (immediate)

Compare (immediate) subtracts an immediate value from a register value. It updates the condition flags based on the result, and discards the result.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#) and [T2](#)).

A1

Encoding

CMP{<c>}{<q>} <Rn>, #<const>

Decode for this encoding

```
let n : integer = UInt(Rn);
let imm32 : bits(32) = A32ExpandImm(imm12);
```

T1

Encoding

CMP{<c>}{<q>} <Rn>, #<imm8>

Decode for this encoding

```
let n : integer = UInt(Rn);
let imm32 : bits(32) = ZeroExtend{}(imm8);
```

T2

Encoding

CMP{<c>}{<q>} <Rn>, #<const>

CMP{<c>}.W <Rn>, #<const> // (<Rd>, <const> can be represented in T1)

Decode for this encoding

```
let n : integer = UInt(Rn);  
let imm32 : bits(32) = T32ExpandImm(i::imm3::imm8);  
if n == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rn>

For the “A1” variant: is the general-purpose source register, encoded in the “Rn” field. The PC can be used, but this is deprecated.

For the “T1” variant: is a general-purpose source register, encoded in the “Rn” field.

For the “T2” variant: is the general-purpose source register, encoded in the “Rn” field.

<const>

For the “A1” variant: an immediate value. See [Modified immediate constants in A32 instructions](#) for the range of values.

For the “T2” variant: an immediate value. See [Modified immediate constants in T32 instructions](#) for the range of values.

<imm8>

Is a 8-bit unsigned immediate, in the range 0 to 255, encoded in the “imm8” field.

Operation

```
if ConditionPassed() then  
    EncodingSpecificOperations();  
    let (result, nzcvc) : (bits(32), bits(4)) = AddWithCarry{32}(R(n), NOT(imm32), '1');  
    PSTATE.[N,Z,C,V] = nzcvc;  
end;
```

C5.1.36 CMP (register)

Compare (register) subtracts an optionally-shifted register value from a register value. It updates the condition flags based on the result, and discards the result.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#), [T2](#), and [T3](#)).

A1

Encoding for the Rotate right with extend variant

Applies when (imm5 == 00000 && stype == 11)

CMP{<c>}{<q>} <Rn>, <Rm>, RRX

Encoding for the Shift or rotate by value variant

Applies when (!(imm5 == 00000 && stype == 11))

CMP{<c>}{<q>} <Rn>, <Rm> {, <shift> #<amount>}

Decode for all variants of this encoding

```
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let (shift_t, shift_n) : (SRTYPE, integer) = DecodeImmShift(stype, imm5);
```

T1

Encoding

CMP{<c>}{<q>} <Rn>, <Rm> // (<Rn> and <Rm> both from R0-R7)

Decode for this encoding

```
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let shift_t : SRTYPE = SRTYPE_LSL;
let shift_n : integer = 0;
```

T2

Encoding

CMP{<c>}{<q>} <Rn>, <Rm> // (<Rn> and <Rm> not both from R0-R7)

Decode for this encoding

```
let n : integer = UInt(N::Rn);
let m : integer = UInt(Rm);
let shift_t : SRTYPE = SRTYPE_LSL;
let shift_n : integer = 0;
if n < 8 && m < 8 then UnpredictableProcedure(); end;
if n == 15 || m == 15 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If $n < 8$ && $m < 8$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes as described, with no change to its behavior and no additional side effects.
- The condition flags become UNKNOWN.

T3

Encoding for the Rotate right with extend variant

Applies when $(imm3 == 000 \ \&\& \ imm2 == 00 \ \&\& \ stype == 11)$

CMP{<c>}{<q>} <Rn>, <Rm>, RRX

Encoding for the Shift or rotate by value variant

Applies when $(!(imm3 == 000 \ \&\& \ imm2 == 00 \ \&\& \ stype == 11))$

CMP{<c>}{<q>} <Rn>, <Rm>, <shift> #<amount>

CMP{<c>}.W <Rn>, <Rm> // (<Rn>, <Rm> can be represented in T1 or T2)

Decode for all variants of this encoding

```
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let (shift_t, shift_n) : (SRTYPE, integer) = DecodeImmShift(stype, imm3::imm2);
// Armv8-A removes UNPREDICTABLE for R13
if n == 15 || m == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rn>

For the “A1 Rotate right with extend” and “A1 Shift or rotate by value” variants: is the first general-purpose source register, encoded in the “Rn” field. The PC can be used, but this is deprecated.

For the “T1”, “T3 Rotate right with extend”, and “T3 Shift or rotate by value” variants: is the first general-purpose source register, encoded in the “Rn” field.

For the “T2” variant: is the first general-purpose source register, encoded in the “N:Rn” field.

<Rm>

For the “A1 Rotate right with extend” and “A1 Shift or rotate by value” variants: is the second general-purpose source register, encoded in the “Rm” field. The PC can be used, but this is deprecated.

For the “T1”, “T2”, “T3 Rotate right with extend”, and “T3 Shift or rotate by value” variants: is the second general-purpose source register, encoded in the “Rm” field.

<shift>

Is the type of shift to be applied to the second source register, encoded in “stype”:

stype	<shift>
00	LSL
01	LSR
10	ASR
11	ROR

<amount>

For the “A1 Shift or rotate by value” variant: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the “imm5” field as <amount> modulo 32.

For the “T3 Shift or rotate by value” variant: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR), encoded in the “imm3:imm2” field as <amount> modulo 32.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let shifted : bits(32) = Shift{}(R(m), shift_t, shift_n, PSTATE.C);
    let (result, nzcvc) : (bits(32), bits(4)) = AddWithCarry{32}(R(n), NOT(shifted), '1');
    PSTATE.[N,Z,C,V] = nzcvc;
end;
```

C5.1.37 CMP (register-shifted register)

Compare (register-shifted register) subtracts a register-shifted register value from a register value. It updates the condition flags based on the result, and discards the result.

Encoding

CMP{<c>}{<q>} <Rn>, <Rm>, <type> <Rs>

Decode for this encoding

```

let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let s : integer = UInt(Rs);
let shift_t : SRTType = DecodeRegShift(stype);
if n == 15 || m == 15 || s == 15 then UnpredictableProcedure(); end;

```

For more information about the CONSTRAINED UNPREDICTABLE behavior, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

 $\langle c \rangle$

See [Standard assembler syntax fields](#).

 $\langle q \rangle$

See [Standard assembler syntax fields](#).

 $\langle R_n \rangle$

Is the first general-purpose source register, encoded in the “Rn” field.

<Rm>

Is the second general-purpose source register, encoded in the “Rm” field.

<type>

Is the type of shift to be applied to the second source register, encoded in “stype”:

stype	<type>
00	LSL
01	LSR
10	ASR
11	ROR

 $\langle R_s \rangle$

Is the third general-purpose source register holding a shift amount in its bottom 8 bits, encoded in the “Rs” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let shift_n : integer = UInt(R(s)[7:0]);
    let shifted : bits(32) = Shift{}(R(m), shift_t, shift_n, PSTATE.C);
    let (result, nzcv) : (bits(32), bits(4)) = AddWithCarry{32}(R(n), NOT(shifted), '1');
    PSTATE.[N,Z,C,V] = nzcv;
end;
```

C5.1.38 CPS, CPSID, CPSIE

Change PE State changes one or more of the **PSTATE**.{A, I, F} interrupt mask bits and, optionally, the **PSTATE**.M mode field, without changing any other **PSTATE** bits.

CPS is treated as NOP if executed in User mode unless it is defined as being CONstrained UNPREDICTABLE elsewhere in this section.

The PE checks whether the value being written to PSTATE.M is legal. See [Illegal changes to PSTATE.M](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#) and [T2](#)).

A1

Encoding for the Change mode variant

Applies when (imod == 00 && M == 1)

```
CPS{<q>} #<mode> // (Cannot be conditional)
```

Encoding for the Interrupt disable variant

Applies when (imod == 11 && M == 0)

```
CPSID{<q>} <iflags> // (Cannot be conditional)
```

Encoding for the Interrupt disable and change mode variant

Applies when (imod == 11 && M == 1)

```
CPSID{<q>}    <iflags> , #<mode> // (Cannot be conditional)
```

Encoding for the Interrupt enable variant

Applies when (imod == 10 && M == 0)

```
CPSIE{<q>} <iflags> // (Cannot be conditional)
```

Encoding for the Interrupt enable and change mode variant

Applies when (imod == 10 && M == 1)

```
CPSIE{<q>}    <iflags> , #<mode> // (Cannot be conditional)
```

Decode for all variants of this encoding

```

if mode != '00000' && M == '0' then UnpredictableProcedure(); end;
if (imod[1] == '1' && A::I::F == '000') || (imod[1] == '0' && A::I::F != '000') then
    UnpredictableProcedure();
end;

let enable : boolean = (imod == '10');
let disable : boolean = (imod == '11');
let changemode : boolean = (M == '1');
let pemode : bits(5) = mode;
let affectA : boolean = (A == '1');
let affectI : boolean = (I == '1');
let affectF : boolean = (F == '1');

if (imod == '00' && M == '0') || imod == '01' then UnpredictableProcedure(); end;

```

CONSTRAINED UNPREDICTABLE behavior

If `imod == '01'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.

If `imod == '00' && M == '0'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.

If `mode != '00000' && M == '0'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes with the additional decode: `changemode = TRUE`.
- The instruction executes as described, and the value specified by `mode` is ignored. There are no additional side-effects.

If `imod<1> == '1' && A:I:F == '000'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction behaves as if `imod<1> == '0'`.
- The instruction behaves as if `A:I:F` has an UNKNOWN nonzero value.

If `imod<1> == '0' && A:I:F != '000'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction behaves as if `imod<1> == '1'`.
- The instruction behaves as if `A:I:F == '000'`.

T1

15	6	5	4	3	2	1	0
1	0	1	1	0	1	1	0
0	0	1	1	im	(0)	A	I
						F	

└─ op

Encoding for the Interrupt disable variant

Applies when `(im == 1)`

`CPSID{<q>} <iflags> // (Not permitted in IT block)`

Encoding for the Interrupt enable variant

Applies when `(im == 0)`

`CPSIE{<q>} <iflags> // (Not permitted in IT block)`

Decode for all variants of this encoding

```
if A::I::F == '000' then UnpredictableProcedure(); end;
let enable : boolean = (im == '0');
let disable : boolean = (im == '1');
let changemode : boolean = FALSE;
let affectA : boolean = (A == '1');
let affectI : boolean = (I == '1');
let affectF : boolean = (F == '1');
let pemode : bits(5) = ARBITRARY : bits(5);
if InITBlock() then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If A:I:F == '000', then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.

T2

Encoding for the Change mode variant

Applies when (imod == 00 && M == 1)

```
CPSID{<q>} #<mode> // (Not permitted in IT block)
```

Encoding for the Interrupt disable variant

Applies when (imod == 11 && M == 0)

```
CPSID.W <iflags> // (Not permitted in IT block)
```

Encoding for the Interrupt disable and change mode variant

Applies when (imod == 11 && M == 1)

```
CPSID{<q>} <iflags>, #<mode> // (Not permitted in IT block)
```

Encoding for the Interrupt enable variant

Applies when (imod == 10 && M == 0)

```
CPSIE.W <iflags> // (Not permitted in IT block)
```

Encoding for the Interrupt enable and change mode variant

Applies when (imod == 10 && M == 1)

```
CPSIE{<q>} <iflags>, #<mode> // (Not permitted in IT block)
```

Decode for all variants of this encoding

```

if imod == '00' && M == '0' then See("Hint instructions"); end;
if mode != '00000' && M == '0' then UnpredictableProcedure(); end;
if (imod[1] == '1' && A::I::F == '000') || (imod[1] == '0' && A::I::F != '000') then
    UnpredictableProcedure();
end;
let enable : boolean = (imod == '10');
let disable : boolean = (imod == '11');
let changemode : boolean = (M == '1');
let pemode : bits(5) = mode;
let affectA : boolean = (A == '1');
let affectI : boolean = (I == '1');
let affectF : boolean = (F == '1');
if imod == '01' || InITBlock() then UnpredictableProcedure(); end;

```

CONSTRAINED UNPREDICTABLE behavior

If `imod == '01'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.

If `mode != '00000' && M == '0'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes with the additional decode: `changemode = TRUE`.
- The instruction executes as described, and the value specified by `mode` is ignored. There are no additional side-effects.

If `imod<1> == '1' && A:I:F == '000'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction behaves as if `imod<1> == '0'`.
- The instruction behaves as if `A:I:F` has an UNKNOWN nonzero value.

If `imod<1> == '0' && A:I:F != '000'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction behaves as if `imod<1> == '1'`.
- The instruction behaves as if `A:I:F == '000'`.

Hint instructions: In encoding T2, if the `imod` field is `0b00` and the `M` bit is `0b0`, a hint instruction is encoded. To determine which hint instruction, see [Branches and miscellaneous control](#).

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<q>

See [Standard assembler syntax fields](#).

<mode>

Is the number of the mode to change to, in the range 0 to 31, encoded in the “mode” field.

<iflags>

Is a sequence of one or more of the following, specifying which interrupt mask bits are affected:

- a** Sets the A bit in the instruction, causing the specified effect on [PSTATE.A](#), the SError interrupt mask bit.
- i** Sets the I bit in the instruction, causing the specified effect on [PSTATE.I](#), the IRQ interrupt mask bit.
- f** Sets the F bit in the instruction, causing the specified effect on [PSTATE.F](#), the FIQ interrupt mask bit.

Operation

```

if CurrentInstrSet() == InstrSet_A32 then
    EncodingSpecificOperations();
    if PSTATE.EL != ELO then
        if enable then
            if affectA then PSTATE.A = '0'; end;
            if affectI then PSTATE.I = '0'; end;

    if PSTATE.EL != ELO then
        if enable then
            if affectA then PSTATE.A = '0'; end;
            if affectI then PSTATE.I = '0'; end;
            if affectF then PSTATE.F = '0'; end;
        end;
        if disable then
            if affectA then PSTATE.A = '1'; end;
            if affectI then PSTATE.I = '1'; end;
            if affectF then PSTATE.F = '1'; end;
        end;
        if changemode then
            // AArch32_WriteModeByInstr() sets PSTATE.IL to 1 if this is an illegal mode change.
            AArch32_WriteModeByInstr(pemode);
        end;
    end;
end;
end;

```

C5.1.39 CRC32

CRC32

CRC32 performs a cyclic redundancy check (CRC) calculation on a value held in a general-purpose register. It takes an input CRC value in the first source operand, performs a CRC on the input value in the second source operand, and returns the output CRC value. The second source operand can be 8, 16, or 32 bits. To align with common usage, the bit order of the values is reversed as part of the operation, and the polynomial 0x04C11DB7 is used for the CRC calculation.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding for the CRC32B variant

Applies when (sz == 00)

CRC32B{<q>} <Rd>, <Rn>, <Rm>

Encoding for the CRC32H variant

Applies when (sz == 01)

CRC32H{<q>} <Rd>, <Rn>, <Rm>

Encoding for the CRC32W variant

Applies when (sz == 10)

CRC32W{ <q> } <Rd>, <Rn>, <Rm>

Decode for all variants of this encoding

```

if !IsFeatureImplemented(FEAT_CRC32) then Undefined(); end;
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let size : integer{} = 8 << UInt(sz);
let crc32c : boolean = (C == '1');
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
if size == 64 then UnpredictableProcedure(); end;
if cond != '1110' then UnpredictableProcedure(); end;

```

CONSTRAINED UNPREDICTABLE behavior

If `size == 64`, then one of the following behaviors must occur:

- The instruction is `UNDEFINED`.
- The instruction executes as `NOP`.
- The instruction executes with the additional decode: `size = 32::`

If `cond != '1110'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes unconditionally.
- The instruction executes conditionally.

T1

Encoding for the CRC32B variant

Applies when (sz == 00)

CRC32B{<q>} <Rd>, <Rn>, <Rm>

Encoding for the CRC32H variant

Applies when (sz == 01)

CRC32H{<q>} <Rd>, <Rn>, <Rm>

Encoding for the CRC32W variant

Applies when (sz == 10)

CRC32W{<q>} <Rd>, <Rn>, <Rm>

Decode for all variants of this encoding

```
if InITBlock() then UnpredictableProcedure(); end;
if !IsFeatureImplemented(FEAT_CRC32) then Undefined(); end;
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let size : integer{} = 8 << UInt(sz);
let crc32c : boolean = (C == '1');
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
if size == 64 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If size == 64, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes with the additional decode: size = 32;

For more information about the CONSTRAINED UNPREDICTABLE behavior, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<q>

See [Standard assembler syntax fields](#). A CRC32 instruction must be unconditional.

<Rd>

Is the general-purpose accumulator output register, encoded in the “Rd” field.

<Rn>

Is the general-purpose accumulator input register, encoded in the “Rn” field.

<Rm>

Is the general-purpose data source register, encoded in the “Rm” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();

    let acc : bits(32) = R(n);           // accumulator
    let val : bits(size) = R(m)[size-1:0]; // input value
    let poly : bits(32) = (if crc32c then 0x1EDC6F41 else 0x04C11DB7)[31:0];
    let tempacc : bits(32+size) = BitReverse{32}(acc)::Zeros{size};
    let tempval : bits(32+size) = BitReverse{size}(val)::Zeros{32};
    // Poly32Mod2 on a bitstring does a polynomial Modulus over {0,1} operation
    R(d) = BitReverse{32}(Poly32Mod2{32+size}(tempacc XOR tempval, poly));
end;
```

C5.1.40 CRC32C

CRC32C

CRC32C performs a cyclic redundancy check (CRC) calculation on a value held in a general-purpose register. It takes an input CRC value in the first source operand, performs a CRC on the input value in the second source operand, and returns the output CRC value. The second source operand can be 8, 16, or 32 bits. To align with common usage, the bit order of the values is reversed as part of the operation, and the polynomial `0x1EDC6F41` is used for the CRC calculation.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding for the CRC32CB variant

Applies when (sz == 00)

CRC32CB{<q>} <Rd>, <Rn>, <Rm>

Encoding for the CRC32CH variant

Applies when (sz == 01)

CRC32CH{<q>} <Rd>, <Rn>, <Rm>

Encoding for the CRC32CW variant

Applies when (sz == 10)

CRC32CW{<q>} <Rd>, <Rn>, <Rm>

Decode for all variants of this encoding

```

if !IsFeatureImplemented(FEAT_CRC32) then Undefined(); end;
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let size : integer{} = 8 << UInt(sz);
let crc32c : boolean = (C == '1');
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
if size == 64 then UnpredictableProcedure(); end;
if cond != '1110' then UnpredictableProcedure(); end;

```

CONSTRAINED UNPREDICTABLE behavior

If `size == 64`, then one of the following behaviors must occur:

- The instruction is `UNDEFINED`.
- The instruction executes as `NOP`.
- The instruction executes with the additional decode: `size = 32::`

If `cond != '1110'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes unconditionally.
- The instruction executes conditionally.

T1

Encoding for the CRC32CB variant

Applies when (sz == 00)

CRC32CB{<q>} <Rd>, <Rn>, <Rm>

Encoding for the CRC32CH variant

Applies when (sz == 01)

CRC32CH{<q>} <Rd>, <Rn>, <Rm>

Encoding for the CRC32CW variant

Applies when (sz == 10)

CRC32CW{<q>} <Rd>, <Rn>, <Rm>

Decode for all variants of this encoding

```

if InITBlock() then UnpredictableProcedure(); end;
if !IsFeatureImplemented(FEAT_CRC32) then Undefined(); end;
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let size : integer{} = 8 << UInt(sz);
let crc32c : boolean = (C == '1');
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
if size == 64 then UnpredictableProcedure(); end;

```

CONSTRAINED UNPREDICTABLE behavior

If `size == 64`, then one of the following behaviors must occur:

- The instruction is `UNDEFINED`.
- The instruction executes as `NOP`.
- The instruction executes with the additional decode: `size = 32;`

For more information about the CONSTRAINED UNPREDICTABLE behavior, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<q>

See [Standard assembler syntax fields](#). A CRC32C instruction must be unconditional.

<Rd>

Is the general-purpose accumulator output register, encoded in the “Rd” field.

<Rn>

Is the general-purpose accumulator input register, encoded in the “Rn” field.

<Rm>

Is the general-purpose data source register, encoded in the “Rm” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();

    let acc : bits(32) = R(n);           // accumulator
    let val : bits(size) = R(m)[size-1:0]; // input value
    let poly : bits(32) = (if crc32c then 0x1EDC6F41 else 0x04C11DB7)[31:0];
    let tempacc : bits(32+size) = BitReverse{32}(acc)::Zeros{size};
    let tempval : bits(32+size) = BitReverse{size}(val)::Zeros{32};
    // Poly32Mod2 on a bitstring does a polynomial Modulus over {0,1} operation
    R(d) = BitReverse{32}(Poly32Mod2{32+size}(tempacc XOR tempval, poly));
end;
```

C5.1.41 **DBG**

Debug hint

DBG executes as a NOP. Arm deprecates any use of the DBG instruction.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

```
DBG{<c>}{<q>} #<option>
```

Decode for this encoding

```
// DBG executes as a NOP. The 'option' field is ignored
```

T1

Encoding

```
DBG{<c>}{<q>} #<option>
```

Decode for this encoding

```
// DBG executes as a NOP. The 'option' field is ignored
```

For more information about the CONSTRAINED UNPREDICTABLE behavior, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

 $\langle c \rangle$

See [Standard assembler syntax fields](#).

 $\langle q \rangle$

See [Standard assembler syntax fields](#).

<option>

Is a 4-bit unsigned immediate, in the range 0 to 15, encoded in the “option” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
end;
```

C5.1.42 DCPS1

Debug Change PE State to EL1 allows the debugger to move the PE into EL1 from EL0 or to a specific mode at the current Exception level.

DCPS1 is UNDEFINED if any of:

- The PE is in Non-debug state.
- EL2 is implemented, EL2 is implemented and enabled in the current Security state, and any of:
 - EL2 is using AArch32 and HCR.TGE is set to 1.
 - EL2 is using AArch64 and HCR_EL2.TGE is set to 1.

When the PE executes DCPS1 at EL0, EL1 or EL3:

- If EL3 or EL1 is using AArch32, the PE enters SVC mode and LR_svc, SPSR_svc, DLR, and DSPSR become UNKNOWN. If DCPS1 is executed in Monitor mode, SCR_NS is cleared to 0.
- If EL1 is using AArch64, the PE enters EL1 using AArch64, selects SP_EL1, and ELR_EL1, ESR_EL1, SPSR_EL1, DLR_EL0 and DSPSR_EL0 become UNKNOWN.

When the PE executes `DCPS1` at EL2 the PE does not change mode, and `ELR_hyp`, `HSR`, `SPSR_hyp`, `DLR` and `DSPSR` become `UNKNOWN`.

For more information on the operation of the DCPS<n> instructions, see [DCPS](#).

Encoding

DCPS1

Decode for this encoding

```
// No additional decoding required.
```

Operation

```

if !Halted() then Undefined(); end;

if EL2Enabled() && PSTATE.EL == EL0 then
    let tge : bit = HCR().TGE;
    if tge == '1' then Undefined(); end;
end;

if PSTATE.EL != EL0 || ELUsingAArch32(EL1) then
    if PSTATE.EL != EL2 then
        AArch32_WriteMode(M32_Svc);
        PSTATE.E = SCTLR().EE;
        Rmode(14, M32_Svc) = ARBITRARY : bits(32);    // LR_svc
        SPSR_svc() = ARBITRARY : bits(32);
    else
        PSTATE.E = HSCTLR().EE;
        ELR_hyp() = ARBITRARY : bits(32);
        HSR() = ARBITRARY : bits(32);
        SPSR_hyp() = ARBITRARY : bits(32);
    end;

    DLR() = ARBITRARY : bits(32);
    DSPSR() = ARBITRARY : bits(32);
end;

```

end;

`UpdateEDSCRFields();` // Update EDSCR PE state flags

C5.1.43 DCPS2

Debug Change PE State to EL2 allows the debugger to move the PE into EL2 from a lower Exception level.

DCPS2 is UNDEFINED if any of:

- The PE is in Non-debug state.
- EL2 is not implemented.
- The PE is in Secure state and any of:
 - Secure EL2 is not implemented.
 - Secure EL2 is implemented and Secure EL2 is disabled.

When the PE executes DCPS2:

- If EL2 is using AArch32, the PE enters Hyp mode and ELR_hyp, HSR, SPSR_hyp, DLR and DSPSR become UNKNOWN.
- If EL2 is using AArch64, the PE enters EL2 using AArch64, selects SP_EL2, and ELR_EL2, ESR_EL2, SPSR_EL2, DLR_EL0 and DSPSR_EL0 become UNKNOWN.

For more information on the operation of the DCPS<n> instructions, see [DCPS](#).

Encoding

DCPS2

Decode for this encoding

```
if !HaveEL(EL2) then Undefined(); end;
```

Operation

```
if !Halted() || EDSCR().HDD == '1' then Undefined(); end;
```

```
if ELUsingAArch32(EL2) then
    AArch32_WriteMode(M32_Hyp);
    PSTATE.E = HSCTLR().EE;

    ELR_hyp() = ARBITRARY : bits(32);
    HSR() = ARBITRARY : bits(32);
    SPSR_hyp() = ARBITRARY : bits(32);

    DLR() = ARBITRARY : bits(32);
    DSPSR() = ARBITRARY : bits(32);
```

end;

```
UpdateEDSCRFields(); // Update EDSCR PE state flags
```

C5.1.44 DCPS3

Debug Change PE State to EL3

This instruction is UNDEFINED.

For more information on the operation of the DCPS<n> instructions, see [DCPS](#).

Encoding

DCPS3

Decode for this encoding

```
if !HaveEL(EL3) then Undefined(); end;
```

Operation

```
if !Halted() then Undefined(); end;
```

C5.1.45 DFB

Data Full Barrier is a memory barrier that ensures the completion of memory accesses.

If executed at EL2, this instruction orders memory accesses irrespective of their Exception level or associated VMID. If executed at EL1 or EL0, this instruction behaves as DSB SY.

This is an alias of **DSB**. This means:

- The encodings in this description are named to match the encodings of [DSB](#).
- The description of [DSB](#) gives the operational pseudocode, any **CONSTRAINED UNPREDICTABLE** behavior, and any operational information for this instruction.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding for the A1 variant

$$\text{DFB} \{ \langle c \rangle \} \{ \langle q \rangle \}$$

is equivalent to

DSB{<c>}{<q>} #12

and is always the preferred disassembly.

T1

Encoding for the T1 variant

$$\text{DFB} \{ \langle c \rangle \} \{ \langle q \rangle \}$$

is equivalent to

DSB{<c>}{<q>} #12

and is always the preferred disassembly.

Assembler Symbols

<c>

For the “A1” variant: see [Standard assembler syntax fields](#). Must be AL or omitted.

For the “T1” variant: see [Standard assembler syntax fields](#).

 $\langle q \rangle$

See [Standard assembler syntax fields](#).

Operation

The description of [DSB](#) gives the operational pseudocode for this instruction.

C5.1.46 DMB

Data Memory Barrier is a memory barrier that ensures the ordering of observations of memory accesses, see [Data Memory Barrier \(DMB\)](#).

The ordering requirements of Data Memory Barrier instruction is as follows:

- EL1 and EL0 memory accesses are ordered only with respect to memory accesses using the same VMID.
- EL2 memory accesses are ordered only with respect to other EL2 memory accesses.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

31	28	27	26	25	21	20	19	8	7	4	3	0

// No additional decoding required

For more information about the CONSTRAINED UNPREDICTABLE behavior, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

For the “A1” variant: see [Standard assembler syntax fields](#). Must be `AL` or omitted.

For the “T1” variant: see [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<option>

Specifies the limitation on the Memory Effects ordered by the barrier operation, and is encoded in “option”.

Note

The instruction supports the following alternative <option> values, but Arm recommends that software does not use these alternative values:

- SH as an alias for ISH.
- SHST as an alias for ISHST.
- UN as an alias for NSH.
- UNST as an alias for NSHST.

For more information on whether a Memory Effect is before or after a barrier instruction, see [Data Memory Barrier \(DMB\)](#).

    DataSynchronizationBarrier(scope, types, vmid_sensitive);
end;
```

C5.1.48 EOR, EORS (immediate)

Bitwise Exclusive-OR (immediate) performs a bitwise exclusive-OR of a register value and an immediate value, and writes the result to the destination register.

If the destination register is not the PC, the EORS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. Arm deprecates any use of these encodings. However, when the destination register is the PC:

- The EOR variant of the instruction is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC](#).
- The EORS variant of the instruction performs an exception return without the use of the stack. In this case:
 - The PE branches to the address written to the PC, and restores [PSTATE](#) from SPSR_<current_mode>.
 - The PE checks SPSR_<current_mode> for an illegal return event. See [Illegal return events from AArch32 state](#).
 - The instruction is UNDEFINED in Hyp mode.
 - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding for the EOR variant

Applies when (S == 0)

EOR{<c>}{<q>} {<Rd>, }<Rn>, #<const>

Encoding for the EORS variant

Applies when (S == 1)

EORS{<c>}{<q>} {<Rd>, }<Rn>, #<const>

Decode for all variants of this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let setflags : boolean = (S == '1');
let a32 : boolean = TRUE;
let imm : bits(12) = imm12;
```

T1

Encoding for the EOR variant

Applies when (S == 0)

EOR{<c>}{<q>} {<Rd>, }<Rn>, #<const>

Encoding for the EORS variant

Applies when (S == 1 && Rd != 1111)

EORS{<c>}{<q>} {<Rd>, }<Rn>, #<const>

Decode for all variants of this encoding

```
if Rd == '1111' && S == '1' then See("TEQ (immediate)"); end;
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let setflags : boolean = (S == '1');
let a32 : boolean = FALSE;
let imm : bits(12) = i::imm3::imm8;
// Armv8-A removes UNPREDICTABLE for R13
if (d == 15 && !setflags) || n == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rd>

For the “A1 EOR” and “A1 EORS” variants: is the general-purpose destination register, encoded in the “Rd” field. If omitted, this register is the same as <Rn>. Arm deprecates using the PC as the destination register, but if the PC is used:

- For the EOR variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC](#).
- For the EORS variant, the instruction performs an exception return, that restores [PSTATE](#) from SPSR_<current_mode>.

For the “T1 EOR” and “T1 EORS” variants: is the general-purpose destination register, encoded in the “Rd” field. If omitted, this register is the same as <Rn>.

<Rn>

For the “A1 EOR” and “A1 EORS” variants: is the general-purpose source register, encoded in the “Rn” field. The PC can be used, but this is deprecated.

For the “T1 EOR” and “T1 EORS” variants: is the general-purpose source register, encoded in the “Rn” field.

<const>

For the “A1 EOR” and “A1 EORS” variants: an immediate value. See [Modified immediate constants in A32 instructions](#) for the range of values.

For the “T1 EOR” and “T1 EORS” variants: an immediate value. See [Modified immediate constants in T32 instructions](#) for the range of values.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let (imm32, carry) : (bits(32), bit) = (if a32 then A32ExpandImm_C(imm, PSTATE.C)
                                             else T32ExpandImm_C(imm, PSTATE.C));

    let result : bits(32) = R(n) XOR imm32;
    if d == 15 then                // Can only occur for A32 encoding
        if setflags then
            ALUExceptionReturn(result);
        else
            ALUWritePC(result);
        end;
    else
        R(d) = result;
        if setflags then
            PSTATE.N = result[31];
            PSTATE.Z = IsZeroBit{32}(result);
            PSTATE.C = carry;
            // PSTATE.V unchanged
        end;
    end;
end;
```

C5.1.49 EOR, EORS (register)

Bitwise Exclusive-OR (register) performs a bitwise exclusive-OR of a register value and an optionally-shifted register value, and writes the result to the destination register.

If the destination register is not the PC, the EORS variant of the instruction updates the condition flags based on the result.

The field descriptions for <RD> identify the encodings where the PC is permitted as the destination register. Arm deprecates any use of these encodings. However, when the destination register is the PC:

- The EOR variant of the instruction is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC](#).
- The EORS variant of the instruction performs an exception return without the use of the stack. In this case:
 - The PE branches to the address written to the PC, and restores **PSTATE** from SPSR_<current_mode>.
 - The PE checks SPSR_<current_mode> for an illegal return event. See [Illegal return events from AArch32 state](#).
 - The instruction is UNDEFINED in Hyp mode.
 - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#) and [T2](#)).

A1

Encoding for the EOR, rotate right with extend variant

Applies when (S == 0 && imm5 == 00000 && stype == 11)

EOR {<c>} {<q>} {<Rd>, }<Rn>, <Rm>, RRX

Encoding for the EOR, shift or rotate by value variant

Applies when (S == 0 && !(imm5 == 00000 && stype == 11))

EOR{<c>}{<q>} {<Rd>, }<Rn>, <Rm> {, <shift> #<amount>}

Encoding for the EORS, rotate right with extend variant

Applies when (S == 1 && imm5 == 00000 && stype == 11)

EORS {<c>} {<q>} {<Rd>, }<Rn>, <Rm>, RRX

Encoding for the EORS, shift or rotate by value variant

Applies when (S == 1 && !(imm5 == 00000 && stype == 11))

EORS{<c>}{<q>}{<Rd>,<Rn>,<Rm>{,<shift>#<amount>}

Decode for all variants of this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let setflags : boolean = (S == '1');
let (shift t, shift n) : (SRTyp, integer) = DecodeImmShift(stype, imm5);
```

T1

Encoding

EOR<c>{<q>} {<Rdn>, }<Rdn>, <Rm> // (InITBlock())

EORS{<q>} {<Rdn>, }<Rdn>, <Rm> // (Outside IT block)

Decode for this encoding

```
let d : integer = UInt(Rdn);
let n : integer = UInt(Rdn);
let m : integer = UInt(Rm);
let setflags : boolean = !InITBlock();
let shift_t : SRTYPE = SRTYPE_LSL;
let shift_n : integer = 0;
```

T2

Encoding for the EOR, rotate right with extend variant

Applies when (S == 0 && imm3 == 000 && imm2 == 00 && stype == 11)

EOR{<c>}{<q>} {<Rd>, }<Rn>, <Rm>, RRX

Encoding for the EOR, shift or rotate by value variant

Applies when (S == 0 && !(imm3 == 000 && imm2 == 00 && stype == 11))

EOR{<c>}{<q>} {<Rd>, }<Rn>, <Rm> {, <shift> #<amount>}

EOR<c>.W {<Rd>, }<Rn>, <Rm> // (Inside IT block, and <Rd>, <Rn>, <Rm> can be represented in T1)

Encoding for the EORS, rotate right with extend variant

Applies when (S == 1 && imm3 == 000 && Rd != 1111 && imm2 == 00 && stype == 11)

EORS{<c>}{<q>} {<Rd>, }<Rn>, <Rm>, RRX

Encoding for the EORS, shift or rotate by value variant

Applies when (S == 1 && Rd != 1111 && !(imm3 == 000 && imm2 == 00 && stype == 11))

EORS{<c>}{<q>} {<Rd>, }<Rn>, <Rm> {, <shift> #<amount>}

EORS.W {<Rd>, }<Rn>, <Rm> // (Outside IT block, and <Rd>, <Rn>, <Rm> can be represented in T1)

Decode for all variants of this encoding

```

if Rd == '1111' && S == '1' then See("TEQ (register)"); end;
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let setflags : boolean = (S == '1');
let (shift_t, shift_n) : (SRTType, integer) = DecodeImmShift(stype, imm3::imm2);
// Armv8-A removes UNPREDICTABLE for R13
if (d == 15 && !setflags) || n == 15 || m == 15 then UnpredictableProcedure(); end;

```

For more information about the CONSTRAINED UNPREDICTABLE behavior, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rd>

For the “A1 EOR, rotate right with extend”, “A1 EOR, shift or rotate by value”, “A1 EORS, rotate right with extend”, and “A1 EORS, shift or rotate by value” variants: is the general-purpose destination register, encoded in the “Rd” field. If omitted, this register is the same as <Rn>. Arm deprecates using the PC as the destination register, but if the PC is used:

- For the EOR variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC](#).
- For the EORS variant, the instruction performs an exception return, that restores [PSTATE](#) from `SPSR_<current_mode>`.

For the “T2 EOR, rotate right with extend”, “T2 EOR, shift or rotate by value”, “T2 EORS, rotate right with extend”, and “T2 EORS, shift or rotate by value” variants: is the general-purpose destination register, encoded in the “Rd” field. If omitted, this register is the same as <Rn>.

<Rn>

For the “A1 EOR, rotate right with extend”, “A1 EOR, shift or rotate by value”, “A1 EORS, rotate right with extend”, and “A1 EORS, shift or rotate by value” variants: is the first general-purpose source register, encoded in the “Rn” field. The PC can be used, but this is deprecated.

For the “T2 EOR, rotate right with extend”, “T2 EOR, shift or rotate by value”, “T2 EORS, rotate right with extend”, and “T2 EORS, shift or rotate by value” variants: is the first general-purpose source register, encoded in the “Rn” field.

<Rm>

For the “A1 EOR, rotate right with extend”, “A1 EOR, shift or rotate by value”, “A1 EORS, rotate right with extend”, and “A1 EORS, shift or rotate by value” variants: is the second general-purpose source register, encoded in the “Rm” field. The PC can be used, but this is deprecated.

For the “T1”, “T2 EOR, rotate right with extend”, “T2 EOR, shift or rotate by value”, “T2 EORS, rotate right with extend”, and “T2 EORS, shift or rotate by value” variants: is the second general-purpose source register, encoded in the “Rm” field.

<shift>

Is the type of shift to be applied to the second source register, encoded in “stype”:

stype	<shift>
00	LSL
01	LSR
10	ASR
11	ROR

<amount>

For the “A1 EOR, shift or rotate by value” and “A1 EORS, shift or rotate by value” variants: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the “imm5” field as <amount> modulo 32.

For the “T2 EOR, shift or rotate by value” and “T2 EORS, shift or rotate by value” variants: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR), encoded in the “imm3:imm2” field as <amount> modulo 32.

<Rdn>

Is the first general-purpose source register and the destination register, encoded in the “Rdn” field.

In T32 assembly:

- Outside an IT block, if EORS <Rd>, <Rn>, <Rd> has <Rd> and <Rn> both in the range R0-R7, it is assembled using encoding T1 as though EORS <Rd>, <Rn> had been written
- Inside an IT block, if EOR<c> <Rd>, <Rn>, <Rd> has <Rd> and <Rn> both in the range R0-R7, it is assembled using encoding T1 as though EOR<c> <Rd>, <Rn> had been written.

To prevent either of these happening, use the .w qualifier.

Operation

```

if ConditionPassed() then
    EncodingSpecificOperations();
    let (shifted, carry) : (bits(32), bit) = Shift_C{32}(R(m), shift_t, shift_n, PSTATE.C);
    let result : bits(32) = R(n) XOR shifted;
    if d == 15 then          // Can only occur for A32 encoding
        if setflags then
            ALUEXceptionReturn(result);
        else
            ALUWritePC(result);
        end;
    else
        R(d) = result;
        if setflags then
            PSTATE.N = result[31];
            PSTATE.Z = IsZeroBit{32}(result);
            PSTATE.C = carry;
            // PSTATE.V unchanged
        end;
    end;
end;
end;

```

C5.1.50 EOR, EORS (register-shifted register)

Bitwise Exclusive-OR (register-shifted register) performs a bitwise exclusive-OR of a register value and a register-shifted register value. It writes the result to the destination register, and can optionally update the condition flags based on the result.

Encoding for the Flag setting variant

Applies when (S == 1)

EORS{<c>}{<q>} {<Rd>, }<Rn>, <Rm>, <shift> <Rs>

Encoding for the Not flag setting variant

Applies when (S == 0)

EOR{<c>}{<q>} {<Rd>, }<Rn>, <Rm>, <shift> <Rs>

Decode for all variants of this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let s : integer = UInt(Rs);
let setflags : boolean = (S == '1');
let shift_t : SRTYPE = DecodeRegShift(stype);
if d == 15 || n == 15 || m == 15 || s == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rd>

Is the general-purpose destination register, encoded in the “Rd” field.

<Rn>

Is the first general-purpose source register, encoded in the “Rn” field.

<Rm>

Is the second general-purpose source register, encoded in the “Rm” field.

<shift>

Is the type of shift to be applied to the second source register, encoded in “stype”:

stype	<shift>
00	LSL
01	LSR
10	ASR
11	ROR

<Rs>

Is the third general-purpose source register holding a shift amount in its bottom 8 bits, encoded in the “Rs” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let shift_n : integer = UInt(R(s)[7:0]);
    let (shifted, carry) : (bits(32), bit) = Shift_C{32}(R(m), shift_t, shift_n, PSTATE.C);
    let result : bits(32) = R(n) XOR shifted;
    R(d) = result;
    if setflags then
        PSTATE.N = result[31];
        PSTATE.Z = IsZeroBit{32}(result);
        PSTATE.C = carry;
        // PSTATE.V unchanged
    end;
end;
```

C5.1.51 ERET

Exception Return.

The PE branches to the address held in the register holding the preferred return address, and restores **PSTATE** from SPSR <current mode>.

The register holding the preferred return address is:

- **ELR_hyp**, when executing in Hyp mode.
- **LR**, when executing in a mode other than Hyp mode, User mode, or System mode.

The PE checks SPSR <current mode> for an illegal return event. See [Illegal return events from AArch32 state](#).

Exception Return is CONSTRAINED UNPREDICTABLE in User mode and System mode.

In Debug state, the T1 encoding of `ERET` executes the DRPS operation.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1).

A1

Encoding

ERET{ <c> } { <q> }

Decode for this encoding

```
// No additional decoding required
```

T1

Encoding

ERET { <c> } { <q> }

Decode for this encoding

```
if InITBlock() && !LastInITBlock() then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    if !Halted() then
        if PSTATE.M IN {M32_User, M32_System} then
            UnpredictableProcedure();           // UNDEFINED or NOP
        else
            let new_pc_value : bits(32) = if PSTATE.EL == EL2 then ELR_hyp() else R(14);
            AArch32_ExceptionReturn(new_pc_value, SPSR_curr());
        end;
    else                                     // Perform DRPS operation in Debug state
        if PSTATE.M == M32_User then
            Undefined();
        elsif PSTATE.M == M32_System then
            UnpredictableProcedure();           // UNDEFINED or NOP
        else
            SynchronizeContext();
            DebugRestorePSR();
        end;
    end;
end;
```

CONSTRAINED UNPREDICTABLE behavior

If PSTATE.M IN {M32_User, M32_System}, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.

C5.1.52 HLT

Halting Breakpoint

Halting breakpoint causes a software breakpoint to occur.

Halting breakpoint is always unconditional, even inside an IT block.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

HLT{<q>} {#}<imm>

Decode for this encoding

```
if EDSCR().HDE == '0' || !HaltingAllowed() then Undefined(); end;
if cond != '1110' then UnpredictableProcedure(); end; // HLT must be encoded with AL condition
```

CONSTRAINED UNPREDICTABLE behavior

If cond != '1110', then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes unconditionally.
- The instruction executes conditionally.

T1

Encoding

HLT{<q>} {#}<imm>

Decode for this encoding

```
if EDSCR().HDE == '0' || !HaltingAllowed() then Undefined(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<q>

See [Standard assembler syntax fields](#). An `HLT` instruction must be unconditional.

<imm>

For the “A1” variant: is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the “imm12:imm4” field. This value is for assembly and disassembly only. It is ignored by the PE, but can be used by a debugger to store more information about the halting breakpoint.

For the “T1” variant: is a 6-bit unsigned immediate, in the range 0 to 63, encoded in the “imm6” field. This value is for assembly and disassembly only. It is ignored by the PE, but can be used by a debugger to store more information about the halting breakpoint.

Operation

```
EncodingSpecificOperations();  
let is_async : boolean = FALSE;  
Halt(DebugHalt_HaltInstruction, is_async);
```

C5.1.53 HVC

Hypervisor Call causes a Hypervisor Call exception. For more information, see [Hypervisor Call \(HVC\) exception](#). Software executing at EL1 can use this instruction to call the hypervisor to request a service.

The HVC instruction is UNDEFINED:

- When [HCR.HCD](#) is set to 1.
- In User mode.

On executing an HVC instruction, the [HSR, Hyp Syndrome Register](#) reports the exception as a Hypervisor Call exception, using the EC value 0x12, and captures the value of the immediate argument, see [Use of the HSR](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

HVC{<q>} {#}<imm16>

Decode for this encoding

```
if cond != '1110' then UnpredictableProcedure(); end;
let imm16 : bits(16) = imm12::imm4;
```

CONSTRAINED UNPREDICTABLE behavior

If cond != '1110', then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes unconditionally.
- The instruction executes conditionally.

T1

Encoding

HVC{<q>} {#}<imm16>

Decode for this encoding

```
let imm16 : bits(16) = imm4::imm12;
if InITBlock() then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<q>

See [Standard assembler syntax fields](#). An HVC instruction must be unconditional.

<imm16>

For the “A1” variant: is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the “imm12:imm4” field. This value is for assembly and disassembly only. It is reported in the HSR but otherwise is ignored by hardware. An HVC handler might interpret imm16, for example to determine the required service.

For the “T1” variant: is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the “imm4:imm12” field. This value is for assembly and disassembly only. It is reported in the HSR but otherwise is ignored by hardware. An HVC handler might interpret imm16, for example to determine the required service.

Operation

```
EncodingSpecificOperations();
if PSTATE.EL IN {EL0, EL3} || !EL2Enabled() then
    Undefined();
end;

var hvc_enable : bit;
hvc_enable = NOT(HCR().HCD);

if hvc_enable == '0' then
    Undefined();
else
    AArch32_CallHypervisor(imm16);
end;
```

CONSTRAINED UNPREDICTABLE behavior

If ELUsingAArch32(EL3) && SCR.HCE == '0' && PSTATE.EL == EL2, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.

C5.1.54 ISB

Instruction Synchronization Barrier flushes the pipeline in the PE and is a context synchronization event. For more information, see [Instruction Synchronization Barrier \(ISB\)](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

31	28	27	26	25	21	20	19	8	7	4	3	0
1	1	1	1	0	1	0	1	0	1	1	0	option

└ opcode

Encoding

ISB{<c>}{<q>}{<option>}

Decode for this encoding

// No additional decoding required

T1

15	13	12	11	10	9		6	5	4	3		0	15	14		12	11	10		8	7			4	3		0
1	1	1	1	0	0	1	1	1	0	1	1	(1)(1)(1)(1)	1	0(0)0		(1)	(1)(1)(1)(1)	0	1	1	0			option			

└opc

Encoding

ISB{<c>}{<q>}{<option>}

Decode for this encoding

// No additional decoding required

For more information about the CONSTRAINED UNPREDICTABLE behavior, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

For the “A1” variant: see [Standard assembler syntax fields](#). Must be `AL` or omitted.

For the “T1” variant: see [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<option>

Specifies an optional limitation on the barrier operation. Values are:

SY Full system barrier operation, encoded as `option = 0b1111`. Can be omitted.

All other encodings of <option> are reserved. The corresponding instructions execute as full system barrier operations, but must not be relied upon by software.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    InstructionSynchronizationBarrier();
end;
```

C5.1.55 IT

If-Then makes up to four following instructions (the IT block) conditional. The conditions for the instructions in the IT block are the same as, or the inverse of, the condition the `IT` instruction specifies for the first instruction in the block.

The `IT` instruction itself does not affect the condition flags, but the execution of the instructions in the IT block can change the condition flags.

16-bit instructions in the IT block, other than `CMP`, `CMN` and `TST`, do not set the condition flags. An `IT` instruction with the `AL` condition can change the behavior without conditional execution.

The architecture permits exception return to an instruction in the IT block only if the restoration of the `CPSR` restores `PSTATE.IT` to a state consistent with the conditions specified by the `IT` instruction. Any other exception return to an instruction in an IT block is UNPREDICTABLE. Any branch to a target instruction in an IT block is not permitted, and if such a branch is made it is UNPREDICTABLE what condition is used when executing that target instruction and any subsequent instruction in the IT block.

An implementation might include ITD controls that can disable the use of `IT` for some instructions, making them UNDEFINED.

For more information see [Conditional execution](#) and [Conditional instructions](#). The first of these sections includes more information about the ITD controls.

Encoding

`IT{<x>{<y>{<z>}}}{<q>} <cond>`

Decode for this encoding

```
if mask == '0000' then See("Related encodings"); end;
if firstcond == '1111' || (firstcond == '1110' && BitCount(mask) != 1) then
    UnpredictableProcedure();
end;
if InITBlock() then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `firstcond == '1111' || (firstcond == '1110' && BitCount(mask) != 1)`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The '1111' condition is treated as being the same as the '1110' condition, meaning always, and the `ITSTATE` state machine is progressed in the same way as for any other `cond_base` value.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Related encodings: [Miscellaneous 16-bit instructions](#).

Assembler Symbols

`<x>`

The condition for the second instruction in the IT block. If omitted, the “mask” field is set to `0b1000`. If present it is encoded in the “mask[3]” field:

T firstcond[0]
E NOT firstcond[0]

<y>

The condition for the third instruction in the IT block. If omitted and <x> is present, the “mask[2:0]” field is set to 0b100. If <y> is present it is encoded in the “mask[2]” field:

T firstcond[0]
E NOT firstcond[0]

<z>

The condition for the fourth instruction in the IT block. If omitted and <y> is present, the “mask[1:0]” field is set to 0b10. If <z> is present, the “mask[0]” field is set to 1, and it is encoded in the “mask[1]” field:

T firstcond[0]
E NOT firstcond[0]

<q>

See [Standard assembler syntax fields](#).

<cond>

The condition for the first instruction in the IT block, encoded in the “firstcond” field. See [Condition codes](#) for the range of conditions available, and the encodings.

The conditions specified in an **IT** instruction must match those specified in the syntax of the instructions in its IT block. When assembling to A32 code, assemblers check **IT** instruction syntax for validity but do not generate assembled instructions for them. See [Conditional instructions](#).

Operation

```
EncodingSpecificOperations();
AArch32_CheckITEnabled(mask);
PSTATE.IT[7:0] = firstcond::mask;
ShouldAdvanceIT = FALSE;
```

C5.1.56 LDA

Load-Acquire Word loads a word from memory and writes it to a register. The instruction also has memory ordering semantics as described in [Load-Acquire, Store-Release](#)

For more information about support for shared memory see [Synchronization and semaphores](#). For information about memory accesses see [Memory accesses](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

LDA{<c>}{<q>} <Rt>, [<Rn>]

Decode for this encoding

```
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
if t == 15 || n == 15 then UnpredictableProcedure(); end;
```

T1

Encoding

LDA{<c>}{<q>} <Rt>, [<Rn>]

Decode for this encoding

```
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
if t == 15 || n == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rt>

Is the general-purpose register to be transferred, encoded in the “Rt” field.

<Rn>

Is the general-purpose base register, encoded in the “Rn” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let address : bits(32) = R(n);
    R(t) = MemO{32}(address);
end;
```

C5.1.57 LDAB

Load-Acquire Byte loads a byte from memory, zero-extends it to form a 32-bit word and writes it to a register. The instruction also has memory ordering semantics as described in [Load-Acquire, Store-Release](#).

For more information about support for shared memory see [Synchronization and semaphores](#). For information about memory accesses see [Memory accesses](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

LDAB{<c>}{<q>} <Rt>, [<Rn>]

Decode for this encoding

```
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
if t == 15 || n == 15 then UnpredictableProcedure(); end;
```

T1

Encoding

LDAB{<c>}{<q>} <Rt>, [<Rn>]

Decode for this encoding

```
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
if t == 15 || n == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rt>

Is the general-purpose register to be transferred, encoded in the “Rt” field.

<Rn>

Is the general-purpose base register, encoded in the “Rn” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let address : bits(32) = R(n);
    R(t) = ZeroExtend{32}(MemO{8}(address));
end;
```

C5.1.58 LDAEX

Load-Acquire Exclusive Word loads a word from memory, writes it to a register and:

- If the address has the Shared Memory attribute, marks the physical address as exclusive access for the executing PE in a global monitor.
- Causes the executing PE to indicate an active exclusive access in the local monitor.

The instruction also has memory ordering semantics as described in [Load-Acquire, Store-Release](#).

For more information about support for shared memory see [Synchronization and semaphores](#). For information about memory accesses see [Memory accesses](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

LDAEX{<c>}{<q>} <Rt>, [<Rn>]

Decode for this encoding

```
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
if t == 15 || n == 15 then UnpredictableProcedure(); end;
```

T1

Encoding

LDAEX{<c>}{<q>} <Rt>, [<Rn>]

Decode for this encoding

```
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
if t == 15 || n == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rt>

Is the general-purpose register to be transferred, encoded in the “Rt” field.

<Rn>

Is the general-purpose base register, encoded in the “Rn” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let address : bits(32) = R(n);
    AArch32_SetExclusiveMonitors(address, 4);
    R(t) = MemO{32}(address);
end;
```

C5.1.59 LDAEXB

Load-Acquire Exclusive Byte loads a byte from memory, zero-extends it to form a 32-bit word, writes it to a register and:

- If the address has the Shared Memory attribute, marks the physical address as exclusive access for the executing PE in a global monitor.
- Causes the executing PE to indicate an active exclusive access in the local monitor.

The instruction also has memory ordering semantics as described in [Load-Acquire, Store-Release](#).

For more information about support for shared memory see [Synchronization and semaphores](#). For information about memory accesses see [Memory accesses](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

LDAEXB{<c>}{<q>} <Rt>, [<Rn>]

Decode for this encoding

```
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
if t == 15 || n == 15 then UnpredictableProcedure(); end;
```

T1

Encoding

LDAEXB{<c>}{<q>} <Rt>, [<Rn>]

Decode for this encoding

```
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
if t == 15 || n == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rt>

Is the general-purpose register to be transferred, encoded in the “Rt” field.

<Rn>

Is the general-purpose base register, encoded in the “Rn” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let address : bits(32) = R(n);
    AArch32_SetExclusiveMonitors(address, 1);
    R(t) = ZeroExtend{32}(MemO{8}(address));
end;
```

C5.1.60 LDAEXD

Load-Acquire Exclusive Doubleword loads a doubleword from memory, writes it to two registers and:

- If the address has the Shared Memory attribute, marks the physical address as exclusive access for the executing PE in a global monitor
- Causes the executing PE to indicate an active exclusive access in the local monitor.

The instruction also acts as a barrier instruction with the ordering requirements described in [Load-Acquire, Store-Release](#).

For more information about support for shared memory see [Synchronization and semaphores](#). For information about memory accesses see [Memory accesses](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

LDAEXD{<c>}{<q>} <Rt>, <Rt2>, [<Rn>]

Decode for this encoding

```
let t : integer = UInt(Rt);
let t2 : integer = t + 1;
let n : integer = UInt(Rn);
if Rt[0] == '1' || t2 == 15 || n == 15 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If Rt<0> == '1', then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes with the additional decode: t<0> = '0'.
- The instruction executes with the additional decode: t2 = t.
- The instruction executes as described, with no change to its behavior and no additional side effects.

If Rt == '1110', then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction is handled as described in Using R15.

T1

Encoding

LDAEXD{<c>}{<q>} <Rt>, <Rt2>, [<Rn>]

Decode for this encoding

```
let t : integer = UInt(Rt);
let t2 : integer = UInt(Rt2);
let n : integer = UInt(Rn);
if t == 15 || t2 == 15 || t == t2 || n == 15 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If $t == t2$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The load instruction executes but the destination register takes an UNKNOWN value.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rt>

For the “A1” variant: is the first general-purpose register to be transferred, encoded in the “Rt” field. <Rt> must be even-numbered and not R14.

For the “T1” variant: is the first general-purpose register to be transferred, encoded in the “Rt” field.

<Rt2>

For the “A1” variant: is the second general-purpose register to be transferred. <Rt2> must be $R(t+1)$.

For the “T1” variant: is the second general-purpose register to be transferred, encoded in the “Rt2” field.

<Rn>

Is the general-purpose base register, encoded in the “Rn” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let address : bits(32) = R(n);
    AArch32_SetExclusiveMonitors(address, 8);
    let value : bits(64) = MemO{64}(address);
    // Extract words from 64-bit loaded value such that R[t] is
    // loaded from address and R[t2] from address+4.
    R(t)  = if BigEndian(AccessType_GPR) then value[63:32] else value[31:0];
    R(t2) = if BigEndian(AccessType_GPR) then value[31:0]  else value[63:32];
end;
```

C5.1.61 LDAEXH

Load-Acquire Exclusive Halfword loads a halfword from memory, zero-extends it to form a 32-bit word, writes it to a register and:

- If the address has the Shared Memory attribute, marks the physical address as exclusive access for the executing PE in a global monitor.
- Causes the executing PE to indicate an active exclusive access in the local monitor.

The instruction also has memory ordering semantics as described in [Load-Acquire, Store-Release](#).

For more information about support for shared memory see [Synchronization and semaphores](#). For information about memory accesses see [Memory accesses](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

LDAEXH{<c>}{<q>} <Rt>, [<Rn>]

Decode for this encoding

```
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
if t == 15 || n == 15 then UnpredictableProcedure(); end;
```

T1

Encoding

LDAEXH{<c>}{<q>} <Rt>, [<Rn>]

Decode for this encoding

```
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
if t == 15 || n == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rt>

Is the general-purpose register to be transferred, encoded in the “Rt” field.

<Rn>

Is the general-purpose base register, encoded in the “Rn” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let address : bits(32) = R(n);
    AArch32_SetExclusiveMonitors(address, 2);
    R(t) = ZeroExtend{32}(MemO{16}(address));
end;
```

C5.1.62 LDAH

Load-Acquire Halfword loads a halfword from memory, zero-extends it to form a 32-bit word and writes it to a register. The instruction also has memory ordering semantics as described in [Load-Acquire, Store-Release](#).

For more information about support for shared memory see [Synchronization and semaphores](#). For information about memory accesses see [Memory accesses](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

LDAH{<c>}{<q>} <Rt>, [<Rn>]

Decode for this encoding

```
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
if t == 15 || n == 15 then UnpredictableProcedure(); end;
```

T1

Encoding

LDAH{<c>}{<q>} <Rt>, [<Rn>]

Decode for this encoding

```
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
if t == 15 || n == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rt>

Is the general-purpose register to be transferred, encoded in the “Rt” field.

<Rn>

Is the general-purpose base register, encoded in the “Rn” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let address : bits(32) = R(n);
    R(t) = ZeroExtend{32}(MemO{16}(address));
end;
```

C5.1.63 LDC (immediate)

Load data to System register (immediate) calculates an address from a base register value and an immediate offset, loads a word from memory, and writes it to the [DBGDTRTXint](#) System register. It can use offset, post-indexed, pre-indexed, or unindexed addressing. For information about memory accesses, see [Memory accesses](#).

In an implementation that includes EL2, the permitted LDC access to [DBGDTRTXint](#) can be trapped to Hyp mode, meaning that an attempt to execute an LDC instruction in a Non-secure mode other than Hyp mode, that would be permitted in the absence of the Hyp trap controls, generates a Hyp Trap exception. For more information, see [HDCR.TDA](#).

For simplicity, the LDC pseudocode does not show this possible trap to Hyp mode.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding for the Offset variant

Applies when (P == 1 && W == 0)

LDC{<c>}{<q>} p14, c5, [<Rn>{, #<+/-><imm>}]

Encoding for the Post-indexed variant

Applies when (P == 0 && W == 1)

LDC{<c>}{<q>} p14, c5, [<Rn>], #<+/-><imm>

Encoding for the Pre-indexed variant

Applies when (P == 1 && W == 1)

LDC{<c>}{<q>} p14, c5, [<Rn>, #<+/-><imm>]!

Encoding for the Unindexed variant

Applies when (P == 0 && U == 1 && W == 0)

LDC{<c>}{<q>} p14, c5, [<Rn>], <option>

Decode for all variants of this encoding

```

if Rn == '1111' then See("LDC (literal)"); end;
if P == '0' && U == '0' && W == '0' then Undefined(); end;
let n : integer = UInt(Rn);
let cp : integer = 14;
let imm32 : bits(32) = ZeroExtend{}(imm8::'00');
let index : boolean = (P == '1');
let add : boolean = (U == '1');
let wback : boolean = (W == '1');
```

T1

Encoding for the Offset variant

Applies when (P == 1 && W == 0)

LDC{<c>}{<q>} p14, c5, [<Rn>{, #<+/-><imm>}]

Encoding for the Post-indexed variant

Applies when (P == 0 && W == 1)

LDC{<c>}{<q>} p14, c5, [<Rn>], #{+/-}<imm>

Encoding for the Pre-indexed variant

Applies when (P == 1 && W == 1)

LDC{<c>}{<q>} p14, c5, [<Rn>, #{+/-}<imm>]!

Encoding for the Unindexed variant

Applies when (P == 0 && U == 1 && W == 0)

LDC{<c>}{<q>} p14, c5, [<Rn>], <option>

Decode for all variants of this encoding

```

if Rn == 'l111' then See("LDC (literal)"); end;
if P == '0' && U == '0' && W == '0' then Undefined(); end;
let n : integer = UInt(Rn);
let cp : integer = 14;
let imm32 : bits(32) = ZeroExtend{imm8::'00'};
let index : boolean = (P == '1');
let add : boolean = (U == '1');
let wback : boolean = (W == '1');

```

Assembler Symbols

 $\langle c \rangle$

See [Standard assembler syntax fields](#).

 $\langle q \rangle$

See [Standard assembler syntax fields](#).

 $\langle R_n \rangle$

Is the general-purpose base register, encoded in the “Rn” field. If the PC is used, see [LDC \(literal\)](#).

+/-

Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in “U”:

U	+/-
0	-
1	+

<imm>

Is the immediate offset used for forming the address, a multiple of 4 in the range 0-1020, defaulting to 0 and encoded in the “imm8” field, as <imm>/4.

<option>

Is an 8-bit immediate, in the range 0 to 255 enclosed in { }, encoded in the “imm8” field. The value of this field is ignored when executing this instruction.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let offset_addr : bits(32) = if add then (R(n) + imm32) else (R(n) - imm32);
    let address : bits(32) = if index then offset_addr else R(n);

    // System register write to DBGDTRTXint.
    AArch32_SysRegWriteM(cp, ThisInstr(), address);

    if wback then R(n) = offset_addr; end;
end;
```

C5.1.64 LDC (literal)

Load data to System register (literal) calculates an address from the PC value and an immediate offset, loads a word from memory, and writes it to the **DBGDTRTXint** System register. For information about memory accesses, see [Memory accesses](#).

In an implementation that includes EL2, the permitted **LDC** access to **DBGDTRTXint** can be trapped to Hyp mode, meaning that an attempt to execute an **LDC** instruction in a Non-secure mode other than Hyp mode, that would be permitted in the absence of the Hyp trap controls, generates a Hyp Trap exception. For more information, see [HDCR.TDA](#).

For simplicity, the **LDC** pseudocode does not show this possible trap to Hyp mode.

It has encodings from the following instruction sets: A32 (**A1**) and T32 (**T1**).

A1

Encoding

Applies when $(!(P == '0' \ \&\& \ U == '0' \ \&\& \ W == '0'))$

LDC{<c>}{<q>} p14, c5, <label> // (Preferred syntax)

LDC{<c>}{<q>} p14, c5, [PC, #{+/-}<imm>]

LDC{<c>}{<q>} p14, c5, [PC], <option>

Decode for this encoding

```

if P == '0' && U == '0' && W == '0' then Undefined(); end;
let index : boolean = (P == '1');
let add : boolean = (U == '1');
let cp : integer = 14;
let imm32 : bits(32) = ZeroExtend{(imm8::'00')};
if W == '1' || (P == '0' && CurrentInstrSet() != InstrSet_A32) then UnpredictableProcedure(); end;

```

CONSTRAINED UNPREDICTABLE behavior

If $W == '1'$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as **NOF**.
- The instruction executes without writeback of the base address.
- The instruction uses the addressing mode described in the equivalent immediate offset instruction.

T1

Encoding

Applies when `(! (P == '0' && U == '0' && W == '0'))`

```
LDC{<c>}{<q>} p14, c5, <label> // (Preferred syntax)
```

LDC{<c>}{<q>} p14, c5, [PC, #{+/-}<imm>]

Decode for this encoding

```
if P == '0' && U == '0' && W == '0' then Undefined(); end;
let index : boolean = (P == '1');
let add : boolean = (U == '1');
let cp : integer = 14;
let imm32 : bits(32) = ZeroExtend{}(imm8::'00');
if W == '1' || (P == '0' && CurrentInstrSet() != InstrSet A32) then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If $W == '1' \parallel P == '0'$, then one of the following behaviors must occur:

- The instruction is `UNDEFINED`.
- The instruction executes as `NOP`.
- The instruction executes without writeback of the base address.
- The instruction executes as `LDC (immediate)` with writeback to the PC. The instruction is handled as described in Using R15.

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

 $\langle q \rangle$

See [Standard assembler syntax fields](#).

<label>

The label of the literal data item that is to be loaded into <Rt>. The assembler calculates the required value of the offset from the `Align(PC, 4)` value of the instruction to this label. Permitted values of the offset are multiples of 4 in the range -1020 to 1020.

If the offset is zero or positive, `imm32` is equal to the offset and `add == TRUE` (encoded as `U == 1`).

If the offset is negative, `imm32` is equal to minus the offset and `add == FALSE` (encoded as `U == 0`).

 $+/ -$

Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in “U”:

U	+/-
0	-
1	+

<imm>

Is the immediate offset used for forming the address, a multiple of 4 in the range 0-1020, defaulting to 0 and encoded in the “imm8” field, as <imm>/4.

<option>

Is an 8-bit immediate, in the range 0 to 255 enclosed in { }, encoded in the “imm8” field. The value of this field is ignored when executing this instruction.

The alternative syntax permits the addition or subtraction of the offset and the immediate offset to be specified separately, including permitting a subtraction of 0 that cannot be specified using the normal syntax. For more information, see [Use of labels in UAL instruction syntax](#).

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let offset_addr : bits(32) = (if add then (AlignDownSize(PC32(),4) + imm32)
                                else (AlignDownSize(PC32(),4) - imm32));
    let address : bits(32) = if index then offset_addr else AlignDownSize(PC32(),4);

    // System register write to DBGDTRTXint.
    AArch32_SysRegWriteM(cp, ThisInstr(), address);
end;
```

C5.1.65 LDM, LDMIA, LDMFD

Load Multiple (Increment After, Full Descending) loads multiple registers from consecutive memory locations using an address from a base register. The consecutive memory locations start at this address, and the address just above the highest of those locations can optionally be written back to the base register.

The lowest-numbered register is loaded from the lowest memory address, through to the highest-numbered register from the highest memory address. See also [Encoding of lists of general-purpose registers and the PC](#).

This instruction is used by the alias **POP (multiple registers)**.

It has encodings from the following instruction sets: A32 (**A1**) and T32 (**T1** and **T2**).

A1

Encoding

```
LDM{IA}{<c>}{<q>} <Rn>{!}, <registers> // (Preferred syntax)
```

```
LDMFD{<c>}{<q>} <Rn>{!}, <registers> // (Alternate syntax, Full Descending stack)
```

Decode for this encoding

```
let n : integer = UInt(Rn);
let registers : bits(16) = register_list;
let wback : boolean = (W == '1');
if n == 15 || BitCount(registers) < 1 then UnpredictableProcedure(); end;
if wback && registers[n] == '1' then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `BitCount(registers) < 1`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes as LDM with the same addressing mode but targeting an unspecified set of registers. These registers might include R15. If the instruction specifies writeback, the modification to the base address on writeback might differ from the number of registers loaded.

If `wback && registers<n> == '1'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such an instruction, the base address might be corrupted so that the instruction cannot be repeated.

T1

Encoding

LDM{IA}{<c>}{<q>} <Rn>{!}, <registers> // (Preferred syntax)

LDMPD{<c>}{<q>} <Rn>{!}, <registers> // (Alternate syntax, Full Descending stack)

Decode for this encoding

```
let n : integer = UInt(Rn);
let registers : bits(16) = '00000000'::register_list;
let wback : boolean = (registers[n] == '0');
if BitCount(registers) < 1 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If BitCount(registers) < 1, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes as LDM with the same addressing mode but targeting an unspecified set of registers. These registers might include R15. If the instruction specifies writeback, the modification to the base address on writeback might differ from the number of registers loaded.

T2

Encoding

LDM{IA}{<c>}.W <Rn>{!}, <registers> // (Preferred syntax, if <Rn>, '!' and <registers> can be
↪represented in T1)

LDMPD{<c>}.W <Rn>{!}, <registers> // (Alternate syntax, Full Descending stack, if <Rn>, '!' and
↪<registers> can be represented in T1)

LDM{IA}{<c>}{<q>} <Rn>{!}, <registers> // (Preferred syntax)

LDMPD{<c>}{<q>} <Rn>{!}, <registers> // (Alternate syntax, Full Descending stack)

Decode for this encoding

```
let n : integer = UInt(Rn);
let registers : bits(16) = P::M::register_list;
let wback : boolean = (W == '1');
if n == 15 || BitCount(registers) < 2 || (P == '1' && M == '1') then UnpredictableProcedure(); end;
if wback && registers[n] == '1' then UnpredictableProcedure(); end;
if registers[13] == '1' then UnpredictableProcedure(); end;
if registers[15] == '1' && InITBlock() && !LastInITBlock() then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `BitCount(registers) < 1`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes as LDM with the same addressing mode but targeting an unspecified set of registers. These registers might include R15. If the instruction specifies writeback, the modification to the base address on writeback might differ from the number of registers loaded.

If `wback && registers<n> == '1'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such an instruction, the base address might be corrupted so that the instruction cannot be repeated.

If `BitCount(registers) == 1`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction loads a single register using the specified addressing modes.
- The instruction executes as LDM with the same addressing mode but targeting an unspecified set of registers. These registers might include R15.

If `registers<13> == '1'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs all of the loads using the specified addressing mode, but R13 is UNKNOWN.

If `P == '1' && M == '1'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction loads the register list and either R14 or R15, both R14 and R15, or neither of these registers.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

IA

Is an optional suffix for the Increment After form.

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rn>

Is the general-purpose base register, encoded in the “Rn” field.

!

For the “A1” and “T2” variants: the address adjusted by the size of the data loaded is written back to the base register. If specified, it is encoded in the “W” field as 1, otherwise this field defaults to 0.

For the “T1” variant: the address adjusted by the size of the data loaded is written back to the base register. It is omitted if <Rn> is included in <registers>, otherwise it must be present.

<registers>

For the “A1” variant: is a list of one or more registers to be loaded, separated by commas and surrounded by { and }.

The PC can be in the list.

Arm deprecates using these instructions with both the LR and the PC in the list.

For the “T1” variant: is a list of one or more registers to be loaded, separated by commas and surrounded by { and }. The registers in the list must be in the range R0-R7, encoded in the “register_list” field.

For the “T2” variant: is a list of one or more registers to be loaded, separated by commas and surrounded by { and }. The registers in the list must be in the range R0-R12, encoded in the “register_list” field, and can optionally contain one of the LR or the PC. If the LR is in the list, the “M” field is set to 1, otherwise it defaults to 0. If the PC is in the list, the “P” field is set to 1, otherwise it defaults to 0.

If the PC is in the list:

- The LR must not be in the list.
- The instruction must be either outside any IT block, or the last instruction in an IT block.

Alias Conditions

Alias	Of variant	Is preferred when
POP (multiple registers)	A1	$W == '1' \ \&\& \ Rn == '1101' \ \&\& \ \text{BitCount}(\text{register_list}) > 1$
POP (multiple registers)	T2	$W == '1' \ \&\& \ Rn == '1101' \ \&\& \ \text{BitCount}(P : M : \text{register_list}) > 1$
POP (multiple registers)	T2	$\text{BitCount}(P : M : \text{register_list}) > 1$

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    var address : bits(32) = R(n);
    let length : integer = 4*BitCount(registers);
    let within8byte : boolean = AllInAlignedQuantity{32}(address, length, 8);
    var data : bits(32);
    for i = 0 to 14 do
        if registers[i] == '1' then
            if i != n then
                R(i) = MemS{32}(address, within8byte);
            else
                data = MemS{32}(address, within8byte);
            end;
            address = address + 4;
        end;
    end;
    if registers[15] == '1' then
        LoadWritePC(MemS{32}(address, within8byte));
    end;

    if wback && registers[n] == '1' then
        R(n) = ARBITRARY : bits(32);
    end;
    if wback && registers[n] == '0' then
        R(n) = R(n) + 4*BitCount(registers);
    end;
    if !wback && registers[n] == '1' then
        R(n) = data;
    end;

end;
```

C5.1.66 LDM (exception return)

Load Multiple (exception return) loads multiple registers from consecutive memory locations using an address from a base register. The [SPSR](#) of the current mode is copied to the [CPSR](#). An address adjusted by the size of the data loaded can optionally be written back to the base register.

The registers loaded include the PC. The word loaded for the PC is treated as an address and a branch occurs to that address.

The PE checks the encoding that is copied to the [CPSR](#) for an illegal return event. See [Illegal return events from AArch32 state](#).

Load Multiple (exception return) is:

- UNDEFINED in Hyp mode.
- UNPREDICTABLE in debug state, and in User mode and System mode.

Encoding

LDM{<amode>}{<c>}{<q>} <Rn>{!}, <registers_with_pc>^

Decode for this encoding

```
let n : integer = UInt(Rn);
let registers : bits(15) = register_list;
let wback : boolean = (W == '1');
let increment : boolean = (U == '1');
let wordhigher : boolean = (P == U);
if n == 15 then UnpredictableProcedure(); end;
if wback && registers[n] == '1' then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If wback && registers<n> == '1', then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs all the loads using the specified addressing mode and the content of the register being written back is UNKNOWN. In addition, if an exception occurs during the execution of this instruction, the base address might be corrupted so that the instruction cannot be repeated.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<amode>

is one of:

- DA** Decrement After. The consecutive memory addresses end at the address in the base register. Encoded as P = 0, U = 0.
- FA** Full Ascending. For this instruction, a synonym for DA.
- DB** Decrement Before. The consecutive memory addresses end one word below the address in the base register. Encoded as P = 1, U = 0.

- EA** Empty Ascending. For this instruction, a synonym for **DB**.
- IA** Increment After. The consecutive memory addresses start at the address in the base register. This is the default. Encoded as P = 0, U = 1.
- FD** Full Descending. For this instruction, a synonym for **IA**.
- IB** Increment Before. The consecutive memory addresses start one word above the address in the base register. Encoded as P = 1, U = 1.
- ED** Empty Descending. For this instruction, a synonym for **IB**.

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rn>

Is the general-purpose base register, encoded in the “Rn” field.

!

The address adjusted by the size of the data loaded is written back to the base register. If specified, it is encoded in the “W” field as 1, otherwise this field defaults to 0.

<registers_with_pc>

Is a list of one or more registers, separated by commas and surrounded by { and }. It specifies the set of registers to be loaded. The registers are loaded with the lowest-numbered register from the lowest memory address, through to the highest-numbered register from the highest memory address. The PC must be specified in the register list, and the instruction causes a branch to the address (data) loaded into the PC. See also [Encoding of lists of general-purpose registers and the PC](#).

Instructions with similar syntax but without the PC included in the registers list are described in [LDM \(User registers\)](#).

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    if PSTATE.EL == EL2 then
        Undefined();
    elseif PSTATE.M IN {M32_User, M32_System} then
        UnpredictableProcedure(); // UNDEFINED or NOP
    else
        let length : integer = 4*BitCount(registers) + 4;
        var address : bits(32) = if increment then R(n) else R(n)-length;
        let within8byte : boolean = AllInAlignedQuantity{32}(address, length, 8);
        if wordhigher then address = address+4; end;
        var data : bits(32);

        for i = 0 to 14 do
            if registers[i] == '1' then
                if i != n then
                    R(i) = MemS{32}(address, within8byte);
                else
                    data = MemS{32}(address, within8byte);
                end;
                address = address + 4;
            end;
        end;
        let new_pc_value : bits(32) = MemS{32}(address, within8byte);

        if wback && registers[n] == '1' then
            R(n) = ARBITRARY : bits(32);
        end;
```

```
        if wback && registers[n] == '0' then
            R(n) = if increment then R(n)+length else R(n)-length;
        end;
        if !wback && registers[n] == '1' then
            R(n) = data;
        end;

        AArch32_ExceptionReturn(new_pc_value, SPSR_curr());
    end;
end;
```

CONSTRAINED UNPREDICTABLE behavior

If `PSTATE.M` IN {`M32_User`, `M32_System`}, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.

C5.1.67 LDM (User registers)

Load Multiple (User registers)

In an EL1 mode other than System mode, Load Multiple (User registers) loads multiple User mode registers from consecutive memory locations using an address from a base register. The registers loaded cannot include the PC. The PE reads the base register value normally, using the current mode to determine the correct Banked version of the register. This instruction cannot writeback to the base register.

Load Multiple (User registers) is UNDEFINED in Hyp mode, and UNPREDICTABLE in User and System modes.

Encoding

LDM{<amode>}{<c>}{<q>} <Rn>, <registers_without_pc>^

Decode for this encoding

```
let n : integer = UInt(Rn);
let registers : bits(15) = register_list;
let increment : boolean = (U == '1');
let wordhigher : boolean = (P == U);
if n == 15 || BitCount(registers) < 1 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `BitCount(registers) < 1`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction operates as an LDM with the same addressing mode but targeting an unspecified set of registers. These registers might include R15.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<amode>

is one of:

- DA** Decrement After. The consecutive memory addresses end at the address in the base register. Encoded as P = 0, U = 0.
- FA** Full Ascending. For this instruction, a synonym for DA.
- DB** Decrement Before. The consecutive memory addresses end one word below the address in the base register. Encoded as P = 1, U = 0.
- EA** Empty Ascending. For this instruction, a synonym for DB.
- IA** Increment After. The consecutive memory addresses start at the address in the base register. This is the default. Encoded as P = 0, U = 1.
- FD** Full Descending. For this instruction, a synonym for IA.
- IB** Increment Before. The consecutive memory addresses start one word above the address in the base register. Encoded as P = 1, U = 1.
- ED** Empty Descending. For this instruction, a synonym for IB.

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rn>

Is the general-purpose base register, encoded in the “Rn” field.

<registers_without_pc>

Is a list of one or more registers, separated by commas and surrounded by { and }. It specifies the set of registers to be loaded by the LDM instruction. The registers are loaded with the lowest-numbered register from the lowest memory address, through to the highest-numbered register from the highest memory address. The PC must not be in the register list. See also [Encoding of lists of general-purpose registers and the PC](#).

Instructions with similar syntax but with the PC included in <registers_without_pc> are described in [LDM \(exception return\)](#).

Operation

```

if ConditionPassed() then
    EncodingSpecificOperations();
    if PSTATE.EL == EL2 then Undefined();
    elsif PSTATE.M IN {M32_User, M32_System} then UnpredictableProcedure();
    else
        let length : integer = 4*BitCount(registers);
        var address : bits(32) = if increment then R(n) else R(n)-length;
        let within8byte : boolean = AllInAlignedQuantity{32}(address, length, 8);
        if wordhigher then address = address+4; end;
        for i = 0 to 14 do
            if registers[i] == '1' then // Load User mode register
                Rmode(i, M32_User) = MemS{32}(address, within8byte); address = address + 4;
            end;
        end;
    end;
end;
end;

```

CONSTRAINED UNPREDICTABLE behavior

If PSTATE.M IN {M32_User, M32_System}, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction operates as an LDM with the same addressing mode but targeting an unspecified set of registers. These registers might include R15.

C5.1.68 LDMDA, LDMFA

Load Multiple Decrement After (Full Ascending) loads multiple registers from consecutive memory locations using an address from a base register. The consecutive memory locations end at this address, and the address just below the lowest of those locations can optionally be written back to the base register.

The lowest-numbered register is loaded from the lowest memory address, through to the highest-numbered register from the highest memory address. See also [Encoding of lists of general-purpose registers and the PC](#).

Encoding

LDMDA{<c>}{<q>} <Rn>{!}, <registers> // (Preferred syntax)

LDMFA{<c>}{<q>} <Rn>{!}, <registers> // (Alternate syntax, Full Ascending stack)

Decode for this encoding

```
let n : integer = UInt(Rn);
let registers : bits(16) = register_list;
let wback : boolean = (W == '1');
if n == 15 || BitCount(registers) < 1 then UnpredictableProcedure(); end;
if wback && registers[n] == '1' then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `BitCount(registers) < 1`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction operates as an LDM with the same addressing mode but targeting an unspecified set of registers. These registers might include R15. If the instruction specifies writeback, the modification to the base address on writeback might differ from the number of registers loaded.

If `wback && registers<n> == '1'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base address might be corrupted so that the instruction cannot be repeated.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rn>

Is the general-purpose base register, encoded in the “Rn” field.

!

The address adjusted by the size of the data loaded is written back to the base register. If specified, it is encoded in the “W” field as 1, otherwise this field defaults to 0.

<registers>

Is a list of one or more registers to be loaded, separated by commas and surrounded by { and }.

The PC can be in the list.

Arm deprecates using these instructions with both the LR and the PC in the list.

Operation

```

if ConditionPassed() then
    EncodingSpecificOperations();
    var address : bits(32) = (R(n) - 4*BitCount(registers)) + 4;
    let length : integer = 4*BitCount(registers);
    let within8byte : boolean = AllInAlignedQuantity{32}(address, length, 8);
    var data : bits(32);
    for i = 0 to 14 do
        if registers[i] == '1' then
            if i != n then
                R(i) = MemS{32}(address, within8byte);
            else
                data = MemS{32}(address, within8byte);
            end;
            address = address + 4;
        end;
    end;
    if registers[15] == '1' then
        LoadWritePC(MemS{32}(address, within8byte));
    end;

    if wback && registers[n] == '1' then
        R(n) = ARBITRARY : bits(32);
    end;
    if wback && registers[n] == '0' then
        R(n) = R(n) - 4*BitCount(registers);
    end;
    if !wback && registers[n] == '1' then
        R(n) = data;
    end;

end;

```

C5.1.69 LDMDB, LDMEA

Load Multiple Decrement Before (Empty Ascending) loads multiple registers from consecutive memory locations using an address from a base register. The consecutive memory locations end just below this address, and the address of the lowest of those locations can optionally be written back to the base register.

The lowest-numbered register is loaded from the lowest memory address, through to the highest-numbered register from the highest memory address. See also [Encoding of lists of general-purpose registers and the PC](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

LDMDB{<c>}{<q>} <Rn>{!}, <registers> // (Preferred syntax)

LDMEA{<c>}{<q>} <Rn>{!}, <registers> // (Alternate syntax, Empty Ascending stack)

Decode for this encoding

```
let n : integer = UInt(Rn);
let registers : bits(16) = register_list;
let wback : boolean = (W == '1');
if n == 15 || BitCount(registers) < 1 then UnpredictableProcedure(); end;
if wback && registers[n] == '1' then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `wback && registers<n> == '1'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such an instruction, the base address might be corrupted so that the instruction cannot be repeated.

If `BitCount(registers) < 1`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes as LDM with the same addressing mode but targeting an unspecified set of registers. These registers might include R15. If the instruction specifies writeback, the modification to the base address on writeback might differ from the number of registers loaded.

T1

Encoding

```
LDMDB{<c>}{<q>} <Rn>{!}, <registers> // (Preferred syntax)
```

```
LDMEA{<c>}{<q>} <Rn>{!}, <registers> // (Alternate syntax, Empty Ascending stack)
```

Decode for this encoding

```

let n : integer = UInt(Rn);
let registers : bits(16) = P::M::register_list;
let wback : boolean = (W == '1');
if n == 15 || BitCount(registers) < 2 || (P == '1' && M == '1') then UnpredictableProcedure(); end;
if wback && registers[n] == '1' then UnpredictableProcedure(); end;
if registers[13] == '1' then UnpredictableProcedure(); end;
if registers[15] == '1' && InITBlock() && !LastInITBlock() then UnpredictableProcedure(); end;

```

CONSTRAINED UNPREDICTABLE behavior

If `wback && registers<n> == '1'`, then one of the following behaviors must occur:

- The instruction is **UNDEFINED**.
- The instruction executes as **NOP**.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is **UNKNOWN**. In addition, if an exception occurs during such an instruction, the base address might be corrupted so that the instruction cannot be repeated.

If `BitCount(registers) < 1`, then one of the following behaviors must occur:

- The instruction is `UNDEFINED`.
- The instruction executes as `NOP`.
- The instruction executes as `LDM` with the same addressing mode but targeting an unspecified set of registers. These registers might include `R15`. If the instruction specifies writeback, the modification to the base address on writeback might differ from the number of registers loaded.

If `BitCount(registers) == 1`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction loads a single register using the specified addressing modes.
- The instruction executes as LDM with the same addressing mode but targeting an unspecified set of registers. These registers might include R15.

If registers<13> == '1', then one of the following behaviors must occur:

- The instruction is **UNDEFINED**.
- The instruction executes as **NOP**.
- The instruction performs all of the loads using the specified addressing mode, but R13 is **UNKNOWN**.

If `P == '1' && M == '1'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction loads the register list and either R14 or R15, both R14 and R15, or neither of these registers.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rn>

Is the general-purpose base register, encoded in the “Rn” field.

!

The address adjusted by the size of the data loaded is written back to the base register. If specified, it is encoded in the “W” field as 1, otherwise this field defaults to 0.

<registers>

For the “A1” variant: is a list of one or more registers to be loaded, separated by commas and surrounded by { and }.

The PC can be in the list.

Arm deprecates using these instructions with both the LR and the PC in the list.

For the “T1” variant: is a list of one or more registers to be loaded, separated by commas and surrounded by { and }. The registers in the list must be in the range R0-R12, encoded in the “register_list” field, and can optionally contain one of the LR or the PC. If the LR is in the list, the “M” field is set to 1, otherwise it defaults to 0. If the PC is in the list, the “P” field is set to 1, otherwise it defaults to 0.

If the PC is in the list:

- The LR must not be in the list.
- The instruction must be either outside any IT block, or the last instruction in an IT block.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    var address : bits(32) = R(n) - 4*BitCount(registers);
    let length : integer = 4*BitCount(registers);
    let within8byte : boolean = AllInAlignedQuantity{32}(address, length, 8);
    var data : bits(32);
    for i = 0 to 14 do
        if registers[i] == '1' then
            if i != n then
                R(i) = MemS{32}(address, within8byte);
            else
                data = MemS{32}(address, within8byte);
            end;
            address = address + 4;
        end;
    end;
    if registers[15] == '1' then
```

```
        LoadWritePC(MemS{32}(address, within8byte));
    end;

    if wback && registers[n] == '1' then
        R(n) = ARBITRARY : bits(32);
    end;
    if wback && registers[n] == '0' then
        R(n) = R(n) - 4*BitCount(registers);
    end;
    if !wback && registers[n] == '1' then
        R(n) = data;
    end;

end;
```

C5.1.70 LDMIB, LDMED

Load Multiple Increment Before (Empty Descending) loads multiple registers from consecutive memory locations using an address from a base register. The consecutive memory locations start just above this address, and the address of the last of those locations can optionally be written back to the base register.

The lowest-numbered register is loaded from the lowest memory address, through to the highest-numbered register from the highest memory address. See also [Encoding of lists of general-purpose registers and the PC](#).

Encoding

```
LDMIB{<c>}{<q>} <Rn>{!}, <registers> // (Preferred syntax)
```

```
LDMED{<c>}{<q>} <Rn>{!}, <registers> // (Alternate syntax, Empty Descending stack)
```

Decode for this encoding

```

let n : integer = UInt(Rn);
let registers : bits(16) = register_list;
let wback : boolean = (W == '1');

if n == 15 || BitCount(registers) < 1 then UnpredictableProcedure(); end;
if wback && registers[n] == '1' then UnpredictableProcedure(); end;

```

CONSTRAINED UNPREDICTABLE behavior

If $\text{BitCount}(\text{registers}) < 1$, then one of the following behaviors must occur:

- The instruction is `UNDEFINED`.
- The instruction executes as `NOP`.
- The instruction operates as an `LDM` with the same addressing mode but targeting an unspecified set of registers. These registers might include `R15`. If the instruction specifies writeback, the modification to the base address on writeback might differ from the number of registers loaded.

If `wback && registers<n> == '1'`, then one of the following behaviors must occur:

- The instruction is **UNDEFINED**.
- The instruction executes as **NOP**.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is **UNKNOWN**. In addition, if an exception occurs during such as instruction, the base address might be corrupted so that the instruction cannot be repeated.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

 $\langle q \rangle$

See [Standard assembler syntax fields](#).

<Rn>

Is the general-purpose base register, encoded in the “Rn” field.

!

The address adjusted by the size of the data loaded is written back to the base register. If specified, it is encoded in the “W” field as 1, otherwise this field defaults to 0.

<registers>

Is a list of one or more registers to be loaded, separated by commas and surrounded by { and }.

The PC can be in the list.

Arm deprecates using these instructions with both the LR and the PC in the list.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    var address : bits(32) = R(n) + 4;
    let length : integer = 4*BitCount(registers);
    let within8byte : boolean = AllInAlignedQuantity{32}(address, length, 8);
    var data : bits(32);
    for i = 0 to 14 do
        if registers[i] == '1' then
            if i != n then
                R(i) = MemS{32}(address, within8byte);
            else
                data = MemS{32}(address, within8byte);
            end;
            address = address + 4;
        end;
    end;
    if registers[15] == '1' then
        LoadWritePC(MemS{32}(address, within8byte));
    end;

    if wback && registers[n] == '1' then
        R(n) = ARBITRARY : bits(32);
    end;
    if wback && registers[n] == '0' then
        R(n) = R(n) + 4*BitCount(registers);
    end;
    if !wback && registers[n] == '1' then
        R(n) = data;
    end;

end;
```

C5.1.71 LDR (immediate)

Load Register (immediate) calculates an address from a base register value and an immediate offset, loads a word from memory, and writes it to a register. It can use offset, post-indexed, or pre-indexed addressing. For information about memory accesses see [Memory accesses](#).

This instruction is used by the alias [POP \(single register\)](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#), [T2](#), [T3](#), and [T4](#)).

A1

Encoding for the Offset variant

Applies when (P == 1 && W == 0)

```
LDR{<c>}{<q>} <Rt>, [<Rn> {, #{+/-}<imm>}]
```

Encoding for the Post-indexed variant

Applies when (P == 0 && W == 0)

```
LDR{<c>}{<q>} <Rt>, [<Rn>], #{+/-}<imm>
```

Encoding for the Pre-indexed variant

Applies when (P == 1 && W == 1)

```
LDR{<c>}{<q>} <Rt>, [<Rn>, #{+/-}<imm>]!
```

Decode for all variants of this encoding

```
if Rn == '1111' then See("LDR (literal)"); end;
if P == '0' && W == '1' then See("LDRT"); end;
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let imm32 : bits(32) = ZeroExtend{(imm12)};
let index : boolean = (P == '1');
let add : boolean = (U == '1');
let wback : boolean = (P == '0') || (W == '1');
if wback && n == t then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If wback && n == t, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such an instruction, the base address might be corrupted so that the instruction cannot be repeated.

T1

Encoding

LDR{<c>}{<q>} <Rt>, [<Rn> {, #}{+}<imm>]}

Decode for this encoding

```
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let imm32 : bits(32) = ZeroExtend{}(imm5::'00');
let index : boolean = TRUE;
let add : boolean = TRUE;
let wback : boolean = FALSE;
```

T2

Encoding

LDR{<c>}{<q>} <Rt>, [SP{, #}{+}<imm>]}

Decode for this encoding

```
let t : integer = UInt(Rt);
let n : integer = 13;
let imm32 : bits(32) = ZeroExtend{}(imm8::'00');
let index : boolean = TRUE;
let add : boolean = TRUE;
let wback : boolean = FALSE;
```

T3

Encoding

LDR{<c>}{<q>} <Rt>, [<Rn> {, #}{+}<imm>]}

LDR{<c>}.W <Rt>, [<Rn> {, #}{+}<imm>}] // (<Rt>, <Rn>, <imm> can be represented in T1 or T2)

Decode for this encoding

```

if Rn == '1111' then See("LDR (literal)"); end;
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let imm32 : bits(32) = ZeroExtend{(imm12);
let index : boolean = TRUE;
let add : boolean = TRUE;
let wback : boolean = FALSE;
if t == 15 && InITBlock() && !LastInITBlock() then UnpredictableProcedure(); end;

```

T4

Encoding for the Offset variant

Applies when (P == 1 && U == 0 && W == 0)

```
LDR{<c>} {<q>} <Rt>, [<Rn> {, #-<imm>}]
```

Encoding for the Post-indexed variant

Applies when (P == 0 && W == 1)

LDR{<c>}{<q>} <Rt>, [<Rn>], # {+/-}<imm>

Encoding for the Pre-indexed variant

Applies when (P == 1 && W == 1)

```
LDR{<c>}{<q>}<Rt>, [<Rn>, # {+/-}<imm>]!
```

Decode for all variants of this encoding

```

if Rn == '1111' then See("LDR (literal)"); end;
if P == '1' && U == '1' && W == '0' then See("LDRT"); end;
if P == '0' && W == '0' then Undefined(); end;
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let imm32 : bits(32) = ZeroExtend{}(imm8);
let index : boolean = (P == '1');
let add : boolean = (U == '1');
let wback : boolean = (W == '1');
if (wback && n == t) || (t == 15 && InITBlock() && !LastInITBlock()) then
  UnpredictableProcedure();
end;

```

CONSTRAINED UNPREDICTABLE behavior

If `wback && n == t`, then one of the following behaviors must occur:

- The instruction is **UNDEFINED**.
- The instruction executes as **NOP**.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is **UNKNOWN**. In addition, if an exception occurs during such an instruction, the base address might be corrupted so that the instruction cannot be repeated.

