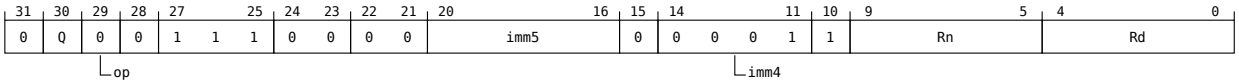
This instruction duplicates the contents of the source general-purpose register into a scalar or each element in a vector, and writes the result to the SIMD&FP destination register.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Advanced SIMD
(FEAT_AdvSIMD)



Encoding

```
DUP <Vd>.<T>, <R><n>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_AdvSIMD) then EndOfDecode(Decode_UNDEF);
if imm5 == 'x0000' then EndOfDecode(Decode_UNDEF);
if imm5 == 'x1000' && Q == '0' then EndOfDecode(Decode_UNDEF);
constant integer size = LowestSetBitNZ(imm5<3:0>);

constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
// imm5<4:size+1> is IGNORED
constant integer esize = 8 << size;
constant integer datasize = 64 << UInt(Q);
```

Assembler Symbols

<**Vd**> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<**T**> Is an arrangement specifier, encoded in "imm5:Q":

imm5	Q	<T>
x0000	x	RESERVED
xxxx1	0	8B
xxxx1	1	16B
xxx10	0	4H
xxx10	1	8H
xx100	0	2S
xx100	1	4S
x1000	0	RESERVED
x1000	1	2D

<**R**> Is the width specifier for the general-purpose source register, encoded in "imm5":

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

imm5	<R>
x0000	RESERVED
xxxx1	W
xxx10	W
xx100	W
x1000	X

Unspecified bits in “imm5” are ignored but should be set to zero by an assembler.

<**n**> Is the number [0-30] of the general-purpose source register or ZR (31), encoded in the “Rn” field.

Operation

```
AArch64.CheckFPAdvSIMDEnabled();
constant bits(esize) element = X[n, esize];
constant integer elements = datasize DIV esize;
bits(datasize) result;

for e = 0 to elements-1
    Elem[result, e, esize] = element;
V[d, datasize] = result;
```

Operational information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

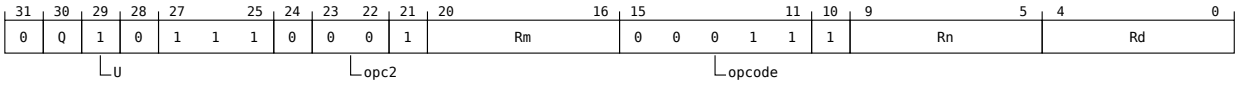
C7.2.34 EOR (vector)

Bitwise exclusive-OR (vector)

This instruction performs a bitwise exclusive-OR operation between the two source SIMD&FP registers, and places the result in the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Three registers of the same type
(FEAT_AdvSIMD)



Encoding

```
EOR <Vd>.<T>, <Vn>.<T>, <Vm>.<T>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_AdvSIMD) then EndOfDecode(Decode_UNDEF);
constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer m = UInt(Rm);
constant integer datasize = 64 << UInt(Q);
```

Assembler Symbols

<**Vd**> Is the name of the SIMD&FP destination register, encoded in the “Rd” field.

<**T**> Is an arrangement specifier, encoded in “Q”:

Q	<T>
0	8B
1	16B

<**Vn**> Is the name of the first SIMD&FP source register, encoded in the “Rn” field.

<**Vm**> Is the name of the second SIMD&FP source register, encoded in the “Rm” field.

Operation

```
AArch64.CheckFPAdvSIMDEnabled();

constant bits(datasize) operand1 = V[m, datasize];
constant bits(datasize) operand2 = Zeros(datasize);
constant bits(datasize) operand3 = Ones(datasize);
constant bits(datasize) operand4 = V[n, datasize];
V[d, datasize] = operand1 EOR ((operand2 EOR operand4) AND operand3);
```

Operational information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

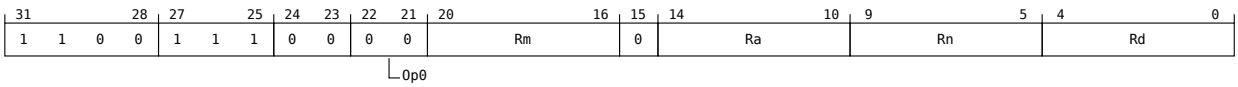
C7.2.35 EOR3

Three-way exclusive-OR

This instruction performs a three-way exclusive-OR of the values in the three source SIMD&FP registers, and writes the result to the destination SIMD&FP register.

Advanced SIMD
(FEAT_SHA3)



Encoding

```
EOR3 <Vd>.16B, <Vn>.16B, <Vm>.16B, <Va>.16B
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_SHA3) then EndOfDecode(Decode_UNDEF);
constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer m = UInt(Rm);
constant integer a = UInt(Ra);
```

Assembler Symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the “Rd” field.

<Vn> Is the name of the first SIMD&FP source register, encoded in the “Rn” field.

<Vm> Is the name of the second SIMD&FP source register, encoded in the “Rm” field.

<Va> Is the name of the third SIMD&FP source register, encoded in the “Ra” field.

Operation

```
AArch64.CheckFPAdvSIMDEnabled();

constant bits(128) operand1 = V[m, 128];
constant bits(128) operand2 = V[n, 128];
constant bits(128) operand3 = V[a, 128];
V[d, 128] = operand2 EOR operand1 EOR operand3;
```

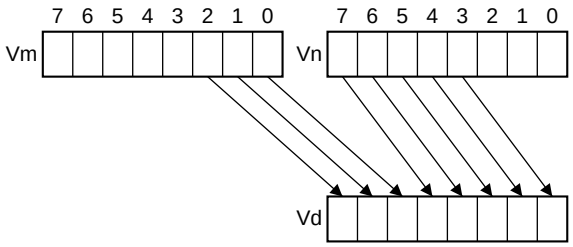
C7.2.36 EXT

Extract vector from pair of vectors

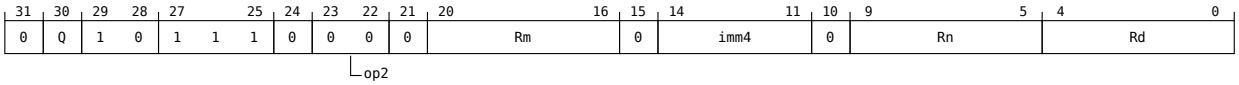
This instruction extracts the lowest vector elements from the second source SIMD&FP register and the highest vector elements from the first source SIMD&FP register, concatenates the results into a vector, and writes the vector to the destination SIMD&FP register vector. The index value specifies the lowest vector element to extract from the first source register, and consecutive elements are extracted from the first, then second, source registers until the destination vector is filled.

The following figure shows an example of the operation of EXT doubleword operation for Q = 0 and imm4<2:0> = 3.



Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Advanced SIMD
(FEAT_AdvSIMD)



Encoding

```
EXT <Vd>.<T>, <Vn>.<T>, <Vm>.<T>, #<index>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_AdvSIMD) then EndOfDecode(Decode_UNDEF);
if Q == '0' && imm4<3> == '1' then EndOfDecode(Decode_UNDEF);

constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer m = UInt(Rm);
constant integer datasize = 64 << UInt(Q);
constant integer position = 8 * UInt(imm4);
```

Assembler Symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<T> Is an arrangement specifier, encoded in "Q":

Q	<T>
0	8B
1	16B

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

<**Vn**> Is the name of the first SIMD&FP source register, encoded in the “Rn” field.

<**Vm**> Is the name of the second SIMD&FP source register, encoded in the “Rm” field.

<**index**> Is the lowest numbered byte element to be extracted, encoded in “Q:imm4”:

Q	imm4<3>	<index>
0	0	UInt(imm4<2:0>)
0	1	RESERVED
1	x	UInt(imm4)

Operation

```
AArch64.CheckFPAdvSIMDEnabled();
constant bits(datasize) hi = V[m, datasize];
constant bits(datasize) lo = V[n, datasize];
constant bits(datasize*2) concat = hi : lo;

V[d, datasize] = concat<(position+datasize)-1:position>;
```

Operational information

C7.2.37 FABD

Floating-point absolute difference (vector)

This instruction subtracts the floating-point values in the elements of the second source SIMD&FP register, from the corresponding floating-point values in the elements of the first source SIMD&FP register, places the absolute value of each result in a vector, and writes the vector to the destination SIMD&FP register.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 4 classes: Scalar half-precision , Scalar single-precision and double-precision , Vector half-precision and Vector single-precision and double-precision

Scalar half-precision

C7.2.41 FACGT

Floating-point absolute compare greater than (vector)

This instruction compares the absolute value of each vector element in the first source SIMD&FP register with the absolute value of the corresponding vector element in the second source SIMD&FP register and if the first value is greater than the second value sets every bit of the corresponding vector element in the destination SIMD&FP register to one, otherwise sets every bit of the corresponding vector element in the destination SIMD&FP register to zero.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 4 classes: Scalar half-precision , Scalar single-precision and double-precision , Vector half-precision and Vector single-precision and double-precision

C7.2.42 FADD (vector)

Floating-point add (vector)

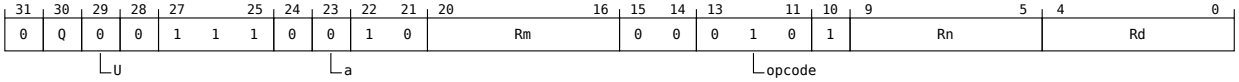
This instruction adds corresponding vector elements in the two source SIMD&FP registers, writes the result into a vector, and writes the vector to the destination SIMD&FP register. All the values in this instruction are floating-point values.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Half-precision and Single-precision and double-precision

Half-precision
(FEAT_AdvSIMD && FEAT_FP16)



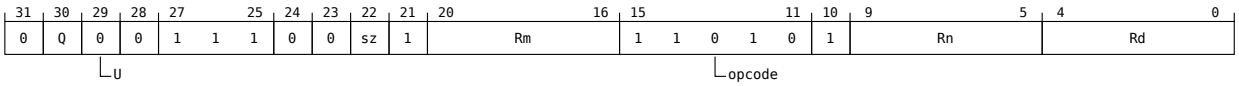
Encoding

```
FADD <Vd>.<T>, <Vn>.<T>, <Vm>.<T>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_AdvSIMD) || !IsFeatureImplemented(FEAT_FP16) then
    EndOfDecode(Decode_UNDEF);
constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer m = UInt(Rm);
constant integer esize = 16;
constant integer datasize = 64 << UInt(Q);
constant integer elements = datasize DIV esize;
```

Single-precision and double-precision
(FEAT_AdvSIMD)



Encoding

```
FADD <Vd>.<T>, <Vn>.<T>, <Vm>.<T>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_AdvSIMD) then EndOfDecode(Decode_UNDEF);
if sz:Q == '10' then EndOfDecode(Decode_UNDEF);
constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer m = UInt(Rm);
constant integer esize = 32 << UInt(sz);

C7.2.45 FADDP (vector)

Floating-point add pairwise (vector)

This instruction creates a vector by concatenating the vector elements of the first source SIMD&FP register after the vector elements of the second source SIMD&FP register, reads each pair of adjacent vector elements from the concatenated vector, adds each pair of values together, places the result into a vector, and writes the vector to the destination SIMD&FP register. All the values in this instruction are floating-point values.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Half-precision and Single-precision and double-precision

C7.2.46 FCADD

Floating-point complex add

This instruction operates on complex numbers that are represented in SIMD&FP registers as pairs of elements, with the more significant element holding the imaginary part of the number and the less significant element holding the real part of the number. Each element holds a floating-point value. It performs the following calculation on the corresponding complex number element pairs from the two source registers:

- Considering the complex number from the second source register on an Argand diagram, the number is rotated counterclockwise by 90 or 270 degrees.
- The rotated complex number is added to the complex number from the first source register.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.47 FCCMP

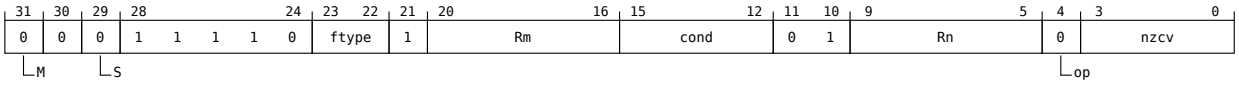
Floating-point conditional quiet compare (scalar)

This instruction compares the two SIMD&FP source register values and writes the result to the PSTATE.{N, Z, C, V} flags. If the condition does not pass, then the PSTATE.{N, Z, C, V} flags are set to the flag bit specifier.

This instruction raises an Invalid Operation floating-point exception if either or both of the operands is a signaling NaN.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.



Encoding for the Half-precision variant
(FEAT_FP16) Applies when `(ftype == 11)`

```
FCCMP <Hn>, <Hm>, #<nzcv>, <cond>
```

Encoding for the Single-precision variant
(FEAT_FP) Applies when `(ftype == 00)`

```
FCCMP <Sn>, <Sm>, #<nzcv>, <cond>
```

Encoding for the Double-precision variant
(FEAT_FP) Applies when `(ftype == 01)`

```

<**Dm**> Is the 64-bit name of the second SIMD&FP source register, encoded in the “Rm” field.

Operation

```
AArch64.CheckFPAdvSIMDEnabled();

constant bits(datasize) operand1 = V[n, datasize];
constant bits(datasize) operand2 = V[m, datasize];

if ConditionHolds(condition) then
    constant boolean signal_all_nans = FALSE;
    flags = FPCompare(operand1, operand2, signal_all_nans, FPCR);

PSTATE.<N,Z,C,V> = flags;
```

Operational information

The IEEE 754 standard specifies that the result of a comparison is precisely one of $<$, $==$, $>$ or unordered. If either or both of the operands is a NaN, they are unordered, and all three of (Operand1 $<$ Operand2), (Operand1 $==$ Operand2) and (Operand1 $>$ Operand2) are false. An unordered comparison sets the PSTATE condition flags to N=0, Z=0, C=1, and V=1.

Non-Confidential

C7.2.48 FCCMPE

Floating-point conditional signaling compare (scalar)

This instruction compares the two SIMD&FP source register values and writes the result to the PSTATE.{N, Z, C, V} flags. If the condition does not pass, then the PSTATE.{N, Z, C, V} flags are set to the flag bit specifier.

This instruction raises an Invalid Operation floating-point exception if either or both of the operands is any type of NaN.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.49 FCMEQ (register)

Floating-point compare equal (vector)

This instruction compares each floating-point value from the first source SIMD&FP register, with the corresponding floating-point value from the second source SIMD&FP register, and if the comparison is equal sets every bit of the corresponding vector element in the destination SIMD&FP register to one, otherwise sets every bit of the corresponding vector element in the destination SIMD&FP register to zero.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 4 classes: Scalar half-precision , Scalar single-precision and double-precision , Vector half-precision and Vector single-precision and double-precision

C7.2.50 FCMEQ (zero)

Floating-point compare equal to zero (vector)

This instruction reads each floating-point value in the source SIMD&FP register and if the value is equal to zero sets every bit of the corresponding vector element in the destination SIMD&FP register to one, otherwise sets every bit of the corresponding vector element in the destination SIMD&FP register to zero.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 4 classes: Scalar half-precision , Scalar single-precision and double-precision , Vector half-precision and Vector single-precision and double-precision

C7.2.55 FCMLA (by element)

Floating-point complex multiply accumulate (by element)

This instruction operates on complex numbers that are represented in SIMD&FP registers as pairs of elements, with the more significant element holding the imaginary part of the number and the less significant element holding the real part of the number. Each element holds a floating-point value. It performs the following calculation on complex numbers from the first source register and the destination register with the specified complex number from the second source register:

- Considering the complex number from the second source register on an Argand diagram, the number is rotated counterclockwise by 0, 90, 180, or 270 degrees.
- The two elements of the transformed complex number are multiplied by:
  - The real element of the complex number from the first source register, if the transformation was a rotation by 0 or 180 degrees.
  - The imaginary element of the complex number from the first source register, if the transformation was a rotation by 90 or 270 degrees.
- The complex number resulting from that multiplication is added to the complex number from the destination register.

The multiplication and addition operations are performed as a fused multiply-add, without any intermediate rounding.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.57 FCMLE (zero)

Floating-point compare less than or equal to zero (vector)

This instruction reads each floating-point value in the source SIMD&FP register and if the value is less than or equal to zero sets every bit of the corresponding vector element in the destination SIMD&FP register to one, otherwise sets every bit of the corresponding vector element in the destination SIMD&FP register to zero.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.59 FCMP

Floating-point quiet compare (scalar)

This instruction compares the two SIMD&FP source register values, or the first SIMD&FP source register value and zero. It writes the result to the PSTATE.{N, Z, C, V} flags.

This instruction raises an Invalid Operation floating-point exception if either or both of the operands is a signaling NaN.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

constant bits(datasize) operand1 = V[n, datasize];
constant bits(datasize) operand2 = if cmp_with_zero then FPZero('0', datasize) else V[m, datasize];

PSTATE.<N,Z,C,V> = FPCompare(operand1, operand2, signal_all_nans, FPCR);
```

Operational information

The IEEE 754 standard specifies that the result of a comparison is precisely one of $<$, $==$, $>$ or unordered. If either or both of the operands is a NaN, they are unordered, and all three of (Operand1 $<$ Operand2), (Operand1 $==$ Operand2) and (Operand1 $>$ Operand2) are false. An unordered comparison sets the PSTATE condition flags to N=0, Z=0, C=1, and V=1.

C7.2.60 FCMPE

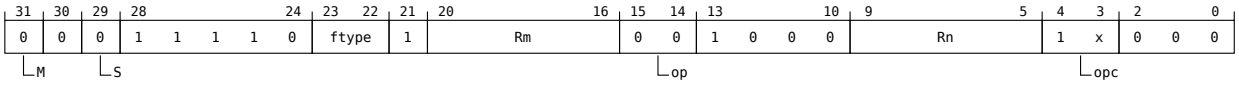
Floating-point signaling compare (scalar)

This instruction compares the two SIMD&FP source register values, or the first SIMD&FP source register value and zero. It writes the result to the PSTATE.{N, Z, C, V} flags.

This instruction raises an Invalid Operation floating-point exception if either or both of the operands is any type of NaN.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.



Encoding for the Half-precision variant

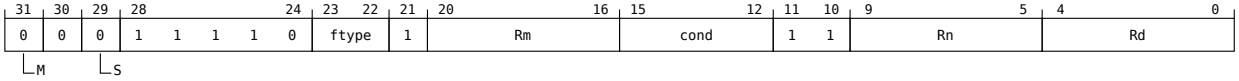
C7.2.61 FCSEL

Floating-point conditional select (scalar)

This instruction allows the SIMD&FP destination register to take the value from either one or the other of two SIMD&FP source registers. If the condition passes, the first SIMD&FP source register value is taken, otherwise the second SIMD&FP source register value is taken.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.



Encoding for the Half-precision variant
(FEAT_FP16) Applies when `(ftype == 11)`

```
FCSEL <Hd>, <Hn>, <Hm>, <cond>
```

Encoding for the Single-precision variant
(FEAT_FP) Applies when `(ftype == 00)`

```
FCSEL <Sd>, <Sn>, <Sm>, <cond>
```

Encoding for the Double-precision variant
(FEAT_FP) Applies when `(ftype == 01)`

```
FCSEL <Dd>, <Dn>, <Dm>, <cond>
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_FP) then EndOfDecode(Decode_UNDEF);
if ftype == '10' then EndOfDecode(Decode_UNDEF);
if ftype == '11' && !IsFeatureImplemented(FEAT_FP16) then EndOfDecode(Decode_UNDEF);

constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer m = UInt(Rm);

constant integer datasize = 8 << UInt(ftype EOR '10');
constant bits(4) condition = cond;
```

Assembler Symbols

<**Hd**> Is the 16-bit name of the SIMD&FP destination register, encoded in the “Rd” field.

<**Hn**> Is the 16-bit name of the first SIMD&FP source register, encoded in the “Rn” field.

<**Hm**> Is the 16-bit name of the second SIMD&FP source register, encoded in the “Rm” field.

<**cond**> Is one of the standard conditions, encoded in the standard way, and encoded in “cond”:

C7.2.62 FCVT

Floating-point convert precision (scalar)

This instruction converts the floating-point value in the SIMD&FP source register to the precision for the destination register data type using the rounding mode that is determined by the FPCR and writes the result to the SIMD&FP destination register.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.63 FCVTAS (vector)

Floating-point convert to signed integer, rounding to nearest with ties to away (vector)

This instruction converts each element in a vector from a floating-point value to a signed integer value using the Round to Nearest with Ties to Away rounding mode and writes the result to the SIMD&FP destination register.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 4 classes: Scalar half-precision , Scalar single-precision and double-precision , Vector half-precision and Vector single-precision and double-precision

C7.2.67 FCVTL, FCVTL2

Floating-point convert to higher precision long (vector)

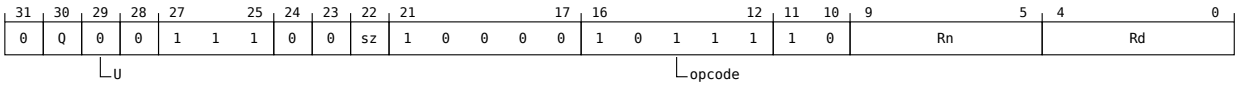
This instruction reads each element in a vector in the SIMD&FP source register, converts each value to double the precision of the source element using the rounding mode that is determined by the FPCR, and writes each result to the equivalent element of the vector in the SIMD&FP destination register.

Where the operation lengthens a 64-bit vector to a 128-bit vector, the `FCVTL2` variant operates on the elements in the top 64 bits of the source register.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Vector single-precision and double-precision (FEAT_AdvSIMD)



Encoding

```
FCVTL{2} <Vd>.<Ta>, <Vn>.<Tb>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_AdvSIMD) then EndOfDecode(Decode_UNDEF);
constant integer d = UInt(Rd);
constant integer n = UInt(Rn);

constant integer esize = 16 << UInt(sz);
constant integer datasize = 64;
constant integer part = UInt(Q);
constant integer elements = datasize DIV esize;
```

C7.2.68 FCVTMS (vector)

Floating-point convert to signed integer, rounding toward minus infinity (vector)

This instruction converts a scalar or each element in a vector from a floating-point value to a signed integer value using the Round towards Minus Infinity rounding mode, and writes the result to the SIMD&FP destination register.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 4 classes: Scalar half-precision , Scalar single-precision and double-precision , Vector half-precision and Vector single-precision and double-precision

C7.2.72 FCVTN, FCVTN2 (double to single-precision, single to half-precision)

Floating-point convert to lower precision narrow (vector)

This instruction reads each vector element in the SIMD&FP source register, converts each result to half the precision of the source element, writes the final result to a vector, and writes the vector to the lower or upper half of the destination SIMD&FP register. The destination vector elements are half as long as the source vector elements. The rounding mode is determined by the FPCR.

FCVTN writes the vector to the lower half of the destination register and clears the upper half. FCVTN2 writes the vector to the upper half of the destination register without affecting the other bits of the register.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Vector single-precision and double-precision

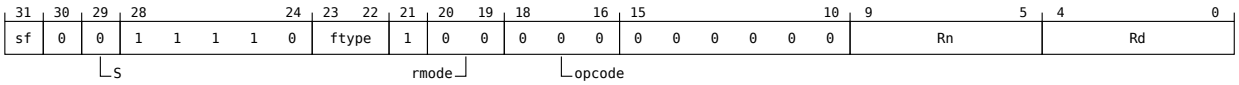
C7.2.74 FCVTNS (scalar)

Floating-point convert to signed integer, rounding to nearest with ties to even (scalar)

This instruction converts the floating-point value in the SIMD&FP source register to a 32-bit or 64-bit signed integer using the Round to Nearest rounding mode, and writes the result to the general-purpose destination register.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.



Encoding for the Half-precision to 32-bit variant
(FEAT_FP16) Applies when `(sf == 0 && ftype == 11)`

```
FCVTNS <Wd>, <Hn>
```

Encoding for the Half-precision to 64-bit variant
(FEAT_FP16) Applies when `(sf == 1 && ftype == 11)`

```
FCVTNS <Xd>, <Hn>
```

Encoding for the Single-precision to 32-bit variant
(FEAT_FP) Applies when `(sf == 0 && ftype == 00)`

```
FCVTNS <Wd>, <Sn>
```

Encoding for the Single-precision to 64-bit variant
(FEAT_FP) Applies when `(sf == 1 && ftype == 00)`

```
FCVTNS <Xd>, <Sn>
```

Encoding for the Double-precision to 32-bit variant
(FEAT_FP) Applies when `(sf == 0 && ftype == 01)`

```
FCVTNS <Wd>, <Dn>
```

Encoding for the Double-precision to 64-bit variant
(FEAT_FP) Applies when `(sf == 1 && ftype == 01)`

```
FCVTNS <Xd>, <Dn>
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_FP) then EndOfDecode(Decode_UNDEF);

C7.2.81 FCVTXN, FCVTXN2

Floating-point convert to lower precision narrow, rounding to odd (vector)

This instruction reads each double-precision element in the source SIMD&FP register, converts each value to single-precision format using the Round to Odd rounding mode, and writes the results to the destination SIMD&FP register.

Note

This instruction uses the Round to Odd rounding mode, which is not defined by the IEEE 754-2008 standard. This rounding mode ensures that if the result of the conversion is inexact, the least significant bit of the mantissa is forced to 1. This rounding mode enables a floating-point value to be converted to a lower precision format via an intermediate precision format while avoiding double rounding errors. For example, a 64-bit floating-point value can be converted to a correctly rounded 16-bit floating-point value by first using this instruction to produce a 32-bit value and then using another instruction with the wanted rounding mode to convert the 32-bit value to the final 16-bit floating-point value.

`FCVTXN` writes the vector to the lower half of the destination register and clears the upper half to 0. `FCVTXN2` writes the vector to the upper half of the destination register without affecting the other bits of the register.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Scalar and Vector

C7.2.88 FCVTZU (scalar, fixed-point)

Floating-point convert to unsigned fixed-point, rounding toward zero (scalar)

This instruction converts the floating-point value in the SIMD&FP source register to a 32-bit or 64-bit fixed-point unsigned integer using the Round towards Zero rounding mode, and writes the result to the general-purpose destination register.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.90 FDIV (vector)

Floating-point divide (vector)

This instruction divides the floating-point values in the elements in the first source SIMD&FP register, by the floating-point values in the corresponding elements in the second source SIMD&FP register, places the results in a vector, and writes the vector to the destination SIMD&FP register.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Half-precision and Single-precision and double-precision

C7.2.92 FJCVTZS

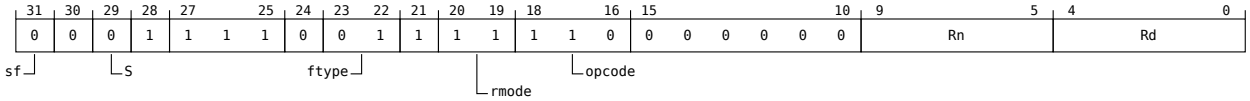
Floating-point Javascript convert to signed fixed-point, rounding toward zero

This instruction converts the double-precision floating-point value in the SIMD&FP source register to a 32-bit signed integer using the Round towards Zero rounding mode, and writes the result to the general-purpose destination register. If the result is too large to be represented as a signed 32-bit integer, then the result is the integer modulo 2^{32}, as held in a 32-bit signed integer.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Double-precision to 32-bit
(FEAT_JSCVT)



Encoding

```
FJCVTZS <Wd>, <Dn>
```

Decode for this encoding

C7.2.94 FMAX (vector)

Floating-point maximum (vector)

This instruction compares corresponding vector elements in the two source SIMD&FP registers, places the larger of each of the two floating-point values into a vector, and writes the vector to the destination SIMD&FP register.

When FPCR.AH is 0, the behavior is as follows:

- Negative zero compares less than positive zero.
- When FPCR.DN is 0, if either element is a NaN, the result is a quiet NaN.
- When FPCR.DN is 1, if either element is a NaN, the result is Default NaN.

When FPCR.AH is 1, the behavior is as follows:

- If both elements are zeros, regardless of the sign of either zero, the result is the second element.
- If either element is a NaN, regardless of the value of FPCR.DN, the result is the second element.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Half-precision and Single-precision and double-precision

C7.2.95 FMAX (scalar)

Floating-point maximum (scalar)

This instruction compares the two source SIMD&FP registers, and writes the larger of the two floating-point values to the destination SIMD&FP register.

When FPCR.AH is 0, the behavior is as follows:

- Negative zero compares less than positive zero.
- When FPCR.DN is 0, if either value is a NaN, the result is a quiet NaN.
- When FPCR.DN is 1, if either value is a NaN, the result is Default NaN.

When FPCR.AH is 1, the behavior is as follows:

- If both values are zeros, regardless of the sign of either zero, the result is the second value.
- If either value is a NaN, regardless of the value of FPCR.DN, the result is the second value.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.96 FMAXNM (vector)

Floating-point maximum number (vector)

This instruction compares corresponding vector elements in the two source SIMD&FP registers, writes the larger of the two floating-point values into a vector, and writes the vector to the destination SIMD&FP register.

Regardless of the value of FPCR.AH, the behavior is as follows:

- Negative zero compares less than positive zero.
- If one element is numeric and the other is a quiet NaN, the result is the numeric value.
- When FPCR.DN is 0, if either element is a signaling NaN or if both elements are NaNs, the result is a quiet NaN.
- When FPCR.DN is 1, if either element is a signaling NaN or if both elements are NaNs, the result is Default NaN.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Half-precision and Single-precision and double-precision

C7.2.99 FMAXNMP (vector)

Floating-point maximum number pairwise (vector)

This instruction creates a vector by concatenating the vector elements of the first source SIMD&FP register after the vector elements of the second source SIMD&FP register, reads each pair of adjacent vector elements in the two source SIMD&FP registers, writes the largest of each pair of values into a vector, and writes the vector to the destination SIMD&FP register. All the values in this instruction are floating-point values.

Regardless of the value of FPCR.AH, the behavior is as follows for each pairwise operation:

- Negative zero compares less than positive zero.
- If one element is numeric and the other is a quiet NaN, the result is the numeric value.
- When FPCR.DN is 0, if either element is a signaling NaN or if both elements are NaNs, the result is a quiet NaN.
- When FPCR.DN is 1, if either element is a signaling NaN or if both elements are NaNs, the result is Default NaN.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.103 FMAXV

Floating-point maximum across vector

This instruction compares all the vector elements in the source SIMD&FP register, and writes the largest of the values as a scalar to the destination SIMD&FP register. All the values in this instruction are floating-point values.

When FPCR.AH is 0, the behavior is as follows:

- Negative zero compares less than positive zero.
- When FPCR.DN is 0, if either value is a NaN, the result is a quiet NaN.
- When FPCR.DN is 1, if either value is a NaN, the result is Default NaN.

When FPCR.AH is 1, the behavior is as follows:

- If both values are zeros, regardless of the sign of either zero, the result is the second value.
- If either value is a NaN, regardless of the value of FPCR.DN, the result is the second value.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Half-precision and Single-precision

C7.2.104 FMIN (vector)

Floating-point minimum (vector)

This instruction compares corresponding elements in the vectors in the two source SIMD&FP registers, places the smaller of each of the two floating-point values into a vector, and writes the vector to the destination SIMD&FP register.

When FPCR.AH is 0, the behavior is as follows:

- Negative zero compares less than positive zero.
- When FPCR.DN is 0, if either element is a NaN, the result is a quiet NaN.
- When FPCR.DN is 1, if either element is a NaN, the result is Default NaN.

When FPCR.AH is 1, the behavior is as follows:

- If both elements are zeros, regardless of the sign of either zero, the result is the second element.
- If either element is a NaN, regardless of the value of FPCR.DN, the result is the second element.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Half-precision and Single-precision and double-precision

C7.2.109 FMINNMP (vector)

Floating-point minimum number pairwise (vector)

This instruction creates a vector by concatenating the vector elements of the first source SIMD&FP register after the vector elements of the second source SIMD&FP register, reads each pair of adjacent vector elements in the two source SIMD&FP registers, writes the smallest of each pair of floating-point values into a vector, and writes the vector to the destination SIMD&FP register. All the values in this instruction are floating-point values.

Regardless of the value of FPCR.AH, the behavior is as follows for each pairwise operation:

- Negative zero compares less than positive zero.
- If one element is numeric and the other is a quiet NaN, the result is the numeric value.
- When FPCR.DN is 0, if either element is a signaling NaN or if both elements are NaNs, the result is a quiet NaN.
- When FPCR.DN is 1, if either element is a signaling NaN or if both elements are NaNs, the result is Default NaN.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.111 FMINP (scalar)

Floating-point minimum of pair of elements (scalar)

This instruction compares two vector elements in the source SIMD&FP register and writes the smallest of the floating-point values as a scalar to the destination SIMD&FP register.

When FPCR.AH is 0, the behavior is as follows for each pairwise operation:

- Negative zero compares less than positive zero.
- When FPCR.DN is 0, if either element is a NaN, the result is a quiet NaN.
- When FPCR.DN is 1, if either element is a NaN, the result is Default NaN.

When FPCR.AH is 1, the behavior is as follows for each pairwise operation:

- If both elements are zeros, regardless of the sign of either zero, the result is the second element.
- If either element is a NaN, regardless of the value of FPCR.DN, the result is the second element.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.112 FMINP (vector)

Floating-point minimum pairwise (vector)

This instruction creates a vector by concatenating the vector elements of the first source SIMD&FP register after the vector elements of the second source SIMD&FP register, reads each pair of adjacent vector elements from the concatenated vector, writes the smaller of each pair of values into a vector, and writes the vector to the destination SIMD&FP register. All the values in this instruction are floating-point values.

When FPCR.AH is 0, the behavior is as follows for each pairwise operation:

- Negative zero compares less than positive zero.
- When FPCR.DN is 0, if either element is a NaN, the result is a quiet NaN.
- When FPCR.DN is 1, if either element is a NaN, the result is Default NaN.

When FPCR.AH is 1, the behavior is as follows for each pairwise operation:

- If both elements are zeros, regardless of the sign of either zero, the result is the second element.
- If either element is a NaN, regardless of the value of FPCR.DN, the result is the second element.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Half-precision and Single-precision and double-precision

Half-precision

C7.2.113 FMINV

Floating-point minimum across vector

This instruction compares all the vector elements in the source SIMD&FP register, and writes the smallest of the values as a scalar to the destination SIMD&FP register. All the values in this instruction are floating-point values.

When FPCR.AH is 0, the behavior is as follows:

- Negative zero compares less than positive zero.
- When FPCR.DN is 0, if either value is a NaN, the result is a quiet NaN.
- When FPCR.DN is 1, if either value is a NaN, the result is Default NaN.

When FPCR.AH is 1, the behavior is as follows:

- If both values are zeros, regardless of the sign of either zero, the result is the second value.
- If either value is a NaN, regardless of the value of FPCR.DN, the result is the second value.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Half-precision and Single-precision

C7.2.119 FMLS (vector)

Floating-point fused multiply-subtract from accumulator (vector)

This instruction multiplies corresponding floating-point values in the vectors in the two source SIMD&FP registers, negates the product, adds the result to the corresponding vector element of the destination SIMD&FP register, and writes the result to the destination SIMD&FP register.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Half-precision and Single-precision and double-precision

Half-precision
(FEAT_AdvSIMD && FEAT_FP16)

C7.2.120 FMLSL, FMLSL2 (by element)

Floating-point fused multiply-subtract long from accumulator (by element)

This instruction multiplies the negated half-precision vector elements in the first source SIMD&FP register by the specified half-precision value in the second source SIMD&FP register, and accumulates the intermediate product without rounding to the corresponding single-precision vector element of the destination SIMD&FP register.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: FMLSL and FMLSL2

C7.2.122 FMOV (vector, immediate)

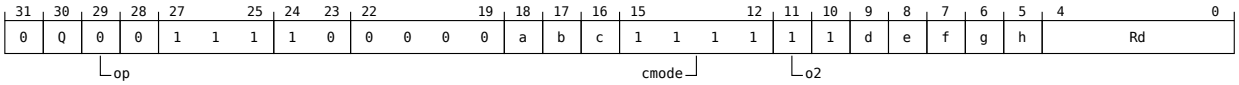
Floating-point move immediate (vector)

This instruction copies an immediate floating-point constant into every element of the SIMD&FP destination register.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Half-precision and Single-precision and double-precision

Half-precision
(FEAT_AdvSIMD && FEAT_FP16)



Encoding

```
FMOV <Vd>.<T>, #<imm>
```

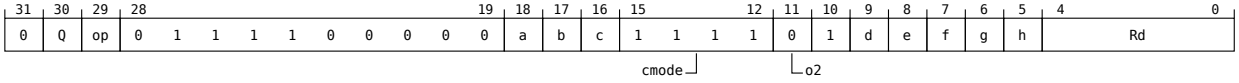
Decode for this encoding

```
if !IsFeatureImplemented(FEAT_AdvSIMD) || !IsFeatureImplemented(FEAT_FP16) then
    EndOfDecode(Decode_UNDEF);

constant integer rd = UInt(Rd);

constant integer datasize = 64 << UInt(Q);
constant bits(8) imm8 = a:b:c:d:e:f:g:h;
constant bits(16) imm16 = imm8<7>:NOT(imm8<6>):Replicate(imm8<6>, 2):imm8<5:0>:Zeros(6);
constant bits(datasize) imm = Replicate(imm16, datasize DIV 16);
```

Single-precision and double-precision
(FEAT_AdvSIMD)



Encoding for the Single-precision variant Applies when `(op == 0)`

```
FMOV <Vd>.<T>, #<imm>
```

Encoding for the Double-precision variant Applies when `(Q == 1 && op == 1)`

```
FMOV <Vd>.2D, #<imm>
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_AdvSIMD) then EndOfDecode(Decode_UNDEF);
if cmode:op == '11111' then
    // FMOV Dn,#imm is in main FP instruction set
    if Q == '0' then EndOfDecode(Decode_UNDEF);

constant integer rd = UInt(Rd);
constant integer datasize = 64 << UInt(Q);
constant bits(64) imm64 = AdvSIMDExpandImm(op, cmode, a:b:c:d:e:f:g:h);
constant bits(datasize) imm = Replicate(imm64, datasize DIV 64);
```

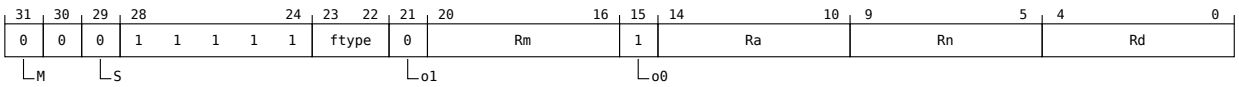
C7.2.126 FMSUB

Floating-point fused multiply-subtract (scalar)

This instruction multiplies the values of the first two SIMD&FP source registers, negates the product, adds that to the value of the third SIMD&FP source register, and writes the result to the SIMD&FP destination register.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.



Encoding for the Half-precision variant
(FEAT_FP16) Applies when `(ftype == 11)`

```
FMSUB <Hd>, <Hn>, <Hm>, <Ha>
```

Encoding for the Single-precision variant
(FEAT_FP) Applies when `(ftype == 00)`

```
FMSUB <Sd>, <Sn>, <Sm>, <Sa>
```

Encoding for the Double-precision variant
(FEAT_FP) Applies when `(ftype == 01)`

```
FMSUB <Dd>, <Dn>, <Dm>, <Da>
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_FP) then EndOfDecode(Decode_UNDEF);
if ftype == '10' then EndOfDecode(Decode_UNDEF);
if ftype == '11' && !IsFeatureImplemented(FEAT_FP16) then EndOfDecode(Decode_UNDEF);

constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer m = UInt(Rm);
constant integer a = UInt(Ra);

constant integer esize = 8 << UInt(ftype EOR '10');
```

Assembler Symbols

<**Hd**> Is the 16-bit name of the SIMD&FP destination register, encoded in the “Rd” field.

<**Hn**> Is the 16-bit name of the first SIMD&FP source register holding the multiplicand, encoded in the “Rn” field.

<**Hm**> Is the 16-bit name of the second SIMD&FP source register holding the multiplier, encoded in the “Rm” field.

<**Ha**> Is the 16-bit name of the third SIMD&FP source register holding the minuend, encoded in the “Ra” field.

<**Sd**> Is the 32-bit name of the SIMD&FP destination register, encoded in the “Rd” field.

<**Sn**> Is the 32-bit name of the first SIMD&FP source register holding the multiplicand, encoded in the “Rn” field.

C7.2.127 FMUL (by element)

Floating-point multiply (by element)

This instruction multiplies the vector elements in the first source SIMD&FP register by the specified value in the second source SIMD&FP register, places the results in a vector, and writes the vector to the destination SIMD&FP register. All the values in this instruction are floating-point values.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 4 classes: Scalar, half-precision , Scalar, single-precision and double-precision , Vector, half-precision and Vector, single-precision and double-precision

C7.2.132 FNEG (vector)

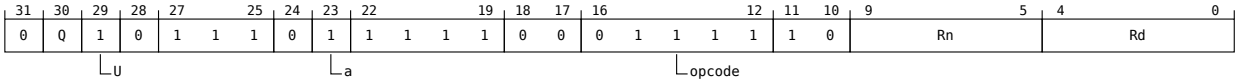
Floating-point negate (vector)

This instruction negates the value of each vector element in the source SIMD&FP register, writes the result to a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Half-precision and Single-precision and double-precision

Half-precision
(FEAT_AdvSIMD && FEAT_FP16)



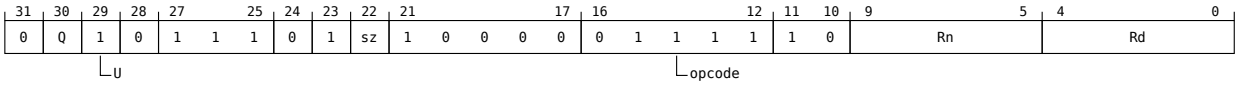
Encoding

```
FNEG <Vd>.<T>, <Vn>.<T>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_AdvSIMD) || !IsFeatureImplemented(FEAT_FP16) then
    EndOfDecode(Decode_UNDEF);
constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer esize = 16;
constant integer datasize = 64 << UInt(Q);
constant integer elements = datasize DIV esize;
```

Single-precision and double-precision
(FEAT_AdvSIMD)



Encoding

```
FNEG <Vd>.<T>, <Vn>.<T>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_AdvSIMD) then EndOfDecode(Decode_UNDEF);
if sz:Q == '10' then EndOfDecode(Decode_UNDEF);
constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer esize = 32 << UInt(sz);
constant integer datasize = 64 << UInt(Q);
constant integer elements = datasize DIV esize;
```

Assembler Symbols

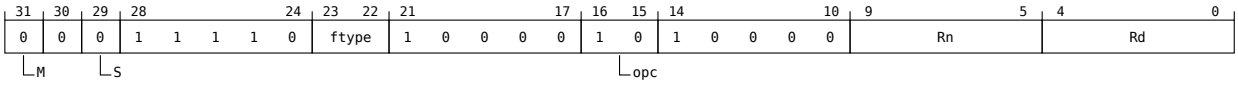
C7.2.133 FNEG (scalar)

Floating-point negate (scalar)

This instruction negates the value in the SIMD&FP source register and writes the result to the SIMD&FP destination register.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.



Encoding for the Half-precision variant
(FEAT_FP16) Applies when `(ftype == 11)`

```
FNEG <Hd>, <Hn>
```

Encoding for the Single-precision variant
(FEAT_FP) Applies when `(ftype == 00)`

```
FNEG <Sd>, <Sn>
```

Encoding for the Double-precision variant
(FEAT_FP) Applies when `(ftype == 01)`

```
FNEG <Dd>, <Dn>
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_FP) then EndOfDecode(Decode_UNDEF);
if ftype == '10' then EndOfDecode(Decode_UNDEF);
if ftype == '11' && !IsFeatureImplemented(FEAT_FP16) then EndOfDecode(Decode_UNDEF);

constant integer d = UInt(Rd);
constant integer n = UInt(Rn);

constant integer esize = 8 << UInt(ftype EOR '10');
```

Assembler Symbols

<**Hd**> Is the 16-bit name of the SIMD&FP destination register, encoded in the “Rd” field.

<**Hn**> Is the 16-bit name of the SIMD&FP source register, encoded in the “Rn” field.

<**Sd**> Is the 32-bit name of the SIMD&FP destination register, encoded in the “Rd” field.

<**Sn**> Is the 32-bit name of the SIMD&FP source register, encoded in the “Rn” field.

<**Dd**> Is the 64-bit name of the SIMD&FP destination register, encoded in the “Rd” field.

<**Dn**> Is the 64-bit name of the SIMD&FP source register, encoded in the “Rn” field.

Operation

```
AArch64.CheckFPAdvSIMDEnabled();

constant bits(esize) operand = V[n, esize];

constant bits(esize) result = FPNeg(operand, FPCR);

V[d, esize] = result;
```

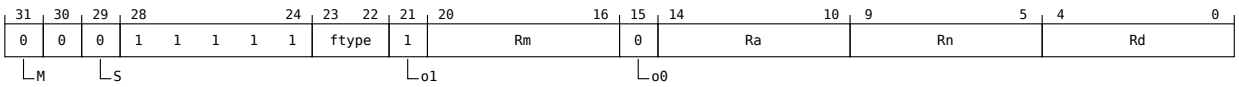
C7.2.134 FNMADD

Floating-point negated fused multiply-add (scalar)

This instruction multiplies the values of the first two SIMD&FP source registers, negates the product, subtracts the value of the third SIMD&FP source register, and writes the result to the destination SIMD&FP register.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.



Encoding for the Half-precision variant
(FEAT_FP16) Applies when `(ftype == 11)`

```
FNMADD <Hd>, <Hn>, <Hm>, <Ha>
```

Encoding for the Single-precision variant
(FEAT_FP) Applies when `(ftype == 00)`

```
FNMADD <Sd>, <Sn>, <Sm>, <Sa>
```

Encoding for the Double-precision variant
(FEAT_FP) Applies when `(ftype == 01)`

```
FNMADD <Dd>, <Dn>, <Dm>, <Da>
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_FP) then EndOfDecode(Decode_UNDEF);
if ftype == '10' then EndOfDecode(Decode_UNDEF);
if ftype == '11' && !IsFeatureImplemented(FEAT_FP16) then EndOfDecode(Decode_UNDEF);

constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer m = UInt(Rm);
constant integer a = UInt(Ra);

constant integer esize = 8 << UInt(ftype EOR '10');
```

Assembler Symbols

<**Hd**> Is the 16-bit name of the SIMD&FP destination register, encoded in the “Rd” field.

C7.2.139 FRECPX

Floating-point reciprocal exponent (scalar)

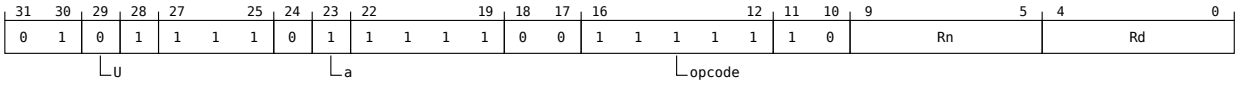
This instruction finds an approximate reciprocal exponent for the source SIMD&FP register and writes the result to the destination SIMD&FP register.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Half-precision and Single-precision and double-precision

Half-precision
(FEAT_AdvSIMD && FEAT_FP16)



Encoding

```
FRECPX <Hd>, <Hn>
```

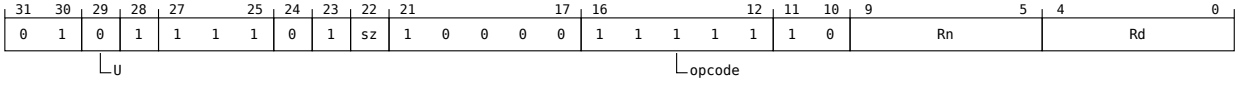
Decode for this encoding

```
if !IsFeatureImplemented(FEAT_AdvSIMD) || !IsFeatureImplemented(FEAT_FP16) then
    EndOfDecode(Decode_UNDEF);

constant integer d = UInt(Rd);
constant integer n = UInt(Rn);

constant integer esize = 16;
```

Single-precision and double-precision
(FEAT_AdvSIMD)



Encoding

```
FRECPX <V><d>, <V><n>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_AdvSIMD) then EndOfDecode(Decode_UNDEF);
constant integer d = UInt(Rd);
constant integer n = UInt(Rn);

constant integer esize = 32 << UInt(sz);
```

C7.2.140 FRINTA (vector)

Floating-point round to integral, to nearest with ties to away (vector)

This instruction rounds a vector of floating-point values in the SIMD&FP source register to integral floating-point values of the same size using the Round to Nearest with Ties to Away rounding mode, and writes the result to the SIMD&FP destination register.

A zero input gives a zero result with the same sign, an infinite input gives an infinite result with the same sign, and a NaN is propagated as for normal arithmetic.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Half-precision and Single-precision and double-precision

C7.2.149 FRINTP (scalar)

Floating-point round to integral, toward plus infinity (scalar)

This instruction rounds a floating-point value in the SIMD&FP source register to an integral floating-point value of the same size using the Round towards Plus Infinity rounding mode, and writes the result to the SIMD&FP destination register.

A zero input gives a zero result with the same sign, an infinite input gives an infinite result with the same sign, and a NaN is propagated as for normal arithmetic.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.150 FRINTX (vector)

Floating-point round to integral exact, using current rounding mode (vector)

This instruction rounds a vector of floating-point values in the SIMD&FP source register to integral floating-point values of the same size using the rounding mode that is determined by the FPCR, and writes the result to the SIMD&FP destination register.

When a result value is not numerically equal to the corresponding input value, an Inexact exception is raised. A zero input gives a zero result with the same sign, an infinite input gives an infinite result with the same sign, and a NaN is propagated as for normal arithmetic.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Half-precision and Single-precision and double-precision

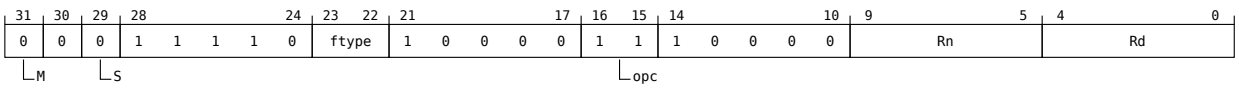
C7.2.157 FSQRT (scalar)

Floating-point square root (scalar)

This instruction calculates the square root of the value in the SIMD&FP source register and writes the result to the SIMD&FP destination register.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.



Encoding for the Half-precision variant
(FEAT_FP16) Applies when `(ftype == 11)`

```
FSQRT <Hd>, <Hn>
```

Encoding for the Single-precision variant
(FEAT_FP) Applies when `(ftype == 00)`

```
FSQRT <Sd>, <Sn>
```

Encoding for the Double-precision variant
(FEAT_FP) Applies when `(ftype == 01)`

```
FSQRT <Dd>, <Dn>
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_FP) then EndOfDecode(Decode_UNDEF);
if ftype == '10' then EndOfDecode(Decode_UNDEF);
if ftype == '11' && !IsFeatureImplemented(FEAT_FP16) then EndOfDecode(Decode_UNDEF);

constant integer d = UInt(Rd);
constant integer n = UInt(Rn);

constant integer esize = 8 << UInt(ftype EOR '10');
```

C7.2.158 FSUB (vector)

Floating-point subtract (vector)

This instruction subtracts the elements in the vector in the second source SIMD&FP register, from the corresponding elements in the vector in the first source SIMD&FP register, places each result into elements of a vector, and writes the vector to the destination SIMD&FP register.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Half-precision and Single-precision and double-precision

Half-precision

C7.2.160 INS (element)

Insert vector element from another vector element

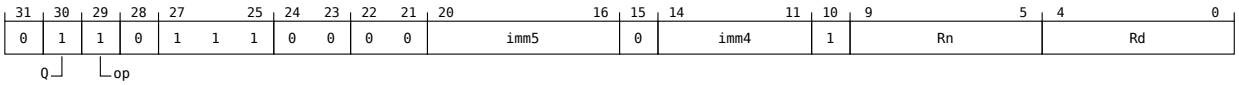
This instruction copies the vector element of the source SIMD&FP register to the specified vector element of the destination SIMD&FP register.

This instruction can insert data into individual elements within a SIMD&FP register without clearing the remaining bits to zero.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This instruction is used by the alias MOV (element).

Advanced SIMD
(FEAT_AdvSIMD)



Encoding

```
INS <Vd>.<Ts>[<index1>], <Vn>.<Ts>[<index2>]
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_AdvSIMD) then EndOfDecode(Decode_UNDEF);
if imm5 == 'x0000' then EndOfDecode(Decode_UNDEF);
constant integer size = LowestSetBitNZ(imm5<3:0>);

constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer dst_index = UInt(imm5<4:size+1>);
constant integer src_index = UInt(imm4<3:size>);
constant integer idxdsize = 64 << UInt(imm4<3>);
// imm4<size-1:0> is IGNORED
constant integer esize = 8 << size;
```

Assembler Symbols

<**Vd**> Is the name of the SIMD&FP destination register, encoded in the “Rd” field.

<**Ts**> Is an element size specifier, encoded in “imm5”:

imm5	<Ts>
x0000	RESERVED
xxxx1	B
xxx10	H
xx100	S
x1000	D

<**index1**> Is the destination element index encoded in “imm5”:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

imm5	<index1>
x0000	RESERVED
xxxx1	UInt(imm5<4:1>)
xxx10	UInt(imm5<4:2>)
xx100	UInt(imm5<4:3>)
x1000	UInt(imm5<4>)

<**Vn**> Is the name of the SIMD&FP source register, encoded in the “Rn” field.

<**index2**> Is the source element index encoded in “imm5:imm4”:

imm5	<index2>
x0000	RESERVED
xxxx1	UInt(imm4)
xxx10	UInt(imm4<3:1>)
xx100	UInt(imm4<3:2>)
x1000	UInt(imm4<3>)

Unspecified bits in “imm4” are ignored but should be set to zero by an assembler.

Operation

```
AArch64.CheckFPAdvSIMDEnabled();
constant bits(idxdsize) operand = V[n, idxdsize];
bits(128) result;

result = V[d, 128];
Elem[result, dst_index, esize] = Elem[operand, src_index, esize];
V[d, 128] = result;
```

Operational information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

C7.2.161 INS (general)

Insert vector element from general-purpose register

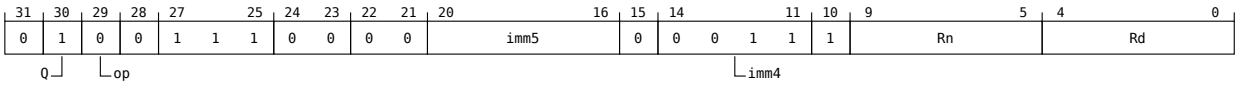
This instruction copies the contents of the source general-purpose register to the specified vector element in the destination SIMD&FP register.

This instruction can insert data into individual elements within a SIMD&FP register without clearing the remaining bits to zero.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This instruction is used by the alias MOV (from general).

Advanced SIMD
(FEAT_AdvSIMD)



Encoding

```
INS <Vd>.<Ts>[<index>], <R><n>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_AdvSIMD) then EndOfDecode(Decode_UNDEF);
if imm5 == 'x0000' then EndOfDecode(Decode_UNDEF);
constant integer size = LowestSetBitNZ(imm5<3:0>);

constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer index = UInt(imm5<4:size+1>);
constant integer esize = 8 << size;
```

Assembler Symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the “Rd” field.

<Ts> Is an element size specifier, encoded in “imm5”:

imm5	<Ts>
x0000	RESERVED
xxxx1	B
xxx10	H
xx100	S
x1000	D

<index> Is the element index encoded in “imm5”:

imm5	<index>
x0000	RESERVED

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

imm5	<index>
xxxx1	UInt(imm5<4:1>)
xxx10	UInt(imm5<4:2>)
xx100	UInt(imm5<4:3>)
x1000	UInt(imm5<4>)

<**R**> Is the width specifier for the general-purpose source register, encoded in “imm5”:

imm5	<R>
x0000	RESERVED
xxxx1	W
xxx10	W
xx100	W
x1000	X

<**n**> Is the number [0-30] of the general-purpose source register or ZR (31), encoded in the “Rn” field.

Operation

```
AArch64.CheckFPAdvSIMDEnabled();
constant bits(esize) element = X[n, esize];
bits(128) result = V[d, 128];

Elem[result, index, esize] = element;
V[d, 128] = result;
```

Operational information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

constant integer n = UInt(Rn);
constant integer m = UInt(Rm);
constant boolean wback = TRUE;
constant boolean nontemporal = FALSE;
```

Assembler Symbols

<**Vt**> Is the name of the first or only SIMD&FP register to be transferred, encoded in the “Rt” field.

<**index**> For the “8-bit”, “8-bit, immediate offset”, and “8-bit, register offset” variants: is the element index, encoded in “Q:S:size”.

For the “16-bit”, “16-bit, immediate offset”, and “16-bit, register offset” variants: is the element index, encoded in “Q:S:size<1>”.

For the “32-bit”, “32-bit, immediate offset”, and “32-bit, register offset” variants: is the element index, encoded in “Q:S”.

For the “64-bit”, “64-bit, immediate offset”, and “64-bit, register offset” variants: is the element index, encoded in “Q”.

<**Xn|SP**> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the “Rn” field.

<**Xm**> Is the 64-bit name of the general-purpose post-index register, excluding XZR, encoded in the “Rm” field.

C7.2.164 LD1R

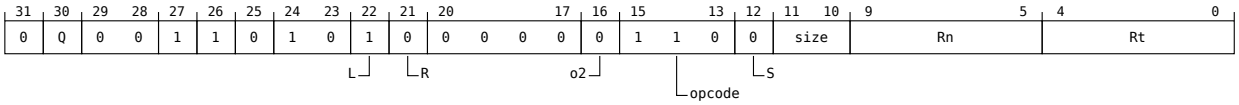
Load one single-element structure and replicate to all lanes (of one register)

This instruction loads a single-element structure from memory and replicates the structure to all the lanes of the SIMD&FP register.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: No offset and Post-index

No offset
(FEAT_AdvSIMD)



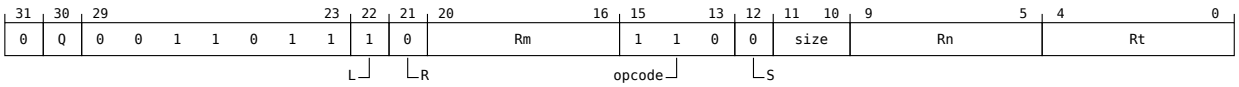
Encoding

```
LD1R { <Vt>.<T> }, [<Xn|SP>]
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_AdvSIMD) then EndOfDecode(Decode_UNDEF);
integer t = UInt(Rt);
constant integer n = UInt(Rn);
constant integer m = integer UNKNOWN;
constant boolean wback = FALSE;
constant boolean nontemporal = FALSE;
```

Post-index
(FEAT_AdvSIMD)



Encoding for the Immediate offset variant Applies when `(Rm == 11111)`

```
LD1R { <Vt>.<T> }, [<Xn|SP>], <imm>
```

Encoding for the Register offset variant Applies when `(Rm != 11111)`

```
LD1R { <Vt>.<T> }, [<Xn|SP>], <Xm>
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_AdvSIMD) then EndOfDecode(Decode_UNDEF);
integer t = UInt(Rt);
constant integer n = UInt(Rn);
constant integer m = UInt(Rm);
constant boolean wback = TRUE;
constant boolean nontemporal = FALSE;
```

C7.2.165 LD2 (multiple structures)

Load multiple 2-element structures to two registers

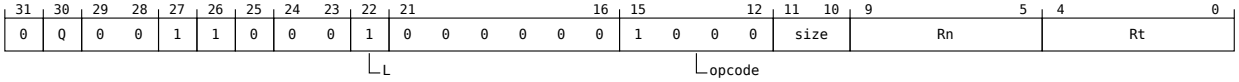
This instruction loads multiple 2-element structures from memory and writes the result to the two SIMD&FP registers, with de-interleaving.

For an example of de-interleaving, see LD3 (multiple structures).

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: No offset and Post-index

No offset
(FEAT_AdvSIMD)



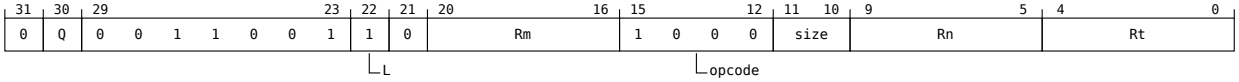
Encoding

```
LD2 { <Vt>.<T>, <Vt2>.<T> }, [<Xn|SP>]
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_AdvSIMD) then EndOfDecode(Decode_UNDEF);
constant integer t = UInt(Rt);
constant integer n = UInt(Rn);
constant integer m = integer UNKNOWN;
constant boolean wback = FALSE;
constant boolean nontemporal = FALSE;
```

Post-index
(FEAT_AdvSIMD)



Encoding for the Immediate offset variant Applies when (Rm == 11111)

```
LD2 { <Vt>.<T>, <Vt2>.<T> }, [<Xn|SP>], <imm>
```

Encoding for the Register offset variant Applies when (Rm != 11111)

```
LD2 { <Vt>.<T>, <Vt2>.<T> }, [<Xn|SP>], <Xm>
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_AdvSIMD) then EndOfDecode(Decode_UNDEF);

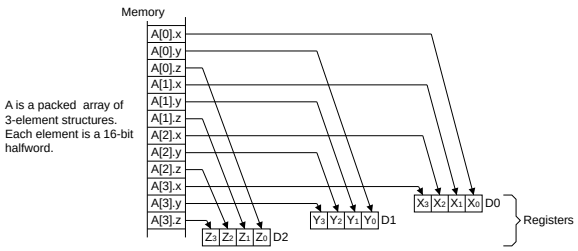
C7.2.168 LD3 (multiple structures)

Load multiple 3-element structures to three registers

This instruction loads multiple 3-element structures from memory and writes the result to the three SIMD&FP registers, with de-interleaving.

The following figure shows an example of the operation of de-interleaving of a LD3.16 (multiple 3-element structures) instruction:.



Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: No offset and Post-index

No offset
(FEAT_AdvSIMD)

<**Vt**> Is the name of the first or only SIMD&FP register to be transferred, encoded in the “Rt” field.

<**T**> Is an arrangement specifier, encoded in “size:Q”:

size	Q	<T>
00	0	8B
00	1	16B
01	0	4H
01	1	8H
10	0	2S
10	1	4S
11	0	RESERVED
11	1	2D

<**Vt2**> Is the name of the second SIMD&FP register to be transferred, encoded as “Rt” plus 1 modulo 32.

<**Vt3**> Is the name of the third SIMD&FP register to be transferred, encoded as “Rt” plus 2 modulo 32.

<**Vt4**> Is the name of the fourth SIMD&FP register to be transferred, encoded as “Rt” plus 3 modulo 32.

<**Xn|SP**> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the “Rn” field.

<**imm**> Is the post-index immediate offset, encoded in “Q”:

Q	<imm>
0	#32
1	#64

<**Xm**> Is the 64-bit name of the general-purpose post-index register, excluding XZR, encoded in the “Rm” field.

Shared Decode

C7.2.172 LD4 (single structure)

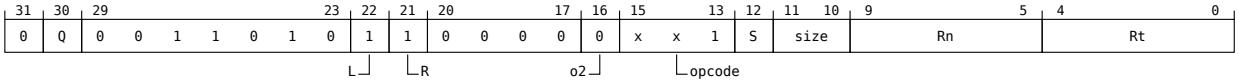
Load single 4-element structure to one lane of four registers

This instruction loads a 4-element structure from memory and writes the result to the corresponding elements of the four SIMD&FP registers without affecting the other bits of the registers.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: No offset and Post-index

No offset
(FEAT_AdvSIMD)



Encoding for the 8-bit variant Applies when `(opcode == 001)`

```
LD4 { <Vt>.B, <Vt2>.B, <Vt3>.B, <Vt4>.B }[<index>], [<Xn|SP>]
```

Encoding for the 16-bit variant Applies when `(opcode == 011 && size == x0)`

```
LD4 { <Vt>.H, <Vt2>.H, <Vt3>.H, <Vt4>.H }[<index>], [<Xn|SP>]
```

Encoding for the 32-bit variant Applies when `(opcode == 101 && size == 00)`

```
LD4 { <Vt>.S, <Vt2>.S, <Vt3>.S, <Vt4>.S }[<index>], [<Xn|SP>]
```

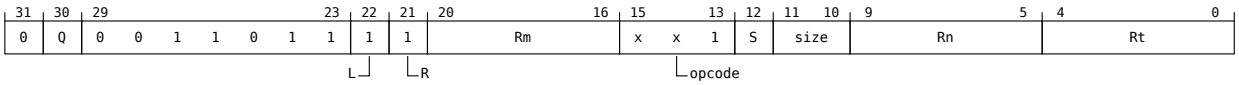
Encoding for the 64-bit variant Applies when `(opcode == 101 && S == 0 && size == 01)`

```
LD4 { <Vt>.D, <Vt2>.D, <Vt3>.D, <Vt4>.D }[<index>], [<Xn|SP>]
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_AdvSIMD) then EndOfDecode(Decode_UNDEF);
integer t = UInt(Rt);
constant integer n = UInt(Rn);
constant integer m = integer UNKNOWN;
constant boolean wback = FALSE;
constant boolean nontemporal = FALSE;
```

Post-index
(FEAT_AdvSIMD)



Encoding for the 8-bit, immediate offset variant Applies when `(Rm == 11111 && opcode == 001)`

```
LD4 { <Vt>.B, <Vt2>.B, <Vt3>.B, <Vt4>.B }[<index>], [<Xn|SP>], #4
```

Encoding for the 8-bit, register offset variant Applies when `(Rm != 11111 && opcode == 001)`

```
LD4 { <Vt>.B, <Vt2>.B, <Vt3>.B, <Vt4>.B }[<index>], [<Xn|SP>], <Xm>
```

C7.2.174 LDNP (SIMD&FP)

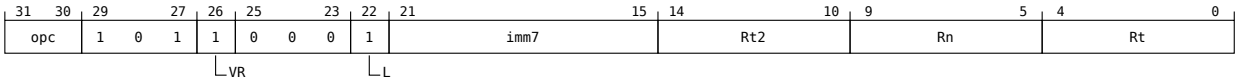
Load pair of SIMD&FP registers, with non-temporal hint

This instruction loads a pair of SIMD&FP registers from memory, issuing a hint to the memory system that the access is non-temporal. The address that is used for the load is calculated from a base register value and an optional immediate offset.

For information about non-temporal pair instructions, see Load/Store SIMD and Floating-point non-temporal pair.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Signed offset
(FEAT_FP)



Encoding for the 32-bit variant Applies when `(opc == 00)`

```
LDNP <St1>, <St2>, [<Xn|SP>{, #<imm>}]
```

Encoding for the 64-bit variant Applies when `(opc == 01)`

```
LDNP <Dt1>, <Dt2>, [<Xn|SP>{, #<imm>}]
```

Encoding for the 128-bit variant Applies when `(opc == 10)`

```
LDNP <Qt1>, <Qt2>, [<Xn|SP>{, #<imm>}]
```

Decode for all variants of this encoding

```
// Empty.
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Architectural Constraints on UNPREDICTABLE behaviors, and particularly LDNP (SIMD&FP).

Assembler Symbols

<**St1**> Is the 32-bit name of the first SIMD&FP register to be transferred, encoded in the “Rt” field.

<**St2**> Is the 32-bit name of the second SIMD&FP register to be transferred, encoded in the “Rt2” field.

<**Xn|SP**> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the “Rn” field.

<**imm**> For the “32-bit” variant: is the optional signed immediate byte offset, a multiple of 4 in the range -256 to 252, defaulting to 0 and encoded in the “imm7” field as <imm>/4.

For the “64-bit” variant: is the optional signed immediate byte offset, a multiple of 8 in the range -512 to 504, defaulting to 0 and encoded in the “imm7” field as <imm>/8.

For the “128-bit” variant: is the optional signed immediate byte offset, a multiple of 16 in the range -1024 to 1008, defaulting to 0 and encoded in the “imm7” field as <imm>/16.

<**Dt1**> Is the 64-bit name of the first SIMD&FP register to be transferred, encoded in the “Rt” field.

<**Dt2**> Is the 64-bit name of the second SIMD&FP register to be transferred, encoded in the “Rt2” field.

<**Qt1**> Is the 128-bit name of the first SIMD&FP register to be transferred, encoded in the “Rt” field.

Assembler Symbols

<**St1**> Is the 32-bit name of the first SIMD&FP register to be transferred, encoded in the “Rt” field.

<**St2**> Is the 32-bit name of the second SIMD&FP register to be transferred, encoded in the “Rt2” field.

<**Xn|SP**> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the “Rn” field.

<**imm**> For the “Post-index 32-bit” and “Pre-index 32-bit” variants: is the signed immediate byte offset, a multiple of 4 in the range -256 to 252, encoded in the “imm7” field as <imm>/4.

For the “Post-index 64-bit” and “Pre-index 64-bit” variants: is the signed immediate byte offset, a multiple of 8 in the range -512 to 504, encoded in the “imm7” field as <imm>/8.

For the “Post-index 128-bit” and “Pre-index 128-bit” variants: is the signed immediate byte offset, a multiple of 16 in the range -1024 to 1008, encoded in the “imm7” field as <imm>/16.

For the “Signed offset 32-bit” variant: is the optional signed immediate byte offset, a multiple of 4 in the range -256 to 252, defaulting to 0 and encoded in the “imm7” field as <imm>/4.

For the “Signed offset 64-bit” variant: is the optional signed immediate byte offset, a multiple of 8 in the range -512 to 504, defaulting to 0 and encoded in the “imm7” field as <imm>/8.

For the “Signed offset 128-bit” variant: is the optional signed immediate byte offset, a multiple of 16 in the range -1024 to 1008, defaulting to 0 and encoded in the “imm7” field as <imm>/16.

<**Dt1**> Is the 64-bit name of the first SIMD&FP register to be transferred, encoded in the “Rt” field.

<**Dt2**> Is the 64-bit name of the second SIMD&FP register to be transferred, encoded in the “Rt2” field.

C7.2.176 LDR (immediate, SIMD&FP)

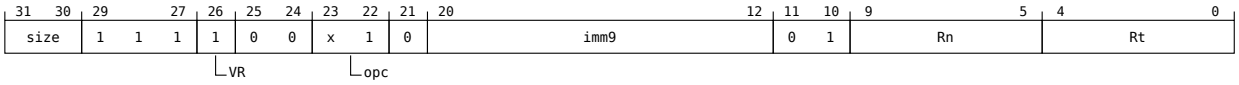
Load SIMD&FP register (immediate offset)

This instruction loads an element from memory, and writes the result as a scalar to the SIMD&FP register. The address that is used for the load is calculated from a base register value, a signed immediate offset, and an optional offset that is a multiple of the element size.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 3 classes: Post-index , Pre-index and Unsigned offset

Post-index
(FEAT_FP)



Encoding for the 8-bit variant Applies when `(size == 00 && opc == 01)`

```
LDR <Bt>, [<Xn|SP>], #<simm>
```

Encoding for the 16-bit variant Applies when `(size == 01 && opc == 01)`

```
LDR <Ht>, [<Xn|SP>], #<simm>
```

Encoding for the 32-bit variant Applies when `(size == 10 && opc == 01)`

```
LDR <St>, [<Xn|SP>], #<simm>
```

Encoding for the 64-bit variant Applies when `(size == 11 && opc == 01)`

```
LDR <Dt>, [<Xn|SP>], #<simm>
```

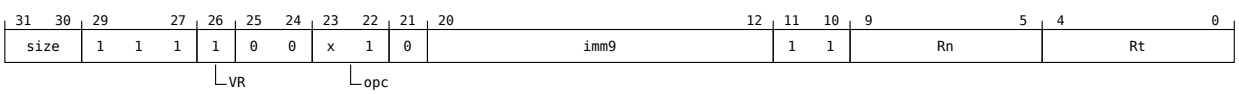
Encoding for the 128-bit variant Applies when `(size == 00 && opc == 11)`

```
LDR <Qt>, [<Xn|SP>], #<simm>
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_FP) then EndOfDecode(Decode_UNDEF);
if opc<1> == '1' && size != '00' then EndOfDecode(Decode_UNDEF);
constant integer scale = if opc<1> == '1' then 4 else UInt(size);
constant boolean wback = TRUE;
constant boolean postindex = TRUE;
constant bits(64) offset = SignExtend(imm9, 64);
```

Pre-index
(FEAT_FP)



Encoding for the 8-bit variant Applies when `(size == 00 && opc == 01)`

Assembler Symbols

<**Bt**> Is the 8-bit name of the SIMD&FP register to be transferred, encoded in the "Rt" field.

<**Xn|SP**> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<**simm**> Is the signed immediate byte offset, in the range -256 to 255, encoded in the "imm9" field.

<**Ht**> Is the 16-bit name of the SIMD&FP register to be transferred, encoded in the "Rt" field.

<**St**> Is the 32-bit name of the SIMD&FP register to be transferred, encoded in the "Rt" field.

<**Dt**> Is the 64-bit name of the SIMD&FP register to be transferred, encoded in the "Rt" field.

<**Qt**> Is the 128-bit name of the SIMD&FP register to be transferred, encoded in the "Rt" field.

<**pimm**> For the "8-bit" variant: is the optional positive immediate byte offset, in the range 0 to 4095, defaulting to 0 and encoded in the "imm12" field.

For the "16-bit" variant: is the optional positive immediate byte offset, a multiple of 2 in the range 0 to 8190, defaulting to 0 and encoded in the "imm12" field as <pimm>/2.

For the "32-bit" variant: is the optional positive immediate byte offset, a multiple of 4 in the range 0 to 16380, defaulting to 0 and encoded in the "imm12" field as <pimm>/4.

For the "64-bit" variant: is the optional positive immediate byte offset, a multiple of 8 in the range 0 to 32760, defaulting to 0 and encoded in the "imm12" field as <pimm>/8.

For the "128-bit" variant: is the optional positive immediate byte offset, a multiple of 16 in the range 0 to 65520, defaulting to 0 and encoded in the "imm12" field as <pimm>/16.

Shared Decode

```
constant integer t = UInt(Rt);
constant integer n = UInt(Rn);
constant integer datasize = 8 << scale;
constant boolean nontemporal = FALSE;
```

Operation

```
AArch64.CheckFPEnabled();

<**Xm**> When option<0> is set to 1, is the 64-bit name of the general-purpose index register, encoded in the "Rm" field.

<**extend**> For the "8-bit with extended register offset" variant: is the index extend specifier, encoded in "option":

option	<extend>
010	UXTW
110	SXTW
111	SXTX

For the "128-bit", "16-bit", "32-bit", and "64-bit" variants: is the index extend/shift specifier, defaulting to LSL, and which must be omitted for the LSL option when <amount> is omitted, encoded in "option":

option	<extend>
010	UXTW
011	LSL
110	SXTW
111	SXTX

<**amount**> For the "8-bit with extended register offset" and "8-bit with shifted register offset" variants: is the index shift amount, it must be #0, encoded in "S" as 0 if omitted, or as 1 if present.

For the "16-bit" variant: is the index shift amount, optional only when <extend> is not LSL. Where it is permitted to be optional, it defaults to #0. It is encoded in "S":

S	<amount>
0	#0
1	#1

For the "32-bit" variant: is the index shift amount, optional only when <extend> is not LSL. Where it is permitted to be optional, it defaults to #0. It is encoded in "S":

S	<amount>
0	#0
1	#2

For the "64-bit" variant: is the index shift amount, optional only when <extend> is not LSL. Where it is permitted to be optional, it defaults to #0. It is encoded in "S":

S	<amount>
0	#0
1	#3

For the "128-bit" variant: is the index shift amount, optional only when <extend> is not LSL. Where it is permitted to be optional, it defaults to #0. It is encoded in "S":

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.

C7.2.180 MLA (by element)

Multiply-add to accumulator (vector, by element)

This instruction multiplies the vector elements in the first source SIMD&FP register by the specified value in the second source SIMD&FP register, and accumulates the results with the vector elements of the destination SIMD&FP register. All the values in this instruction are unsigned integer values.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Vector
(FEAT_AdvSIMD)

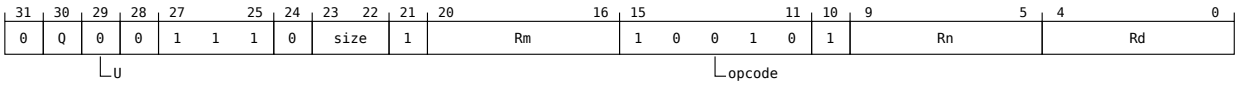
C7.2.181 MLA (vector)

Multiply-add to accumulator (vector)

This instruction multiplies corresponding elements in the vectors of the two source SIMD&FP registers, and accumulates the results with the vector elements of the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Three registers of the same type
(FEAT_AdvSIMD)



Encoding

```
MLA <Vd>.<T>, <Vn>.<T>, <Vm>.<T>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_AdvSIMD) then EndOfDecode(Decode_UNDEF);
constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer m = UInt(Rm);
if size == '11' then EndOfDecode(Decode_UNDEF);
constant integer esize = 8 << UInt(size);
constant integer datasize = 64 << UInt(Q);
constant integer elements = datasize DIV esize;

C7.2.184 MOV (scalar)

Move vector element to scalar

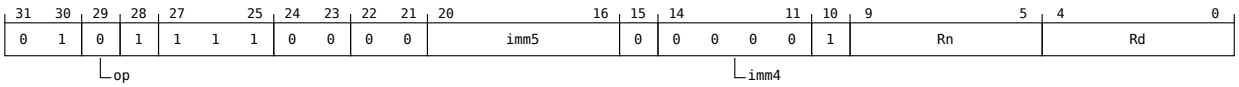
This instruction duplicates the specified vector element in the SIMD&FP source register into a scalar, and writes the result to the SIMD&FP destination register.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This is an alias of DUP (element). This means:

- The encodings in this description are named to match the encodings of DUP (element).
- The description of DUP (element) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

Scalar
(FEAT_AdvSIMD)



Encoding

```
MOV <V><d>, <Vn>.<T>[<index>]
```

is equivalent to

```
DUP <V><d>, <Vn>.<T>[<index>]
```

and is always the preferred disassembly.

Assembler Symbols

C7.2.185 MOV (element)

Move vector element to another vector element

This instruction copies the vector element of the source SIMD&FP register to the specified vector element of the destination SIMD&FP register.

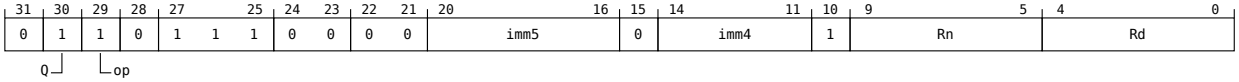
This instruction can insert data into individual elements within a SIMD&FP register without clearing the remaining bits to zero.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This is an alias of INS (element). This means:

- The encodings in this description are named to match the encodings of INS (element).
- The description of INS (element) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

Advanced SIMD
(FEAT_AdvSIMD)



Encoding

```
MOV <Vd>.<Ts>[<index1>], <Vn>.<Ts>[<index2>]
```

is equivalent to

```
INS <Vd>.<Ts>[<index1>], <Vn>.<Ts>[<index2>]
```

and is always the preferred disassembly.

Assembler Symbols

<**Vd**> Is the name of the SIMD&FP destination register, encoded in the “Rd” field.

xxx10	UInt(imm4<3:1>)
xx100	UInt(imm4<3:2>)
x1000	UInt(imm4<3>)

Unspecified bits in “imm4” are ignored but should be set to zero by an assembler.

Operation

The description of INS (element) gives the operational pseudocode for this instruction.

Operational Information

The description of INS (element) gives the operational information for this instruction.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C7.2.186 MOV (from general)

Move general-purpose register to a vector element

This instruction copies the contents of the source general-purpose register to the specified vector element in the destination SIMD&FP register.

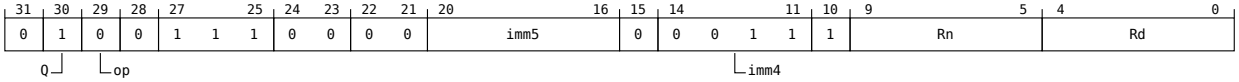
This instruction can insert data into individual elements within a SIMD&FP register without clearing the remaining bits to zero.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This is an alias of INS (general). This means:

- The encodings in this description are named to match the encodings of INS (general).
- The description of INS (general) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

Advanced SIMD
(FEAT_AdvSIMD)



Encoding

```
MOV <Vd>.<Ts>[<index>], <R><n>
```

is equivalent to

```
INS <Vd>.<Ts>[<index>], <R><n>
```

and is always the preferred disassembly.

Assembler Symbols

<**Vd**> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<**Ts**> Is an element size specifier, encoded in "imm5":

imm5	<**Ts**>
x0000	RESERVED
xxxx1	B
xxx10	H
xx100	S
x1000	D

imm5	<R>
x0000	RESERVED
xxxx1	W
xxx10	W
xx100	W
x1000	X

<**n**> Is the number [0-30] of the general-purpose source register or ZR (31), encoded in the “Rn” field.

Operation

The description of INS (general) gives the operational pseudocode for this instruction.

Operational Information

The description of INS (general) gives the operational information for this instruction.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C7.2.187 MOV (vector)

Move vector

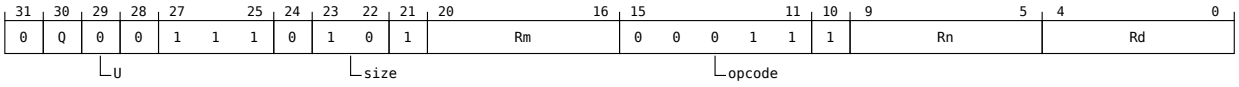
This instruction copies the vector in the source SIMD&FP register into the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This is an alias of ORR (vector, register). This means:

- The encodings in this description are named to match the encodings of ORR (vector, register).
- The description of ORR (vector, register) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

Three registers of the same type
(FEAT_AdvSIMD)



Encoding

```
MOV <Vd>.<T>, <Vn>.<T>
```

is equivalent to

```
ORR <Vd>.<T>, <Vn>.<T>, <Vn>.<T>
```

and is the preferred disassembly when `Rm == Rn`.

Assembler Symbols

<**Vd**> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<**T**> Is an arrangement specifier, encoded in "Q":

Q	<T>
0	8B
1	16B

<**Vn**> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

Operation

The description of ORR (vector, register) gives the operational pseudocode for this instruction.

Operational Information

The description of ORR (vector, register) gives the operational information for this instruction.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C7.2.188 MOV (to general)

Move vector element to general-purpose register

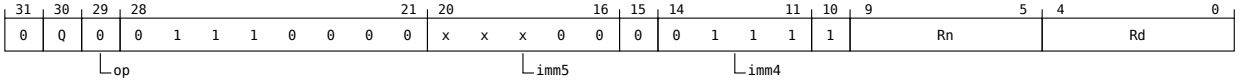
This instruction reads the unsigned integer from the source SIMD&FP register, zero-extends it to form a 32-bit or 64-bit value, and writes the result to the destination general-purpose register.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This is an alias of UMOV. This means:

- The encodings in this description are named to match the encodings of UMOV.
- The description of UMOV gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

Advanced SIMD
(FEAT_AdvSIMD)



Encoding for the 32-bit variant Applies when `(Q == 0 && imm5 == xx100)`

```
MOV <Wd>, <Vn>.S[<index>]
```

is equivalent to

```
UMOV <Wd>, <Vn>.S[<index>]
```

and is always the preferred disassembly.

Encoding for the 64-bit variant Applies when `(Q == 1 && imm5 == x1000)`

```
MOV <Xd>, <Vn>.D[<index>]
```

is equivalent to

```
UMOV <Xd>, <Vn>.D[<index>]
```

and is always the preferred disassembly.

Assembler Symbols

<**Wd**> Is the 32-bit name of the general-purpose destination register, encoded in the “Rd” field.

<**Vn**> Is the name of the SIMD&FP source register, encoded in the “Rn” field.

<**index**> For the “32-bit” variant: is the element index encoded in “imm5<4:3>”.

For the “64-bit” variant: is the element index encoded in “imm5<4>”.

<**Xd**> Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

Operation

The description of UMOV gives the operational pseudocode for this instruction.

Operational Information

The description of UMOV gives the operational information for this instruction.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

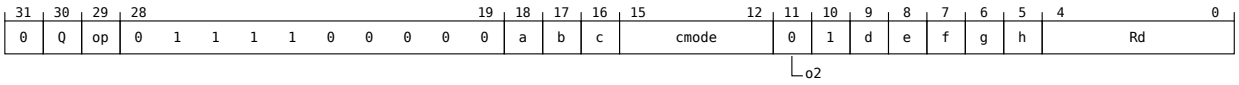
C7.2.189 MOVI

Move immediate (vector)

This instruction places an immediate constant into every vector element of the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Advanced SIMD
(FEAT_AdvSIMD)



Encoding for the 8-bit variant Applies when `(op == 0 && cmode == 1110)`

```
MOVI <Vd>.<T>, #<imm8>{, LSL #0}
```

Encoding for the 16-bit shifted immediate variant Applies when `(op == 0 && cmode == 10x0)`

```
MOVI <Vd>.<T>, #<imm8>{, LSL #<amount>}
```

Encoding for the 32-bit shifted immediate variant Applies when `(op == 0 && cmode == 0xx0)`

```
MOVI <Vd>.<T>, #<imm8>{, LSL #<amount>}
```

Encoding for the 32-bit shifting ones variant Applies when `(op == 0 && cmode == 110x)`

```
MOVI <Vd>.<T>, #<imm8>, MSL #<amount>
```

Encoding for the 64-bit scalar variant Applies when `(Q == 0 && op == 1 && cmode == 1110)`

```
MOVI <Dd>, #<imm>
```

Encoding for the 64-bit vector variant Applies when `(Q == 1 && op == 1 && cmode == 1110)`

```
MOVI <Vd>.2D, #<imm>
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_AdvSIMD) then EndOfDecode(Decode_UNDEF);
constant integer rd = UInt(Rd);
constant integer datasize = 64 << UInt(Q);
constant bits(64) imm64 = AdvSIMDExpandImm(op, cmode, a:b:c:d:e:f:g:h);
constant bits(datasize) imm = Replicate(imm64, datasize DIV 64);
```

Assembler Symbols

<**Vd**> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<**T**> For the "8-bit" variant: is an arrangement specifier, encoded in "Q":

Q	<T>
0	8B
1	16B

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.

<**m**> Is the number of the second SIMD&FP source register, encoded in "size:M:Rm":

size	<**m**>
00	RESERVED
01	UInt('0':Rm)
10	UInt(M:Rm)
11	RESERVED

Restricted to 0-15 when element size <Ts> is H.

<**Ts**> Is an element size specifier, encoded in "size":

size	<**Ts**>
00	RESERVED
01	H
10	S
11	RESERVED

<**index**> Is the element index, encoded in "size:H:L:M":

size	<**index**>
00	RESERVED
01	UInt(H:L:M)
10	UInt(H:L)
11	RESERVED

Operation

```
AArch64.CheckFPAdvSIMDEnabled();
constant bits(datasize) operand1 = V[n, datasize];
constant bits(idxdsize) operand2 = V[m, idxdsize];
bits(datasize) result;
integer element1;
integer element2;
bits(esize) product;

element2 = UInt(Elem[operand2, index, esize]);
for e = 0 to elements-1
    element1 = UInt(Elem[operand1, e, esize]);
    product = (element1 * element2)<esize-1:0>;
    Elem[result, e, esize] = product;

V[d, datasize] = result;
```

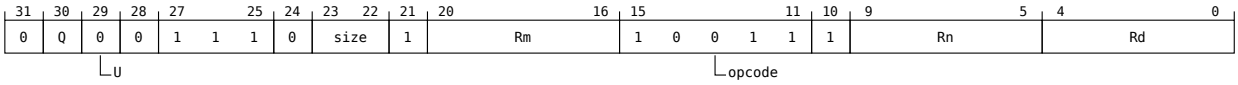
C7.2.191 MUL (vector)

Multiply (vector)

This instruction multiplies corresponding elements in the vectors of the two source SIMD&FP registers, places the results in a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Three registers of the same type
(FEAT_AdvSIMD)



Encoding

```
MUL <Vd>.<T>, <Vn>.<T>, <Vm>.<T>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_AdvSIMD) then EndOfDecode(Decode_UNDEF);
if U == '1' && size != '00' then EndOfDecode(Decode_UNDEF);
if size == '11' then EndOfDecode(Decode_UNDEF);
constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer m = UInt(Rm);
constant integer esize = 8 << UInt(size);
constant integer datasize = 64 << UInt(Q);
constant integer elements = datasize DIV esize;
```

Assembler Symbols

<**Vd**> Is the name of the SIMD&FP destination register, encoded in the “Rd” field.

<**T**> Is an arrangement specifier, encoded in “size:Q”:

size	Q	<T>
00	0	8B
00	1	16B
01	0	4H
01	1	8H
10	0	2S
10	1	4S
11	x	RESERVED

<**Vn**> Is the name of the first SIMD&FP source register, encoded in the “Rn” field.

<**Vm**> Is the name of the second SIMD&FP source register, encoded in the “Rm” field.

Operation

C7.2.192 MVN

Bitwise NOT (vector)

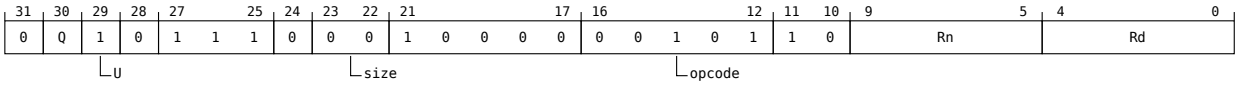
This instruction reads each vector element from the source SIMD&FP register, places the inverse of each value into a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This is an alias of NOT. This means:

- The encodings in this description are named to match the encodings of NOT.
- The description of NOT gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

Vector
(FEAT_AdvSIMD)



Encoding

```
MVN <Vd>.<T>, <Vn>.<T>
```

is equivalent to

```
NOT <Vd>.<T>, <Vn>.<T>
```

and is always the preferred disassembly.

Assembler Symbols

<**Vd**> Is the name of the SIMD&FP destination register, encoded in the “Rd” field.

<**T**> Is an arrangement specifier, encoded in “Q”:

Q	<T>
0	8B
1	16B

<**Vn**> Is the name of the SIMD&FP source register, encoded in the “Rn” field.

Operation

The description of NOT gives the operational pseudocode for this instruction.

Operational Information

The description of NOT gives the operational information for this instruction.

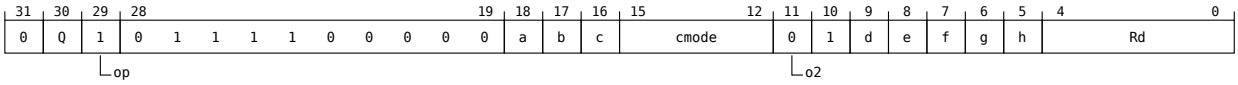
C7.2.193 MVNI

Move inverted immediate (vector)

This instruction places the inverse of an immediate constant into every vector element of the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Advanced SIMD
(FEAT_AdvSIMD)



Encoding for the 16-bit shifted immediate variant Applies when `(cmode == 10x0)`

```
MVNI <Vd>.<T>, #<imm8>{, LSL #<amount>}
```

Encoding for the 32-bit shifted immediate variant Applies when `(cmode == 0xx0)`

```
MVNI <Vd>.<T>, #<imm8>{, LSL #<amount>}
```

Encoding for the 32-bit shifting ones variant Applies when `(cmode == 110x)`

```
MVNI <Vd>.<T>, #<imm8>, MSL #<amount>
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_AdvSIMD) then EndOfDecode(Decode_UNDEF);
constant integer rd = UInt(Rd);
constant integer datasize = 64 << UInt(Q);
constant bits(64) imm64 = AdvSIMDExpandImm(op, cmode, a:b:c:d:e:f:g:h);
constant bits(datasize) imm = Replicate(imm64, datasize DIV 64);
```

Assembler Symbols

<**Vd**> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<**T**> For the "16-bit shifted immediate" variant: is an arrangement specifier, encoded in "Q":

Q	<T>
0	4H

C7.2.194 NEG (vector)

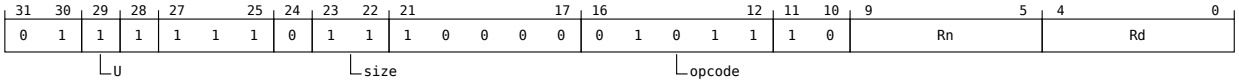
Negate (vector)

This instruction reads each vector element from the source SIMD&FP register, negates each value, puts the result into a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Scalar and Vector

Scalar
(FEAT_AdvSIMD)



Encoding

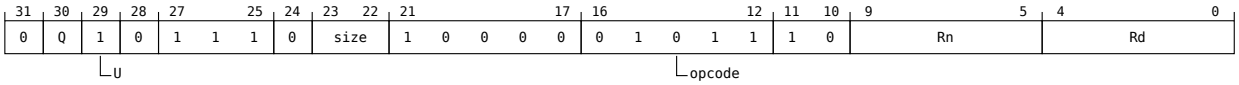
```
NEG D<d>, D<n>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_AdvSIMD) then EndOfDecode(Decode_UNDEF);
if size != '11' then EndOfDecode(Decode_UNDEF);
constant integer d = UInt(Rd);
constant integer n = UInt(Rn);

constant integer esize = 8 << UInt(size);
constant integer datasize = esize;
constant integer elements = 1;
```

Vector
(FEAT_AdvSIMD)



Encoding

```
NEG <Vd>.<T>, <Vn>.<T>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_AdvSIMD) then EndOfDecode(Decode_UNDEF);
if size:Q == '110' then EndOfDecode(Decode_UNDEF);
constant integer d = UInt(Rd);
constant integer n = UInt(Rn);

constant integer esize = 8 << UInt(size);
constant integer datasize = 64 << UInt(Q);
constant integer elements = datasize DIV esize;
```

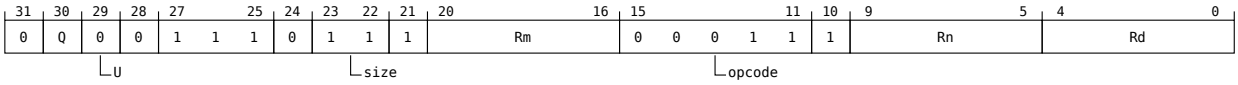
C7.2.196 ORN (vector)

Bitwise inclusive OR NOT (vector)

This instruction performs a bitwise OR NOT between the two source SIMD&FP registers, and writes the result to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Three registers of the same type
(FEAT_AdvSIMD)



Encoding

```
ORN <Vd>.<T>, <Vn>.<T>, <Vm>.<T>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_AdvSIMD) then EndOfDecode(Decode_UNDEF);
constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer m = UInt(Rm);
constant integer datasize = 64 << UInt(Q);
```

Assembler Symbols

<**Vd**> Is the name of the SIMD&FP destination register, encoded in the “Rd” field.

<**T**> Is an arrangement specifier, encoded in “Q”:

Q	<T>
0	8B
1	16B

<**Vn**> Is the name of the first SIMD&FP source register, encoded in the “Rn” field.

<**Vm**> Is the name of the second SIMD&FP source register, encoded in the “Rm” field.

Operation

```
AArch64.CheckFPAdvSIMDEnabled();
constant bits(datasize) operand1 = V[n, datasize];
constant bits(datasize) operand2 = NOT(V[m, datasize]);
V[d, datasize] = operand1 OR operand2;
```

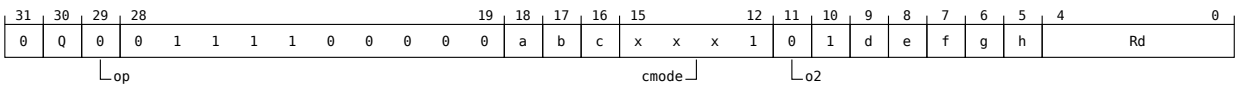
C7.2.197 ORR (vector, immediate)

Bitwise inclusive OR (vector, immediate)

This instruction reads each vector element from the destination SIMD&FP register, performs a bitwise OR between each result and an immediate constant, places the result into a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Shifted immediate
(FEAT_AdvSIMD)



Encoding for the 16-bit variant Applies when `(cmode == 10x1)`

```
ORR <Vd>.<T>, #<imm8>{, LSL #<amount>}
```

Encoding for the 32-bit variant Applies when `(cmode == 0xx1)`

```
ORR <Vd>.<T>, #<imm8>{, LSL #<amount>}
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_AdvSIMD) then EndOfDecode(Decode_UNDEF);
constant integer rd = UInt(Rd);
constant integer datasize = 64 << UInt(Q);
constant bits(64) imm64 = AdvSIMDExpandImm(op, cmode, a:b:c:d:e:f:g:h);
constant bits(datasize) imm = Replicate(imm64, datasize DIV 64);
```

Assembler Symbols

<**Vd**> Is the name of the SIMD&FP register, encoded in the "Rd" field.

<**T**> For the "16-bit" variant: is an arrangement specifier, encoded in "Q":

Q	<T>

C7.2.200 PMULL, PMULL2

Polynomial multiply long

This instruction multiplies corresponding elements in the lower or upper half of the vectors of the two source SIMD&FP registers, places the results in a vector, and writes the vector to the destination SIMD&FP register. The destination vector elements are twice as long as the elements that are multiplied.

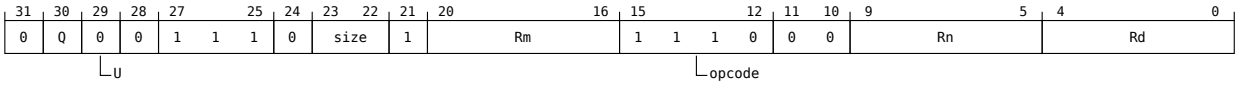
For information about multiplying polynomials, see Polynomial arithmetic over {0, 1}.

The PMULL instruction extracts each source vector from the lower half of each source register. The PMULL2 instruction extracts each source vector from the upper half of each source register.

The PMULL and PMULL2 variants that operate on 64-bit source elements are defined only when FEAT_PMULL is implemented.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Three registers, not all the same type
(FEAT_AdvSIMD)



Encoding

```
PMULL{2} <Vd>.<Ta>, <Vn>.<Tb>, <Vm>.<Tb>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_AdvSIMD) then EndOfDecode(Decode_UNDEF);
if size == '01' || size == '10' then EndOfDecode(Decode_UNDEF);
if size == '11' && !IsFeatureImplemented(FEAT_PMULL) then EndOfDecode(Decode_UNDEF);
constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer m = UInt(Rm);
constant integer esize = 8 << UInt(size);
constant integer datasize = 64;
constant integer part = UInt(Q);
constant integer elements = datasize DIV esize;
```

Assembler Symbols

2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in “Q”:

Q	2
0	[absent]
1	[present]

<**Vd**> Is the name of the SIMD&FP destination register, encoded in the “Rd” field.

<**Ta**> Is an arrangement specifier, encoded in “size”:

size	<Ta>
00	8H
01	RESERVED
10	RESERVED
11	1Q

The ’1Q’ arrangement is only allocated in an implementation that includes the Cryptographic Extension, and is otherwise RESERVED.

<Vn> Is the name of the first SIMD&FP source register, encoded in the “Rn” field.

<Tb> Is an arrangement specifier, encoded in “size:Q”:

size	Q	<Tb>
00	0	8B
00	1	16B
01	x	RESERVED
10	x	RESERVED
11	0	1D
11	1	2D

<Vm> Is the name of the second SIMD&FP source register, encoded in the “Rm” field.

Operation

```
AArch64.CheckFPAdvSIMDEnabled();
constant bits(datasize) operand1 = Vpart[n, part, datasize];
constant bits(datasize) operand2 = Vpart[m, part, datasize];
bits(2*datasize) result;
bits(esize) element1;
bits(esize) element2;

for e = 0 to elements-1
    element1 = Elem[operand1, e, esize];
    element2 = Elem[operand2, e, esize];
    Elem[result, e, 2*esize] = PolynomialMult(element1, element2);

V[d, 2*datasize] = result;
```

Operational information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C7.2.201 RADDHN, RADDHN2

Rounding add returning high narrow

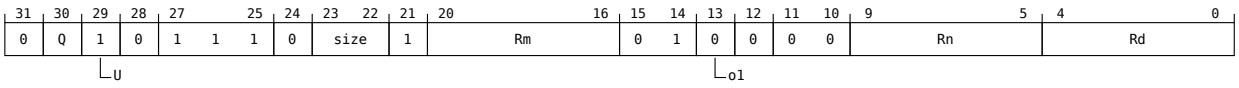
This instruction adds each vector element in the first source SIMD&FP register to the corresponding vector element in the second source SIMD&FP register, places the most significant half of the result into a vector, and writes the vector to the lower or upper half of the destination SIMD&FP register.

The results are rounded. For truncated results, see ADDHN.

The `RADDHN` instruction writes the vector to the lower half of the destination register and clears the upper half. The `RADDHN2` instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Three registers, not all the same type
(FEAT_AdvSIMD)



Encoding

```
RADDHN{2} <Vd>.<Tb>, <Vn>.<Ta>, <Vm>.<Ta>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_AdvSIMD) then EndOfDecode(Decode_UNDEF);
if size == '11' then EndOfDecode(Decode_UNDEF);
constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer m = UInt(Rm);

constant integer esize = 8 << UInt(size);
constant integer datasize = 64;
constant integer part = UInt(Q);
constant integer elements = datasize DIV esize;
constant boolean round = TRUE;
```

Assembler Symbols

2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in “Q”:

Q	2
0	[absent]
1	[present]

<**Vd**> Is the name of the SIMD&FP destination register, encoded in the “Rd” field.

<**Tb**> Is an arrangement specifier, encoded in “size:Q”:

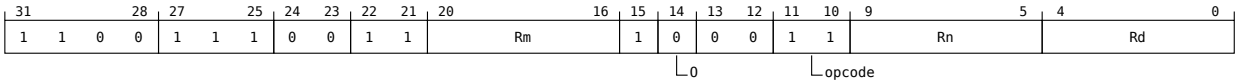
C7.2.202 RAX1

Rotate and exclusive-OR

This instruction rotates each 64-bit element of the 128-bit vector in a source SIMD&FP register left by 1, performs a bitwise exclusive-OR of the resulting 128-bit vector and the vector in another source SIMD&FP register, and writes the result to the destination SIMD&FP register.

Advanced SIMD
(FEAT_SHA3)



Encoding

```
RAX1 <Vd>.2D, <Vn>.2D, <Vm>.2D
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_SHA3) then EndOfDecode(Decode_UNDEF);
constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer m = UInt(Rm);
```

Assembler Symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the “Rd” field.

<Vn> Is the name of the first SIMD&FP source register, encoded in the “Rn” field.

<Vm> Is the name of the second SIMD&FP source register, encoded in the “Rm” field.

Operation

```
AArch64.CheckFPAdvSIMDEnabled();

constant bits(128) Vm = V[m, 128];
constant bits(128) Vn = V[n, 128];
V[d, 128] = Vn EOR (ROL(Vm<127:64>, 1):ROL(Vm<63:0>, 1));
```

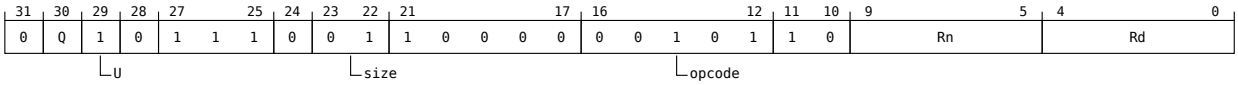
C7.2.203 RBIT (vector)

Reverse bit order (vector)

This instruction reads each vector element from the source SIMD&FP register, reverses the bits of the element, places the results into a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Vector
(FEAT_AdvSIMD)



Encoding

```
RBIT <Vd>.<T>, <Vn>.<T>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_AdvSIMD) then EndOfDecode(Decode_UNDEF);
constant integer d = UInt(Rd);
constant integer n = UInt(Rn);

constant integer esize = 8;
constant integer datasize = 64 << UInt(Q);
constant integer elements = datasize DIV 8;
```

Assembler Symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<T> Is an arrangement specifier, encoded in "Q":

Q	<T>
0	8B
1	16B

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

Operation

```
AArch64.CheckFPAdvSIMDEnabled();
constant bits(datasize) operand = V[n, datasize];
bits(datasize) result;
bits(esize) element;
bits(esize) rev;

for e = 0 to elements-1
    element = Elem[operand, e, esize];
    for i = 0 to esize-1
        rev<(esize-1)-i> = element<i>;
    Elem[result, e, esize] = rev;

V[d, datasize] = result;

C7.2.207 RSHRN, RSHRN2

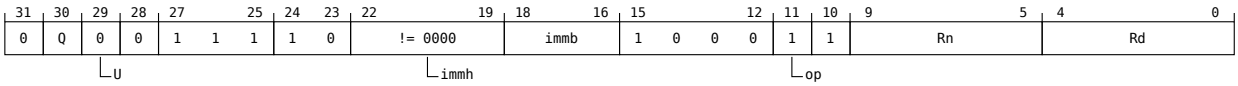
Rounding shift right narrow (immediate)

This instruction reads each unsigned integer value from the vector in the source SIMD&FP register, right shifts each result by an immediate value, writes the final result to a vector, and writes the vector to the lower or upper half of the destination SIMD&FP register. The destination vector elements are half as long as the source vector elements. The results are rounded. For truncated results, see SHRN.

The `RSHRN` instruction writes the vector to the lower half of the destination register and clears the upper half. The `RSHRN2` instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Vector
(FEAT_AdvSIMD)



Encoding

```
RSHRN{2} <Vd>.<Tb>, <Vn>.<Ta>, #<shift>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_AdvSIMD) then EndOfDecode(Decode_UNDEF);
if immh<3> == '1' then EndOfDecode(Decode_UNDEF);

constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer esize = 8 << HighestSetBitNZ(immh<2:0>);
constant integer datasize = 64;
constant integer part = UInt(Q);
constant integer elements = datasize DIV esize;

constant integer shift = (2 * esize) - UInt(immh:immb);
constant boolean round = TRUE;
```

Assembler Symbols

2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in “Q”:

Q	2
0	[absent]
1	[present]

<**Vd**> Is the name of the SIMD&FP destination register, encoded in the “Rd” field.

<**Tb**> Is an arrangement specifier, encoded in “immh:Q”:

C7.2.208 RSUBHN, RSUBHN2

Rounding subtract returning high narrow

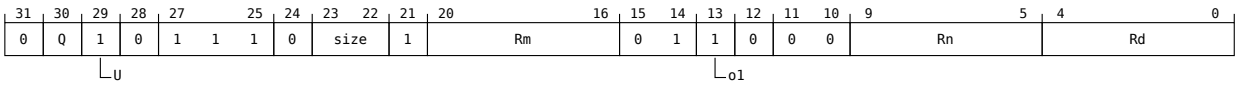
This instruction subtracts each vector element of the second source SIMD&FP register from the corresponding vector element of the first source SIMD&FP register, places the most significant half of the result into a vector, and writes the vector to the lower or upper half of the destination SIMD&FP register.

The results are rounded. For truncated results, see SUBHN.

The `RSUBHN` instruction writes the vector to the lower half of the destination register and clears the upper half. The `RSUBHN2` instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Three registers, not all the same type
(FEAT_AdvSIMD)



Encoding

```
RSUBHN{2} <Vd>.<Tb>, <Vn>.<Ta>, <Vm>.<Ta>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_AdvSIMD) then EndOfDecode(Decode_UNDEF);
if size == '11' then EndOfDecode(Decode_UNDEF);
constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer m = UInt(Rm);

constant integer esize = 8 << UInt(size);
constant integer datasize = 64;
constant integer part = UInt(Q);
constant integer elements = datasize DIV esize;
constant boolean round = TRUE;
```

Assembler Symbols

2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in “Q”:

Q	2
0	[absent]
1	[present]

<**Vd**> Is the name of the SIMD&FP destination register, encoded in the “Rd” field.

C7.2.213 SADALP

Signed add and accumulate long pairwise

This instruction adds pairs of adjacent signed integer values from the vector in the source SIMD&FP register and accumulates the results into the vector elements of the destination SIMD&FP register. The destination vector elements are twice as long as the source vector elements.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Vector

C7.2.214 SADDL, SADDL2

Signed add long (vector)

This instruction adds each vector element in the lower or upper half of the first source SIMD&FP register to the corresponding vector element of the second source SIMD&FP register, places the results into a vector, and writes the vector to the destination SIMD&FP register. The destination vector elements are twice as long as the source vector elements. All the values in this instruction are signed integer values.

The SADDL instruction extracts each source vector from the lower half of each source register. The SADDL2 instruction extracts each source vector from the upper half of each source register.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Three registers, not all the same type

C7.2.217 SADDW, SADDW2

Signed add wide

This instruction adds vector elements of the first source SIMD&FP register to the corresponding vector elements in the lower or upper half of the second source SIMD&FP register, places the results in a vector, and writes the vector to the SIMD&FP destination register.

The `SADDW` instruction extracts the second source vector from the lower half of the second source register. The `SADDW2` instruction extracts the second source vector from the upper half of the second source register.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.218 SCVTF (vector, fixed-point)

Signed fixed-point convert to floating-point (vector)

This instruction converts each element in a vector from fixed-point to floating-point using the rounding mode that is specified by the FPCR, and writes the result to the SIMD&FP destination register.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Scalar and Vector

C7.2.220 SCVTF (scalar, fixed-point)

Signed fixed-point convert to floating-point (scalar)

This instruction converts the signed value in the 32-bit or 64-bit general-purpose source register to a floating-point value using the rounding mode that is specified by the FPCR, and writes the result to the SIMD&FP destination register.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

constant boolean unsigned = FALSE;
```

Assembler Symbols

<**Hd**> Is the 16-bit name of the SIMD&FP destination register, encoded in the "Rd" field.

<**Wn**> Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.

<**fbits**> For the "32-bit to double-precision", "32-bit to half-precision", and "32-bit to single-precision" variants: is the number of bits after the binary point in the fixed-point source, in the range 1 to 32, encoded as 64 minus "scale".

For the "64-bit to double-precision", "64-bit to half-precision", and "64-bit to single-precision" variants: is the number of bits after the binary point in the fixed-point source, in the range 1 to 64, encoded as 64 minus "scale".

<**Xn**> Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.

<**Sd**> Is the 32-bit name of the SIMD&FP destination register, encoded in the "Rd" field.

<**Dd**> Is the 64-bit name of the SIMD&FP destination register, encoded in the "Rd" field.

Operation

```
AArch64.CheckFPAdvSIMDEnabled();

constant integer fltsize = decode_fltsize;
constant FPRounding rounding = FPRoundingMode(FPCR);

constant bits(intsize) intval = X[n, intsize];
constant bits(fltsize) fltval = FixedToFP(intval, fracbits, unsigned, FPCR, rounding, fltsize);

V[d, fltsize] = fltval;
```

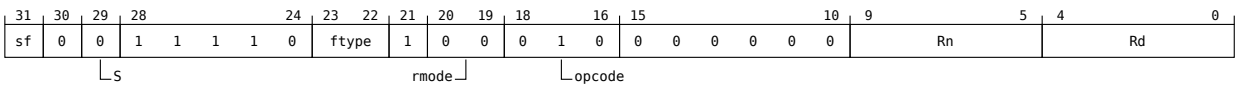
C7.2.221 SCVTF (scalar, integer)

Signed integer convert to floating-point (scalar)

This instruction converts the signed integer value in the general-purpose source register to a floating-point value using the rounding mode that is specified by the FPCR, and writes the result to the SIMD&FP destination register.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.



Encoding for the 32-bit to half-precision variant
(FEAT_FP16) Applies when `(sf == 0 && ftype == 11)`

```
SCVTF <Hd>, <Wn>
```

Encoding for the 32-bit to single-precision variant
(FEAT_FP) Applies when `(sf == 0 && ftype == 00)`

```
SCVTF <Sd>, <Wn>
```

Encoding for the 32-bit to double-precision variant
(FEAT_FP) Applies when `(sf == 0 && ftype == 01)`

```
SCVTF <Dd>, <Wn>
```

Encoding for the 64-bit to half-precision variant
(FEAT_FP16) Applies when `(sf == 1 && ftype == 11)`

```
SCVTF <Hd>, <Xn>
```

Encoding for the 64-bit to single-precision variant
(FEAT_FP) Applies when `(sf == 1 && ftype == 00)`

```
SCVTF <Sd>, <Xn>
```

Encoding for the 64-bit to double-precision variant
(FEAT_FP) Applies when `(sf == 1 && ftype == 01)`

```
SCVTF <Dd>, <Xn>
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_FP) then EndOfDecode(Decode_UNDEF);
if ftype == '10' then EndOfDecode(Decode_UNDEF);
if ftype == '11' && !IsFeatureImplemented(FEAT_FP16) then EndOfDecode(Decode_UNDEF);

constant integer d = UInt(Rd);
constant integer n = UInt(Rn);

constant integer intsize = 32 << UInt(sf);
constant integer decode_fltsize = 8 << UInt(ftype EOR '10');
constant boolean unsigned    = FALSE;
```

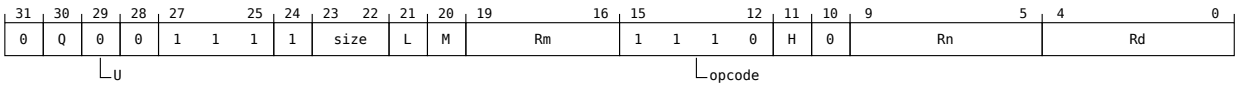
C7.2.222 SDOT (by element)

Dot product signed arithmetic (vector, by element)

This instruction performs the dot product of the four 8-bit elements in each 32-bit element of the first source register with the four 8-bit elements of an indexed 32-bit element in the second source register, accumulating the result into the corresponding 32-bit element of the destination register.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Vector
(FEAT_DotProd)



Encoding

```
SDOT <Vd>.<Ta>, <Vn>.<Tb>, <Vm>.4B[<index>]
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_DotProd) then EndOfDecode(Decode_UNDEF);
if size  != '10' then EndOfDecode(Decode_UNDEF);

constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer m = UInt(M:Rm);
constant integer index = UInt(H:L);

constant integer esize = 8 << UInt(size);
constant integer datasize = 64 << UInt(Q);
constant integer elements = datasize DIV esize;
```

Assembler Symbols

<**Vd**> Is the name of the SIMD&FP third source and destination register, encoded in the “Rd” field.

<**Ta**> Is an arrangement specifier, encoded in “Q”:

Q	<Ta>
0	2S
1	4S

<**Vn**> Is the name of the first SIMD&FP source register, encoded in the “Rn” field.

<**Tb**> Is an arrangement specifier, encoded in “Q”:

Q	<Tb>
0	8B
1	16B

<**Vm**> Is the name of the second SIMD&FP source register, encoded in the “M:Rm” fields.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

<**index**> Is the element index, encoded in the “H:L” fields.

Operation

```
AArch64.CheckFPAdvSIMDEnabled();
constant bits(datasize) operand1 = V[n, datasize];
constant bits(128) operand2 = V[m, 128];
bits(datasize) result = V[d, datasize];
for e = 0 to elements-1
    integer res = 0;
    integer element1, element2;
    for i = 0 to 3
        element1 = SInt(Elem[operand1, 4 * e + i, esize DIV 4]);
        element2 = SInt(Elem[operand2, 4 * index + i, esize DIV 4]);

        res = res + element1 * element2;
    Elem[result, e, esize] = Elem[result, e, esize] + res;
V[d, datasize] = result;
```

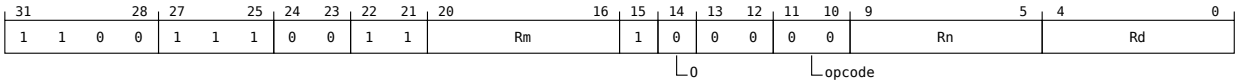
C7.2.234 SHA512H

SHA512 hash update part 1

This instruction takes the values from the three 128-bit source SIMD&FP registers and produces a 128-bit output value that combines the sigma1 and chi functions of two iterations of the SHA512 calculation. It returns this value to the destination SIMD&FP register.

Advanced SIMD
(FEAT_SHA512)



Encoding

```
SHA512H <Qd>, <Qn>, <Vm>.2D
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_SHA512) then EndOfDecode(Decode_UNDEF);
constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer m = UInt(Rm);
```

Assembler Symbols

<Qd> Is the 128-bit name of the SIMD&FP source and destination register, encoded in the "Rd" field.

<Qn> Is the 128-bit name of the second SIMD&FP source register, encoded in the "Rn" field.

<Vm> Is the name of the third SIMD&FP source register, encoded in the "Rm" field.

Operation

```
AArch64.CheckFPAdvSIMDEnabled();

bits(128) Vtmp;
bits(64)  MSigma1;
bits(64)  tmp;
constant bits(128) x = V[n, 128];
constant bits(128) y = V[m, 128];
constant bits(128) w = V[d, 128];

MSigma1 =  ROR(y<127:64>, 14) EOR ROR(y<127:64>, 18) EOR ROR(y<127:64>, 41);
Vtmp<127:64> =  (y<127:64> AND x<63:0>) EOR (NOT(y<127:64>) AND x<127:64>);
Vtmp<127:64> = (Vtmp<127:64> + MSigma1 +  w<127:64>);
tmp = Vtmp<127:64> + y<63:0>;
MSigma1 = ROR(tmp, 14) EOR ROR(tmp, 18) EOR ROR(tmp, 41);
Vtmp<63:0> = (tmp AND y<127:64>) EOR (NOT(tmp) AND x<63:0>);
Vtmp<63:0> = (Vtmp<63:0> + MSigma1 + w<63:0>);
V[d, 128] =  Vtmp;
```

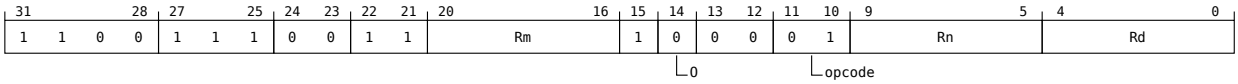
C7.2.235 SHA512H2

SHA512 hash update part 2

This instruction takes the values from the three 128-bit source SIMD&FP registers and produces a 128-bit output value that combines the sigma0 and majority functions of two iterations of the SHA512 calculation. It returns this value to the destination SIMD&FP register.

Advanced SIMD
(FEAT_SHA512)



Encoding

```
SHA512H2 <Qd>, <Qn>, <Vm>.2D
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_SHA512) then EndOfDecode(Decode_UNDEF);
constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer m = UInt(Rm);
```

Assembler Symbols

<Qd> Is the 128-bit name of the SIMD&FP source and destination register, encoded in the "Rd" field.

<Qn> Is the 128-bit name of the second SIMD&FP source register, encoded in the "Rn" field.

<Vm> Is the name of the third SIMD&FP source register, encoded in the "Rm" field.

Operation

```
AArch64.CheckFPAdvSIMDEnabled();

bits(128) Vtmp;
bits(64) NSigma0;
constant bits(128) x = V[n, 128];
constant bits(128) y = V[m, 128];
constant bits(128) w = V[d, 128];

NSigma0 =  ROR(y<63:0>, 28) EOR ROR(y<63:0>, 34) EOR ROR(y<63:0>, 39);
Vtmp<127:64> = SHAmajority(x<63:0>, y<127:64>, y<63:0>);
Vtmp<127:64> = (Vtmp<127:64> + NSigma0 +  w<127:64>);
NSigma0 =  ROR(Vtmp<127:64>, 28) EOR ROR(Vtmp<127:64>, 34) EOR ROR(Vtmp<127:64>, 39);
Vtmp<63:0> = SHAmajority(Vtmp<127:64>, y<63:0>, y<127:64>);
Vtmp<63:0> =   (Vtmp<63:0> + NSigma0 + w<63:0>);

V[d, 128] = Vtmp;
```

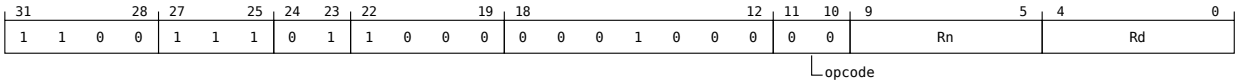
C7.2.236 SHA512SU0

SHA512 schedule update 0

This instruction takes the values from the two 128-bit source SIMD&FP registers and produces a 128-bit output value that combines the gamma0 functions of two iterations of the SHA512 schedule update that are performed after the first 16 iterations within a block. It returns this value to the destination SIMD&FP register.

Advanced SIMD
(FEAT_SHA512)



Encoding

```
SHA512SU0 <Vd>.2D, <Vn>.2D
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_SHA512) then EndOfDecode(Decode_UNDEF);
constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
```

Assembler Symbols

<Vd> Is the name of the SIMD&FP source and destination register, encoded in the "Rd" field.

<Vn> Is the name of the second SIMD&FP source register, encoded in the "Rn" field.

Operation

```
AArch64.CheckFPAdvSIMDEnabled();

bits(64) sig0;
bits(128) Vtmp;
constant bits(128) x = V[n, 128];
constant bits(128) w = V[d, 128];
sig0 = ROR(w<127:64>, 1) EOR ROR(w<127:64>, 8) EOR ('0000000':w<127:71>);
Vtmp<63:0> = w<63:0> + sig0;
sig0 = ROR(x<63:0>, 1) EOR ROR(x<63:0>, 8) EOR ('0000000':x<63:7>);
Vtmp<127:64> = w<127:64> + sig0;
V[d, 128] = Vtmp;
```

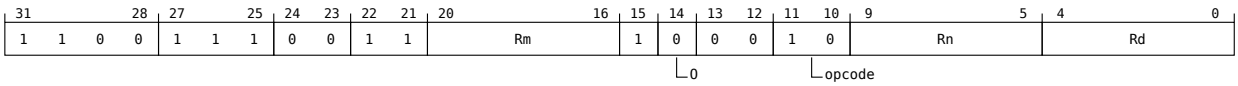
C7.2.237 SHA512SU1

SHA512 schedule update 1

This instruction takes the values from the three source SIMD&FP registers and produces a 128-bit output value that combines the gamma1 functions of two iterations of the SHA512 schedule update that are performed after the first 16 iterations within a block. It returns this value to the destination SIMD&FP register.

Advanced SIMD
(FEAT_SHA512)



Encoding

```
SHA512SU1 <Vd>.2D, <Vn>.2D, <Vm>.2D
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_SHA512) then EndOfDecode(Decode_UNDEF);
constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer m = UInt(Rm);
```

Assembler Symbols

<Vd> Is the name of the SIMD&FP source and destination register, encoded in the "Rd" field.

<Vn> Is the name of the second SIMD&FP source register, encoded in the "Rn" field.

<Vm> Is the name of the third SIMD&FP source register, encoded in the "Rm" field.

Operation

```
AArch64.CheckFPAdvSIMDEnabled();

bits(64) sig1;
bits(128) Vtmp;
constant bits(128) x = V[n, 128];
constant bits(128) y = V[m, 128];
constant bits(128) w = V[d, 128];

sig1 = ROR(x<127:64>, 19) EOR ROR(x<127:64>, 61) EOR ('000000':x<127:70>);
Vtmp<127:64> = w<127:64> + sig1 + y<127:64>;
sig1 = ROR(x<63:0>, 19) EOR ROR(x<63:0>, 61) EOR ('000000':x<63:6>);
Vtmp<63:0> = w<63:0> + sig1 + y<63:0>;

C7.2.238 SHADD

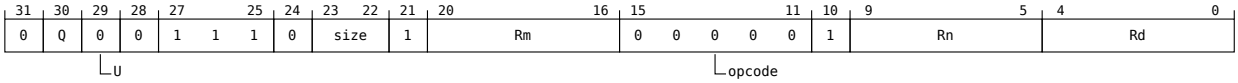
Signed halving add

This instruction adds corresponding signed integer values from the two source SIMD&FP registers, shifts each result right one bit, places the results into a vector, and writes the vector to the destination SIMD&FP register.

The results are truncated. For rounded results, see SRHADD.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Three registers of the same type
(FEAT_AdvSIMD)



Encoding

```
SHADD <Vd>.<T>, <Vn>.<T>, <Vm>.<T>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_AdvSIMD) then EndOfDecode(Decode_UNDEF);
if size == '11' then EndOfDecode(Decode_UNDEF);
constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer m = UInt(Rm);
constant integer esize = 8 << UInt(size);
constant integer datasize = 64 << UInt(Q);
constant integer elements = datasize DIV esize;
```

Assembler Symbols

<**Vd**> Is the name of the SIMD&FP destination register, encoded in the “Rd” field.

<**T**> Is an arrangement specifier, encoded in “size:Q”:

size	Q	<T>
00	0	8B
00	1	16B
01	0	4H
01	1	8H
10	0	2S
10	1	4S
11	x	RESERVED

<**Vn**> Is the name of the first SIMD&FP source register, encoded in the “Rn” field.

<**Vm**> Is the name of the second SIMD&FP source register, encoded in the “Rm” field.

Operation

C7.2.239 SHL

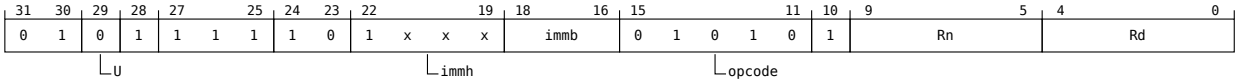
Shift left (immediate)

This instruction reads each value from a vector, left shifts each result by an immediate value, writes the final result to a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Scalar and Vector

Scalar
(FEAT_AdvSIMD)



Encoding

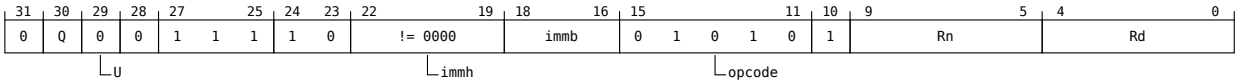
```
SHL D<d>, D<n>, #<shift>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_AdvSIMD) then EndOfDecode(Decode_UNDEF);
if immh<3> != '1' then EndOfDecode(Decode_UNDEF);

constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer esize = 8 << 3;
constant integer datasize = esize;
constant integer elements = 1;
constant integer shift = UInt(immh:immb) - esize;
```

Vector
(FEAT_AdvSIMD)



Encoding

```
SHL <Vd>.<T>, <Vn>.<T>, #<shift>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_AdvSIMD) then EndOfDecode(Decode_UNDEF);
if immh<3>:Q == '10' then EndOfDecode(Decode_UNDEF);

constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer esize = 8 << HighestSetBitNZ(immh);
constant integer datasize = 64 << UInt(Q);
constant integer elements = datasize DIV esize;
constant integer shift = UInt(immh:immb) - esize;

C7.2.240 SHLL, SHLL2

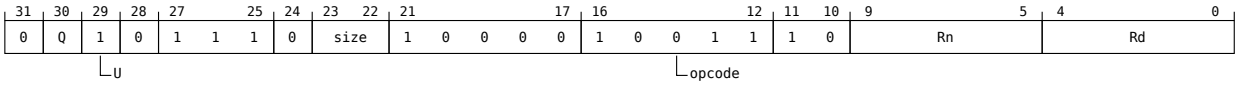
Shift left long (by element size)

This instruction reads each vector element in the lower or upper half of the source SIMD&FP register, left shifts each result by the element size, writes the final result to a vector, and writes the vector to the destination SIMD&FP register. The destination vector elements are twice as long as the source vector elements.

The SHLL instruction extracts vector elements from the lower half of the source register. The SHLL2 instruction extracts vector elements from the upper half of the source register.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Vector
(FEAT_AdvSIMD)



Encoding

```
SHLL{2} <Vd>.<Ta>, <Vn>.<Tb>, #<shift>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_AdvSIMD) then EndOfDecode(Decode_UNDEF);
constant integer d = UInt(Rd);
constant integer n = UInt(Rn);

if size == '11' then EndOfDecode(Decode_UNDEF);
constant integer esize = 8 << UInt(size);
constant integer datasize = 64;
constant integer part = UInt(Q);
constant integer elements = datasize DIV esize;

constant integer shift = esize;
```

Assembler Symbols

2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in "Q":

Q	2
0	[absent]
1	[present]

<**Vd**> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<**Ta**> Is an arrangement specifier, encoded in "size":

size	<Ta>
00	8H

C7.2.241 SHRN, SHRN2

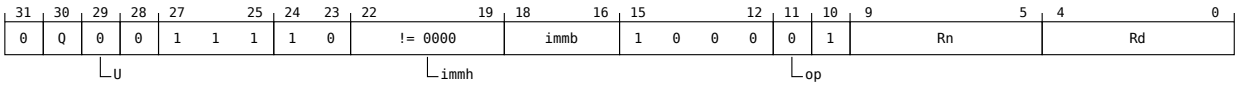
Shift right narrow (immediate)

This instruction reads each unsigned integer value from the source SIMD&FP register, right shifts each result by an immediate value, puts the final result into a vector, and writes the vector to the lower or upper half of the destination SIMD&FP register. The destination vector elements are half as long as the source vector elements. The results are truncated. For rounded results, see RSHRN.

The SHRN instruction writes the vector to the lower half of the destination register and clears the upper half. The SHRN2 instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Vector
(FEAT_AdvSIMD)



Encoding

```
SHRN{2} <Vd>.<Tb>, <Vn>.<Ta>, #<shift>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_AdvSIMD) then EndOfDecode(Decode_UNDEF);
if immh<3> == '1' then EndOfDecode(Decode_UNDEF);

constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer esize = 8 << HighestSetBitNZ(immh<2:0>);
constant integer datasize = 64;
constant integer part = UInt(Q);
constant integer elements = datasize DIV esize;

constant integer shift = (2 * esize) - UInt(immh:immb);
constant boolean round = FALSE;
```

Assembler Symbols

2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in "Q":

Q	2
0	[absent]
1	[present]

<**Vd**> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

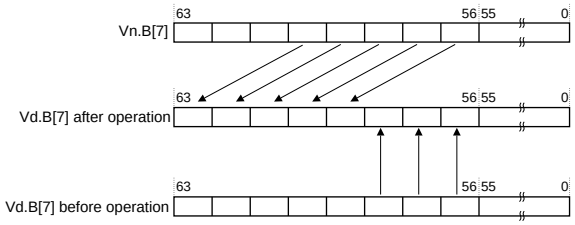
C7.2.243 SLI

Shift left and insert (immediate)

This instruction reads each vector element in the source SIMD&FP register, left shifts each vector element by an immediate value, and inserts the result into the corresponding vector element in the destination SIMD&FP register such that the new zero bits created by the shift are not inserted but retain their existing value. Bits shifted out of the left of each vector element in the source register are lost.

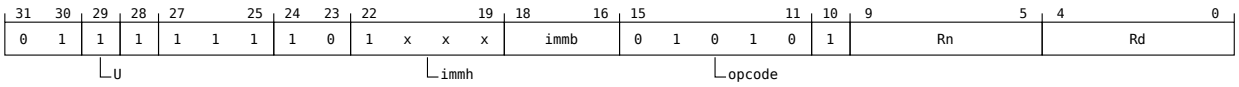
The following figure shows an example of the operation of shift left by 3 for an 8-bit vector element.



Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Scalar and Vector

Scalar
(FEAT_AdvSIMD)



Encoding

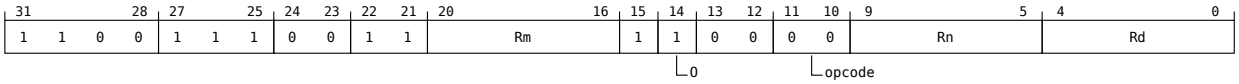
C7.2.244 SM3PARTW1

SM3PARTW1

This instruction takes three 128-bit vectors from the three source SIMD&FP registers and returns a 128-bit result in the destination SIMD&FP register. The result is obtained by a three-way exclusive-OR of the elements within the input vectors with some fixed rotations, see the Operation pseudocode for more information.

Advanced SIMD
(FEAT_SM3)



Encoding

```
SM3PARTW1 <Vd>.4S, <Vn>.4S, <Vm>.4S
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_SM3) then EndOfDecode(Decode_UNDEF);
constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer m = UInt(Rm);
```

Assembler Symbols

<Vd> Is the name of the SIMD&FP source and destination register, encoded in the "Rd" field.

<Vn> Is the name of the second SIMD&FP source register, encoded in the "Rn" field.

<Vm> Is the name of the third SIMD&FP source register, encoded in the "Rm" field.

Operation

```
AArch64.CheckFPAdvSIMDEnabled();

constant bits(128) Vm = V[m, 128];
constant bits(128) Vn = V[n, 128];
constant bits(128) Vd = V[d, 128];
bits(128) result;

result<95:0> = (Vd EOR Vn)<95:0> EOR (ROL(Vm<127:96>, 15):ROL(Vm<95:64>, 15):ROL(Vm<63:32>, 15));

for i = 0 to 3
    if i == 3 then
        result<127:96> = (Vd EOR Vn)<127:96> EOR (ROL(result<31:0>, 15));
    result<(32*i)+31:(32*i)> = (result<(32*i)+31:(32*i)> EOR ROL(result<(32*i)+31:(32*i)>, 15) EOR
                                ROL(result<(32*i)+31:(32*i)>, 23));
V[d, 128] = result;
```

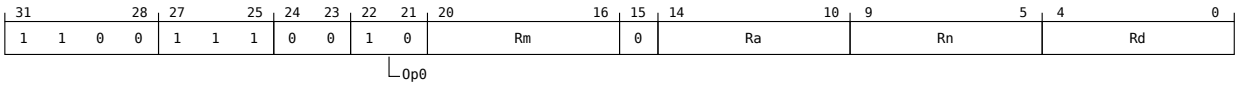
C7.2.246 SM3SS1

SM3SS1

This instruction rotates the top 32 bits of the 128-bit vector in the first source SIMD&FP register by 12, and adds that 32-bit value to the two other 32-bit values held in the top 32 bits of each of the 128-bit vectors in the second and third source SIMD&FP registers, rotating this result left by 7 and writing the final result into the top 32 bits of the vector in the destination SIMD&FP register, with the bottom 96 bits of the vector being written to 0.

Advanced SIMD
(FEAT_SM3)



Encoding

```
SM3SS1 <Vd>.4S, <Vn>.4S, <Vm>.4S, <Va>.4S
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_SM3) then EndOfDecode(Decode_UNDEF);
constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer m = UInt(Rm);
constant integer a = UInt(Ra);
```

Assembler Symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the “Rd” field.

<Vn> Is the name of the first SIMD&FP source register, encoded in the “Rn” field.

<Vm> Is the name of the second SIMD&FP source register, encoded in the “Rm” field.

<Va> Is the name of the third SIMD&FP source register, encoded in the “Ra” field.

Operation

```
AArch64.CheckFPAdvSIMDEnabled();

constant bits(128) Vm = V[m, 128];
constant bits(128) Vn = V[n, 128];
constant bits(128) Va = V[a, 128];

bits(128) result;
result<127:96> = ROL((ROL(Vn<127:96>, 12) + Vm<127:96> + Va<127:96>), 7);
result<95:0> = Zeros(96);
V[d, 128] = result;

C7.2.247 SM3TT1A

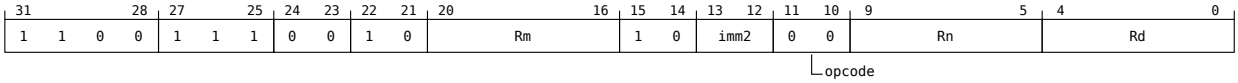
SM3TT1A

This instruction takes three 128-bit vectors from three source SIMD&FP registers and a 2-bit immediate index value, and returns a 128-bit result in the destination SIMD&FP register. It performs a three-way exclusive-OR of the three 32-bit fields held in the upper three elements of the first source vector, and adds the resulting 32-bit value and the following three other 32-bit values:

- The bottom 32-bit element of the first source vector, Vd, that was used for the three-way exclusive-OR.
- The result of the exclusive-OR of the top 32-bit element of the second source vector, Vn, with a rotation left by 12 of the top 32-bit element of the first source vector.
- A 32-bit element indexed out of the third source vector, Vm.

The result of this addition is returned as the top element of the result. The other elements of the result are taken from elements of the first source vector, with the element returned in bits<63:32> being rotated left by 9.

Advanced SIMD
(FEAT_SM3)



Encoding

```
SM3TT1A <Vd>.4S, <Vn>.4S, <Vm>.S[<imm2>]
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_SM3) then EndOfDecode(Decode_UNDEF);

C7.2.248 SM3TT1B

SM3TT1B

This instruction takes three 128-bit vectors from three source SIMD&FP registers and a 2-bit immediate index value, and returns a 128-bit result in the destination SIMD&FP register. It performs a 32-bit majority function between the three 32-bit fields held in the upper three elements of the first source vector, and adds the resulting 32-bit value and the following three other 32-bit values:

- The bottom 32-bit element of the first source vector, Vd, that was used for the 32-bit majority function.
- The result of the exclusive-OR of the top 32-bit element of the second source vector, Vn, with a rotation left by 12 of the top 32-bit element of the first source vector.
- A 32-bit element indexed out of the third source vector, Vm.

The result of this addition is returned as the top element of the result. The other elements of the result are taken from elements of the first source vector, with the element returned in bits<63:32> being rotated left by 9.

C7.2.249 SM3TT2A

SM3TT2A

This instruction takes three 128-bit vectors from three source SIMD&FP register and a 2-bit immediate index value, and returns a 128-bit result in the destination SIMD&FP register. It performs a three-way exclusive-OR of the three 32-bit fields held in the upper three elements of the first source vector, and adds the resulting 32-bit value and the following three other 32-bit values:

- The bottom 32-bit element of the first source vector, Vd, that was used for the three-way exclusive-OR.
- The 32-bit element held in the top 32 bits of the second source vector, Vn.
- A 32-bit element indexed out of the third source vector, Vm.

A three-way exclusive-OR is performed of the result of this addition, the result of the addition rotated left by 9, and the result of the addition rotated left by 17. The result of this exclusive-OR is returned as the top element of the returned result. The other elements of this result are taken from elements of the first source vector, with the element returned in bits<63:32> being rotated left by 19.

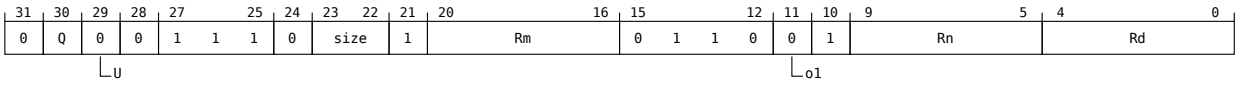
C7.2.253 SMAX

Signed maximum (vector)

This instruction compares corresponding elements in the vectors in the two source SIMD&FP registers, places the larger of each pair of signed integer values into a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Three registers of the same type
(FEAT_AdvSIMD)



Encoding

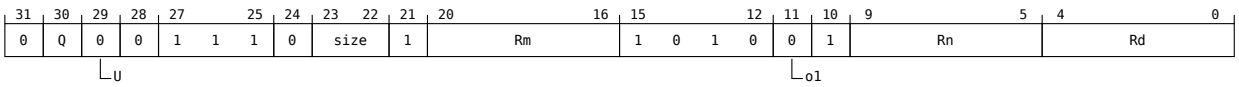
C7.2.254 SMAXP

Signed maximum pairwise

This instruction creates a vector by concatenating the vector elements of the first source SIMD&FP register after the vector elements of the second source SIMD&FP register, reads each pair of adjacent vector elements in the two source SIMD&FP registers, writes the largest of each pair of signed integer values into a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Three registers of the same type
(FEAT_AdvSIMD)



Encoding

```
SMAXP <Vd>.<T>, <Vn>.<T>, <Vm>.<T>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_AdvSIMD) then EndOfDecode(Decode_UNDEF);
if size == '11' then EndOfDecode(Decode_UNDEF);
constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer m = UInt(Rm);
constant integer esize = 8 << UInt(size);
constant integer datasize = 64 << UInt(Q);
constant integer elements = datasize DIV esize;
```

Assembler Symbols

<**Vd**> Is the name of the SIMD&FP destination register, encoded in the “Rd” field.

<**T**> Is an arrangement specifier, encoded in “size:Q”:

size	Q	<T>

C7.2.255 SMAXV

Signed maximum across vector

This instruction compares all the vector elements in the source SIMD&FP register, and writes the largest of the values as a scalar to the destination SIMD&FP register. All the values in this instruction are signed integer values.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.259 SMLAL, SMLAL2 (by element)

Signed multiply-add long (vector, by element)

This instruction multiplies each vector element in the lower or upper half of the first source SIMD&FP register by the specified vector element in the second source SIMD&FP register, and accumulates the results with the vector elements of the destination SIMD&FP register. The destination vector elements are twice as long as the elements that are multiplied. All the values in this instruction are signed integer values.

The `SMLAL` instruction extracts vector elements from the lower half of the first source register. The `SMLAL2` instruction extracts vector elements from the upper half of the first source register.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Vector

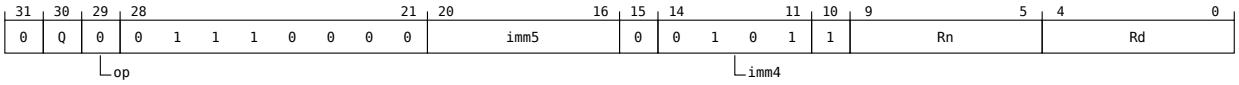
C7.2.263 SMOV

Signed move vector element to general-purpose register

This instruction reads the signed integer from the source SIMD&FP register, sign-extends it to form a 32-bit or 64-bit value, and writes the result to destination general-purpose register.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Advanced SIMD
(FEAT_AdvSIMD)



Encoding for the 32-bit variant Applies when `(Q == 0)`

```
SMOV <Wd>, <Vn>.<Ts>[<index>]
```

Encoding for the 64-bit variant Applies when `(Q == 1)`

```
SMOV <Xd>, <Vn>.<Ts>[<index>]
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_AdvSIMD) then EndOfDecode(Decode_UNDEF);
if imm5 == 'xx000' then EndOfDecode(Decode_UNDEF);
constant integer size = LowestSetBitNZ(imm5<2:0>);

constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer esize = 8 << size;
constant integer datasize = 32 << UInt(Q);
if datasize <= esize then EndOfDecode(Decode_UNDEF);
constant integer index = UInt(imm5<4:size+1>);
constant integer idxdsize = 64 << UInt(imm5<4>);
```

Assembler Symbols

<**Wd**> Is the 32-bit name of the general-purpose destination register, encoded in the “Rd” field.

<**Vn**> Is the name of the SIMD&FP source register, encoded in the “Rn” field.

<**Ts**> For the “32-bit” variant: is an element size specifier, encoded in “imm5”:

imm5	<Ts>
xxx00	RESERVED
xxxx1	B
xxx10	H

For the “64-bit” variant: is an element size specifier, encoded in “imm5”:

Non-Confidential

imm5	<Ts>
xx000	RESERVED
xxxx1	B
xxx10	H
xx100	S

<**index**> For the “32-bit” variant: is the element index encoded in “imm5”:

imm5	<index>
xxx00	RESERVED
xxxx1	UInt(imm5<4:1>)
xxx10	UInt(imm5<4:2>)

For the “64-bit” variant: is the element index encoded in “imm5”:

imm5	<index>
xx000	RESERVED
xxxx1	UInt(imm5<4:1>)
xxx10	UInt(imm5<4:2>)
xx100	UInt(imm5<4:3>)

<**Xd**> Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

Operation

```
AArch64.CheckFPAdvSIMDEnabled();
constant bits(idxdsize) operand = V[n, idxdsize];

X[d, datasize] = SignExtend(Elem[operand, index, esize], datasize);
```

C7.2.264 SMULL, SMULL2 (by element)

Signed multiply long (vector, by element)

This instruction multiplies each vector element in the lower or upper half of the first source SIMD&FP register by the specified vector element of the second source SIMD&FP register, places the result in a vector, and writes the vector to the destination SIMD&FP register. The destination vector elements are twice as long as the elements that are multiplied.

The `SMULL` instruction extracts vector elements from the lower half of the first source register. The `SMULL2` instruction extracts vector elements from the upper half of the first source register.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Vector

C7.2.265 SMULL, SMULL2 (vector)

Signed multiply long (vector)

This instruction multiplies corresponding signed integer values in the lower or upper half of the vectors of the two source SIMD&FP registers, places the results in a vector, and writes the vector to the destination SIMD&FP register.

The destination vector elements are twice as long as the elements that are multiplied.

The SMULL instruction extracts each source vector from the lower half of each source register. The SMULL2 instruction extracts each source vector from the upper half of each source register.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Three registers, not all the same type

C7.2.266 SQABS

Signed saturating absolute value

This instruction reads each vector element from the source SIMD&FP register, puts the absolute value of the result into a vector, and writes the vector to the destination SIMD&FP register. All the values in this instruction are signed integer values.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit FPSR.QC is set.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Scalar and Vector

C7.2.270 SQDMLSL, SQDMLSL2 (by element)

Signed saturating doubling multiply-subtract long (by element)

This instruction multiplies each vector element in the lower or upper half of the first source SIMD&FP register by the specified vector element of the second source SIMD&FP register, doubles the results, and subtracts the final results from the vector elements of the destination SIMD&FP register. The destination vector elements are twice as long as the elements that are multiplied. All the values in this instruction are signed integer values.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit FPSR.QC is set.

The `SQDMLSL` instruction extracts vector elements from the lower half of the first source register. The `SQDMLSL2` instruction extracts vector elements from the upper half of the first source register.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Scalar and Vector

C7.2.272 SQDMULH (by element)

Signed saturating doubling multiply returning high half (by element)

This instruction multiplies each vector element in the first source SIMD&FP register by the specified vector element of the second source SIMD&FP register, doubles the results, places the most significant half of the final results into a vector, and writes the vector to the destination SIMD&FP register.

The results are truncated. For rounded results, see SQRDMULH.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Scalar and Vector

C7.2.275 SQDMULL, SQDMULL2 (vector)

Signed saturating doubling multiply long

This instruction multiplies corresponding vector elements in the lower or upper half of the two source SIMD&FP registers, doubles the results, places the final results in a vector, and writes the vector to the destination SIMD&FP register.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit FPSR.QC is set.

The `SQDMULL` instruction extracts each source vector from the lower half of each source register. The `SQDMULL2` instruction extracts each source vector from the upper half of each source register.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Scalar and Vector

Scalar

C7.2.281 SQRDMULH (by element)

Signed saturating rounding doubling multiply returning high half (by element)

This instruction multiplies each vector element in the first source SIMD&FP register by the specified vector element of the second source SIMD&FP register, doubles the results, places the most significant half of the final results into a vector, and writes the vector to the destination SIMD&FP register.

The results are rounded. For truncated results, see SQDMULH.

If any of the results overflows, they are saturated. If saturation occurs, the cumulative saturation bit FPSR.QC is set.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Scalar and Vector

C7.2.282 SQRDMULH (vector)

Signed saturating rounding doubling multiply returning high half

This instruction multiplies the values of corresponding elements of the two source SIMD&FP registers, doubles the results, places the most significant half of the final results into a vector, and writes the vector to the destination SIMD&FP register.

The results are rounded. For truncated results, see SQDMULH.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit FPSR.QC is set.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Scalar and Vector

C7.2.283 SQRSHL

Signed saturating rounding shift left (register)

This instruction takes each vector element in the first source SIMD&FP register, shifts it by a value from the least significant byte of the corresponding vector element of the second source SIMD&FP register, places the results into a vector, and writes the vector to the destination SIMD&FP register.

If the shift value is positive, the operation is a left shift. Otherwise, it is a right shift. The results are rounded. For truncated results, see SQSHL.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit FPSR.QC is set.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Scalar and Vector

C7.2.284 SQRSHRN, SQRSHRN2

Signed saturating rounded shift right narrow (immediate)

This instruction reads each vector element in the source SIMD&FP register, right shifts each result by an immediate value, saturates each shifted result to a value that is half the original width, puts the final result into a vector, and writes the vector to the lower or upper half of the destination SIMD&FP register. All the values in this instruction are signed integer values. The destination vector elements are half as long as the source vector elements. The results are rounded. For truncated results, see SQSHRN.

The `SQRSHRN` instruction writes the vector to the lower half of the destination register and clears the upper half. The `SQRSHRN2` instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

If saturation occurs, the cumulative saturation bit FPSR.QC is set.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Scalar and Vector

C7.2.285 SQRSHRUN, SQRSHRUN2

Signed saturating rounded shift right unsigned narrow (immediate)

This instruction reads each signed integer value in the vector of the source SIMD&FP register, right shifts each value by an immediate value, saturates the result to an unsigned integer value that is half the original width, places the final result into a vector, and writes the vector to the destination SIMD&FP register. The results are rounded. For truncated results, see SQSHRUN.

The `SQRSHRUN` instruction writes the vector to the lower half of the destination register and clears the upper half. The `SQRSHRUN2` instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

If saturation occurs, the cumulative saturation bit FPSR.QC is set.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Scalar and Vector

C7.2.286 SQSHL (immediate)

Signed saturating shift left (immediate)

This instruction reads each vector element in the source SIMD&FP register, shifts each result by an immediate value, places the final result in a vector, and writes the vector to the destination SIMD&FP register. The results are truncated. For rounded results, see UQRSHL.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit FPSR.QC is set.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Scalar and Vector

C7.2.287 SQSHL (register)

Signed saturating shift left (register)

This instruction takes each element in the vector of the first source SIMD&FP register, shifts each element by a value from the least significant byte of the corresponding element of the second source SIMD&FP register, places the results in a vector, and writes the vector to the destination SIMD&FP register.

If the shift value is positive, the operation is a left shift. Otherwise, it is a right shift. The results are truncated. For rounded results, see SQRSHL.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit FPSR.QC is set.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Scalar and Vector

C7.2.289 SQSHRN, SQSHRN2

Signed saturating shift right narrow (immediate)

This instruction reads each vector element in the source SIMD&FP register, right shifts and truncates each result by an immediate value, saturates each shifted result to a value that is half the original width, puts the final result into a vector, and writes the vector to the lower or upper half of the destination SIMD&FP register. All the values in this instruction are signed integer values. The destination vector elements are half as long as the source vector elements. For rounded results, see SQRSHRN.

The `SQSHRN` instruction writes the vector to the lower half of the destination register and clears the upper half. The `SQSHRN2` instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

If saturation occurs, the cumulative saturation bit FPSR.QC is set.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Scalar and Vector

C7.2.293 SQXTUN, SQXTUN2

Signed saturating extract unsigned narrow

This instruction reads each signed integer value in the vector of the source SIMD&FP register, saturates the value to an unsigned integer value that is half the original width, places the result into a vector, and writes the vector to the lower or upper half of the destination SIMD&FP register. The destination vector elements are half as long as the source vector elements.

If saturation occurs, the cumulative saturation bit FPSR.QC is set.

The `SQXTUN` instruction writes the vector to the lower half of the destination register and clears the upper half. The `SQXTUN2` instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Scalar and Vector

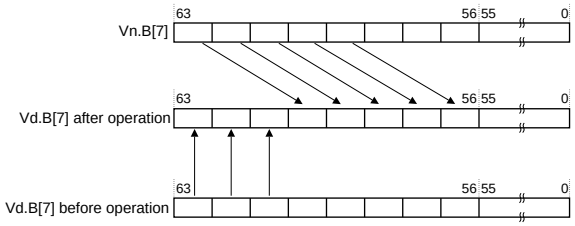
C7.2.295 SRI

Shift right and insert (immediate)

This instruction reads each vector element in the source SIMD&FP register, right shifts each vector element by an immediate value, and inserts the result into the corresponding vector element in the destination SIMD&FP register such that the new zero bits created by the shift are not inserted but retain their existing value. Bits shifted out of the right of each vector element of the source register are lost.

The following figure shows an example of the operation of shift right by 3 for an 8-bit vector element.



Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Scalar and Vector

11	1	2D

<**Vn**> Is the name of the first SIMD&FP source register, encoded in the “Rn” field.

<**Vm**> Is the name of the second SIMD&FP source register, encoded in the “Rm” field.

Operation

```
AArch64.CheckFPAdvSIMDEnabled();
constant bits(datasize) operand1 = V[n, datasize];
constant bits(datasize) operand2 = V[m, datasize];
bits(datasize) result;

for e = 0 to elements-1
    integer element = SInt(Elem[operand1, e, esize]);
    integer shift = ShiftSat(SInt(Elem[operand2, e, esize]<7:0>), esize);
    if shift >= 0 then // left shift
        element = element << shift;
    else               // right shift
        shift = -shift;
        element = RShr(element, shift, rounding);

    Elem[result, e, esize] = element<esize-1:0>;

V[d, datasize] = result;
```

C7.2.300 SSHLL, SSHLL2

Signed shift left long (immediate)

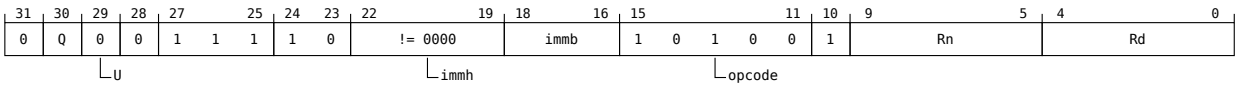
This instruction reads each vector element from the source SIMD&FP register, left shifts each vector element by the specified shift amount, places the result into a vector, and writes the vector to the destination SIMD&FP register. The destination vector elements are twice as long as the source vector elements. All the values in this instruction are signed integer values.

The SSHLL instruction extracts vector elements from the lower half of the source register. The SSHLL2 instruction extracts vector elements from the upper half of the source register.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This instruction is used by the alias SXTL, SXTL2.

Vector
(FEAT_AdvSIMD)



Encoding

```
SSHLL{2} <Vd>.<Ta>, <Vn>.<Tb>, #<shift>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_AdvSIMD) then EndOfDecode(Decode_UNDEF);
if immh<3> == '1' then EndOfDecode(Decode_UNDEF);

constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer esize = 8 << HighestSetBitNZ(immh<2:0>);
constant integer datasize = 64;
constant integer part = UInt(Q);
constant integer elements = datasize DIV esize;

constant integer shift = UInt(immh:immb) - esize;
constant boolean unsigned = FALSE;
```

Assembler Symbols

2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in “Q”:

Q	2
0	[absent]
1	[present]

<**Vd**> Is the name of the SIMD&FP destination register, encoded in the “Rd” field.

<**Ta**> Is an arrangement specifier, encoded in “immh”:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

immh	<Ta>
0001	8H
001x	4S
01xx	2D
1xxx	RESERVED

<**Vn**> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

C7.2.301 SSHR

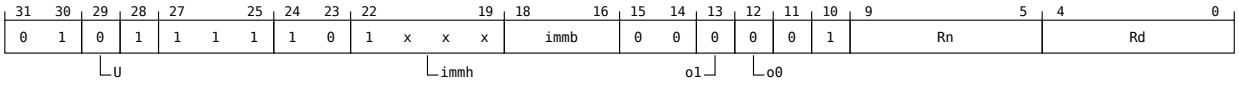
Signed shift right (immediate)

This instruction reads each vector element in the source SIMD&FP register, right shifts each result by an immediate value, places the final result into a vector, and writes the vector to the destination SIMD&FP register. All the values in this instruction are signed integer values. The results are truncated. For rounded results, see SRSHR.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Scalar and Vector

Scalar
(FEAT_AdvSIMD)



Encoding

```
SSHR D<d>, D<n>, #<shift>
```

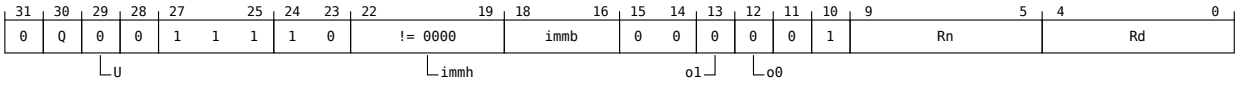
Decode for this encoding

```
if !IsFeatureImplemented(FEAT_AdvSIMD) then EndOfDecode(Decode_UNDEF);
if immh<3> != '1' then EndOfDecode(Decode_UNDEF);

constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer esize = 8 << 3;
constant integer datasize = esize;
constant integer elements = 1;

constant integer shift = (esize * 2) - UInt(immh:immb);
constant boolean unsigned = FALSE;
constant boolean round = FALSE;
```

Vector
(FEAT_AdvSIMD)



Encoding

```
SSHR <Vd>.<T>, <Vn>.<T>, #<shift>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_AdvSIMD) then EndOfDecode(Decode_UNDEF);
if immh<3>:Q == '10' then EndOfDecode(Decode_UNDEF);

constant integer d = UInt(Rd);

C7.2.303 SSUBL, SSUBL2

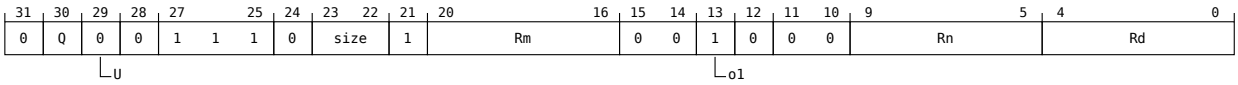
Signed subtract long

This instruction subtracts each vector element in the lower or upper half of the second source SIMD&FP register from the corresponding vector element of the first source SIMD&FP register, places the results into a vector, and writes the vector to the destination SIMD&FP register. All the values in this instruction are signed integer values. The destination vector elements are twice as long as the source vector elements.

The `SSUBL` instruction extracts each source vector from the lower half of each source register. The `SSUBL2` instruction extracts each source vector from the upper half of each source register.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Three registers, not all the same type
(FEAT_AdvSIMD)



Encoding

```
SSUBL{2} <Vd>.<Ta>, <Vn>.<Tb>, <Vm>.<Tb>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_AdvSIMD) then EndOfDecode(Decode_UNDEF);
if size == '11' then EndOfDecode(Decode_UNDEF);
constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer m = UInt(Rm);

constant integer esize = 8 << UInt(size);
constant integer datasize = 64;
constant integer part = UInt(Q);
constant integer elements = datasize DIV esize;
```

Assembler Symbols

C7.2.305 ST1 (multiple structures)

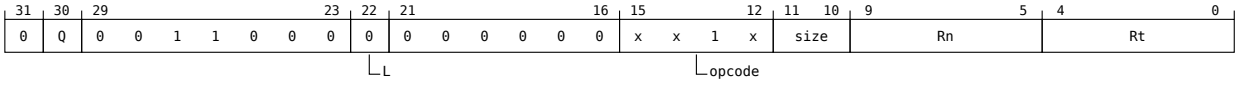
Store multiple single-element structures from one, two, three, or four registers

This instruction stores elements to memory from one, two, three, or four SIMD&FP registers, without interleaving. Every element of each register is stored.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: No offset and Post-index

No offset
(FEAT_AdvSIMD)



Encoding for the One register variant Applies when `(opcode == 0111)`

```
ST1 { <Vt>.<T> }, [<Xn|SP>]
```

Encoding for the Two registers variant Applies when `(opcode == 1010)`

```
ST1 { <Vt>.<T>, <Vt2>.<T> }, [<Xn|SP>]
```

Encoding for the Three registers variant Applies when `(opcode == 0110)`

```
ST1 { <Vt>.<T>, <Vt2>.<T>, <Vt3>.<T> }, [<Xn|SP>]
```

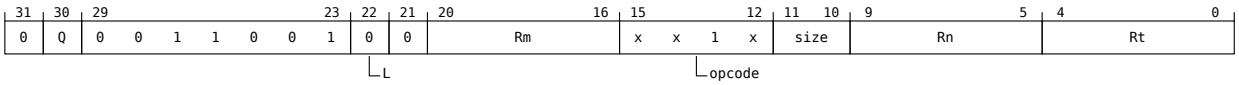
Encoding for the Four registers variant Applies when `(opcode == 0010)`

```
ST1 { <Vt>.<T>, <Vt2>.<T>, <Vt3>.<T>, <Vt4>.<T> }, [<Xn|SP>]
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_AdvSIMD) then EndOfDecode(Decode_UNDEF);
constant integer t = UInt(Rt);
constant integer n = UInt(Rn);
constant integer m = integer UNKNOWN;
constant boolean wback = FALSE;
constant boolean nontemporal = FALSE;
```

Post-index
(FEAT_AdvSIMD)



Encoding for the One register, immediate offset variant Applies when `(Rm == 11111 && opcode == 0111)`

```
ST1 { <Vt>.<T> }, [<Xn|SP>], <imm>
```

Encoding for the One register, register offset variant Applies when `(Rm != 11111 && opcode == 0111)`

```
ST1 { <Vt>.<T> }, [<Xn|SP>], <Xm>
```

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.

```
ST1 { <Vt>.<T>, <Vt2>.<T> }, [<Xn|SP>], <imm>
```

Encoding for the Two registers, register offset variant Applies when `(Rm != 11111 && opcode == 1010)`

```
ST1 { <Vt>.<T>, <Vt2>.<T> }, [<Xn|SP>], <Xm>
```

Encoding for the Three registers, immediate offset variant Applies when `(Rm == 11111 && opcode == 0110)`

```
ST1 { <Vt>.<T>, <Vt2>.<T>, <Vt3>.<T> }, [<Xn|SP>], <imm>
```

Encoding for the Three registers, register offset variant Applies when `(Rm != 11111 && opcode == 0110)`

```
ST1 { <Vt>.<T>, <Vt2>.<T>, <Vt3>.<T> }, [<Xn|SP>], <Xm>
```

Encoding for the Four registers, immediate offset variant Applies when `(Rm == 11111 && opcode == 0010)`

```
ST1 { <Vt>.<T>, <Vt2>.<T>, <Vt3>.<T>, <Vt4>.<T> }, [<Xn|SP>], <imm>
```

Encoding for the Four registers, register offset variant Applies when `(Rm != 11111 && opcode == 0010)`

```
ST1 { <Vt>.<T>, <Vt2>.<T>, <Vt3>.<T>, <Vt4>.<T> }, [<Xn|SP>], <Xm>
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_AdvSIMD) then EndOfDecode(Decode_UNDEF);
constant integer t = UInt(Rt);
constant integer n = UInt(Rn);
constant integer m = UInt(Rm);
constant boolean wback = TRUE;
constant boolean nontemporal = FALSE;
```

Assembler Symbols

<**Vt**> Is the name of the first or only SIMD&FP register to be transferred, encoded in the “Rt” field.