For more information about the **CONSTRAINED UNPREDICTABLE** behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rt>

For the “A1 Offset”, “A1 Post-indexed”, and “A1 Pre-indexed” variants: is the general-purpose register to be transferred, encoded in the “Rt” field. The PC can be used. If the PC is used, the instruction branches to the address (data) loaded to the PC. This is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC](#).

For the “T1” and “T2” variants: is the general-purpose register to be transferred, encoded in the “Rt” field.

For the “T3”, “T4 Offset”, “T4 Post-indexed”, and “T4 Pre-indexed” variants: is the general-purpose register to be transferred, encoded in the “Rt” field. The PC can be used, provided the instruction is either outside an IT block or the last instruction of an IT block. If the PC is used, the instruction branches to the address (data) loaded to the PC. This is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC](#).

<Rn>

For the “A1 Offset”, “A1 Post-indexed”, “A1 Pre-indexed”, “T3”, “T4 Offset”, “T4 Post-indexed”, and “T4 Pre-indexed” variants: is the general-purpose base register, encoded in the “Rn” field. For PC use see [LDR \(literal\)](#).

For the “T1” variant: is the general-purpose base register, encoded in the “Rn” field.

+/-

Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in “U”:

U	+/-
0	-
1	+

<imm>

For the “A1 Offset”, “A1 Post-indexed”, and “A1 Pre-indexed” variants: is the 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 if omitted, and encoded in the “imm12” field.

For the “T1” variant: is the optional positive unsigned immediate byte offset, a multiple of 4, in the range 0 to 124, defaulting to 0 and encoded in the “imm5” field as `<imm>/4`.

For the “T2” variant: is the optional positive unsigned immediate byte offset, a multiple of 4, in the range 0 to 1020, defaulting to 0 and encoded in the “imm8” field as <imm>/4.

For the “T3” variant: is an optional 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 and encoded in the “imm12” field.

For the “T4 Offset”, “T4 Post-indexed”, and “T4 Pre-indexed” variants: is an 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 if omitted, and encoded in the “imm8” field.

+

Specifies the offset is added to the base register.

Alias Conditions

Alias	Of variant	Is preferred when
POP (single register)	A1 Post-indexed	P == '0' && U == '1' && W == '0' && Rn == '1101' && imm12 == '000000000100'
POP (single register)	T4 Post-indexed	Rn == '1101' && P == '0' && U == '1' && W == '1' && imm8 == '00000100'

Operation

```
if CurrentInstrSet() == InstrSet_A32 then
  if ConditionPassed() then
    EncodingSpecificOperations();
    let offset_addr : bits(32) = if add then (R(n) + imm32) else (R(n) - imm32);
    let address : bits(32) = if index then offset_addr else R(n);
    let data : bits(32) = MemU{32}(address);
    if wback then R(n) = offset_addr; end;
    if t == 15 then
      if address[1:0] == '00' then
        LoadWritePC(data);
      else
        UnpredictableProcedure();
      end;
    else
      R(t) = data;
    end;
  end;
else
  if ConditionPassed() then
    EncodingSpecificOperations();
    let offset_addr : bits(32) = if add then (R(n) + imm32) else (R(n) - imm32);
    let address : bits(32) = if index then offset_addr else R(n);
    let data : bits(32) = MemU{32}(address);
    if wback then R(n) = offset_addr; end;
    if t == 15 then
      if address[1:0] == '00' then
        LoadWritePC(data);
      else
        UnpredictableProcedure();
      end;
    else
      R(t) = data;
    end;
  end;
end;
```

C5.1.72 LDR (literal)

Load Register (literal) calculates an address from the PC value and an immediate offset, loads a word from memory, and writes it to a register. For information about memory accesses see [Memory accesses](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#) and [T2](#)).

A1

Decode for this encoding

```
let t : integer = UInt(Rt);
let imm32 : bits(32) = ZeroExtend{}(imm8::'00');
let add : boolean = TRUE;
```

T2

Encoding

```
LDR{<c>}.W <Rt>, <label> // (Preferred syntax)
```

LDR{<c>}{<q>} <Rt>, <label> // (Preferred syntax, and <Rt>, <label> can be represented in T1)

```
LDR{<c>}{<q>} <Rt>, [PC, #(<+/-><imm>)] // (Alternative syntax)
```

Decode for this encoding

```

let t : integer = UInt(Rt);
let imm32 : bits(32) = ZeroExtend{}(imm12);
let add : boolean = (U == '1');
if t == 15 && InITBlock() && !LastInITBlock() then UnpredictableProcedure(); end;

```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

 $\langle q \rangle$

See [Standard assembler syntax fields](#).

<Rt>

For the “A1” variant: is the general-purpose register to be transferred, encoded in the “Rt” field. The PC can be used. If the PC is used, the instruction branches to the address (data) loaded to the PC. This is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC](#).

For the “T1” variant: is the general-purpose register to be transferred, encoded in the “Rt” field.

For the “T2” variant: is the general-purpose register to be transferred, encoded in the “Rt” field. The SP can be used. The PC can be used, provided the instruction is either outside an IT block or the last instruction of an IT block. If the PC is used, the instruction branches to the address (data) loaded to the PC. This is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC](#).

<label>

For the “A1” and “T2” variants: the label of the literal data item that is to be loaded into `<Rt>`. The assembler calculates the required value of the offset from the `Align(PC, 4)` value of the instruction to this label. Permitted values of the offset are -4095 to 4095.

If the offset is zero or positive, `imm32` is equal to the offset and `add == TRUE`, encoded as `U == 1`.

If the offset is negative, `imm32` is equal to minus the offset and `add == FALSE`, encoded as `U == 0`.

For the “T1” variant: the label of the literal data item that is to be loaded into `<Rt>`. The assembler calculates the required value of the offset from the `Align(PC, 4)` value of the instruction to this label. Permitted values of the offset are Multiples of four in the range 0 to 1020.

`+/-`

Specifies the offset is added to or subtracted from the base register, defaulting to `+` if omitted and encoded in “U”:

U	+/-
0	-
1	+

`<imm>`

For the “A1” variant: is the 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 if omitted, and encoded in the “`imm12`” field.

For the “T2” variant: is a 12-bit unsigned immediate byte offset, in the range 0 to 4095, encoded in the “`imm12`” field.

The alternative syntax permits the addition or subtraction of the offset and the immediate offset to be specified separately, including permitting a subtraction of 0 that cannot be specified using the normal syntax. For more information, see [Use of labels in UAL instruction syntax](#).

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let base : bits(32) = AlignDownSize(PC32(), 4);
    let address : bits(32) = if add then (base + imm32) else (base - imm32);
    let data : bits(32) = MemU{32}(address);
    if t == 15 then
        if address[1:0] == '00' then
            LoadWritePC(data);
        else
            UnpredictableProcedure();
        end;
    else
        R(t) = data;
    end;
end;
```

C5.1.73 LDR (register)

Load Register (register) calculates an address from a base register value and an offset register value, loads a word from memory, and writes it to a register. The offset register value can optionally be shifted. For information about memory accesses, see [Memory accesses](#).

The T32 form of `LDR (register)` does not support register writeback.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#) and [T2](#)).

A1

Encoding for the Offset variant

Applies when (P == 1 && W == 0)

LDR{<c>}{<q>}<Rt>,[<Rn>,{+/-}<Rm>{,<shift>}]

Encoding for the Post-indexed variant

Applies when (P == 0 && W == 0)

LDR{<c>}{<q>} <Rt>, [<Rn>], {+/-}<Rm>{, <shift>}

Encoding for the Pre-indexed variant

Applies when (P == 1 && W == 1)

LDR{<c>}{<q>} <Rt>, [<Rn>, {+/-}<Rm>{, <shift>}]!

Decode for all variants of this encoding

```

if P == '0' && W == '1' then See("LDRT"); end;
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let index : boolean = (P == '1');
let add : boolean = (U == '1');
let wback : boolean = (P == '0') || (W == '1');
let (shift_t, shift_n) : (SRTType, integer) = DecodeImmShift(stype, imm5);
if m == 15 then UnpredictableProcedure(); end;
if wback && (n == 15 || n == t) then UnpredictableProcedure(); end;

```

CONSTRAINED UNPREDICTABLE behavior

If `wback && n == t`, then one of the following behaviors must occur:

- The instruction is **UNDEFINED**.
- The instruction executes as **NOP**.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is **UNKNOWN**. In addition, if an exception occurs during such as instruction, the base address might be corrupted so that the instruction cannot be repeated.

T1

Encoding

LDR{<c>}{<q>} <Rt>, [<Rn>, {+}<Rm>]

Decode for this encoding

```

let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let shift_t : SRTYPE = SRTYPE_LSL;
let shift_n : integer = 0;
let index : boolean = TRUE;
let add : boolean = TRUE;
let wback : boolean = FALSE;

```

T2

Encoding

LDR{<c>}{<q>} <Rt>, [<Rn>, {+}<Rm>{, LSL #<imm>}]

LDR{<c>}.W <Rt>, [<Rn>, {+}<Rm>] // (<Rt>, <Rn>, <Rm> can be represented in T1)

Decode for this encoding

```

if Rn == '1111' then See("LDR (literal)"); end;
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let shift_t : SRTYPE = SRTYPE_LSL;
let shift_n : integer = UInt(imm2);
// Armv8-A removes UNPREDICTABLE for R13
if m == 15 then UnpredictableProcedure(); end;
if t == 15 && InITBlock() && !LastInITBlock() then UnpredictableProcedure(); end;
let index : boolean = TRUE;
let add : boolean = TRUE;
let wback : boolean = FALSE;

```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rt>

For the “Offset”, “Post-indexed”, and “Pre-indexed” variants: is the general-purpose register to be transferred, encoded in the “Rt” field. The PC can be used. If the PC is used, the instruction branches to the address (data) loaded to the PC. This branch is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC](#).

For the “T1” variant: is the general-purpose register to be transferred, encoded in the “Rt” field.

For the “T2” variant: is the general-purpose register to be transferred, encoded in the “Rt” field. The PC can be used, provided the instruction is either outside an IT block or the last instruction of an IT block. If the PC is used, the instruction branches to the address (data) loaded to the PC. This is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC](#).

<Rn>

For the “Offset”, “Post-indexed”, and “Pre-indexed” variants: is the general-purpose base register, encoded in the “Rn” field. The PC can be used in the offset variant.

For the “T1” and “T2” variants: is the general-purpose base register, encoded in the “Rn” field.

+/-

Specifies the index register is added to or subtracted from the base register, defaulting to + if omitted and encoded in “U”:

U	+/-
0	-
1	+

<Rm>

Is the general-purpose index register, encoded in the “Rm” field.

<shift>

The shift to apply to the value read from <Rm>. If absent, no shift is applied. Otherwise, see [Shifts applied to a register](#).

+

Specifies the index register is added to the base register.

<imm>

If present, the size of the left shift to apply to the value from <Rm>, in the range 1-3. <imm> is encoded in imm2. If absent, no shift is specified and imm2 is encoded as 0b00.

Operation

```
if CurrentInstrSet() == InstrSet_A32 then
    if ConditionPassed() then
        EncodingSpecificOperations();
        let offset : bits(32) = Shift{}(R(m), shift_t, shift_n, PSTATE.C);
        let offset_addr : bits(32) = if add then (R(n) + offset) else (R(n) - offset);
        let address : bits(32) = if index then offset_addr else R(n);
        let data : bits(32) = MemU{32}(address);
        if wback then R(n) = offset_addr; end;
        if t == 15 then
            if address[1:0] == '00' then
                LoadWritePC(data);
            else
                UnpredictableProcedure();
            end;
        else
            R(t) = data;
        end;
    end;
else
    if ConditionPassed() then
        EncodingSpecificOperations();
        let offset : bits(32) = Shift{}(R(m), shift_t, shift_n, PSTATE.C);
        let offset_addr : bits(32) = (R(n) + offset);
        let address : bits(32) = offset_addr;
        let data : bits(32) = MemU{32}(address);
        if t == 15 then
            if address[1:0] == '00' then
                LoadWritePC(data);
            else
                UnpredictableProcedure();
            end;
        else
            R(t) = data;
        end;
    end;
end;
```

C5.1.74 LDRB (immediate)

Load Register Byte (immediate) calculates an address from a base register value and an immediate offset, loads a byte from memory, zero-extends it to form a 32-bit word, and writes it to a register. It can use offset, post-indexed, or pre-indexed addressing. For information about memory accesses see [Memory accesses](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#), [T2](#), and [T3](#)).

A1

Encoding for the Offset variant

Applies when (P == 1 && W == 0)

```
LDRB{<c>}{<q>} <Rt>, [<Rn> {, #{+/-}<imm>}]
```

Encoding for the Post-indexed variant

Applies when (P == 0 && W == 0)

```
LDRB{<c>}{<q>} <Rt>, [<Rn>], #{+/-}<imm>
```

Encoding for the Pre-indexed variant

Applies when (P == 1 && W == 1)

```
LDRB{<c>}{<q>} <Rt>, [<Rn>, #{+/-}<imm>]!
```

Decode for all variants of this encoding

```
if Rn == '1111' then See("LDRB (literal)"); end;
if P == '0' && W == '1' then See("LDRBT"); end;
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let imm32 : bits(32) = ZeroExtend{}(imm12);
let index : boolean = (P == '1');
let add : boolean = (U == '1');
let wback : boolean = (P == '0') || (W == '1');
if t == 15 || (wback && n == t) then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If wback && n == t, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such an instruction, the base address might be corrupted so that the instruction cannot be repeated.

T1

Encoding

LDRB{<c>}{<q>} <Rt>, [<Rn> {, #<+><imm>}]

Decode for this encoding

```

let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let imm32 : bits(32) = ZeroExtend{}(imm5);
let index : boolean = TRUE;
let add : boolean = TRUE;
let wback : boolean = FALSE;

```

T2

Encoding

LDRB{<c>}{<q>} <Rt>, [<Rn> {, #<+><imm>}]

LDRB{<c>}.W <Rt>, [<Rn> {, #<+><imm>}] // (<Rt>, <Rn>, <imm> can be represented in T1)

Decode for this encoding

```

if Rt == '1111' then See("PLD"); end;
if Rn == '1111' then See("LDRB (literal)"); end;
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let imm32 : bits(32) = ZeroExtend{}(imm12);
let index : boolean = TRUE;
let add : boolean = TRUE;
let wback : boolean = FALSE;
// Armv8-A removes UNPREDICTABLE for R13

```

T3

Encoding for the Offset variant

Applies when (Rt != 1111 && P == 1 && U == 0 && W == 0)

LDRB{<c>}{<q>}<Rt>,[<Rn>{,<#->imm>}]

Encoding for the Post-indexed variant

Applies when (P == 0 && W == 1)

LDRB{<c>}{<q>} <Rt>, [<Rn>], # {+/-}<imm>

Encoding for the Pre-indexed variant

Applies when (P == 1 && W == 1)

```
LDRB{<c>}{<q>} <Rt>, [<Rn>, #<+/-><imm>]!
```

Decode for all variants of this encoding

```

if Rt == '1111' && P == '1' && U == '0' && W == '0' then See("PLD, PLDW (immediate)"); end;
if Rn == '1111' then See("LDRB (literal)"); end;
if P == '1' && U == '1' && W == '0' then See("LDRBT"); end;
if P == '0' && W == '0' then Undefined(); end;
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let imm32 : bits(32) = ZeroExtend{}(imm8);
let index : boolean = (P == '1');
let add : boolean = (U == '1');
let wback : boolean = (W == '1');
if (t == 15 && W == '1') || (wback && n == t) then UnpredictableProcedure(); end;
// Armv8-A removes UNPREDICTABLE for R13

```

CONSTRAINED UNPREDICTABLE behavior

If $w_{back} \ \&\& \ n == t$, then one of the following behaviors must occur:

- The instruction is `UNDEFINED`.
- The instruction executes as `NOP`.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is `UNKNOWN`. In addition, if an exception occurs during such an instruction, the base address might be corrupted so that the instruction cannot be repeated.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rt>

Is the general-purpose register to be transferred, encoded in the “Rt” field.

<Rn>

For the “A1 Offset”, “A1 Post-indexed”, “A1 Pre-indexed”, “T2”, “T3 Offset”, “T3 Post-indexed”, and “T3 Pre-indexed” variants: is the general-purpose base register, encoded in the “Rn” field. For PC use see [LDRB \(literal\)](#).

For the “T1” variant: is the general-purpose base register, encoded in the “Rn” field.

+/-

Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in “U”:

U	+/-
0	-
1	+

<imm>

For the “A1 Offset”, “A1 Post-indexed”, and “A1 Pre-indexed” variants: is the 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 if omitted, and encoded in the “imm12” field.

For the “T1” variant: is an optional 5-bit unsigned immediate byte offset, in the range 0 to 31, defaulting to 0 and encoded in the “imm5” field.

For the “T2” variant: is an optional 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 and encoded in the “imm12” field.

For the “T3 Offset”, “T3 Post-indexed”, and “T3 Pre-indexed” variants: is an 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 if omitted, and encoded in the “imm8” field.

+

Specifies the offset is added to the base register.

Operation

```
if CurrentInstrSet() == InstrSet_A32 then
  if ConditionPassed() then
    EncodingSpecificOperations();
    let offset_addr : bits(32) = if add then (R(n) + imm32) else (R(n) - imm32);
    let address : bits(32) = if index then offset_addr else R(n);
    R(t) = ZeroExtend{32}(MemU{8}(address));
    if wback then R(n) = offset_addr; end;
  end;
else
  if ConditionPassed() then
    EncodingSpecificOperations();
    let offset_addr : bits(32) = if add then (R(n) + imm32) else (R(n) - imm32);
    let address : bits(32) = if index then offset_addr else R(n);
```

```
    R(t) = ZeroExtend{32}(MemU{8}(address));  
    if wback then R(n) = offset_addr; end;  
end;  
end;
```

C5.1.75 LDRB (literal)

Load Register Byte (literal) calculates an address from the PC value and an immediate offset, loads a byte from memory, zero-extends it to form a 32-bit word, and writes it to a register. For information about memory accesses see [Memory accesses](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

Applies when $(!(P == '0' \ \&\& \ W == '1'))$

LDRB{<c>}{<q>} <Rt>, <label> // (Normal form)

LDRB{<c>}{<q>} <Rt>, [PC, #{+/-}<imm>] // (Alternative form)

Decode for this encoding

```

if P == '0' && W == '1' then See("LDRBT"); end;
let t : integer = UInt(Rt);
let imm32 : bits(32) = ZeroExtend{}(imm12);
let add : boolean = (U == '1');
let wback : boolean = (P == '0') || (W == '1');
if t == 15 || wback then UnpredictableProcedure(); end;

```

CONSTRAINED UNPREDICTABLE behavior

If wback, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes with the additional decode: wback = FALSE;
- The instruction treats bit[24] as the P bit, and bit[21] as the writeback (W) bit, and uses the same addressing mode as described in LDRB (immediate). The instruction uses post-indexed addressing when P == '0' and uses pre-indexed addressing otherwise. The instruction is handled as described in Using R15.

T1

Encoding

LDRB{<c>}{<q>} <Rt>, <label> // (Preferred syntax)

LDRB{<c>}{<q>} <Rt>, [PC, #{+/-}<imm>] // (Alternative syntax)

Decode for this encoding

```
if Rt == '1111' then See("PLD"); end;
let t : integer = UInt(Rt);
let imm32 : bits(32) = ZeroExtend{}(imm12);
let add : boolean = (U == '1');
// Armv8-A removes UNPREDICTABLE for R13
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rt>

Is the general-purpose register to be transferred, encoded in the “Rt” field.

<label>

The label of the literal data item that is to be loaded into <Rt>. The assembler calculates the required value of the offset from the `Align(PC, 4)` value of the instruction to this label. Permitted values of the offset are -4095 to 4095.

If the offset is zero or positive, `imm32` is equal to the offset and `add == TRUE`, encoded as `U == 1`.

If the offset is negative, `imm32` is equal to minus the offset and `add == FALSE`, encoded as `U == 0`.

+/-

Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in “U”:

U	+/-
0	-
1	+

<imm>

For the “A1” variant: is the 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 if omitted, and encoded in the “imm12” field.

For the “T1” variant: is a 12-bit unsigned immediate byte offset, in the range 0 to 4095, encoded in the “imm12” field.

The alternative syntax permits the addition or subtraction of the offset and the immediate offset to be specified separately, including permitting a subtraction of 0 that cannot be specified using the normal syntax. For more information, see [Use of labels in UAL instruction syntax](#).

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let base : bits(32) = AlignDownSize(PC32(), 4);
    let address : bits(32) = if add then (base + imm32) else (base - imm32);
    R(t) = ZeroExtend{32}(MemU{8}(address));
end;
```

C5.1.76 LDRB (register)

Load Register Byte (register) calculates an address from a base register value and an offset register value, loads a byte from memory, zero-extends it to form a 32-bit word, and writes it to a register. The offset register value can optionally be shifted. For information about memory accesses see [Memory accesses](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#) and [T2](#)).

A1

Encoding for the Offset variant

Applies when (P == 1 && W == 0)

```
LDRB{<c>}{<q>} <Rt>, [<Rn>, {+/-}<Rm>{, <shift>}]
```

Encoding for the Post-indexed variant

Applies when (P == 0 && W == 0)

```
LDRB{<c>}{<q>} <Rt>, [<Rn>], {+/-}<Rm>{, <shift>}]
```

Encoding for the Pre-indexed variant

Applies when (P == 1 && W == 1)

```
LDRB{<c>}{<q>} <Rt>, [<Rn>, {+/-}<Rm>{, <shift>}]!
```

Decode for all variants of this encoding

```
if P == '0' && W == '1' then See("LDRBT"); end;
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let index : boolean = (P == '1');
let add : boolean = (U == '1');
let wback : boolean = (P == '0') || (W == '1');
let (shift_t, shift_n) : (SRTYPE, integer) = DecodeImmShift(stype, imm5);
if t == 15 || m == 15 then UnpredictableProcedure(); end;
if wback && (n == 15 || n == t) then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If wback && n == t, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base address might be corrupted so that the instruction cannot be repeated.

T1

Encoding

LDRB{<c>}{<q>} <Rt>, [<Rn>, {+}<Rm>]

Decode for this encoding

```
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let index : boolean = TRUE;
let add : boolean = TRUE;
let wback : boolean = FALSE;
let shift_t : SRTtype = SRTtype_LSL;
let shift_n : integer = 0;
```

T2

Encoding

```
LDRB{<c>}{<q>} <Rt>, [<Rn>, {+}<Rm>{, LSL #<imm>}]
```

LDRB{<c>}.W <Rt>, [<Rn>, {+}<Rm>] // (<Rt>, <Rn>, <Rm> can be represented in T1)

Decode for this encoding

```

if Rt == '1111' then See("PLD"); end;
if Rn == '1111' then See("LDRB (literal)"); end;
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let index : boolean = TRUE;
let add : boolean = TRUE;
let wback : boolean = FALSE;
let shift_t : SRTYPE = SRTYPE_LSL;
let shift_n : integer = UInt(imm2);
// Armv8-A removes UNPREDICTABLE for R13
if m == 15 then UnpredictableProcedure(); end;

```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rt>

Is the general-purpose register to be transferred, encoded in the “Rt” field.

<Rn>

For the “Offset”, “Post-indexed”, and “Pre-indexed” variants: is the general-purpose base register, encoded in the “Rn” field. The PC can be used in the offset variant.

For the “T1” and “T2” variants: is the general-purpose base register, encoded in the “Rn” field.

+/-

Specifies the index register is added to or subtracted from the base register, defaulting to + if omitted and encoded in “U”:

U	+/-
0	-
1	+

<Rm>

Is the general-purpose index register, encoded in the “Rm” field.

<shift>

The shift to apply to the value read from <Rm>. If absent, no shift is applied. Otherwise, see [Shifts applied to a register](#).

+

Specifies the index register is added to the base register.

<imm>

If present, the size of the left shift to apply to the value from <Rm>, in the range 1-3. <imm> is encoded in imm2. If absent, no shift is specified and imm2 is encoded as 0b00.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let offset : bits(32) = Shift{}(R(m), shift_t, shift_n, PSTATE.C);
    let offset_addr : bits(32) = if add then (R(n) + offset) else (R(n) - offset);
    let address : bits(32) = if index then offset_addr else R(n);
    R(t) = ZeroExtend{32}(MemU{8}(address));
    if wback then R(n) = offset_addr; end;
end;
```

C5.1.77 LDRBT

Load Register Byte Unprivileged loads a byte from memory, zero-extends it to form a 32-bit word, and writes it to a register. For information about memory accesses see [Memory accesses](#).

The memory access is restricted as if the PE were running in User mode. This makes no difference if the PE is actually running in User mode.

LDRBT is UNPREDICTABLE in Hyp mode.

The T32 instruction uses an offset addressing mode, that calculates the address used for the memory access from a base register value and an immediate offset, and leaves the base register unchanged.

The A32 instruction uses a post-indexed addressing mode, that uses a base register value as the address for the memory access, and calculates a new address from a base register value and an offset and writes it back to the base register. The offset can be an immediate value or an optionally-shifted register value.

It has encodings from the following instruction sets: A32 ([A1](#) and [A2](#)) and T32 ([T1](#)).

A1

Encoding

LDRBT{<C>}{<Q>} <Rt>, [<Rn>] {, #(<+/->)<imm>}

Decode for this encoding

```
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let postindex : boolean = TRUE;
let add : boolean = (U == '1');
let register_form : boolean = FALSE;
let imm32 : bits(32) = ZeroExtend{}(imm12);
let m : integer = ARBITRARY : integer;
let shift_n : integer = ARBITRARY : integer;
let shift_t : SRTYPE = ARBITRARY : SRTYPE;
if t == 15 || n == 15 || n == t then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If $n == 15$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction uses post-indexed addressing with the base register as PC. This is handled as described in [Using R15](#).
- The instruction uses immediate offset addressing with the base register as PC, without writeback.

If $n == t$ && $n != 15$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base address might be corrupted so that the instruction cannot be repeated.

A2

Encoding

LDRBT{<c>}{<q>} <Rt>, [<Rn>], {+/-}<Rm>{, <shift>}

Decode for this encoding

```

let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let postindex : boolean = TRUE;
let add : boolean = (U == '1');
let register_form : boolean = TRUE;
let (shift_t, shift_n) : (SRType, integer) = DecodeImmShift(stype, imm5);
let imm32 : bits(32) = ARBITRARY : bits(32);
if t == 15 || n == 15 || n == t || m == 15 then UnpredictableProcedure(); end;

```

CONSTRAINED UNPREDICTABLE behavior

If $n == t$ && $n != 15$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base address might be corrupted so that the instruction cannot be repeated.

T1

Encoding

LDRBT{<c>}{<q>} <Rt>, [<Rn> {, #+}<imm>}]

Decode for this encoding

```
if Rn == '1111' then See("LDRB (literal)"); end;  
let t : integer = UInt(Rt);  
let n : integer = UInt(Rn);  
let postindex : boolean = FALSE;  
let add : boolean = TRUE;  
let register_form : boolean = FALSE;  
let imm32 : bits(32) = ZeroExtend{}(imm8);  
let m : integer = ARBITRARY : integer;  
let shift_n : integer = ARBITRARY : integer;  
let shift_t : SRTYPE = ARBITRARY : SRTYPE;  
// Armv8-A removes UNPREDICTABLE for R13  
if t == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rt>

For the “A1” variant: is the general-purpose register to be transferred, encoded in the “Rt” field. The PC can be used, but this is deprecated.

For the “A2” and “T1” variants: is the general-purpose register to be transferred, encoded in the “Rt” field.

<Rn>

Is the general-purpose base register, encoded in the “Rn” field.

+/-

For the “A1” variant: specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in “U”:

U	+/-
0	-
1	+

For the “A2” variant: specifies the index register is added to or subtracted from the base register, defaulting to + if omitted and encoded in “U”:

U	+/-
0	-
1	+

<imm>

For the “A1” variant: is the 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 if omitted, and encoded in the “imm12” field.

For the “T1” variant: is an optional 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 and encoded in the “imm8” field.

<Rm>

Is the general-purpose index register, encoded in the “Rm” field.

<shift>

The shift to apply to the value read from <Rm>. If absent, no shift is applied. Otherwise, see [Shifts applied to a register](#).

+

Specifies the offset is added to the base register.

Operation

```

if ConditionPassed() then
    EncodingSpecificOperations();
    if PSTATE.EL == EL2 then UnpredictableProcedure(); end;           // Hyp mode
    let offset : bits(32) = (if register_form then Shift{32}(R(m), shift_t, shift_n, PSTATE.C)
                             else imm32);
    let offset_addr : bits(32) = if add then (R(n) + offset) else (R(n) - offset);
    let address : bits(32) = if postindex then R(n) else offset_addr;
    R(t) = ZeroExtend{32}(MemU_unpriv{8}(address));
    if postindex then R(n) = offset_addr; end;
end;

```

CONSTRAINED UNPREDICTABLE behavior

If PSTATE.EL == EL2, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes as LDRB (immediate).

C5.1.78 LDRD (immediate)

Load Register Dual (immediate) calculates an address from a base register value and an immediate offset, loads two words from memory, and writes them to two registers. It can use offset, post-indexed, or pre-indexed addressing. For information about memory accesses see [Memory accesses](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding for the Offset variant

Applies when (P == 1 && W == 0)

```
LDRD{<c>}{<q>} <Rt>, <Rt2>, [<Rn> {, #<+/-><imm>}]
```

Encoding for the Post-indexed variant

Applies when (P == 0 && W == 0)

```
LDRD{<c>}{<q>} <Rt>, <Rt2>, [<Rn>], #<+/-><imm>
```

Encoding for the Pre-indexed variant

Applies when (P == 1 && W == 1)

```
LDRD{<c>}{<q>} <Rt>, <Rt2>, [<Rn>, #<+/-><imm>]!
```

Decode for all variants of this encoding

```
if Rn == '1111' then See("LDRD (literal)"); end;
if Rt[0] == '1' then UnpredictableProcedure(); end;
let t : integer = UInt(Rt);
let t2 : integer = t + 1;
let n : integer = UInt(Rn);
let imm32 : bits(32) = ZeroExtend{(imm4H::imm4L)};
let index : boolean = (P == '1');
let add : boolean = (U == '1');
let wback : boolean = (P == '0') || (W == '1');
if P == '0' && W == '1' then UnpredictableProcedure(); end;
if wback && (n == t || n == t2) then UnpredictableProcedure(); end;
if t2 == 15 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If wback && (n == t || n == t2), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such an instruction, the base address might be corrupted so that the instruction cannot be repeated.

If P == '0' && W == '1', then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes as an LDRD using one of offset, post-indexed, or pre-indexed addressing.

If $R_{t<0} == '1'$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes with the additional decode: $t<0> = '0'$.
- The instruction executes with the additional decode: $t2 = t$.
- The instruction executes as described, with no change to its behavior and no additional side-effects. This does not apply when $Rt == '1111'$.

T1

Encoding for the Offset variant

Applies when (P == 1 && W == 0)

```
LDRD{<c>}{<q>}<Rt>, <Rt2>, [<Rn> {, # {+/-}<imm>}]
```

Encoding for the Post-indexed variant

Applies when (P == 0 && W == 1)

```
LDRD{<c>}{<q>}    <Rt>, <Rt2>, [<Rn>], #<+/-><imm>
```

Encoding for the Pre-indexed variant

Applies when (P == 1 && W == 1)

```
LDRD{<c>}{<q>}    <Rt>, <Rt2>, [<Rn>, #<+/-><imm>]!
```

Decode for all variants of this encoding

```

if P == '0' && W == '0' then See("Related encodings"); end;
if Rn == '1111' then See("LDRD (literal)"); end;
let t : integer = UInt(Rt);
let t2 : integer = UInt(Rt2);
let n : integer = UInt(Rn);
let imm32 : bits(32) = ZeroExtend{}(imm8::'00');
let index : boolean = (P == '1');
let add : boolean = (U == '1');
let wback : boolean = (W == '1');
if wback && (n == t || n == t2) then UnpredictableProcedure(); end;
// Armv8-A removes UNPREDICTABLE for R13
if t == 15 || t2 == 15 || t == t2 then UnpredictableProcedure(); end;

```

CONSTRAINED UNPREDICTABLE behavior

If `wback && (n == t || n == t2)`, then one of the following behaviors must occur:

- The instruction is **UNDEFINED**.
- The instruction executes as **NOP**.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is **UNKNOWN**. In addition, if an exception occurs during such an instruction, the base address might be corrupted so that the instruction cannot be repeated.

If `t == t2`, then one of the following behaviors must occur:

- The instruction is **UNDEFINED**.
- The instruction executes as **NOP**.
- The load instruction executes but the destination register takes an **UNKNOWN** value.

For more information about the **CONSTRAINED UNPREDICTABLE** behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Related encodings: [Load/store dual](#), [load/store exclusive](#), [table branch](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rt>

For the “A1 Offset”, “A1 Post-indexed”, and “A1 Pre-indexed” variants: is the first general-purpose register to be transferred, encoded in the “Rt” field. This register must be even-numbered and not R14.

For the “T1 Offset”, “T1 Post-indexed”, and “T1 Pre-indexed” variants: is the first general-purpose register to be transferred, encoded in the “Rt” field.

<Rt2>

For the “A1 Offset”, “A1 Post-indexed”, and “A1 Pre-indexed” variants: is the second general-purpose register to be transferred. This register must be `<R (t+1)>`.

For the “T1 Offset”, “T1 Post-indexed”, and “T1 Pre-indexed” variants: is the second general-purpose register to be transferred, encoded in the “Rt2” field.

<Rn>

Is the general-purpose base register, encoded in the “Rn” field. For PC use see [LDRD \(literal\)](#).

+/-

Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in “U”:

U	+/-
0	-
1	+

<imm>

For the “A1 Offset”, “A1 Post-indexed”, and “A1 Pre-indexed” variants: is the 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 if omitted, and encoded in the “imm4H:imm4L” field.

For the “T1 Offset”, “T1 Post-indexed”, and “T1 Pre-indexed” variants: is the unsigned immediate byte offset, a multiple of 4, in the range 0 to 1020, defaulting to 0 if omitted, and encoded in the “imm8” field as <imm>/4.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
let offset_addr : bits(32) = if add then (R(n) + imm32) else (R(n) - imm32);
let address : bits(32) = if index then offset_addr else R(n);
if IsAlignedSize(address, 8) then
    let data : bits(64) = MemA{64}(address);
    if BigEndian(AccessType_GPR) then
        R(t)  = data[63:32];
        R(t2) = data[31:0];
    else
        R(t)  = data[31:0];
        R(t2) = data[63:32];
    end;
else
    let data1 : bits(32) = MemA{32}(address);
    let data2 : bits(32) = MemA{32}(address+4);
    R(t)  = data1;
    R(t2) = data2;
end;
if wback then R(n) = offset_addr; end;
end;
```

C5.1.79 LDRD (literal)

Load Register Dual (literal) calculates an address from the PC value and an immediate offset, loads two words from memory, and writes them to two registers. For information about memory accesses see [Memory accesses](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

```
LDRD{<c>}{<q>} <Rt>, <Rt2>, <label> // (Normal form)
```

```
LDRD{<c>}{<q>}    <Rt>, <Rt2>, [PC, #{+/-}<imm>] // (Alternative form)
```

Decode for this encoding

```

if Rt[0] == '1' then UnpredictableProcedure(); end;
let t : integer = UInt(Rt);
let t2 : integer = t + 1;
let imm32 : bits(32) = ZeroExtend{(imm4H::imm4L)};
let add : boolean = (U == '1');
if t2 == 15 then UnpredictableProcedure(); end;

```

CONSTRAINED UNPREDICTABLE behavior

If $R_{t<0} == '1'$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes with the additional decode: $t<0> = '0'$.
- The instruction executes with the additional decode: $t2 = t$.
- The instruction executes as described, with no change to its behavior and no additional side-effects. This does not apply when $Rt == '1111'$.

If $P == '0' \parallel W == '1'$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes as if $P = 1$ and $W = 0$.

T1

Encoding

Applies when $(!(P == '0' \ \&\& \ W == '0'))$

LDRD{<c>}{<q>} <Rt>, <Rt2>, <label> // (Normal form)

LDRD{<c>}{<q>} <Rt>, <Rt2>, [PC, #{+/-}<imm>] // (Alternative form)

Decode for this encoding

```
if P == '0' && W == '0' then See("Related encodings"); end;
let t : integer = UInt(Rt);
let t2 : integer = UInt(Rt2);
let imm32 : bits(32) = ZeroExtend{}(imm8::'00');
let add : boolean = (U == '1');
// Armv8-A removes UNPREDICTABLE for R13
if t == 15 || t2 == 15 || t == t2 then UnpredictableProcedure(); end;
if W == '1' then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If $t == t_2$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The load instruction executes but the destination register takes an UNKNOWN value.

If $W == '1'$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes without writeback of the base address.
- The instruction uses post-indexed addressing when $P == '0'$ and uses pre-indexed addressing otherwise. The instruction is handled as described in Using R15.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Related encodings: [Load/Store dual](#), [Load/Store-Exclusive](#), [Load-Acquire/Store-Release](#), [table branch](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rt>

For the “A1” variant: is the first general-purpose register to be transferred, encoded in the “Rt” field. This register must be even-numbered and not R14.

For the “T1” variant: is the first general-purpose register to be transferred, encoded in the “Rt” field.

<Rt2>

For the “A1” variant: is the second general-purpose register to be transferred. This register must be $\langle R(t+1) \rangle$.

For the “T1” variant: is the second general-purpose register to be transferred, encoded in the “Rt2” field.

<label>

For the “A1” variant: the label of the literal data item that is to be loaded into <Rt>. The assembler calculates the required value of the offset from the `Align(PC, 4)` value of the instruction to this label. Any value in the range -255 to 255 is permitted. If the offset is zero or positive, `imm32` is equal to the offset and `add == TRUE`, encoded as `U == 1`. If the offset is negative, `imm32` is equal to minus the offset and `add == FALSE`, encoded as `U == 0`.

For the “T1” variant: the label of the literal data item that is to be loaded into <Rt>. The assembler calculates the required value of the offset from the `Align(PC, 4)` value of the instruction to this label. Permitted values of the offset are multiples of 4 in the range -1020 to 1020.

If the offset is zero or positive, `imm32` is equal to the offset and `add == TRUE`, encoded as `U == 1`.

If the offset is negative, `imm32` is equal to minus the offset and `add == FALSE`, encoded as `U == 0`.

+/-

Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in “U”:

U	+/-
0	–
1	+

<imm>

For the “A1” variant: is the 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 if omitted, and encoded in the “imm4H:imm4L” field.

For the “T1” variant: is the optional 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 and encoded in the “imm8” field.

The alternative syntax permits the addition or subtraction of the offset and the immediate offset to be specified separately, including permitting a subtraction of 0 that cannot be specified using the normal syntax. For more information, see [Use of labels in UAL instruction syntax](#).

Operation

```

if ConditionPassed() then
    EncodingSpecificOperations();
    let address : bits(32) = (if add then (AlignDownSize(PC32(),4) + imm32)
                                else (AlignDownSize(PC32(),4) - imm32));
    if IsAlignedSize(address, 8) then
        let data : bits(64) = MemA{64}(address);
        if BigEndian(AccessType_GPR) then
            R(t)  = data[63:32];
            R(t2) = data[31:0];
        else
            R(t)  = data[31:0];
            R(t2) = data[63:32];
        end;
    else
        let data1 : bits(32) = MemA{32}(address);
        let data2 : bits(32) = MemA{32}(address+4);
        R(t)  = data1;
        R(t2) = data2;
    end;
end;
```

C5.1.80 LDRD (register)

Load Register Dual (register) calculates an address from a base register value and a register offset, loads two words from memory, and writes them to two registers. It can use offset, post-indexed, or pre-indexed addressing. For information about memory accesses see [Memory accesses](#).

Encoding for the Offset variant

Applies when (P == 1 && W == 0)

```
LDRD{<c>}{<q>} <Rt>, <Rt2>, [<Rn>, {+/-}<Rm>]
```

Encoding for the Post-indexed variant

Applies when (P == 0 && W == 0)

```
LDRD{<c>}{<q>} <Rt>, <Rt2>, [<Rn>], {+/-}<Rm>
```

Encoding for the Pre-indexed variant

Applies when (P == 1 && W == 1)

```
LDRD{<c>}{<q>} <Rt>, <Rt2>, [<Rn>, {+/-}<Rm>]!
```

Decode for all variants of this encoding

```
if Rt[0] == '1' then UnpredictableProcedure(); end;
let t : integer = UInt(Rt);
let t2 : integer = t + 1;
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let index : boolean = (P == '1');
let add : boolean = (U == '1');
let wback : boolean = (P == '0') || (W == '1');
if P == '0' && W == '1' then UnpredictableProcedure(); end;
if t2 == 15 || m == 15 || m == t || m == t2 then UnpredictableProcedure(); end;
if wback && (n == 15 || n == t || n == t2) then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If wback && (n == t || n == t2), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base address might be corrupted so that the instruction cannot be repeated.

If P == '0' && W == '1', then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes as an LDRD using one of offset, post-indexed, or pre-indexed addressing.

If $m == t \mid \mid m == t2$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction loads register Rm with an UNKNOWN value.

If $Rt < 0 > == '1'$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes with the additional decode: $t < 0 > = '0'$.
- The instruction executes with the additional decode: $t2 = t$.
- The instruction executes as described, with no change to its behavior and no additional side-effects. This does not apply when $Rt == '1111'$.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rt>

Is the first general-purpose register to be transferred, encoded in the “Rt” field. This register must be even-numbered and not R14.

<Rt2>

Is the second general-purpose register to be transferred. This register must be $<R(t+1)>$.

<Rn>

Is the general-purpose base register, encoded in the “Rn” field. The PC can be used in the offset variant.

+/-

Specifies the index register is added to or subtracted from the base register, defaulting to + if omitted and encoded in “U”:

U	+/-
0	-
1	+

<Rm>

Is the general-purpose index register, encoded in the “Rm” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let offset_addr : bits(32) = if add then (R(n) + R(m)) else (R(n) - R(m));
    let address : bits(32) = if index then offset_addr else R(n);
    if IsAlignedSize(address, 8) then
        let data : bits(64) = MemA{64}(address);
        if BigEndian(AccessType_GPR) then
            R(t)  = data[63:32];
            R(t2) = data[31:0];
        else
            R(t)  = data[31:0];
            R(t2) = data[63:32];
        end;
    else
        let data1 : bits(32) = MemA{32}(address);
        let data2 : bits(32) = MemA{32}(address+4);
        R(t)  = data1;
        R(t2) = data2;
    end;

    if wback then R(n) = offset_addr; end;
end;
```

C5.1.81 LDREX

Load Register Exclusive calculates an address from a base register value and an immediate offset, loads a word from memory, writes it to a register and:

- If the address has the Shared Memory attribute, marks the physical address as exclusive access for the executing PE in a global monitor.
- Causes the executing PE to indicate an active exclusive access in the local monitor.

For more information about support for shared memory see [Synchronization and semaphores](#). For information about memory accesses see [Memory accesses](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

LDREX{<c>}{<q>} <Rt>, [<Rn> {, {#}<imm>}]

Decode for this encoding

```
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let imm32 : bits(32) = Zeros{}; // Zero offset
if t == 15 || n == 15 then UnpredictableProcedure(); end;
```

T1

Encoding

LDREX{<c>}{<q>} <Rt>, [<Rn> {, #<imm>}]

Decode for this encoding

```
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let imm32 : bits(32) = ZeroExtend{}(imm8::'00');
// Armv8-A removes UNPREDICTABLE for R13
if t == 15 || n == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rt>

Is the general-purpose register to be transferred, encoded in the “Rt” field.

<Rn>

Is the general-purpose base register, encoded in the “Rn” field.

<imm>

For the “A1” variant: the immediate offset added to the value of <Rn> to calculate the address. <imm> can only be 0 or omitted.

For the “T1” variant: the immediate offset added to the value of <Rn> to calculate the address. <imm> can be omitted, meaning an offset of 0. Values are multiples of 4 in the range 0-1020.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let address : bits(32) = R(n) + imm32;
    AArch32_SetExclusiveMonitors(address, 4);
    R(t) = MemA{32}(address);
end;
```

C5.1.82 LDREXB

Load Register Exclusive Byte derives an address from a base register value, loads a byte from memory, zero-extends it to form a 32-bit word, writes it to a register and:

- If the address has the Shared Memory attribute, marks the physical address as exclusive access for the executing PE in a global monitor.
- Causes the executing PE to indicate an active exclusive access in the local monitor.

For more information about support for shared memory see [Synchronization and semaphores](#). For information about memory accesses see [Memory accesses](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

LDREXB{<c>}{<q>} <Rt>, [<Rn>]

Decode for this encoding

```
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
if t == 15 || n == 15 then UnpredictableProcedure(); end;
```

T1

Encoding

LDREXB{<c>}{<q>} <Rt>, [<Rn>]

Decode for this encoding

```
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
// Armv8-A removes UNPREDICTABLE for R13
if t == 15 || n == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rt>

Is the general-purpose register to be transferred, encoded in the “Rt” field.

<Rn>

Is the general-purpose base register, encoded in the “Rn” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let address : bits(32) = R(n);
    AArch32_SetExclusiveMonitors(address, 1);
    R(t) = ZeroExtend{32}(MemA{8}(address));
end;
```

C5.1.83 LDREXD

Load Register Exclusive Doubleword derives an address from a base register value, loads a 64-bit doubleword from memory, writes it to two registers and:

- If the address has the Shared Memory attribute, marks the physical address as exclusive access for the executing PE in a global monitor.
- Causes the executing PE to indicate an active exclusive access in the local monitor.

For more information about support for shared memory see [Synchronization and semaphores](#). For information about memory accesses see [Memory accesses](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

LDREXD{<c>}{<q>} <Rt>, <Rt2>, [<Rn>]

Decode for this encoding

```
let t : integer = UInt(Rt);
let t2 : integer = t + 1;
let n : integer = UInt(Rn);
if Rt[0] == '1' || t2 == 15 || n == 15 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If Rt<0> == '1', then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes with the additional decode: t<0> = '0'.
- The instruction executes with the additional decode: t2 = t.
- The instruction executes as described, with no change to its behavior and no additional side effects.

If Rt == '1110', then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction is handled as described in Using R15.

T1

Encoding

LDRDREXD{<c>}{<q>} <Rt>, <Rt2>, [<Rn>]

Decode for this encoding

```
let t : integer = UInt(Rt);
let t2 : integer = UInt(Rt2);
let n : integer = UInt(Rn);
if t == 15 || t2 == 15 || t == t2 || n == 15 then UnpredictableProcedure(); end;
// Armv8-A removes UNPREDICTABLE for R13
```

CONSTRAINED UNPREDICTABLE behavior

If $t == t2$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The load instruction executes but the destination register takes an UNKNOWN value.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rt>

For the “A1” variant: is the first general-purpose register to be transferred, encoded in the “Rt” field. <Rt> must be even-numbered and not R14.

For the “T1” variant: is the first general-purpose register to be transferred, encoded in the “Rt” field.

<Rt2>

For the “A1” variant: is the second general-purpose register to be transferred. <Rt2> must be $\langle R(t+1) \rangle$.

For the “T1” variant: is the second general-purpose register to be transferred, encoded in the “Rt2” field.

<Rn>

Is the general-purpose base register, encoded in the “Rn” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let address : bits(32) = R(n);
    AArch32_SetExclusiveMonitors(address,8);
    let value : bits(64) = MemA{64}(address);

    // Extract words from 64-bit loaded value such that R[t] is
    // loaded from address and R[t2] from address+4.
    R(t)  = if BigEndian(AccessType_GPR) then value[63:32] else value[31:0];
    R(t2) = if BigEndian(AccessType_GPR) then value[31:0]  else value[63:32];
end;
```

C5.1.84 LDREXH

Load Register Exclusive Halfword derives an address from a base register value, loads a halfword from memory, zero-extends it to form a 32-bit word, writes it to a register and:

- If the address has the Shared Memory attribute, marks the physical address as exclusive access for the executing PE in a global monitor.
- Causes the executing PE to indicate an active exclusive access in the local monitor.

For more information about support for shared memory see [Synchronization and semaphores](#). For information about memory accesses see [Memory accesses](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

LDREXH{<c>}{<q>} <Rt>, [<Rn>]

Decode for this encoding

```
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
if t == 15 || n == 15 then UnpredictableProcedure(); end;
```

T1

Encoding

LDREXH{<c>}{<q>} <Rt>, [<Rn>]

Decode for this encoding

```
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
// Armv8-A removes UNPREDICTABLE for R13
if t == 15 || n == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rt>

Is the general-purpose register to be transferred, encoded in the “Rt” field.

<Rn>

Is the general-purpose base register, encoded in the “Rn” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let address : bits(32) = R(n);
    AArch32_SetExclusiveMonitors(address, 2);
    R(t) = ZeroExtend{32}(MemA{16}(address));
end;
```

C5.1.85 LDRH (immediate)

Load Register Halfword (immediate) calculates an address from a base register value and an immediate offset, loads a halfword from memory, zero-extends it to form a 32-bit word, and writes it to a register. It can use offset, post-indexed, or pre-indexed addressing. For information about memory accesses see [Memory accesses](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#), [T2](#), and [T3](#)).

A1

Encoding for the Offset variant

Applies when (P == 1 && W == 0)

```
LDRH{<c>}{<q>} <Rt>, [<Rn> {, #{+/-}<imm>}]
```

Encoding for the Post-indexed variant

Applies when (P == 0 && W == 0)

```
LDRH{<c>}{<q>} <Rt>, [<Rn>], #{+/-}<imm>
```

Encoding for the Pre-indexed variant

Applies when (P == 1 && W == 1)

```
LDRH{<c>}{<q>} <Rt>, [<Rn>, #{+/-}<imm>]!
```

Decode for all variants of this encoding

```
if Rn == '1111' then See("LDRH (literal)"); end;
if P == '0' && W == '1' then See("LDRHT"); end;
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let imm32 : bits(32) = ZeroExtend{(imm4H::imm4L)};
let index : boolean = (P == '1');
let add : boolean = (U == '1');
let wback : boolean = (P == '0') || (W == '1');
if t == 15 || (wback && n == t) then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If wback && n == t, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such an instruction, the base address might be corrupted so that the instruction cannot be repeated.

T1

Encoding

```
LDRH{<c>}{<q>} <Rt>, [<Rn> {, #<+><imm>}]
```

Decode for this encoding

```
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let imm32 : bits(32) = ZeroExtend{}(imm5::'0');
let index : boolean = TRUE;
let add : boolean = TRUE;
let wback : boolean = FALSE;
```

T2

Encoding

```
LDRH{<c>}{<q>} <Rt>, [<Rn> {, #<+><imm>}]
```

```
LDRH{<c>}.W <Rt>, [<Rn> {, #<+><imm>}] // (<Rt>, <Rn>, <imm> can be represented in T1)
```

Decode for this encoding

```
if Rt == '1111' then See("PLD (immediate)"); end;
if Rn == '1111' then See("LDRH (literal)"); end;
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let imm32 : bits(32) = ZeroExtend{}(imm12);
let index : boolean = TRUE;
let add : boolean = TRUE;
let wback : boolean = FALSE;
// Armv8-A removes UNPREDICTABLE for R13
```

T3

Encoding for the Offset variant

Applies when (Rt != 1111 && P == 1 && U == 0 && W == 0)

LDRH{<c>}{<q>} <Rt>, [<Rn> {, #-<imm>}]

Encoding for the Post-indexed variant

Applies when (P == 0 && W == 1)

LDRH{<c>}{<q>} <Rt>, [<Rn>], #{+/-}<imm>

Encoding for the Pre-indexed variant

Applies when (P == 1 && W == 1)

LDRH{<c>}{<q>} <Rt>, [<Rn>, #{+/-}<imm>]!

Decode for all variants of this encoding

```

if Rn == '1111' then See("LDRH (literal)"); end;
if Rt == '1111' && P == '1' && U == '0' && W == '0' then See("PLDW (immediate)"); end;
if P == '1' && U == '1' && W == '0' then See("LDRHT"); end;
if P == '0' && W == '0' then Undefined(); end;
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let imm32 : bits(32) = ZeroExtend{}(imm8);
let index : boolean = (P == '1');
let add : boolean = (U == '1');
let wback : boolean = (W == '1');
if (t == 15 && W == '1') || (wback && n == t) then UnpredictableProcedure(); end;
// Armv8-A removes UNPREDICTABLE for R13

```

CONSTRAINED UNPREDICTABLE behavior

If wback && n == t, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such an instruction, the base address might be corrupted so that the instruction cannot be repeated.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rt>

Is the general-purpose register to be transferred, encoded in the “Rt” field.

<Rn>

For the “A1 Offset”, “A1 Post-indexed”, “A1 Pre-indexed”, “T2”, “T3 Offset”, “T3 Post-indexed”, and “T3 Pre-indexed” variants: is the general-purpose base register, encoded in the “Rn” field. For PC use see [LDRH \(literal\)](#).

For the “T1” variant: is the general-purpose base register, encoded in the “Rn” field.

+/-

Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in “U”:

U	+/-
0	-
1	+

<imm>

For the “A1 Offset”, “A1 Post-indexed”, and “A1 Pre-indexed” variants: is the 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 if omitted, and encoded in the “imm4H:imm4L” field.

For the “T1” variant: is the optional positive unsigned immediate byte offset, a multiple of 2, in the range 0 to 62, defaulting to 0 and encoded in the “imm5” field as <imm>/2.

For the “T2” variant: is an optional 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 and encoded in the “imm12” field.

For the “T3 Offset”, “T3 Post-indexed”, and “T3 Pre-indexed” variants: is an 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 if omitted, and encoded in the “imm8” field.

+

Specifies the offset is added to the base register.

Operation

```
if CurrentInstrSet() == InstrSet_A32 then
  if ConditionPassed() then
    EncodingSpecificOperations();
    let offset_addr : bits(32) = if add then (R(n) + imm32) else (R(n) - imm32);
    let address : bits(32) = if index then offset_addr else R(n);
    let data : bits(16) = MemU{16}(address);
    if wback then R(n) = offset_addr; end;
    R(t) = ZeroExtend{32}(data);
  end;
else
  if ConditionPassed() then
    EncodingSpecificOperations();
    let offset_addr : bits(32) = if add then (R(n) + imm32) else (R(n) - imm32);
```

```
        let address : bits(32) = if index then offset_addr else R(n);
        let data : bits(16) = MemU{16}(address);
        if wback then R(n) = offset_addr; end;
        R(t) = ZeroExtend{32}(data);
    end;
end;
```

C5.1.86 LDRH (literal)

Load Register Halfword (literal) calculates an address from the PC value and an immediate offset, loads a halfword from memory, zero-extends it to form a 32-bit word, and writes it to a register. For information about memory accesses see [Memory accesses](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

Applies when $(!(P == '0' \ \&\& \ W == '1'))$

LDRH{<c>}{<q>} <Rt>, <label> // (Normal form)

LDRH{<c>}{<q>} <Rt>, [PC, #{+/-}<imm>] // (Alternative form)

Decode for this encoding

```

if P == '0' && W == '1' then See("LDRHT"); end;
let t : integer = UInt(Rt);
let imm32 : bits(32) = ZeroExtend{(imm4H::imm4L)};
let add : boolean = (U == '1');
let wback : boolean = (P == '0') || (W == '1');
if t == 15 || wback then UnpredictableProcedure(); end;

```

CONSTRAINED UNPREDICTABLE behavior

If wback, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes with the additional decode: wback = FALSE;.
- The instruction treats bit[24] as the P bit, and bit[21] as the writeback (W) bit, and uses the same addressing mode as described in LDRH (immediate). The instruction uses post-indexed addressing when P == '0' and uses pre-indexed addressing otherwise. The instruction is handled as described in Using R15.

T1

Encoding

LDRH{<c>}{<q>} <Rt>, <label> // (Preferred syntax)

LDRH{<c>}{<q>} <Rt>, [PC, #{+/-}<imm>] // (Alternative syntax)

Decode for this encoding

```
if Rt == '1111' then See("PLD (literal)"); end;  
let t : integer = UInt(Rt);  
let imm32 : bits(32) = ZeroExtend{}(imm12);  
let add : boolean = (U == '1');  
// Armv8-A removes UNPREDICTABLE for R13
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rt>

Is the general-purpose register to be transferred, encoded in the “Rt” field.

<label>

For the “A1” variant: the label of the literal data item that is to be loaded into <Rt>. The assembler calculates the required value of the offset from the `Align(PC, 4)` value of the instruction to this label. Any value in the range -255 to 255 is permitted. If the offset is zero or positive, `imm32` is equal to the offset and `add == TRUE`, encoded as `U == 1`. If the offset is negative, `imm32` is equal to minus the offset and `add == FALSE`, encoded as `U == 0`.

For the “T1” variant: the label of the literal data item that is to be loaded into <Rt>. The assembler calculates the required value of the offset from the `Align(PC, 4)` value of the instruction to this label. Permitted values of the offset are -4095 to 4095.

If the offset is zero or positive, `imm32` is equal to the offset and `add == TRUE`, encoded as `U == 1`.

If the offset is negative, `imm32` is equal to minus the offset and `add == FALSE`, encoded as `U == 0`.

+/-

Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in “U”:

U	+/-
0	-
1	+

<imm>

For the “A1” variant: is the 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 if omitted, and encoded in the “imm4H:imm4L” field.

For the “T1” variant: is a 12-bit unsigned immediate byte offset, in the range 0 to 4095, encoded in the “imm12” field.

The alternative syntax permits the addition or subtraction of the offset and the immediate offset to be specified separately, including permitting a subtraction of 0 that cannot be specified using the normal syntax. For more information, see [Use of labels in UAL instruction syntax](#).

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let base : bits(32) = AlignDownSize(PC32(),4);
    let address : bits(32) = if add then (base + imm32) else (base - imm32);
    let data : bits(16) = MemU{16}(address);
    R(t) = ZeroExtend{32}(data);
end;
```

C5.1.87 LDRH (register)

Load Register Halfword (register) calculates an address from a base register value and an offset register value, loads a halfword from memory, zero-extends it to form a 32-bit word, and writes it to a register. The offset register value can be shifted left by 0, 1, 2, or 3 bits. For information about memory accesses see [Memory accesses](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#) and [T2](#)).

A1

Encoding for the Offset variant

Applies when (P == 1 && W == 0)

$$\text{LDRH}\{\langle c \rangle\}\{\langle q \rangle\} \quad \langle Rt \rangle, \quad [\langle Rn \rangle, \quad \{+/-\}\langle Rm \rangle]$$

Encoding for the Post-indexed variant

Applies when (P == 0 && W == 0)

$$\text{LDRH}\{\langle c \rangle\}\{\langle q \rangle\} \quad \langle \text{Rt} \rangle, \quad [\langle \text{Rn} \rangle], \quad \{+/-\} \langle \text{Rm} \rangle$$

Encoding for the Pre-indexed variant

Applies when (P == 1 && W == 1)

$$\text{LDRH}\{\langle c \rangle\}\{\langle q \rangle\} \quad \langle Rt \rangle, \quad [\langle Rn \rangle, \{+/-\}\langle Rm \rangle]!$$

Decode for all variants of this encoding

```

if P == '0' && W == '1' then See("LDRHT"); end;
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let index : boolean = (P == '1');
let add : boolean = (U == '1');
let wback : boolean = (P == '0') || (W == '1');
let shift_t : SRTtype = SRTtype_LSL;
let shift_n : integer = 0;
if t == 15 || m == 15 then UnpredictableProcedure(); end;
if wback && (n == 15 || n == t) then UnpredictableProcedure(); end;

```

CONSTRAINED UNPREDICTABLE behavior

If `wback && n == t`, then one of the following behaviors must occur:

- The instruction is **UNDEFINED**.
- The instruction executes as **NOP**.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is **UNKNOWN**. In addition, if an exception occurs during such as instruction, the base address might be corrupted so that the instruction cannot be repeated.

T1

Encoding

LDRH{<c>}{<q>} <Rt>, [<Rn>, {+}<Rm>]

Decode for this encoding

```

let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let index : boolean = TRUE;
let add : boolean = TRUE;
let wback : boolean = FALSE;
let shift_t : SRTYPE = SRTYPE_LSL;
let shift_n : integer = 0;

```

T2

Encoding

LDRH{<c>}{<q>} <Rt>, [<Rn>, {+}<Rm>{, LSL #<imm>}]

LDRH{<c>}.W <Rt>, [<Rn>, {+}<Rm>] // (<Rt>, <Rn>, <Rm> can be represented in T1)

Decode for this encoding

```

if Rn == '1111' then See("LDRH (literal)"); end;
if Rt == '1111' then See("PLDW (register)"); end;
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let index : boolean = TRUE;
let add : boolean = TRUE;
let wback : boolean = FALSE;
let shift_t : SRTYPE = SRTYPE_LSL;
let shift_n : integer = UInt(imm2);
// Armv8-A removes UNPREDICTABLE for R13
if m == 15 then UnpredictableProcedure(); end;

```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rt>

Is the general-purpose register to be transferred, encoded in the “Rt” field.

<Rn>

For the “Offset”, “Post-indexed”, and “Pre-indexed” variants: is the general-purpose base register, encoded in the “Rn” field. The PC can be used in the offset variant.

For the “T1” and “T2” variants: is the general-purpose base register, encoded in the “Rn” field.

+/-

Specifies the index register is added to or subtracted from the base register, defaulting to + if omitted and encoded in “U”:

U	+/-
0	-
1	+

<Rm>

Is the general-purpose index register, encoded in the “Rm” field.

+

Specifies the index register is added to the base register.

<imm>

If present, the size of the left shift to apply to the value from <Rm>, in the range 1-3. <imm> is encoded in imm2. If absent, no shift is specified and imm2 is encoded as 0b00.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let offset : bits(32) = Shift{}(R(m), shift_t, shift_n, PSTATE.C);
    let offset_addr : bits(32) = if add then (R(n) + offset) else (R(n) - offset);
    let address : bits(32) = if index then offset_addr else R(n);
    let data : bits(16) = MemU{16}(address);
    if wback then R(n) = offset_addr; end;
    R(t) = ZeroExtend{32}(data);
end;
```

C5.1.88 LDRHT

Load Register Halfword Unprivileged loads a halfword from memory, zero-extends it to form a 32-bit word, and writes it to a register. For information about memory accesses see [Memory accesses](#).

The memory access is restricted as if the PE were running in User mode. This makes no difference if the PE is actually running in User mode.

LDRHT is UNPREDICTABLE in Hyp mode.

The T32 instruction uses an offset addressing mode, that calculates the address used for the memory access from a base register value and an immediate offset, and leaves the base register unchanged.

The A32 instruction uses a post-indexed addressing mode, that uses a base register value as the address for the memory access, and calculates a new address from a base register value and an offset and writes it back to the base register. The offset can be an immediate value or a register value.

It has encodings from the following instruction sets: A32 ([A1](#) and [A2](#)) and T32 ([T1](#)).

A1

Encoding

LDRHT{<c>}{<q>} <Rt>, [<Rn>] {, #(<+/->)<imm>}

Decode for this encoding

```
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let postindex : boolean = TRUE;
let add : boolean = (U == '1');
let register_form : boolean = FALSE;
let imm32 : bits(32) = ZeroExtend{}(imm4H::imm4L);
let m : integer = ARBITRARY : integer;
if t == 15 || n == 15 || n == t then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If $n == 15$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction uses post-indexed addressing with the base register as PC. This is handled as described in [Using R15](#).
- The instruction is treated as if $\text{bit}[24] == '1'$ and $\text{bit}[21] == '0'$. The instruction uses immediate offset addressing with the base register as PC, without writeback.

If $n == t \ \&\& \ n \neq 15$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base address might be corrupted so that the instruction cannot be repeated.

A2

Encoding

LDRHT{<c>}{<q>} <Rt>, [<Rn>], {+/-}<Rm>

Decode for this encoding

```
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let postindex : boolean = TRUE;
let add : boolean = (U == '1');
let register_form : boolean = TRUE;
let imm32 : bits(32) = ARBITRARY : bits(32);
if t == 15 || n == 15 || n == t || m == 15 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If $n == t$ && $n != 15$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base address might be corrupted so that the instruction cannot be repeated.

T1

Encoding

LDRHT{<c>}{<q>} <Rt>, [<Rn> {, #+}<imm>]

Decode for this encoding

```
if Rn == '1111' then See("LDRH (literal)"); end;
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let postindex : boolean = FALSE;
let add : boolean = TRUE;
let register_form : boolean = FALSE;
let imm32 : bits(32) = ZeroExtend{ }(imm8);
let m : integer = ARBITRARY : integer;
// Armv8-A removes UNPREDICTABLE for R13
if t == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rt>

Is the general-purpose register to be transferred, encoded in the “Rt” field.

<Rn>

Is the general-purpose base register, encoded in the “Rn” field.

+/-

For the “A1” variant: specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in “U”:

U	+/-
0	-
1	+

For the “A2” variant: specifies the index register is added to or subtracted from the base register, defaulting to + if omitted and encoded in “U”:

U	+/-
0	-
1	+

<imm>

For the “A1” variant: is the 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 if omitted, and encoded in the “imm4H:imm4L” field.

For the “T1” variant: is an optional 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 and encoded in the “imm8” field.

<Rm>

Is the general-purpose index register, encoded in the “Rm” field.

+

Specifies the offset is added to the base register.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    if PSTATE.EL == EL2 then UnpredictableProcedure(); end;           // Hyp mode
    let offset : bits(32) = if register_form then R(m) else imm32;
    let offset_addr : bits(32) = if add then (R(n) + offset) else (R(n) - offset);
    let address : bits(32) = if postindex then R(n) else offset_addr;
    let data : bits(16) = MemU_unpriv{16}(address);
    if postindex then R(n) = offset_addr; end;
    R(t) = ZeroExtend{32}(data);
end;
```

CONSTRAINED UNPREDICTABLE behavior

If PSTATE.EL == EL2, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes as LDRH (immediate).

C5.1.89 LDRSB (immediate)

Load Register Signed Byte (immediate) calculates an address from a base register value and an immediate offset, loads a byte from memory, sign-extends it to form a 32-bit word, and writes it to a register. It can use offset, post-indexed, or pre-indexed addressing. For information about memory accesses see [Memory accesses](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#) and [T2](#)).

A1

Encoding for the Offset variant

Applies when (P == 1 && W == 0)

LDRSB{<c>}{<q>} <Rt>, [<Rn> {, #<+/-><imm>}]

Encoding for the Post-indexed variant

Applies when (P == 0 && W == 0)

LDRSB{<c>}{<q>} <Rt>, [<Rn>], #<+/-><imm>

Encoding for the Pre-indexed variant

Applies when (P == 1 && W == 1)

LDRSB{<c>}{<q>} <Rt>, [<Rn>, #<+/-><imm>]!

Decode for all variants of this encoding

```

if Rn == '1111' then See("LDRSB (literal)"); end;
if P == '0' && W == '1' then See("LDRSBT"); end;
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let imm32 : bits(32) = ZeroExtend{(imm4H::imm4L)};
let index : boolean = (P == '1');
let add : boolean = (U == '1');
let wback : boolean = (P == '0') || (W == '1');
if t == 15 || (wback && n == t) then UnpredictableProcedure(); end;

```

CONSTRAINED UNPREDICTABLE behavior

If wback && n == t, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such an instruction, the base address might be corrupted so that the instruction cannot be repeated.

T1

Encoding

LDRSB{<c>}{<q>} <Rt>, [<Rn> {, #<+><imm>}]

Decode for this encoding

```

if Rt == '1111' then See("PLI"); end;
if Rn == '1111' then See("LDRSB (literal)"); end;
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let imm32 : bits(32) = ZeroExtend{}(imm12);
let index : boolean = TRUE;
let add : boolean = TRUE;
let wback : boolean = FALSE;
// Armv8-A removes UNPREDICTABLE for R13

```

T2

Encoding for the Offset variant

Applies when (Rt != 1111 && P == 1 && U == 0 && W == 0)

LDRSB{<c>}{<q>} <Rt>, [<Rn> {, #-<imm>}]

Encoding for the Post-indexed variant

Applies when (P == 0 && W == 1)

LDRSB{<c>}{<q>} <Rt>, [<Rn>], #<+/-><imm>

Encoding for the Pre-indexed variant

Applies when (P == 1 && W == 1)

LDRSB{<c>}{<q>} <Rt>, [<Rn>, #<+/-><imm>]!

Decode for all variants of this encoding

```
if Rt == '1111' && P == '1' && U == '0' && W == '0' then See("PLI"); end;
if Rn == '1111' then See("LDRSB (literal)"); end;
if P == '1' && U == '1' && W == '0' then See("LDRSBT"); end;
if P == '0' && W == '0' then Undefined(); end;
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let imm32 : bits(32) = ZeroExtend{}(imm8);
let index : boolean = (P == '1');
let add : boolean = (U == '1');
let wback : boolean = (W == '1');
if (t == 15 && W == '1') || (wback && n == t) then UnpredictableProcedure(); end;
// Armv8-A removes UNPREDICTABLE for R13
```

CONSTRAINED UNPREDICTABLE behavior

If `wback && n == t`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such an instruction, the base address might be corrupted so that the instruction cannot be repeated.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rt>

Is the general-purpose register to be transferred, encoded in the “Rt” field.

<Rn>

Is the general-purpose base register, encoded in the “Rn” field. For PC use see [LDRSB \(literal\)](#).

+/-

Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in “U”:

U	+/-
0	-
1	+

<imm>

For the “A1 Offset”, “A1 Post-indexed”, and “A1 Pre-indexed” variants: is the 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 if omitted, and encoded in the “imm4H:imm4L” field.

For the “T1” variant: is an optional 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 and encoded in the “imm12” field.

For the “T2 Offset”, “T2 Post-indexed”, and “T2 Pre-indexed” variants: is an 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 if omitted, and encoded in the “imm8” field.

+

Specifies the offset is added to the base register.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let offset_addr : bits(32) = if add then (R(n) + imm32) else (R(n) - imm32);
    let address : bits(32) = if index then offset_addr else R(n);
    R(t) = SignExtend{32}(MemU{8}(address));
    if wback then R(n) = offset_addr; end;
end;
```

C5.1.90 LDRSB (literal)

Load Register Signed Byte (lrbt) calculates an address from the PC value and an immediate offset, loads a byte from memory, sign-extends it to form a 32-bit word, and writes it to a register. For information about memory accesses see [Memory accesses](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

Applies when `( ! (P == '0' && W == '1') )`

```
LDRSB{<c>}{<q>}    <Rt>, <label> // (Normal form)
```

```
LDRSB{<c>}{<q>}    <Rt>, [PC, #{+/-}<imm>] // (Alternative form)
```

Decode for this encoding

```

if P == '0' && W == '1' then See("LDRSBT"); end;
let t : integer = UInt(Rt);
let imm32 : bits(32) = ZeroExtend{}(imm4H::imm4L);
let add : boolean = (U == '1');
let wback : boolean = (P == '0') || (W == '1');
if t == 15 || wback then UnpredictableProcedure(); end;

```

CONSTRAINED UNPREDICTABLE behavior

If `wback`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes with the additional decode: wback = FALSE;.
- The instruction treats bit[24] as the P bit, and bit[21] as the writeback (W) bit, and uses the same addressing mode as described in LDRSB (immediate). The instruction uses post-indexed addressing when P = '0' and uses pre-indexed addressing otherwise. The instruction is handled as described in Using R15.

T1

Encoding

```
LDRSB{<c>}{<q>} <Rt>, <label> // (Preferred syntax)
```

```
LDRSB{<c>}{<q>} <Rt>, [PC, #{+/-}<imm>] // (Alternative syntax)
```

Decode for this encoding

```
if Rt == '1111' then See("PLI"); end;  
let t : integer = UInt(Rt);  
let imm32 : bits(32) = ZeroExtend{}(imm12);  
let add : boolean = (U == '1');  
// Armv8-A removes UNPREDICTABLE for R13
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rt>

Is the general-purpose register to be transferred, encoded in the “Rt” field.

<label>

For the “A1” variant: the label of the literal data item that is to be loaded into <Rt>. The assembler calculates the required value of the offset from the `Align(PC, 4)` value of the instruction to this label. Any value in the range -255 to 255 is permitted. If the offset is zero or positive, `imm32` is equal to the offset and `add == TRUE`, encoded as `U == 1`. If the offset is negative, `imm32` is equal to minus the offset and `add == FALSE`, encoded as `U == 0`.

For the “T1” variant: the label of the literal data item that is to be loaded into <Rt>. The assembler calculates the required value of the offset from the `Align(PC, 4)` value of the instruction to this label. Permitted values of the offset are -4095 to 4095.

If the offset is zero or positive, `imm32` is equal to the offset and `add == TRUE`, encoded as `U == 1`.

If the offset is negative, `imm32` is equal to minus the offset and `add == FALSE`, encoded as `U == 0`.

+/-

Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in “U”:

U	+/-
0	-
1	+

<imm>

For the “A1” variant: is the 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 if omitted, and encoded in the “imm4H:imm4L” field.

For the “T1” variant: is a 12-bit unsigned immediate byte offset, in the range 0 to 4095, encoded in the “imm12” field.

The alternative syntax permits the addition or subtraction of the offset and the immediate offset to be specified separately, including permitting a subtraction of 0 that cannot be specified using the normal syntax. For more information, see [Use of labels in UAL instruction syntax](#).

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let base : bits(32) = AlignDownSize(PC32(),4);
    let address : bits(32) = if add then (base + imm32) else (base - imm32);
    R(t) = SignExtend{32}(MemU{8}(address));
end;
```

C5.1.91 LDRSB (register)

Load Register Signed Byte (register) calculates an address from a base register value and an offset register value, loads a byte from memory, sign-extends it to form a 32-bit word, and writes it to a register. The offset register value can be shifted left by 0, 1, 2, or 3 bits. For information about memory accesses see [Memory accesses](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#) and [T2](#)).

A1

Encoding for the Offset variant

Applies when (P == 1 && W == 0)

$$\text{LDRSB}\{\langle c \rangle\}\{\langle q \rangle\} \quad \langle Rt \rangle, [\langle Rn \rangle, \{+/-\}\langle Rm \rangle]$$

Encoding for the Post-indexed variant

Applies when (P == 0 && W == 0)

LDRSB{<c>}{<q>}<Rt>,[<Rn>],{+/-}<Rm>

Encoding for the Pre-indexed variant

Applies when (P == 1 && W == 1)

LDRSB{<c>}{<q>}<Rt>,[<Rn>,{+/-}<Rm>]!

Decode for all variants of this encoding

```

if P == '0' && W == '1' then See("LDRSBT"); end;
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let index : boolean = (P == '1');
let add : boolean = (U == '1');
let wback : boolean = (P == '0') || (W == '1');
let shift_t : SRTtype = SRTtype_LSL;
let shift_n : integer = 0;
if t == 15 || m == 15 then UnpredictableProcedure(); end;
if wback && (n == 15 || n == t) then UnpredictableProcedure(); end;

```

CONSTRAINED UNPREDICTABLE behavior

If `wback && n == t`, then one of the following behaviors must occur:

- The instruction is **UNDEFINED**.
- The instruction executes as **NOP**.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is **UNKNOWN**. In addition, if an exception occurs during such as instruction, the base address might be corrupted so that the instruction cannot be repeated.

T1

Encoding

LDRSB{<c>}{<q>} <Rt>, [<Rn>, {+}<Rm>]

Decode for this encoding

```
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let index : boolean = TRUE;
let add : boolean = TRUE;
let wback : boolean = FALSE;
let shift_t : SRTYPE = SRTYPE_LSL;
let shift_n : integer = 0;
```

T2

Encoding

LDRSB{<c>}{<q>} <Rt>, [<Rn>, {+}<Rm>{, LSL #<imm>}]

LDRSB{<c>}.W <Rt>, [<Rn>, {+}<Rm>] // (<Rt>, <Rn>, <Rm> can be represented in T1)

Decode for this encoding

```
if Rt == '1111' then See("PLI"); end;
if Rn == '1111' then See("LDRSB (literal)"); end;
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let index : boolean = TRUE;
let add : boolean = TRUE;
let wback : boolean = FALSE;
let shift_t : SRTYPE = SRTYPE_LSL;
let shift_n : integer = UInt(imm2);
// Armv8-A removes UNPREDICTABLE for R13
if m == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rt>

Is the general-purpose register to be transferred, encoded in the “Rt” field.

<Rn>

For the “Offset”, “Post-indexed”, and “Pre-indexed” variants: is the general-purpose base register, encoded in the “Rn” field. The PC can be used in the offset variant.

For the “T1” and “T2” variants: is the general-purpose base register, encoded in the “Rn” field.

+/-

Specifies the index register is added to or subtracted from the base register, defaulting to + if omitted and encoded in “U”:

U	+/-
0	-
1	+

<Rm>

Is the general-purpose index register, encoded in the “Rm” field.

+

Specifies the index register is added to the base register.

<imm>

If present, the size of the left shift to apply to the value from <Rm>, in the range 1-3. <imm> is encoded in imm2. If absent, no shift is specified and imm2 is encoded as 0b00.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let offset : bits(32) = Shift{(R(m), shift_t, shift_n, PSTATE.C);
    let offset_addr : bits(32) = if add then (R(n) + offset) else (R(n) - offset);
    let address : bits(32) = if index then offset_addr else R(n);
    R(t) = SignExtend{32}(MemU{8}(address));
    if wback then R(n) = offset_addr; end;
end;
```

C5.1.92 LDRSBT

Load Register Signed Byte Unprivileged loads a byte from memory, sign-extends it to form a 32-bit word, and writes it to a register. For information about memory accesses see [Memory accesses](#).

The memory access is restricted as if the PE were running in User mode. This makes no difference if the PE is actually running in User mode.

LDRSBT is UNPREDICTABLE in Hyp mode.

The T32 instruction uses an offset addressing mode, that calculates the address used for the memory access from a base register value and an immediate offset, and leaves the base register unchanged.

The A32 instruction uses a post-indexed addressing mode, that uses a base register value as the address for the memory access, and calculates a new address from a base register value and an offset and writes it back to the base register. The offset can be an immediate value or a register value.

It has encodings from the following instruction sets: A32 ([A1](#) and [A2](#)) and T32 ([T1](#)).

A1

Encoding

LDRSBT{<c>}{<q>} <Rt>, [<Rn>] {, #<+/-><imm>}

Decode for this encoding

```
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let postindex : boolean = TRUE;
let add : boolean = (U == '1');
let register_form : boolean = FALSE;
let imm32 : bits(32) = ZeroExtend{}(imm4H::imm4L);
let m : integer = ARBITRARY : integer;
if t == 15 || n == 15 || n == t then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `n == 15`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction uses post-indexed addressing with the base register as PC. This is handled as described in [Using R15](#).
- The instruction is treated as if `bit[24] == '1'` and `bit[21] == '0'`. The instruction uses immediate offset addressing with the base register as PC, without writeback.

If `n == t && n != 15`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base address might be corrupted so that the instruction cannot be repeated.

A2

Encoding

$$\text{LDRSBT}\{\langle c \rangle\}\{\langle q \rangle\} \quad \langle Rt \rangle, \quad [\langle Rn \rangle], \quad \{+/-\}\langle Rm \rangle$$

Decode for this encoding

```

let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let postindex : boolean = TRUE;
let add : boolean = (U == '1');
let register_form : boolean = TRUE;
let imm32 : bits(32) = ARBITRARY : bits(32);
if t == 15 || n == 15 || n == t || m == 15 then UnpredictableProcedure(); end;

```

CONSTRAINED UNPREDICTABLE behavior

If `n == t` && `n != 15`, then one of the following behaviors must occur:

- The instruction is **UNDEFINED**.
- The instruction executes as **NOP**.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is **UNKNOWN**. In addition, if an exception occurs during such as instruction, the base address might be corrupted so that the instruction cannot be repeated.

T1

Encoding

LDRSBT{<c>}{<q>}<Rt>,[<Rn>{, # {+<imm>}]

Decode for this encoding

```

if Rn == 'l1l1' then See("LDRSB (literal)"); end;
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let postindex : boolean = FALSE;
let add : boolean = TRUE;
let register_form : boolean = FALSE;
let imm32 : bits(32) = ZeroExtend{}(imm8);
let m : integer = ARBITRARY : integer;
// Armv8-A removes UNPREDICTABLE for R13
if t == 15 then UnpredictableProcedure(); end;

```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rt>

Is the general-purpose register to be transferred, encoded in the “Rt” field.

<Rn>

Is the general-purpose base register, encoded in the “Rn” field.

+/-

For the “A1” variant: specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in “U”:

U	+/-
0	-
1	+

For the “A2” variant: specifies the index register is added to or subtracted from the base register, defaulting to + if omitted and encoded in “U”:

U	+/-
0	-
1	+

<imm>

For the “A1” variant: is the 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 if omitted, and encoded in the “imm4H:imm4L” field.

For the “T1” variant: is an optional 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 and encoded in the “imm8” field.

<Rm>

Is the general-purpose index register, encoded in the “Rm” field.

+

Specifies the offset is added to the base register.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
if PSTATE.EL == EL2 then UnpredictableProcedure(); end;           // Hyp mode
let offset : bits(32) = if register_form then R(m) else imm32;
```

```
let offset_addr : bits(32) = if add then (R(n) + offset) else (R(n) - offset);  
let address : bits(32) = if postindex then R(n) else offset_addr;  
R(t) = SignExtend{32}(MemU_unpriv{8}(address));  
if postindex then R(n) = offset_addr; end;  
end;
```

CONSTRAINED UNPREDICTABLE behavior

If `PSTATE.EL == EL2`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes as LDRSB (immediate).

C5.1.93 LDRSH (immediate)

Load Register Signed Halfword (immediate) calculates an address from a base register value and an immediate offset, loads a halfword from memory, sign-extends it to form a 32-bit word, and writes it to a register. It can use offset, post-indexed, or pre-indexed addressing. For information about memory accesses see [Memory accesses](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#) and [T2](#)).

A1

Encoding for the Offset variant

Applies when (P == 1 && W == 0)

```
LDRSH{<c>}{<q>} <Rt>, [<Rn> {, # {+/-}<imm>}]
```

Encoding for the Post-indexed variant

Applies when (P == 0 && W == 0)

```
LDRSH{<c>}{<q>} <Rt>, [<Rn>], # {+/-}<imm>
```

Encoding for the Pre-indexed variant

Applies when (P == 1 && W == 1)

```
LDRSH{<c>}{<q>} <Rt>, [<Rn>, # {+/-}<imm>]!
```

Decode for all variants of this encoding

```
if Rn == '1111' then See("LDRSH (literal)"); end;
if P == '0' && W == '1' then See("LDRSHT"); end;
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let imm32 : bits(32) = ZeroExtend{(imm4H::imm4L)};
let index : boolean = (P == '1');
let add : boolean = (U == '1');
let wback : boolean = (P == '0') || (W == '1');
if t == 15 || (wback && n == t) then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If wback && n == t, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such an instruction, the base address might be corrupted so that the instruction cannot be repeated.

T1

Encoding

LDRSH{<c>}{<q>} <Rt>, [<Rn> {, #<+><imm>}]

Decode for this encoding

```

if Rn == '1111' then See("LDRSH (literal)"); end;
if Rt == '1111' then See("Related instructions"); end;
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let imm32 : bits(32) = ZeroExtend{}(imm12);
let index : boolean = TRUE;
let add : boolean = TRUE;
let wback : boolean = FALSE;
// Armv8-A removes UNPREDICTABLE for R13

```

T2

Encoding for the Offset variant

Applies when (Rt != 1111 && P == 1 && U == 0 && W == 0)

LDRSH{<c>}{<q>} <Rt>, [<Rn> {, #-<imm>}]

Encoding for the Post-indexed variant

Applies when (P == 0 && W == 1)

LDRSH{<c>}{<q>} <Rt>, [<Rn>], #<+/-><imm>

Encoding for the Pre-indexed variant

Applies when (P == 1 && W == 1)

LDRSH{<c>}{<q>} <Rt>, [<Rn>, #<+/-><imm>]!

Decode for all variants of this encoding

```
if Rn == '1111' then See("LDRSH (literal)"); end;  
if Rt == '1111' && P == '1' && U == '0' && W == '0' then See("Related instructions"); end;  
if P == '1' && U == '1' && W == '0' then See("LDRSHT"); end;  
if P == '0' && W == '0' then Undefined(); end;  
let t : integer = UInt(Rt);  
let n : integer = UInt(Rn);  
let imm32 : bits(32) = ZeroExtend{}(imm8);  
let index : boolean = (P == '1');  
let add : boolean = (U == '1');  
let wback : boolean = (W == '1');  
if (t == 15 && W == '1') || (wback && n == t) then UnpredictableProcedure(); end;  
// Armv8-A removes UNPREDICTABLE for R13
```

CONSTRAINED UNPREDICTABLE behavior

If wback && n == t, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such an instruction, the base address might be corrupted so that the instruction cannot be repeated.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Related instructions: [Load/store single](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rt>

Is the general-purpose register to be transferred, encoded in the “Rt” field.

<Rn>

Is the general-purpose base register, encoded in the “Rn” field. For PC use see [LDRSH \(literal\)](#).

+/-

Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in “U”:

U	+/-
0	-
1	+

<imm>

For the “A1 Offset”, “A1 Post-indexed”, and “A1 Pre-indexed” variants: is the 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 if omitted, and encoded in the “imm4H:imm4L” field.

For the “T1” variant: is an optional 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 and encoded in the “imm12” field.

For the “T2 Offset”, “T2 Post-indexed”, and “T2 Pre-indexed” variants: is an 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 if omitted, and encoded in the “imm8” field.

+

Specifies the offset is added to the base register.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let offset_addr : bits(32) = if add then (R(n) + imm32) else (R(n) - imm32);
    let address : bits(32) = if index then offset_addr else R(n);
    let data : bits(16) = MemU{16}(address);
    if wback then R(n) = offset_addr; end;
    R(t) = SignExtend{32}(data);
end;
```

C5.1.94 LDRSH (literal)

Load Register Signed Halfword (literal) calculates an address from the PC value and an immediate offset, loads a halfword from memory, sign-extends it to form a 32-bit word, and writes it to a register. For information about memory accesses see [Memory accesses](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

Applies when $(!(P == '0' \ \&\& \ W == '1'))$

LDRSH{<c>}{<q>} <Rt>, <label> // (Normal form)

LDRSH{<c>}{<q>} <Rt>, [PC, #{+/-}<imm>] // (Alternative form)

Decode for this encoding

```

if P == '0' && W == '1' then See("LDRSHT"); end;
let t : integer = UInt(Rt);
let imm32 : bits(32) = ZeroExtend{(imm4H::imm4L)};
let add : boolean = (U == '1');
let wback : boolean = (P == '0') || (W == '1');
if t == 15 || wback then UnpredictableProcedure(); end;

```

CONSTRAINED UNPREDICTABLE behavior

If wback, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes with the additional decode: wback = FALSE;.
- The instruction treats bit[24] as the P bit, and bit[21] as the writeback (W) bit, and uses the same addressing mode as described in LDRSH (immediate). The instruction uses post-indexed addressing when P == '0' and uses pre-indexed addressing otherwise. The instruction is handled as described in Using R15.

T1

Encoding

LDRSH{<c>}{<q>} <Rt>, <label> // (Preferred syntax)

LDRSH{<c>}{<q>} <Rt>, [PC, #{+/-}<imm>] // (Alternative syntax)

Decode for this encoding

```
if Rt == '1111' then See("Related instructions"); end;  
let t : integer = UInt(Rt);  
let imm32 : bits(32) = ZeroExtend{}(imm12);  
let add : boolean = (U == '1');  
// Armv8-A removes UNPREDICTABLE for R13
```

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rt>

Is the general-purpose register to be transferred, encoded in the “Rt” field.

<label>

For the “A1” variant: the label of the literal data item that is to be loaded into <Rt>. The assembler calculates the required value of the offset from the `Align(PC, 4)` value of the instruction to this label. Any value in the range -255 to 255 is permitted. If the offset is zero or positive, `imm32` is equal to the offset and `add == TRUE`, encoded as `U == 1`. If the offset is negative, `imm32` is equal to minus the offset and `add == FALSE`, encoded as `U == 0`.

For the “T1” variant: the label of the literal data item that is to be loaded into <Rt>. The assembler calculates the required value of the offset from the `Align(PC, 4)` value of the instruction to this label. Permitted values of the offset are -4095 to 4095.

If the offset is zero or positive, `imm32` is equal to the offset and `add == TRUE`, encoded as `U == 1`.

If the offset is negative, `imm32` is equal to minus the offset and `add == FALSE`, encoded as `U == 0`.

+/-

Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in “U”:

U	+/-
0	-
1	+

<imm>

For the “A1” variant: is the 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 if omitted, and encoded in the “imm4H:imm4L” field.

For the “T1” variant: is a 12-bit unsigned immediate byte offset, in the range 0 to 4095, encoded in the “imm12” field.

The alternative syntax permits the addition or subtraction of the offset and the immediate offset to be specified separately, including permitting a subtraction of 0 that cannot be specified using the normal syntax. For more information, see [Use of labels in UAL instruction syntax](#).

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let base : bits(32) = AlignDownSize(PC32(),4);
    let address : bits(32) = if add then (base + imm32) else (base - imm32);
    let data : bits(16) = MemU{16}(address);
    R(t) = SignExtend{32}(data);
end;
```

C5.1.95 LDRSH (register)

Load Register Signed Halfword (register) calculates an address from a base register value and an offset register value, loads a halfword from memory, sign-extends it to form a 32-bit word, and writes it to a register. The offset register value can be shifted left by 0, 1, 2, or 3 bits. For information about memory accesses see [Memory accesses](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#) and [T2](#)).

A1

Encoding for the Offset variant

Applies when (P == 1 && W == 0)

LDRSH{<c>}{<q>} <Rt>, [<Rn>, {+/-}<Rm>]

Encoding for the Post-indexed variant

Applies when (P == 0 && W == 0)

LDRSH{<c>}{<q>} <Rt>, [<Rn>], {+/-}<Rm>

Encoding for the Pre-indexed variant

Applies when (P == 1 && W == 1)

```
LDRSH{<c>}{<q>} <Rt>, [<Rn>, {+/-}<Rm>]!
```

Decode for all variants of this encoding

```

if P == '0' && W == '1' then See("LDRSHT"); end;
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let index : boolean = (P == '1');
let add : boolean = (U == '1');
let wback : boolean = (P == '0') || (W == '1');
let shift_t : SRTtype = SRTtype_LSL;
let shift_n : integer = 0;
if t == 15 || m == 15 then UnpredictableProcedure(); end;
if wback && (n == 15 || n == t) then UnpredictableProcedure(); end;

```

CONSTRAINED UNPREDICTABLE behavior

If `wback && n == t`, then one of the following behaviors must occur:

- The instruction is **UNDEFINED**.
- The instruction executes as **NOP**.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is **UNKNOWN**. In addition, if an exception occurs during such as instruction, the base address might be corrupted so that the instruction cannot be repeated.

if m == 15 then UnpredictableProcedure(); end;

```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Related instructions: Load/store, signed (register offset).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rt>

Is the general-purpose register to be transferred, encoded in the “Rt” field.

<Rn>

For the “Offset”, “Post-indexed”, and “Pre-indexed” variants: is the general-purpose base register, encoded in the “Rn” field. The PC can be used in the offset variant.

For the “T1” and “T2” variants: is the general-purpose base register, encoded in the “Rn” field.

+/-

Specifies the index register is added to or subtracted from the base register, defaulting to + if omitted and encoded in “U”:

U	+/-
0	-
1	+

<Rm>

Is the general-purpose index register, encoded in the “Rm” field.

+

Specifies the index register is added to the base register.