<**T**> Is an arrangement specifier, encoded in “size:Q”:

size	Q	<T>
00	0	8B
00	1	16B
01	0	4H
01	1	8H
10	0	2S
10	1	4S
11	0	1D
11	1	2D

<**Xn|SP**> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the “Rn” field.

<**Vt2**> Is the name of the second SIMD&FP register to be transferred, encoded as “Rt” plus 1 modulo 32.

<**Vt3**> Is the name of the third SIMD&FP register to be transferred, encoded as “Rt” plus 2 modulo 32.

<**Vt4**> Is the name of the fourth SIMD&FP register to be transferred, encoded as “Rt” plus 3 modulo 32.

C7.2.306 ST1 (single structure)

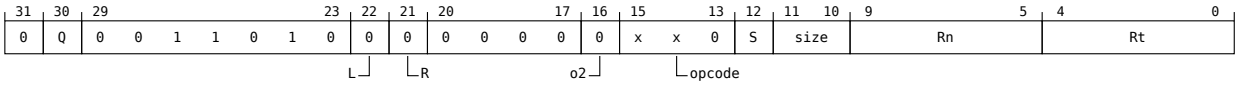
Store a single-element structure from one lane of one register

This instruction stores the specified element of a SIMD&FP register to memory.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: No offset and Post-index

No offset
(FEAT_AdvSIMD)



Encoding for the 8-bit variant Applies when `(opcode == 000)`

```
ST1 { <Vt>.B }[<index>], [<Xn|SP>]
```

Encoding for the 16-bit variant Applies when `(opcode == 010 && size == x0)`

```
ST1 { <Vt>.H }[<index>], [<Xn|SP>]
```

Encoding for the 32-bit variant Applies when `(opcode == 100 && size == 00)`

```
ST1 { <Vt>.S }[<index>], [<Xn|SP>]
```

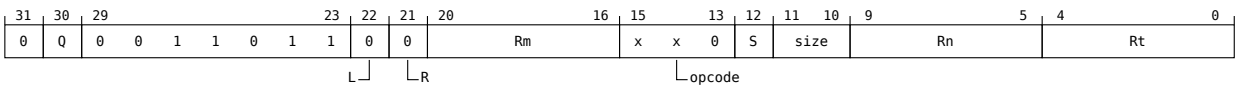
Encoding for the 64-bit variant Applies when `(opcode == 100 && S == 0 && size == 01)`

```
ST1 { <Vt>.D }[<index>], [<Xn|SP>]
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_AdvSIMD) then EndOfDecode(Decode_UNDEF);
integer t = UInt(Rt);
constant integer n = UInt(Rn);
constant integer m = integer UNKNOWN;
constant boolean wback = FALSE;
constant boolean nontemporal = FALSE;
```

Post-index
(FEAT_AdvSIMD)



Encoding for the 8-bit, immediate offset variant Applies when `(Rm == 11111 && opcode == 000)`

```
ST1 { <Vt>.B }[<index>], [<Xn|SP>], #1
```

Encoding for the 8-bit, register offset variant Applies when `(Rm != 11111 && opcode == 000)`

```
ST1 { <Vt>.B }[<index>], [<Xn|SP>], <Xm>
```

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Encoding for the 16-bit, immediate offset variant Applies when `(Rm == 11111 && opcode == 010 && size == x0)`

```
ST1 { <Vt>.H }[<index>], [<Xn|SP>], #2
```

Encoding for the 16-bit, register offset variant Applies when `(Rm != 11111 && opcode == 010 && size == x0)`

```
ST1 { <Vt>.H }[<index>], [<Xn|SP>], <Xm>
```

Encoding for the 32-bit, immediate offset variant Applies when `(Rm == 11111 && opcode == 100 && size == 00)`

```
ST1 { <Vt>.S }[<index>], [<Xn|SP>], #4
```

Encoding for the 32-bit, register offset variant Applies when `(Rm != 11111 && opcode == 100 && size == 00)`

```

```

Assembler Symbols

<**Vt**> Is the name of the first or only SIMD&FP register to be transferred, encoded in the “Rt” field.

<**index**> For the “8-bit”, “8-bit, immediate offset”, and “8-bit, register offset” variants: is the element index, encoded in “Q:S:size”.

For the “16-bit”, “16-bit, immediate offset”, and “16-bit, register offset” variants: is the element index, encoded in “Q:S:size<1>”.

For the “32-bit”, “32-bit, immediate offset”, and “32-bit, register offset” variants: is the element index, encoded in “Q:S”.

For the “64-bit”, “64-bit, immediate offset”, and “64-bit, register offset” variants: is the element index, encoded in “Q”.

<**Xn|SP**> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the “Rn” field.

<**Xm**> Is the 64-bit name of the general-purpose post-index register, excluding XZR, encoded in the “Rm” field.

Shared Decode

C7.2.310 ST3 (single structure)

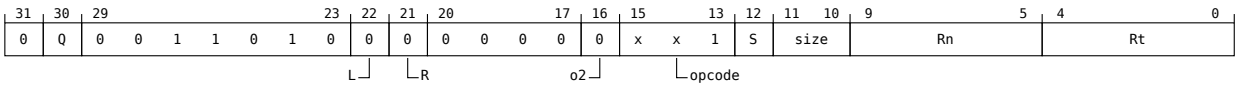
Store single 3-element structure from one lane of three registers

This instruction stores a 3-element structure to memory from corresponding elements of three SIMD&FP registers.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: No offset and Post-index

No offset
(FEAT_AdvSIMD)



Encoding for the 8-bit variant Applies when `(opcode == 001)`

```
ST3 { <Vt>.B, <Vt2>.B, <Vt3>.B }[<index>], [<Xn|SP>]
```

Encoding for the 16-bit variant Applies when `(opcode == 011 && size == x0)`

```
ST3 { <Vt>.H, <Vt2>.H, <Vt3>.H }[<index>], [<Xn|SP>]
```

Encoding for the 32-bit variant Applies when `(opcode == 101 && size == 00)`

```
ST3 { <Vt>.S, <Vt2>.S, <Vt3>.S }[<index>], [<Xn|SP>]
```

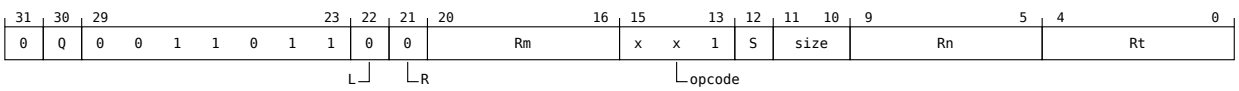
Encoding for the 64-bit variant Applies when `(opcode == 101 && S == 0 && size == 01)`

```
ST3 { <Vt>.D, <Vt2>.D, <Vt3>.D }[<index>], [<Xn|SP>]
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_AdvSIMD) then EndOfDecode(Decode_UNDEF);
integer t = UInt(Rt);
constant integer n = UInt(Rn);
constant integer m = integer UNKNOWN;
constant boolean wback = FALSE;
constant boolean nontemporal = FALSE;
```

Post-index
(FEAT_AdvSIMD)



Encoding for the 8-bit, immediate offset variant Applies when `(Rm == 11111 && opcode == 001)`

```
ST3 { <Vt>.B, <Vt2>.B, <Vt3>.B }[<index>], [<Xn|SP>], #3
```

Encoding for the 8-bit, register offset variant Applies when `(Rm != 11111 && opcode == 001)`

```
ST3 { <Vt>.B, <Vt2>.B, <Vt3>.B }[<index>], [<Xn|SP>], <Xm>
```

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Encoding for the 16-bit, immediate offset variant Applies when `(Rm == 11111 && opcode == 011 && size == x0)`

```
ST3 { <Vt>.H, <Vt2>.H, <Vt3>.H }[<index>], [<Xn|SP>], #6
```

Encoding for the 16-bit, register offset variant Applies when `(Rm != 11111 && opcode == 011 && size == x0)`

```
ST3 { <Vt>.H, <Vt2>.H, <Vt3>.H }[<index>], [<Xn|SP>], <Xm>
```

Encoding for the 32-bit, immediate offset variant Applies when `(Rm == 11111 && opcode == 101 && size == 00)`

```
ST3 { <Vt>.S, <Vt2>.S, <Vt3>.S }[<index>], [<Xn|SP>], #12
```

Encoding for the 32-bit, register offset variant Applies when `(Rm != 11111 && opcode == 101 && size == 00)`

```
ST3 { <Vt>.S, <Vt2>.S, <Vt3>.S }[<index>], [<Xn|SP>], <Xm>
```

Encoding for the 64-bit, immediate offset variant Applies when `(Rm == 11111 && opcode == 101 && S == 0 && size == 01)`

```
ST3 { <Vt>.D, <Vt2>.D, <Vt3>.D }[<index>], [<Xn|SP>], #24
```

Encoding for the 64-bit, register offset variant Applies when `(Rm != 11111 && opcode == 101 && S == 0 && size == 01)`

```
ST3 { <Vt>.D, <Vt2>.D, <Vt3>.D }[<index>], [<Xn|SP>], <Xm>
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_AdvSIMD) then EndOfDecode(Decode_UNDEF);
integer t = UInt(Rt);
constant integer n = UInt(Rn);
constant integer m = UInt(Rm);
constant boolean wback = TRUE;
constant boolean nontemporal = FALSE;
```

Assembler Symbols

<**Vt**> Is the name of the first or only SIMD&FP register to be transferred, encoded in the “Rt” field.

<**Vt2**> Is the name of the second SIMD&FP register to be transferred, encoded as “Rt” plus 1 modulo 32.

<**Vt3**> Is the name of the third SIMD&FP register to be transferred, encoded as “Rt” plus 2 modulo 32.

<**index**> For the “8-bit”, “8-bit, immediate offset”, and “8-bit, register offset” variants: is the element index, encoded in “Q:S:size”.

For the “16-bit”, “16-bit, immediate offset”, and “16-bit, register offset” variants: is the element index, encoded in “Q:S:size<1>”.

For the “32-bit”, “32-bit, immediate offset”, and “32-bit, register offset” variants: is the element index, encoded in “Q:S”.

For the “64-bit”, “64-bit, immediate offset”, and “64-bit, register offset” variants: is the element index, encoded in “Q”.

<**Xn|SP**> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the “Rn” field.

<**Xm**> Is the 64-bit name of the general-purpose post-index register, excluding XZR, encoded in the “Rm” field.

C7.2.311 ST4 (multiple structures)

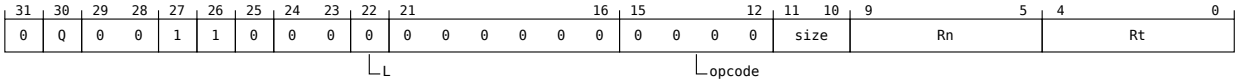
Store multiple 4-element structures from four registers

This instruction stores multiple 4-element structures to memory from four SIMD&FP registers, with interleaving. Every element of each register is stored.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: No offset and Post-index

No offset
(FEAT_AdvSIMD)



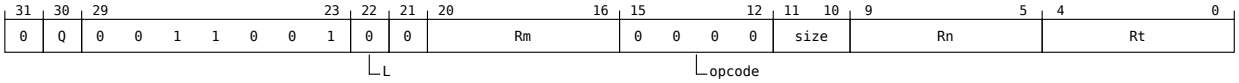
Encoding

```
ST4 { <Vt>.<T>, <Vt2>.<T>, <Vt3>.<T>, <Vt4>.<T> }, [<Xn|SP>]
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_AdvSIMD) then EndOfDecode(Decode_UNDEF);
constant integer t = UInt(Rt);
constant integer n = UInt(Rn);
constant integer m = integer UNKNOWN;
constant boolean wback = FALSE;
constant boolean nontemporal = FALSE;
```

Post-index
(FEAT_AdvSIMD)



Encoding for the Immediate offset variant Applies when `(Rm == 11111)`

```
ST4 { <Vt>.<T>, <Vt2>.<T>, <Vt3>.<T>, <Vt4>.<T> }, [<Xn|SP>], <imm>
```

Encoding for the Register offset variant Applies when `(Rm != 11111)`

```
ST4 { <Vt>.<T>, <Vt2>.<T>, <Vt3>.<T>, <Vt4>.<T> }, [<Xn|SP>], <Xm>
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_AdvSIMD) then EndOfDecode(Decode_UNDEF);
constant integer t = UInt(Rt);
constant integer n = UInt(Rn);
constant integer m = UInt(Rm);

<**Vt**> Is the name of the first or only SIMD&FP register to be transferred, encoded in the “Rt” field.

<**T**> Is an arrangement specifier, encoded in “size:Q”:

size	Q	<T>
00	0	8B
00	1	16B
01	0	4H
01	1	8H
10	0	2S
10	1	4S
11	0	RESERVED
11	1	2D

<**Vt2**> Is the name of the second SIMD&FP register to be transferred, encoded as “Rt” plus 1 modulo 32.

<**Vt3**> Is the name of the third SIMD&FP register to be transferred, encoded as “Rt” plus 2 modulo 32.

<**Vt4**> Is the name of the fourth SIMD&FP register to be transferred, encoded as “Rt” plus 3 modulo 32.

<**Xn|SP**> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the “Rn” field.

<**imm**> Is the post-index immediate offset, encoded in “Q”:

Q	<imm>
0	#32
1	#64

<**Xm**> Is the 64-bit name of the general-purpose post-index register, excluding XZR, encoded in the “Rm” field.

Shared Decode

C7.2.313 STADD, STADDL

Atomic add on word or doubleword, without return

This instruction atomically loads a 32-bit word or 64-bit doubleword from memory, adds the value held in a register to it, and stores the result back to memory.

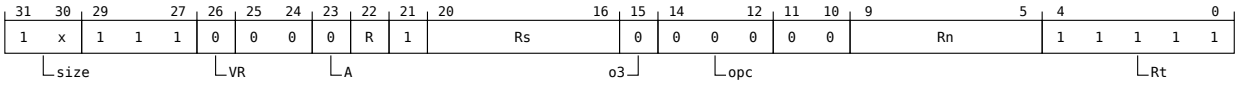
- STADD does not have release semantics.
- STADDL stores to memory with release semantics, as described in Load-Acquire, Store-Release.

For information about addressing modes, see Load/Store addressing modes.

This is an alias of LDADD, LDADDA, LDADDAL, LDADDL. This means:

- The encodings in this description are named to match the encodings of LDADD, LDADDA, LDADDAL, LDADDL.
- The description of LDADD, LDADDA, LDADDAL, LDADDL gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

Integer
(FEAT_LSE)



Encoding for the 32-bit no memory ordering variant Applies when `(size == 10 && R == 0)`

```
STADD <Ws>, [<Xn|SP>]
```

is equivalent to

```
LDADD <Ws>, WZR, [<Xn|SP>]
```

and is always the preferred disassembly.

Encoding for the 32-bit release variant Applies when `(size == 10 && R == 1)`

```
STADDL <Ws>, [<Xn|SP>]
```

is equivalent to

```
LDADDL <Ws>, WZR, [<Xn|SP>]
```

and is always the preferred disassembly.

Encoding for the 64-bit no memory ordering variant Applies when `(size == 11 && R == 0)`

```
STADD <Xs>, [<Xn|SP>]
```

is equivalent to

```
LDADD <Xs>, XZR, [<Xn|SP>]
```

and is always the preferred disassembly.

Encoding for the 64-bit release variant Applies when `(size == 11 && R == 1)`

```
STADDL <Xs>, [<Xn|SP>]
```

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

is equivalent to

```
LDADDL <Xs>, XZR, [<Xn|SP>]
```

and is always the preferred disassembly.

Assembler Symbols

<**Ws**> Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the “Rs” field.

<**Xn**|**SP**> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the “Rn” field.

<**Xs**> Is the 64-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the “Rs” field.

Operation

The description of LDADD, LDADDA, LDADDAL, LDADDL gives the operational pseudocode for this instruction.

Operational Information

The description of LDADD, LDADDA, LDADDAL, LDADDL gives the operational information for this instruction.

C7.2.314 STADDB, STADDLB

Atomic add on byte, without return

This instruction atomically loads an 8-bit byte from memory, adds the value held in a register to it, and stores the result back to memory.

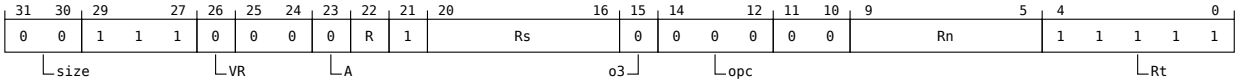
- `STADDB` does not have release semantics.
- `STADDLB` stores to memory with release semantics, as described in Load-Acquire, Store-Release.

For information about addressing modes, see Load/Store addressing modes.

This is an alias of LDADDB, LDADDAB, LDADDALB, LDADDLB. This means:

- The encodings in this description are named to match the encodings of LDADDB, LDADDAB, LDADDALB, LDADDLB.
- The description of LDADDB, LDADDAB, LDADDALB, LDADDLB gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

Integer
(FEAT_LSE)



Encoding for the No memory ordering variant Applies when `(R == 0)`

```
STADDB <Ws>, [<Xn|SP>]
```

is equivalent to

```
LDADDB <Ws>, WZR, [<Xn|SP>]
```

and is always the preferred disassembly.

Encoding for the Release variant Applies when `(R == 1)`

```
STADDLB <Ws>, [<Xn|SP>]
```

is equivalent to

```
LDADDLB <Ws>, WZR, [<Xn|SP>]
```

and is always the preferred disassembly.

Assembler Symbols

<**Ws**> Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.

<**Xn|SP**> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

C7.2.315 STADDH, STADDLH

Atomic add on halfword, without return

This instruction atomically loads a 16-bit halfword from memory, adds the value held in a register to it, and stores the result back to memory.

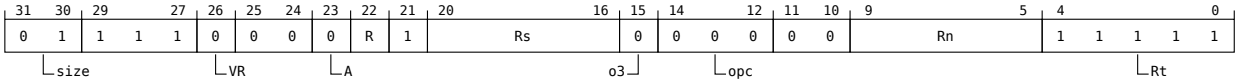
- STADDH does not have release semantics.
- STADDLH stores to memory with release semantics, as described in Load-Acquire, Store-Release.

For information about addressing modes, see Load/Store addressing modes.

This is an alias of LDADDH, LDADDAH, LDADDALH, LDADDLH. This means:

- The encodings in this description are named to match the encodings of LDADDH, LDADDAH, LDADDALH, LDADDLH.
- The description of LDADDH, LDADDAH, LDADDALH, LDADDLH gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

Integer
(FEAT_LSE)



Encoding for the No memory ordering variant Applies when (R == 0)

```
STADDH <Ws>, [<Xn|SP>]
```

is equivalent to

```
LDADDH <Ws>, WZR, [<Xn|SP>]
```

and is always the preferred disassembly.

Encoding for the Release variant Applies when (R == 1)

```
STADDLH <Ws>, [<Xn|SP>]
```

is equivalent to

```
LDADDLH <Ws>, WZR, [<Xn|SP>]
```

and is always the preferred disassembly.

Assembler Symbols

<**Ws**> Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.

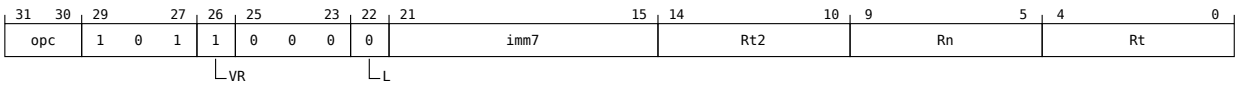
C7.2.316 STNP (SIMD&FP)

Store pair of SIMD&FP registers, with non-temporal hint

This instruction stores a pair of SIMD&FP registers to memory, issuing a hint to the memory system that the access is non-temporal. The address used for the store is calculated from an address from a base register value and an immediate offset. For information about non-temporal pair instructions, see Load/Store SIMD and Floating-point non-temporal pair.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Signed offset
(FEAT_FP)



Encoding for the 32-bit variant Applies when `(opc == 00)`

```
STNP <St1>, <St2>, [<Xn|SP>{, #<imm>}]
```

Encoding for the 64-bit variant Applies when `(opc == 01)`

```
STNP <Dt1>, <Dt2>, [<Xn|SP>{, #<imm>}]
```

Encoding for the 128-bit variant Applies when `(opc == 10)`

```
STNP <Qt1>, <Qt2>, [<Xn|SP>{, #<imm>}]
```

Decode for all variants of this encoding

```
// Empty.
```

Assembler Symbols

<**St1**> Is the 32-bit name of the first SIMD&FP register to be transferred, encoded in the “Rt” field.

<**St2**> Is the 32-bit name of the second SIMD&FP register to be transferred, encoded in the “Rt2” field.

<**Xn|SP**> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the “Rn” field.

<**imm**> For the “32-bit” variant: is the optional signed immediate byte offset, a multiple of 4 in the range -256 to 252, defaulting to 0 and encoded in the “imm7” field as <imm>/4.

For the “64-bit” variant: is the optional signed immediate byte offset, a multiple of 8 in the range -512 to 504, defaulting to 0 and encoded in the “imm7” field as <imm>/8.

For the “128-bit” variant: is the optional signed immediate byte offset, a multiple of 16 in the range -1024 to 1008, defaulting to 0 and encoded in the “imm7” field as <imm>/16.

<**Dt1**> Is the 64-bit name of the first SIMD&FP register to be transferred, encoded in the “Rt” field.

<**Dt2**> Is the 64-bit name of the second SIMD&FP register to be transferred, encoded in the “Rt2” field.

<**Qt1**> Is the 128-bit name of the first SIMD&FP register to be transferred, encoded in the “Rt” field.

<**Qt2**> Is the 128-bit name of the second SIMD&FP register to be transferred, encoded in the “Rt2” field.

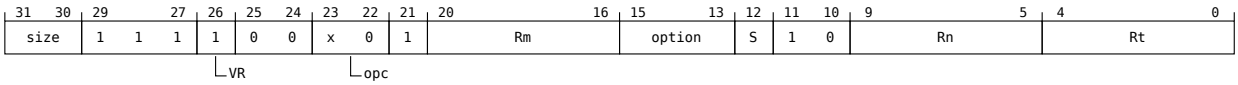
C7.2.319 STR (register, SIMD&FP)

Store SIMD&FP register (register offset)

This instruction stores a single SIMD&FP register to memory. The address that is used for the store is calculated from a base register value and an offset register value. The offset can be optionally shifted and extended.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

SIMD&FP registers
(FEAT_FP)



Encoding for the 8-bit with extended register offset variant Applies when `(size == 00 && opc == 00 && option != 011)`

```
STR <Bt>, [<Xn|SP>, (<Wm>|<Xm>), <extend> {<amount>}]
```

Encoding for the 8-bit with shifted register offset variant Applies when `(size == 00 && opc == 00 && option == 011)`

```
STR <Bt>, [<Xn|SP>, <Xm>{, LSL <amount>}]
```

Encoding for the 16-bit variant Applies when `(size == 01 && opc == 00)`

```
STR <Ht>, [<Xn|SP>, (<Wm>|<Xm>){, <extend> {<amount>}}]
```

Encoding for the 32-bit variant Applies when `(size == 10 && opc == 00)`

```
STR <St>, [<Xn|SP>, (<Wm>|<Xm>){, <extend> {<amount>}}]
```

Encoding for the 64-bit variant Applies when `(size == 11 && opc == 00)`

```
STR <Dt>, [<Xn|SP>, (<Wm>|<Xm>){, <extend> {<amount>}}]
```

Encoding for the 128-bit variant Applies when `(size == 00 && opc == 10)`

```
STR <Qt>, [<Xn|SP>, (<Wm>|<Xm>){, <extend> {<amount>}}]
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_FP) then EndOfDecode(Decode_UNDEF);
if option<1> == '0' then EndOfDecode(Decode_UNDEF);             // sub-word index
if opc<1> == '1' && size != '00' then EndOfDecode(Decode_UNDEF);
constant integer scale = if opc<1> == '1' then 4 else UInt(size);
constant ExtendType extend_type = DecodeRegExtend(option);
constant integer shift = if S == '1' then scale else 0;
```

Assembler Symbols

<**Bt**> Is the 8-bit name of the SIMD&FP register to be transferred, encoded in the “Rt” field.

<**Xn**|**SP**> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the “Rn” field.

<**Wm**> When option<0> is set to 0, is the 32-bit name of the general-purpose index register, encoded in the “Rm” field.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

<**Xm**> When option<0> is set to 1, is the 64-bit name of the general-purpose index register, encoded in the "Rm" field.

<**extend**> For the "8-bit with extended register offset" variant: is the index extend specifier, encoded in "option":

option	<extend>
010	UXTW
110	SXTW
111	SXTX

For the "128-bit", "16-bit", "32-bit", and "64-bit" variants: is the index extend/shift specifier, defaulting to LSL, and which must be omitted for the LSL option when <amount> is omitted, encoded in "option":

option	<extend>
010	UXTW
011	LSL
110	SXTW
111	SXTX

<**amount**> For the "8-bit with extended register offset" and "8-bit with shifted register offset" variants: is the index shift amount, it must be #0, encoded in "S" as 0 if omitted, or as 1 if present.

For the "16-bit" variant: is the index shift amount, optional only when <extend> is not LSL. Where it is permitted to be optional, it defaults to #0. It is encoded in "S":

S	<amount>
0	#0
1	#1

For the "32-bit" variant: is the index shift amount, optional only when <extend> is not LSL. Where it is permitted to be optional, it defaults to #0. It is encoded in "S":

S	<amount>
0	#0
1	#2

For the "64-bit" variant: is the index shift amount, optional only when <extend> is not LSL. Where it is permitted to be optional, it defaults to #0. It is encoded in "S":

S	<amount>
0	#0
1	#3

For the "128-bit" variant: is the index shift amount, optional only when <extend> is not LSL. Where it is permitted to be optional, it defaults to #0. It is encoded in "S":

<**Ht**> Is the 16-bit name of the SIMD&FP register to be transferred, encoded in the "Rt" field.

<**St**> Is the 32-bit name of the SIMD&FP register to be transferred, encoded in the "Rt" field.

<**Dt**> Is the 64-bit name of the SIMD&FP register to be transferred, encoded in the "Rt" field.

<**Qt**> Is the 128-bit name of the SIMD&FP register to be transferred, encoded in the "Rt" field.

Shared Decode

```
constant integer t = UInt(Rt);
constant integer n = UInt(Rn);
constant integer m = UInt(Rm);
constant integer datasize = 8 << scale;
constant boolean nontemporal = FALSE;
```

Operation

```
AArch64.CheckFPEnabled();
constant bits(64) offset = ExtendReg(m, extend_type, shift, 64);
bits(64) address;

constant boolean privileged = PSTATE.EL != EL0;
constant AccessDescriptor accdesc = CreateAccDescASIMD(MemOp_STORE, nontemporal, privileged);

if n == 31 then
    CheckSPAlignment();
    address = SP[64];
else
    address = X[n, 64];

address = AddressAdd(address, offset, accdesc);

Mem[address, datasize DIV 8, accdesc] = V[t, datasize];
```

Operational information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

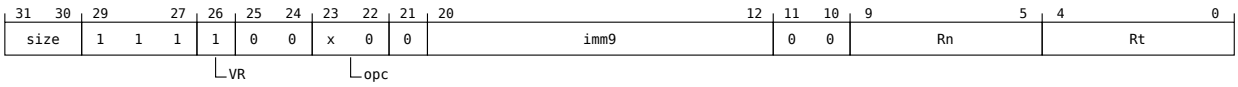
C7.2.320 STUR (SIMD&FP)

Store SIMD&FP register (unscaled offset)

This instruction stores a single SIMD&FP register to memory. The address that is used for the store is calculated from a base register value and an optional immediate offset.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Unscaled offset
(FEAT_FP)



Encoding for the 8-bit variant Applies when `(size == 00 && opc == 00)`

```
STUR <Bt>, [<Xn|SP>{, #<simm>}]
```

Encoding for the 16-bit variant Applies when `(size == 01 && opc == 00)`

```
STUR <Ht>, [<Xn|SP>{, #<simm>}]
```

Encoding for the 32-bit variant Applies when `(size == 10 && opc == 00)`

```
STUR <St>, [<Xn|SP>{, #<simm>}]
```

Encoding for the 64-bit variant Applies when `(size == 11 && opc == 00)`

```
STUR <Dt>, [<Xn|SP>{, #<simm>}]
```

Encoding for the 128-bit variant Applies when `(size == 00 && opc == 10)`

```
STUR <Qt>, [<Xn|SP>{, #<simm>}]
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_FP) then EndOfDecode(Decode_UNDEF);
if opc<1> == '1' && size != '00' then EndOfDecode(Decode_UNDEF);
constant integer scale = if opc<1> == '1' then 4 else UInt(size);
constant bits(64) offset = SignExtend(imm9, 64);
```

Assembler Symbols

<**Bt**> Is the 8-bit name of the SIMD&FP register to be transferred, encoded in the “Rt” field.

<**Xn|SP**> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the “Rn” field.

<**simm**> Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the “imm9” field.

<**Ht**> Is the 16-bit name of the SIMD&FP register to be transferred, encoded in the “Rt” field.

<**St**> Is the 32-bit name of the SIMD&FP register to be transferred, encoded in the “Rt” field.

<**Dt**> Is the 64-bit name of the SIMD&FP register to be transferred, encoded in the “Rt” field.

<**Qt**> Is the 128-bit name of the SIMD&FP register to be transferred, encoded in the “Rt” field.

C7.2.322 SUBHN, SUBHN2

Subtract returning high narrow

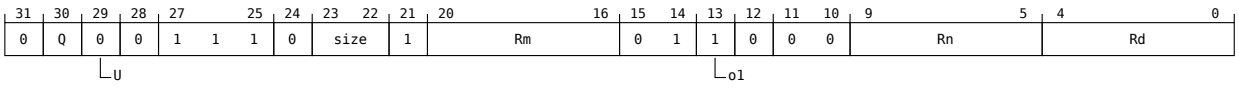
This instruction subtracts each vector element in the second source SIMD&FP register from the corresponding vector element in the first source SIMD&FP register, places the most significant half of the result into a vector, and writes the vector to the lower or upper half of the destination SIMD&FP register. All the values in this instruction are signed integer values.

The results are truncated. For rounded results, see RSUBHN.

The SUBHN instruction writes the vector to the lower half of the destination register and clears the upper half. The SUBHN2 instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Three registers, not all the same type
(FEAT_AdvSIMD)



Encoding

```

C7.2.323 SUQADD

Signed saturating accumulate of unsigned value

This instruction adds the unsigned integer values of the vector elements in the source SIMD&FP register to corresponding signed integer values of the vector elements in the destination SIMD&FP register, and writes the resulting signed integer values to the destination SIMD&FP register.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit FPSR.QC is set.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Scalar and Vector

Scalar

C7.2.324 SXTL, SXTL2

Signed extend long

This instruction duplicates each vector element in the lower or upper half of the source SIMD&FP register into a vector, and writes the vector to the destination SIMD&FP register. The destination vector elements are twice as long as the source vector elements. All the values in this instruction are signed integer values.

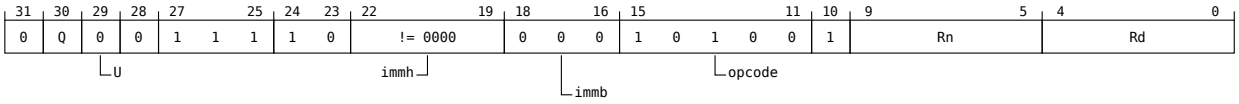
The `SXTL` instruction extracts the source vector from the lower half of the source register. The `SXTL2` instruction extracts the source vector from the upper half of the source register.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This is an alias of SSHLL, SSHLL2. This means:

- The encodings in this description are named to match the encodings of SSHLL, SSHLL2.
- The description of SSHLL, SSHLL2 gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

Vector
(FEAT_AdvSIMD)



Encoding

```
SXTL{2} <Vd>.<Ta>, <Vn>.<Tb>
```

is equivalent to

```
SSHLL{2} <Vd>.<Ta>, <Vn>.<Tb>, #0
```

and is the preferred disassembly when `BitCount(immh) == 1`.

Assembler Symbols

2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in "Q":

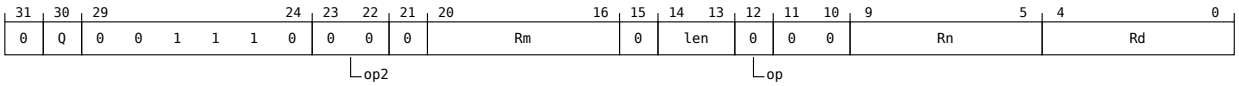
C7.2.325 TBL

Table vector lookup

This instruction reads each value from the vector elements in the index source SIMD&FP register, uses each result as an index to perform a lookup in a table of bytes that is described by one to four source table SIMD&FP registers, places the lookup result in a vector, and writes the vector to the destination SIMD&FP register. If an index is out of range for the table, the result for that lookup is 0. If more than one source register is used to describe the table, the first source register describes the lowest bytes of the table.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Advanced SIMD
(FEAT_AdvSIMD)



Encoding for the Single register table variant Applies when `(len == 00)`

```
TBL <Vd>.<Ta>, { <Vn>.16B }, <Vm>.<Ta>

C7.2.326 TBX

Table vector lookup extension

This instruction reads each value from the vector elements in the index source SIMD&FP register, uses each result as an index to perform a lookup in a table of bytes that is described by one to four source table SIMD&FP registers, places the lookup result in a vector, and writes the vector to the destination SIMD&FP register. If an index is out of range for the table, the existing value in the vector element of the destination register is left unchanged. If more than one source register is used to describe the table, the first source register describes the lowest bytes of the table.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Advanced SIMD
(FEAT_AdvSIMD)

C7.2.327 TRN1

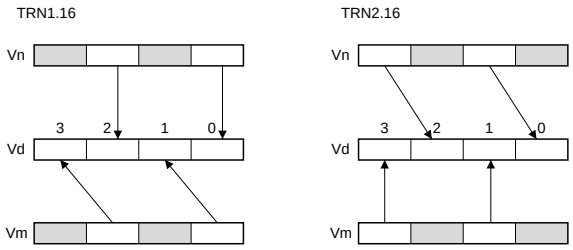
Transpose vectors (primary)

This instruction reads corresponding even-numbered vector elements from the two source SIMD&FP registers, starting at zero, places each result into consecutive elements of a vector, and writes the vector to the destination SIMD&FP register. Vector elements from the first source register are placed into even-numbered elements of the destination vector, starting at zero, while vector elements from the second source register are placed into odd-numbered elements of the destination vector.

Note

By using this instruction with `TRN2`, a 2 x 2 matrix can be transposed.

The following figure shows an example of the operation of TRN1 and TRN2 halfword operations where Q = 0.



Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Advanced SIMD

C7.2.328 TRN2

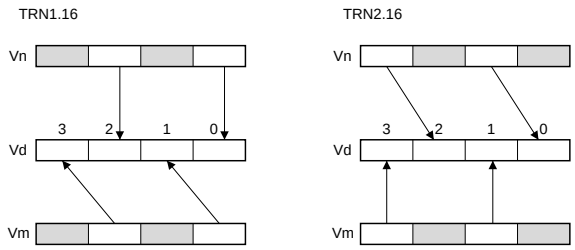
Transpose vectors (secondary)

This instruction reads corresponding odd-numbered vector elements from the two source SIMD&FP registers, places each result into consecutive elements of a vector, and writes the vector to the destination SIMD&FP register. Vector elements from the first source register are placed into even-numbered elements of the destination vector, starting at zero, while vector elements from the second source register are placed into odd-numbered elements of the destination vector.

Note

By using this instruction with `TRN1`, a 2 x 2 matrix can be transposed.

The following figure shows an example of the operation of TRN1 and TRN2 halfword operations where Q = 0.



Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.330 UABAL, UABAL2

Unsigned absolute difference and accumulate long

This instruction subtracts the vector elements in the lower or upper half of the second source SIMD&FP register from the corresponding vector elements of the first source SIMD&FP register, and accumulates the absolute values of the results into the vector elements of the destination SIMD&FP register. The destination vector elements are twice as long as the source vector elements. All the values in this instruction are unsigned integer values.

The `UABAL` instruction extracts each source vector from the lower half of each source register. The `UABAL2` instruction extracts each source vector from the upper half of each source register.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Three registers, not all the same type
(FEAT_AdvSIMD)

C7.2.338 UCVTF (vector, fixed-point)

Unsigned fixed-point convert to floating-point (vector)

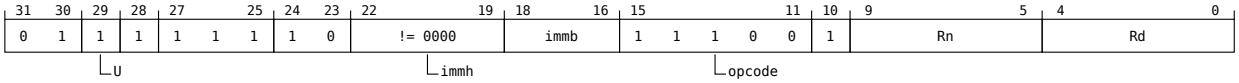
This instruction converts each element in a vector from fixed-point to floating-point using the rounding mode that is specified by the FPCR, and writes the result to the SIMD&FP destination register.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Scalar and Vector

Scalar
(FEAT_AdvSIMD)



Encoding

```
UCVTF <V><d>, <V><n>, #<fbits>
```

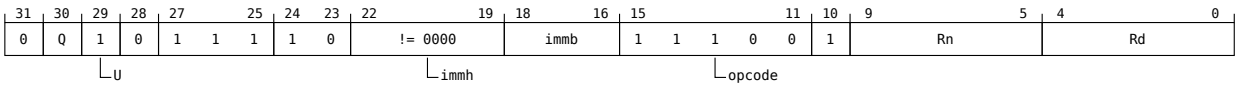
Decode for this encoding

```
if !IsFeatureImplemented(FEAT_AdvSIMD) then EndOfDecode(Decode_UNDEF);
if immh IN {'000x'} || (immh IN {'001x'} && !IsFeatureImplemented(FEAT_FP16)) then
    EndOfDecode(Decode_UNDEF);

constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer esize = if immh IN {'1xxx'} then 64 else if immh IN {'01xx'} then 32 else 16;
constant integer datasize = esize;
constant integer elements = 1;

constant integer fracbits = (esize * 2) - UInt(immh:immb);
constant boolean unsigned = TRUE;
```

Vector
(FEAT_AdvSIMD)



Encoding

```
UCVTF <Vd>.<T>, <Vn>.<T>, #<fbits>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_AdvSIMD) then EndOfDecode(Decode_UNDEF);
if immh IN {'000x'} || (immh IN {'001x'} && !IsFeatureImplemented(FEAT_FP16)) then
    EndOfDecode(Decode_UNDEF);

C7.2.344 UHADD

Unsigned halving add

This instruction adds corresponding unsigned integer values from the two source SIMD&FP registers, shifts each result right one bit, places the results into a vector, and writes the vector to the destination SIMD&FP register.

The results are truncated. For rounded results, see URHADD.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

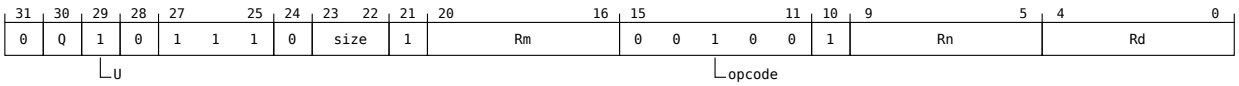
C7.2.345 UHSUB

Unsigned halving subtract

This instruction subtracts the vector elements in the second source SIMD&FP register from the corresponding vector elements in the first source SIMD&FP register, shifts each result right one bit, places each result into a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Three registers of the same type
(FEAT_AdvSIMD)



Encoding

```
UHSUB <Vd>.<T>, <Vn>.<T>, <Vm>.<T>
```

Decode for this encoding

```

C7.2.355 UMLSL, UMLSL2 (vector)

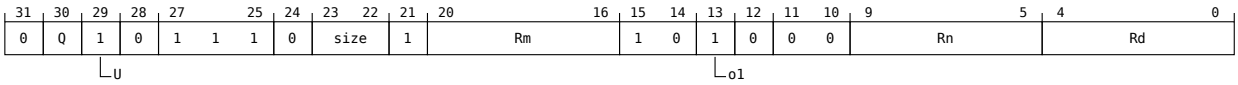
Unsigned multiply-subtract long (vector)

This instruction multiplies corresponding vector elements in the lower or upper half of the two source SIMD&FP registers, and subtracts the results from the vector elements of the destination SIMD&FP register. The destination vector elements are twice as long as the elements that are multiplied. All the values in this instruction are unsigned integer values.

The `UMLSL` instruction extracts each source vector from the lower half of each source register. The `UMLSL2` instruction extracts each source vector from the upper half of each source register.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Three registers, not all the same type
(FEAT_AdvSIMD)



Encoding

```
UMLSL{2} <Vd>.<Ta>, <Vn>.<Tb>, <Vm>.<Tb>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_AdvSIMD) then EndOfDecode(Decode_UNDEF);
if size == '11' then EndOfDecode(Decode_UNDEF);
constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer m = UInt(Rm);

constant integer esize = 8 << UInt(size);
constant integer datasize = 64;
constant integer part = UInt(Q);
constant integer elements = datasize DIV esize;
```

C7.2.356 UMOV

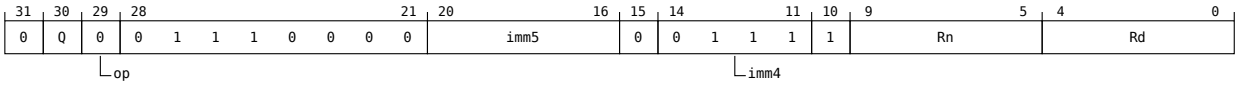
Unsigned move vector element to general-purpose register

This instruction reads the unsigned integer from the source SIMD&FP register, zero-extends it to form a 32-bit or 64-bit value, and writes the result to the destination general-purpose register.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This instruction is used by the alias MOV (to general).

Advanced SIMD
(FEAT_AdvSIMD)



Encoding for the 32-bit variant Applies when `(Q == 0)`

```
UMOV <Wd>, <Vn>.<Ts>[<index>]
```

Encoding for the 64-bit variant Applies when `(Q == 1 && imm5 == x1000)`

```
UMOV <Xd>, <Vn>.D[<index>]
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_AdvSIMD) then EndOfDecode(Decode_UNDEF);
if imm5 == 'x0000' then EndOfDecode(Decode_UNDEF);
constant integer size = LowestSetBitNZ(imm5<3:0>);

constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer esize = 8 << size;
constant integer datasize = 32 << UInt(Q);
if datasize == 64 && esize < 64 then EndOfDecode(Decode_UNDEF);
if datasize == 32 && esize >= 64 then EndOfDecode(Decode_UNDEF);
constant integer index = UInt(imm5<4:size+1>);
constant integer idxdsize = 64 << UInt(imm5<4>);
```

Assembler Symbols

<**Wd**> Is the 32-bit name of the general-purpose destination register, encoded in the “Rd” field.

<**Vn**> Is the name of the SIMD&FP source register, encoded in the “Rn” field.

<**Ts**> Is an element size specifier, encoded in “imm5”:

imm5	<Ts>
xx000	RESERVED
xxxx1	B
xxx10	H
xx100	S

<**index**> For the “32-bit” variant: is the element index encoded in “imm5”:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

imm5	<index>
xx000	RESERVED
xxxx1	UInt(imm5<4:1>)
xxx10	UInt(imm5<4:2>)
xx100	UInt(imm5<4:3>)

For the “64-bit” variant: is the element index encoded in “imm5<4>”.

<**Xd**> Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

Alias Conditions

Alias	Of variant	Is preferred when
MOV (to general)	32-bit	imm5 IN {'xx100'}
MOV (to general)	64-bit	imm5 IN {'x1000'}

Operation

```
AArch64.CheckFPAdvSIMDEnabled();
constant bits(idxdsize) operand = V[n, idxdsize];

X[d, datasize] = ZeroExtend(Elem[operand, index, esize], datasize);
```

C7.2.357 UMULL, UMULL2 (by element)

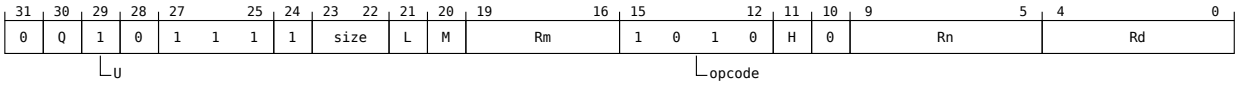
Unsigned multiply long (vector, by element)

This instruction multiplies each vector element in the lower or upper half of the first source SIMD&FP register by the specified vector element of the second source SIMD&FP register, places the results in a vector, and writes the vector to the destination SIMD&FP register. The destination vector elements are twice as long as the elements that are multiplied.

The `UMULL` instruction extracts vector elements from the lower half of the first source register. The `UMULL2` instruction extracts vector elements from the upper half of the first source register.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Vector
(FEAT_AdvSIMD)



Encoding

```
UMULL{2} <Vd>.<Ta>, <Vn>.<Tb>, V<m>.<Ts>[<index>]

C7.2.360 UQRSHL

Unsigned saturating rounding shift left (register)

This instruction takes each vector element of the first source SIMD&FP register, shifts the vector element by a value from the least significant byte of the corresponding vector element of the second source SIMD&FP register, places the results into a vector, and writes the vector to the destination SIMD&FP register.

If the shift value is positive, the operation is a left shift. Otherwise, it is a right shift. The results are rounded. For truncated results, see UQSHL.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit FPSR.QC is set.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Scalar and Vector

C7.2.361 UQRSHRN, UQRSHRN2

Unsigned saturating rounded shift right narrow (immediate)

This instruction reads each vector element in the source SIMD&FP register, right shifts each result by an immediate value, puts the final result into a vector, and writes the vector to the lower or upper half of the destination SIMD&FP register. All the values in this instruction are unsigned integer values. The results are rounded. For truncated results, see UQSHRN.

The `UQRSHRN` instruction writes the vector to the lower half of the destination register and clears the upper half. The `UQRSHRN2` instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit FPSR.QC is set.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Scalar and Vector

C7.2.362 UQSHL (immediate)

Unsigned saturating shift left (immediate)

This instruction takes each vector element in the source SIMD&FP register, shifts it by an immediate value, places the results in a vector, and writes the vector to the destination SIMD&FP register. The results are truncated. For rounded results, see UQRSHL.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit FPSR.QC is set.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Scalar and Vector

C7.2.363 UQSHL (register)

Unsigned saturating shift left (register)

This instruction takes each element in the vector of the first source SIMD&FP register, shifts the element by a value from the least significant byte of the corresponding element of the second source SIMD&FP register, places the results in a vector, and writes the vector to the destination SIMD&FP register.

If the shift value is positive, the operation is a left shift. Otherwise, it is a right shift. The results are truncated. For rounded results, see UQRSHL.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit FPSR.QC is set.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Scalar and Vector

C7.2.364 UQSHRN, UQSHRN2

Unsigned saturating shift right narrow (immediate)

This instruction reads each vector element in the source SIMD&FP register, right shifts each result by an immediate value, saturates each shifted result to a value that is half the original width, puts the final result into a vector, and writes the vector to the lower or upper half of the destination SIMD&FP register. All the values in this instruction are unsigned integer values. The results are truncated. For rounded results, see UQRSHRN.

The `UQSHRN` instruction writes the vector to the lower half of the destination register and clears the upper half. The `UQSHRN2` instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit FPSR.QC is set.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Scalar and Vector

C7.2.368 URHADD

Unsigned rounding halving add

This instruction adds corresponding unsigned integer values from the two source SIMD&FP registers, shifts each result right one bit, places the results into a vector, and writes the vector to the destination SIMD&FP register.

The results are rounded. For truncated results, see UHADD.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Three registers of the same type

C7.2.369 URSHL

Unsigned rounding shift left (register)

This instruction takes each element in the vector of the first source SIMD&FP register, shifts the vector element by a value from the least significant byte of the corresponding element of the second source SIMD&FP register, places the results in a vector, and writes the vector to the destination SIMD&FP register.

If the shift value is positive, the operation is a left shift. If the shift value is negative, it is a rounding right shift.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Scalar and Vector

Scalar

C7.2.374 USHLL, USHLL2

Unsigned shift left long (immediate)

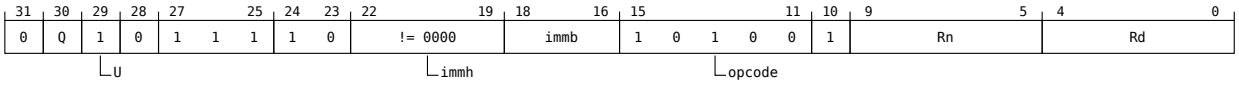
This instruction reads each vector element in the lower or upper half of the source SIMD&FP register, shifts the unsigned integer value left by the specified number of bits, places the result into a vector, and writes the vector to the destination SIMD&FP register. The destination vector elements are twice as long as the source vector elements.

The `USHLL` instruction extracts vector elements from the lower half of the source register. The `USHLL2` instruction extracts vector elements from the upper half of the source register.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This instruction is used by the alias UXTL, UXTL2.

Vector
(FEAT_AdvSIMD)



Encoding

```
USHLL{2} <Vd>.<Ta>, <Vn>.<Tb>, #<shift>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_AdvSIMD) then EndOfDecode(Decode_UNDEF);
if immh<3> == '1' then EndOfDecode(Decode_UNDEF);

constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer esize = 8 << HighestSetBitNZ(immh<2:0>);
constant integer datasize = 64;
constant integer part = UInt(Q);
constant integer elements = datasize DIV esize;

constant integer shift = UInt(immh:immb) - esize;
constant boolean unsigned = TRUE;
```

Assembler Symbols

2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in "Q":

Q	2
0	[absent]
1	[present]

<**Vd**> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<**Ta**> Is an arrangement specifier, encoded in "immh":

C7.2.376 USQADD

Unsigned saturating accumulate of signed value

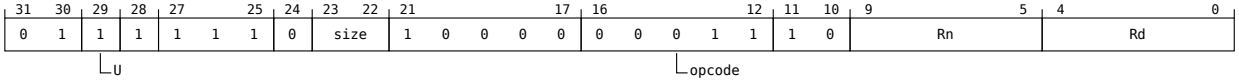
This instruction adds the signed integer values of the vector elements in the source SIMD&FP register to corresponding unsigned integer values of the vector elements in the destination SIMD&FP register, and accumulates the resulting unsigned integer values with the vector elements of the destination SIMD&FP register.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit FPSR.QC is set.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Scalar and Vector

Scalar
(FEAT_AdvSIMD)



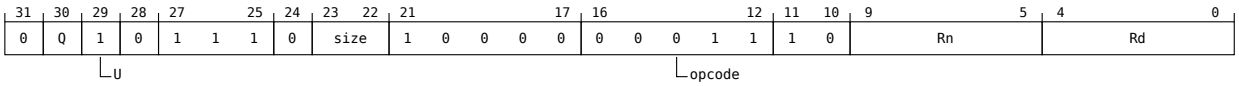
Encoding

```
USQADD <V><d>, <V><n>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_AdvSIMD) then EndOfDecode(Decode_UNDEF);
constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer esize = 8 << UInt(size);
constant integer datasize = esize;
constant integer elements = 1;
constant boolean unsigned = TRUE;
```

Vector
(FEAT_AdvSIMD)



Encoding

```
USQADD <Vd>.<T>, <Vn>.<T>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_AdvSIMD) then EndOfDecode(Decode_UNDEF);
if size:Q == '110' then EndOfDecode(Decode_UNDEF);

constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer esize = 8 << UInt(size);

C7.2.377 USRA

Unsigned shift right and accumulate (immediate)

This instruction reads each vector element in the source SIMD&FP register, right shifts each result by an immediate value, and accumulates the final results with the vector elements of the destination SIMD&FP register. All the values in this instruction are unsigned integer values. The results are truncated. For rounded results, see URSRA.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Scalar and Vector

C7.2.378 USUBL, USUBL2

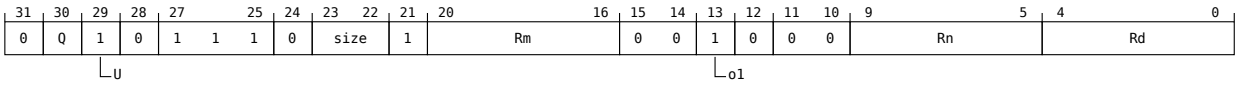
Unsigned subtract long

This instruction subtracts each vector element in the lower or upper half of the second source SIMD&FP register from the corresponding vector element of the first source SIMD&FP register, places the result into a vector, and writes the vector to the destination SIMD&FP register. All the values in this instruction are unsigned integer values. The destination vector elements are twice as long as the source vector elements.

The `USUBL` instruction extracts each source vector from the lower half of each source register. The `USUBL2` instruction extracts each source vector from the upper half of each source register.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Three registers, not all the same type
(FEAT_AdvSIMD)



Encoding

```
USUBL{2} <Vd>.<Ta>, <Vn>.<Tb>, <Vm>.<Tb>
```

Decode for this encoding

C7.2.380 UXTL, UXTL2

Unsigned extend long

This instruction copies each vector element from the lower or upper half of the source SIMD&FP register into a vector, and writes the vector to the destination SIMD&FP register. The destination vector elements are twice as long as the source vector elements.

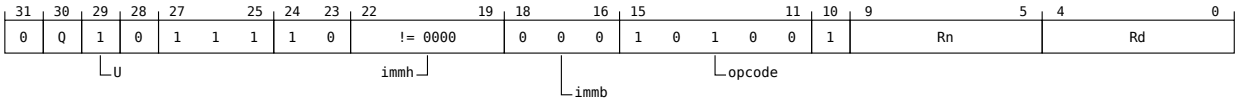
The `UXTL` instruction extracts vector elements from the lower half of the source register. The `UXTL2` instruction extracts vector elements from the upper half of the source register.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This is an alias of USHLL, USHLL2. This means:

- The encodings in this description are named to match the encodings of USHLL, USHLL2.
- The description of USHLL, USHLL2 gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

Vector
(FEAT_AdvSIMD)



Encoding

```
UXTL{2} <Vd>.<Ta>, <Vn>.<Tb>
```

is equivalent to

```
USHLL{2} <Vd>.<Ta>, <Vn>.<Tb>, #0
```

and is the preferred disassembly when `BitCount(immh) == 1`.

Assembler Symbols

2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in "Q":

C7.2.381 UZP1

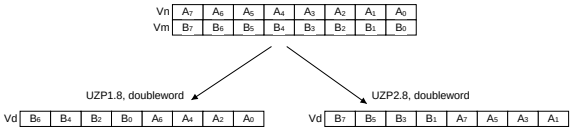
Unzip vectors (primary)

This instruction reads corresponding even-numbered vector elements from the two source SIMD&FP registers, starting at zero, places the result from the first source register into consecutive elements in the lower half of a vector, and the result from the second source register into consecutive elements in the upper half of a vector, and writes the vector to the destination SIMD&FP register.

Note

This instruction can be used with `UZP2` to de-interleave two vectors.

The following figure shows an example of the operation of UZP1 and UZP2 with the arrangement specifier 8B.



Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.383 XAR

Exclusive-OR and rotate

This instruction performs a bitwise exclusive-OR of the 128-bit vectors in the two source SIMD&FP registers, rotates each 64-bit element of the resulting 128-bit vector right by the value specified by a 6-bit immediate value, and writes the result to the destination SIMD&FP register.

Advanced SIMD
(FEAT_SHA3)

Encoding

```
XAR <Vd>.2D, <Vn>.2D, <Vm>.2D, #<imm6>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_SHA3) then EndOfDecode(Decode_UNDEF);
constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer m = UInt(Rm);
```

Assembler Symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the “Rd” field.

<Vn> Is the name of the first SIMD&FP source register, encoded in the “Rn” field.

<Vm> Is the name of the second SIMD&FP source register, encoded in the “Rm” field.

<imm6> Is a rotation right, encoded in “imm6”.

Operation

```
AArch64.CheckFPAdvSIMDEnabled();

constant bits(128) Vm = V[m, 128];
constant bits(128) Vn = V[n, 128];
constant bits(128) tmp = Vn EOR Vm;
V[d, 128] = ROR(tmp<127:64>, UInt(imm6)):ROR(tmp<63:0>, UInt(imm6));
```

Operational information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C7.2.384 XTN, XTN2

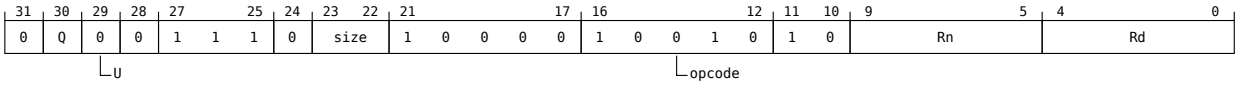
Extract narrow

This instruction reads each vector element from the source SIMD&FP register, narrows each value to half the original width, places the result into a vector, and writes the vector to the lower or upper half of the destination SIMD&FP register. The destination vector elements are half as long as the source vector elements.

The XTN instruction writes the vector to the lower half of the destination register and clears the upper half. The XTN2 instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Vector
(FEAT_AdvSIMD)



Encoding

```
XTN{2} <Vd>.<Tb>, <Vn>.<Ta>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_AdvSIMD) then EndOfDecode(Decode_UNDEF);
if size == '11' then EndOfDecode(Decode_UNDEF);
constant integer d = UInt(Rd);
constant integer n = UInt(Rn);

constant integer esize = 8 << UInt(size);
constant integer datasize = 64;
constant integer part = UInt(Q);
constant integer elements = datasize DIV esize;
```

Assembler Symbols

2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in "Q":

Q	2
0	[absent]
1	[present]

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

C7.2.385 ZIP1

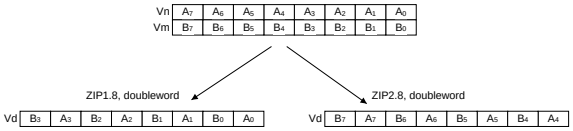
Zip vectors (primary)

This instruction reads adjacent vector elements from the lower half of two source SIMD&FP registers as pairs, interleaves the pairs and places them into a vector, and writes the vector to the destination SIMD&FP register. The first pair from the first source register is placed into the two lowest vector elements, with subsequent pairs taken alternately from each source register.

Note

This instruction can be used with `ZIP2` to interleave two vectors.

The following figure shows an example of the operation of ZIP1 and ZIP2 with the arrangement specifier 8B.



Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.386 ZIP2

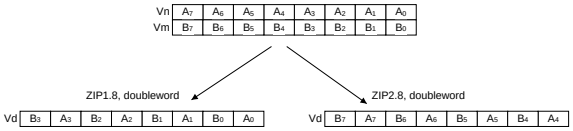
Zip vectors (secondary)

This instruction reads adjacent vector elements from the upper half of two source SIMD&FP registers as pairs, interleaves the pairs and places them into a vector, and writes the vector to the destination SIMD&FP register. The first pair from the first source register is placed into the two lowest vector elements, with subsequent pairs taken alternately from each source register.

Note

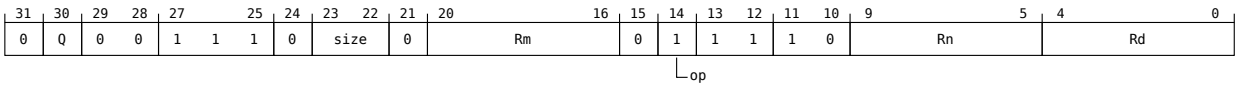
This instruction can be used with `ZIP1` to interleave two vectors.

The following figure shows an example of the operation of ZIP1 and ZIP2 with the arrangement specifier 8B.



Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Advanced SIMD
(FEAT_AdvSIMD)



Encoding

```
ZIP2 <Vd>.<T>, <Vn>.<T>, <Vm>.<T>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_AdvSIMD) then EndOfDecode(Decode_UNDEF);
if size:Q == '110' then EndOfDecode(Decode_UNDEF);

constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer m = UInt(Rm);
constant integer esize = 8 << UInt(size);
constant integer datasize = 64 << UInt(Q);
constant integer elements = datasize DIV esize;
constant integer part = UInt(op);
constant integer pairs = elements DIV 2;
```

Chapter D1
The AArch64 System Level Programmers' Model

This chapter describes the AArch64 system level programmers' model. It contains the following sections:

- Exception levels.
- Registers for instruction processing and exception handling.
- Exceptions.
- Process state, PSTATE.
- Resets and power domains.
- Mechanisms for entering a low-power state.
- Self-hosted debug.
- Event monitors.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D1.1 Exception levels

R_{HTTFQ} The architecture defines three *Exception levels*: EL0, EL1 and EL2.

R_{VNPYH} EL2 is the highest Exception level and EL0 is the lowest. Therefore, EL2 is higher than EL1, and EL1 is higher than EL0.

R_{SWGNJ} A PE must implement EL0, EL1 and EL2.

I_{WRRKQ} EL2 provides support for the virtualization of EL0 and EL1.

R_{CCQWK} Unprivileged execution is any execution that occurs at EL0.

R_{NZZNS} The current Exception level changes only when any of the following occur:

- Taking an exception.
- Returning from an exception.
- Processor reset.
- Exiting from Debug state.
- If in Debug state, executing a DCPSx instruction.
- If in Debug state, executing a DRPS instruction.

R_{XRQKF} The *target Exception level* is the Exception level to which an exception is taken.

R_{FFJBB} Each exception type has a target Exception level that is either:

- Implicit in the type of the exception.
- Defined by configuration bits in the System registers.

R_{TKYYF} An exception cannot be taken to EL0.

R_{QNTPB} An exception cannot cause entry to a lower Exception level.

D1.1.1 Execution state

R_{PCFKP} The architecture defines one Execution state, AArch64 state using 64-bit processing.

R_{BDMRT} If an Exception level is using AArch64, then all higher Exception levels are using AArch64.

D1.1.2 Security states

R_{RVPDR} The architecture defines one *Security state*, Secure state.

R_{NRXJT} The architecture defines the following *Physical Address* (PA) spaces:

- Secure.
- Non-secure.

I_{NDJCC} Memory assigned to the Secure physical address space cannot be read or modified by an agent associated with Non-secure state.

I_{YFMYJ} For details on the System Agent and Non-secure Protected PA spaces, see Granular Data Isolation.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D1.1.3 Effect of not implementing an Exception level

R_{ZSYWZ} SCR_EL3.NS has a notional value of 0, meaning that the Security state is Secure.

R_{KFGRW} An exception cannot be taken to an unimplemented Exception level. This means that exceptions will target either EL1 or EL2.

D1.1.3.1 Typical Exception level usage model

I_{WCCCB} The architecture does not specify what software uses which Exception level. Such choices are outside the scope of the architecture. However, the following is a common usage model for the Exception levels:

Exception level	Usage
EL0	Applications.
EL1	OS kernel and associated functions that are typically described as privileged.
EL2	Hypervisor.

D1.2 Registers for instruction processing and exception handling

I_{BCVRH} In the Arm architecture, registers are split into two main categories:

- Registers that provide system control or status reporting.
- Registers that are used in instruction processing, for example to accumulate a result, and in handling exceptions.

For more information, see AArch64 System Register Descriptions.

D1.2.1 The general-purpose registers

R_{JBKTZ} The general-purpose register bank comprises the 31 general-purpose registers, R0-R30.

I_{RKTLT} The general-purpose register bank is associated with instructions in the base instruction set.

R_{YDKHJ} The general-purpose registers can be accessed as either of the following:

- 31 64-bit registers, X0-X30.
- 31 32-bit registers, W0-W30.

I_{PVGXY} When a Warm reset is asserted, the general-purpose registers are reset to an architecturally UNKNOWN value.
For more information, see Register size and Registers in AArch64 Execution state.

D1.2.2 The stack pointer registers

R_{VSNWX} Each Exception level has a dedicated stack pointer register. The stack pointer registers are:

- SP_EL0.
- SP_EL1.
- SP_EL2.

I_{YPMHQ} When a Warm reset is asserted, the stack pointers are reset to an architecturally UNKNOWN value.
For more information, see Special purpose registers and PC alignment checking.

D1.2.2.1 Stack pointer register selection

R_{LQMQQ} The PE uses the following stack pointers:

- If executing at EL0, then the PE uses the EL0 stack pointer, SP_EL0.
- If executing at EL1 or EL2, then the PE uses the stack pointer determined by PSTATE.SP:
  - If PSTATE.SP is 0, then the PE uses the EL0 stack pointer, SP_EL0.
  - If PSTATE.SP is 1, then the PE uses the stack pointer for the current Exception level.

I_{CSFMY} When an exception is taken, the stack pointer for the target Exception level is selected.

I_{VYNZY} The selected stack pointer can be indicated by a suffix to the Exception level:

- The t suffix, referring to thread, indicates use of the SP_EL0 stack pointer.
- The h suffix, referring to handler, indicates use of the SP_ELx stack pointer.

I_{QZDYD} The following are the AArch64 stack pointer options:

Exception level (EL)	Stack pointer (SP) option
EL0	SP_EL0
EL1	SP_EL1, SP_EL0

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Exception level (EL)	Stack pointer (SP) option
EL2	SP_EL2, SP_EL0

D1.2.3 The SIMD and floating-point registers

R_{JSCYH} The SIMD and floating-point register bank comprises the 32 quadword (128-bit) SIMD and floating-point registers, V0-V31.

I_{LMMMW} The SIMD and floating-point register bank is used for floating-point, vector, and other SIMD-related scalar operations.

R_{LFCJZ} The SIMD and floating-point registers can be accessed as any of the following:

- 32 quadword (128-bit) registers, Q0-Q31.
- 32 doubleword (64-bit) registers, D0-D31.
- 32 word (32-bit) registers, S0-S31.
- 32 halfword (16-bit) registers, H0-H31.
- 32 byte (8-bit) registers, B0-B31.
- 128-bit vectors of elements.
- 64-bit vectors of elements.

I_{KFYJJ} When a Warm reset is asserted, the SIMD and floating-point registers are reset to an architecturally UNKNOWN value.
For more information, see Registers in AArch64 Execution state.

D1.2.4 Saved Program Status Registers

R_{PJSSD} In AArch64 state, each implemented Exception level to which an exception can be taken has a Saved Program Status Register (SPSR). The following are the SPSRs:

- For exceptions taken to EL1 using AArch64, SPSR_EL1.
- For exceptions taken to EL2 using AArch64, SPSR_EL2.

I_{DVBPS} When a Warm reset is asserted, the SPSRs are reset to an architecturally UNKNOWN value.
For more information, see Process state, PSTATE.

D1.2.5 Exception Link Registers

R_{JQBYN} Exception Link Registers hold preferred exception return addresses.

R_{XFSNH} In AArch64 state, each implemented Exception level to which an exception can be taken has an Exception Link Register (ELR). The following are the ELRs:

- For exceptions taken to EL1, ELR_EL1.
- For exceptions taken to EL2, ELR_EL2.

I_{SHJSC} When a Warm reset is asserted, the ELRs are reset to an architecturally UNKNOWN value.
For more information, see Preferred exception return address.

Non-Confidential

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D1.3 Exceptions

D1.3.1 Exception entry terminology

D1.3.1.1 Taken, taken from, and taken to

R_{VDFHD} When the PE responds to an exception, an exception is *taken*.

R_{FXGFX} The PE state immediately before taking the exception is the state the exception is *taken from*.

R_{WTMVN} The PE state immediately after taking the exception is the state the exception is *taken to*.

D1.3.1.2 Exception generating instructions

R_{QPPFN} *Exception generating instructions* intentionally produce a precise exception in the instruction stream immediately after the exception generating instruction. They are:

- HVC.
- SMC.
- SVC.

D1.3.1.3 Synchronous and asynchronous exceptions

R_{FQHGR} If all of the following apply, an exception is *synchronous*:

- The exception is generated as a result of direct execution or attempted execution of an instruction.
- The preferred exception return address has an architecturally defined relationship with the instruction that caused the exception.
- The exception is precise.

R_{PCXDH} An exception is *asynchronous* if it is not synchronous.

R_{JPZPR} Asynchronous exceptions taken to AArch64 state are also known as interrupts.

D1.3.1.4 Definition of a precise exception and imprecise exception

R_{HVZKH} An exception is *precise* if on taking the exception, the PE state and the memory system state is consistent with the PE having executed all of the instructions up to but not including the point in the instruction stream where the exception was taken from, and none afterwards. However, for an instruction executing immediately at the point in the instruction stream that the exception was taken from, the definition of precise also permits any of the following:

- For synchronous Data Abort and Watchpoint exceptions that are taken to AArch64 state generated by an instruction that performs more than one single-copy atomic memory access, the values in registers or memory affected by the instructions can be UNKNOWN, if all of the following apply:
  - The accesses affecting those registers or memory locations do not, themselves, generate exceptions or debug events.
  - The registers are not involved in the calculation of the memory address used by the instruction.
- For synchronous Data Abort and Watchpoint exceptions that are generated from load or store instructions executed in AArch64 state, all the following can occur:
  - If the instruction was a load to either the base address register or the offset register, that register is restored to the original value, and any other destination registers become UNKNOWN.
  - If the instruction was a load that does not load the base address register or the offset register, then the destination registers become UNKNOWN.
  - If the instruction was an atomic that attempted both a load and a store, and the load was to the base address register, a source register or a compare register, that register is restored to the original value. Otherwise, that destination register becomes UNKNOWN.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- For implementations that include synchronous exception generation for floating-point exceptions, when a floating-point exception is taken, it is permitted that the cumulative floating-point exception bits are not restored.
- For a precise exception that is taken from AArch64 state during an instruction that performs more than one single-copy atomic memory access, the values in registers or memory affected by the instructions can be UNKNOWN, if all of the following apply:
  - The accesses affecting those registers or memory locations do not, themselves, generate exceptions or debug events.
  - The registers are not involved in the calculation of the memory address used by the instruction.

R_{ZNCXP} An exception is *imprecise* if it is not a precise exception.

R_{LSGJD} Except for SError exceptions, all exceptions taken to AArch64 state are precise. For each occurrence of an SError exception, whether the interrupt is precise or imprecise is IMPLEMENTATION DEFINED.

I_{ZNNNY} An asynchronous Data Abort exception generated by a load that causes an SError exception to be taken at some point later in the instruction stream than the load that generated the exception, is usually imprecise. The SError exception is usually imprecise because the data returned from the load is UNKNOWN, and so can have corrupted the state that is presented at the time that the exception is taken.

D1.3.1.5 Preferred exception return address

I_{LQPWH} The *preferred exception return address* is an address that software might return to after handling an exception in order to resume execution.

I_{HBQRX} The preferred exception return address is determined by the type of the exception.

R_{DPLYN} For an exception taken to an Exception level, ELx, using AArch64, the Exception Link Register for that Exception level, ELR_ELx, is set to the preferred exception return address.

R_{VBQMV} For asynchronous exceptions, the preferred exception return address is the address of the instruction following the instruction boundary at which the interrupt occurs.

R_{QYCWH} For synchronous exceptions other than exception generating instructions, the preferred exception return address is the address of the instruction that generates the exception.

R_{DKWPP} For an exception generating instruction that is executed, the preferred exception return address is the address of the instruction that follows the exception generating instruction.

R_{LBLBR} For an exception generating instruction that is trapped, disabled, or is UNDEFINED because the Exception level has insufficient privilege to execute the instruction, the preferred exception return address is the address of the exception generating instruction.

D1.3.1.6 Exception vectors

R_{FKKHH} When an exception is taken to an Exception level that is using AArch64, execution starts at the *exception vector*.

I_{QLHPV} The memory at the exception vector for an exception is expected to contain the handler code that corresponds to that exception category.

R_{BRCKV} The vector base address for an Exception level, ELx, is defined by the Vector Base Address Register, VBAR_ELx.

R_{PJKRC} Each exception category has an exception vector at a fixed offset from the vector base address.

I_{YCTHH} Exceptions taken to AArch64 are categorized for the purpose of assigning exception vectors based on the following information:

- Whether the exception is one of the following:
  - Synchronous exception, excluding synchronous External aborts.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

  - Synchronous External abort.
  - SError exceptions, including vSErrors and delegated SError exceptions.
  - IRQ or vIRQ interrupts.
  - FIQ or vFIQ interrupts.
- Information about the Exception level that the exception came from.
- Information about the SP in use.
- The state of the register file.

For information on synchronous exceptions, see Synchronous exception types. For information on asynchronous exceptions, see Asynchronous exception types.

R_{RYXCL} The following tables describe the offsets that are added to the vector base address to describe the exception vector:

Exception taken from	Offset for exception type Synchronous exceptions, excluding External aborts	IRQ and vIRQ	FIQ and vFIQ
Current Exception level with SP_EL0.	0x000	0x080	0x100
Current Exception level with SP_ELx, x > 0.	0x200	0x280	0x300
Lower Exception level, where the implemented level immediately lower than the target level is using AArch64.	0x400	0x480	0x500

Exception taken from	Offset for exception type Synchronous External aborts	SError and vSError
Current Exception level with SP_EL0.	0x000	0x180
Current Exception level with SP_ELx, x > 0.	0x200	0x380
Lower Exception level, where the implemented level immediately lower than the target level is using AArch64.	0x400	0x580

D1.3.2 Exception entry

R_{DQXFW} When an exception is taken to an Exception level, ELx, that is using AArch64 state, all the following occur:

- Fields in SPSR_ELx are written according to their description in SPSR_ELx, based on the values in PSTATE immediately before the exception was taken.
- The preferred exception return address is written to ELR_ELx.
- The contents of PSTATE immediately after the exception is taken is as described in rule R_{YVRLT}.
- For synchronous exceptions and SError exceptions, exception syndrome information is written to ESR_ELx.
- Execution starts from the exception vector at the target Exception level.

R_{YVRLT} When an exception is taken to an Exception level, ELx, that is using AArch64 state, after recording the previous values in SPSR_ELx, the following PSTATE bits are set:

- PSTATE.EL is set to the target Exception level.
- All of PSTATE.{D, A, I, F, SP} are set to 1.
- PSTATE.{IL, nRW} are set to 0.
- PSTATE.SS is set according to the rules in AArch64 Self-hosted Debug.
- If FEAT_PAN is implemented, then for any of the following situations, PSTATE.PAN is set to 1:
  - The target Exception level is EL1 and SCTLR_EL1.SPAN is 0.
  - The exception is taken from EL0, the target Exception level is EL2 using AArch64, the Effective value of HCR_EL2.{TGE, E2H} is {1, 1}, and SCTLR_EL2.SPAN is 0.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- If FEAT_UAO is implemented, then PSTATE.UAO is set to 0.
- If FEAT_SSBS is implemented, then PSTATE.SSBS is set to the value of SCTLR_ELx.DSSBS.

R_{SRXVW} If the Effective value of SCTLR_ELx.IESB is 1 at the target Exception level, an exception taken to AArch64 state is an error synchronization event.

R_{GKPZX} Exception entry is a Context synchronization event. For the purposes of the memory model, exception entry is an Instruction Fetch Barrier effect.

I_{FZTLH} The ordering of error synchronization and context synchronization on exception entry is described in the pseudocode.

I_{LBHFM} See also Taking error exceptions.

D1.3.2.1 Synchronous exception entry

I_{VWGYJ} For synchronous exceptions that result in the exception handler emulating the instruction and returning to the following instruction, the handler typically completes by ensuring the state of the PE on returning from the exception is consistent with the emulated instruction having been executed. This usually includes ensuring the value of SPSR_ELx.BTYPE is consistent with the instruction being emulated having executed.

For SVCand HVC instructions, when these instructions execute without being trapped, the value of SPSR_ELx already points to the following instruction. However SPSR_ELx.BTYPE is not guaranteed to be 0 and so might not be consistent with the SVC or HVC instruction having executed. This might subsequently cause a Branch Target exception at the instruction after the SVC or HVC instruction.

R_{ZTSSH} For any of the following synchronous exception types, when an exception is taken to an Exception level, ELx, a *virtual address* (VA) that characterizes the exception is captured in FAR_ELx:

- An Instruction Abort exception.
- A Data Abort exception.
- A PC alignment fault exception.
- A Watchpoint exception.

For synchronous External aborts that are not caused by translation table walks, it is CONSTRAINED UNPREDICTABLE whether the FAR_ELx contains a VA that characterizes the exception. The ESR_ELx.FnV bit in the ISS encoding for the External abort indicates the validity of the VA in FAR_ELx:

- If ESR_ELx.FnV in the ISS encoding for the External abort is 1, the VA in FAR_ELx is UNKNOWN.
- If ESR_ELx.FnV in the ISS encoding for the External abort is 0, the VA in FAR_ELx is valid.

For all other exceptions taken to ELx, FAR_ELx is UNKNOWN.

R_{YJHVH} For Instruction Abort or Data Abort exceptions caused by any of the following faults, when an exception is taken to EL2, an *intermediate physical address* (IPA) that characterizes the exception is captured in HPFAR_EL2:

- A Translation fault, Access Flag fault, or Address Size fault on a stage 2 translation not on a stage 1 translation table walk.
- A Translation fault, Access flag fault, Address Size fault, or Permission fault on stage 2 translation of an address accessed in a stage 1 translation table walk.

For all other exceptions taken to EL2 using AArch64, HPFAR_EL2 is UNKNOWN.

R_{TGQRC} For Instruction Abort or Data Abort exceptions caused by an External abort, when FEAT_PFAR is implemented:

- If all of the following apply, then ESR_ELx.PFV is set to 0:
  - The exception is taken to EL1.
  - EL2 is implemented and enabled in the current Security state.
  - The Effective value of HCR_EL2.VM is 1.
- Otherwise, ESR_ELx.PFV is set to an IMPLEMENTATION DEFINED value of 0 or 1.

For all other Instruction Abort and Data Abort exceptions, ESR_ELx.PFV is set to 0.

On taking an Instruction Abort or Data Abort exception:

- If ESR_ELx.PFV is set to 1 by the PE, then a physical address space that characterizes the exception and a PA are captured in PFAR_ELx. The fault granule size is defined by D_{LVGRB}.
- If ESR_ELx.PFV is set to 0 by the PE, then the applicable PFAR_ELx register is set to an UNKNOWN value.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

PFAR_ELx never records the Intermediate Physical Address (IPA). PFAR_ELx might reveal a faulting physical addresses to a guest operating system if stage 2 translation is not being used and some other method is used to hide physical addresses from the guest (such as shadow page tables).

R_{YZKWJ} For all exceptions other than Instruction Abort and Data Abort exceptions, the applicable PFAR_ELx register is set to an UNKNOWN value.

D1.3.2.2 Asynchronous exception entry

R_{JBKRW} If any of the following apply, when a physical SError exception is taken to AArch64 state, the pending state of the physical SError is cleared:

- FEAT_DoubleFault is implemented.
- If FEAT_RAS is implemented, and on taking the SError exception, the syndrome recorded in ESR_ELx indicates an SError other than IMPLEMENTATION DEFINED or uncategorized SError exception syndrome. See Taking error exceptions.

Otherwise, it is IMPLEMENTATION DEFINED whether the pending state of the physical SError is cleared. This IMPLEMENTATION DEFINED behavior might vary according to the type of the SError exception.

R_{SYZRH} When a virtual SError exception is taken to AArch64 state, HCR_EL2.VSE is set to 0.

D1.3.3 Exception return terminology

D1.3.3.1 Return, return from, return to

R_{MMSFW} An exception return is caused by the execution of an exception return instruction.

R_{JDJHH} The PE state immediately before an exception return instruction is executed is the state the exception *returns from*.

R_{HNVMN} The PE state immediately after the execution of an exception return instruction is the state the exception *returns to*.

D1.3.4 Exception return

R_{SKNJF} In AArch64 state, the Exception return instructions are ERET, ERETAA, and ERETAB.

R_{PKJFB} The Exception return instructions are UNDEFINED in EL0.

R_{SVBYH} An exception return is either legal or illegal.

D1.3.4.1 Legal exception returns from AArch64 state

R_{BWCFK} On a legal exception return from an Exception level, ELx, all of the following occur:

- If SCTLR_ELx.IESB is 1, and the Exception return instruction does not generate an exception, the PE inserts an error synchronization event before the Exception return instruction.
- Fields in PSTATE that have a corresponding field in SPSR_ELx are written according to their description in SPSR_ELx.
- The PC is set to the value in ELR_ELx.
- The Event Register for the PE executing the Exception return instruction is set.
- The local Exclusives monitor for the PE executing the Exception return instruction is cleared. It is IMPLEMENTATION DEFINED whether clearing the local Exclusives monitor also clears the global Exclusives monitor.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D1.3.4.2 Illegal exception returns from AArch64 state

R_{FHSGL} If in AArch64 state, any of the following situations can cause an illegal exception return:

- A return is made to an Exception level higher than the current Exception level.
- A return is made to EL1 HCR_EL2.TGE is 1.
- A return where the SPSR_ELx.M[4] bit is 1.
- A return where the SPSR_ELx.M[3:0] bits are set to a reserved value.

R_{HWWQH} On an illegal exception return from an Exception level, ELx, all of the following occur:

- If SCTLR_ELx.IESB is 1, the PE inserts an error synchronization event before the Exception return instruction.
- The PC is set to the value in ELR_ELx.
- PSTATE.IL is set to 1.
- PSTATE.{EL, nRW, SP} are unchanged.
- PSTATE.{N, Z, C, V, D, A, I, F} are set to the associated values in SPSR_ELx.
- PSTATE.SS is handled as if the return is a legal exception return.
- If FEAT_PAN is implemented, then PSTATE.PAN is set to the associated value in SPSR_ELx.
- All of the following are UNKNOWN:
  - If FEAT_UAO is implemented, then PSTATE.UAO.
  - If FEAT_DIT is implemented, then PSTATE.DIT.
  - If FEAT_SSBS is implemented, then PSTATE.SSBS.
- The Event Register for the PE executing the Exception return instruction is set.
- The local Exclusives monitor for the PE executing the Exception return instruction is cleared. It is IMPLEMENTATION DEFINED whether clearing the local Exclusives monitor also clears the global Exclusives monitor.
- After the PC has been set to the value held in ELR_ELx and the contents of PSTATE have been set to the value held in SPSR_ELx, the ELR_ELx and SPSR_ELx become UNKNOWN.

D1.3.5 Synchronous exception types

R_{FGCQD} All of the following are synchronous exceptions:

- Any exception generated by attempting to execute an instruction that is UNDEFINED, including:
  - Attempts to execute instructions at an inappropriate Exception level.
  - Attempts to execute instructions when they are disabled.
  - Attempts to execute instruction bit patterns that are not allocated.
- Any exception caused by attempts to execute an instruction when the value of PSTATE.IL is 1. These are called Illegal Execution State exceptions.
- Any exception caused by the use of a misaligned SP. These are called SP Alignment Fault exceptions.
- Any exception caused by attempting to execute an instruction with a misaligned PC. These are called PC Alignment Fault exceptions.
- Any exception caused by a pointer authentication instruction authentication failure. These are called PAC Fail exceptions.
- Any exception caused by the exception generating instructions SVC or HVC. These are respectively called Supervisor Call (SVC) exceptions or Hypervisor Call (HVC) exceptions.
- Traps on attempts to execute instructions that the System registers define as instructions that are trapped to a higher Exception level. These are called Trap exceptions.
- Any exception caused by Instruction Aborts that were generated by the memory address translation system that was associated with attempts to execute instructions from areas of memory that generate faults. These are called Instruction Abort exceptions.
- Any exception caused by Data Aborts that were generated by the memory address translation system that are associated with attempts to read or write memory that generate faults. These are called Data Abort exceptions.
- Any exception caused by Data Aborts because of a misaligned address. These are called Data Abort exceptions.
- All of the debug exceptions:
  - Breakpoint Instruction exceptions.
  - Breakpoint exceptions.
  - Watchpoint exceptions.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

  - Software Step exceptions.
- In an implementation that supports the trapping of floating-point exceptions, any exception caused by trapped floating-point exceptions. These are called Trapped Floating-point exceptions.
- An IMPLEMENTATION DEFINED set of exceptions caused by External aborts.

I_{XRFSY} The architecture permits, but does not require, synchronous or asynchronous handling of External aborts.

I_{WRXPC} The RAS architecture specifies some situations that must be handled synchronously.

D1.3.5.1 Taking synchronous exceptions from EL0

R_{NBBHH} If EL2 is using AArch64 and the Effective value of HCR_EL2.TGE is 1, when any of the following exceptions are taken from EL0, they are taken to EL2, unless routed to a higher Exception level. If EL2 is using AArch64 and the Effective value of HCR_EL2.TGE is 0, when any of the following exceptions are taken from EL0, they are taken to EL1, unless routed to a higher Exception level:

- Stage 1 Data Abort.
- Stage 1 Instruction Abort.
- PC Alignment fault.
- SP Alignment fault.
- Trapped Floating-point exception.
- Supervisor Call.
- Undefined Instruction exception.
- PAC Fail exception.
- WFE trap.
- WFI trap.
- Advanced SIMD and floating-point Access trap.
- Synchronous External aborts.
- PMU exceptions.

If EL2 is using AArch64 and either HCR_EL2.TGE is 1 or MDCR_EL2.TDE is 1, when any of the following debug exceptions are taken from EL0, they are taken to EL2. If EL2 is using AArch64 and both HCR_EL2.TGE is 0 and MDCR_EL2.TDE is 0, when any of the following debug exceptions are taken from EL0, they are taken to EL1:

- Breakpoint exception.
- Software Breakpoint exception.
- Software Step exception.
- Watchpoint exception.

If EL2 is using AArch64 and either HCR_EL2.TGE is 1 or MDCR_EL2.TDE is 1, when a Vector Catch exception is taken from EL0, it is taken to EL2. If EL2 is using AArch64 and both HCR_EL2.TGE is 0 and MDCR_EL2.TDE is 0, a Vector Catch exception cannot be taken.

R_{JNBTN} For an exception that is taken from EL0 to EL2 because the value of HCR_EL2.TGE is 1:

- If the exception would have been reported in ESR_EL1 using any EC value other than `0x07`, then the EC value and corresponding ISS encoding that would have been used to report the exception in ESR_EL1 are used to report the exception in ESR_EL2.
- If the exception would have been reported in ESR_EL1 using the EC value `0x07`, then the EC value `0x00` and ISS encoding value `0x00` are reported in ESR_EL2.

D1.3.5.2 Exception levels for taking a synchronous External abort

R_{YYFRT} If all of the following are true, then a synchronous External abort exception is taken to EL2:

- The exception is taken from EL1 or EL0.
- Any of the following are true:
  - The Effective value of HCR_EL2.TEA is 1.
  - The exception was generated by an External abort.
  - The Effective value of HCR_EL2.TGE is 1. This can only occur at EL0.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Otherwise, if FEAT_DoubleFault2 is implemented and all of the following are true, then a synchronous External abort exception is taken to EL2:

- EL2 is implemented, enabled in the current Security state, and using AArch64.
- The Effective value of HCRX_EL2.TMEA is 1.
- PSTATE.A is 1.
- The exception is taken from EL1.

Otherwise, all of the following apply:

- A synchronous External abort exception taken from EL2 is taken to EL2.
- When EL1 is using AArch64, synchronous External abort exception taken from EL1 or EL0 is taken to EL1 using AArch64.

I_{VLBJF} The terms used in the tables in I_{NZCZW} have the following meanings:

HCR If EL2 is using AArch64, this is the Effective value of a field in HCR_EL2.

PSTATE The Effective value of a field in PSTATE.

TGE The Effective value of HCR.TGE. If EL2 is not implemented, or if EL2 is disabled in the current Security state, then the Effective value of HCR.TGE is 0.

A The Effective value of PSTATE.A.

EL1 The exception is taken to EL1.

EL2 The exception is taken to EL2.

n/a Not applicable. The field does not exist in the register in this configuration or the Exception level is not accessible in this configuration.

I_{NZCZW} The following table summarizes the destination Exception level for a synchronous External abort exception taken from ELx, and all of the following applies:

- The error was generated by a stage 1 fault on an access that is not a u System register access. See R_{VLBJF} for details of other cases.
- Either EDSCR.INTdis is `0b00` or invasive debug is disabled.

HCR	PSTATE	Exception taken from		
TGE	A	EL0	EL1	EL2
`0b0`	`0b0`	EL1	EL1	EL2
`0b0`	`0b1`	EL1	EL2	EL2
`0b1`	`0b0`	EL2	n/a	EL2
`0b1`	`0b1`	EL2	n/a	EL2

D1.3.5.3 Prioritization of Synchronous exceptions taken to AArch64 state

R_{ZFGJP} The following list shows the priorities for synchronous exceptions taken to an Exception level using AArch64. The highest priority is 1.

Priority	Synchronous exception type
1	Reset Catch debug event. See Reset Catch debug events.
2	Exception Catch debug event if it has a priority of 2. See Exception Catch debug event.
3	Halting Step debug event. See Halting Step debug events.
4	Software Step Exception used during Debug. See Software Step exceptions.
5	Synchronous PMU exception. See Synchronous exception-based event profiling.
6	Exception Catch debug events. See Exception Catch debug event.
7	PC alignment fault exception. See PC alignment checking.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Priority	Synchronous exception type
8	N/A
9	Instruction Abort exceptions, including exceptions generated by an MMU or MPU fault for the translation of an instruction fetch. See - MMU fault prioritization from a single address translation stage. • MPU memory translations and faults
10	Breakpoint exceptions. See Breakpoint exceptions.
11	N/A
12	N/A
13	Software Breakpoint exceptions, caused by execution of a Breakpoint instruction.
14	N/A
15	N/A
16	Exceptions taken from EL1 to EL2 because of the configuration of one of the following: • HSTR_EL2.Tn. • HCR_EL2.TIDCP.
17	Exceptions that occur as a result of attempting to execute an instruction that is UNDEFINED for one or more of the following reasons: • Attempting to execute a `UDF` instruction. • Attempting to execute an unallocated instruction encoding, including an encoding for an instruction that is not implemented in the PE implementation. • Attempting to execute an instruction that is defined to never be accessible at the current Exception level and Security state, regardless of any enables or traps. • Debug state execution of an instruction encoding that is not accessible in Debug state. • Non-debug state execution of an instruction encoding that is not accessible in Non-debug state. • Attempting to execute an `HVC` instruction, when `HVC` instructions are disabled by HCR_EL2.HCD. • Attempting to execute an `MSR` or `MRS` instruction to SP_EL0, when SPSel.SP is 0. • Attempting to execute an `MSR` or `MRS` instruction using an _EL12 register name, when HCR_EL2.E2H is 0. • Attempting to execute an `HLT` instruction, when `HLT` instructions are disabled by EDSCR.HDE or halting is prohibited. • If in Debug state attempting to execute a `DCPS2` instruction in EL1 or EL0. • Attempting to execute an instruction that is UNDEFINED because all of the following apply: — Programming FPCR.{Stride, Len} to nonzero values is supported. — One or more of FPCR.{Stride, Len} is nonzero.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Priority	Synchronous exception type
18	Exceptions that occur as a result of attempting to execute an instruction that is UNDEFINED for one or more of the following reasons: • Attempting to execute a UDF instruction. • Attempting to execute an unallocated instruction encoding, including an encoding for an instruction that is not implemented in the PE implementation. • Attempting to execute an instruction that is defined to never be accessible at the current Exception level and Security state, regardless of any enables or traps. • Debug state execution of an instruction encoding that is not accessible in Debug state. • Non-debug state execution of an instruction encoding that is not accessible in Non-debug state. • Attempting to execute an HVC instruction, when HVC instructions are disabled by HCR_EL2.HCD. • Attempting to execute an MSR or MRS instruction to SP_EL0, when SPSel.SP is 0. • Attempting to execute an MSR or MRS instruction using an _EL12 register name, when the Effective value of HCR_EL2.E2H is 0. • If FEAT_FGT and FEAT_PMUv3 are implemented, attempting to execute an MSR or MRS instruction in AArch64 state,that accesses a register associated with an unimplemented PMU event counter. • Attempting to execute an HLT instruction, when HLT instructions are disabled by EDSCR.HDE or halting is prohibited. • If in Debug state: — Attempting to execute a DCPS1 instruction in Non-secure EL0 HCR_EL2.TGE is 1. — Attempting to execute a DCPS2 instruction in EL1 or EL0, when EL2 is disabled in the current Security state or is not implemented. • Attempting to execute an instruction that is UNDEFINED because all of the following apply: — EL1 is using AArch64. — Programming FPCR.{Stride, Len} to nonzero values is supported. — One or more of FPCR.{Stride, Len} is nonzero.
19	If all of the following apply, any exception that is generated by a configurable trap or enable: • The exception is not already covered by priorities 4-18. • The exception is taken to EL1, or, if HCR_EL2.TGE is 1, is taken to EL2.
20	As the result of one of the following configuration controls, an exception taken from EL0 to EL2: • When the exception is taken to AArch64 state: — HSTR_EL2.T*n*. — HCR_EL2.TIDCP.
21	N/A
22	As the result of one of the following configuration controls, an exception taken to EL2: • When the exception is taken to AArch64 state: CPTR_EL2, other than those controls covered in priority 21.
23	As the result of a configuration control in one of the following registers, an exception taken to EL2: • When the exception is taken to AArch64 state: — HCR_EL2: Other than a setting made in the {TIDCP, NV} fields, and MRS/MSR instruction using an _EL12 register name when HCR_EL2.E2H is 0. — CNTHCTL_EL2: Any setting. — MDCR_EL2: Any setting.

D1.3.5.4 Trapping of floating-point exceptions

R_{TSQFJ} Execution of a floating-point instruction, or execution of an Advanced SIMD instruction that performs floating-point operations, can generate an exceptional condition, called a floating-point exception.

R_{BBSGN} For each of the following floating-point exceptions, it is IMPLEMENTATION DEFINED whether an implementation includes synchronous exception generation:

- Input Denormal.
- Inexact.
- Underflow.
- Overflow.
- Divide by Zero.
- Invalid Operation.

I_{YRVSW} The architecture does not support asynchronous reporting of floating-point exceptions. If an implementation does not support synchronous exception generation from a floating-point exception, then that synchronous exception is never generated and all statements on when that synchronous exception is generated do not apply.

I_{KJTLV} For any of the implemented floating-point exceptions listed in R_{BBSGN}, FPCR provides control bits to enable synchronous exception generation.

R_{GXMQK} The Exception level that a Trapped Floating-point exception is taken to is defined as follows:

- If executing at EL0:
  - If the Effective value of HCR_EL2.TGE is 0, the exception is taken to EL1.
  - If the Effective value of HCR_EL2.TGE is 1, the exception is taken to EL2.
- If executing at EL1, the exception is taken to EL1.
- If executing at EL2, the exception is taken to EL2.

R_{TRWMV} If an implementation includes synchronous exception generation for floating-point exceptions in AArch64 state, when the execution of separate operations in separate SIMD elements causes multiple floating-point exceptions, the ESR_ELx reports only the exceptions associated with one element that the instruction uses. The architecture does not specify which element is reported.

R_{VJNYH} When a floating-point exception is trapped, all of the following apply:

- When the trapped floating-point exception is taken, it is IMPLEMENTATION DEFINED whether the FPSR is restored to the value of the FPSR immediately before the instruction that generated the trapped floating-point exception.When the trapped floating-point exception is taken, if the FPSR is not restored, it is CONSTRAINED UNPREDICTABLE which untrapped floating-point exceptions, if any, are indicated by the corresponding FPSR cumulative floating-point exception bits having the value 1.
- In ESR_ELx at the target Exception level, all of the following apply:
  - The highest priority trapped floating-point exception has a floating-point exception trapped bit set to 1.
  - If any other untrapped floating-point exceptions are generated by the same operation, each untrapped exception has a floating-point exception trapped bit set to 0. This applies to both higher priority and lower priority untrapped floating-point exceptions.
  - If any lower priority trapped floating-point exceptions are generated by the same operation, for each exception, it is CONSTRAINED UNPREDICTABLE whether the floating-point exception trapped bit is set to 1.

R_{FTPRW} For trapped floating-point exceptions from Advanced SIMD instructions, the architecture does not define the floating-point exception prioritization between different elements of the instruction.

D1.3.6 Asynchronous exception types

R_{ZNTKG} The Arm architecture Exception model distinguishes the following classes of asynchronous exceptions:

- Physical Interrupts
- Virtual Interrupts

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- PMU exceptions, see Exception-based event profiling.

There are the following types of physical interrupt:

- SError (also described as a System Error)
- IRQ
- FIQ

There are the following types of virtual interrupt:

- vSError (also described as a Virtual System Error)
- Delegated SError
- vIRQ
- vFIQ

R_{SLLMN} IRQ, FIQ, vIRQ, and vFIQ interrupts are precise asynchronous exceptions.

R_{PBKNX} The mechanism by which Superpriority is assigned is IMPLEMENTATION DEFINED.

R_{DXHJZ} Each physical interrupt type can be assigned a target Exception level of EL1 or EL2.

I_{VMWYT} ISR_EL1 shows the pending status of the physical interrupts, the physical SError exception, the virtual interrupts, and the virtual and delegated SError exceptions, as follows:

- When read from EL1:
  - The pending status of whichever virtual interrupts are enabled, and of the virtual SError exception if enabled. If the virtual SError exception is not enabled and the delegated SError exception is enabled, the pending status of the delegated SError exception.
- When read from EL2:
  - The pending status of the delegated SError exception, if the delegated SError exception is enabled.

Otherwise, when read from EL1, EL2, or EL3, the pending status of the physical interrupts, and of the physical SError exception.

I_{RWYFW} An implementation might support other mechanisms for signaling a virtual interrupt.

I_{WRGNC} PMU exceptions can also be an asynchronous exception type. See Exception-based event profiling.

I_{XHCGZ} The mechanism by which physical interrupts are signaled to the PE are IMPLEMENTATION DEFINED and might be either edge or level sensitive. A common implementation choice is that the IRQ and FIQ interrupts are level sensitive, and this is supported by the Generic Interrupt Controller (GIC).

I_{YSKZH} The physical SError exception is often used, amongst other things, for communicating External aborts from the memory system that are to be taken asynchronously.

R_{KTWMT} For an External abort generated by the memory system that is taken asynchronously using the SError exception, the SError exception always behaves as an edge-triggered interrupt. For any other sources of SError exceptions, it is IMPLEMENTATION DEFINED whether they are edge-triggered or level-sensitive.

R_{VVBQF} When taking the SError exception to an Exception level using AArch64, ESR_ELx at the target Exception level is updated to describe the SError exception.

If FEAT_RAS is implemented, then when taking a vSError exception to an Exception level using AArch64, ESR_ELx at the target Exception level is updated with exception syndrome information from VSESR_EL2.

R_{RKDNV} When taking an IRQ, vIRQ, FIQ or vFIQ interrupt to an Exception level using AArch64, ESR_ELx at the target Exception level is not updated.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D1.3.6.1 Virtual interrupts

R_{MLLVN} Each virtual interrupt type can be independently enabled from EL2. If a virtual interrupt type is enabled from EL2, the target Exception level for the corresponding physical interrupt is not EL1.

R_{BCXJB} If HCR_EL2.TGE is 0, then setting an HCR_EL2.{FMO, IMO} routing control bit to 1 enables the corresponding virtual interrupt.
If HCR_EL2.TGE is 1, virtual interrupts are disabled.

R_{CDCKC} If HCR_EL2.TGE is 0, then setting the Effective value of either the HCR_EL2.AMO or HCRX_EL2.TMEA routing control bit to 1 enables the virtual SError exception.
If HCR_EL2.TGE is 1, then virtual SError exceptions are disabled.

R_{NVFXB} If a virtual interrupt type is enabled, that type of interrupt can be generated by any one of the following:

- Execution at EL0 or EL1 if the corresponding virtual interrupt pending bit, HCR_EL2.{VSE, VI, VF}, is 1.
- For a vIRQ or a vFIQ, by an IMPLEMENTATION DEFINED mechanism. This might be a signal from an interrupt controller.

R_{SDVLM} If a virtual interrupt is disabled, the virtual interrupt cannot be taken.

R_{MZWNH} When taking a vIRQ or a vFIQ interrupt, the corresponding virtual interrupt pending bit in HCR_EL2 retains its state.

I_{QVCWH} If the virtual interrupt pending bits are used, the vIRQ or vFIQ exception handler must cause software executing at EL2 to set their corresponding virtual interrupt pending bits to 0.

I_{YPRNB} When taking a vSError exception, HCR_EL2.VSE is cleared to 0.

D1.3.6.2 Establishing the target Exception level of an asynchronous exception

R_{QZPXL} The R_{NMMXK} table uses the following terms:

Term	Meaning
IRQ FIQ	The Effective value of these fields is 0.
TGE	If EL2 is not implemented, the Effective value of HCR_EL2.TGE is 0.
IMO FMO	If EL2 is not implemented, the Effective value of these fields is 0.
RW	HCR_EL2.RW
EL1	The exception is taken to EL1.
EL2	The exception is taken to EL2.
C	The interrupt is not taken and remains pending, regardless of the PSTATE.{I, F, ALLINT} interrupt masks.
n/a	Not applicable. The field does not exist in the register in this configuration or the Exception level is not accessible in this configuration.

R_{NMMXK} The following table describes the routing of physical FIQ and IRQ interrupts if the highest implemented Exception level is using AArch64 and either EDSCR.INTdis is `0b00` or invasive debug is disabled.

Table D1-8 FIQ and IRQ interrupt exception targets

SCR_EL3				Target when taken from		
NS	EEL2	IRQ FIQ	RW	EL0	EL1	EL2
0	1	0	x	EL1	EL1	C
0	1	0	x	EL1	EL1	C

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

SCR_EL3				Target when taken from		
NS	EEL2	IRQ FIQ	RW	EL0	EL1	EL2
0	1	0	x	EL2	EL2	EL2
0	1	0	x	EL2	n/a	EL2
0	1	1	x	EL2	EL2	C
0	1	1	x	C	n/a	C

Table D1-9 FIQ and IRQ interrupt exception targets

HCR			Target when taken from		
TGE	IMO FMO	RW	EL0	EL1	EL2
0	0	0	IRQ, FIQ	IRQ, FIQ	C
0	0	1	EL1	EL1	C
0	0	x	EL1	EL1	C
0	1	x	EL2	EL2	EL2
1	x	x	EL2	n/a	EL2
0	0	0	FIQ	FIQ	C
0	0	1	EL1	EL1	C
0	0	x	EL1	EL1	C
0	1	x	EL2	EL2	EL2
1	x	x	EL2	n/a	EL2

R_{ZZYHK} The R_{MGNFZ} tables use the following terms:

Term	Meaning
HCR_EL2	The Effective value of a field in HCR_EL2.
TGE	If EL2 is not implemented, or if EL2 is disabled in the current Security state, then the Effective value of HCR_EL2.TGE is 0.
AMO	If EL2 is not implemented, or if EL2 is disabled in the current Security state, the Effective value of HCR_EL2.AMO is 0.
PSTATE	The value of a field in PSTATE.
A	The value of PSTATE.A.
EL1	The exception is taken to EL1.
EL2	The exception is taken to EL2.
C	The interrupt is not taken and remains pending, regardless of the PSTATE.A mask.
n/a	Not applicable. The field does not exist in the register in this configuration or the Exception level is not accessible in this configuration.

R_{MGNFZ} The following tables describe the routing of SError exceptions taken from ELx.

All of the following apply to these tables:

- SCR_EL3.{NS, EEL2} are not shown because R_{ZZYHK} describes Effective values involving Security states.
- Either EDSCR.INTdis is `0b00` or invasive debug is disabled.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Table D1-11 SError exception target when EL2 is using AArch64

HCR_EL2		PSTATE	Taken from		
TGE	AMO	A	EL0	EL1	EL2
0b0	0b0	x	EL1	EL1	C
0b0	0b0	0b1	EL2	EL2	C
0b0	0b0	0b0	EL1	EL1	C
0b0	0b0	0b1	EL1	EL2	C
0b0	0b0	0b1	EL2	EL2	EL2
0b1	x	x	EL2	n/a	EL2
0b0	0b0	0b1	EL1	EL2	EL2
0b0	0b0	0b0	EL1	EL1	EL2
0b0	0b1	0b0	EL2	EL2	EL2
0b0	0b1	0b1	EL2	EL2	EL2
0b1	x	0b1	EL2	n/a	EL2
0b1	x	0b0	EL2	n/a	EL2

D1.3.6.3 Asynchronous exception masking

R_{HDMYQ} An interrupt can be masked. A masked interrupt is not taken and remains pending.

R_{ZZBPC} Whether an interrupt is masked is determined by all of the following:

- The PSTATE.{A, I, F, SP} bits.
- Whether an IRQ or FIQ interrupt has Superpriority.
- The implemented Exception levels.
- The configuration of the Hypervisor Configuration Registers.
- For an SError, whether the exception is non-maskable.
- The configuration of the Secure Configuration Register.

R_{LMWZH} If in AArch64 state and the target Exception level of an interrupt is lower than the current Exception level, the interrupt is masked.

D1.3.6.3.1 Physical interrupt masking

R_{MHWBP} If the target Exception level of a physical IRQ interrupt is the current Exception level, ELx, the following controls determine whether the interrupt is masked:

PSTATE.I	IRQ
0	Not masked
1	Masked

R_{GFXKY} If the target Exception level of a physical FIQ interrupt is the current Exception level, ELx, the following controls determine whether the interrupt is masked:

R_{YSVFS} If the target Exception level of a physical SError is the current Exception level, the PSTATE.A control determines whether the interrupt is masked.

R_{XCFNZ} If the target Exception level of a physical interrupt is higher than the current Exception level, all of the following apply:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- If the target Exception level is EL2 and any of the following are true, the interrupt cannot be masked by the PSTATE.{A, I, F} bits.
  - The Effective value of HCR_EL2.TGE is 0.
- If the target Exception level is EL2 and all of the following are true, the interrupt can be masked by the PSTATE.{A, I, F} bits:
  - The Effective value of HCR_EL2.TGE is 1.

I_{KDYCN} The ability to execute in EL0 with interrupts taken to EL1 masked is required by some user level driver code.

R_{HPRNX} The R_{SXLWJ} table uses the following terms:

Term	Meaning
A	When the interrupt is pending, it is taken regardless of the value of the PSTATE.{A, I, F, ALLINT} interrupt masks.
B	When the interrupt is pending, it might be subject to masking, as defined in R_{MHWBP} or R_{GFXKY}. If the interrupt is masked, it is not taken. If the interrupt is not masked, it is taken.
C	When the interrupt is pending, it is not taken, regardless of the value of the PSTATE.{A, I, F} interrupt masks.
n/a	Not applicable.

R_{SXLWJ} The following table describes the target and masking of physical FIQ and IRQ interrupts, if the highest implemented Exception level is using AArch64.

Table D1-14 FIQ and IRQ interrupt exception targets and masking

HCR		Effect of the interrupt mask when executing at:		
TGE	IMO FMO	EL0	EL1	EL2
0	0	B	B	C
0	1	A	A	B
1	x	A	n/a	B
1	x	A	n/a	A

D1.3.6.3.2 Virtual interrupt masking

R_{SNLJH} The following controls determine whether a virtual IRQ interrupt is masked:

PSTATE.I	vIRQ
0	Not Masked
1	Masked

R_{XSPSG} The following controls determine whether a virtual FIQ interrupt is masked:

PSTATE.F	vFIQ
0	Not Masked
1	Masked

R_{GYGBD} Virtual interrupts can only be taken from EL0 or EL1 and can only be taken to EL1. If executing at EL2, all types of virtual interrupts are always masked.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D1.3.6.4 Prioritization of interrupts

R_{NLHMN} For all of the following Context synchronization events, if an interrupt is pending before the Context synchronization event, and the interrupt remains pending and is not masked after the Context synchronization event, the interrupt is taken before the first instruction after the Context synchronization event:

- Execution of an ISB instruction.
- Exception entry.
- Exception return.
- Exit from Debug state.

If the first instruction after the Context synchronization event generates a synchronous exception, the architecture does not define whether the PE takes the interrupt or the synchronous exception first.

I_{RDBWJ} A RAS error synchronization event defines additional requirements for taking an SError exception.

R_{QVRHH} Other than the behaviors described in R_{NLHMN}, an unmasked, pending interrupt must be taken in finite time.

R_{ZQPLL} If an unmasked interrupt was pending but is changed to not pending before it is taken, it is CONSTRAINED UNPREDICTABLE whether or not the interrupt is taken. If the interrupt is taken, it is taken before the first Context synchronization event after the interrupt was changed to be not pending.

D1.3.6.5 Taking an interrupt during a multi-access load or store

R_{ZBFSL} If in AArch64 state, interrupts can be taken during a sequence of memory accesses caused by a single load or store instruction. This is true regardless of the memory type being accessed.
In this situation, the behavior is consistent with the requirements described in R_{TNVSL} in Definition of a precise exception and imprecise exception.

D1.3.7 UNDEFINED instructions

R_{ZLJDF} An instruction which is UNDEFINED generates a synchronous exception for that instruction unless there is a higher priority exception generated for that instruction.

R_{QNGXB} The Exception level that the synchronous Undefined Instruction exception is taken to is defined as follows:

- If executing at EL0:
  - If the Effective value of HCR_EL2.TGE is 0, the exception is taken to EL1.
  - If the Effective value of HCR_EL2.TGE is 1, the exception is taken to EL2.
- If executing at EL1, the exception is taken to EL1.
- If executing at EL2, the exception is taken to EL2.

D1.3.8 Configurable instruction controls

R_{QMWPZ} *Configurable instruction controls* are control bits held in System registers that determine whether attempting to execute an instruction generates a synchronous exception at the point in the instruction stream of that instruction, and the instruction is not executed.

I_{ZSSHJ} Configurable instruction controls might be referred to by any of the following names:

- Instruction enables.
- Instruction disables.
- Trap controls.

The definitions of each type overlap, and in some cases is historical. Describing a register control field as an instruction enable, an instruction disable, or a trap control, gives no indication of how an exception that is generated as a consequence of the value of that field is handled or reported. Each configurable instruction control defines how the exception that is generated as a consequence of the configurable instruction control is handled or reported.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

R_{VWWGJ} An exception can only be generated as a result of a configurable instruction control if all the following apply:

- The instruction generating the exception does not also generate a higher priority exception.
- The instruction generating the exception is not UNPREDICTABLE or CONSTRAINED UNPREDICTABLE in the PE state in which the instruction is executed.

R_{JTXTF} It is UNPREDICTABLE / CONSTRAINED UNPREDICTABLE whether configurable instruction controls generate an exception when the instruction is UNPREDICTABLE or CONSTRAINED UNPREDICTABLE in the PE state in which the instruction is executed, with all of the following constraints:

- If the instruction description explicitly states that the configurable instruction control is applied with higher priority than the CONSTRAINED UNPREDICTABLE behavior, then the configurable instruction control generates an exception.
- The CONSTRAINED UNPREDICTABLE behaviors cannot lead to any behavior that is prohibited by the general definition of UNPREDICTABLE.

I_{BJBMF} UNPREDICTABLE and CONSTRAINED UNPREDICTABLE instructions can generate exceptions as a result of configurable instruction controls, but the architecture does not require them to do so.

Note: Many CONSTRAINED UNPREDICTABLE behaviors for instructions include an allowance that the CONSTRAINED UNPREDICTABLE instruction behaves the same way as a closely related instruction that is not CONSTRAINED UNPREDICTABLE. In those cases, the instruction enable, disable, or trap control that causes in exception on the closely related instruction will cause the same exception on the CONSTRAINED UNPREDICTABLE instruction.

I_{TFGPW} An implementation might provide more controls, in IMPLEMENTATION DEFINED registers, to provide control of trapping of IMPLEMENTATION DEFINED features.

R_{QQLHG} When a configurable instruction control causes an exception, the exception is taken and the instruction is not executed, and therefore all the following are true:

- The preferred exception return address of the exception is the instruction that generates the exception.
- There are no changes to the registers accessed by the instruction, including as a result of side-effects of a register access.

D1.3.8.1 EL0 and EL1 configurable instruction controls

I_{TJPQP} The following EL0 and EL1 System registers contain configurable instruction controls:

Register name	Register description
CPACR_EL1	Architectural Feature Access Control Register
MDSCR_EL1	Monitor System Debug Control Register
PMUSERENR_EL0	Performance Monitors User Enable Register
SCTLR_EL1	System Control Register (EL1)
TCR_EL1	Translation Control Register (EL1)

D1.3.8.2 EL2 configurable instruction controls

I_{BLDYL} The following EL2 System registers contain configurable instruction controls:

Register name	Register description
CPTR_EL2	Architectural Feature Trap Register, EL2
HCR_EL2	Hypervisor Configuration Register
HSTR_EL2	Hypervisor System Trap Register

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Register name	Register description
MDCR_EL2	Monitor Debug Configuration Register, EL2
SCTLR_EL2	System Control Register, EL2
TCR_EL2	Translation Control Register, EL2

D1.3.9 Exception generating instructions

I_{YRYNQ} The exception generating instructions are commonly called system calls and refer to the instructions that generate any of the following synchronous exception types:

- Supervisor Call exception.
- Hypervisor Call exception.
- Secure Monitor Call exception.

R_{JZKSX} If the PE is executing at EL0, the `HVC` instruction is UNDEFINED.

R_{BRCQB} A Supervisor Call is generated by executing an `SVC` instruction.

R_{MTFVD} A Supervisor Call exception is taken to the following Exception levels:

- If executing at EL0:
  - If the Effective value of HCR_EL2.TGE is 0, the exception is taken to EL1.
  - If the Effective value of HCR_EL2.TGE is 1, the exception is taken to EL2.
- If executing at EL1, the exception is taken to EL1.
- If executing at EL2, the exception is taken to EL2.

I_{NCTDB} A Supervisor Call enables software executing at EL0 to make a call to an operating system or other software executing at EL1.

R_{LLLGJ} If EL2 is implemented and the `HVC` instruction is not UNDEFINED, a Hypervisor Call is generated by executing an `HVC` instruction.

R_{LQBSH} A Hypervisor Call exception is taken to the following Exception levels:

- When taken from EL1, the exception is taken to EL2.
- When taken from EL2, the exception is taken to EL2.

R_{HMXQS} If any of the following are true, the `SMC` instruction is UNDEFINED:

- The PE is executing at EL0.
- The `SMC` instruction is not trapped to EL2 by HCR_EL2.TSC.

D1.3.10 Program Counter and stack pointer alignment

D1.3.10.1 PC alignment checking

R_{QCCWG} If bits [1:0] of the PC are not `0b00`, there is a misaligned PC.

R_{SJLDM} The execution of an instruction with a misaligned PC generates a synchronous PC Alignment exception on that instruction.

R_{THMSY} A PC Alignment exception is taken to the following Exception levels:

- If executing at EL0:
  - If HCR_EL2.TGE is 0, the exception is taken to EL1.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

  - If HCR_EL2.TGE is 1, the exception it taken to EL2.
- If executing at EL1, the exception is taken to EL1.
- If executing at EL2, the exception is taken to EL2.

R_{MVTQT} When a PC Alignment Fault exception is taken to an Exception level, ELx, using AArch64, the ELR_ELx and the FAR_ELx both hold the entire PC in its misaligned form.

I_{VFXPV} A misalignment of the PC is an indication of a serious error, for example software corruption of an address.

D1.3.10.2 SP alignment checking

R_{RDMXG} When the SP is used as the base address of a calculation, regardless of any offset applied by the instruction, if bits [3:0] of the SP are not `0b0000`, there is a misaligned SP.

R_{TFVSM} If SP alignment checking is enabled, then the execution of a load or store using the SP with a misaligned SP generates a synchronous SP Alignment exception on that load or store.

R_{JQXVP} PRFM instructions that use the SP do not perform stack alignment checking.

R_{WXBYR} The following bits enable SP alignment checking at each Exception level when that Exception level is using AArch64.

- SCTLR_EL1.SA controls EL1.
- SCTLR_EL2.SA controls EL2.

R_{GVQYS} An SP Alignment exception is taken to the following Exception levels:

- If executing at EL0:
  - If HCR_EL2.TGE is 0, the exception is taken to EL1
  - If HCR_EL2.TGE is 1, the exception it taken to EL2.
- If executing at EL1, the exception is taken to EL1.
- If executing at EL2, the exception is taken to EL2.

Non-Confidential

D1.4 Process state, PSTATE

R_{SPCZF} Process state, or PSTATE, is an abstraction of process state information.

I_{LPKMT} All Arm instruction sets provide instructions that operate on elements of PSTATE.

I_{ZHGST} PSTATE is defined in pseudocode as the PSTATE structure, of type `ProcState`.

D1.4.1 PSTATE fields that are meaningful in AArch64 state

I_{LLLXL} PSTATE fields that are meaningful in AArch64 state are grouped into the following categories:

- Condition flags.
- Execution state controls.
- Exception mask bits.
- Access control bits.
- Timing control bits.
- Speculation control bits.

R_{PCDTX} The following PSTATE bits are meaningful in AArch64 state:

PSTATE field name	PSTATE field group	Required implemented feature	Value when a Warm reset is asserted	Additional details
N, Negative condition flag	Condition flags	-	-	-
Z, Zero condition flag	Condition flags	-	-	-
C, Carry condition flag	Condition flags	-	-	-
V, Overflow condition flag	Condition flags	-	-	-
SS, Software Step bit	Execution state controls	-	0	-
IL, Illegal Execution state bit	Execution state controls	-	0	-
nRW, Current Execution state bit	Execution state controls	-	0	If the current Execution state is AArch64, the PSTATE.nRW bit is 0.
EL, Current Exception level field	Execution state controls	-	When a Warm reset is asserted into an Exception level using AArch64, the PSTATE.EL field holds the encoding for the highest implemented Exception level, EL2.	-
SP, Stack pointer register selection bit	Execution state controls	-	1	-
D, Debug exception mask bit	Exception mask bits	-	1	-
A, I, F Asynchronous exception mask bits	Exception mask bits	-	1	-
PAN, Privileged Access Never state bit	Access control bits	FEAT_PAN	-	-
UAO, User Access Override bit	Access control bits	FEAT_UAO	-	-
DIT, Data Independent Timing bit	Timing control bits	FEAT_DIT	0	-

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

PSTATE field name	PSTATE field group	Required implemented feature	Value when a Warm reset is asserted	Additional details
SSBS, Speculative Store Bypass Safe bit	Speculation control bits	FEAT_SSBS	IMPLEMENTATION DEFINED	-

D1.4.1.1 Accessing PSTATE fields

R_{LYGBS} In AArch64 state, PSTATE fields are accessed using Special-purpose registers that are directly read using the MRS (register) instructions, and directly written using the MSR (register) instructions.

R_{DGPCL} If in AArch64 state, the following Special-purpose registers can access the PSTATE fields that hold AArch64 state:

Special-purpose register	PSTATE fields
NZCV	N, Z, C, V
DAIF	D, A, I, F
CurrentEL	EL
SPSel	SP
PAN	PAN
UAO	UAO
DIT	DIT
SSBS	SSBS

All other PSTATE fields do not have direct read and write access.

R_{BRSMZ} Software can use the MSR (immediate) instructions to directly write to PSTATE.{D, A, I, F, SP, PAN, UAO, DIT, SSBS}.

R_{CWYCH} The following PSTATE fields can be accessed at EL0:

- PSTATE.{N, Z, C, V, SSBS, DIT}.
- If SCTLR_EL1.UMA is 1, PSTATE.{D, A, I, F}.
- All other PSTATE access instructions can be executed at EL1 or higher and are UNDEFINED at EL0.

R_{HXYGT} Writes to the PSTATE fields have side-effects on various aspects of the PE operation. For side-effects caused by writes to a PSTATE field, all of the following are true:

- The side-effect is guaranteed not to be visible to earlier instructions in the Execution stream.
- The side-effect is guaranteed to be visible to later instructions in the Execution stream.

Other side-effects might occur but are not guaranteed.

Non-Confidential

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D1.5 Resets and power domains

I_{DQXXZ} The PE logic is split into a Debug power domain and a Core power domain. Cold and Warm resets, reset elements in the Core power domain. An External debug reset can reset the Debug power domain. Other resets might be implemented.

D1.5.1 Power domains and reset domains

R_{PQLRX} The architecture defines the following power domains:

- The Core power domain.
- The Debug power domain.
- The system counter power domain.
- If trace is implemented, a power domain for the Trace Unit.
- If FEAT_RAS is implemented, there may be one or more IMPLEMENTATION DEFINED error recovery power domains. The relationship between these power domains and other power domains is IMPLEMENTATION DEFINED. For error records associated with the PE, this is the same as the Core power domain.

I_{QBPTS} The power domains are described as logical because the architecture does not require two physical power domains.

R_{PDMKB} It is IMPLEMENTATION DEFINED whether each power domain powers up and powers down separately or together.

R_{ZDVQQ} The Core power domain contains:

- Non-debug registers and logic.
- Self-hosted debug registers and logic.
- Shared debug registers and logic.
- Some external debug registers and logic.

R_{GTVLN} The Debug power domain contains:

- The interface between the PE and the external debugger.
- Some external debug registers.

R_{MLXWM} If an external debugger is connected to the PE, the Debug power domain is powered up.

I_{KTSWK} For more information on access permissions for the external debug interface registers, see Access permissions for the External debug interface registers or the individual register descriptions.

D1.5.2 Reset types

I_{YHXXB} The architecture defines the following resets:

- Warm reset.
- Cold reset.
- External Debug reset.
- Trace unit reset. See Resetting the trace unit.
- Timer reset.
- If FEAT_RAS is implemented, there may be one or more IMPLEMENTATION DEFINED error recovery resets. The relationship between this reset and other resets is IMPLEMENTATION DEFINED. For error records associated with the PE, the error recovery reset is the same as Warm reset.

I_{FMTCY} Other resets are IMPLEMENTATION DEFINED and can be mapped onto the architecturally-defined resets.

R_{PXXYQ} Mechanisms to assert resets, other than RMR_ELx, are IMPLEMENTATION DEFINED. One such mechanism is EDPRCR.CWRR. Any reset-asserting mechanism that software can command, including hardware mechanisms directly exposed to software, must only be accessible at the highest Exception level.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

R_{HLDGD} When a Cold reset is asserted, for each register in the Core power domain, the reset sets the register to its architecturally-defined reset value.

R_{PJXVL} When a Warm reset is asserted, registers and logic in the Core power domain that are affected by the Warm reset are reset to their architecturally-defined reset value. Registers and logic that are only reset by a Cold reset are unaffected by a Warm reset.

R_{NBKHK} When an External Debug reset is asserted, the External Debug reset domain is reset and affected registers are set to their architecturally-defined External debug reset values. The Cold reset domain is unaffected.

R_{RKSZM} When a Cold reset is asserted, a Warm reset is asserted.

I_{VBZBW} Every register field that has storage belongs to exactly one reset domain. Each System register field definition defines the reset domain and the reset value.

I_{MWTXK} If RMR_ELx is implemented, writing 1 to RMR_ELx.RR requests a Warm reset.

R_{SGXSW} Writing 1 to RMR_ELx.RR is only a request for a Warm reset. The reset is not guaranteed to occur unless the following code sequence is executed:

```
; In addition, interrupts and debug requests for this PE should be disabled
; in the system before running this sequence to ensure the WFI suspends execution,
        MOV Wy, #3          ; for AArch64, #2 for AArch32; y is any register
        DSB                 ; ensure all stores etc are complete
        MSR RMR_ELx, Wy     ; request the reset
        ISB                 ; synchronize change to the RMR
Loop
        WFI                 ; enter a quiescent state
        B Loop
```

R_{DDTVZ} It is IMPLEMENTATION DEFINED whether a Warm reset can be asserted without using RMR_ELx.

I_{LWNDC} Arm recommends that a Warm reset can be asserted independently of a Cold reset.

I_{QLZGF} A Warm reset allows debugging across a reset of the PE logic in the Core power domain.

R_{SKGMH} It is IMPLEMENTATION DEFINED whether an External Debug reset and a Cold reset can be asserted independently.

I_{WTJYS} Arm recommends that when separate Core and Debug power domains are implemented, the External Debug reset and Cold reset can be asserted independently.

D1.5.3 Reset behavior

I_{TWYCF} Immediately after a reset, much of the PE state is architecturally UNKNOWN. However, some of the PE state is defined, see the individual register descriptions for more information. The state that is reset to known values is sufficient to permit predictable initial execution at the highest Exception level, such that this execution is then capable of initializing the remaining state of the system where necessary before use.

R_{JYLQV} When a Cold or Warm reset is asserted, all of the following occur:

- The PE enters the highest implemented Exception level.
- The stack pointer for the highest implemented Exception level, SP_ELx, is selected.

R_{BPKQV} When a Cold or Warm reset is deasserted, execution starts at an IMPLEMENTATION DEFINED address, anywhere in the *Physical Address* (PA) range. RVBAR_EL2, holds the address at which the PE starts execution.

I_{QSCPY} When a Cold or Warm reset is deasserted, the IMPLEMENTATION DEFINED address from which the PE starts execution is typically set either by a hardwired configuration of the PE or by configuration input signals.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

R_{RRJLM} When a Warm reset is asserted, all of the following are architecturally UNKNOWN:

- All general-purpose, SIMD, and floating-point registers.
- The global exclusive monitor for the PE.
- The local exclusive monitor for the PE.
- System and Special-purpose registers with a reset value of architecturally UNKNOWN.

I_{KWHDG} When a Cold or Warm reset is asserted, PSTATE.{SS, IL, nRW, EL, SP, D, A, I, F, DIT} fields are set to known values.

R_{BGSHC} When a Cold or Warm reset is asserted, the TLBs and caches are in an IMPLEMENTATION DEFINED state.

R_{XNNNH} When a Cold or Warm reset has been asserted and before the memory management system is enabled, the TLBs, caches or both might need to be invalidated by IMPLEMENTATION DEFINED invalidation sequences.

R_{TZHFZ} When a Cold or Warm reset has been asserted and before Normal memory accesses are permitted to be Cacheable, the TLBs, caches or both might need to be invalidated by IMPLEMENTATION DEFINED invalidation sequences.

R_{KMCGN} If IMPLEMENTATION DEFINED resets are implemented, each IMPLEMENTATION DEFINED reset can treat the cache and TLB state differently.

R_{TJGFQ} If IMPLEMENTATION DEFINED resets are implemented, for each IMPLEMENTATION DEFINED reset, the TLBs, caches, or both might require a different IMPLEMENTATION DEFINED invalidation sequence.

I_{PHDMZ} The IMPLEMENTATION DEFINED invalidation sequence might be a NOP.

D1.5.3.1 External debug access to registers in reset

R_{VFMKQ} If External Debug reset is asserted, for each register that can be accessed by the external debug interface, a register access by the external debug interface has one of the following IMPLEMENTATION DEFINED results:

- The external debug interface can access the register, and the access result is IMPLEMENTATION DEFINED.
- The external debug interface cannot access the register.

I_{QHHMQ} If either a Cold or Warm reset is asserted, accesses of registers or register fields might be direct accesses or indirect side-effects of an access.

R_{YKRBF} If either a Cold or Warm reset is asserted, external debug interface accesses of a register or register field have the following effects:

Access	Register or register field reset behavior	Effect on register or register field
Write	Reset by the reset signal	Set to CONSTRAINED UNPREDICTABLE choice of the reset value or the value written.
Write	Not reset by the reset signal	Set to the value written.
Read	Reset by the reset signal	Returns an UNKNOWN value.
Read	Not reset by the reset signal	Returns the value of the register or register field.

D1.6 Mechanisms for entering a low-power state

I_{RTNZD} The architecture provides the following mechanisms that software can use to indicate that the PE can enter low-power state:

- Wait for Event.
- Wait for Interrupt.

D1.6.1 Wait for Event

I_{ZZQGW} The Wait for Event mechanism behavior depends on the interaction of all of the following:

- The Event Register for the PE. See The Event Register.
- The Wait for Event (WFE) or Wait for Event with Timeout (WFET) instruction. See The Wait for Event and Wait for Event with Timeout instructions.
- WFE wakeup events. See WFE wakeup events in AArch64 state.
- The Send Event instructions, SEV and SEVL, that can cause WFE wakeup events. See The Send Event instructions.

R_{TJTFC} The architecture does not define the exact nature of the low-power state entered by WFE or WFET, except that when a WFE or WFET instruction is executed, memory coherency and architectural state are not lost.

I_{WBMQQ} The Wait for Event mechanism is associated with suspending execution on a PE for power saving, therefore Arm recommends that the Event Register is set infrequently. Software must only use the setting of the Event Register as a hint, and must not assume that any particular message is sent as a result of the setting of the Event Register.

D1.6.1.1 The Event Register

R_{PVKKP} The Event Register is a single bit register for each PE.

I_{TZVVM} The event register is a conceptual register and cannot be explicitly accessed.

I_{PDJMB} If the Event Register is 1, then an event has occurred since the register was last cleared and the event might require some action by the PE.

R_{RJYVC} When the PE executes a WFE or WFET instruction, all of the following apply:

- If the Event Register is 0, then the PE can enter the low-power state.
- If the Event Register is 1, then all of the following apply:
  - The PE does not suspend operation.
  - The Event Register is cleared to 0.
  - The WFE or WFET instruction completes immediately.

R_{DDGLZ} The reset value of the Event Register is UNKNOWN.

R_{XRZRK} The Event Register for a PE is set by any of the following:

- A Send Event instruction, SEV, executed by any PE in the system.
- A Send Event Local instruction, SEVL, executed by the PE.
- An exception return.
- The clearing of the global monitor for the PE.
- An event from a Generic Timer event stream, see Event streams.
- An event sent by some IMPLEMENTATION DEFINED mechanism.

I_{PJZBB} The Event Register is cleared only by a Wait for Event (WFE) instruction or a Wait for Event with Timeout (WFET) instruction.

I_{ZXJPD} Software cannot read or write the value of the Event Register directly.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D1.6.1.2 Trapping of WFE and WFET

I_{KMHTB} The WFE and WFET instructions are available at all Exception levels. Attempts to enter a low-power state made by software executing at EL0 or EL1 can be configured to trap to EL2.

D1.6.1.3 WFE wakeup events in AArch64 state

I_{LRPVP} If a WFE or WFET instruction puts a PE into low-power state, a WFE wakeup event received by the PE causes that PE to exit low-power state.

R_{KBMFC} All of the following are WFE wakeup events:

- The execution of an SEV instruction on any PE in a multiprocessor system.
- Any physical SError exception, physical IRQ interrupt, or physical FIQ interrupt received by the PE that is not disabled by EDSCR.INTdis and either of the following is true:
  - The interrupt is marked as A in the tables in Asynchronous exception masking, regardless of the value of the corresponding PSTATE.{A, I, F} mask bit.
  - The interrupt is marked as B in the tables in Asynchronous exception masking and any of the following are true:
    - The value of the corresponding PSTATE.{A, I, F} mask bit is 0.
    - AllIntMask is 0 and the IRQ or FIQ interrupt has Superpriority.
      See R_{MHWBP} and R_{GFXKY}.
- If all of the following apply, any virtual SError exception, virtual IRQ interrupt, or virtual FIQ interrupt received by the PE:
  - The PE is executing at EL1 or EL0.
  - The interrupt is not disabled by EDSCR.INTdis.
  - The interrupt or exception is marked as B in the table in Virtual interrupt masking and any of the following are true:
    - The value of the corresponding PSTATE.{A, I, F} mask bit is 0.
    - AllIntMask is 0 and the vIRQ or vFIQ interrupt has Superpriority.
      See R_{SNLJH} and R_{XSPSG}.
- If all the following apply, any delegated SError exception received by the PE:
  - The PE is executing at EL2, EL1, or EL0.
  - The exception is not disabled by EDSCR.INTdis.
  - Either of the following is true:
    - The exception is marked as A in the table in Delegated SError exception masking.
    - The exception is marked as B in the table in Delegated SError exception masking and PSTATE.A is 0.
- If halting is allowed, an asynchronous External Debug Request debug event. For the definition of halting, see Halting allowed and halting prohibited and External Debug Request debug event.
- An event sent by the timer event stream for the PE. See Event streams.
- An event caused by the clearing of the global monitor for the PE.
- An event sent by some IMPLEMENTATION DEFINED mechanism.
- When FEAT_WFxT is implemented, for `WFET` instructions, a local timeout event caused by the virtual count threshold value, expressed in CNTVCT_EL0, being equaled or exceeded.

I_{FRZZX} Not all of the wakeup events in R_{KBMFC} set the Event Register.

D1.6.1.4 The Send Event instructions

R_{DQRMZ} The Send Event instructions are:

- `SEV`, Send Event: Causes an event to be signaled to all PEs in a multiprocessor system.
- `SEVL`, Send Event Local: Causes an event to be signaled locally without requiring the event to be signaled to other PEs in a multiprocessor system.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I_{FVQBK} An SEVL instruction might signal an event to other PEs by an IMPLEMENTATION DEFINED mechanism, but it is not required to do so.

R_{HTDFW} The mechanism that signals an event to other PEs is IMPLEMENTATION DEFINED.

R_{RLHHM} When an event is signaled by an SEV instruction, the ordering of the event with respect to the completion of memory accesses by instructions before the SEV instruction is not guaranteed.

I_{DVZXD} Arm recommends that software includes a DSB instruction before any SEV instruction. DSB instruction ensures that no instructions, including any SEV instructions, that appear in program order after the DSB instruction, can execute until the DSB instruction has completed. See Data Synchronization Barrier.

R_{QJDQV} The SEVL instruction appears to execute in program order relative to any subsequent WFE or WFET instruction executed on the same PE.

I_{HWHBP} The behavior in R_{QJDQV} applies without the need for any explicit insertion of barrier instructions.

D1.6.2 Wait for Interrupt mechanism

I_{LMJGQ} A PE can use the Wait for Interrupt mechanism to enter a low-power state.

R_{DBXLJ} Software can use the Wait for Interrupt (WFI) instruction to cause the PE to enter a low-power state.

R_{HSPJD} If a Wait for Interrupt (WFI) instruction causes the PE to enter a low-power state, the PE remains in that low-power state until any of the following occur:

- The PE detects a WFI wakeup event.
- An IMPLEMENTATION DEFINED wake event that is architecturally permitted to occur at any time.
- A reset is asserted.

I_{MFLXH} The architecture permits all of the following:

- The PE is permitted to leave the low-power state for any reason.
- The PE is permitted to treat WFI as a NOP, but this is not recommended for lowest power operation.

R_{MRVLC} When the PE leaves a low-power state that was entered because of a WFI instruction, the WFI instruction completes.

R_{HJPJY} Except for all or the following, the architecture does not define the exact nature of the low-power state:

- When a WFI instruction is executed, the architecture requires that memory coherency is not lost.
- If the system is configured such that the WFI instruction can be completed, then the architecture requires that the architectural state is not lost.

I_{WWYXS} In some implementations, based on the configuration of system specific registers, WFI can be used as part of a powerdown sequence where no interrupts will cause WFI wakeup events, and restoration of power involves resetting of the PE. In those cases, the WFI is permitted to cause a loss of architectural state, as it is assumed that this state will have been saved by software as part of the powerdown sequence before the WFI.

I_{CHMWP} The WFI instruction are available at all Exception levels. Attempts to enter a low-power state made by software executing at EL0, EL1, or EL2 can be configured to trap to a higher Exception level.

D1.6.2.1 WFI wakeup events

I_{CYKVZ} In this section, AllIntMask refers to the value described in R_{XZPDT}.

R_{VRLPB} All of the following are WFI wakeup events:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- Any physical SError exception, physical IRQ interrupt, or physical FIQ interrupt received by the PE that is marked as A or B in the tables in Asynchronous exception masking, regardless of the value of the corresponding PSTATE.{A, I, F} mask bit.
- If the PE is executing at EL1 or EL0, any virtual SError exception, virtual IRQ interrupt, or virtual FIQ interrupt received by the PE, that is marked as B in the tables in Virtual interrupt masking, regardless of the value of the corresponding PSTATE.{A, I, F} mask bit.
- If the PE is executing at EL2, EL1, or EL0, any delegated SError exception received by the PE that is marked as A or B in the table in Delegated SError exception masking, regardless of the value of PSTATE.A.
- If halting is allowed, an asynchronous External Debug Request debug event. For the definition of halting, see Halting allowed and halting prohibited and External Debug Request debug event.
- An event sent by an IMPLEMENTATION DEFINED mechanism.

R_{NLVGY} WFI wakeup events are never disabled by EDSCR.INTdis, and are never masked by the PSTATE.{A, I, F} mask bits, or by the state of AllIntMask. If wakeup is invoked by an interrupt that is disabled or masked, the interrupt is not taken.

I_{VCDGW} Because debug events are WFI wakeup events, Arm recommends that Wait for Interrupt is used as part of an idle loop rather than waiting for a single specific interrupt event to occur and then moving forward. This ensures that the intervention of debug while waiting does not significantly change the function of the program being debugged.

I_{FXRXC} If the PE is in WFx state when a PMU Capture event occurs, it must wake-up to service the request. Arm recommends the Capture event is not treated as an IMPLEMENTATION DEFINED WFx wake-up event and the PE returns to standby after. See PMU snapshots.

I_{ZQWXZ} The architecture does not require the WFI mechanism to drain down any pending memory activity before suspending execution, and software must not rely on the WFI mechanism operating in this way.

D1.6.3 Pending PMU Exception

I_{WNMSV} A pending PMU exception is not required to be a WFE wakeup event or WFI wakeup event.

Arm recommends that an unmasked asynchronous PMU exception that is pending when a `WFE` or `WFI` instruction is executed is treated as an IMPLEMENTATION DEFINED wakeup event, to allow timely processing of the PMU event. For example, when other telemetry data needs to be collected by software from the system.

However, if a PMU overflow occurs as the PE enters a low-power WFx state, then the PE might not register the pending PMU exception before entering the WFx state.

A similar condition applies when using PMU interrupts, because the PE has to assert the interrupt request to the interrupt controller before entering the WFx state for it to be a wakeup event. This is due to IMPLEMENTATION SPECIFIC timings that determine whether a PMU overflow causes a WFx wakeup or prevents the PE from entering the WFx state.

I_{VPTQY} In I_{WNMSV}, pending means that, if the PMU exception were unmasked, a PMU exception would be taken by a simple sequential execution of the program before the execution of the next instruction.

D1.6.4 Using WFI to indicate an idle state on bus interfaces

R_{TZPSV} When all of the following are true, the IMPLEMENTATION DEFINED mechanism for entering powerdown state can be completed:

- The IMPLEMENTATION DEFINED mechanism forces quiescence on a PE.
- The IMPLEMENTATION DEFINED mechanism prevents any possible WFI wakeup events.

R_{VWDWJ} The mechanism for entering powerdown state is IMPLEMENTATION DEFINED.

I_{FFGGG} Although the mechanism for entering powerdown state is IMPLEMENTATION DEFINED, the WFI and WFE mechanisms are often used to enter powerdown state.

R_{RMBKR} If a WFI powerdown mechanism is implemented, when a WFI instruction is executed, the PE completes all current operations and any associated bus activity also completes. When all current PE operations and associated bus activity are complete, the PE can signal to an external power controller that there is no ongoing bus activity.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

R_{CLTZY} After a WFI instruction is executed and all currently executing instructions and related bus activity has completed, the PE is waiting for an interrupt and is in *idle state*. If in idle state, the PE can process memory-mapped or external debug interface accesses to debug registers.

I_{CYBLG} The indication of idle state to the system normally only applies to the non-debug functional interfaces used by the PE, not the debug interfaces.

R_{DHHKY} If OSDLR_EL1.DLK is 1, the PE does not signal the idle state to the control logic unless it can also guarantee that the debug interface is idle. For more information about the OS Double Lock, see Debug behavior when the OS Double Lock is locked.

I_{WRZGC} In a PE that implements separate Core and Debug power domains, the debug interface referred to in this section is the interface between the Core and Debug power domains, since the signal to the power controller indicates that the Core power domain is idle. For more information about the power domains, see Power domains and debug.

I_{RFLDH} The exact nature of the debug interface is IMPLEMENTATION DEFINED, but the use of Wait for Interrupt as the only architecturally-defined mechanism that completely suspends execution makes it suitable as the preferred powerdown entry mechanism.

D1.7 Self-hosted debug

I_{MJGPY} The architecture supports both of the following:

Self-hosted debug

The PE itself hosts a debugger. The debugger programs the PE to generate debug exceptions. Debug exceptions are accommodated in the Arm Exception model.

External debug

The PE is controlled by an external debugger. The debugger programs the PE to generate debug events, that cause the PE to enter Debug state. In Debug state, the PE is halted.

D1.7.1 Debug exceptions

I_{PWPHY} If a debugger has programmed the PE to generate Debug exceptions, the Debug exceptions occur during normal program flow.

I_{DSWBH} For example, a software developer might use a debugger contained in an operating system to debug an application. To do this, the debugger might enable one or more debug exceptions.

I_{BXVCF} The debug exceptions are all of the following:

- Breakpoint Instruction exceptions.
- Breakpoint exceptions.
- Watchpoint exceptions.
- Vector Catch exceptions.
- Software Step exceptions.

I_{VYKHK} The PE can only generate a particular debug exception if all of the following are true:

- Debug exceptions are enabled from the current Exception level and Security state. See Enabling debug exceptions from the current Exception level and Security state. Breakpoint Instruction exceptions are always enabled from the current Exception level and Security state.
- A debugger has enabled that particular debug exception. All of the debug exceptions except for Breakpoint Instruction exceptions have an enable control contained in the MDSCR_EL1. See The debug exception enable controls.

I_{GRWSG} Breakpoints and watchpoints can cause entry to Debug state instead of causing debug exceptions. See About External Debug.

D1.7.2 The PSTATE debug mask bit, D

R_{DYRLS} The debug exception mask bit, PSTATE.D, can mask Watchpoint, Breakpoint, and Software Step exceptions if the target Exception level is the current Exception level.

R_{RDYDM} If in AArch64 state and the target Exception level of a debug exception is lower than the current Exception level, the debug exception is masked.

R_{JWZFQ} If the target Exception level is higher than the current Exception level, debug exceptions are not masked by PSTATE.D.

R_{KCHGM} If PSTATE.D is 1 and the PE is already handling an exception in AArch64 state, the Watchpoint, Breakpoint, and Software Step exceptions are masked.

I_{LVYYH} If an exception is already being handled, masking prevents software from generating another instance of an exception and prevents recursive entry into the exception handler and loss of return state.

R_{NCHXS} Masking debug interrupts with PSTATE.D prevents the generation of new debug exceptions, therefore, any masked debug exceptions are not taken if PSTATE.D is later set to 0.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I_{VSTYD} The behavior described in R_{NCHXS} differs from the behavior for interrupts, where the PSTATE.{A, I, F} mask prevents the interrupt from being taken, but instead the interrupt remains pending.

I_{KWFMZ} When an exception is taken, PSTATE.D is set to 1.

D1.8 Event monitors

I_{YVDTB} The architecture supports the following non-invasive architectural components that allow for event monitoring:

Performance Monitors

The Performance Monitors have a wide feature set, flexible selection of counted events, and are read/write in operation.

D1.8.1 The Performance Monitors Extension

I_{ZSPVV} The System registers provide access to a Performance Monitoring Unit (PMU), defined as the OPTIONAL Performance Monitors Extension to the architecture, a non-invasive debug resource that provides information about the operation of the PE.

The PMU provides:

- A 64-bit cycle counter.
- An IMPLEMENTATION DEFINED number of event counters. The events that can be counted are:
  - Architectural and microarchitectural events that are likely to be consistent across many microarchitectures. The PMU architecture uses event numbers to identify an event, and the PMU specification defines which event number must be used for each of these architectural and microarchitectural events.
  - IMPLEMENTATION SPECIFIC events. The PMU specification reserves event numbers for IMPLEMENTATION SPECIFIC events.

For more information, see The Performance Monitors Extension.

Chapter D2
AArch64 Self-hosted Debug

When the PE is using self-hosted debug, it generates *debug exceptions*. This chapter describes the AArch64 self-hosted debug Exception model. It is organized as follows:

Introductory information

- About self-hosted debug.
- The debug exception enable controls.

The debug Exception model

- Routing debug exceptions.
- Enabling debug exceptions from the current Exception level and Security state.
- The effect of powerdown on debug exceptions.
- Summary of the routing and enabling of debug exceptions.
- Pseudocode description of debug exceptions.

The debug exceptions

- Breakpoint Instruction exceptions.
- Breakpoint exceptions.
- Watchpoint exceptions.
- Software Step exceptions.

Synchronization requirements

The behavior of self-hosted debug after changes to System registers, or after changes to the authentication interface, but before a Context Synchronization event guarantees the effects of the changes:

- Synchronization and debug exceptions.

Non-Confidential

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D2.1 About self-hosted debug

Self-hosted debug supports debugging through the generation and handling of *debug exceptions*, which are taken using the Exception model described in The AArch64 System Level Programmers' Model. This section introduces some terms that are used in describing self-hosted debug, and then introduces the debug exceptions. See:

- Definition of a debugger in the context of self-hosted debug.
- Context ID and Process ID.
- About debug exceptions.

D2.1.1 Definition of a debugger in the context of self-hosted debug

Within this chapter, *debugger* means that part of an operating system, or higher level of system software, that handles debug exceptions and programs the Debug system registers. An operating system with rich application environments might provide debug services that support a debugger user interface executing at EL0. From the architectural perspective, the debug services are the debugger.

D2.1.2 Context ID and Process ID

A CONTEXTIDR_ELx identifies the current *Context ID*, which is used by:

- The debug logic, for breakpoint and watchpoint matching.
- Implemented trace logic, to identify the current process.

In AArch64 state, the CONTEXTIDR_ELx has a single field, PROCID, that is defined as the *Process Identifier* (Process ID). Therefore, in AArch64 state, the Context ID and Process ID are identical.

D2.1.3 About debug exceptions

Debug exceptions occur during normal program flow if a debugger has programmed the PE to generate them. For example, a software developer might use a debugger contained in an operating system to debug an application. To do this, the debugger enables one or more debug exceptions. The debug exceptions that can be generated in stage 1 of an AArch64 translation regime are:

- Breakpoint Instruction exceptions.
- Breakpoint exceptions, generated by hardware breakpoints.
- Watchpoint exceptions, generated by hardware watchpoints.
- Software Step exceptions.

Other than Breakpoint Instruction exceptions, the PE can generate a particular debug exception only if all of the following are true:

- The OS Lock is unlocked.
- `DoubleLockStatus()` == FALSE.
- Debug exceptions are not disabled from the current Exception level and Security state.
  See Enabling debug exceptions from the current Exception level and Security state.
- A debugger has not disabled that particular debug exception.
  All of the debug exceptions except for Breakpoint Instruction exceptions have an enable control contained in the MDSCR_EL1. See The debug exception enable controls.

Breakpoint Instruction exceptions are always enabled.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

If *halting is allowed* and EDSCR.HDE is 1, hardware breakpoints and watchpoints cause entry to Debug state instead of causing debug exceptions. In Debug state, the PE is halted.
For the definition of halting is allowed, see Halting allowed and halting prohibited.

The following list summarizes each of the debug exceptions:

Breakpoint Instruction exceptions

Breakpoint instructions generate these. Breakpoint instructions are instructions that software developers can use to cause exceptions at particular points in the program flow.

The breakpoint instruction is `BRK #<immediate>`. Whenever one of these is committed for execution, the PE takes a Breakpoint Instruction exception.

Breakpoint Instruction exceptions cannot be masked. The PE takes Breakpoint Instruction exceptions regardless of both of the following:

- The current Exception level.
- The current Security state.

For more information, see Breakpoint Instruction exceptions.

Breakpoint exceptions

The architecture provides 2-16 hardware breakpoints. These can be programmed to generate Breakpoint exceptions based on one or more of particular instruction addresses, accesses to any address in an instruction address range, or particular PE contexts.

For example, a software developer might program a hardware breakpoint to generate a Breakpoint exception whenever the instruction with address `0x1000` is committed for execution.

The architecture supports the following types of hardware breakpoint for use in stage 1 of an AArch64 translation regime:

- Address.
  - Comparisons are made with the virtual address of each instruction in the program flow.
- Context:
  - Context ID Match. Matches with the Context ID held in the CONTEXTIDR_EL1, and if FEAT_VHE is implemented, CONTEXTIDR_EL2.

An Address breakpoint can link to a Context-matching breakpoint, so that the Address breakpoint generates a Breakpoint exception only if the PE is in a particular context when the address match occurs.

A breakpoint generates a Breakpoint exception whenever an instruction that causes a match is committed for execution.

If halting is allowed and EDSCR.HDE is 1, hardware breakpoints cause entry to Debug state. That is, they halt the PE. See Debug State.

Otherwise:

- If debug exceptions are enabled, hardware breakpoints cause Breakpoint exceptions.
- If debug exceptions are disabled, hardware breakpoints are ignored.

For more information, see Breakpoint exceptions.

Watchpoint exceptions

The architecture provides 2-16 hardware watchpoints. These can be programmed to generate Watchpoint exceptions based on accesses to particular data addresses, or based on accesses to any address in a data address range.

For example, a software developer might program a hardware watchpoint to generate a Watchpoint exception on an access to any address in the data address range `0x1000` - `0x101F`.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

A hardware watchpoint can link to a hardware breakpoint if the hardware breakpoint is a Context matching breakpoint with linking enabled. In this case, the watchpoint generates a Watchpoint exception only if the PE is in a particular context when the data address match occurs.

The smallest data address size that a watchpoint can be programmed to match on is a byte. A single watchpoint can be programmed to match on one or more bytes.

A watchpoint generates a Watchpoint exception whenever an instruction that initiates an access that causes a match is committed for execution.

If halting is allowed and EDSCR.HDE is 1, hardware watchpoints cause entry to Debug state. That is, they halt the PE. See Debug State.

Otherwise:

- If debug exceptions are enabled, hardware watchpoints cause Watchpoint exceptions.
- If debug exceptions are disabled, hardware watchpoints are ignored.

For more information, see Watchpoint exceptions.

Software Step exceptions

Software step is a resource that a debugger can use to make the PE single-step instructions.

For example, by using software step, debugger software executing at a higher Exception level can debug software executing at a lower Exception level, by making it single-step instructions.

After the software being debugged has single-stepped an instruction, the PE takes a Software Step exception.

If debug exceptions are enabled, Software Step exceptions can be generated.

If debug exceptions are disabled, software step is inactive.

For more information, see Software Step exceptions.

Table D2-1 summarizes PE behavior and shows the location of the pseudocode for each of the debug exceptions.

Table D2-1 PE behavior and pseudocode for each of the debug exceptions

Debug exception	PE behavior if debug exceptions are:		Pseudocode
	Enabled	Disabled	
Breakpoint Instruction exceptions	Takes the exception	Takes the exception	Pseudocode description of Breakpoint Instruction exceptions
Breakpoint exceptions	Takes the exception[a]	Ignored	Pseudocode description of Breakpoint exceptions taken from an AArch64 stage 1 translation regime
Watchpoint exceptions	Takes the exception[a]	Ignored	Pseudocode description of Watchpoint exceptions taken from AArch64 state
Software Step exceptions	Takes the exception	Not applicable[b]	Pseudocode description of Software Step exceptions

a. If halting is allowed and EDSCR.HDE is 1, hardware breakpoints and watchpoints cause the PE to enter Debug state instead of causing debug exceptions. See Debug State.

b. Software Step is inactive if debug exceptions are disabled. No Software Step exceptions can be generated.

D2.2 Routing debug exceptions

Debug exceptions are routed to the *debug target Exception level*, EL_D, according to the following controls:

- HCR_EL2.TGE.
- MDCR_EL2.TDE.
- The Security state when the exception is taken.
- The Exception level where the exception is taken.

This means that, for all debug exceptions, EL_D is either EL1 or EL2.

Note

If EL2 is not implemented, the Effective value of HCR_EL2.TGE is 0 and the Effective value of MDCR_EL2.TDE is 0. Throughout this section, references to the values of these fields are to the Effective values of the fields.

The routing of debug exceptions is as follows:

Debug exceptions taken when EL2 is implemented and enabled in the current Security state

The routing of debug exceptions taken depends on the values of MDCR_EL2.TDE and HCR_EL2.TGE:

If the Effective value of {MDCR_EL2.TDE, HCR_EL2.TGE} is not {0, 0}

Debug exceptions are routed to EL2, EL_D is EL2.

Otherwise

Debug exceptions behave as follows:

- Debug exceptions taken from EL1 and EL0 are routed to EL1. EL_D is EL1.
- Breakpoint Instruction exceptions taken from EL2 are routed to EL2.
- All other debug exceptions are disabled from EL2 using AArch64.

TDE or TGE Means the logical OR of the Effective value of MDCR_EL2.TDE and the Effective value of HCR_EL2.TGE.

Table D2-2 Routing of exceptions

TDE or TGE	EL_D when executing in:		
	EL0	EL1	EL2
0	EL1	EL1	(EL1)
1	EL2	EL2	EL2

D2.2.1 Pseudocode description of routing debug exceptions

`DebugTarget()` returns the current debug target Exception level.

`DebugTargetFrom()` returns the debug target Exception level for the specified Security state.

These functions are described in R-profile Architecture Pseudocode.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D2.3 The debug exception enable controls

The enable controls for each debug exception are as follows:

Breakpoint Instruction exceptions

None. Breakpoint Instruction exceptions are always enabled.

Breakpoint exceptions

MDSCR_EL1.MDE, plus an enable control for each breakpoint, DBGBCR<n>_EL1.E.

Watchpoint exceptions

MDSCR_EL1.MDE, plus an enable control for each watchpoint, DBGWCR<n>_EL1.E.

Vector Catch exceptions

MDSCR_EL1.MDE.Vector catch exceptions cannot be generated in AArch 64 state.

Software Step exceptions

MDSCR_EL1.SS.

In addition, for all debug exceptions other than Breakpoint Instruction exceptions, software must configure the controls that enable debug exceptions from the current Exception level and Security state. See Enabling debug exceptions from the current Exception level and Security state.

The PE cannot take a debug exception if debug exceptions are disabled from either the current Exception level or the current Security state.

Breakpoint Instruction exceptions are always enabled from the current Exception level and Security state.

D2.3.1 Enabling debug exceptions from the current Exception level and Security state

Debug exceptions are enabled from the current Exception level, where EL_D is the Exception level defined in Routing debug exceptions, as follows:

- When executing at any Exception level that is higher than EL_D:
  - Breakpoint Instruction exceptions are enabled.
  - All other debug exceptions are disabled.
- When executing at EL_D:
  - Breakpoint Instruction exceptions are enabled.
  - All other debug exceptions are disabled if either of the following is true:
    - The Local (kernel) Debug Enable bit, MDSCR_EL1.KDE, is 0.
    - The Debug exception mask bit, PSTATE.D, is 1.

  This means that a debugger must explicitly enable these debug exceptions from EL_D by setting MDSCR_EL1.KDE to 1 and PSTATE.D to 0.
- When executing at EL1, EL_D is EL2, and FEAT_NV2 is implemented:
  - Watchpoint debug exceptions generated by a System register access converted to a memory access because the Effective value of HCR_EL2.NV2 is 1 are disabled if MDSCR_EL1.KDE is 0 and enabled if MDSCR_EL1.KDE is 1. The value of PSTATE.D is ignored.
  - All other debug exceptions are enabled.
- Otherwise all debug exceptions are enabled.

D2.3.2 Pseudocode description of enabling debug exceptions

`AArch64.GenerateDebugExceptions()` determines whether debug exceptions other than Breakpoint Instruction exceptions are enabled from the current Exception level and Security state.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

`AArch64.GenerateDebugExceptionsFrom()` determines whether debug exceptions other than Breakpoint Instruction exceptions are enabled from the specified Exception level and Security state.

These functions are described in R-profile Architecture Pseudocode.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D2.4 The effect of powerdown on debug exceptions

Debug OS Save and Restore sequences describes the *powerdown save routine* and the *restore routine*.

When executing either routine, software must use the OS Lock to disable generation of all of the following:

- Breakpoint exceptions.
- Watchpoint exceptions.
- Software Step exceptions.

This is because the generation of these exceptions depends on the state of the debug registers, and the state of the debug registers might be lost over these routines.

If the OS Lock is unlocked, and `DoubleLockStatus()` == FALSE, debug exceptions other than Breakpoint Instruction exceptions are enabled.

If OS Lock is locked, or if `DoubleLockStatus()` ==TRUE, debug exceptions other than Breakpoint Instruction exceptions are disabled.

Breakpoint Instruction exceptions are enabled regardless of the state of the OS Lock and the OS Double Lock.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D2.5 Summary of the routing and enabling of debug exceptions

Behavior is as follows:

Breakpoint Instruction exceptions

These are always enabled, regardless of the current Exception level and Security state. A Breakpoint Instruction exception taken from EL2 is routed to EL2. A Breakpoint Instruction exception taken from EL0 or EL1 is always routed to EL_D.

All other debug exceptions

Table D2-3 shows the valid combinations of MDCR_EL2.TDE, MDSCR_EL1.KDE, and PSTATE.D, and for each combination shows where these exceptions are enabled from and where they are taken to.

In the table:

Lock Means the value of (OSLSR_EL1.OSLK == '1' || `DoubleLockStatus()`).

TGE Means the value of HCR_EL2.TGE.

TDE Means the value of MDCR_EL2.TDE.

KDE Means the value of MDSCR_EL1.KDE.

D Means the value of PSTATE.D.

n/a Means not applicable. The PE cannot be executing at this Exception level.

- Means that debug exceptions are disabled from that Exception level.

Table D2-3 Routing of Breakpoint, Watchpoint, and Software Step exceptions

Debug state	Lock	TGE	TDE	KDE	D	EL_D when enabled from:		
						EL0	EL1	EL2
Yes	X	X	X	X	X	-	-	-
No	TRUE	X	X	X	X	-	-	-
	FALSE	X	X	X	X	-	-	-
		X	X	0	X	EL1	-	n/a
				1	0	EL1	EL1	n/a
					1	EL1	-	n/a
				1	0	EL1	EL1	-
					1	EL1	-	-

D2.6 Pseudocode description of debug exceptions

The `AArch64.Abort()` function processes `FaultRecord` objects, as described in Abort exceptions, and generates a debug exception.

Some functions called by `AArch64.Abort()` are:

- `AArch64.BreakpointException()`.
- `AArch64.WatchpointException()`.
- `AArch64.InstructionAbort()`.
- `AArch64.DataAbort()`.

These functions are defined in R-profile Architecture Pseudocode.

D2.7 Breakpoint Instruction exceptions

This section describes Breakpoint Instruction exceptions.

A Breakpoint Instruction exception results from the execution of an A64 `BRK` instruction.

The following subsections describe Breakpoint Instruction exceptions in a translation regime:

- About Breakpoint Instruction exceptions.
- Breakpoint instructions.
- Exception syndrome information and preferred return address.
- Pseudocode description of Breakpoint Instruction exceptions.

D2.7.1 About Breakpoint Instruction exceptions

A *breakpoint* is an event that results from the execution of an instruction, which is based on either:

- The instruction address, the PE context, or both. This type of breakpoint is called a *hardware breakpoint.*
- The instruction itself. That is, the instruction is a *breakpoint instruction*. These can be included in the program that the PE executes. This type of breakpoint is called a *software breakpoint*.

Breakpoint Instruction exceptions, which this section describes, are software breakpoints. Breakpoint exceptions describes hardware breakpoints.

There is no enable control for Breakpoint Instruction exceptions. They are always enabled, and cannot be masked.

A Breakpoint Instruction exception is generated whenever a breakpoint instruction is committed for execution, regardless of the current Exception level.

Note

Debuggers using breakpoint instructions must be aware of the rules for concurrent modification and execution of instructions. See Concurrent modification and execution of instructions.

D2.7.2 Breakpoint instructions

The breakpoint instruction in the A64 instruction set is `BRK #<immediate>`. It is unconditional.

For details of the instruction encoding, see BRK.

D2.7.3 Exception syndrome information and preferred return address

See the following:

- Exception syndrome information.
- Preferred return address.

D2.7.3.1 Exception syndrome information

On taking a Breakpoint Instruction exception, the PE records information about the exception in the *Exception Syndrome Register* (ESR) at the Exception level the exception is taken to in ESR_ELx

shows the information that the PE records.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Table D2-4 Information recorded in the ESR_ELx

ESR_ELx field	Information recorded in ESR_EL1 or ESR_EL2	
Exception Class, EC	The PE sets this to `0x3C` for an A64 `BRK` instruction.	
Instruction Length, IL	The PE sets this to 1 for an A64 `BRK` instruction.	
Instruction Specific Syndrome, ISS	**ISS[24:16]**	RES0.
	ISS[15:0]	The PE copies the instruction Comment field value into here, zero extended as necessary.

Note

- If debug exceptions are routed to EL2, it is the exception that is routed, not the instruction that is trapped. Therefore, if a Breakpoint Instruction exception is routed to EL2, ESR_EL2.EC is set to the same value as if the exception was taken to EL1.
- For information about how debug exceptions can be routed to EL2, see Routing debug exceptions.

D2.7.3.2 Preferred return address

The preferred return address is the address of the breakpoint instruction, not the next instruction. This is different to the behavior of other exception-generating instructions, like `SVC`.

D2.7.4 Pseudocode description of Breakpoint Instruction exceptions

`AArch64.SoftwareBreakpoint()` generates a Breakpoint Instruction exception.

This function is defined in R-profile Architecture Pseudocode.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D2.8 Breakpoint exceptions

This section describes Breakpoint exceptions in stage 1 of an AArch64 translation regime.

This section contains the following subsections:

- About Breakpoint exceptions.
- Breakpoint types and linking of breakpoints.
- Execution conditions for which a breakpoint generates Breakpoint exceptions.
- Breakpoint instruction address comparisons.
- Breakpoint context comparisons.
- Breakpoint usage constraints.
- Preferred return address.
- Pseudocode description of Breakpoint exceptions taken from an AArch64 stage 1 translation regime.

D2.8.1 About Breakpoint exceptions

A *breakpoint* is an event that results from the execution of an instruction, which is based on either:

- The instruction address, the PE context, or both. This type of breakpoint is called a *hardware breakpoint.*
- The instruction itself. That is, the instruction is a *breakpoint instruction*. These can be included in the program that the PE executes. This type of breakpoint is called a *software breakpoint*.

Breakpoint exceptions are generated by *Breakpoint debug events*. Breakpoint debug events are generated by hardware breakpoints. Software breakpoints are described in Breakpoint Instruction exceptions.

An implementation can include between 2-16 hardware breakpoints.

To use an implemented hardware breakpoint, a debugger programs the following registers for the breakpoint:

- The *Breakpoint Control Register*, DBGBCR<n>_EL1. This contains controls for the breakpoint, for example an enable control.
- The *Breakpoint Value Register*, DBGBVR<n>_EL1. This holds the value used for breakpoint matching, which is one of:
  - An instruction virtual address.
  - A Context ID.
  - A VMID value.
  - A concatenation of both a Context ID value and a VMID value.
  - If FEAT_VHE is implemented, a concatenation of two Context ID values.

These registers are numbered, so that:

- DBGBCR0_EL1 and DBGBVR0_EL1 are for breakpoint number zero.
- DBGBCR1_EL1 and DBGBVR1_EL1 are for breakpoint number one.
- . . .
- DBGBCR<n-1>_EL1 and DBGBVR<n-1>_EL1 are for breakpoint number (n-1).

A debugger can link a breakpoint that is programmed with an address and a breakpoint that is programmed with anything other than an address together, so that a Breakpoint debug event is generated only if both breakpoints match.

For each instruction in the program flow, all of the breakpoints are tested. When a breakpoint is tested, it generates a Breakpoint debug event if all of the following are true:

- The breakpoint is enabled. That is, the Effective value of DBGBCR<n>_EL1.E is 1.
- The conditions specified in the DBGBCR<n>_EL1 are met.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- The comparison with the value held in the DBGBVR<n>_EL1 is successful.
- If the breakpoint is linked to another breakpoint, the comparisons made by that other breakpoint are also successful.
- The instruction is committed for execution.

If halting is allowed and EDSCR.HDE is 1, Breakpoint debug events cause entry to Debug state.

Otherwise, if debug exceptions are:

- Enabled, Breakpoint debug events generate Breakpoint exceptions.
- Disabled, Breakpoint debug events are ignored.

Note

The remainder of this Breakpoint exceptions section, including all subsections, describes breakpoints as generating Breakpoint exceptions.
However, the behavior described also applies if breakpoints are causing entry to Debug state.

The debug exception enable controls describes the enable controls for Breakpoint debug events.

D2.8.2 Breakpoint types and linking of breakpoints

Each implemented breakpoint is one of the following:

- A *context-aware* breakpoint. This is a breakpoint that can be programmed to generate a Breakpoint exception on any one of the following:
  - An instruction address match or mismatch.
  - A Context ID match, with the value held in CONTEXTIDR_EL1 or the value held in CONTEXTIDR_EL2.
- A breakpoint that is not *context-aware*. These can only be programmed to generate a Breakpoint exception on an instruction address match.

Up to 16 *context-aware* breakpoints can be implemented, and the number implemented is identified by ID_AA64DFR0_EL1.CTX_CMPs.

The highest numbered breakpoints are *context-aware*.

At least one breakpoint must be *context-aware*.

Any breakpoint that is programmed to generate a Breakpoint exception on an instruction address match is categorized as an *Address breakpoint*. Breakpoints that are programmed to match on anything else are categorized as *Context breakpoints*.

When a debugger programs a breakpoint to be an Address or a Context breakpoint, it must also program that breakpoint so that it is either:

- Used in isolation. In this case, the breakpoint is called an *Unlinked breakpoint*.
- Linked to another Context matching breakpoint. In this case, the breakpoint is called a *Linked breakpoint*.
- Enabled for linking from another breakpoint or watchpoint. In this case, the breakpoint has *Linking enabled* and does not generate debug events in isolation.

By linking an Address breakpoint and a Context breakpoint together, the debugger can create a breakpoint pair that generates a Breakpoint exception only if the PE is in a particular context when an instruction address match occurs. This is shown in Example D2-1.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Example D2-1 Linking an Address breakpoint and a Context breakpoint

For example, a debugger might:

1. Program breakpoint number one to be a *Linked Address Match breakpoint*.
2. Program breakpoint number five to be a *Context matching breakpoint with linking enabled*.
3. Link these two breakpoints together. A Breakpoint exception is generated only if both the instruction address matches and the Context ID matches.

The *Breakpoint Type* field for a breakpoint, DBGBCR<n>_EL1.BT, controls the breakpoint type and whether the breakpoint is enabled for linking.

D2.8.2.1 Rules for linking breakpoints

The rules for breakpoint linking are as follows:

- Only Linked Address breakpoint types can be linked.
- Any type of Linked Address breakpoint can link to any type of Context matching breakpoint with linking enabled.
  The *Linked Breakpoint Number* field, DBGBCR<n>_EL1.LBN, for the Linked Address breakpoint specifies the particular Context matching breakpoint that the Linked Address breakpoint links to, and:
  - The LBN field are ignored if the breakpoint is not a Linked Address breakpoint.
  - DBGBCR<n>_EL1.{SSC, HMC, PMC} for the Linked Address breakpoint define the execution conditions that the breakpoint pair generates Breakpoint exceptions for. See Execution conditions for which a breakpoint generates Breakpoint exceptions.
  - DBGBCR<n>_EL1.{SSC, HMC, PMC} for the Context matching breakpoint with linking enabled are ignored.
- Linked Address breakpoints cannot link to watchpoints. The LBN field always specify a breakpoint.
- If a Linked Address breakpoint links to a breakpoint that is not *context-aware* or does not have linking enabled, the behavior of the Linked Address breakpoint is CONSTRAINED UNPREDICTABLE. See Other usage constraints for Address breakpoints.

A single Context matching breakpoint with linking enabled might be linked to by all, or any combination of, the following:

- Multiple Linked Address breakpoints.
- Multiple Linked watchpoints.

If no linked breakpoints and no linked watchpoints link to a breakpoint programmed with linking enabled, then the breakpoint does not generate any Breakpoint exceptions or debug events.

Figure D2-1 shows an example of permitted breakpoint and watchpoint linking.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

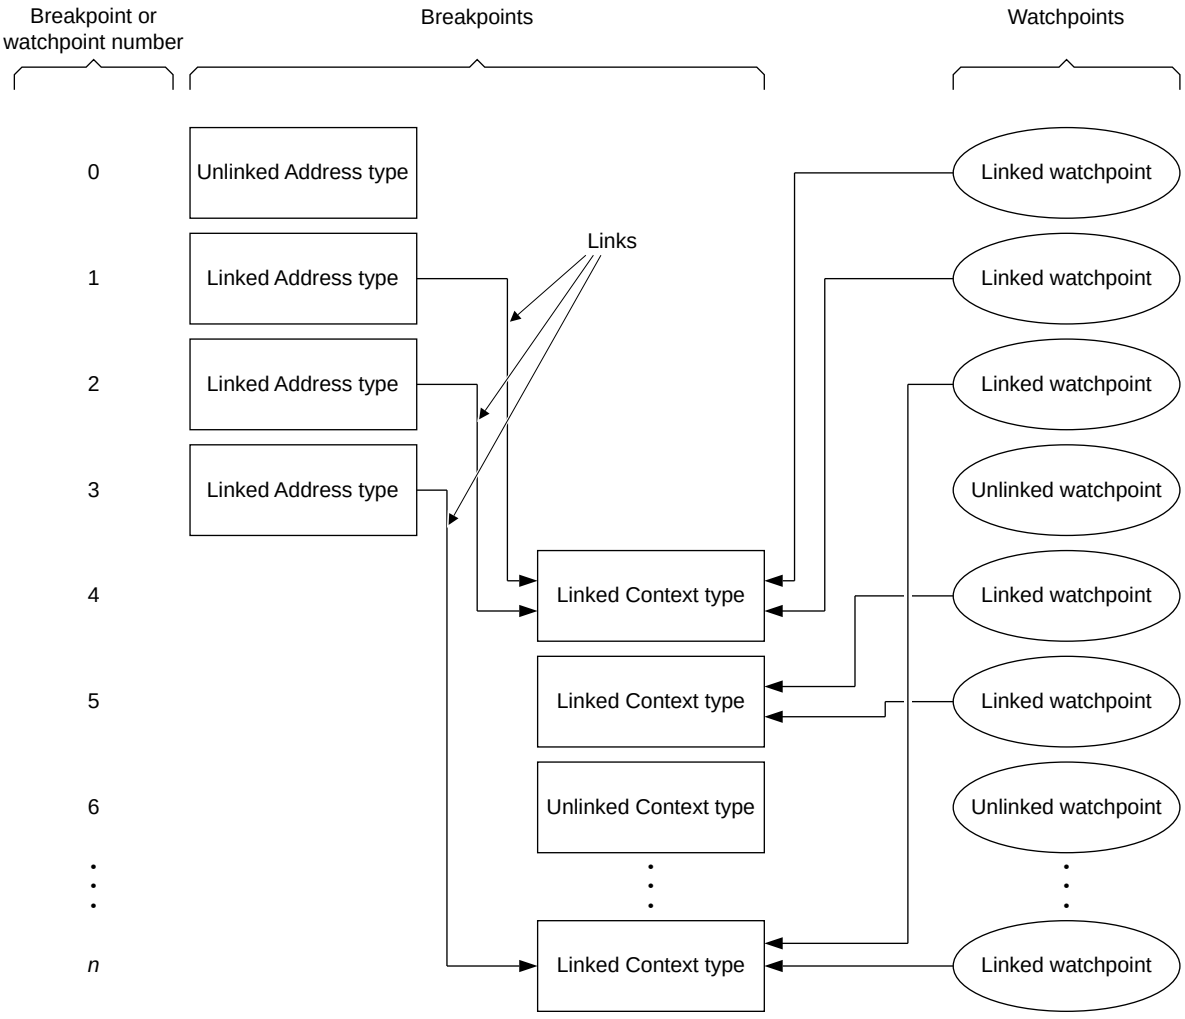

Figure D2-1 The role of linking in Breakpoint and Watchpoint exception generation

In Figure D2-1, each Linked Address breakpoint can generate a Breakpoint exception only if the comparisons made by both it, and the breakpoint that it links to, are successful. Similarly, each Linked watchpoint can only generate a Watchpoint exception if the comparisons made by both it, and the breakpoint that it links to, are successful.

D2.8.2.2 Breakpoint types defined by DBGBCR<n>_EL1.BT

The following lists provides more detail about each breakpoint type:

`0b0000`**, Unlinked Address Match breakpoint**

Generation of a Breakpoint exception depends on both:

- DBGBCR<n>_EL1.{SSC, HMC, PMC}. These define the execution conditions for which the breakpoint generates Breakpoint exceptions. See Execution conditions for which a breakpoint generates Breakpoint exceptions.
- A successful address match, as described in Breakpoint instruction address comparisons.

DBGBCR<n>_EL1.LBN for this breakpoint are ignored.

`0b0001`**, Linked Address Match breakpoint**

Generation of a Breakpoint exception depends on all of the following:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- DBGBCR<n>_EL1.{SSC, HMC, PMC} for this breakpoint. These define the execution conditions that the breakpoint generates Breakpoint exceptions for. See Execution conditions for which a breakpoint generates Breakpoint exceptions.
- A successful address match defined by this breakpoint, as described in Breakpoint instruction address comparisons.
- A successful context match defined by the Context breakpoint with linking enabled that this breakpoint links to.

DBGBCR<n>_EL1.LBN for this breakpoint selects the Context breakpoint with linking enabled that this breakpoint links to.

`0b0010`**, Context ID Match breakpoint**

BT == `0b0010` is a reserved value if the breakpoint is not a context-aware breakpoint.

For context-aware breakpoints, generation of a Breakpoint exception depends on both:

- DBGBCR<n>_EL1.{SSC, HMC, PMC}. These define the execution conditions for which the breakpoint generates Breakpoint exceptions. See Execution conditions for which a breakpoint generates Breakpoint exceptions.
- A successful Context ID match, as described in Breakpoint context comparisons.

The value of DBGBVR<n>_EL1.ContextID is compared with the current Context ID.

CONTEXTIDR_EL2 holds the current Context ID when all of:

- The implementation includes FEAT_VHE.
- The PE is executing at EL0 and HCR_EL2.TGE is 1, or the PE is executing at EL2.

Otherwise, CONTEXTIDR_EL1 holds the current Context ID.

DBGBCR<n>_EL1.{LBN, BAS} for this breakpoint are ignored

`0b0011`**, Context ID Match breakpoint with linking enabled**

BT == `0b0011` is a reserved value if the breakpoint is not a context-aware breakpoint.

For context-aware breakpoints, one of the following applies:

- If no Linked breakpoints or Linked watchpoints link to this breakpoint, then the breakpoint does not generate any debug exceptions.
- Generation of a Breakpoint exception depends on both:
  - A successful instruction address match, defined by a Linked Address breakpoint that links to this breakpoint, see Breakpoint instruction address comparisons.
  - A successful Context ID match defined by this breakpoint, as described in Breakpoint context comparisons.
- Generation of a Watchpoint exception depends on both:
  - A successful data address match, defined by a Linked watchpoint that links to this breakpoint, see Watchpoint data address comparisons.
  - A successful Context ID match defined by this breakpoint, as described in Breakpoint context comparisons.

The value of DBGBVR<n>_EL1.ContextID is compared with the current Context ID.

CONTEXTIDR_EL2 holds the current Context ID when all of:

- The implementation includes FEAT_VHE.
- The PE is executing at EL0 and HCR_EL2.TGE is 1, or the PE is executing at EL2.

Otherwise, CONTEXTIDR_EL1 holds the current Context ID.

DBGBCR<n>_EL1.{LBN, SSC, HMC, BAS, PMC} for this breakpoint are ignored.

`0b0110`**, CONTEXTIDR_EL1 Match breakpoint**

BT == `0b0110` is a reserved value if either:

- The breakpoint is not a context-aware breakpoint.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- The implementation does not include FEAT_VHE.

In an implementation that includes FEAT_VHE, for context-aware breakpoints, generation of a Breakpoint exception depends on both:

- DBGBCR<n>_EL1.{SSC, HMC, PMC}. These define the execution conditions for which the breakpoint generates Breakpoint exceptions.
- A successful Context ID match defined by this breakpoint, as described in Breakpoint context comparisons.

The Context ID check is made against the value in CONTEXTIDR_EL1. The value of DBGBVR<n>_EL1.ContextID is compared with the Context ID value held in CONTEXTIDR_EL1.

DBGBCR<n>_EL1.{LBN, BAS} for this breakpoint are ignored.

`0b0111`**, CONTEXTIDR_EL1 Match breakpoint with linking enabled**

BT == `0b0111` is a reserved value if either:

- The breakpoint is not a context-aware breakpoint.
- The implementation does not include FEAT_VHE.

In an implementation that includes FEAT_VHE, for context-aware breakpoints, one of the following applies:

- If no Linked breakpoints or Linked watchpoints link to this breakpoint, then the breakpoint does not generate any debug exceptions.
- Generation of a Breakpoint exception depends on both:
  - A successful instruction address match, defined by a Linked Address match breakpoint that links to this breakpoint, see Breakpoint instruction address comparisons.
  - A successful Context ID match defined by this breakpoint, as described in Breakpoint context comparisons.
- Generation of a Watchpoint exception depends on both:
  - A successful data address match, defined by a Linked watchpoint that links to this breakpoint, see Watchpoint data address comparisons.
  - A successful Context ID match defined by this breakpoint, as described in Breakpoint context comparisons.

The Context ID check is made against the value in CONTEXTIDR_EL1. The value of DBGBVR<n>_EL1.ContextID is compared with the Context ID value held in CONTEXTIDR_EL1.

DBGBCR<n>_EL1.{LBNX, LBN, SSCE, SSC, HMC, BAS, PMC} for this breakpoint are ignored.

`0b1000`**, VMID Match breakpoint**

BT == `0b1000` is a reserved value if the breakpoint is not a context-aware breakpoint.

For context-aware breakpoints, generation of a Breakpoint exception depends on both:

- DBGBCR<n>_EL1.{SSC, HMC, PMC}. These define the execution conditions for which the breakpoint generates Breakpoint exceptions. See Execution conditions for which a breakpoint generates Breakpoint exceptions.
- A successful VMID match, as described in Breakpoint context comparisons.

DBGBCR<n>_EL1.{LBN, BAS} for this breakpoint are ignored.

`0b1001`**, VMID Match breakpoint with linking enabled**

BT == `0b1001` is a reserved value if the breakpoint is not a context-matching breakpoint.

For context-aware breakpoints, one of the following applies:

- If no Linked breakpoints or Linked watchpoints link to this breakpoint, then the breakpoint does not generate any debug exceptions.
- Generation of a Breakpoint exception depends on both:
  - A successful instruction address match, defined by a Linked Address Match breakpoint that links to this breakpoint. See Breakpoint instruction address comparisons.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

— A successful VMID match defined by this breakpoint, as described in Breakpoint context comparisons.

- Generation of a Watchpoint exception depends on both:
  — A successful data address match, defined by a Linked watchpoint that links to this breakpoint, see Watchpoint data address comparisons.
  — A successful VMID match defined by this breakpoint, as described in Breakpoint context comparisons.

DBGBCR<n>_EL1.{LBN, SSC, HMC, BAS, PMC} for this breakpoint are ignored.

`0b1010`**, Context ID and VMID Match breakpoint**

BT == `0b1010` is a reserved value if the breakpoint is not a context-aware breakpoint.

When EL2 is implemented, for context-aware breakpoints, generation of a Breakpoint exception depends on all of the following:

- DBGBCR<n>_EL1.{SSC, HMC, PMC}. These define the execution conditions that the breakpoint generates a Breakpoint exception for. See Execution conditions for which a breakpoint generates Breakpoint exceptions.
- A successful Context ID match, as described in Breakpoint context comparisons.
- A successful VMID match.

The value of DBGBVR<n>_EL1.ContextID is compared with CONTEXTIDR_EL1.

Breakpoint context comparisons describes the requirements for a successful Context ID match and a successful VMID match.

DBGBCR<n>_EL1.{LBN, BAS} for this breakpoint are ignored.

`0b1011`**, Context ID and VMID Match breakpoint with linking enabled**

BT == `0b1011` is a reserved value if the breakpoint is not a context-aware breakpoint.

When EL2 is implemented, for context-aware breakpoints, one of the following applies:

- If no Linked breakpoints or Linked watchpoints link to this breakpoint, then the breakpoint does not generate any debug exceptions.
- Generation of a Breakpoint exception depends on all of the following:
  — A successful instruction address match, defined by a Linked Address breakpoint that links to this breakpoint, see Breakpoint instruction address comparisons.
  — A successful Context ID match defined by this breakpoint, as described in Breakpoint context comparisons.
  — A successful VMID match defined by this breakpoint.
- Generation of a Watchpoint exception depends on all of the following:
  — A successful data address match, defined by a Linked watchpoint that links to this breakpoint, see Watchpoint data address comparisons.
  — A successful Context ID match defined by this breakpoint, as described in Breakpoint context comparisons.
  — A successful VMID match defined by this breakpoint.

The value of DBGBVR<n>_EL1.ContextID is compared with CONTEXTIDR_EL1.

Breakpoint context comparisons describes the requirements for a successful Context ID match and a successful VMID match by this breakpoint.

DBGBCR<n>_EL1.{LBN, SSC, HMC, BAS, PMC} for this breakpoint are ignored.

`0b1100`**, CONTEXTIDR_EL2 Match breakpoint**

BT == `0b1100` is a reserved value if either:

- The breakpoint is not a context-aware breakpoint.
- FEAT_VHE is not implemented and FEAT_Debugv8p2 is not implemented, which means the implementation does not include CONTEXTIDR_EL2.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

In an implementation in which FEAT_VHE is implemented or FEAT_Debugv8p2 is implemented, for context-aware breakpoints, generation of a Breakpoint exception depends on both:

- DBGBCR<n>_EL1.{SSC, HMC, PMC}. These define the execution conditions for which the breakpoint generates Breakpoint exceptions.
- A successful CONTEXTIDR_EL2 match, as described in Breakpoint context comparisons.

The Context ID check is made against the value in CONTEXTIDR_EL2. The value of DBGBVR<n>_EL1 is compared with the Context ID value held in CONTEXTIDR_EL2.

DBGBCR<n>_EL1.{LBN, BAS} for this breakpoint are ignored.

`0b1101`**, CONTEXTIDR_EL2 Match breakpoint with linking enabled**

BT == `0b1101` is a reserved value if either:

- The breakpoint is not a context-aware breakpoint.
- FEAT_VHE is not implemented and FEAT_Debugv8p2 is not implemented, which means the implementation does not include CONTEXTIDR_EL2.

In an implementation in which FEAT_VHE is implemented or FEAT_Debugv8p2 is implemented, for context-aware breakpoints, either:

- If no Linked breakpoints or Linked watchpoints link to this breakpoint, then the breakpoint does not generate any debug exceptions.
- Generation of a Breakpoint exception depends on both:
  - A successful instruction address match, defined by a Linked Address match breakpoint that links to this breakpoint, see Breakpoint instruction address comparisons.
  - A successful CONTEXTIDR_EL2 match, as described in Breakpoint context comparisons.
- Generation of a Watchpoint exception depends on both:
  - A successful data address match, defined by a Linked watchpoint that links to this breakpoint, see Watchpoint data address comparisons.
  - A successful CONTEXTIDR_EL2 match, as described in Breakpoint context comparisons.

The Context ID check is made against the value in CONTEXTIDR_EL2. The value of DBGBVR<n>_EL1 is compared with the Context ID value held in CONTEXTIDR_EL2.

DBGBCR<n>_EL1.{LBN, SSC, HMC, BAS, PMC} for this breakpoint are ignored.

`0b1110`**, Full Context ID Match breakpoint**

BT == `0b1110` is a reserved value if either:

- The breakpoint is not a context-aware breakpoint.
- FEAT_VHE is not implemented and FEAT_Debugv8p2 is not implemented, which means the implementation does not include CONTEXTIDR_EL2.

In an implementation in which FEAT_VHE is implemented or FEAT_Debugv8p2 is implemented, for context-aware breakpoints, generation of a Breakpoint exception depends on both:

- DBGBCR<n>_EL1.{SSC, HMC, PMC}. These define the execution conditions for which the breakpoint generates Breakpoint exceptions.
- A successful Context ID match, as described in Breakpoint context comparisons.

The Context ID check is made against the values in both CONTEXTIDR_EL1 and CONTEXTIDR_EL2. The value of DBGBVR<n>_EL1[31:0] is compared with the Context ID value held in CONTEXTIDR_EL1, and the value of DBGBVR<n>_EL1[63:32] is compared with the Context ID value held in CONTEXTIDR_EL2. Both comparisons must match for the Context ID check.

DBGBCR<n>_EL1.{LBN, BAS} for this breakpoint are ignored.

`0b1111`**, Full Context ID Match breakpoint with linking enabled**

BT == `0b1111` is a reserved value if either:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- The breakpoint is not a context-aware breakpoint.
- FEAT_VHE is not implemented and FEAT_Debugv8p2 is not implemented, which means the implementation does not include CONTEXTIDR_EL2.

In an implementation in which FEAT_VHE is implemented or FEAT_Debugv8p2 is implemented, for context-aware breakpoints, one of the following applies:

- If no Linked breakpoints or Linked watchpoints link to this breakpoint, then the breakpoint does not generate any debug exceptions.
- Generation of a Breakpoint exception depends on both:
  - A successful instruction address match, defined by a Linked Address match breakpoint that links to this breakpoint, see Breakpoint instruction address comparisons.
  - A successful Context ID match, as described in Breakpoint context comparisons.
- Generation of a Watchpoint exception depends on both:
  - A successful data address match, defined by a Linked watchpoint that links to this breakpoint, see Watchpoint data address comparisons.
  - A successful Context ID match, as described in Breakpoint context comparisons.

The Context ID check is made against the values in both CONTEXTIDR_EL1 and CONTEXTIDR_EL2. The value of DBGBVR<n>_EL1[31:0] is compared with the Context ID value held in CONTEXTIDR_EL1, and the value of DBGBVR<n>_EL1[63:32] is compared with the Context ID value held in CONTEXTIDR_EL2. Both comparisons must match for the Context ID check.

DBGBCR<n>_EL1.{LBN, SSC, HMC, BAS, PMC} for this breakpoint are ignored.

D2.8.3 Execution conditions for which a breakpoint generates Breakpoint exceptions

Each breakpoint can be programmed so that it generates Breakpoint exceptions only for certain execution conditions. For example, a breakpoint might be programmed to generate Breakpoint exceptions only when the PE is executing at EL0 in Secure state.

In the table:

Y or - Means that a breakpoint programmed with the values of HMC, SSCE, SSC, and PMC shown in that row:

Y Can generate Breakpoint exceptions in that Exception level and Security state.

- Cannot generate Breakpoint exceptions in that Exception level and Security state.

Table D2-5 Summary of breakpoint HMC, SSC, and PMC encodings

DBGBCR<n>_EL1			Exception Level		
HMC	SSC	PMC	EL2	EL1	EL0
0	00	01	-	Y	-
0	00	10	-	-	Y
0	00	11	-	Y	Y
0	10	01	-	Y	-
0	10	10	-	-	Y
0	10	11	-	Y	Y
0	11	00	Y	-	-
0	11	01	Y	Y	-

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

DBGBCR<n>_EL1			Exception Level		
HMC	SSC	PMC	EL2	EL1	EL0
0	11	11	Y	Y	Y
1	00	01	Y	Y	-
1	00	11	Y	Y	Y
1	01	00	Y	-	-
1	01	01	Y	Y	-
1	01	11	Y	Y	Y
1	10	01	Y	Y	-
1	10	11	Y	Y	Y
1	11	00	Y	-	-
1	11	01	Y	Y	-
1	11	11	Y	Y	Y
1	01	00	Y	-	-

All combinations of HMC, SSC, and PMC that Table D2-5 does not show are reserved. A combination in Table D2-5 might be reserved if an Exception level or Security state is not implemented. For information about which combinations of HMC, SSCE, SSC and PMC are reserved if an Exception level or Security state are not implemented, See Reserved DBGBCR<n>_EL1.{SSC, HMC, PMC} values.

D2.8.4 Breakpoint instruction address comparisons

In this subsection, the term `AddrTop` represents the most significant bit of a virtual address used by breakpoint data address comparisons. `AddrTop` is:

- 55, if address tagging is used for the address. See Address tagging.
- 63, otherwise.

Note

When stage 1 translation is enabled, in AArch64 state, the virtual address size is determined by the configured input address size for the stage 1 translation. Software can configure a smaller address width for a virtual address, see Input address size configuration. Attempting to translate an address that is larger than the configured input address size generates a Translation fault.
When stage 1 translation is disabled, using an address that is larger than the implemented PA size generates an Address size fault. The implemented PA size is IMPLEMENTATION DEFINED, as described in Implemented physical address size. These faults have a higher priority than breakpoints.

An address comparison is successful if bits [`AddrTop`:2] of the current instruction virtual address are equal to DBGBVR<n>_EL1[`AddrTop`:2].

Note

DBGBVR<n>_EL1 is a 64-bit register. The most significant bits of this register are sign-extension bits. DBGBVR<n>_EL1[1:0] are RES0 and are ignored.

All instructions are word-aligned and DBGBCR<n>_EL1.BAS is RES1.

If the implementation is an AArch64-only implementation, all instructions are word-aligned and DBGBCR<n>_EL1.BAS is RES1.

Figure D2-2 shows a summary of when Address Match breakpoints programmed with particular BAS values generate Breakpoint exceptions. The figure contains four parts:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- A column showing the row number, on the left.
- An instruction set and instruction size table.
- A location of instruction figure.
- A BAS field values table, on the right.

To use the figure, read across the rows. For example, row 7 shows that a breakpoint with DBGBCR<n>_EL1.BAS programmed as either `0b0011` or `0b1111` generates Breakpoint exceptions for A64 instructions. A64 instructions are always at word-aligned addresses.

Note

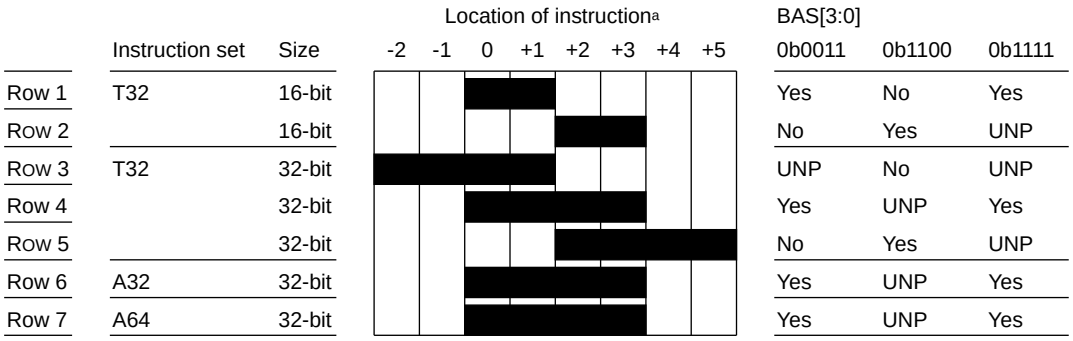
To breakpoint on an A64 instruction, Arm recommends that the debugger programs DBGBCR<n>_EL1.BAS as `0b1111`.

In the figure:

Yes Means that the breakpoint generates a Breakpoint exception.

No Means that the breakpoint does not generate a Breakpoint exception.

UNP Means that is it CONSTRAINED UNPREDICTABLE whether the breakpoint generates a Breakpoint exception. See Other usage constraints for Address breakpoints.



a. 0 means the word-aligned address held in the DBGBVR<n>_EL1[maxAddressSize:2]:00.
The other locations are as follows:
- -2 means ((DBGBVR<n>_EL1[maxAddressSize:2]:00) - 2).
- -1 means ((DBGBVR<n>_EL1[maxAddressSize:2]:00) - 1).
- ...
- ...
- +5 means ((DBGBVR<n>_EL1[maxAddressSize:2]:00) + 5).

The solid areas show the location of the instruction.

Figure D2-2 Summary of BAS field meanings for Address Match breakpoints

D2.8.5 Breakpoint context comparisons

The breakpoint type defined by DBGBCR<n>_EL1.BT determines what context comparison is required, if any. ????? Table D2-6 shows the BT values that require a comparison, and the match required for the comparison to be successful.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Table D2-6 Breakpoint Context ID and VMID comparison tests

DBGBVR<n>_EL1.BT	Test required for successful context comparison
0b001x	• When FEAT_VHE is implemented, EL2 is using AArch64, the Effective value of HCR_EL2.E2H is 1, and either the PE is executing at EL0 with HCR_EL2.TGE set to 1, or the PE is executing at EL2, CONTEXTIDR_EL2 must match the DBGBVR<n>_EL1.ContextID value. • Otherwise, CONTEXTIDR_EL1 must match the DBGBVR<n>_EL1.ContextID value.
0b011x	CONTEXTIDR_EL1 must match the DBGBVR<n>_EL1.ContextID value.
0b100x	VSCTLR_EL2.VMID must match the DBGBVR<n>_EL1.VMID value.
0b101x	CONTEXTIDR_EL1 must match the DBGBVR<n>_EL1.ContextID value and VSCTLR_EL2.VMID must match the DBGBVR<n>_EL1.VMID value.
0b110x	CONTEXTIDR_EL2 must match the DBGBVR<n>_EL1.ContextID2 value, DBGBVR<n>_EL1[63:32].
0b111x	Both: • CONTEXTIDR_EL1 must match the DBGBVR<n>_EL1.ContextID value, DBGBVR<n>_EL1[31:0]. • CONTEXTIDR_EL2 must match the DBGBVR<n>_EL1.ContextID2 value, DBGBVR<n>_EL1[63:32].

No Context ID or VMID comparison is required for other valid DBGBCR<n>_EL1, Debug Breakpoint Control Registers, n = 0 - 63.BT values.

Context breakpoints do not generate Breakpoint exceptions when any of:

- The comparison uses the value of CONTEXTIDR_EL1 when the PE is executing at EL1 or EL0.
- The comparison uses the value of CONTEXTIDR_EL2 when the PE is executing at EL2.
- The comparison uses the current VMID value and the PE is executing at EL2.

Note

- For Context matching breakpoints with linking enabled, DBGBCR<n>_EL1.{LBN, SSC, HMC, PMC} are RES0 and are ignored.

D2.8.6 Breakpoint usage constraints

See the following sections:

- Reserved DBGBCR<n>_EL1.BT values.
- Reserved DBGBCR<n>_EL1.{SSC, HMC, PMC} values.
- Usage constraints on DBGBCR<n>_EL1.LBN values.
- Other usage constraints for Address breakpoints.
- Other usage constraints for Context breakpoints.

D2.8.6.1 Reserved DBGBCR<n>_EL1.BT values

Table D2-7 shows when particular DBGBCR<n>_EL1.BT values are reserved.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Table D2-7 Reserved BT values

BT value	Breakpoint type	Reserved
0b001x	Context ID Match	If the breakpoint is not *context-aware*.
0b011x	CONTEXTIDR_EL1 Match	If the breakpoint is not *context-aware*.
0b110x	CONTEXTIDR_EL2 Match	If the breakpoint is not *context-aware*.
0b111x	Full Context ID Match	

If a breakpoint is programmed with one of these reserved BT values:

- The breakpoint must behave as if it is either:
  - Disabled.
  - Programmed with a BT value that is not reserved, other than for a direct or external read of DBGBCR<n>_EL1.
- For a direct or external read of DBGBCR<n>_EL1, if the reserved {BT2, BT} value:
  - Has no function for any execution conditions, the value read back is UNKNOWN.
  - Has a function for execution conditions other than the current execution conditions, the value read back is the value written. This permits software to save and restore the {BT2, BT} value so that the breakpoint functions for the other execution conditions.

The behavior of breakpoints with reserved {BT2, BT} values might change in future revisions of the architecture. For this reason, software must not rely on the behavior described here.

D2.8.6.2 Reserved DBGBCR<n>_EL1.{SSC, HMC, PMC} values

Table D2-8 shows when particular combinations of DBGBCR<n>_EL1.{SSCE, SSC, HMC, PMC} are reserved in stage 1 of an AArch64 translation regime.

Table D2-8 Reserved HMC, SSCE, SSC, and PMC combinations

HMC, SSC, and PMC combination	Reserved
All combinations with and SSC set to 0b01 or 0b10, except for the combination with HMC set to 1, SSC set to 0b01, and PMC set to 0b00.	
Combinations not included in Table D2-5.	Always.

For all breakpoints except Context matching breakpoints with linking enabled, if a breakpoint is programmed with one of these reserved combinations:

- If the reserved combination has a function for other execution conditions:
  - The breakpoint must behave as if it is disabled.
  - A direct or external read of DBGBCR<n>_EL1.{SSC, HMC, PMC} returns the values written. This means that software can save and restore the combination so that the breakpoint can function for the other execution conditions.
- If the reserved combination does not have a function for other execution conditions:
  - It must behave either as if it is programmed with a combination that is not reserved or as if it is disabled.
  - A direct or external read of DBGBCR<n>_EL1.{SSC, HMC, PMC} returns UNKNOWN values.

If the breakpoint is a Context matching breakpoint with linking enabled, then:

- The values of HMC, SSC, and PMC are ignored.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- A direct or external read of DBGBCR<n>_EL1.{SSC, HMC, PMC} returns UNKNOWN values

The behavior of breakpoints with reserved combinations of HMC, SSC, and PMC might change in future revisions of the architecture. For this reason, software must not rely on the behavior described here.

D2.8.6.3 Usage constraints on DBGBCR<n>_EL1.LBN values

For Linked Address breakpoints

A Linked Address breakpoint must link to a *context-aware* breakpoint. For a Linked Address breakpoint, any DBGBCR<n>_EL1.LBN value that is not for a *context-aware* breakpoint is reserved.

If a Linked Address breakpoint links to a breakpoint that is not implemented, or that is not *context-aware*, then reads of DBGBCR<n>_EL1.LBN return an UNKNOWN value and behavior is CONSTRAINED UNPREDICTABLE. The Linked Address breakpoint behaves as if it is either:

- Disabled.
- Linked to an UNKNOWN *context-aware* breakpoint.

If a Linked Address breakpoint links to a breakpoint that is implemented and that is *context-aware*, but that is either not enabled or not programmed as a Context matching breakpoint with linking enabled, it behaves as if it is disabled.

For all other breakpoint types

DBGBCR<n>_EL1.LBN reads UNKNOWN and its value is ignored.

D2.8.6.4 Other usage constraints for Address breakpoints

For all Address breakpoints

- DBGBVR<n>_EL1[1:0] are RES0 and are ignored.

D2.8.6.5 Other usage constraints for Context breakpoints

For all Context breakpoints

Any bits of DBGBVR<n>_EL1 that are not used to specify Context ID or VMID are RES0 and are ignored.

For breakpoints with linking enabled

If no Linked Address breakpoints or Linked watchpoints link to a breakpoint with linking enabled, the breakpoint with linking enabled does not generate any Breakpoint exceptions.

D2.8.7 Preferred return address

The preferred return address of a Breakpoint exception is the address of the instruction that was not executed because the PE took the Breakpoint exception instead.

This means that the preferred return address is the address of the instruction that caused the exception.

D2.8.8 Pseudocode description of Breakpoint exceptions taken from an AArch64 stage 1 translation regime

`AArch64.BreakpointValueMatch()` tests the value in DBGBVR<n>_EL1.

`AArch64.StateMatch`() tests the values in DBGBCR<n>_EL1.{ SSC, HMC, PMC} and, if the breakpoint links to a breakpoint with linking enabled, also tests the Context matching breakpoint.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

`AArch64.BreakpointMatch()` tests a committed instruction against all breakpoints.

`AArch64.CheckBreakpoint()` generates a Breakpoint exception if all of the following are true:

- MDSCR_EL1.MDE is 1.
- Debug exceptions are enabled from the current Exception level and Security state. See Enabling debug exceptions from the current Exception level and Security state.
- All of the conditions required for Breakpoint exception generation are met. See About Breakpoint exceptions.

Note

`AArch64.CheckBreakpoint()` might halt the PE and cause it to enter Debug state. External debug uses Debug state.

`AArch64.BreakpointException()` is called to generate a Breakpoint exception.

These functions are defined in R-profile Architecture Pseudocode.

D2.9 Watchpoint exceptions

This section describes Watchpoint exceptions in stage 1 of an AArch64 translation regime.

This section contains the following subsections:

- About Watchpoint exceptions.
- Watchpoint types and linking of watchpoints.
- Execution conditions for which a watchpoint generates Watchpoint exceptions.
- Watchpoint data address comparisons.
- Watchpoint behavior for certain instruction classes.
- Watchpoint usage constraints.
- Exception syndrome information, fault address information, and preferred return address.
- Pseudocode description of Watchpoint exceptions taken from AArch64 state.

D2.9.1 About Watchpoint exceptions

A *watchpoint* is an event that results from the execution of an instruction, based on a data address. Watchpoints are also known as *data breakpoints*.

A watchpoint operates as follows:

1. A debugger programs the watchpoint with a data address, or a data address range.
2. The watchpoint generates a *Watchpoint debug event* on an access to the address, or any address in the address range.

A watchpoint never generates a Watchpoint debug event on an instruction fetch.

An implementation can include between 2-16 watchpoints. In an implementation, ID_AA64DFR0_EL1.WRPs and EDDFR1.WRPs show how many are implemented.

To use an implemented watchpoint, a debugger programs the following registers for the watchpoint:

- The *Watchpoint Control Register*, DBGWCR<n>_EL1. This contains controls for the watchpoint, for example an enable control.
- The *Watchpoint Value Register*, DBGWVR<n>_EL1. This holds the data virtual address used for watchpoint matching.

These registers are numbered, so that:

- DBGWCR0_EL1 and DBGWVR0_EL1 are for watchpoint number zero.
- DBGWCR1_EL1 and DBGWVR1_EL1 are for watchpoint number one.
- . . .
- DBGWCR<n-1>_EL1 and DBGWVR<n-1>_EL1 are for watchpoint number (n-1).

A watchpoint can:

- Be programmed to generate Watchpoint debug events on read accesses only, on write accesses only, or on both types of access.
- Link to a *Context matching breakpoint with linking enabled*, so that a Watchpoint debug event is generated only if the PE is in a particular context when the address match occurs.
- Be programmed as an address match watchpoint or an address mismatch watchpoint. See Watchpoint data address comparisons.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

A single watchpoint can be programmed to match or mismatch on one or more address bytes. A watchpoint generates a Watchpoint debug event on an access to any byte that it is watching. The number of bytes a watchpoint is watching is either:

- One to eight bytes, provided that these bytes are contiguous and that they are all in the same naturally-aligned doubleword. A debugger uses the *Byte Address Select* field, DBGWCR<n>_EL1.BAS, to select the bytes. See Programming a watchpoint range with eight bytes or fewer.
- Eight bytes to 2GB, provided that both of the following are true:
  - The number of bytes is a power-of-two.
  - The range starts at an address that is aligned to the range size.

  A debugger uses the *MASK* field, DBGWCR<n>_EL1.MASK, to program a watchpoint with eight bytes to 2GB. See Programming a watchpoint range with eight or more bytes.

A debugger must use either the BAS field or the MASK field. If it uses both, whether the watchpoint generates Watchpoint debug events is CONSTRAINED UNPREDICTABLE. See Programming dependencies of the BAS and MASK fields.

For each memory access, all of the watchpoints are tested. When a watchpoint is tested, it generates a Watchpoint debug event if all of the following are true:

- The conditions specified in the DBGWCR<n>_EL1 are met. This includes all of the following:
  - The watchpoint is enabled. See DBGWCR<n>_EL1.E.
  - The type of the access. That is, whether the access is a load, a store, or both. See DBGWCR<n>_EL1.LST.
  - The Security state, Exception level, and privilege of the access. See Execution conditions for which a watchpoint generates Watchpoint exceptions.
  - If the watchpoint links to a breakpoint with linking enabled, the comparison or comparisons made by the breakpoint. See Rules for linking watchpoints.

  Together, these define the *context* of the data access that the watchpoint matches.
- The comparison with the address held in the DBGWVR<n>_EL1 is successful. See Watchpoint data address comparisons.
- The instruction that initiates the memory access is committed for execution.
- The instruction that initiates the memory access passes its Condition code check.
- If the access is due to a System register access instruction executed at EL1 and transformed into a memory access by the mechanism described in Enhanced support for nested virtualization and one of the following is true:
  - EDSCR.HDE is set to 1 and halting is allowed.
  - Debug exceptions are enabled at EL2. For more information, see Enabling debug exceptions from the current Exception level and Security state.

If multiple watchpoints can generate a Watchpoint debug event for an access, then, for all watchpoints that are enabled and match the context of the data access:

- The Boolean equality comparison results of all the address match watchpoints are OR'd together to generate a first result.
- The Boolean inequality comparison results of all the address mismatch watchpoints are AND'd together to generate a second result.

A watchpoint debug event is generated if any of the following apply:

- The first result is true and all enabled watchpoints are address match watchpoints.
- The second result is true and all enabled watchpoints are address mismatch watchpoints.
- Both the first and second results are true, and both address match watchpoints and address mismatch watchpoints are enabled.

The pseudocode function `AArch64.CheckWatchpoint()` describes the details for combining the results of individual watchpoints to determine the final result of watchpoint match.

If halting is allowed and EDSCR.HDE is 1, Watchpoint debug events cause entry to Debug state. Otherwise, if debug exceptions are:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- Enabled, Watchpoint debug events generate Watchpoint exceptions.
- Disabled, Watchpoint debug events are ignored.

Note

The remainder of this Watchpoint Exceptions section, including all subsections, describes watchpoints as generating Watchpoint exceptions.
However, unless specified otherwise, the behavior described also applies if watchpoints are causing entry to Debug state.

The debug exception enable controls describes the enable controls for Watchpoint debug events.

D2.9.2 Watchpoint types and linking of watchpoints

When a debugger programs a watchpoint, it must program that watchpoint so that:

- It is either:
  - Used in isolation. In this case, the watchpoint is called an *Unlinked watchpoint*.
  - Linked to a breakpoint with linking enabled. In this case, the watchpoint is called a *Linked watchpoint*.
- And is either:
  - An address match watchpoint.
  - An address mismatch watchpoint.

When a Linked watchpoint links to an Address matching breakpoint with linking enabled, the Linked watchpoint generates a Watchpoint exception only if the address of the instruction that made the matching access was executed from a specific address or in range of addresses.

When a Linked watchpoint links to a Context matching breakpoint with linking enabled, or a Linked watchpoint links to a Linked Address matching breakpoint with linking enabled that links to a Context matching breakpoint with linking enabled, the Linked watchpoint generates a Watchpoint exception only if the PE is in a particular context when the data address match occurs.

Example D2-2 Linking a watchpoint and an Address matching breakpoint

For example, a debugger might:

1. Program watchpoint number one with a data address.
2. Program breakpoint number five to be a *Linked VMID Match breakpoint*.
3. Link the watchpoint and the breakpoint together. A Watchpoint exception is generated only if both the data address matches and the VMID matches.

D2.9.2.1 Rules for linking watchpoints

The rules for watchpoint linking are as follows:

- Only Linked watchpoints can be linked.
- A Linked watchpoint can be linked to any breakpoint with linking enabled.
- A Linked watchpoint can link to any type of breakpoint with linking enabled. The *Linked Breakpoint Number* field, DBGWCR<n>_EL1.{ LBN}, for the Linked watchpoint specifies the particular breakpoint that the Linked watchpoint links to, and:
  - DBGWCR<n>_EL1.{SSC, HMC, PAC} for the Linked watchpoint defines the execution conditions that the watchpoint generates Watchpoint exceptions for. See Execution conditions for which a watchpoint generates Watchpoint exceptions.
  - DBGBCR<n>_EL1.{ SSC, HMC, PMC} for the breakpoint with linking enabled are ignored.
- A Linked watchpoint cannot link to another watchpoint. The { LBN} fields always specify a breakpoint.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- If any of the following apply, then the behavior of the Linked watchpoint is CONSTRAINED UNPREDICTABLE:
  - The Linked watchpoint is linked to a breakpoint that does not support linking.
  - The Linked watchpoint is linked to a breakpoint that is not context aware.
  - The Linked watchpoint is linked to an Address matching breakpoint.
  - The Linked watchpoint is linked to an unimplemented breakpoint.
  - The Linked watchpoint or Linked breakpoint is linked to a breakpoint that does not have linking enabled.

  See Watchpoint usage constraints.

- Multiple Linked watchpoints can link to a single breakpoint with linking enabled.

  Note

  Multiple Address breakpoints can also link to a single breakpoint with linking enabled. Breakpoint exceptions describes breakpoints.

- If an instruction address generates a breakpoint match for more than one enabled Address matching breakpoint with linking enabled, then it is CONSTRAINED UNPREDICTABLE whether Watchpoint exceptions and debug events are generated.

Figure D2-1 shows an example of permitted watchpoint linking.

D2.9.3 Execution conditions for which a watchpoint generates Watchpoint exceptions

Each watchpoint can be programmed so that it generates Watchpoint exceptions only for certain execution conditions. For example, a watchpoint might be programmed to generate Watchpoint exceptions only for Non-secure EL2 accesses.

DBGWCR<n>_EL1.{SSC, HMC, PAC} define the execution conditions a watchpoint generates Watchpoint exceptions for, as follows:

Security State Control, SSC

SSC control whether the watchpoint generates Watchpoint exceptions in only one Security state or in multiple Security states.

Note

This is determined by the Security state of the PE, not from the physical address space attribute returned by the translation of the virtual address on which the watchpoint is set.

Higher Mode Control, HMC, and Privileged Access Control, PAC

HMC and PAC together control which Exception levels and privilege levels the watchpoint generates Watchpoint exceptions in.

The PAC control relates to the privilege of the memory access, not to the Exception level at which the access was made.

Example D2-3 PAC condition for generating a Watchpoint exception

This means that, if the PE executes a Load unprivileged or Store unprivileged instruction at EL1, the resulting data access triggers a watchpoint only if both:

- PAC is programmed to a value that generates watchpoints on EL0 accesses.
- All other conditions for generating the watchpoint are met.

Example A64 Load unprivileged and Store unprivileged instructions are `LDTR` and `STTR`.

Table D2-9 shows the valid combinations of HMC, SSC, and PAC, and for each combination shows which Exception levels watchpoints generate Watchpoint exceptions in.

In the table:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Y or - Means that a watchpoint programmed with the values of HMC, SSC, and PAC shown in that row:

Y Can generate Watchpoint exceptions in that Exception level and Security state.

- Cannot generate Watchpoint exceptions in that Exception level and Security state.

Table D2-9 Summary of watchpoint HMC, SSC, and PAC encodings

HMC	SSC	PAC	EL2	EL1	EL0
0	00	01	-	Y	-
0	00	10	-	-	Y
0	00	11	-	Y	Y
0	01	01	-	Y	-
0	01	10	-	-	Y
0	01	11	-	Y	Y
0	11	00	Y	-	-
0	11	01	Y	Y	-
0	11	11	Y	Y	Y
1	00	01	Y	Y	-
1	00	11	Y	Y	Y
1	01	00	Y	-	-
1	01	01	-	Y	-
1	01	11	-	Y	Y
1	10	11	Y	-	Y
1	11	00	Y	-	-
1	11	01	Y	Y	-
1	11	11	Y	Y	Y

All combinations of HMC, SSC, and PAC that Table D2-9 does not show are reserved.

For information about which combinations of HMC, SSC and PAC are reserved if an Exception level or Security state are not implemented or enabled, see Reserved DBGWCR<n>_EL1.{SSC, HMC, PAC} values.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D2.9.4 Watchpoint data address comparisons

In this subsection, the term `AddrTop` represents the most significant bit of a virtual address used by watchpoint data address comparisons. `AddrTop` is:

- 55, if address tagging is used for the address. See Address tagging.
- 63, otherwise.

Note

When stage 1 translation is enabled, in AArch64 state, the virtual address size is determined by the configured input address size for the stage 1 translation. Software can configure a smaller address width for a virtual address. See Input address size configuration. Attempting to translate an address that is larger than the configured input address size generates a Translation fault.
When stage 1 translation is disabled, using an address that is larger than the implemented PA size generates an Address size fault. The implemented PA size is IMPLEMENTATION DEFINED, as described in Implemented physical address size. These faults have a higher priority than watchpoints.

Bits [`AddrTop`:2] of the data address are compared with DBGWVR<n>_EL1[`AddrTop`:2], taking into account all of the following:

- The size of the access. See Size of the data access.
- The bytes selected by DBGWVR<n>_EL1.BAS. See Programming a watchpoint range with eight bytes or fewer.
- Any address ranges indicated by DBGWVR<n>_EL1.MASK. See Programming a watchpoint range with eight or more bytes.

The comparison is successful if any of following are true:

- The watchpoint is an address match watchpoint, and the two values being compared match.
- The watchpoint is an address mismatch watchpoint, and the two values being compared do not match.

Note

- DBGWVR<n>_EL1 is a 64-bit register. The most significant bits of this register are sign-extension bits.
- DBGWVR<n>_EL1[1:0] are RES0 and are ignored.

D2.9.4.1 Size of the data access

Because watchpoints can be programmed to generate Watchpoint exceptions on individual bytes, the size of each data access must be taken into account. The address of every byte in a data access is compared, and:

- In the case of an address match watchpoint, the watchpoint generates a Watchpoint exception if any byte address matches. See Example D2-4.
- In the case of an address mismatch watchpoint, the watchpoint generates a Watchpoint exception if any byte address does not match. See Example D2-5.

Example D2-4

1. A debugger programs an address match watchpoint to generate Watchpoint exceptions only when the byte at address `0x1009` is accessed.
2. The PE accesses the unaligned doubleword starting at address `0x1003`.

In this scenario, the watchpoint generates a Watchpoint exception.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Example D2-5

1. A debugger programs an address mismatch watchpoint to generate Watchpoint exceptions when any address other than the byte at address `0x1009` is accessed.
2. The PE accesses the unaligned doubleword starting at address `0x1003`.

In this scenario, the watchpoint generates a Watchpoint exception.

The size of data accesses initiated by `DC ZVA` instructions is the DC ZVA block size that DCZID_EL0.BS defines.

The size of data accesses initiated by `DC IVAC` instructions is an IMPLEMENTATION DEFINED size that is both:

- From the inclusive range between:
  - The size that CTR_EL0.DminLine defines.
  - 2KB.
- A power-of-two.

For both of these instructions:

- The lowest address accessed by the instruction is the address supplied to the instruction, rounded down to the nearest multiple of the access size initiated by that instruction.
- The highest address accessed is (size - 1) bytes above the lowest address accessed.

See also Watchpoint behavior on accesses by the DC IVAC instruction and the DC ZVA instruction.

D2.9.4.2 Programming a watchpoint range with eight bytes or fewer

The Byte Address Select field, DBGWCR<n>_EL1.BAS, selects bytes in the doubleword starting at the address contained in DBGWVR<n>_EL1.

If the address programmed into the DBGWVR<n>_EL1 is:

- Doubleword-aligned:
  - All eight bits of DBGWCR<n>_EL1.BAS are used.
- Word-aligned but not doubleword-aligned:
  - Only DBGWCR<n>_EL1.BAS[3:0] are used. In this case, DBGWCR<n>_EL1.BAS[7:4] are RES0.

An address match watchpoint generates a Watchpoint exception when an access accesses any byte address that DBGWCR<n>_EL1.BAS selects. An address mismatch watchpoint generates a Watchpoint exception when an access accesses any byte address that DBGWCR<n>_EL1.BAS does not select.

Table D2-10 Supported BAS values when the DBGWVR<n>_EL1 address alignment is doubleword

BAS value	Description
`0b00000000`	No byte selected.
BAS[0] == 1	Byte at address DBGWVR<n>_EL1[`AddrTop`:3]:`000` selected.
BAS[1] == 1	Byte at address DBGWVR<n>_EL1[`AddrTop`:3]:`001` selected.
BAS[2] == 1	Byte at address DBGWVR<n>_EL1[`AddrTop`:3]:`010` selected.
BAS[3] == 1	Byte at address DBGWVR<n>_EL1[`AddrTop`:3]:`011` selected.
BAS[4] == 1	Byte at address DBGWVR<n>_EL1[`AddrTop`:3]:`100` selected.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

BAS value	Description
BAS[5] == 1	Byte at address DBGWVR<n>_EL1[AddrTop:3]:101 selected.
BAS[6] == 1	Byte at address DBGWVR<n>_EL1[AddrTop:3]:110 selected.
BAS[7] == 1	Byte at address DBGWVR<n>_EL1[AddrTop:3]:111 selected.

Table D2-11 Supported BAS values when the DBGWVR<n>_EL1 address alignment is word

BAS value[a]	Description
0b00000000	No byte selected.
BAS[0] == 1	Byte at address DBGWVR<n>_EL1[AddrTop:2]:00 selected.
BAS[1] == 1	Byte at address DBGWVR<n>_EL1[AddrTop:2]:01 selected.
BAS[2] == 1	Byte at address DBGWVR<n>_EL1[AddrTop:2]:10 selected.
BAS[3] == 1	Byte at address DBGWVR<n>_EL1[AddrTop:2]:11 selected.

a. DBGWCR<n>_EL1.BAS[7:4] are RES0.

If the BAS field selects more than one byte, the bytes it selects must be contiguous. For watchpoint behavior when its BAS field selects non-contiguous bytes, see Other usage constraints.

When programming the BAS field with anything other than 0b11111111, a debugger must program DBGWCR<n>_EL1.MASK to 0b00000. See Programming dependencies of the BAS and MASK fields.

A watchpoint generates a Watchpoint exception whenever a watched byte is accessed, even if:

- The access size is smaller or larger than the address region being watched.
- The access is misaligned, and the base address of the access is not in the doubleword or word of memory addressed by the DBGWVR<n>_EL1[AddrTop:3]. See Example D2-4.

Example D2-6

The following are some example configurations of the BAS field:

- To program an address match watchpoint to generate a Watchpoint exception on the byte at address 0x1003, program:
  - DBGWVR<n>_EL1 with 0x1000.
  - DBGWCR<n>_EL1.BAS to be 0b00001000.
- To program an address match watchpoint to generate a Watchpoint exception on the bytes at addresses 0x2003, 0x2004 and 0x2005, program:
  - DBGWVR<n>_EL1 with 0x2000.
  - DBGWCR<n>_EL1.BAS to be 0b00111000.
- If the address programmed into the DBGWVR<n>_EL1 is doubleword-aligned:
  - To generate a Watchpoint exception when any byte in the word starting at the doubleword-aligned address is accessed, program DBGWCR<n>_EL1.BAS to be 0b00001111.
  - To generate a Watchpoint exception when any byte in the word starting at address DBGWVR<n>_EL1[31:3]:100 is accessed, program DBGWCR<n>_EL1.BAS to be 0b11110000.

Note

Arm deprecates programming a DBGWVR<n>_EL1 with an address that is not doubleword-aligned.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D2.9.4.3 Programming a watchpoint range with eight or more bytes

A debugger can use the *MASK* field, DBGWCR<n>_EL1.MASK, to program a single watchpoint with a data address range. The range must meet all of the following criteria:

- It is a size that is:
  - A power-of-two.
  - A minimum of eight bytes.
  - A maximum of 2GB.
- It starts at an address that is aligned to the size.

The MASK field specifies the number of least significant data address bits that must be masked. Up to 31 least significant bits can be masked.

If *m* least significant address bits are masked, an address match watchpoint generates a Watchpoint exception on all of the following:

- Address DBGWVR<n>_EL1[`AddrTop`:*m*]:000...0.
- Address DBGWVR<n>_EL1[`AddrTop`:*m*]:111...1.
- Any address between these two addresses.

An address mismatch breakpoint generates a Watchpoint exception for any address outside of the range.

Example D2-7

If the four least significant address bits are masked, Watchpoint exceptions are generated for all addresses between DBGWVR<n>_EL1[`AddrTop`:4]:0000 and DBGWVR<n>_EL1[`AddrTop`:4]:1111, including these addresses.

When masking address bits, a debugger must both:

- Program DBGWCR<n>_EL1.BAS to be `0b11111111`. See Programming dependencies of the BAS and MASK fields.
- In the DBGWVR<n>_EL1, set the masked address bits to 0. For watchpoint behavior when any of the masked address bits are not 0, see Other usage constraints.

D2.9.5 Watchpoint behavior for certain instruction classes

Under normal operating conditions, the following do not generate Watchpoint exceptions:

- Instruction cache maintenance instructions.
- Address translation instructions.
- TLB maintenance instructions.
- Prefetch memory instructions.
- All data cache maintenance instructions except `DC IVAC`.

However, the debug architecture allows for IMPLEMENTATION DEFINED controls, such as those in ACTLR registers, to enable watchpoints on an IMPLEMENTATION DEFINED subset of these instructions. Whether a watchpoint treats the instruction as a load or a store, and the access size of instruction cache, address translation, and TLB operations are IMPLEMENTATION DEFINED.

The access size of the IMPLEMENTATION DEFINED instruction cache, address translation, and TLB operations which generate Watchpoint exceptions are IMPLEMENTATION DEFINED.

See also the following subsections:

- Watchpoint behavior on accesses by Store-Exclusive instructions.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- Watchpoint behavior on accesses by the DC IVAC instruction and the DC ZVA instruction.

D2.9.5.1 Watchpoint behavior on accesses by Store-Exclusive instructions

If a watchpoint matches on a data access caused by a Store-Exclusive instruction, then:

- If the store fails because an Exclusives monitor does not permit it, it is IMPLEMENTATION DEFINED whether the watchpoint generates a Watchpoint exception.
- Otherwise, the watchpoint generates a Watchpoint exception.

D2.9.5.2 Watchpoint behavior on accesses by the DC IVAC instruction and the DC ZVA instruction

`DC ZVA` operations can generate Watchpoint exceptions.

If the Point of Coherency is before any level of cache, it is IMPLEMENTATION DEFINED whether a DC IVAC instruction can generate a Watchpoint exception. Otherwise, DC IVAC operations can generate Watchpoint exceptions.

`DC IVAC` and `DC ZVA` operations are treated as data stores by DBGWCR<n>_EL1.LSC.

Note

For the size of data accesses performed by the `DC IVAC` instruction and the `DC ZVA` instruction, see Watchpoint data address comparisons. The size of all data accesses must be considered because watchpoints can be programmed to match on individual bytes.

D2.9.6 Watchpoint usage constraints

See the following:

- Reserved DBGBCR<n>_EL1.BT values when using Watchpoints.
- Reserved DBGWCR<n>_EL1.{SSC, HMC, PAC} values.
- Usage constraints on DBGWCR<n>_EL1.LBN values.
- Programming dependencies of the BAS and MASK fields.
- Reserved DBGWCR<n>_EL1.BAS values.
- Reserved DBGWCR<n>_EL1.MASK values.
- Other usage constraints.

D2.9.6.1 Reserved DBGBCR<n>_EL1.BT values when using Watchpoints

It is CONSTRAINED UNPREDICTABLE whether Watchpoint exceptions and debug events are generated if DBGBCR<n>_EL1.BT is a reserved value. See Reserved DBGBCR<n>_EL1.BT values.

D2.9.6.2 Reserved DBGWCR<n>_EL1.{SSC, HMC, PAC} values

Table D2-12 shows when particular combinations of DBGWCR<n>_EL1.{SSC, HMC, PAC} are reserved.

Table D2-12 Reserved SSC, HMC, and PAC combinations

HMC, SSC, and PAC combination	Reserved
Combinations not included in Table D2-9.	Always.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

If a watchpoint is programmed with one of these reserved combinations:

- The watchpoint must behave as if it is either:
  - Disabled.
  - Programmed with a combination that is not reserved, other than for a direct or external read of DBGWCR<n>_EL1.
- For a direct or external read of DBGWCR<n>_EL1, if the reserved combination:
  - Has no function for any execution conditions, the value read back for each of SSC, HMC, and PMC is UNKNOWN.
  - Has a function for execution conditions other than the current execution conditions, the value read back is the value written. This permits software to save and restore the combination so that the watchpoint functions for the other execution conditions.

The behavior of watchpoints with reserved combinations of SSC, HMC, and PAC might change in future revisions of the architecture. For this reason, software must not rely on the behavior described here.

D2.9.6.3 Usage constraints on DBGWCR<n>_EL1.LBN values

For Linked Watchpoints

A Linked watchpoint must link to a *context-aware* breakpoint. For a Linked watchpoint, any DBGWCR<n>_EL1.LBN value that is not for a *context-aware* breakpoint is reserved.

If a Linked watchpoint links to a breakpoint that is not implemented, or does not support linking, then reads of DBGWCR<n>_EL1.LBN return an UNKNOWN value and the behavior is CONSTRAINED UNPREDICTABLE. The Linked watchpoint behaves as if it is either:

- Disabled
- Linked to an UNKNOWN breakpoint that supports linking.

If a Linked watchpoint links to one of the following implemented breakpoints, then it behaves as if it is disabled:

- A breakpoint that is *context-aware*, but that is either not enabled or not programmed as a Context matching breakpoint with linking enabled.
- A breakpoint that supports address matching with linking and is not programmed as an Address matching breakpoint with linking enabled.

It is CONSTRAINED UNPREDICTABLE whether Watchpoint exceptions and debug events are generated if an instruction address generates a breakpoint match for more than one enabled Address matching breakpoint with linking enabled.

For Unlinked Watchpoints For Unlinked watchpoints, DBGWCR<n>_EL1.LBN reads UNKNOWN and its value is ignored.

D2.9.6.4 Programming dependencies of the BAS and MASK fields

When programming a watchpoint, a debugger must use either:

- The MASK field, to program the watchpoint with an address range that can be eight bytes to 2GB.
- The BAS field, to select which bytes in the doubleword or word starting at the address contained in the DBGWVR<n>_EL1 the watchpoint must generate Watchpoint exceptions for.

If the debugger uses the:

- MASK field, it must program BAS to be `0b11111111`, so that all bytes in the doubleword or word are selected.
- BAS field, it must program MASK to be `0b00000`, so that the MASK field does not indicate any address ranges.

If an enabled watchpoint has a MASK field that is nonzero and a BAS field that is not set to `0b11111111`, then for each byte in the address range, it is CONSTRAINED UNPREDICTABLE whether or not a Watchpoint exception is generated.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D2.9.6.5 Reserved DBGWCR<n>_EL1.BAS values

The BAS field must be programmed with a value `Zeros(8-n-m):Ones(n):Zeros(m)`, where:

- `n` is a nonzero positive integer less-than-or-equal-to 8.
- `m` is a positive integer less-than 8.
- `n+m` is less-than-or-equal-to 8.

All other values are reserved.

Note

If `x` is zero, then `Zeros(x)` is an empty bitstring.

If DBGWVR<n>_EL1[2] is 1, DBGWCR<n>_EL1.BAS[7:4] are RES0 and are ignored.

If a watchpoint is programmed with a reserved BAS value:

- It is CONSTRAINED UNPREDICTABLE whether the watchpoint generates a Watchpoint exception for each byte in the doubleword or word of memory addressed by the DBGWVR<n>_EL1.
- A direct or external read of DBGWCR<n>_EL1.BAS returns an UNKNOWN value.

Software must not rely on these properties as the behavior of reserved values might change in a future revision of the architecture.

D2.9.6.6 Reserved DBGWCR<n>_EL1.MASK values

If a watchpoint is programmed with a reserved MASK value:

- The watchpoint must behave as if it is either:
  - Disabled.
  - Programmed with an UNKNOWN value that is not reserved, that might be `0b00000`, other than for a direct or external read of DBGWCR<n>_EL1.
- A direct or external read of DBGWCR<n>_EL1.MASK returns an UNKNOWN value.

D2.9.6.7 Other usage constraints

For all watchpoints:

- DBGWVR<n>_EL1[1:0] are RES0 and are ignored.
- If DBGWCR<n>_EL1.MASK is nonzero, and any masked bits of DBGWVR<n>_EL1 are not 0, it is CONSTRAINED UNPREDICTABLE whether the watchpoint generates a Watchpoint exception when the unmasked bits match.
- A watchpoint never generates any Watchpoint exceptions if DBGWCR<n>_EL1.LSC is `0b00`.

D2.9.7 Exception syndrome information, fault address information, and preferred return address

On taking a Watchpoint exception or entering Debug state for a Watchpoint debug event, the PE records the following:

- Information about the debug event or exception in a *syndrome register*. No information is recorded if the watchpoint causes the PE to enter Debug state.
- An address that the debugger can use to determine the memory location that caused the watchpoint, in a *Fault Address Register*. No address is recorded if the PE sets the FnV bit in the syndrome register to 1, as described in Fault address information.

The syndrome register and fault address register used are one of the following:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- For a Watchpoint exception taken to EL1, ESR_EL1 and FAR_EL1.
- For a Watchpoint exception taken to EL2, ESR_EL2 and FAR_EL2.
- For a Watchpoint debug event that causes entry to Debug state, EDHSR, if implemented, and EDWAR.

In cases where one instruction triggers multiple watchpoints, only one address is recorded.

See ISS encoding for an exception from a Watchpoint exception for more information.

This section uses the following terms:

Naturally-aligned block of memory

Means:

- A power-of-two size.
- No larger than the `DC ZVA` block size defined by the DCZID_EL0.BS field, if ESR_ELx.FnP or EDHSR.FnP is 0.
- No larger than the smallest implemented translation granule if ESR_ELx.FnP or EDHSR.FnP is 1.
- Contains a watchpointed address accessed by the memory access or set of contiguous memory accesses that triggered the watchpoint.

The size of the naturally-aligned block of memory is IMPLEMENTATION DEFINED. There is no architectural means of discovering the size.

Watchpointed address

Is defined as any address for which at least one of the address match watchpoints generates a watchpoint match.

For more information, see the subsections that follow. These are:

- Exception syndrome information.
- Fault address information.
- Preferred return address.

D2.9.7.1 Exception syndrome information

R_{KSSHC} If a watchpoint matches an access that is due to a *relaxed watchpoint access*, then the PE:

- Sets ESR_ELx.FnV to an IMPLEMENTATION DEFINED value, 0 or 1, on taking a Watchpoint exception generated by the watchpoint match.
- If FEAT_EDHSR is implemented, sets EDHSR.FnV to an IMPLEMENTATION DEFINED value, 0 or 1, on entering Debug state on a Watchpoint debug event generated by the watchpoint match.

Otherwise, ESR_ELx.FnV or EDHSR.FnV is set to 0.

R_{RLWSF} When the PE sets ESR_ELx.FnV to 0 on taking a Watchpoint exception generated by a watchpoint match:

- If the lowest watchpointed address that is higher than or equal to the address recorded in FAR_ELx might not have been accessed by the instruction, other than as permitted by R_{LVLYV}, the PE sets ESR_ELx.FnP to 1.
- Otherwise, the PE sets ESR_ELx.FnP to 0.

R_{TLMWP} When FEAT_Debugv8p2 is implemented, the PE behavior on taking a Watchpoint exception is as follows:

- If the PE sets ESR_ELx.FnV to 1 or ESR_ELx.FnP to 1, then the PE sets ESR_ELx.WPTV to 1.
- If the address recorded in FAR_ELx is not within a naturally-aligned block of memory, then the PE sets ESR_ELx.WPTV to 1.
- Otherwise, the PE sets ESR_ELx.WPTV to an IMPLEMENTATION DEFINED value, 0 or 1.

On a watchpoint match generated by watchpoint <*n*>:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- If the PE sets ESR_ELx.WPTV to 1 on taking a Watchpoint exception generated by the watchpoint match, then ESR_ELx.WPT is set to <*n*>.
- If FEAT_EDHSR is implemented and the PE sets EDHSR.WPTV to 1 on entering Debug state on a Watchpoint debug event generated by the watchpoint match, then EDHSR.WPT is set to <*n*>.
- Otherwise, ESR_ELx.WPT or EDHSR.WPT is UNKNOWN.

R_{XQBQN} When an instruction generates multiple watchpoint matches and the PE sets ESR_ELx.WPTV to 1 on taking a Watchpoint exception generated by the watchpoint match,or on entering Debug state on a Watchpoint debug event generated by the watchpoint match, then the value <n> reported in ESR_ELx.WPT is defined as follows:

- If all the matching watchpoints are address match watchpoints or all the matching watchpoints are address mismatch watchpoints, then <n> is any watchpoint that generates a watchpoint match.
- Otherwise, <n> is any address match watchpoint that generates a watchpoint match.

D2.9.7.2 Fault address information

D2.9.7.2.1 Address recorded for Watchpoint exceptions generated by zeroing and data cache maintenance instructions

R_{GBDMM} For a watchpoint triggered by a DC ZVA instruction, or a Data Cache maintenance operation, the address recorded in FAR_ELx or EDWAR is both:

- Any address accessed by the instruction.
- Within a naturally-aligned block of memory.

Note

Despite the mnemonic, the DC ZVA instruction is not a data cache maintenance instruction.

D2.9.7.2.2 Address recorded for Watchpoint exceptions generated by other instructions

The address recorded by other instructions must be both:

- From the inclusive range between:
  - The lowest address accessed by the memory access or set of contiguous memory accesses that triggered the watchpoint.
  - The highest watchpointed address accessed by the memory access or set of contiguous memory accesses that triggered the watchpoint.
- Within a naturally-aligned block of memory.

Example D2-8 Address recorded for a watchpoint programmed on `0x8019`

A debugger programs a watchpoint to generate a Watchpoint exception on any access to the byte `0x8019`.
An A32 load multiple instruction then loads nine registers starting from address `0x8004` upwards. This triggers the watchpoint.
If the `DC ZVA` block size is:

- 32 bytes, the address that the PE records must be between `0x8004` and `0x8019` inclusive.
- 16 bytes, the address that the PE records must be between `0x8010` and `0x8019` inclusive.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D2.9.7.3 Preferred return address

The preferred return address of a Watchpoint exception is the address of the instruction that was not executed because the PE took the Watchpoint exception instead.

This means that the preferred return address is the address of the instruction that caused the exception.

D2.9.8 Pseudocode description of Watchpoint exceptions taken from AArch64 state

`AArch64.WatchpointByteMatch()` tests an individual byte accessed by an operation.

`AArch64.StateMatch()` tests the values in DBGWCR<n>_EL1.{HMC, SSCE, SSC, PAC}, and if the watchpoint links to a breakpoint with linking enabled, also tests the breakpoint that the watchpoint links to.

`AArch64.WatchpointMatch()` tests the value in DBGWVR<n>_EL1.

`AArch64.CheckWatchpoint()` generates a `FaultRecord` that `AArch64.Abort()` raises a Watchpoint exception for if all of the following are true:

- MDSCR_EL1.MDE is 1.
- Debug exceptions are enabled from the current Exception level and Security state. See Enabling debug exceptions from the current Exception level and Security state.
- All of the conditions required for Watchpoint exception generation are met. See About Watchpoint exceptions.

Note

`AArch64.CheckWatchpoint()` might halt the PE and cause it to enter Debug state. External debug uses Debug state.

`AArch64.WatchpointException()` is called to generate a Watchpoint exception.

These functions are defined in Pseudocode for AArch64 operation.

D2.10 Software Step exceptions

The following subsections describe Software Step exceptions:

- About Software Step exceptions.
- Rules for setting MDSCR_EL1.SS to 1.
- The software step state machine.
- Entering the active-not-pending state.
- Behavior in the active-not-pending state.
- Entering the active-pending state.
- Behavior in the active-pending state.
- Exception syndrome information and preferred return address.
- Additional considerations.
- Pseudocode description of Software Step exceptions.

D2.10.1 About Software Step exceptions

Software step is a resource that a debugger can use to make the PE single-step instructions.

For example, by using software step, debugger software executing at a higher Exception level can single-step instructions at a lower Exception level.

Operation is as follows:

1. A debugger:
   a. Enables software step by setting MDSCR_EL1.SS to 1. See The debug exception enable controls.
   b. Executes an exception return instruction, to branch to the instruction to be single-stepped in the software being debugged.
   c. Optionally configures the MDSTEPOP_EL1 register. See Behavior in the active-not-pending state.
2. The PE then:
   a. Executes the instruction to be single-stepped.
   b. Takes a Software Step exception on the next instruction, returning control to the debugger.

However, another exception might be generated while the instruction is being stepped. This exception is either:

- A synchronous exception that is generated by the instruction being stepped.
- An asynchronous exception that is taken before or after the instruction being stepped.

The PE can take a Software Step exception only if debug exceptions are enabled from the current Exception level and Security state. See Enabling debug exceptions from the current Exception level and Security state.

A state machine describes the behavior of software step, shown in The software step state machine.

Throughout this Software Step exceptions section, including in all subsections, EL_D means the Exception level that Software Step exceptions are targeting. Routing debug exceptions defines EL_D as the *debug target Exception level*.

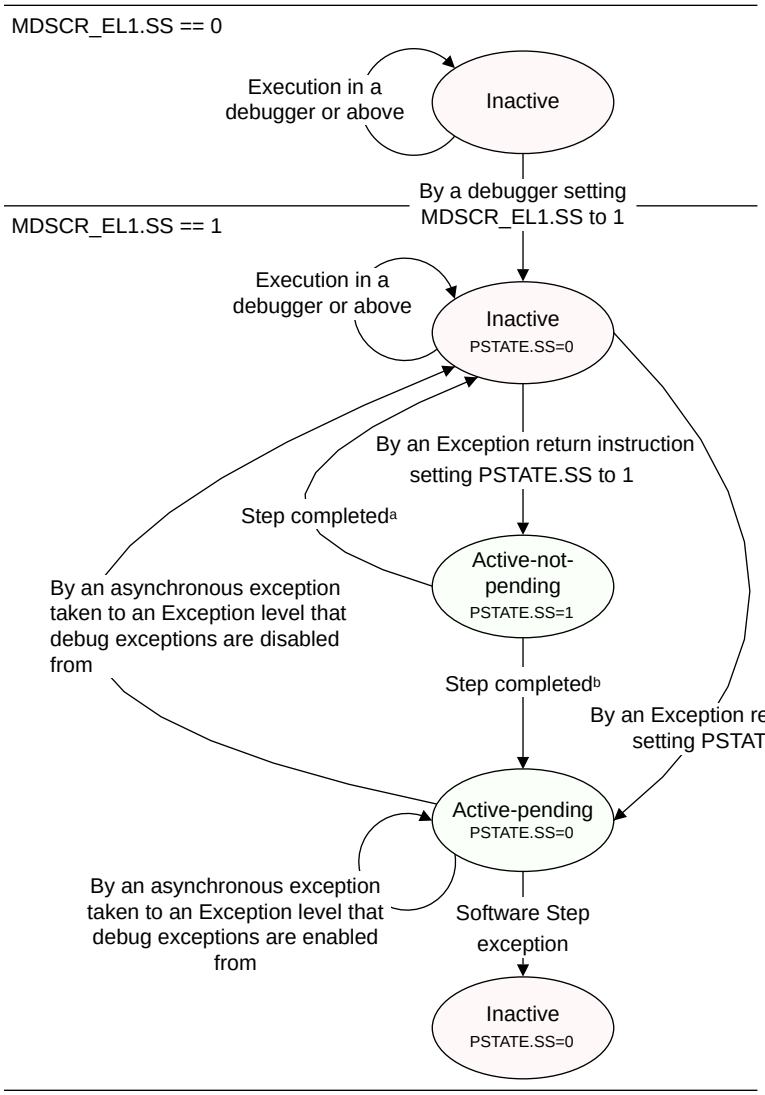
D2.10.2 Rules for setting MDSCR_EL1.SS to 1

Debugger software must be executing in an Exception level and Security state that debug exceptions are disabled from when it sets MDSCR_EL1.SS to 1.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D2.10.3 The software step state machine

In Figure D2-3, the OS Lock is unlocked and `DoubleLockStatus()` == FALSE.



Execution is at either:

- An Exception level that is higher than EL_D.
- EL_D with (PSTATE.D == 1 || MDSCR_EL1.KDE == 0).

This is termed *execution in a debugger or above*.

To make the PE single-step an instruction, the debugger:

1. Sets SPSR_ELx.SS to 1.
2. Programs the ELR_ELx to point to the instruction to be stepped.
3. Executes an Exception return instruction.

Execution is in the software being debugged, at either:

- An Exception level that is lower than EL_D.
- EL_D with (PSTATE.D == 0 && MDSCR_EL1.KDE == 1).

Execution is in the software being debugged, at either:

- An Exception level that is lower than EL_D.
- EL_D with (PSTATE.D == 0 && MDSCR_EL1.KDE == 1).

A Software Step exception is pending.

Execution has returned to the debugger.

a. The step is the PE either:
   - Taking an exception to an Exception level that debug exceptions are disabled from.
   - If execution is at EL_D with MDSCR_EL1.KDE == 1, executing an instruction that sets PSTATE.D to 1.

   Software step is inactive when debug exceptions are disabled from the current Exception level, and debug exceptions are disabled from EL_D when PSTATE.D is 1.

b. The step is the PE either:
   - Executing the instruction to be stepped without taking an exception.
   - Taking an exception to an Exception level that debug exceptions are enabled from. The Exception level might be using AArch64 or AArch32.

c. Or, if execution is at EL_D with MDSCR_EL1.KDE == 1, by software setting PSTATE.D to 0.

Figure D2-3 Software step state machine

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

For a description of when debug exceptions are enabled or disabled from an Exception level, see Enabling debug exceptions from the current Exception level and Security state.

For more information about how a step is completed, see Behavior in the active-not-pending state.

The software step states are:

Inactive Software step is inactive. It cannot generate any Software Step exceptions or affect PE execution. Software step is inactive whenever any of the following are true:

- Debug exceptions are disabled from the current Exception level.
- MDSCR_EL1.SS is 0.

Active-not-pending

None of the conditions mentioned in Inactive are true, therefore software step is active.

The instruction to be stepped is usually the instruction in memory at the address specified by the PC.

Active-pending

None of the conditions mentioned in Inactive are true, therefore software step is active.

A Software Step exception is pending on the current instruction.

Whenever software step is active, whether the state machine is in the active-not pending state or the active-pending state depends on PSTATE.SS. Table D2-13 shows this.

Table D2-13 State machine states

Debug exception enable status in the current Exception level and Security state	MDSCR_EL1.SS	PSTATE.SS	State machine state
Disabled	X	X	Inactive
Enabled	0	X	Inactive
Enabled	1	1	Active-not-pending
Enabled	1	0	Active-pending

D2.10.4 Entering the active-not-pending state

Software step can only enter the active-not-pending state from the inactive state.

Software step:

- Enters the active-not-pending state when an Exception return instruction writes 1 to PSTATE.SS, by copying from SPSR_ELx.SS when it restores PSTATE.
- Might enter the active-not-pending state on exiting Debug state when DSPSR_EL0.SS is 1. See Exiting Debug state.

An Exception return instruction only copies 1 from SPSR_ELx.SS to PSTATE.SS if all of the following are true:

- MDSCR_EL1.SS is 1.
- Debug exceptions are disabled from the current Exception level.
- Debug exceptions are enabled from the Exception level that the Exception return instruction targets.

Otherwise, Exception return instructions set PSTATE.SS to 0, regardless of the value of SPSR_ELx.SS.

Table D2-14 shows this. In the table:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Lock Means the value of (OSLSR_EL1.OSLK == '1' || `DoubleLockStatus()`).

TGE Means the value of HCR_EL2.TGE. If EL2 is not implemented, the PE behaves as if this is 0.

TDE Means the Effective value of MDCR_EL2.TDE. See Routing debug exceptions.

Table D2-14 Value an Exception return instruction writes to PSTATE.SS

MDSCR_EL1.SS	Lock	TGE	TDE	Value an Exception return instruction writes to PSTATE.SS
0	X	X	X	0
1	TRUE	X	X	0
	FALSE	X	X	See Table D2-15
		0	0	See Table D2-15
			1	See Table D2-16
		1	X	See Table D2-16

For:

- If EL_D is EL1 using AArch64, Table D2-15 shows the value an Exception return instruction writes to PSTATE.SS.
- If EL_D is EL2 using AArch64, Table D2-16 shows the value an Exception return instruction writes to PSTATE.SS.

In both tables:

From EL Means the Exception level at which the PE executes the Exception return instruction.

Target EL Is the target Exception level of the Exception return instruction.

Note

If the Exception return instruction is an illegal exception return, the target Exception level of the Exception return instruction is the current Exception level. See Illegal exception returns from AArch64 state.

KDE Is MDSCR_EL1.KDE. See Enabling debug exceptions from the current Exception level and Security state

Table D2-15 Value an Exception return instruction writes to PSTATE.SS if EL_D is EL1 using AArch64

					Software step enable status at:		
From EL	Target EL	KDE	PSTATE.D	SPSR_ELx.D	From EL	Target EL	Value an Exception return instruction writes to PSTATE.SS
EL2	EL2	X	X	X	Disabled	Disabled	0
	EL1	0	X	X	Disabled	Disabled	0
		1	X	1	Disabled	Disabled	0
				0	Disabled	Enabled	SPSR_EL2.SS
	EL0	X	X	X	Disabled	Enabled	SPSR_EL2.SS

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

From EL	Target EL	KDE	PSTATE.D	SPSR_ELx.D	Software step enable status at: From EL	Software step enable status at: Target EL	Value an Exception return instruction writes to PSTATE.SS
EL1	EL1	0	X	X	Disabled	Disabled	0
		1	0	X	Enabled[a]	-[b]	0
			1	1	Disabled	Disabled	0
				0	Disabled	Enabled	SPSR_EL1.SS
	EL0	0	X	X	Disabled	Enabled	SPSR_EL1.SS
		1	0	X	Enabled[a]	Enabled	0
			1	X	Disabled	Enabled	SPSR_EL1.SS

a. Because MDSCR_EL1.SS == 1, it means that the Exception return instruction is itself being stepped.

b. Depends on SPSR_EL1.D.

Table D2-16 Value an Exception return instruction writes to PSTATE.SS if EL_D is EL2 using AArch64

From EL	Target EL	KDE	PSTATE.D	SPSR_ELx.D	Software step enable status at: From EL	Software step enable status at: Target EL	Value an Exception return instruction writes to PSTATE.SS
EL2	EL2	0	X	X	Disabled	Disabled	0
		1	0	X	Enabled[a]	-[b]	0
			1	1	Disabled	Disabled	0
				0	Disabled	Enabled	SPSR_EL2.SS
	EL1	0	X	X	Disabled	Enabled	SPSR_EL2.SS
		1	0	X	Enabled[a]	Enabled	0
			1	X	Disabled	Enabled	SPSR_EL2.SS
	EL0	0	X	X	Disabled	Enabled	SPSR_EL2.SS
		1	0	X	Enabled[a]	Enabled	0
			1	X	Disabled	Enabled	SPSR_EL2.SS
EL1	EL1	X	X	X	Enabled[a]	Enabled	0
	EL0	X	X	X	Enabled[a]	Enabled	0

a. Because MDSCR_EL1.SS == 1, it means that the Exception return instruction is itself being stepped.

b. Depends on SPSR_EL2.D.

D2.10.5 Behavior in the active-not-pending state

In this state, the PE does one of the following:

- Executes the instruction to be stepped and either:
  - Completes it without taking a synchronous exception.
  - Takes a synchronous exception if the instruction generates one.
- Takes an asynchronous exception without executing any instructions.
- Enters Debug state because of a *Halting debug event*.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The instruction to be stepped is usually the instruction in memory at the address specified by the PC.

If the PE executes the instruction without taking any exceptions, then the PE sets PSTATE.SS to 0, meaning that after the instruction has been executed:

- If the instruction has disabled debug by setting PSTATE.D to 1 then software step advances to the inactive state.
- If the instruction disables software step by a direct write to a System register, for example a write to MDSCR_EL1.KDE or MDSCR_EL1.SS, then software step might advance to the inactive state. These writes require explicit synchronization to guarantee their effect. See Synchronization and the software step state machine.
- Otherwise, software step advances to the active-pending state. See Behavior in the active-pending state.

If the PE takes either a synchronous or an asynchronous exception, behavior is as described in one of the following:

- If the PE takes an exception to an Exception level that is using AArch64.

If the PE enters Debug state because of a Halting debug event, behavior is as described in Entering Debug state and Software Step.

D2.10.5.1 If the PE takes an exception to an Exception level that is using AArch64

As part of exception entry, the PE does all of the following:

- Sets SPSR_ELx.SS to 0 or 1, depending on the exception. See Table D2-17.
- It is UNPREDICTABLE whether SPSR_ELx.SS to 0 or 1 when an SError exception is taken to ELx without executing the instruction.
- Sets PSTATE.SS to 0. This causes software step to enter either the active-pending state or the inactive state, depending on whether debug exceptions are enabled or disabled from the Exception level that the exception is taken to:

  Enabled Software step enters the active-pending state.

  Disabled Software step enters the inactive state.

  In either case, on taking the exception, a step is complete.
- Sets PSTATE.D to 1.

Table D2-17 Categorization of exceptions, for setting SPSR_ELx.SS to 0 or 1

Exception description	Exceptions	SPSR_ELx.SS
Exceptions whose preferred return address is for the instruction that follows the instruction to be stepped.	Supervisor Call (SVC) exceptions. Hypervisor Call (HVC) exceptions. Secure Monitor Call (SMC) exceptions.	0
Exceptions whose preferred return address is the address of the instruction to be stepped.	All other synchronous exceptions, and asynchronous exceptions that are taken before the instruction to be stepped.	1

Note

If an SMC instruction executed at Non-secure EL1 is trapped to EL2 because HCR_EL2.TSC is 1, the exception is a Trap exception, not a Secure Monitor Call exception, and so SPSR_ELx.SS is set to 1, not 0.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D2.10.5.2 Summary of behavior in the active-not-pending state

Table D2-18 summarizes behavior in the active-not-pending state.

Table D2-18 Summary of behavior in the active-not-pending state

Event	Value written to PSTATE.SS	Details[a]	Value written to SPSR_ELx.SS	Next state
No exception	0	Disables Software step	n/a	Inactive
		Otherwise	n/a	Active-pending
Exception	0	Supervisor Call (SVC) Hypervisor Call (HVC)	0	Active-pending or inactive[b]
		Other	1	

a. For the *No exception* rows, this column shows the effect of the event.

For the *Exception* rows, this column shows the exception taken.

b. Which state software step enters depends on whether debug exceptions are enabled or disabled from the target Exception level. See Figure D2-3.

D2.10.6 Entering the active-pending state

Software step enters the active-pending state after any of the following operations, provided that both:

- MDSCR_EL1.SS is 1.
- Debug exceptions are enabled from the Exception level and Security state that execution is in after the operation.

The operations are:

While software step is in the active-not-pending state

The PE either:

- Executing the instruction to be stepped without taking any exceptions.
- Taking an exception.

While software step is in the active-pending state

The PE takes an asynchronous exception.

While software step is in the inactive state

The PE executes either:

- An Exception return instruction when SPSR_ELx.SS is 0.
- An instruction that enables debug by setting PSTATE.D to 0.

Note

If entry to the active-pending state is because of the PE taking an exception, it means that the exception is one that is taken to EL1 when MDCR_EL2.TDE is 1 and EL2 is implemented and enabled in the current Security state. Otherwise, debug exceptions are masked by PSTATE.D, therefore they would be disabled from the target Exception level of the exception.

In addition, software step might enter the active-pending state either:

- After a direct write to a System register, for example a write to MDSCR_EL1.KDE or MDSCR_EL1.SS. These writes require explicit synchronization to guarantee their effect. See Synchronization and the software step state machine.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- On exiting Debug state when DSPSR_EL0.SS is 0. See Exiting Debug state.

D2.10.7 Behavior in the active-pending state

When the PE is in the active-pending state, a Software Step exception is taken before the PE executes an instruction.

The Software Step exception has higher priority than all other types of synchronous exception. However, the prioritization of this exception with respect to any unmasked pending asynchronous exception is not defined by the architecture.

For more information, see the following:

- Prioritization of Synchronous exceptions taken to AArch64 state.
- Prioritization of interrupts.
- Architectural requirements for taking asynchronous exceptions.

D2.10.8 Exception syndrome information and preferred return address

See the following:

- Exception syndrome information.
- Preferred return address.

D2.10.8.1 Exception syndrome information

On taking a Software Step exception, the PE records information about the exception in the Exception Syndrome Register (ESR_ELx) at the Exception level the exception is taken to. See ISS encoding for an exception from a Software Step exception for more information.

If no instruction was stepped because software step entered the active-pending state from the inactive state without passing through the active-not-pending state, then ESR_ELx.{ISV, EX} are set to {0, 0}.

When an instruction has been stepped, if the stepped instruction was a conditional Load-Exclusive instruction that failed its Condition code test, then ESR_ELx.ISV is set to 1 and ESR_ELx.EX is set to a CONSTRAINED UNPREDICTABLE choice of 0 or 1.

When an instruction has been stepped, if the stepped instruction was an Exception return instruction or an `ISB`. then ESR_ELx.ISV is set to a CONSTRAINED UNPREDICTABLE choice of 0 or 1, and ESR_ELx.EX is set to 0.

If the PE is executing at EL1 or EL0, and the Effective value of MDCR_EL2.TDE is 1, then a different exception might be taken to EL1 before the Software Step exception is taken to EL2. In this case, on taking the Software Step exception ESR_EL2.ISV is set to a CONSTRAINED UNPREDICTABLE choice of 0 or 1, and:

- If ESR_EL2.ISV is set to 1, then ESR_EL2.EX is set to the correct value for the instruction.
- If ESR_EL2.ISV is set to 0, then ESR_EL2.EX is set to 0.

Other than for the cases described above, when an instruction has been stepped:

- ESR_ELx.ISV is set to 1, to indicate that ESR_ELx.EX is valid.
- If the instruction stepped was a Load-Exclusive instruction, then ESR_ELx.EX is set to 1. Otherwise, ESR_ELx.EX is set to 0.

Note

If the PE cannot determine the correct value of ESR_ELx.EX for the stepped instruction, then it sets ESR_ELx.{ISV, EX} to {0, 0}. For example, the exception is taken before the PE decodes the stepped instruction, or the exception means the PE has no valid stepped instruction to decode.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

A Load-Exclusive instruction is any instruction that has a mnemonic starting with either `LDX` or `LDAX`.

Note

An implementation that always sets ISV to 0 and never sets EX is not compliant.

Table D2-19 summarizes the possible values that the PE can record in ESR_ELx.{ISV, EX}.

Table D2-19 Values that the PE can record in ESR_ELx.{ISV, EX}

Description	ESR_ELx.ISV	ESR_ELx.EX
Syndrome data is not available because no instruction was stepped.	0	0
Syndrome data is available because an instruction was stepped. The instruction stepped was a conditional Load-Exclusive instruction that failed its Condition code test.	1	0 or 1
Syndrome data is available because an instruction was stepped. The instruction stepped was an Exception Return instruction or an `ISB`.	0 or 1	0
A different exception is taken before the Software Step exception.	0	0
	1	Set to the correct value for the instruction.
Syndrome data is available because an instruction was stepped. The instruction stepped was an instruction other than a Load-Exclusive instruction, an Exception Return instruction, or an `ISB`, and no other exception was taken before the Software Step exception.	1	0
Syndrome data is available because an instruction was stepped. The instruction stepped was a Load-Exclusive instruction that was either not conditional or did not fail its Condition code test.	1	1

D2.10.8.2 Preferred return address

The preferred return of a Software Step exception is the address of the instruction that was not executed because the PE took the Software Step exception instead.

D2.10.9 Additional considerations

This section contains the following:

- Behavior when an Exception return instruction is an illegal exception return.
- Behavior when the instruction stepped writes a misaligned PC value.
- Stepping code that uses Exclusives monitors.
- Synchronization and the software step state machine.

D2.10.9.1 Behavior when an Exception return instruction is an illegal exception return

If the conditions for entering the active-not-pending state in Entering the active-not-pending state are met, but the PE executes an Exception return instruction that is an illegal exception return, the exception return must be taken to the same Exception level that it was taken from. In this scenario, even though the Exception level remains the same before and after the Exception return instruction, software step can advance from the inactive state to one of the active states. Consider the following case:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

1. MDSCR_EL1.SS is 1 and software step is inactive. The current Exception level is EL1 using AArch64, the OS Lock and OS Double Lock are unlocked, and MDCR_EL2.TDE is 0, MDSCR_EL1.KDE is 1, and PSTATE.D is 1.

   PSTATE.D == 1 is the reason why software step is inactive, because PSTATE.D == 1 means that debug exceptions are disabled from the current Exception level.
2. The PE executes an Exception return instruction.
3. The intended target of the Exception return instruction is EL2. This means that the Exception return instruction is an illegal exception return because the intended target is higher than the Exception level the Exception return instruction it is executed at. In this case, the Exception return instruction must target EL1 instead of EL2.

   If SPSR_EL1.D is 0, then on the Exception return instruction PSTATE.D becomes 0 and debug exceptions become enabled from the current Exception level. Software step therefore advances from the inactive state to one of the active states.

Which active state software step advances to depends on whether SPSR_ELx.SS is 1 or 0:

- If SPSR_ELx.SS is 1, software step advances to the active-not-pending state.

  In this case, an Illegal Execution state exception is pending on the instruction to be stepped, and the PE takes the Illegal Execution state exception instead of executing the instruction to be stepped.
- If SPSR_ELx.SS is 0, software step advances to the active-pending state.

  In this case, a Software Step exception and an Illegal Execution state exception are both pending. The Software Step exception has higher priority. On taking the Software Step exception, the PE sets SPSR_ELx.IL to 1.

Note

Prioritization of Synchronous exceptions taken to AArch64 state shows the relative priorities of synchronous exceptions.

D2.10.9.2 Behavior when the instruction stepped writes a misaligned PC value

An indirect branch that writes a misaligned PC value might generate a PC alignment fault exception at the target of the branch. However, if the indirect branch is stepped using software step, the PE takes a Software Step exception instead, because the Software Step exception has higher priority. Behavior on returning from the Software Step exception depends on which Execution state the Exception level being returned to is using:

AArch64 A PC alignment fault exception is generated.

D2.10.9.3 Stepping code that uses Exclusives monitors

The A-profile architecture provides no mechanism for preserving the state of the Exclusives monitors when a Load-Exclusive or a Store-Exclusive instruction is stepped.

However, for certain progressions through the software step state machine, on taking a Software Step exception, the PE provides an indication of whether the instruction stepped was a Load-Exclusive instruction.

Debugger software can use this to detect the state of the Exclusives monitors. For example, if the PE reports that the instruction stepped was a Load-Exclusive instruction, the debugger is aware that the next Store-Exclusive operation will fail, because all Exclusives monitors are cleared on returning from the Software Step exception. The debugger must then take action to ensure that the code being stepped makes forwards progress.

For more information on how the PE reports whether the instruction stepped was a Load-Exclusive instruction, see Exception syndrome information and preferred return address.

D2.10.9.4 Synchronization and the software step state machine

Any of the following can cause transitions between software step states:

- A direct write to a System register.
- A direct write to a Special-purpose register.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- A write to an external debug register.

The software step state machine indirectly reads some of these registers and so is not guaranteed to observe any new values until after a Context Synchronization event has occurred.

Between a write to the register and the next Context Synchronization event, it is CONSTRAINED UNPREDICTABLE whether software step uses the state of the PE before the write, or the state of the PE after the write.

After a Context Synchronization event, the state machine must use the state of the PE after the write.

Example D2-9 Example of synchronization and software step state machine changing states

1. Software changes MDSCR_EL1.SS from 0 to 1 when debug exceptions are enabled.
2. The PE executes some instructions.
3. A Context Synchronization event occurs.

During step 2, it is CONSTRAINED UNPREDICTABLE whether software step remains in the inactive state, as if MDSCR_EL1.SS is 0, or enters the active-pending state because MDSCR_EL1.SS is 1. If it is in the:

- Inactive state, then after the Context Synchronization event, it must enter the active-pending state.
- Active-pending state, the PE might take a Software Step exception before the Context Synchronization event.

Note

A direct write to a Special-purpose register does not require explicit synchronization.

D2.10.10 Pseudocode description of Software Step exceptions

`SSAdvance()` advances software step from the active-not-pending state to the active-pending state, by setting PSTATE.SS to 0. It is called on completing execution of each instruction.

`CheckSoftwareStep()` checks whether software step is in the active-pending state, and if it is, generates a Software Step exception. It is called before each instruction executed, regardless of Execution state, before checking for any other synchronous exceptions.

`DebugExceptionReturnSS()` returns the value to write to PSTATE.SS on an exception return or an exit from Debug state. See Entering the active-not-pending state.

These functions are defined in R-profile Architecture Pseudocode.

D2.11 Synchronization and debug exceptions

The behavior of debug depends on all of the following:

- The state of the external debug authentication interface.
- Indirect reads of:
  - External debug registers.
  - System registers, including system debug registers.
  - Special-purpose registers.

If a change is made to any of these, the effect of that change on debug exception generation cannot be relied on until after a Context Synchronization event has occurred. Similarly, the effect of the change on the software step state machine cannot be relied on until after a Context Synchronization event has occurred.

For any instructions executed between the time when the change is made and the time when the next Context Synchronization event occurs, it is CONSTRAINED UNPREDICTABLE whether debug uses the state of the PE before the change, or the state of the PE after the change.

Example D2-10 Example of synchronization and Breakpoint exception generation

1. Software changes MDSCR_EL1.MDE from 0 to 1.
2. An instruction is executed, that would cause a Breakpoint exception if self-hosted debug uses the state of the PE after the change.
3. A Context Synchronization event occurs.

In this case, it is CONSTRAINED UNPREDICTABLE whether the instruction generates a Breakpoint exception.

Example D2-11 Example of synchronization and debug exceptions generation

1. Software unlocks the OS Lock.
2. The PE executes some instructions.
3. A Context Synchronization event occurs.

During the time when the PE is executing some instructions, step 2, it is CONSTRAINED UNPREDICTABLE whether debug exceptions other than Breakpoint Instruction exceptions can be generated.

Note

Chapter D3
AArch64 Self-hosted Trace

This chapter describes the AArch64 self-hosted trace:

Introductory information:

- About self-hosted trace.
- Trace sinks.
- Register controls to enable self-hosted trace.

Prohibited regions in trace:

- Controls to prohibit trace at Exception levels.
- Self-hosted trace and visibility of virtual data.

Timestamps and Synchronization:

- Self-hosted trace timestamps.
- Synchronization in self-hosted trace.

Non-Confidential

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D3.1 About self-hosted trace

A trace unit generates trace data to describe the program flow of the PE.

The trace unit can be an implementation of any of the following:

- In Armv8, a standard Arm Embedded Trace Macrocell (ETM). See *Arm® Embedded Trace Macrocell Architecture Specification, ETMv4*.
- An IMPLEMENTATION DEFINED trace function.

If an Armv8.4-compliant PE implements an ETM Architecture trace unit that includes the ETM System register interface, FEAT_TRF must be implemented.

If any of the following are true, then Arm recommends that FEAT_TRF is implemented, but this is not mandatory:

- An Armv8.4-compliant PE implements an IMPLEMENTATION DEFINED trace unit.
- An Armv8.4-compliant PE implements an ETM Architecture trace unit but does not implement the ETM System register interface.

Self-hosted trace happens when the agent controlling the trace collection is part of the same software stack as the software being traced. The agent controls prohibited regions. The information collected by the agent is sent to a trace sink.

The trace unit and the PE must have the same view of the debug authentication interface. If FEAT_TRF is implemented, `ExternalNoninvasiveDebugEnabled`() is always TRUE.

D3.1.1 Trace sinks

The trace unit sends the trace data to a trace sink. A system might include multiple trace sinks, and allow software to configure which trace sink or sinks are used.

An example of an internal trace sink is an Embedded Trace Router (ETR), which allows software to define a buffer in memory. Trace data is written to this buffer.

In Armv8, Arm recommends that a system that includes FEAT_TRF incorporates an ETR, and follows the system architecture described by the *CoreSight Base System Architecture (CS-BSA)*.

D3.1.2 Register controls to enable self-hosted trace

If FEAT_TRF is implemented, self-hosted trace is enabled if any of the following are true:

- EDSCR.TFO == 0.
- EDSCR.TFO == 1, and `ExternalSecureNoninvasiveDebugEnabled`() == FALSE.
- EDSCR.TFO ==1, the PE executes in Secure state, and `ExternalSecureNoninvasiveDebugEnabled`() == FALSE.
- EDSCR.TFO ==1, and `ExternalRealmNoninvasiveDebugEnabled`() == FALSE.

The pseudocode function `SelfHostedTraceEnabled`() shows these rules.

If FEAT_TRF is not implemented, `SelfHostedTraceEnabled`() returns FALSE.

While `SelfHostedTraceEnabled`() is FALSE, `ExternalNoninvasiveDebugAllowed`() controls whether tracing is prohibited or allowed in each Security state.

The self-hosted trace extensions do not provide any mechanism to control software access to the trace unit external debug interface.

D3.2 Prohibited regions in self-hosted trace

Trace is not generated in prohibited regions. The pseudocode function `TraceAllowed`() indicates whether tracing is allowed in the current Security state and Exception level.

The IMPLEMENTATION DEFINED debug authentication interface can allow an external agent to disable the self-hosted trace extension.

D3.2.1 Controls to prohibit trace at Exception levels

If `SelfHostedTraceEnabled`() == TRUE, TRFCR_EL1 and TRFCR_EL2 control whether trace is prohibited at an Exception level. While `SelfHostedTraceEnabled`() == FALSE, the registers TRFCR_EL1 and TRFCR_EL2 are ignored.

If `SelfHostedTraceEnabled`() == TRUE, tracing is prohibited at EL0 if one of the following is true:

- The Effective value of HCR_EL2.TGE == 0 and TRFCR_EL1.E0TRE == 0.
- The Effective value of HCR_EL2.TGE == 1 and TRFCR_EL2.E0HTRE == 0.

If `SelfHostedTraceEnabled`() == TRUE, tracing is prohibited at EL1 if TRFCR_EL1.E1TRE == 0.

If `SelfHostedTraceEnabled`() == TRUE, tracing is prohibited at EL2 if TRFCR_EL2.E2TRE == 0.

The pseudocode `TraceAllowed()` shows the above rules.

When PMCR_EL0.X==0, no PMU events are exported to the trace unit.

PMU events are exported to the trace unit.

If `SelfHostedTraceEnabled`() == TRUE, Table D3-1 shows the prohibited regions by Exception level and state.

In the table:

TGE Means the Effective value of HCR_EL2.TGE.

P Means prohibited.

E2TRE Means prohibited if TRFCR_EL2.E2TRE == 0.

E1TRE Means prohibited if TRFCR_EL1.E1TRE == 0.

E0HTRE Means prohibited if TRFCR_EL2.E0HTRE == 0.

E0TRE Means prohibited if TRFCR_EL1.E0TRE == 0.

n/a Not applicable.

If FEAT_TRBE is not implemented, trace is allowed unless otherwise prohibited in Table D3-1.

Table D3-1 Prohibited regions

Controls		Tracing prohibited at		
State	TGE	EL2	EL1	EL0
Non-secure	0	E2TRE	E1TRE	E0TRE
	1	E2TRE	n/a	E0HTRE
Secure	0	E2TRE	E1TRE	E0TRE
	1	E2TRE	n/a	E0HTRE

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D3.2.2 Self-hosted trace and visibility of virtual data

A hypervisor can use TRFCR_EL2.CX to control visibility of CONTEXTIDR_EL2 and VSCTLR_EL2.VMID.

If `SelfHostedTraceEnabled`() == TRUE and TRFCR_EL2.CX == 0:

- The values of CONTEXTIDR_EL2 and VSCTLR_EL2.VMID are not traced.
- Comparisons between CONTEXTIDR_EL2 and VSCTLR_EL2.VMID do not match and results of comparison are not exposed through the comparators.

The trace unit can either prohibit trace for these values, or can record a CONTEXTIDR_EL2 or VSCTLR_EL2.VMID value of zero in the trace.

Non-Confidential

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D3.3 Self-hosted trace timestamps

The trace timestamp is a value that represents the passage of time in real-time. It is calculated from a counter which increments all the time, when the PE is generating trace and when the PE is in a prohibited region.

While SelfHostedTraceEnabled() == FALSE, the external trace provides the trace timestamp. If the external trace is a standard CoreSight system, the relationship between CoreSight time and the Generic Timer counter is IMPLEMENTATION DEFINED.

When SelfHostedTraceEnabled() == TRUE, the trace timestamp is one of the following:

- Physical time, which is defined by the physical count value returned by PhysicalCountInt().
- If FEAT_ECV is implemented, offset physical time, which is defined as the value of (PhysicalCountInt() - CNTPOFF_EL2).
- Virtual time, which is defined as the value of (PhysicalCountInt() - CNTVOFF_EL2). The virtual offset is always CNTVOFF_EL2, including when a read of CNTVCT_EL0 at the current Exception level would treat the virtual offset as zero.

The following fields control which counter is used for self-hosted trace:

- TRFCR_EL2.TS.
- TRFCR_EL1.TS.

The timestamp used for trace is shown in Table D3-2.

In Table D3-2, if CNTHCTL_EL2.ECV is 0 the value of physical offset is zero, otherwise the value of physical offset is the value of CNTPOFF_EL2:

Table D3-2 Timestamp used for trace.

SelfHostedTraceEnabled()	TRFCR_EL2.TS	TRFCR_EL1.TS	Timestamp traced
FALSE	xx	xx	CoreSight time
TRUE	0b00	0b01	PhysicalCountInt() - CNTVOFF_EL2
	0b00	0b10	PhysicalCountInt() - physical offset
	0b00	0b11	PhysicalCountInt()
	0b01	xx	PhysicalCountInt() - CNTVOFF_EL2
	0b10	xx	PhysicalCountInt() - physical offset
	0b11	xx	PhysicalCountInt()

Note

The counter value used for the trace timestamp is not affected by the Effective value of HCR_EL2.E2H, or whether EL2 is enabled or disabled in the current Security state.

D3.4 Synchronization in self-hosted trace

The trace unit is an indirect observer of the System registers.

While SelfHostedTraceEnabled() == TRUE, indirect reads of the trace filter control fields, TRFCR_EL1.{E1TRE, E0TRE} and TRFCR_EL2.{E2TRE, E0HTRE} are treated as indirect reads made by the instruction being traced. For these register fields, in addition to the standard requirements for synchronization of System register accesses, when a trace filter control value is changed and synchronization is not explicitly specified, one of the following occurs:

- The behavior of the PE must be consistent with the control value having the old value.
- The behavior of the PE must change the control value at a point in the simple sequential execution of the program, so that before that point, the behavior of the PE is consistent with the control value having the old value, and after that point the behavior of the PE is consistent with the control value having the new value.

If there are multiple direct writes to the register without explicit synchronization, the behavior is consistent with the writes occurring in program order.

The TSB CSYNC operation is used to ensure that a trace operation, due to a trace unit generating trace for an instruction has completed. The TSB CSYNC operation can be reordered with respect to other instructions, so must be combined with at least one Context synchronization event to ensure the operations are executed in the required order. This means that a direct write to TRFCR_EL1 or TRFCR_EL2 is guaranteed to be observed by the trace unit only after a subsequent Context synchronization event. For more information, see Trace Synchronization Barrier.

While SelfHostedTraceEnabled() == FALSE, the trace unit might impose stronger synchronization requirements.

Chapter D4
The AArch64 System Level Memory Model

This chapter provides a system level view of the general features of the memory system. It contains the following sections:

- About the memory system architecture.
- Address space.
- Mixed-endian support in AArch64.
- Cache support.
- External aborts.
- Memory barrier instructions.
- Pseudocode description of general memory System instructions.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D4.1 About the memory system architecture

The Arm architecture supports different implementation choices for the memory system microarchitecture and memory hierarchy, depending on the requirements of the system being implemented. In this respect, the memory system architecture describes a design space in which an implementation is made. The architecture does not prescribe a particular form for the memory systems. Key concepts are abstracted in a way that permits implementation choices to be made while enabling the development of common software routines that do not have to be specific to a particular microarchitectural form of the memory system. For more information about the concept of a hierarchical memory system see Memory hierarchy.

D4.1.1 Form of the memory system architecture

The R-profile architecture includes a *Virtual Memory System Architecture* (VMSA), and a *Protected Memory System Architecture* (PMSA). The AArch64 Virtual Memory System Architecture describes the AArch64 view of the VMSA. The AArch64 Protected Memory System Architecture describes the AArch64 view of the PMSA.

D4.1.2 Memory attributes

Memory types and attributes describes the memory attributes, including how different memory types have different attributes. Each location in memory has a set of memory attributes, and the translation tables define the virtual memory locations, and the attributes for each location.

Table D4-1 shows the memory attributes that are visible at the system level.

Table D4-1 Memory attribute summary

Memory type	Shareability	Cacheability
Device[a]	Outer Shareable	Non-cacheable.
Normal	One of: • Non-shareable. • Inner Shareable. • Outer Shareable.	One of[b]: • Non-cacheable. • Write-Through Cacheable. • Write-Back Cacheable.

a. Takes additional attributes, see Device memory.

b. See also Cacheability, cache allocation hints, and cache transient hints.

For more information on cacheability and shareability see Shareable Normal memory, Non-shareable Normal memory, and Caches and memory hierarchy.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D4.2 Address space

The architecture is designed to support a wide range of applications with different memory requirements. It supports a range of *physical address* (PA) sizes, and provides associated control and identification mechanisms. For more information, see Implemented physical address size.

D4.2.1 Virtual address space overflow

When a PE performs a Simple sequential execution of instructions, it calculates:

```
(address_of_current_instruction) + (size_of_executed_instruction)
```

This calculation is performed after each instruction to determine which instruction to execute next.

If the address calculation performed after executing an instruction overflows `0xFFFF_FFFF_FFFF_FFFF`, the program counter becomes UNKNOWN. Similarly, if the address calculation based on the program counter for the value of the link register or exception link register overflows `0xFFFF_FFFF_FFFF_FFFF`, then those registers also become UNKNOWN.

Note

Address tags are not propagated to the program counter, so the tag does not affect the address calculation.

Where an instruction accesses a sequential set of bytes that crosses the `0xFFFF_FFFF_FFFF_FFFF` boundary when tagged addresses are not used, or the `0xXXFF_FFFF_FFFF_FFFF` boundary when tagged addresses are used, then the virtual address accessed for the bytes above this boundary is UNKNOWN.

When tagged addresses are used, the value of the tag associated with the address also becomes UNKNOWN.

Note

The behaviors described in this section apply only for the upper bound of the upper VA range, in translation regimes that have two VA ranges. They do not apply for address calculations relating to the top of the lower VA range.

D4.3 Mixed-endian support in AArch64

A control bit, SCTLR_EL1.E0E is provided to allow the endianness of explicit data accesses made while executing at EL0 to be controlled independently of those made while executing at EL1. Table D4-2 shows the endianness of explicit data accesses and translation table walks.

Table D4-2 Endianness support

Exception level	Explicit data accesses	Stage 1 translation table walks
EL0	SCTLR_EL1.E0E	SCTLR_EL1.EE
EL1	SCTLR_EL1.EE	SCTLR_EL1.EE
EL2	SCTLR_EL2.EE	SCTLR_EL2.EE

Note

SCTLR_EL1.E0E has no effect on the endianness of the Explicit Memory Effects generated by unprivileged memory access instructions, when these are executed at EL1.

AArch64 state provides the following options for endianness support:

- All Exception levels support mixed-endianness:
  - SCTLR_ELx.EE, SCTLR_EL1.E0E, and SCTLR_EL2.E0E are RW.
- Only EL0 supports mixed-endianness and EL1and EL2 support only little-endianness:
  - SCTLR_ELx.EE is RES0, and SCTLR_EL1.E0E and SCTLR_EL2.E0E are RW.
- Only EL0 supports mixed-endianness and EL1and EL2 support only big-endianness:
  - SCTLR_ELx.EE is RES1, and SCTLR_EL1.E0E and SCTLR_EL2.E0E are RW.
- All Exception levels support only little-endianness:
  - SCTLR_ELx.EE, SCTLR_EL1.E0E, and SCTLR_EL2.E0E are RES0.
- All Exception levels support only big-endianness:
  - SCTLR_ELx.EE, SCTLR_EL1.E0E, and SCTLR_EL2.E0E are RES1.

The `BigEndian()` function determines whether the current Exception level and Execution state are using big-endian data. This function is defined in A-profile Architecture Pseudocode.

For more information about endianness in the Arm architecture see Endian support.

D4.4 Cache support

This section describes the cache identification and control mechanisms, and the A64 cache maintenance instructions, in the following sections:

- General behavior of the caches.
- Cache identification.
- Cacheability, cache allocation hints, and cache transient hints.
- Enabling and disabling the caching of memory accesses.
- Behavior of caches at reset
- Non-cacheable accesses and instruction caches.
- About cache maintenance in AArch64 state.
- A64 Cache maintenance instructions
- Data cache zero instruction.
- Cache lockdown.
- System level caches.
- Branch prediction.
- Execution, data prediction and prefetching restriction System instructions.

See also Caches.

D4.4.1 General behavior of the caches

When a memory location has a Normal Cacheable memory attribute, determining whether a copy of the memory location is held in a cache still depends on many aspects of the implementation. The following non-exhaustive list of factors might be involved:

- The size, line length, and associativity of the cache.
- The cache allocation algorithm.
- Activity by other elements of the system that can access the memory.
- Speculative instruction fetching algorithms.
- Speculative data fetching algorithms.
- Interrupt behaviors.

Given this range of factors, and the large variety of cache systems that might be implemented, the architecture cannot guarantee whether:

- A memory location present in the cache remains in the cache.
- A memory location not present in the cache is brought into the cache.

Instead, the following principles apply to the behavior of caches:

- The architecture has a concept of an entry locked down in the cache. How lockdown is achieved is IMPLEMENTATION DEFINED, and lockdown might not be supported by:
  - A particular implementation.
  - Some memory attributes.
- An unlocked entry in a cache might not remain in that cache. The architecture does not guarantee that an unlocked cache entry remains in the cache or remains incoherent with the rest of memory. Software must not assume that an unlocked item that remains in the cache remains dirty.
- A locked entry in a cache is guaranteed to remain in that cache. The architecture does not guarantee that a locked cache entry remains incoherent with the rest of memory, that is, it might not remain dirty.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

For more information, see The interaction of cache lockdown with cache maintenance instructions.

- Any memory location that has a Normal Cacheable attribute at either the current Exception level or at a higher Exception level can be allocated to a cache at any time.
- It is guaranteed that no memory location will be allocated into a Data or Unified cache if that location does not have a Normal Cacheable attribute in either:
  - The translation regime at the current Exception level.
  - The translation regime at any higher Exception level.
- For data accesses, any memory location with a Normal Inner Shareable or Normal Outer Shareable attribute is guaranteed to be coherent with all Requesters in its shareability domain.
- Any memory location is not guaranteed to remain incoherent with the rest of memory.
- The eviction of a cache entry from a cache level can overwrite memory that has been written by another observer only if the entry contains a memory location that has been written to by an observer in the shareability domain of that memory location. The maximum size of the memory that can be overwritten is called the *Cache Write-back Granule*. In some implementations the CTR_EL0 identifies the Cache Write-back Granule.
- The allocation of a memory location into a cache cannot cause the most recent value of that memory location to become invisible to an observer if it was previously visible to that observer.

Note

The Cacheability attribute of an address is determined by the applicable translation table entry for that address, as modified by any applicable System register Cacheability controls, such as the SCTLR_EL1.{I, C} controls.

For the purpose of these principles, a cache entry covers at least 16 bytes and no more than 2KB of contiguous address space, aligned to the size of the cache entry.

D4.4.2 Cache identification

The cache identification registers describe the implemented caches that are affected by cache maintenance instructions executed on the PE. This includes the cache maintenance instructions that:

- Affect the entire cache, for example IC IALLU.
- Operate by VA, for example IC IVAU.
- Operate by set/way, for example DC ISW.

The cache identification registers are:

- The Cache Type Register, CTR_EL0, that defines:
  - The minimum line length of any of the instruction caches affected by the instruction cache maintenance instructions.
  - The minimum line length of any of the data or unified caches, affected by the data cache maintenance instruction.
  - The cache indexing and tagging policy of the Level 1 instruction cache.

  Note

  It is IMPLEMENTATION DEFINED whether caches beyond the PoC will be reported by this mechanism, and because of the possible existence of system caches some caches before the PoC might not be reported. For more information about system caches see System level caches.
- A single Cache Level ID Register, CLIDR_EL1, that defines:
  - The type of cache that is implemented and can be maintained using the architected cache maintenance instructions that operate by set/way or operate on the entire cache at each cache level, up to the maximum of seven levels.
  - The *Level of Coherence* (LoC) for the caches. See Terms used in describing the cache maintenance instructions for the definition of LoC.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

  - The *Level of Unification Uniprocessor* (LoUU) for the caches. See Terms used in describing the cache maintenance instructions for the definition of LoUU.
  - An optional ICB field to indicate the boundary between the caches use for caching Inner Cacheable memory regions and those used only for caching Outer Cacheable regions.
- A single Cache Size Selection Register, CSSELR_EL1, that selects the cache level and sort of cache (Instruction, Data/Unified/Tag) of the current Cache Size Identification Register.
- For each implemented cache that is identifiable by this mechanism, across all the levels of caching, a Cache Size Identification Register, CCSIDR_EL1, that defines:
  - The number of sets, associativity and line length of the cache. See Terms used in describing the cache maintenance instructions for a definition of these terms.

Note

From Armv8.3, multiple formats of the Cache Size Identification Register are supported. For more information, see Possible formats of the Cache Size Identification Register, CCSIDR_EL1.

To determine the cache topology associated with a PE:

1. Read the Cache Type Register to find the indexing and tagging policy used for the Level 1 instruction cache. This register also provides the size of the smallest cache lines used for the instruction caches, and for the data and unified caches. These values are used in cache maintenance instructions.
2. Read the Cache Level ID Register to find what caches are implemented. The register includes seven Cache type fields, for cache levels 1 to 7. Scanning these fields, starting from Level 1, identifies the instruction, data or unified caches implemented at each level. This scan ends when it reaches a level at which no caches are defined. The Cache Level ID Register also specifies the Level of Unification (LoU) and the Level of Coherence (LoC) for the cache implementation.
3. For each cache identified at stage 2:
   - Write to the Cache Size Selection Register to select the required cache. A cache is identified by its level, and whether it is:
     - An instruction cache.
     - A data or unified cache.
   - Read the Cache Size Identification Register to find details of the cache.

D4.4.2.1 Possible formats of the Cache Size Identification Register, CCSIDR_EL1

From Armv8.3, the Cache Size Identification Register, CCSIDR_EL1 has two different formats available for defining the number of sets and associativity of the cache. For a definition of these terms, see Terms used in describing the cache maintenance instructions.

When FEAT_CCIDX is implemented:

- CCSIDR_EL1 is a 64-bit register.
- The length of the CCSIDR_EL1.Assoc field is 21 bits. This limits the associativity of the currently selected cache to 2^{21}.
- The length of the CCSIDR_EL1.NumSets field is 24 bits. This limits the number of sets in the currently selected cache to 2^{24}.

This is the 64-bit format of the Cache Size Identification Register.

When FEAT_CCIDX is not implemented:

- CCSIDR_EL1 is a 32-bit register.
- The length of the CCSIDR_EL1.Assoc field is 10 bits. This limits the associativity of the currently selected cache to 2^{10}.
- The length of the CCSIDR_EL1.NumSets field is 15 bits. This limits the number of sets in the currently selected cache to 2^{15}.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

This is the 32-bit format of the Cache Size Identification Register.

When one of these formats is implemented, it is implemented across all the levels of caching.

D4.4.3 Cacheability, cache allocation hints, and cache transient hints

Cacheability applies only to Normal memory, and can be defined independently for Inner and Outer cache locations. All types of Device memory are always treated as Non-cacheable.

As described in Memory types and attributes, the memory attributes include a cacheability attribute that is one of:

- Non-cacheable.
- Write-Through cacheable.
- Write-Back cacheable.

Cacheability attributes other than Non-cacheable can be complemented by a *cache allocation hint*. This is an indication to the memory system of whether allocating a value to a cache is likely to improve performance. In addition, it is IMPLEMENTATION DEFINED whether a *cache transient hint* is supported, see Transient cacheability hint.

The cache allocation hints are assigned independently for read and write accesses, and therefore when the Transient hint is supported the following cache allocation hints can be assigned:

For read accesses: Read-Allocate, Transient Read-Allocate, or No Read-Allocate.

For write accesses: Write-Allocate, Transient Write-Allocate, or No Write-Allocate.

Note

- A Cacheable location with both No Read-Allocate and No Write-Allocate hints is not the same as a Non-cacheable location. A Non-cacheable location has coherency guarantees for all observers within the system that do not apply for a location that is Cacheable, No Read-Allocate, No Write-Allocate.
- Implementations can use the cache allocation hints to limit cache pollution to a part of a cache, such as to a subset of ways.
- For VMSAv8-64 translation table walks, the TCR_EL1.{IRGN*n*, ORGN*n*} fields define the memory attributes of the translation tables, including the cacheability. However, this assignment supports only a subset of the cacheability attributes described in this section.

The architecture does not require an implementation to make any use of cache allocation hints. This means an implementation might not make any distinction between memory locations with attributes that differ only in their cache allocation hint.

D4.4.3.1 Transient cacheability hint

In Armv8, it is IMPLEMENTATION DEFINED whether a Transient hint is supported. In an implementation that supports the Transient hint, the Transient hint is a qualifier of the cache allocation hints, and indicates that the benefit of caching is for a relatively short period. It indicates that it might be better to restrict allocation of transient entries, to avoid possibly casting-out other, less transient, entries.

Note

The architecture does not specify what is meant by a *relatively short period*.

The description of the AArch64 MAIR_EL1, MAIR_EL2 registers, includes the assignment of the Transient hint in an implementation that supports this option. In this assignment:

- The Transient hint is defined independently for Inner Cacheable and Outer Cacheable memory regions.
- A single Transient hint applies to both read and write accesses to a memory region.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D4.4.4 Enabling and disabling the caching of memory accesses

Cacheability control fields can force all memory locations with the Normal memory type to be treated as Non-cacheable, regardless of their assigned Cacheability attribute. Independent controls are provided for each stage of address translation, with separate controls for:

- Data accesses. These controls also apply to accesses to the translation tables.
- Instruction accesses.

Note

These Cacheability controls replace the cache enable controls provided in previous versions of the Arm architecture.

The Cacheability control fields and their effects are as follows:

For the EL1&0 translation regime

- When the value of SCTLR_EL1.C is 0:
  - All stage 1 translations for data accesses to Normal memory are Non-cacheable.
  - All accesses to the EL1&0 stage 1 translation tables are Non-cacheable.
- When the value of SCTLR_EL1.I is 0:
  - All stage 1 translations for instruction accesses to Normal memory are Non-cacheable.
- When the value of HCR_EL2.CD is 1 all stage 2 translations for data accesses to Normal memory are Non-cacheable.
- When the value of HCR_EL2.ID is 1 all stage 2 translations for instruction accesses to Normal memory are Non-cacheable.
- When the value of HCR_EL2.DC is 1, all stage 1 translations and all accesses to the EL1&0 stage 1 translation tables, are treated as accesses to Normal Non-shareable Inner Write-Back Cacheable Read-Allocate Write-Allocate, Outer Write-Back Cacheable Read-Allocate Write-Allocate memory, regardless of the value of SCTLR_EL1.{I, C}. This applies to translations for both data and instruction accesses.
- The stage 1 and stage 2 cacheability attributes are combined as described in Combining stage 1 and stage 2 Cacheability attributes for Normal memory.
- The SCTLR_EL1.{C, I} and HCR_EL2.DC fields have no effect on the EL2 translation regimes.
- The HCR_EL2.{ID, CD} fields affect only stage 2 of the EL1&0 translation regime.

D4.4.5 Behavior of caches at reset

The behavior of caches at reset is as follows:

- All caches reset to IMPLEMENTATION DEFINED states that might be UNKNOWN.
- The Cacheability control fields described in Enabling and disabling the caching of memory accesses reset to values that force all memory locations to be treated as Non-cacheable.

  Note

  This applies only to the controls that apply to the Translation regime that is used by the Exception level and Security state entered on reset.

- An implementation can require the use of a specific cache initialization routine to invalidate its storage array before caching is enabled. The exact form of any required initialization routine is IMPLEMENTATION DEFINED, and the routine must be documented clearly as part of the documentation of the device.
- If an implementation permits cache hits when the Cacheability control fields force all memory locations to be treated as Non-cacheable then the cache initialization routine must:
  - Provide a mechanism to ensure the correct initialization of the caches.
  - Be documented clearly as part of the documentation of the device.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

In particular, if an implementation permits cache hits when the Cacheability controls force all memory locations to be treated as Non-cacheable, and the cache contents are not invalidated at reset, the initialization routine must avoid any possibility of running from an uninitialized cache. It is acceptable for an initialization routine to require a fixed instruction sequence to be placed in a restricted range of memory.

- Arm recommends that whenever an invalidation routine is required, it is based on the cache maintenance instructions.

See also TLB behavior at reset.

D4.4.6 Non-cacheable accesses and instruction caches

In AArch64 state, instruction accesses to Non-cacheable Normal memory can be held in instruction caches.

Correspondingly, the sequence for ensuring that modifications to instructions are available for execution must include invalidation of the modified locations from the instruction cache, even if the instructions are held in Normal Non-cacheable memory. This includes cases where System register Cacheability control fields force instruction accesses to memory to be Non-cacheable.

Therefore when using self-modified code in Non-cacheable space in a uniprocessor system, the following sequence is required:

```
; Enter this code with <Wt> containing the new 32-bit instruction
; to be held at a location pointed to by <Xn> in Normal Non-cacheable memory.
STR <Wt>, [Xn]
DSB ISH; Ensure visibility of the data stored
IC IVAU, [Xn] ; Invalidate instruction cache by VA to PoU
DSB ISH; Ensure completion of the invalidations
ISB ;
```

In a multiprocessor system, the IC IVAU for a non-cacheable location is broadcast to all PEs within the Inner Shareable domain of the PE running this sequence. This is despite non-cacheable normal memory locations being treated as Outer Shared in other parts of the architecture.

Additional software steps might be required to synchronize the threads with other PEs. This might be necessary so that the PEs executing the modified instructions can execute an `ISB` after completing the invalidation, and to avoid issues associated with concurrent modification and execution of instruction sequences. See also Concurrent modification and execution of instructions and Concurrent modification and execution of instructions.

Larger blocks of instructions can be modified using the IC IALLU instruction for a uniprocessor system, or an IC IALLUIS for a multiprocessor system.

Note

This section applies even when the Cacheability control fields force instruction accesses to memory in AArch64 state to be Non-cacheable, as described in Enabling and disabling the caching of memory accesses.

D4.4.7 About cache maintenance in AArch64 state

The following sections give general information about cache maintenance:

- Terms used in describing the cache maintenance instructions.
- Abstraction of the cache hierarchy.

The following sections describe the A64 cache maintenance instructions:

- The instruction cache maintenance instruction (IC).
- The data cache maintenance instruction (DC).

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

Some descriptions of the cache maintenance instructions refer to the cacheability of the address on which the instruction operates. The Cacheability of an address is determined by the applicable translation table entry for that address, as modified by any applicable System register Cacheability controls, such as the SCTLR_EL1.{I, C} controls.

D4.4.7.1 Terms used in describing the cache maintenance instructions

A *memory location* is a byte that is associated with an address in a particular address space. For example, address `0x1000` in the Physical address space is a different memory location from address `0x1000` in the Secure physical address space.

The term *Resource* means a physical entity that can be accessed at one or more memory locations. A Resource *associated with* a physical address space is accessible in that physical address space.

Note

An example of a Resource is a byte of memory that can be accessible at a fixed address but in different physical address spaces, determined by a configuration option.

Cache maintenance instructions are defined to act on particular memory locations. Depending on the instruction type, the scope is defined as one of:

- By the virtual address of the memory location to be maintained, referred to as operating *by VA*.
- By the physical address of the memory location to be maintained, referred to as operating *by PA*.
- By a mechanism that describes the location in the hardware of the cache, referred to as operating *by set/way*.

In addition, for instruction caches, there are instructions that invalidate all entries.

The following subsections define the terms used in the descriptions of the cache maintenance instructions:

- Terminology for cache maintenance instructions operating by set/way.
- Terminology for Clean, Invalidate, and Clean and Invalidate instructions.

Note

There is no terminology specific to cache maintenance instructions that operate by VA. When all applicable stages of translation are disabled, the VA used is identical to the PA. For more information about memory system behavior when address translation is disabled, see The effects of disabling an address translation stage.

D4.4.7.1.1 Terminology for cache maintenance instructions operating by set/way

Cache maintenance instruction that operate by set/way refer to the particular structures in a cache. Three parameters describe the location in a cache hierarchy that an instruction works on. These parameters are:

Level The cache level of the hierarchy. The number of levels of cache is IMPLEMENTATION DEFINED. The cache levels that can be managed using the architected cache maintenance instructions that operate by set/way can be determined from the CLIDR_EL1.

In the Arm architecture, the lower numbered cache levels are those closest to the PE. See Memory hierarchy.

Set Each level of a cache is split up into a number of *sets*. Each set is a set of locations in a cache level to which an address can be assigned. Usually, the set number is an IMPLEMENTATION DEFINED function of an address.

In the Arm architecture, sets are numbered from 0.

Way The associativity of a cache is the number of locations in a set to which a specific address can be assigned. The *way* number specifies one of these locations.

In the Arm architecture, ways are numbered from 0.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

Because the allocation of a memory address to a cache location is entirely IMPLEMENTATION DEFINED, Arm expects that most portable software will use only the cache maintenance instructions by set/way as single steps in a routine to perform maintenance on the entire cache.

D4.4.7.1.2 Terminology for Clean, Invalidate, and Clean and Invalidate instructions

Caches introduce coherency problems in two possible directions:

1. An update to a memory location by a PE that accesses a cache might not be visible to other observers that can access memory. This can occur because new updates are still in the cache and are not visible yet to the other observers that do not access that cache.
2. Updates to memory locations by other observers that can access memory might not be visible to a PE that accesses a cache. This can occur when the cache contains an old, or *stale*, copy of the memory location that has been updated.

The *Clean* and *Invalidate* instructions address these two issues. The definitions of these instructions are:

Clean A cache clean instruction ensures that updates made by an observer that controls the cache are made visible to other observers that can access memory at the point to which the instruction is performed. Once the Clean has completed, the new memory values are guaranteed to be visible to the point to which the instruction is performed, for example to the Point of Unification.

The cleaning of a cache entry from a cache can overwrite memory that has been written by another observer only if the entry contains a location that has been written to by an observer in the shareability domain of that memory location.

Invalidate A cache invalidate instruction ensures that updates made visible by observers that access memory at the point to which the invalidate is defined, are made visible to an observer that controls the cache. This might result in the loss of updates to the locations affected by the invalidate instruction that have been written by observers that access the cache, if those updates have not been cleaned from the cache since they were made.

If the address of an entry on which the invalidate instruction operates is Normal, Non-cacheable or any type of Device memory then an invalidate instruction also ensures that this address is not present in the cache.

Note

Entries for addresses that are Normal Cacheable can be allocated to the cache at any time, and so the cache invalidate instruction cannot ensure that the address is not present in a cache.

Clean and Invalidate

A cache *clean and invalidate* instruction behaves as the execution of a clean instruction followed immediately by an invalidate instruction. Both instructions are performed to the same location.

The points to which a cache maintenance instruction can be defined differ depending on whether the instruction operates by VA or by set/way:

- For instructions operating by set/way, the point is defined to be to the next level of caching. For the All operations, the point is defined as the Point of Unification for each location held in the cache.
- For instructions operating by VA, the following conceptual points are defined:

Point of Coherency (PoC)

The point at which all agents that can access memory are guaranteed to see the same copy of a memory location for accesses of any memory type or cacheability attribute. In many cases this is effectively the main system memory, although the architecture does not prohibit the implementation of caches beyond the PoC that have no effect on the coherency between memory system agents.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

The presence of system caches can affect the determination of the Point of Coherency as described in System level caches.

Point of Unification (PoU)

The PoU for a PE is the point by which the instruction and data caches and the translation table walks of that PE are guaranteed to see the same copy of a memory location. In many cases, the Point of Unification is the point in a uniprocessor memory system by which the instruction and data caches and the translation table walks have merged.

The PoU for an Inner Shareable shareability domain is the point by which the instruction and data caches and the translation table walks of all the PEs in that Inner Shareable shareability domain are guaranteed to see the same copy of a memory location. Defining this point permits self-modifying software to ensure future instruction fetches are associated with the modified version of the software by using the standard correctness policy of:

1. Clean data cache entry by address.
2. Invalidate instruction cache entry by address.

Point of Persistence (PoP)

When FEAT_DPB is implemented: The point in a memory system, if it exists, at or beyond the Point of Coherency, where a write to memory is maintained when system power is removed, and reliably recovered when power is restored to the affected locations in memory.

When FEAT_DPB and FEAT_DPB2 are implemented: The point in a memory system where there is a system guarantee that there is sufficient energy within the system to ensure that a write to memory will be persistent if system power is removed.

Note

Such memory is sometimes called non-volatile memory. For example, the Storage-class memory shown in Figure B1-3 could be used as target memory for this feature.

Point of Deep Persistence (PoDP) The point in a memory system where any writes that have reached that point are persistent, even in the event of an instantaneous hardware failure of the power system.

The following fields in the CLIDR_EL1 relate to the PoC and PoU:

LoC, Level of Coherence

This field defines the last level of cache that must be cleaned or invalidated when cleaning or invalidating to the Point of Coherency. The LoC value is a cache level, so, for example, if LoC contains the value 3:

- A clean to the Point of Coherency operation requires the level 1, level 2 and level 3 caches to be cleaned.
- Level 4 cache is the first level that does not have to be maintained.

If the LoC field value is `0x0`, this means that no levels of cache need to cleaned or invalidated when cleaning or invalidating to the Point of Coherency.

If the LoC field value is a nonzero value that corresponds to a level that is not implemented, this indicates that all implemented caches are before the Point of Coherency.

LoUU, Level of Unification, uniprocessor

This field defines the last level of data cache that must be cleaned, or the last level of instruction cache that must be invalidated, when cleaning or invalidating to the Point of Unification for the PE. As with LoC, the LoUU value is a cache level.

If the LoUU field value is `0x0`, this means that no levels of data cache need to be cleaned or invalidated when cleaning or invalidating to the Point of Unification.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

If the LoUU field value is a nonzero value that corresponds to a level that is not implemented, this indicates that all implemented caches are before the Point of Unification.

LoUIS, Level of Unification, Inner Shareable

In any implementation:

- This field defines the last level of data or unified cache that must be cleaned, or the last level of instruction or unified cache that must be invalidated, when cleaning or invalidating to the Point of Unification for the Inner Shareable shareability domain. As with LoC, the LoUIS value is a cache level.
- If the LoUIS field value is `0x0`, this means that no levels of data or unified cache need to cleaned or invalidated when cleaning or invalidating to the Point of Unification for the Inner Shareable shareability domain.
- If the LoUIS field value is a nonzero value that corresponds to a level that is not implemented, this indicates that all implemented caches are before the Point of Unification.

D4.4.7.2 Abstraction of the cache hierarchy

The following subsections describe the abstraction of the cache hierarchy:

- Cache maintenance instructions that operate by VA.
- Cache maintenance instructions that operate by set/way.

D4.4.7.2.1 Cache maintenance instructions that operate by VA

The VA-based cache maintenance instructions are described as operating by VA. Each of these instructions is always qualified as being one of:

- Performed to the Point of Coherency.
- Performed to the Point of Unification.
- When FEAT_DPB is implemented, performed to the Point of Persistence.
- When FEAT_PoPS is implemented, performed to the Point of Physical Storage.

See Terms used in describing the cache maintenance instructions for definitions of these terms, and for more information about possible meanings of VA.

A64 Cache maintenance instructions lists the VA-based maintenance instructions.

The CTR_EL0 holds minimum line length values for:

- The instruction caches.
- The data and unified caches.

These values support efficient invalidation of a range of VAs, because this value is the most efficient address stride to use to apply a sequence of VA-based maintenance instructions to a range of VAs.

For the Invalidate data or unified cache line by VA instruction, the Cache Write-back Granule field of the CTR_EL0 defines the maximum granule that a single invalidate instruction can invalidate. This meaning of the Cache Write-back Granule is in addition to its defining the maximum size that can be written back.

D4.4.7.2.2 Cache maintenance instructions that operate by set/way

A64 Cache maintenance instructions lists the set/way-based maintenance instructions. Some encodings of these instructions include a required field that specifies the cache level for the instruction:

- A clean instruction cleans from the level of cache specified through to at least the next level of cache, moving further from the PE.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- An invalidate instruction invalidates only at the level specified.

D4.4.8 A64 Cache maintenance instructions

The A64 cache maintenance instructions are part of the A64 System instruction class in the register encoding space. For encoding details and other general information on these System instructions, see System instructions, SYS and Cache maintenance instructions, and data cache zero operations.

The following subsections give more information about these instructions:

- The instruction cache maintenance instruction (IC).
- The data cache maintenance instruction (DC).
- EL0 accessibility of cache maintenance instructions.
- General requirements for the scope of maintenance instructions.
- Effects of instructions that operate by VA to the PoC.
- Effects of instructions that operate by VA to the PoP.
- Effects of instructions that operate by VA to the PoPS.
- Effects of instructions that operate by VA to the PoU.
- Effects of All and set/way maintenance instructions.
- Effects of virtualization and Security state on the cache maintenance instructions.
- Boundary conditions for cache maintenance instructions.
- Ordering and completion of data and instruction cache instructions.
- Performing cache maintenance instructions.

D4.4.8.1 The instruction cache maintenance instruction (`IC`)

System instructions describes the A64 assembly syntax for this instruction.

When an `IC` instruction requires an address argument this takes the form of a 64-bit register that holds the VA argument. No alignment restrictions apply for this address.

Any cache maintenance instruction operating by VA includes as part of any required VA to PA translation:

- For an instruction executed at EL1, or at EL2 when the Effective value of HCR_EL2.E2H is 1, the current ASID.
- The current Security state.
- Whether the instruction was executed at EL1 or EL2.
- For an instruction executed at EL1, the current VMID.

That VA to PA translation might fault. However, for an instruction cache maintenance instruction that operates by VA:

- It is IMPLEMENTATION DEFINED whether the instruction can generate:
  - An Access flag fault.
  - A Translation fault.
- The instruction cannot generate a Permission fault, except for the possible generation of a Permission fault by the execution of an IC IVAU instruction at EL0 when the specified address does not have read access at EL0, as described in EL0 accessibility of cache maintenance instructions.

For more information about possible faults on a cache maintenance instruction that operates by VA, see Memory aborts.

See also Ordering and completion of data and instruction cache instructions.

If CTR_EL0.DIC is 1, then it is IMPLEMENTATION DEFINED whether each of the IC instructions is treated as a `NOP`.

If an IC instruction that operates by VA is treated as a `NOP`, it does not perform translation and all the following apply:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- No MMU faults can be generated.
- If hardware update of AF is enabled, AF is not required to be set.

If an IC instruction is treated as a NOP, then it is IMPLEMENTATION DEFINED whether the execution of the instruction can be trapped.

D4.4.8.2 The data cache maintenance instruction (DC)

System instructions describes the A64 assembly syntax for this instruction.

When a DC instruction requires a set/way/level argument this takes the form of a 64-bit register, the upper 32 bits of which are RES0.

If a data cache maintenance by set/way instruction specifies a set, way, or level argument that is larger than the value supported by the implementation then the instruction is CONSTRAINED UNPREDICTABLE, see Out of range values of the Set/Way/Index fields in cache maintenance instructions or the instruction description.

When a DC instruction requires an address argument this takes the form of a 64-bit register that holds the VA argument. No alignment restrictions apply for this address.

Any cache maintenance instruction operating by VA includes as part of any required VA to PA translation:

- For an instruction executed at EL1, or at EL2 when the Effective value of HCR_EL2.E2H is 1, the current ASID.
- The current Security state.
- Whether the instruction is executed at EL1 or EL2.
- For an instruction executed at EL1, the current VMID.

That VA to PA translation might fault. However, a data or unified cache maintenance instruction that operates by VA cannot generate a Permission fault except in the following cases:

- The possible generation of a Permission fault by:
  - The execution of a DC IVAC instruction when the specified address does not have write permission.
  - The execution of an enabled DC instruction at EL0 when the specified address does not have read access at EL0, as described in EL0 accessibility of cache maintenance instructions.

  The description of Permission faults includes possible constraints on the generation of Permission faults on cache maintenance by VA instructions.

For more information about possible faults on a VA to PA translation, see Memory aborts.

When executed at EL1, a DC ISW instruction performs a clean and invalidate, meaning it performs the same maintenance as a DC CISW instruction, if all of the following apply:

- EL2 is implemented and enabled in the current Security state.
- Either:
  - The value of HCR_EL2.SWIO is 1, forcing a cache clean to perform a clean and invalidate.
  - The value of HCR_EL2.VM is 1, meaning EL1&0 stage two address translation is enabled.

When executed at EL1, a DC IVAC instruction performs a clean and invalidate, meaning it performs the same maintenance as a DC CIVAC instruction, if all of the following apply:

- EL2 is implemented and enabled in the current Security state.
- The value of HCR_EL2.VM is 1, meaning EL1&0 stage two address translation is enabled.

When FEAT_DPB is implemented, meaning the DC CVAP instruction is implemented, if the memory system does not support the Point of Persistence, a data cache clean to the PoP, DC CVAP, behaves as a data cache clean to the PoC, DC CVAC.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

- Support for the Point of Persistence does not change the definition or behavior of the CLIDR_EL1 System register.
- Because a `DSB SYS` instruction will not complete until all previous DC CVAP instructions have completed, the following sequence can be used to ensure the completion of any store to the Point of Persistence, where the store might be to Non-cacheable memory:

```
DMB            ; Note this can be any DMB that applies to both loads and stores
DC CVAP, Xt
DSB SYS
```

- If caches that are invisible to the programmer exist beyond the Point of Coherency but before the Point of Persistence and hold data that is marked as Non-cacheable, the DC CVAP operation causes the Non-cacheable locations to be cleaned from those caches.

If there are caches after the Point of Coherency and FEAT_PoPS is not implemented, then the DC CIVAC and DC CIGDVAC instructions are not sufficient to remove all copies of a poisoned Location and it is IMPLEMENTATION DEFINED whether any IMPLEMENTATION DEFINED mechanism exists to remove poison from a Location.

See Clearing Deferred errors from poisoned Locations for more information on removing poison from a Location.

If a memory fault that sets the FAR for the translation regime applicable for the cache maintenance instruction is generated from a data cache maintenance instruction, the FAR holds the address specified in the register argument of the instruction.

See also EL0 accessibility of cache maintenance instructions and Ordering and completion of data and instruction cache instructions.

For all the following DC instructions, it is IMPLEMENTATION DEFINED whether the instruction is treated as a `NOP`:

- A DC to the PoU and the LoUIS and LoUU are 0.
- A DC to the PoC and the LoC is 0.
- A DC to the PoP and the memory system does not support the Point of Persistence, and the LoC is 0.
- A DC to the PoDP and the memory system does not support the Point of Deep Persistence, and does not support the Point of Persistence, and the LoC is 0.

If a DC instruction that operates by VA is treated as a `NOP`, it does not perform translation and all the following apply:

- No MMU or MPU faults can be generated.
- If hardware update of AF is enabled, AF is not required to be set.

If a DC instruction is treated as a `NOP`, then it is IMPLEMENTATION DEFINED whether the execution of the instruction can be trapped.

D4.4.8.3 EL0 accessibility of cache maintenance instructions

Software executing at EL0 can access data cache maintenance instructions and instruction cache maintenance instructions that operate by virtual address. When EL0 use of these instructions is disabled because SCTLR_EL1.UCI is 0, executing one of these instructions at EL0 generates a trap to EL1, which is reported using EC = `0x18`.

Note

DC CVAP is implemented only if FEAT_DPB is implemented.

For these instructions read access permission for the virtual address is required. When the value of SCTLR_EL1.UCI is 1:

- If the `DC` instruction is executed at EL0 and the address specified in the argument cannot be read at EL0, a Permission fault might be generated.
- For the IC IVAU instruction, if the instruction is executed at EL0 and the address specified in the argument cannot be read at EL0, it is IMPLEMENTATION DEFINED whether a Permission fault is generated.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

For more information, see the description of Permission faults, In the case of a DC instruction executed at EL0 when the address specified cannot be read at EL0 the Permission fault is generated unless one of the permitted constraints described in that section applies and means the fault cannot be generated.

Software can read the CTR_EL0 to discover the stride needed for cache maintenance instructions. The SCTLR_EL1.UCT bit enables EL0 access to the CTR_EL0. When EL0 access to the Cache Type register is disabled, a register access instruction executed at EL0 is trapped to EL1 using EC = 0x18.

D4.4.8.4 General requirements for the scope of maintenance instructions

The specification of the cache maintenance instructions describes what each instruction is guaranteed to do in a system. It does not limit other behaviors that might occur, provided they are consistent with the requirements described in General behavior of the caches, Behavior of caches at reset, and Prefetching into cache.

This means that as a side-effect of a cache maintenance instruction:

- Any location in the cache might be cleaned.
- Any unlocked location in the cache might be cleaned and invalidated.

Note

Arm recommends that, for best performance, such side-effects are kept to a minimum. Arm strongly recommends that the side-effects of operations performed in one Security state do not have a significant performance impact on execution in another Security state.

If an implementation can overwrite Allocation Tags in memory that have been written by another observer, where the Allocation Tags have not been written by an observer in the Shareability domain of that memory location, then:

- A cache maintenance operation which cleans data from a cache level must also clean the associated Allocation Tags.
- A cache maintenance operation which invalidates, or cleans and invalidates data from a cache level, must also clean and invalidate the associated Allocation Tags.

D4.4.8.5 Effects of instructions that operate by VA to the PoC

For Normal memory that is not Inner Non-cacheable, Outer Non-cacheable, cache maintenance instructions that operate by VA to the PoC affect the caches of other PEs in the shareability domain described by the shareability attributes of the VA supplied with the instruction.

For Device memory or Normal memory that is Inner Non-cacheable, Outer Non-cacheable, these instructions affect the caches of all PEs in the Outer Shareable shareability domain of the PE on which the instructions are operating.

In all cases, for any affected PE, these instructions affect all data and unified caches to the PoC. Table D4-3 shows the scope of these Data and unified cache maintenance instructions.

Table D4-3 PEs affected by cache maintenance instructions to the PoC

Shareability	PEs affected	Effective to
Non-shareable	The PE executing the instruction	The PoC of the entire system
Inner Shareable	All PEs in the same Inner Shareable shareability domain as the PE executing the instruction	The PoC of the entire system
Outer Shareable	All PEs in the same Outer Shareable shareability domain as the PE executing the instruction	The PoC of the entire system

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

It is IMPLEMENTATION DEFINED by the system whether the cache maintenance instructions have an effect on the caches of observers that are not PEs within the affected shareability domain to which the cache maintenance instructions apply.

D4.4.8.6 Effects of instructions that operate by VA to the PoP

For Normal memory that is not Inner Non-cacheable, Outer Non-cacheable, cache maintenance instructions that operate by VA to the PoP affect the caches of other PEs in the shareability domain described by the shareability attributes of the VA supplied with the instruction.

For Device memory or Normal memory that is Inner Non-cacheable, Outer Non-cacheable, these instructions affect the caches of all PEs in the Outer Shareable shareability domain of the PE on which the instructions are operating.

In all cases, for any affected PE, these instructions affect all data and unified caches to the PoP. Table D4-4 shows the scope of these Data and unified cache maintenance to the PoP instructions.

Table D4-4 PEs affected by cache maintenance instructions to the PoP

Shareability	PEs affected	Effective to
Non-shareable	The PE executing the instruction	The PoP of the entire system
Inner Shareable	All PEs in the same Inner Shareable shareability domain as the PE executing the instruction	The PoP of the entire system
Outer Shareable	All PEs in the same Outer Shareable shareability domain as the PE executing the instruction	The PoP of the entire system

Note

It is IMPLEMENTATION DEFINED by the system whether the cache maintenance instructions have an effect on the caches of observers that are not PEs within the affected shareability domain to which the cache maintenance instructions apply.

D4.4.8.7 Effects of instructions that operate by VA to the PoPS

For Normal memory that is not Inner Non-cacheable, Outer Non-cacheable, cache maintenance instructions that operate by VA to the PoPS affect the caches of other PEs in the shareability domain described by the shareability attributes of the VA supplied with the instruction.

For Device memory or Normal memory that is Inner Non-cacheable, Outer Non-cacheable, these instructions affect the caches of all PEs in the Outer Shareable shareability domain of the PE on which the instructions are operating.

In all cases, for any affected PE, these instructions affect all data and unified caches to the PoPS. Table D4-5 shows the scope of these Data and unified cache maintenance to the PoPS instructions.

Table D4-5 PEs affected by cache maintenance instructions to the PoPS

Shareability	PEs affected	Effective to
Non-shareable	The PE executing the instruction.	The PoPS of the entire system.
Inner Shareable	All PEs in the same Inner Shareable shareability domain as the PE executing the instruction.	The PoPS of the entire system.
Outer Shareable	All PEs in the same Outer Shareable shareability domain as the PE executing the instruction.	The PoPS of the entire system.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

It is IMPLEMENTATION DEFINED by the system whether the cache maintenance instructions have an effect on the caches of observers that are not PEs within the affected shareability domain to which the cache maintenance instructions apply.

D4.4.8.8 Effects of instructions that operate by VA to the PoU

For cache maintenance instructions that operate by VA to the PoU, Table D4-6 shows how, for a VA in a Normal or Device memory location, the shareability attribute of the VA determines the minimum set of PEs affected, and the point to which the instruction must be effective.

Table D4-6 PEs affected by cache maintenance instructions to the PoU

Shareability	PEs affected	Effective to
Non-shareable	The PE executing the instruction	The PoU of instruction cache fills, data cache fills and write-backs, and translation table walks, on the PE executing the instruction
Inner Shareable or Outer Shareable	All PEs in the same Inner Shareable shareability domain as the PE executing the instruction	The PoU of instruction cache fills, data cache fills and write-backs, and translation table walks, of all PEs in the same Inner Shareable shareability domain as the PE executing the instruction

Note

- The set of PEs guaranteed to be affected is never greater than the PEs in the Inner Shareable shareability domain containing the PE executing the instruction.
- It is IMPLEMENTATION DEFINED by the system whether the cache maintenance instructions have an effect on the caches of observers that are not PEs within the affected shareability domain to which the cache maintenance instructions apply.

D4.4.8.9 Effects of All and set/way maintenance instructions

The DC set/way instructions apply only to the caches of the PE that performs the instruction. IC IALLU instructions apply only to the caches of the PE that performs the instruction, unless HCR_EL2.FB=1, which causes the instructions to be broadcast within the Inner Shareable domain when executed from EL1.

The IC IALLUIS instruction can affect the caches of all PEs in the same Inner Shareable shareability domain as the PE that performs the instruction. This instruction has an effect to the Point of Unification of instruction cache fills, data cache fills, and write-backs, and translation table walks, of all PEs in the same Inner Shareable shareability domain.

Note

- The possible presence of system caches, as described in System level caches, means architecture does not guarantee that all levels of the cache can be maintained using set/way instructions.
- It is IMPLEMENTATION DEFINED by the system whether the cache maintenance instructions have an effect on the caches of observers that are not PEs within the affected shareability domain to which the cache maintenance instructions apply.

D4.4.8.10 Effects of virtualization and Security state on the cache maintenance instructions

Each Security state has its own physical address (PA) space, therefore cache entries are associated with PA space.

Table D4-7 shows the effects of virtualization and security on the cache maintenance instructions. In the table, the *Specified entries* are entries that the architecture requires the instruction to affect.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

The rules described in General behavior of the caches mean that an instruction might also affect other entries.

Table D4-7 Effects of virtualization and security on the maintenance instructions

Cache maintenance instructions	Security state	Specified entries
Data or unified cache maintenance instructions		
Invalidate, Clean, or Clean and Invalidate by VA: DC IVAC, DC CVAC, DC CVAP, DC CVAU, DC CIVAC, DC CVAP	Non-secure and Secure.	All lines that hold the PA that, in the current Security state, is mapped to by the combination of all of : • The specified VA. • For an instruction executed at EL0 the current VMID.[a]
Invalidate, Clean, or Clean and Invalidate by set/way: DC ISW, DC CSW, DCCISW	Non-secure	Line specified by set/way provided that the entry comes from the Non-secure PA space.
	Secure	Line specified by set/way provided that the entry comes from the Secure or Non-secure PA space.
Instruction cache maintenance instructions		
Invalidate by VA: IC IVAU	Non-secure and Secure.	All lines corresponding to the specified VA[b] in the current translation regime and: • For an instruction executed at EL0 the current VMID.[a]
Invalidate All: IC IALLU, IC IALLUIS	Non-secure and Secure.	For an instruction executed at: • EL1 all instruction cache lines containing Secure or Non-secure entries associated with the current VMID. • EL2 all instruction cache lines containing Non-secure entries.

a. Dependencies on the VMID apply even when HCR_EL2.VM is set to 0. The architecture does not define a reset value for VTTBR_EL2.VMID, and therefore, in any implementation that includes EL2, the boot software executed when reset is deasserted must initialize VTTBR_EL2.VMID.

b. The type of instruction cache used affects the interpretation of the specified entries in this table such that:

- For a PIPT instruction cache, the cache maintenance applies to all entries whose physical address corresponds to the specified address.
- For a VIPT instruction cache, the cache maintenance applies to entries whose virtual index and physical tag corresponds to the specified address.

For information on types of instruction cache see Instruction caches.

For locked entries and entries that might be locked, the behavior of cache maintenance instructions described in The interaction of cache lockdown with cache maintenance instructions applies.

With an implementation that generates aborts if entries are locked or might be locked in the cache, when the use of lockdown aborts is enabled, these aborts can occur on any cache maintenance instructions.

In an implementation that includes EL2:

- The architecture does not require cache cleaning when switching between virtual machines. Cache invalidation by set/way must not present an opportunity for one virtual machine to corrupt state associated with a second virtual machine. To ensure this requirement is met, invalidate by set/way instructions can, instead, perform a clean and invalidate by set/way.
- As described in The data cache maintenance instruction (DC), the AArch64 Data cache invalidate instructions, DC IVAC and DC ISW, when executed at EL1 and EL0,
  can be configured to perform a cache clean as well as a cache invalidation.
- TLB invalidate instructions and IC IALLU instructions executed at EL1 are broadcast across the Inner Shareable domain when all of the following are true:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

— EL2 is implemented and enabled in the current Security state.
— The value of HCR_EL2.FB is 1.

For more information about the cache maintenance instructions, see About cache maintenance in AArch64 state, A64 Cache maintenance instructions, and The AArch64 Virtual Memory System Architecture.

D4.4.8.11 Boundary conditions for cache maintenance instructions

Cache maintenance instructions operate on the caches regardless of whether the System register Cacheability controls force all memory accesses to be Non-cacheable.

For VA-based cache maintenance instructions, the instruction operates on the caches regardless of the memory type and cacheability attributes marked for the memory address in the VMSA translation table entries. This means that the effects of the cache maintenance instructions can apply regardless of:

- Whether the address accessed:
  — Is Normal memory or Device memory.
  — Has the Cacheable attribute or the Non-cacheable attribute.
- Any applicable domain control of the address accessed.
- The access permissions for the address accessed, other than the effect of the stage two write permission on data or unified cache invalidation instructions.

D4.4.8.12 Ordering and completion of data and instruction cache instructions

All data cache instructions, other than DC ZVA that specify an address:

- Execute in program order relative to loads or stores that have all of the following properties:
  — Access an address in Normal memory with either Inner Write Through or Inner Write Back attributes within the same cache line of minimum size, as indicated by CTR_EL0.DMinLine.
  — Use an address with the same cacheability attributes as the address passed to the data cache instruction.
- Can execute in any order relative to loads or stores that have all of the following properties:
  — Access an address in Normal memory with either Inner Write Through or Inner Write Back attributes within the same cache line of minimum size, as indicated by CTR_EL0.DMinLine.
  — Use an address with different cacheability attributes as the address passed to the data cache instruction.
  — Do not have a `DMB` or `DSB` executed between the load or store instruction and the data cache instruction.
- Can execute in any order relative to loads or stores that access any address with the Device memory attribute, or with Normal memory with Inner Non-cacheable attribute unless a `DMB` or `DSB` is executed between the instructions.
- Execute in program order relative to other data cache instructions, other than DC ZVA that specify an address within the same cache line of minimum size, as indicated by CTR_EL0.DMinLine.
- Can execute in any order relative to loads or stores that access an address in a different cache line of minimum size, as indicated by CTR_EL0.DMinLine, unless a `DMB` or `DSB` is executed between the instructions.
- Can execute in any order relative to other data cache instructions, other than DC ZVA that specify an address in a different cache line of minimum size, as indicated by CTR_EL0.DMinLine, unless a `DMB` or `DSB` is executed between the instructions.
- Can execute in any order relative to instruction cache maintenance instructions unless a `DSB` is executed between the instructions.
- Can execute in any order relative to data cache maintenance instructions that do not specify an address unless a `DMB` or `DSB` is executed between the instructions.

Note

- Data cache ordering rules by address are consistent with physically indexed physically tagged caches. See Data and unified caches.
- Data cache zero instruction describes the ordering and completion rules for Data Cache Zero.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

All data cache maintenance instructions that do not specify an address:

- Can execute in any order relative to data cache maintenance instructions that do not specify an address unless a DMB or DSB is executed between the instructions.
- Can execute in any order relative to data cache maintenance instructions that specify an address, unless a DMB or DSB is executed between the instructions.
- Can execute in any order relative to loads or stores unless a DMB or DSB is executed between the instructions.
- Can execute in any order relative to instruction cache maintenance instructions unless a DSB is executed between the instructions.

All instruction cache maintenance instructions can execute in any order relative to other instruction cache instructions, data cache instructions, loads, and stores unless a DSB is executed between the instructions.

A cache maintenance instruction can complete at any time after it is executed, but is only guaranteed to be complete, and its effects visible to other observers, following a DSB instruction executed by the PE that executed the cache maintenance instruction. See also the requirements for cache maintenance instructions in Completion and endpoint ordering.

In all cases, where the text in this section refers to a DMB or a DSB, this means a DMB or DSB whose required access type is both loads and stores.

Note

This section specifies the memory ordering requirements of DMB and DSB based on the required access type as specified by the <option> parameter. DSB has additional requirements with respect to execution of instructions appearing in program order after the DSB as described in Data Synchronization Barrier. These additional requirements create the effect of additional memory ordering beyond what is specified in this section.

D4.4.8.12.1 Ordering and completion of Data Cache Clean to Point of Persistence

The update of the persistent memory as a result of Data Cache Clean to the Point of Persistence is guaranteed to have occurred either after:

- The execution of a DSB applying to both reads and writes after the execution of the Data Cache Clean to the Point of Persistence.
- The update to persistent memory caused by a different Data Cache Clean to the Point of Persistence that is ordered after a DMB applying to both reads and writes that appears after the original Data Cache Clean to the Point of Persistence.

Note

This second point is an aspect of the fact that the Data Cache Clean to the Point of Persistence instructions are ordered by DMB, and this controls the order of arrival in persistent memory.

The ordering effect for the Data Cache Clean to the Point of Persistence by DMB applying to both read and writes is not sufficient to ensure that in Example D4-1, observation of the value '1' in the memory location X3 implies that the Data Cache Clean to the Point of Persistence has caused an update of persistent memory:

Example D4-1 The ordering effect for the Data Cache Clean to the Point of Persistence

```
; initial condition has [X3]=0

DC CVADP, X1
DMB
MOV X2,#1
STR X2, [X3]
```

However, in Example D4-2, the ordering effects of the DMB instruction will ensure that the location pointed by P0: X1 will reach the Point of Persistence before, or at the same time as, the location pointed by P1:X8.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Example D4-2 The ordering effect for the Data Cache Clean to the Point of Persistence

```
; initial conditions has P0: X3 and P1: X3 point to the same location, which is 0 at the start of
    ↪this example

P0
    DC CVAP, X1
    DMB
    MOV X2, #1
    STR X2, [X3]

P1
loop
    LDR X2, [X3]
    CBZ X2, loop
    DMB
    DC CVAP, X8
```

D4.4.8.12.2 Ordering and completion of Data Cache Clean to Point of Deep Persistence

The update of the deep persistent memory as a result of Data Cache Clean to the Point of Deep Persistence is guaranteed to have occurred either after:

- The execution of a DSB applying to both reads and writes after the execution of the Data Cache Clean to the Point of Deep Persistence.
- The update to deep persistent memory caused by a different Data Cache Clean to the Point of Deep Persistence that is ordered after a `DMB` applying to both reads and writes that appears after the original Data Cache Clean to the Point of Deep Persistence.

Note

This second point is an aspect of the fact that the Data Cache Clean to the Point of Deep Persistence instructions are ordered by DMB, and this controls the order of arrival in deep persistent memory.

The ordering effect for the Data Cache Clean to the Point of Deep Persistence by `DMB` applying to both read and writes is not sufficient to ensure that in Example D4-3, observation of the value '1' in the memory location X3 implies that the Data Cache Clean to the Point of Deep Persistence has caused an update of deep persistent memory:

Example D4-3 The ordering effect for the Data Cache Clean to the Point of Deep Persistence

```
; initial conditions has [X3]=0

DC CVADP, X1
DMB
MOV X2,#1
STR X2, [X3]
```

However, in Example D4-4, the ordering effects of the `DMB` instruction will ensure that the location pointed by P0: X1 will reach the Point of Deep Persistence before, or at the same time as, the location pointed by P1: X8.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Example D4-4 The ordering effect for the Data Cache Clean to the Point of Deep Persistence

```
; initial conditions has P0: X3 and P1: X3 point to the same location, which is 0 at the start of
    ↪this example
P0
    DC CVADP, X1
    DMB
    MOV X2, #1
    STR X2, [X3]

P1
loop
    LDR X2, [X3]
    CBZ X2, loop
    DMB
    DC CVADP, X8
```

D4.4.8.13 Performing cache maintenance instructions

To ensure all cache lines in a block of address space are maintained through all levels of cache Arm strongly recommends that software:

- For data or unified cache maintenance, uses the CTR_EL0.DMinLine value to determine the loop increment size for a loop of data cache maintenance by VA instructions.
- For instruction cache maintenance, uses the CTR_EL0.IMinLine value to determine the loop increment size for a loop of instruction cache maintenance by VA instructions.

D4.4.8.13.1 Example code for cache maintenance instructions

The cache maintenance instructions by set/way can clean or invalidate, or both, the entirety of one or more levels of cache attached to a PE. However, unless all PEs attached to the caches regard all memory locations as Non-cacheable, it is not possible to prevent locations being allocated into the cache during such a sequence of the cache maintenance instructions.

Note

Since the set/way instructions are performed only locally, there is no guarantee of the atomicity of cache maintenance between different PEs, even if those different PEs are each executing the same cache maintenance instructions at the same time. Since any cacheable line can be allocated into the cache at any time, it is possible for a cache line to migrate from an entry in the cache of one PE to the cache of a different PE in a way that means the line is not affected by set/way based cache maintenance. Therefore, Arm strongly discourages the use of set/way instructions to manage coherency in coherent systems. The expected use of the cache maintenance instructions that operate by set/way is limited to the cache maintenance associated with the powerdown and powerup of caches, if this is required by the implementation.
The limitations of cache maintenance by set/way mean maintenance by set/way does not happen on multiple PEs, and cannot be made to happen atomically for each address on each PE. Therefore in multiprocessor or multithreaded systems, the use of cache maintenance by set/way to clean, or clean and invalidate, the entire cache for coherency management with very large buffers or with buffers with unknown address can fail to provide the expected coherency results because of speculation by other PEs, or possibly by other threads. The only way that these instructions can be used in this way is to first ensure that all PEs that might cause speculative accesses to caches that need to be maintained are not capable of generating speculative accesses. This can be achieved by ensuring that those PEs have no memory locations with a Normal Cacheable attribute. Such an approach can have very large system performance effects, and Arm advises implementers to use hardware coherency mechanisms in systems where this will be an issue.
System level caches refers to other limitations of cache maintenance by set/way.

The following example code for cleaning a data or unified cache to the Point of Coherency illustrates a generic mechanism for cleaning the entire data or unified cache to the Point of Coherency. It assumes that the current Cache Size Identification Register is in 32-bit format. For more information, see Possible formats of the Cache Size Identification Register, CCSIDR_EL1.