<imm>

If present, the size of the left shift to apply to the value from <Rm>, in the range 1-3. <imm> is encoded in imm2. If absent, no shift is specified and imm2 is encoded as 0b00.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let offset : bits(32) = Shift{}(R(m), shift_t, shift_n, PSTATE.C);
    let offset_addr : bits(32) = if add then (R(n) + offset) else (R(n) - offset);
    let address : bits(32) = if index then offset_addr else R(n);
    let data : bits(16) = MemU{16}(address);
    if wback then R(n) = offset_addr; end;
    R(t) = SignExtend{32}(data);
end;
```

C5.1.96 LDRSHT

Load Register Signed Halfword Unprivileged loads a halfword from memory, sign-extends it to form a 32-bit word, and writes it to a register. For information about memory accesses see [Memory accesses](#).

The memory access is restricted as if the PE were running in User mode. This makes no difference if the PE is actually running in User mode.

LDRSHT is UNPREDICTABLE in Hyp mode.

The T32 instruction uses an offset addressing mode, that calculates the address used for the memory access from a base register value and an immediate offset, and leaves the base register unchanged.

The A32 instruction uses a post-indexed addressing mode, that uses a base register value as the address for the memory access, and calculates a new address from a base register value and an offset and writes it back to the base register. The offset can be an immediate value or a register value.

It has encodings from the following instruction sets: A32 ([A1](#) and [A2](#)) and T32 ([T1](#)).

A1

Encoding

LDRSHT{<c>}{<q>} <Rt>, [<Rn>] {, #<+/-><imm>}

Decode for this encoding

```
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let postindex : boolean = TRUE;
let add : boolean = (U == '1');
let register_form : boolean = FALSE;
let imm32 : bits(32) = ZeroExtend{}(imm4H::imm4L);
let m : integer = ARBITRARY : integer;
if t == 15 || n == 15 || n == t then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If $n == 15$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction uses post-indexed addressing with the base register as PC. This is handled as described in [Using R15](#).
- The instruction is treated as if $\text{bit}[24] == '1'$ and $\text{bit}[21] == '0'$. The instruction uses immediate offset addressing with the base register as PC, without writeback.

If $n == t \ \&\& \ n \neq 15$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base address might be corrupted so that the instruction cannot be repeated.

A2

Encoding

LDRSHT{<c>}{<q>} <Rt>, [<Rn>], {+/-}<Rm>

Decode for this encoding

```
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let postindex : boolean = TRUE;
let add : boolean = (U == '1');
let register_form : boolean = TRUE;
let imm32 : bits(32) = ARBITRARY : bits(32);
if t == 15 || n == 15 || n == t || m == 15 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If $n == t$ && $n != 15$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base address might be corrupted so that the instruction cannot be repeated.

T1

Encoding

LDRSHT{<c>}{<q>} <Rt>, [<Rn> {, #+}<imm>]

Decode for this encoding

```
if Rn == '1111' then See("LDRSH (literal)"); end;
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let postindex : boolean = FALSE;
let add : boolean = TRUE;
let register_form : boolean = FALSE;
let imm32 : bits(32) = ZeroExtend{}(imm8);
let m : integer = ARBITRARY : integer;
// Armv8-A removes UNPREDICTABLE for R13
if t == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rt>

Is the general-purpose register to be transferred, encoded in the “Rt” field.

<Rn>

Is the general-purpose base register, encoded in the “Rn” field.

+/-

For the “A1” variant: specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in “U”:

U	+/-
0	-
1	+

For the “A2” variant: specifies the index register is added to or subtracted from the base register, defaulting to + if omitted and encoded in “U”:

U	+/-
0	-
1	+

<imm>

For the “A1” variant: is the 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 if omitted, and encoded in the “imm4H:imm4L” field.

For the “T1” variant: is an optional 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 and encoded in the “imm8” field.

<Rm>

Is the general-purpose index register, encoded in the “Rm” field.

+

Specifies the offset is added to the base register.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
if PSTATE.EL == EL2 then UnpredictableProcedure(); end;           // Hyp mode
let offset : bits(32) = if register_form then R(m) else imm32;
```

```
let offset_addr : bits(32) = if add then (R(n) + offset) else (R(n) - offset);  
let address : bits(32) = if postindex then R(n) else offset_addr;  
let data : bits(16) = MemU_unpriv{16}(address);  
if postindex then R(n) = offset_addr; end;  
R(t) = SignExtend{32}(data);  
end;
```

CONSTRAINED UNPREDICTABLE behavior

If `PSTATE.EL == EL2`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes as LDRSH (immediate).

C5.1.97 LDRT

Load Register Unprivileged loads a word from memory, and writes it to a register. For information about memory accesses see [Memory accesses](#).

The memory access is restricted as if the PE were running in User mode. This makes no difference if the PE is actually running in User mode.

LDRT is UNPREDICTABLE in Hyp mode.

The T32 instruction uses an offset addressing mode, that calculates the address used for the memory access from a base register value and an immediate offset, and leaves the base register unchanged.

The A32 instruction uses a post-indexed addressing mode, that uses a base register value as the address for the memory access, and calculates a new address from a base register value and an offset and writes it back to the base register. The offset can be an immediate value or an optionally-shifted register value.

It has encodings from the following instruction sets: A32 ([A1](#) and [A2](#)) and T32 ([T1](#)).

A1

Encoding

LDRT{<c>}{<q>} <Rt>, [<Rn>] {, #<+/-><imm>}

Decode for this encoding

```

let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let postindex : boolean = TRUE;
let add : boolean = (U == '1');
let register_form : boolean = FALSE;
let imm32 : bits(32) = ZeroExtend{}(imm12);
let m : integer = ARBITRARY : integer;
let shift_n : integer = ARBITRARY : integer;
let shift_t : SRTYPE = ARBITRARY : SRTYPE;
if t == 15 || n == 15 || n == t then UnpredictableProcedure(); end;

```

CONSTRAINED UNPREDICTABLE behavior

If $n == 15$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction uses post-indexed addressing with the base register as PC. This is handled as described in Using R15.
- The instruction is treated as if $\text{bit}[24] == '1'$ and $\text{bit}[21] == '0'$. The instruction uses immediate offset addressing with the base register as PC, without writeback.

If $n == t \ \&\& \ n \neq 15$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base address might be corrupted so that the instruction cannot be repeated.

A2

Encoding

LDRT{<c>}{<q>} <Rt>, [<Rn>], {+/-}<Rm>{, <shift>}

Decode for this encoding

```
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let postindex : boolean = TRUE;
let add : boolean = (U == '1');
let register_form : boolean = TRUE;
let (shift_t, shift_n) : (SRType, integer) = DecodeImmShift(stype, imm5);
let imm32 : bits(32) = ARBITRARY : bits(32);
if t == 15 || n == 15 || n == t || m == 15 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If $n == t$ && $n != 15$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base address might be corrupted so that the instruction cannot be repeated.

T1

Encoding

LDRT{<c>}{<q>} <Rt>, [<Rn> {, #{+}<imm>}]

Decode for this encoding

```
if Rn == '1111' then See("LDR (literal)"); end;  
let t : integer = UInt(Rt);  
let n : integer = UInt(Rn);  
let postindex : boolean = FALSE;  
let add : boolean = TRUE;  
let register_form : boolean = FALSE;  
let imm32 : bits(32) = ZeroExtend{}(imm8);  
let m : integer = ARBITRARY : integer;  
let shift_n : integer = ARBITRARY : integer;  
let shift_t : SRTYPE = ARBITRARY : SRTYPE;  
// Armv8-A removes UNPREDICTABLE for R13  
if t == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rt>

For the “A1” variant: is the general-purpose register to be transferred, encoded in the “Rt” field. The PC can be used, but this is deprecated.

For the “A2” and “T1” variants: is the general-purpose register to be transferred, encoded in the “Rt” field.

<Rn>

Is the general-purpose base register, encoded in the “Rn” field.

+/-

For the “A1” variant: specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in “U”:

U	+/-
0	-
1	+

For the “A2” variant: specifies the index register is added to or subtracted from the base register, defaulting to + if omitted and encoded in “U”:

U	+/-
0	-
1	+

<imm>

For the “A1” variant: is the 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 if omitted, and encoded in the “imm12” field.

For the “T1” variant: is an optional 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 and encoded in the “imm8” field.

<Rm>

Is the general-purpose index register, encoded in the “Rm” field.

<shift>

The shift to apply to the value read from <Rm>. If absent, no shift is applied. Otherwise, see [Shifts applied to a register](#).

+

Specifies the offset is added to the base register.

Operation

```

if ConditionPassed() then
    EncodingSpecificOperations();
    if PSTATE.EL == EL2 then UnpredictableProcedure(); end;           // Hyp mode
    let offset : bits(32) = (if register_form then Shift{32}(R(m), shift_t, shift_n, PSTATE.C)
                             else imm32);
    let offset_addr : bits(32) = if add then (R(n) + offset) else (R(n) - offset);
    let address : bits(32) = if postindex then R(n) else offset_addr;
    let data : bits(32) = MemU_unpriv{32}(address);
    if postindex then R(n) = offset_addr; end;
    R(t) = data;
end;

```

CONSTRAINED UNPREDICTABLE behavior

If PSTATE.EL == EL2, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes as LDR (immediate).

C5.1.98 LSL (immediate)

Logical Shift Left (immediate) shifts a register value left by an immediate number of bits, shifting in zeros, and writes the result to the destination register.

This is an alias of [MOV, MOVS \(register\)](#). This means:

- The encodings in this description are named to match the encodings of [MOV, MOVS \(register\)](#).
- The description of [MOV, MOVS \(register\)](#) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T2](#) and [T3](#)).

A1

Encoding for the MOV, shift or rotate by value variant

LSL{<c>}{<q>} {<Rd>, }<Rm>, #<imm>

is equivalent to

MOV{<c>}{<q>} <Rd>, <Rm>, LSL #<imm>

and is always the preferred disassembly.

T2

Encoding for the T2 variant

LSL<c>{<q>} {<Rd>, }<Rm>, #<imm>

is equivalent to

MOV<c>{<q>} <Rd>, <Rm>, LSL #<imm>

and is the preferred disassembly when `InITBlock()`.

T3

Encoding for the MOV, shift or rotate by value variant

Applies when $(!(\text{imm3} == 000 \ \&\& \ \text{imm2} == 00))$

```
LSL{<c>}{<q>} {<Rd>}, <Rm>, #<imm>
```

```
LSL<c>.W {<Rd>}, <Rm>, #<imm> // (!InITBlock() && UInt(Rd) < 8 && UInt(Rm) < 8)
```

is equivalent to

```
MOV{<c>}{<q>} <Rd>, <Rm>, LSL #<imm>
```

and is always the preferred disassembly.

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rd>

For the “A1 MOV, shift or rotate by value” variant: is the general-purpose destination register, encoded in the “Rd” field. Arm deprecates using the PC as the destination register, but if the PC is used, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC](#).

For the “T2” and “T3 MOV, shift or rotate by value” variants: is the general-purpose destination register, encoded in the “Rd” field.

<Rm>

For the “A1 MOV, shift or rotate by value” variant: is the general-purpose source register, encoded in the “Rm” field. The PC can be used, but this is deprecated.

For the “T2” and “T3 MOV, shift or rotate by value” variants: is the general-purpose source register, encoded in the “Rm” field.

<imm>

For the “A1 MOV, shift or rotate by value” variant: is the shift amount, in the range 0 to 31, encoded in the “imm5” field as <imm> modulo 32.

For the “T2” variant: is the shift amount, in the range 1 to 31, encoded in the “imm5” field as <amount> modulo 32.

For the “T3 MOV, shift or rotate by value” variant: is the shift amount, in the range 0 to 31, encoded in the “imm3:imm2” field as <imm> modulo 32.

Operation

The description of [MOV, MOVS \(register\)](#) gives the operational pseudocode for this instruction.

C5.1.99 LSL (register)

Logical Shift Left (register) shifts a register value left by a variable number of bits, shifting in zeros, and writes the result to the destination register. The variable number of bits is read from the bottom byte of a register.

This is an alias of [MOV, MOVS \(register-shifted register\)](#). This means:

- The encodings in this description are named to match the encodings of [MOV, MOVS \(register-shifted register\)](#).
- The description of [MOV, MOVS \(register-shifted register\)](#) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#) and [T2](#)).

A1

Encoding for the Not flag setting variant

LSL{<c>}{<q>} {<Rd>, }<Rm>, <Rs>

is equivalent to

MOV{<c>}{<q>} <Rd>, <Rm>, LSL <Rs>

and is always the preferred disassembly.

T1

Encoding for the Logical shift left variant

LSL<c>{<q>} {<Rdm>, }<Rdm>, <Rs>

is equivalent to

MOV<c>{<q>} <Rdm>, <Rdm>, LSL <Rs>

and is the preferred disassembly when `InITBlock()`.

T2

Encoding for the Not flag setting variant

```
LSL{<c>}{<q>}{<Rd>, }<Rm>, <Rs>
```

```
LSL<c>.W {<Rd>, }<Rm>, <Rs> // (InITBlock() && (UInt(Rd) < 8 && Rd == Rm && UInt(Rs) < 8))
```

is equivalent to

```
MOV{<c>}{<q>}{<Rd>, <Rm>, LSL <Rs>
```

and is always the preferred disassembly.

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rd>

Is the general-purpose destination register, encoded in the “Rd” field.

<Rm>

Is the first general-purpose source register, encoded in the “Rm” field.

<Rs>

Is the second general-purpose source register holding a shift amount in its bottom 8 bits, encoded in the “Rs” field.

<Rdm>

Is the first general-purpose source register and the destination register, encoded in the “Rdm” field.

Operation

The description of [MOV, MOVS \(register-shifted register\)](#) gives the operational pseudocode for this instruction.

C5.1.100 LSLS (immediate)

Logical Shift Left, setting flags (immediate) shifts a register value left by an immediate number of bits, shifting in zeros, and writes the result to the destination register.

If the destination register is not the PC, this instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. Arm deprecates any use of these encodings. However, when the destination register is the PC:

- The PE branches to the address written to the PC, and restores [PSTATE](#) from SPSR_<current_mode>.
- The PE checks SPSR_<current_mode> for an illegal return event. See [Illegal return events from AArch32 state](#).
- The instruction is UNDEFINED in Hyp mode.
- The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

This is an alias of [MOV, MOVS \(register\)](#). This means:

- The encodings in this description are named to match the encodings of [MOV, MOVS \(register\)](#).
- The description of [MOV, MOVS \(register\)](#) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T2](#) and [T3](#)).

A1

Encoding for the MOVs, shift or rotate by value variant

LSLS{<c>}{<q>} {<Rd>, }<Rm>, #<imm>

is equivalent to

MOVS{<c>}{<q>} <Rd>, <Rm>, LSL #<imm>

and is always the preferred disassembly.

T2

Encoding for the T2 variant

LSLS{<q>} {<Rd>, }<Rm>, #<imm>

is equivalent to

MOVS<c>{<q>} <Rd>, <Rm>, LSL #<imm>

and is the preferred disassembly when !InITBlock().

T3

Encoding for the MOVS, shift or rotate by value variant

Applies when $(!(imm3 == 000 \ \&\& \ imm2 == 00))$

LSLS{<c>}{<q>} {<Rd>, }<Rm>, #<imm>

LSLS.W {<Rd>, }<Rm>, #<imm> // (!InITBlock() && UInt(Rd) < 8 && UInt(Rm) < 8)

is equivalent to

MOVS{<c>}{<q>} <Rd>, <Rm>, LSL #<imm>

and is always the preferred disassembly.

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rd>

For the “A1 MOVS, shift or rotate by value” variant: is the general-purpose destination register, encoded in the “Rd” field. Arm deprecates using the PC as the destination register, but if the PC is used, the instruction performs an exception return, that restores [PSTATE](#) from SPSR_<current_mode>.

For the “T2” and “T3 MOVS, shift or rotate by value” variants: is the general-purpose destination register, encoded in the “Rd” field.

<Rm>

For the “A1 MOVS, shift or rotate by value” variant: is the general-purpose source register, encoded in the “Rm” field. The PC can be used, but this is deprecated.

For the “T2” and “T3 MOVS, shift or rotate by value” variants: is the general-purpose source register, encoded in the “Rm” field.

<imm>

For the “A1 MOVS, shift or rotate by value” variant: is the shift amount, in the range 0 to 31, encoded in the “imm5” field as <imm> modulo 32.

For the “T2” variant: is the shift amount, in the range 1 to 31, encoded in the “imm5” field as <amount> modulo 32.

For the “T3 MOVS, shift or rotate by value” variant: is the shift amount, in the range 0 to 31, encoded in the “imm3:imm2” field as <imm> modulo 32.

Operation

The description of [MOV](#), [MOVS \(register\)](#) gives the operational pseudocode for this instruction.

C5.1.101 LSLS (register)

Logical Shift Left, setting flags (register) shifts a register value left by a variable number of bits, shifting in zeros, writes the result to the destination register, and updates the condition flags based on the result. The variable number of bits is read from the bottom byte of a register.

This is an alias of [MOV, MOVS \(register-shifted register\)](#). This means:

- The encodings in this description are named to match the encodings of [MOV, MOVS \(register-shifted register\)](#).
- The description of [MOV, MOVS \(register-shifted register\)](#) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#) and [T2](#)).

A1

Encoding for the Flag setting variant

LSLS{<c>}{<q>} {<Rd>, }<Rm>, <Rs>

is equivalent to

MOVS{<c>}{<q>} <Rd>, <Rm>, LSL <Rs>

and is always the preferred disassembly.

T1

Encoding for the Logical shift left variant

LSLS{<q>} {<Rdm>, }<Rdm>, <Rs>

is equivalent to

MOVS{<q>} <Rdm>, <Rdm>, LSL <Rs>

and is the preferred disassembly when !InITBlock().

T2

Encoding for the Flag setting variant

$$\text{LSLS}\{\langle c \rangle\}\{\langle q \rangle\} \quad \{\langle Rd \rangle, \} \langle Rm \rangle, \langle Rs \rangle$$

```
LSLS.W {<Rd>, }<Rm>, <Rs> // (!InITBlock() && (UInt(Rd) < 8 && Rd == Rm && UInt(Rs) < 8))
```

is equivalent to

MOVS{<c>}{<q>} <Rd>, <Rm>, LSL <Rs>

and is always the preferred disassembly.

Assembler Symbols

 $\langle c \rangle$

See [Standard assembler syntax fields](#).

 $\langle q \rangle$

See [Standard assembler syntax fields](#).

<Rd>

Is the general-purpose destination register, encoded in the “Rd” field.

<Rm>

Is the first general-purpose source register, encoded in the “Rm” field.

 $\langle R_s \rangle$

Is the second general-purpose source register holding a shift amount in its bottom 8 bits, encoded in the “Rs” field.

<Rdm>

Is the first general-purpose source register and the destination register, encoded in the “Rdm” field.

Operation

The description of [MOV, MOVS \(register-shifted register\)](#) gives the operational pseudocode for this instruction.

C5.1.102 LSR (immediate)

Logical Shift Right (immediate) shifts a register value right by an immediate number of bits, shifting in zeros, and writes the result to the destination register.

This is an alias of [MOV, MOVS \(register\)](#). This means:

- The encodings in this description are named to match the encodings of [MOV, MOVS \(register\)](#).
- The description of [MOV, MOVS \(register\)](#) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T2](#) and [T3](#)).

A1

Encoding for the MOV, shift or rotate by value variant

LSR{<c>}{<q>} {<Rd>, }<Rm>, #<imm>

is equivalent to

MOV{<c>}{<q>} <Rd>, <Rm>, LSR #<imm>

and is always the preferred disassembly.

T2

Encoding for the T2 variant

LSR<c>{<q>} {<Rd>, }<Rm>, #<imm>

is equivalent to

MOV<c>{<q>} <Rd>, <Rm>, LSR #<imm>

and is the preferred disassembly when `InITBlock()`.

T3

Encoding for the MOV, shift or rotate by value variant

```
LSR{<c>}{<q>}{<Rd>,<Rm>,<imm>}
```

```
LSR<c>.W {<Rd>,<Rm>,<imm> // (!InITBlock() && UInt(Rd) < 8 && UInt(Rm) < 8)
```

is equivalent to

```
MOV{<c>}{<q>}{<Rd>,<Rm>,<imm>}
```

and is always the preferred disassembly.

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rd>

For the “A1 MOV, shift or rotate by value” variant: is the general-purpose destination register, encoded in the “Rd” field. Arm deprecates using the PC as the destination register, but if the PC is used, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC](#).

For the “T2” and “T3 MOV, shift or rotate by value” variants: is the general-purpose destination register, encoded in the “Rd” field.

<Rm>

For the “A1 MOV, shift or rotate by value” variant: is the general-purpose source register, encoded in the “Rm” field. The PC can be used, but this is deprecated.

For the “T2” and “T3 MOV, shift or rotate by value” variants: is the general-purpose source register, encoded in the “Rm” field.

<imm>

For the “A1 MOV, shift or rotate by value” and “T2” variants: is the shift amount, in the range 1 to 32, encoded in the “imm5” field as <imm> modulo 32.

For the “T3 MOV, shift or rotate by value” variant: is the shift amount, in the range 1 to 32, encoded in the “imm3:imm2” field as <imm> modulo 32.

Operation

The description of [MOV, MOVS \(register\)](#) gives the operational pseudocode for this instruction.

C5.1.103 LSR (register)

Logical Shift Right (register) shifts a register value right by a variable number of bits, shifting in zeros, and writes the result to the destination register. The variable number of bits is read from the bottom byte of a register.

This is an alias of [MOV, MOVS \(register-shifted register\)](#). This means:

- The encodings in this description are named to match the encodings of [MOV, MOVS \(register-shifted register\)](#).
- The description of [MOV, MOVS \(register-shifted register\)](#) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#) and [T2](#)).

A1

Encoding for the Not flag setting variant

LSR{<c>}{<q>} {<Rd>, }<Rm>, <Rs>

is equivalent to

MOV{<c>}{<q>} <Rd>, <Rm>, LSR <Rs>

and is always the preferred disassembly.

T1

Encoding for the Logical shift right variant

LSR<c>{<q>} {<Rdm>, }<Rdm>, <Rs>

is equivalent to

MOV<c>{<q>} <Rdm>, <Rdm>, LSR <Rs>

and is the preferred disassembly when `InITBlock()`.

T2

Encoding for the Not flag setting variant

```
LSR{<c>}{<q>}{<Rd>, }<Rm>, <Rs>
```

```
LSR<c>.W {<Rd>, }<Rm>, <Rs> // (InITBlock() && (UInt(Rd) < 8 && Rd == Rm && UInt(Rs) < 8))
```

is equivalent to

```
MOV{<c>}{<q>}{<Rd>, <Rm>, LSR <Rs>}
```

and is always the preferred disassembly.

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rd>

Is the general-purpose destination register, encoded in the “Rd” field.

<Rm>

Is the first general-purpose source register, encoded in the “Rm” field.

<Rs>

Is the second general-purpose source register holding a shift amount in its bottom 8 bits, encoded in the “Rs” field.

<Rdm>

Is the first general-purpose source register and the destination register, encoded in the “Rdm” field.

Operation

The description of [MOV, MOVS \(register-shifted register\)](#) gives the operational pseudocode for this instruction.

C5.1.104 LSRS (immediate)

Logical Shift Right, setting flags (immediate) shifts a register value right by an immediate number of bits, shifting in zeros, and writes the result to the destination register.

If the destination register is not the PC, this instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. Arm deprecates any use of these encodings. However, when the destination register is the PC:

- The PE branches to the address written to the PC, and restores [PSTATE](#) from SPSR_<current_mode>.
- The PE checks SPSR_<current_mode> for an illegal return event. See [Illegal return events from AArch32 state](#).
- The instruction is UNDEFINED in Hyp mode.
- The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

This is an alias of [MOV, MOVS \(register\)](#). This means:

- The encodings in this description are named to match the encodings of [MOV, MOVS \(register\)](#).
- The description of [MOV, MOVS \(register\)](#) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T2](#) and [T3](#)).

A1

Encoding for the MOVS, shift or rotate by value variant

LSRS{<c>}{<q>} {<Rd>, }<Rm>, #<imm>

is equivalent to

MOVS{<c>}{<q>} <Rd>, <Rm>, LSR #<imm>

and is always the preferred disassembly.

T2

Encoding for the T2 variant

LSRS{<q>} {<Rd>, }<Rm>, #<imm>

is equivalent to

MOVS<c>{<q>} <Rd>, <Rm>, LSR #<imm>

and is the preferred disassembly when !InITBlock().

T3

Encoding for the MOVS, shift or rotate by value variant

```
LSRS{<c>}{<q>} {<Rd>, }<Rm>, #<imm>
```

```
LSRS.W {<Rd>, }<Rm>, #<imm> // (!InITBlock() && UInt(Rd) < 8 && UInt(Rm) < 8)
```

is equivalent to

```
MOVS{<c>}{<q>} <Rd>, <Rm>, LSR #<imm>
```

and is always the preferred disassembly.

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rd>

For the “A1 MOVS, shift or rotate by value” variant: is the general-purpose destination register, encoded in the “Rd” field. Arm deprecates using the PC as the destination register, but if the PC is used, the instruction performs an exception return, that restores [PSTATE](#) from `SPSR_<current_mode>`.

For the “T2” and “T3 MOVS, shift or rotate by value” variants: is the general-purpose destination register, encoded in the “Rd” field.

<Rm>

For the “A1 MOVS, shift or rotate by value” variant: is the general-purpose source register, encoded in the “Rm” field. The PC can be used, but this is deprecated.

For the “T2” and “T3 MOVS, shift or rotate by value” variants: is the general-purpose source register, encoded in the “Rm” field.

<imm>

For the “A1 MOVS, shift or rotate by value” and “T2” variants: is the shift amount, in the range 1 to 32, encoded in the “imm5” field as <imm> modulo 32.

For the “T3 MOVS, shift or rotate by value” variant: is the shift amount, in the range 1 to 32, encoded in the “imm3:imm2” field as <imm> modulo 32.

Operation

The description of [MOV](#), [MOVS \(register\)](#) gives the operational pseudocode for this instruction.

C5.1.105 LSRS (register)

Logical Shift Right, setting flags (register) shifts a register value right by an immediate number of bits, shifting in zeros, writes the result to the destination register, and updates the condition flags based on the result. The variable number of bits is read from the bottom byte of a register.

This is an alias of [MOV, MOVS \(register-shifted register\)](#). This means:

- The encodings in this description are named to match the encodings of [MOV, MOVS \(register-shifted register\)](#).
- The description of [MOV, MOVS \(register-shifted register\)](#) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#) and [T2](#)).

A1

Encoding for the Flag setting variant

LSRS{<c>}{<q>} {<Rd>, }<Rm>, <Rs>

is equivalent to

MOVS{<c>}{<q>} <Rd>, <Rm>, LSR <Rs>

and is always the preferred disassembly.

T1

Encoding for the Logical shift right variant

LSRS{<q>} {<Rdm>, }<Rdm>, <Rs>

is equivalent to

MOVS{<q>} <Rdm>, <Rdm>, LSR <Rs>

and is the preferred disassembly when !InITBlock().

T2

Encoding for the Flag setting variant

```
LSRS{<c>}{<q>} {<Rd>, }<Rm>, <Rs>  
  
LSRS.W {<Rd>, }<Rm>, <Rs> // (!InITBlock() && (UInt(Rd) < 8 && Rd == Rm && UInt(Rs) < 8))
```

is equivalent to

```
MOVS{<c>}{<q>} <Rd>, <Rm>, LSR <Rs>
```

and is always the preferred disassembly.

Assembler Symbols

<c>
See [Standard assembler syntax fields](#).

<q>
See [Standard assembler syntax fields](#).

<Rd>
Is the general-purpose destination register, encoded in the “Rd” field.

<Rm>
Is the first general-purpose source register, encoded in the “Rm” field.

<Rs>
Is the second general-purpose source register holding a shift amount in its bottom 8 bits, encoded in the “Rs” field.

<Rdm>
Is the first general-purpose source register and the destination register, encoded in the “Rdm” field.

Operation

The description of [MOV, MOVS \(register-shifted register\)](#) gives the operational pseudocode for this instruction.

C5.1.106 MCR

Move to System register from general-purpose register or execute a System instruction. This instruction copies the value of a general-purpose register to a System register, or executes a System instruction.

The System register and System instruction descriptions identify valid encodings for this instruction. Other encodings are UNDEFINED. For more information see [About the AArch32 System register interface](#) and [General behavior of System registers](#).

In an implementation that includes EL2, MCR accesses to System registers can be trapped to Hyp mode, meaning that an attempt to execute an MCR instruction in a Non-secure mode other than Hyp mode, that would be permitted in the absence of the Hyp trap controls, generates a Hyp Trap exception. For more information, see [EL2 configurable instruction enables, disables, and traps](#).

Because of the range of possible traps to Hyp mode, the MCR pseudocode does not show these possible traps.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1).

A1

Encoding

MCR{<c>}{<q>} <coproc>, {#}<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2>}

Decode for this encoding

```
let t : integer = UInt(Rt);
let cp : integer = if cp15 == '0' then 14 else 15;
// Armv8-A removes UNPREDICTABLE for R13
if t == 15 then UnpredictableProcedure(); end;
```

T1

Encoding

MCR{<c>}{<q>} <coproc>, {#}<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2>}

Decode for this encoding

```
let t : integer = UInt(Rt);
let cp : integer = if cp15 == '0' then 14 else 15;
// Armv8-A removes UNPREDICTABLE for R13
if t == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<coproc>

Is the System register encoding space, encoded in “cp15”:

cp15	<coproc>
0	p14
1	p15

<opc1>

Is the opc1 parameter within the System register encoding space, in the range 0 to 7, encoded in the “opc1” field.

<Rt>

Is the general-purpose register to be transferred, encoded in the “Rt” field.

<CRn>

Is the CRn parameter within the System register encoding space, in the range c0 to c15, encoded in the “CRn” field.

<CRm>

Is the CRm parameter within the System register encoding space, in the range c0 to c15, encoded in the “CRm” field.

<opc2>

Is the opc2 parameter within the System register encoding space, in the range 0 to 7, encoded in the “opc2” field.

The possible values of { <coproc>, <opc1>, <CRn>, <CRm>, <opc2> } encode the entire System register and System instruction encoding space. Not all of this space is allocated, and the System register and System instruction descriptions identify the allocated encodings.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    AArch32_SysRegWrite(cp, ThisInstr(), t);
end;
```

C5.1.107 MCRR

Move to System register from two general-purpose registers. This instruction copies the values of two general-purpose registers to a System register.

The System register descriptions identify valid encodings for this instruction. Other encodings are UNDEFINED. For more information see [About the AArch32 System register interface](#) and [General behavior of System registers](#).

In an implementation that includes EL2, MCRR accesses to System registers can be trapped to Hyp mode, meaning that an attempt to execute an MCRR instruction in a Non-secure mode other than Hyp mode, that would be permitted in the absence of the Hyp trap controls, generates a Hyp Trap exception. For more information, see [EL2 configurable instruction enables, disables, and traps](#).

Because of the range of possible traps to Hyp mode, the MCRR pseudocode does not show these possible traps.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1).

A1

Encoding

MCRR{<c>}{<q>} <coproc>, {#}<opc1>, <Rt>, <Rt2>, <CRm>

Decode for this encoding

```
let t : integer = UInt(Rt);
let t2 : integer = UInt(Rt2);
let cp : integer = if cp15 == '0' then 14 else 15;
if t == 15 || t2 == 15 then UnpredictableProcedure(); end;
// Armv8-A removes UNPREDICTABLE for R13
```

T1

Encoding

MCRR{<c>}{<q>} <coproc>, {#}<opc1>, <Rt>, <Rt2>, <CRm>

Decode for this encoding

```
let t : integer = UInt(Rt);
let t2 : integer = UInt(Rt2);
let cp : integer = if cp15 == '0' then 14 else 15;
if t == 15 || t2 == 15 then UnpredictableProcedure(); end;
// Armv8-A removes UNPREDICTABLE for R13
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<coproc>

Is the System register encoding space, encoded in “cp15”:

cp15	<coproc>
0	p14
1	p15

<opc1>

Is the opc1 parameter within the System register encoding space, in the range 0 to 15, encoded in the “opc1” field.

<Rt>

Is the first general-purpose register that is transferred into, encoded in the “Rt” field.

<Rt2>

Is the second general-purpose register that is transferred into, encoded in the “Rt2” field.

<CRm>

Is the CRm parameter within the System register encoding space, in the range c0 to c15, encoded in the “CRm” field.

The possible values of { <coproc>, <opc1>, <CRm> } encode the entire System register encoding space. Not all of this space is allocated, and the System register descriptions identify the allocated encodings.

For the permitted uses of these instructions, as described in this manual, <Rt2> transfers bits[63:32] of the selected System register, while <Rt> transfers bits[31:0].

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    AArch32_SysRegWrite64(cp, ThisInstr(), t, t2);
end;
```

C5.1.108 MLA, MLAS

Multiply Accumulate multiplies two register values, and adds a third register value. The least significant 32 bits of the result are written to the destination register. These 32 bits do not depend on whether the source register values are considered to be signed values or unsigned values.

In an A32 instruction, the condition flags can optionally be updated based on the result. Use of this option adversely affects performance on many implementations.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding for the Flag setting variant

Applies when (S == 1)

MLAS{<c>}{<q>} <Rd>, <Rn>, <Rm>, <Ra>

Encoding for the Not flag setting variant

Applies when (S == 0)

MLA{<c>}{<q>} <Rd>, <Rn>, <Rm>, <Ra>

Decode for all variants of this encoding

```

let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let a : integer = UInt(Ra);
let setflags : boolean = (S == '1');
if d == 15 || n == 15 || m == 15 || a == 15 then UnpredictableProcedure(); end;

```

T1

Encoding

MLA{<c>}{<q>} <Rd>, <Rn>, <Rm>, <Ra>

Decode for this encoding

```

if Ra == '1111' then See("MUL"); end;
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let a : integer = UInt(Ra);
let setflags : boolean = FALSE;
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;

```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rd>

Is the general-purpose destination register, encoded in the “Rd” field.

<Rn>

Is the first general-purpose source register holding the multiplicand, encoded in the “Rn” field.

<Rm>

Is the second general-purpose source register holding the multiplier, encoded in the “Rm” field.

<Ra>

Is the third general-purpose source register holding the addend, encoded in the “Ra” field.

Operation

```

if ConditionPassed() then
    EncodingSpecificOperations();
    let operand1 : integer = SInt(R(n)); // operand1 = UInt(R[n]) produces the same final results
    let operand2 : integer = SInt(R(m)); // operand2 = UInt(R[m]) produces the same final results
    let addend : integer = SInt(R(a)); // addend = UInt(R[a]) produces the same final results
    let result : integer = operand1 * operand2 + addend;
    R(d) = result[31:0];
    if setflags then
        PSTATE.N = result[31];
        PSTATE.Z = IsZeroBit{32}(result[31:0]);
        // PSTATE.C, PSTATE.V unchanged
    end;
end;

```

C5.1.109 MLS

Multiply and Subtract multiplies two register values, and subtracts the product from a third register value. The least significant 32 bits of the result are written to the destination register. These 32 bits do not depend on whether the source register values are considered to be signed values or unsigned values.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

MLS{<c>}{<q>} <Rd>, <Rn>, <Rm>, <Ra>

Decode for this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let a : integer = UInt(Ra);
if d == 15 || n == 15 || m == 15 || a == 15 then UnpredictableProcedure(); end;
```

T1

Encoding

MLS{<c>}{<q>} <Rd>, <Rn>, <Rm>, <Ra>

Decode for this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let a : integer = UInt(Ra);
if d == 15 || n == 15 || m == 15 || a == 15 then UnpredictableProcedure(); end;
// Armv8-A removes UNPREDICTABLE for R13
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rd>

Is the general-purpose destination register, encoded in the “Rd” field.

<Rn>

Is the first general-purpose source register holding the multiplicand, encoded in the “Rn” field.

<Rm>

Is the second general-purpose source register holding the multiplier, encoded in the “Rm” field.

<Ra>

Is the third general-purpose source register holding the minuend, encoded in the “Ra” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let operand1 : integer = SInt(R(n)); // operand1 = UInt(R[n]) produces the same final results
    let operand2 : integer = SInt(R(m)); // operand2 = UInt(R[m]) produces the same final results
    let addend : integer = SInt(R(a)); // addend = UInt(R[a]) produces the same final results
    let result : integer = addend - operand1 * operand2;
    R(d) = result[31:0];
end;
```

C5.1.110 MOV, MOVS (immediate)

Move (immediate) writes an immediate value to the destination register.

If the destination register is not the PC, the MOVS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. Arm deprecates any use of these encodings. However, when the destination register is the PC:

- The MOV variant of the instruction is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC](#).
- The MOVS variant of the instruction performs an exception return without the use of the stack. In this case:
 - The PE branches to the address written to the PC, and restores **PSTATE** from SPSR_<current_mode>.
 - The PE checks SPSR_<current_mode> for an illegal return event. See [Illegal return events from AArch32 state](#).
 - The instruction is UNDEFINED in Hyp mode.
 - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

It has encodings from the following instruction sets: A32 ([A1](#) and [A2](#)) and T32 ([T1](#), [T2](#), and [T3](#)).

A1

Encoding for the MOV variant

Applies when (S == 0)

MOV{<c>}{<q>} <Rd>, #<const>

Encoding for the MOVS variant

Applies when (S == 1)

MOVS{<c>}{<q>} <Rd>, #<const>

Decode for all variants of this encoding

```
let d : integer = UInt(Rd);
let setflags : boolean = (S == '1');
let (imm32, carry) : (bits(32), bit) = A32ExpandImm_C(imm12, PSTATE.C);
```

A2

Encoding

MOV{<c>}{<q>} <Rd>, #<imm16> // (<imm16> can not be represented in A1)

MOVW{<c>}{<q>} <Rd>, #<imm16> // (<imm16> can be represented in A1)

Decode for this encoding

```
let d : integer = UInt(Rd);
let setflags : boolean = FALSE;
let imm32 : bits(32) = ZeroExtend{}(imm4::imm12);
let carry : bit = ARBITRARY : bit;
if d == 15 then UnpredictableProcedure(); end;
```

T1

Encoding

```
MOV<c>{<q>} <Rd>, #<imm8> // (InITBlock())
```

```
MOVS{<q>} <Rd>, #<imm8> // (Outside IT block)
```

Decode for this encoding

```
let d : integer = UInt(Rd);
let setflags : boolean = !InITBlock();
let imm32 : bits(32) = ZeroExtend{}(imm8);
let carry : bit = PSTATE.C;
```

T2

Encoding for the MOV variant

Applies when (S == 0)

```
MOV{<c>}{<q>} <Rd>, #<const>
```

```
MOV<c>.W <Rd>, #<const> // (Inside IT block, and <Rd>, <const> can be represented in T1)
```

Encoding for the MOVS variant

Applies when (S == 1)

```
MOVS{<c>}{<q>} <Rd>, #<const>
```

```
MOVS.W <Rd>, #<const> // (Outside IT block, and <Rd>, <const> can be represented in T1)
```

Decode for all variants of this encoding

```
let d : integer = UInt(Rd);
let setflags : boolean = (S == '1');
let (imm32, carry) : (bits(32), bit) = T32ExpandImm_C(i::imm3::imm8, PSTATE.C);
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 then UnpredictableProcedure(); end;
```

T3

Encoding

```
MOV{<c>}{<q>} <Rd>, #<imm16> // (<imm16> cannot be represented in T1 or T2)
```

```
MOVW{<c>}{<q>} <Rd>, #<imm16> // (<imm16> can be represented in T1 or T2)
```

Decode for this encoding

```
let d : integer = UInt(Rd);
let setflags : boolean = FALSE;
let imm32 : bits(32) = ZeroExtend{}(imm4::i::imm3::imm8);
let carry : bit = ARBITRARY : bit;
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rd>

For the “A1 MOV” and “A1 MOVS” variants: is the general-purpose destination register, encoded in the “Rd” field. Arm deprecates using the PC as the destination register, but if the PC is used:

- For the MOV variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC](#).
- For the MOVS variant, the instruction performs an exception return, that restores [PSTATE](#) from `SPSR_<current_mode>`.

For the “A2”, “T1”, “T2 MOV”, “T2 MOVS”, and “T3” variants: is the general-purpose destination register, encoded in the “Rd” field.

<const>

For the “A1 MOV” and “A1 MOVS” variants: an immediate value. See [Modified immediate constants in A32 instructions](#) for the range of values.

For the “T2 MOV” and “T2 MOVS” variants: an immediate value. See [Modified immediate constants in T32 instructions](#) for the range of values.

<imm16>

For the “A2” variant: is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the “imm4:imm12” field.

For the “T3” variant: is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the “imm4:i:imm3:imm8” field.

<imm8>

Is a 8-bit unsigned immediate, in the range 0 to 255, encoded in the “imm8” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let result : bits(32) = imm32;
    if d == 15 then          // Can only occur for encoding A1
        if setflags then
            ALUExceptionReturn(result);
        else
            ALUWritePC(result);
        end;
    else
        R(d) = result;
        if setflags then
            PSTATE.N = result[31];
            PSTATE.Z = IsZeroBit{32}(result);
            PSTATE.C = carry;
            // PSTATE.V unchanged
        end;
    end;
end;
```

C5.1.111 MOV, MOVS (register)

Move (register) copies a value from a register to the destination register.

If the destination register is not the PC, the MOVS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. If the destination register is the PC:

- The MOV variant of the instruction is a branch. In the T32 instruction set (encoding T1) this is a simple branch, and in the A32 instruction set it is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC](#).
- The MOVS variant of the instruction performs an exception return without the use of the stack. In this case:
 - The PE branches to the address written to the PC, and restores [PSTATE](#) from SPSR_<current_mode>.
 - The PE checks SPSR_<current_mode> for an illegal return event. See [Illegal return events from AArch32 state](#).
 - The instruction is UNDEFINED in Hyp mode.
 - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

This instruction is used by the aliases [ASRS \(immediate\)](#), [ASR \(immediate\)](#), [LSLS \(immediate\)](#), [LSL \(immediate\)](#), [LSRS \(immediate\)](#), [LSR \(immediate\)](#), [RORS \(immediate\)](#), [ROR \(immediate\)](#), [RRXS](#), and [RRX](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#), [T2](#), and [T3](#)).

A1

Encoding for the MOV, rotate right with extend variant

Applies when (S == 0 && imm5 == 00000 && stype == 11)

MOV{<c>}{<q>} <Rd>, <Rm>, RRX

Encoding for the MOV, shift or rotate by value variant

Applies when (S == 0 && !(imm5 == 00000 && stype == 11))

MOV{<c>}{<q>} <Rd>, <Rm> {, <shift> #<amount>}

Encoding for the MOVS, rotate right with extend variant

Applies when (S == 1 && imm5 == 00000 && stype == 11)

MOVS{<c>}{<q>} <Rd>, <Rm>, RRX

Encoding for the MOVS, shift or rotate by value variant

Applies when (S == 1 && !(imm5 == 00000 && stype == 11))

MOVS{<c>}{<q>} <Rd>, <Rm> {, <shift> #<amount>}

Decode for all variants of this encoding

```
let d : integer = UInt(Rd);
let m : integer = UInt(Rm);
let setflags : boolean = (S == '1');
let (shift_t, shift_n) : (SRTYPE, integer) = DecodeImmShift(stype, imm5);
```

T1

Encoding

MOV{<c>}{<q>} <Rd>, <Rm>

Decode for this encoding

```
let d : integer = UInt(D::Rd);
let m : integer = UInt(Rm);
let setflags : boolean = FALSE;
let shift_t : SRTYPE = SRTYPE_LSL;
let shift_n : integer = 0;
if d == 15 && InITBlock() && !LastInITBlock() then UnpredictableProcedure(); end;
```

T2

Encoding

MOV<c>{<q>} <Rd>, <Rm> {, <shift> #<amount>} // (InITBlock())

MOVS{<q>} <Rd>, <Rm> {, <shift> #<amount>} // (Outside IT block)

Decode for this encoding

```
let d : integer = UInt(Rd);
let m : integer = UInt(Rm);
let setflags : boolean = !InITBlock();
let (shift_t, shift_n) : (SRTYPE, integer) = DecodeImmShift(op, imm5);
if op == '00' && imm5 == '00000' && InITBlock() then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If op == '00' && imm5 == '00000' && InITBlock(), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passed its condition code check.
- The instruction executes as NOP, as if it failed its condition code check.
- The instruction executes as MOV Rd, Rm.

T3

Encoding for the MOV, rotate right with extend variant

Applies when (S == 0 && imm3 == 000 && imm2 == 00 && stype == 11)

```
MOV{<c>}{<q>} <Rd>, <Rm>, RRX
```

Encoding for the MOV, shift or rotate by value variant

Applies when (S == 0 && !(imm3 == 000 && imm2 == 00 && stype == 11))

```
MOV{<c>}{<q>} <Rd>, <Rm> {, <shift> #<amount>}
```

```
MOV{<c>}.W <Rd>, <Rm> {, LSL #0} // (<Rd>, <Rm> can be represented in T1)
```

```
MOV<c>.W <Rd>, <Rm> {, <shift> #<amount>} // (Inside IT block, and <Rd>, <Rm>, <shift>, <amount> can be  

↪ represented in T2)
```

Encoding for the MOVS, rotate right with extend variant

Applies when (S == 1 && imm3 == 000 && imm2 == 00 && stype == 11)

```
MOVS{<c>}{<q>} <Rd>, <Rm>, RRX
```

Encoding for the MOVS, shift or rotate by value variant

Applies when (S == 1 && !(imm3 == 000 && imm2 == 00 && stype == 11))

```
MOVS{<c>}{<q>} <Rd>, <Rm> {, <shift> #<amount>}
```

```
MOVS.W <Rd>, <Rm> {, <shift> #<amount>} // (Outside IT block, and <Rd>, <Rm>, <shift>, <amount> can be  

↪ represented in T1 or T2)
```

Decode for all variants of this encoding

```
let d : integer = UInt(Rd);
let m : integer = UInt(Rm);
let setflags : boolean = (S == '1');
let (shift_t, shift_n) : (SRTYPE, integer) = DecodeImmShift(stype, imm3::imm2);
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 || m == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rd>

For the “A1 MOV, rotate right with extend”, “A1 MOV, shift or rotate by value”, “A1 MOVS, rotate right with extend”, and “A1 MOVS, shift or rotate by value” variants: is the general-purpose destination register, encoded in the “Rd” field. If the PC is used:

- For the MOV variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC](#). Arm deprecates use of the instruction if <Rn> is the PC.
- For the MOVS variant, the instruction performs an exception return, that restores [PSTATE](#) from SPSR_<current_mode>. Arm deprecates use of the instruction if <Rn> is not the LR, or if the optional shift or RRX argument is specified.

For the “T1” variant: is the general-purpose destination register, encoded in the “D:Rd” field. If the PC is used:

- The instruction causes a branch to the address moved to the PC. This is a simple branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC](#).
- The instruction must either be outside an IT block or the last instruction of an IT block.

For the “T2”, “T3 MOV, rotate right with extend”, “T3 MOV, shift or rotate by value”, “T3 MOVS, rotate right with extend”, and “T3 MOVS, shift or rotate by value” variants: is the general-purpose destination register, encoded in the “Rd” field.

<Rm>

For the “A1 MOV, rotate right with extend”, “A1 MOV, shift or rotate by value”, “A1 MOVS, rotate right with extend”, “A1 MOVS, shift or rotate by value”, and “T1” variants: is the general-purpose source register, encoded in the “Rm” field. The PC can be used. Arm deprecates use of the instruction if <Rd> is the PC.

For the “T2”, “T3 MOV, rotate right with extend”, “T3 MOV, shift or rotate by value”, “T3 MOVS, rotate right with extend”, and “T3 MOVS, shift or rotate by value” variants: is the general-purpose source register, encoded in the “Rm” field.

<shift>

For the “A1 MOV, shift or rotate by value”, “A1 MOVS, shift or rotate by value”, “T3 MOV, shift or rotate by value”, and “T3 MOVS, shift or rotate by value” variants: is the type of shift to be applied to the source register, encoded in “stype”:

stype	<shift>
00	LSL
01	LSR
10	ASR
11	ROR

For the “T2” variant: is the type of shift to be applied to the source register, encoded in “op”:

op	<shift>
00	LSL
01	LSR
10	ASR

<amount>

For the “A1 MOV, shift or rotate by value” and “A1 MOVs, shift or rotate by value” variants: is the shift amount, in the range 0 to 31 (when <shift> = LSL), or 1 to 31 (when <shift> = ROR) or 1 to 32 (when <shift> = LSR or ASR), encoded in the “imm5” field as <amount> modulo 32.

For the “T2” variant: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR), encoded in the “imm5” field as <amount> modulo 32.

For the “T3 MOV, shift or rotate by value” and “T3 MOVs, shift or rotate by value” variants: is the shift amount, in the range 0 to 31 (when <shift> = LSL) or 1 to 31 (when <shift> = ROR), or 1 to 32 (when <shift> = LSR or ASR), encoded in the “imm3:imm2” field as <amount> modulo 32.

Alias Conditions

Alias	Of variant	Is preferred when
ASRS (immediate)	T3 MOVs, shift or rotate by value, A1 MOVs, shift or rotate by value	S == '1' && stype == '10'
ASRS (immediate)	T2	op == '10' && !InITBlock()

RRX	A1 MOV, rotate right with extend	S == '0' && imm5 == '00000' && stype == '11'
RRX	T3 MOV, rotate right with extend	S == '0' && imm3 == '000' && imm2 == '00' && stype == '11'

Operation

```

if ConditionPassed() then
    EncodingSpecificOperations();
    let (shifted, carry) : (bits(32), bit) = Shift_C{32}(R(m), shift_t, shift_n, PSTATE.C);
    let result : bits(32) = shifted;
    if d == 15 then
        if setflags then
            ALUEXCEPTIONReturn(result);
        else
            ALUWritePC(result);
        end;
    else
        R(d) = result;
        if setflags then
            PSTATE.N = result[31];
            PSTATE.Z = IsZeroBit{32}(result);
            PSTATE.C = carry;
            // PSTATE.V unchanged

```

```
        end;  
    end;  
end;
```

C5.1.112 MOV, MOVS (register-shifted register)

Move (register-shifted register) copies a register-shifted register value to the destination register. It can optionally update the condition flags based on the value.

This instruction is used by the aliases [ASRS \(register\)](#), [ASR \(register\)](#), [LSLS \(register\)](#), [LSL \(register\)](#), [LSRS \(register\)](#), [LSR \(register\)](#), [RORS \(register\)](#), and [ROR \(register\)](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#) and [T2](#)).

A1

Encoding for the Flag setting variant

Applies when (S == 1)

```
MOV{<c>}{<q>} <Rd>, <Rm>, <shift> <Rs>
```

Encoding for the Not flag setting variant

Applies when (S == 0)

```
MOV{<c>}{<q>} <Rd>, <Rm>, <shift> <Rs>
```

Decode for all variants of this encoding

```
let d : integer = UInt(Rd);
let m : integer = UInt(Rm);
let s : integer = UInt(Rs);
let setflags : boolean = (S == '1');
let shift_t : SRTYPE = DecodeRegShift(stype);
if d == 15 || m == 15 || s == 15 then UnpredictableProcedure(); end;
```

T1

Encoding for the Arithmetic shift right variant

Applies when (op == 0100)

```
MOV<c>{<q>} <Rdm>, <Rdm>, ASR <Rs> // (InITBlock())
```

```
MOV{<q>} <Rdm>, <Rdm>, ASR <Rs> // (Outside IT block)
```

Encoding for the Logical shift left variant

Applies when (op == 0010)

```
MOV<c>{<q>} <Rdm>, <Rdm>, LSL <Rs> // (InITBlock())

MOV<c>{<q>} <Rdm>, <Rdm>, LSL <Rs> // (Outside IT block)
```

Encoding for the Logical shift right variant

Applies when (op == 0011)

```
MOV<c>{<q>} <Rdm>, <Rdm>, LSR <Rs> // (InITBlock())

MOV<c>{<q>} <Rdm>, <Rdm>, LSR <Rs> // (Outside IT block)
```

Encoding for the Rotate right variant

Applies when (op == 0111)

```
MOV<c>{<q>} <Rdm>, <Rdm>, ROR <Rs> // (InITBlock())

MOV<c>{<q>} <Rdm>, <Rdm>, ROR <Rs> // (Outside IT block)
```

Decode for all variants of this encoding

```
if ! op IN {'0010', '0011', '0100', '0111'} then See("Related encodings"); end;
let d : integer = UInt(Rdm);
let m : integer = UInt(Rdm);
let s : integer = UInt(Rs);
let setflags : boolean = !InITBlock();
let shift_t : SRTYPE = DecodeRegShift(op[2]:op[0]);
```

T2

Encoding for the Flag setting variant

Applies when (S == 1)

```
MOV<c>{<q>} <Rd>, <Rm>, <shift> <Rs>

MOV<c>.W <Rd>, <Rm>, <shift> <Rs> // (Outside IT block, and <Rd>, <Rm>, <shift>, <Rs> can be represented
↳in T1)
```

Encoding for the Not flag setting variant

Applies when (S == 0)

```
MOV{<c>}{<q>} <Rd>, <Rm>, <shift> <Rs>

MOV<c>.W <Rd>, <Rm>, <shift> <Rs> // (Inside IT block, and <Rd>, <Rm>, <shift>, <Rs> can be represented
↳in T1)
```

Decode for all variants of this encoding

```
let d : integer = UInt(Rd);
let m : integer = UInt(Rm);
let s : integer = UInt(Rs);
let setflags : boolean = (S == '1');
let shift_t : SRTYPE = DecodeRegShift(stype);
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 || m == 15 || s == 15 then UnpredictableProcedure(); end;
```

Related encodings: In encoding T1, for an `op` field value that is not described above, see [Data-processing \(two low registers\)](#).

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rd>

Is the general-purpose destination register, encoded in the “Rd” field.

<Rm>

Is the general-purpose source register, encoded in the “Rm” field.

<shift>

Is the type of shift to be applied to the second source register, encoded in “stype”:

stype	<shift>
00	LSL
01	LSR
10	ASR
11	ROR

<Rs>

Is the general-purpose source register holding a shift amount in its bottom 8 bits, encoded in the “Rs” field.

<Rdm>

Is the general-purpose source register and the destination register, encoded in the “Rdm” field.

Alias Conditions

Alias	Of variant	Is preferred when
ASRS (register)	A1 Flag setting	S == '1' && stype == '10'
ASRS (register)	T1 Arithmetic shift right	op == '0100' && !InITBlock()
ASRS (register)	T2 Flag setting	stype == '10' && S == '1'
ASRS (register)	T2 Flag setting	Unconditionally
ASR (register)	A1 Not flag setting	S == '0' && stype == '10'
ASR (register)	T1 Arithmetic shift right	op == '0100' && InITBlock()
ASR (register)	T2 Not flag setting	stype == '10' && S == '0'
ASR (register)	T2 Not flag setting	Unconditionally
LSLS (register)	A1 Flag setting	S == '1' && stype == '00'
LSLS (register)	T1 Logical shift left	op == '0010' && !InITBlock()
LSLS (register)	T2 Flag setting	stype == '00' && S == '1'
LSLS (register)	T2 Flag setting	Unconditionally
LSL (register)	A1 Not flag setting	S == '0' && stype == '00'
LSL (register)	T1 Logical shift left	op == '0010' && InITBlock()
LSL (register)	T2 Not flag setting	stype == '00' && S == '0'
LSL (register)	T2 Not flag setting	Unconditionally
LSRS (register)	A1 Flag setting	S == '1' && stype == '01'
LSRS (register)	T1 Logical shift right	op == '0011' && !InITBlock()
LSRS (register)	T2 Flag setting	stype == '01' && S == '1'
LSRS (register)	T2 Flag setting	Unconditionally
LSR (register)	A1 Not flag setting	S == '0' && stype == '01'
LSR (register)	T1 Logical shift right	op == '0011' && InITBlock()
LSR (register)	T2 Not flag setting	stype == '01' && S == '0'
LSR (register)	T2 Not flag setting	Unconditionally
RORS (register)	A1 Flag setting	S == '1' && stype == '11'
RORS (register)	T1 Rotate right	op == '0111' && !InITBlock()
RORS (register)	T2 Flag setting	stype == '11' && S == '1'
RORS (register)	T2 Flag setting	Unconditionally
ROR (register)	A1 Not flag setting	S == '0' && stype == '11'
ROR (register)	T1 Rotate right	op == '0111' && InITBlock()
ROR (register)	T2 Not flag setting	stype == '11' && S == '0'
ROR (register)	T2 Not flag setting	Unconditionally

Operation

```

if ConditionPassed() then
    EncodingSpecificOperations();
    let shift_n : integer = UInt(R(s)[7:0]);
    let (result, carry) : (bits(32), bit) = Shift_C[32](R(m), shift_t, shift_n, PSTATE.C);
    R(d) = result;
    if setflags then
        PSTATE.N = result[31];
        PSTATE.Z = IsZeroBit[32](result);

```

```
        PSTATE.C = carry;  
        // PSTATE.V unchanged  
    end;  
end;
```

C5.1.113 MOV_T

Move Top writes an immediate value to the top halfword of the destination register. It does not affect the contents of the bottom halfword.

It has encodings from the following instruction sets: A32 (**A1**) and T32 (**T1**).

A1

Encoding

MOV_T{<c>}{<q>} <Rd>, #<imm16>

Decode for this encoding

```
let d : integer = UInt(Rd);
let imm16 : bits(16) = imm4::imm12;
if d == 15 then UnpredictableProcedure(); end;
```

T1

Encoding

MOV_T{<c>}{<q>} <Rd>, #<imm16>

Decode for this encoding

```
let d : integer = UInt(Rd);
let imm16 : bits(16) = imm4::i::imm3::imm8;
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rd>

Is the general-purpose destination register, encoded in the “Rd” field.

<imm16>

For the “A1” variant: is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the “imm4:imm12” field.

For the “T1” variant: is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the “imm4:i:imm3:imm8” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    R(d)[31:16] = imm16;
    // R[d]<15:0> unchanged
end;
```

C5.1.114 MRC

Move to general-purpose register from System register. This instruction copies the value of a System register to a general-purpose register.

The System register descriptions identify valid encodings for this instruction. Other encodings are UNDEFINED. For more information see [About the AArch32 System register interface](#) and [General behavior of System registers](#).

In an implementation that includes EL2, MRC accesses to system control registers can be trapped to Hyp mode, meaning that an attempt to execute an MRC instruction in a Non-secure mode other than Hyp mode, that would be permitted in the absence of the Hyp trap controls, generates a Hyp Trap exception. For more information, see [EL2 configurable instruction enables, disables, and traps](#).

Because of the range of possible traps to Hyp mode, the MRC pseudocode does not show these possible traps.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

MRC{<c>}{<q>} <coproc>, {#}<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2>}

Decode for this encoding

```
let t : integer = UInt(Rt);
let cp : integer = if cp15 == '0' then 14 else 15;
// Armv8-A removes UNPREDICTABLE for R13
```

T1

Encoding

MRC{<c>}{<q>} <coproc>, {#}<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2>}

Decode for this encoding

```
let t : integer = UInt(Rt);
let cp : integer = if cp15 == '0' then 14 else 15;
// Armv8-A removes UNPREDICTABLE for R13
```

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<coproc>

Is the System register encoding space, encoded in “cp15”:

cp15	<coproc>
0	p14
1	p15

<opc1>

Is the opc1 parameter within the System register encoding space, in the range 0 to 7, encoded in the “opc1” field.

<Rt>

Is the general-purpose register to be transferred or APSR_nzcv (encoded as 0b1111), encoded in the “Rt” field. If APSR_nzcv is used, bits [31:28] of the transferred value are written to the [PSTATE](#) condition flags.

<CRn>

Is the CRn parameter within the System register encoding space, in the range c0 to c15, encoded in the “CRn” field.

<CRm>

Is the CRm parameter within the System register encoding space, in the range c0 to c15, encoded in the “CRm” field.

<opc2>

Is the opc2 parameter within the System register encoding space, in the range 0 to 7, encoded in the “opc2” field.

The possible values of { <coproc>, <opc1>, <CRn>, <CRm>, <opc2> } encode the entire System register and System instruction encoding space. Not all of this space is allocated, and the System register and System instruction descriptions identify the allocated encodings.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();

    if t != 15 || AArch32_SysRegReadCanWriteAPSR(cp, ThisInstr()) then
        AArch32_SysRegRead(cp, ThisInstr(), t);
    else
        UnpredictableProcedure();
    end;
end;
```

C5.1.115 MRRC

Move to two general-purpose registers from System register. This instruction copies the value of a System register to two general-purpose registers.

The System register descriptions identify valid encodings for this instruction. Other encodings are UNDEFINED. For more information see [About the AArch32 System register interface](#) and [General behavior of System registers](#).

In an implementation that includes EL2, MRRC accesses to System registers can be trapped to Hyp mode, meaning that an attempt to execute an MRRC instruction in a Non-secure mode other than Hyp mode, that would be permitted in the absence of the Hyp trap controls, generates a Hyp Trap exception. For more information, see [EL2 configurable instruction enables, disables, and traps](#).

Because of the range of possible traps to Hyp mode, the MRRC pseudocode does not show these possible traps.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1).

A1

Encoding

MRRC{<c>}{<q>} <coproc>, {#}<opc1>, <Rt>, <Rt2>, <CRm>

Decode for this encoding

```
let t : integer = UInt(Rt);
let t2 : integer = UInt(Rt2);
let cp : integer = if cp15 == '0' then 14 else 15;
// Armv8-A removes UNPREDICTABLE for R13
if t == 15 || t2 == 15 || t == t2 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If $t == t2$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The value in the destination register is UNKNOWN.

T1

Encoding

MRRC{<c>}{<q>} <coproc>, {#}<opc1>, <Rt>, <Rt2>, <CRm>

Decode for this encoding

```
let t : integer = UInt(Rt);
let t2 : integer = UInt(Rt2);
let cp : integer = if cp15 == '0' then 14 else 15;
// Armv8-A removes UNPREDICTABLE for R13
if t == 15 || t2 == 15 || t == t2 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `t == t2`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The value in the destination register is UNKNOWN.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<coproc>

Is the System register encoding space, encoded in “cp15”:

cp15	<coproc>
0	p14
1	p15

<opc1>

Is the `opc1` parameter within the System register encoding space, in the range 0 to 15, encoded in the “opc1” field.

<Rt>

Is the first general-purpose register that is transferred into, encoded in the “Rt” field.

<Rt2>

Is the second general-purpose register that is transferred into, encoded in the “Rt2” field.

<CRm>

Is the `CRm` parameter within the System register encoding space, in the range c0 to c15, encoded in the “CRm” field.

The possible values of { <coproc>, <opc1>, <CRm> } encode the entire System register encoding space. Not all of this space is allocated, and the System register descriptions identify the allocated encodings.

For the permitted uses of these instructions, as described in this manual, <Rt2> transfers bits[63:32] of the selected System register, while <Rt> transfers bits[31:0].

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    AArch32_SysRegRead64(cp, ThisInstr(), t, t2);
end;
```

C5.1.116 MRS

Move Special register to general-purpose register moves the value of the [APSR](#), [CPSR](#), or [SPSR](#) `<current_mode>` into a general-purpose register.

Arm recommends the [APSR](#) form when only the N, Z, C, V, Q, and GE[3:0] bits are being written. For more information, see [APSR](#).

An MRS that accesses the [SPSRs](#) is UNPREDICTABLE if executed in User mode or System mode.

An MRS that is executed in User mode and accesses the [CPSR](#) returns an UNKNOWN value for the [CPSR](#). {E, A, I, F, M} fields.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

MRS{<c>}{<q>} <Rd>, <spec_reg>

Decode for this encoding

```
let d : integer = UInt(Rd);
let read_spsr : boolean = (R == '1');
if d == 15 then UnpredictableProcedure(); end;
```

T1

Encoding

MRS{<c>}{<q>} <Rd>, <spec_reg>

Decode for this encoding

```
let d : integer = UInt(Rd);
let read_spsr : boolean = (R == '1');
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rd>

Is the general-purpose destination register, encoded in the “Rd” field.

<spec_reg>

Is the special register to be accessed, encoded in “R”:

R	<spec_reg>
0	CPSR APSR
1	SPSR

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    if read_spsr then
        if PSTATE.M IN {M32_User,M32_System} then
            UnpredictableProcedure();
        else
            R(d) = SPSR_curr();
        end;
    else
        // CPSR has same bit assignments as SPSR, but with the IT, J, SS, IL, and T bits masked out.
        let maskval : bits(32) = '11111000 11101111 00000011 11011111';
        var psr_val : bits(32) = GetPSRFromPSTATE{32}(AArch32_NonDebugState) AND maskval;
        if PSTATE.EL == EL0 then
            // If accessed from User mode return UNKNOWN values for E, A, I, F bits, bits<9:6>,
            // and for the M field, bits<4:0>
            psr_val[9:6] = ARBITRARY : bits(4);
            psr_val[4:0] = ARBITRARY : bits(5);
        end;
        R(d) = psr_val;
    end;
end;
```

CONSTRAINED UNPREDICTABLE behavior

If PSTATE.M IN {M32_User, M32_System} && read_spsr, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.

C5.1.117 MRS (Banked register)

Move Banked or Special register to general-purpose register

Move to Register from Banked or Special register moves the value from the Banked general-purpose register or [Saved Program Status Registers \(SPSRs\)](#) of the specified mode, or the value of [ELR_hyp](#), to a general-purpose register.

MRS (Banked register) is UNPREDICTABLE if executed in User mode.

When EL3 is using AArch64, if an MRS (Banked register) instruction that is executed in a Secure EL1 mode would access SPSR_mon, SP_mon, or LR_mon, it is trapped to EL3.

The effect of using an MRS (Banked register) instruction with a register argument that is not valid for the current mode is UNPREDICTABLE. For more information see [Usage restrictions on the Banked register transfer instructions](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

MRS{<c>}{<q>} <Rd>, <banked_reg>

Decode for this encoding

```
let d : integer = UInt(Rd);
let read_spsr : boolean = (R == '1');
if d == 15 then UnpredictableProcedure(); end;
let SYSm : bits(5) = M::M1;
```

T1

Encoding

MRS{<c>}{<q>} <Rd>, <banked_reg>

Decode for this encoding

```
let d : integer = UInt(Rd);
let read_spsr : boolean = (R == '1');
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 then UnpredictableProcedure(); end;
let SYSm : bits(5) = M::M1;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rd>

Is the general-purpose destination register, encoded in the “Rd” field.

<banked_reg>

Is the name of the banked register to be transferred to or from, encoded in “R:M:M1”:

```

CONSTRAINED UNPREDICTABLE behavior

If `PSTATE.EL == EL0`, then one of the following behaviors must occur:

- The instruction is `UNDEFINED`.
- The instruction executes as `NOP`.

C5.1.118 MSR (Banked register)

Move general-purpose register to Banked or Special register

Move to Banked or Special register from general-purpose register moves the value of a general-purpose register to the Banked general-purpose register or [Saved Program Status Registers \(SPSRs\)](#) of the specified mode, or to [ELR_hyp](#).

MSR (Banked register) is UNPREDICTABLE if executed in User mode.

When EL3 is using AArch64, if an MSR (Banked register) instruction that is executed in a Secure EL1 mode would access SPSR_mon, SP_mon, or LR_mon, it is trapped to EL3.

The effect of using an MSR (Banked register) instruction with a register argument that is not valid for the current mode is UNPREDICTABLE. For more information see [Usage restrictions on the Banked register transfer instructions](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

MSR{<c>}{<q>} <banked_reg>, <Rn>

Decode for this encoding

```
let n : integer = UInt(Rn);
let write_spsr : boolean = (R == '1');
if n == 15 then UnpredictableProcedure(); end;
let SYSm : bits(5) = M::M1;
```

T1

Encoding

MSR{<c>}{<q>} <banked_reg>, <Rn>

Decode for this encoding

```
let n : integer = UInt(Rn);
let write_spsr : boolean = (R == '1');
// Armv8-A removes UNPREDICTABLE for R13
if n == 15 then UnpredictableProcedure(); end;
let SYSm : bits(5) = M::M1;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

                Rmode(m, M32_Svc) = R(n);
            when '1010x' => // Access the Abort mode registers
                // LR when SYSm[0] == 0, otherwise SP
                let m : integer = 14 - UInt(SYSm[0]);
                Rmode(m, M32_Abort) = R(n);
            when '1011x' => // Access the Undefined mode registers
                // LR when SYSm[0] == 0, otherwise SP
                let m : integer = 14 - UInt(SYSm[0]);
                Rmode(m, M32_Undef) = R(n);
            when '1110x' => // Access Monitor registers
                // LR when SYSm[0] == 0, otherwise SP
                let m : integer = 14 - UInt(SYSm[0]);
                Rmode(m, M32_Monitor) = R(n);
            when '11110' => // Access ELR_hyp register
                ELR_hyp() = R(n);
            when '11111' => // Access SP_hyp register
                Rmode(13, M32_Hyp) = R(n);
        end;
    else
        case c of
            when Constraint_UNDEF =>
                Undefined();
            when Constraint_NOP, Constraint_UNKNOWN =>
                ExecuteAsNOP();
            when Constraint_ANYREG =>
                WriteAnyAllocatedRegister(R(n));
        end;
    end;
end;
end;
end;
end;

```

CONSTRAINED UNPREDICTABLE behavior

If `PSTATE.EL == EL0`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.

- The instruction executes as `NOP`.

C5.1.119 MSR (immediate)

Move immediate value to Special register moves selected bits of an immediate value to the corresponding bits in the [APSR](#), [CPSR](#), or [SPSR](#)_*<current_mode>*.

Because of the Do-Not-Modify nature of its reserved bits, the immediate form of `MSR` is normally only useful at the Application level for writing to `APSR_nzcvq` (`CPSR_ℱ`).

If an `MSR` (immediate) moves selected bits of an immediate value to the [CPSR](#), the PE checks whether the value being written to `PSTATE.M` is legal. See [Illegal changes to PSTATE.M](#).

An `MSR` (immediate) executed in User mode:

- Is **CONSTRAINED UNPREDICTABLE** if it attempts to update the [SPSR](#).
- Otherwise, does not update any [CPSR](#) field that is accessible only at EL1 or higher,

An `MSR` (immediate) executed in System mode is **CONSTRAINED UNPREDICTABLE** if it attempts to update the [SPSR](#).

The [CPSR.E](#) bit is writable from any mode using an `MSR` instruction. Arm deprecates using this to change its value.

Encoding

Applies when `(!(R == 0 && mask == 0000))`

```
MSR{<c>}{<q>} <spec_reg>, #<imm>
```

Decode for this encoding

```
if mask == '0000' && R == '0' then See("Related encodings"); end;
let imm32 : bits(32) = A32ExpandImm(imm12);
let write_spsr : boolean = (R == '1');
if mask == '0000' then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `mask == '0000' && R == '1'`, then one of the following behaviors must occur:

- The instruction is **UNDEFINED**.
- The instruction executes as **NOP**.

For more information about the **CONSTRAINED UNPREDICTABLE** behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Related encodings: [Move Special Register and Hints \(immediate\)](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<spec_reg>

Is one of:

- APSR_<bits>.
- CPSR_<fields>.
- SPSR_<fields>.

For CPSR and SPSR, <fields> is a sequence of one or more of the following:

- c** mask<0> = '1' to enable writing of bits<7:0> of the destination PSR.
- x** mask<1> = '1' to enable writing of bits<15:8> of the destination PSR.
- s** mask<2> = '1' to enable writing of bits<23:16> of the destination PSR.
- f** mask<3> = '1' to enable writing of bits<31:24> of the destination PSR.

For APSR, <bits> is one of nzcvq, g, or nzcvqg. These map to the following CPSR_<fields> values:

- APSR_nzcvq is the same as CPSR_f (mask == '1000').
- APSR_g is the same as CPSR_s (mask == '0100').
- APSR_nzcvqg is the same as CPSR_fs (mask == '1100').

Arm recommends the APSR_<bits> forms when only the N, Z, C, V, Q, and GE[3:0] bits are being written. For more information, see [The Application Program Status Register, APSR](#).

<imm>

Is an immediate value. See [Modified immediate constants in A32 instructions](#) for the range of values.

Operation

```

if ConditionPassed() then
    EncodingSpecificOperations();
    if write_spsr then
        if PSTATE.M IN {M32_User,M32_System} then
            UnpredictableProcedure();
        else
            SPSRWriteByInstr(imm32, mask);
        end;
    else
        // Attempts to change to an illegal mode will invoke the Illegal Execution state mechanism
        CPSRWriteByInstr(imm32, mask);
    end;
end;

```

CONSTRAINED UNPREDICTABLE behavior

If PSTATE.M IN {M32_User,M32_System} && write_spsr, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.

C5.1.120 MSR (register)

Move general-purpose register to Special register moves selected bits of a general-purpose register to the [APSR](#), [CPSR](#) or [SPSR](#)_*<current_mode>*.

Because of the Do-Not-Modify nature of its reserved bits, a read-modify-write sequence is normally required when the MSR instruction is being used at Application level and its destination is not [APSR_nzcvq](#) ([CPSR_f](#)).

If an MSR (register) moves selected bits of an immediate value to the [CPSR](#), the PE checks whether the value being written to [PSTATE.M](#) is legal. See [Illegal changes to PSTATE.M](#).

An MSR (register) executed in User mode:

- Is UNPREDICTABLE if it attempts to update the [SPSR](#).
- Otherwise, does not update any [CPSR](#) field that is accessible only at EL1 or higher.

An MSR (register) executed in System mode is UNPREDICTABLE if it attempts to update the [SPSR](#).

The [CPSR.E](#) bit is writable from any mode using an MSR instruction. Arm deprecates using this to change its value.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

MSR{<c>}{<q>} <spec_reg>, <Rn>

Decode for this encoding

```
let n : integer = UInt(Rn);
let write_spsr : boolean = (R == '1');
if mask == '0000' then UnpredictableProcedure(); end;
if n == 15 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If mask == '0000', then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.

T1

Encoding

MSR{<c>}{<q>} <spec_reg>, <Rn>

Decode for this encoding

```
let n : integer = UInt(Rn);
let write_spsr : boolean = (R == '1');
if mask == '0000' then UnpredictableProcedure(); end;
// Armv8-A removes UNPREDICTABLE for R13
if n == 15 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `mask == '0000'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<spec_reg>

Is one of:

- APSR_<bits>.
- CPSR_<fields>.
- SPSR_<fields>.

For CPSR and SPSR, <fields> is a sequence of one or more of the following:

c mask<0> = '1' to enable writing of bits<7:0> of the destination PSR.
x mask<1> = '1' to enable writing of bits<15:8> of the destination PSR.
s mask<2> = '1' to enable writing of bits<23:16> of the destination PSR.
f mask<3> = '1' to enable writing of bits<31:24> of the destination PSR.

For APSR, <bits> is one of `nzcvq`, `g`, or `nzcvqg`. These map to the following CPSR_<fields> values:

- APSR_<nzcvq> is the same as CPSR_<f> (mask == '1000').
- APSR_<g> is the same as CPSR_<s> (mask == '0100').
- APSR_<nzcvqg> is the same as CPSR_<fs> (mask == '1100').

Arm recommends the APSR_<bits> forms when only the N, Z, C, V, Q, and GE[3:0] bits are being written. For more information, see [The Application Program Status Register, APSR](#).

<Rn>

Is the general-purpose source register, encoded in the “Rn” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    if write_spsr then
        if PSTATE.M IN {M32_User, M32_System} then
            UnpredictableProcedure();
        else
            SPSRWriteByInstr(R(n), mask);
        end;
```

```
    else
        // Attempts to change to an illegal mode will invoke the Illegal Execution state mechanism
        CPSRWriteByInstr(R(n), mask);
    end;
end;
```

CONSTRAINED UNPREDICTABLE behavior

If `write_spsr && PSTATE.M` IN {M32_User, M32_System}, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.

C5.1.121 MUL, Muls

Multiply multiplies two register values. The least significant 32 bits of the result are written to the destination register. These 32 bits do not depend on whether the source register values are considered to be signed values or unsigned values.

Optionally, it can update the condition flags based on the result. In the T32 instruction set, this option is limited to only a few forms of the instruction. Use of this option adversely affects performance on many implementations.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1 and T2).

A1

Encoding for the Flag setting variant

Applies when (S == 1)

MULS{<c>}{<q>} <Rd>, <Rn>{, <Rm>}

Encoding for the Not flag setting variant

Applies when (S == 0)

MUL{<c>}{<q>} <Rd>, <Rn>{, <Rm>}

Decode for all variants of this encoding

```

let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let setflags : boolean = (S == '1');
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;

```

T1

Encoding

MUL<c>{<q>} <Rdm>, <Rn>{, <Rdm>} // (InITBlock())

MULS{<q>} <Rdm>, <Rn>{, <Rdm>} // (Outside IT block)

Decode for this encoding

```

let d : integer = UInt(Rdm);
let n : integer = UInt(Rn);
let m : integer = UInt(Rdm);
let setflags : boolean = !InITBlock();

```

T2

Encoding

```
MUL{<c>}{<q>} <Rd>, <Rn>{, <Rm>}  
  
MUL<c>.W <Rd>, <Rn>{, <Rm>} // (Inside IT block, and <Rd>, <Rn>, <Rm> can be represented in T1)
```

Decode for this encoding

```
let d : integer = UInt(Rd);  
let n : integer = UInt(Rn);  
let m : integer = UInt(Rm);  
let setflags : boolean = FALSE;  
// Armv8-A removes UNPREDICTABLE for R13  
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

- <c>
See [Standard assembler syntax fields](#).
- <q>
See [Standard assembler syntax fields](#).
- <Rd>
Is the general-purpose destination register, encoded in the “Rd” field.
- <Rn>
Is the first general-purpose source register holding the multiplicand, encoded in the “Rn” field.
- <Rm>
Is the second general-purpose source register holding the multiplier, encoded in the “Rm” field. If omitted, <Rd> is used.
- <Rdm>
Is the second general-purpose source register holding the multiplier and the destination register, encoded in the “Rdm” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let operand1 : integer = SInt(R(n)); // operand1 = UInt(R[n]) produces the same final results
    let operand2 : integer = SInt(R(m)); // operand2 = UInt(R[m]) produces the same final results
    let result : integer = operand1 * operand2;
    R(d) = result[31:0];
    if setflags then
        PSTATE.N = result[31];
        PSTATE.Z = IsZeroBit{32}(result[31:0]);
        // PSTATE.C, PSTATE.V unchanged
    end;
end;
```

C5.1.122 MVN, MVNS (immediate)

Bitwise NOT (immediate) writes the bitwise inverse of an immediate value to the destination register.

If the destination register is not the PC, the MVNS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. ARM deprecates any use of these encodings. However, when the destination register is the PC:

- The MVN variant of the instruction is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC](#).
- The MVNS variant of the instruction performs an exception return without the use of the stack. In this case:
 - The PE branches to the address written to the PC, and restores [PSTATE](#) from SPSR_<current_mode>.
 - The PE checks SPSR_<current_mode> for an illegal return event. See [Illegal return events from AArch32 state](#).
 - The instruction is UNDEFINED in Hyp mode.
 - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding for the MVN variant

Applies when (S == 0)

MVN{<c>}{<q>} <Rd>, #<const>

Encoding for the MVNS variant

Applies when (S == 1)

MVNS{<c>}{<q>} <Rd>, #<const>

Decode for all variants of this encoding

```
let d : integer = UInt(Rd);
let setflags : boolean = (S == '1');
let a32 : boolean = TRUE;
let imm : bits(12) = imm12;
```

T1

Encoding for the MVN variant

Applies when (S == 0)

MVN{<c>}{<q>} <Rd>, #<const>

Encoding for the MVNS variant

Applies when (S == 1)

MVNS{<c>}{<q>} <Rd>, #<const>

Decode for all variants of this encoding

```
let d : integer = UInt(Rd);
let setflags : boolean = (S == '1');
let a32 : boolean = FALSE;
let imm : bits(12) = i::imm3::imm8;
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rd>

For the “A1 MVN” and “A1 MVNS” variants: is the general-purpose destination register, encoded in the “Rd” field. Arm deprecates using the PC as the destination register, but if the PC is used:

- For the MVN variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC](#).
- For the MVNS variant, the instruction performs an exception return, that restores [PSTATE](#) from `SPSR_<current_mode>`.

For the “T1 MVN” and “T1 MVNS” variants: is the general-purpose destination register, encoded in the “Rd” field.

<const>

For the “A1 MVN” and “A1 MVNS” variants: an immediate value. See [Modified immediate constants in A32 instructions](#) for the range of values.

For the “T1 MVN” and “T1 MVNS” variants: an immediate value. See [Modified immediate constants in T32 instructions](#) for the range of values.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let (imm32, carry) : (bits(32), bit) = (if a32 then A32ExpandImm_C(imm, PSTATE.C)
                                           else T32ExpandImm_C(imm, PSTATE.C));

    let result : bits(32) = NOT(imm32);
    if d == 15 then // Can only occur for A32 encoding
        if setflags then
            ALUExceptionReturn(result);
        else
            ALUWritePC(result);
    end;
```

```
    else
        R(d) = result;
        if setflags then
            PSTATE.N = result[31];
            PSTATE.Z = IsZeroBit{32}(result);
            PSTATE.C = carry;
            // PSTATE.V unchanged
        end;
    end;
end;
```

C5.1.123 MVN, MVNS (register)

Bitwise NOT (register) writes the bitwise inverse of a register value to the destination register.

If the destination register is not the PC, the MVNS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. ARM deprecates any use of these encodings. However, when the destination register is the PC:

- The MVN variant of the instruction is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC](#).
- The MVNS variant of the instruction performs an exception return without the use of the stack. In this case:
 - The PE branches to the address written to the PC, and restores **PSTATE** from SPSR_<current_mode>.
 - The PE checks SPSR_<current_mode> for an illegal return event. See [Illegal return events from AArch32 state](#).
 - The instruction is UNDEFINED in Hyp mode.
 - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#) and [T2](#)).

A1

Encoding for the MVN, rotate right with extend variant

Applies when (S == 0 && imm5 == 00000 && stype == 11)

MVN{<c>}{<q>} <Rd>, <Rm>, RRX

Encoding for the MVN, shift or rotate by value variant

Applies when (S == 0 && !(imm5 == 00000 && stype == 11))

MVN{<c>}{<q>} <Rd>, <Rm> {, <shift> #<amount>}

Encoding for the MVNS, rotate right with extend variant

Applies when (S == 1 && imm5 == 00000 && stype == 11)

MVNS{<c>}{<q>} <Rd>, <Rm>, RRX

Encoding for the MVNS, shift or rotate by value variant

Applies when (S == 1 && !(imm5 == 00000 && stype == 11))

MVNS{<c>}{<q>} <Rd>, <Rm> {, <shift> #<amount>}

Decode for all variants of this encoding

```
let d : integer = UInt(Rd);
let m : integer = UInt(Rm);
let setflags : boolean = (S == '1');
let (shift_t, shift_n) : (SRTYPE, integer) = DecodeImmShift(stype, imm5);
```

T1

Encoding

```
MVN<c>{<q>} <Rd>, <Rm> // (InITBlock())
```

```
MVNS{<q>} <Rd>, <Rm> // (Outside IT block)
```

Decode for this encoding

```
let d : integer = UInt(Rd);
let m : integer = UInt(Rm);
let setflags : boolean = !InITBlock();
let shift_t : SRTYPE = SRTYPE_LSL;
let shift_n : integer = 0;
```

T2

Encoding for the MVN, rotate right with extend variant

Applies when (S == 0 && imm3 == 000 && imm2 == 00 && stype == 11)

```
MVN{<c>}{<q>} <Rd>, <Rm>, RRX
```

Encoding for the MVN, shift or rotate by value variant

Applies when (S == 0 && !(imm3 == 000 && imm2 == 00 && stype == 11))

```
MVN{<c>}{<q>} <Rd>, <Rm> {, <shift> #<amount>}
```

```
MVN<c>.W <Rd>, <Rm> // (Inside IT block, and <Rd>, <Rm> can be represented in T1)
```

Encoding for the MVNS, rotate right with extend variant

Applies when (S == 1 && imm3 == 000 && imm2 == 00 && stype == 11)

```
MVNS{<c>}{<q>} <Rd>, <Rm>, RRX
```

Encoding for the MVNS, shift or rotate by value variant

Applies when (S == 1 && !(imm3 == 000 && imm2 == 00 && stype == 11))

```
MVNS{<c>}{<q>} <Rd>, <Rm> {, <shift> #<amount>}
```

```
MVNS.W <Rd>, <Rm> // (Outside IT block, and <Rd>, <Rm> can be represented in T1)
```

Decode for all variants of this encoding

```
let d : integer = UInt(Rd);
let m : integer = UInt(Rm);
let setflags : boolean = (S == '1');
let (shift_t, shift_n) : (SRType, integer) = DecodeImmShift(stype, imm3::imm2);
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 || m == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rd>

For the “A1 MVN, rotate right with extend”, “A1 MVN, shift or rotate by value”, “A1 MVNS, rotate right with extend”, and “A1 MVNS, shift or rotate by value” variants: is the general-purpose destination register, encoded in the “Rd” field. Arm deprecates using the PC as the destination register, but if the PC is used:

- For the MVN variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC](#).
- For the MVNS variant, the instruction performs an exception return, that restores [PSTATE](#) from `SPSR_<current_mode>`.

For the “T1”, “T2 MVN, rotate right with extend”, “T2 MVN, shift or rotate by value”, “T2 MVNS, rotate right with extend”, and “T2 MVNS, shift or rotate by value” variants: is the general-purpose destination register, encoded in the “Rd” field.

<Rm>

For the “A1 MVN, rotate right with extend”, “A1 MVN, shift or rotate by value”, “A1 MVNS, rotate right with extend”, and “A1 MVNS, shift or rotate by value” variants: is the general-purpose source register, encoded in the “Rm” field. The PC can be used, but this is deprecated.

For the “T1”, “T2 MVN, rotate right with extend”, “T2 MVN, shift or rotate by value”, “T2 MVNS, rotate right with extend”, and “T2 MVNS, shift or rotate by value” variants: is the general-purpose source register, encoded in the “Rm” field.

<shift>

Is the type of shift to be applied to the source register, encoded in “stype”:

stype	<shift>
00	LSL
01	LSR
10	ASR
11	ROR

<amount>

For the “A1 MVN, shift or rotate by value” and “A1 MVNS, shift or rotate by value” variants: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR), encoded in the “imm5” field as <amount> modulo 32.

For the “T2 MVN, shift or rotate by value” and “T2 MVNS, shift or rotate by value” variants: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR), encoded in the “imm3:imm2” field as <amount> modulo 32.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let (shifted, carry) : (bits(32), bit) = Shift_C{32}(R(m), shift_t, shift_n, PSTATE.C);
    let result : bits(32) = NOT(shifted);
    if d == 15 then          // Can only occur for A32 encoding
        if setflags then
            ALUExceptionReturn(result);
        else
            ALUWritePC(result);
        end;
    else
        R(d) = result;
        if setflags then
            PSTATE.N = result[31];
            PSTATE.Z = IsZeroBit{32}(result);
            PSTATE.C = carry;
            // PSTATE.V unchanged
        end;
    end;
end;
end;
```

C5.1.124 MVN, MVNS (register-shifted register)

Bitwise NOT (register-shifted register) writes the bitwise inverse of a register-shifted register value to the destination register. It can optionally update the condition flags based on the result.

Encoding for the Flag setting variant

Applies when (S == 1)

MVNS{<c>}{<q>} <Rd>, <Rm>, <shift> <Rs>

Encoding for the Not flag setting variant

Applies when (S == 0)

MVN{<c>}{<q>} <Rd>, <Rm>, <shift> <Rs>

Decode for all variants of this encoding

```
let d : integer = UInt(Rd);
let m : integer = UInt(Rm);
let s : integer = UInt(Rs);
let setflags : boolean = (S == '1');
let shift_t : SType = DecodeRegShift(stype);
if d == 15 || m == 15 || s == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rd>

Is the general-purpose destination register, encoded in the “Rd” field.

<Rm>

Is the general-purpose source register, encoded in the “Rm” field.

<shift>

Is the type of shift to be applied to the second source register, encoded in “stype”:

stype	<shift>
00	LSL
01	LSR
10	ASR
11	ROR

<Rs>

Is the general-purpose source register holding a shift amount in its bottom 8 bits, encoded in the “Rs” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let shift_n : integer = UInt(R(s)[7:0]);
    let (shifted, carry) : (bits(32), bit) = Shift_C{32}(R(m), shift_t, shift_n, PSTATE.C);
    let result : bits(32) = NOT(shifted);
    R(d) = result;
    if setflags then
        PSTATE.N = result[31];
        PSTATE.Z = IsZeroBit{32}(result);
        PSTATE.C = carry;
        // PSTATE.V unchanged
    end;
end;
```

C5.1.125 NOP

No Operation does nothing. This instruction can be used for instruction alignment purposes.

Note

The timing effects of including a NOP instruction in a program are not guaranteed. It can increase execution time, leave it unchanged, or even reduce it. Therefore, NOP instructions are not suitable for timing loops.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1 and T2).

A1

31	28	27	26	25	24	23	22	21	20	19	16	15	12	11	0				
!=1111				0 0		1	1 0		0	1 0		0 0 0 0		(1)(1)(1)(1)		(0)(0)(0)(0)00000000			
└─ cond				└─ R				└─ imm4				└─ imm12							

Encoding

NOP{<c>}{<q>}

Decode for this encoding

// No additional decoding required

T1

15	12	11	8	7	4	3	0
1	0	1	1	1	1	1	1
└─ hint							

Encoding

NOP{<c>}{<q>}

Decode for this encoding

// No additional decoding required

T2

15	13	12	11	10	9	6	5	4	3	0	15	14	12	11	10	8	7	4	3	0	
1	1	1	1	0	0	1	1	1	0	1	0	(1)(1)(1)(1)	1	0(0)0	(0)	0	0	0	0	0	0
															hint			option			

Encoding

NOP{<c>}.w

Decode for this encoding

// No additional decoding required

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    // Do nothing
end;
```

C5.1.126 ORN, ORNS (immediate)

Bitwise OR NOT (immediate) performs a bitwise (inclusive) OR of a register value and the complement of an immediate value, and writes the result to the destination register. It can optionally update the condition flags based on the result.

Encoding for the Flag setting variant

Applies when (S == 1)

ORNS{<c>}{<q>} {<Rd>, }<Rn>, #<const>

Encoding for the Not flag setting variant

Applies when (S == 0)

ORN{<c>}{<q>} {<Rd>, }<Rn>, #<const>

Decode for all variants of this encoding

```

if Rn == '1111' then See("MVN (immediate)"); end;
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let setflags : boolean = (S == '1');
let a32 : boolean = FALSE;
let imm : bits(12) = i::imm3::imm8;
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 then UnpredictableProcedure(); end;

```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rd>

Is the general-purpose destination register, encoded in the “Rd” field. If omitted, this register is the same as <Rn>.

<Rn>

Is the general-purpose source register, encoded in the “Rn” field.

<const>

An immediate value. See [Modified immediate constants in T32 instructions](#) for the range of values.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let (imm32, carry) : (bits(32), bit) = (if a32 then A32ExpandImm_C(imm, PSTATE.C)
                                             else T32ExpandImm_C(imm, PSTATE.C));

    let result : bits(32) = R(n) OR NOT(imm32);
    R(d) = result;
    if setflags then
        PSTATE.N = result[31];
        PSTATE.Z = IsZeroBit{32}(result);
        PSTATE.C = carry;
        // PSTATE.V unchanged
    end;
end;
```

C5.1.127 ORN, ORNS (register)

Bitwise OR NOT (register) performs a bitwise (inclusive) OR of a register value and the complement of an optionally-shifted register value, and writes the result to the destination register. It can optionally update the condition flags based on the result.

Encoding for the ORN, rotate right with extend variant

Applies when (S == 0 && imm3 == 000 && imm2 == 00 && stype == 11)

ORN{<c>}{<q>} {<Rd>, }<Rn>, <Rm>, RRX

Encoding for the ORN, shift or rotate by value variant

Applies when (S == 0 && !(imm3 == 000 && imm2 == 00 && stype == 11))

ORN{<c>}{<q>} {<Rd>, }<Rn>, <Rm> {, <shift> #<amount>}

Encoding for the ORNS, rotate right with extend variant

Applies when (S == 1 && imm3 == 000 && imm2 == 00 && stype == 11)

ORNS{<c>}{<q>} {<Rd>, }<Rn>, <Rm>, RRX

Encoding for the ORNS, shift or rotate by value variant

Applies when (S == 1 && !(imm3 == 000 && imm2 == 00 && stype == 11))

ORNS{<c>}{<q>} {<Rd>, }<Rn>, <Rm> {, <shift> #<amount>}

Decode for all variants of this encoding

```

if Rn == '1111' then See("MVN (register)"); end;
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let setflags : boolean = (S == '1');
let (shift_t, shift_n) : (SRTYPE, integer) = DecodeImmShift(stype, imm3::imm2);
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 || m == 15 then UnpredictableProcedure(); end;

```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rd>

Is the general-purpose destination register, encoded in the “Rd” field.

<Rn>

Is the first general-purpose source register, encoded in the “Rn” field.

<Rm>

Is the second general-purpose source register, encoded in the “Rm” field.

<shift>

Is the type of shift to be applied to the second source register, encoded in “stype”:

stype	<shift>
00	LSL
01	LSR
10	ASR
11	ROR

<amount>

Is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR), encoded in the “imm3:imm2” field as <amount> modulo 32.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let (shifted, carry) : (bits(32), bit) = Shift_C{32}(R(m), shift_t, shift_n, PSTATE.C);
    let result : bits(32) = R(n) OR NOT(shifted);
    R(d) = result;
    if setflags then
        PSTATE.N = result[31];
        PSTATE.Z = IsZeroBit{32}(result);
        PSTATE.C = carry;
        // PSTATE.V unchanged
    end;
end;
```

C5.1.128 ORR, ORRS (immediate)

Bitwise OR (immediate) performs a bitwise (inclusive) OR of a register value and an immediate value, and writes the result to the destination register.

If the destination register is not the PC, the ORRS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. ARM deprecates any use of these encodings. However, when the destination register is the PC:

- The ORR variant of the instruction is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC](#).
- The ORRS variant of the instruction performs an exception return without the use of the stack. In this case:
 - The PE branches to the address written to the PC, and restores [PSTATE](#) from SPSR_<current_mode>.
 - The PE checks SPSR_<current_mode> for an illegal return event. See [Illegal return events from AArch32 state](#).
 - The instruction is UNDEFINED in Hyp mode.
 - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding for the ORR variant

Applies when (S == 0)

```
ORR{<c>}{<q>} {<Rd>, }<Rn>, #<const>
```

Encoding for the ORRS variant

Applies when (S == 1)

```
ORRS{<c>}{<q>} {<Rd>, }<Rn>, #<const>
```

Decode for all variants of this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let setflags : boolean = (S == '1');
let a32 : boolean = TRUE;
let imm : bits(12) = imm12;
```

T1

Encoding for the ORR variant

Applies when (S == 0)

```
ORR{<c>}{<q>} {<Rd>, }<Rn>, #<const>
```

Encoding for the ORRS variant

Applies when (S == 1)

```
ORRS{<c>}{<q>} {<Rd>, }<Rn>, #<const>
```

Decode for all variants of this encoding

```
if Rn == '1111' then See("MOV (immediate)"); end;
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let setflags : boolean = (S == '1');
let a32 : boolean = FALSE;
let imm : bits(12) = i::imm3::imm8;
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rd>

For the “A1 ORR” and “A1 ORRS” variants: is the general-purpose destination register, encoded in the “Rd” field. If omitted, this register is the same as <Rn>. Arm deprecates using the PC as the destination register, but if the PC is used:

- For the ORR variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC](#).
- For the ORRS variant, the instruction performs an exception return, that restores [PSTATE](#) from `SPSR_<current_mode>`.

For the “T1 ORR” and “T1 ORRS” variants: is the general-purpose destination register, encoded in the “Rd” field. If omitted, this register is the same as <Rn>.

<Rn>

For the “A1 ORR” and “A1 ORRS” variants: is the general-purpose source register, encoded in the “Rn” field. The PC can be used, but this is deprecated.

For the “T1 ORR” and “T1 ORRS” variants: is the general-purpose source register, encoded in the “Rn” field.

<const>

For the “A1 ORR” and “A1 ORRS” variants: an immediate value. See [Modified immediate constants in A32 instructions](#) for the range of values.

For the “T1 ORR” and “T1 ORRS” variants: an immediate value. See [Modified immediate constants in T32 instructions](#) for the range of values.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let (imm32, carry) : (bits(32), bit) = (if a32 then A32ExpandImm_C(imm, PSTATE.C)
                                             else T32ExpandImm_C(imm, PSTATE.C));

    let result : bits(32) = R(n) OR imm32;
    if d == 15 then                // Can only occur for A32 encoding
        if setflags then
            ALUExceptionReturn(result);
        else
            ALUWritePC(result);
        end;
    else
        R(d) = result;
        if setflags then
            PSTATE.N = result[31];
            PSTATE.Z = IsZeroBit{32}(result);
            PSTATE.C = carry;
            // PSTATE.V unchanged
        end;
    end;
end;
```

C5.1.129 ORR, ORRS (register)

Bitwise OR (register) performs a bitwise (inclusive) OR of a register value and an optionally-shifted register value, and writes the result to the destination register.

If the destination register is not the PC, the ORRS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. ARM deprecates any use of these encodings. However, when the destination register is the PC:

- The ORR variant of the instruction is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC](#).
- The ORRS variant of the instruction performs an exception return without the use of the stack. In this case:
 - The PE branches to the address written to the PC, and restores [PSTATE](#) from SPSR_<current_mode>.
 - The PE checks SPSR_<current_mode> for an illegal return event. See [Illegal return events from AArch32 state](#).
 - The instruction is UNDEFINED in Hyp mode.
 - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#) and [T2](#)).

A1

Encoding for the ORR, rotate right with extend variant

Applies when (S == 0 && imm5 == 00000 && stype == 11)

ORR{<c>}{<q>} {<Rd>, }<Rn>, <Rm>, RRX

Encoding for the ORR, shift or rotate by value variant

Applies when (S == 0 && !(imm5 == 00000 && stype == 11))

ORR{<c>}{<q>} {<Rd>, }<Rn>, <Rm> {, <shift> #<amount>}

Encoding for the ORRS, rotate right with extend variant

Applies when (S == 1 && imm5 == 00000 && stype == 11)

ORRS{<c>}{<q>} {<Rd>, }<Rn>, <Rm>, RRX

Encoding for the ORRS, shift or rotate by value variant

Applies when (S == 1 && !(imm5 == 00000 && stype == 11))

ORRS{<c>}{<q>} {<Rd>, }<Rn>, <Rm> {, <shift> #<amount>}

Decode for all variants of this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let setflags : boolean = (S == '1');
let (shift_t, shift_n) : (SRTType, integer) = DecodeImmShift(stype, imm5);
```

T1

Encoding

```
ORR<c>{<q>} {<Rdn>, }<Rdn>, <Rm> // (InITBlock())
```

ORRS{<g>} {<Rdn>, }<Rdn>, <Rm> // (Outside IT block)

Decode for this encoding

```
let d : integer = UInt(Rdn);
let n : integer = UInt(Rdn);
let m : integer = UInt(Rm);
let setflags : boolean = !InITBlock();
let shift_t : SRTYPE = SRTYPE_LSL;
let shift n : integer = 0;
```

T2

Encoding for the ORR, rotate right with extend variant

Applies when (S == 0 && imm3 == 000 && imm2 == 00 && stype == 11)

ORR { <c> } { <q> } { <Rd> , } <Rn> , <Rm> , RRX

Encoding for the ORR, shift or rotate by value variant

Applies when (S == 0 && !(imm3 == 000 && imm2 == 00 && stype == 11))

```
ORR{<c>}{<q>}{<Rd>,<Rn>,<Rm>{,<shift>#<amount>}
```

ORR<c>.W {<Rd>, }<Rn>, <Rm> // (Inside IT block, and <Rd>, <Rn>, <Rm> can be represented in T1)

Encoding for the ORRS, rotate right with extend variant

Applies when (S == 1 && imm3 == 000 && imm2 == 00 && stype == 11)

ORRS {<c>} {<q>} {<Rd>, }<Rn>, <Rm>, RRX

Encoding for the ORRS, shift or rotate by value variant

Applies when (S == 1 && !(imm3 == 000 && imm2 == 00 && stype == 11))

```
ORRS {<c>} {<q>} {<Rd> , } <Rn> , <Rm> { , <shift> #<amount> }
```

ORRS.W {<Rd>, }<Rn>, <Rm> // (Outside IT block, and <Rd>, <Rn>, <Rm> can be represented in T1)

Decode for all variants of this encoding

```
if Rn == '1111' then See("Related encodings"); end;
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let setflags : boolean = (S == '1');
let (shift_t, shift_n) : (SRTYPE, integer) = DecodeImmShift(stype, imm3::imm2);
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 || m == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Related encodings: [Data-processing \(shifted register\)](#)

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rd>

For the “A1 ORR, rotate right with extend”, “A1 ORR, shift or rotate by value”, “A1 ORRS, rotate right with extend”, and “A1 ORRS, shift or rotate by value” variants: is the general-purpose destination register, encoded in the “Rd” field. If omitted, this register is the same as <Rn>. Arm deprecates using the PC as the destination register, but if the PC is used:

- For the ORR variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC](#).
- For the ORRS variant, the instruction performs an exception return, that restores [PSTATE](#) from `SPSR_<current_mode>`.

For the “T2 ORR, rotate right with extend”, “T2 ORR, shift or rotate by value”, “T2 ORRS, rotate right with extend”, and “T2 ORRS, shift or rotate by value” variants: is the general-purpose destination register, encoded in the “Rd” field. If omitted, this register is the same as <Rn>.

<Rn>

For the “A1 ORR, rotate right with extend”, “A1 ORR, shift or rotate by value”, “A1 ORRS, rotate right with extend”, and “A1 ORRS, shift or rotate by value” variants: is the first general-purpose source register, encoded in the “Rn” field. The PC can be used, but this is deprecated.

For the “T2 ORR, rotate right with extend”, “T2 ORR, shift or rotate by value”, “T2 ORRS, rotate right with extend”, and “T2 ORRS, shift or rotate by value” variants: is the first general-purpose source register, encoded in the “Rn” field.

<Rm>

For the “A1 ORR, rotate right with extend”, “A1 ORR, shift or rotate by value”, “A1 ORRS, rotate right with extend”, and “A1 ORRS, shift or rotate by value” variants: is the second general-purpose source register, encoded in the “Rm” field. The PC can be used, but this is deprecated.

For the “T1”, “T2 ORR, rotate right with extend”, “T2 ORR, shift or rotate by value”, “T2 ORRS, rotate right with extend”, and “T2 ORRS, shift or rotate by value” variants: is the second general-purpose source register, encoded in the “Rm” field.

<shift>

Is the type of shift to be applied to the second source register, encoded in “stype”:

stype	<shift>
00	LSL
01	LSR
10	ASR
11	ROR

<amount>

For the “A1 ORR, shift or rotate by value” and “A1 ORRS, shift or rotate by value” variants: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR), encoded in the “imm5” field as <amount> modulo 32.

For the “T2 ORR, shift or rotate by value” and “T2 ORRS, shift or rotate by value” variants: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR), encoded in the “imm3:imm2” field as <amount> modulo 32.

<Rdn>

Is the first general-purpose source register and the destination register, encoded in the “Rdn” field.

In T32 assembly:

- Outside an IT block, if ORRS <Rd>, <Rn>, <Rd> is written with <Rd> and <Rn> both in the range R0-R7, it is assembled using encoding T1 as though ORRS <Rd>, <Rn> had been written.
- Inside an IT block, if ORR<c> <Rd>, <Rn>, <Rd> is written with <Rd> and <Rn> both in the range R0-R7, it is assembled using encoding T1 as though ORR<c> <Rd>, <Rn> had been written.

To prevent either of these happening, use the .w qualifier.

Operation

```

if ConditionPassed() then
    EncodingSpecificOperations();
    let (shifted, carry) : (bits(32), bit) = Shift_C[32](R(m), shift_t, shift_n, PSTATE.C);
    let result : bits(32) = R(n) OR shifted;
    if d == 15 then // Can only occur for A32 encoding
        if setflags then
            ALUEXceptionReturn(result);
        else
            ALUWritePC(result);
        end;
    else
        R(d) = result;
        if setflags then
            PSTATE.N = result[31];
            PSTATE.Z = IsZeroBit[32](result);
            PSTATE.C = carry;
            // PSTATE.V unchanged
        end;
    end;
end;
end;

```

C5.1.130 ORR, ORRS (register-shifted register)

Bitwise OR (register-shifted register) performs a bitwise (inclusive) OR of a register value and a register-shifted register value, and writes the result to the destination register. It can optionally update the condition flags based on the result.

Encoding for the Flag setting variant

Applies when (S == 1)

```
ORR{<c>}{<q>} {<Rd>, }<Rn>, <Rm>, <shift> <Rs>
```

Encoding for the Not flag setting variant

Applies when (S == 0)

```
ORR{<c>}{<q>} {<Rd>, }<Rn>, <Rm>, <shift> <Rs>
```

Decode for all variants of this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let s : integer = UInt(Rs);
let setflags : boolean = (S == '1');
let shift_t : SRTYPE = DecodeRegShift(stype);
if d == 15 || n == 15 || m == 15 || s == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rd>

Is the general-purpose destination register, encoded in the “Rd” field.

<Rn>

Is the first general-purpose source register, encoded in the “Rn” field.

<Rm>

Is the second general-purpose source register, encoded in the “Rm” field.

<shift>

Is the type of shift to be applied to the second source register, encoded in “stype”:

stype	<shift>
00	LSL
01	LSR
10	ASR
11	ROR

<Rs>

Is the general-purpose source register holding a shift amount in its bottom 8 bits, encoded in the “Rs” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let shift_n : integer = UInt(R(s)[7:0]);
    let (shifted, carry) : (bits(32), bit) = Shift_C{32}(R(m), shift_t, shift_n, PSTATE.C);
    let result : bits(32) = R(n) OR shifted;
    R(d) = result;
    if setflags then
        PSTATE.N = result[31];
        PSTATE.Z = IsZeroBit{32}(result);
        PSTATE.C = carry;
        // PSTATE.V unchanged
    end;
end;
```

C5.1.131 PKHBT, PKHTB

Pack Halfword combines one halfword of its first operand with the other halfword of its shifted second operand.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1).

A1

Encoding for the PKHBT variant

Applies when (tb == 0)

```
PKHBT{<c>}{<q>} {<Rd>, }<Rn>, <Rm> {, LSL #<imm>}
```

Encoding for the PKHTB variant

Applies when (tb == 1)

```
PKHTB{<c>}{<q>} {<Rd>, }<Rn>, <Rm> {, ASR #<imm>}
```

Decode for all variants of this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let tbform : boolean = (tb == '1');
let (shift_t, shift_n) : (SRTtype, integer) = DecodeImmShift(tb::'0', imm5);
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
```

T1

Encoding for the PKHBT variant

Applies when (tb == 0)

```
PKHBT{<c>}{<q>} {<Rd>, }<Rn>, <Rm> {, LSL #<imm>} // (tbform == FALSE)
```

Encoding for the PKHTB variant

Applies when (tb == 1)

```
PKHTB{<c>}{<q>} {<Rd>, }<Rn>, <Rm> {, ASR #<imm>} // (tbform == TRUE)
```

Decode for all variants of this encoding

```

if S == '1' || T == '1' then Undefined(); end;
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let tbform : boolean = (tb == '1');
let (shift_t, shift_n) : (SRTType, integer) = DecodeImmShift(tb::'0', imm3::imm2);
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;

```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rd>

Is the general-purpose destination register, encoded in the “Rd” field.

<Rn>

Is the first general-purpose source register, encoded in the “Rn” field.

<Rm>

Is the second general-purpose source register, encoded in the “Rm” field.

<imm>

For the “A1 PKHBT” and “A1 PKHTB” variants: the shift to apply to the value read from <Rm>, encoded in the “imm5” field.

For PKHBT, it is one of:

omitted No shift, encoded as 0b000000.

1-31 Left shift by specified number of bits, encoded as a binary number.

For PKHTB, it is one of:

omitted Instruction is a pseudo-instruction and is assembled as though PKHBT{<c>}{<q>} <Rd>, <Rm>, <Rn> had been written.

1-32 Arithmetic right shift by specified number of bits. A shift by 32 bits is encoded as 0b000000. Other shift amounts are encoded as binary numbers.

Note

An assembler can permit <imm> = 0 to mean the same thing as omitting the shift, but this is not standard UAL and must not be used for disassembly.

For the “T1 PKHBT” and “T1 PKHTB” variants: the shift to apply to the value read from <Rm>, encoded in the “imm3:imm2” field.

For PKHBT, it is one of:

omitted No shift, encoded as 0b000000.

1-31 Left shift by specified number of bits, encoded as a binary number.

For PKHTB, it is one of:

omitted Instruction is a pseudo-instruction and is assembled as though PKHBT{<c>}{<q>} <Rd>, <Rm>, <Rn> had been written.

1-32 Arithmetic right shift by specified number of bits. A shift by 32 bits is encoded as 0b00000. Other shift amounts are encoded as binary numbers.

Note

An assembler can permit <imm> = 0 to mean the same thing as omitting the shift, but this is not standard UAL and must not be used for disassembly.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let operand2 : bits(32) = Shift{ } (R(m), shift_t, shift_n, PSTATE.C); // PSTATE.C ignored
    R(d)[15:0] = if tbform then operand2[15:0] else R(n)[15:0];
    R(d)[31:16] = if tbform then R(n)[31:16] else operand2[31:16];
end;
```

C5.1.132 PLD, PLDW (immediate)

Preload Data (immediate) signals the memory system that data memory accesses from a specified address are likely in the near future. The memory system can respond by taking actions that are expected to speed up the memory accesses when they do occur, such as preloading the cache line containing the specified address into the data cache.

The PLD instruction signals that the likely memory access is a read, and the PLDW instruction signals that it is a write.

The effect of a PLD or PLDW instruction is IMPLEMENTATION DEFINED. For more information, see [Preloading caches](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#) and [T2](#)).

A1

Encoding for the Preload read variant

Applies when (R == 1)

```
PLD{<c>}{<q>}  [<Rn> {, #(<+/->)<imm>}]
```

Encoding for the Preload write variant

Applies when (R == 0)

```
PLDW{<c>}{<q>}  [<Rn> {, #(<+/->)<imm>}]
```

Decode for all variants of this encoding

```
if Rn == '1111' then See("PLD (literal)"); end;
let n : integer = UInt(Rn);
let imm32 : bits(32) = ZeroExtend{}(imm12);
let add : boolean = (U == '1');
let is_pldw : boolean = (R == '0');
```

T1

Encoding for the Preload read variant

Applies when (W == 0)

```
PLD{<c>}{<q>}  [<Rn> {, #(<+>)<imm>}]
```

Encoding for the Preload write variant

Applies when (W == 1)

```
PLDW{<c>}{<q>}  [<Rn> {, #(<+>)<imm>}]
```

Decode for all variants of this encoding

```
if Rn == '1111' then See("PLD (literal)"); end;  
let n : integer = UInt(Rn);  
let imm32 : bits(32) = ZeroExtend{}(imm12);  
let add : boolean = TRUE;  
let is_pldw : boolean = (W == '1');
```

T2

Encoding for the Preload read variant

Applies when (W == 0)

```
PLD{<c>}{<q>} [<Rn> {, #-<imm>}]
```

Encoding for the Preload write variant

Applies when (W == 1)

```
PLDW{<c>}{<q>} [<Rn> {, #-<imm>}]
```

Decode for all variants of this encoding

```
if Rn == '1111' then See("PLD (literal)"); end;  
let n : integer = UInt(Rn);  
let imm32 : bits(32) = ZeroExtend{}(imm8);  
let add : boolean = FALSE;  
let is_pldw : boolean = (W == '1');
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

For the “A1 Preload read” and “A1 Preload write” variants: see [Standard assembler syntax fields](#). Must be AL or omitted.

For the “T1 Preload read”, “T1 Preload write”, “T2 Preload read”, and “T2 Preload write” variants: see [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rn>

Is the general-purpose base register, encoded in the “Rn” field. If the PC is used, see [PLD \(literal\)](#).

+/-

Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in “U”:

U	+/-
0	-
1	+

<imm>

For the “A1 Preload read” and “A1 Preload write” variants: is the optional 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 and encoded in the “imm12” field.

For the “T1 Preload read” and “T1 Preload write” variants: is an optional 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 and encoded in the “imm12” field.

For the “T2 Preload read” and “T2 Preload write” variants: is an 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 if omitted, and encoded in the “imm8” field.

+

Specifies the offset is added to the base register.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let address : bits(32) = if add then (R(n) + imm32) else (R(n) - imm32);
    if is_pldw then
        Hint_PreloadDataForWrite(address);
    else
        Hint_PreloadData(address);
    end;
end;
```

C5.1.133 PLD (literal)

Preload Data (literal) signals the memory system that data memory accesses from a specified address are likely in the near future. The memory system can respond by taking actions that are expected to speed up the memory accesses when they do occur, such as preloading the cache line containing the specified address into the data cache.

The effect of a PLD instruction is IMPLEMENTATION DEFINED. For more information, see [Preloading caches](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

```
PLD{<c>}{<q>} <label> // (Normal form)
```

```
PLD{<c>}{<q>} [PC, #{+/-}<imm>] // (Alternative form)
```

Decode for this encoding

```
let imm32 : bits(32) = ZeroExtend{}(imm12);
let add : boolean = (U == '1');
```

T1

Encoding

```
PLD{<c>}{<q>} <label> // (Preferred syntax)
```

```
PLD{<c>}{<q>} [PC, #{+/-}<imm>] // (Alternative syntax)
```

Decode for this encoding

```
let imm32 : bits(32) = ZeroExtend{}(imm12);
let add : boolean = (U == '1');
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

For the “A1” variant: see [Standard assembler syntax fields](#). Must be AL or omitted.
For the “T1” variant: see [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<label>

The label of the literal data item that is likely to be accessed in the near future. The assembler calculates the required value of the offset from the `Align(PC, 4)` value of the instruction to this label. The offset must be in the range -4095 to 4095.

If the offset is zero or positive, `imm32` is equal to the offset and `add == TRUE`.

If the offset is negative, `imm32` is equal to minus the offset and `add == FALSE`.

+/-

Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in “U”:

U	+/-
0	-
1	+

<imm>

For the “A1” variant: is the 12-bit unsigned immediate byte offset, in the range 0 to 4095, encoded in the “imm12” field.

For the “T1” variant: is a 12-bit unsigned immediate byte offset, in the range 0 to 4095, encoded in the “imm12” field.

The alternative syntax permits the addition or subtraction of the offset and the immediate offset to be specified separately, including permitting a subtraction of 0 that cannot be specified using the normal syntax. For more information, see [Use of labels in UAL instruction syntax](#).

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let address : bits(32) = (if add then (AlignDownSize(PC32(),4) + imm32)
                             else (AlignDownSize(PC32(),4) - imm32));
    Hint_PreloadData(address);
end;
```

C5.1.134 PLD, PLDW (register)

Preload Data (register) signals the memory system that data memory accesses from a specified address are likely in the near future. The memory system can respond by taking actions that are expected to speed up the memory accesses when they do occur, such as preloading the cache line containing the specified address into the data cache.

The PLD instruction signals that the likely memory access is a read, and the PLDW instruction signals that it is a write.

The effect of a PLD or PLDW instruction is IMPLEMENTATION DEFINED. For more information, see [Preloading caches](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding for the Preload read, optional shift or rotate variant

Applies when (R == 1 && !(imm5 == 00000 && stype == 11))

```
PLD{<c>}{<q>}  [<Rn>, {+/-}<Rm> {, <shift> #<amount>}]
```

Encoding for the Preload read, rotate right with extend variant

Applies when (R == 1 && imm5 == 00000 && stype == 11)

```
PLD{<c>}{<q>}  [<Rn>, {+/-}<Rm> , RRX]
```

Encoding for the Preload write, optional shift or rotate variant

Applies when (R == 0 && !(imm5 == 00000 && stype == 11))

```
PLDW{<c>}{<q>}  [<Rn>, {+/-}<Rm> {, <shift> #<amount>}]
```

Encoding for the Preload write, rotate right with extend variant

Applies when (R == 0 && imm5 == 00000 && stype == 11)

```
PLDW{<c>}{<q>}  [<Rn>, {+/-}<Rm> , RRX]
```

Decode for all variants of this encoding

```
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let add : boolean = (U == '1');
let is_pldw : boolean = (R == '0');
let (shift_t, shift_n) : (SRTType, integer) = DecodeImmShift(stype, imm5);
if m == 15 || (n == 15 && is_pldw) then UnpredictableProcedure(); end;
```

T1

Encoding for the Preload read variant

Applies when $(W == 0)$

```
PLD{<c>}{<q>}[<Rn>,{+<Rm>{, LSL #<amount>}]
```

Encoding for the Preload write variant

Applies when ($\bar{W} == 1$)

```
PLDW{<c>}{<q>}    [<Rn>, {+}<Rm> {, LSL #<amount>}]
```

Decode for all variants of this encoding

```

if Rn == '1111' then See("PLD (literal)"); end;
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let add : boolean = TRUE;
let is_pldw : boolean = (W == '1');
let shift_t : SRTtype = SRTtype_LSL;
let shift_n : integer = UInt(imm2);
// Armv8-A removes UNPREDICTABLE for R13
if m == 15 then UnpredictableProcedure(); end;

```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

For the “Preload read, optional shift or rotate”, “Preload read, rotate right with extend”, “Preload write, optional shift or rotate”, and “Preload write, rotate right with extend” variants: see [Standard assembler syntax fields](#). <c> must be AL or omitted.

For the “Preload read” and “Preload write” variants: see [Standard assembler syntax fields](#).

 $\langle q \rangle$

See [Standard assembler syntax fields](#).

<Rn>

For the “Preload read, optional shift or rotate”, “Preload read, rotate right with extend”, “Preload write, optional shift or rotate”, and “Preload write, rotate right with extend” variants: is the general-purpose base register, encoded in the “Rn” field. The PC can be used.

For the “Preload read” and “Preload write” variants: is the general-purpose base register, encoded in the “Rn” field.

 $+/ -$

Specifies the index register is added to or subtracted from the base register, defaulting to + if omitted and encoded in “U”.

U	+/-
0	-
1	+

<Rm>

Is the general-purpose index register, encoded in the “Rm” field.

<shift>

Is the type of shift to be applied to the index register, encoded in “stype”:

stype	<shift>
00	LSL
01	LSR
10	ASR
11	ROR

<amount>

For the “Preload read, optional shift or rotate” and “Preload write, optional shift or rotate” variants: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the “imm5” field as <amount> modulo 32.

For the “Preload read” and “Preload write” variants: is the shift amount, in the range 0 to 3, defaulting to 0 and encoded in the “imm2” field.

+

Specifies the index register is added to the base register.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let offset : bits(32) = Shift{}(R(m), shift_t, shift_n, PSTATE.C);
    let address : bits(32) = if add then (R(n) + offset) else (R(n) - offset);
    if is_pldw then
        Hint_PreloadDataForWrite(address);
    else
        Hint_PreloadData(address);
    end;
end;
```

C5.1.135 PLI (immediate, literal)

Preload Instruction (immediate, literal)

Preload Instruction signals the memory system that instruction memory accesses from a specified address are likely in the near future. The memory system can respond by taking actions that are expected to speed up the memory accesses when they do occur, such as pre-loading the cache line containing the specified address into the instruction cache.

The effect of a PLI instruction is IMPLEMENTATION DEFINED. For more information, see [Preloading caches](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#), [T2](#), and [T3](#)).

A1

Encoding

PLI{<c>}{<q>} [<Rn> {, #(<+/->)<imm>}] // (Preferred syntax)

PLI{<c>}{<q>} <label> // (Normal form)

PLI{<c>}{<q>} [PC, #(<+/->)<imm>] // (Alternative form)

Decode for this encoding

```
let n : integer = UInt(Rn);
let imm32 : bits(32) = ZeroExtend{}(imm12);
let add : boolean = (U == '1');
```

T1

Encoding

PLI{<c>}{<q>} [<Rn> {, #(<+>)<imm>}]

Decode for this encoding

```
if Rn == '1111' then See("encoding T3"); end;
let n : integer = UInt(Rn);
let imm32 : bits(32) = ZeroExtend{}(imm12);
let add : boolean = TRUE;
```

T2

Encoding

```
PLI{<c>}{<q>} [<Rn> {, #-<imm>}]
```

Decode for this encoding

```
if Rn == '1111' then See("encoding T3"); end;
let n : integer = UInt(Rn);
let imm32 : bits(32) = ZeroExtend{}(imm8);
let add : boolean = FALSE;
```

T3

Encoding

```
PLI{<c>}{<q>} <label> // (Preferred syntax)
```

```
PLI{<c>}{<q>} [PC, #{+/-}<imm>] // (Alternative syntax)
```

Decode for this encoding

```
let n : integer = 15;
let imm32 : bits(32) = ZeroExtend{}(imm12);
let add : boolean = (U == '1');
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

For the “A1” variant: see [Standard assembler syntax fields](#). Must be AL or omitted.

For the “T1”, “T2”, and “T3” variants: see [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rn>

Is the general-purpose base register, encoded in the “Rn” field.

+/-

Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in “U”:

U	+/-
0	-
1	+

<imm>

For the “A1” variant: is the optional 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 and encoded in the “imm12” field.

For the “T1” variant: is an optional 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 and encoded in the “imm12” field.

For the “T2” variant: is an 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 if omitted, and encoded in the “imm8” field.

For the “T3” variant: is a 12-bit unsigned immediate byte offset, in the range 0 to 4095, encoded in the “imm12” field.

<label>

The label of the instruction that is likely to be accessed in the near future. The assembler calculates the required value of the offset from the `Align(PC, 4)` value of the instruction to this label. The offset must be in the range -4095 to 4095.

If the offset is zero or positive, `imm32` is equal to the offset and `add == TRUE`.

If the offset is negative, `imm32` is equal to minus the offset and `add == FALSE`.

+

Specifies the offset is added to the base register.

For the literal forms of the instruction, encoding T3 is used, or `Rn` is encoded as `0b1111` in encoding A1, to indicate that the PC is the base register.

The alternative literal syntax permits the addition or subtraction of the offset and the immediate offset to be specified separately, including permitting a subtraction of 0 that cannot be specified using the normal syntax. For more information, see [Use of labels in UAL instruction syntax](#).

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let base : bits(32) = if n == 15 then AlignDownSize(PC32(),4) else R(n);
    let address : bits(32) = if add then (base + imm32) else (base - imm32);
    Hint_PreloadInstr(address);
end;
```

C5.1.136 PLI (register)

Preload Instruction (register)

Preload Instruction signals the memory system that instruction memory accesses from a specified address are likely in the near future. The memory system can respond by taking actions that are expected to speed up the memory accesses when they do occur, such as pre-loading the cache line containing the specified address into the instruction cache.

The effect of a PLI instruction is IMPLEMENTATION DEFINED. For more information, see [Preloading caches](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding for the Rotate right with extend variant

Applies when (imm5 == 00000 && stype == 11)

```
PLI{<c>}{<q>}  [<Rn>, {+/-}<Rm> , RRX]
```

Encoding for the Shift or rotate by value variant

Applies when (!(imm5 == 00000 && stype == 11))

```
PLI{<c>}{<q>}  [<Rn>, {+/-}<Rm> {, <shift> #<amount>}]
```

Decode for all variants of this encoding

```
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let add : boolean = (U == '1');
let (shift_t, shift_n) : (SRTType, integer) = DecodeImmShift(stype, imm5);
if m == 15 then UnpredictableProcedure(); end;
```

T1

Encoding

```
PLI{<c>}{<q>}  [<Rn>, {+}<Rm> {, LSL #<amount>}]
```

Decode for this encoding

```
if Rn == '1111' then See("PLI (immediate, literal)"); end;  
let n : integer = UInt(Rn);  
let m : integer = UInt(Rm);  
let add : boolean = TRUE;  
let shift_t : SRTYPE = SRTYPE_LSL;  
let shift_n : integer = UInt(imm2);  
// Armv8-A removes UNPREDICTABLE for R13  
if m == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

For the “Rotate right with extend” and “Shift or rotate by value” variants: see [Standard assembler syntax fields](#).
<c> must be AL or omitted.

For the “T1” variant: see [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rn>

Is the general-purpose base register, encoded in the “Rn” field.

+/-

Specifies the index register is added to or subtracted from the base register, defaulting to + if omitted and encoded in “U”:

U	+/-
0	-
1	+

<Rm>

Is the general-purpose index register, encoded in the “Rm” field.

<shift>

Is the type of shift to be applied to the index register, encoded in “stype”:

stype	<shift>
00	LSL
01	LSR
10	ASR
11	ROR

<amount>

For the “Shift or rotate by value” variant: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the “imm5” field as <amount> modulo 32.

For the “T1” variant: is the shift amount, in the range 0 to 3, defaulting to 0 and encoded in the “imm2” field.

+

Specifies the index register is added to the base register.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let offset : bits(32) = Shift{}(R(m), shift_t, shift_n, PSTATE.C);
    let address : bits(32) = if add then (R(n) + offset) else (R(n) - offset);
    Hint_PreloadInstr(address);
end;
```

C5.1.137 POP

Pop Multiple Registers from Stack loads multiple general-purpose registers from the stack, loading from consecutive memory locations starting at the address in SP, and updates SP to point just above the loaded data.

The lowest-numbered register is loaded from the lowest memory address, through to the highest-numbered register from the highest memory address. See also [Encoding of lists of general-purpose registers and the PC](#).

The registers loaded can include the PC, causing a branch to a loaded address. This is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC](#).

Encoding

```
POP{<c>}{<q>} <registers> // (Preferred syntax)
```

```
LDM{<c>}{<q>} SP!, <registers> // (Alternate syntax)
```

Decode for this encoding

```
let registers : bits(16) = P::'0000000'::register_list;
let UnalignedAllowed : boolean = FALSE;
if BitCount(registers) < 1 then UnpredictableProcedure(); end;
if registers[15] == '1' && InITBlock() && !LastInITBlock() then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `BitCount(registers) < 1`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction targets an unspecified set of registers. These registers might include R15. If the instruction specifies writeback, the modification to the base address on writeback might differ from the number of registers loaded.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<registers>

Is a list of one or more registers to be loaded, separated by commas and surrounded by { and }.

The registers in the list must be in the range R0-R7, encoded in the “register_list” field, and can optionally include the PC. If the PC is in the list, the “P” field is set to 1, otherwise this field defaults to 0.

If the PC is in the list, the instruction must be either outside any IT block, or the last instruction in an IT block.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
var address : bits(32) = R(13);
for i = 0 to 14 do
    if registers[i] == '1' then
        R(i) = if UnalignedAllowed then MemU{32}(address) else MemA{32}(address);
        address = address + 4;
    end;
end;
if registers[15] == '1' then
    if UnalignedAllowed then
        if address[1:0] == '00' then
            LoadWritePC(MemU{32}(address));
        else
            UnpredictableProcedure();
        end;
    else
        LoadWritePC(MemA{32}(address));
    end;
end;
if registers[13] == '0' then R(13) = R(13) + 4*BitCount(registers); end;
if registers[13] == '1' then R(13) = ARBITRARY : bits(32); end;
end;
```

C5.1.138 POP (multiple registers)

Pop Multiple Registers from Stack loads multiple general-purpose registers from the stack, loading from consecutive memory locations starting at the address in SP, and updates SP to point just above the loaded data.

This is an alias of [LDM](#), [LDMIA](#), [LDMFD](#). This means:

- The encodings in this description are named to match the encodings of [LDM](#), [LDMIA](#), [LDMFD](#).
- The description of [LDM](#), [LDMIA](#), [LDMFD](#) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T2](#)).

A1

Encoding for the A1 variant

```
POP{<c>}{<q>} <registers>
```

is equivalent to

```
LDM{IA}{<c>}{<q>} SP!, <registers>
```

and is the preferred disassembly when `BitCount(register_list) > 1`.

T2

Encoding for the T2 variant

```
POP{<c>}{<q>} <registers>
```

```
POP{<c>}.W <registers> // (M == 0 && register_list[13:8] == '000000')
```

is equivalent to

```
LDM{IA}{<c>}.W SP!, <registers>
```

and is the preferred disassembly when `BitCount(P :: M :: register_list) > 1`.

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<registers>

For the “A1” variant: is a list of two or more registers to be loaded, separated by commas and surrounded by { and }. The lowest-numbered register is loaded from the lowest memory address, through to the highest-numbered register from the highest memory address. See also [Encoding of lists of general-purpose registers and the PC](#).

If the SP is in the list, the value of the SP after such an instruction is UNKNOWN.

The PC can be in the list. If it is, the instruction branches to the address loaded to the PC. This is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC](#).

Arm deprecates the use of this instruction with both the LR and the PC in the list.

For the “T2” variant: is a list of two or more registers to be loaded, separated by commas and surrounded by { and }. The lowest-numbered register is loaded from the lowest memory address, through to the highest-numbered register from the highest memory address. See also [Encoding of lists of general-purpose registers and the PC](#).

The registers in the list must be in the range R0-R12, encoded in the “register_list” field, and can optionally contain one of the LR or the PC. If the LR is in the list, the “M” field is set to 1, otherwise it defaults to 0. If the PC is in the list, the “P” field is set to 1, otherwise it defaults to 0.

The PC can be in the list. If it is, the instruction branches to the address loaded to the PC. This is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC](#). If the PC is in the list:

- The LR must not be in the list.
- The instruction must be either outside any IT block, or the last instruction in an IT block.

Operation

The description of [LDM](#), [LDMIA](#), [LDMFD](#) gives the operational pseudocode for this instruction.

C5.1.139 POP (single register)

Pop Single Register from Stack loads a single general-purpose register from the stack, loading from the address in SP, and updates SP to point just above the loaded data.

This is an alias of [LDR \(immediate\)](#). This means:

- The encodings in this description are named to match the encodings of [LDR \(immediate\)](#).
- The description of [LDR \(immediate\)](#) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T4](#)).

A1

Encoding for the Post-indexed variant

POP{<c>}{<q>} <single_register_list>

is equivalent to

LDR{<c>}{<q>} <Rt>, [SP], #4

and is always the preferred disassembly.

T4

Encoding for the Post-indexed variant

POP{<c>}{<q>} <single_register_list>

is equivalent to

LDR{<c>}{<q>} <Rt>, [SP], #4

and is always the preferred disassembly.

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<single_register_list>

Is the general-purpose register <Rt> to be loaded surrounded by { and }.

Operation

The description of [LDR \(immediate\)](#) gives the operational pseudocode for this instruction.

C5.1.140 PUSH

Push Multiple Registers to Stack stores multiple general-purpose registers to the stack, storing to consecutive memory locations ending just below the address in SP, and updates SP to point to the start of the stored data.

The lowest-numbered register is stored to the lowest memory address, through to the highest-numbered register to the highest memory address. See also [Encoding of lists of general-purpose registers and the PC](#).

Encoding

```
PUSH{<c>}{<q>} <registers> // (Preferred syntax)
```

```
STMDB{<c>}{<q>} SP!, <registers> // (Alternate syntax)
```

Decode for this encoding

```
let registers : bits(16) = '0'::M::'000000'::register_list;
let UnalignedAllowed : boolean = FALSE;
if BitCount(registers) < 1 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `BitCount(registers) < 1`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction targets an unspecified set of registers. These registers might include R15. If the instruction specifies writeback, the modification to the base address on writeback might differ from the number of registers loaded.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<registers>

Is a list of one or more registers to be stored, separated by commas and surrounded by { and }.

The registers in the list must be in the range R0-R7, encoded in the “register_list” field, and can optionally include the LR. If the LR is in the list, the “M” field is set to 1, otherwise this field defaults to 0.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    var address : bits(32) = R(13) - 4*BitCount(registers);
    for i = 0 to 14 do
        if registers[i] == '1' then
            if i == 13 && i != LowestSetBit(registers) then // Only possible for encoding A1
                MemA{32}(address) = ARBITRARY : bits(32);
            else
                if UnalignedAllowed then
                    MemU{32}(address) = R(i);
                else
                    MemA{32}(address) = R(i);
                end;
            end;
            address = address + 4;
        end;
    end;
    if registers[15] == '1' then // Only possible for encoding A1 or A2
        if UnalignedAllowed then
            MemU{32}(address) = PCStoreValue();
        else
            MemA{32}(address) = PCStoreValue();
        end;
    end;
    R(13) = R(13) - 4*BitCount(registers);
end;
```

C5.1.141 PUSH (multiple registers)

Push multiple registers to Stack stores multiple general-purpose registers to the stack, storing to consecutive memory locations ending just below the address in SP, and updates SP to point to the start of the stored data.

This is an alias of [STMDB](#), [STMFD](#). This means:

- The encodings in this description are named to match the encodings of [STMDB](#), [STMFD](#).
- The description of [STMDB](#), [STMFD](#) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding for the A1 variant

PUSH{<c>}{<q>} <registers>

is equivalent to

STMDB{<c>}{<q>} SP!, <registers>

and is the preferred disassembly when `BitCount(register_list) > 1`.

T1

Encoding for the T1 variant

PUSH{<c>}{<q>} <registers>

PUSH{<c>}.W <registers> // (register_list[13:8] == '000000')

is equivalent to

STMDB{<c>}{<q>} SP!, <registers>

and is the preferred disassembly when `BitCount(M :: register_list) > 1`.

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<registers>

For the “A1” variant: is a list of two or more registers to be stored, separated by commas and surrounded by { and }. The lowest-numbered register is stored to the lowest memory address, through to the highest-numbered register to the highest memory address. See also [Encoding of lists of general-purpose registers and the PC](#).

The SP and PC can be in the list. However:

- Arm deprecates the use of instructions that include the PC in the list.
- If the SP is in the list, and it is not the lowest-numbered register in the list, the instruction stores an UNKNOWN value for the SP.

For the “T1” variant: is a list of one or more registers to be stored, separated by commas and surrounded by { and }. The lowest-numbered register is stored to the lowest memory address, through to the highest-numbered register to the highest memory address. See also [Encoding of lists of general-purpose registers and the PC](#).

The registers in the list must be in the range R0-R12, encoded in the “register_list” field, and can optionally contain the LR. If the LR is in the list, the “M” field is set to 1, otherwise it defaults to 0.

Operation

The description of [STMDB](#), [STMTD](#) gives the operational pseudocode for this instruction.

C5.1.142 PUSH (single register)

Push Single Register to Stack stores a single general-purpose register to the stack, storing to the 32-bit word below the address in SP, and updates SP to point to the start of the stored data.

This is an alias of [STR \(immediate\)](#). This means:

- The encodings in this description are named to match the encodings of [STR \(immediate\)](#).
- The description of [STR \(immediate\)](#) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T4](#)).

A1

Encoding for the Pre-indexed variant

`PUSH{<c>}{<q>} <single_register_list>`

is equivalent to

`STR{<c>}{<q>} <Rt>, [SP, #-4]!`

and is always the preferred disassembly.

T4

Encoding for the Pre-indexed variant

`PUSH{<c>}{<q>} <single_register_list> // (Standard syntax)`

is equivalent to

`STR{<c>}{<q>} <Rt>, [SP, #-4]!`

and is always the preferred disassembly.

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<single_register_list>

Is the general-purpose register <Rt> to be stored surrounded by { and }.

Operation

The description of [STR \(immediate\)](#) gives the operational pseudocode for this instruction.

C5.1.143 QADD

Saturating Add adds two register values, saturates the result to the 32-bit signed integer range -2^{31} to $(2^{31} - 1)$, and writes the result to the destination register. If saturation occurs, it sets [PSTATE.Q](#) to 1.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

QADD{<c>}{<q>}{<Rd>,<Rm>,<Rn>}

Decode for this encoding

```

let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;

```

T1

Encoding

QADD{<c>}{<q>}{<Rd>,<Rm>,<Rn>}

Decode for this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
```

For more information about the **CONSTRAINED UNPREDICTABLE** behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rd>

Is the general-purpose destination register, encoded in the “Rd” field.

<Rm>

Is the first general-purpose source register, encoded in the “Rm” field.

<Rn>

Is the second general-purpose source register, encoded in the “Rn” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let (r, sat) : (bits(32), boolean) = SignedSatQ{32}(SInt(R(m)) + SInt(R(n)));
    R(d) = r;
    if sat then
        PSTATE.Q = '1';
    end;
end;
```

C5.1.144 QADD16

Saturating Add 16 performs two 16-bit integer additions, saturates the results to the 16-bit signed integer range $-2^{15} \leq x \leq 2^{15} - 1$, and writes the results to the destination register.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

QADD16{<c>}{<q>} {<Rd>, }<Rn>, <Rm>

Decode for this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
```

T1

Encoding

QADD16{<c>}{<q>} {<Rd>, }<Rn>, <Rm>

Decode for this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rd>

Is the general-purpose destination register, encoded in the “Rd” field.

<Rn>

Is the first general-purpose source register, encoded in the “Rn” field.

<Rm>

Is the second general-purpose source register, encoded in the “Rm” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let sum1 : integer = SInt(R(n)[15:0]) + SInt(R(m)[15:0]);
    let sum2 : integer = SInt(R(n)[31:16]) + SInt(R(m)[31:16]);
    R(d)[15:0] = SignedSat{16}(sum1);
    R(d)[31:16] = SignedSat{16}(sum2);
end;
```

C5.1.145 QADD8

Saturating Add 8 performs four 8-bit integer additions, saturates the results to the 8-bit signed integer range $-2^7 \leq x \leq 2^7 - 1$, and writes the results to the destination register.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

QADD8{<c>}{<q>} {<Rd>, }<Rn>, <Rm>

Decode for this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
```

T1

Encoding

QADD8{<c>}{<q>} {<Rd>, }<Rn>, <Rm>

Decode for this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rd>

Is the general-purpose destination register, encoded in the “Rd” field.

<Rn>

Is the first general-purpose source register, encoded in the “Rn” field.

<Rm>

Is the second general-purpose source register, encoded in the “Rm” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let sum1 : integer = SInt(R(n)[7:0]) + SInt(R(m)[7:0]);
    let sum2 : integer = SInt(R(n)[15:8]) + SInt(R(m)[15:8]);
    let sum3 : integer = SInt(R(n)[23:16]) + SInt(R(m)[23:16]);
    let sum4 : integer = SInt(R(n)[31:24]) + SInt(R(m)[31:24]);
    R(d)[7:0] = SignedSat{8}(sum1);
    R(d)[15:8] = SignedSat{8}(sum2);
    R(d)[23:16] = SignedSat{8}(sum3);
    R(d)[31:24] = SignedSat{8}(sum4);
end;
```

C5.1.146 QASX

Saturating Add and Subtract with Exchange exchanges the two halfwords of the second operand, performs one 16-bit integer addition and one 16-bit subtraction, saturates the results to the 16-bit signed integer range $-2^{15} \leq x \leq 2^{15} - 1$, and writes the results to the destination register.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

QASX{<c>}{<q>} {<Rd>, }<Rn>, <Rm>

Decode for this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
```

T1

Encoding

QASX{<c>}{<q>} {<Rd>, }<Rn>, <Rm>

Decode for this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rd>

Is the general-purpose destination register, encoded in the “Rd” field.

<Rn>

Is the first general-purpose source register, encoded in the “Rn” field.

<Rm>

Is the second general-purpose source register, encoded in the “Rm” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let diff : integer = SInt(R(n)[15:0]) - SInt(R(m)[31:16]);
    let sum : integer = SInt(R(n)[31:16]) + SInt(R(m)[15:0]);
    R(d)[15:0] = SignedSat{16}(diff);
    R(d)[31:16] = SignedSat{16}(sum);
end;
```

C5.1.147 QDADD

Saturating Double and Add adds a doubled register value to another register value, and writes the result to the destination register. Both the doubling and the addition have their results saturated to the 32-bit signed integer range $-2^{31} \leq x \leq 2^{31} - 1$. If saturation occurs in either operation, it sets [PSTATE.Q](#) to 1.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

QDADD{<c>}{<q>}{<Rd>,<Rm>,<Rn>}

Decode for this encoding

```

let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;

```

T1

Encoding

QDADD{<c>}{<q>}{<Rd>,<Rm>,<Rn>}

Decode for this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
```

For more information about the **CONSTRAINED UNPREDICTABLE** behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rd>

Is the general-purpose destination register, encoded in the “Rd” field.

<Rm>

Is the first general-purpose source register, encoded in the “Rm” field.

<Rn>

Is the second general-purpose source register, encoded in the “Rn” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let (doubled, sat1) : (bits(32), boolean) = SignedSatQ{32}(2 * SInt(R(n)));
    let (r, sat2) : (bits(32), boolean) = SignedSatQ{32}(SInt(R(m)) + SInt(doubled));
    R(d) = r;
    if sat1 || sat2 then
        PSTATE.Q = '1';
    end;
end;
```

C5.1.148 QDSUB

Saturating Double and Subtract subtracts a doubled register value from another register value, and writes the result to the destination register. Both the doubling and the subtraction have their results saturated to the 32-bit signed integer range $-2^{31} \leq x \leq 2^{31} - 1$. If saturation occurs in either operation, it sets [PSTATE.Q](#) to 1.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

QDSUB {<c>} {<q>} {<Rd>, }<Rm>, <Rn>

Decode for this encoding

```

let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;

```

T1

Encoding

QDSUB{<c>}{<q>}{<Rd>, }<Rm>, <Rn>

Decode for this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
```

For more information about the **CONSTRAINED UNPREDICTABLE** behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rd>

Is the general-purpose destination register, encoded in the “Rd” field.

<Rm>

Is the first general-purpose source register, encoded in the “Rm” field.

<Rn>

Is the second general-purpose source register, encoded in the “Rn” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let (doubled, sat1) : (bits(32), boolean) = SignedSatQ{32}(2 * SInt(R(n)));
    let (r, sat2) : (bits(32), boolean) = SignedSatQ{32}(SInt(R(m)) - SInt(doubled));
    R(d) = r;
    if sat1 || sat2 then
        PSTATE.Q = '1';
    end;
end;
```

C5.1.149 QSAX

Saturating Subtract and Add with Exchange exchanges the two halfwords of the second operand, performs one 16-bit integer subtraction and one 16-bit addition, saturates the results to the 16-bit signed integer range $-2^{15} \leq x \leq 2^{15} - 1$, and writes the results to the destination register.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

QSAX{<c>}{<q>} {<Rd>, }<Rn>, <Rm>

Decode for this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
```

T1

Encoding

QSAX{<c>}{<q>} {<Rd>, }<Rn>, <Rm>

Decode for this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rd>

Is the general-purpose destination register, encoded in the “Rd” field.

<Rn>

Is the first general-purpose source register, encoded in the “Rn” field.

<Rm>

Is the second general-purpose source register, encoded in the “Rm” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let sum : integer = SInt(R(n)[15:0]) + SInt(R(m)[31:16]);
    let diff : integer = SInt(R(n)[31:16]) - SInt(R(m)[15:0]);
    R(d)[15:0] = SignedSat{16}(sum);
    R(d)[31:16] = SignedSat{16}(diff);
end;
```

C5.1.150 QSUB

Saturating Subtract subtracts one register value from another register value, saturates the result to the 32-bit signed integer range $-2^{31} \leq x \leq 2^{31} - 1$, and writes the result to the destination register. If saturation occurs, it sets [PSTATE.Q](#) to 1.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

QSUB{<c>}{<q>} {<Rd>, }<Rm>, <Rn>

Decode for this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
```

T1

Encoding

QSUB{<c>}{<q>} {<Rd>, }<Rm>, <Rn>

Decode for this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rd>

Is the general-purpose destination register, encoded in the “Rd” field.

<Rm>

Is the first general-purpose source register, encoded in the “Rm” field.

<Rn>

Is the second general-purpose source register, encoded in the “Rn” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let (r, sat) : (bits(32), boolean) = SignedSatQ{32}(SInt(R(m)) - SInt(R(n)));
    R(d) = r;
    if sat then
        PSTATE.Q = '1';
    end;
end;
```

C5.1.151 QSUB16

Saturating Subtract 16 performs two 16-bit integer subtractions, saturates the results to the 16-bit signed integer range $-2^{15} \leq x \leq 2^{15} - 1$, and writes the results to the destination register.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

QSUB16{<c>}{<q>} {<Rd>, }<Rn>, <Rm>

Decode for this encoding

```

let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;

```

T1

Encoding

QSUB16{<c>}{<q>}{<Rd>, }<Rn>, <Rm>

Decode for this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rd>

Is the general-purpose destination register, encoded in the “Rd” field.

<Rn>

Is the first general-purpose source register, encoded in the “Rn” field.

<Rm>

Is the second general-purpose source register, encoded in the “Rm” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let diff1 : integer = SInt(R(n)[15:0]) - SInt(R(m)[15:0]);
    let diff2 : integer = SInt(R(n)[31:16]) - SInt(R(m)[31:16]);
    R(d)[15:0] = SignedSat{16}(diff1);
    R(d)[31:16] = SignedSat{16}(diff2);
end;
```

C5.1.152 QSUB8

Saturating Subtract 8 performs four 8-bit integer subtractions, saturates the results to the 8-bit signed integer range $-2^7 \leq x \leq 2^7 - 1$, and writes the results to the destination register.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1).

A1

Encoding

QSUB8{<c>}{<q>} {<Rd>, }<Rn>, <Rm>

Decode for this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
```

T1

Encoding

QSUB8{<c>}{<q>} {<Rd>, }<Rn>, <Rm>

Decode for this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rd>

Is the general-purpose destination register, encoded in the “Rd” field.

<Rn>

Is the first general-purpose source register, encoded in the “Rn” field.

<Rm>

Is the second general-purpose source register, encoded in the “Rm” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let diff1 : integer = SInt(R(n)[7:0]) - SInt(R(m)[7:0]);
    let diff2 : integer = SInt(R(n)[15:8]) - SInt(R(m)[15:8]);
    let diff3 : integer = SInt(R(n)[23:16]) - SInt(R(m)[23:16]);
    let diff4 : integer = SInt(R(n)[31:24]) - SInt(R(m)[31:24]);
    R(d)[7:0] = SignedSat{8}(diff1);
    R(d)[15:8] = SignedSat{8}(diff2);
    R(d)[23:16] = SignedSat{8}(diff3);
    R(d)[31:24] = SignedSat{8}(diff4);
end;
```

C5.1.153 RBIT

Reverse Bits reverses the bit order in a 32-bit register.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

RBIT{<c>}{<q>} <Rd>, <Rm>

Decode for this encoding

```
let d : integer = UInt(Rd);
let m : integer = UInt(Rm);
if d == 15 || m == 15 then UnpredictableProcedure(); end;
```

T1

Encoding

RBIT{<c>}{<q>} <Rd>, <Rm>

Decode for this encoding

```
let d : integer = UInt(Rd);
let m : integer = UInt(Rm);
let n : integer = UInt(Rn);
// Armv8-A removes UNPREDICTABLE for R13
if m != n || d == 15 || m == 15 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If $m \neq n$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes with the additional decode: $m = \text{UInt}(Rn)$.
- The instruction executes with the additional decode: $m = \text{UInt}(Rm)$.
- The value in the destination register is UNKNOWN.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rd>

Is the general-purpose destination register, encoded in the “Rd” field.

<Rm>

For the “A1” variant: is the general-purpose source register, encoded in the “Rm” field.

For the “T1” variant: is the general-purpose source register, encoded in the “Rm” field. It must be encoded with an identical value in the “Rn” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    var result : bits(32);
    for i = 0 to 31 do
        result[31-i] = R(m)[i];
    end;
    R(d) = result;
end;
```

C5.1.154 REV16

Byte-Reverse Packed Halfword reverses the byte order in each 16-bit halfword of a 32-bit register.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#) and [T2](#)).

A1

Encoding

REV16{<c>}{<q>} <Rd>, <Rm>

Decode for this encoding

```
let d : integer = UInt(Rd);
let m : integer = UInt(Rm);
if d == 15 || m == 15 then UnpredictableProcedure(); end;
```

T1

Encoding

REV16{<c>}{<q>} <Rd>, <Rm>

Decode for this encoding

```
let d : integer = UInt(Rd);
let m : integer = UInt(Rm);
```

T2

Encoding

REV16{<c>}{<q>} <Rd>, <Rm>

REV16{<c>}.W <Rd>, <Rm> // (<Rd>, <Rm> can be represented in T1)

Decode for this encoding

```
let d : integer = UInt(Rd);
let m : integer = UInt(Rm);
let n : integer = UInt(Rn);
// Armv8-A removes UNPREDICTABLE for R13
if m != n || d == 15 || m == 15 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If $m \neq n$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes with the additional decode: $m = \text{UInt}(Rn)$;
- The instruction executes with the additional decode: $m = \text{UInt}(Rm)$;
- The value in the destination register is UNKNOWN.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rd>

Is the general-purpose destination register, encoded in the “Rd” field.

<Rm>

For the “A1” and “T1” variants: is the general-purpose source register, encoded in the “Rm” field.

For the “T2” variant: is the general-purpose source register, encoded in the “Rm” field. It must be encoded with an identical value in the “Rn” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    var result : bits(32);
    result[31:24] = R(m)[23:16];
    result[23:16] = R(m)[31:24];
    result[15:8]  = R(m)[7:0];
    result[7:0]  = R(m)[15:8];
    R(d) = result;
end;
```

C5.1.155 REV

Byte-Reverse Word reverses the byte order in a 32-bit register.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#) and [T2](#)).

A1

Encoding

REV{<c>}{<q>} <Rd>, <Rm>

Decode for this encoding

```
let d : integer = UInt(Rd);
let m : integer = UInt(Rm);
if d == 15 || m == 15 then UnpredictableProcedure(); end;
```

T1

Encoding

REV{<c>}{<q>} <Rd>, <Rm>

Decode for this encoding

```
let d : integer = UInt(Rd);
let m : integer = UInt(Rm);
```

T2

Encoding

REV{<c>}{<q>} <Rd>, <Rm>

REV{<c>}.W <Rd>, <Rm> // (<Rd>, <Rm> can be represented in T1)

Decode for this encoding

```
let d : integer = UInt(Rd);
let m : integer = UInt(Rm);
let n : integer = UInt(Rn);
// Armv8-A removes UNPREDICTABLE for R13
if m != n || d == 15 || m == 15 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If $m \neq n$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes with the additional decode: $m = \text{UInt}(Rn)$;
- The instruction executes with the additional decode: $m = \text{UInt}(Rm)$;
- The value in the destination register is UNKNOWN.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rd>

Is the general-purpose destination register, encoded in the “Rd” field.

<Rm>

For the “A1” and “T1” variants: is the general-purpose source register, encoded in the “Rm” field.

For the “T2” variant: is the general-purpose source register, encoded in the “Rm” field. It must be encoded with an identical value in the “Rn” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    var result : bits(32);
    result[31:24] = R(m)[7:0];
    result[23:16] = R(m)[15:8];
    result[15:8]  = R(m)[23:16];
    result[7:0]   = R(m)[31:24];
    R(d) = result;
end;
```

C5.1.156 REVSH

Byte-Reverse Signed Halfword reverses the byte order in the lower 16-bit halfword of a 32-bit register, and sign-extends the result to 32 bits.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#) and [T2](#)).

A1

Encoding

REVSH{<c>}{<q>} <Rd>, <Rm>

Decode for this encoding

```
let d : integer = UInt(Rd);
let m : integer = UInt(Rm);
if d == 15 || m == 15 then UnpredictableProcedure(); end;
```

T1

Encoding

REVSH{<c>}{<q>} <Rd>, <Rm>

Decode for this encoding

```
let d : integer = UInt(Rd);
let m : integer = UInt(Rm);
```

T2

Encoding

REVSH{<c>}{<q>} <Rd>, <Rm>

REVSH{<c>}.W <Rd>, <Rm> // (<Rd>, <Rm> can be represented in T1)

Decode for this encoding

```
let d : integer = UInt(Rd);
let m : integer = UInt(Rm);
let n : integer = UInt(Rn);
// Armv8-A removes UNPREDICTABLE for R13
if m != n || d == 15 || m == 15 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If $m \neq n$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes with the additional decode: $m = \text{UInt}(Rn)$;
- The instruction executes with the additional decode: $m = \text{UInt}(Rm)$;
- The value in the destination register is UNKNOWN.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rd>

Is the general-purpose destination register, encoded in the “Rd” field.

<Rm>

For the “A1” and “T1” variants: is the general-purpose source register, encoded in the “Rm” field.

For the “T2” variant: is the general-purpose source register, encoded in the “Rm” field. It must be encoded with an identical value in the “Rn” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    var result : bits(32);
    result[31:8] = SignExtend{24}(R(m)[7:0]);
    result[7:0]  = R(m)[15:8];
    R(d) = result;
end;
```

C5.1.157 RFE, RFEDA, RFEDB, RFEIA, RFEIB

Return From Exception loads two consecutive memory locations using an address in a base register:

- The word loaded from the lower address is treated as an instruction address. The PE branches to it.
- The word loaded from the higher address is used to restore [PSTATE](#). This word must be in the format of an SPSR.

An address adjusted by the size of the data loaded can optionally be written back to the base register.

The PE checks the value of the word loaded from the higher address for an illegal return event. See [Illegal return events from AArch32 state](#).

RFE is UNDEFINED in Hyp mode and CONSTRAINED UNPREDICTABLE in User mode.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#) and [T2](#)).

A1

Encoding for the Decrement After variant

Applies when (P == 0 && U == 0)

RFEDA{<c>}{<q>} <Rn>{!} // (Preferred syntax)

RFEEFA{<c>}{<q>} <Rn>{!} // (Alternate syntax, Full Ascending stack)

Encoding for the Decrement Before variant

Applies when (P == 1 && U == 0)

RFEDB{<c>}{<q>} <Rn>{!} // (Preferred syntax)

RFEEBA{<c>}{<q>} <Rn>{!} // (Alternate syntax, Empty Ascending stack)

Encoding for the Increment After variant

Applies when (P == 0 && U == 1)

RFEIA{<c>}{<q>} <Rn>{!} // (Preferred syntax)

RFEIFA{<c>}{<q>} <Rn>{!} // (Alternate syntax, Full Descending stack)

Encoding for the Increment Before variant

Applies when (P == 1 && U == 1)

RFEIB{<c>}{<q>} <Rn>{!} // (Preferred syntax)

RFEIBA{<c>}{<q>} <Rn>{!} // (Alternate syntax, Empty Descending stack)

Decode for all variants of this encoding

```
let n : integer = UInt(Rn);
let wback : boolean = (W == '1');
let increment : boolean = (U == '1');
let wordhigher : boolean = (P == U);
if n == 15 then UnpredictableProcedure(); end;
```

T1

Encoding

RFE^{DB}{<c>}{<q>} <Rn>{!} // (Outside or last in IT block, preferred syntax)

RFE^{FA}{<c>}{<q>} <Rn>{!} // (Outside or last in IT block, alternate syntax, Full Ascending stack)

Decode for this encoding

```
let n : integer = UInt(Rn);
let wback : boolean = (W == '1');
let increment : boolean = FALSE;
let wordhigher : boolean = FALSE;
if n == 15 then UnpredictableProcedure(); end;
if InITBlock() && !LastInITBlock() then UnpredictableProcedure(); end;
```

T2

Encoding

RFE{IA}{<c>}{<q>} <Rn>{!} // (Outside or last in IT block, preferred syntax)

RFE^{FD}{<c>}{<q>} <Rn>{!} // (Outside or last in IT block, alternate syntax, Full Descending stack)

Decode for this encoding

```
let n : integer = UInt(Rn);
let wback : boolean = (W == '1');
let increment : boolean = TRUE;
let wordhigher : boolean = FALSE;
if n == 15 then UnpredictableProcedure(); end;
if InITBlock() && !LastInITBlock() then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

For the “Decrement After”, “Decrement Before”, “Increment After”, and “Increment Before” variants: see [Standard assembler syntax fields](#). <c> must be AL or omitted.

For the “T1” and “T2” variants: see [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rn>

Is the general-purpose base register, encoded in the “Rn” field.

!

The address adjusted by the size of the data loaded is written back to the base register. If specified, it is encoded in the “W” field as 1, otherwise this field defaults to 0.

IA

For the “Increment After” variant: is an optional suffix to indicate the Increment After variant.

For the “T2” variant: is an optional suffix for the Increment After form.

RFEFA, RFEEA, RFEFD, and RFEED are pseudo-instructions for RFEDA, RFEDB, RFEIA, and RFEIB respectively, referring to their use for popping data from Full Ascending, Empty Ascending, Full Descending, and Empty Descending stacks.

Operation

```

if ConditionPassed() then
    EncodingSpecificOperations();
    if PSTATE.EL == EL2 then
        Undefined();
    elseif PSTATE.EL == EL0 then
        UnpredictableProcedure();           // UNDEFINED or NOP
    else
        var address : bits(32) = if increment then R(n) else R(n)-8;
        if wordhigher then address = address+4; end;
        let new_pc_value : bits(32) = MemA{32}(address);
        let spsr : bits(32) = MemA{32}(address+4);
        if wback then R(n) = if increment then R(n)+8 else R(n)-8; end;
        AArch32_ExceptionReturn(new_pc_value, spsr);
    end;
end;

```

CONSTRAINED UNPREDICTABLE behavior

If PSTATE.EL == EL0, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.

C5.1.158 ROR (immediate)

Rotate Right (immediate) provides the value of the contents of a register rotated by a constant value. The bits that are rotated off the right end are inserted into the vacated bit positions on the left.

This is an alias of [MOV, MOVS \(register\)](#). This means:

- The encodings in this description are named to match the encodings of [MOV, MOVS \(register\)](#).
- The description of [MOV, MOVS \(register\)](#) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T3](#)).

A1

Encoding for the MOV, shift or rotate by value variant

ROR{<c>}{<q>} {<Rd>, }<Rm>, #<imm>

is equivalent to

MOV{<c>}{<q>} <Rd>, <Rm>, ROR #<imm>

and is always the preferred disassembly.

T3

Encoding for the MOV, shift or rotate by value variant

Applies when (! (imm3 == 000 && imm2 == 00))

ROR{<c>}{<q>} {<Rd>, }<Rm>, #<imm>

is equivalent to

MOV{<c>}{<q>} <Rd>, <Rm>, ROR #<imm>

and is always the preferred disassembly.

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rd>

For the “A1 MOV, shift or rotate by value” variant: is the general-purpose destination register, encoded in the “Rd” field. Arm deprecates using the PC as the destination register, but if the PC is used, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC](#).

For the “T3 MOV, shift or rotate by value” variant: is the general-purpose destination register, encoded in the “Rd” field.

<Rm>

For the “A1 MOV, shift or rotate by value” variant: is the general-purpose source register, encoded in the “Rm” field. The PC can be used, but this is deprecated.

For the “T3 MOV, shift or rotate by value” variant: is the general-purpose source register, encoded in the “Rm” field.

<imm>

For the “A1 MOV, shift or rotate by value” variant: is the shift amount, in the range 1 to 31, encoded in the “imm5” field.

For the “T3 MOV, shift or rotate by value” variant: is the shift amount, in the range 1 to 31, encoded in the “imm3:imm2” field.

Operation

The description of [MOV, MOVS \(register\)](#) gives the operational pseudocode for this instruction.

C5.1.159 ROR (register)

Rotate Right (register) provides the value of the contents of a register rotated by a variable number of bits. The bits that are rotated off the right end are inserted into the vacated bit positions on the left. The variable number of bits is read from the bottom byte of a register.

This is an alias of [MOV, MOVS \(register-shifted register\)](#). This means:

- The encodings in this description are named to match the encodings of [MOV, MOVS \(register-shifted register\)](#).
- The description of [MOV, MOVS \(register-shifted register\)](#) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#) and [T2](#)).

A1

Encoding for the Not flag setting variant

ROR{<c>}{<q>} {<Rd>, }<Rm>, <Rs>

is equivalent to

MOV{<c>}{<q>} <Rd>, <Rm>, ROR <Rs>

and is always the preferred disassembly.

T1

Encoding for the Rotate right variant

ROR<c>{<q>} {<Rdm>, }<Rdm>, <Rs>

is equivalent to

MOV<c>{<q>} <Rdm>, <Rdm>, ROR <Rs>

and is the preferred disassembly when `InITBlock()`.

T2

Encoding for the Not flag setting variant

ROR{<c>}{<q>} {<Rd>, }<Rm>, <Rs>

```
ROR<c>.W {<Rd>, }<Rm>, <Rs> // (InITBlock() && (UInt(Rd) < 8 && Rd == Rm && UInt(Rs) < 8))
```

is equivalent to

MOV{<c>}{<q>} <Rd>, <Rm>, ROR <Rs>

and is always the preferred disassembly.

Assembler Symbols

 $\langle c \rangle$

See [Standard assembler syntax fields](#).

 $\langle q \rangle$

See [Standard assembler syntax fields](#).

<Rd>

Is the general-purpose destination register, encoded in the “Rd” field.

<Rm>

Is the first general-purpose source register, encoded in the “Rm” field.

 $\langle R_s \rangle$

Is the second general-purpose source register holding a rotate amount in its bottom 8 bits, encoded in the “Rs” field.

<Rdm>

Is the first general-purpose source register and the destination register, encoded in the “Rdm” field.

Operation

The description of [MOV, MOVS \(register-shifted register\)](#) gives the operational pseudocode for this instruction.

C5.1.160 RORS (immediate)

Rotate Right, setting flags (immediate) provides the value of the contents of a register rotated by a constant value. The bits that are rotated off the right end are inserted into the vacated bit positions on the left.

If the destination register is not the PC, this instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. Arm deprecates any use of these encodings. However, when the destination register is the PC:

- The PE branches to the address written to the PC, and restores [PSTATE](#) from SPSR_<current_mode>.
- The PE checks SPSR_<current_mode> for an illegal return event. See [Illegal return events from AArch32 state](#).
- The instruction is UNDEFINED in Hyp mode.
- The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

This is an alias of [MOV, MOVs \(register\)](#). This means:

- The encodings in this description are named to match the encodings of [MOV, MOVs \(register\)](#).
- The description of [MOV, MOVs \(register\)](#) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T3](#)).

A1

Encoding for the MOVs, shift or rotate by value variant

RORS{<c>}{<q>} {<Rd>, }<Rm>, #<imm>

is equivalent to

MOVS{<c>}{<q>} <Rd>, <Rm>, ROR #<imm>

and is always the preferred disassembly.

T3

Encoding for the MOVs, shift or rotate by value variant

Applies when (! (imm3 == 000 && imm2 == 00))

RORS{<c>}{<q>} {<Rd>, }<Rm>, #<imm>

is equivalent to

MOVS{<c>} {<q>} <Rd>, <Rm>, ROR #<imm>

and is always the preferred disassembly.

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rd>

For the “A1 MOVS, shift or rotate by value” variant: is the general-purpose destination register, encoded in the “Rd” field. Arm deprecates using the PC as the destination register, but if the PC is used, the instruction performs an exception return, that restores [PSTATE](#) from SPSR_<current_mode>.

For the “T3 MOVS, shift or rotate by value” variant: is the general-purpose destination register, encoded in the “Rd” field.

<Rm>

For the “A1 MOVS, shift or rotate by value” variant: is the general-purpose source register, encoded in the “Rm” field. The PC can be used, but this is deprecated.

For the “T3 MOVS, shift or rotate by value” variant: is the general-purpose source register, encoded in the “Rm” field.

<imm>

For the “A1 MOVS, shift or rotate by value” variant: is the shift amount, in the range 1 to 31, encoded in the “imm5” field.

For the “T3 MOVS, shift or rotate by value” variant: is the shift amount, in the range 1 to 31, encoded in the “imm3:imm2” field.

Operation

The description of [MOV, MOVS \(register\)](#) gives the operational pseudocode for this instruction.

C5.1.161 RORS (register)

Rotate Right, setting flags (register) provides the value of the contents of a register rotated by a variable number of bits, and updates the condition flags based on the result. The bits that are rotated off the right end are inserted into the vacated bit positions on the left. The variable number of bits is read from the bottom byte of a register.

This is an alias of [MOV, MOVS \(register-shifted register\)](#). This means:

- The encodings in this description are named to match the encodings of [MOV, MOVS \(register-shifted register\)](#).
- The description of [MOV, MOVS \(register-shifted register\)](#) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#) and [T2](#)).

A1

Encoding for the Flag setting variant

RORS{<c>}{<q>} {<Rd>, }<Rm>, <Rs>

is equivalent to

MOVS{<c>}{<q>} <Rd>, <Rm>, ROR <Rs>

and is always the preferred disassembly.

T1

Encoding for the Rotate right variant

RORS{<q>} {<Rdm>, }<Rdm>, <Rs>

is equivalent to

MOVS{<q>} <Rdm>, <Rdm>, ROR <Rs>

and is the preferred disassembly when !InITBlock().

T2

Encoding for the Flag setting variant

RORS { <c> } { <q> } { <Rd>, } <Rm>, <Rs>

```
RORS.W {<Rd>, }<Rm>, <Rs> // (!InITBlock() && (UInt(Rd) < 8 && Rd == Rm && UInt(Rs) < 8))
```

is equivalent to

MOVS{<c>}{<q>} <Rd>, <Rm>, ROR <Rs>

and is always the preferred disassembly.

Assembler Symbols

 $\langle c \rangle$

See [Standard assembler syntax fields](#).

 $\langle q \rangle$

See [Standard assembler syntax fields](#).

<Rd>

Is the general-purpose destination register, encoded in the “Rd” field.

<Rm>

Is the first general-purpose source register, encoded in the “Rm” field.

 $\langle R_s \rangle$

Is the second general-purpose source register holding a rotate amount in its bottom 8 bits, encoded in the “Rs” field.

<Rdm>

Is the first general-purpose source register and the destination register, encoded in the “Rdm” field.

Operation

The description of **MOV, MOVS (register-shifted register)** gives the operational pseudocode for this instruction.

C5.1.162 RRX

Rotate Right with Extend provides the value of the contents of a register shifted right by one place, with the Carry flag shifted into bit[31].

This is an alias of [MOV, MOVS \(register\)](#). This means:

- The encodings in this description are named to match the encodings of [MOV, MOVS \(register\)](#).
- The description of [MOV, MOVS \(register\)](#) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T3](#)).

A1

Encoding for the MOV, rotate right with extend variant

RRX{<c>}{<q>}{<Rd>,<Rm>}

is equivalent to

MOV{<c>}{<q>}{<Rd>,<Rm>},RRX

and is always the preferred disassembly.

T3

Encoding for the MOV, rotate right with extend variant

RRX{<c>}{<q>}{<Rd>,<Rm>}

is equivalent to

MOV{<c>}{<q>}{<Rd>,<Rm>},RRX

and is always the preferred disassembly.

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rd>

For the “A1 MOV, rotate right with extend” variant: is the general-purpose destination register, encoded in the “Rd” field. Arm deprecates using the PC as the destination register, but if the PC is used, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC](#).

For the “T3 MOV, rotate right with extend” variant: is the general-purpose destination register, encoded in the “Rd” field.

<Rm>

For the “A1 MOV, rotate right with extend” variant: is the general-purpose source register, encoded in the “Rm” field. The PC can be used, but this is deprecated.

For the “T3 MOV, rotate right with extend” variant: is the general-purpose source register, encoded in the “Rm” field.

Operation

The description of [MOV, MOVS \(register\)](#) gives the operational pseudocode for this instruction.

C5.1.163 RRXS

Rotate Right with Extend, setting flags provides the value of the contents of a register shifted right by one place, with the Carry flag shifted into bit[31].

If the destination register is not the PC, this instruction updates the condition flags based on the result, and bit[0] is shifted into the Carry flag.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. Arm deprecates any use of these encodings. However, when the destination register is the PC:

- The PE branches to the address written to the PC, and restores [PSTATE](#) from SPSR_<current_mode>.
- The PE checks SPSR_<current_mode> for an illegal return event. See [Illegal return events from AArch32 state](#).
- The instruction is UNDEFINED in Hyp mode.
- The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

This is an alias of [MOV, MOVS \(register\)](#). This means:

- The encodings in this description are named to match the encodings of [MOV, MOVS \(register\)](#).
- The description of [MOV, MOVS \(register\)](#) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T3](#)).

A1

Encoding for the MOVS, rotate right with extend variant

RRXS{<c>}{<q>} {<Rd>, }<Rm>

is equivalent to

MOVS{<c>}{<q>} <Rd>, <Rm>, RRX

and is always the preferred disassembly.

T3

Encoding for the MOVS, rotate right with extend variant

RRXS{<c>}{<q>} {<Rd>, }<Rm>

is equivalent to

MOVS{<c>}{<q>} <Rd>, <Rm>, RRX

and is always the preferred disassembly.

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rd>

For the “A1 MOVS, rotate right with extend” variant: is the general-purpose destination register, encoded in the “Rd” field. Arm deprecates using the PC as the destination register, but if the PC is used, the instruction performs an exception return, that restores [PSTATE](#) from SPSR_<current_mode>.

For the “T3 MOVS, rotate right with extend” variant: is the general-purpose destination register, encoded in the “Rd” field.

<Rm>

For the “A1 MOVS, rotate right with extend” variant: is the general-purpose source register, encoded in the “Rm” field. The PC can be used, but this is deprecated.

For the “T3 MOVS, rotate right with extend” variant: is the general-purpose source register, encoded in the “Rm” field.

Operation

The description of [MOV, MOVS \(register\)](#) gives the operational pseudocode for this instruction.

C5.1.164 RSB, RSBS (immediate)

Reverse Subtract (immediate) subtracts a register value from an immediate value, and writes the result to the destination register.

If the destination register is not the PC, the RSBS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. ARM deprecates any use of these encodings. However, when the destination register is the PC:

- The RSB variant of the instruction is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC](#).
- The RSBS variant of the instruction performs an exception return without the use of the stack. In this case:
 - The PE branches to the address written to the PC, and restores [PSTATE](#) from SPSR_<current_mode>.
 - The PE checks SPSR_<current_mode> for an illegal return event. See [Illegal return events from AArch32 state](#).
 - The instruction is UNDEFINED in Hyp mode.
 - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#) and [T2](#)).

A1

Encoding for the RSB variant

Applies when (S == 0)

```
RSB{<c>}{<q>} {<Rd>, }<Rn>, #<const>
```

Encoding for the RSBS variant

Applies when (S == 1)

```
RSBS{<c>}{<q>} {<Rd>, }<Rn>, #<const>
```

Decode for all variants of this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let setflags : boolean = (S == '1');
let imm32 : bits(32) = A32ExpandImm(imm12);
```

T1

Encoding

RSB<c>{<q>} {<Rd>, }<Rn>, #0 // (InITBlock())

RSBS{<q>} {<Rd>, }<Rn>, #0 // (Outside IT block)

Decode for this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let setflags : boolean = !InITBlock();
let imm32 : bits(32) = Zeros{}; // immediate = #0
```

T2

Encoding for the RSB variant

Applies when (S == 0)

RSB{<c>}{<q>} {<Rd>, }<Rn>, #<const>

RSB<c>.W {<Rd>, }<Rn>, #0 // (Inside IT block)

Encoding for the RSBS variant

Applies when (S == 1)

RSBS{<c>}{<q>} {<Rd>, }<Rn>, #<const>

RSBS.W {<Rd>, }<Rn>, #0 // (Outside IT block)

Decode for all variants of this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let setflags : boolean = (S == '1');
let imm32 : bits(32) = T32ExpandImm(i::imm3::imm8);
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 || n == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rd>

For the “A1 RSB” and “A1 RSBS” variants: is the general-purpose destination register, encoded in the “Rd” field. If omitted, this register is the same as <Rn>. Arm deprecates using the PC as the destination register, but if the PC is used:

- For the RSB variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC](#).
- For the RSBS variant, the instruction performs an exception return, that restores [PSTATE](#) from `SPSR_<current_mode>`.

For the “T1”, “T2 RSB”, and “T2 RSBS” variants: is the general-purpose destination register, encoded in the “Rd” field. If omitted, this register is the same as <Rn>.

<Rn>

For the “A1 RSB” and “A1 RSBS” variants: is the general-purpose source register, encoded in the “Rn” field. The PC can be used, but this is deprecated.

For the “T1”, “T2 RSB”, and “T2 RSBS” variants: is the general-purpose source register, encoded in the “Rn” field.

<const>

For the “A1 RSB” and “A1 RSBS” variants: an immediate value. See [Modified immediate constants in A32 instructions](#) for the range of values.

For the “T2 RSB” and “T2 RSBS” variants: an immediate value. See [Modified immediate constants in T32 instructions](#) for the range of values.

Operation

```

if ConditionPassed() then
    EncodingSpecificOperations();
    let (result, nzcvc) : (bits(32), bits(4)) = AddWithCarry{32}(NOT(R(n)), imm32, '1');
    if d == 15 then          // Can only occur for A32 encoding
        if setflags then
            ALUExceptionReturn(result);
        else
            ALUWritePC(result);
        end;
    else
        R(d) = result;
        if setflags then
            PSTATE.[N,Z,C,V] = nzcvc;
        end;
    end;
end;
end;

```

C5.1.165 RSB, RSBS (register)

Reverse Subtract (register) subtracts a register value from an optionally-shifted register value, and writes the result to the destination register.

If the destination register is not the PC, the RSBS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. ARM deprecates any use of these encodings. However, when the destination register is the PC:

- The RSB variant of the instruction is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC](#).
- The RSBS variant of the instruction performs an exception return without the use of the stack. In this case:
 - The PE branches to the address written to the PC, and restores **PSTATE** from SPSR_<current_mode>.
 - The PE checks SPSR_<current_mode> for an illegal return event. See [Illegal return events from AArch32 state](#).
 - The instruction is UNDEFINED in Hyp mode.
 - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding for the RSB, rotate right with extend variant

Applies when (S == 0 && imm5 == 00000 && stype == 11)

RSB{<c>}{<q>} {<Rd>, }<Rn>, <Rm>, RRX

Encoding for the RSB, shift or rotate by value variant

Applies when (S == 0 && !(imm5 == 00000 && stype == 11))

RSB{<c>}{<q>} {<Rd>, }<Rn>, <Rm> {, <shift> #<amount>}

Encoding for the RSBS, rotate right with extend variant

Applies when (S == 1 && imm5 == 00000 && stype == 11)

RSBS{<c>}{<q>} {<Rd>, }<Rn>, <Rm>, RRX

Encoding for the RSBS, shift or rotate by value variant

Applies when (S == 1 && !(imm5 == 00000 && stype == 11))

RSBS{<c>}{<q>} {<Rd>, }<Rn>, <Rm> {, <shift> #<amount>}

Decode for all variants of this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let setflags : boolean = (S == '1');
let (shift_t, shift_n) : (SRTType, integer) = DecodeImmShift(stype, imm5);
```

T1

Encoding for the RSB, rotate right with extend variant

Applies when (S == 0 && imm3 == 000 && imm2 == 00 && stype == 11)

RSB { <c> } { <q> } { <Rd>, } <Rn>, <Rm>, RRX

Encoding for the RSB, shift or rotate by value variant

Applies when (S == 0 && !(imm3 == 000 && imm2 == 00 && stype == 11))

```
RSB{<c>}{<q>}{<Rd>,<Rn>,<Rm>,<shift>#<amount>}
```

Encoding for the RSBS, rotate right with extend variant

Applies when (S == 1 && imm3 == 000 && imm2 == 00 && stype == 11)

$$\text{RSBS}\{\langle c \rangle\}\{\langle q \rangle\}\{\langle Rd \rangle, \langle Rn \rangle, \langle Rm \rangle, \text{RRX}$$

Encoding for the RSBS, shift or rotate by value variant

Applies when (S == 1 && !(imm3 == 000 && imm2 == 00 && stype == 11))

```
RSBS {<c>} {<q>} {<Rd> , } <Rn> , <Rm> { , <shift> #<amount> }
```

Decode for all variants of this encoding

```

let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let setflags : boolean = (S == '1');
let (shift_t, shift_n) : (SRTType, integer) = DecodeImmShift(stype, imm3::imm2);
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;

```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

 $\langle q \rangle$

See [Standard assembler syntax fields](#).

<Rd>

For the “A1 RSB, rotate right with extend”, “A1 RSB, shift or rotate by value”, “A1 RSBS, rotate right with extend”, and “A1 RSBS, shift or rotate by value” variants: is the general-purpose destination register, encoded in the “Rd” field. If omitted, this register is the same as <Rn>. Arm deprecates using the PC as the destination register, but if the PC is used:

- For the RSB variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC](#).
- For the RSBS variant, the instruction performs an exception return, that restores [PSTATE](#) from `SPSR_<current_mode>`.

For the “T1 RSB, rotate right with extend”, “T1 RSB, shift or rotate by value”, “T1 RSBS, rotate right with extend”, and “T1 RSBS, shift or rotate by value” variants: is the general-purpose destination register, encoded in the “Rd” field. If omitted, this register is the same as `<Rn>`.

<Rn>

For the “A1 RSB, rotate right with extend”, “A1 RSB, shift or rotate by value”, “A1 RSBS, rotate right with extend”, and “A1 RSBS, shift or rotate by value” variants: is the first general-purpose source register, encoded in the “Rn” field. The PC can be used, but this is deprecated.

For the “T1 RSB, rotate right with extend”, “T1 RSB, shift or rotate by value”, “T1 RSBS, rotate right with extend”, and “T1 RSBS, shift or rotate by value” variants: is the first general-purpose source register, encoded in the “Rn” field.

<Rm>

For the “A1 RSB, rotate right with extend”, “A1 RSB, shift or rotate by value”, “A1 RSBS, rotate right with extend”, and “A1 RSBS, shift or rotate by value” variants: is the second general-purpose source register, encoded in the “Rm” field. The PC can be used, but this is deprecated.

For the “T1 RSB, rotate right with extend”, “T1 RSB, shift or rotate by value”, “T1 RSBS, rotate right with extend”, and “T1 RSBS, shift or rotate by value” variants: is the second general-purpose source register, encoded in the “Rm” field.

<shift>

Is the type of shift to be applied to the second source register, encoded in “stype”:

stype	<shift>
00	LSL
01	LSR
10	ASR
11	ROR

<amount>

For the “A1 RSB, shift or rotate by value” and “A1 RSBS, shift or rotate by value” variants: is the shift amount, in the range 1 to 31 (when `<shift>` = LSL or ROR) or 1 to 32 (when `<shift>` = LSR or ASR) encoded in the “imm5” field as `<amount>` modulo 32.

For the “T1 RSB, shift or rotate by value” and “T1 RSBS, shift or rotate by value” variants: is the shift amount, in the range 1 to 31 (when `<shift>` = LSL or ROR) or 1 to 32 (when `<shift>` = LSR or ASR), encoded in the “imm3:imm2” field as `<amount>` modulo 32.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let shifted : bits(32) = Shift{ }(R(m), shift_t, shift_n, PSTATE.C);
    let (result, nzc_v) : (bits(32), bits(4)) = AddWithCarry{32}(NOT(R(n)), shifted, '1');
    if d == 15 then // Can only occur for A32 encoding
        if setflags then
            ALUExceptionReturn(result);
        else
```

```
        ALUWritePC(result);
    end;
else
    R(d) = result;
    if setflags then
        PSTATE.[N,Z,C,V] = nzcvc;
    end;
end;
end;
```

C5.1.166 RSB, RSBS (register-shifted register)

Reverse Subtract (register-shifted register) subtracts a register value from a register-shifted register value, and writes the result to the destination register. It can optionally update the condition flags based on the result.

Encoding for the Flag setting variant

Applies when (S == 1)

RSBS{<c>}{<q>} {<Rd>, }<Rn>, <Rm>, <shift> <Rs>

Encoding for the Not flag setting variant

Applies when (S == 0)

RSB{<c>}{<q>} {<Rd>, }<Rn>, <Rm>, <shift> <Rs>

Decode for all variants of this encoding

```

let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let s : integer = UInt(Rs);
let setflags : boolean = (S == '1');
let shift_t : SRTYPE = DecodeRegShift(stype);
if d == 15 || n == 15 || m == 15 || s == 15 then UnpredictableProcedure(); end;

```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rd>

Is the general-purpose destination register, encoded in the “Rd” field.

<Rn>

Is the first general-purpose source register, encoded in the “Rn” field.

<Rm>

Is the second general-purpose source register, encoded in the “Rm” field.

<shift>

Is the type of shift to be applied to the second source register, encoded in “stype”:

stype	<shift>
00	LSL
01	LSR
10	ASR
11	ROR

<Rs>

Is the third general-purpose source register holding a shift amount in its bottom 8 bits, encoded in the “Rs” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let shift_n : integer = UInt(R(s)[7:0]);
    let shifted : bits(32) = Shift{}(R(m), shift_t, shift_n, PSTATE.C);
    let (result, nzcvc) : (bits(32), bits(4)) = AddWithCarry{32}(NOT(R(n)), shifted, '1');
    R(d) = result;
    if setflags then
        PSTATE.[N,Z,C,V] = nzcvc;
    end;
end;
```

C5.1.167 RSC, RSCS (immediate)

Reverse Subtract with Carry (immediate) subtracts a register value and the value of NOT (Carry flag) from an immediate value, and writes the result to the destination register.

If the destination register is not the PC, the RSCS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. ARM deprecates any use of these encodings. However, when the destination register is the PC:

- The RSC variant of the instruction is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC](#).
- The RSCS variant of the instruction performs an exception return without the use of the stack. In this case:
 - The PE branches to the address written to the PC, and restores **PSTATE** from SPSR_<current_mode>.
 - The PE checks SPSR_<current_mode> for an illegal return event. See [Illegal return events from AArch32 state](#).
 - The instruction is UNDEFINED in Hyp mode.
 - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

Encoding for the RSC variant

Applies when (S == 0)

RSC{<c>}{<q>} {<Rd>, }<Rn>, #<const>

Encoding for the RSCS variant

Applies when (S == 1)

RSCS{<c>}{<q>} {<Rd>, }<Rn>, #<const>

Decode for all variants of this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let setflags : boolean = (S == '1');
let imm32 : bits(32) = A32ExpandImm(imm12);
```

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rd>

Is the general-purpose destination register, encoded in the “Rd” field. If omitted, this register is the same as <Rn>. Arm deprecates using the PC as the destination register, but if the PC is used:

- For the RSC variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC](#).

- For the RSCS variant, the instruction performs an exception return, that restores [PSTATE](#) from `SPSR_<current_mode>`.

<Rn>

Is the general-purpose source register, encoded in the “Rn” field. The PC can be used, but this is deprecated.

<const>

An immediate value. See [Modified immediate constants in A32 instructions](#) for the range of values.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let (result, nzcvc) : (bits(32), bits(4)) = AddWithCarry{32}(NOT(R(n)), imm32, PSTATE.C);
    if d == 15 then
        if setflags then
            ALUExceptionReturn(result);
        else
            ALUWritePC(result);
        end;
    else
        R(d) = result;
        if setflags then
            PSTATE.[N,Z,C,V] = nzcvc;
        end;
    end;
end;
```

C5.1.168 RSC, RSCS (register)

Reverse Subtract with Carry (register) subtracts a register value and the value of NOT (Carry flag) from an optionally-shifted register value, and writes the result to the destination register.

If the destination register is not the PC, the RSCS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. ARM deprecates any use of these encodings. However, when the destination register is the PC:

- The RSC variant of the instruction is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC](#).
- The RSCS variant of the instruction performs an exception return without the use of the stack. In this case:
 - The PE branches to the address written to the PC, and restores [PSTATE](#) from SPSR_<current_mode>.
 - The PE checks SPSR_<current_mode> for an illegal return event. See [Illegal return events from AArch32 state](#).
 - The instruction is UNDEFINED in Hyp mode.
 - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

Encoding for the RSC, rotate right with extend variant

Applies when (S == 0 && imm5 == 00000 && stype == 11)

RSC{<c>}{<q>} {<Rd>, }<Rn>, <Rm>, RRX

Encoding for the RSC, shift or rotate by value variant

Applies when (S == 0 && !(imm5 == 00000 && stype == 11))

RSC{<c>}{<q>} {<Rd>, }<Rn>, <Rm> {, <shift> #<amount>}

Encoding for the RSCS, rotate right with extend variant

Applies when (S == 1 && imm5 == 00000 && stype == 11)

RSCS{<c>}{<q>} {<Rd>, }<Rn>, <Rm>, RRX

Encoding for the RSCS, shift or rotate by value variant

Applies when (S == 1 && !(imm5 == 00000 && stype == 11))

RSCS{<c>}{<q>} {<Rd>, }<Rn>, <Rm> {, <shift> #<amount>}

Decode for all variants of this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let setflags : boolean = (S == '1');
let (shift_t, shift_n) : (SRTYPE, integer) = DecodeImmShift(stype, imm5);
```

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rd>

Is the general-purpose destination register, encoded in the “Rd” field. If omitted, this register is the same as <Rn>. Arm deprecates using the PC as the destination register, but if the PC is used:

- For the RSC variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC](#).
- For the RSCS variant, the instruction performs an exception return, that restores [PSTATE](#) from `SPSR_<current_mode>`.

<Rn>

Is the first general-purpose source register, encoded in the “Rn” field. The PC can be used, but this is deprecated.

<Rm>

Is the second general-purpose source register, encoded in the “Rm” field. The PC can be used, but this is deprecated.

<shift>

Is the type of shift to be applied to the second source register, encoded in “stype”:

stype	<shift>
00	LSL
01	LSR
10	ASR
11	ROR

<amount>

Is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the “imm5” field as <amount> modulo 32.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let shifted : bits(32) = Shift{}(R(m), shift_t, shift_n, PSTATE.C);
    let (result, nzcvc) : (bits(32), bits(4)) = AddWithCarry{32}(NOT(R(n)), shifted, PSTATE.C);
    if d == 15 then
        if setflags then
            ALUExceptionReturn(result);
        else
            ALUWritePC(result);
        end;
    else
        R(d) = result;
        if setflags then
```

```
        PSTATE.[N,Z,C,V] = nzcvc;  
    end;  
end;  
end;
```

C5.1.169 RSC, RSCS (register-shifted register)

Reverse Subtract (register-shifted register) subtracts a register value and the value of NOT (Carry flag) from a register-shifted register value, and writes the result to the destination register. It can optionally update the condition flags based on the result.

Encoding for the Flag setting variant

Applies when (S == 1)

RSCS{<c>}{<q>} {<Rd>, }<Rn>, <Rm>, <shift> <Rs>

Encoding for the Not flag setting variant

Applies when (S == 0)

RSC{<c>}{<q>} {<Rd>, }<Rn>, <Rm>, <shift> <Rs>

Decode for all variants of this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let s : integer = UInt(Rs);
let setflags : boolean = (S == '1');
let shift_t : SRTYPE = DecodeRegShift(stype);
if d == 15 || n == 15 || m == 15 || s == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rd>

Is the general-purpose destination register, encoded in the “Rd” field.

<Rn>

Is the first general-purpose source register, encoded in the “Rn” field.

<Rm>

Is the second general-purpose source register, encoded in the “Rm” field.

<shift>

Is the type of shift to be applied to the second source register, encoded in “stype”:

stype	<shift>
00	LSL
01	LSR
10	ASR
11	ROR

<Rs>

Is the third general-purpose source register holding a shift amount in its bottom 8 bits, encoded in the “Rs” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let shift_n : integer = UInt(R(s)[7:0]);
    let shifted : bits(32) = Shift{}(R(m), shift_t, shift_n, PSTATE.C);
    let (result, nzcvc) : (bits(32), bits(4)) = AddWithCarry{32}(NOT(R(n)), shifted, PSTATE.C);
    R(d) = result;
    if setflags then
        PSTATE.[N,Z,C,V] = nzcvc;
    end;
end;
```

C5.1.170 SADD16

Signed Add 16 performs two 16-bit signed integer additions, and writes the results to the destination register. It sets [PSTATE.GE](#) according to the results of the additions.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

SADD16{<c>}{<q>} {<Rd>, }<Rn>, <Rm>

Decode for this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
```

T1

Encoding

SADD16{<c>}{<q>} {<Rd>, }<Rn>, <Rm>

Decode for this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rd>

Is the general-purpose destination register, encoded in the “Rd” field.

<Rn>

Is the first general-purpose source register, encoded in the “Rn” field.

<Rm>

Is the second general-purpose source register, encoded in the “Rm” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let sum1 : integer = SInt(R(n)[15:0]) + SInt(R(m)[15:0]);
    let sum2 : integer = SInt(R(n)[31:16]) + SInt(R(m)[31:16]);
    R(d)[15:0] = sum1[15:0];
    R(d)[31:16] = sum2[15:0];
    PSTATE.GE[1:0] = if sum1 >= 0 then '11' else '00';
    PSTATE.GE[3:2] = if sum2 >= 0 then '11' else '00';
end;
```

C5.1.171 SADD8

Signed Add 8 performs four 8-bit signed integer additions, and writes the results to the destination register. It sets [PSTATE.GE](#) according to the results of the additions.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

SADD8{<c>}{<q>} {<Rd>, }<Rn>, <Rm>

Decode for this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
```

T1

Encoding

SADD8{<c>}{<q>} {<Rd>, }<Rn>, <Rm>

Decode for this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rd>

Is the general-purpose destination register, encoded in the “Rd” field.

<Rn>

Is the first general-purpose source register, encoded in the “Rn” field.

<Rm>

Is the second general-purpose source register, encoded in the “Rm” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let sum1 : integer = SInt(R(n)[7:0]) + SInt(R(m)[7:0]);
    let sum2 : integer = SInt(R(n)[15:8]) + SInt(R(m)[15:8]);
    let sum3 : integer = SInt(R(n)[23:16]) + SInt(R(m)[23:16]);
    let sum4 : integer = SInt(R(n)[31:24]) + SInt(R(m)[31:24]);
    R(d)[7:0] = sum1[7:0];
    R(d)[15:8] = sum2[7:0];
    R(d)[23:16] = sum3[7:0];
    R(d)[31:24] = sum4[7:0];
    PSTATE.GE[0] = if sum1 >= 0 then '1' else '0';
    PSTATE.GE[1] = if sum2 >= 0 then '1' else '0';
    PSTATE.GE[2] = if sum3 >= 0 then '1' else '0';
    PSTATE.GE[3] = if sum4 >= 0 then '1' else '0';
end;
```

C5.1.172 SASX

Signed Add and Subtract with Exchange exchanges the two halfwords of the second operand, performs one 16-bit integer addition and one 16-bit subtraction, and writes the results to the destination register. It sets `PSTATE.GE` according to the results.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

SASX{<c>}{<q>}{<Rd>,<Rn>,<Rm>}

Decode for this encoding

```

let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;

```

T1

Encoding

SASX{<c>}{<q>}{<Rd>, }<Rn>, <Rm>

Decode for this encoding

```

let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);

// Armv8-A removes UNPREDICTABLE for R13
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;

```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rd>

Is the general-purpose destination register, encoded in the “Rd” field.

<Rn>

Is the first general-purpose source register, encoded in the “Rn” field.

<Rm>

Is the second general-purpose source register, encoded in the “Rm” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let diff : integer = SInt(R(n)[15:0]) - SInt(R(m)[31:16]);
    let sum : integer = SInt(R(n)[31:16]) + SInt(R(m)[15:0]);
    R(d)[15:0] = diff[15:0];
    R(d)[31:16] = sum[15:0];
    PSTATE.GE[1:0] = if diff >= 0 then '11' else '00';
    PSTATE.GE[3:2] = if sum >= 0 then '11' else '00';
end;
```

C5.1.173 SBC, SBCS (immediate)

Subtract with Carry (immediate) subtracts an immediate value and the value of NOT (Carry flag) from a register value, and writes the result to the destination register.

If the destination register is not the PC, the SBCS variant of the instruction updates the condition flags based on the result.

The field descriptions for <rd> identify the encodings where the PC is permitted as the destination register. ARM deprecates any use of these encodings. However, when the destination register is the PC:

- The SBC variant of the instruction is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC](#).
- The SBCS variant of the instruction performs an exception return without the use of the stack. In this case:
 - The PE branches to the address written to the PC, and restores **PSTATE** from SPSR_<current_mode>.
 - The PE checks SPSR_<current_mode> for an illegal return event. See [Illegal return events from AArch32 state](#).
 - The instruction is UNDEFINED in Hyp mode.
 - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding for the SBC variant

Applies when $(S == 0)$

SBC {<c>} {<q>} {<Rd>, }<Rn>, #<const>

Encoding for the SBCS variant

Applies when (S == 1)

```
SBCS{<c>} {<q>} {<Rd>, }<Rn>, #<const>
```

Decode for all variants of this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let setflags : boolean = (S == '1');
let imm32 : bits(32) = A32ExpandImm(imm12);
```

T1

Encoding for the SBC variant

Applies when $(S == 0)$

SBC{<c>}{<q>} {<Rd>, }<Rn>, #<const>

Encoding for the SBCS variant

Applies when (S == 1)

SBCS{<c>}{<q>} {<Rd>, }<Rn>, #<const>

Decode for all variants of this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let setflags : boolean = (S == '1');
let imm32 : bits(32) = T32ExpandImm(i::imm3::imm8);
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 || n == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rd>

For the “A1 SBC” and “A1 SBCS” variants: is the general-purpose destination register, encoded in the “Rd” field. If omitted, this register is the same as <Rn>. Arm deprecates using the PC as the destination register, but if the PC is used:

- For the SBC variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC](#).
- For the SBCS variant, the instruction performs an exception return, that restores [PSTATE](#) from `SPSR_<current_mode>`.

For the “T1 SBC” and “T1 SBCS” variants: is the general-purpose destination register, encoded in the “Rd” field. If omitted, this register is the same as <Rn>.

<Rn>

For the “A1 SBC” and “A1 SBCS” variants: is the general-purpose source register, encoded in the “Rn” field. The PC can be used, but this is deprecated.

For the “T1 SBC” and “T1 SBCS” variants: is the general-purpose source register, encoded in the “Rn” field.

<const>

For the “A1 SBC” and “A1 SBCS” variants: an immediate value. See [Modified immediate constants in A32 instructions](#) for the range of values.

For the “T1 SBC” and “T1 SBCS” variants: an immediate value. See [Modified immediate constants in T32 instructions](#) for the range of values.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let (result, nzcvc) : (bits(32), bits(4)) = AddWithCarry{32}(R(n), NOT(imm32), PSTATE.C);
    if d == 15 then          // Can only occur for A32 encoding
        if setflags then
            ALUEXCEPTIONReturn(result);
        else
            ALUWritePC(result);
        end;
    else
        R(d) = result;
        if setflags then
            PSTATE.[N,Z,C,V] = nzcvc;
        end;
    end;
end;
```

C5.1.174 SBC, SBCS (register)

Subtract with Carry (register) subtracts an optionally-shifted register value and the value of NOT (Carry flag) from a register value, and writes the result to the destination register.

If the destination register is not the PC, the SBCS variant of the instruction updates the condition flags based on the result.

The field descriptions for <rd> identify the encodings where the PC is permitted as the destination register. ARM deprecates any use of these encodings. However, when the destination register is the PC:

- The SBC variant of the instruction is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC](#).
- The SBCS variant of the instruction performs an exception return without the use of the stack. In this case:
 - The PE branches to the address written to the PC, and restores **PSTATE** from SPSR_<current_mode>.
 - The PE checks SPSR_<current_mode> for an illegal return event. See [Illegal return events from AArch32 state](#).
 - The instruction is UNDEFINED in Hyp mode.
 - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#) and [T2](#)).

A1

Encoding for the SBC, rotate right with extend variant

Applies when (S == 0 && imm5 == 00000 && stype == 11)

SBC{<c>}{<q>}{<Rd>,<Rn>,<Rm>,RRX

Encoding for the SBC, shift or rotate by value variant

Applies when (S == 0 && !(imm5 == 00000 && stype == 11))

SBC{<c>}{<q>}{<Rd>,<Rn>,<Rm>{,<shift>#<amount>}

Encoding for the SBCS, rotate right with extend variant

Applies when (S == 1 && imm5 == 00000 && stype == 11)

SBCS{<c>}{<q>}{<Rd>, }<Rn>, <Rm>, RRX

Encoding for the SBCS, shift or rotate by value variant

Applies when (S == 1 && !(imm5 == 00000 && stype == 11))

SBCS{<c>}{<q>}{<Rd>,<Rn>,<Rm>{,<shift>#<amount>}

Decode for all variants of this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let setflags : boolean = (S == '1');
let (shift t, shift n) : (SRTyp, integer) = DecodeImmShift(stype, imm5);
```

T1

Encoding

```
SBC<c>{<q>} {<Rdn>, }<Rdn>, <Rm> // (InITBlock())
```

SBCS{<q>} {<Rdn>, }<Rdn>, <Rm> // (Outside IT block)

Decode for this encoding

```
let d : integer = UInt(Rdn);
let n : integer = UInt(Rdn);
let m : integer = UInt(Rm);
let setflags : boolean = !InITBlock();
let shift_t : SRTYPE = SRTYPE_LSL;
let shift_n : integer = 0;
```

T2

Encoding for the SBC, rotate right with extend variant

Applies when (S == 0 && imm3 == 000 && imm2 == 00 && stype == 11)

SBC {<c>} {<q>} {<Rd>, }<Rn>, <Rm>, RRX

Encoding for the SBC, shift or rotate by value variant

Applies when (S == 0 && !(imm3 == 000 && imm2 == 00 && stype == 11))

SBC{<c>}{<q>}{<Rd>, }<Rn>, <Rm> {, <shift> #<amount>}

SBC<c>.W {<Rd>, }<Rn>, <Rm> // (Inside IT block, and <Rd>, <Rn>, <Rm> can be represented in T1)

Encoding for the SBCS, rotate right with extend variant

Applies when (S == 1 && imm3 == 000 && imm2 == 00 && stype == 11)

SBCS{<c>}{<q>}{<Rd>,<Rn>,<Rm>,<RR>

Encoding for the SBCS, shift or rotate by value variant

Applies when (S == 1 && !(imm3 == 000 && imm2 == 00 && stype == 11))

SBCS{<c>}{<q>} {<Rd>, }<Rn>, <Rm> {, <shift> #<amount>}

SBCS.W {<Rd>, }<Rn>, <Rm> // (Outside IT block, and <Rd>, <Rn>, <Rm> can be represented in T1)

Decode for all variants of this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let setflags : boolean = (S == '1');
let (shift_t, shift_n) : (SRTType, integer) = DecodeImmShift(stype, imm3::imm2);
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rd>

For the “A1 SBC, rotate right with extend”, “A1 SBC, shift or rotate by value”, “A1 SBCS, rotate right with extend”, and “A1 SBCS, shift or rotate by value” variants: is the general-purpose destination register, encoded in the “Rd” field. If omitted, this register is the same as <Rn>. Arm deprecates using the PC as the destination register, but if the PC is used:

- For the SBC variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC](#).
- For the SBCS variant, the instruction performs an exception return, that restores [PSTATE](#) from `SPSR_<current_mode>`.

For the “T2 SBC, rotate right with extend”, “T2 SBC, shift or rotate by value”, “T2 SBCS, rotate right with extend”, and “T2 SBCS, shift or rotate by value” variants: is the general-purpose destination register, encoded in the “Rd” field. If omitted, this register is the same as <Rn>.

<Rn>

For the “A1 SBC, rotate right with extend”, “A1 SBC, shift or rotate by value”, “A1 SBCS, rotate right with extend”, and “A1 SBCS, shift or rotate by value” variants: is the first general-purpose source register, encoded in the “Rn” field. The PC can be used, but this is deprecated.

For the “T2 SBC, rotate right with extend”, “T2 SBC, shift or rotate by value”, “T2 SBCS, rotate right with extend”, and “T2 SBCS, shift or rotate by value” variants: is the first general-purpose source register, encoded in the “Rn” field.

<Rm>

For the “A1 SBC, rotate right with extend”, “A1 SBC, shift or rotate by value”, “A1 SBCS, rotate right with extend”, and “A1 SBCS, shift or rotate by value” variants: is the second general-purpose source register, encoded in the “Rm” field. The PC can be used, but this is deprecated.

For the “T1”, “T2 SBC, rotate right with extend”, “T2 SBC, shift or rotate by value”, “T2 SBCS, rotate right with extend”, and “T2 SBCS, shift or rotate by value” variants: is the second general-purpose source register, encoded in the “Rm” field.

<shift>

Is the type of shift to be applied to the second source register, encoded in “stype”:

stype	<shift>
00	LSL
01	LSR
10	ASR
11	ROR

<amount>

For the “A1 SBC, shift or rotate by value” and “A1 SBCS, shift or rotate by value” variants: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the “imm5” field as <amount> modulo 32.

For the “T2 SBC, shift or rotate by value” and “T2 SBCS, shift or rotate by value” variants: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR), encoded in the “imm3:imm2” field as <amount> modulo 32.

<Rdn>

Is the first general-purpose source register and the destination register, encoded in the “Rdn” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let shifted : bits(32) = Shift{}(R(m), shift_t, shift_n, PSTATE.C);
    let (result, nzcvc) : (bits(32), bits(4)) = AddWithCarry{32}(R(n), NOT(shifted), PSTATE.C);
    if d == 15 then // Can only occur for A32 encoding
        if setflags then
            ALUExceptionReturn(result);
        else
            ALUWritePC(result);
        end;
    else
        R(d) = result;
        if setflags then
            PSTATE.[N,Z,C,V] = nzcvc;
        end;
    end;
end;
```

C5.1.175 SBC, SBCS (register-shifted register)

Subtract with Carry (register-shifted register) subtracts a register-shifted register value and the value of NOT (Carry flag) from a register value, and writes the result to the destination register. It can optionally update the condition flags based on the result.

Encoding for the Flag setting variant

Applies when (S == 1)

SBCS{<c>}{<q>} {<Rd>, }<Rn>, <Rm>, <shift> <Rs>

Encoding for the Not flag setting variant

Applies when (S == 0)

SBC{<c>}{<q>} {<Rd>, }<Rn>, <Rm>, <shift> <Rs>

Decode for all variants of this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let s : integer = UInt(Rs);
let setflags : boolean = (S == '1');
let shift_t : SRTYPE = DecodeRegShift(stype);
if d == 15 || n == 15 || m == 15 || s == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rd>

Is the general-purpose destination register, encoded in the “Rd” field.

<Rn>

Is the first general-purpose source register, encoded in the “Rn” field.

<Rm>

Is the second general-purpose source register, encoded in the “Rm” field.

<shift>

Is the type of shift to be applied to the second source register, encoded in “stype”:

stype	<shift>
00	LSL
01	LSR
10	ASR
11	ROR

<Rs>

Is the third general-purpose source register holding a shift amount in its bottom 8 bits, encoded in the “Rs” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let shift_n : integer = UInt(R(s)[7:0]);
    let shifted : bits(32) = Shift{}(R(m), shift_t, shift_n, PSTATE.C);
    let (result, nzcvc) : (bits(32), bits(4)) = AddWithCarry{32}(R(n), NOT(shifted), PSTATE.C);
    R(d) = result;
    if setflags then
        PSTATE.[N,Z,C,V] = nzcvc;
    end;
end;
```

C5.1.176 SBFX

Signed Bit Field Extract extracts any number of adjacent bits at any position from a register, sign-extends them to 32 bits, and writes the result to the destination register.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1).

A1

Encoding

SBFX{<c>}{<q>} <Rd>, <Rn>, #<lsb>, #<width>

Decode for this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let lsbit : integer{} = UInt(lsb);
let widthminus1 : integer{} = UInt(widthm1);
let msbit : integer{} = lsbit + widthminus1;
if d == 15 || n == 15 then UnpredictableProcedure(); end;
if msbit > 31 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `msbit > 31`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The value in the destination register is UNKNOWN.

T1

Encoding

SBFX{<c>}{<q>} <Rd>, <Rn>, #<lsb>, #<width>

Decode for this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let lsbit : integer{} = UInt(imm3::imm2);
let widthminus1 : integer{} = UInt(widthm1);
let msbit : integer{} = lsbit + widthminus1;
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 || n == 15 then UnpredictableProcedure(); end;
if msbit > 31 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `msbit > 31`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The value in the destination register is UNKNOWN.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rd>

Is the general-purpose destination register, encoded in the “Rd” field.

<Rn>

Is the general-purpose source register, encoded in the “Rn” field.

<lsb>

For the “A1” variant: is the bit number of the least significant bit in the field, in the range 0 to 31, encoded in the “lsb” field.

For the “T1” variant: is the bit number of the least significant bit in the field, in the range 0 to 31, encoded in the “imm3:imm2” field.

<width>

Is the width of the field, in the range 1 to 32-`<lsb>`, encoded in the “widthm1” field as `<width>-1`.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    R(d) = SignExtend{32}(R(n)[msbit:lsbit]);
end;
```

C5.1.177 SDIV

Signed Divide divides a 32-bit signed integer register value by a 32-bit signed integer register value, and writes the result to the destination register. The condition flags are not affected.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

SDIV{<c>}{<q>}{<Rd>,<Rn>,<Rm>}

Decode for this encoding

```

let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;

```

T1

Encoding

$$\text{SDIV}\{\langle c \rangle\}\{\langle q \rangle\} \quad \{\langle Rd \rangle, \} \langle Rn \rangle, \langle Rm \rangle$$

Decode for this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rd>

Is the general-purpose destination register, encoded in the “Rd” field.

<Rn>

Is the first general-purpose source register holding the dividend, encoded in the “Rn” field.

<Rm>

Is the second general-purpose source register holding the divisor, encoded in the “Rm” field.

Overflow

If the signed integer division $0x80000000 / 0xFFFFFFFF$ is performed, the pseudocode produces the intermediate integer result $+2^{31}$, that overflows the 32-bit signed integer range. No indication of this overflow case is produced, and the 32-bit result written to <Rd> must be the bottom 32 bits of the binary representation of $+2^{31}$. So the result of the division is $0x80000000$.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let dividend : integer = SInt(R(n));
    let divisor : integer = SInt(R(m));
    var result : integer;
    if divisor == 0 then
        result = 0;
    elsif (dividend < 0) == (divisor < 0) then
        result = Abs(dividend) DIVRM Abs(divisor);    // same signs - positive result
    else
        result = -(Abs(dividend) DIVRM Abs(divisor)); // different signs - negative result
    end;
    R(d) = result[31:0];
end;
```

C5.1.178 SEL

Select Bytes selects each byte of its result from either its first operand or its second operand, according to the values of the [PSTATE.GE](#) flags.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

SEL{<c>}{<q>} {<Rd>, }<Rn>, <Rm>

Decode for this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
```

T1

Encoding

SEL{<c>}{<q>} {<Rd>, }<Rn>, <Rm>

Decode for this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rd>

Is the general-purpose destination register, encoded in the “Rd” field.

<Rn>

Is the first general-purpose source register, encoded in the “Rn” field.

<Rm>

Is the second general-purpose source register, encoded in the “Rm” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    R(d)[7:0]   = if PSTATE.GE[0] == '1' then R(n)[7:0]   else R(m)[7:0];
    R(d)[15:8]  = if PSTATE.GE[1] == '1' then R(n)[15:8]  else R(m)[15:8];
    R(d)[23:16] = if PSTATE.GE[2] == '1' then R(n)[23:16] else R(m)[23:16];
    R(d)[31:24] = if PSTATE.GE[3] == '1' then R(n)[31:24] else R(m)[31:24];
end;
```

C5.1.179 SETEND

Set Endianness writes a new value to `PSTATE.E`.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

```
SETEND(<q> <endian_specifier> // (Cannot be conditional)
```

Decode for this encoding

```
let set_bigend : boolean = (E == '1');
```

T1

Encoding

```
SETEND(<q> <endian_specifier> // (Not permitted in IT block)
```

Decode for this encoding

```
let set_bigend : boolean = (E == '1');  
if InITBlock() then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<q>

See [Standard assembler syntax fields](#).

<endian_specifier>

Is the endianness to be selected, and the value to be set in `PSTATE.E`, encoded in “E”:

E	<endian_specifier>
0	LE
1	BE

Operation

```
EncodingSpecificOperations();  
AArch32_CheckSETENDEnabled();  
PSTATE.E = if set_bigend then '1' else '0';
```

C5.1.180 SEV

Send Event is a hint instruction. It causes an event to be signaled to all PEs in the multiprocessor system. For more information, see [Wait For Event and Send Event](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#) and [T2](#)).

A1

Encoding

SEV{<c>}{<q>}

Decode for this encoding

// No additional decoding required

T1

Encoding

SEV{<c>}{<q>}

Decode for this encoding

// No additional decoding required

T2

Encoding

SEV{<c>}.W

Decode for this encoding

// No additional decoding required

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    SendEvent();
end;
```

C5.1.181 SEVL

Send Event Local is a hint instruction that causes an event to be signaled locally without requiring the event to be signaled to other PEs in the multiprocessor system. It can prime a wait-loop which starts with a *WFE* instruction.

It has encodings from the following instruction sets: A32 (**A1**) and T32 (**T1** and **T2**).

A1

Encoding

SEVL{<c>}{<q>}

Decode for this encoding

// No additional decoding required

T1

Encoding

SEVL{<c>}{<q>}

Decode for this encoding

// No additional decoding required

T2

Encoding

SEVL{<c>}.W

Decode for this encoding

// No additional decoding required

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    SendEventLocal();
end;
```

C5.1.182 SHADD16

Signed Halving Add 16 performs two signed 16-bit integer additions, halves the results, and writes the results to the destination register.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

SHADD16{<c>}{<q>} {<Rd>, }<Rn>, <Rm>

Decode for this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
```

T1

Encoding

SHADD16{<c>}{<q>} {<Rd>, }<Rn>, <Rm>

Decode for this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rd>

Is the general-purpose destination register, encoded in the “Rd” field.

<Rn>

Is the first general-purpose source register, encoded in the “Rn” field.

<Rm>

Is the second general-purpose source register, encoded in the “Rm” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let sum1 : integer = SInt(R(n)[15:0]) + SInt(R(m)[15:0]);
    let sum2 : integer = SInt(R(n)[31:16]) + SInt(R(m)[31:16]);
    R(d)[15:0] = sum1[16:1];
    R(d)[31:16] = sum2[16:1];
end;
```

C5.1.183 SHADD8

Signed Halving Add 8 performs four signed 8-bit integer additions, halves the results, and writes the results to the destination register.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

SHADD8{<c>}{<q>} {<Rd>, }<Rn>, <Rm>

Decode for this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
```

T1

Encoding

SHADD8{<c>}{<q>} {<Rd>, }<Rn>, <Rm>

Decode for this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rd>

Is the general-purpose destination register, encoded in the “Rd” field.

<Rn>

Is the first general-purpose source register, encoded in the “Rn” field.

<Rm>

Is the second general-purpose source register, encoded in the “Rm” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let sum1 : integer = SInt(R(n)[7:0]) + SInt(R(m)[7:0]);
    let sum2 : integer = SInt(R(n)[15:8]) + SInt(R(m)[15:8]);
    let sum3 : integer = SInt(R(n)[23:16]) + SInt(R(m)[23:16]);
    let sum4 : integer = SInt(R(n)[31:24]) + SInt(R(m)[31:24]);
    R(d)[7:0]    = sum1[8:1];
    R(d)[15:8]   = sum2[8:1];
    R(d)[23:16]  = sum3[8:1];
    R(d)[31:24]  = sum4[8:1];
end;
```

C5.1.184 SHASX

Signed Halving Add and Subtract with Exchange exchanges the two halfwords of the second operand, performs one signed 16-bit integer addition and one signed 16-bit subtraction, halves the results, and writes the results to the destination register.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

SHASX{<c>}{<q>} {<Rd>, }<Rn>, <Rm>

Decode for this encoding

```

let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;

```

T1

Encoding

SHASX{<c>}{<q>} {<Rd>, }<Rn>, <Rm>

Decode for this encoding

```

let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;

```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rd>

Is the general-purpose destination register, encoded in the “Rd” field.

<Rn>

Is the first general-purpose source register, encoded in the “Rn” field.

<Rm>

Is the second general-purpose source register, encoded in the “Rm” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let diff : integer = SInt(R(n)[15:0]) - SInt(R(m)[31:16]);
    let sum : integer = SInt(R(n)[31:16]) + SInt(R(m)[15:0]);
    R(d)[15:0] = diff[16:1];
    R(d)[31:16] = sum[16:1];
end;
```

C5.1.185 SHSAX

Signed Halving Subtract and Add with Exchange exchanges the two halfwords of the second operand, performs one signed 16-bit integer subtraction and one signed 16-bit addition, halves the results, and writes the results to the destination register.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

SHSAX{<c>}{<q>} {<Rd>, }<Rn>, <Rm>

Decode for this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
```

T1

Encoding

SHSAX{<c>}{<q>} {<Rd>, }<Rn>, <Rm>

Decode for this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rd>

Is the general-purpose destination register, encoded in the “Rd” field.

<Rn>

Is the first general-purpose source register, encoded in the “Rn” field.

<Rm>

Is the second general-purpose source register, encoded in the “Rm” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let sum : integer = SInt(R(n)[15:0]) + SInt(R(m)[31:16]);
    let diff : integer = SInt(R(n)[31:16]) - SInt(R(m)[15:0]);
    R(d)[15:0] = sum[16:1];
    R(d)[31:16] = diff[16:1];
end;
```

C5.1.186 SHSUB16

Signed Halving Subtract 16 performs two signed 16-bit integer subtractions, halves the results, and writes the results to the destination register.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

SHSUB16{<c>}{<q>} {<Rd>, }<Rn>, <Rm>

Decode for this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
```

T1

Encoding

SHSUB16{<c>}{<q>} {<Rd>, }<Rn>, <Rm>

Decode for this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rd>

Is the general-purpose destination register, encoded in the “Rd” field.

<Rn>

Is the first general-purpose source register, encoded in the “Rn” field.

<Rm>

Is the second general-purpose source register, encoded in the “Rm” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let diff1 : integer = SInt(R(n)[15:0]) - SInt(R(m)[15:0]);
    let diff2 : integer = SInt(R(n)[31:16]) - SInt(R(m)[31:16]);
    R(d)[15:0] = diff1[16:1];
    R(d)[31:16] = diff2[16:1];
end;
```

C5.1.187 SHSUB8

Signed Halving Subtract 8 performs four signed 8-bit integer subtractions, halves the results, and writes the results to the destination register.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

SHSUB8{<c>}{<q>} {<Rd>, }<Rn>, <Rm>

Decode for this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
```

T1

Encoding

SHSUB8{<c>}{<q>} {<Rd>, }<Rn>, <Rm>

Decode for this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rd>

Is the general-purpose destination register, encoded in the “Rd” field.

<Rn>

Is the first general-purpose source register, encoded in the “Rn” field.

<Rm>

Is the second general-purpose source register, encoded in the “Rm” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let diff1 : integer = SInt(R(n)[7:0]) - SInt(R(m)[7:0]);
    let diff2 : integer = SInt(R(n)[15:8]) - SInt(R(m)[15:8]);
    let diff3 : integer = SInt(R(n)[23:16]) - SInt(R(m)[23:16]);
    let diff4 : integer = SInt(R(n)[31:24]) - SInt(R(m)[31:24]);
    R(d)[7:0] = diff1[8:1];
    R(d)[15:8] = diff2[8:1];
    R(d)[23:16] = diff3[8:1];
    R(d)[31:24] = diff4[8:1];
end;
```

C5.1.188 SMC

Secure Monitor Call

This instruction is UNDEFINED.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

$$\text{SMC}\{\langle c \rangle\}\{\langle \alpha \rangle\}\{\#\}\langle \text{imm4} \rangle$$

Decode for this encoding

```
// imm4 is for assembly/disassembly only and is ignored by hardware
```

T1

Encoding

SMC { <c> } { <q> } { # } <imm4>

Decode for this encoding

```
// imm4 is for assembly/disassembly only and is ignored by hardware
if InITBlock() && !LastInITBlock() then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

 $\langle q \rangle$

See [Standard assembler syntax fields](#).

<imm4>

Is a 4-bit unsigned immediate value, in the range 0 to 15, encoded in the “imm4” field. This is ignored by the PE. The Secure Monitor Call exception handler (Secure Monitor code) can use this value to determine what service is being requested, but Arm does not recommend this.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();

    AArch32_CheckForSMCUndefOrTrap();

    Undefined();

end;
```

CONSTRAINED UNPREDICTABLE behavior

If `SCR.SCD == '1' && CurrentSecurityState() == SS_Secure`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.

C5.1.189 **SMLABB, SMLABT, SMLATB, SMLATT**

Signed Multiply Accumulate (halfwords) performs a signed multiply accumulate operation. The multiply acts on two signed 16-bit quantities, taken from either the bottom or the top half of their respective source registers. The other halves of these source registers are ignored. The 32-bit product is added to a 32-bit accumulate value and the result is written to the destination register.

If overflow occurs during the addition of the accumulate value, the instruction sets **PSTATE.Q** to 1. It is not possible for overflow to occur during the multiplication.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding for the SMLABB variant

Applies when (M == 0 && N == 0)

SMLABB{<c>}{<q>}<Rd>, <Rn>, <Rm>, <Ra>

Encoding for the SMLABT variant

Applies when (M == 1 && N == 0)

SMLABT{<c>}{<q>}<Rd>,<Rn>,<Rm>,<Ra>

Encoding for the SMLATB variant

Applies when (M == 0 && N == 1)

SMLATB{<c>}{<q>}<Rd>,<Rn>,<Rm>,<Ra>

Encoding for the SMLATT variant

Applies when (M == 1 && N == 1)

SMLATT{<c>}{<q>} <Rd>, <Rn>, <Rm>, <Ra>

<Rd>

Is the general-purpose destination register, encoded in the “Rd” field.

<Rn>

Is the first general-purpose source register holding the multiplicand in the bottom or top half (selected by <x>), encoded in the “Rn” field.

<Rm>

Is the second general-purpose source register holding the multiplier in the bottom or top half (selected by <y>), encoded in the “Rm” field.

<Ra>

Is the third general-purpose source register holding the addend, encoded in the “Ra” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let operand1 : bits(16) = R(n)[n_index*:16];
    let operand2 : bits(16) = R(m)[m_index*:16];
    let result : integer = SInt(operand1) * SInt(operand2) + SInt(R(a));
    R(d) = result[31:0];
    if result != SInt(result[31:0]) then // Signed overflow
        PSTATE.Q = '1';
    end;
end;
```

C5.1.190 SMLAD, SMLADX

Signed Multiply Accumulate Dual performs two signed 16 x 16-bit multiplications. It adds the products to a 32-bit accumulate operand.

Optionally, the instruction can exchange the halfwords of the second operand before performing the arithmetic. This produces top x bottom and bottom x top multiplication.

This instruction sets `PSTATE.Q` to 1 if the accumulate operation overflows. Overflow cannot occur during the multiplications.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

<RdLo>

Is the general-purpose source register holding the lower 32 bits of the addend, and the destination register for the lower 32 bits of the result, encoded in the “RdLo” field.

<RdHi>

Is the general-purpose source register holding the upper 32 bits of the addend, and the destination register for the upper 32 bits of the result, encoded in the “RdHi” field.

<Rn>

Is the first general-purpose source register holding the multiplicand, encoded in the “Rn” field.

<Rm>

Is the second general-purpose source register holding the multiplier, encoded in the “Rm” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let result : integer = SInt(R(n)) * SInt(R(m)) + SInt(R(dHi)::R(dLo));
    R(dHi) = result[63:32];
    R(dLo) = result[31:0];
    if setflags then
        PSTATE.N = result[63];
        PSTATE.Z = IsZeroBit{64}(result[63:0]);
        // PSTATE.C, PSTATE.V unchanged
    end;
end;
```

C5.1.192 SMLALBB, SMLALBT, SMLALTB, SMLALTT

Signed Multiply Accumulate Long (halfwords)

Signed Multiply Accumulate Long (halfwords) multiplies two signed 16-bit values to produce a 32-bit value, and accumulates this with a 64-bit value. The multiply acts on two signed 16-bit quantities, taken from either the bottom or the top half of their respective source registers. The other halves of these source registers are ignored. The 32-bit product is sign-extended and accumulated with a 64-bit accumulate value.

Overflow is possible during this instruction, but only as a result of the 64-bit addition. This overflow is not detected if it occurs. Instead, the result wraps around modulo 2^{64} .

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

if dLo == 15 || dHi == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
// Armv8-A removes UNPREDICTABLE for R13
if dHi == dLo then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If dHi == dLo, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The value in the destination register is UNKNOWN.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<RdLo>

Is the general-purpose source register holding the lower 32 bits of the addend, and the destination register for the lower 32 bits of the result, encoded in the “RdLo” field.

<RdHi>

Is the general-purpose source register holding the upper 32 bits of the addend, and the destination register for the upper 32 bits of the result, encoded in the “RdHi” field.

<Rn>

Is the first general-purpose source register, encoded in the “Rn” field.

<Rm>

Is the second general-purpose source register, encoded in the “Rm” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let operand2 : bits(32) = if m_swap then ROR(R(m),16) else R(m);
    let product1 : integer = SInt(R(n)[15:0]) * SInt(operand2[15:0]);
    let product2 : integer = SInt(R(n)[31:16]) * SInt(operand2[31:16]);
    let result : integer = product1 + product2 + SInt(R(dHi)::R(dLo));
    R(dHi) = result[63:32];
    R(dLo) = result[31:0];
end;
```

C5.1.194 SMLAWB, SMLAWT

Signed Multiply Accumulate (word by halfword) performs a signed multiply accumulate operation. The multiply acts on a signed 32-bit quantity and a signed 16-bit quantity. The signed 16-bit quantity is taken from either the bottom or the top half of its source register. The other half of the second source register is ignored. The top 32 bits of the 48-bit product are added to a 32-bit accumulate value and the result is written to the destination register. The bottom 16 bits of the 48-bit product are ignored.

If overflow occurs during the addition of the accumulate value, the instruction sets [PSTATE.Q](#) to 1. No overflow can occur during the multiplication.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding for the SMLAWB variant

if dHi == dLo then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If dHi == dLo, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The value in the destination register is UNKNOWN.

T1

Encoding for the SMLS LD variant

Applies when (M == 0)

SMLS LD{<c>}{<q>} <RdLo>, <RdHi>, <Rn>, <Rm>

Encoding for the SMLS LD X variant

Applies when (M == 1)

SMLS LD X{<c>}{<q>} <RdLo>, <RdHi>, <Rn>, <Rm>

Decode for all variants of this encoding

```
let dLo : integer = UInt(RdLo);
let dHi : integer = UInt(RdHi);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let m_swap : boolean = (M == '1');
if dLo == 15 || dHi == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
// Armv8-A removes UPREDICTABLE for R13
if dHi == dLo then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If dHi == dLo, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The value in the destination register is UNKNOWN.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<RdLo>

Is the general-purpose source register holding the lower 32 bits of the addend, and the destination register for the lower 32 bits of the result, encoded in the “RdLo” field.

<RdHi>

Is the general-purpose source register holding the upper 32 bits of the addend, and the destination register for the upper 32 bits of the result, encoded in the “RdHi” field.

<Rn>

Is the first general-purpose source register, encoded in the “Rn” field.

<Rm>

Is the second general-purpose source register, encoded in the “Rm” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let operand2 : bits(32) = if m_swap then ROR(R(m),16) else R(m);
    let product1 : integer = SInt(R(n)[15:0]) * SInt(operand2[15:0]);
    let product2 : integer = SInt(R(n)[31:16]) * SInt(operand2[31:16]);
    let result : integer = (product1 - product2) + SInt(R(dHi)::R(dLo));
    R(dHi) = result[63:32];
    R(dLo) = result[31:0];
end;
```

C5.1.197 SMMLA, SMMLAR

Signed Most Significant Word Multiply Accumulate

Signed Most Significant Word Multiply Accumulate multiplies two signed 32-bit values, extracts the most significant 32 bits of the result, and adds an accumulate value.

Optionally, the instruction can specify that the result is rounded instead of being truncated. In this case, the constant `0x80000000` is added to the product before the high word is extracted.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding for the SMMLA variant

Applies when $(R == 0)$

SMMLA { <c> } { <q> } <Rd>, <Rn>, <Rm>, <Ra>

Encoding for the SMMLAR variant

Applies when $(R == 1)$

SMMLAR{<c>}{<q>}<Rd>,<Rn>,<Rm>,<Ra>

Decode for all variants of this encoding

```

if Ra == '1111' then See("SMMUL"); end;
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let a : integer = UInt(Ra);
let round : boolean = (R == '1');
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;

```

T1

Encoding for the SMMLA variant

Applies when ($R = 0$)

$$\text{SMMLA} \{ \langle c \rangle \} \{ \langle q \rangle \} \quad \langle Rd \rangle, \quad \langle Rn \rangle, \quad \langle Rm \rangle, \quad \langle Ra \rangle$$

Encoding for the SMMLAR variant

Applies when (R == 1)

SMMLAR{<c>}{<q>} <Rd>, <Rn>, <Rm>, <Ra>

Decode for all variants of this encoding

```
if Ra == '1111' then See("SMMUL"); end;
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let a : integer = UInt(Ra);
let round : boolean = (R == '1');
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rd>

Is the general-purpose destination register, encoded in the “Rd” field.

<Rn>

Is the first general-purpose source register holding the multiplicand, encoded in the “Rn” field.

<Rm>

Is the second general-purpose source register holding the multiplier, encoded in the “Rm” field.

<Ra>

Is the third general-purpose source register holding the addend, encoded in the “Ra” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
var result : integer = (SInt(R(a)) << 32) + SInt(R(n)) * SInt(R(m));
if round then result = result + 0x80000000; end;
R(d) = result[63:32];
end;
```

C5.1.198 SMMLS, SMMLSR

Signed Most Significant Word Multiply Subtract

Signed Most Significant Word Multiply Subtract multiplies two signed 32-bit values, subtracts the result from a 32-bit accumulate value that is shifted left by 32 bits, and extracts the most significant 32 bits of the result of that subtraction.

Optionally, the instruction can specify that the result of the instruction is rounded instead of being truncated. In this case, the constant `0x80000000` is added to the result of the subtraction before the high word is extracted.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding for the SMMLS variant

Applies when $(R == 0)$

SMMLS { <c> } { <q> } <Rd>, <Rn>, <Rm>, <Ra>

Encoding for the SMMLSR variant

Applies when $(R == 1)$

$$\text{SMMLSR}\{\langle c \rangle\}\{\langle q \rangle\} \quad \langle Rd \rangle, \langle Rn \rangle, \langle Rm \rangle, \langle Ra \rangle$$

Decode for all variants of this encoding

```

let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let a : integer = UInt(Ra);

let round : boolean = (R == '1');

if d == 15 || n == 15 || m == 15 || a == 15 then UnpredictableProcedure(); end;

```

T1

Encoding for the SMMLS variant

Applies when $(R == 0)$

SMMLS {<c>} {<q>} <Rd>, <Rn>, <Rm>, <Ra>

Encoding for the SMMLSR variant

Applies when $(R == 1)$

$$\text{SMMLSR}\{\langle c \rangle\}\{\langle q \rangle\} \quad \langle Rd \rangle, \langle Rn \rangle, \langle Rm \rangle, \langle Ra \rangle$$

Decode for all variants of this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let a : integer = UInt(Ra);
let round : boolean = (R == '1');
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 || n == 15 || m == 15 || a == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rd>

Is the general-purpose destination register, encoded in the “Rd” field.

<Rn>

Is the first general-purpose source register holding the multiplicand, encoded in the “Rn” field.

<Rm>

Is the second general-purpose source register holding the multiplier, encoded in the “Rm” field.

<Ra>

Is the third general-purpose source register holding the addend, encoded in the “Ra” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
var result : integer = (SInt(R(a)) << 32) - SInt(R(n)) * SInt(R(m));
if round then result = result + 0x80000000; end;
R(d) = result[63:32];
end;
```

C5.1.199 SMMUL, SMMULR

Signed Most Significant Word Multiply

Signed Most Significant Word Multiply multiplies two signed 32-bit values, extracts the most significant 32 bits of the result, and writes those bits to the destination register.

Optionally, the instruction can specify that the result is rounded instead of being truncated. In this case, the constant 0×80000000 is added to the product before the high word is extracted.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1).

A1

Encoding for the SMMUL variant

Applies when (R == 0)

SMMUL{<c>}{<q>} {<Rd>, }<Rn>, <Rm>

Encoding for the SMMULR variant

Applies when (R == 1)

SMMULR{<c>}{<q>} {<Rd>, }<Rn>, <Rm>

Decode for all variants of this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let round : boolean = (R == '1');
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
```

T1

Encoding for the SMMUL variant

Applies when (R == 0)

SMMUL{<c>}{<q>} {<Rd>, }<Rn>, <Rm>

Encoding for the SMMULR variant

Applies when (R == 1)

SMMULR{<c>}{<q>} {<Rd>, }<Rn>, <Rm>

Decode for all variants of this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let round : boolean = (R == '1');
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rd>

Is the general-purpose destination register, encoded in the “Rd” field.

<Rn>

Is the first general-purpose source register, encoded in the “Rn” field.

<Rm>

Is the second general-purpose source register, encoded in the “Rm” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    var result : integer = SInt(R(n)) * SInt(R(m));
    if round then result = result + 0x80000000; end;
    R(d) = result[63:32];
end;
```

C5.1.200 SMUAD, SMUADX

Signed Dual Multiply Add

Signed Dual Multiply Add performs two signed 16 x 16-bit multiplications. It adds the products together, and writes the result to the destination register.

Optionally, the instruction can exchange the halfwords of the second operand before performing the arithmetic. This produces top x bottom and bottom x top multiplication.

This instruction sets [PSTATE.Q](#) to 1 if the addition overflows. The multiplications cannot overflow.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding for the SMUAD variant

Applies when (M == 0)

SMUAD{<c>}{<q>} {<Rd>, }<Rn>, <Rm>

Encoding for the SMUADX variant

Applies when (M == 1)

SMUADX{<c>}{<q>} {<Rd>, }<Rn>, <Rm>

Decode for all variants of this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let m_swap : boolean = (M == '1');
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
```

T1

Encoding for the SMUAD variant

Applies when (M == 0)

SMUAD{<c>}{<q>} {<Rd>, }<Rn>, <Rm>

Encoding for the SMUADX variant

Applies when (M == 1)

SMUADX{<c>}{<q>} {<Rd>, }<Rn>, <Rm>

Decode for all variants of this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let m_swap : boolean = (M == '1');
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rd>

Is the general-purpose destination register, encoded in the “Rd” field.

<Rn>

Is the first general-purpose source register, encoded in the “Rn” field.

<Rm>

Is the second general-purpose source register, encoded in the “Rm” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let operand2 : bits(32) = if m_swap then ROR(R(m),16) else R(m);
    let product1 : integer = SInt(R(n)[15:0]) * SInt(operand2[15:0]);
    let product2 : integer = SInt(R(n)[31:16]) * SInt(operand2[31:16]);
    let result : integer = product1 + product2;
    R(d) = result[31:0];
    if result != SInt(result[31:0]) then // Signed overflow
        PSTATE.Q = '1';
    end;
end;
```

C5.1.201 SMULBB, SMULBT, SMULTB, SMULTT

Signed Multiply (halfwords)

Signed Multiply (halfwords) multiplies two signed 16-bit quantities, taken from either the bottom or the top half of their respective source registers. The other halves of these source registers are ignored. The 32-bit product is written to the destination register. No overflow is possible during this instruction.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding for the SMULBB variant

Applies when (M == 0 && N == 0)

SMULBB{<c>}{<q>} {<Rd>, }<Rn>, <Rm>

Encoding for the SMULBT variant

Applies when (M == 1 && N == 0)

SMULBT{<c>}{<q>} {<Rd>, }<Rn>, <Rm>

Encoding for the SMULTB variant

Applies when (M == 0 && N == 1)

SMULTB{<c>}{<q>} {<Rd>, }<Rn>, <Rm>

Encoding for the SMULTT variant

Applies when (M == 1 && N == 1)

SMULTT{<c>}{<q>} {<Rd>, }<Rn>, <Rm>

Decode for all variants of this encoding

```

let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let n_index : integer = UInt(N);
let m_index : integer = UInt(M);
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;

```

T1

Encoding for the SMULBB variant

Applies when (N == 0 && M == 0)

SMULBB{<c>}{<q>}{<Rd>,<Rn>,<Rm>}

Encoding for the SMULBT variant

Applies when (N == 0 && M == 1)

SMULBT{<c>}{<q>}{<Rd>,<Rn>,<Rm>}

Encoding for the SMULTB variant

Applies when (N == 1 && M == 0)

SMULTB{<c>}{<q>}{<Rd>,<Rn>,<Rm>}

Encoding for the SMULTT variant

Applies when (N == 1 && M == 1)

SMULTT{<c>}{<q>}{<Rd>,<Rn>,<Rm>}

Decode for all variants of this encoding

```

let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let n_index : integer = UInt(N);
let m_index : integer = UInt(M);
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;

```

For more information about the **CONSTRAINED UNPREDICTABLE** behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

 $\langle c \rangle$

See [Standard assembler syntax fields](#).

 $\langle q \rangle$

See [Standard assembler syntax fields](#).

<Rd>

Is the general-purpose destination register, encoded in the “Rd” field.

<Rn>

Is the first general-purpose source register holding the multiplicand in the bottom or top half (selected by <x>), encoded in the “Rn” field.

<Rm>

Is the second general-purpose source register holding the multiplier in the bottom or top half (selected by <y>), encoded in the “Rm” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let operand1 : bits(16) = R(n)[n_index*:16];
    let operand2 : bits(16) = R(m)[m_index*:16];
    let result : integer = SInt(operand1) * SInt(operand2);
    R(d) = result[31:0];
    // Signed overflow cannot occur
end;
```

C5.1.202 SMULL, SMULLS

Signed Multiply Long multiplies two 32-bit signed values to produce a 64-bit result.

In A32 instructions, the condition flags can optionally be updated based on the result. Use of this option adversely affects performance on many implementations.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding for the Flag setting variant

Applies when (S == 1)

```
SMULLS{<c>}{<q>}    <RdLo>, <RdHi>, <Rn>, <Rm>
```

Encoding for the Not flag setting variant

Applies when $(S == 0)$

```
SMULL{<c>}{<q>}    <RdLo>, <RdHi>, <Rn>, <Rm>
```

Decode for all variants of this encoding

```

let dLo : integer = UInt(RdLo);
let dHi : integer = UInt(RdHi);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let setflags : boolean = (S == '1');
if dLo == 15 || dHi == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
if dHi == dLo then UnpredictableProcedure(); end;

```

CONSTRAINED UNPREDICTABLE behavior

If $d_{Hi} == d_{Lo}$, then one of the following behaviors must occur:

- The instruction is **UNDEFINED**.
- The instruction executes as **NOP**.
- The value in the destination register is **UNKNOWN**.

T1

Encoding

SMULL{<c>}{<q>} <RdLo>, <RdHi>, <Rn>, <Rm>

Decode for this encoding

```
let dLo : integer = UInt(RdLo);
let dHi : integer = UInt(RdHi);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let setflags : boolean = FALSE;
if dLo == 15 || dHi == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
// Armv8-A removes UNPREDICTABLE for R13
if dHi == dLo then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `dHi == dLo`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The value in the destination register is UNKNOWN.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<RdLo>

Is the general-purpose destination register for the lower 32 bits of the result, encoded in the “RdLo” field.

<RdHi>

Is the general-purpose destination register for the upper 32 bits of the result, encoded in the “RdHi” field.

<Rn>

Is the first general-purpose source register holding the multiplicand, encoded in the “Rn” field.

<Rm>

Is the second general-purpose source register holding the multiplier, encoded in the “Rm” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let result : integer = SInt(R(n)) * SInt(R(m));
    R(dHi) = result[63:32];
    R(dLo) = result[31:0];
    if setflags then
        PSTATE.N = result[63];
        PSTATE.Z = IsZeroBit{64}(result[63:0]);
        // PSTATE.C, PSTATE.V unchanged
    end;
end;
```

C5.1.203 SMULWB, SMULWT

Signed Multiply (word by halfword)

Signed Multiply (word by halfword) multiplies a signed 32-bit quantity and a signed 16-bit quantity. The signed 16-bit quantity is taken from either the bottom or the top half of its source register. The other half of the second source register is ignored. The top 32 bits of the 48-bit product are written to the destination register. The bottom 16 bits of the 48-bit product are ignored. No overflow is possible during this instruction.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1).

A1

Encoding for the SMULWB variant

Applies when (M == 0)

SMULWB{<c>}{<q>} {<Rd>, }<Rn>, <Rm>

Encoding for the SMULWT variant

Applies when (M == 1)

SMULWT{<c>}{<q>} {<Rd>, }<Rn>, <Rm>

Decode for all variants of this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let m_high : boolean = (M == '1');
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
```

T1

Encoding for the SMULWB variant

Applies when (M == 0)

SMULWB{<c>}{<q>} {<Rd>, }<Rn>, <Rm>

Encoding for the SMULWT variant

Applies when (M == 1)

SMULWT{<c>}{<q>} {<Rd>, }<Rn>, <Rm>

Decode for all variants of this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let m_high : boolean = (M == '1');
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rd>

Is the general-purpose destination register, encoded in the “Rd” field.

<Rn>

Is the first general-purpose source register holding the multiplicand, encoded in the “Rn” field.

<Rm>

Is the second general-purpose source register holding the multiplier in the bottom or top half (selected by <y>), encoded in the “Rm” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let operand2 : bits(16) = if m_high then R(m)[31:16] else R(m)[15:0];
    let product : integer = SInt(R(n)) * SInt(operand2);
    R(d) = product[47:16];
    // Signed overflow cannot occur
end;
```

C5.1.204 SMUSD, SMUSDX

Signed Multiply Subtract Dual

Signed Multiply Subtract Dual performs two signed 16 x 16-bit multiplications. It subtracts one of the products from the other, and writes the result to the destination register.

Optionally, the instruction can exchange the halfwords of the second operand before performing the arithmetic. This produces top x bottom and bottom x top multiplication.

Overflow cannot occur.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding for the SMUSD variant

Applies when (M == 0)

SMUSD{<c>}{<q>} {<Rd>, }<Rn>, <Rm>

Encoding for the SMUSDX variant

Applies when (M == 1)

SMUSDX{<c>}{<q>} {<Rd>, }<Rn>, <Rm>

Decode for all variants of this encoding

```

let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let m_swap : boolean = (M == '1');
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;

```

T1

Encoding for the SMUSD variant

Applies when (M == 0)

SMUSD{<c>}{<q>} {<Rd>, }<Rn>, <Rm>

Encoding for the SMUSDX variant

Applies when (M == 1)

SMUSDX{<c>}{<q>} {<Rd>, }<Rn>, <Rm>

Decode for all variants of this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let m_swap : boolean = (M == '1');
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rd>

Is the general-purpose destination register, encoded in the “Rd” field.

<Rn>

Is the first general-purpose source register, encoded in the “Rn” field.

<Rm>

Is the second general-purpose source register, encoded in the “Rm” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let operand2 : bits(32) = if m_swap then ROR(R(m),16) else R(m);
    let product1 : integer = SInt(R(n)[15:0]) * SInt(operand2[15:0]);
    let product2 : integer = SInt(R(n)[31:16]) * SInt(operand2[31:16]);
    let result : integer = product1 - product2;
    R(d) = result[31:0];
    // Signed overflow cannot occur
end;
```

C5.1.205 SRS, SRSDA, SRSDB, SRSIA, SRSIB

Store Return State stores the LR_<current_mode> and SPSR_<current_mode> to the stack of a specified mode. For information about memory accesses see [Memory accesses](#).

SRS is UNDEFINED in Hyp mode.

SRS is CONSTRAINED UNPREDICTABLE if it is executed in User or System mode, or if the specified mode is any of the following:

- Not implemented.
- A mode that [AArch32 PE modes](#) does not show.
- Hyp mode.
- Monitor mode, if the SRS instruction is executed in Non-secure state.

If EL3 is using AArch64 and an SRS instruction that is executed in a Secure EL1 mode specifies Monitor mode, it is trapped to EL3.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#) and [T2](#)).

A1

Encoding for the Decrement After variant

Applies when (P == 0 && U == 0)

SRSDA{<c>}{<q>} SP{!}, #<mode>

Encoding for the Decrement Before variant

Applies when (P == 1 && U == 0)

SRSDB{<c>}{<q>} SP{!}, #<mode>

Encoding for the Increment After variant

Applies when (P == 0 && U == 1)

SRS{IA}{<c>}{<q>} SP{!}, #<mode>

Encoding for the Increment Before variant

Applies when (P == 1 && U == 1)

SRSIB{<c>}{<q>} SP{!}, #<mode>

Decode for all variants of this encoding

```
let wback : boolean = (W == '1');
let increment : boolean = (U == '1');
let wordhigher : boolean = (P == U);
```

T1

Encoding

SRSDB{<c>}{<q>} SP{!}, #<mode>

Decode for this encoding

```
let wback : boolean = (W == '1');
let increment : boolean = FALSE;
let wordhigher : boolean = FALSE;
```

T2

Encoding

SRS{IA}{<c>}{<q>} SP{!}, #<mode>

Decode for this encoding

```
let wback : boolean = (W == '1');
let increment : boolean = TRUE;
let wordhigher : boolean = FALSE;
```

For more information about the **CONSTRAINED UNPREDICTABLE** behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly [SRS \(T32\)](#) and [SRS \(A32\)](#).

Assembler Symbols

 $\langle c \rangle$

For the “Decrement After”, “Decrement Before”, “Increment After”, and “Increment Before” variants: see [Standard assembler syntax fields](#). `<C>` must be `ALL` or omitted.

For the “T1” and “T2” variants: see [Standard assembler syntax fields](#).

 $\langle q \rangle$

See [Standard assembler syntax fields](#).

!

The address adjusted by the size of the data loaded is written back to the base register. If specified, it is encoded in the “W” field as 1, otherwise this field defaults to 0.

<mode>

Is the number of the mode whose Banked SP is used as the base register, encoded in the “mode” field. For details of PE modes and their numbers see [AArch32 state PE modes](#).

IA

For the “Increment After” variant: is an optional suffix to indicate the Increment After variant.

For the “T2” variant: is an optional suffix for the Increment After form.

SRSFA, SRSEA, SRSFD, and SRSED are pseudo-instructions for SRSIB, SRSIA, SRSDB, and SRSDA respectively, referring to their use for pushing data onto Full Ascending, Empty Ascending, Full Descending, and Empty Descending stacks.

Operation

```

if CurrentInstrSet() == InstrSet_A32 then
    if ConditionPassed() then
        EncodingSpecificOperations();
        if PSTATE.EL == EL2 then           // UNDEFINED at EL2
            Undefined();
        end;

        // Check for UNPREDICTABLE cases. The definition of UNPREDICTABLE does not permit these
        // to be security holes
        if PSTATE.M IN {M32_User,M32_System} then
            UnpredictableProcedure();
        elsif mode == M32_Hyp then          // Check for attempt to access Hyp mode SP
            UnpredictableProcedure();
        elsif mode == M32_Monitor then      // Check for attempt to access Monitor mode SP
            if !HaveEL(EL3) || CurrentSecurityState() != SS_Secure then
                UnpredictableProcedure();
            end;
        elsif BadMode(mode) then
            UnpredictableProcedure();
        end;

        let base : bits(32) = Rmode(13,mode);
        var address : bits(32) = if increment then base else base-8;
        if wordhigher then address = address+4; end;
        MemA{32}(address) = LR();
        MemA{32}(address+4) = SPSR_curr();
        if wback then Rmode(13,mode) = if increment then base+8 else base-8; end;
    end;
else
    if ConditionPassed() then
        EncodingSpecificOperations();
        if PSTATE.EL == EL2 then           // UNDEFINED at EL2
            Undefined();
        end;

        // Check for UNPREDICTABLE cases. The definition of UNPREDICTABLE does not permit these
        // to be security holes
        if PSTATE.M IN {M32_User,M32_System} then
            UnpredictableProcedure();
        elsif mode == M32_Hyp then          // Check for attempt to access Hyp mode SP
            UnpredictableProcedure();
        elsif mode == M32_Monitor then      // Check for attempt to access Monitor mode SP
            if !HaveEL(EL3) || CurrentSecurityState() != SS_Secure then
                UnpredictableProcedure();
            end;
        elsif BadMode(mode) then
            UnpredictableProcedure();
        end;

        let base : bits(32) = Rmode(13,mode);

```

```
var address : bits(32) = if increment then base else base-8;  
if wordhigher then address = address+4; end;  
MemA{32}(address) = LR();  
MemA{32}(address+4) = SPSR_curr();  
if wback then Rmode(13,mode) = if increment then base+8 else base-8; end;  
end;  
end;
```

CONSTRAINED UNPREDICTABLE behavior

If `PSTATE.M` IN {`M32_User`,`M32_System`}, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.

If `mode == M32_Hyp`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.

If `mode == M32_Monitor` && (!`HaveEL(EL3)` || `CurrentSecurityState()` != `SS_Secure`), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.

If `BadMode(mode)`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction stores to the stack of the mode in which it is executed.
- The instruction stores to an UNKNOWN address, and if the instruction specifies writeback then any general-purpose register that can be accessed from the current Exception level without a privilege violation becomes UNKNOWN.

C5.1.206 SSAT

Signed Saturate saturates an optionally-shifted signed value to a selectable signed range.

This instruction sets [PSTATE.Q](#) to 1 if the operation saturates.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding for the Arithmetic shift right variant

Applies when (sh == 1)

SSAT{<c>}{<q>} <Rd>, #<imm>, <Rn>, ASR #<amount>

Encoding for the Logical shift left variant

Applies when (sh == 0)

SSAT{<c>}{<q>} <Rd>, #<imm>, <Rn> {, LSL #<amount>}

Decode for all variants of this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let saturate_to : integer{} = UInt(sat_imm)+1;
let (shift_t, shift_n) : (SRTType, integer) = DecodeImmShift(sh::'0', imm5);
if d == 15 || n == 15 then UnpredictableProcedure(); end;
```

T1

Encoding for the Arithmetic shift right variant

Applies when (sh == 1 && !(imm3 == 000 && imm2 == 00))

SSAT{<c>}{<q>} <Rd>, #<imm>, <Rn>, ASR #<amount>

Encoding for the Logical shift left variant

Applies when (sh == 0)

SSAT{<c>}{<q>} <Rd>, #<imm>, <Rn> {, LSL #<amount>}

Decode for all variants of this encoding

```

if sh == '1' && (imm3::imm2) == '00000' then See("SSAT16"); end;
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let saturate_to : integer{} = UInt(sat_imm)+1;
let (shift_t, shift_n) : (SRTType, integer) = DecodeImmShift(sh::'0', imm3::imm2);
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 || n == 15 then UnpredictableProcedure(); end;

```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rd>

Is the general-purpose destination register, encoded in the “Rd” field.

<imm>

Is the bit position for saturation, in the range 1 to 32, encoded in the “sat_imm” field as <imm>-1.

<Rn>

Is the general-purpose source register, encoded in the “Rn” field.

<amount>

For the “A1 Arithmetic shift right” variant: is the shift amount, in the range 1 to 32 encoded in the “imm5” field as <amount> modulo 32.

For the “A1 Logical shift left” variant: is the optional shift amount, in the range 0 to 31, defaulting to 0 and encoded in the “imm5” field.

For the “T1 Arithmetic shift right” variant: is the shift amount, in the range 1 to 31 encoded in the “imm3:imm2” field as <amount>.

For the “T1 Logical shift left” variant: is the optional shift amount, in the range 0 to 31, defaulting to 0 and encoded in the “imm3:imm2” field.

Operation

```

if ConditionPassed() then
    EncodingSpecificOperations();
    let operand : bits(32) = Shift{}(R(n), shift_t, shift_n, PSTATE.C); // PSTATE.C ignored
    let (result, sat) : (bits(saturate_to), boolean) = SignedSatQ{saturate_to}(SInt(operand));
    R(d) = SignExtend{32}(result);
    if sat then
        PSTATE.Q = '1';
    end;
end;

```

C5.1.207 SSAT16

Signed Saturate 16 saturates two signed 16-bit values to a selected signed range.

This instruction sets **PSTATE.Q** to 1 if the operation saturates.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

SSAT16{<c>}{<q>} <Rd>, #<imm>, <Rn>

Decode for this encoding

```

let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let saturate_to : integer{} = UInt(sat_imm)+1;
if d == 15 || n == 15 then UnpredictableProcedure(); end;

```

T1

Encoding

SSAT16{<c>}{<q>} <Rd>, #<imm>, <Rn>

Decode for this encoding

```

let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let saturate_to : integer{} = UInt(sat_imm)+1;
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 || n == 15 then UnpredictableProcedure(); end;

```

For more information about the **CONSTRAINED UNPREDICTABLE** behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rd>

Is the general-purpose destination register, encoded in the “Rd” field.

<imm>

Is the bit position for saturation, in the range 1 to 16, encoded in the “sat_imm” field as <imm>-1.

<Rn>

Is the general-purpose source register, encoded in the “Rn” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let (result1, sat1) : (bits(saturate_to), boolean) = SignedSatQ{saturate_to}(SInt(R(n)[15:0]));
    let (result2, sat2) : (bits(saturate_to), boolean) = SignedSatQ{saturate_to}(SInt(R(n)[31:16]));
    R(d)[15:0] = SignExtend{16}(result1);
    R(d)[31:16] = SignExtend{16}(result2);
    if sat1 || sat2 then
        PSTATE.Q = '1';
    end;
end;
```

C5.1.208 SSAX

Signed Subtract and Add with Exchange exchanges the two halfwords of the second operand, performs one 16-bit integer subtraction and one 16-bit addition, and writes the results to the destination register. It sets [PSTATE.GE](#) according to the results.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

SSAX{<c>}{<q>} {<Rd>, }<Rn>, <Rm>

Decode for this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
```

T1

Encoding

SSAX{<c>}{<q>} {<Rd>, }<Rn>, <Rm>

Decode for this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rd>

Is the general-purpose destination register, encoded in the “Rd” field.

<Rn>

Is the first general-purpose source register, encoded in the “Rn” field.

<Rm>

Is the second general-purpose source register, encoded in the “Rm” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let sum : integer = SInt(R(n)[15:0]) + SInt(R(m)[31:16]);
    let diff : integer = SInt(R(n)[31:16]) - SInt(R(m)[15:0]);
    R(d)[15:0] = sum[15:0];
    R(d)[31:16] = diff[15:0];
    PSTATE.GE[1:0] = if sum >= 0 then '11' else '00';
    PSTATE.GE[3:2] = if diff >= 0 then '11' else '00';
end;
```

C5.1.209 SSUB16

Signed Subtract 16 performs two 16-bit signed integer subtractions, and writes the results to the destination register. It sets **PSTATE**.GE according to the results of the subtractions.

It has encodings from the following instruction sets: A32 (**A1**) and T32 (**T1**).

A1

Encoding

SSUB16{<c>}{<q>} {<Rd>, }<Rn>, <Rm>

Decode for this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
```

T1

Encoding

SSUB16{<c>}{<q>} {<Rd>, }<Rn>, <Rm>

Decode for this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rd>

Is the general-purpose destination register, encoded in the “Rd” field.

<Rn>

Is the first general-purpose source register, encoded in the “Rn” field.

<Rm>

Is the second general-purpose source register, encoded in the “Rm” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let diff1 : integer = SInt(R(n)[15:0]) - SInt(R(m)[15:0]);
    let diff2 : integer = SInt(R(n)[31:16]) - SInt(R(m)[31:16]);
    R(d)[15:0] = diff1[15:0];
    R(d)[31:16] = diff2[15:0];
    PSTATE.GE[1:0] = if diff1 >= 0 then '11' else '00';
    PSTATE.GE[3:2] = if diff2 >= 0 then '11' else '00';
end;
```

C5.1.210 SSUB8

Signed Subtract 8 performs four 8-bit signed integer subtractions, and writes the results to the destination register. It sets [PSTATE.GE](#) according to the results of the subtractions.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

SSUB8{<c>}{<q>} {<Rd>, }<Rn>, <Rm>

Decode for this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
```

T1

Encoding

SSUB8{<c>}{<q>} {<Rd>, }<Rn>, <Rm>

Decode for this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rd>

Is the general-purpose destination register, encoded in the “Rd” field.

<Rn>

Is the first general-purpose source register, encoded in the “Rn” field.

<Rm>

Is the second general-purpose source register, encoded in the “Rm” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let diff1 : integer = SInt(R(n)[7:0]) - SInt(R(m)[7:0]);
    let diff2 : integer = SInt(R(n)[15:8]) - SInt(R(m)[15:8]);
    let diff3 : integer = SInt(R(n)[23:16]) - SInt(R(m)[23:16]);
    let diff4 : integer = SInt(R(n)[31:24]) - SInt(R(m)[31:24]);
    R(d)[7:0] = diff1[7:0];
    R(d)[15:8] = diff2[7:0];
    R(d)[23:16] = diff3[7:0];
    R(d)[31:24] = diff4[7:0];
    PSTATE.GE[0] = if diff1 >= 0 then '1' else '0';
    PSTATE.GE[1] = if diff2 >= 0 then '1' else '0';
    PSTATE.GE[2] = if diff3 >= 0 then '1' else '0';
    PSTATE.GE[3] = if diff4 >= 0 then '1' else '0';
end;
```

C5.1.211 STC

Store data to System register calculates an address from a base register value and an immediate offset, and stores a word from the [DBGDTRRXint](#) System register to memory. It can use offset, post-indexed, pre-indexed, or unindexed addressing. For information about memory accesses, see [Memory accesses](#).

In an implementation that includes EL2, the permitted `STC` access to [DBGDTRRXint](#) can be trapped to Hyp mode, meaning that an attempt to execute an `STC` instruction in a Non-secure mode other than Hyp mode, that would be permitted in the absence of the Hyp trap controls, generates a Hyp Trap exception. For more information, see [HDCR.TDA](#).

For simplicity, the `STC` pseudocode does not show this possible trap to Hyp mode.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding for the Offset variant

Applies when (P == 1 && W == 0)

STC{<c>}{<q>} p14, c5, [<Rn>{, #<+/-><imm>}]

Encoding for the Post-indexed variant

Applies when (P == 0 && W == 1)

STC{<c>}{<q>} p14, c5, [<Rn>], #<+/-><imm>

Encoding for the Pre-indexed variant

Applies when (P == 1 && W == 1)

STC{<c>}{<q>} p14, c5, [<Rn>, #<+/-><imm>]!

Encoding for the Unindexed variant

Applies when (P == 0 && U == 1 && W == 0)

STC{<c>}{<q>} p14, c5, [<Rn>], <option>

Decode for all variants of this encoding

```

if P == '0' && U == '0' && W == '0' then Undefined(); end;
let n : integer = UInt(Rn);
let cp : integer = 14;
let imm32 : bits(32) = ZeroExtend{(imm8::'00')};
let index : boolean = (P == '1');
let add : boolean = (U == '1');
let wback : boolean = (W == '1');
if n == 15 && (wback || CurrentInstrSet() != InstrSet_A32) then UnpredictableProcedure(); end;

```

CONSTRAINED UNPREDICTABLE behavior

If $n == 15$ && $wback$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes without writeback of the base address.
- The instruction executes with writeback to the PC. The instruction is handled as described in Using R15.

T1

Encoding for the Offset variant

Applies when $(P == 1 \ \&\& \ W == 0)$

STC{<c>}{<q>} p14, c5, [<Rn>{, #<+/-><imm>}]

Encoding for the Post-indexed variant

Applies when $(P == 0 \ \&\& \ W == 1)$

STC{<c>}{<q>} p14, c5, [<Rn>], #<+/-><imm>

Encoding for the Pre-indexed variant

Applies when $(P == 1 \ \&\& \ W == 1)$

STC{<c>}{<q>} p14, c5, [<Rn>, #<+/-><imm>]!

Encoding for the Unindexed variant

Applies when $(P == 0 \ \&\& \ U == 1 \ \&\& \ W == 0)$

STC{<c>}{<q>} p14, c5, [<Rn>], <option>

Decode for all variants of this encoding

```

if P == '0' && U == '0' && W == '0' then Undefined(); end;
let n : integer = UInt(Rn);
let cp : integer = 14;
let imm32 : bits(32) = ZeroExtend{(imm8::'00')};
let index : boolean = (P == '1');
let add : boolean = (U == '1');
let wback : boolean = (W == '1');
if n == 15 && (wback || CurrentInstrSet() != InstrSet_A32) then UnpredictableProcedure(); end;

```

CONSTRAINED UNPREDICTABLE behavior

If `n == 15`, then one of the following behaviors must occur:

- The instruction is `UNDEFINED`.
- The instruction executes as `NOP`.
- The instruction executes without writeback of the base address.
- The instruction executes with writeback to the PC. The instruction is handled as described in Using R15.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

`<c>`

See [Standard assembler syntax fields](#).

`<q>`

See [Standard assembler syntax fields](#).

`<Rn>`

For the “A1 Offset” and “A1 Unindexed” variants: is the general-purpose base register, encoded in the “Rn” field. The PC can be used, but this is deprecated.

For the “A1 Post-indexed”, “A1 Pre-indexed”, “T1 Offset”, “T1 Post-indexed”, “T1 Pre-indexed”, and “T1 Unindexed” variants: is the general-purpose base register, encoded in the “Rn” field.

`+/-`

Specifies the offset is added to or subtracted from the base register, defaulting to `+` if omitted and encoded in “U”:

U	+/-
0	-
1	+

`<imm>`

Is the immediate offset used for forming the address, a multiple of 4 in the range 0-1020, defaulting to 0 and encoded in the “imm8” field, as `<imm>/4`.

`<option>`

Is an 8-bit immediate, in the range 0 to 255 enclosed in { }, encoded in the “imm8” field. The value of this field is ignored when executing this instruction.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let offset_addr : bits(32) = if add then (R(n) + imm32) else (R(n) - imm32);
    let address : bits(32) = if index then offset_addr else R(n);

    // System register read from DBGDTRXint.
    AArch32_SysRegRead(cp, ThisInstr(), address[31:0]);
    if wback then R(n) = offset_addr; end;
end;
```

C5.1.212 STL

Store-Release Word stores a word from a register to memory. The instruction also has memory ordering semantics as described in [Load-Acquire](#), [Store-Release](#).

For more information about support for shared memory see [Synchronization and semaphores](#). For information about memory accesses see [Memory accesses](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

STL{<c>}{<q>} <Rt>, [<Rn>]

Decode for this encoding

```
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
if t == 15 || n == 15 then UnpredictableProcedure(); end;
```

T1

Encoding

STL{<c>}{<q>} <Rt>, [<Rn>]

Decode for this encoding

```
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
if t == 15 || n == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rt>

Is the general-purpose register to be transferred, encoded in the “Rt” field.

<Rn>

Is the general-purpose base register, encoded in the “Rn” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let address : bits(32) = R(n);
    MemO{32}(address) = R(t);
end;
```

C5.1.213 STLB

Store-Release Byte stores a byte from a register to memory. The instruction also has memory ordering semantics as described in [Load-Acquire](#), [Store-Release](#).

For more information about support for shared memory see [Synchronization and semaphores](#). For information about memory accesses see [Memory accesses](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

STLB{<c>}{<q>} <Rt>, [<Rn>]

Decode for this encoding

```
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
if t == 15 || n == 15 then UnpredictableProcedure(); end;
```

T1

Encoding

STLB{<c>}{<q>} <Rt>, [<Rn>]

Decode for this encoding

```
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
if t == 15 || n == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rt>

Is the general-purpose register to be transferred, encoded in the “Rt” field.

<Rn>

Is the general-purpose base register, encoded in the “Rn” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let address : bits(32) = R(n);
    MemO{8}(address) = R(t)[7:0];
end;
```

C5.1.214 STLEX

Store-Release Exclusive Word stores a word from a register to memory if the executing PE has exclusive access to the memory at that address, and returns a status value of 0 if the store was successful, or of 1 if no store was performed.

The instruction also has memory ordering semantics as described in [Load-Acquire, Store-Release](#).

For more information about support for shared memory see [Synchronization and semaphores](#). For information about memory accesses see [Memory accesses](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

STLEX{<c>}{<q>} <Rd>, <Rt>, [<Rn>]

Decode for this encoding

```
let d : integer = UInt(Rd);
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
if d == 15 || t == 15 || n == 15 then UnpredictableProcedure(); end;
if d == n || d == t then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If $d == t$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction executes but the value stored is UNKNOWN.

If $d == n$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs the store to an UNKNOWN address.

T1

Encoding

STLEX{<c>}{<q>} <Rd>, <Rt>, [<Rn>]

Decode for this encoding

```
let d : integer = UInt(Rd);
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
if d == 15 || t == 15 || n == 15 then UnpredictableProcedure(); end;
if d == n || d == t then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If $d == t$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction executes but the value stored is UNKNOWN.

If $d == n$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs the store to an UNKNOWN address.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rd>

Is the destination general-purpose register into which the status result of the store exclusive is written, encoded in the “Rd” field. The value returned is:

- 0 If the operation updates memory.
- 1 If the operation fails to update memory.

<Rt>

Is the general-purpose register to be transferred, encoded in the “Rt” field.

<Rn>

Is the general-purpose base register, encoded in the “Rn” field.

Aborts and alignment

If a synchronous Data Abort exception is generated by the execution of this instruction:

- Memory is not updated.
- <Rd> is not updated.

A non word-aligned memory address causes an Alignment fault Data Abort exception to be generated, subject to the following rules:

- If `AArch32.ExclusiveMonitorsPass()` returns `TRUE`, the exception is generated.
- Otherwise, it is IMPLEMENTATION DEFINED whether the exception is generated.

If `AArch32.ExclusiveMonitorsPass()` returns `FALSE` and the memory address, if accessed, would generate a synchronous Data Abort exception, it is IMPLEMENTATION DEFINED whether the exception is generated.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
let address : bits(32) = R(n);
if AArch32_ExclusiveMonitorsPass(address,4) then
    MemO{32}(address) = R(t);
    R(d) = ZeroExtend{32}('0');
else
    R(d) = ZeroExtend{32}('1');
end;
end;
```

C5.1.215 STLEXB

Store-Release Exclusive Byte stores a byte from a register to memory if the executing PE has exclusive access to the memory at that address, and returns a status value of 0 if the store was successful, or of 1 if no store was performed.

The instruction also has memory ordering semantics as described in [Load-Acquire, Store-Release](#).

For more information about support for shared memory see [Synchronization and semaphores](#). For information about memory accesses see [Memory accesses](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

STLEXB{<c>}{<q>} <Rd>, <Rt>, [<Rn>]

Decode for this encoding

```
let d : integer = UInt(Rd);
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
if d == 15 || t == 15 || n == 15 then UnpredictableProcedure(); end;
if d == n || d == t then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If $d == t$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction executes but the value stored is UNKNOWN.

If $d == n$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs the store to an UNKNOWN address.

T1

Encoding

STLEXB{<c>}{<q>} <Rd>, <Rt>, [<Rn>]

Decode for this encoding

```
let d : integer = UInt(Rd);  
let t : integer = UInt(Rt);  
let n : integer = UInt(Rn);  
if d == 15 || t == 15 || n == 15 then UnpredictableProcedure(); end;  
if d == n || d == t then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If $d == t$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction executes but the value stored is UNKNOWN.

If $d == n$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs the store to an UNKNOWN address.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rd>

Is the destination general-purpose register into which the status result of the store exclusive is written, encoded in the “Rd” field. The value returned is:

- 0 If the operation updates memory.
- 1 If the operation fails to update memory.

<Rt>

Is the general-purpose register to be transferred, encoded in the “Rt” field.

<Rn>

Is the general-purpose base register, encoded in the “Rn” field.

Aborts

If a synchronous Data Abort exception is generated by the execution of this instruction:

- Memory is not updated.
- <Rd> is not updated.

If `AArch32.ExclusiveMonitorsPass()` returns `FALSE` and the memory address, if accessed, would generate a synchronous Data Abort exception, it is IMPLEMENTATION DEFINED whether the exception is generated.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
let address : bits(32) = R(n);
if AArch32_ExclusiveMonitorsPass(address,1) then
    MemO{8}(address) = R(t)[7:0];
    R(d) = ZeroExtend{32}('0');
else
    R(d) = ZeroExtend{32}('1');
end;
end;
```

C5.1.216 STLEXD

Store-Release Exclusive Doubleword stores a doubleword from two registers to memory if the executing PE has exclusive access to the memory at that address, and returns a status value of 0 if the store was successful, or of 1 if no store was performed.

The instruction also has memory ordering semantics as described in [Load-Acquire, Store-Release](#).

For more information about support for shared memory see [Synchronization and semaphores](#). For information about memory accesses see [Memory accesses](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

STLEXD{<c>}{<q>} <Rd>, <Rt>, <Rt2>, [<Rn>]

Decode for this encoding

```
let t : integer = UInt(Rt);
let t2 : integer = t + 1;
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
if d == 15 || Rt[0] == '1' || t2 == 15 || n == 15 then UnpredictableProcedure(); end;
if d == n || d == t || d == t2 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If $d == t$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction executes but the value stored is UNKNOWN.

If $d == n$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs the store to an UNKNOWN address.

If $Rt<0> == '1'$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes with the additional decode: $Rt<0> = '0'$.
- The instruction executes with the additional decode: $t2 = t$.
- The instruction executes as described, with no change to its behavior and no additional side effects.

If $Rt == '1110'$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction is handled as described in Using R15.

T1

Encoding

STLEXD{<c>}{<q>} <Rd>, <Rt>, <Rt2>, [<Rn>]

Decode for this encoding

```
let d : integer = UInt(Rd);
let t : integer = UInt(Rt);
let t2 : integer = UInt(Rt2);
let n : integer = UInt(Rn);
if d == 15 || t == 15 || t2 == 15 || n == 15 then UnpredictableProcedure(); end;
if d == n || d == t || d == t2 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If $d == t$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction executes but the value stored is UNKNOWN.

If $d == n$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs the store to an UNKNOWN address.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rd>

Is the destination general-purpose register into which the status result of the store exclusive is written, encoded in the “Rd” field. The value returned is:

- 0 If the operation updates memory.
- 1 If the operation fails to update memory.

<Rt>

For the “A1” variant: is the first general-purpose register to be transferred, encoded in the “Rt” field. <Rt> must be even-numbered and not R14.

For the “T1” variant: is the first general-purpose register to be transferred, encoded in the “Rt” field.

<Rt2>

For the “A1” variant: is the second general-purpose register to be transferred. <Rt2> must be <R(t+1)>.

For the “T1” variant: is the second general-purpose register to be transferred, encoded in the “Rt2” field.

<Rn>

Is the general-purpose base register, encoded in the “Rn” field.

Aborts and alignment

If a synchronous Data Abort exception is generated by the execution of this instruction:

- Memory is not updated.
- <Rd> is not updated.

A non word-aligned memory address causes an Alignment fault Data Abort exception to be generated, subject to the following rules:

- If `AArch32.ExclusiveMonitorsPass()` returns `TRUE`, the exception is generated.
- Otherwise, it is IMPLEMENTATION DEFINED whether the exception is generated.

If `AArch32.ExclusiveMonitorsPass()` returns `FALSE` and the memory address, if accessed, would generate a synchronous Data Abort exception, it is IMPLEMENTATION DEFINED whether the exception is generated.

Operation

```

if ConditionPassed() then
    EncodingSpecificOperations();
    let address : bits(32) = R(n);
    // Create doubleword to store such that R[t] will be stored at address and R[t2] at address+4.
    let value : bits(64) = if BigEndian(AccessType_GPR) then R(t)::R(t2) else R(t2)::R(t);
    if AArch32_ExclusiveMonitorsPass(address, 8) then
        MemO{64}(address) = value;
        R(d) = ZeroExtend{32}('0');
    else
        R(d) = ZeroExtend{32}('1');
    end;
end;

```

C5.1.217 STLEXH

Store-Release Exclusive Halfword stores a halfword from a register to memory if the executing PE has exclusive access to the memory at that address, and returns a status value of 0 if the store was successful, or of 1 if no store was performed.

The instruction also has memory ordering semantics as described in [Load-Acquire, Store-Release](#).

For more information about support for shared memory see [Synchronization and semaphores](#). For information about memory accesses see [Memory accesses](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

STLEXH{<c>}{<q>} <Rd>, <Rt>, [<Rn>]

Decode for this encoding

```
let d : integer = UInt(Rd);
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
if d == 15 || t == 15 || n == 15 then UnpredictableProcedure(); end;
if d == n || d == t then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If $d == t$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction executes but the value stored is UNKNOWN.

If $d == n$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs the store to an UNKNOWN address.

T1

Encoding

STLEXH{<c>}{<q>} <Rd>, <Rt>, [<Rn>]

Decode for this encoding

```
let d : integer = UInt(Rd);
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
if d == 15 || t == 15 || n == 15 then UnpredictableProcedure(); end;
if d == n || d == t then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If $d == t$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction executes but the value stored is UNKNOWN.

If $d == n$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs the store to an UNKNOWN address.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rd>

Is the destination general-purpose register into which the status result of the store exclusive is written, encoded in the “Rd” field. The value returned is:

- 0 If the operation updates memory.
- 1 If the operation fails to update memory.

<Rt>

Is the general-purpose register to be transferred, encoded in the “Rt” field.

<Rn>

Is the general-purpose base register, encoded in the “Rn” field.

Aborts and alignment

If a synchronous Data Abort exception is generated by the execution of this instruction:

- Memory is not updated
- <Rd> is not updated.

A non word-aligned memory address causes an Alignment fault Data Abort exception to be generated, subject to the following rules:

- If `AArch32.ExclusiveMonitorsPass()` returns `TRUE`, the exception is generated.
- Otherwise, it is IMPLEMENTATION DEFINED whether the exception is generated.

If `AArch32.ExclusiveMonitorsPass()` returns `FALSE` and the memory address, if accessed, would generate a synchronous Data Abort exception, it is IMPLEMENTATION DEFINED whether the exception is generated.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
let address : bits(32) = R(n);
if AArch32_ExclusiveMonitorsPass(address,2) then
    MemO{16}(address) = R(t)[15:0];
    R(d) = ZeroExtend{32}('0');
else
    R(d) = ZeroExtend{32}('1');
end;
end;
```

C5.1.218 STLH

Store-Release Halfword stores a halfword from a register to memory. The instruction also has memory ordering semantics as described in [Load-Acquire, Store-Release](#).

For more information about support for shared memory see [Synchronization and semaphores](#). For information about memory accesses see [Memory accesses](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

STLH{<c>}{<q>} <Rt>, [<Rn>]

Decode for this encoding

```
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
if t == 15 || n == 15 then UnpredictableProcedure(); end;
```

T1

Encoding

STLH{<c>}{<q>} <Rt>, [<Rn>]

Decode for this encoding

```
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
if t == 15 || n == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rt>

Is the general-purpose register to be transferred, encoded in the “Rt” field.

<Rn>

Is the general-purpose base register, encoded in the “Rn” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let address : bits(32) = R(n);
    MemO{16}(address) = R(t)[15:0];
end;
```

C5.1.219 STM, STMIA, STMEA

Store Multiple (Increment After, Empty Ascending) stores multiple registers to consecutive memory locations using an address from a base register. The consecutive memory locations start at this address, and the address just above the last of those locations can optionally be written back to the base register.

The lowest-numbered register is loaded from the lowest memory address, through to the highest-numbered register from the highest memory address. See also [Encoding of lists of general-purpose registers and the PC](#).

It has encodings from the following instruction sets: A32 (A1) and T32 (T1 and T2).

A1

Encoding

```
STM{IA}{<c>}{<q>} <Rn>{!}, <registers> // (Preferred syntax)
```

```
STMEA{<c>}{<q>} <Rn>{!}, <registers> // (Alternate syntax, Empty Ascending stack)
```

Decode for this encoding

```
let n : integer = UInt(Rn);
let registers : bits(16) = register_list;
let wback : boolean = (W == '1');
if n == 15 || BitCount(registers) < 1 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `BitCount(registers) < 1`, then one of the following behaviors must occur:

- The instruction is `UNDEFINED`.
- The instruction executes as `NOP`.
- The instruction operates as an `STM` with the same addressing mode but targeting an unspecified set of registers. These registers might include `R15`. If the instruction specifies writeback, the modification to the base address on writeback might differ from the number of registers stored.

If `n == 15` && `wback`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes without writeback of the base address.
- The instruction executes with writeback to the PC. The instruction is handled as described in Using R15.

T1

Encoding

STM{IA}{<c>}{<q>} <Rn>!, <registers> // (Preferred syntax)

STMEA{<c>}{<q>} <Rn>!, <registers> // (Alternate syntax, Empty Ascending stack)

Decode for this encoding

```
let n : integer = UInt(Rn);
let registers : bits(16) = '00000000'::register_list;
let wback : boolean = TRUE;
if BitCount(registers) < 1 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `BitCount(registers) < 1`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction operates as an STM with the same addressing mode but targeting an unspecified set of registers. These registers might include R15. If the instruction specifies writeback, the modification to the base address on writeback might differ from the number of registers stored.

If `n == 15 && wback`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes without writeback of the base address.
- The instruction executes with writeback to the PC. The instruction is handled as described in Using R15.

T2

Encoding

STM{IA}{<c>}.W <Rn>{!}, <registers> // (Preferred syntax, if <Rn>, '!' and <registers> can be
→ represented in T1)

STMEA{<c>}.W <Rn>{!}, <registers> // (Alternate syntax, Empty Ascending stack, if <Rn>, '!' and
→ <registers> can be represented in T1)

STM{IA}{<c>}{<q>} <Rn>{!}, <registers> // (Preferred syntax)

STMEA{<c>}{<q>} <Rn>{!}, <registers> // (Alternate syntax, Empty Ascending stack)

Decode for this encoding

```
let n : integer = UInt(Rn);
let registers : bits(16) = P::M::register_list;
let wback : boolean = (W == '1');
if n == 15 || BitCount(registers) < 2 then UnpredictableProcedure(); end;
if wback && registers[n] == '1' then UnpredictableProcedure(); end;
if registers[13] == '1' then UnpredictableProcedure(); end;
if registers[15] == '1' then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `BitCount(registers) < 1`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction operates as an STM with the same addressing mode but targeting an unspecified set of registers. These registers might include R15. If the instruction specifies writeback, the modification to the base address on writeback might differ from the number of registers stored.

If `BitCount(registers) == 1`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes as described, with no change to its behavior and no additional side effects.
- The instruction operates as an STM with the same addressing mode but targeting an unspecified set of registers. These registers might include R15.

If `wback && registers<n> == '1'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction executes but the value stored for the base register is UNKNOWN.

If `registers<13> == '1'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction performs all of the stores using the specified addressing mode but the value of R13 is UNKNOWN.

If `registers<15> == '1'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction performs all of the stores using the specified addressing mode but the value of R15 is UNKNOWN.

If `n == 15 && wback`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes without writeback of the base address.
- The instruction executes with writeback to the PC. The instruction is handled as described in Using R15.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

IA

Is an optional suffix for the Increment After form.

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rn>

Is the general-purpose base register, encoded in the “Rn” field.

!

The address adjusted by the size of the data loaded is written back to the base register. If specified, it is encoded in the “W” field as 1, otherwise this field defaults to 0.

<registers>

For the “A1” variant: is a list of one or more registers to be stored, separated by commas and surrounded by { and }.

The PC can be in the list. However, Arm deprecates the use of instructions that include the PC in the list.

If base register writeback is specified, and the base register is not the lowest-numbered register in the list, such an instruction stores an UNKNOWN value for the base register.

For the “T1” variant: is a list of one or more registers to be stored, separated by commas and surrounded by { and }. The registers in the list must be in the range R0-R7, encoded in the “register_list” field. If the base register is not the lowest-numbered register in the list, such an instruction stores an UNKNOWN value for the base register.

For the “T2” variant: is a list of one or more registers to be stored, separated by commas and surrounded by { and }.

The registers in the list must be in the range R0-R12, encoded in the “register_list” field, and can optionally contain the LR. If the LR is in the list, the “M” field is set to 1, otherwise it defaults to 0.

Operation

```

if ConditionPassed() then
    EncodingSpecificOperations();
    var address : bits(32) = R(n);
    let length : integer = 4*BitCount(registers);
    let within8byte : boolean = AllInAlignedQuantity{32}(address, length, 8);
    for i = 0 to 14 do
        if registers[i] == '1' then
            if i == n && wback && i != LowestSetBit(registers) then
                // Only possible for encodings T1 and A1
                MemS{32}(address, within8byte) = ARBITRARY : bits(32);
            else
                MemS{32}(address, within8byte) = R(i);
            end;
            address = address + 4;
        end;
    end;
    if registers[15] == '1' then // Only possible for encoding A1
        MemS{32}(address, within8byte) = PCStoreValue();
    end;
    if wback then R(n) = R(n) + 4*BitCount(registers); end;
end;

```

C5.1.220 STM (User registers)

Store Multiple (User registers)

In an EL1 mode other than System mode, Store Multiple (User registers) stores multiple User mode registers to consecutive memory locations using an address from a base register. The PE reads the base register value normally, using the current mode to determine the correct Banked version of the register. This instruction cannot writeback to the base register.

Store Multiple (User registers) is UNDEFINED in Hyp mode, and CONSTRAINED UNPREDICTABLE in User or System modes.

Encoding

STM{<amode>}{<c>}{<q>} <Rn>, <registers>^

Decode for this encoding

```
let n : integer = UInt(Rn);
let registers : bits(16) = register_list;
let increment : boolean = (U == '1');
let wordhigher : boolean = (P == U);
if n == 15 || BitCount(registers) < 1 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If BitCount(registers) < 1, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction operates as an STM with the same addressing mode but targeting an unspecified set of registers. These registers might include R15.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<amode>

is one of:

- DA** Decrement After. The consecutive memory addresses end at the address in the base register. Encoded as P = 0, U = 0.
- ED** Empty Descending. For this instruction, a synonym for DA.
- DB** Decrement Before. The consecutive memory addresses end one word below the address in the base register. Encoded as P = 1, U = 0.
- FD** Full Descending. For this instruction, a synonym for DB.
- IA** Increment After. The consecutive memory addresses start at the address in the base register. This is the default. Encoded as P = 0, U = 1.
- EA** Empty Ascending. For this instruction, a synonym for IA.
- IB** Increment Before. The consecutive memory addresses start one word above the address in the base register. Encoded as P = 1, U = 1.
- FA** Full Ascending. For this instruction, a synonym for IB.

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rn>

Is the general-purpose base register, encoded in the “Rn” field.

<registers>

Is a list of one or more registers, separated by commas and surrounded by { and }. It specifies the set of registers to be stored by the STM instruction. The registers are stored with the lowest-numbered register to the lowest memory address, through to the highest-numbered register to the highest memory address. See also [Encoding of lists of general-purpose registers and the PC](#).

Operation

```

if ConditionPassed() then
    EncodingSpecificOperations();
    if PSTATE.EL == EL2 then
        Undefined();
    elseif PSTATE.M IN {M32_User,M32_System} then
        UnpredictableProcedure();
    else
        let length : integer = 4*BitCount(registers);
        var address : bits(32) = if increment then R(n) else R(n)-length;
        let within8byte : boolean = AllInAlignedQuantity{32}(address, length, 8);
        if wordhigher then address = address+4; end;
        for i = 0 to 14 do
            if registers[i] == '1' then // Store User mode register
                MemS{32}(address, within8byte) = Rmode(i, M32_User);
                address = address + 4;
            end;
        end;
        if registers[15] == '1' then
            MemS{32}(address, within8byte) = PCStoreValue();
        end;
    end;
end;

```

CONSTRAINED UNPREDICTABLE behavior

If PSTATE.M IN {M32_User,M32_System}, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction operates as an STM with the same addressing mode but targeting an unspecified set of registers. These registers might include R15.

C5.1.221 STMDA, STMED

Store Multiple Decrement After (Empty Descending) stores multiple registers to consecutive memory locations using an address from a base register. The consecutive memory locations end at this address, and the address just below the lowest of those locations can optionally be written back to the base register.

The lowest-numbered register is loaded from the lowest memory address, through to the highest-numbered register from the highest memory address. See also [Encoding of lists of general-purpose registers and the PC](#).

Encoding

```
STMDA{<c>}{<q>} <Rn>{!}, <registers> // (Preferred syntax)

STMED{<c>}{<q>} <Rn>{!}, <registers> // (Alternate syntax, Empty Descending stack)
```

Decode for this encoding

```
let n : integer = UInt(Rn);
let registers : bits(16) = register_list;
let wback : boolean = (W == '1');
if n == 15 || BitCount(registers) < 1 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `BitCount(registers) < 1`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction targets an unspecified set of registers. These registers might include R15. If the instruction specifies writeback, the modification to the base address on writeback might differ from the number of registers stored.

If `n == 15 && wback`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes without writeback of the base address.
- The instruction uses the addressing mode described in the equivalent immediate offset instruction.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>
See [Standard assembler syntax fields](#).

<q>
See [Standard assembler syntax fields](#).

<Rn>

Is the general-purpose base register, encoded in the “Rn” field.

!

The address adjusted by the size of the data loaded is written back to the base register. If specified, it is encoded in the “W” field as 1, otherwise this field defaults to 0.

<registers>

Is a list of one or more registers to be stored, separated by commas and surrounded by { and }.

The PC can be in the list. However, Arm deprecates the use of instructions that include the PC in the list.

If base register writeback is specified, and the base register is not the lowest-numbered register in the list, such an instruction stores an UNKNOWN value for the base register.

Operation

```

if ConditionPassed() then
    EncodingSpecificOperations();
    var address : bits(32) = (R(n) - 4*BitCount(registers)) + 4;
    let length : integer = 4*BitCount(registers);
    let within8byte : boolean = AllInAlignedQuantity{32}(address, length, 8);
    for i = 0 to 14 do
        if registers[i] == '1' then
            if i == n && wback && i != LowestSetBit(registers) then
                MemS{32}(address, within8byte) = ARBITRARY : bits(32);
            else
                MemS{32}(address, within8byte) = R(i);
            end;
            address = address + 4;
        end;
    end;
    if registers[15] == '1' then
        MemS{32}(address, within8byte) = PCStoreValue();
    end;
    if wback then R(n) = R(n) - 4*BitCount(registers); end;
end;

```

C5.1.222 STMDB, STMFd

Store Multiple Decrement Before (Full Descending) stores multiple registers to consecutive memory locations using an address from a base register. The consecutive memory locations end just below this address, and the address of the first of those locations can optionally be written back to the base register.

The lowest-numbered register is loaded from the lowest memory address, through to the highest-numbered register from the highest memory address. See also [Encoding of lists of general-purpose registers and the PC](#).

This instruction is used by the alias [PUSH \(multiple registers\)](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

STMDB{<c>}{<q>} <Rn>{!}, <registers> // (Preferred syntax)

STMFd{<c>}{<q>} <Rn>{!}, <registers> // (Alternate syntax, Full Descending stack)

Decode for this encoding

```
let n : integer = UInt(Rn);
let registers : bits(16) = register_list;
let wback : boolean = (W == '1');
if n == 15 || BitCount(registers) < 1 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `BitCount(registers) < 1`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction operates as an STM with the same addressing mode but targeting an unspecified set of registers. These registers might include R15. If the instruction specifies writeback, the modification to the base address on writeback might differ from the number of registers stored.

T1

Encoding

STMDB{<c>}{<q>} <Rn>{!}, <registers> // (Preferred syntax)

STMFd{<c>}{<q>} <Rn>{!}, <registers> // (Alternate syntax, Full Descending stack)

Decode for this encoding

```
let n : integer = UInt(Rn);
let registers : bits(16) = P::M::register_list;
let wback : boolean = (W == '1');
if n == 15 || BitCount(registers) < 2 then UnpredictableProcedure(); end;
if wback && registers[n] == '1' then UnpredictableProcedure(); end;
if registers[13] == '1' then UnpredictableProcedure(); end;
if registers[15] == '1' then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `BitCount(registers) < 1`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction operates as an STM with the same addressing mode but targeting an unspecified set of registers. These registers might include R15. If the instruction specifies writeback, the modification to the base address on writeback might differ from the number of registers stored.

If `wback && registers<n> == '1'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction executes but the value stored for the base register is UNKNOWN.

If `BitCount(registers) == 1`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes as described, with no change to its behavior and no additional side effects.
- The instruction operates as an STM with the same addressing mode but targeting an unspecified set of registers. These registers might include R15.

If `registers<13> == '1'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes as described, with no change to its behavior and no additional side effects.
- The store instruction performs all of the stores using the specified addressing mode but the value of R13 is UNKNOWN.

If `registers<15> == '1'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction performs all of the stores using the specified addressing mode but the value of R15 is UNKNOWN.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rn>

Is the general-purpose base register, encoded in the “Rn” field.

!

The address adjusted by the size of the data loaded is written back to the base register. If specified, it is encoded in the “W” field as 1, otherwise this field defaults to 0.

<registers>

For the “A1” variant: is a list of one or more registers to be stored, separated by commas and surrounded by { and }.

The PC can be in the list. However, Arm deprecates the use of instructions that include the PC in the list.

If base register writeback is specified, and the base register is not the lowest-numbered register in the list, such an instruction stores an UNKNOWN value for the base register.

For the “T1” variant: is a list of one or more registers to be stored, separated by commas and surrounded by { and }.

The registers in the list must be in the range R0-R12, encoded in the “register_list” field, and can optionally contain the LR. If the LR is in the list, the “M” field is set to 1, otherwise it defaults to 0.

Alias Conditions

Alias	Of variant	Is preferred when
PUSH (multiple registers)	A1	W == '1' && Rn == '1101' && BitCount(register_list) > 1
PUSH (multiple registers)	T1	W == '1' && Rn == '1101' && BitCount(M : register_list) > 1
PUSH (multiple registers)	T1	BitCount(M : register_list) > 1

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    var address : bits(32) = R(n) - 4*BitCount(registers);
    let length : integer = 4*BitCount(registers);
    let within8byte : boolean = AllInAlignedQuantity{32}(address, length, 8);
    for i = 0 to 14 do
        if registers[i] == '1' then
            if i == n && wback && i != LowestSetBit(registers) then
                MemS{32}(address, within8byte) = ARBITRARY : bits(32);
            else
                MemS{32}(address, within8byte) = R(i);
            end;
            address = address + 4;
        end;
    end;
```

```
    if registers[15] == '1' then // Only possible for encoding A1
        MemS{32}(address, within8byte) = PCStoreValue();
    end;
    if wback then R(n) = R(n) - 4*BitCount(registers); end;
end;
```

C5.1.223 STMIB, STMFA

Store Multiple Increment Before (Full Ascending) stores multiple registers to consecutive memory locations using an address from a base register. The consecutive memory locations start just above this address, and the address of the last of those locations can optionally be written back to the base register.

The lowest-numbered register is loaded from the lowest memory address, through to the highest-numbered register from the highest memory address. See also [Encoding of lists of general-purpose registers and the PC](#).

Encoding

```
STMIB{<c>}{<q>} <Rn>{!}, <registers> // (Preferred syntax)
```

```
STMFA{<c>}{<q>} <Rn>{!}, <registers> // (Alternate syntax, Full Ascending stack)
```

Decode for this encoding

```
let n : integer = UInt(Rn);
let registers : bits(16) = register_list;
let wback : boolean = (W == '1');
if n == 15 || BitCount(registers) < 1 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `BitCount(registers) < 1`, then one of the following behaviors must occur:

- The instruction is `UNDEFINED`.
- The instruction executes as `NOP`.
- The instruction operates as an `STM` with the same addressing mode but targeting an unspecified set of registers. These registers might include `R15`. If the instruction specifies writeback, the modification to the base address on writeback might differ from the number of registers stored.

If `n == 15` && `wback`, then one of the following behaviors must occur:

- The instruction is `UNDEFINED`.
- The instruction executes as `NOP`.
- The instruction executes without writeback of the base address.
- The instruction uses the addressing mode described in the equivalent immediate offset instruction.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

 $\langle q \rangle$

See [Standard assembler syntax fields](#).

<Rn>

Is the general-purpose base register, encoded in the “Rn” field.

!

The address adjusted by the size of the data loaded is written back to the base register. If specified, it is encoded in the “W” field as 1, otherwise this field defaults to 0.

<registers>

Is a list of one or more registers to be stored, separated by commas and surrounded by { and }.

The PC can be in the list. However, Arm deprecates the use of instructions that include the PC in the list.

If base register writeback is specified, and the base register is not the lowest-numbered register in the list, such an instruction stores an UNKNOWN value for the base register.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    var address : bits(32) = R(n) + 4;
    let length : integer = 4*BitCount(registers);
    let within8byte : boolean = AllInAlignedQuantity{32}(address, length, 8);
    for i = 0 to 14 do
        if registers[i] == '1' then
            if i == n && wback && i != LowestSetBit(registers) then
                MemS{32}(address, within8byte) = ARBITRARY : bits(32);
            else
                MemS{32}(address, within8byte) = R(i);
            end;
            address = address + 4;
        end;
    end;
    if registers[15] == '1' then
        MemS{32}(address, within8byte) = PCStoreValue();
    end;
    if wback then R(n) = R(n) + 4*BitCount(registers); end;
end;
```

C5.1.224 STR (immediate)

Store Register (immediate) calculates an address from a base register value and an immediate offset, and stores a word from a register to memory. It can use offset, post-indexed, or pre-indexed addressing. For information about memory accesses see [Memory accesses](#).

This instruction is used by the alias [PUSH \(single register\)](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#), [T2](#), [T3](#), and [T4](#)).

A1

Encoding for the Offset variant

Applies when (P == 1 && W == 0)

STR{<c>}{<q>} <Rt>, [<Rn> {, #<+/-><imm>}]

Encoding for the Post-indexed variant

Applies when (P == 0 && W == 0)

STR{<c>}{<q>} <Rt>, [<Rn>], #<+/-><imm>

Encoding for the Pre-indexed variant

Applies when (P == 1 && W == 1)

STR{<c>}{<q>} <Rt>, [<Rn>, #<+/-><imm>]!

Decode for all variants of this encoding

```

if P == '0' && W == '1' then See("STRT"); end;
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let imm32 : bits(32) = ZeroExtend{}(imm12);
let index : boolean = (P == '1');
let add : boolean = (U == '1');
let wback : boolean = (P == '0') || (W == '1');
if wback && (n == 15 || n == t) then UnpredictableProcedure(); end;

```

CONSTRAINED UNPREDICTABLE behavior

If wback && n == t, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction executes but the value stored is UNKNOWN.

If wback && n == 15, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes without writeback of the base address.
- The instruction uses the addressing mode described in the equivalent immediate offset instruction.

T1

Encoding

STR{<c>}{<q>} <Rt>, [<Rn> {, #<+><imm>}]

Decode for this encoding

```
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let imm32 : bits(32) = ZeroExtend{(imm5::'00')};
let index : boolean = TRUE;
let add : boolean = TRUE;
let wback : boolean = FALSE;
```

T2

Encoding

STR{<c>}{<q>} <Rt>, [SP{, #<+><imm>}]

Decode for this encoding

```
let t : integer = UInt(Rt);
let n : integer = 13;
let imm32 : bits(32) = ZeroExtend{(imm8::'00')};
let index : boolean = TRUE;
let add : boolean = TRUE;
let wback : boolean = FALSE;
```

T3

Encoding

STR{<c>}{<q>} <Rt>, [<Rn> {, #<+><imm>}]

STR{<c>}.W <Rt>, [<Rn> {, #<+><imm>}] // (<Rt>, <Rn>, <imm> can be represented in T1 or T2)

Decode for this encoding

```

if Rn == '1111' then Undefined(); end;
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let imm32 : bits(32) = ZeroExtend{}(imm12);
let index : boolean = TRUE;
let add : boolean = TRUE;
let wback : boolean = FALSE;
if t == 15 then UnpredictableProcedure(); end;

```

CONSTRAINED UNPREDICTABLE behavior

If $t = 15$, then one of the following behaviors must occur:

- The instruction is `UNDEFINED`.
- The instruction executes as `NOP`.
- The store instruction performs the store using the specified addressing mode but the value corresponding to R15 is `UNKNOWN`.

T4

Encoding for the Offset variant

Applies when (P == 1 && U == 0 && W == 0)

STR{<c>}{<q>}<Rt>,[<Rn>{,<#-<imm>}]

Encoding for the Post-indexed variant

Applies when (P == 0 && W == 1)

STR{<c>}{<q>} <Rt>, [<Rn>], #{+/-}<imm>

Encoding for the Pre-indexed variant

Applies when (P == 1 && W == 1)

STR{<c>}{<q>} <Rt>, [<Rn>, # {+/-}<imm>]!

Decode for all variants of this encoding

```

if P == '1' && U == '1' && W == '0' then See("STRT"); end;
if Rn == '1111' || (P == '0' && W == '0') then Undefined(); end;
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let imm32 : bits(32) = ZeroExtend{}(imm8);
let index : boolean = (P == '1');
let add : boolean = (U == '1');
let wback : boolean = (W == '1');
if t == 15 || (wback && n == t) then UnpredictableProcedure(); end;

```

CONSTRAINED UNPREDICTABLE behavior

If `wback && n == t`, then one of the following behaviors must occur:

- The instruction is `UNDEFINED`.
- The instruction executes as `NOP`.
- The store instruction executes but the value stored is `UNKNOWN`.

If `t == 15`, then one of the following behaviors must occur:

- The instruction is `UNDEFINED`.
- The instruction executes as `NOP`.
- The store instruction performs the store using the specified addressing mode but the value corresponding to R15 is `UNKNOWN`.

For more information about the `CONSTRAINED UNPREDICTABLE` behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

`<c>`

See [Standard assembler syntax fields](#).

`<q>`

See [Standard assembler syntax fields](#).

`<Rt>`

For the “A1 Offset”, “A1 Post-indexed”, and “A1 Pre-indexed” variants: is the general-purpose register to be transferred, encoded in the “Rt” field. The PC can be used, but this is deprecated.

For the “T1”, “T2”, “T3”, “T4 Offset”, “T4 Post-indexed”, and “T4 Pre-indexed” variants: is the general-purpose register to be transferred, encoded in the “Rt” field.

`<Rn>`

For the “A1 Offset”, “A1 Post-indexed”, and “A1 Pre-indexed” variants: is the general-purpose base register, encoded in the “Rn” field. The PC can be used in the offset variant, but this is deprecated.

For the “T1”, “T3”, “T4 Offset”, “T4 Post-indexed”, and “T4 Pre-indexed” variants: is the general-purpose base register, encoded in the “Rn” field.

`+/-`

Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in “U”:

U	+/-
0	-
1	+

`<imm>`

For the “A1 Offset”, “A1 Post-indexed”, and “A1 Pre-indexed” variants: is the 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 if omitted, and encoded in the “imm12” field.

For the “T1” variant: is the optional positive unsigned immediate byte offset, a multiple of 4, in the range 0 to 124, defaulting to 0 and encoded in the “imm5” field as `<imm>/4`.

For the “T2” variant: is the optional positive unsigned immediate byte offset, a multiple of 4, in the range 0 to 1020, defaulting to 0 and encoded in the “imm8” field as <imm>/4.

For the “T3” variant: is an optional 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 and encoded in the “imm12” field.

For the “T4 Offset”, “T4 Post-indexed”, and “T4 Pre-indexed” variants: is an 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 if omitted, and encoded in the “imm8” field.

+

Specifies the offset is added to the base register.

Alias Conditions

Alias	Of variant	Is preferred when
PUSH (single register)	A1 Pre-indexed	P == '1' && U == '0' && W == '1' && Rn == '1101' && imm12 == '000000000100'
PUSH (single register)	T4 Pre-indexed	Rn == '1101' && P == '1' && U == '0' && W == '1' && imm8 == '00000100'

Operation

```
if CurrentInstrSet() == InstrSet_A32 then
  if ConditionPassed() then
    EncodingSpecificOperations();
    let offset_addr : bits(32) = if add then (R(n) + imm32) else (R(n) - imm32);
    let address : bits(32) = if index then offset_addr else R(n);
    MemU{32}(address) = if t == 15 then PCStoreValue() else R(t);
    if wback then R(n) = offset_addr; end;
  end;
else
  if ConditionPassed() then
    EncodingSpecificOperations();
    let offset_addr : bits(32) = if add then (R(n) + imm32) else (R(n) - imm32);
    let address : bits(32) = if index then offset_addr else R(n);
    MemU{32}(address) = R(t);
    if wback then R(n) = offset_addr; end;
  end;
end;
```

C5.1.225 STR (register)

Store Register (register) calculates an address from a base register value and an offset register value, stores a word from a register to memory. The offset register value can optionally be shifted. For information about memory accesses see [Memory accesses](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#) and [T2](#)).

A1

Encoding for the Offset variant

Applies when (P == 1 && W == 0)

```
STR{<c>}{<q>} <Rt>, [<Rn>, {+/-}<Rm>{, <shift>}]
```

Encoding for the Post-indexed variant

Applies when (P == 0 && W == 0)

```
STR{<c>}{<q>} <Rt>, [<Rn>], {+/-}<Rm>{, <shift>}
```

Encoding for the Pre-indexed variant

Applies when (P == 1 && W == 1)

```
STR{<c>}{<q>} <Rt>, [<Rn>, {+/-}<Rm>{, <shift>}]!
```

Decode for all variants of this encoding

```
if P == '0' && W == '1' then See("STRT"); end;
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let index : boolean = (P == '1');
let add : boolean = (U == '1');
let wback : boolean = (P == '0') || (W == '1');
let (shift_t, shift_n) : (SRTType, integer) = DecodeImmShift(stype, imm5);
if m == 15 then UnpredictableProcedure(); end;
if wback && (n == 15 || n == t) then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If wback && n == t, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction executes but the value stored is UNKNOWN.

If wback && n == 15, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes without writeback of the base address.
- The instruction uses the addressing mode described in the equivalent immediate offset instruction.

T1

Encoding

STR{<c>}{<q>} <Rt>, [<Rn>, {+}<Rm>]

Decode for this encoding

```
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let index : boolean = TRUE;
let add : boolean = TRUE;
let wback : boolean = FALSE;
let shift_t : SRTYPE = SRTYPE_LSL;
let shift_n : integer = 0;
```

T2

Encoding

STR{<c>}{<q>} <Rt>, [<Rn>, {+}<Rm>{, LSL #<imm>}]

STR{<c>}.W <Rt>, [<Rn>, {+}<Rm>] // (<Rt>, <Rn>, <Rm> can be represented in T1)

Decode for this encoding

```
if Rn == '1111' then Undefined(); end;
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let index : boolean = TRUE;
let add : boolean = TRUE;
let wback : boolean = FALSE;
let shift_t : SRTYPE = SRTYPE_LSL;
let shift_n : integer = UInt(imm2);
// Armv8-A removes UNPREDICTABLE for R13
if t == 15 || m == 15 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `t == 15`, then one of the following behaviors must occur:

- The instruction is `UNDEFINED`.
- The instruction executes as `NOP`.
- The store instruction performs the store using the specified addressing mode but the value corresponding to `R15` is `UNKNOWN`.

For more information about the `CONSTRAINED UNPREDICTABLE` behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

`<c>`

See [Standard assembler syntax fields](#).

`<q>`

See [Standard assembler syntax fields](#).

`<Rt>`

For the “Offset”, “Post-indexed”, and “Pre-indexed” variants: is the general-purpose register to be transferred, encoded in the “Rt” field. The PC can be used, but this is deprecated.

For the “T1” and “T2” variants: is the general-purpose register to be transferred, encoded in the “Rt” field.

`<Rn>`

For the “Offset”, “Post-indexed”, and “Pre-indexed” variants: is the general-purpose base register, encoded in the “Rn” field. The PC can be used in the offset variant, but this is deprecated.

For the “T1” and “T2” variants: is the general-purpose base register, encoded in the “Rn” field.

`+/-`

Specifies the index register is added to or subtracted from the base register, defaulting to `+` if omitted and encoded in “U”:

U	+/-
0	-
1	+

`<Rm>`

Is the general-purpose index register, encoded in the “Rm” field.

`<shift>`

The shift to apply to the value read from `<Rm>`. If absent, no shift is applied. Otherwise, see [Shifts applied to a register](#).

`+`

Specifies the index register is added to the base register.

`<imm>`

If present, the size of the left shift to apply to the value from `<Rm>`, in the range 1-3. `<imm>` is encoded in `imm2`. If absent, no shift is specified and `imm2` is encoded as `0b00`.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let offset : bits(32) = Shift{}(R(m), shift_t, shift_n, PSTATE.C);
    let offset_addr : bits(32) = if add then (R(n) + offset) else (R(n) - offset);
    let address : bits(32) = if index then offset_addr else R(n);
    var data : bits(32);
    if t == 15 then // Only possible for encoding A1
        data = PCStoreValue();
    else
        data = R(t);
    end;
    MemU{32}(address) = data;
    if wback then R(n) = offset_addr; end;
end;
```

C5.1.226 STRB (immediate)

Store Register Byte (immediate) calculates an address from a base register value and an immediate offset, and stores a byte from a register to memory. It can use offset, post-indexed, or pre-indexed addressing. For information about memory accesses see [Memory accesses](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#), [T2](#), and [T3](#)).

A1

Encoding for the Offset variant

Applies when (P == 1 && W == 0)

```
STRB{<c>}{<q>} <Rt>, [<Rn> {, # {+/-}<imm>}]
```

Encoding for the Post-indexed variant

Applies when (P == 0 && W == 0)

```
STRB{<c>}{<q>} <Rt>, [<Rn>], # {+/-}<imm>
```

Encoding for the Pre-indexed variant

Applies when (P == 1 && W == 1)

```
STRB{<c>}{<q>} <Rt>, [<Rn>, # {+/-}<imm>]!
```

Decode for all variants of this encoding

```
if P == '0' && W == '1' then See("STRBT"); end;
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let imm32 : bits(32) = ZeroExtend{}(imm12);
let index : boolean = (P == '1');
let add : boolean = (U == '1');
let wback : boolean = (P == '0') || (W == '1');
if t == 15 then UnpredictableProcedure(); end;
if wback && (n == 15 || n == t) then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If t == 15, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction performs the store using the specified addressing mode but the value corresponding to R15 is UNKNOWN.

If wback && n == t, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction executes but the value stored is UNKNOWN.

If `wback && n == 15`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes without writeback of the base address.
- The instruction uses the addressing mode described in the equivalent immediate offset instruction.

T1

Encoding

STRB{<c>}{<q>} <Rt>, [<Rn> {, #<+><imm>}]

Decode for this encoding

```
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let imm32 : bits(32) = ZeroExtend{}(imm5);
let index : boolean = TRUE;
let add : boolean = TRUE;
let wback : boolean = FALSE;
```

T2

Encoding

STRB{<c>}{<q>} <Rt>, [<Rn> {, #<+><imm>}]

STRB{<c>}.W <Rt>, [<Rn> {, #<+><imm>}] // (<Rt>, <Rn>, <imm> can be represented in T1)

Decode for this encoding

```
if Rn == '1111' then Undefined(); end;
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let imm32 : bits(32) = ZeroExtend{}(imm12);
let index : boolean = TRUE;
let add : boolean = TRUE;
let wback : boolean = FALSE;
// Armv8-A removes UNPREDICTABLE for R13
if t == 15 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If $t == 15$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction performs the store using the specified addressing mode but the value corresponding to R15 is UNKNOWN.

T3

Encoding for the Offset variant

Applies when $(P == 1 \ \&\& \ U == 0 \ \&\& \ W == 0)$

```
STRB{<c>}{<q>} <Rt>, [<Rn> {, #-<imm>}]
```

Encoding for the Post-indexed variant

Applies when $(P == 0 \ \&\& \ W == 1)$

```
STRB{<c>}{<q>} <Rt>, [<Rn>], #{+/-}<imm>
```

Encoding for the Pre-indexed variant

Applies when $(P == 1 \ \&\& \ W == 1)$

```
STRB{<c>}{<q>} <Rt>, [<Rn>, #{+/-}<imm>]!
```

Decode for all variants of this encoding

```
if P == '1' && U == '1' && W == '0' then See("STRBT"); end;
if Rn == '1111' || (P == '0' && W == '0') then Undefined(); end;
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let imm32 : bits(32) = ZeroExtend{}(imm8);
let index : boolean = (P == '1');
let add : boolean = (U == '1');
let wback : boolean = (W == '1');
// Armv8-A removes UNPREDICTABLE for R13
if t == 15 || (wback && n == t) then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If $t == 15$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction performs the store using the specified addressing mode but the value corresponding to R15 is UNKNOWN.

If $wback \ \&\& \ n == t$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction executes but the value stored is UNKNOWN.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rt>

Is the general-purpose register to be transferred, encoded in the “Rt” field.

<Rn>

For the “A1 Offset”, “A1 Post-indexed”, and “A1 Pre-indexed” variants: is the general-purpose base register, encoded in the “Rn” field. The PC can be used in the offset variant, but this is deprecated.

For the “T1”, “T2”, “T3 Offset”, “T3 Post-indexed”, and “T3 Pre-indexed” variants: is the general-purpose base register, encoded in the “Rn” field.

+/-

Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in “U”:

U	+/-
0	-
1	+

<imm>

For the “A1 Offset”, “A1 Post-indexed”, and “A1 Pre-indexed” variants: is the 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 if omitted, and encoded in the “imm12” field.

For the “T1” variant: is an optional 5-bit unsigned immediate byte offset, in the range 0 to 31, defaulting to 0 and encoded in the “imm5” field.

For the “T2” variant: is an optional 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 and encoded in the “imm12” field.

For the “T3 Offset”, “T3 Post-indexed”, and “T3 Pre-indexed” variants: is an 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 if omitted, and encoded in the “imm8” field.

+

Specifies the offset is added to the base register.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
let offset_addr : bits(32) = if add then (R(n) + imm32) else (R(n) - imm32);
let address : bits(32) = if index then offset_addr else R(n);
```

```
MemU{8}(address) = R(t)[7:0];  
if wback then R(n) = offset_addr; end;  
end;
```

C5.1.227 STRB (register)

Store Register Byte (register) calculates an address from a base register value and an offset register value, and stores a byte from a register to memory. The offset register value can optionally be shifted. For information about memory accesses see [Memory accesses](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#) and [T2](#)).

A1

Encoding for the Offset variant

Applies when (P == 1 && W == 0)

```
STRB{<c>}{<q>} <Rt>, [<Rn>, {+/-}<Rm>{, <shift>}]
```

Encoding for the Post-indexed variant

Applies when (P == 0 && W == 0)

```
STRB{<c>}{<q>} <Rt>, [<Rn>], {+/-}<Rm>{, <shift>}]
```

Encoding for the Pre-indexed variant

Applies when (P == 1 && W == 1)

```
STRB{<c>}{<q>} <Rt>, [<Rn>, {+/-}<Rm>{, <shift>}]!
```

Decode for all variants of this encoding

```
if P == '0' && W == '1' then See("STRBT"); end;
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let index : boolean = (P == '1');
let add : boolean = (U == '1');
let wback : boolean = (P == '0') || (W == '1');
let (shift_t, shift_n) : (SRTtype, integer) = DecodeImmShift(stype, imm5);
if t == 15 || m == 15 then UnpredictableProcedure(); end;
if wback && (n == 15 || n == t) then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If t == 15, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction performs the store using the specified addressing mode but the value corresponding to R15 is UNKNOWN.

If wback && n == t, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.

- The store instruction executes but the value stored is UNKNOWN.

If `wback && n == 15`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes without writeback of the base address.
- The instruction uses the addressing mode described in the equivalent immediate offset instruction.

T1

Encoding

STRB{<c>}{<q>} <Rt>, [<Rn>, {+}<Rm>]

Decode for this encoding

```
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let index : boolean = TRUE;
let add : boolean = TRUE;
let wback : boolean = FALSE;
let shift_t : SRTYPE = SRTYPE_LSL;
let shift_n : integer = 0;
```

T2

Encoding

STRB{<c>}{<q>} <Rt>, [<Rn>, {+}<Rm>{, LSL #<imm>}]

STRB{<c>}.W <Rt>, [<Rn>, {+}<Rm>] // (<Rt>, <Rn>, <Rm> can be represented in T1)

Decode for this encoding

```
if Rn == '1111' then Undefined(); end;
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let index : boolean = TRUE;
let add : boolean = TRUE;
let wback : boolean = FALSE;
let shift_t : SRTYPE = SRTYPE_LSL;
let shift_n : integer = UInt(imm2);
// Armv8-A removes UNPREDICTABLE for R13
if t == 15 || m == 15 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If t == 15, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction performs the store using the specified addressing mode but the value corresponding to R15 is UNKNOWN.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rt>

Is the general-purpose register to be transferred, encoded in the “Rt” field.

<Rn>

For the “Offset”, “Post-indexed”, and “Pre-indexed” variants: is the general-purpose base register, encoded in the “Rn” field. The PC can be used in the offset variant, but this is deprecated.

For the “T1” and “T2” variants: is the general-purpose base register, encoded in the “Rn” field.

+/-

Specifies the index register is added to or subtracted from the base register, defaulting to + if omitted and encoded in “U”:

U	+/-
0	-
1	+

<Rm>

Is the general-purpose index register, encoded in the “Rm” field.

<shift>

The shift to apply to the value read from <Rm>. If absent, no shift is applied. Otherwise, see [Shifts applied to a register](#).

+

Specifies the index register is added to the base register.

<imm>

If present, the size of the left shift to apply to the value from <Rm>, in the range 1-3. <imm> is encoded in imm2. If absent, no shift is specified and imm2 is encoded as 0b00.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let offset : bits(32) = Shift{}(R(m), shift_t, shift_n, PSTATE.C);
    let offset_addr : bits(32) = if add then (R(n) + offset) else (R(n) - offset);
    let address : bits(32) = if index then offset_addr else R(n);
    MemU{8}(address) = R(t)[7:0];
    if wback then R(n) = offset_addr; end;
end;
```

C5.1.228 STRBT

Store Register Byte Unprivileged stores a byte from a register to memory. For information about memory accesses see [Memory accesses](#).

The memory access is restricted as if the PE were running in User mode. This makes no difference if the PE is actually running in User mode.

STRBT is UNPREDICTABLE in Hyp mode.

The T32 instruction uses an offset addressing mode, that calculates the address used for the memory access from a base register value and an immediate offset, and leaves the base register unchanged.

The A32 instruction uses a post-indexed addressing mode, that uses a base register value as the address for the memory access, and calculates a new address from a base register value and an offset and writes it back to the base register. The offset can be an immediate value or an optionally-shifted register value.

It has encodings from the following instruction sets: A32 ([A1](#) and [A2](#)) and T32 ([T1](#)).

A1

Encoding

STRBT{<c>}{<q>} <Rt>, [<Rn>] {, #<+/-><imm>}

Decode for this encoding

```
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let postindex : boolean = TRUE;
let add : boolean = (U == '1');
let register_form : boolean = FALSE;
let imm32 : bits(32) = ZeroExtend{}(imm12);
let m : integer = ARBITRARY : integer;
let shift_n : integer = ARBITRARY : integer;
let shift_t : SRTYPE = ARBITRARY : SRTYPE;
if t == 15 || n == 15 || n == t then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If $t == 15$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction performs the store using the specified addressing mode but the value corresponding to R15 is UNKNOWN.

If $n == t$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction executes but the value stored is UNKNOWN.

If $n == 15$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction uses post-indexed addressing with the base register as PC. This is handled as described in Using R15.
- The instruction is treated as if bit[24] == 1 and bit[21] == 0. The instruction uses immediate offset addressing with the base register as PC, without writeback.

A2

Encoding

STRBT{<c>}{<q>} <Rt>, [<Rn>], {+/-}<Rm>{, <shift>}

Decode for this encoding

```

let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let postindex : boolean = TRUE;
let add : boolean = (U == '1');
let register_form : boolean = TRUE;
let (shift_t, shift_n) : (SRTType, integer) = DecodeImmShift(stype, imm5);
let imm32 : bits(32) = ARBITRARY : bits(32);
if t == 15 || n == 15 || m == t || m == 15 then UnpredictableProcedure(); end;

```

CONSTRAINED UNPREDICTABLE behavior

If t == 15, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction performs the store using the specified addressing mode but the value corresponding to R15 is UNKNOWN.

If n == t, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction executes but the value stored is UNKNOWN.

If n == 15, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction uses post-indexed addressing with the base register as PC. This is handled as described in Using R15.
- The instruction is treated as if bit[24] == 1 and bit[21] == 0. The instruction uses immediate offset addressing with the base register as PC, without writeback.

T1

Encoding

STRBT{<c>}{<q>}<Rt>,[<Rn>{,##+<imm>}]

Decode for this encoding

```

if Rn == 'l1ll' then Undefined(); end;
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let postindex : boolean = FALSE;
let add : boolean = TRUE;
let register_form : boolean = FALSE;
let imm32 : bits(32) = ZeroExtend{(imm8)};
let m : integer = ARBITRARY : integer;
let shift_n : integer = ARBITRARY : integer;
let shift_t : SRTType = ARBITRARY : SRTType;
// Armv8-A removes UNPREDICTABLE for R13
if t == 15 then UnpredictableProcedure(); end;

```

CONSTRAINED UNPREDICTABLE behavior

If $t = 15$, then one of the following behaviors must occur:

- The instruction is `UNDEFINED`.
- The instruction executes as `NOP`.
- The store instruction performs the store using the specified addressing mode but the value corresponding to `R15` is `UNKNOWN`.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

 $\langle q \rangle$

See [Standard assembler syntax fields](#).

 $\langle R_t \rangle$

For the “A1” variant: is the general-purpose register to be transferred, encoded in the “Rt” field. The PC can be used, but this is deprecated.

For the “A2” and “T1” variants: is the general-purpose register to be transferred, encoded in the “Rt” field.

 $\langle R_n \rangle$

Is the general-purpose base register, encoded in the “Rn” field.

+/-

For the “A1” variant: specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in “U”:

U	+/-
0	-
1	+

For the “A2” variant: specifies the index register is added to or subtracted from the base register, defaulting to + if omitted and encoded in “U”:

U	+/-
0	-
1	+

<imm>

For the “A1” variant: is the 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 if omitted, and encoded in the “imm12” field.

For the “T1” variant: is an optional 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 and encoded in the “imm8” field.

<Rm>

Is the general-purpose index register, encoded in the “Rm” field.

<shift>

The shift to apply to the value read from <Rm>. If absent, no shift is applied. Otherwise, see [Shifts applied to a register](#).

+

Specifies the offset is added to the base register.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    if PSTATE.EL == EL2 then UnpredictableProcedure(); end; // Hyp mode
    let offset : bits(32) = (if register_form then Shift{32}(R(m), shift_t, shift_n, PSTATE.C)
                           else imm32);
    let offset_addr : bits(32) = if add then (R(n) + offset) else (R(n) - offset);
    let address : bits(32) = if postindex then R(n) else offset_addr;
    MemU_unpriv{8}(address) = R(t)[7:0];
    if postindex then R(n) = offset_addr; end;
end;
```

CONSTRAINED UNPREDICTABLE behavior

If `PSTATE.EL == EL2`, then one of the following behaviors must occur:

- The instruction is `UNDEFINED`.
- The instruction executes as `NOP`.
- The instruction executes as `STRB (immediate)`.

C5.1.229 STRD (immediate)

Store Register Dual (immediate) calculates an address from a base register value and an immediate offset, and stores two words from two registers to memory. It can use offset, post-indexed, or pre-indexed addressing. For information about memory accesses see [Memory accesses](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding for the Offset variant

Applies when (P == 1 && W == 0)

```
STRD{<c>}{<q>} <Rt>, <Rt2>, [<Rn> {, #<+/-><imm>}]
```

Encoding for the Post-indexed variant

Applies when (P == 0 && W == 0)

```
STRD{<c>}{<q>} <Rt>, <Rt2>, [<Rn>], #<+/-><imm>
```

Encoding for the Pre-indexed variant

Applies when (P == 1 && W == 1)

```
STRD{<c>}{<q>} <Rt>, <Rt2>, [<Rn>, #<+/-><imm>]!
```

Decode for all variants of this encoding

```
if Rt[0] == '1' then UnpredictableProcedure(); end;
let t : integer = UInt(Rt);
let t2 : integer = t + 1;
let n : integer = UInt(Rn);
let imm32 : bits(32) = ZeroExtend{(imm4H::imm4L)};
let index : boolean = (P == '1');
let add : boolean = (U == '1');
let wback : boolean = (P == '0') || (W == '1');
if P == '0' && W == '1' then UnpredictableProcedure(); end;
if wback && (n == 15 || n == t || n == t2) then UnpredictableProcedure(); end;
if t2 == 15 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If t == 15 || t2 == 15, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction performs the store using the specified addressing mode but the value corresponding to R15 is UNKNOWN.

If wback && (n == t || n == t2), then one of the following behaviors must occur:

- The instruction is UNDEFINED.

- The instruction executes as NOP.
- The store instruction executes but the value stored is UNKNOWN.

If `wback && n == 15`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes without writeback of the base address.
- The instruction uses the addressing mode described in the equivalent immediate offset instruction.

If `Rt<0> == '1'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes with the additional decode: `t<0> = '0'`.
- The instruction executes with the additional decode: `t2 = t`.
- The instruction executes as described, with no change to its behavior and no additional side-effects. This does not apply when `Rt == '1111'`.

If `P == '0' && W == '1'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes as an LDRD using one of offset, post-indexed, or pre-indexed addressing.

T1

Encoding for the Offset variant

Applies when (`P == 1 && W == 0`)

STRD{<c>}{<q>} <Rt>, <Rt2>, [<Rn> {, #<+/-><imm>}]

Encoding for the Post-indexed variant

Applies when (`P == 0 && W == 1`)

STRD{<c>}{<q>} <Rt>, <Rt2>, [<Rn>], #<+/-><imm>

Encoding for the Pre-indexed variant

Applies when (`P == 1 && W == 1`)

STRD{<c>}{<q>} <Rt>, <Rt2>, [<Rn>, #<+/-><imm>]!

Decode for all variants of this encoding

```
if P == '0' && W == '0' then See("Related encodings"); end;
let t : integer = UInt(Rt);
let t2 : integer = UInt(Rt2);
let n : integer = UInt(Rn);
let imm32 : bits(32) = ZeroExtend{}(imm8::'00');
let index : boolean = (P == '1');
let add : boolean = (U == '1');
let wback : boolean = (W == '1');
if wback && (n == t || n == t2) then UnpredictableProcedure(); end;
// Armv8-A removes UNPREDICTABLE for R13
if n == 15 || t == 15 || t2 == 15 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `t == 15 || t2 == 15`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction performs the store using the specified addressing mode but the value corresponding to R15 is UNKNOWN.

If `wback && (n == t || n == t2)`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction executes but the value stored is UNKNOWN.

If `wback && n == 15`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes without writeback of the base address.
- The instruction uses the addressing mode described in the equivalent immediate offset instruction.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Related encodings: [Load/store dual](#), [load/store exclusive](#), [table branch](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rt>

For the “A1 Offset”, “A1 Post-indexed”, and “A1 Pre-indexed” variants: is the first general-purpose register to be transferred, encoded in the “Rt” field. This register must be even-numbered and not R14.

For the “T1 Offset”, “T1 Post-indexed”, and “T1 Pre-indexed” variants: is the first general-purpose register to be transferred, encoded in the “Rt” field.

<Rt2>

For the “A1 Offset”, “A1 Post-indexed”, and “A1 Pre-indexed” variants: is the second general-purpose register to be transferred. This register must be <R(t+1)>.

For the “T1 Offset”, “T1 Post-indexed”, and “T1 Pre-indexed” variants: is the second general-purpose register to be transferred, encoded in the “Rt2” field.

<Rn>

For the “A1 Offset”, “A1 Post-indexed”, and “A1 Pre-indexed” variants: is the general-purpose base register, encoded in the “Rn” field. The PC can be used in the offset variant, but this is deprecated.

For the “T1 Offset”, “T1 Post-indexed”, and “T1 Pre-indexed” variants: is the general-purpose base register, encoded in the “Rn” field.

+/-

Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in “U”:

U	+/-
0	-
1	+

<imm>

For the “A1 Offset”, “A1 Post-indexed”, and “A1 Pre-indexed” variants: is the 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 if omitted, and encoded in the “imm4H:imm4L” field.

For the “T1 Offset”, “T1 Post-indexed”, and “T1 Pre-indexed” variants: is the unsigned immediate byte offset, a multiple of 4, in the range 0 to 1020, defaulting to 0 if omitted, and encoded in the “imm8” field as <imm>/4.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let offset_addr : bits(32) = if add then (R(n) + imm32) else (R(n) - imm32);
    let address : bits(32) = if index then offset_addr else R(n);
    if IsAlignedSize(address, 8) then
        var data : bits(64);
        if BigEndian(AccessType_GPR) then
            data[63:32] = R(t);
            data[31:0] = R(t2);
        else
            data[31:0] = R(t);
            data[63:32] = R(t2);
        end;
        MemA{64}(address) = data;
    else
        MemA{32}(address) = R(t);
        MemA{32}(address+4) = R(t2);
    end;
    if wback then R(n) = offset_addr; end;
end;
```

C5.1.230 STRD (register)

Store Register Dual (register) calculates an address from a base register value and a register offset, and stores two words from two registers to memory. It can use offset, post-indexed, or pre-indexed addressing. For information about memory accesses see [Memory accesses](#).

Encoding for the Offset variant

Applies when (P == 1 && W == 0)

STRD{<c>}{<q>} <Rt>, <Rt2>, [<Rn>, {+/-}<Rm>]

Encoding for the Post-indexed variant

Applies when (P == 0 && W == 0)

$$\text{STRD}\{\langle c \rangle\}\{\langle q \rangle\} \quad \langle \text{Rt} \rangle, \quad \langle \text{Rt2} \rangle, \quad [\langle \text{Rn} \rangle], \quad \{+/-\} \langle \text{Rm} \rangle$$

Encoding for the Pre-indexed variant

Applies when (P == 1 && W == 1)

$$\text{STRD}\{\langle c \rangle\}\{\langle q \rangle\} \quad \langle \text{Rt} \rangle, \langle \text{Rt2} \rangle, [\langle \text{Rn} \rangle, \{+/-\}\langle \text{Rm} \rangle]!$$

Decode for all variants of this encoding

```

if Rt[0] == '1' then UnpredictableProcedure(); end;
let t : integer = UInt(Rt);
let t2 : integer = t + 1;
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let index : boolean = (P == '1');
let add : boolean = (U == '1');
let wback : boolean = (P == '0') || (W == '1');
if P == '0' && W == '1' then UnpredictableProcedure(); end;
if t2 == 15 || m == 15 then UnpredictableProcedure(); end;
if wback && (n == 15 || n == t || n == t2) then UnpredictableProcedure(); end;

```

CONSTRAINED UNPREDICTABLE behavior

If $t_1 == 15 \parallel t_2 == 15$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction performs the store using the specified addressing mode but the value corresponding to R15 is UNKNOWN.

If `wback && (n == t || n == t2)`, then one of the following behaviors must occur:

- The instruction is **UNDEFINED**.
- The instruction executes as **NOP**.
- The store instruction executes but the value stored is **UNKNOWN**.

If `wback && n == 15`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes without writeback of the base address.
- The instruction uses the addressing mode described in the equivalent immediate offset instruction.

If $Rt < 0 > == '1'$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes with the additional decode: $t < 0 > = '0'$.
- The instruction executes with the additional decode: $t2 = t$.
- The instruction executes as described, with no change to its behavior and no additional side-effects. This does not apply when $Rt == '1111'$.

If $P == '0'$ & $W == '1'$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes with the additional decode: $P = '1'; W = '0'$.
- The instruction executes with the additional decode: $P = '1'; W = '1'$.
- The instruction executes with the additional decode: $P = '0'; W = '0'$.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rt>

Is the first general-purpose register to be transferred, encoded in the “Rt” field. This register must be even-numbered and not R14.

<Rt2>

Is the second general-purpose register to be transferred. This register must be $<R(t+1)>$.

<Rn>

Is the general-purpose base register, encoded in the “Rn” field. The PC can be used in the offset variant, but this is deprecated.

+/-

Specifies the index register is added to or subtracted from the base register, defaulting to + if omitted and encoded in “U”:

U	+/-
0	-
1	+

<Rm>

Is the general-purpose index register, encoded in the “Rm” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let offset_addr : bits(32) = if add then (R(n) + R(m)) else (R(n) - R(m));
    let address : bits(32) = if index then offset_addr else R(n);
    if IsAlignedSize(address, 8) then
        var data : bits(64);
        if BigEndian(AccessType_GPR) then
            data[63:32] = R(t);
            data[31:0] = R(t2);
        else
            data[31:0] = R(t);
            data[63:32] = R(t2);
        end;
        MemA{64}(address) = data;
    else
        MemA{32}(address) = R(t);
        MemA{32}(address+4) = R(t2);
    end;
    if wback then R(n) = offset_addr; end;
end;
```

C5.1.231 STREX

Store Register Exclusive calculates an address from a base register value and an immediate offset, stores a word from a register to the calculated address if the PE has exclusive access to the memory at that address, and returns a status value of 0 if the store was successful, or of 1 if no store was performed.

For more information about support for shared memory see [Synchronization and semaphores](#). For information about memory accesses see [Memory accesses](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

STREX{<c>}{<q>} <Rd>, <Rt>, [<Rn> {, {#}<imm>}]

Decode for this encoding

```
let d : integer = UInt(Rd);
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let imm32 : bits(32) = Zeros{}; // Zero offset
if d == 15 || t == 15 || n == 15 then UnpredictableProcedure(); end;
if d == n || d == t then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If $d == t$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction executes but the value stored is UNKNOWN.

If $d == n$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs the store to an UNKNOWN address.

T1

Encoding

STREX{<c>}{<q>} <Rd>, <Rt>, [<Rn> {, {#}<imm>}]

Decode for this encoding

```
let d : integer = UInt(Rd);
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let imm32 : bits(32) = ZeroExtend{}(imm8::'00');
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 || t == 15 || n == 15 then UnpredictableProcedure(); end;
if d == n || d == t then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If $d == t$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction executes but the value stored is UNKNOWN.

If $d == n$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs the store to an UNKNOWN address.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rd>

Is the destination general-purpose register into which the status result of the store exclusive is written, encoded in the “Rd” field. The value returned is:

- 0 If the operation updates memory.
- 1 If the operation fails to update memory.

<Rt>

Is the general-purpose register to be transferred, encoded in the “Rt” field.

<Rn>

Is the general-purpose base register, encoded in the “Rn” field.

<imm>

For the “A1” variant: the immediate offset added to the value of <Rn> to calculate the address. <imm> can only be 0 or omitted.

For the “T1” variant: the immediate offset added to the value of <Rn> to calculate the address. <imm> can be omitted, meaning an offset of 0. Values are multiples of 4 in the range 0-1020.

Aborts and alignment

If a synchronous Data Abort exception is generated by the execution of this instruction:

- Memory is not updated.
- <Rd> is not updated.

A non word-aligned memory address causes an Alignment fault Data Abort exception to be generated, subject to the following rules:

- If `AArch32.ExclusiveMonitorsPass()` returns `TRUE`, the exception is generated.
- Otherwise, it is IMPLEMENTATION DEFINED whether the exception is generated.

If `AArch32.ExclusiveMonitorsPass()` returns `FALSE` and the memory address, if accessed, would generate a synchronous Data Abort exception, it is IMPLEMENTATION DEFINED whether the exception is generated.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let address : bits(32) = R(n) + imm32;
    if AArch32_ExclusiveMonitorsPass(address,4) then
        MemA{32}(address) = R(t);
        R(d) = ZeroExtend{32}('0');
    else
        R(d) = ZeroExtend{32}('1');
    end;
end;
```

C5.1.232 STREXB

Store Register Exclusive Byte derives an address from a base register value, stores a byte from a register to the derived address if the executing PE has exclusive access to the memory at that address, and returns a status value of 0 if the store was successful, or of 1 if no store was performed.

For more information about support for shared memory see [Synchronization and semaphores](#). For information about memory accesses see [Memory accesses](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

STREXB{<c>}{<q>} <Rd>, <Rt>, [<Rn>]

Decode for this encoding

```
let d : integer = UInt(Rd);
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
if d == 15 || t == 15 || n == 15 then UnpredictableProcedure(); end;
if d == n || d == t then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If $d == t$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction executes but the value stored is UNKNOWN.

If $d == n$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs the store to an UNKNOWN address.

T1

Encoding

STREXB{<c>}{<q>} <Rd>, <Rt>, [<Rn>]

Decode for this encoding

```
let d : integer = UInt(Rd);  
let t : integer = UInt(Rt);  
let n : integer = UInt(Rn);  
// Armv8-A removes UNPREDICTABLE for R13  
if d == 15 || t == 15 || n == 15 then UnpredictableProcedure(); end;  
if d == n || d == t then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If $d == t$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction executes but the value stored is UNKNOWN.

If $d == n$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs the store to an UNKNOWN address.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rd>

Is the destination general-purpose register into which the status result of the store exclusive is written, encoded in the “Rd” field. The value returned is:

- 0 If the operation updates memory.
- 1 If the operation fails to update memory.

<Rt>

Is the general-purpose register to be transferred, encoded in the “Rt” field.

<Rn>

Is the general-purpose base register, encoded in the “Rn” field.

Aborts

If a synchronous Data Abort exception is generated by the execution of this instruction:

- Memory is not updated.
- <Rd> is not updated.

If `AArch32.ExclusiveMonitorsPass()` returns FALSE and the memory address, if accessed, would generate a synchronous Data Abort exception, it is IMPLEMENTATION DEFINED whether the exception is generated.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
let address : bits(32) = R(n);
if AArch32_ExclusiveMonitorsPass(address,1) then
    MemA{8}(address) = R(t)[7:0];
    R(d) = ZeroExtend(32)('0');
else
    R(d) = ZeroExtend(32)('1');
end;
end;
```

C5.1.233 STREXD

Store Register Exclusive Doubleword derives an address from a base register value, stores a 64-bit doubleword from two registers to the derived address if the executing PE has exclusive access to the memory at that address, and returns a status value of 0 if the store was successful, or of 1 if no store was performed.

For more information about support for shared memory see [Synchronization and semaphores](#). For information about memory accesses see [Memory accesses](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

STREXD{<c>}{<q>} <Rd>, <Rt>, <Rt2>, [<Rn>]

Decode for this encoding

```
let t : integer = UInt(Rt);
let t2 : integer = t + 1;
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
if d == 15 || Rt[0] == '1' || t2 == 15 || n == 15 then UnpredictableProcedure(); end;
if d == n || d == t || d == t2 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If $d == t$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction executes but the value stored is UNKNOWN.

If $d == n$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs the store to an UNKNOWN address.

If $Rt<0> == '1'$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes with the additional decode: $Rt<0> = '0'$.
- The instruction executes with the additional decode: $t2 = t$.
- The instruction executes as described, with no change to its behavior and no additional side effects.

If $Rt == '1110'$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction is handled as described in Using R15.

T1

Encoding

STREXD{<c>}{<q>} <Rd>, <Rt>, <Rt2>, [<Rn>]

Decode for this encoding

```
let d : integer = UInt(Rd);
let t : integer = UInt(Rt);
let t2 : integer = UInt(Rt2);
let n : integer = UInt(Rn);
if d == 15 || t == 15 || t2 == 15 || n == 15 then UnpredictableProcedure(); end;
// Armv8-A removes UNPREDICTABLE for R13
if d == n || d == t || d == t2 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If $d == t$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction executes but the value stored is UNKNOWN.

If $d == n$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs the store to an UNKNOWN address.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rd>

Is the destination general-purpose register into which the status result of the store exclusive is written, encoded in the “Rd” field. The value returned is:

- 0 If the operation updates memory.
- 1 If the operation fails to update memory.

<Rd> must not be the same as <Rn>, <Rt>, or <Rt2>.

<Rt>

For the “A1” variant: is the first general-purpose register to be transferred, encoded in the “Rt” field. <Rt> must be even-numbered and not R14.

For the “T1” variant: is the first general-purpose register to be transferred, encoded in the “Rt” field.

<Rt2>

For the “A1” variant: is the second general-purpose register to be transferred. <Rt2> must be <R(t+1)>.

For the “T1” variant: is the second general-purpose register to be transferred, encoded in the “Rt2” field.

<Rn>

Is the general-purpose base register, encoded in the “Rn” field.

Aborts and alignment

If a synchronous Data Abort exception is generated by the execution of this instruction:

- Memory is not updated.
- <Rd> is not updated.

A non doubleword-aligned memory address causes an Alignment fault Data Abort exception to be generated, subject to the following rules:

- If `AArch32.ExclusiveMonitorsPass()` returns `TRUE`, the exception is generated.
- Otherwise, it is IMPLEMENTATION DEFINED whether the exception is generated.

If `AArch32.ExclusiveMonitorsPass()` returns `FALSE` and the memory address, if accessed, would generate a synchronous Data Abort exception, it is IMPLEMENTATION DEFINED whether the exception is generated.

Operation

```

if ConditionPassed() then
    EncodingSpecificOperations();
    let address : bits(32) = R(n);

    // Create doubleword to store such that R[t] will be stored at address and R[t2] at address+4.
    let value : bits(64) = if BigEndian(AccessType_GPR) then R(t)::R(t2) else R(t2)::R(t);

    if AArch32_ExclusiveMonitorsPass(address,8) then
        MemA{64}(address) = value;
        R(d) = ZeroExtend{32}('0');
    else
        R(d) = ZeroExtend{32}('1');
    end;
end;
end;
```

C5.1.234 STREXH

Store Register Exclusive Halfword derives an address from a base register value, stores a halfword from a register to the derived address if the executing PE has exclusive access to the memory at that address, and returns a status value of 0 if the store was successful, or of 1 if no store was performed.

For more information about support for shared memory see [Synchronization and semaphores](#). For information about memory accesses see [Memory accesses](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

STREXH{<c>}{<q>} <Rd>, <Rt>, [<Rn>]

Decode for this encoding

```
let d : integer = UInt(Rd);
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
if d == 15 || t == 15 || n == 15 then UnpredictableProcedure(); end;
if d == n || d == t then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `d == t`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction executes but the value stored is UNKNOWN.

If `d == n`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs the store to an UNKNOWN address.

T1

Encoding

STREXH{<c>}{<q>} <Rd>, <Rt>, [<Rn>]

Decode for this encoding

```
let d : integer = UInt(Rd);
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 || t == 15 || n == 15 then UnpredictableProcedure(); end;
if d == n || d == t then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If $d == t$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction executes but the value stored is UNKNOWN.

If $d == n$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs the store to an UNKNOWN address.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rd>

Is the destination general-purpose register into which the status result of the store exclusive is written, encoded in the “Rd” field. The value returned is:

- 0 If the operation updates memory.
- 1 If the operation fails to update memory.

<Rt>

Is the general-purpose register to be transferred, encoded in the “Rt” field.

<Rn>

Is the general-purpose base register, encoded in the “Rn” field.

Aborts and alignment

If a synchronous Data Abort exception is generated by the execution of this instruction:

- Memory is not updated.
- <Rd> is not updated.

A non halfword-aligned memory address causes an Alignment fault Data Abort exception to be generated, subject to the following rules:

- If `AArch32.ExclusiveMonitorsPass()` returns `TRUE`, the exception is generated.
- Otherwise, it is IMPLEMENTATION DEFINED whether the exception is generated.

If `AArch32.ExclusiveMonitorsPass()` returns `FALSE` and the memory address, if accessed, would generate a synchronous Data Abort exception, it is IMPLEMENTATION DEFINED whether the exception is generated.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
let address : bits(32) = R(n);
if AArch32_ExclusiveMonitorsPass(address,2) then
    MemA{16}(address) = R(t)[15:0];
    R(d) = ZeroExtend{32}('0');
else
    R(d) = ZeroExtend{32}('1');
end;
end;
```

C5.1.235 STRH (immediate)

Store Register Halfword (immediate) calculates an address from a base register value and an immediate offset, and stores a halfword from a register to memory. It can use offset, post-indexed, or pre-indexed addressing. For information about memory accesses see [Memory accesses](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#), [T2](#), and [T3](#)).

A1

Encoding for the Offset variant

Applies when (P == 1 && W == 0)

```
STRH{<c>}{<q>} <Rt>, [<Rn> {, #{+/-}<imm>}]
```

Encoding for the Post-indexed variant

Applies when (P == 0 && W == 0)

```
STRH{<c>}{<q>} <Rt>, [<Rn>], #{+/-}<imm>
```

Encoding for the Pre-indexed variant

Applies when (P == 1 && W == 1)

```
STRH{<c>}{<q>} <Rt>, [<Rn>, #{+/-}<imm>]!
```

Decode for all variants of this encoding

```
if P == '0' && W == '1' then See("STRHT"); end;
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let imm32 : bits(32) = ZeroExtend{}(imm4H::imm4L);
let index : boolean = (P == '1');
let add : boolean = (U == '1');
let wback : boolean = (P == '0') || (W == '1');
if t == 15 then UnpredictableProcedure(); end;
if wback && (n == 15 || n == t) then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If t == 15, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction performs the store using the specified addressing mode but the value corresponding to R15 is UNKNOWN.

If wback && n == t, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction executes but the value stored is UNKNOWN.

If `wback && n == 15`, then one of the following behaviors must occur:

- The instruction is `UNDEFINED`.
- The instruction executes as `NOF`.
- The instruction executes without writeback of the base address.
- The instruction uses the addressing mode described in the equivalent immediate offset instruction.

T1

Encoding

STRH{<c>}{<q>}<Rt>,[<Rn>{,<#>{<+><imm>}}]

Decode for this encoding

```

let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let imm32 : bits(32) = ZeroExtend{imm5::'0'};
let index : boolean = TRUE;
let add : boolean = TRUE;
let wback : boolean = FALSE;

```

T2

Encoding

STRH{<c>}{<q>}<Rt>,[<Rn>{,<#>{<+><imm>}]

```
STRH{<c>}.W <Rt>, [<Rn> {, #{+<imm>}}] // (<Rt>, <Rn>, <imm> can be represented in T1)
```

Decode for this encoding

```

if Rn == 'l1l1' then Undefined(); end;
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let imm32 : bits(32) = ZeroExtend{}(imm12);
let index : boolean = TRUE;
let add : boolean = TRUE;
let wback : boolean = FALSE;
// Armv8-A removes UNPREDICTABLE for R13
if t == 15 then UnpredictableProcedure(); end;

```

CONSTRAINED UNPREDICTABLE behavior

If $t == 15$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction performs the store using the specified addressing mode but the value corresponding to R15 is UNKNOWN.

T3

Encoding for the Offset variant

Applies when $(P == 1 \ \&\& \ U == 0 \ \&\& \ W == 0)$

STRH{<c>}{<q>} <Rt>, [<Rn> {, #-<imm>}]

Encoding for the Post-indexed variant

Applies when $(P == 0 \ \&\& \ W == 1)$

STRH{<c>}{<q>} <Rt>, [<Rn>], #{+/-}<imm>

Encoding for the Pre-indexed variant

Applies when $(P == 1 \ \&\& \ W == 1)$

STRH{<c>}{<q>} <Rt>, [<Rn>, #{+/-}<imm>]!

Decode for all variants of this encoding

```

if P == '1' && U == '1' && W == '0' then See("STRHT"); end;
if Rn == '1111' || (P == '0' && W == '0') then Undefined(); end;
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let imm32 : bits(32) = ZeroExtend{}(imm8);
let index : boolean = (P == '1');
let add : boolean = (U == '1');
let wback : boolean = (W == '1');
// Armv8-A removes UNPREDICTABLE for R13
if t == 15 || (wback && n == t) then UnpredictableProcedure(); end;

```

CONSTRAINED UNPREDICTABLE behavior

If $t == 15$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction performs the store using the specified addressing mode but the value corresponding to R15 is UNKNOWN.

If $wback \ \&\& \ n == t$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction executes but the value stored is UNKNOWN.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rt>

Is the general-purpose register to be transferred, encoded in the “Rt” field.

<Rn>

For the “A1 Offset” variant: is the general-purpose base register, encoded in the “Rn” field. The PC can be used in the offset variant, but this is deprecated.

For the “A1 Post-indexed”, “A1 Pre-indexed”, “T1”, “T2”, “T3 Offset”, “T3 Post-indexed”, and “T3 Pre-indexed” variants: is the general-purpose base register, encoded in the “Rn” field.

+/-

Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in “U”:

U	+/-
0	-
1	+

<imm>

For the “A1 Offset”, “A1 Post-indexed”, and “A1 Pre-indexed” variants: is the 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 if omitted, and encoded in the “imm4H:imm4L” field.

For the “T1” variant: is the optional positive unsigned immediate byte offset, a multiple of 2, in the range 0 to 62, defaulting to 0 and encoded in the “imm5” field as <imm>/2.

For the “T2” variant: is an optional 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 and encoded in the “imm12” field.

For the “T3 Offset”, “T3 Post-indexed”, and “T3 Pre-indexed” variants: is an 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 if omitted, and encoded in the “imm8” field.

+

Specifies the offset is added to the base register.

Operation

```
if CurrentInstrSet() == InstrSet_A32 then
  if ConditionPassed() then
    EncodingSpecificOperations();
    let offset_addr : bits(32) = if add then (R(n) + imm32) else (R(n) - imm32);
```

```
        let address : bits(32) = if index then offset_addr else R(n);
        MemU{16}(address) = R(t)[15:0];
        if wback then R(n) = offset_addr; end;
    end;
else
    if ConditionPassed() then
        EncodingSpecificOperations();
        let offset_addr : bits(32) = if add then (R(n) + imm32) else (R(n) - imm32);
        let address : bits(32) = if index then offset_addr else R(n);
        MemU{16}(address) = R(t)[15:0];
        if wback then R(n) = offset_addr; end;
    end;
end;
```

C5.1.236 STRH (register)

Store Register Halfword (register) calculates an address from a base register value and an offset register value, and stores a halfword from a register to memory. The offset register value can be shifted left by 0, 1, 2, or 3 bits. For information about memory accesses see [Memory accesses](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#) and [T2](#)).

A1

Encoding for the Offset variant

Applies when (P == 1 && W == 0)

STRH{<c>}{<q>} <Rt>, [<Rn>, {+/-}<Rm>]

Encoding for the Post-indexed variant

Applies when (P == 0 && W == 0)

STRH{<c>}{<q>} <Rt>, [<Rn>], {+/-}<Rm>

Encoding for the Pre-indexed variant

Applies when (P == 1 && W == 1)

STRH{<c>}{<q>} <Rt>, [<Rn>, {+/-}<Rm>]!

Decode for all variants of this encoding

```

if P == '0' && W == '1' then See("STRHT"); end;
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let index : boolean = (P == '1');
let add : boolean = (U == '1');
let wback : boolean = (P == '0') || (W == '1');
let shift_t : SRTYPE = SRTYPE_LSL;
let shift_n : integer = 0;
if t == 15 || m == 15 then UnpredictableProcedure(); end;
if wback && (n == 15 || n == t) then UnpredictableProcedure(); end;

```

CONSTRAINED UNPREDICTABLE behavior

If t == 15, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction performs the store using the specified addressing mode but the value corresponding to R15 is UNKNOWN.

If wback && n == t, then one of the following behaviors must occur:

- The instruction is UNDEFINED.

- The instruction executes as NOP.
- The store instruction executes but the value stored is UNKNOWN.

If `wback && n == 15`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes without writeback of the base address.
- The instruction uses the addressing mode described in the equivalent immediate offset instruction.

T1

Encoding

STRH{<c>}{<q>} <Rt>, [<Rn>, {+}<Rm>]

Decode for this encoding

```

let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let index : boolean = TRUE;
let add : boolean = TRUE;
let wback : boolean = FALSE;
let shift_t : SRTYPE = SRTYPE_LSL;
let shift_n : integer = 0;

```

T2

Encoding

STRH{<c>}{<q>} <Rt>, [<Rn>, {+}<Rm>{, LSL #<imm>}]

STRH{<c>}.W <Rt>, [<Rn>, {+}<Rm>] // (<Rt>, <Rn>, <Rm> can be represented in T1)

Decode for this encoding

```
if Rn == '1111' then Undefined(); end;
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let index : boolean = TRUE;
let add : boolean = TRUE;
let wback : boolean = FALSE;
let shift_t : SRTYPE = SRTYPE_LSL;
let shift_n : integer = UInt(imm2);
// Armv8-A removes UNPREDICTABLE for R13
if t == 15 || m == 15 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `t == 15`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction performs the store using the specified addressing mode but the value corresponding to R15 is UNKNOWN.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rt>

Is the general-purpose register to be transferred, encoded in the “Rt” field.

<Rn>

For the “Offset”, “Post-indexed”, and “Pre-indexed” variants: is the general-purpose base register, encoded in the “Rn” field. The PC can be used in the offset variant, but this is deprecated.

For the “T1” and “T2” variants: is the general-purpose base register, encoded in the “Rn” field.

+/-

Specifies the index register is added to or subtracted from the base register, defaulting to + if omitted and encoded in “U”:

U	+/-
0	–
1	+

<Rm>

Is the general-purpose index register, encoded in the “Rm” field.

+

Specifies the index register is added to the base register.

<imm>

If present, the size of the left shift to apply to the value from <Rm>, in the range 1-3. <imm> is encoded in imm2. If absent, no shift is specified and imm2 is encoded as 0b00.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let offset : bits(32) = Shift{}(R(m), shift_t, shift_n, PSTATE.C);
    let offset_addr : bits(32) = if add then (R(n) + offset) else (R(n) - offset);
    let address : bits(32) = if index then offset_addr else R(n);
    MemU{16}(address) = R(t)[15:0];
    if wback then R(n) = offset_addr; end;
end;
```

C5.1.237 STRHT

Store Register Halfword Unprivileged stores a halfword from a register to memory. For information about memory accesses see [Memory accesses](#).

The memory access is restricted as if the PE were running in User mode. This makes no difference if the PE is actually running in User mode.

STRHT is UNPREDICTABLE in Hyp mode.

The T32 instruction uses an offset addressing mode, that calculates the address used for the memory access from a base register value and an immediate offset, and leaves the base register unchanged.

The A32 instruction uses a post-indexed addressing mode, that uses a base register value as the address for the memory access, and calculates a new address from a base register value and an offset and writes it back to the base register. The offset can be an immediate value or a register value.

It has encodings from the following instruction sets: A32 ([A1](#) and [A2](#)) and T32 ([T1](#)).

A1

Encoding

```
STRHT{<c>}{<q>} <Rt>, [<Rn>] {, #(+/-)<imm>}
```

Decode for this encoding

```
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let postindex : boolean = TRUE;
let add : boolean = (U == '1');
let register_form : boolean = FALSE;
let imm32 : bits(32) = ZeroExtend{}(imm4H::imm4L);
let m : integer = ARBITRARY : integer;
if t == 15 || n == 15 || n == t then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If $t == 15$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction performs the store using the specified addressing mode but the value corresponding to R15 is UNKNOWN.

If $n == t$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction executes but the value stored is UNKNOWN.

If $n == 15$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.

- The instruction executes as NOP.
- The instruction uses post-indexed addressing with the base register as PC. This is handled as described in Using R15.
- The instruction is treated as if bit[24] == 1 and bit[21] == 0. The instruction uses immediate offset addressing with the base register as PC, without writeback.

A2

Encoding

STRHT{<c>}{<q>} <Rt>, [<Rn>], {+/-}<Rm>

Decode for this encoding

```
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let postindex : boolean = TRUE;
let add : boolean = (U == '1');
let register_form : boolean = TRUE;
let imm32 : bits(32) = ARBITRARY : bits(32);
if t == 15 || n == 15 || m == t || m == 15 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If $t == 15$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction performs the store using the specified addressing mode but the value corresponding to R15 is UNKNOWN.

If $n == t$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction executes but the value stored is UNKNOWN.

If $n == 15$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction uses post-indexed addressing with the base register as PC. This is handled as described in Using R15.
- The instruction is treated as if bit[24] == 1 and bit[21] == 0. The instruction uses immediate offset addressing with the base register as PC, without writeback.

T1

Encoding

STRHT{<c>}{<q>} <Rt>, [<Rn> {, #<+><imm>}]

Decode for this encoding

```

if Rn == '1111' then Undefined(); end;
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let postindex : boolean = FALSE;
let add : boolean = TRUE;
let register_form : boolean = FALSE;
let imm32 : bits(32) = ZeroExtend{}(imm8);
let m : integer = ARBITRARY : integer;
// Armv8-A removes UNPREDICTABLE for R13
if t == 15 then UnpredictableProcedure(); end;

```

CONSTRAINED UNPREDICTABLE behavior

If $t == 15$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction performs the store using the specified addressing mode but the value corresponding to R15 is UNKNOWN.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rt>

Is the general-purpose register to be transferred, encoded in the “Rt” field.

<Rn>

Is the general-purpose base register, encoded in the “Rn” field.

+/-

For the “A1” variant: specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in “U”:

U	+/-
0	-
1	+

For the “A2” variant: specifies the index register is added to or subtracted from the base register, defaulting to + if omitted and encoded in “U”:

U	+/-
0	-
1	+

<imm>

For the “A1” variant: is the 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 if omitted, and encoded in the “imm4H:imm4L” field.

For the “T1” variant: is an optional 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 and encoded in the “imm8” field.

<Rm>

Is the general-purpose index register, encoded in the “Rm” field.

+

Specifies the offset is added to the base register.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    if PSTATE.EL == EL2 then UnpredictableProcedure(); end; // Hyp mode
    let offset : bits(32) = if register_form then R(m) else imm32;
    let offset_addr : bits(32) = if add then (R(n) + offset) else (R(n) - offset);
    let address : bits(32) = if postindex then R(n) else offset_addr;
    MemU_unpriv{16}(address) = R(t)[15:0];
    if postindex then R(n) = offset_addr; end;
end;
```

CONSTRAINED UNPREDICTABLE behavior

If PSTATE.EL == EL2, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes as STRH (immediate).

C5.1.238 STRT

Store Register Unprivileged stores a word from a register to memory. For information about memory accesses see [Memory accesses](#).

The memory access is restricted as if the PE were running in User mode. This makes no difference if the PE is actually running in User mode.

STRT is UNPREDICTABLE in Hyp mode.

The T32 instruction uses an offset addressing mode, that calculates the address used for the memory access from a base register value and an immediate offset, and leaves the base register unchanged.

The A32 instruction uses a post-indexed addressing mode, that uses a base register value as the address for the memory access, and calculates a new address from a base register value and an offset and writes it back to the base register. The offset can be an immediate value or an optionally-shifted register value.

It has encodings from the following instruction sets: A32 ([A1](#) and [A2](#)) and T32 ([T1](#)).

A1

Encoding

STRT{<c>}{<q>} <Rt>, [<Rn>] {, #<+/-><imm>}

Decode for this encoding

```

let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let postindex : boolean = TRUE;
let add : boolean = (U == '1');
let register_form : boolean = FALSE;
let imm32 : bits(32) = ZeroExtend{}(imm12);
let m : integer = ARBITRARY : integer;
let shift_n : integer = ARBITRARY : integer;
let shift_t : SRTYPE = ARBITRARY : SRTYPE;
if n == 15 || n == t then UnpredictableProcedure(); end;

```

CONSTRAINED UNPREDICTABLE behavior

If $n == t$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction executes but the value stored is UNKNOWN.

If $n == 15$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction uses post-indexed addressing with the base register as PC. This is handled as described in Using R15.
- The instruction is treated as if $\text{bit}[24] == 1$ and $\text{bit}[21] == 0$. The instruction uses immediate offset addressing with the base register as PC, without writeback.

A2

Encoding

STRT{<c>}{<q>} <Rt>, [<Rn>], {+/-}<Rm>{, <shift>}

Decode for this encoding

```

let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let postindex : boolean = TRUE;
let add : boolean = (U == '1');
let register_form : boolean = TRUE;
let (shift_t, shift_n) : (SRTType, integer) = DecodeImmShift(stype, imm5);
let imm32 : bits(32) = ARBITRARY : bits(32);
if n == 15 || n == t || m == 15 then UnpredictableProcedure(); end;

```

CONSTRAINED UNPREDICTABLE behavior

If $n == t$, then one of the following behaviors must occur:

- The instruction is **UNDEFINED**.
- The instruction executes as **NOP**.
- The store instruction executes but the value stored is **UNKNOWN**.

If $n = 15$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction uses post-indexed addressing with the base register as PC. This is handled as described in Using R15.
- The instruction is treated as if $\text{bit}[24] = 1$ and $\text{bit}[21] = 0$. The instruction uses immediate offset addressing with the base register as PC, without writeback.

T1

Encoding

STRT{<c>} {<q>} <Rt>, [<Rn> {, # {+<imm>}]

Decode for this encoding

```
if Rn == '1111' then Undefined(); end;
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let postindex : boolean = FALSE;
let add : boolean = TRUE;
let register_form : boolean = FALSE;
let imm32 : bits(32) = ZeroExtend{}(imm8);
let m : integer = ARBITRARY : integer;
let shift_n : integer = ARBITRARY : integer;
let shift_t : SRTYPE = ARBITRARY : SRTYPE;
// Armv8-A removes UNPREDICTABLE for R13
if t == 15 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `t == 15`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction performs the store using the specified addressing mode but the value corresponding to R15 is UNKNOWN.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rt>

For the “A1” and “A2” variants: is the general-purpose register to be transferred, encoded in the “Rt” field. The PC can be used, but this is deprecated.

For the “T1” variant: is the general-purpose register to be transferred, encoded in the “Rt” field.

<Rn>

Is the general-purpose base register, encoded in the “Rn” field.

+/-

For the “A1” variant: specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in “U”:

U	+/-
0	-
1	+

For the “A2” variant: specifies the index register is added to or subtracted from the base register, defaulting to + if omitted and encoded in “U”:

U	+/-
0	-
1	+

<imm>

For the “A1” variant: is the 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 if omitted, and encoded in the “imm12” field.

For the “T1” variant: is an optional 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 and encoded in the “imm8” field.

<Rm>

Is the general-purpose index register, encoded in the “Rm” field.

<shift>

The shift to apply to the value read from <Rm>. If absent, no shift is applied. Otherwise, see [Shifts applied to a register](#).

+

Specifies the offset is added to the base register.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    if PSTATE.EL == EL2 then UnpredictableProcedure(); end;           // Hyp mode
    let offset : bits(32) = (if register_form then Shift{32}(R(m), shift_t, shift_n, PSTATE.C)
                             else imm32);
    let offset_addr : bits(32) = if add then (R(n) + offset) else (R(n) - offset);
    let address : bits(32) = if postindex then R(n) else offset_addr;
    var data : bits(32);
    if t == 15 then // Only possible for encodings A1 and A2
        data = PCStoreValue();
    else
        data = R(t);
    end;
    MemU_unpriv{32}(address) = data;
    if postindex then R(n) = offset_addr; end;
end;
```

CONSTRAINED UNPREDICTABLE behavior

If PSTATE.EL == EL2, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes as STR (immediate).

C5.1.239 SUB (immediate, from PC)

Subtract from PC subtracts an immediate value from the Align(PC, 4) value to form a PC-relative address, and writes the result to the destination register. Arm recommends that, where possible, software avoids using this alias.

This is an alias of [ADR](#). This means:

- The encodings in this description are named to match the encodings of [ADR](#).
- The description of [ADR](#) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

It has encodings from the following instruction sets: A32 ([A2](#)) and T32 ([T2](#)).

A2

Encoding for the A2 variant

SUB{<c>}{<q>} <Rd>, PC, #<const>

is equivalent to

ADR{<c>}{<q>} <Rd>, <label>

and is the preferred disassembly when imm12 == '000000000000'.

T2

Encoding for the T2 variant

SUB{<c>}{<q>} <Rd>, PC, #<imm12>

is equivalent to

ADR{<c>}{<q>} <Rd>, <label>

and is the preferred disassembly when i :: imm3 :: imm8 == '000000000000'.

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rd>

For the “A2” variant: is the general-purpose destination register, encoded in the “Rd” field. If the PC is used, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC](#).

For the “T2” variant: is the general-purpose destination register, encoded in the “Rd” field.

<const>

An immediate value. See [Modified immediate constants in A32 instructions](#) for the range of values.

<imm12>

Is a 12-bit unsigned immediate, in the range 0 to 4095, encoded in the “i:imm3:imm8” field.

Operation

The description of [ADR](#) gives the operational pseudocode for this instruction.

C5.1.240 SUB, SUBS (immediate)

Subtract (immediate) subtracts an immediate value from a register value, and writes the result to the destination register.

If the destination register is not the PC, the SUBS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. If the destination register is the PC:

- The SUB variant of the instruction is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC](#).
- The SUBS variant of the instruction performs an exception return without the use of the stack. In this case:
 - The PE branches to the address written to the PC, and restores `PSTATE` from `SPSR_<current_mode>`.
 - The PE checks `SPSR_<current_mode>` for an illegal return event. See [Illegal return events from AArch32 state](#).
 - The instruction is UNDEFINED in Hyp mode, except for encoding T5 with <imm8> set to zero, which is the encoding for the `ERET` instruction, see `ERET`.
 - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#), [T2](#), [T3](#), [T4](#), and [T5](#)).

A1

Encoding for the SUB variant

Applies when (S == 0 && Rn != 11x1)

SUB{<c>}{<q>} {<Rd>, }<Rn>, #<const>

Encoding for the SUBS variant

Applies when (S == 1 && Rn != 1101)

SUBS{<c>}{<q>} {<Rd>, }<Rn>, #<const>

Decode for all variants of this encoding

```

if Rn == '1111' && S == '0' then See("ADR"); end;
if Rn == '1101' then See("SUB (SP minus immediate)"); end;
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let setflags : boolean = (S == '1');
let imm32 : bits(32) = A32ExpandImm(imm12);
    
```

T1

Encoding

SUB<c>{<q>} <Rd>, <Rn>, #<imm3> // (InITBlock())

SUBS{<q>} <Rd>, <Rn>, #<imm3> // (Outside IT block)

Decode for this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let setflags : boolean = !InITBlock();
let imm32 : bits(32) = ZeroExtend{}(imm3);
```

T2

Encoding

SUB<c>{<q>} <Rdn>, #<imm8> // (InITBlock() && UInt(Rdn) < 8 && UInt(imm8) < 8)

SUB<c>{<q>} {<Rdn>, }<Rdn>, #<imm8> // (Inside IT block, and <Rdn>, <imm8> cannot be represented in T1)

SUBS{<q>} <Rdn>, #<imm8> // (Outside IT block, and <Rdn>, <imm8> can be represented in T1)

SUBS{<q>} {<Rdn>, }<Rdn>, #<imm8> // (Outside IT block, and <Rdn>, <imm8> cannot be represented in T1)

Decode for this encoding

```
let d : integer = UInt(Rdn);
let n : integer = UInt(Rdn);
let setflags : boolean = !InITBlock();
let imm32 : bits(32) = ZeroExtend{}(imm8);
```

T3

Encoding for the SUB variant

Applies when (S == 0)

SUB{<c>}{<q>} {<Rd>, }<Rn>, #<const>

SUB<c>.W {<Rd>, }<Rn>, #<const> // (Inside IT block, and <Rd>, <Rn>, <const> can be represented in T1
→ or T2)

Encoding for the SUBS variant

Applies when (S == 1 && Rd != 1111)

SUBS{<c>}{<q>} {<Rd>, }<Rn>, #<const>

SUBS.W {<Rd>, }<Rn>, #<const> // (Outside IT block, and <Rd>, <Rn>, <const> can be represented in T1 or
↪T2)

Decode for all variants of this encoding

```
if Rd == '1111' && S == '1' then See("CMP (immediate)"); end;
if Rn == '1101' then See("SUB (SP minus immediate)"); end;
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let setflags : boolean = (S == '1');
let imm32 : bits(32) = T32ExpandImm(i::imm3::imm8);
// Armv8-A removes UNPREDICTABLE for R13
if (d == 15 && !setflags) || n == 15 then UnpredictableProcedure(); end;
```

T4

Encoding

SUB{<c>}{<q>} {<Rd>, }<Rn>, #<imm12> // (<imm12> cannot be represented in T1, T2, or T3)

SUBW{<c>}{<q>} {<Rd>, }<Rn>, #<imm12> // (<imm12> can be represented in T1, T2, or T3)

Decode for this encoding

```
if Rn == '1111' then See("ADR"); end;
if Rn == '1101' then See("SUB (SP minus immediate)"); end;
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let setflags : boolean = FALSE;
let imm32 : bits(32) = ZeroExtend{}(i::imm3::imm8);
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 then UnpredictableProcedure(); end;
```

T5

Encoding

Applies when (!(Rn == 1110 && imm8 == 00000000))

SUBS{<c>}{<q>} PC, LR, #<imm8>

Decode for this encoding

```
if Rn == '1110' && IsZero(imm8) then See("ERET"); end;
let d : integer = 15;
let n : integer = UInt(Rn);
let setflags : boolean = TRUE;
let imm32 : bits(32) = ZeroExtend{(imm8)};
if n != 14 then UnpredictableProcedure(); end;
if InITBlock() && !LastInITBlock() then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly [SUBS PC, LR and related instructions \(A32\)](#) and [SUBS PC, LR and related instructions \(T32\)](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rd>

For the “A1 SUB” and “A1 SUBS” variants: is the general-purpose destination register, encoded in the “Rd” field. If omitted, this register is the same as <Rn>. If the PC is used:

- For the SUB variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC](#).
- For the SUBS variant, the instruction performs an exception return, that restores [PSTATE](#) from `SPSR_<current_mode>`. Arm deprecates use of this instruction unless <Rn> is the LR.

For the “T1”, “T3 SUB”, “T3 SUBS”, and “T4” variants: is the general-purpose destination register, encoded in the “Rd” field. If omitted, this register is the same as <Rn>.

<Rn>

For the “A1 SUB”, “A1 SUBS”, and “T4” variants: is the general-purpose source register, encoded in the “Rn” field. If the SP is used, see [SUB \(SP minus immediate\)](#). If the PC is used, see [ADR](#).

For the “T1” variant: is the general-purpose source register, encoded in the “Rn” field.

For the “T3 SUB” and “T3 SUBS” variants: is the general-purpose source register, encoded in the “Rn” field. If the SP is used, see [SUB \(SP minus immediate\)](#).

<const>

For the “A1 SUB” and “A1 SUBS” variants: an immediate value. See [Modified immediate constants in A32 instructions](#) for the range of values.

For the “T3 SUB” and “T3 SUBS” variants: an immediate value. See [Modified immediate constants in T32 instructions](#) for the range of values.

<imm3>

Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the “imm3” field.

<Rdn>

Is the general-purpose source and destination register, encoded in the “Rdn” field.

<imm8>

For the “T2” variant: is a 8-bit unsigned immediate, in the range 0 to 255, encoded in the “imm8” field.

For the “T5” variant: is a 8-bit unsigned immediate, in the range 0 to 255, encoded in the “imm8” field. If <Rn> is the LR, and zero is used, see ERET.

<imm12>

Is a 12-bit unsigned immediate, in the range 0 to 4095, encoded in the “i:imm3:imm8” field.

In the T32 instruction set, `MOVS{<c>}{<q>} PC, LR` is a pseudo-instruction for `SUBS{<c>}{<q>} PC, LR, #0`.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let (result, nzcvc) : (bits(32), bits(4)) = AddWithCarry{32}(R(n), NOT(imm32), '1');
    if d == 15 then
        if setflags then
            ALUEXceptionReturn(result);
        else
            ALUWritePC(result);
        end;
    else
        R(d) = result;
        if setflags then
            PSTATE.[N,Z,C,V] = nzcvc;
        end;
    end;
end;
```

C5.1.241 SUB, SUBS (register)

Subtract (register) subtracts an optionally-shifted register value from a register value, and writes the result to the destination register.

If the destination register is not the PC, the SUBS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. However, when the destination register is the PC:

- The SUB variant of the instruction is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC](#).
- The SUBS variant of the instruction performs an exception return without the use of the stack. Arm deprecates use of this instruction. However, in this case:
 - The PE branches to the address written to the PC, and restores **PSTATE** from SPSR_<current_mode>.
 - The PE checks SPSR_<current_mode> for an illegal return event. See [Illegal return events from AArch32 state](#).
 - The instruction is UNDEFINED in Hyp mode.
 - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#) and [T2](#)).

A1

Encoding for the SUB, rotate right with extend variant

Applies when (S == 0 && imm5 == 00000 && stype == 11)

SUB{<c>}{<q>} {<Rd>, }<Rn>, <Rm>, RRX

Encoding for the SUB, shift or rotate by value variant

Applies when (S == 0 && !(imm5 == 00000 && stype == 11))

SUB{<c>}{<q>} {<Rd>, }<Rn>, <Rm> {, <shift> #<amount>}

Encoding for the SUBS, rotate right with extend variant

Applies when (S == 1 && imm5 == 00000 && stype == 11)

SUBS{<c>}{<q>} {<Rd>, }<Rn>, <Rm>, RRX

Encoding for the SUBS, shift or rotate by value variant

Applies when (S == 1 && !(imm5 == 00000 && stype == 11))

SUBS{<c>}{<q>} {<Rd>, }<Rn>, <Rm> {, <shift> #<amount>}

Decode for all variants of this encoding

```

if Rn == '1101' then See("SUB (SP minus register)"); end;
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let setflags : boolean = (S == '1');
let (shift_t, shift_n) : (SRTType, integer) = DecodeImmShift(stype, imm5);

```

T1

Encoding

SUB<c>{<q>} <Rd>, <Rn>, <Rm> // (InITBlock())

SUBS{<q>} {<Rd>, }<Rn>, <Rm> // (Outside IT block)

Decode for this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let setflags : boolean = !InITBlock();
let shift_t : SRTYPE = SRTYPE_LSL;
let shift_n : integer = 0;
```

T2

Encoding for the SUB, rotate right with extend variant

Applies when (S == 0 && imm3 == 000 && imm2 == 00 && stype == 11)

SUB{<c>}{<q>} {<Rd>, }<Rn>, <Rm>, RRX

Encoding for the SUB, shift or rotate by value variant

Applies when (S == 0 && !(imm3 == 000 && imm2 == 00 && stype == 11))

SUB{<c>}{<q>} {<Rd>, }<Rn>, <Rm> {, <shift> #<amount>}

SUB<c>.W {<Rd>, }<Rn>, <Rm> // (Inside IT block, and <Rd>, <Rn>, <Rm> can be represented in T1)

Encoding for the SUBS, rotate right with extend variant

Applies when (S == 1 && imm3 == 000 && Rd != 1111 && imm2 == 00 && stype == 11)

SUBS{<c>}{<q>} {<Rd>, }<Rn>, <Rm>, RRX

Encoding for the SUBS, shift or rotate by value variant

Applies when (S == 1 && Rd != 1111 && !(imm3 == 000 && imm2 == 00 && stype == 11))

SUBS{<c>}{<q>} {<Rd>, }<Rn>, <Rm> {, <shift> #<amount>}

SUBS.W {<Rd>, }<Rn>, <Rm> // (Outside IT block, and <Rd>, <Rn>, <Rm> can be represented in T1)

Decode for all variants of this encoding

```

if Rd == '1111' && S == '1' then See("CMP (register)"); end;
if Rn == '1101' then See("SUB (SP minus register)"); end;
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let setflags : boolean = (S == '1');
let (shift_t, shift_n) : (SRTYPE, integer) = DecodeImmShift(stype, imm3::imm2);
// Armv8-A removes UNPREDICTABLE for R13
if (d == 15 && !setflags) || n == 15 || m == 15 then UnpredictableProcedure(); end;

```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rd>

For the “A1 SUB, rotate right with extend”, “A1 SUB, shift or rotate by value”, “A1 SUBS, rotate right with extend”, and “A1 SUBS, shift or rotate by value” variants: is the general-purpose destination register, encoded in the “Rd” field. If omitted, this register is the same as <Rn>. Arm deprecates using the PC as the destination register, but if the PC is used:

- For the SUB variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC](#).
- For the SUBS variant, the instruction performs an exception return, that restores [PSTATE](#) from `SPSR_current_mode`.

For the “T1”, “T2 SUB, rotate right with extend”, “T2 SUB, shift or rotate by value”, “T2 SUBS, rotate right with extend”, and “T2 SUBS, shift or rotate by value” variants: is the general-purpose destination register, encoded in the “Rd” field. If omitted, this register is the same as <Rn>.

<Rn>

For the “A1 SUB, rotate right with extend”, “A1 SUB, shift or rotate by value”, “A1 SUBS, rotate right with extend”, and “A1 SUBS, shift or rotate by value” variants: is the first general-purpose source register, encoded in the “Rn” field. The PC can be used, but this is deprecated. If the SP is used, see [SUB \(SP minus register\)](#).

For the “T1” variant: is the first general-purpose source register, encoded in the “Rn” field.

For the “T2 SUB, rotate right with extend”, “T2 SUB, shift or rotate by value”, “T2 SUBS, rotate right with extend”, and “T2 SUBS, shift or rotate by value” variants: is the first general-purpose source register, encoded in the “Rn” field. If the SP is used, see [SUB \(SP minus register\)](#).

<Rm>

For the “A1 SUB, rotate right with extend”, “A1 SUB, shift or rotate by value”, “A1 SUBS, rotate right with extend”, and “A1 SUBS, shift or rotate by value” variants: is the second general-purpose source register, encoded in the “Rm” field. The PC can be used, but this is deprecated.

For the “T1”, “T2 SUB, rotate right with extend”, “T2 SUB, shift or rotate by value”, “T2 SUBS, rotate right with extend”, and “T2 SUBS, shift or rotate by value” variants: is the second general-purpose source register, encoded in the “Rm” field.

<shift>

Is the type of shift to be applied to the second source register, encoded in “stype”:

stype	<shift>
00	LSL
01	LSR
10	ASR
11	ROR

<amount>

For the “A1 SUB, shift or rotate by value” and “A1 SUBS, shift or rotate by value” variants: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the “imm5” field as <amount> modulo 32.

For the “T2 SUB, shift or rotate by value” and “T2 SUBS, shift or rotate by value” variants: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR), encoded in the “imm3:imm2” field as <amount> modulo 32.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let shifted : bits(32) = Shift{}(R(m), shift_t, shift_n, PSTATE.C);
    let (result, nzcvc) : (bits(32), bits(4)) = AddWithCarry{32}(R(n), NOT(shifted), '1');
    if d == 15 then // Can only occur for A32 encoding
        if setflags then
            ALUExceptionReturn(result);
        else
            ALUWritePC(result);
        end;
    else
        R(d) = result;
        if setflags then
            PSTATE.[N,Z,C,V] = nzcvc;
        end;
    end;
end;
```

C5.1.242 SUB, SUBS (register-shifted register)

Subtract (register-shifted register) subtracts a register-shifted register value from a register value, and writes the result to the destination register. It can optionally update the condition flags based on the result.

Encoding for the Flag setting variant

Applies when (S == 1)

SUBS{<c>}{<q>} {<Rd>, }<Rn>, <Rm>, <shift> <Rs>

Encoding for the Not flag setting variant

Applies when (S == 0)

SUB{<c>}{<q>} {<Rd>, }<Rn>, <Rm>, <shift> <Rs>

Decode for all variants of this encoding

```

let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let s : integer = UInt(Rs);
let setflags : boolean = (S == '1');
let shift_t : SRTYPE = DecodeRegShift(stype);
if d == 15 || n == 15 || m == 15 || s == 15 then UnpredictableProcedure(); end;

```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rd>

Is the general-purpose destination register, encoded in the “Rd” field.

<Rn>

Is the first general-purpose source register, encoded in the “Rn” field.

<Rm>

Is the second general-purpose source register, encoded in the “Rm” field.

<shift>

Is the type of shift to be applied to the second source register, encoded in “stype”:

stype	<shift>
00	LSL
01	LSR
10	ASR
11	ROR

<Rs>

Is the third general-purpose source register holding a shift amount in its bottom 8 bits, encoded in the “Rs” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let shift_n : integer = UInt(R(s)[7:0]);
    let shifted : bits(32) = Shift{}(R(m), shift_t, shift_n, PSTATE.C);
    let (result, nzcvc) : (bits(32), bits(4)) = AddWithCarry{32}(R(n), NOT(shifted), '1');
    R(d) = result;
    if setflags then
        PSTATE.[N,Z,C,V] = nzcvc;
    end;
end;
```

C5.1.243 SUB, SUBS (SP minus immediate)

Subtract from SP (immediate) subtracts an immediate value from the SP value, and writes the result to the destination register.

If the destination register is not the PC, the SUBS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. If the destination register is the PC:

- The SUB variant of the instruction is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC](#).
- The SUBS variant of the instruction performs an exception return without the use of the stack. Arm deprecates use of this instruction. However, in this case:
 - The PE branches to the address written to the PC, and restores **PSTATE** from SPSR_<current_mode>.
 - The PE checks SPSR_<current_mode> for an illegal return event. See [Illegal return events from AArch32 state](#).
 - The instruction is UNDEFINED in Hyp mode.
 - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#), [T2](#), and [T3](#)).

A1

Encoding for the SUB variant

Applies when (S == 0)

SUB{<c>}{<q>} {<Rd>}, }SP, #<const>

Encoding for the SUBS variant

Applies when (S == 1)

SUBS{<c>}{<q>} {<Rd>}, }SP, #<const>

Decode for all variants of this encoding

```
let d : integer = UInt(Rd);
let setflags : boolean = (S == '1');
let imm32 : bits(32) = A32ExpandImm(imm12);
```

T1

Encoding

SUB{<c>}{<q>} {SP, }SP, #<imm7>

Decode for this encoding

```
let d : integer = 13;
let setflags : boolean = FALSE;
let imm32 : bits(32) = ZeroExtend{}(imm7::'00');
```

T2

Encoding for the SUB variant

Applies when (S == 0)

```
SUB{<c>}{<q>} {<Rd>, }SP, #<const>
```

```
SUB{<c>}.W {<Rd>, }SP, #<const> // (<Rd>, <const> can be represented in T1)
```

Encoding for the SUBS variant

Applies when (S == 1 && Rd != 1111)

```
SUBS{<c>}{<q>} {<Rd>, }SP, #<const>
```

Decode for all variants of this encoding

```
if Rd == '1111' && S == '1' then See("CMP (immediate)"); end;
let d : integer = UInt(Rd);
let setflags : boolean = (S == '1');
let imm32 : bits(32) = T32ExpandImm(i::imm3::imm8);
if d == 15 && !setflags then UnpredictableProcedure(); end;
```

T3

Encoding

```
SUB{<c>}{<q>} {<Rd>, }SP, #<imm12> // (<imm12> cannot be represented in T1, T2, or T3)
```

```
SUBW{<c>}{<q>} {<Rd>, }SP, #<imm12> // (<imm12> can be represented in T1, T2, or T3)
```

Decode for this encoding

```
let d : integer = UInt(Rd);
let setflags : boolean = FALSE;
let imm32 : bits(32) = ZeroExtend{}(i::imm3::imm8);
if d == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rd>

For the “A1 SUB” and “A1 SUBS” variants: is the general-purpose destination register, encoded in the “Rd” field. If omitted, this register is the SP. If the PC is used:

- For the SUB variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC](#).
- For the SUBS variant, the instruction performs an exception return, that restores [PSTATE](#) from `SPSR_<current_mode>`. Arm deprecates use of this instruction unless <Rn> is the LR.

For the “T2 SUB”, “T2 SUBS”, and “T3” variants: is the general-purpose destination register, encoded in the “Rd” field. If omitted, this register is the SP.

<const>

For the “A1 SUB” and “A1 SUBS” variants: an immediate value. See [Modified immediate constants in A32 instructions](#) for the range of values.

For the “T2 SUB” and “T2 SUBS” variants: an immediate value. See [Modified immediate constants in T32 instructions](#) for the range of values.

SP

Is the stack pointer.

<imm7>

Is the unsigned immediate, a multiple of 4, in the range 0 to 508, encoded in the “imm7” field as <imm7>/4.

<imm12>

Is a 12-bit unsigned immediate, in the range 0 to 4095, encoded in the “i:imm3:imm8” field.

Operation

```

if ConditionPassed() then
    EncodingSpecificOperations();
    let (result, nzcvc) : (bits(32), bits(4)) = AddWithCarry{32}(R(13), NOT(imm32), '1');
    if d == 15 then // Can only occur for A32 encoding
        if setflags then
            ALUExceptionReturn(result);
        else
            ALUWritePC(result);
        end;
    else
        R(d) = result;
        if setflags then
            PSTATE.[N,Z,C,V] = nzcvc;
        end;
    end;
end;
end;

```

C5.1.244 SUB, SUBS (SP minus register)

Subtract from SP (register) subtracts an optionally-shifted register value from the SP value, and writes the result to the destination register.

If the destination register is not the PC, the SUBS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. If the destination register is the PC:

- The SUB variant of the instruction is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC](#).
- The SUBS variant of the instruction performs an exception return without the use of the stack. Arm deprecates use of this instruction. However, in this case:
 - The PE branches to the address written to the PC, and restores **PSTATE** from SPSR_<current_mode>.
 - The PE checks SPSR_<current_mode> for an illegal return event. See [Illegal return events from AArch32 state](#).
 - The instruction is UNDEFINED in Hyp mode.
 - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding for the SUB, rotate right with extend variant

Applies when (S == 0 && imm5 == 00000 && stype == 11)

SUB{<c>}{<q>} {<Rd>, }SP, <Rm> , RRX

Encoding for the SUB, shift or rotate by value variant

Applies when (S == 0 && !(imm5 == 00000 && stype == 11))

SUB{<c>}{<q>} {<Rd>, }SP, <Rm> {, <shift> #<amount>}

Encoding for the SUBS, rotate right with extend variant

Applies when (S == 1 && imm5 == 00000 && stype == 11)

SUBS{<c>}{<q>} {<Rd>, }SP, <Rm> , RRX

Encoding for the SUBS, shift or rotate by value variant

Applies when (S == 1 && !(imm5 == 00000 && stype == 11))

SUBS{<c>}{<q>} {<Rd>, }SP, <Rm> {, <shift> #<amount>}

Decode for all variants of this encoding

```
let d : integer = UInt(Rd);
let m : integer = UInt(Rm);
let setflags : boolean = (S == '1');
let (shift_t, shift_n) : (SRTType, integer) = DecodeImmShift(stype, imm5);
```

T1

Encoding for the SUB, rotate right with extend variant

Applies when (S == 0 && imm3 == 000 && imm2 == 00 && stype == 11)

SUB{<c>}{<q>} {<Rd>, }SP, <Rm>, RRX

Encoding for the SUB, shift or rotate by value variant

Applies when (S == 0 && !(imm3 == 000 && imm2 == 00 && stype == 11))

SUB{<c>}{<q>} {<Rd>, }SP, <Rm> {, <shift> #<amount>} // (Preferred syntax)

SUB{<c>}.W {<Rd>, }SP, <Rm>

Encoding for the SUBS, rotate right with extend variant

Applies when (S == 1 && imm3 == 000 && Rd != 1111 && imm2 == 00 && stype == 11)

SUBS{<c>}{<q>} {<Rd>, }SP, <Rm>, RRX

Encoding for the SUBS, shift or rotate by value variant

Applies when (S == 1 && Rd != 1111 && !(imm3 == 000 && imm2 == 00 && stype == 11))

SUBS{<c>}{<q>} {<Rd>, }SP, <Rm> {, <shift> #<amount>}

Decode for all variants of this encoding

```
if Rd == '1111' && S == '1' then See("CMP (register)"); end;
let d : integer = UInt(Rd);
let m : integer = UInt(Rm);
let setflags : boolean = (S == '1');
let (shift_t, shift_n) : (SRTyp, integer) = DecodeImmShift(stype, imm3::imm2);
// Armv8-A removes UNPREDICTABLE for R13
if (d == 15 && !setflags) || m == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rd>

For the “A1 SUB, rotate right with extend”, “A1 SUB, shift or rotate by value”, “A1 SUBS, rotate right with extend”, and “A1 SUBS, shift or rotate by value” variants: is the general-purpose destination register, encoded in the “Rd” field. If omitted, this register is the SP. Arm deprecates using the PC as the destination register, but if the PC is used:

- For the SUB variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC](#).
- For the SUBS variant, the instruction performs an exception return, that restores [PSTATE](#) from `SPSR_<current_mode>`.

For the “T1 SUB, rotate right with extend”, “T1 SUB, shift or rotate by value”, “T1 SUBS, rotate right with extend”, and “T1 SUBS, shift or rotate by value” variants: is the general-purpose destination register, encoded in the “Rd” field. If omitted, this register is the SP.

<Rm>

For the “A1 SUB, rotate right with extend”, “A1 SUB, shift or rotate by value”, “A1 SUBS, rotate right with extend”, and “A1 SUBS, shift or rotate by value” variants: is the second general-purpose source register, encoded in the “Rm” field. The PC can be used, but this is deprecated.

For the “T1 SUB, rotate right with extend”, “T1 SUB, shift or rotate by value”, “T1 SUBS, rotate right with extend”, and “T1 SUBS, shift or rotate by value” variants: is the second general-purpose source register, encoded in the “Rm” field.

<shift>

Is the type of shift to be applied to the second source register, encoded in “stype”:

stype	<shift>
00	LSL
01	LSR
10	ASR
11	ROR

<amount>

For the “A1 SUB, shift or rotate by value” and “A1 SUBS, shift or rotate by value” variants: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the “imm5” field as <amount> modulo 32.

For the “T1 SUB, shift or rotate by value” and “T1 SUBS, shift or rotate by value” variants: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR), encoded in the “imm3:imm2” field as <amount> modulo 32.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let shifted : bits(32) = Shift{}(R(m), shift_t, shift_n, PSTATE.C);
    let (result, nzcvc) : (bits(32), bits(4)) = AddWithCarry{32}(R(13), NOT(shifted), '1');
    if d == 15 then // Can only occur for A32 encoding
        if setflags then
            ALUExceptionReturn(result);
        else
            ALUWritePC(result);
        end;
    else
        R(d) = result;
        if setflags then
            PSTATE.[N,Z,C,V] = nzcvc;
        end;
    end;
end;
```

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<imm>

For the “A1” variant: is a 24-bit unsigned immediate, in the range 0 to 16777215, encoded in the “imm24” field. This value is for assembly and disassembly only. SVC handlers in some systems interpret imm24 in software, for example to determine the required service.

For the “T1” variant: is a 8-bit unsigned immediate, in the range 0 to 255, encoded in the “imm8” field. This value is for assembly and disassembly only. SVC handlers in some systems interpret imm8 in software, for example to determine the required service.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    AArch32_CallSupervisor(imm32[15:0]);
end;
```

C5.1.246 SXTAB

Signed Extend and Add Byte extracts an 8-bit value from a register, sign-extends it to 32 bits, adds the result to the value in another register, and writes the final result to the destination register. The instruction can specify a rotation by 0, 8, 16, or 24 bits before extracting the 8-bit value.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

SXTAB{<c>}{<q>} {<Rd>, }<Rn>, <Rm> {, ROR #<amount>}

Decode for this encoding

```
if Rn == '1111' then See("SXTB"); end;
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let rotation : integer = UInt(rotate::'000');
if d == 15 || m == 15 then UnpredictableProcedure(); end;
```

T1

Encoding

SXTAB{<c>}{<q>} {<Rd>, }<Rn>, <Rm> {, ROR #<amount>}

Decode for this encoding

```
if Rn == '1111' then See("SXTB"); end;
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let rotation : integer = UInt(rotate::'000');
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 || m == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rd>

Is the general-purpose destination register, encoded in the “Rd” field.

<Rn>

Is the first general-purpose source register, encoded in the “Rn” field.

<Rm>

Is the second general-purpose source register, encoded in the “Rm” field.

<amount>

Is the rotate amount, encoded in “rotate”:

rotate	<amount>
00	[absent]
01	8
10	16
11	24

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let rotated : bits(32) = ROR(R(m), rotation);
    R(d) = R(n) + SignExtend{32}(rotated[7:0]);
end;
```

C5.1.247 SXTAB16

Signed Extend and Add Byte 16

Signed Extend and Add Byte 16 extracts two 8-bit values from a register, sign-extends them to 16 bits each, adds the results to two 16-bit values from another register, and writes the final results to the destination register. The instruction can specify a rotation by 0, 8, 16, or 24 bits before extracting the 8-bit values.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

SXTAB16{<c>}{<q>} {<Rd>, }<Rn>, <Rm> {, ROR #<amount>}

Decode for this encoding

```
if Rn == '1111' then See("SXTB16"); end;
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let rotation : integer = UInt(rotate::'000');
if d == 15 || m == 15 then UnpredictableProcedure(); end;
```

T1

Encoding

SXTAB16{<c>}{<q>} {<Rd>, }<Rn>, <Rm> {, ROR #<amount>}

Decode for this encoding

```
if Rn == '1111' then See("SXTB16"); end;
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let rotation : integer = UInt(rotate::'000');
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 || m == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<amount>

Is the rotate amount, encoded in “rotate”:

rotate	<amount>
00	[absent]
01	8
10	16
11	24

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let rotated : bits(32) = ROR(R(m), rotation);
    R(d)[15:0] = R(n)[15:0] + SignExtend{16}(rotated[7:0]);
    R(d)[31:16] = R(n)[31:16] + SignExtend{16}(rotated[23:16]);
end;
```

C5.1.248 SXTAH

Signed Extend and Add Halfword extracts a 16-bit value from a register, sign-extends it to 32 bits, adds the result to a value from another register, and writes the final result to the destination register. The instruction can specify a rotation by 0, 8, 16, or 24 bits before extracting the 16-bit value.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

SXTAH{<c>}{<q>} {<Rd>, }<Rn>, <Rm> {, ROR #<amount>}

Decode for this encoding

```
if Rn == '1111' then See("SXTH"); end;
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let rotation : integer = UInt(rotate::'000');
if d == 15 || m == 15 then UnpredictableProcedure(); end;
```

T1

Encoding

SXTAH{<c>}{<q>} {<Rd>, }<Rn>, <Rm> {, ROR #<amount>}

Decode for this encoding

```
if Rn == '1111' then See("SXTH"); end;
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let rotation : integer = UInt(rotate::'000');
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 || m == 15 then UnpredictableProcedure(); end;
```

    let rotated : bits(32) = ROR(R(m), rotation);
    R(d) = SignExtend{32}(rotated[15:0]);
end;
```

C5.1.252 **TBB, TBH**

Table Branch Byte or Halfword causes a PC-relative forward branch using a table of single byte or halfword offsets. A base register provides a pointer to the table, and a second register supplies an index into the table. The branch length is twice the value returned from the table.

Encoding for the Byte variant

Applies when $(H == 0)$

```
TBB{<c>}{<q>}    [<Rn>, <Rm>] // (Outside or last in IT block)
```

Encoding for the Halfword variant

Applies when $(H == 1)$

```
TBH{<c>}{<q>}    [<Rn>, <Rm>, LSL #1] // (Outside or last in IT block)
```

Decode for all variants of this encoding

```
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let is_tbh : boolean = (H == '1');
// Armv8-A removes UNPREDICTABLE for R13
if m == 15 then UnpredictableProcedure(); end;
if !IntBlock() && !LastIntBlock() then UnpredictableProcedure(); end;
```

For more information about the **CONSTRAINED UNPREDICTABLE** behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

 $\langle c \rangle$

See [Standard assembler syntax fields](#).

 $\langle q \rangle$

See [Standard assembler syntax fields](#).

 $\langle R_n \rangle$

Is the general-purpose base register holding the address of the table of branch lengths, encoded in the “Rn” field. The PC can be used. If it is, the table immediately follows this instruction.

<Rm>

For the “Byte” variant: is the general-purpose index register, encoded in the “Rm” field. This register contains an integer pointing to a single byte in the table. The offset in the table is the value of the index.

For the “Halfword” variant: is the general-purpose index register, encoded in the “Rm” field. This register contains an integer pointing to a halfword in the table. The offset in the table is twice the value of the index.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
var halfwords : integer;
if is_tbh then
    halfwords = UInt(MemU{16}(R(n)+LSL(R(m), 1)));
else
    halfwords = UInt(MemU{8}(R(n)+R(m)));
end;
BranchWritePC(PC32() + 2*halfwords, BranchType_INDIR);
end;
```

C5.1.253 TEQ (immediate)

Test Equivalence (immediate) performs a bitwise exclusive OR operation on a register value and an immediate value. It updates the condition flags based on the result, and discards the result.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

TEQ{<c>}{<q>} <Rn>, #<const>

Decode for this encoding

```
let n : integer = UInt(Rn);
let a32 : boolean = TRUE;
let imm : bits(12) = imm12;
```

T1

Encoding

TEQ{<c>}{<q>} <Rn>, #<const>

Decode for this encoding

```
let n : integer = UInt(Rn);
let a32 : boolean = FALSE;
let imm : bits(12) = i::imm3::imm8;
// Armv8-A removes UNPREDICTABLE for R13
if n == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rn>

For the “A1” variant: is the general-purpose source register, encoded in the “Rn” field. The PC can be used, but this is deprecated.

For the “T1” variant: is the general-purpose source register, encoded in the “Rn” field.

<const>

For the “A1” variant: an immediate value. See [Modified immediate constants in A32 instructions](#) for the range of values.

For the “T1” variant: an immediate value. See [Modified immediate constants in T32 instructions](#) for the range of values.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let (imm32, carry) : (bits(32), bit) = (if a32 then A32ExpandImm_C(imm, PSTATE.C)
                                            else T32ExpandImm_C(imm, PSTATE.C));

    let result : bits(32) = R(n) XOR imm32;
    PSTATE.N = result[31];
    PSTATE.Z = IsZeroBit{32}(result);
    PSTATE.C = carry;
    // PSTATE.V unchanged
end;
```

C5.1.254 TEQ (register)

Test Equivalence (register) performs a bitwise exclusive-OR operation on a register value and an optionally-shifted register value. It updates the condition flags based on the result, and discards the result.

It has encodings from the following instruction sets: A32 (**A1**) and T32 (**T1**).

A1

Encoding for the Rotate right with extend variant

Applies when (imm5 == 00000 && stype == 11)

TEQ{<c>}{<q>} <Rn>, <Rm>, RRX

Encoding for the Shift or rotate by value variant

Applies when (!(imm5 == 00000 && stype == 11))

TEQ{<c>}{<q>} <Rn>, <Rm> {, <shift> #<amount>}

Decode for all variants of this encoding

```
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let (shift_t, shift_n) : (SRTYPE, integer) = DecodeImmShift(stype, imm5);
```

T1

Encoding for the Rotate right with extend variant

Applies when (imm3 == 000 && imm2 == 00 && stype == 11)

TEQ{<c>}{<q>} <Rn>, <Rm>, RRX

Encoding for the Shift or rotate by value variant

Applies when (!(imm3 == 000 && imm2 == 00 && stype == 11))

TEQ{<c>}{<q>} <Rn>, <Rm> {, <shift> #<amount>}

Decode for all variants of this encoding

```
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let (shift_t, shift_n) : (SRTYPE, integer) = DecodeImmShift(stype, imm3::imm2);
// Armv8-A removes UNPREDICTABLE for R13
if n == 15 || m == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

See [Standard assembler syntax fields](#).

<Rn>

For the “A1 Rotate right with extend” and “A1 Shift or rotate by value” variants: is the first general-purpose source register, encoded in the “Rn” field. The PC can be used, but this is deprecated.

For the “T1 Rotate right with extend” and “T1 Shift or rotate by value” variants: is the first general-purpose source register, encoded in the “Rn” field.

<Rm>

For the “A1 Rotate right with extend” and “A1 Shift or rotate by value” variants: is the second general-purpose source register, encoded in the “Rm” field. The PC can be used, but this is deprecated.

For the “T1 Rotate right with extend” and “T1 Shift or rotate by value” variants: is the second general-purpose source register, encoded in the “Rm” field.

<shift>

Is the type of shift to be applied to the second source register, encoded in “stype”:

stype	<shift>
00	LSL
01	LSR
10	ASR
11	ROR

<amount>

For the “A1 Shift or rotate by value” variant: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the “imm5” field as <amount> modulo 32.

For the “T1 Shift or rotate by value” variant: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR), encoded in the “imm3:imm2” field as <amount> modulo 32.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let (shifted, carry) : (bits(32), bit) = Shift_C{32}(R(m), shift_t, shift_n, PSTATE.C);
    let result : bits(32) = R(n) XOR shifted;
    PSTATE.N = result[31];
    PSTATE.Z = IsZeroBit{32}(result);
    PSTATE.C = carry;
    // PSTATE.V unchanged
end;
```

C5.1.255 **TEQ (register-shifted register)**

Test Equivalence (register-shifted register) performs a bitwise exclusive-OR operation on a register value and a register-shifted register value. It updates the condition flags based on the result, and discards the result.

Encoding

TEQ{<c>}{<q>} <Rn>, <Rm>, <type> <Rs>

Decode for this encoding

```
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let s : integer = UInt(Rs);
let shift_t : SRTYPE = DecodeRegShift(stype);
if n == 15 || m == 15 || s == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rn>

Is the first general-purpose source register, encoded in the “Rn” field.

<Rm>

Is the second general-purpose source register, encoded in the “Rm” field.

<type>

Is the type of shift to be applied to the second source register, encoded in “stype”:

stype	<type>
00	LSL
01	LSR
10	ASR
11	ROR

<Rs>

Is the third general-purpose source register holding a shift amount in its bottom 8 bits, encoded in the “Rs” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let shift_n : integer = UInt(R(s)[7:0]);
    let (shifted, carry) : (bits(32), bit) = Shift_C{32}(R(m), shift_t, shift_n, PSTATE.C);
    let result : bits(32) = R(n) XOR shifted;
    PSTATE.N = result[31];
    PSTATE.Z = IsZeroBit{32}(result);
    PSTATE.C = carry;
    // PSTATE.V unchanged
end;
```

C5.1.256 TST (immediate)

Test (immediate) performs a bitwise AND operation on a register value and an immediate value. It updates the condition flags based on the result, and discards the result.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

TST{<c>}{<q>} <Rn>, #<const>

Decode for this encoding

```
let n : integer = UInt(Rn);
let a32 : boolean = TRUE;
let imm : bits(12) = imm12;
```

T1

Encoding

TST{<c>}{<q>} <Rn>, #<const>

Decode for this encoding

```
let n : integer = UInt(Rn);
let a32 : boolean = FALSE;
let imm : bits(12) = i::imm3::imm8;
// Armv8-A removes UNPREDICTABLE for R13
if n == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rn>

For the “A1” variant: is the general-purpose source register, encoded in the “Rn” field. The PC can be used, but this is deprecated.

For the “T1” variant: is the general-purpose source register, encoded in the “Rn” field.

<const>

For the “A1” variant: an immediate value. See [Modified immediate constants in A32 instructions](#) for the range of values.

For the “T1” variant: an immediate value. See [Modified immediate constants in T32 instructions](#) for the range of values.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let (imm32, carry) : (bits(32), bit) = (if a32 then A32ExpandImm_C(imm, PSTATE.C)
                                            else T32ExpandImm_C(imm, PSTATE.C));

    let result : bits(32) = R(n) AND imm32;
    PSTATE.N = result[31];
    PSTATE.Z = IsZeroBit{32}(result);
    PSTATE.C = carry;
    // PSTATE.V unchanged
end;
```

C5.1.257 TST (register)

Test (register) performs a bitwise AND operation on a register value and an optionally-shifted register value. It updates the condition flags based on the result, and discards the result.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#) and [T2](#)).

A1

Encoding for the Rotate right with extend variant

Applies when (imm5 == 00000 && stype == 11)

TST{<c>}{<q>} <Rn>, <Rm>, RRX

Encoding for the Shift or rotate by value variant

Applies when (!(imm5 == 00000 && stype == 11))

TST{<c>}{<q>} <Rn>, <Rm> {, <shift> #<amount>}

Decode for all variants of this encoding

```
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let (shift_t, shift_n) : (SRTYPE, integer) = DecodeImmShift(stype, imm5);
```

T1

Encoding

TST{<c>}{<q>} <Rn>, <Rm>

Decode for this encoding

```
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let shift_t : SRTYPE = SRTYPE_LSL;
let shift_n : integer = 0;
```

T2

Encoding for the Rotate right with extend variant

Applies when (imm3 == 000 && imm2 == 00 && stype == 11)

TST{<c>}{<q>}<Rn>, <Rm>, RRX

Encoding for the Shift or rotate by value variant

Applies when `(!(imm3 == 000 && imm2 == 00 && stype == 11))`

TST{<c>}{<q>} <Rn>, <Rm> {, <shift> #<amount>}

TST{<c>}.W <Rn>, <Rm> // (<Rn>, <Rm> can be represented in T1)

Decode for all variants of this encoding

```

let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let (shift_t, shift_n) : (SRTType, integer) = DecodeImmShift(stype, imm3::imm2);
// Armv8-A removes UNPREDICTABLE for R13
if n == 15 || m == 15 then UnpredictableProcedure(); end;

```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

 $\langle q \rangle$

See [Standard assembler syntax fields](#).

 $\langle R_n \rangle$

For the “A1 Rotate right with extend” and “A1 Shift or rotate by value” variants: is the first general-purpose source register, encoded in the “Rn” field. The PC can be used, but this is deprecated.

For the “T1”, “T2 Rotate right with extend”, and “T2 Shift or rotate by value” variants: is the first general-purpose source register, encoded in the “Rn” field.

<Rm>

For the “A1 Rotate right with extend” and “A1 Shift or rotate by value” variants: is the second general-purpose source register, encoded in the “Rm” field. The PC can be used, but this is deprecated.

For the “T1”, “T2 Rotate right with extend”, and “T2 Shift or rotate by value” variants: is the second general-purpose source register, encoded in the “Rm” field.

<shift>

Is the type of shift to be applied to the second source register, encoded in “stype”:

stype	<shift>
00	LSL
01	LSR
10	ASR
11	ROR

<amount>

For the “A1 Shift or rotate by value” variant: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the “imm5” field as <amount> modulo 32.

For the “T2 Shift or rotate by value” variant: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR), encoded in the “imm3:imm2” field as <amount> modulo 32.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let (shifted, carry) : (bits(32), bit) = Shift_C{32}(R(m), shift_t, shift_n, PSTATE.C);
    let result : bits(32) = R(n) AND shifted;
    PSTATE.N = result[31];
    PSTATE.Z = IsZeroBit{32}(result);
    PSTATE.C = carry;
    // PSTATE.V unchanged
end;
```

C5.1.258 TST (register-shifted register)

Test (register-shifted register) performs a bitwise AND operation on a register value and a register-shifted register value. It updates the condition flags based on the result, and discards the result.

Encoding

TST{<c>}{<q>} <Rn>, <Rm>, <type> <Rs>

Decode for this encoding

```
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let s : integer = UInt(Rs);
let shift_t : SType = DecodeRegShift(stype);
if n == 15 || m == 15 || s == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rn>

Is the first general-purpose source register, encoded in the “Rn” field.

<Rm>

Is the second general-purpose source register, encoded in the “Rm” field.

<type>

Is the type of shift to be applied to the second source register, encoded in “stype”:

stype	<type>
00	LSL
01	LSR
10	ASR
11	ROR

<Rs>

Is the third general-purpose source register holding a shift amount in its bottom 8 bits, encoded in the “Rs” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let shift_n : integer = UInt(R(s)[7:0]);
    let (shifted, carry) : (bits(32), bit) = Shift_C{32}(R(m), shift_t, shift_n, PSTATE.C);
    let result : bits(32) = R(n) AND shifted;
    PSTATE.N = result[31];
    PSTATE.Z = IsZeroBit{32}(result);
    PSTATE.C = carry;
    // PSTATE.V unchanged
end;
```

C5.1.259 UADD16

Unsigned Add 16 performs two 16-bit unsigned integer additions, and writes the results to the destination register. It sets [PSTATE.GE](#) according to the results of the additions.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

UADD16{<c>}{<q>} {<Rd>, }<Rn>, <Rm>

Decode for this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
```

T1

Encoding

UADD16{<c>}{<q>} {<Rd>, }<Rn>, <Rm>

Decode for this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rd>

Is the general-purpose destination register, encoded in the “Rd” field.

<Rn>

Is the first general-purpose source register, encoded in the “Rn” field.

<Rm>

Is the second general-purpose source register, encoded in the “Rm” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let sum1 : integer = UInt(R(n)[15:0]) + UInt(R(m)[15:0]);
    let sum2 : integer = UInt(R(n)[31:16]) + UInt(R(m)[31:16]);
    R(d)[15:0] = sum1[15:0];
    R(d)[31:16] = sum2[15:0];
    PSTATE.GE[1:0] = if sum1 >= 0x10000 then '11' else '00';
    PSTATE.GE[3:2] = if sum2 >= 0x10000 then '11' else '00';
end;
```

C5.1.260 UADD8

Unsigned Add 8 performs four unsigned 8-bit integer additions, and writes the results to the destination register. It sets [PSTATE.GE](#) according to the results of the additions.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

UADD8{<c>}{<q>} {<Rd>, }<Rn>, <Rm>

Decode for this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
```

T1

Encoding

UADD8{<c>}{<q>} {<Rd>, }<Rn>, <Rm>

Decode for this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rd>

Is the general-purpose destination register, encoded in the “Rd” field.

<Rn>

Is the first general-purpose source register, encoded in the “Rn” field.

<Rm>

Is the second general-purpose source register, encoded in the “Rm” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let sum1 : integer = UInt(R(n)[7:0]) + UInt(R(m)[7:0]);
    let sum2 : integer = UInt(R(n)[15:8]) + UInt(R(m)[15:8]);
    let sum3 : integer = UInt(R(n)[23:16]) + UInt(R(m)[23:16]);
    let sum4 : integer = UInt(R(n)[31:24]) + UInt(R(m)[31:24]);
    R(d)[7:0] = sum1[7:0];
    R(d)[15:8] = sum2[7:0];
    R(d)[23:16] = sum3[7:0];
    R(d)[31:24] = sum4[7:0];
    PSTATE.GE[0] = if sum1 >= 0x100 then '1' else '0';
    PSTATE.GE[1] = if sum2 >= 0x100 then '1' else '0';
    PSTATE.GE[2] = if sum3 >= 0x100 then '1' else '0';
    PSTATE.GE[3] = if sum4 >= 0x100 then '1' else '0';
end;
```

C5.1.261 UASX

Unsigned Add and Subtract with Exchange exchanges the two halfwords of the second operand, performs one unsigned 16-bit integer addition and one unsigned 16-bit subtraction, and writes the results to the destination register. It sets [PSTATE.GE](#) according to the results.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

UASX{<c>}{<q>} {<Rd>, }<Rn>, <Rm>

Decode for this encoding

```

let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;

```

T1

Encoding

UASX{<c>}{<q>} {<Rd>, }<Rn>, <Rm>

Decode for this encoding

```

let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;

```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rd>

Is the general-purpose destination register, encoded in the “Rd” field.

<Rn>

Is the first general-purpose source register, encoded in the “Rn” field.

<Rm>

Is the second general-purpose source register, encoded in the “Rm” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let diff : integer = UInt(R(n)[15:0]) - UInt(R(m)[31:16]);
    let sum : integer = UInt(R(n)[31:16]) + UInt(R(m)[15:0]);
    R(d)[15:0] = diff[15:0];
    R(d)[31:16] = sum[15:0];
    PSTATE.GE[1:0] = if diff >= 0 then '11' else '00';
    PSTATE.GE[3:2] = if sum >= 0x10000 then '11' else '00';
end;
```

C5.1.262 UBFX

Unsigned Bit Field Extract extracts any number of adjacent bits at any position from a register, zero-extends them to 32 bits, and writes the result to the destination register.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

UBFX{<c>}{<q>} <Rd>, <Rn>, #<lsb>, #<width>

Decode for this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let lsbit : integer{} = UInt(lsb);
let widthminus1 : integer{} = UInt(widthm1);
let msbit : integer{} = lsbit + widthminus1;
if d == 15 || n == 15 then UnpredictableProcedure(); end;
if msbit > 31 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `msbit > 31`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The value in the destination register is UNKNOWN.

T1

Encoding

UBFX{<c>}{<q>} <Rd>, <Rn>, #<lsb>, #<width>

Decode for this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let lsbit : integer{} = UInt(imm3::imm2);
let widthminus1 : integer{} = UInt(widthm1);
let msbit : integer{} = lsbit + widthminus1;
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 || n == 15 then UnpredictableProcedure(); end;
if msbit > 31 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `msbit > 31`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The value in the destination register is UNKNOWN.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rd>

Is the general-purpose destination register, encoded in the “Rd” field.

<Rn>

Is the general-purpose source register, encoded in the “Rn” field.

<lsb>

For the “A1” variant: is the bit number of the least significant bit in the field, in the range 0 to 31, encoded in the “lsb” field.

For the “T1” variant: is the bit number of the least significant bit in the field, in the range 0 to 31, encoded in the “imm3:imm2” field.

<width>

Is the width of the field, in the range 1 to 32-`<lsb>`, encoded in the “widthm1” field as `<width>-1`.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    R(d) = ZeroExtend{32}(R(n)[msbit:lsbit]);
end;
```

C5.1.263 UDF

Permanently Undefined generates an Undefined Instruction exception.

The encodings for UDF used in this section are defined as permanently UNDEFINED. However:

- With the T32 instruction set, Arm deprecates using the UDF instruction in an IT block.
- In the A32 instruction set, UDF is not conditional.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#) and [T2](#)).

A1

Encoding

UDF{<c>}{<q>}{#}<imm>

Decode for this encoding

```
let imm32 : bits(32) = ZeroExtend{}(imm12::imm4);
// imm32 is for assembly and disassembly only, and is ignored by hardware.
```

T1

Encoding

UDF{<c>}{<q>}{#}<imm>

Decode for this encoding

```
let imm32 : bits(32) = ZeroExtend{}(imm8);
// imm32 is for assembly and disassembly only, and is ignored by hardware.
```

T2

Encoding

```
UDF{<c>}{<q>} {#}<imm>
```

```
UDF{<c>}.W {#}<imm> // (<imm> can be represented in T1)
```

Decode for this encoding

```
let imm32 : bits(32) = ZeroExtend{}(imm4::imm12);  
// imm32 is for assembly and disassembly only, and is ignored by hardware.
```

Assembler Symbols

<c>

For the “A1” variant: see [Standard assembler syntax fields](#). <c> must be AL or omitted.

For the “T1” and “T2” variants: see [Standard assembler syntax fields](#). Arm deprecates using any <c> value other than AL.

<q>

See [Standard assembler syntax fields](#).

<imm>

For the “A1” variant: is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the “imm12:imm4” field. The PE ignores the value of this constant.

For the “T1” variant: is a 8-bit unsigned immediate, in the range 0 to 255, encoded in the “imm8” field. The PE ignores the value of this constant.

For the “T2” variant: is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the “imm4:imm12” field. The PE ignores the value of this constant.

Operation

```
if ConditionPassed() then  
    EncodingSpecificOperations();  
    Undefined();  
end;
```

C5.1.264 UDIV

Unsigned Divide divides a 32-bit unsigned integer register value by a 32-bit unsigned integer register value, and writes the result to the destination register. The condition flags are not affected.

See [Divide instructions](#) for more information about this instruction.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

UDIV{<c>}{<q>} {<Rd>, }<Rn>, <Rm>

Decode for this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
```

T1

Encoding

UDIV{<c>}{<q>} {<Rd>, }<Rn>, <Rm>

Decode for this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rd>

Is the general-purpose destination register, encoded in the “Rd” field.

<Rn>

Is the first general-purpose source register holding the dividend, encoded in the “Rn” field.

<Rm>

Is the second general-purpose source register holding the divisor, encoded in the “Rm” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let dividend : integer = UInt(R(n));
    let divisor : integer = UInt(R(m));
    var result : integer;
    if divisor == 0 then
        result = 0;
    else
        result = dividend DIVRM divisor;
    end;
    R(d) = result[31:0];
end;
```

C5.1.265 UHADD16

Unsigned Halving Add 16 performs two unsigned 16-bit integer additions, halves the results, and writes the results to the destination register.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

UHADD16{<c>}{<q>} {<Rd>, }<Rn>, <Rm>

Decode for this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
```

T1

Encoding

UHADD16{<c>}{<q>} {<Rd>, }<Rn>, <Rm>

Decode for this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rd>

Is the general-purpose destination register, encoded in the “Rd” field.

<Rn>

Is the first general-purpose source register, encoded in the “Rn” field.

<Rm>

Is the second general-purpose source register, encoded in the “Rm” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let sum1 : integer = UInt(R(n)[15:0]) + UInt(R(m)[15:0]);
    let sum2 : integer = UInt(R(n)[31:16]) + UInt(R(m)[31:16]);
    R(d)[15:0] = sum1[16:1];
    R(d)[31:16] = sum2[16:1];
end;
```

C5.1.266 UHADD8

Unsigned Halving Add 8 performs four unsigned 8-bit integer additions, halves the results, and writes the results to the destination register.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

UHADD8{<c>}{<q>} {<Rd>, }<Rn>, <Rm>

Decode for this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
```

T1

Encoding

UHADD8{<c>}{<q>} {<Rd>, }<Rn>, <Rm>

Decode for this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rd>

Is the general-purpose destination register, encoded in the “Rd” field.

<Rn>

Is the first general-purpose source register, encoded in the “Rn” field.

<Rm>

Is the second general-purpose source register, encoded in the “Rm” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let sum1 : integer = UInt(R(n)[7:0]) + UInt(R(m)[7:0]);
    let sum2 : integer = UInt(R(n)[15:8]) + UInt(R(m)[15:8]);
    let sum3 : integer = UInt(R(n)[23:16]) + UInt(R(m)[23:16]);
    let sum4 : integer = UInt(R(n)[31:24]) + UInt(R(m)[31:24]);
    R(d)[7:0]    = sum1[8:1];
    R(d)[15:8]   = sum2[8:1];
    R(d)[23:16]  = sum3[8:1];
    R(d)[31:24]  = sum4[8:1];
end;
```

C5.1.267 UHASX

Unsigned Halving Add and Subtract with Exchange exchanges the two halfwords of the second operand, performs one unsigned 16-bit integer addition and one unsigned 16-bit subtraction, halves the results, and writes the results to the destination register.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

UHASX{<c>}{<q>} {<Rd>, }<Rn>, <Rm>

Decode for this encoding

```

let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;

```

T1

Encoding

UHASX{<c>}{<q>} {<Rd>, }<Rn>, <Rm>

Decode for this encoding

```

let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;

```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

<q>

See [Standard assembler syntax fields](#).

<Rd>

Is the general-purpose destination register, encoded in the “Rd” field.

<Rn>

Is the first general-purpose source register, encoded in the “Rn” field.

<Rm>

Is the second general-purpose source register, encoded in the “Rm” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let diff : integer = UInt(R(n)[15:0]) - UInt(R(m)[31:16]);
    let sum : integer = UInt(R(n)[31:16]) + UInt(R(m)[15:0]);
    R(d)[15:0] = diff[16:1];
    R(d)[31:16] = sum[16:1];
end;
```

C5.1.268 UHSAX

Unsigned Halving Subtract and Add with Exchange exchanges the two halfwords of the second operand, performs one unsigned 16-bit integer subtraction and one unsigned 16-bit addition, halves the results, and writes the results to the destination register.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

UHSAX{<c>}{<q>} {<Rd>, }<Rn>, <Rm>

Decode for this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
```

T1

Encoding

UHSAX{<c>}{<q>} {<Rd>, }<Rn>, <Rm>

Decode for this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
```

Is the second general-purpose source register, encoded in the “Rm” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let sum : integer = UInt(R(n)[15:0]) + UInt(R(m)[31:16]);
    let diff : integer = UInt(R(n)[31:16]) - UInt(R(m)[15:0]);
    R(d)[15:0] = sum[16:1];
    R(d)[31:16] = diff[16:1];
end;
```

C5.1.269 UHSUB16

Unsigned Halving Subtract 16 performs two unsigned 16-bit integer subtractions, halves the results, and writes the results to the destination register.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

UHSUB16{<c>}{<q>} {<Rd>, }<Rn>, <Rm>

Decode for this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
```

T1

Encoding

UHSUB16{<c>}{<q>} {<Rd>, }<Rn>, <Rm>

Decode for this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
```

Is the second general-purpose source register, encoded in the “Rm” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let diff1 : integer = UInt(R(n)[15:0]) - UInt(R(m)[15:0]);
    let diff2 : integer = UInt(R(n)[31:16]) - UInt(R(m)[31:16]);
    R(d)[15:0] = diff1[16:1];
    R(d)[31:16] = diff2[16:1];
end;
```

C5.1.270 UHSUB8

Unsigned Halving Subtract 8 performs four unsigned 8-bit integer subtractions, halves the results, and writes the results to the destination register.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

UHSUB8{<c>}{<q>} {<Rd>, }<Rn>, <Rm>

Decode for this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
```

T1

Encoding

UHSUB8{<c>}{<q>} {<Rd>, }<Rn>, <Rm>

Decode for this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

<Rm>

Is the second general-purpose source register, encoded in the “Rm” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let diff1 : integer = UInt(R(n)[7:0]) - UInt(R(m)[7:0]);
    let diff2 : integer = UInt(R(n)[15:8]) - UInt(R(m)[15:8]);
    let diff3 : integer = UInt(R(n)[23:16]) - UInt(R(m)[23:16]);
    let diff4 : integer = UInt(R(n)[31:24]) - UInt(R(m)[31:24]);
    R(d)[7:0]    = diff1[8:1];
    R(d)[15:8]   = diff2[8:1];
    R(d)[23:16]  = diff3[8:1];
    R(d)[31:24]  = diff4[8:1];
end;
```

C5.1.271 UMAAL

Unsigned Multiply Accumulate Accumulate Long multiplies two unsigned 32-bit values to produce a 64-bit value, adds two unsigned 32-bit values, and writes the 64-bit result to two registers.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

UMAAL{<c>}{<q>} <RdLo>, <RdHi>, <Rn>, <Rm>

Decode for this encoding

```
let dLo : integer = UInt(RdLo);
let dHi : integer = UInt(RdHi);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
if dLo == 15 || dHi == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
if dHi == dLo then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If $dHi == dLo$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The value in the destination register is UNKNOWN.

T1

Encoding

UMAAL{<c>}{<q>} <RdLo>, <RdHi>, <Rn>, <Rm>

Decode for this encoding

```
let dLo : integer = UInt(RdLo);
let dHi : integer = UInt(RdHi);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
if dLo == 15 || dHi == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
// Armv8-A removes UNPREDICTABLE for R13
if dHi == dLo then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If $dHi == dLo$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The value in the destination register is UNKNOWN.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<RdLo>

Is the general-purpose source register holding the first addend and the destination register for the lower 32 bits of the result, encoded in the “RdLo” field.

<RdHi>

Is the general-purpose source register holding the second addend and the destination register for the upper 32 bits of the result, encoded in the “RdHi” field.

<Rn>

Is the first general-purpose source register holding the multiplicand, encoded in the “Rn” field.

<Rm>

Is the second general-purpose source register holding the multiplier, encoded in the “Rm” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
let result : integer = UInt(R(n)) * UInt(R(m)) + UInt(R(dHi)) + UInt(R(dLo));
R(dHi) = result[63:32];
R(dLo) = result[31:0];
end;
```

C5.1.272 UMLAL, UMLALS

Unsigned Multiply Accumulate Long multiplies two unsigned 32-bit values to produce a 64-bit value, and accumulates this with a 64-bit value.

In A32 instructions, the condition flags can optionally be updated based on the result. Use of this option adversely affects performance on many implementations.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding for the Flag setting variant

Applies when (S == 1)

UMLALS{<c>}{<q>} <RdLo>, <RdHi>, <Rn>, <Rm>

Encoding for the Not flag setting variant

Applies when $(S == 0)$

UMLAL{<c>}{<q>}<RdLo>, <RdHi>, <Rn>, <Rm>

Decode for all variants of this encoding

```

let dLo : integer = UInt(RdLo);
let dHi : integer = UInt(RdHi);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);

let setflags : boolean = (S == '1');
if dLo == 15 || dHi == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
if dHi == dLo then UnpredictableProcedure(); end;

```

CONSTRAINED UNPREDICTABLE behavior

If $d_{Hi} == d_{Lo}$, then one of the following behaviors must occur:

- The instruction is **UNDEFINED**.
- The instruction executes as **NOP**.
- The value in the destination register is **UNKNOWN**.

T1

Encoding

UMLAL{<c>}{<q>}<RdLo>,<RdHi>,<Rn>,<Rm>

Decode for this encoding

```
let dLo : integer = UInt(RdLo);
let dHi : integer = UInt(RdHi);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let setflags : boolean = FALSE;
if dLo == 15 || dHi == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
// Armv8-A removes UNPREDICTABLE for R13
if dHi == dLo then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `dHi == dLo`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The value in the destination register is UNKNOWN.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<RdLo>

Is the general-purpose source register holding the lower 32 bits of the addend, and the destination register for the lower 32 bits of the result, encoded in the “RdLo” field.

<RdHi>

Is the general-purpose source register holding the upper 32 bits of the addend, and the destination register for the upper 32 bits of the result, encoded in the “RdHi” field.

<Rn>

Is the first general-purpose source register holding the multiplicand, encoded in the “Rn” field.

<Rm>

Is the second general-purpose source register holding the multiplier, encoded in the “Rm” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let result : integer = UInt(R(n)) * UInt(R(m)) + UInt(R(dHi)::R(dLo));
    R(dHi) = result[63:32];
    R(dLo) = result[31:0];
    if setflags then
        PSTATE.N = result[63];
        PSTATE.Z = IsZeroBit{64}(result[63:0]);
        // PSTATE.C, PSTATE.V unchanged
    end;
end;
```

C5.1.273 UMULL, UMULLS

Unsigned Multiply Long multiplies two 32-bit unsigned values to produce a 64-bit result.

In A32 instructions, the condition flags can optionally be updated based on the result. Use of this option adversely affects performance on many implementations.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding for the Flag setting variant

Applies when (S == 1)

UMULLS{<c>}{<q>} <RdLo>, <RdHi>, <Rn>, <Rm>

Encoding for the Not flag setting variant

Applies when $(S == 0)$

UMULL{<c>}{<q>} <RdLo>, <RdHi>, <Rn>, <Rm>

Decode for all variants of this encoding

```

let dLo : integer = UInt(RdLo);
let dHi : integer = UInt(RdHi);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let setflags : boolean = (S == '1');
if dLo == 15 || dHi == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
if dHi == dLo then UnpredictableProcedure(); end;

```

CONSTRAINED UNPREDICTABLE behavior

If $d_{Hi} == d_{Lo}$, then one of the following behaviors must occur:

- The instruction is **UNDEFINED**.
- The instruction executes as **NOP**.
- The value in the destination register is **UNKNOWN**.

T1

Encoding

UMULL{<c>}{<q>} <RdLo>, <RdHi>, <Rn>, <Rm>

Decode for this encoding

```
let dLo : integer = UInt(RdLo);
let dHi : integer = UInt(RdHi);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let setflags : boolean = FALSE;
if dLo == 15 || dHi == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
// Armv8-A removes UNPREDICTABLE for R13
if dHi == dLo then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `dHi == dLo`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The value in the destination register is UNKNOWN.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<RdLo>

Is the general-purpose destination register for the lower 32 bits of the result, encoded in the “RdLo” field.

<RdHi>

Is the general-purpose destination register for the upper 32 bits of the result, encoded in the “RdHi” field.

<Rn>

Is the first general-purpose source register holding the multiplicand, encoded in the “Rn” field.

<Rm>

Is the second general-purpose source register holding the multiplier, encoded in the “Rm” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let result : integer = UInt(R(n)) * UInt(R(m));
    R(dHi) = result[63:32];
    R(dLo) = result[31:0];
    if setflags then
        PSTATE.N = result[63];
        PSTATE.Z = IsZeroBit{64}(result[63:0]);
        // PSTATE.C, PSTATE.V unchanged
    end;
end;
```

C5.1.274 UQADD16

Unsigned Saturating Add 16 performs two unsigned 16-bit integer additions, saturates the results to the 16-bit unsigned integer range $0 \leq x \leq 2^{16} - 1$, and writes the results to the destination register.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

UQADD16{<c>}{<q>} {<Rd>, }<Rn>, <Rm>

Decode for this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
```

T1

Encoding

UQADD16{<c>}{<q>} {<Rd>, }<Rn>, <Rm>

Decode for this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
```

<Rd>

Is the general-purpose destination register, encoded in the “Rd” field.

<Rn>

Is the first general-purpose source register, encoded in the “Rn” field.

<Rm>

Is the second general-purpose source register, encoded in the “Rm” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let sum1 : integer = UInt(R(n)[15:0]) + UInt(R(m)[15:0]);
    let sum2 : integer = UInt(R(n)[31:16]) + UInt(R(m)[31:16]);
    R(d)[15:0] = UnsignedSat{16}(sum1);
    R(d)[31:16] = UnsignedSat{16}(sum2);
end;
```

C5.1.275 UQADD8

Unsigned Saturating Add 8 performs four unsigned 8-bit integer additions, saturates the results to the 8-bit unsigned integer range $0 \leq x \leq 2^8 - 1$, and writes the results to the destination register.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

UQADD8{<c>}{<q>} {<Rd>, }<Rn>, <Rm>

Decode for this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
```

T1

Encoding

UQADD8{<c>}{<q>} {<Rd>, }<Rn>, <Rm>

Decode for this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

Is the second general-purpose source register, encoded in the “Rm” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let sum1 : integer = UInt(R(n)[7:0]) + UInt(R(m)[7:0]);
    let sum2 : integer = UInt(R(n)[15:8]) + UInt(R(m)[15:8]);
    let sum3 : integer = UInt(R(n)[23:16]) + UInt(R(m)[23:16]);
    let sum4 : integer = UInt(R(n)[31:24]) + UInt(R(m)[31:24]);
    R(d)[7:0] = UnsignedSat{8}(sum1);
    R(d)[15:8] = UnsignedSat{8}(sum2);
    R(d)[23:16] = UnsignedSat{8}(sum3);
    R(d)[31:24] = UnsignedSat{8}(sum4);
end;
```

C5.1.276 UQASX

Unsigned Saturating Add and Subtract with Exchange exchanges the two halfwords of the second operand, performs one unsigned 16-bit integer addition and one unsigned 16-bit subtraction, saturates the results to the 16-bit unsigned integer range $0 \leq x \leq 2^{16} - 1$, and writes the results to the destination register.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

UQASX{<c>}{<q>} {<Rd>, }<Rn>, <Rm>

Decode for this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
```

T1

Encoding

UQASX{<c>}{<q>} {<Rd>, }<Rn>, <Rm>

Decode for this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
```

<Rd>

Is the general-purpose destination register, encoded in the “Rd” field.

<Rn>

Is the first general-purpose source register, encoded in the “Rn” field.

<Rm>

Is the second general-purpose source register, encoded in the “Rm” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let diff : integer = UInt(R(n)[15:0]) - UInt(R(m)[31:16]);
    let sum : integer = UInt(R(n)[31:16]) + UInt(R(m)[15:0]);
    R(d)[15:0] = UnsignedSat{16}(diff);
    R(d)[31:16] = UnsignedSat{16}(sum);
end;
```

C5.1.277 UQSAX

Unsigned Saturating Subtract and Add with Exchange exchanges the two halfwords of the second operand, performs one unsigned 16-bit integer subtraction and one unsigned 16-bit addition, saturates the results to the 16-bit unsigned integer range $0 \leq x \leq 2^{16} - 1$, and writes the results to the destination register.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

UQSAX{<c>}{<q>} {<Rd>, }<Rn>, <Rm>

Decode for this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
```

T1

Encoding

UQSAX{<c>}{<q>} {<Rd>, }<Rn>, <Rm>

Decode for this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Is the first general-purpose source register, encoded in the “Rn” field.

<Rm>

Is the second general-purpose source register, encoded in the “Rm” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let sum : integer = UInt(R(n)[15:0]) + UInt(R(m)[31:16]);
    let diff : integer = UInt(R(n)[31:16]) - UInt(R(m)[15:0]);
    R(d)[15:0] = UnsignedSat{16}(sum);
    R(d)[31:16] = UnsignedSat{16}(diff);
end;
```

C5.1.278 UQSUB16

Unsigned Saturating Subtract 16 performs two unsigned 16-bit integer subtractions, saturates the results to the 16-bit unsigned integer range $0 \leq x \leq 2^{16} - 1$, and writes the results to the destination register.

It has encodings from the following instruction sets: A32 (**A1**) and T32 (**T1**).

A1

Encoding

UQSUB16{<c>}{<q>} {<Rd>, }<Rn>, <Rm>

Decode for this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
```

T1

Encoding

UQSUB16{<c>}{<q>} {<Rd>, }<Rn>, <Rm>

Decode for this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
```

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let absdiff1 : integer = Abs(UInt(R(n)[7:0]) - UInt(R(m)[7:0]));
    let absdiff2 : integer = Abs(UInt(R(n)[15:8]) - UInt(R(m)[15:8]));
    let absdiff3 : integer = Abs(UInt(R(n)[23:16]) - UInt(R(m)[23:16]));
    let absdiff4 : integer = Abs(UInt(R(n)[31:24]) - UInt(R(m)[31:24]));
    let result : integer = absdiff1 + absdiff2 + absdiff3 + absdiff4;
    R(d) = result[31:0];
end;
```

C5.1.281 USADA8

Unsigned Sum of Absolute Differences and Accumulate

Unsigned Sum of Absolute Differences and Accumulate performs four unsigned 8-bit subtractions, and adds the absolute values of the differences to a 32-bit accumulate operand.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

USDA8{<c>}{<q>}<Rd>,<Rn>,<Rm>,<Ra>

Decode for this encoding

```

if Ra == '1111' then See("USAD8"); end;
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let a : integer = UInt(Ra);
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;

```

T1

Encoding

USDA8 { <c> } { <q> } <Rd> , <Rn> , <Rm> , <Ra>

Decode for this encoding

```

if Ra == '1111' then See("USAD8"); end;
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let a : integer = UInt(Ra);
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;

```

<Rd>

Is the general-purpose destination register, encoded in the “Rd” field.

<Rn>

Is the first general-purpose source register, encoded in the “Rn” field.

<Rm>

Is the second general-purpose source register, encoded in the “Rm” field.

<Ra>

Is the third general-purpose source register holding the addend, encoded in the “Ra” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let absdiff1 : integer = Abs(UInt(R(n)[7:0]) - UInt(R(m)[7:0]));
    let absdiff2 : integer = Abs(UInt(R(n)[15:8]) - UInt(R(m)[15:8]));
    let absdiff3 : integer = Abs(UInt(R(n)[23:16]) - UInt(R(m)[23:16]));
    let absdiff4 : integer = Abs(UInt(R(n)[31:24]) - UInt(R(m)[31:24]));
    let result : integer = UInt(R(a)) + absdiff1 + absdiff2 + absdiff3 + absdiff4;
    R(d) = result[31:0];
end;
```

C5.1.282 USAT

Unsigned Saturate saturates an optionally-shifted signed value to a selected unsigned range.

This instruction sets [PSTATE.Q](#) to 1 if the operation saturates.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding for the Arithmetic shift right variant

Applies when (sh == 1)

USAT{<c>}{<q>} <Rd>, #<imm>, <Rn>, ASR #<amount>

Encoding for the Logical shift left variant

Applies when (sh == 0)

USAT{<c>}{<q>} <Rd>, #<imm>, <Rn> {, LSL #<amount>}

Decode for all variants of this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let saturate_to : integer{} = UInt(sat_imm);
let (shift_t, shift_n) : (SRTType, integer) = DecodeImmShift(sh::'0', imm5);
if d == 15 || n == 15 then UnpredictableProcedure(); end;
```

T1

Encoding for the Arithmetic shift right variant

Applies when (sh == 1 && !(imm3 == 000 && imm2 == 00))

USAT{<c>}{<q>} <Rd>, #<imm>, <Rn>, ASR #<amount>

Encoding for the Logical shift left variant

Applies when (sh == 0)

USAT{<c>}{<q>} <Rd>, #<imm>, <Rn> {, LSL #<amount>}

Decode for all variants of this encoding

```

if sh == '1' && (imm3::imm2) == '00000' then See("USAT16"); end;
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let saturate_to : integer{} = UInt(sat_imm);
let (shift_t, shift_n) : (SRTType, integer) = DecodeImmShift(sh::'0', imm3::imm2);
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 || n == 15 then UnpredictableProcedure(); end;

```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rd>

Is the general-purpose destination register, encoded in the “Rd” field.

<imm>

Is the bit position for saturation, in the range 0 to 31, encoded in the “sat_imm” field.

<Rn>

Is the general-purpose source register, encoded in the “Rn” field.

<amount>

For the “A1 Arithmetic shift right” variant: is the shift amount, in the range 1 to 32 encoded in the “imm5” field as <amount> modulo 32.

For the “A1 Logical shift left” variant: is the optional shift amount, in the range 0 to 31, defaulting to 0 and encoded in the “imm5” field.

For the “T1 Arithmetic shift right” variant: is the shift amount, in the range 1 to 31 encoded in the “imm3:imm2” field as <amount>.

For the “T1 Logical shift left” variant: is the optional shift amount, in the range 0 to 31, defaulting to 0 and encoded in the “imm3:imm2” field.

Operation

```

if ConditionPassed() then
    EncodingSpecificOperations();
    let operand : bits(32) = Shift{}(R(n), shift_t, shift_n, PSTATE.C); // PSTATE.C ignored
    let (result, sat) : (bits(saturate_to), boolean) = UnsignedSatQ{saturate_to}(SInt(operand));
    R(d) = ZeroExtend{32}(result);
    if sat then
        PSTATE.Q = '1';
    end;
end;

```

C5.1.283 USAT16

Unsigned Saturate 16 saturates two signed 16-bit values to a selected unsigned range.

This instruction sets **PSTATE.Q** to 1 if the operation saturates.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

USAT16{<c>}{<q>} <Rd>, #<imm>, <Rn>

Decode for this encoding

```

let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let saturate_to : integer{} = UInt(sat_imm);
if d == 15 || n == 15 then UnpredictableProcedure(); end;

```

T1

Encoding

USAT16{<c>}{<q>} <Rd>, #<imm>, <Rn>

Decode for this encoding

```

let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let saturate_to : integer{} = UInt(sat_imm);
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 || n == 15 then UnpredictableProcedure(); end;

```

For more information about the **CONSTRAINED UNPREDICTABLE** behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rd>

Is the general-purpose destination register, encoded in the “Rd” field.

<imm>

Is the bit position for saturation, in the range 0 to 15, encoded in the “sat_imm” field.

<Rn>

Is the general-purpose source register, encoded in the “Rn” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let operand1 = SInt(R(n)[15:0]);
    let operand2 = SInt(R(n)[31:16]);
    let (result1, sat1) : (bits(saturate_to), boolean) = UnsignedSatQ(saturate_to)(operand1);
    let (result2, sat2) : (bits(saturate_to), boolean) = UnsignedSatQ(saturate_to)(operand2);
    R(d)[15:0] = ZeroExtend{16}(result1);
    R(d)[31:16] = ZeroExtend{16}(result2);
    if sat1 || sat2 then
        PSTATE.Q = '1';
    end;
end;
```

C5.1.284 USAX

Unsigned Subtract and Add with Exchange exchanges the two halfwords of the second operand, performs one unsigned 16-bit integer subtraction and one unsigned 16-bit addition, and writes the results to the destination register. It sets [PSTATE.GE](#) according to the results.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

USAX{<c>}{<q>} {<Rd>, }<Rn>, <Rm>

Decode for this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
```

T1

Encoding

USAX{<c>}{<q>} {<Rd>, }<Rn>, <Rm>

Decode for this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<Rn>

Is the first general-purpose source register, encoded in the “Rn” field.

<Rm>

Is the second general-purpose source register, encoded in the “Rm” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let sum : integer = UInt(R(n)[15:0]) + UInt(R(m)[31:16]);
    let diff : integer = UInt(R(n)[31:16]) - UInt(R(m)[15:0]);
    R(d)[15:0] = sum[15:0];
    R(d)[31:16] = diff[15:0];
    PSTATE.GE[1:0] = if sum >= 0x10000 then '11' else '00';
    PSTATE.GE[3:2] = if diff >= 0 then '11' else '00';
end;
```

C5.1.285 USUB16

Unsigned Subtract 16 performs two 16-bit unsigned integer subtractions, and writes the results to the destination register. It sets [PSTATE.GE](#) according to the results of the subtractions.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

USUB16{<c>}{<q>} {<Rd>, }<Rn>, <Rm>

Decode for this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
```

T1

Encoding

USUB16{<c>}{<q>} {<Rd>, }<Rn>, <Rm>

Decode for this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
```

    let diff4 : integer = UInt(R(n)[31:24]) - UInt(R(m)[31:24]);
    R(d)[7:0] = diff1[7:0];
    R(d)[15:8] = diff2[7:0];
    R(d)[23:16] = diff3[7:0];
    R(d)[31:24] = diff4[7:0];
    PSTATE.GE[0] = if diff1 >= 0 then '1' else '0';
    PSTATE.GE[1] = if diff2 >= 0 then '1' else '0';
    PSTATE.GE[2] = if diff3 >= 0 then '1' else '0';
    PSTATE.GE[3] = if diff4 >= 0 then '1' else '0';
end;
```

C5.1.287 UXTAB

Unsigned Extend and Add Byte

Unsigned Extend and Add Byte extracts an 8-bit value from a register, zero-extends it to 32 bits, adds the result to the value in another register, and writes the final result to the destination register. The instruction can specify a rotation by 0, 8, 16, or 24 bits before extracting the 8-bit value.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

UXTAB{<c>}{<q>} {<Rd>, }<Rn>, <Rm> {, ROR #<amount>}

Decode for this encoding

```
if Rn == '1111' then See("UXTB"); end;
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let rotation : integer = UInt(rotate::'000');
if d == 15 || m == 15 then UnpredictableProcedure(); end;
```

T1

Encoding

UXTAB{<c>}{<q>} {<Rd>, }<Rn>, <Rm> {, ROR #<amount>}

Decode for this encoding

```
if Rn == '1111' then See("UXTB"); end;
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let rotation : integer = UInt(rotate::'000');
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 || m == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

Is the general-purpose destination register, encoded in the “Rd” field.

<Rn>

Is the first general-purpose source register, encoded in the “Rn” field.

<Rm>

Is the second general-purpose source register, encoded in the “Rm” field.

<amount>

Is the rotate amount, encoded in “rotate”:

rotate	<amount>
00	[absent]
01	8
10	16
11	24

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let rotated : bits(32) = ROR(R(m), rotation);
    R(d) = R(n) + ZeroExtend{32}(rotated[7:0]);
end;
```

C5.1.288 UXTAB16

Unsigned Extend and Add Byte 16

Unsigned Extend and Add Byte 16 extracts two 8-bit values from a register, zero-extends them to 16 bits each, adds the results to two 16-bit values from another register, and writes the final results to the destination register. The instruction can specify a rotation by 0, 8, 16, or 24 bits before extracting the 8-bit values.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

```
UXTAB16{<c>}{<q>} {<Rd>, }<Rn>, <Rm> {, ROR #<amount>}
```

Decode for this encoding

```
if Rn == '1111' then See("UXTB16"); end;
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let rotation : integer = UInt(rotate::'000');
if d == 15 || m == 15 then UnpredictableProcedure(); end;
```

T1

Encoding

```
UXTAB16{<c>}{<q>} {<Rd>, }<Rn>, <Rm> {, ROR #<amount>}
```

Decode for this encoding

```
if Rn == '1111' then See("UXTB16"); end;
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let rotation : integer = UInt(rotate::'000');
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 || m == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rd>

Is the general-purpose destination register, encoded in the “Rd” field.

<Rn>

Is the second general-purpose source register, encoded in the “Rm” field.

<amount>

Is the rotate amount, encoded in “rotate”:

rotate	<amount>
00	[absent]
01	8
10	16
11	24

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let rotated : bits(32) = ROR(R(m), rotation);
    R(d)[15:0] = R(n)[15:0] + ZeroExtend{16}(rotated[7:0]);
    R(d)[31:16] = R(n)[31:16] + ZeroExtend{16}(rotated[23:16]);
end;
```

C5.1.289 UXTAH

Unsigned Extend and Add Halfword

Unsigned Extend and Add Halfword extracts a 16-bit value from a register, zero-extends it to 32 bits, adds the result to a value from another register, and writes the final result to the destination register. The instruction can specify a rotation by 0, 8, 16, or 24 bits before extracting the 16-bit value.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

UXTAH{<c>}{<q>} {<Rd>, }<Rn>, <Rm> {, ROR #<amount>}

Decode for this encoding

```
if Rn == '1111' then See("UXTH"); end;
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let rotation : integer = UInt(rotate::'000');
if d == 15 || m == 15 then UnpredictableProcedure(); end;
```

T1

Encoding

UXTAH{<c>}{<q>} {<Rd>, }<Rn>, <Rm> {, ROR #<amount>}

Decode for this encoding

```
if Rn == '1111' then See("UXTH"); end;
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let rotation : integer = UInt(rotate::'000');
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 || m == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

rotate	<amount>
00	[absent]
01	8
10	16
11	24

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let rotated : bits(32) = ROR(R(m), rotation);
    R(d)[15:0] = ZeroExtend{16}(rotated[7:0]);
    R(d)[31:16] = ZeroExtend{16}(rotated[23:16]);
end;
```

C5.1.292 UXTH

Unsigned Extend Halfword

Unsigned Extend Halfword extracts a 16-bit value from a register, zero-extends it to 32 bits, and writes the result to the destination register. The instruction can specify a rotation by 0, 8, 16, or 24 bits before extracting the 16-bit value.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#) and [T2](#)).

A1

Encoding

```
UXTH{<c>}{<q>} {<Rd>, }<Rm> {, ROR #<amount>}
```

Decode for this encoding

```
let d : integer = UInt(Rd);
let m : integer = UInt(Rm);
let rotation : integer = UInt(rotate::'000');
if d == 15 || m == 15 then UnpredictableProcedure(); end;
```

T1

Encoding

```
UXTH{<c>}{<q>} {<Rd>, }<Rm>
```

Decode for this encoding

```
let d : integer = UInt(Rd);
let m : integer = UInt(Rm);
let rotation : integer = 0;
```

T2

Encoding

```
UXTH{<c>}{<q>} {<Rd>, }<Rm> {, ROR #<amount>}  
  
UXTH{<c>}.W {<Rd>, }<Rm> // (<Rd>, <Rm> can be represented in T1)
```

Decode for this encoding

```
let d : integer = UInt(Rd);  
let m : integer = UInt(Rm);  
let rotation : integer = UInt(rotate::'000');  
// Armv8-A removes UNPREDICTABLE for R13  
if d == 15 || m == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

00	[absent]
01	8
10	16
11	24

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let rotated : bits(32) = ROR(R(m), rotation);
    R(d) = ZeroExtend{32}(rotated[15:0]);
end;
```

C5.1.293 WFE

Wait For Event is a hint instruction that indicates that the PE can enter a low-power state and remain there until a wakeup event occurs. Wakeup events include the event signaled as a result of executing the `SEV` instruction on any PE in the multiprocessor system. For more information, see [Wait For Event and Send Event](#).

As described in [Wait For Event and Send Event](#), the execution of a `WFE` instruction that would otherwise cause entry to a low-power state can be trapped to a higher Exception level, see [HCR.TWE](#), [SCR.TWE](#), and [SCTLR.nTWE](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#) and [T2](#)).

A1

Encoding

WFE{<c>}{<q>}

Decode for this encoding

// No additional decoding required

T1

Encoding

WFE{<c>}{<q>}

Decode for this encoding

// No additional decoding required

T2

Encoding

WFE{<c>}.W

Decode for this encoding

// No additional decoding required

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
if IsEventRegisterSet() then
    ClearEventRegister();
else
    if PSTATE.EL == EL0 then
        // Check for traps described by the OS.
        AArch32_CheckForWfxTrap(EL1, WfxType_WFE);
    end;
    if PSTATE.EL IN {EL0, EL1} && EL2Enabled() then
        // Check for traps described by the Hypervisor.
        AArch32_CheckForWfxTrap(EL2, WfxType_WFE);
    end;
    WaitForEvent();
end;
end;
```

C5.1.294 WFI

Wait For Interrupt is a hint instruction that indicates that the PE can enter a low-power state and remain there until a wakeup event occurs. For more information, see [Wait For Interrupt](#).

As described in [Wait For Interrupt](#), the execution of a `WFI` instruction that would otherwise cause entry to a low-power state can be trapped to a higher Exception level, see [HCR.TWI](#), [SCR.TWI](#), and [SCTLR.nTWI](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#) and [T2](#)).

A1

Encoding

`WFI{<c>}{<q>}`

Decode for this encoding

// No additional decoding required

T1

Encoding

`WFI{<c>}{<q>}`

Decode for this encoding

// No additional decoding required

T2

Encoding

`WFI{<c>}.W`

Decode for this encoding

// No additional decoding required

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    if !AArch32_InterruptPending() then
        if PSTATE.EL == EL0 then
            // Check for traps described by the OS.
            AArch32_CheckForWfxTrap(EL1, WfxType_WFI);
        end;
        if PSTATE.EL IN {EL0, EL1} && EL2Enabled() then
            // Check for traps described by the Hypervisor.
            AArch32_CheckForWfxTrap(EL2, WfxType_WFI);
        end;
        WaitForInterrupt();
    end;
end;
```

C5.1.295 YIELD

Yield hint

YIELD is a hint instruction. Software with a multithreading capability can use a **YIELD** instruction to indicate to the PE that it is performing a task, for example a spin-lock, that could be swapped out to improve overall system performance. The PE can use this hint to suspend and resume multiple software threads if it supports the capability.

For more information about the recommended use of this instruction see [The Yield instruction](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#) and [T2](#)).

A1

Encoding

YIELD{<c>}{<q>}

Decode for this encoding

// No additional decoding required

T1

Encoding

YIELD{<c>}{<q>}

Decode for this encoding

// No additional decoding required

T2

Encoding

YIELD{<c>}.W

Decode for this encoding

// No additional decoding required

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    Hint_Yield();
end;
```

C5.2 Encoding and use of banked register transfer instructions

Software executing at EL1 or higher can use the `MRS` (banked register) and `MSR` (banked register) instructions to transfer values between the general-purpose registers and Special-purpose registers. One particular use of these instructions is for a hypervisor to save or restore the register values of a Guest OS. The following sections give more information about these instructions:

- [Register arguments in the banked register transfer instructions.](#)
- [Usage restrictions on the banked register transfer instructions.](#)
- [Encoding the register argument in the banked register transfer instructions.](#)
- [Pseudocode support for the banked register transfer instructions.](#)

For descriptions of the instructions see [MRS \(Banked register\)](#) and [MSR \(Banked register\)](#).

C5.2.1 Register arguments in the banked register transfer instructions

Figure C5-1 shows the banked general-purpose registers and Special-purpose registers:

		Associated PE mode							
		User or System	Hyp	Supervisor	Abort	Undefined	Monitor	IRQ	FIQ
General-purpose registers	R8_usr								R8_fiq
	R9_usr								R9_fiq
	R10_usr								R10_fiq
	R11_usr								R11_fiq
	R12_usr								R12_fiq
	SP_usr	SP_usr	SP_hyp	SP_svc	SP_abt	SP_und	SP_mon	SP_irq	SP_fiq
Special-purpose registers	LR_usr			LR_svc	LR_abt	LR_und	LR_mon	LR_irq	LR_fiq
		SPSR_hyp	SPSR_svc	SPSR_abt	SPSR_und	SPSR_mon	SPSR_irq	SPSR_fiq	
		ELR_hyp							

For the general-purpose registers, if no other register is shown, the *current mode register* is the `_usr` register. So, for example, the full set of current mode registers, including the registers that are not banked:

- For Hyp mode, is {R0_usr - R12_usr, SP_hyp, LR_usr, SPSR_hyp, ELR_hyp}.
- For Abort mode, is {R0_usr - R12_usr, SP_abt, LR_abt, SPSR_abt}.

Figure C5-1 Banking of general-purpose and Special-purpose registers

Note

- System mode uses the same set of registers as User mode. Neither of these modes can access an [SPSR](#), except that System mode can use the `MRS` (banked register) and `MSR` (banked register) instructions to access some [SPSRs](#), as described in [Usage restrictions on the banked register transfer instructions](#).
- General-purpose registers R0-R7, that are not banked, cannot be accessed using the `MRS` (banked register) and `MSR` (banked register) instructions.
- In addition to the registers shown in [Figure C5-1](#), the [DLR](#) and [DSPSR](#) are AArch32 System registers that map onto the AArch64 Special-purpose registers `DLR_EL0` and `DSPSR_EL0`. However, [DLR](#) and [DSPSR](#) are not accessible using the `MRS` (banked register) and `MSR` (banked register) instructions.

Software using an `MRS` (banked register) or `MSR` (banked register) instruction specifies one of these registers using a name shown in [Figure C5-1](#), or an alternative name for SP or LR. These registers can be grouped as follows:

R8-R12	Each of these registers has two banked copies, <code>_usr</code> and <code>_fiq</code> , for example R8_usr and R8_fiq.
SP	There is a banked copy of SP for every mode except System mode. For example, SP_svc is the SP for Supervisor mode.
LR	There is a banked copy of LR for every mode except System mode and Hyp mode. For example, LR_svc is the LR for Supervisor mode.

SPSR	There is a banked copy of SPSR for every mode except System mode and User mode.
ELR_hyp	Except for the operations provided by MRS (banked register) and MSR (banked register) , ELR_hyp is accessible only from Hyp mode. It is not banked.

C5.2.2 Usage restrictions on the banked register transfer instructions

[MRS \(banked register\)](#) and [MSR \(banked register\)](#) instructions are **CONSTRAINED UNPREDICTABLE** if any of the following applies:

- The instruction is executed in User mode.
- The instruction accesses a banked register that is not implemented, or that either:
 - Is not accessible from the current Privilege level and Security state.
 - Can be accessed from the current mode by using a different instruction.

[MSR \(banked register\)](#) and [MRS \(banked register\)](#) describes the permitted **CONSTRAINED UNPREDICTABLE** behavior.

An [MRS \(banked register\)](#) instruction or an [MSR \(banked register\)](#) instruction executed:

- At Non-secure EL1 cannot access any Hyp mode banked registers.
- At Non-secure EL1 or EL2 cannot access any Monitor mode banked registers.
- In a Secure mode other than Monitor mode cannot access any Hyp banked registers.

This means that the banked registers that [MRS \(banked register\)](#) and [MSR \(banked register\)](#) instructions cannot access are:

From Hyp mode

- The current mode registers R8_usr-R12_usr, SP_hyp, LR_usr, and SPSR_hyp.

Note

[MRS \(banked register\)](#) and [MSR \(banked register\)](#) instructions can access the current mode register [ELR_hyp](#).

From FIQ mode

- The Hyp mode registers SP_hyp, SPSR_hyp, and [ELR_hyp](#).
- The current mode registers R8_fiq-R12_fiq, SP_fiq, LR_fiq, and SPSR_fiq.

From System mode

- The Hyp mode registers SP_hyp, SPSR_hyp, and [ELR_hyp](#).
- The current mode registers R8_usr-R12_usr, SP_usr, and LR_usr.

From Supervisor mode, Abort mode, Undefined mode, and IRQ mode

- The Hyp mode registers SP_hyp, SPSR_hyp, and [ELR_hyp](#).
- The current mode registers R8_usr-R12_usr, SP_<current_mode>, LR_<current_mode>, and SPSR_<current_mode>.

For more information, see:

- [Encoding the register argument in the banked register transfer instructions.](#)
- [Pseudocode support for the banked register transfer instructions.](#)
- [MRS \(Banked register\).](#)
- [MSR \(Banked register\).](#)

Note

CONSTRAINED UNPREDICTABLE behavior must not give access to registers that are not accessible from the current Privilege level and Security state.

C5.2.3 Encoding the register argument in the banked register transfer instructions

The `MRS` (banked register) and `MSR` (banked register) instructions include a 5-bit field, `SYSm`, and an `R` bit, that together encode the register argument for the instruction.

When the `R` bit is set to 0, the argument is a register other than a banked copy of the `SPSR`, and [Table C5-119](#) shows how the `SYSm` field defines the required register argument.

Table C5-119 Banked register encodings when `R==0`

SYSm<2:0>	SYSm<4:3>			
	0b00	0b01	0b10	0b11
0b000	R8_usr	R8_fiq	LR_irq	CONSTRAINED UNPREDICTABLE
0b001	R9_usr	R9_fiq	SP_irq	CONSTRAINED UNPREDICTABLE
0b010	R10_usr	R10_fiq	LR_svc	CONSTRAINED UNPREDICTABLE
0b011	R11_usr	R11_fiq	SP_svc	CONSTRAINED UNPREDICTABLE
0b100	R12_usr	R12_fiq	LR_abt	LR_mon
0b101	SP_usr	SP_fiq	SP_abt	SP_mon
0b110	LR_usr	LR_fiq	LR_und	ELR_hyp
0b111	CONSTRAINED UNPREDICTABLE	CONSTRAINED UNPREDICTABLE	SP_und	SP_hyp

When the `R` bit is set to 1, the argument is a banked copy of the `SPSR`, and [Table C5-120](#) shows how the `SYSm` field defines the required register argument.

Table C5-120 Banked register encodings when `R==1`

SYSm<2:0>	SYSm<4:3>			
	0b00	0b01	0b10	0b11
0b000	CONSTRAINED UNPREDICTABLE	CONSTRAINED UNPREDICTABLE	SPSR_irq	CONSTRAINED UNPREDICTABLE
0b001	CONSTRAINED UNPREDICTABLE	CONSTRAINED UNPREDICTABLE	CONSTRAINED UNPREDICTABLE	CONSTRAINED UNPREDICTABLE
0b010	CONSTRAINED UNPREDICTABLE	CONSTRAINED UNPREDICTABLE	SPSR_svc	CONSTRAINED UNPREDICTABLE
0b011	CONSTRAINED UNPREDICTABLE	CONSTRAINED UNPREDICTABLE	CONSTRAINED UNPREDICTABLE	CONSTRAINED UNPREDICTABLE
0b100	CONSTRAINED UNPREDICTABLE	CONSTRAINED UNPREDICTABLE	SPSR_abt	SPSR_mon
0b101	CONSTRAINED UNPREDICTABLE	CONSTRAINED UNPREDICTABLE	CONSTRAINED UNPREDICTABLE	CONSTRAINED UNPREDICTABLE
0b110	CONSTRAINED UNPREDICTABLE	SPSR_fiq	SPSR_und	SPSR_hyp
0b111	CONSTRAINED UNPREDICTABLE	CONSTRAINED UNPREDICTABLE	CONSTRAINED UNPREDICTABLE	CONSTRAINED UNPREDICTABLE

C5.2.4 Pseudocode support for the banked register transfer instructions

The pseudocode functions `BankedRegisterAccessValid()` and `SPSRaccessValid()` check the validity of `MRS` (banked register) and `MSR` (banked register) accesses. That is, they filter the accesses that are `CONSTRAINED UNPREDICTABLE` either because:

- They attempt to access a register that [Usage restrictions on the banked register transfer instructions](#) shows is not accessible.
- They use an `SYSm<4:0>` encoding that [Encoding the register argument in the banked register transfer instructions](#) shows as `CONSTRAINED UNPREDICTABLE`.

`BankedRegisterAccessValid()` applies to accesses to the banked general-purpose registers, or to `ELR_hyp`, and `SPSRaccessValid()` applies to accesses to the `SPSRs`.

Chapter C6

T32 and A32 Advanced SIMD and Floating-point Instruction Descriptions

This chapter describes each instruction. It contains the following sections:

- [Alphabetical list of Advanced SIMD and floating-point instructions](#)

Note

Some headings in this chapter use the term *floating-point register*. This is an abbreviated description, and means a register in the Advanced SIMD and floating-point register file.

C6.1 Alphabetical list of Advanced SIMD and floating-point instructions

This section lists every Advanced SIMD and floating-point instruction in the T32 and A32 instruction sets. For details of the format used see [Format of instruction descriptions](#).

This section is formatted so that each instruction description starts on a new page.

C6.1.1 AESD

AES single round decryption.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

(FEAT_AES)

Encoding

AESD.<dt> <Qd>, <Qm>

Decode for this encoding

```

if !IsFeatureImplemented(FEAT_AES) then Undefined(); end;
if size != '00' then Undefined(); end;

let d : integer = UInt(D::Vd);
let m : integer = UInt(M::Vm);

```

T1

(FEAT_AES)

Encoding

AESD.<dt> <Qd>, <Qm>

Decode for this encoding

```

if InITBlock() then UnpredictableProcedure(); end;
if !IsFeatureImplemented(FEAT_AES) then Undefined(); end;
if size != '00' then Undefined(); end;
if Vd[0] == '1' || Vm[0] == '1' then Undefined(); end;
let d : integer = UInt(D::Vd);
let m : integer = UInt(M::Vm);

```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<dt>

Is the data type, encoded in “size”:

size	<dt>
00	8
01	RESERVED
1x	RESERVED

<Qd>

Is the 128-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field as <Qd>*2.

<Qm>

Is the 128-bit name of the SIMD&FP source register, encoded in the “M:Vm” field as <Qm>*2.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations(); CheckCryptoEnabled32();
    let operand1 : bits(128) = Q(d>>1);
    let operand2 : bits(128) = Q(m>>1);
    Q(d>>1) = AESInvSubBytes(AESInvShiftRows(operand1 XOR operand2));
end;
```

C6.1.2 AESE

AES single round encryption.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

(FEAT_AES)

Encoding

AESE.<dt> <Qd>, <Qm>

Decode for this encoding

```

if !IsFeatureImplemented(FEAT_AES) then Undefined(); end;
if size != '00' then Undefined(); end;
if Vd[0] == '1' || Vm[0] == '1' then Undefined(); end;
let d : integer = UInt(D::Vd);
let m : integer = UInt(M::Vm);

```

T1

(FEAT_AES)

Encoding

AESE.<dt> <Qd>, <Qm>

Decode for this encoding

```

if InITBlock() then UnpredictableProcedure(); end;
if !IsFeatureImplemented(FEAT_AES) then Undefined(); end;
if size != '00' then Undefined(); end;
if Vd[0] == '1' || Vm[0] == '1' then Undefined(); end;
let d : integer = UInt(D::Vd);
let m : integer = UInt(M::Vm);

```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<dt>

Is the data type, encoded in “size”:

size	<dt>
00	8
01	RESERVED
1x	RESERVED

<Qd>

Is the 128-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field as <Qd>*2.

<Qm>

Is the 128-bit name of the SIMD&FP source register, encoded in the “M:Vm” field as <Qm>*2.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations(); CheckCryptoEnabled32();
    let operand1 : bits(128) = Q(d>>1);
    let operand2 : bits(128) = Q(m>>1);
    Q(d>>1) = AESSubBytes(AESShiftRows(operand1 XOR operand2));
end;
```

C6.1.3 AESIMC

AES inverse mix columns.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

(FEAT_AES)

Encoding

AESIMC.<dt> <Qd>, <Qm>

Decode for this encoding

```

if !IsFeatureImplemented(FEAT_AES) then Undefined(); end;
if size != '00' then Undefined(); end;
if Vd[0] == '1' || Vm[0] == '1' then Undefined(); end;
let d : integer = UInt(D::Vd);
let m : integer = UInt(M::Vm);

```

T1

(FEAT_AES)

Encoding

AESIMC.<dt> <Qd>, <Qm>

Decode for this encoding

```

if InITBlock() then UnpredictableProcedure(); end;
if !IsFeatureImplemented(FEAT_AES) then Undefined(); end;
if size != '00' then Undefined(); end;
if Vd[0] == '1' || Vm[0] == '1' then Undefined(); end;
let d : integer = UInt(D::Vd);
let m : integer = UInt(M::Vm);

```

Assembler Symbols

<dt>

Is the data type, encoded in “size”:

size	<dt>

<Qm>

Is the 128-bit name of the SIMD&FP source register, encoded in the “M:Vm” field as <Qm>*2.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations(); CheckCryptoEnabled32();
    Q(d>>1) = AESInvMixColumns(Q(m>>1));
end;
```

C6.1.4 AESMC

AES mix columns.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

(FEAT_AES)

Encoding

AESMC.<dt> <Qd>, <Qm>

Decode for this encoding

```

if !IsFeatureImplemented(FEAT_AES) then Undefined(); end;
if size != '00' then Undefined(); end;
if Vd[0] == '1' || Vm[0] == '1' then Undefined(); end;
let d : integer = UInt(D::Vd);
let m : integer = UInt(M::Vm);

```

T1

(FEAT_AES)

Encoding

AESMC.<dt> <Qd>, <Qm>

Decode for this encoding

```

if InITBlock() then UnpredictableProcedure(); end;
if !IsFeatureImplemented(FEAT_AES) then Undefined(); end;
if size != '00' then Undefined(); end;
if Vd[0] == '1' || Vm[0] == '1' then Undefined(); end;
let d : integer = UInt(D::Vd);
let m : integer = UInt(M::Vm);

```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<dt>

Is the data type, encoded in “size”:

size	<dt>
00	8
01	RESERVED
1x	RESERVED

<Qd>

Is the 128-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field as <Qd>*2.

<Qm>

Is the 128-bit name of the SIMD&FP source register, encoded in the “M:Vm” field as <Qm>*2.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations(); CheckCryptoEnabled32();
    Q(d>>1) = AESMixColumns(Q(m>>1));
end;
```

C6.1.5 FLDM*X (FLDMDBX, FLDMIAX)

FLDM*X

FLDMDBX is the Decrement Before variant of this instruction, and FLDMIAX is the Increment After variant. FLDM*X loads multiple SIMD&FP registers from consecutive locations in the Advanced SIMD and floating-point register file using an address from a general-purpose register.

Arm deprecates use of FLDMDBX and FLDMIAX, except for disassembly purposes, and reassembly of disassembled code.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information, see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 (A1) and T32 (T1).

A1

Encoding for the Decrement Before variant

Applies when (P == 1 && U == 0 && W == 1)

```
FLDMDBX{<c>}{<q>} <Rn>!, <dreglist>
```

Encoding for the Increment After variant

Applies when (P == 0 && U == 1)

```
FLDMIAX{<c>}{<q>} <Rn>{!}, <dreglist>
```

Decode for all variants of this encoding

```
if P == '0' && U == '0' && W == '0' then See("Related encodings"); end;
if P == '1' && W == '0' then See("VLDL"); end;
if P == U && W == '1' then Undefined(); end;
// Remaining combinations are PUW = 010 (IA without !), 011 (IA with !), 101 (DB with !)
let single_regs : boolean = FALSE;
let add : boolean = (U == '1');
let wback : boolean = (W == '1');
let d : integer = UInt(D::Vd);
let n : integer = UInt(Rn);
let imm32 : bits(32) = ZeroExtend{imm8::'00'};
let regs : integer = UInt(imm8) DIVRM 2; // If UInt(imm8) is odd, see "FLDM*X".
if n == 15 && (wback || CurrentInstrSet() != InstrSet_A32) then UnpredictableProcedure(); end;
if regs == 0 || regs > 16 || (d+regs) > 32 then UnpredictableProcedure(); end;
if imm8[0] == '1' && (d+regs) > 16 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If regs == 0, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction operates as a VLDM with the same addressing mode but loads no registers.

If $\text{regs} > 16 \parallel (\text{d+regs}) > 16$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

T1

Encoding for the Decrement Before variant

Applies when $(P == 1 \ \&\& \ U == 0 \ \&\& \ W == 1)$

```
FLDMDXB{<c>}{<q>} <Rn>!, <dreglist>
```

Encoding for the Increment After variant

Applies when $(P == 0 \ \&\& \ U == 1)$

```
FLDMIAX{<c>}{<q>} <Rn>{!}, <dreglist>
```

Decode for all variants of this encoding

```
if P == '0' && U == '0' && W == '0' then See("Related encodings"); end;
if P == '1' && W == '0' then See("VLDR"); end;
if P == U && W == '1' then Undefined(); end;
// Remaining combinations are PUW = 010 (IA without !), 011 (IA with !), 101 (DB with !)
let single_regs : boolean = FALSE;
let add : boolean = (U == '1');
let wback : boolean = (W == '1');
let d : integer = UInt(D::Vd);
let n : integer = UInt(Rn);
let imm32 : bits(32) = ZeroExtend{(imm8::'00')};
let regs : integer = UInt(imm8) DIVRM 2; // If UInt(imm8) is odd, see "FLDM*X".
if n == 15 && (wback || CurrentInstrSet() != InstrSet_A32) then UnpredictableProcedure(); end;
if regs == 0 || regs > 16 || (d+regs) > 32 then UnpredictableProcedure(); end;
if imm8[0] == '1' && (d+regs) > 16 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If $\text{regs} == 0$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction operates as a VLDM with the same addressing mode but loads no registers.

If $\text{regs} > 16 \parallel (\text{d+regs}) > 16$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Related encodings: See [Advanced SIMD and floating-point 64-bit move](#) for the T32 instruction set, or [Advanced SIMD and floating-point 64-bit move](#) for the A32 instruction set.

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rn>

Is the general-purpose base register, encoded in the “Rn” field. If writeback is not specified, the PC can be used.

<dreglist>

Is the list of consecutively numbered 64-bit SIMD&FP registers to be transferred. The first register in the list is encoded in “D:Vd”, and “imm8” is set to twice the number of registers in the list plus one. The list must contain at least one register, all registers must be in the range D0-D15, and must not contain more than 16 registers.

!

Specifies base register writeback, encoded in “W”:

W	!
0	[absent]
1	[present]

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckVFPEEnabled(TRUE);
    var address : bits(32) = if add then R(n) else R(n)-imm32;

    for r = 0 to regs-1 do
        if single_regs then
            S(d+r) = MemA{32}(address);
            address = address+4;
        else
            let word1 : bits(32) = MemA{32}(address);
            let word2 : bits(32) = MemA{32}(address+4);
            address = address+8;

            // Combine the word-aligned words in the correct order for current endianness.
            D(d+r) = if BigEndian(AccessType_ASIMD) then word1::word2 else word2::word1;
        end;
    end;

    if wback then R(n) = if add then R(n)+imm32 else R(n)-imm32; end;
end;
```

C6.1.6 FSTMDBX, FSTMIAX

FSTMX stores multiple SIMD&FP registers from the Advanced SIMD and floating-point register file to consecutive locations in using an address from a general-purpose register.

Arm deprecates use of FSTMDBX and FSTMIAX, except for disassembly purposes, and reassembly of disassembled code.

Depending on settings in the [CPACR](#), [NSACR](#), [HCPTR](#), and [FPEXC](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information, see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding for the Decrement Before variant

Applies when (P == 1 && U == 0 && W == 1)

```
FSTMDBX{<c>}{<q>} <Rn>!, <dreglist>
```

Encoding for the Increment After variant

Applies when (P == 0 && U == 1)

```
FSTMIAX{<c>}{<q>} <Rn>{!}, <dreglist>
```

Decode for all variants of this encoding

```
if P == '0' && U == '0' && W == '0' then See("Related encodings"); end;
if P == '1' && W == '0' then See("VSTR"); end;
if P == U && W == '1' then Undefined(); end;
// Remaining combinations are PUW = 010 (IA without !), 011 (IA with !), 101 (DB with !)
let single_regs : boolean = FALSE;
let add : boolean = (U == '1');
let wback : boolean = (W == '1');
let d : integer = UInt(D::Vd);
let n : integer = UInt(Rn);
let imm32 : bits(32) = ZeroExtend{}(imm8::'00');
let regs : integer = UInt(imm8) DIVRM 2; // If UInt(imm8) is odd, see "FSTDBMX, FSTMIAX".
if n == 15 && (wback || CurrentInstrSet() != InstrSet_A32) then UnpredictableProcedure(); end;
if regs == 0 || regs > 16 || (d+regs) > 32 then UnpredictableProcedure(); end;
if imm8[0] == '1' && (d+regs) > 16 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If regs == 0, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction operates as a `VSTM` with the same addressing mode but stores no registers.

If regs > 16 || (d+regs) > 16, then one of the following behaviors must occur:

- The instruction is `UNDEFINED`.
- The instruction executes as `NOP`.
- The memory locations specified by the instruction and the number of registers specified by the instruction become `UNKNOWN`. If the instruction specifies writeback, then that register becomes `UNKNOWN`. This behavior does not affect any other memory locations.

T1

Encoding for the Decrement Before variant

Applies when (P == 1 && U == 0 && W == 1)

```
FSTMDBX{<c>}{<q>}<Rn>!, <dreglist>
```

Encoding for the Increment After variant

Applies when (P == 0 && U == 1)

```
FSTMIAX{<c>} {<q>}    <Rn>{!}, <dreglist>
```

Decode for all variants of this encoding

```

if P == '0' && U == '0' && W == '0' then See("Related encodings"); end;
if P == '1' && W == '0' then See("VSTR"); end;
if P == U && W == '1' then Undefined(); end;
// Remaining combinations are PUW = 010 (IA without !), 011 (IA with !), 101 (DB with !)
let single_regs : boolean = FALSE;
let add : boolean = (U == '1');
let wback : boolean = (W == '1');
let d : integer = UInt(D::Vd);
let n : integer = UInt(Rn);
let imm32 : bits(32) = ZeroExtend{}(imm8::'00');
let regs : integer = UInt(imm8) DIVRM 2; // If UInt(imm8) is odd, see "FSTDBMX, FSTMIAX".
if n == 15 && (wback || CurrentInstrSet() != InstrSet_A32) then UnpredictableProcedure(); end;
if regs == 0 || regs > 16 || (d+regs) > 32 then UnpredictableProcedure(); end;
if imm8[0] == '1' && (d+regs) > 16 then UnpredictableProcedure(); end;

```

CONSTRAINED UNPREDICTABLE behavior

If $\text{regs} == 0$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction operates as a VSTM with the same addressing mode but stores no registers.

If $\text{regs} > 16 \mid\mid (\text{d+regs}) > 16$, then one of the following behaviors must occur:

- The instruction is `UNDEFINED`.
- The instruction executes as `NOP`.
- The memory locations specified by the instruction and the number of registers specified by the instruction become `UNKNOWN`. If the instruction specifies writeback, then that register becomes `UNKNOWN`. This behavior does not affect any other memory locations.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Related encodings: See [Advanced SIMD and floating-point 64-bit move](#) for the T32 instruction set, or [Advanced SIMD and floating-point 64-bit move](#) for the A32 instruction set.

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Rn>

Is the general-purpose base register, encoded in the “Rn” field. If writeback is not specified, the PC can be used. However, Arm deprecates use of the PC.

<dreglist>

Is the list of consecutively numbered 64-bit SIMD&FP registers to be transferred. The first register in the list is encoded in “D:Vd”, and “imm8” is set to twice the number of registers in the list plus one. The list must contain at least one register, all registers must be in the range D0-D15, and must not contain more than 16 registers.

        end;
    end;

    if wback then R(n) = if add then R(n)+imm32 else R(n)-imm32; end;
end;
```

C6.1.7 SHA1C

SHA1 hash update (choose).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

(FEAT_SHA1)

Encoding

SHA1C.32 <Qd>, <Qn>, <Qm>

Decode for this encoding

```

if !IsFeatureImplemented(FEAT_SHA1) then Undefined(); end;
if Q != '1' then Undefined(); end;
if Vd[0] == '1' || Vn[0] == '1' || Vm[0] == '1' then Undefined(); end;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);

```

T1

(FEAT_SHA1)

Encoding

SHA1C.32 <Qd>, <Qn>, <Qm>

Decode for this encoding

```

if InITBlock() then UnpredictableProcedure(); end;
if !IsFeatureImplemented(FEAT_SHA1) then Undefined(); end;
if Q != '1' then Undefined(); end;
if Vd[0] == '1' || Vn[0] == '1' || Vm[0] == '1' then Undefined(); end;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);

```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<Qd>

Is the 128-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field as <Qd>*2.

<Qn>

Is the 128-bit name of the first SIMD&FP source register, encoded in the “N:Vn” field as <Qn>*2.

<Qm>

Is the 128-bit name of the second SIMD&FP source register, encoded in the “M:Vm” field as <Qm>*2.

Operation

```

if ConditionPassed() then
    EncodingSpecificOperations();
    CheckCryptoEnabled32();
    var x : bits(128) = Q(d>>1);
    var y : bits(32) = Q(n>>1)[31:0]; // Note: 32 bits wide
    let w : bits(128) = Q(m>>1);
    for e = 0 to 3 do
        let t : bits(32) = SHAchoose(x[63:32], x[95:64], x[127:96]);
        y = y + ROL(x[31:0], 5) + t + w[e*:32];
        x[63:32] = ROL(x[63:32], 30);
        let yx : bits(160) = ROL(y::x, 32);
        (y, x) = (yx[128+:32], yx[0+:128]);
    end;
    Q(d>>1) = x;
end;

```

C6.1.8 SHA1H

SHA1 fixed rotate.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

(FEAT_SHA1)

Encoding

SHA1H.32 <Qd>, <Qm>

Decode for this encoding

```

if !IsFeatureImplemented(FEAT_SHA1) then Undefined(); end;
if size != '10' then Undefined(); end;
if Vd[0] == '1' || Vm[0] == '1' then Undefined(); end;
let d : integer = UInt(D::Vd);

Assembler Symbols

<Qd>

Is the 128-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field as <Qd>*2.

<Qn>

Is the 128-bit name of the first SIMD&FP source register, encoded in the “N:Vn” field as <Qn>*2.

<Qm>

Is the 128-bit name of the second SIMD&FP source register, encoded in the “M:Vm” field as <Qm>*2.

Operation

```

if ConditionPassed() then
    EncodingSpecificOperations();
    CheckCryptoEnabled32();
    var x : bits(128) = Q(d>>1);
    var y : bits(32) = Q(n>>1)[31:0]; // Note: 32 bits wide
    let w : bits(128) = Q(m>>1);
    for e = 0 to 3 do
        let t : bits(32) = SHAMajority{(x[63:32], x[95:64], x[127:96]);
        y = y + ROL(x[31:0], 5) + t + w[e*:32];
        x[63:32] = ROL(x[63:32], 30);
        let yx : bits(160) = ROL(y::x, 32);
        (y, x) = (yx[128+:32], yx[0+:128]);
    end;
    Q(d>>1) = x;
end;

```

C6.1.10 SHA1P

SHA1 hash update (parity).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

(FEAT_SHA1)

Encoding

SHA1P.32 <Qd>, <Qn>, <Qm>

Decode for this encoding

```

if !IsFeatureImplemented(FEAT_SHA1) then Undefined(); end;
if Q != '1' then Undefined(); end;
if Vd[0] == '1' || Vn[0] == '1' || Vm[0] == '1' then Undefined(); end;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);

```

T1

(FEAT_SHA1)

Encoding

SHA1P.32 <Qd>, <Qn>, <Qm>

Decode for this encoding

```

if InITBlock() then UnpredictableProcedure(); end;
if !IsFeatureImplemented(FEAT_SHA1) then Undefined(); end;
if Q != '1' then Undefined(); end;
if Vd[0] == '1' || Vn[0] == '1' || Vm[0] == '1' then Undefined(); end;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);

```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<Qd>

Is the 128-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field as <Qd>*2.

<Qn>

Is the 128-bit name of the first SIMD&FP source register, encoded in the “N:Vn” field as <Qn>*2.

<Qm>

Is the 128-bit name of the second SIMD&FP source register, encoded in the “M:Vm” field as <Qm>*2.

Operation

```

if ConditionPassed() then
    EncodingSpecificOperations();
    CheckCryptoEnabled32();
    var x : bits(128) = Q(d>>1);
    var y : bits(32) = Q(n>>1)[31:0]; // Note: 32 bits wide
    let w : bits(128) = Q(m>>1);
    for e = 0 to 3 do
        let t : bits(32) = SHAparsity(x[63:32], x[95:64], x[127:96]);
        y = y + ROL(x[31:0], 5) + t + w[e*:32];
        x[63:32] = ROL(x[63:32], 30);
        let yx : bits(160) = ROL(y::x, 32);
        (y, x) = (yx[128+:32], yx[0+:128]);
    end;
    Q(d>>1) = x;
end;

```

C6.1.11 SHA1SU0

SHA1 schedule update 0.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

(FEAT_SHA1)

Encoding

SHA1SU0.32 <Qd>, <Qn>, <Qm>

Decode for this encoding

```

if !IsFeatureImplemented(FEAT_SHA1) then Undefined(); end;
if Q != '1' then Undefined(); end;
if Vd[0] == '1' || Vn[0] == '1' || Vm[0] == '1' then Undefined(); end;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);

```

T1

(FEAT_SHA1)

Encoding

SHA1SU0.32 <Qd>, <Qn>, <Qm>

Decode for this encoding

```

if InITBlock() then UnpredictableProcedure(); end;
if !IsFeatureImplemented(FEAT_SHA1) then Undefined(); end;
if Q != '1' then Undefined(); end;
if Vd[0] == '1' || Vn[0] == '1' || Vm[0] == '1' then Undefined(); end;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);

```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<Qd>

Is the 128-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field as <Qd>*2.

<Qn>

Is the 128-bit name of the first SIMD&FP source register, encoded in the “N:Vn” field as <Qn>*2.

<Qm>

Is the 128-bit name of the second SIMD&FP source register, encoded in the “M:Vm” field as <Qm>*2.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckCryptoEnabled32();
    let op1 : bits(128) = Q(d>>1);
    var op2 : bits(128) = Q(n>>1);
    let op3 : bits(128) = Q(m>>1);
    op2 = op2[63:0] :: op1[127:64];
    Q(d>>1) = op1 XOR op2 XOR op3;
end;
```

C6.1.12 SHA1SU1

SHA1 schedule update 1.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

(FEAT_SHA1)

Encoding

SHA1SU1.32 <Qd>, <Qm>

Decode for this encoding

```

if !IsFeatureImplemented(FEAT_SHA1) then Undefined(); end;
if size != '10' then Undefined(); end;
if Vd[0] == '1' || Vm[0] == '1' then Undefined(); end;
let d : integer = UInt(D::Vd);
let m : integer = UInt(M::Vm);

```

T1

(FEAT_SHA1)

Encoding

SHA1SU1.32 <Qd>, <Qm>

Decode for this encoding

```

if InITBlock() then UnpredictableProcedure(); end;
if !IsFeatureImplemented(FEAT_SHA1) then Undefined(); end;
if size != '10' then Undefined(); end;
if Vd[0] == '1' || Vm[0] == '1' then Undefined(); end;
let d : integer = UInt(D::Vd);
let m : integer = UInt(M::Vm);

```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<Qd>

Is the 128-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field as <Qd>*2.

<Qm>

Is the 128-bit name of the SIMD&FP source register, encoded in the “M:Vm” field as <Qm>*2.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckCryptoEnabled32();
    let X : bits(128) = Q(d>>1);
    let Y : bits(128) = Q(m>>1);
    let T : bits(128) = X XOR LSR(Y, 32);
    let W0 : bits(32) = ROL(T[31:0], 1);
    let W1 : bits(32) = ROL(T[63:32], 1);
    let W2 : bits(32) = ROL(T[95:64], 1);

    Q(d>>1) = W3::W2::W1::W0;
end;
```

C6.1.13 SHA256H

SHA256 hash update part 1.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

(FEAT_SHA256)

Encoding

SHA256H.32 <Qd>, <Qn>, <Qm>

Decode for this encoding

```

if !IsFeatureImplemented(FEAT_SHA256) then Undefined(); end;
if Q != '1' then Undefined(); end;
if Vd[0] == '1' || Vn[0] == '1' || Vm[0] == '1' then Undefined(); end;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);

```

T1

(FEAT_SHA256)

Encoding

SHA256H.32 <Qd>, <Qn>, <Qm>

Decode for this encoding

```

if InITBlock() then UnpredictableProcedure(); end;
if !IsFeatureImplemented(FEAT_SHA256) then Undefined(); end;
if Q != '1' then Undefined(); end;
if Vd[0] == '1' || Vn[0] == '1' || Vm[0] == '1' then Undefined(); end;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);

```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<Qd>

Is the 128-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field as <Qd>*2.

<Qn>

Is the 128-bit name of the first SIMD&FP source register, encoded in the “N:Vn” field as <Qn>*2.

<Qm>

Is the 128-bit name of the second SIMD&FP source register, encoded in the “M:Vm” field as <Qm>*2.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckCryptoEnabled32();
    let X : bits(128) = Q(d>>1);
    let Y : bits(128) = Q(n>>1);

    end;

    Q(d>>1) = result;
end;

```

C6.1.17 VABA

Vector Absolute Difference and Accumulate subtracts the elements of one vector from the corresponding elements of another vector, and accumulates the absolute values of the results into the elements of the destination vector.

Operand and result elements are all integers of the same length.

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0)

VABA{<c>}{<q>}.<dt> <Dd>, <Dn>, <Dm>

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

VABA{<c>}{<q>}.<dt> <Qd>, <Qn>, <Qm>

Decode for all variants of this encoding

```

if size == '11' then Undefined(); end;
if Q == '1' && (Vd[0] == '1' || Vn[0] == '1' || Vm[0] == '1') then Undefined(); end;
let unsigned : boolean = (U == '1');
let long_destination : boolean = FALSE;
let esize : integer{} = 8 << UInt(size);
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);
let elements : integer = 64 DIV esize;
let regs : integer = if Q == '0' then 1 else 2;

```

T1

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0)

VABA{<c>}{<q>}.<dt> <Dd>, <Dn>, <Dm>

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

VABA{<c>}{<q>}.<dt> <Qd>, <Qn>, <Qm>

Decode for all variants of this encoding

```
if size == '11' then Undefined(); end;
if Q == '1' && (Vd[0] == '1' || Vn[0] == '1' || Vm[0] == '1') then Undefined(); end;
let unsigned : boolean = (U == '1');
let long_destination : boolean = FALSE;
let esize : integer{} = 8 << UInt(size);
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);
let elements : integer = 64 DIV esize;
let regs : integer = if Q == '0' then 1 else 2;
```

Assembler Symbols

<c>

For the “A1 128-bit SIMD vector” and “A1 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#). This encoding must be unconditional.

For the “T1 128-bit SIMD vector” and “T1 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<dt>

Is the data type for the elements of the operands, encoded in “U:size”:

U	size	<dt>
0	00	S8
0	01	S16
0	10	S32
1	00	U8
1	01	U16
1	10	U32

<Dd>

Is the 64-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field.

<Dn>

Is the 64-bit name of the first SIMD&FP source register, encoded in the “N:Vn” field.

<Dm>

Is the 64-bit name of the second SIMD&FP source register, encoded in the “M:Vm” field.

<Qd>

Is the 128-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field as <Qd>*2.

<Qn>

Is the 128-bit name of the first SIMD&FP source register, encoded in the “N:Vn” field as <Qn>*2.

<Qm>

Is the 128-bit name of the second SIMD&FP source register, encoded in the “M:Vm” field as <Qm>*2.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();
    for r = 0 to regs-1 do
        for e = 0 to elements-1 do
            let op1elt : bits(esize) = Din(n+r)[e*:esize];
            let op2elt : bits(esize) = Din(m+r)[e*:esize];
            let element1 : integer = if unsigned then UInt(op1elt) else SInt(op1elt);
            let element2 : integer = if unsigned then UInt(op2elt) else SInt(op2elt);
            let absdiff : integer = Abs(element1 - element2);
            if long_destination then
                Q(d>>1)[e*:(2*esize)] = Qin(d>>1)[e*:(2*esize)] + absdiff;
            else
                D(d+r)[e*:esize] = Din(d+r)[e*:esize] + absdiff;
            end;
        end;
    end;
end;
```

C6.1.18 VABAL

Vector Absolute Difference and Accumulate Long subtracts the elements of one vector from the corresponding elements of another vector, and accumulates the absolute values of the results into the elements of the destination vector.

Operand elements are all integers of the same length, and the result elements are double the length of the operands.

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

VABAL{<c>}{<q>}.<dt> <Qd>, <Dn>, <Dm>

Decode for this encoding

```

if size == '11' then See("Related encodings"); end;
if Vd[0] == '1' then Undefined(); end;
let unsigned : boolean = (U == '1');
let long_destination : boolean = TRUE;
let esize : integer{} = 8 << UInt(size);
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);
let elements : integer = 64 DIV esize;
let regs : integer = 1;

```

T1

Encoding

VABAL{<c>}{<q>}.<dt> <Qd>, <Dn>, <Dm>

Decode for this encoding

```
if size == '11' then See("Related encodings"); end;
if Vd[0] == '1' then Undefined(); end;
let unsigned : boolean = (U == '1');
let long_destination : boolean = TRUE;
let esize : integer{} = 8 << UInt(size);
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);
let elements : integer = 64 DIV esize;
let regs : integer = 1;
```

Related encodings: See [Advanced SIMD data-processing](#) for the T32 instruction set, or [Advanced SIMD data-processing](#) for the A32 instruction set.

Assembler Symbols

<c>

For the “A1” variant: see [Standard assembler syntax fields](#). This encoding must be unconditional.
For the “T1” variant: see [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<dt>

Is the data type for the elements of the operands, encoded in “U:size”:

U	size	<dt>
0	00	S8
0	01	S16
0	10	S32
1	00	U8
1	01	U16
1	10	U32

<Qd>

Is the 128-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field as <Qd>*2.

<Dn>

Is the 64-bit name of the first SIMD&FP source register, encoded in the “N:Vn” field.

<Dm>

Is the 64-bit name of the second SIMD&FP source register, encoded in the “M:Vm” field.

Operation

```
if ConditionPassed() then
  EncodingSpecificOperations();
  CheckAdvSIMDEnabled();
  for r = 0 to regs-1 do
    for e = 0 to elements-1 do
```

```
    let op1elt : bits(esize) = Din(n+r)[e*:esize];
    let op2elt : bits(esize) = Din(m+r)[e*:esize];
    let element1 : integer = if unsigned then UInt(op1elt) else SInt(op1elt);
    let element2 : integer = if unsigned then UInt(op2elt) else SInt(op2elt);
    let absdiff : integer = Abs(element1 - element2);
    if long_destination then
        Q(d>>1)[e*:(2*esize)] = Qin(d>>1)[e*:(2*esize)] + absdiff;
    else
        D(d+r)[e*:esize] = Din(d+r)[e*:esize] + absdiff;
    end;
end;
end;
end;
```

C6.1.19 VABD (floating-point)

Vector Absolute Difference (floating-point) subtracts the elements of one vector from the corresponding elements of another vector, and places the absolute values of the results in the elements of the destination vector.

Operand and result elements are floating-point numbers of the same size.

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be `UNDEFINED`, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding for the 64-bit SIMD vector variant

Applies when ($Q == 0$)

VABD{<c>}{<q>}.<dt> {<Dd>, }<Dn>, <Dm>

Encoding for the 128-bit SIMD vector variant

Applies when ($Q == 1$)

VABD{<c>}{<q>}.<dt> {<Qd>, }<Qn>, <Qm>

Decode for all variants of this encoding

```

if Q == '1' && (Vd[0] == '1' || Vn[0] == '1' || Vm[0] == '1') then Undefined(); end;
if sz == '1' then Undefined(); end;
let esize : integer() = 32;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);
let elements : integer = 64 DIV esize;
let regs : integer = if Q == '0' then 1 else 2;

```

T1

Encoding for the 64-bit SIMD vector variant

Applies when ($Q == 0$)

VABD{<c>}{<q>}.<dt> {<Dd>, }<Dn>, <Dm>

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

VABD{<c>}{<q>}.<dt> {<Qd>, }<Qn>, <Qm>

Decode for all variants of this encoding

```
if Q == '1' && (Vd[0] == '1' || Vn[0] == '1' || Vm[0] == '1') then Undefined(); end;
if sz == '1' then Undefined(); end;
let esize : integer{} = 32;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);
let elements : integer = 64 DIV esize;
let regs : integer = if Q == '0' then 1 else 2;
```

CONSTRAINED UNPREDICTABLE behavior

If sz == '1' && InITBlock(), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

Assembler Symbols

<c>

For the “A1 128-bit SIMD vector” and “A1 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#). This encoding must be unconditional.

For the “T1 128-bit SIMD vector” and “T1 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<dt>

Is the data type for the elements of the vectors, encoded in “sz”:

sz	<dt>
0	F32
1	F16

<Dd>

Is the 64-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field.

<Dn>

Is the 64-bit name of the first SIMD&FP source register, encoded in the “N:Vn” field.

<Dm>

Is the 64-bit name of the second SIMD&FP source register, encoded in the “M:Vm” field.

<Qd>

Is the 128-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field as <Qd>*2.

<Qn>

Is the 128-bit name of the first SIMD&FP source register, encoded in the “N:Vn” field as <Qn>*2.

<Qm>

Is the 128-bit name of the second SIMD&FP source register, encoded in the “M:Vm” field as <Qm>*2.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();
    let fpcr : FPCR_Type = StandardFPCR();
    for r = 0 to regs-1 do
        for e = 0 to elements-1 do
            let op1elt : bits(esize) = D(n+r)[e*:esize];
            let op2elt : bits(esize) = D(m+r)[e*:esize];
            D(d+r)[e*:esize] = FPAbs{esize}(FPSub{esize}(op1elt, op2elt, fpcr), fpcr);
        end;
    end;
end;
```

C6.1.20 VABD (integer)

Vector Absolute Difference (integer) subtracts the elements of one vector from the corresponding elements of another vector, and places the absolute values of the results in the elements of the destination vector.

Operand and result elements are all integers of the same length.

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0)

VABD{<c>}{<q>}.<dt> {<Dd>, }<Dn>, <Dm>

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

VABD{<c>}{<q>}.<dt> {<Qd>, }<Qn>, <Qm>

Decode for all variants of this encoding

```

if size == '11' then Undefined(); end;
if Q == '1' && (Vd[0] == '1' || Vn[0] == '1' || Vm[0] == '1') then Undefined(); end;
let unsigned : boolean = (U == '1');
let long_destination : boolean = FALSE;
let esize : integer{} = 8 << UInt(size);
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);
let elements : integer = 64 DIV esize;
let regs : integer = if Q == '0' then 1 else 2;

```

T1

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0)

VABD{<c>}{<q>}.<dt> {<Dd>, }<Dn>, <Dm>

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

VABD{<c>}{<q>}.<dt> {<Qd>, }<Qn>, <Qm>

Decode for all variants of this encoding

```
if size == '11' then Undefined(); end;
if Q == '1' && (Vd[0] == '1' || Vn[0] == '1' || Vm[0] == '1') then Undefined(); end;
let unsigned : boolean = (U == '1');
let long_destination : boolean = FALSE;
let esize : integer{} = 8 << UInt(size);
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);
let elements : integer = 64 DIV esize;
let regs : integer = if Q == '0' then 1 else 2;
```

Assembler Symbols

<c>

For the “A1 128-bit SIMD vector” and “A1 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#). This encoding must be unconditional.

For the “T1 128-bit SIMD vector” and “T1 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<dt>

Is the data type for the elements of the operands, encoded in “U:size”:

U	size	<dt>
0	00	S8
0	01	S16
0	10	S32
1	00	U8
1	01	U16
1	10	U32

<Dd>

Is the 64-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field.

<Dn>

Is the 64-bit name of the first SIMD&FP source register, encoded in the “N:Vn” field.

<Dm>

Is the 64-bit name of the second SIMD&FP source register, encoded in the “M:Vm” field.

<Qd>

Is the 128-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field as <Qd>*2.

<Qn>

Is the 128-bit name of the first SIMD&FP source register, encoded in the “N:Vn” field as <Qn>*2.

<Qm>

Is the 128-bit name of the second SIMD&FP source register, encoded in the “M:Vm” field as <Qm>*2.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();
    for r = 0 to regs-1 do
        for e = 0 to elements-1 do
            let op1elt : bits(esize) = Din(n+r)[e*:esize];
            let op2elt : bits(esize) = Din(m+r)[e*:esize];
            let element1 : integer = if unsigned then UInt(op1elt) else SInt(op1elt);
            let element2 : integer = if unsigned then UInt(op2elt) else SInt(op2elt);
            let absdiff : integer = Abs(element1 - element2);
            if long_destination then
                Q(d>>1)[e*:(2*esize)] = absdiff[2*esize-1:0];
            else
                D(d+r)[e*:esize] = absdiff[esize-1:0];
            end;
        end;
    end;
end;
```

C6.1.21 VABDL (integer)

Vector Absolute Difference Long (integer) subtracts the elements of one vector from the corresponding elements of another vector, and places the absolute values of the results in the elements of the destination vector.

Operand elements are all integers of the same length, and the result elements are double the length of the operands.

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

VABDL{<c>}{<q>}.<dt> <Qd>, <Dn>, <Dm>

Decode for this encoding

```

if size == '11' then See("Related encodings"); end;
if Vd[0] == '1' then Undefined(); end;
let unsigned : boolean = (U == '1');
let long_destination : boolean = TRUE;
let esize : integer{} = 8 << UInt(size);
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);
let elements : integer = 64 DIV esize;
let regs : integer = 1;

```

T1

Encoding

VABDL{<c>}{<q>}.<dt> <Qd>, <Dn>, <Dm>

Decode for this encoding

```
if size == '11' then See("Related encodings"); end;
if Vd[0] == '1' then Undefined(); end;
let unsigned : boolean = (U == '1');
let long_destination : boolean = TRUE;
let esize : integer{} = 8 << UInt(size);
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);
let elements : integer = 64 DIV esize;
let regs : integer = 1;
```

Related encodings: See [Advanced SIMD data-processing](#) for the T32 instruction set, or [Advanced SIMD data-processing](#) for the A32 instruction set.

Assembler Symbols

<c>

For the “A1” variant: see [Standard assembler syntax fields](#). This encoding must be unconditional.
For the “T1” variant: see [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<dt>

Is the data type for the elements of the operands, encoded in “U:size”:

U	size	<dt>
0	00	S8
0	01	S16
0	10	S32
1	00	U8
1	01	U16
1	10	U32

<Qd>

Is the 128-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field as <Qd>*2.

<Dn>

Is the 64-bit name of the first SIMD&FP source register, encoded in the “N:Vn” field.

<Dm>

Is the 64-bit name of the second SIMD&FP source register, encoded in the “M:Vm” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();
    for r = 0 to regs-1 do
        for e = 0 to elements-1 do
```

```
    let op1elt : bits(esize) = Din(n+r)[e*:esize];
    let op2elt : bits(esize) = Din(m+r)[e*:esize];
    let element1 : integer = if unsigned then UInt(op1elt) else SInt(op1elt);
    let element2 : integer = if unsigned then UInt(op2elt) else SInt(op2elt);
    let absdiff : integer = Abs(element1 - element2);
    if long_destination then
        Q(d>>1)[e*:(2*esize)] = absdiff[2*esize-1:0];
    else
        D(d+r)[e*:esize] = absdiff[esize-1:0];
    end;
end;
end;
end;
```

C6.1.22 VABS

Vector Absolute takes the absolute value of each element in a vector, and places the results in a second vector. The floating-point version only clears the sign bit.

Depending on settings in the [CPACR](#), [NSACR](#), [HCPTR](#), and [FPEXC](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#) and [A2](#)) and T32 ([T1](#) and [T2](#)).

A1

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0)

VABS{<c>}{<q>}.<dt> <Dd>, <Dm>

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

VABS{<c>}{<q>}.<dt> <Qd>, <Qm>

Decode for all variants of this encoding

```

if size == '11' || (F == '1' && size != '10') then Undefined(); end;
if Q == '1' && (Vd[0] == '1' || Vm[0] == '1') then Undefined(); end;
let advsimd : boolean = TRUE;
let floating_point : boolean = (F == '1');
let esize : integer{} = 8 << UInt(size);
let elements : integer = 64 DIV esize;
let d : integer = UInt(D::Vd);
let m : integer = UInt(M::Vm);
let regs : integer = if Q == '0' then 1 else 2;

```

A2

Encoding for the Single-precision scalar variant

Applies when (size == 10)

VABS{<c>}{<q>}.F32 <Sd>, <Sm>

Encoding for the Double-precision scalar variant

Applies when (size == 11)

VABS{<c>}{<q>}.F64 <Dd>, <Dm>

Decode for all variants of this encoding

```

if FPSCR().Len != '000' || FPSCR().Stride != '00' then Undefined(); end;
if size != '1x' then Undefined(); end;
let advsimd : boolean = FALSE;
let esize : integer{} = 8 << UInt(size);
let d : integer = if size == '1l' then UInt(D::Vd) else UInt(Vd::D);
let m : integer = if size == '1l' then UInt(M::Vm) else UInt(Vm::M);
let floating_point : boolean = ARBITRARY : boolean;
let regs : integer = ARBITRARY : integer;
let elements : integer = ARBITRARY : integer;

```

CONSTRAINED UNPREDICTABLE behavior

If `size == '01' && cond != '1110'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

T1

Encoding for the 64-bit SIMD vector variant

Applies when ($Q == 0$)

VABS{<c>}{<q>},<dt> <Dd>, <Dm>

Encoding for the 128-bit SIMD vector variant

Applies when ($Q == 1$)

$$\text{VABS}\{\langle c \rangle\}\{\langle q \rangle\}.\langle dt \rangle \quad \langle Qd \rangle, \quad \langle Qm \rangle$$

Decode for all variants of this encoding

```

if size == '11' || (F == '1' && size != '10') then Undefined(); end;
if Q == '1' && (Vd[0] == '1' || Vm[0] == '1') then Undefined(); end;
let advsimd : boolean = TRUE;
let floating_point : boolean = (F == '1');
let esize : integer{} = 8 << UInt(size);
let elements : integer = 64 DIV esize;
let d : integer = UInt(D::Vd);
let m : integer = UInt(M::Vm);
let regs : integer = if Q == '0' then 1 else 2;

```

CONSTRAINED UNPREDICTABLE behavior

If `F == '1' && size == '01' && InITBlock()`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

T2

Encoding for the Single-precision scalar variant

Applies when `(size == 10)`

VABS{<c>}{<q>}.F32 <Sd>, <Sm>

Encoding for the Double-precision scalar variant

Applies when `(size == 11)`

VABS{<c>}{<q>}.F64 <Dd>, <Dm>

Decode for all variants of this encoding

```

if FPSCR().Len != '000' || FPSCR().Stride != '00' then Undefined(); end;
if size != '1x' then Undefined(); end;
let advsimd : boolean = FALSE;
let esize : integer{} = 8 << UInt(size);
let d : integer = if size == '11' then UInt(D::Vd) else UInt(Vd::D);
let m : integer = if size == '11' then UInt(M::Vm) else UInt(Vm::M);
let floating_point : boolean = ARBITRARY : boolean;
let regs : integer = ARBITRARY : integer;
let elements : integer = ARBITRARY : integer;

```

CONSTRAINED UNPREDICTABLE behavior

If `size == '01' && InITBlock()`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

Assembler Symbols

<c>

For the “A1 128-bit SIMD vector” and “A1 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#). This encoding must be unconditional.

For the “A2 Double-precision scalar”, “A2 Single-precision scalar”, “T1 128-bit SIMD vector”, “T1 64-bit SIMD vector”, “T2 Double-precision scalar”, and “T2 Single-precision scalar” variants: see [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<dt>

Is the data type for the elements of the vectors, encoded in “F:size”:

F	size	<dt>
0	00	S8
0	01	S16
0	10	S32
1	01	F16
1	10	F32

<Dd>

Is the 64-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field.

<Dm>

Is the 64-bit name of the SIMD&FP source register, encoded in the “M:Vm” field.

<Qd>

Is the 128-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field as <Qd>*2.

<Qm>

Is the 128-bit name of the SIMD&FP source register, encoded in the “M:Vm” field as <Qm>*2.

<Sd>

Is the 32-bit name of the SIMD&FP destination register, encoded in the “Vd:D” field.

<Sm>

Is the 32-bit name of the SIMD&FP source register, encoded in the “Vm:M” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDOrVFPEEnabled(TRUE, advsimd);
    if advsimd then // Advanced SIMD instruction
        let fpcr : FPCR_Type = StandardFPCR();
        for r = 0 to regs-1 do
            for e = 0 to elements-1 do
                if floating_point then
                    D(d+r)[e*:esize] = FPAbs{esize}(D(m+r)[e*:esize], fpcr);
                else
                    let result : integer = Abs(SInt(D(m+r)[e*:esize]));
                    D(d+r)[e*:esize] = result[esize-1:0];
                end;
            end;
        end;
    else // VFP instruction
        let fpcr : FPCR_Type = EffectiveFPCR();
        case esize of
```

```
        when 32 => S(d) = FPAbs{32}(S(m), fpcr);  
        when 64 => D(d) = FPAbs{64}(D(m), fpcr);  
    end;  
end;  
end;
```

C6.1.23 VACGE

Vector Absolute Compare Greater Than or Equal takes the absolute value of each element in a vector, and compares it with the absolute value of the corresponding element of a second vector. If the first is greater than or equal to the second, the corresponding element in the destination vector is set to all ones. Otherwise, it is set to all zeros.

The operands and result can be quadword or doubleword vectors. They must all be the same size.

The operand vector elements are floating-point numbers. The result vector elements are the same size as the operand vector elements.

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

This instruction is used by the pseudo-instruction [VACLE](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0)

VACGE{<c>}{<q>}.<dt> {<Dd>, }<Dn>, <Dm>

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

VACGE{<c>}{<q>}.<dt> {<Qd>, }<Qn>, <Qm>

Decode for all variants of this encoding

```

if Q == '1' && (Vd[0] == '1' || Vn[0] == '1' || Vm[0] == '1') then Undefined(); end;
if sz == '1' then Undefined(); end;
let or_equal : boolean = (op == '0');
let esize : integer{} = 32;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);
let elements : integer = 64 DIV esize;
let regs : integer = if Q == '0' then 1 else 2;

```

T1

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0)

VACGE{<c>}{<q>}.<dt> {<Dd>, }<Dn>, <Dm>

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

VACGE{<c>}{<q>}.<dt> {<Qd>, }<Qn>, <Qm>

Decode for all variants of this encoding

```
if Q == '1' && (Vd[0] == '1' || Vn[0] == '1' || Vm[0] == '1') then Undefined(); end;
if sz == '1' then Undefined(); end;
let or_equal : boolean = (op == '0');
let esize : integer{} = 32;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);
let elements : integer = 64 DIV esize;
let regs : integer = if Q == '0' then 1 else 2;
```

CONSTRAINED UNPREDICTABLE behavior

If sz == '1' && InITBlock(), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

Is the 64-bit name of the first SIMD&FP source register, encoded in the “N:Vn” field.

<Dm>

Is the 64-bit name of the second SIMD&FP source register, encoded in the “M:Vm” field.

<Qd>

Is the 128-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field as <Qd>*2.

<Qn>

Is the 128-bit name of the first SIMD&FP source register, encoded in the “N:Vn” field as <Qn>*2.

<Qm>

Is the 128-bit name of the second SIMD&FP source register, encoded in the “M:Vm” field as <Qm>*2.

Operation

```

if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();
    let fpcr : FPCR_Type = StandardFPCR();
    for r = 0 to regs-1 do
        for e = 0 to elements-1 do
            let op1 : bits(esize) = FPAbs{}(D(n+r)[e*:esize], fpcr);
            let op2 : bits(esize) = FPAbs{}(D(m+r)[e*:esize], fpcr);
            var test_passed : boolean;
            if or_equal then
                test_passed = FPCompareGE{esize}(op1, op2, fpcr);
            else
                test_passed = FPCompareGT{esize}(op1, op2, fpcr);
            end;
            D(d+r)[e*:esize] = if test_passed then Ones{esize} else Zeros{esize};
        end;
    end;
end;

```

C6.1.24 VACGT

Vector Absolute Compare Greater Than takes the absolute value of each element in a vector, and compares it with the absolute value of the corresponding element of a second vector. If the first is greater than the second, the corresponding element in the destination vector is set to all ones. Otherwise, it is set to all zeros.

The operands and result can be quadword or doubleword vectors. They must all be the same size.

The operand vector elements are floating-point numbers. The result vector elements are the same size as the operand vector elements.

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

This instruction is used by the pseudo-instruction [VACLT](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0)

VACGT{<c>}{<q>}.<dt> {<Dd>, }<Dn>, <Dm>

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

VACGT{<c>}{<q>}.<dt> {<Qd>, }<Qn>, <Qm>

Decode for all variants of this encoding

```

if Q == '1' && (Vd[0] == '1' || Vn[0] == '1' || Vm[0] == '1') then Undefined(); end;
if sz == '1' then Undefined(); end;
let or_equal : boolean = (op == '0');
let esize : integer{} = 32;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);
let elements : integer = 64 DIV esize;
let regs : integer = if Q == '0' then 1 else 2;

```

T1

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0)

VACGT{<c>}{<q>}.<dt> {<Dd>, }<Dn>, <Dm>

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

VACGT{<c>}{<q>}.<dt> {<Qd>, }<Qn>, <Qm>

Decode for all variants of this encoding

```
if Q == '1' && (Vd[0] == '1' || Vn[0] == '1' || Vm[0] == '1') then Undefined(); end;
if sz == '1' then Undefined(); end;
let or_equal : boolean = (op == '0');
let esize : integer{} = 32;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);
let elements : integer = 64 DIV esize;
let regs : integer = if Q == '0' then 1 else 2;
```

CONSTRAINED UNPREDICTABLE behavior

If sz == '1' && InITBlock(), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

Assembler Symbols

<c>

For the “A1 128-bit SIMD vector” and “A1 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#). This encoding must be unconditional.

For the “T1 128-bit SIMD vector” and “T1 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<dt>

Is the data type for the elements of the vectors, encoded in “sz”:

sz	<dt>
0	F32
1	F16

<Dd>

Is the 64-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field.

<Dn>

Is the 64-bit name of the first SIMD&FP source register, encoded in the “N:Vn” field.

<Dm>

Is the 64-bit name of the second SIMD&FP source register, encoded in the “M:Vm” field.

<Qd>

Is the 128-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field as <Qd>*2.

<Qn>

Is the 128-bit name of the first SIMD&FP source register, encoded in the “N:Vn” field as <Qn>*2.

<Qm>

Is the 128-bit name of the second SIMD&FP source register, encoded in the “M:Vm” field as <Qm>*2.

Operation

```

if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();
    let fpcr : FPCR_Type = StandardFPCR();
    for r = 0 to regs-1 do
        for e = 0 to elements-1 do
            let op1 : bits(esize) = FPAbs{}(D(n+r)[e*:esize], fpcr);
            let op2 : bits(esize) = FPAbs{}(D(m+r)[e*:esize], fpcr);
            var test_passed : boolean;
            if or_equal then
                test_passed = FPCompareGE{esize}(op1, op2, fpcr);
            else
                test_passed = FPCompareGT{esize}(op1, op2, fpcr);
            end;
            D(d+r)[e*:esize] = if test_passed then Ones{esize} else Zeros{esize};
        end;
    end;
end;

```

C6.1.25 VACLE

Vector Absolute Compare Less Than or Equal takes the absolute value of each element in a vector, and compares it with the absolute value of the corresponding element of a second vector. If the first is less than or equal to the second, the corresponding element in the destination vector is set to all ones. Otherwise, it is set to all zeros.

This is a pseudo-instruction of [VACGE](#). This means:

- The encodings in this description are named to match the encodings of [VACGE](#).
- The assembler syntax is used only for assembly, and is not used on disassembly.
- The description of [VACGE](#) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0)

VACLE{<c>}{<q>}.<dt> {<Dd>, }<Dn>, <Dm>

is equivalent to

VACGE{<c>}{<q>}.<dt> <Dd>, <Dm>, <Dn>

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

VACLE{<c>}{<q>}.<dt> {<Qd>, }<Qn>, <Qm>

is equivalent to

VACGE{<c>}{<q>}.<dt> <Qd>, <Qm>, <Qn>

T1

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0)

VACLE{<c>}{<q>}.<dt> {<Dd>, }<Dn>, <Dm>

is equivalent to

VACGE{<c>}{<q>}.<dt> <Dd>, <Dm>, <Dn>

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

VACLE{<c>}{<q>}.<dt> {<Qd>, }<Qn>, <Qm>

is equivalent to

VACGE{<c>}{<q>}.<dt> <Qd>, <Qm>, <Qn>

Assembler Symbols

<c>

For the “A1 128-bit SIMD vector” and “A1 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#).
This encoding must be unconditional.

For the “T1 128-bit SIMD vector” and “T1 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<dt>

Is the data type for the elements of the vectors, encoded in “sz”:

sz	<dt>
0	F32
1	F16

<Dd>

Is the 64-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field.

<Dn>

Is the 64-bit name of the first SIMD&FP source register, encoded in the “N:Vn” field.

<Dm>

Is the 64-bit name of the second SIMD&FP source register, encoded in the “M:Vm” field.

<Qd>

Is the 128-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field as <Qd>*2.

<Qn>

Is the 128-bit name of the first SIMD&FP source register, encoded in the “N:Vn” field as <Qn>*2.

<Qm>

Is the 128-bit name of the second SIMD&FP source register, encoded in the “M:Vm” field as <Qm>*2.

Operation

The description of [VACGE](#) gives the operational pseudocode for this instruction.

C6.1.26 VACLT

Vector Absolute Compare Less Than takes the absolute value of each element in a vector, and compares it with the absolute value of the corresponding element of a second vector. If the first is less than the second, the corresponding element in the destination vector is set to all ones. Otherwise, it is set to all zeros.

This is a pseudo-instruction of [VACGT](#). This means:

- The encodings in this description are named to match the encodings of [VACGT](#).
- The assembler syntax is used only for assembly, and is not used on disassembly.
- The description of [VACGT](#) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0)

VACLT{<c>}{<q>}.<dt> {<Dd>, }<Dn>, <Dm>

is equivalent to

VACGT{<c>}{<q>}.<dt> <Dd>, <Dm>, <Dn>

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

VACLT{<c>}{<q>}.<dt> {<Qd>, }<Qn>, <Qm>

is equivalent to

VACGT{<c>}{<q>}.<dt> <Qd>, <Qm>, <Qn>

T1

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0)

VACLT{<c>}{<q>}.<dt> {<Dd>, }<Dn>, <Dm>

is equivalent to

VACGT{<c>}{<q>}.<dt> <Dd>, <Dm>, <Dn>

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

VACLT{<c>}{<q>}.<dt> {<Qd>, }<Qn>, <Qm>

is equivalent to

VACGT{<c>}{<q>}.<dt> <Qd>, <Qm>, <Qn>

Assembler Symbols

<c>

For the “A1 128-bit SIMD vector” and “A1 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#).
This encoding must be unconditional.

For the “T1 128-bit SIMD vector” and “T1 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<dt>

Is the data type for the elements of the vectors, encoded in “sz”:

sz	<dt>
0	F32
1	F16

<Dd>

Is the 64-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field.

<Dn>

Is the 64-bit name of the first SIMD&FP source register, encoded in the “N:Vn” field.

<Dm>

Is the 64-bit name of the second SIMD&FP source register, encoded in the “M:Vm” field.

<Qd>

Is the 128-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field as <Qd>*2.

<Qn>

Is the 128-bit name of the first SIMD&FP source register, encoded in the “N:Vn” field as <Qn>*2.

<Qm>

Is the 128-bit name of the second SIMD&FP source register, encoded in the “M:Vm” field as <Qm>*2.

Operation

The description of [VACGT](#) gives the operational pseudocode for this instruction.

C6.1.27 VADD (floating-point)

Vector Add (floating-point) adds corresponding elements in two vectors, and places the results in the destination vector.

Depending on settings in the [CPACR](#), [NSACR](#), [HCPTR](#), and [FPXEC](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#) and [A2](#)) and T32 ([T1](#) and [T2](#)).

A1

Encoding for the 64-bit SIMD vector variant

Applies when ($Q == 0$)

VADD{<c>}{<q>}.<dt> {<Dd>, }<Dn>, <Dm>

Encoding for the 128-bit SIMD vector variant

Applies when ($Q == 1$)

$$\text{VADD}\{\langle c \rangle\}\{\langle q \rangle\}.\langle dt \rangle \quad \{\langle Qd \rangle, \} \langle Qn \rangle, \langle Qm \rangle$$

Decode for all variants of this encoding

```

if Q == '1' && (Vd[0] == '1' || Vn[0] == '1' || Vm[0] == '1') then Undefined(); end;
if sz == '1' then Undefined(); end;
let advsimd : boolean = TRUE;
let esize : integer{} = 32 >> UInt(sz);
let elements : integer = 64 DIV esize;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);
let regs : integer = if Q == '0' then 1 else 2;

```

A2

Encoding for the Single-precision scalar variant

Applies when (size == 10)

```
VADD{<c>}{<q>}.F32 {<Sd>, }<Sn>, <Sm>
```

Encoding for the Double-precision scalar variant

Applies when (size == 11)

VADD{<c>} {<q>}.F64 {<Dd>, }<Dn>, <Dm>

Decode for all variants of this encoding

```

if FPSCR().Len != '000' || FPSCR().Stride != '00' then Undefined(); end;
if size != '1x' then Undefined(); end;
let advsimd : boolean = FALSE;
let esize : integer{} = 8 << UInt(size);
let d : integer = if size == '11' then UInt(D::Vd) else UInt(Vd::D);
let n : integer = if size == '11' then UInt(N::Vn) else UInt(Vn::N);
let m : integer = if size == '11' then UInt(M::Vm) else UInt(Vm::M);
let regs : integer = ARBITRARY : integer;
let elements : integer = ARBITRARY : integer;

```

CONSTRAINED UNPREDICTABLE behavior

If `size == '01' && cond != '1110'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

T1

Encoding for the 64-bit SIMD vector variant

Applies when ($Q == 0$)

VADD{<c>}{<q>}.<dt> {<Dd>, }<Dn>, <Dm>

Encoding for the 128-bit SIMD vector variant

Applies when ($Q == 1$)

$$\text{VADD}\{\langle c \rangle\}\{\langle q \rangle\}.\langle dt \rangle \quad \{\langle Qd \rangle, \} \langle Qn \rangle, \langle Qm \rangle$$

Decode for all variants of this encoding

```

if Q == '1' && (Vd[0] == '1' || Vn[0] == '1' || Vm[0] == '1') then Undefined(); end;
if sz == '1' then Undefined(); end;
let advsimd : boolean = TRUE;
let esize : integer{} = 32 >> UInt(sz);
let elements : integer = 64 DIV esize;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);
let regs : integer = if Q == '0' then 1 else 2;

```

CONSTRAINED UNPREDICTABLE behavior

If `sz == '1'` && `InITBlock()`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

T2

Encoding for the Single-precision scalar variant

Applies when `(size == 10)`

VADD{<c>}{<q>}.F32 {<Sd>, }<Sn>, <Sm>

Encoding for the Double-precision scalar variant

Applies when `(size == 11)`

VADD{<c>}{<q>}.F64 {<Dd>, }<Dn>, <Dm>

Decode for all variants of this encoding

```

if FPSCR().Len != '000' || FPSCR().Stride != '00' then Undefined(); end;
if size != '1x' then Undefined(); end;
let advsimd : boolean = FALSE;
let esize : integer{} = 8 << UInt(size);
let d : integer = if size == '11' then UInt(D::Vd) else UInt(Vd::D);
let n : integer = if size == '11' then UInt(N::Vn) else UInt(Vn::N);
let m : integer = if size == '11' then UInt(M::Vm) else UInt(Vm::M);
let regs : integer = ARBITRARY : integer;
let elements : integer = ARBITRARY : integer;

```

CONSTRAINED UNPREDICTABLE behavior

If `size == '01'` && `InITBlock()`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

Assembler Symbols

<c>

For the “A1 128-bit SIMD vector” and “A1 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#). This encoding must be unconditional.

For the “A2 Double-precision scalar”, “A2 Single-precision scalar”, “T1 128-bit SIMD vector”, “T1 64-bit SIMD vector”, “T2 Double-precision scalar”, and “T2 Single-precision scalar” variants: see [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<dt>

Is the data type for the elements of the vectors, encoded in “sz”:

sz	<dt>
0	F32
1	F16

<Dd>

Is the 64-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field.

<Dn>

Is the 64-bit name of the first SIMD&FP source register, encoded in the “N:Vn” field.

<Dm>

Is the 64-bit name of the second SIMD&FP source register, encoded in the “M:Vm” field.

<Qd>

Is the 128-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field as <Qd>*2.

<Qn>

Is the 128-bit name of the first SIMD&FP source register, encoded in the “N:Vn” field as <Qn>*2.

<Qm>

Is the 128-bit name of the second SIMD&FP source register, encoded in the “M:Vm” field as <Qm>*2.

<Sd>

Is the 32-bit name of the SIMD&FP destination register, encoded in the “Vd:D” field.

<Sn>

Is the 32-bit name of the first SIMD&FP source register, encoded in the “Vn:N” field.

<Sm>

Is the 32-bit name of the second SIMD&FP source register, encoded in the “Vm:M” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDOrVFPEEnabled(TRUE, advsimd);
    if advsimd then // Advanced SIMD instruction
        let fpcr : FPCR_Type = StandardFPCR();
        for r = 0 to regs-1 do
            for e = 0 to elements-1 do
                D(d+r)[e*:esize] = FPAdd{esize}(D(n+r)[e*:esize], D(m+r)[e*:esize], fpcr);
            end;
        end;
    else // VFP instruction
```

```
    let fpcr : FPCR_Type = EffectiveFPCR();  
    case esize of  
    when 32 =>  
        S(d) = FPAdd{32}(S(n), S(m), fpcr);

<Qm>

Is the 128-bit name of the second SIMD&FP source register, encoded in the “M:Vm” field as <Qm>*2.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();
    for r = 0 to regs-1 do
        for e = 0 to elements-1 do
            D(d+r)[e*:esize] = D(n+r)[e*:esize] + D(m+r)[e*:esize];
        end;
    end;
end;
```

C6.1.29 VADDHN

Vector Add and Narrow, returning High Half adds corresponding elements in two quadword vectors, and places the most significant half of each result in a doubleword vector. The results are truncated. For rounded results, see [VRADDHN](#).

The operand elements can be 16-bit, 32-bit, or 64-bit integers. There is no distinction between signed and unsigned integers.

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

T1

Encoding

VADDHN{<c>}{<q>}.<dt> <Dd>, <Qn>, <Qm>

Decode for this encoding

```

if size == '11' then See("Related encodings"); end;
if Vn[0] == '1' || Vm[0] == '1' then Undefined(); end;
let esize : integer{} = 8 << UInt(size);
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);
let elements : integer = 64 DIV esize;

```

Related encodings: See [Advanced SIMD data-processing](#) for the T32 instruction set, or [Advanced SIMD data-processing](#) for the A32 instruction set.

Assembler Symbols

<c>

For the “A1” variant: see [Standard assembler syntax fields](#). This encoding must be unconditional.

For the “T1” variant: see [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<dt>

Is the data type for the elements of the operands, encoded in “size”:

size	<dt>
00	I16
01	I32
10	I64

<Dd>

Is the 64-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field.

<Qn>

Is the 128-bit name of the first SIMD&FP source register, encoded in the “N:Vn” field as <Qn>*2.

<Qm>

Is the 128-bit name of the second SIMD&FP source register, encoded in the “M:Vm” field as <Qm>*2.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();
    for e = 0 to elements-1 do
        let result : bits(2*esize) = Qin(n>>1)[e:(2*esize)] + Qin(m>>1)[e:(2*esize)];
        D(d)[e*:esize] = result[2*esize-1:esize];
    end;
end;
```

C6.1.30 VADDL

Vector Add Long adds corresponding elements in two doubleword vectors, and places the results in a quadword vector. Before adding, it sign-extends or zero-extends the elements of both operands.

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

31	28	27	26	25	24	23	22	21	20	19	16	15	12	11	9	8	7	6	5	4	3	0		
1	1	1	1	0	0	1	U	1	D	!=11	Vn		Vd		0	0	0	0	N	0	M	0	Vm	
size											op													

Encoding

VADDL{<c>}{<q>}.<dt> <Qd>, <Dn>, <Dm>

Decode for this encoding

```

if size == '11' then See("Related encodings"); end;
if Vd[0] == '1' || (op == '1' && Vn[0] == '1') then Undefined(); end;
let unsigned : boolean = (U == '1');
let is_vaddw : boolean = (op == '1');
let esize : integer{} = 8 << UInt(size);
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);
let elements : integer = 64 DIV esize;

```

T1

15	13	12	11	10	9	8	7	6	5	4	3	0	15	12	11	9	8	7	6	5	4	3	0		
1	1	1	U	1	1	1	1	1	D	!=11	Vn		Vd			0	0	0	0	N	0	M	0	Vm	
size											op														

Encoding

VADDL{<c>}{<q>}.<dt> <Qd>, <Dn>, <Dm>

Decode for this encoding

```

if size == '11' then See("Related encodings"); end;
if Vd[0] == '1' || (op == '1' && Vn[0] == '1') then Undefined(); end;
let unsigned : boolean = (U == '1');
let is_vaddw : boolean = (op == '1');
let esize : integer{} = 8 << UInt(size);
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);
let elements : integer = 64 DIV esize;

```

Related encodings: See [Advanced SIMD data-processing](#) for the T32 instruction set, or [Advanced SIMD data-processing](#) for the A32 instruction set.

Assembler Symbols

<c>

For the “A1” variant: see [Standard assembler syntax fields](#). This encoding must be unconditional.

For the “T1” variant: see [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<dt>

Is the data type for the elements of the second operand vector, encoded in “U:size”:

U	size	<dt>
0	00	S8
0	01	S16
0	10	S32
1	00	U8
1	01	U16
1	10	U32

<Qd>

Is the 128-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field as <Qd>*2.

<Dn>

Is the 64-bit name of the first SIMD&FP source register, encoded in the “N:Vn” field.

<Dm>

Is the 64-bit name of the second SIMD&FP source register, encoded in the “M:Vm” field.

Operation

```

if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();
    for e = 0 to elements-1 do
        var element1 : integer;
        if is_vaddw then
            let op1elt : bits(2*esize) = Qin(n>>1)[e*:(2*esize)];
            element1 = if unsigned then UInt(op1elt) else SInt(op1elt);
        else
            let op1elt : bits(esize) = Din(n)[e*:(esize)];
            element1 = if unsigned then UInt(op1elt) else SInt(op1elt);
        end;
        let op2elt : bits(esize) = Din(m)[e*:(esize)];
        let element2 : integer = if unsigned then UInt(op2elt) else SInt(op2elt);
        let result : integer = element1 + element2;
        Q(d>>1)[e*:(2*esize)] = result[2*esize-1:0];
    end;
end;

```

C6.1.31 VADDW

Vector Add Wide adds corresponding elements in one quadword and one doubleword vector, and places the results in a quadword vector. Before adding, it sign-extends or zero-extends the elements of the doubleword operand.

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

31	28	27	26	25	24	23	22	21	20	19	16	15	12	11	9	8	7	6	5	4	3	0		
1	1	1	1	0	0	1	U	1	D	!=11	Vn		Vd		0	0	0	1	N	0	M	0	Vm	
size											op													

Encoding

VADDW{<c>}{<q>}.<dt> {<Qd>, }<Qn>, <Dm>

Decode for this encoding

```

if size == '11' then See("Related encodings"); end;
if Vd[0] == '1' || (op == '1' && Vn[0] == '1') then Undefined(); end;
let unsigned : boolean = (U == '1');
let is_vaddw : boolean = (op == '1');
let esize : integer{} = 8 << UInt(size);
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);
let elements : integer = 64 DIV esize;

```

T1

15	13	12	11	10	9	8	7	6	5	4	3	0	15	12	11	9	8	7	6	5	4	3	0	
1	1	1	U	1	1	1	1	1	D	!=11	Vn		Vd		0	0	0	1	N	0	M	0	Vm	
size												op												

Encoding

VADDW{<c>}{<q>}.<dt> {<Qd>, }<Qn>, <Dm>

Decode for this encoding

```

if size == '11' then See("Related encodings"); end;
if Vd[0] == '1' || (op == '1' && Vn[0] == '1') then Undefined(); end;
let unsigned : boolean = (U == '1');
let is_vaddw : boolean = (op == '1');
let esize : integer{} = 8 << UInt(size);
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);
let elements : integer = 64 DIV esize;

```

Related encodings: See [Advanced SIMD data-processing](#) for the T32 instruction set, or [Advanced SIMD data-processing](#) for the A32 instruction set.

Assembler Symbols

<c>

For the “A1” variant: see [Standard assembler syntax fields](#). This encoding must be unconditional.

For the “T1” variant: see [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<dt>

Is the data type for the elements of the second operand vector, encoded in “U:size”:

U	size	<dt>
0	00	S8
0	01	S16
0	10	S32
1	00	U8
1	01	U16
1	10	U32

<Qd>

Is the 128-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field as <Qd>*2.

<Qn>

Is the 128-bit name of the first SIMD&FP source register, encoded in the “N:Vn” field as <Qn>*2.

<Dm>

Is the 64-bit name of the second SIMD&FP source register, encoded in the “M:Vm” field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();
    for e = 0 to elements-1 do
        var element1 : integer;
        if is_vaddw then
            let op1elt : bits(2*esize) = Qin(n>>1)[e*:(2*esize)];
            element1 = if unsigned then UInt(op1elt) else SInt(op1elt);
        else
            let op1elt : bits(esize) = Din(n)[e*:esize];
            element1 = if unsigned then UInt(op1elt) else SInt(op1elt);
        end;
        let op2elt : bits(esize) = Din(m)[e*:esize];
        let element2 : integer = if unsigned then UInt(op2elt) else SInt(op2elt);
        let result : integer = element1 + element2;
        Q(d>>1)[e*:(2*esize)] = result[2*esize-1:0];
    end;
end;
```

C6.1.32 VAND (register)

Vector Bitwise AND (register) performs a bitwise AND operation between two registers, and places the result in the destination register.

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0)

VAND{<c>}{<q>}{.<dt>} {<Dd>, }<Dn>, <Dm>

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

VAND{<c>}{<q>}{.<dt>} {<Qd>, }<Qn>, <Qm>

Decode for all variants of this encoding

```

if Q == '1' && (Vd[0] == '1' || Vn[0] == '1' || Vm[0] == '1') then Undefined(); end;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);
let regs : integer = if Q == '0' then 1 else 2;

```

T1

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0)

VAND{<c>}{<q>}{.<dt>} {<Dd>, }<Dn>, <Dm>

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

VAND{<c>}{<q>}{.<dt>} {<Qd>, }<Qn>, <Qm>

Decode for all variants of this encoding

```
if Q == '1' && (Vd[0] == '1' || Vn[0] == '1' || Vm[0] == '1') then Undefined(); end;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);
let regs : integer = if Q == '0' then 1 else 2;
```

Assembler Symbols

<c>

For the “A1 128-bit SIMD vector” and “A1 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#). This encoding must be unconditional.

For the “T1 128-bit SIMD vector” and “T1 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<dt>

An optional data type. It is ignored by assemblers, and does not affect the encoding.

<Dd>

Is the 64-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field.

<Dn>

Is the 64-bit name of the first SIMD&FP source register, encoded in the “N:Vn” field.

<Dm>

Is the 64-bit name of the second SIMD&FP source register, encoded in the “M:Vm” field.

<Qd>

Is the 128-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field as <Qd>*2.

<Qn>

Is the 128-bit name of the first SIMD&FP source register, encoded in the “N:Vn” field as <Qn>*2.

<Qm>

Is the 128-bit name of the second SIMD&FP source register, encoded in the “M:Vm” field as <Qm>*2.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();
    for r = 0 to regs-1 do
        D(d+r) = D(n+r) AND D(m+r);
    end;
end;
```

C6.1.33 VAND (immediate)

Vector Bitwise AND (immediate) performs a bitwise AND between a register value and an immediate value, and returns the result into the destination vector.

This is a pseudo-instruction of [VBIC \(immediate\)](#). This means:

- The encodings in this description are named to match the encodings of [VBIC \(immediate\)](#).
- The assembler syntax is used only for assembly, and is not used on disassembly.
- The description of [VBIC \(immediate\)](#) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

It has encodings from the following instruction sets: A32 ([A1](#) and [A2](#)) and T32 ([T1](#) and [T2](#)).

A1

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0)

VAND{<c>}{<q>}.I32 {<Dd>, }<Dd>, #<imm>

is equivalent to

VBIC{<c>}{<q>}.I32 <Dd>, #~<imm>

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

VAND{<c>}{<q>}.I32 {<Qd>, }<Qd>, #<imm>

is equivalent to

VBIC{<c>}{<q>}.I32 <Qd>, #~<imm>

A2

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0)

VAND{<c>}{<q>}.I16 {<Dd>, }<Dd>, #<imm>

is equivalent to

VBIC{<c>}{<q>}.I16 <Dd>, #~<imm>

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

VAND{<c>}{<q>}.I16 {<Qd>, }<Qd>, #<imm>

is equivalent to

VBIC{<c>}{<q>}.I16 <Qd>, #~<imm>

T1

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0)

VAND{<c>}{<q>}.I32 {<Dd>, }<Dd>, #<imm>

is equivalent to

VBIC{<c>}{<q>}.I32 <Dd>, #~<imm>

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

VAND{<c>}{<q>}.I32 {<Qd>, }<Qd>, #<imm>

is equivalent to

VBIC{<c>}{<q>}.I32 <Qd>, #~<imm>

T2

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0)

VAND{<c>}{<q>}.I16 {<Dd>, }<Dd>, #<imm>

is equivalent to

VBIC{<c>}{<q>}.I16 <Dd>, #~<imm>

Encoding for the 128-bit SIMD vector variant

Applies when ($Q == 1$)

VAND{<c>}{<q>}.I16 {<Qd>, }<Qd>, #<imm>

is equivalent to

VBIC{<c>}{<q>}.I16 <Qd>, #~<imm>

Assembler Symbols

<c>

For the “A1 128-bit SIMD vector”, “A1 64-bit SIMD vector”, “A2 128-bit SIMD vector”, and “A2 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#). This encoding must be unconditional.

For the “T1 128-bit SIMD vector”, “T1 64-bit SIMD vector”, “T2 128-bit SIMD vector”, and “T2 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Dd>

Is the 64-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field.

<imm>

Is a constant of the specified type that is replicated to fill the destination register. For details of the range of constants available and the encoding of <imm>, see [Modified immediate constants in T32 and A32 Advanced SIMD instructions](#).

<Qd>

Is the 128-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field as <Qd>*2.

Operation

The description of [VBIC \(immediate\)](#) gives the operational pseudocode for this instruction.

C6.1.34 VBIC (immediate)

Vector Bitwise Bit Clear (immediate) performs a bitwise AND between a register value and the complement of an immediate value, and returns the result into the destination vector.

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

This instruction is used by the pseudo-instruction [VAND \(immediate\)](#).

It has encodings from the following instruction sets: A32 ([A1](#) and [A2](#)) and T32 ([T1](#) and [T2](#)).

A1

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0)

```
VBIC{<c>}{<q>}.I32 {<Dd>, }<Dd>, #<imm>
```

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

```
VBIC{<c>}{<q>}.I32 {<Qd>, }<Qd>, #<imm>
```

Decode for all variants of this encoding

```
if cmode[0] == '0' || cmode[3:2] == '11' then See("Related encodings"); end;
if Q == '1' && Vd[0] == '1' then Undefined(); end;
let imm64 : bits(64) = AdvSIMDExpandImm('1', cmode, i::imm3::imm4);
let d : integer = UInt(D::Vd);
let regs : integer = if Q == '0' then 1 else 2;
```

A2

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0)

```
VBIC{<c>}{<q>}.I16 {<Dd>, }<Dd>, #<imm>
```

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

```
VBIC{<c>}{<q>}.I16 {<Qd>, }<Qd>, #<imm>
```

Decode for all variants of this encoding

```
if cmode[0] == '0' || cmode[3:2] == '11' then See("Related encodings"); end;
if Q == '1' && Vd[0] == '1' then Undefined(); end;
let imm64 : bits(64) = AdvSIMDEExpandImm('1', cmode, i::imm3::imm4);
let d : integer = UInt(D::Vd);
let regs : integer = if Q == '0' then 1 else 2;
```

T1

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0)

```
VBIC{<c>}{<q>}.I32 {<Dd>, }<Dd>, #<imm>
```

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

```
VBIC{<c>}{<q>}.I32 {<Qd>, }<Qd>, #<imm>
```

Decode for all variants of this encoding

```
if cmode[0] == '0' || cmode[3:2] == '11' then See("Related encodings"); end;
if Q == '1' && Vd[0] == '1' then Undefined(); end;
let imm64 : bits(64) = AdvSIMDEExpandImm('1', cmode, i::imm3::imm4);
let d : integer = UInt(D::Vd);
let regs : integer = if Q == '0' then 1 else 2;
```

T2

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0)

```
VBIC{<c>}{<q>}.I16 {<Dd>, }<Dd>, #<imm>
```

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

```
VBIC{<c>}{<q>}.I16 {<Qd>, }<Qd>, #<imm>
```

Decode for all variants of this encoding

```

if cmode[0] == '0' || cmode[3:2] == '11' then See("Related encodings"); end;
if Q == '1' && Vd[0] == '1' then Undefined(); end;
let imm64 : bits(64) = AdvSIMDExpandImm('1', cmode, i::imm3::imm4);
let d : integer = UInt(D::Vd);
let regs : integer = if Q == '0' then 1 else 2;

```

Related encodings: See [Advanced SIMD one register and modified immediate](#) for the T32 instruction set, or [Advanced SIMD one register and modified immediate](#) for the A32 instruction set.

Assembler Symbols

<c>

For the “A1 128-bit SIMD vector”, “A1 64-bit SIMD vector”, “A2 128-bit SIMD vector”, and “A2 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#). This encoding must be unconditional.

For the “T1 128-bit SIMD vector”, “T1 64-bit SIMD vector”, “T2 128-bit SIMD vector”, and “T2 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Dd>

Is the 64-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field.

<imm>

Is a constant of the specified type that is replicated to fill the destination register. For details of the range of constants available and the encoding of <imm>, see [Modified immediate constants in T32 and A32 Advanced SIMD instructions](#).

<Qd>

Is the 128-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field as <Qd>*2.

The I8, I64, and F32 data types are permitted as pseudo-instructions, if the immediate can be represented by this instruction, and are encoded using a permitted encoding of the I16 or I32 data type.

Operation

```

if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();
    for r = 0 to regs-1 do
        D(d+r) = D(d+r) AND NOT(imm64);
    end;
end;

```

C6.1.35 VBIC (register)

Vector Bitwise Bit Clear (register) performs a bitwise AND between a register value and the complement of a register value, and places the result in the destination register.

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0)

VBIC{<c>}{<q>}{.<dt>} {<Dd>, }<Dn>, <Dm>

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

VBIC{<c>}{<q>}{.<dt>} {<Qd>, }<Qn>, <Qm>

Decode for all variants of this encoding

```

if Q == '1' && (Vd[0] == '1' || Vn[0] == '1' || Vm[0] == '1') then Undefined(); end;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);
let regs : integer = if Q == '0' then 1 else 2;

```

T1

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0)

VBIC{<c>}{<q>}{.<dt>} {<Dd>, }<Dn>, <Dm>

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

VBIC{<c>}{<q>}{.<dt>} {<Qd>, }<Qn>, <Qm>

Decode for all variants of this encoding

```
if Q == '1' && (Vd[0] == '1' || Vn[0] == '1' || Vm[0] == '1') then Undefined(); end;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);
let regs : integer = if Q == '0' then 1 else 2;
```

Assembler Symbols

<q>

See [Standard assembler syntax fields](#).

<dt>

An optional data type. It is ignored by assemblers, and does not affect the encoding.

<Dd>

Is the 64-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field.

<Dn>

Is the 64-bit name of the first SIMD&FP source register, encoded in the “N:Vn” field.

<Dm>

Is the 64-bit name of the second SIMD&FP source register, encoded in the “M:Vm” field.

<Qd>

Is the 128-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field as <Qd>*2.

<Qn>

Is the 128-bit name of the first SIMD&FP source register, encoded in the “N:Vn” field as <Qn>*2.

<Qm>

Is the 128-bit name of the second SIMD&FP source register, encoded in the “M:Vm” field as <Qm>*2.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();
    for r = 0 to regs-1 do
        D(d+r) = D(n+r) AND NOT(D(m+r));
    end;
end;
```

C6.1.36 VBIF

Vector Bitwise Insert if False inserts each bit from the first source register into the destination register if the corresponding bit of the second source register is 0, otherwise leaves the bit in the destination register unchanged.

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0)

VBIF{<c>}{<q>}{.<dt>} {<Dd>, }<Dn>, <Dm>

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

VBIF{<c>}{<q>}{.<dt>} {<Qd>, }<Qn>, <Qm>

Decode for all variants of this encoding

```

if Q == '1' && (Vd[0] == '1' || Vn[0] == '1' || Vm[0] == '1') then Undefined(); end;
if op == '00' then See("VEOR"); end;
var operation : VBitOps;
if op == '01' then operation = VBitOps_VBSL; end;
if op == '10' then operation = VBitOps_VBIT; end;
if op == '11' then operation = VBitOps_VBIF; end;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);
let regs : integer = if Q == '0' then 1 else 2;

```

T1

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0)

VBIF{<c>}{<q>}{.<dt>} {<Dd>, }<Dn>, <Dm>

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

VBITF{<c>}{<q>}{.<dt>} {<Qd>, }<Qn>, <Qm>

Decode for all variants of this encoding

```
if Q == '1' && (Vd[0] == '1' || Vn[0] == '1' || Vm[0] == '1') then Undefined(); end;
if op == '00' then See("VEOR"); end;
var operation : VBitOps;
if op == '01' then operation = VBitOps_VBSL; end;
if op == '10' then operation = VBitOps_VBIT; end;
if op == '11' then operation = VBitOps_VBIT; end;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);
let regs : integer = if Q == '0' then 1 else 2;
```

Assembler Symbols

<c>

For the “A1 128-bit SIMD vector” and “A1 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#). This encoding must be unconditional.

For the “T1 128-bit SIMD vector” and “T1 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<dt>

An optional data type. It is ignored by assemblers, and does not affect the encoding.

<Dd>

Is the 64-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field.

<Dn>

Is the 64-bit name of the first SIMD&FP source register, encoded in the “N:Vn” field.

<Dm>

Is the 64-bit name of the second SIMD&FP source register, encoded in the “M:Vm” field.

<Qd>

Is the 128-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field as <Qd>*2.

<Qn>

Is the 128-bit name of the first SIMD&FP source register, encoded in the “N:Vn” field as <Qn>*2.

<Qm>

Is the 128-bit name of the second SIMD&FP source register, encoded in the “M:Vm” field as <Qm>*2.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();
    for r = 0 to regs-1 do
        case operation of
            when VBitOps_VBIF => D(d+r) = (D(d+r) AND D(m+r)) OR (D(n+r) AND NOT(D(m+r)));
            when VBitOps_VBIT => D(d+r) = (D(n+r) AND D(m+r)) OR (D(d+r) AND NOT(D(m+r)));
            when VBitOps_VBSL => D(d+r) = (D(n+r) AND D(d+r)) OR (D(m+r) AND NOT(D(d+r)));
        end;
    end;
end;
```

C6.1.37 VBIT

Vector Bitwise Insert if True inserts each bit from the first source register into the destination register if the corresponding bit of the second source register is 1, otherwise leaves the bit in the destination register unchanged.

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be `UNDEFINED`, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding for the 64-bit SIMD vector variant

Applies when ($Q == 0$)

```
VBIT{<c>}{<q>}{.<dt>}{<Dd>,<Dn>,<Dm>}
```

Encoding for the 128-bit SIMD vector variant

Applies when ($Q == 1$)

```
VBIT{<c>}{<q>}{.<dt>}{<Od>,<On>,<Om>}
```

Decode for all variants of this encoding

```

if Q == '1' && (Vd[0] == '1' || Vn[0] == '1' || Vm[0] == '1') then Undefined(); end;
if op == '00' then See("VEOR"); end;
var operation : VBitOps;

            when VBitOps_VBSL => D(d+r) = (D(n+r) AND D(d+r)) OR (D(m+r) AND NOT(D(d+r)));
        end;
    end;
end;
end;

```

C6.1.39 VCEQ (immediate #0)

Vector Compare Equal to Zero takes each element in a vector, and compares it with zero. If it is equal to zero, the corresponding element in the destination vector is set to all ones. Otherwise, it is set to all zeros.

The operand vector elements are the same type, and are integers or floating-point numbers. The result vector elements are fields the same size as the operand vector elements.

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding for the 64-bit SIMD vector variant

Applies when ($Q == 0$)

```
VCEQ{<c>}{<q>}.<dt> {<Dd>, }<Dm>, #0
```

Encoding for the 128-bit SIMD vector variant

Applies when ($Q == 1$)

```
VCEQ{<c>}{<q>}.<dt> {<Qd>, }<Qm>, #0
```

Decode for all variants of this encoding

```

if size == '11' || (F == '1' && size != '10') then Undefined(); end;
if Q == '1' && (Vd[0] == '1' || Vm[0] == '1') then Undefined(); end;
let floating_point : boolean = (F == '1');
let esize : integer{} = 8 << UInt(size);
let d : integer = UInt(D::Vd);
let m : integer = UInt(M::Vm);
let elements : integer = 64 DIV esize;
let regs : integer = if Q == '0' then 1 else 2;

```

T1

Encoding for the 64-bit SIMD vector variant

Applies when ($Q == 0$)

```
VCEO{<c>}{<q>}.<dt> {<Dd>, }<Dm>, #0
```

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

VCEQ{<c>}{<q>}.<dt> {<Qd>, }<Qm>, #0

Decode for all variants of this encoding

```
if size == '11' || (F == '1' && size != '10') then Undefined(); end;
if Q == '1' && (Vd[0] == '1' || Vm[0] == '1') then Undefined(); end;
let floating_point : boolean = (F == '1');
let esize : integer{} = 8 << UInt(size);
let elements : integer = 64 DIV esize;
let d : integer = UInt(D::Vd);
let m : integer = UInt(M::Vm);
let regs : integer = if Q == '0' then 1 else 2;
```

CONSTRAINED UNPREDICTABLE behavior

If F == '1' && size == '01' && InITBlock(), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

Assembler Symbols

<c>

For the “A1 128-bit SIMD vector” and “A1 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#). This encoding must be unconditional.

For the “T1 128-bit SIMD vector” and “T1 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<dt>

Is the data type for the elements of the operands, encoded in “F:size”:

F	size	<dt>
0	00	I8
0	01	I16
0	10	I32
1	01	F16
1	10	F32

<Dd>

Is the 64-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field.

<Dm>

Is the 64-bit name of the SIMD&FP source register, encoded in the “M:Vm” field.

<Qd>

Is the 128-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field as <Qd>*2.

<Qm>

Is the 128-bit name of the SIMD&FP source register, encoded in the “M:Vm” field as <Qm>*2.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();
    for r = 0 to regs-1 do
        for e = 0 to elements-1 do
            var test_passed : boolean;
            if floating_point then
                let zero : bits(esize) = FPZero({'0'});
                test_passed = FPCompareEQ(esize)(D(m+r)[e*:esize], zero, StandardFPCR());
            else
                test_passed = (D(m+r)[e*:esize] == Zeros(esize));
            end;
            D(d+r)[e*:esize] = if test_passed then Ones(esize) else Zeros(esize);
        end;
    end;
end;
```

C6.1.40 VCEQ (register)

Vector Compare Equal takes each element in a vector, and compares it with the corresponding element of a second vector. If they are equal, the corresponding element in the destination vector is set to all ones. Otherwise, it is set to all zeros.

The operand vector elements are the same type, and are integers or floating-point numbers. The result vector elements are fields the same size as the operand vector elements.

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#) and [A2](#)) and T32 ([T1](#) and [T2](#)).

A1

Encoding for the 64-bit SIMD vector variant

C6.1.41 VCGE (immediate #0)

Vector Compare Greater Than or Equal to Zero takes each element in a vector, and compares it with zero. If it is greater than or equal to zero, the corresponding element in the destination vector is set to all ones. Otherwise, it is set to all zeros.

The operand vector elements are the same type, and are signed integers or floating-point numbers. The result vector elements are fields the same size as the operand vector elements.

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be `UNDEFINED`, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding for the 64-bit SIMD vector variant

Applies when ($Q == 0$)

```
VCGE{<c>}{<q>}.<dt> {<Dd>, }<Dm>, #0
```

Encoding for the 128-bit SIMD vector variant

Applies when ($Q == 1$)

```
VCGE{<c>}{<q>}.<dt> {<Qd>, }<Qm>, #0
```

Decode for all variants of this encoding

```

if size == '1l' || (F == '1' && size != '10') then Undefined(); end;
if Q == '1' && (Vd[0] == '1' || Vm[0] == '1') then Undefined(); end;
let floating_point : boolean = (F == '1');
let esize : integer{} = 8 << UInt(size);
let elements : integer = 64 DIV esize;
let d : integer = UInt(D::Vd);
let m : integer = UInt(M::Vm);
let regs : integer = if Q == '0' then 1 else 2;

```

T1

Encoding for the 64-bit SIMD vector variant

Applies when ($Q == 0$)

```
VCGE{<c>}{<q>}.<dt> {<Dd>, }<Dm>, #0
```

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

VCGE{<c>}{<q>}.<dt> {<Qd>, }<Qm>, #0

Decode for all variants of this encoding

```
if size == '11' || (F == '1' && size != '10') then Undefined(); end;
if Q == '1' && (Vd[0] == '1' || Vm[0] == '1') then Undefined(); end;
let floating_point : boolean = (F == '1');
let esize : integer{} = 8 << UInt(size);
let elements : integer = 64 DIV esize;
let d : integer = UInt(D::Vd);
let m : integer = UInt(M::Vm);
let regs : integer = if Q == '0' then 1 else 2;
```

CONSTRAINED UNPREDICTABLE behavior

If F == '1' && size == '01' && InITBlock(), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

Assembler Symbols

<c>

For the “A1 128-bit SIMD vector” and “A1 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#). This encoding must be unconditional.

For the “T1 128-bit SIMD vector” and “T1 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<dt>

Is the data type for the elements of the operands, encoded in “F:size”:

F	size	<dt>
0	00	S8
0	01	S16
0	10	S32
1	01	F16
1	10	F32

<Dd>

Is the 64-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field.

<Dm>

Is the 64-bit name of the SIMD&FP source register, encoded in the “M:Vm” field.

<Qd>

Is the 128-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field as <Qd>*2.

<Qm>

Is the 128-bit name of the SIMD&FP source register, encoded in the “M:Vm” field as <Qm>*2.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();
    for r = 0 to regs-1 do
        for e = 0 to elements-1 do

                                                                    StandardFPCR());
            end;
        end;
    end;

```

```
        D(d+r)[e*:esize] = if test_passed then Ones{esize} else Zeros{esize};  
    end;  
end;  
end;
```

C6.1.45 VCLE (immediate #0)

Vector Compare Less Than or Equal to Zero takes each element in a vector, and compares it with zero. If it is less than or equal to zero, the corresponding element in the destination vector is set to all ones. Otherwise, it is set to all zeros.

The operand vector elements are the same type, and are signed integers or floating-point numbers. The result vector elements are fields the same size as the operand vector elements.

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be `UNDEFINED`, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding for the 64-bit SIMD vector variant

Applies when ($Q == 0$)

```
VCLE{<c>}{<q>}.<dt> {<Dd>, }<Dm>, #0
```

Encoding for the 128-bit SIMD vector variant

Applies when ($Q == 1$)

```
VCLE{<c>}{<q>}.<dt> {<Qd>, }<Qm>, #0
```

Decode for all variants of this encoding

```

if size == '1l' || (F == '1' && size != '10') then Undefined(); end;
if Q == '1' && (Vd[0] == '1' || Vm[0] == '1') then Undefined(); end;
let floating_point : boolean = (F == '1');
let esize : integer{} = 8 << UInt(size);
let elements : integer = 64 DIV esize;
let d : integer = UInt(D::Vd);
let m : integer = UInt(M::Vm);
let regs : integer = if Q == '0' then 1 else 2;

```

T1

Encoding for the 64-bit SIMD vector variant

Applies when ($Q == 0$)

```
VCLE{<c>}{<q>}.<dt> {<Dd>, }<Dm>, #0
```

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

VCLE{<c>}{<q>}.<dt> {<Qd>, }<Qm>, #0

Decode for all variants of this encoding

```
if size == '11' || (F == '1' && size != '10') then Undefined(); end;
if Q == '1' && (Vd[0] == '1' || Vm[0] == '1') then Undefined(); end;
let floating_point : boolean = (F == '1');
let esize : integer{} = 8 << UInt(size);
let elements : integer = 64 DIV esize;
let d : integer = UInt(D::Vd);
let m : integer = UInt(M::Vm);
let regs : integer = if Q == '0' then 1 else 2;
```

CONSTRAINED UNPREDICTABLE behavior

If F == '1' && size == '01' && InITBlock(), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

Assembler Symbols

<c>

For the “A1 128-bit SIMD vector” and “A1 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#). This encoding must be unconditional.

For the “T1 128-bit SIMD vector” and “T1 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<dt>

Is the data type for the elements of the operands, encoded in “F:size”:

F	size	<dt>
0	00	S8
0	01	S16
0	10	S32
1	01	F16
1	10	F32

<Dd>

Is the 64-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field.

<Dm>

Is the 64-bit name of the SIMD&FP source register, encoded in the “M:Vm” field.

<Qd>

Is the 128-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field as <Qd>*2.

<Qm>

Is the 128-bit name of the SIMD&FP source register, encoded in the “M:Vm” field as <Qm>*2.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();
    for r = 0 to regs-1 do
        for e = 0 to elements-1 do
            var test_passed : boolean;
            if floating_point then
                let zero : bits(esize) = FPZero({'0'});
                test_passed = FPCompareGE(esize)(zero, D(m+r)[e*:esize], StandardFPCR());
            else
                test_passed = (SInt(D(m+r)[e*:esize]) <= 0);
            end;
            D(d+r)[e*:esize] = if test_passed then Ones(esize) else Zeros(esize);
        end;
    end;
end;
```

C6.1.46 VCLE (register)

Vector Compare Less Than or Equal takes each element in a vector, and compares it with the corresponding element of a second vector. If the first is less than or equal to the second, the corresponding element in the destination vector is set to all ones. Otherwise, it is set to all zeros.

This is a pseudo-instruction of [VCGE \(register\)](#). This means:

- The encodings in this description are named to match the encodings of [VCGE \(register\)](#).
- The assembler syntax is used only for assembly, and is not used on disassembly.
- The description of [VCGE \(register\)](#) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

It has encodings from the following instruction sets: A32 ([A1](#) and [A2](#)) and T32 ([T1](#) and [T2](#)).

A1

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0)

VCLE{<c>}{<q>}.<dt> {<Dd>, }<Dn>, <Dm>

is equivalent to

VCGE{<c>}{<q>}.<dt> <Dd>, <Dm>, <Dn>

Is the 128-bit name of the first SIMD&FP source register, encoded in the “N:Vn” field as <Qn>*2.

<Qm>

Is the 128-bit name of the second SIMD&FP source register, encoded in the “M:Vm” field as <Qm>*2.

Operation

The description of [VCGE \(register\)](#) gives the operational pseudocode for this instruction.

C6.1.47 VCLS

Vector Count Leading Sign Bits determines the number of consecutive bits following the topmost bit, that are the same as the topmost bit, in each element in a vector, and places the results in a second vector. The result does not include the topmost bit itself.

The operand vector elements can be any one of 8-bit, 16-bit, or 32-bit signed integers.

The result vector elements are the same data type as the operand vector elements.

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0)

let esize : integer{} = 8 << UInt(size);
let elements : integer = 64 DIV esize;
let d : integer = UInt(D::Vd);
let m : integer = UInt(M::Vm);
let regs : integer = if Q == '0' then 1 else 2;

```

T1

Encoding for the 64-bit SIMD vector variant

Applies when ($Q == 0$)

VCLZ{<c>}{<q>}.<dt> <Dd>, <Dm>

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

VCLZ{<c>}{<q>}.<dt> <Qd>, <Qm>

Decode for all variants of this encoding

```
if size == '11' then Undefined(); end;
if Q == '1' && (Vd[0] == '1' || Vm[0] == '1') then Undefined(); end;
let esize : integer{} = 8 << UInt(size);
let elements : integer = 64 DIV esize;
let d : integer = UInt(D::Vd);
let m : integer = UInt(M::Vm);
let regs : integer = if Q == '0' then 1 else 2;
```

Assembler Symbols

<c>

For the “A1 128-bit SIMD vector” and “A1 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#). This encoding must be unconditional.

For the “T1 128-bit SIMD vector” and “T1 64-bit SIMD vector” variants: see [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<dt>

Is the data type for the elements of the operands, encoded in “size”:

size	<dt>
00	I8
01	I16
10	I32

<Dd>

Is the 64-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field.

<Dm>

Is the 64-bit name of the SIMD&FP source register, encoded in the “M:Vm” field.

<Qd>

Is the 128-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field as <Qd>*2.

<Qm>

Is the 128-bit name of the SIMD&FP source register, encoded in the “M:Vm” field as <Qm>*2.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();
    for r = 0 to regs-1 do
        for e = 0 to elements-1 do
            D(d+r)[e*:esize] = CountLeadingZeroBits(D(m+r)[e*:esize])[esize-1:0];
        end;
    end;
end;
```

C6.1.51 VCMF

Vector Compare compares two floating-point registers, or one floating-point register and zero. It writes the result to the **FPSCR** flags. These are normally transferred to the **PSTATE**.{N, Z, C, V} Condition flags by a subsequent **VMRS** instruction.

This instruction raises an Invalid Operation floating-point exception if either or both of the operands is a signaling NaN.

Depending on settings in the **CPACR**, **NSACR**, and **HCPTR** registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be **UNDEFINED**, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 (**A1** and **A2**) and T32 (**T1** and **T2**).

A1

Encoding for the Single-precision scalar variant

Applies when (size == 10)

`VCMF{<c>}{<q>}.F32 <Sd>, <Sm>`

Encoding for the Double-precision scalar variant

Applies when (size == 11)

`VCMF{<c>}{<q>}.F64 <Dd>, <Dm>`

Decode for all variants of this encoding

```

if size != '1x' then Undefined(); end;
let quiet_nan_exc : boolean = (E == '1');
let with_zero : boolean = FALSE;
let esize : integer{} = 8 << UInt(size);
let d : integer = if size == '11' then UInt(D::Vd) else UInt(Vd::D);
let m : integer = if size == '11' then UInt(M::Vm) else UInt(Vm::M);

```

CONSTRAINED UNPREDICTABLE behavior

If size == '01' && cond != '1110', then one of the following behaviors must occur:

- The instruction is **UNDEFINED**.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as **NOP**. This means it behaves as if it fails the Condition code check.

A2

Encoding for the Single-precision scalar variant

Applies when (size == 10)

VCMP{<c>}{<q>}.F32 <Sd>, #0.0

Encoding for the Double-precision scalar variant

Applies when (size == 11)

VCMP{<c>}{<q>}.F64 <Dd>, #0.0

Decode for all variants of this encoding

```

if size != '1x' then Undefined(); end;
let quiet_nan_exc : boolean = (E == '1');
let with_zero : boolean = TRUE;
let esize : integer{} = 8 << UInt(size);
let d : integer = if size == '11' then UInt(D::Vd) else UInt(Vd::D);
let m : integer = ARBITRARY : integer;

```

CONSTRAINED UNPREDICTABLE behavior

If size == '01' && cond != '1110', then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

T1

Encoding for the Single-precision scalar variant

Applies when (size == 10)

VCMP{<c>}{<q>}.F32 <Sd>, <Sm>

Encoding for the Double-precision scalar variant

Applies when (size == 11)

VCMP{<c>}{<q>}.F64 <Dd>, <Dm>

Decode for all variants of this encoding

```

if size != '1x' then Undefined(); end;
let quiet_nan_exc : boolean = (E == '1');
let with_zero : boolean = FALSE;
let esize : integer{} = 8 << UInt(size);
let d : integer = if size == '11' then UInt(D::Vd) else UInt(Vd::D);
let m : integer = if size == '11' then UInt(M::Vm) else UInt(Vm::M);

```

CONSTRAINED UNPREDICTABLE behavior

If `size == '01' && InITBlock()`, then one of the following behaviors must occur:

- The instruction is `UNDEFINED`.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as `NOP`. This means it behaves as if it fails the Condition code check.

T2

Encoding for the Single-precision scalar variant

Applies when (size == 10)

VCMP{<c>} {<q>}.F32 <Sd>, #0.0

Encoding for the Double-precision scalar variant

Applies when (size == 11)

VCMP{<c>}{<q>}.F64 <Dd>, #0.0

Decode for all variants of this encoding

```

if size != '1x' then Undefined(); end;
let quiet_nan_exc : boolean = (E == '1');
let with_zero : boolean = TRUE;
let esize : integer{} = 8 << UInt(size);
let d : integer = if size == '11' then UInt(D::Vd) else UInt(Vd::D);
let m : integer = ARBITRARY : integer;

```

CONSTRAINED UNPREDICTABLE behavior

If `size == '01' && InITBlock()`, then one of the following behaviors must occur:

- The instruction is `UNDEFINED`.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as `NOP`. This means it behaves as if it fails the Condition code check.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>

See [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<Sd>

Is the 32-bit name of the SIMD&FP destination register, encoded in the “Vd:D” field.

<Sm>

Is the 32-bit name of the SIMD&FP source register, encoded in the “Vm:M” field.

<Dd>

Is the 64-bit name of the SIMD&FP destination register, encoded in the “D:Vd” field.

<Dm>

Is the 64-bit name of the SIMD&FP source register, encoded in the “M:Vm” field.

Operation

```

if ConditionPassed() then
    EncodingSpecificOperations();
    CheckVFPEEnabled(TRUE);
    let fpcr : FPCR_Type = EffectiveFPCR();
    var nzcvc : bits(4);
    case esize of
        when 32 =>
            let op32 : bits(32) = if with_zero then FPZero{32}('0') else S(m);
            nzcvc = FPCompare{32}(S(d), op32, quiet_nan_exc, fpcr);
        when 64 =>
            let op64 : bits(64) = if with_zero then FPZero{64}('0') else D(m);
            nzcvc = FPCompare{64}(D(d), op64, quiet_nan_exc, fpcr);
    end;

    FPSCR()[31:28] = nzcvc; // FPSCR.[N,Z,C,V] set to nzcvc
end;

```

Operational Information

The IEEE 754 standard specifies that the result of a comparison is precisely one of <, ==, >, or unordered. If either or both of the operands is a NaN, they are unordered, and all three of (Operand1 < Operand2), (Operand1 == Operand2), and (Operand1 > Operand2) are false. An unordered comparison sets the [FPSCR](#) condition flags to N=0, Z=0, C=1, and V=1.

C6.1.52 VCMPE

Vector Compare, raising Invalid Operation on NaN compares two floating-point registers, or one floating-point register and zero. It writes the result to the [FPSCR](#) flags. These are normally transferred to the [PSTATE](#).{N, Z, C, V} Condition flags by a subsequent [VMRS](#) instruction.

This instruction raises an Invalid Operation floating-point exception if either or both of the operands is any type of NaN.

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#) and [A2](#)) and T32 ([T1](#) and [T2](#)).

A1

Encoding for the Single-precision scalar variant

Applies when (size == 10)

VCMPE{<c>}{<q>}.F32 <Sd>, <Sm>

Encoding for the Double-precision scalar variant

Applies when (size == 11)

VCMPE{<c>}{<q>}.F64 <Dd>, <Dm>

Decode for all variants of this encoding

```

if size != '1x' then Undefined(); end;
let quiet_nan_exc : boolean = (E == '1');
let with_zero : boolean = FALSE;
let esize : integer{} = 8 << UInt(size);
let d : integer = if size == '11' then UInt(D::Vd) else UInt(Vd::D);
let m : integer = if size == '11' then UInt(M::Vm) else UInt(Vm::M);

```

CONSTRAINED UNPREDICTABLE behavior

If size == '01' && cond != '1110', then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

A2

Encoding for the Single-precision scalar variant

Applies when (size == 10)

VCMPE{<c>}{<q>}.F32 <Sd>, #0.0

Encoding for the Double-precision scalar variant

Applies when (size == 11)

VCMPE{<c>}{<q>}.F64 <Dd>, #0.0

Decode for all variants of this encoding

```

if size != '1x' then Undefined(); end;
let quiet_nan_exc : boolean = (E == '1');
let with_zero : boolean = TRUE;
let esize : integer() = 8 << UInt(size);
let d : integer = if size == '11' then UInt(D::Vd) else UInt(Vd::D);
let m : integer = ARBITRARY : integer;

```

CONSTRAINED UNPREDICTABLE behavior

If size == '01' && cond != '1110', then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

T1

Encoding for the Single-precision scalar variant

Applies when (size == 10)