```
        MRS     X0, CLIDR_EL1
        AND     W3, W0, #0x07000000     // Get 2 x Level of Coherence
        LSR     W3, W3, #23
        CBZ     W3, Finished
        MOV     W10, #0                 // W10 = 2 x cache level
        MOV     W8, #1                  // W8 = constant 0b1
Loop1:  ADD     W2, W10, W10, LSR #1    // Calculate 3 x cache level
        LSR     W1, W0, W2              // extract 3-bit cache type for this level
        AND     W1, W1, #0x7
        CMP     W1, #2
        B.LT    Skip                    // No data or unified cache at this level
        MSR     CSSELR_EL1, X10         // Select this cache level
        ISB                             // Synchronize change of CSSELR
        MRS     X1, CCSIDR_EL1          // Read CCSIDR
        AND     W2, W1, #7              // W2 = log2(linelen)-4
        ADD     W2, W2, #4              // W2 = log2(linelen)
        UBFX    W4, W1, #3, #10         // W4 = max way number, right aligned
        CLZ     W5, W4                  // W5 = 32-log2(ways), bit position of way in DC operand
        LSL     W9, W4, W5              // W9 = max way number, aligned to position in DC operand
        LSL     W16, W8, W5             // W16 = amount to decrement way number per iteration
Loop2:  UBFX    W7, W1, #13, #15        // W7 = max set number, right aligned
        LSL     W7, W7, W2              // W7 = max set number, aligned to position in DC operand
        LSL     W17, W8, W2             // W17 = amount to decrement set number per iteration
Loop3:  ORR     W11, W10, W9            // W11 = combine way number and cache number ...
        ORR     W11, W11, W7            //  ... and set number for DC operand
        DC      CSW, X11                // Do data cache clean by set and way
        SUBS    W7, W7, W17             // Decrement set number
        B.GE    Loop3
        SUBS    X9, X9, X16             // Decrement way number
        B.GE    Loop2
Skip:   ADD     W10, W10, #2            // Increment 2 x cache level
        CMP     W3, W10
        DSB                             // Ensure completion of previous cache maintenance instruction
        B.GT    Loop1
Finished:
```

Similar approaches can be used for all cache maintenance instructions.

D4.4.9 Data cache zero instruction

The Data Cache Zero by Address instruction, DC ZVA, writes `0x00` to each byte of a block of *N* bytes, aligned in memory to *N* bytes in size, where:

- The block in memory is identified by the address supplied as an argument to the DC ZVA instruction. There are no alignment restrictions on this address.

  Note

  This means that each byte of the block of memory that includes the supplied address is set to zero.

- The DCZID_EL0 register indicates the block size, *N* bytes, that is written with byte values of zero.

Software can restrict access to this instruction. See Configurable instruction controls and the description of the DC ZVA instruction.

The DC ZVA instruction behaves as a set of stores to the location being accessed, and:

- Generates a Permission fault if the translation regime being used when the instruction is executed does not permit writes to the locations.
- Requires the same considerations for ordering and the management of coherency as any other store instruction.

In addition:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- When the instruction is executed, it can generate memory faults or watchpoints that are prioritized in the same way as other memory related faults or watchpoints. Where a synchronous Data Abort fault or a watchpoint is generated, the CM bit in the syndrome field is not set to 1, which would be the case for all other cache maintenance instructions. See ISS encoding for an exception from a Data Abort for more information about the encoding of the associated ESR_ELx.ISS field.
- If the memory region being zeroed is any type of Device memory, then `DC ZVA` generates an Alignment fault which is prioritized in the same way as other alignment faults that are determined by the memory type.

Note

The architecture makes no statements about whether or not a DC ZVA instruction causes allocation to any particular level of the cache, for addresses that have a cacheable attribute for those levels of cache.
Despite its mnemonic, the DC ZVA instruction is not a data cache maintenance instruction.

D4.4.10 Cache lockdown

The concept of an entry locked in a cache is allowed, but not architecturally defined. How lockdown is achieved is IMPLEMENTATION DEFINED and might not be supported by:

- An implementation.
- Some memory attributes.

An unlocked entry in a cache might not remain in that cache. The architecture does not guarantee that an unlocked cache entry remains in the cache or remains incoherent with the rest of memory. Software must not assume that an unlocked item that remains in the cache remains dirty.

A locked entry in a cache is guaranteed to remain in that cache. The architecture does not guarantee that a locked cache entry remains incoherent with the rest of memory, that is, it might not remain dirty.

D4.4.10.1 The interaction of cache lockdown with cache maintenance instructions

The interaction of cache lockdown and cache maintenance instructions is IMPLEMENTATION DEFINED. However, an architecturally-defined cache maintenance instruction on a locked cache line must comply with the following general rules:

- The effect of the following instructions on locked cache entries is IMPLEMENTATION DEFINED:
  - Cache clean by set/way, DC CSW.
  - Cache invalidate by set/way, DC ISW.
  - Cache clean and invalidate by set/way, DC CISW.
  - Instruction cache invalidate all, IC IALLU and IC IALLUIS.

  However, one of the following approaches must be adopted in all these cases:

  1. If the instruction specified an invalidation, a locked entry is not invalidated from the cache.
  2. If the instruction specified a clean it is IMPLEMENTATION DEFINED whether locked entries are cleaned.
  3. If an entry is locked down, or could be locked down, an IMPLEMENTATION DEFINED Data Abort exception is generated, using the DFSC value defined for this purpose, see ISS encoding for an exception from a Data Abort.

  This permits a usage model for cache invalidate routines to operate on a large range of addresses by performing the required operation on the entire cache, without having to consider whether any cache entries are locked.
- The effect of the following instructions on locked cache entries is IMPLEMENTATION DEFINED:
  - Cache clean by virtual address, DC CVAC, DC CVAP, and DC CVAU.
  - Cache invalidate by virtual address, DC IVAC.
  - Cache clean and invalidate by virtual address, DC CIVAC.

  However, one of the following approaches must be adopted in all these cases:

  1. If the instruction specified an invalidation, a locked entry is invalidated from the cache. For the clean and invalidate instructions, the entry must be cleaned before it is invalidated.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

2. If the instruction specified an invalidation, a locked entry is not invalidated from the cache. If the instruction specified a clean it is IMPLEMENTATION DEFINED whether locked entries are cleaned.
3. If an entry is locked down, or could be locked down, an IMPLEMENTATION DEFINED Data Abort exception is generated, using the DFSC value defined for this purpose. See ESR_ELx.

In an implementation that includes EL2 enabled in the current Security state, if HCR_EL2.TIDCP is set to 1, any exception relating to lockdown of an entry is routed to EL2.

Note

An implementation that uses an abort mechanism for entries that can be locked down but are not actually locked down must:

- Document the IMPLEMENTATION DEFINED instruction sequences that perform the required operations on entries that are not locked down.
- Implement one of the other permitted alternatives for the locked entries.

Arm recommends that, when possible, such IMPLEMENTATION DEFINED instruction sequences use architecturally-defined instructions. This minimizes the number of customized instructions required.
In addition, an implementation that uses an abort to handle cache maintenance instructions for entries that might be locked must provide a mechanism that ensures that no entries are locked in the cache.
The reset setting of the cache must be that no cache entries are locked.

D4.4.10.1.1 Additional cache functions for the implementation of lockdown

An implementation can add additional cache maintenance functions for the handling of lockdown in the IMPLEMENTATION DEFINED spaces reserved for Cache Lockdown, see Reserved encodings for IMPLEMENTATION DEFINED registers.

D4.4.11 System level caches

The Arm Architecture defines a *system cache* as a cache that is not described in the PE Cache Identification registers, CCSIDR_EL1 and CLIDR_EL1, and for which the set/way cache maintenance instructions do not apply.

Conceptually, three classes of system cache can be envisaged:

1. System caches which lie before the Point of Coherency and cannot be managed by any cache maintenance instructions. Such systems fundamentally undermine the concept of cache maintenance instructions operating to the Point of Coherency, as they imply the use of non-architecture mechanisms to manage coherency. The use of such systems in the Arm architecture is explicitly prohibited.
2. System caches which lie before the Point of Coherency and can be managed by cache maintenance by address instructions that apply to the Point of Coherency, but cannot be managed by cache maintenance by set/way instructions. Where maintenance of the entirety of such a cache must be performed, as in the case for power management, it must be performed using non-architectural mechanisms.
3. System caches which lie beyond the Point of Coherency and so are invisible to the software for the purpose of managing coherency.

Note

If maintenance of the entirety of such a cache is supported, it is an IMPLEMENTATION DEFINED property of the system.

D4.4.12 Branch prediction

In the AArch64 architecture, branch predictors are not architecturally visible.

For details on the restrictions on the effects of speculation for branch predictors, see Restrictions on the effects of speculation.

D4.5 External aborts

The Arm architecture defines External aborts as errors that occur in the memory system, other than those that are detected by the MMU, MPU, or debug logic. An External abort might signal a data corruption to the PE. For example, a memory location might have been corrupted, and this corruption is detected by hardware using a parity or error correction code (ECC). The error might have been propagated. The RAS Extension provides mechanisms for software to determine the extent of the corruption and contain propagation of the error. For more information, see RAS PE Architecture.

An External abort is one of the following:

- Synchronous.
- Precise asynchronous.
- Imprecise asynchronous.

For more information, see Exception entry terminology.

The RAS Extension provides a more granular taxonomy of aborts. When the RAS Extension is not implemented, the Arm architecture does not provide any method to distinguish between precise asynchronous and imprecise asynchronous External aborts.

It is IMPLEMENTATION DEFINED which External aborts, if any, are supported.

External aborts on data accesses and translation table walks on data accesses can be either synchronous or asynchronous.

When FEAT_DoubleFault is not implemented, External aborts on instruction fetches and translation table walks on instruction fetches can be either synchronous or asynchronous.

When FEAT_DoubleFault is implemented, all External abort exceptions on instruction fetches and translation table walks on instruction fetches must be synchronous.

A synchronous External abort on an instruction fetch, including a translation table walk on an instruction fetch, is taken precisely using the Instruction Abort exception.

A synchronous External abort on a data read or write, including a translation table walk on a data read or write, is taken precisely using the Data Abort exception.

See Synchronous exception types.

An asynchronous External abort is taken using the SError exception. See Asynchronous exception types.

The effect of a failed memory access is described in Definition of a precise exception and imprecise exception.

Normally, External aborts are rare. An imprecise asynchronous External abort is likely to be fatal to the process that is running, Arm recommends that implementations make External aborts precise wherever possible.

The following subsections give more information about possible External aborts:

- Provision for the classification of External aborts.
- Parity or ECC error reporting, RAS Extension not implemented.

D4.5.1 Provision for the classification of External aborts

In AArch64 state, an implementation can use ESR_ELx.EA, ISS[9], to provide more information about synchronous External aborts. For all synchronous aborts other than synchronous External aborts, ESR_ELx.EA, ISS[9], returns a value of 0.

If the FEAT_RAS is implemented:

- The ESR_ELx.SET field provides information about the state of the PE following a synchronous External abort.
- The ESR_ELx.AET field might contain more information following an asynchronous abort taken as an SError exception.
- The implementation might define error record registers.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

For more information, see:

- ISS encoding for an exception from an Instruction Abort.
- ISS encoding for an exception from a Data Abort.
- ISS encoding for an SError exception.
- Taking error exceptions.

D4.5.2 Parity or ECC error reporting, RAS Extension not implemented

The Arm architecture supports the reporting of both synchronous and asynchronous parity or ECC errors from the cache system. It is IMPLEMENTATION DEFINED what parity or ECC errors in the cache systems, if any, result in synchronous or asynchronous parity or ECC errors.

A fault code is defined for reporting parity or ECC errors. However, when parity or ECC error reporting is implemented, it is IMPLEMENTATION DEFINED whether a parity or ECC error is reported using the assigned fault code or using another appropriate encoding.

For all purposes other than the Fault status encoding, parity or ECC errors are treated as External aborts.

D4.6 Memory barrier instructions

Memory barriers describes the memory barrier instructions. This section describes the system level controls of those instructions.

D4.6.1 EL2 control of the shareability of data barrier instructions executed at EL0 or EL1

In an implementation that includes EL2 enabled in the current Security state and supports shareability limitations on the data barrier instructions, the HCR_EL2.BSU field can modify the required shareability of an instruction that is executed at EL0 or EL1. Table D4-8 shows the encoding of this field.

Table D4-8 EL2 control of shareability of barrier instructions executed at EL0 or EL1

HCR_EL2.BSU	Minimum shareability of barrier instructions
00	No effect, shareability is as specified by the instruction
01	Inner Shareable
10	Outer Shareable
11	Full system

For an instruction executed at EL0 or EL1, Table D4-9 shows how the HCR_EL2.BSU is combined with the shareability specified by the argument of the `DMB` or `DSB` instruction to give the scope of the instruction.

Table D4-9 Effect of HCR_EL2.BSU on barrier instructions executed at EL1 or EL0

Shareability specified by the `DMB` or `DSB` argument	HCR_EL2.BSU	Resultant shareability
Full system	Any	Full system
Outer Shareable	`00`, `01`, or `10`	Outer Shareable
	`11`, Full system	Full system
Inner Shareable	`00` or `01`	Inner Shareable
	`10`, Outer Shareable	Outer Shareable
	`11`, Full system	Full system
Non-shareable	`00`, No effect	Non-shareable
	`01`, Inner Shareable	Inner Shareable
	`10`, Outer Shareable	Outer Shareable
	`11`, Full system	Full system

D4.7 Pseudocode description of general memory System instructions

This section lists the pseudocode describing general memory operations:

- Memory data type definitions.
- Basic memory access.
- Aligned memory access.
- Unaligned memory access.
- Exclusives monitors operations.
- Access permission checking.
- Abort exceptions.
- Memory barriers.

D4.7.1 Memory data type definitions

This section lists the memory data types.

The memory data types are:

- Address descriptor, defined by the `AddressDescriptor` type.
- Full address, defined by the `FullAddress` type.
- Memory attributes, defined by the `MemoryAttributes` type.
- Memory type, defined by the `MemType` enumeration.
- Device memory type, defined by the `DeviceType` enumeration.
- Normal memory attributes, defined by the `MemAttrHints` type.
- Cacheability attributes, defined by the `MemAttr_NC`, `MemAttr_WT`, and `MemAttr_WB` constants.
- Allocation hints, defined by the `MemHint_No`, `MemHint_WA`, `MemHint_RA`, and `MemHint_RWA` constants.
- Access permissions, defined by the `Permissions` type.

These types are defined in A-profile Architecture Pseudocode.

D4.7.2 Basic memory access

The `PhysMemRead()` and `PhysMemWrite()` functions perform single-copy atomic, aligned, little-endian memory accesses of `size` bytes to or from the underlying physical memory array of bytes.

The attributes in `memaddrdesc.memattrs` are used by the memory system to determine caching and ordering behaviors as described in Memory types and attributes, Ordering relations, and Atomicity in the Arm architecture.

D4.7.3 Aligned memory access

The two `MemSingle[]` accessors, non-assignment (memory read) `AArch64.MemSingle[]` and assignment (memory write) `AArch64.MemSingle[]`, make atomic, little-endian accesses of `size` bytes.

D4.7.4 Unaligned memory access

The two `Mem[]` accessors, Non-assignment (memory read) `Mem[]` and Assignment (memory write) `Mem[]`, make accesses of the required type. If an access is not architecturally defined to be atomic, `Mem[]` synthesizes accesses from multiple calls to `AArch64.MemSingle[]`. It also reverses the byte order if the access is big-endian.

The `IsAligned()` function checks the alignment of memory accesses.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D4.7.5 Exclusives monitors operations

The `AArch64.SetExclusiveMonitors()` function sets the Exclusives monitors for a block of bytes, the size of which is determined by `size`, at the virtual address defined by `address`.

The `AArch64.ExclusiveMonitorsPass()` function checks whether the Exclusives monitors are set to include the location of a number of bytes specified by `size`, at the virtual address defined by `address`. The atomic write that follows after the Exclusives monitors have been set must be to the same physical address. It is permitted, but not required, for this function to return FALSE if the virtual address is not the same as that used in the previous call to `AArch64.SetExclusiveMonitors()`.

The `ExclusiveMonitorsStatus()` function returns 0 if the previous atomic write was to the same physical memory locations selected by `AArch64.ExclusiveMonitorsPass()` and therefore succeeded. Otherwise the function returns 1, indicating that the address translation delivered a different physical address.

The `MarkExclusiveGlobal()` procedure takes as arguments a `FullAddress paddress`, the PE identifier `processorid` and the size of the transfer. The procedure records that the PE `processorid` has requested exclusive access covering at least `size` bytes from address `paddress`. The size of the location marked as exclusive is IMPLEMENTATION DEFINED, up to a limit of 2KB and no smaller than two words, and aligned in the address space to the size of the location. It is CONSTRAINED UNPREDICTABLE whether this causes any previous request for exclusive access to any other address by the same PE to be cleared.

The `MarkExclusiveLocal()` procedure takes as arguments a `FullAddress paddress`, the PE identifier `processorid` and the size of the transfer. The procedure records in a local record that PE `processorid` has requested exclusive access to an address covering at least `size` bytes from address paddress. The size of the location marked as exclusive is IMPLEMENTATION DEFINED, and can at its largest cover the whole of memory but is no smaller than two words, and is aligned in the address space to the size of the location. It is IMPLEMENTATION DEFINED whether this procedure also performs a `MarkExclusiveGlobal()` using the same parameters.

The `IsExclusiveGlobal()` function takes as arguments a `FullAddress paddress`, the PE identifier `processorid` and the size of the transfer. The function returns TRUE if the PE `processorid` has marked in a global record an address range as exclusive access requested that covers at least `size` bytes from address `paddress`. It is IMPLEMENTATION DEFINED whether it returns TRUE or FALSE if a global record has marked a different address as exclusive access requested. If no address is marked in a global record as exclusive access, `IsExclusiveGlobal()` returns FALSE.

The `IsExclusiveLocal()` function takes as arguments a `FullAddress paddress`, the PE identifier `processorid` and the size of the transfer. The function returns TRUE if the PE `processorid` has marked an address range as exclusive access requested that covers at least the `size` bytes from address `paddress`. It is IMPLEMENTATION DEFINED whether this function returns TRUE or FALSE if the address marked as exclusive access requested does not cover all of `size` bytes from address `paddress`. If no address is marked as exclusive access requested, then this function returns FALSE. It is IMPLEMENTATION DEFINED whether this result is ANDed with the result of `IsExclusiveGlobal()` with the same parameters.

The `ClearExclusiveByAddress()` procedure takes as arguments a `FullAddress paddress`, the PE identifier `processorid` and the size of the transfer. The procedure clears the global records of all PEs, other than `processorid`, for which an address region including any of `size` bytes starting from `paddress` has had a request for an exclusive access. It is IMPLEMENTATION DEFINED whether the equivalent global record of the PE `processorid` is also cleared if any of `size` bytes starting from `paddress` has had a request for an exclusive access, or if any other address has had a request for an exclusive access.

The `ClearExclusiveLocal()` procedure takes as arguments the PE identifier `processorid`. The procedure clears the local record of PE `processorid` for which an address has had a request for an exclusive access. It is IMPLEMENTATION DEFINED whether this operation also clears the global record of PE `processorid` that an address has had a request for an exclusive access.

D4.7.6 Access permission checking

The AArch64.S1CheckPermissions() and AArch64.S2CheckPermissions() functions are used by the architecture to perform access permission checking based on attributes derived from the Translation Tables descriptors.

The interpretation of access permission is shown in Memory access control.

D4.7.7 Abort exceptions

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The `AArch64.Abort()` function generates either a Data Abort or an Instruction Abort exception by calling `AArch64.DataAbort()` or `AArch64.InstructionAbort()`. It also can generate a debug exception for debug related faults, see AArch64 Self-hosted Debug.

The `AArch64.DataAbort()` function generates a Data Abort exception, routes the exception to EL2, and records the information required for the Exception Syndrome registers, ESR_ELx. See ISS encoding for an exception from a Data Abort. A second stage abort might also record the intermediate physical address, IPA, but this depends on the type of the abort.

For a synchronous abort, `AArch64.DataAbort()` also sets the FAR to the VA of the abort.

The `AArch64.InstructionAbort()` function generates an Instruction Abort exception, routes the exception to EL2, and records the information required for the Exception Syndrome registers, ESR_ELx, see ISS encoding for an exception from an Instruction Abort. A second stage abort might also record the intermediate physical address, IPA, but this depends on the type of the abort.

For a synchronous abort, `AArch64.InstructionAbort()` also sets the FAR to the VA of the abort.

The `FaultRecord` type describes a fault. Functions that check for faults return a record of this type appropriate to the type of fault.

The function `NoFault()` returns a null record that indicates no fault. The `IsFault()` function tests whether a `FaultRecord` contains a fault.

D4.7.8 Memory barriers

The definition for the memory barrier functions is given by the enumerations `MBReqDomain` and `MBReqTypes`.

These enumerations define the required shareability domains and required access types used as arguments for `DMB` and `DSB` instructions.

The procedures `DataMemoryBarrier`, `DataSynchronizationBarrier`, and `InstructionSynchronizationBarrier` perform the memory barriers.

Chapter D5
The AArch64 Virtual Memory System Architecture

This chapter provides a system level view of the AArch64 *Virtual Memory System Architecture* (VMSA), the memory system architecture of an A-profile implementation that is executing in AArch64 state. It contains the following sections:

- Address translation.
- Translation process.
- Translation table descriptor formats.
- Memory access control.
- Memory region attributes.
- Other descriptor fields.
- Address tagging.
- Pointer authentication.
- Memory aborts.
- Translation Lookaside Buffers.
- TLB maintenance.
- Caches.
- Pseudocode description of VMSAv8-64 address translation.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D5.1 Address translation

I_{BGZDZ} Armv8-R AArch64 supports VMSAv8-64 as an optional memory system architecture at stage 1 of the EL1&0 translation regime, and supports general-purpose operating systems, such as Linux and Android at EL1. With VMSAv8-64 supported at EL1 the Armv8-R AArch64 architecture profile can have the following memory system configurations:

- PMSAv8-64 at EL1 and EL2.
- PMSAv8-64 or VMSAv8-64 at EL1 and PMSAv8-64 at EL2.

I_{QTYRQ} The MSA and MSA_frac fields in ID_AA64MMFR0_EL1 identify the memory system configurations supported at EL1.

R_{BYTPV} All translation regimes in the R-profile VMSAv8-64 are Secure.

R_{YLPHH} In the Armv8-R AArch64 architecture the only permitted value of ID_AA64MMFR0_EL1.MSA is `0b1111`. When ID_AA64MMFR0_EL1.MSA_frac is `0b0010`, the stage 1 of the EL1&0 translation regime can enable the PMSAv8-64 or VMSAv8-64 architecture.

R_{VFJNJ} It is IMPLEMENTATION DEFINED whether a physical location is visible to a VMSAv8-64 context and to page table accesses, and it is permissible for an implementation to raise an External abort in this case.

I_{CCTQS} Address translation converts the addresses used by instructions to the addresses used by the physical memory system.

R_{CRPHV} When a data address or instruction address is used in an instruction, it is a *virtual address* (VA). This includes any address stored in one of the following registers:

- *Program counter* (PC).
- *Stack pointers* (SP).
- *Link register* (LR).
- *Exception link register* (ELR).

R_{CRDGS} When an access is made to the physical memory system, a *physical address* (PA) is used.

R_{KCNRX} An address translation maps a VA to a PA.

R_{ZKJWW} An address translation stage maps an *input address* (IA) to an *output address* (OA).

R_{BCKLH} If one address translation stage is used, then a VA is mapped to a PA using all of the following steps:

1. The VA is input as the IA to the translation stage.
2. The PA is output as the OA from the translation stage.

R_{HLQJT} The Armv8-R AArch64 VMSAv8-64 architecture does not support a VMSAv8-64 stage 2 translation regime. Memory accesses that would be subject to a stage 2 translation are managed by the PMSAv8-64 and is implemented by the EL2 MPU. References to the stage 2 translation refer to the permissions checks performed by the EL2 MPU.
If two address translation stages are used, then a VA is mapped to a PA using all of the following steps:

1. The VA is input as the IA to the stage 1 translation.
2. The *intermediate physical address* (IPA) is output as the OA from the stage 1 translation.
3. The IPA is input as the IA to the stage 2 translation, a permissions check by the EL2 MPU.
4. The memory access is either permitted by the EL2 MPU or a fault is generated.

For more information, see The AArch64 Protected Memory System Architecture.

I_{MBNVX} If an address translation stage is disabled, then the value of the OA is the same as the IA.

I_{YXNZL} When an IA is translated to an OA, using VMSAv8-64, an address translation stage uses a set of memory mapped translation tables that hold all of the following information:

- The OA corresponding to the IA.
- For accesses made from Secure state, whether the OA access is to the Secure or Non-secure address map.
- The OA memory access permissions.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- The OA memory region attributes.

I_{FJFQR} When an IA is translated by an address translation stage, all of the following apply:

- A translation table lookup reads an entry from a translation table.
- A translation table entry resolves a subset of the IA.
- Multiple translation table entries can be required to completely resolve an IA.
- An address translation can require multiple lookups across different lookup levels and multiple translation tables.

R_{JTYJP} When memory is accessed, the *Memory Management Unit* (MMU) controls address translation, memory access permissions, memory attribute determination, and memory attribute checking.

R_{RJPRG} When the MMU cannot translate the IA, an MMU fault is generated.

R_{ZCVCZ} When a stage 1 translation cannot translate an IA, a stage 1 MMU fault is generated.

I_{ZWCKD} For more information, see:

- Implemented physical address size.
- Output address size configuration.
- Supported virtual address ranges.
- Input address size configuration.
- Intermediate physical address size configuration.
- Translation process.
- The effects of disabling an address translation stage.
- Memory aborts
- The AArch64 Protected Memory System Architecture.

D5.1.1 Translation granules

I_{GZDPY} The translation granule size determines the number of bits resolved by each lookup level when mapping from an IA to OA, and the maximum size of a single translation table.

R_{ZVQXW} The VMSA defines all of the following translation granule sizes:

- 4KB.
- 16KB.
- 64KB.

R_{JZCBC} For each translation granule size, and translation stage, support is IMPLEMENTATION DEFINED.

R_{FZCLK} The stage 1 translation can be configured to use one of the supported translation granule sizes.

R_{QKCFY} A page is the smallest memory region in which an IA to OA mapping can be specified.

I_{MGPLT} The translation granule determines all of the following:

- The translation process used to resolve an IA to an OA.
- The page size of the address translation stage.
- The number of address bits required to address a page.
- The maximum translation table size of the address translation stage.
- The number of address bits that can be resolved in a single translation table lookup.

I_{KZLYC} For all of the following reasons, a larger translation granule can reduce the number of translation lookup levels:

- The larger granule uses a larger translation table with more entries.
- A single lookup can resolve more IA bits.
- The larger page size means more of the least significant address bits are used to address within a page and do not require translation because those bits are flat-mapped from IA to OA.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I_{QRLDB} Arm recommends separating memory-mapped peripherals by an integer multiple of the largest granule size supported by the PEs in the system, to allow independent management of each peripheral.

D5.1.2 Translation regimes

I_{CJMWY} A translation regime determines how a VA is mapped to a PA. The translation regime is affected by the current Security state, the current Exception level, the enabled Exception levels, HCR_EL2 settings, and implemented features.

I_{QQMYL} If a software agent, such as an operating system, uses or configures stage 1 translations, then that software agent might be unaware of all of the following:

- The EL2 MPU.
- The distinction between IPA and PA.

D5.1.2.1 Secure EL1&0 translation regime

R_{DKYXN} If one of the following applies, then stage 1 of the Secure EL1&0 translation regime is used to translate addresses:

- Memory is accessed from EL1.
- Memory is accessed from EL0 and the Effective value of HCR_EL2.TGE is 0.

R_{NRSBW} The Secure EL1&0 translation regime, supports all of the following:

- Translation stage 1 that does all the following:
  - Maps VAs to IPAs.
  - Supports two VA ranges and the use of ASIDs.

For more information, see Use of ASIDs and VMIDs to reduce TLB maintenance requirements.

R_{XMCNY} If the PE supports both PMSAv8-64 and VMSAv8-64 at EL1, then VTCR_EL2.MSA determines the memory system architecture enabled at stage 1 of the Secure EL1&0 translation regime. Depending on the enabled memory system architecture, stage 1 of the Secure EL1&0 translation regime is controlled by either of the following:

- An EL1 MPU for PMSAv8-64.
- An MMU for VMSAv8-64.

D5.1.2.2 Secure EL2 translation regime

R_{MBXNP} The stage 2 of the Secure EL1&0 translation regime and the stage 1 of the Secure EL2 translation regime are controlled by the EL2 MPU. Armv8-R AArch64 uses the same translation format and Fault encodings as the VMSAv8-64.

D5.1.3 The system registers relevant to MMU operation

I_{RJZKJ} If a System register name has a numeric suffix, then the suffix indicates the lowest Exception level that can access the register.

I_{HZYYY} Translation stages are enabled and controlled by the registers specified in the following table.

Table D5-1 Registers that enable and control translation stages

Translation Stage	Controlled from	Controlling registers
EL1&0 stage 1	EL1	SCTLR_EL1, TCR_EL1, MAIR_EL1, AMAIR_EL1, TTBR0_EL1, TTBR1_EL1, HCR_EL2

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I_{LBPSZ} The following table lists the System register common abbreviations used in VMSAv8-64. The common abbreviation is used to describe features that apply to multiple translation regimes or translation stages.

Table D5-2 Common System register abbreviations used in VMSAv8-64

Common Abbreviation	Translation stage	Exception level EL1	EL2
AMAIR_ELx	-	AMAIR_EL1	AMAIR_EL2
MAIR_ELx	-	MAIR_EL1	MAIR_EL2
SCTLR_ELx	-	SCTLR_EL1	SCTLR_EL2
TCR_ELx	Stage 1	TCR_EL1	TCR_EL2
	Stage 2		VTCR_EL2, VSTCR_EL2
TTBR_ELx	Stage 1	TTBR0_EL1, TTBR1_EL1	
TTBRn_ELx	Stage 1	TTBR0_EL1, TTBR1_EL1	
TTBR0_ELx	Stage 1	TTBR0_EL1	
TTBR1_ELx	Stage 1	TTBR1_EL1	

I_{RGGJW} When software that enables or disables an address translation stage uses a PA that differs from the VA, speculative instruction fetching can cause complications. If software controls address translations that apply to the software itself, then when that software enables or disables an address translation stage, Arm recommends that the software uses a PA that is identical to the VA.

I_{DLLGV} For more information, see:

- Register name disambiguation by Exception level.

D5.1.4 Out-of-context translation regimes

I_{PTDBT} Software is required to consider the effects on registers and translation tables when a context switch is made from one translation regime to another.

D5.1.4.1 Speculative memory accesses from out-of-context translation regimes

R_{NRJPP} If an implementation is executing at EL2, the PE is not permitted to use the registers associated with the EL1&0 translation regime to speculatively access memory or translation tables.

R_{LFHQG} When an exception to a higher Exception level occurs, memory accesses caused by the translation table walk for the lower exception level can continue speculatively after the higher Exception level is entered.

I_{QVPYJ} When an exception to a higher Exception level occurs, executing a DSB instruction after entering that higher Exception level ensures that the memory accesses caused by the translation table walk are completed.

D5.1.4.2 Register changes when changing virtual machine

I_{XHBRX} If EL2 is enabled, when a switch from one virtual machine to another occurs, software executing at EL0 or EL1 expects register fields controlling or affecting the EL1&0 regime are modified consistently before the next virtual machine starts execution.

I_{SFZVV} If the registers fields controlling or affecting the EL1&0 translation regime are modified when changing a virtual machine, then all of the following apply:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- Software executing at EL2 does the modification.
- The registers are modified out-of-context from software executing at EL1 or EL0.
- When modifying the registers, no synchronization precautions are required until the exception return to EL1 or EL0.

D5.1.5 Implemented physical address size

I_{FRVXB} The implemented PA size is indicated by the value of the ID_AA64MMFR0_EL1.PARange field, as shown in the following table. All other values of the ID_AA64MMFR0_EL1.PARange field are reserved.

Table D5-3 Implemented physical address size

ID_AA64MMFR0_EL1.PARange	PA memory size	PA address size
0b0000	4GB	32 bits, PA[31:0]
0b0001	64GB	36 bits, PA[35:0]
0b0010	1TB	40 bits, PA[39:0]
0b0011	4TB	42 bits, PA[41:0]
0b0100	16TB	44 bits, PA[43:0]
0b0101	256TB	48 bits, PA[47:0]
0b0110	4PB	52 bits, PA[51:0]

R_{HGNFW} If the implemented PA size is greater than 48 bits, then FEAT_LPA is required.

D5.1.6 Output address size configuration

R_{VRZGZ} For a translation stage that uses the VMSAv8-64 translation system, the maximun OA size that can be described by translation table entries is one of the following:

- If FEAT_LPA is not implemented, then 48 bits.
- If FEAT_LPA is implemented, then 52 bits.

I_{XSLRQ} When VTCR_EL2.MSA is 1, the OA size from a translation stage is configured by the associated TCR_EL1.IPS field, as shown in the following table.

Table D5-4 Output address size configuration

TCR_EL1.IPS	OA memory size	OA address size
0b000	4GB	32 bits, OA[31:0]
0b001	64GB	36 bits, OA[35:0]
0b010	1TB	40 bits, OA[39:0]
0b011	4TB	42 bits, OA[41:0]
0b100	16TB	44 bits, OA[43:0]
0b101	256TB	48 bits, OA[47:0]
0b110	4PB	52 bits, OA[51:0]
0b111	64PB	56 bits, OA[55:0]

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I_{MNZFV} The TCR_EL1.IPS field is three bits and has the same encoding as the three least significant bits of ID_AA64MMFR0_EL1.PARange.

R_{CLPQT} The OA size from a translation stage cannot be larger than the implemented PA size. If the OA size represented by TCR_EL1.IPS is larger than the implemented PA size, then the OA size is treated as being the same as the implemented PA size.

I_{PKBTM} Arm strongly recommends that software avoids configuring TCR_EL1.IPS to a value greater than the implemented PA size.

I_{HGDWP} If a translation stage is enabled and the translation stage OA is larger than the implemented PA size, then an Address size fault is generated at the lookup level in the translation stage that generated the OA.

D5.1.7 Supported virtual address ranges

R_{HJYSS} The Hypervisor running at EL2 selects the memory system architecture for each Guest operating system by configuring VTCR_EL2.MSA.

I_{XGSBK} By allowing the configuration of the memory system architecture on a per guest basis allows the Hypervisor to support multiple Guest operating systems utilizing either the PMSAv8-64 or VMSAv8-64.

R_{ZBNPW} Memory accesses by both the VMSAv8-64 and PMSAv8-64 guests at EL1 are further validated by the EL2 MPU.

Note

The Secure Check Control, VSTCR_EL2.SC does not differentiate between translation table walk or memory accesses.

R_{VFFXF} If multiuple VMSAv8-64 or PMSAv8-64 guests are present, then these guests must be configured to use non-conflicting physical memory addresses.

I_{YMKBT} The VA size is determined by configuring the stage 1 translation IA size.
For more information, see Input address size configuration.

R_{XFMCS} For a translation stage that uses the VMSAv8-64 translation system, the maximun OA size that can be described by translation table entries is one of the following:

- If FEAT_LVA is not implemented, then 48 bits.
- If FEAT_LVA is implemented, then 52 bits.

I_{KRQBC} Only stage 1 address translation in the EL1&0 translation regimes support two VA ranges.

R_{BXWQW} If a translation regime supports two VA ranges, then each VA range represents an independent mapping from IA to OA.

R_{GZPNP} If a translation regime supports a single VA range, then all of the following apply:

- The maximum IA width is 56 bits.
- If the maximum VA size is 48 bits, then the maximum VA range is `0x0000_0000_0000_0000` to `0x0000_FFFF_FFFF_FFFF`.
- If the maximum VA size is 52 bits, then the maximum VA range is `0x0000_0000_0000_0000` to `0x000F_FFFF_FFFF_FFFF`.
- If the maximum VA size is 56 bits, then the maximum VA range is `0x0000_0000_0000_0000` to `0x00FF_FFFF_FFFF_FFFF`.

R_{ZNYRD} If a translation regime supports two VA ranges, then all of the following apply:

- The maximum IA width is 55 bits.
- IA bit[55] determines one of the following VA ranges:
  - If IA bit[55] is 0, the lower VA range is used.
  - If IA bit[55] is 1, the upper VA range is used.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- The maximum lower VA range is one of the following:
  - If the maximum VA size is 48 bits, then the maximum VA range is `0x0000_0000_0000_0000` to `0x0000_FFFF_FFFF_FFFF`.
  - If the maximum VA size is 52 bits, then the maximum VA range is `0x0000_0000_0000_0000` to `0x000F_FFFF_FFFF_FFFF`.
- The maximum upper VA range is one of the following:
  - If the maximum VA size is 48 bits, then the maximum VA range is `0xFFFF_0000_0000_0000` to `0xFFFF_FFFF_FFFF_FFFF`.
  - If the maximum VA size is 52 bits, then the maximum VA range is `0xFFF0_0000_0000_0000` to `0xFFFF_FFFF_FFFF_FFFF`.

R_{CSSJN} If the configured size of the upper VA range is less than the maximum, then all of the following apply:

- The range starting address is greater than the address used by the maximum VA size.
- The range ending address is `0xFFFF_FFFF_FFFF_FFFF`.

I_{THWTD} A 48-bit VA range defines an address space of 256TB. A 52-bit VA range defines an address space of 4PB.

D5.1.8 Input address size configuration

R_{TLMML} If a translation stage supports a single VA range, then TCR_ELx.T0SZ configures the IA size, translated using TTBR0_ELx.

R_{GMLRF} If a translation stage supports two VA ranges, then all of the following TCR_ELx.T*n*SZ fields specify the IA size:

- TCR_ELx.T0SZ configures the IA size of the lower VA range, translated using TTBR0_ELx.
- TCR_ELx.T1SZ configures the IA size of the upper VA range, translated using TTBR1_ELx.

I_{GRZSP} The stage 1 translation IA size is defined as 64-TCR_ELx.T*n*SZ.

R_{PLCGL} For all translation stages, the following table shows how the maximum permitted T*n*SZ value is determined:

Table D5-5 Determining the maximum permitted T*n*SZ value

Translation granule size	FEAT_TTST not implemented	FEAT_TTST implemented
4KB	39	48
16KB	39	48
64KB	39	47

I_{FTBXR} If TCR_ELx.T*n*SZ configures an IA size that is smaller than the maximum size, then each one-bit reduction in the IA size has one of the following effects on the lookup level that the table walk starts with:

- The translation table size is reduced by one half.
- The table walk starts one level later.

R_{YXNYW} If the value of T*n*SZ is greater than the maximum permitted value, then any use of the T*n*SZ value causes one of the following IMPLEMENTATION DEFINED behaviors to occur:

- For all purposes other than reading back the value, the implementation behaves as if the T*n*SZ field has the maximum permitted value.
- Any use generates a level 0 Translation fault.

R_{VJFMB} For a stage 1 translation using the VMSAv8-64 translation system, the minimum Effective value of T*n*SZ is one of the following:

- For the 4KB or 16KB translation granule the minimum Effective value of T*n*SZ is 16.
- For the 64KB translation granule, one of the following:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

— If FEAT_LVA is not implemented, then the minimum Effective value of T*n*SZ is 16.
— If FEAT_LVA is implemented, then the minimum Effective value of T*n*SZ is 12.

R_{VCDSW} If all of the following apply, then a stage 1 level 0 Address size fault is generated:

- Stage 1 translation is disabled.
- The IA size is larger than the implemented PA size.

I_{QZVXG} For an address translation stage, when an attempt is made to translate an address larger than the configured IA size, a level 0 Translation fault at that translation stage is generated.

R_{SXWGM} For a stage 1 address translation, if the value of T*n*SZ is smaller than the minimum Effective value, then when using the T*n*SZ value to translate an address, one of the following applies:

- If FEAT_LVA is not implemented, then it is IMPLEMENTATION DEFINED which of the following behaviors occurs:
  — For all uses other than reading back the value, the implementation behaves as if the T*n*SZ field has a value of 16.
  — When using the T*n*SZ value to translate an address, a stage 1 level 0 Translation fault is generated.
- If FEAT_LVA is implemented, then when using the T*n*SZ value to translate an address, a stage 1 level 0 Translation fault is generated.

D5.1.9 Intermediate physical address size configuration

R_{VPYYR} In the Armv8-R architecture stage 2 translations are handled by the EL2 MPU, according to the rules describing the PMSAv8-64.

I_{DDFLH} For more information, see The AArch64 Protected Memory System Architecture.

D5.2 Translation process

I_{GDSWV} The translation of a VA to a PA begins with reading the translation table base address register, followed by a walk through the translation tables to read the descriptors associated with the mapping.

D5.2.1 Translation table walk

R_{GXDYN} A translation table walk is the set of translation table lookups that are required to do all of the following:

- For a single stage translation at stage 1, translate a VA to a PA.
- For two translation stages and stage 1 is disabled, translate an IPA to a PA.
- For a two stage translation, all of the following:
  - For a stage 1 translation, translate a VA to an IPA.
  - For stage 2, no translation occurs and the IPA is treated as a physical address and the EL2 MPU enforces the configured access permissions.

R_{RHQPX} When a translation table walk begins, the initial translation table lookup uses the translation table base address stored in the TTBR_ELx register to locate the translation table.

R_{XFCRX} When a translation table lookup occurs, the descriptor held in the translation table entry is read as an 8-byte single-copy atomic access.
For information on the translation table alignment requirements, see Translation table alignment.

R_{YPWQG} The descriptor type indicates one of the following:

- The translation table walk is complete and the translation table entry is the final entry.
- The translation table walk requires an extra lookup at the next higher lookup level.
- The descriptor is invalid.

R_{NMTJN} All of the following descriptor types conclude the translation process:

- Page descriptor.
- Block descriptor.
- Invalid descriptor.

For more information, see Translation table descriptor formats.

I_{WMLYG} When an Invalid descriptor is returned during the translation process, a Translation fault at the current lookup level is generated.

I_{QPHCD} When an extra lookup level is required, the descriptor contains all of the following information:

- The translation table base address of the next lookup level.
- For stage 1 descriptors, if the Effective value of TCR_ELx.HPD*n* is 0, then the descriptor has hierarchical access permissions that are applied to the final translation.
- If the translation is made in a Secure translation regime, then a stage 1 descriptor indicates whether the base address is in the Secure address space or the Non-secure address space, unless a hierarchical control at a previous lookup level has indicated that it is required to be in the Non-secure address space.

For more information, see Security state of translation table lookups.

R_{VSJGV} For a translation lookup level, the translation table base address is one of the following:

- For the initial lookup level, the aligned value of the appropriate TTBR_ELx.BADDR field.
- For subsequent lookup levels, the next-level translation table base address returned by the previous lookup level.

I_{ZMMXH} When the last lookup level of a translation stage returns a valid descriptor, it contains all of the following:

- The OA from the translation stage.
- The memory region access permissions.
- The memory region attributes.

For more information, see Memory region attributes and Memory access control.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

R_{NLLYJ} When a translation table walk succeeds, all of the following are returned:

- The OA.
- If the translation table walk is made in a Secure translation regime, then the information returned indicates whether the OA is in the Secure IPA or PA space, or the Non-secure IPA or PA space.
- The output memory region attributes.
- The output memory region access permissions.

For more information, see Security state of translation table lookups.

I_{VPFHD} The following figure is a generalized view of a single address translation stage with three lookup levels.

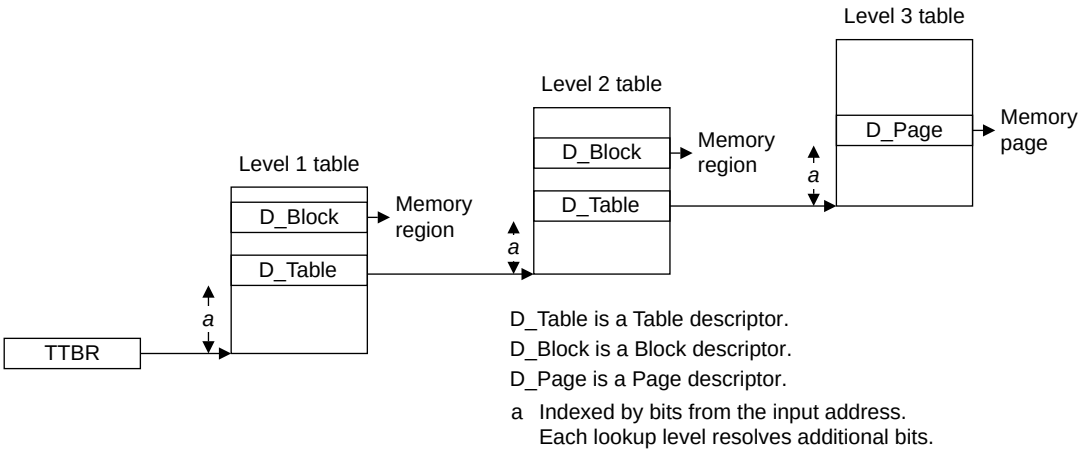

Figure D5-1 Generalized view of a single address translation stage

I_{JWQFM} If all of the following are true, then a translation table entry is permitted to be cached in a Translation Lookaside Buffer (TLB):

- The entry is valid.
- Using the entry does not generate a Translation fault, an Address size fault, or an Access flag fault.

I_{ZTRGT} TLB caching can reduce the number of required translation table lookups.

D5.2.2 Translation table base address register

I_{TLWRN} For a translation stage, the translation table base address register, TTBR_ELx, holds the translation table base address of the initial lookup.

R_{DXLKR} For a translation stage that supports two VA ranges, two translation table base address registers are required.

I_{HPFDM} Software can use TCR_ELx.TnSZ to configure the translation stage IA size to be smaller than the supported size.

R_{PNHHK} For stage 1 address translations in EL1&0, all of the following apply:

- The stage 1 translation table base address held in the TTBR_ELx register is an IPA.
- The stage 1 translation table base address returned by a Table descriptor is an IPA.
- Accesses to stage 1 translation tables are subject to a stage 2 translation.

R_{GYQHZ} For an address translation stage, the translation table base address in TTBR_ELx is defined for the supported OA size of that stage.

I_{SXSYL} For the VMSAv8-64 translation system, the number of {I}PA bits held in TTBR_ELx is determined by the granule size and OA address size. The bits used for each granule size when using the maximum OA address size of 48 bits or 52 bits

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

are shown in the following table. Software might be required to set one or more of the low-order base address bits to zero to align the table to the table size.

Table D5-6 {I}PA bits held in TTBR_ELx

Granule size	Maximum OA size	Translation table base address	{I}PA bits held in TTBR_ELx
4KB, 16KB, or 64KB	52 bits	TTBR_ELx[5:2]	{I}PA[51:48]
4KB	48 bits or 52 bits	TTBR_ELx[47:12]	{I}PA[47:12]
16KB	48 bits or 52 bits	TTBR_ELx[47:14]	{I}PA[47:14]
64KB	48 bits or 52 bits	TTBR_ELx[47:16]	{I}PA[47:16]

I_{QTPMQ} If an address translation stage uses an OA size smaller than the maximum, then the upper bits of the translation table base address in TTBR_ELx corresponding to the upper bits of OA size are required to be set by software to zero.

I_{LXTNH} If TCR_ELx.T*n*SZ specifies an IA size that is smaller than the maximum size resolved at the initial lookup level, then more low-order TTBR_ELx bits are used to hold the translation table base address.

R_{VPBBF} If an address translation stage uses an OA size smaller than the maximum and if the bits above the configured OA size of the translation table base address in TTBR_ELx are not set to zero, then an Address size fault is generated and reports all of the following:

- A translation level 0 lookup as generating the fault, regardless of whether or not the translation stage starts with a level 0 lookup.
- The translation stage that generated the fault.

R_{DYDPX} Direct writes to TTBR0_ELx and TTBR1_ELx occur in program order relative to one another, without the need for explicit synchronization. For any one translation, all indirect reads of TTBR0_ELx and TTBR1_ELx that are made as part of the translation observe only one point in that order of direct writes.

I_{RBMTM} Consistent with the general requirements for direct writes to System registers, direct writes to TTBR_ELx are not required to be observed by indirect reads until completion of a Context synchronization event.

I_{QBVNF}

Example D5-1 Changing translation table base address and ASID value when TCR_EL1.A1=0

The following is an example software sequence for changing translation table base address and ASID value when TCR_EL1.A1=0:

```
Change TTBR1 to point only at global entries
Change TTBR0 (includes changing the ASID)
Change TTBR1 to point at tables containing non-global entries
ISB
```

I_{GRBLY}

Example D5-2 Changing translation table base address and ASID value when TCR_EL1.A1=1

The following is an example software sequence for changing translation table base address and ASID value when TCR_EL1.A1=1:

```
Change TTBR0 to point to no valid entries
Change TTBR1 (includes changing the ASID)
Change TTBR0 to point at tables containing valid entries
ISB
```

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I_{BSFJP} For more information, see System registers relevant to MMU operation.

D5.2.3 Selection between TTBR0_ELx and TTBR1_ELx when two VA ranges are supported

R_{HCTPT} If a stage 1 translation regime supports two VA ranges, then the translation regime TTBR_ELx registers point to all of the following address ranges:

- For the lower VA range that begins at address `0x0000_0000_0000_0000`, TTBR0_ELx points to the translation table for the initial lookup level.
- For the upper VA range that ends at address `0xFFFF_FFFF_FFFF_FFFF`, TTBR1_ELx points to the translation table for the initial lookup level.

R_{YYVYV} If a stage 1 translation regime supports two VA ranges, then the TCR_ELx.{T0SZ, T1SZ} fields configure all of the following address range sizes:

- The lower VA range is `0x0000_0000_0000_0000` to $(2^{(64-T0SZ)} - 1)$.
- The upper VA range is $(2^{64} - 2^{(64-T1SZ)})$ to `0xFFFF_FFFF_FFFF_FFFF`.

I_{THCZK} If a stage 1 translation regime supports two VA ranges, when an accessed address is not in the lower VA range or the upper VA range, a stage 1 level 0 Translation fault is generated.

I_{BCMMD} The following figure illustrates the two address ranges translated by the tables the TTBR_ELx registers point to.

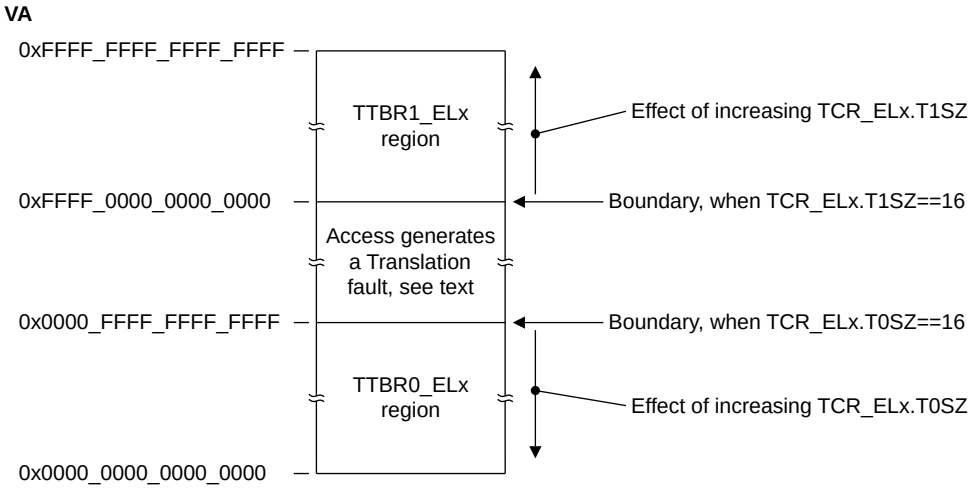

Figure D5-2 Example of a stage 1 translation that supports two VA ranges

R_{VZCSR} If a stage 1 translation regime supports two VA ranges, then all of the following are used to select the TTBR_ELx:

- If VA bit[55] is zero, then TTBR0_ELx is selected.
- If VA bit[55] is one, then TTBR1_ELx is selected.

I_{ZFSYQ} If a stage 1 translation regime supports two VA ranges and TCR_ELx.EPD*n* is one, then when a TLB miss occurs based on TTBRn_ELx, a level 0 Translation fault is generated, and no translation table walk is done.

I_{QBLKT} For more information, see Address tagging.

D5.2.3.1 Preventing EL0 access to halves of the address map

R_{BNDVG} All statements in this section require implementation of FEAT_E0PD.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I_{PZZHN} The TCR_ELx.{E0PD0, E0PD1} fields can be used to prevent EL0 access to the addresses translated by the corresponding TTBR0_ELx or TTBR1_ELx.

I_{RFRSQ} When the TCR_ELx.{E0PD0, E0PD1} fields prevent EL0 access to an address translated by TTBR0_ELx or TTBR1_ELx, then a level 0 Translation fault is generated.

R_{DDFWH} When the TCR_ELx.{E0PD0, E0PD1} fields generate a level 0 Translation fault, then all of the following apply:

- The time needed to take the fault should be the same whether or not the address accessed is present in a TLB, to mitigate attacks that use fault timing.
- The fault generated does not affect any micro-architectural state of the PE in a manner that is different if the address accessed is present in a TLB or not, to prevent this information being used to determine the presence of the address in a TLB.

R_{CZWGX} When the TCR_ELx.{E0PD0, E0PD1} fields generate a level 0 Translation fault, the fault is not counted as a TLB miss for performance monitoring features.

D5.2.4 Translation table and translation table lookup properties

I_{SLRTY} Translation table and translation table lookup properties include the table size, table alignment, table endianness, and memory attributes.

D5.2.4.1 Translation table size

R_{RVHGW} The descriptor size in a translation table entry is an eight-byte, or 64-bit, object.

R_{WDRNX} If *n* is the number of bits resolved by a lookup level, then the number of translation table entries required at that lookup level is 2^n.

R_{NVTHS} The size of a translation table in bytes is determined by multiplying the number of entries by the descriptor size.

I_{KNSPW} The maximum number of translation table entries is determined by the translation granule size, which is defined by one of the following:

- For a stage 1 translation that supports one VA range, TCR_ELx.TG0.
- For a stage 1 translation that can support two VA ranges, all of the following:
  - For the lower VA range, TCR_ELx.TG0.
  - For the upper VA range, TCR_ELx.TG1.

D5.2.4.2 Translation table alignment

R_{KBLCR} A translation table is required to be aligned to one of the following:

- For the VMSAv8-64 translation system, if the translation table has fewer than eight entries and an OA size greater than 48 bits is used, then the table is aligned to 64 bytes.
- Otherwise, the translation table is aligned to the size of that translation table.

I_{TBPFK} Only when all of the following are true is it possible to have fewer than 8 translation table entries:

- The translation table is at the initial lookup level.
- Concatenated translation tables are not used.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D5.2.4.3 Translation table lookup endianness

I_{KLNSQ} When a translation table lookup reads a translation table entry the read is an 8-byte single-copy atomic access.

R_{FDKMS} The endianness of a translation table lookup is determined by the appropriate SCTLR_EL1, System Control Register (EL1).EE bit.

R_{PZVGH} Changing an SCTLR_EL1, System Control Register (EL1).EE bit requires synchronization before the change is guaranteed to be visible to subsequent operations.
For more information, see Synchronization requirements for AArch64 System registers.

I_{QJDJV} Arm does not recommend changing an SCTLR_EL1, System Control Register (EL1).EE bit unless one or more of the following apply:

- The translation table lookups affected by the modified SCTLR_EL1, System Control Register (EL1).EE bit belong to an out-of-context translation regime.
- For any translation stage affected by the modified SCTLR_EL1, System Control Register (EL1).EE bit, address translation is disabled.

D5.2.4.4 Translation table lookup memory attributes

I_{TXCPH} For a translation table lookup in an address translation stage, the TCR_ELx and VTCR_EL2 registers determine the memory Cacheability and Shareability attributes that apply.

R_{ZZSYD} For a translation table lookup in an address translation stage, the required memory type is Normal memory.

R_{XGXKR} When memory locations that hold the translation tables are accessed by software, and the memory accesses and the translation table walks have mismatched memory attributes, the behavior is the same as different memory accesses to the same memory location using mismatched memory attributes.
For more information, see Mismatched memory attributes.

I_{BSKKL} Arm recommends that the memory attributes applied by the TCR_ELx to the translation tables are the same as the attributes that are applied by other accesses to the memory that holds the translation tables.

I_{WVTXS} For more information on Normal and Device memory and on the Cacheability and Shareability attributes, see Memory types and attributes.

D5.2.5 Translation table walk properties

D5.2.5.1 Ordering of memory accesses from translation table walks

R_{TGRMW} A translation table walk is considered to be a separate observer. An explicit write to the translation tables might be observed by that separate observer for either of the following:

- A translation table walk caused by a different explicit write generated by the same instruction.
- A translation table walk caused by an explicit access generated by any instruction appearing in program order after the instruction doing the explicit write to the translation table.

R_{SPVBD} The explicit write to the translation tables is guaranteed to be observable, to the extent required by the Shareability attributes, only after the execution of a DSB instruction. This DSB instruction and the instruction that performed the explicit write to the translation tables must have been executed by the same PE.

R_{RGPMV} Any writes to the translation tables are not observed by any translation table accesses associated with an explicit memory access generated by a load or store that occurs in program order before the instruction that performs the write to the translation tables.

I_{LTSNZ} For more information, see:

- External visibility requirement.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- Memory barriers.

D5.2.5.2 Security state of translation table lookups

R_{PXRPP} For a translation table walk in a Non-secure translation regime, all translation table lookups are done to Non-secure IPA or PA space.

I_{KGBDL} The OA space of the Secure EL1&0 stage 1 translation regime is PA space.

R_{SCHHQ} For a stage 1 translation table walk in a Secure Translation Regime, the OA space at stage 1 of the translation table lookups is determined by all of the following:

- The initial translation table lookup is done to Secure OA space.
- When the Table descriptor lookup is to Secure OA space, the descriptor NSTable bit determines one of the following:
  - If NSTable is zero, the next translation table lookup is done to Secure OA space.
  - If NSTable is one, the next translation table lookup is done to Non-secure OA space.
- When the Table descriptor lookup is to Non-secure OA space, the next translation table lookup is done to Non-secure OA space.

For more information, see Hierarchical control of Secure or Non-secure memory accesses.

D5.2.6 VMSAv8-64 translation using the 4KB granule

R_{LCVYF} All statements in this section and subsections require a translation stage use the VMSAv8-64 translation system.

I_{SZLLC} Address translations that use the 4KB granule have a 4KB page size. Depending on the settings and supported features, up to 40 address bits are resolved using up to 5 lookup levels.

R_{NNSVF} For the 4KB translation granule, OA[51:48] are treated as `0b0000`.

R_{SMKJL} For each lookup level supported by the 4KB translation granule, the following table describes the translation table properties at that level.

Table D5-7 4KB granule translation table properties at each lookup level

Lookup level	Index into translation table	Maximum entries in table	Contents of translation table entries
-1	-	-	Lookup level not supported
0	IA[47:39]	512	Table descriptors
1	IA[38:30]	512	Table descriptors and Block descriptors
2	IA[29:21]	512	Table descriptors and Block descriptors
3	IA[20:12]	512	Page descriptors

R_{VHWNS} For the 4KB translation granule, a translation resolved by a Page descriptor at lookup level 3 has all of the following properties:

- The page size is 4KB.
- The translation can resolve a page using IA[47:12].
- The page is addressed by OA[47:12].
- IA[11:0] is mapped directly to OA[11:0].

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.

R_{NHKBC} For the 4KB translation granule, a translation resolved by a Block descriptor at the specified lookup level has all of the properties shown in the following table:

Table D5-8 4KB granule block descriptor properties at each lookup level

Lookup level	Size of memory region addressed by Block descriptor	Bit range that is direct mapped from IA to OA	IA bit range that selects Block descriptor
0	Not supported	-	-
1	1GB	IA[29:0] maps to OA[29:0]	IA[47:30]
2	2MB	IA[20:0] maps to OA[20:0]	IA[47:21]

D5.2.6.1 VMSAv8-64 Stage 1 address translation using the 4KB translation granule

R_{GWNBR} For the 4KB translation granule, when a stage 1 translation table walk is started, the initial lookup level is determined by the value of the TCR_ELx.T*n*SZ field as shown in the following table.

Table D5-9 4KB granule, determining stage 1 initial lookup level

Initial lookup level	T*n*SZ minimum value	Maximum IA bits resolved	T*n*SZ maximum value	Minimum IA bits resolved	Additional requirements
0	16	IA[47:12]	24	IA[39:12]	-
1	25	IA[38:12]	33	IA[30:12]	-
2	34	IA[29:12]	39	IA[24:12]	-
2	40	IA[23:12]	42	IA[21:12]	FEAT_TTST is implemented
3	43	IA[20:12]	48	IA[15:12]	FEAT_TTST is implemented

I_{JCHLN} For a stage 1 translation in the 4KB translation granule, depending on the IA size, the initial lookup level is indexed by up to 9 bits and all remaining lookup levels are indexed by exactly 9 bits.

D5.2.6.2 Finding the descriptor when using the VMSAv8-64 4KB translation granule

R_{VMPRR} For the 4KB translation granule, the following table shows the algorithm to find the descriptor address at each supported lookup level, using of all of the following information:

- The translation table base address, *BaseAddr*.
- The number of bits in the supported PA size, *PAsize*.
- The IA supplied to the translation stage and used as an index into the translation table.
- For each initial lookup level, the permitted range of values for TCR_ELx.T*n*SZ.

Table D5-10 4KB granule, finding the descriptor address

Lookup level	Stage 1 translation table descriptor address
-1	if 12 <= T*n*SZ <= 15 then *x* = (19 - T*n*SZ) BaseAddr[PAsize-1:*x*]:IA[*x*+44:48]:`0b000`
0	if 16 <= T*n*SZ <= 24 then *x* = (28 - T*n*SZ) else *x* = 12 BaseAddr[PAsize-1:*x*]:IA[*x*+35:39]:`0b000`
1	if 25 <= T*n*SZ <= 33 then *x* = (37 - T*n*SZ) else *x* = 12 BaseAddr[PAsize-1:*x*]:IA[*x*+26:30]:`0b000`
2	if 34 <= T*n*SZ <= 42 else *x* = 12 BaseAddr[PAsize-1:*x*]:IA[*x*+17:21]:`0b000`
3	if 43 <= T*n*SZ <= 48 then *x* = (55 - T*n*SZ) else *x* = 12 BaseAddr[PAsize-1:*x*]:IA[*x*+8:12]:`0b000`

D5.2.7 VMSAv8-64 translation using the 16KB granule

R_{QSQNQ} All statements in this section and subsections require a translation stage use the VMSAv8-64 translation system.

I_{TDTCY} Address translations that use the 16KB granule have a 16KB page size. Depending on the settings and supported features, up to 38 address bits are resolved using up to 4 lookup levels.

I_{JCYXY} For the 16KB translation granule, the maximum VA and PA supported by a translation regime is 48 bits.

R_{CDLYH} For the 16KB translation granule then OA[51:48] are treated as `0b0000`.

R_{CWKJW} For each lookup level supported by the 16KB translation granule, the following table describes the translation table properties at that level.

Table D5-11 16KB granule translation table properties at each lookup level

Lookup level	Index into translation table	Maximum entries in table	Contents of translation table entries
0	IA[47]	232	Table descriptors Lookup level 0 supported only at stage 1
1	IA[46:36]	2048	Table descriptors
2	IA[35:25]	2048	Table descriptors and Block descriptors
3	IA[24:14]	2048	Page descriptors

R_{YHJLX} For the 16KB translation granule, a translation resolved by a Page descriptor at lookup level 3 has all of the following properties:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- The page size is 16KB.
- The translation can resolve a page using the maximum address ranges IA[47:14].
- The page is addressed by OA[47:14].
- IA[13:0] is mapped directly to OA[13:0].

R_{FFHSQ} For the 16KB translation granule, a translation resolved by a Block descriptor at the specified lookup level has all of the properties shown in the following table:

Table D5-12 16KB granule block descriptor properties at each lookup level

Lookup level	Size of memory region addressed by Block descriptor	Bit range that is direct mapped from IA to OA	IA bit range that selects Block descriptor
1	Not supported	-	-
2	32MB	IA[24:0] maps to OA[24:0]	IA[47:25]

D5.2.7.1 VMSAv8-64 Stage 1 address translation using the 16KB translation granule

R_{WDCVZ} For the 16KB translation granule, when a stage 1 translation table walk is started, the initial lookup level is determined by the value of the TCR_ELx.T*n*SZ field as shown in the following table:

Table D5-13 16KB granule, determining stage 1 initial lookup level

Initial lookup level	T*n*SZ minimum value	Maximum IA bits resolved	T*n*SZ maximum value	Minimum IA bits resolved	Additional requirements
0	16	IA[47:14]	16	IA[47:14]	-
1	17	IA[46:14]	27	IA[36:14]	-
2	28	IA[35:14]	38	IA[25:14]	-
3	39	IA[24:14]	39	IA[24:14]	-
3	40	IA[23:14]	48	IA[15:14]	FEAT_TTST is implemented

I_{FLDKN} For a stage 1 translation in the 16KB translation granule, depending on the IA size, the initial lookup level is indexed by up to 11 bits and all remaining lookup levels are indexed by exactly 11 bits.

I_{KSSHJ} For the 16KB translation granule and a 52-bit IA, the following figure is a generalized view of a stage 1 address translation. An IA and an OA larger than 48 bits requires that the Effective value of TCR_ELx.DS is 1. The 64GB block size requires that the Effective value of TCR_ELx.DS is 1.

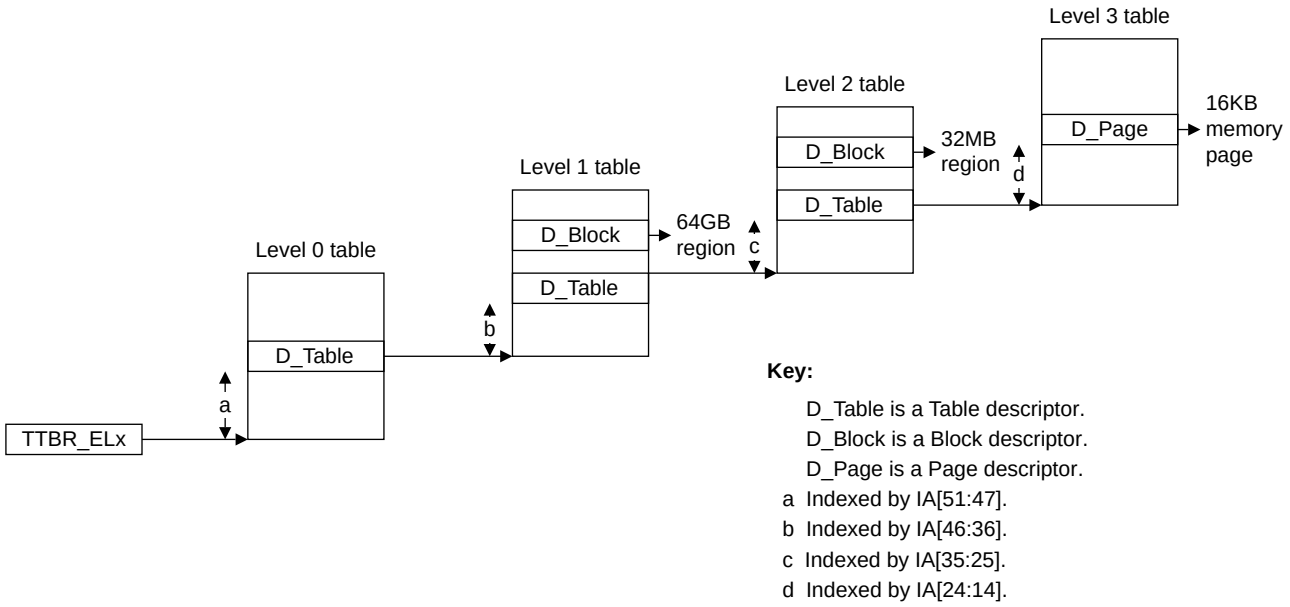

Figure D5-3 Generalized view of a stage 1 address translation using the 16KB granule

D5.2.7.2 Finding the descriptor when using the VMSAv8-64 16KB translation granule

R_{VVQFC} For the 16KB translation granule, the following table shows the algorithm to find the descriptor address at each supported lookup level, using of all of the following information:

- The translation table base address, *BaseAddr*.
- The number of bits in the supported PA size, *PAsize*.
- The IA supplied to the translation stage and used as an index into the translation table.
- For each initial lookup level, the permitted range of values for TCR_ELx.T*n*SZ.

Table D5-14 16KB granule, finding the descriptor address

Lookup level	Stage 1 translation table descriptor address
0	if 12 <= T*n*SZ <= 16 then *x* = (20 - T*n*SZ) BaseAddr[PAsize-1:*x*]:IA[*x*+43:47]:`0b000`
1	if 17 <= T*n*SZ <= 27 then *x* = (31 - T*n*SZ) else *x* = 14 BaseAddr[PAsize-1:*x*]:IA[*x*+32:36]:`0b000`
2	if 28 <= T*n*SZ <= 38 then *x* = (42 - T*n*SZ) else *x* = 14 BaseAddr[PAsize-1:*x*]:IA[*x*+21:25]:`0b000`
3	if 39 <= T*n*SZ <= 48 then *x* = (53 - T*n*SZ) else *x* = 14 BaseAddr[PAsize-1:*x*]:IA[*x*+10:14]:`0b000`

D5.2.8 VMSAv8-64 translation using the 64KB granule

R_{RGNZV} All statements in this section and subsections require a translation stage use the VMSAv8-64 translation system.

I_{VDPWL} Address translations that use the 64KB granule have a 64KB page size. Depending on the settings and supported features, up to 36 address bits are resolved using up to 3 lookup levels.

I_{LRFQD} For the 64KB translation granule, the maximum VA size supported by a translation regime is one of the following:

- If FEAT_LVA is not implemented, then the maximum VA supported is 48 bits.
- If FEAT_LVA is implemented, then the maximum VA supported is 52 bits.

I_{YZDPC} For the 64KB translation granule, the maximum PA size supported by a translation regime is one of the following:

- If FEAT_LPA is not implemented, then the maximum PA supported is 48 bits.
- If FEAT_LPA is implemented, then the maximum PA supported is 52 bits.

R_{NSQXP} For the 64KB translation granule, if FEAT_LPA is not implemented, then OA[51:48] are treated as `0b0000`.

R_{MLLGN} For each lookup level supported by the 64KB translation granule, the following table describes the translation table properties at that level.

Table D5-15 64KB granule translation table properties at each lookup level

Lookup level	Index into translation table	Maximum entries in table	Contents of translation table entries	Additional requirements for stage 1
1	IA[47:42]	64	Table descriptors	-
			Table descriptors and Block descriptors	FEAT_LPA
	IA[51:42]	1024	Table descriptors	FEAT_LVA
			Table descriptors and Block descriptors	FEAT_LVA, FEAT_LPA
2	IA[41:29]	8192	Table descriptors and Block descriptors	-
3	IA[28:16]	8192	Page descriptors	-

R_{RVYWB} For the 64KB translation granule, a translation resolved by a Page descriptor at lookup level 3 has all of the following properties:

- The page size is 64KB.
- For stage 1, the translation can resolve a page using one of the following maximum address ranges:
  - If FEAT_LVA is not implemented, then IA[47:16].
  - If FEAT_LVA is implemented, then IA[51:16].
- For stage 1, the page is addressed by one of the following:
  - If FEAT_LPA is not implemented, then OA[47:16].
  - If FEAT_LPA is implemented, then OA[51:16].
- IA[15:0] is mapped directly to OA[15:0].

R_{RBNGS} For the 64KB translation granule, a translation resolved by a Block descriptor at the specified lookup level has all of the properties shown in the following table:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Table D5-16 64KB granule block descriptor properties at each lookup level

Lookup level	Size of memory region addressed by Block descriptor	Bit range that is direct mapped from IA to OA	IA bit range that selects Block descriptor	Additional requirements for stage 1	Additional requirements for stage 2
1	4TB	IA[41:0] maps to OA[41:0]	IA[47:42]	FEAT_LPA	FEAT_LPA
			IA[51:42]	FEAT_LVA, FEAT_LPA	FEAT_LPA
2	512MB	IA[28:0] maps to OA[28:0]	IA[47:29]	-	-
			IA[51:29]	FEAT_LVA	FEAT_LPA

I_{TVDSK} For the 64KB translation granule, the following figure shows how the maximum 52-bit IA size is resolved. For a stage 1 translation, an IA larger than 48 bits requires the implementation of FEAT_LVA.

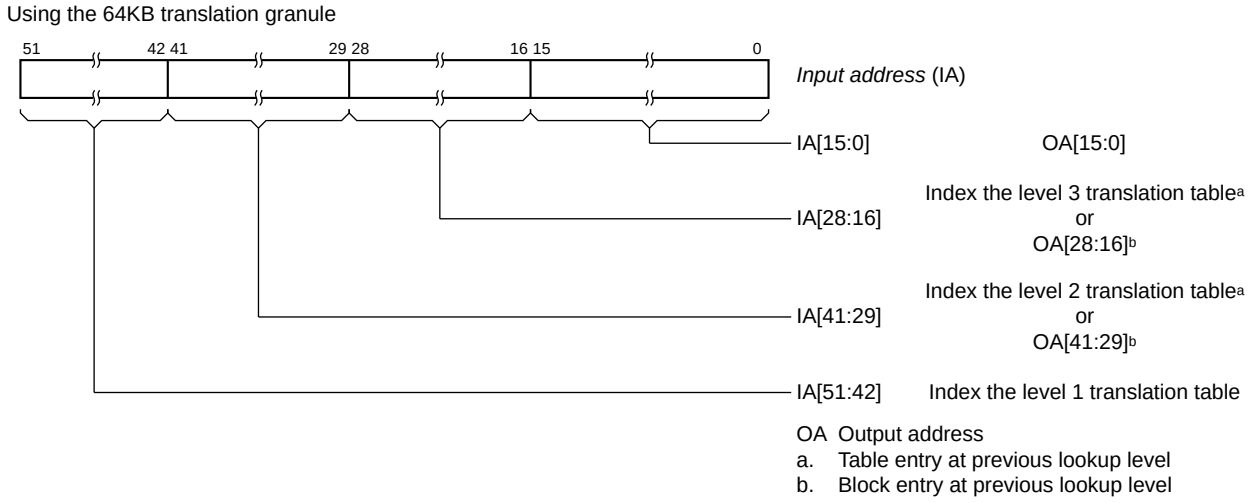

Figure D5-4 52-bit IA resolved using 64KB translation granule

D5.2.8.1 VMSAv8-64 Stage 1 address translation using the 64KB translation granule

R_{FMBKV} For the 64KB translation granule, when a stage 1 translation table walk is started, the initial lookup level is determined by the value of the TCR_ELx.T*n*SZ field as shown in the following table:

Table D5-17 64KB granule, determining stage 1 initial lookup level

Initial lookup level	T*n*SZ minimum value	Maximum IA bits resolved	T*n*SZ maximum value	Minimum IA bits resolved	Additional requirements
1	12	IA[51:16]	15	IA[48:16]	FEAT_LVA is implemented
1	16	IA[47:16]	21	IA[42:16]	-
2	22	IA[41:16]	34	IA[29:16]	-
3	35	IA[28:16]	39	IA[24:16]	-
3	40	IA[23:16]	47	IA[16:16]	FEAT_TTST is implemented

I_{FQFFW} For a stage 1 translation in the 64KB translation granule, depending on the IA size, the initial lookup level is indexed by up to 13 bits and all remaining lookup levels are indexed by exactly 13 bits.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I_{MRDWZ} For the 64KB translation granule and a 52-bit IA, the following figure is a generalized view of a stage 1 address translation. An IA larger than 48 bits requires implementation of FEAT_LVA, and an OA larger than 48 bits requires implementation of FEAT_LPA. The 4TB block size requires implementation of FEAT_LPA.

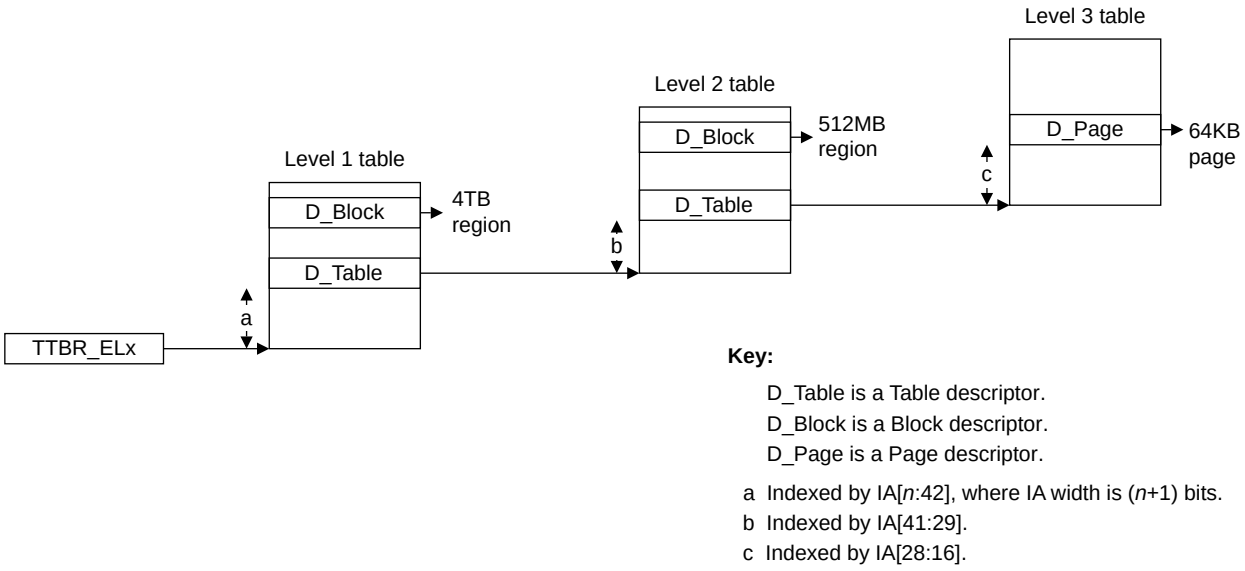

Figure D5-5 Generalized view of a stage 1 address translation using the 64KB granule

D5.2.8.2 Finding the descriptor when using the VMSAv8-64 64KB translation granule

R_{VYNTC} For the 64KB translation granule, the following table shows the algorithm to find the descriptor address at each supported lookup level, using of all of the following information:

- The translation table base address, *BaseAddr*.
- The number of bits in the supported PA size, *PAsize*.
- The IA supplied to the translation stage and used as an index into the translation table.
- For each initial lookup level, the permitted range of values for TCR_ELx.T*n*SZ.

Table D5-18 64KB granule, finding the descriptor address

Lookup level	Stage 1 translation table descriptor address
1	if 12 <= T*n*SZ <= 21 then *x* = (25 - T*n*SZ) BaseAddr[PAsize-1:*x*]:IA[*x*+38:42]:`0b000`
2	if 22 <= T*n*SZ <= 34 then *x* = (38 - T*n*SZ) else *x* = 16 BaseAddr[PAsize-1:*x*]:IA[*x*+25:29]:`0b000`
3	if 35 <= T*n*SZ <= 47 then *x* = (51 - T*n*SZ) else *x* = 16 BaseAddr[PAsize-1:*x*]:IA[*x*+12:16]:`0b000`

D5.2.9 The effects of disabling an address translation stage

I_{QMGZS} Stage 1 tranlsations can be disabled. Setting VTCR_EL2.MSA to 0 disables the VMSAv8-64 memory architecture and enables the PMSAv8-64 memory architecture.

For more information, see The AArch64 Protected Memory System Architecture

D5.2.9.1 Effect of disabling address translation on maintenance and address translation instructions

R_{SJBMV} Cache maintenance instructions act on the target location regardless of all of the following:

- Whether or not any address translation stages are disabled.
- The memory attribute values.

R_{ZSSPZ} For an address translation stage that is disabled, cache maintenance instructions use flat address mapping.

R_{FZYGN} If an address translation stage is disabled, TLB maintenance operations are not affected.

I_{HRNPD} For more information, see:

- A64 Cache maintenance instructions.
- Address translation instructions.
- TLB maintenance instructions.

D5.2.10 Address translation instructions

I_{TMFCK} Address translation instructions return the result of translating an IA using a specified translation stage or regime.

I_{NQTNR} An address translation instruction has all of the following properties:

- An IA is supplied as the argument to the instruction.
- The instruction encoding determines the translation stage and regime used by the translation.
- The PAR_EL1 register is updated with the translation result.
- If an address translation stage is controlled by a higher Exception level than the Exception level at which the address translation instruction is executed, then the instruction is UNDEFINED.

I_{TSJPJ} The A64 assembly language syntax of an address translation instruction is `AT <operation>, <Xt>`.

I_{RTMLK} The `<operation>` in `AT <operation>, <Xt>` is one of the following:

- `S1E1R`, `S1E1W`, `S1E0R`, `S1E0W`, `S12E1R`, `S12E1W`, `S12E0R`, `S12E0W`, `S1E2R`, `S1E2W`, `S1E3R`, or `S1E3W`.
- If FEAT_PAN2 is implemented, `then S1E1WP` or `S1E1RP`.

I_{SLTTL} The `<operation>` in `AT <operation>, <Xt>` has a structure of `<stages><el>(<read|write>{<pan>})|<ignore>` with all of the following components:

- `<stages>` is one of the following address translation stages:
  - `S1` specifies a stage 1 translation.
- `<el>` is one of the following Exception levels that apply to the translation:
  - `E0` specifies EL0.
  - `E1` specifies EL1.
  - `E2` specifies EL2.
- `<read|write>` is one of the following:
  - `R` specifies Read.
  - `W` specifies Write.
- If FEAT_PAN2 is implemented, then the `<pan>` component is included and has all of the following properties:
  - `P` determines whether the PSTATE.PAN value is considered when determining permissions. For more information, see PSTATE.PAN.
  - The field is optional.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

— If `<stages>=S1` and `<el>=E1`, the field is permitted.
— If `<stages>!=S1` or `<el>!=E1`, the field is not permitted.

I_{XLYWF} If `<el>` is higher than the current Exception level, then the address translation instruction is UNDEFINED.

I_{SYHWD} The `<Xt>` in `AT <operation>, <Xt>` specifies the 64-bit register holding the address to be translated.

R_{NJGLC} When an address is translated by an address translation instruction, no alignment restrictions exist and therefore an address translation instruction cannot generate an Alignment fault.

I_{LRNWF} Execution of an AT instruction may result in a successful translation reported in PAR_EL1, an MMU fault being reported in PAR_EL1, or an MMU fault generating an exception.
For more information see:

- MMU faults generated by address translation instructions
- Address translation instructions, successful address translation

R_{NWDPJ} When an address translation instruction is executed, the specified translation stage and regime determines all of the following:

- The entries in TLB caching structures that are permitted to be used.
- How the translation table walk is done.

R_{NPZWX} When an address translation instruction is executed, it is IMPLEMENTATION DEFINED whether the result can be returned from a TLB, or a translation table walk occurs.

I_{WGXJK} If TLB entries might differ from the underlying translation tables held in memory, such as when waiting for a maintenance or synchronization event to complete after updating the translation tables, Arm recommends not using the address translation instructions.

D5.2.10.1 Address translation instructions, successful address translation

R_{LRYRY} When an address translation instruction successfully translates an address, all of the following are updated in PAR_EL1:

- PAR_EL1.F is set to 0.
- The resulting OA is returned in PAR_EL1.PA, and the resulting attributes are returned in the other fields of PAR_EL1.

I_{PVCPF} When populating PAR_EL1 with the result of an address translation instruction, the fetches of stage 1 or stage 2 descriptors use the appropriate MECID register values for the translation regime.

I_{QKWHX} The architecture defines a single PAR, PAR_EL1, that is used regardless of all of the following:

- The Exception level at which the address translation instruction was executed.
- The Exception level that controls the address translation stage or stages used by the address translation instruction.

D5.2.10.2 Address translation instructions, effect of translation regime

I_{KJDTT} The value of HCR_EL2.DC affects all of the following instructions:

- `AT S1E0*`.
- `AT S1E1*`.
- `AT S12E0*`.
- `AT S12E1*`.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D5.2.10.3 Address translation instructions, synchronization requirements

I_{JTYVP} When an address translation instruction is executed, explicit synchronization is required to guarantee the result is visible to subsequent direct reads of PAR_EL1.

For more information, see Synchronization requirements for AArch64 System registers.

I_{PCPWC} Requiring explicit synchronization after executing an address translation instruction is consistent with the general requirement that the effect of a write to a System register requires explicit synchronization before the result is guaranteed to be visible to subsequent instructions.

Non-Confidential

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D5.3 Translation table descriptor formats

R_{KSQZW} If an address translation stage is controlled by an Exception level that is using AArch64, then the translation table uses 64-bit descriptors.

R_{JXLYN} A translation descriptor has one of the following formats:

- An invalid descriptor format.
- A Table descriptor format that points to the next-level translation table.
- A Block descriptor or Page descriptor format that defines the memory access properties.
- A reserved format.

R_{KHVQT} The value of descriptor bit[0] determines one of the following:

- If descriptor bit[0] is 0, then the descriptor is invalid.
- If descriptor bit[0] is 1, then the descriptor is valid.

R_{RWMFF} For 64-bit descriptors used by the VMSAv8-64 translation system, if descriptor bit[0] is 1, then the descriptor type is determined by one of the following values of descriptor bit[1]:

- For lookup levels less than lookup level 3, one of the following:
  - If bit[1] is 0, then the descriptor is a Block descriptor.
  - If bit[1] is 1, then the descriptor is a Table descriptor.
- For lookup level 3, one of the following:
  - If bit[1] is 0, then the descriptor is reserved, and treated as invalid.
  - If bit[1] is 1, then the descriptor is a Page descriptor.

Table D5-19 Determination of descriptor type, VMSAv8-64 translation system

Descriptor bit[0]	bit[1]	Descriptor type	Condition
0	-	Invalid	-
1	0	Block	Lookup level is not 3
		Reserved, treated as invalid	Lookup level is 3
	1	Table	Lookup level is not 3
		Page	Lookup level is 3

R_{CQGPJ} For Table descriptors, if the Effective value of the SKL field is 0, then the next-level table address is one of the following:

- For a level -2 Table descriptor, the base address of a level -1 table.
- For a level -1 Table descriptor, the base address of a level 0 table.
- For a level 0 Table descriptor, the base address of a level 1 table.
- For a level 1 Table descriptor, the base address of a level 2 table.
- For a level 2 Table descriptor, the base address of a level 3 table.

D5.3.1 VMSAv8-64 descriptor formats

D5.3.1.1 VMSAv8-64 Table descriptor format

I_{TWKLX} The following figure shows all of following stage 1 VMSAv8-64 Table descriptor formats:

- 4KB, 16KB, and 64KB granules using a 48-bit next-level table address.
- If FEAT_LPA is implemented, the 64KB granule using a 52-bit next-level table address.

4KB and 16KB granules, 52-bit OA

64KB granule, 52-bit OA

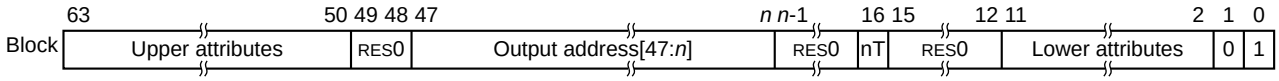
For the 4KB granule size, the level 0 descriptor *n* is 39, the level 1 descriptor *n* is 30, and the level 2 descriptor *n* is 21.

For the 16KB granule size, the level 1 descriptor *n* is 36, and the level 2 descriptor *n* is 25.

For the 64KB granule size, the level 1 descriptor *n* is 42, and the level 2 descriptor *n* is 29.

4KB, 16KB, and 64KB granules, 48-bit OA



For the 4KB granule size, the level 1 descriptor *n* is 30, and the level 2 descriptor *n* is 21.

For the 16KB granule size, the level 2 descriptor *n* is 25.

For the 64KB granule size, the level 2 descriptor *n* is 29.

Figure D5-8 VMSAv8-64 Block descriptor formats

I_{WNCLB} The following figure shows all of the following VMSAv8-64 Page descriptor formats:

- 4KB, 16KB, and 64KB granules using a 48-bit OA.
- If FEAT_LPA is supported, the 64KB granule using a 52-bit OA.

Table D5-21 Stage 1 VMSAv8-64 Block and Page descriptor fields

Bit position	Field	Condition
[63]	IGNORED	Non-secure or Secure state, EL1&0 translation regime.
[62:60]	IGNORED	FEAT_HPDS2 is not implemented or PBHA is not enabled by the corresponding TCR_ELx.HWU*nn* control bit.
	PBHA[3:1]	FEAT_HPDS2 is implemented and the PBHA bit is enabled by the corresponding TCR_ELx.HWU*nn* control bit. See Page Based Hardware attributes.
	POIndex[2:0]	Stage 1 Overlay permissions enabled. See Stage 1 Overlay permissions.
[59]	IGNORED	FEAT_HPDS2 is implemented and the PBHA bit is enabled by the corresponding TCR_ELx.HWU*nn* control bit.
	PBHA[0]	FEAT_HPDS2 is implemented and the PBHA bit is enabled by the corresponding TCR_ELx.HWU*nn* control bit. See Page Based Hardware attributes.
[58:56]	Reserved for software use	-
[55]	IGNORED	-
[54]	Execute-never (XN)	The translation regime supports a single privilege level. See Stage 1 instruction execution using Direct permissions.
	Unprivileged Execute-never (UXN)	The translation regime supports two privilege levels. See Stage 1 instruction execution using Direct permissions.
	Privileged Execute-never (PXN)	The Effective value of UXN is 0. See Stage 1 instruction execution using Direct permissions
	PIIndex[3]	Stage 1 Indirect permissions enabled, regardless of other feature settings. See Stage 1 Indirect permissions.
[53]	RES0	One of the following: • The translation regime supports a single privilege level. • The EL1&0 translation regime and the Effective value of HCR_EL2.{NV, NV1} is {1, 1}. See Stage 1 instruction execution using Direct permissions
	PXN	The translation regime supports two privilege levels. See Stage 1 instruction execution using Direct permissions.
	PIIndex[2]	Stage 1 Indirect permissions enabled, regardless of other feature settings. See Stage 1 Indirect permissions.
[52]	Contiguous	The Effective value of PnCH is 0. See The Contiguous bit.
	Protected	The Effective value of PnCH is 1. See Stage 1 Protected Attribute.
[51]	Dirty bit modifier (DBM)	Stage 1 Indirect permissions are disabled. See Hardware management of the dirty state.
	PIIndex[1]	Stage 1 Indirect permissions are enabled. See Stage 1 Indirect permissions.
[50]	RES0	
[49:48]	RES0

Bit position	Field	Condition
Block[47:17]	OAB[47:30]	The 4KB translation granule and the descriptor is a level 1 Block descriptor. Descriptor bits [29:17] are RES0.
	OAB[47:21]	The 4KB translation granule and the descriptor is a level 2 Block descriptor. Descriptor bits [20:17] are RES0.
	OAB[47:36]	The 16KB translation granule, the Effective value of TCR_ELx.DS is 1, and the descriptor is a level 1 Block descriptor. Descriptor bits [35:17] are RES0.
	OAB[47:25]	The 16KB translation granule and the descriptor is a level 2 Block descriptor. Descriptor bits [24:17] are RES0.
	OAB[47:42]	The 64KB translation granule, FEAT_LPA is implemented, and the descriptor is a level 1 Block descriptor. Descriptor bits [41:17] are RES0.
	OAB[47:29]	The 64KB translation granule and the descriptor is a level 2 Block descriptor. Descriptor bits [28:17] are RES0.
Block[16]	RES0	FEAT_BBML1 is not implemented.
	nT	FEAT_BBML1 is implemented. See Table and Block entry.
Block[15:12]	RES0	One of the following: • FEAT_LPA is not implemented. • FEAT_LPA is implemented, and the 4KB or 16KB translation granule is used.
	OAB[51:48]	FEAT_LPA is implemented and the 64KB translation granule is used.
Page[47:12]	OAB[47:12]	The 4KB translation granule is used.
	OAB[47:14]	The 16KB translation granule is used. Descriptor bits [13:12] are RES0.
	OAB[47:16]	The 64KB translation granule and FEAT_LPA is not implemented. Descriptor bits [15:12] are RES0.
	OAB[47:16]: OAB[51:48]	The 64KB translation granule and FEAT_LPA is implemented.
[11]	RES0	The translation regime supports a single privilege level and the Security state is not Root state.
	Not global (nG)	The translation regime supports two privilege levels. See Global and process-specific translation table entries.
[10]	Access flag (AF)	- See The Access flag.
[9:8]	Shareability (SH[1:0])	One of the following: • The 4KB or 16KB translation granule is used, and the Effective value of TCR_ELx.DS is 0. • The 64KB translation granule is used. See Stage 1 Shareability attributes.
	OAB[51:50]	The 4KB or 16KB translation granule is used, and the Effective value of TCR_ELx.DS is 1.
[7]	AP[2]	Stage 1 Indirect permissions are disabled. See Stage 1 data accesses using Direct permissions.
	nDirty	Stage 1 Indirect permissions are enabled. See The dirty state.
[6]	RES1	Stage 1 Indirect permissions are disabled and the translation regime supports a single privilege level.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Bit position	Field	Condition
	AP[1]	Stage 1 Indirect permissions are disabled and the translation regime supports two privilege levels. See Stage 1 data accesses using Direct permissions.
	PIIndex[0]	Stage 1 Indirect permissions are enabled. See Stage 1 Indirect permissions.
[5]	RES0	The access is from Non-secure state using the EL1&0 translation regime.
	NS	The access is from Secure state.
[4:2]	AttrIndx[2:0]	See Stage 1 memory type and Cacheability attributes.
[1]	Block descriptor	0, for lookup levels less than lookup level 3.
	Page descriptor	1, for lookup level 3.
[0]	Valid descriptor	1.

D5.3.1.3 VMSAv8-64 Invalid descriptor format

RVRYZC For stage 1 translations, the following table defines the fields in the VMSAv8-64 Invalid descriptor. IGNORED fields are available for software use.

Table D5-22 Stage 1 VMSAv8-64 Invalid descriptor fields

Bit position	Field	Condition
[63:53]	IGNORED	-
[52]	IGNORED	The Effective value of PnCH is 0.
	Protected	The Effective value of PnCH is 1. See Stage 1 Protected Attribute.
[51:1]	IGNORED	-
[0]	Invalid descriptor	0.

D5.4 Memory access control

I_{SHRMH} Fields in the descriptors, PSTATE, and system registers determine the permissions used to control access to memory and instruction execution.

R_{MNKWG} *Direct permissions* use one or more of the following to determine the base permissions that control whether or not a location can be accessed, the type of access that is permitted, and the privilege level necessary to access the location:

- The access permissions in Block descriptors and Page descriptors.
- If enabled, then the hierarchical access permissions in Table descriptors.

R_{XRLBM} *Indirect permissions* use all of the following to determine the base permissions that control whether or not a location can be accessed, the type of access that is permitted, and the privilege level necessary to access the location:

- The *Permission Indirection Index* (PIIndex) field in Block descriptors and Page descriptors.
- For each translation regime, a Permission Indirection Register (PIR) indexed by PIIndex.

D5.4.1 Stage 1 permissions

R_{TDNYB} All statements in this section apply when stage 1 uses VMSAv8-64.

R_{WBLJK} The following table lists the stage 1 permissions and the access type that is permitted when that permission is present. If the stage 1 permission is not present, that access type is not permitted.

Table D5-23 Stage 1 permissions

Stage 1 permission	Access type permitted
UnprivRead	Unprivileged data read.
UnprivWrite	Unprivileged data write.
PrivRead	Privileged data read.
PrivWrite	Privileged data write.
Execute	Instruction execution.

R_{KCFNV} If stage 1 translation is disabled, that is VTCR_EL2.MSA is 0, the PMSAv8-64 is used.

I_{KSRWD} If stage 1 translation is enabled, then stage 1 permissions are determined by Stage 1 Base permissions.
For more information, see Stage 1 Base permissions.

D5.4.1.1 Stage 1 Base permissions

I_{NHTTP} Stage 1 Direct permissions are used.

D5.4.1.2 Stage 1 Direct permissions

D5.4.1.2.1 Stage 1 data accesses using Direct permissions

R_{CBNKR} For a stage 1 translation that supports one Exception level, the following table shows the possible data access permissions.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Table D5-24 Data access permissions for a stage 1 translation supporting one Exception level

AP[2]	Permissions
0	PrivRead, PrivWrite
1	PrivRead

R_{MGGZM} For a stage 1 translation that supports one Exception level, AP[1] is RES1.

R_{RNGJG} For a stage 1 translation that supports two Exception levels, the following table shows the possible data access permissions at EL0 and the corresponding higher Exception level.

Table D5-25 Data access permissions for a stage 1 translation supporting two Exception levels

AP[2:1]	Permissions
00	PrivRead, PrivWrite
01	PrivRead, PrivWrite, UnprivRead, UnprivWrite
10	PrivRead
11	PrivRead, UnprivRead

I_{BVWWD} If hardware management of dirty state is enabled at stage 1, then the AP[2] bit can be cleared by hardware in some situations.
For more information, see Hardware management of the dirty state.

D5.4.1.2.2 Hierarchical control of data access Direct permissions

I_{VZXYY} Translation table entries at a given lookup level can limit data access Direct permissions at subsequent lookup levels.

R_{YTXKB} For a stage 1 translation, when hierarchical control is enabled, the Table descriptor APTable[1:0] field limits the data access permissions of subsequent stage 1 translation lookup levels, regardless of the Direct permissions in subsequent lookup levels, as shown in the following table:

Table D5-26 Effect of APTable[1:0] on subsequent lookup levels

APTable[1:0]	Effect at subsequent lookup levels
00	No effect on data access permissions.
01	Removes UnprivRead and UnprivWrite.
10	Removes UnprivWrite and PrivWrite.
11	Removes UnprivRead, UnprivWrite, and PrivWrite.

I_{GQYCH} For a Permission fault, the level of the Block descriptor or Page descriptor is reported regardless of whether the lack of permissions was caused by configuration of the APTable or AP fields.

I_{PCLHM} For translation regimes that support one Exception level, APTable[0] is RES0.

I_{TPCPS} The APTable[1:0] settings are combined with the descriptor access permissions in subsequent lookup levels. They do not change the values entered in those descriptors, nor restrict what values can be entered.

I_{PKGJC} For the translation regime controlled by a TCR_ELx, one or more of the following can be used to disable the Table descriptor APTable[1:0] field so that it is IGNORED by the PE and the behavior is as if the value is 0:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- If the Effective value of TCR_ELx.HPD{0} is 1, hierarchical data access permission is disabled in the translation tables pointed to by TTBR0_ELx.
- If the Effective value of TCR_ELx.HPD1 is 1, hierarchical data access permission is disabled in the translation tables pointed to by TTBR1_ELx.

I_{YQWJF} The descriptor APTable field affects all subsequent lookup levels. When an APTable field is changed, software is required to use a break-before-make sequence, including TLB maintenance for all lookup levels for the VA range translated by the descriptor.

D5.4.1.2.3 Stage 1 instruction execution using Direct permissions

I_{DXKST} The instruction Execute-never, Unprivileged execute-never, and Privileged execute-never fields in a Block descriptor and Page descriptor are used to control instruction execution permissions under the Direct permissions scheme by a stage 1 translation.

R_{TRZVM} For a stage 1 translation that supports one Exception level, the XN field in the Block descriptor and Page descriptor has all of the following properties:

- If the Effective value of XN is 0, then PrivExecute is not removed by this bit.
- If the Effective value of XN is 1, then PrivExecute is removed.

R_{RBDFT} For a stage 1 translation that supports two Exception levels, the UXN field in the Block descriptor and Page descriptor has all of the following properties:

- If the Effective value of UXN is 0, then UnprivExecute is not removed by this bit.
- If the Effective value of UXN is 1, then UnprivExecute is removed.

R_{LWPVL} For a stage 1 translation that supports two Exception levels, the PXN field in the Block descriptor and Page descriptor has all of the following properties:

- If the Effective value of PXN is 0, then PrivExecute is not removed by this bit.
- If the Effective value of PXN is 1, then PrivExecute is removed.

R_{VWLLR} For stage 1 translations that support two Exception levels, if UnprivWrite is present, then PrivExecute is removed.

D5.4.1.2.4 Preventing execution from writable locations

I_{KDRYB} There are register control fields that can be used to force writable memory to be treated as XN, PXN, or UXN, regardless of the value of the corresponding descriptor fields.

R_{JLSNH} For unprivileged accesses in the EL1&0 translation regime, if SCTLR_EL1, System Control Register (EL1).WXN is 1, UnprivWrite is present, and UnprivExecute is present, then UnprivWXN is applied. Otherwise, UnprivWXN is removed.

R_{SYMMB} For privileged accesses in all translation regimes, if SCTLR_EL1, System Control Register (EL1).WXN is 1, PrivWrite is present, and PrivExecute is present, then PrivWXN is applied. Otherwise, PrivWXN is removed.

I_{TBVCH} For a stage 1 translation in a translation regime that supports two Exception levels, the corresponding SCTLR_EL1, System Control Register (EL1).WXN field does all of the following:

- If the value is 0, then there is no effect on access permissions.
- If the value is 1, then all of the following apply:
  - If the memory region has UnprivWrite, then UnprivExecute is removed, regardless of the value of the Block descriptor or Page descriptor UXN field.
  - If the memory region has PrivWrite, then PrivExecute is removed, regardless of the value of the Block descriptor or Page descriptor PXN field.

I_{FQVWM} For a stage 1 translation in a translation regime that applies to a single Exception level, the corresponding SCTLR_EL1, System Control Register (EL1).WXN field does all of the following:

- If the value is 0, then there is no effect on access permissions.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- If the value is 1 and if the memory region is PrivWrite, then PrivExecute is removed, regardless of the value of the Block descriptor or Page descriptor XN field.

I_{XLDPQ} The SCTLR_EL1, System Control Register (EL1).WXN field reduces the memory footprint available for code injection attacks by introducing an invariant that writable memory regions are not executable.

I_{RNXSK} For the lifetime of a given virtual machine, Arm expects the SCTLR_EL1, System Control Register (EL1).WXN field to remain static in normal operation.

I_{PNSFD} SCTLR_EL1, System Control Register (EL1).WXN is permitted to be cached in a TLB.

D5.4.2 Effects on instruction execution permissions and restrictions on instruction fetch

I_{CSNFS} The descriptors contain fields used to control instruction execution permissions in stage 1 translations.

R_{BCSYZ} If instruction execution is not permitted by one of the following, then the memory region is execute-never:

- Stage 1 Direct permissions are in use, and XN is 1, or both UXN and PXN are 1.
- Stage 1 Indirect permissions are in use and mark the region as execute-never.
- The configuration of the EL2 MPU.

See also R_{RSXJG} and R_{SYLGW}.

R_{BFDZQ} If a memory region is execute-never at the current Exception level, then speculative instruction fetch from that memory region is prohibited.

R_{DYKWD} If a memory region is execute-never at the current Exception level, then when an attempt to execute from that memory region occurs, a Permission fault is generated at the first translation stage that determines the region is execute-never.

I_{PTMPK} If Device memory is not execute-never, then speculative instruction fetch from that memory region is permitted.

I_{ZZSZZ} For all Exception levels from which a read-sensitive memory region can be accessed, to avoid the possibility of a speculative fetch affecting that memory region, software is expected to define that memory region as execute-never.

R_{WRCYB} Except for the purposes of PSTATE.PAN, the descriptor execute-never fields do not prevent data accesses to the memory region translated by the descriptor.

D5.4.3 Effect of PSTATE on access permission

I_{LGNSH} PSTATE.PAN affects memory access permissions decoded from memory access control fields in the descriptors. PSTATE.UAO affects the privilege level of a memory access.
For more information on PSTATE, see Process state, PSTATE.

D5.4.3.1 PSTATE.PAN

I_{KTCFZ} PSTATE.PAN is used to prevent privileged data accesses to virtual memory addresses that are accessible from EL0.

R_{NCMTC} All statements in this section require implementation of FEAT_PAN.

R_{TBYDZ} For a translation regime, if one or more of the following apply, then the PSTATE.PAN bit has no effect in that regime:

- Stage 1 translation is disabled.
- Stage 1 translation supports a single privilege level.

R_{XTSQH} If the Effective value of PSTATE.PAN is 1, then a privileged data access from any of the following Exception levels to a virtual memory address that is accessible to data accesses at EL0 generates a stage 1 Permission fault:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- A privileged data access from EL1.
- If the Effective value of HCR_EL2.E2H is 1, then a privileged data access from EL2.

R_{DGQQK} If the value of PSTATE.PAN is 0, then a privileged data access is permitted from the corresponding privileged Exception level to a virtual memory address that is accessible at EL0.

I_{ZBRBM} When taking an exception from an EL in AArch64 state to an ELx, PSTATE.PAN is saved to and restored from SPSR_ELx.PAN.

I_{FNLWP} When entering and exiting Debug state, PSTATE.PAN is saved to and restored from DSPSR_EL0.PAN.

I_{GXFBR} When taking an exception to EL1, SCTLR_EL1.SPAN determines whether PSTATE.PAN is set to 1 or the value of PSTATE.PAN is unchanged.
When taking an exception to EL2, PSTATE.PAN remains unchanged.

R_{PMTWB} The PSTATE.PAN bit has no effect on all of the following:

- Instruction fetches.
- Data cache instructions, except DC ZVA, DC GZVA, and DC GVA.
- If FEAT_PAN2 is not implemented, then address translation instructions.
- If FEAT_PAN2 is implemented, then the address translation instructions other than AT S1E1RP and AT S1E1WP.

I_{ZRSWJ} Software can access PSTATE.PAN using all of the following instructions:

- Software can use MSR (immediate) `PAN, #Imm4` to modify PSTATE.PAN.
- Software can use MSR (register) `PAN, Xt` to modify PSTATE.PAN.
- Software can use MRS `Xt, PAN` to read PSTATE.PAN.

I_{GYGGV} If the PE is in Debug state, then a debugger can use the DRPS instruction to modify PSTATE.PAN.

D5.4.3.2 PSTATE.UAO

I_{WZGDY} PSTATE.UAO is used to control whether, for unprivileged memory access instructions, memory accesses described as unprivileged by the instruction are treated as privileged or unprivileged.

R_{NMGWS} All statements in this section require implementation of FEAT_UAO.

R_{ZVNJS} Unprivileged memory access instructions are all of the following:

- The instructions described in Load/store unprivileged.

R_{NDDVQ} If the value of PSTATE.UAO is 1, then a load/store unprivileged instruction executed at any of the following Exception levels is subject to the same access permissions as the corresponding load/store register instruction:

- EL1.
- If the Effective value of HCR_EL2.TGE is 1, EL2.

I_{CVRWF} When an exception occurs, all of the following apply to PSTATE.UAO:

- When taking an exception to ELx, PSTATE.UAO is saved to SPSR_ELx.UAO and then set to 0.
- When returning from an exception at ELx, PSTATE.UAO is restored from SPSR_ELx.UAO.

I_{QWJDP} When entering and exiting Debug state, PSTATE.UAO is saved to and restored from DSPSR_EL0.UAO.

I_{JQRCG} Software can access PSTATE.UAO using all of the following instructions:

- Software can use MSR (immediate) `UAO, #Imm4` to modify PSTATE.UAO.
- Software can use MSR (register) `UAO, Xt` to modify PSTATE.UAO.
- Software can use MRS `Xt, UAO` to read PSTATE.UAO.

I_{VCMLT} If the PE is in Debug state, a debugger can use the DRPS instruction to modify PSTATE.UAO.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D5.4.4 Controlling memory access Security state

I_{RLRVY} The Non-secure, NS, bit in Block descriptors and Page descriptors, and the Non-secure table, NSTable, bit in Table descriptors are used to provide control over accesses from Secure state to Secure and Non-secure memory.

R_{PRTVS} In this section and subsections, *IPA or PA space* refers to the OA space of stage 1 translations.

R_{KZLVM} For a Secure translation regime, if the translation table entry is in Secure IPA or PA space, then the Block descriptor and Page descriptor NS determines all of the following:

- If NS is 0, an access to the OA specified by the descriptor is to Secure IPA or PA space.
- If NS is 1, an access to the OA specified by the descriptor is to Non-secure IPA or PA space.

R_{SKGDK} For all of the following, if a Block or Page descriptor has NS set to 1, then the OA is in the Non-secure PA space.

R_{FKJXR} For a Secure translation regime, when the descriptor is fetched from Non-secure IPA or PA space, all of the following apply to the descriptor:

- The descriptor NS and NSTable bits exist but they are SBZ instead of RES0.
- The OA or next-level table base address specified by the descriptor is in Non-secure IPA or PA space.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.

D5.5 Hardware updates to the translation tables

I_{FNBGK} All of the following determine whether hardware can update the descriptor access flag and dirty state:

- The features implemented and enabled by the PE.
- The descriptor type.
- The translation regime.
- The translation stage.

I_{CGGMJ} Hardware updates to the translation tables are subject to memory ordering requirements and restrictions on the memory types.

D5.5.1 The Access flag

R_{XFXTY} The AF in a Block descriptor and Page descriptor indicates one of the following:

- If the value is 0, then the memory region has not been accessed since the value of AF was last set to 0.
- If the value is 1, then the memory region has been accessed since the value of AF was last set to 0.

R_{DWZCQ} Descriptors with AF set to zero can never be cached in a TLB.
For more information about when translation table entries are permitted to be cached in a TLB, see Translation Lookaside Buffers.

D5.5.1.1 Software management of the Access flag

I_{CDQDG} If the AF is not managed by hardware, software management of the AF is required.

R_{SWTYY} For an implementation that does not manage the AF in hardware, when an attempt is made to translate an address using a descriptor with an AF of 0, an Access flag fault is generated.

I_{FDYZF} For an implementation that does not manage the AF in hardware, when an Access flag fault is generated, software is expected to set the AF to 1 in the descriptor that generated the fault.

I_{KQMYT} Setting the AF to 1 prevents the Access flag fault from being generated the next time an attempt is made to translate an address using that descriptor.

I_{HQBRF} When software sets the AF to 1, there is no requirement to perform TLB invalidation after setting the flag because entries with an AF set to 0 are never held in a TLB.

I_{BMRWH} If a system incorporates components that can autonomously update translation table entries that are shared with the PE, then any changes by system software to translation table entries with an AF of 0 should avoid the possibility of simultaneous updates. This excludes changes to the AF value. For example, this can be done by using a Load-Exclusive/Store-Exclusive loop or an atomic compare-and-swap operation.

D5.5.1.2 Hardware management of the Access flag

R_{WMGCW} All statements in this section require implementation of the OPTIONAL feature, FEAT_HAFDBS.

R_{LFTXR} When the PE performs a hardware update of the AF, it sets the AF to 1 in the corresponding descriptor in memory, in a coherent manner, using an atomic read-modify-write of that descriptor.

R_{HDHQG} For a translation stage, if the value of the corresponding TCR_ELx.HA is 1, then AF hardware management is enabled.

I_{BDRJG} For each translation stage, AF hardware management can be enabled independently.

R_{HDTRB} If AF hardware management is enabled, then hardware updates the AF when a memory access is made using a Block descriptor or Page descriptor and all of the following apply:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- The access does not generate an Alignment fault based on the memory type, or a Permission fault.
- If AF hardware management was disabled or not implemented, the access would have generated an Access flag fault.

R_{QSPMS} If AF hardware management is enabled, then it is CONSTRAINED UNPREDICTABLE whether hardware updates the AF when a memory access is made using a Block descriptor or Page descriptor and all of the following apply:

- The access generates an Alignment fault based on the memory type, a Permission fault, or any fault that has a lower priority than a Permission fault from that stage of translation.
- If AF hardware management were disabled or not implemented, the access would have generated an Access flag fault.

I_{RGQLZ} If hardware does not update the AF from 0 to 1, then the descriptor is not permitted to be cached in a TLB.

R_{VNHWC} If AF hardware management is enabled in one or both translation stages, then when a memory access occurs, one or more of the following can be updated:

- The stage 1 AF.
- Each of the stage 2 AFs used to translate accesses to the stage 1 translation table walk and the OA.

I_{CVNQR} For stage 1 translations, if AF hardware management is enabled, then when stage 2 translation does not permit access to the OA returned by the stage 1 translation, it is permitted, but not required, for the stage 1 AF to be updated.

I_{MYQJN} For stage 2 translations, if AF hardware management is enabled, then when stage 1 translation does not permit access, it is permitted, but not required, for the stage 2 AF to be updated.

R_{LHQRX} If AF hardware management is enabled and a speculative access is successfully translated, then it is permitted, but not required, for hardware to update the AF.

R_{GGYFS} When a speculative access occurs, the rules determining the AF hardware update apply.

I_{GXGPN} When the translation of an architecturally executed memory access occurs, the architecture requires that AF is set to 1.

I_{LLCCB} When a translation occurs, the AF is permitted to be set to 1 even in the case where no architecturally executed memory access occurs. This could be due to a speculative memory access.

I_{PJWQY} When hardware updates of the Access Flag are enabled, it is permitted to update the Access Flag speculatively. This is not affected by the granule protection check on the output address of the translation.

R_{XQSMX} For an address translation stage, if AF hardware management is enabled, then when an address translation instruction is executed, all of the following apply:

- Hardware is permitted, but not required, to update the AF in the Block or Page descriptor that resolves the translation.
- If hardware attempts to update the AF and the update generates a fault, it is IMPLEMENTATION DEFINED whether this is reported as a Data Abort or not.
- If a Data Abort does not occur, then the instruction reports a result in the PAR as if the descriptors used to translate the address have an AF value of 1.

I_{ZWQRX} For more information, see Using break-before-make when updating translation table entries.

I_{KJBFT} If an implementation does not generate Access flag faults for cache maintenance by VA instructions, it is not required to perform hardware updates of AF for those cache maintenance instructions.
See also MMU faults generated by cache maintenance operations.

D5.5.2 The dirty state

I_{HTJWZ} The dirty state is used to indicate a memory block or page has been modified. When hardware update of the dirty state is enabled, the descriptor DBM field indicates whether the descriptor is a candidate for hardware updates of the dirty state.

R_{LRMSH} For the purpose of FEAT_HAFDBS dirty state management, a Block descriptor or Page descriptor can be described as having one of the following states:

- Non-writable.
- Writable-clean.
- Writable-dirty.

R_{XSTDV} If a Block descriptor or Page descriptor is not writable-clean and not writable-dirty, then it is described as *non-writable*.

R_{CLBGT} For a translation stage using Indirect permissions, software or hardware is permitted to manage the dirty state.

R_{DQQCV} For a translation stage using Direct permissions, only hardware is permitted to manage the dirty state.

R_{VRNVZ} For more information on managing the dirty state in hardware, see Hardware management of the dirty state.

I_{CPTSY} For a stage 1 translation using Indirect permissions at ELx, if the Effective value of TCR_ELx.HD is 0, then dirty state is managed by software.

R_{QXCRT} For stage 1 translations using Indirect permissions that grant write permission, the following table shows the descriptor state based on the Block descriptor and Page descriptor nDirty field:

nDirty field	Descriptor state
0	Writable-dirty
1	Writable-clean

Note

The polarity of the nDirty field matches the polarity of the AP[2] field used by Direct permissions.

R_{PPGMC} For write accesses translated by a writable-clean descriptor, if the descriptor dirty state is managed by software, then a Permission fault due to dirty state is generated. For information on the priority of a Permission fault due to dirty state, see Prioritization of Permission faults.

D5.5.2.1 Hardware management of the dirty state

R_{QRTKG} All statements in this section require implementation of the OPTIONAL feature, FEAT_HAFDBS, which supports both hardware update of the Access flag and hardware update of the dirty state.

I_{FLYZP} For stage 1 translations, if the Effective value of the corresponding TCR_ELx.HD is 1, then dirty state hardware management is enabled.

I_{DLNSK} If a translation stage uses Direct permissions and hardware update of the dirty state is enabled, then the descriptor DBM field indicates whether the descriptor is a candidate for hardware updates of the dirty state.

R_{PZFQC} For translations using Direct permissions, if the DBM field in a Block descriptor or Page descriptor is 0, then all of the following apply:

- For write accesses translated by the descriptor, the generation of Permission faults are unaffected by FEAT_HAFDBS.
- Hardware does not update the dirty state.

R_{XZFQH} For each translation stage using Direct permissions, if all of the following apply, then a Block descriptor or Page descriptor is described as *writable-clean*:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- Dirty state hardware update is enabled at that translation stage.
- The descriptor DBM field is 1.
- For a descriptor used by stage 1 translation, the AP[2] field is 1 and this is the only reason that a Permission fault would be generated due to a write access if dirty state hardware management were disabled.

R_{BRFGY} For each translation stage using Direct permissions, if all of the following apply, then a Block descriptor or Page descriptor is described as *writable-dirty*:

- Dirty state hardware update is enabled at that translation stage.
- The descriptor DBM field is 1.
- For a stage 1 translation, the AP[2] field is 0.

I_{HFBCN} If a translation stage uses Indirect permissions, then dirty state hardware management is not separately determined by each Block descriptor and Page descriptor. This is different from the case where a translation stage uses Direct permissions, and the DBM field indicates whether the descriptor is a candidate for dirty state hardware updates.

I_{BFDYL} Only if a descriptor is writable-clean, then hardware can update the dirty state.

R_{TYCNM} For write accesses translated by a writable-clean descriptor, if the descriptor dirty state is managed by hardware, then a Permission fault due to dirty state is not generated.

R_{NSXRD} For write accesses translated by a writable-clean descriptor, if all of the following apply, then hardware updates that descriptor to writable-dirty:

- The descriptor dirty state is managed by hardware.
- The only reason that a Permission fault would be generated due to that write access would be if dirty state hardware management were disabled.

R_{PQJJR} For a translation stage, when the dirty state is updated by hardware, the PE updates the corresponding descriptor in memory, in a coherent manner, using an atomic read-modify-write of that descriptor to change the descriptor from writable-clean to writable-dirty.

R_{PRHKD} If the requirements to update both the Access flag and dirty state by hardware are met, the PE is permitted to update the Access flag to 1 as part of the same atomic read-modify-write of the descriptor that performs the dirty state update.

I_{DSHLJ} For a translation stage, Access flag faults are reported with higher priority than Permission faults. Therefore, it is not permitted for hardware to update the dirty state so that a descriptor is writable-dirty but has the Access flag clear.

R_{SGJBL} When the dirty state is updated by hardware, the PE is required to check that any copy of the descriptor cached in a TLB is not stale with regard to the descriptor in memory.

I_{YZSVV} If the descriptor has changed, then the PE is required to use the new information from the descriptor in memory, regardless of whether the modified descriptor has a different OA, different attributes, or generates a fault.

I_{WZRPC} For performance purposes, when the dirty state is updated by hardware, the PE should update or invalidate any TLB entry that contains a previously-cached copy of the descriptor. This is to prevent multiple writes by the PE from causing multiple updates to the descriptor.

I_{HQBGN} Arm expects many implementations to cause a translation table walk to occur when dirty state hardware management causes an update of a translation table descriptor.

R_{RNMLQ} If a write access translated by a writable-clean descriptor is performed architecturally, then hardware updates the dirty state of that descriptor.

R_{QDRWL} If an instruction that generates more than one single-copy atomic memory access has a fault on some, but not all, of those memory accesses, then all of the following apply:

- All accesses that do not fault are permitted to cause hardware updates of the dirty state.
- For faulting accesses that meet the requirements for hardware updates of the dirty state, those accesses are also permitted to cause hardware updates of the dirty state.

I_{BSLWF} For more information, see:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- MMU fault prioritization from a single address translation stage.
- Faults and watchpoints.

D5.5.2.2 Implications of enabling the dirty state management mechanism

R_{YWCDD} All statements in this section require implementation of the OPTIONAL feature, FEAT_HAFDBS, which supports both hardware update of the Access flag and hardware update of the dirty state.

R_{TTLCV} For stage 1 translations, translations using a descriptor in the writable-clean state are considered writable for the purposes of the corresponding SCTLR_ELx.WXN control.

I_{NSYYW} For stage 1 translations, if the corresponding SCTLR_ELx.WXN is 1, then all of the following apply:

- For a translation regime that supports a single privilege level, translations using a writable-clean descriptor are treated as execute-never.
- For a translation regime that supports two privilege levels, translations using a privileged writable-clean descriptor are treated as privileged execute-never.
- For a translation regime that supports two privilege levels, translations using an unprivileged writable-clean descriptor are treated as unprivileged execute-never.

R_{NKLQN} For a translation regime that supports two privilege levels, translations using an unprivileged writable-clean descriptor are treated as privileged execute-never.

R_{RKMHW} For the following instructions that require write permission, if the address specified in the instruction is translated by a writable-clean descriptor and hardware management of Dirty state is enabled for the corresponding stage of translation, then the descriptor is considered to grant write access and the hardware does not update the Dirty state of that descriptor:

- Data cache invalidation instruction, DC IVAC.
- Data cache and instruction cache maintenance instructions that are affected by FEAT_CMOW.
- Address translation instructions, AT S12E0W, AT S12E1W, AT S1E0W, AT S1E1W, AT S1E2W, AT S1E3W.

R_{MKSBQ} For all of the following cases, if the stage 1 descriptor is writable-clean, then it is IMPLEMENTATION DEFINED whether hardware updates the dirty state:

- A Store-Exclusive instruction to the memory location fails because the Exclusives monitor is not in the exclusive state.
- A synchronous External abort is generated on a write to the memory location.
- A Watchpoint exception is generated on a write to the memory location.

R_{KLVVN} A hardware update of the dirty state performed by one PE does not require invalidation of any corresponding TLB entries in other PEs.

R_{TXGHB} For a CAS or CASP instruction to an address translated by a writable-clean descriptor, if the comparison fails and the location is therefore not updated, then it is CONSTRAINED UNPREDICTABLE whether hardware updates the dirty state.

D5.5.3 Ordering of hardware updates to the translation tables

R_{MKHJS} A hardware update to the translation table that is caused by a load or a store, including an atomic instruction, is guaranteed to be observed, to the extent required by the Shareability attributes:

- Before a load or store, including an atomic instruction, to an arbitrary address, other than the address of the translation table entry, that appears in program order after the load or store, including an atomic instruction, causing the update to the translation table entry only if a DSB with the appropriate Shareability attributes, where the DSB applies to both loads and stores, is executed between the load or store, including an atomic instruction, that caused the update to the translation table and the subsequent load or store.
- Before a load to the translation table entry that is being updated that appears in program order after the load or store, including an atomic instruction, causing the update to the translation table entry only if a DSB with the appropriate Shareability attributes, where the DSB applies to both loads and stores, is executed between the load or store, including an atomic instruction, that caused the update to the translation table and the subsequent load.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- Before a store or atomic access to the translation table entry that is being updated that appears in program order after the load or store, including an atomic instruction, causing the update to the translation table entry.
- Before a cache maintenance instruction to an arbitrary address appearing in program order after the load or store, including an atomic instruction, causing the update to the translation table entry only if a DSB with the appropriate Shareability attributes, where the DSB applies to both loads and stores, is executed between the load or store, including an atomic instructing that caused the update to the translation table entry and the subsequent cache maintenance instruction.

R_{PLLLM} An update to the translation table that is caused by a load is not ordered with respect to the load itself.

R_{FSZNW} An update to the translation table that is caused by a store or an atomic access is observed by all observers, to the extent required by the Shareability attributes, before the store itself in the case that the store is to the same location as the translation table update.

R_{RZYCN} An update to the translation table that is caused by a store or an atomic access is not ordered with respect to the store itself in the case that the store is not the same location as the translation table update.

D5.5.4 Restriction on memory types for hardware updates to translation tables

I_{YTWWW} A translation table can be placed in Normal memory with any Cacheability.

I_{XPRCJ} If hardware update of translation table entries is enabled, software is required to ensure that the translation table is located in memory that supports atomic read-modify-write updates in a coherent manner.

I_{MYHXH} Atomicity properties can only be met at the system level, and some system implementations might not support this functionality in all memory regions, including all of the following:

- Any system memory type that does not support hardware cache coherency.
- Non-cacheable memory, or memory that is treated as Non-cacheable, in an implementation that does not support hardware cache coherency.

I_{PCHYY} The system implementation determines which memory type is treated as Non-cacheable.

R_{WLTNL} All of the following Conventional memory types architecturally guarantee that hardware updates of the translation tables are atomic:

- Inner Shareable, Inner Write-Back, Outer Write-Back Normal memory.
- Outer Shareable, Inner Write-Back, Outer Write-Back Normal memory.

R_{NNNMB} If a translation table hardware update is not atomic as observed by other agents that can access memory, then the update can have one or more of the following effects:

- A synchronous External abort on the translation table walk is generated.
- The instruction generates an SError exception.
- An MMU fault is generated, reported as an Unsupported atomic hardware update using one of the following Fault status codes:
  - For Data Abort exceptions, ESR_ELx.DFSC = `0b110001`.
  - For Instruction Abort exceptions, ESR_ELx.IFSC = `0b110001`.
  - For an abort on a write to the Statistical Profiling buffer, PMBSR_EL1.FSC = `0b110001`.
- The hardware updates occur and all of the following apply:
  - There is no guarantee that the memory accesses are done atomically in regard to accesses to memory by other agents.
  - The instruction might also generate an SError exception.

R_{VSXXT} If a translation table hardware update is not atomic as observed by other agents that can access memory, and the update generates an MMU fault, all of the following apply:

- For the EL1&0 translation regime, one of the following:
  - If the atomic hardware update is not supported in the stage 1 translation due to the defined memory type, then this exception is a stage 1 abort and is taken to EL1.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

  - In all other cases, the exception is taken to EL2.
- For a translation stage, the MMU fault priority is at an IMPLEMENTATION DEFINED point between all of the following:
  - Immediately before the priority of an Access flag fault that is generated at the same translation stage.
  - Immediately after the priority of a Permission fault that is generated at the same translation stage.

I_{FGVJW} For more information, see Possible implementation restrictions on using atomic instructions.

D5.6 Memory region attributes

I_{SGDKK} The memory region attributes in a descriptor define the memory type, Cacheability, and whether the memory region is Shareable. For translation regimes that support two translation stages, the stage 1 and stage 2 memory region attributes are combined to produce a resultant memory type and Cacheability, and Shareability.

I_{XCFWR} All of the following apply to the memory region attributes:

- The stage 1 OA attributes are derived from a combination of the Block descriptor and Page descriptor AttrIndx[3:0] field, and the MAIR_ELx and MAIR2_ELx register fields.
- The stage 1 translation table walk attributes are derived from the TCR_ELx.{IRGN*n*, ORGN*n*, SH*n*} fields.
- The SCTLR_EL1, System Control Register (EL1).{C, I} fields might override stage 1 attributes.
- For the EL1&0 translation regime the HCR_EL2.{CD, DC} fields might override stage 1 attributes.
- All of the following HCR_EL2.FWB values affect the attributes passed to the EL2 MPU:
  - When the Effective value of HCR_EL2.FWB is 0, memory attributes are derived from the MemAttr[3:2] descriptor bits, then combined with stage 1 attributes.
  - When the Effective value of HCR_EL2.FWB is 1, memory attributes are derived from the MemAttr[2:0] descriptor bits.
- For Device memory and Normal Non-cacheable mappings from stage 1, normalization of the Shareability that is input to the memory attributes is IMPLEMENTATION DEFINED.

I_{LHJDF} The effects of combining memory attributes defined by the hypervisor are expected to be functionally transparent to the Guest OS.

D5.6.1 Stage 1 memory type and Cacheability attributes

R_{HHGNL} If FEAT_AIE is not implemented, all of the following apply:

- For a stage 1 translation, the Block descriptor and Page descriptor AttrIndx[2:0] field holds the value *n* used to select the 8-bit field MAIR_ELx.Attr<*n*> that specifies the memory region attributes of the descriptor OA.
- It is IMPLEMENTATION DEFINED how AttrIndx[2:0] is used to index into AMAIR_ELx.

I_{FZMTR} For the memory region specified by a Block descriptor and Page descriptor, the MAIR_ELx.Attr<*n*> or MAIR2_ELx.Attr<*n*> field selected by the descriptor AttrIndx[2:0] field defines all of the following:

- The Device or Normal memory type.
- For Device memory, any one of the following Device memory types:
  - Device-nGnRnE.
  - Device-nGnRE.
  - Device-nGRE.
  - Device-GRE.
- For Normal memory, all of the following:
  - For both inner and outer Cacheability, one of the Non-cacheable, Write-Through, or Write-Back attributes.
  - For Write-Through Cacheable and Write-Back Cacheable regions, the Read-Allocate and Write-Allocate hints, each of which is Allocate or No Allocate, and the Transient allocation hints.

For more information, see Memory region tagging types.

I_{NSVYS} The memory attributes obtained from MAIR_ELx.Attr<*n*>, MAIR2_ELx.Attr<*n*>, AMAIR_ELx.Attr<*n*>, and AMAIR2_ELx.Attr<*n*> are permitted to be cached in a TLB.

I_{QNNGV} For some translation regimes, the memory region attributes determined from translation tables, MAIR_ELx, and MAIR2_ELx values might be overridden by the configuration of SCTLR_EL1, System Control Register (EL1).{C, I} and HCR_EL2.DC.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D5.6.2 Stage 1 Shareability attributes

R_{ZWYSH} For Normal Cacheable memory the SH[1:0] field in a stage 1 translation Block descriptor and Page descriptor encodes the Shareability attributes of the descriptor OA, as shown in the following table:

Table D5-28 Stage 1 Shareability attributes

SH[1:0]	Normal memory
00	Non-shareable
01	Reserved, CONSTRAINED UNPREDICTABLE as described in Reserved values in System and memory-mapped registers and translation table entries.
10	Outer Shareable
11	Inner Shareable

R_{PYFVQ} If a region is mapped as Device memory or Normal Non-cacheable memory after all enabled translation stages, then the region has an effective Shareability attribute of Outer Shareable.

D5.6.3 Stage 2 memory type and Cacheability attributes

R_{WYQVN} For any stage 2 translation, if the final memory type any is Normal Cacheable type, then all of the following apply:

- If the output of stage 1 specifies a Cacheable memory type, then the final cache allocation hints are the stage 1 cache allocation hints.
- If the output of stage 1 does not specify a Cacheable memory type, then the final cache allocation hints are Read Allocate, Write Allocate.

R_{KTSYP} Stage 2 translation configuration does not assign cache allocation hints.

I_{BBJDH} If the memory type from a stage 2 translation causes a stage 1 translation table walk to a Device memory type, then one of the following occurs:

- If HCR_EL2.PTW is 0, then the translation table walk occurs as if it is to Normal Non-cacheable memory, and the walk can be done speculatively.
- If HCR_EL2.PTW is 1, then the memory access generates a stage 2 Permission fault.

D5.7 Other descriptor fields

D5.7.1 Table and Block entry

R_{DFJNG} All statements in this section require implementation of FEAT_BBML1.

I_{GTPVH} The nT bit is supported in the VMSAv8-64 Block descriptors.

I_{XPRKH} Setting the nT bit in a Table descriptor or Block descriptor guarantees that, when changing the table or block size, accesses translated by the translation table entry do not break coherency, ordering guarantees or uniprocessor semantics, or fail to clear the Exclusives monitors.

R_{MRRPW} When using a Table descriptor or Block descriptor with the nT bit set to 1, all of the following apply:

- It is IMPLEMENTATION DEFINED whether a Translation fault is generated.
- If a Translation fault is not generated, a TLB conflict abort can be generated.

For more information, see Support levels for changing table or block size.

I_{DXRJK} If the nT bit in a Table descriptor or Block descriptor is 1, then the translation performance can be significantly impacted.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D5.8 Address tagging

I_{XWNGB} When address tagging is enabled, the top eight bits of the VA are ignored for the purposes of address translation and they are instead described as an address tag. An address tag might be used for software purposes, a Logical Address Tag, or both.

R_{LVTFP} If address tagging is enabled in a translation regime, then the top eight bits of the VA, bits[63:56], have all of the following properties:

- Bits[63:56] are the address tag.
- The bits are ignored during address translation.
- If the translation system is enabled, then the bits are ignored when determining whether the address is out of range and therefore generates a Translation fault.
- If the translation system is not enabled, then the bits are ignored when determining whether the address is out of range and therefore generates an Address size fault.

D5.8.1 Address tag control

I_{CKLSG} Address tagging is controlled using the *Top Byte Ignore* (TBI) field in the TCR_ELx register.

R_{BLBYZ} For a stage 1 translation that supports a single VA range, TCR_ELx.TBI{0} determines whether address tagging is enabled.

R_{LPCSW} For a stage 1 translation that supports two VA ranges, all of the following determine whether address tagging is enabled:

- TCR_ELx.TBI0 determines whether the lower address range uses address tags.
- TCR_ELx.TBI1 determines whether the upper address range uses address tags.

R_{KYBQL} The TCR_ELx.TBI{*n*} bit controls address tagging whether or not the corresponding stage 1 translation is enabled.

I_{PRTHR} If FEAT_PAuth is implemented and a TCR_ELx.TBI{*n*} bit enables address tagging, then the corresponding TCR_ELx.TBID{*n*} bit determines whether address tagging applies to both instruction addresses and data addresses, or just data addresses. For more information, see Pointer authentication.

D5.8.2 Effect of address tagging on the PC

I_{WKJBM} This section describes how the top byte of an address is considered when address tagging is enabled and an address is propagated to the PC for a branch, procedure return, exception, or exception return occurs.

R_{BBQKQ} For a stage 1 translation that supports a single VA range, if address tagging for instruction accesses is enabled in an Exception level, ELx, then bits[63:56] of the address loaded into the PC are forced to `0x00` in all of the following cases:

- A branch or procedure return within ELx.
- An exception is taken to ELx.
- When an exception return does not generate an Illegal exception return, any exception return to ELx.
- Exiting from Debug state to ELx.

R_{FWHLV} For a stage 1 translation that supports two VA ranges, if address tagging for instruction accesses is enabled in an Exception level, ELx, then bits[63:56] of the address loaded into the PC are a sign-extension of address bit[55] in all of the following cases:

- A branch or procedure return within ELx.
- An exception is taken to ELx.
- When an exception return does not generate an Illegal exception return, any exception return to ELx.
- Exiting from Debug state to ELx.

R_{WGTRC} When address tagging is enabled and an address causes a Data Abort or a *Watchpoint exception*, the address tag is included in the VA returned in the FAR.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D5.9 Pointer authentication

I_{XDNDT} AArch64 state supports signing the contents of a 64-bit general-purpose register that contains an address with a *pointer authentication code* (PAC), and authenticating the contents of a register with a PAC before the register is used as the target of an indirect branch, or the base register of a load or store instruction.

R_{STHJF} All statements in this section and subsections require implementation of FEAT_PAuth.

R_{JZTGK} Pointer authentication is supported only in AArch64 state.

I_{PKPFN} If Pointer authentication is implemented, then both of the following are true:

- Exactly one of ID_AA64ISAR1_EL1.GPI, ID_AA64ISAR1_EL1.GPA, or ID_AA64ISAR2_EL1.GPA3 fields is nonzero.
- Exactly one of ID_AA64ISAR1_EL1.API, ID_AA64ISAR1_EL1.APA, or ID_AA64ISAR2_EL1.APA3 fields is nonzero.

Otherwise, all of these ID fields are zero.

I_{GMTCR} Pointer authentication functionality is the same whether address translation is enabled or disabled, but is useful only when address translation is enabled.

D5.9.1 PAC field

I_{KQZPC} The pointer authentication mechanism treats the upper bits of a pointer in a 64-bit general-purpose register as a PAC field.

I_{BSXBR} The TCR_ELx.{T0SZ, T1SZ} fields are used to configure the size and location of the PAC field.

R_{DLVDN} When a 64-bit general-purpose register, Xd, holds an address with a PAC field, the location of the PAC field is determined by all of the following:

- The `bottom_PAC_bit` is 64-TCR_ELx.T*n*SZ, and the value of *n* is determined as follows:
  - If inserting a PAC into an address and address tagging is not used, then the value of Xd[63] is the value of *n*.
  - Otherwise, the value of Xd[55] is the value of *n*.
- If address tagging is used, then all of the following apply:
  - If `bottom_PAC_bit` is > 52 and the stage 1 translation supports a single VA range, then the PAC field is Xd[55:`bottom_PAC_bit`].
  - Otherwise, the PAC field is Xd[54:`bottom_PAC_bit`].
- If address tagging is not used and logical address tagging is used, then all of the following apply:
  - If `bottom_PAC_bit` is > 52 and the stage 1 translation supports a single VA range, then the PAC field is Xd[63:60, 55:`bottom_PAC_bit`].
  - Otherwise, the PAC field is Xd[63:60, 54:`bottom_PAC_bit`].
- If both address tagging and logical address tagging are not used, then all of the following apply:
  - If `bottom_PAC_bit` is > 52 and the stage 1 translation supports a single VA range, then the PAC field is Xd[63:`bottom_PAC_bit`].
  - Otherwise, the PAC field is Xd[63:56, 54:`bottom_PAC_bit`].

For more information, see Address tagging.

I_{VZRCW} In the case where address tagging is not used, then any use of a VA that has differing values of bit [63] and bit [55] is a non-canonical VA that will generate a fault.

I_{HLQVM} If the TCR_ELx.TBID{*n*} bit is used to restrict address tagging to data addresses, then instruction addresses can use Xd[63:56] bits to produce larger pointer authentication code fields.

I_{DJNGK} For all of the following reasons, if FEAT_PAuth2 is implemented, FEAT_FPAC is not implemented, and stage 1 translation is disabled, then Arm recommends not setting the TCR_ELx.T*n*SZ values to indicate an address range that is smaller than the PA size:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- For some PAC values, if TCR_ELx.T*n*SZ is set to indicate an address range that is smaller than the PA size, the address generated by a failed PAC authentication might be an address within the PA size because the upper address bits, those between the PA size and the size indicated by the TCR_ELx.T*n*SZ field, are taken from the result of the authentication process.
- Accessing memory using such an address that has failed PAC authentication does not generate an Address size fault.
- The memory access is done using upper address bits, those between the PA size and the size indicated by the TCR_ELx.T*n*SZ field, taken from the result of the authentication process.

R_{VMZGK} If the value in TCR_ELx.T*n*SZ is outside the permitted range, then one of the following CONSTRAINED UNPREDICTABLE results occur:

- The TCR_ELx.T*n*SZ value configures the `bottom_PAC_bit` value.
- The minimum permitted TCR_ELx.T*n*SZ value configures the `bottom_PAC_bit` value.
- The maximum permitted TCR_ELx.T*n*SZ value configures the `bottom_PAC_bit` value.

R_{FCMCH} If a PE treats an out of range TCR_ELx.T*n*SZ value as the maximum permitted field value or the minimum permitted field value for all purposes except reading the field value, then that behavior also applies to determining `bottom_PAC_bit`.

D5.9.2 PAC generation and verification keys

I_{RSXKN} For pointer authentication, all of the following 128-bit PAC keys are provided:

- Instruction address PAC key A, APIAKey_EL1, is the concatenation of the register values APIAKeyHi_EL1:APIAKeyLo_EL1.
- Instruction address PAC key B, APIBKey_EL1, is the concatenation of the register values APIBKeyHi_EL1:APIBKeyLo_EL1.
- Data address PAC key A, APDAKey_EL1, is the concatenation of the register values APDAKeyHi_EL1:APDAKeyLo_EL1.
- Data address PAC key B, APDBKey_EL1, is the concatenation of the register values APDBKeyHi_EL1:APDBKeyLo_EL1.
- Generic authentication PAC key A, APGAKey_EL1, is the concatenation of the register values APGAKeyHi_EL1:APGAKeyLo_EL1.

I_{KBYGG} For an Exception level, all of the following bits in the SCTLR_ELx registers are used to enable PAC generation and validation:

- SCTLR_EL1, System Control Register (EL1).EnIA enables instruction address pointer authentication using the `APIAKey_EL1` key.
- SCTLR_EL1, System Control Register (EL1).EnIB enables instruction address pointer authentication using the `APIBKey_EL1` key.
- SCTLR_EL1, System Control Register (EL1).EnDA enables data address pointer authentication using the `APDAKey_EL1` key.
- SCTLR_EL1, System Control Register (EL1).EnDB enables data address pointer authentication using the `APDBKey_EL1` key.

I_{GMQNP} All Exception levels use the same set of registers to hold PAC keys.

I_{GLRSR} When switching between Exception levels, software is expected to apply all of the following:

- Software is expected to switch the PAC keys between Exception levels.
- Software is expected to not leave the values of the current keys present in memory, typically done by zeroing those locations after switching.

D5.9.3 PAC instructions

I_{VXGGK} When a 64-bit general-purpose register is used as the target of an indirect branch instruction or the base register in a load instruction, all of the following instructions can be used to authenticate the register contents and prepare the register to be used:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- Instructions that insert a PAC into the PAC field.
- Instructions that extract the value in the PAC field and check that the value is correct.
- Instructions that remove the PAC field in the register and replace it with the pointer sign-extension bits, without verification.

I_{KCKSC} An instruction that inserts a PAC into the PAC field of a 64-bit general-purpose register generates the PAC using the value of the 64-register and one or two other 64-bit diversifier values.

I_{WCZPC} FEAT_PAuth_LR provides instructions that allow signing of the 64-bit value in LR against the value of SP and a PC-relative instruction address.

R_{TMSKZ} An instruction that inserts a PAC into the PAC field of a 64-bit general-purpose register, operates on the PAC field in one of the following ways:

- If FEAT_PAuth2 is not implemented, then the pointer authentication mechanism replaces the PAC field with the PAC.
- If FEAT_PAuth2 is implemented, then the pointer authentication mechanism exclusive-ORs the bits in the PAC field with the PAC.

R_{TFBFT} When FEAT_PAuth2 is not implemented and when performing a PAC operation on a non-canonical address then the PAC is modified to make it incorrect, and one of the following applies:

- If FEAT_EPAC is implemented, then the pointer authentication mechanism sets the PAC field to 0.
- If FEAT_EPAC is not implemented, then the pointer authentication mechanism inverts one of the bits of the PAC as follows:
  - When address tagging is not used, bit [62] is inverted.
  - Otherwise, bit [54] is inverted.

I_{KBKGF} An instruction that extracts the PAC from the PAC field and checks that the value is correct does all of the following:

- The check is based on the value of the register and one or two other 64-bit diversifier values.
- If the value is correct, the PAC is replaced with the extension bits.
- If the value is incorrect, all of the following occur:
  - The PAC is replaced with the extension bits.
  - Two extension bits are set to a unique, fixed value, such that the 64-bit value represents a non-canonical VA. This is referred to as making the VA non-canonical.

I_{RZFZG} Multiple versions of pointer authentication instructions support different use cases. Some instructions combine a pointer authentication operation with another operation.

R_{WNKCJ} If PAC generation and validation is disabled, then the PACGA and `XPAC*` instructions are not affected and are always enabled.

R_{WDYDC} If PAC generation and validation is disabled, then all of the following apply:

- Instructions that insert a PAC into the address in a 64-bit general-purpose register execute as `NOPs`.
- Instructions that authenticate a PAC execute as `NOPs`.
- If an instruction combines pointer authentication with another operation, then all of the following apply:
  - The pointer authentication does not occur.
  - The combined operation behaves the same as the equivalent instruction that does not do pointer authentication.

I_{RHMHV} All of the following are examples of the resulting behavior of instructions that combine pointer authentication with another operation, if PAC generation and validation is disabled:

- A `RETAA` instruction operates as a RET instruction.
- A `LDRAA Xt, [Xn, #<simm10>]!` instruction operates as a `LDR Xt, [Xn, #<simm10>]!` instruction.

I_{ZVGYK} The PACGA instruction generates a 32-bit PAC from two 64-bit values and a generic key.

I_{ZPGRZ} The PACGA instruction can be used to protect small memory blocks. PACGA instructions can be chained to protect an arbitrary-sized memory block.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I_{PXWQC} For pointer authentication instructions other than the PACGA instruction, the PAC is generated using one of the following IMPLEMENTATION DEFINED methods:

- If FEAT_PACQARMA5 is implemented, then ID_AA64ISAR1_EL1.APA is nonzero and the QARMA5 block cipher algorithm is used.
- If FEAT_PACIMP is implemented, then ID_AA64ISAR1_EL1.API is nonzero and an IMPLEMENTATION DEFINED algorithm is used.
- If FEAT_PACQARMA3 is implemented, then ID_AA64ISAR2_EL1.APA3 is nonzero and the QARMA3 block cipher algorithm is used.

I_{WXMCQ} For the PACGA instruction, the PAC is generated using one of the following IMPLEMENTATION DEFINED methods:

- If FEAT_PACQARMA5 is implemented, then ID_AA64ISAR1_EL1.GPA is nonzero and the QARMA5 block cipher algorithm is used.
- If FEAT_PACIMP is implemented, then ID_AA64ISAR1_EL1.GPI is nonzero and an IMPLEMENTATION DEFINED algorithm is used.
- If FEAT_PACQARMA3 is implemented, then ID_AA64ISAR2_EL1.GPA3 is nonzero and the QARMA3 block cipher algorithm is used.

R_{ZYPJV} For a PAC generated using the `ComputePAC()` pseudocode function, where the PAC generation uses an IMPLEMENTATION DEFINED algorithm then the IMPLEMENTATION DEFINED algorithm uses the same arguments as the `ComputePAC()` function.

For a PAC generated using the `ComputePAC2()` pseudocode function, where the PAC generation uses an IMPLEMENTATION DEFINED algorithm then the IMPLEMENTATION DEFINED algorithm uses the same arguments as the `ComputePAC2()` function.

R_{JTRCS} For a set of arguments passed to the `ComputePAC()` or `ComputePAC2()` pseudocode function, the same result is produced by all PEs that an execution thread could migrate between.

R_{DPXKM} The `ComputePAC2()` pseudocode function generates a PAC for 64-bit data, using a 128-bit PAC key and two diversifiers.

R_{MLLDB} If `ComputePAC2()` is implemented using FEAT_PACQARMA5 or FEAT_PACQARMA3, then the two diversifiers are concatenated into a single 64-bit diversifier as follows:

- Bits[31:0] of the 64-bit diversifier hold the value modifier1<35:4>.
- Bits[63:32] of the 64-bit diversifier hold the value modifier2<36:5>.

I_{RNXPW} Arm strongly recommends that software at EL0 does not mix pointer authentication mechanisms. For example, using the PACGA instruction to create a PAC and using other pointer authentication instructions to authenticate, or using an instruction which uses a specific key to sign a pointer and using an instruction which uses a different key to authenticate that pointer.

D5.9.4 Faulting on pointer authentication

I_{XBGSY} A PAC authentication failure for a given VA can cause a fault to be generated in the following three manners, according to the type of the instruction and whether FEAT_FPAC and FEAT_FPACCOMBINE are implemented:

- The PAC instruction makes the VA non-canonical, such that a subsequent use of the VA generates a fault. In this case, the PAC instruction does not directly generate the fault.
- The PAC instruction makes the VA non-canonical and uses that VA such that a fault is generated by that instruction.
- The PAC instruction directly generates a PAC Fail exception, with EC code `0b011100`.

R_{MLWGL} If an instruction is a combined instruction that includes pointer authentication, then when the PAC is incorrect in a given VA, one of the following behaviors occurs:

- For a combined authenticate and load instruction, then:
  - If FEAT_FPACCOMBINE is not implemented, the VA is made non-canonical and then used as the address for the load.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

  - If FEAT_FPACCOMBINE is implemented, then the instruction generates a PAC Fail exception, with EC code `0b011100`.
- For a combined authenticate and branch instruction, then:
  - If FEAT_FPACCOMBINE is not implemented, the VA is made non-canonical and the PC is updated to this non-canonical value.
  - If FEAT_FPACCOMBINE is implemented, then the instruction generates a PAC Fail exception, with EC code `0b011100`.

R_{KJSRQ} For a PAC authentication instruction, `AUT*`, when the PAC is incorrect for a given VA, one of the following behaviors occurs:

- If FEAT_FPAC is not implemented, the VA is made non-canonical.
- If FEAT_FPAC is implemented, then the instruction generates a PAC Fail exception, with EC code `0b011100`.

R_{XXFXH} Predicting the result of a PAC Authentication is a form of control flow prediction.

R_{GKVYD} Prediction of the results of a PAC Authentication must adhere to the requirements of FEAT_FPACC_SPEC, if implemented.

D5.10 Memory aborts

R_{SQLMR} For a VMSAv8-64 implementation, all of the following abort mechanisms can cause the PE to take an exception due to a failed memory access:

- A *Debug exception* generated by the self-hosted debug system. For more information, see AArch64 Self-hosted Debug.
- An *Alignment fault* generated by a memory access that is not aligned as required by the operation. For more information, see Alignment support.
- An *MMU fault* generated by the fault checking sequence in the appropriate translation regime. For more information, see MMU fault types.
- An *External abort* generated by the memory system and not by self-hosted debug, alignment checking, or MMU checking. For more information, see External aborts.

R_{XXMXW} For AArch64 state, MMU faults are synchronous exceptions that are reported as one of the following:

- Data Aborts due to data memory access faults.
- Instruction Aborts due to instruction fetch faults.

For more information, see Synchronous exception types.

I_{WFYSR} In some cases, an MMU fault generated as part of `AT` instruction execution is reported in PAR_EL1 rather than as a synchronous abort.

I_{YMZWZ} When an MMU fault is generated and reported as an Instruction Abort or Data Abort, the Exception level that the exception is taken to depends on the translation regime and translation stage that caused the fault.

I_{DHWPX} When a memory access abort generates an exception, all of the following registers are used to record context information:

- A Fault Address Register, FAR_ELx.
- An Exception Syndrome Register, ESR_ELx.

I_{XLTCG} When an MMU fault is generated, the fault context saved in the ESR_ELx at the Exception level that the fault is taken to depends on all of the following:

- Whether the fault is reported as an Instruction Abort or as a Data Abort.
- Whether the exception is taken from the same or a lower Exception level.

I_{FVNYG} For an Instruction Abort, only the following two exceptions have a higher priority in the exception priority hierarchy:

- Software Step exception.
- PC alignment fault exception.

I_{SRPXB} For a Data Abort, only Watchpoint exceptions have a lower priority in the exception priority hierarchy.

D5.10.1 MMU fault types

R_{YLSQG} All of the following MMU fault types are supported, and there are no other MMU fault types:

- Alignment fault on a data access. For more information, see Alignment support.
- Translation fault.
- Address size fault.
- Synchronous External abort on a translation table walk.
- Access flag fault.
- Permission fault.
- TLB conflict abort.

R_{GKZPW} When an attempt to access Device memory generates an MMU fault, no memory access occurs.

R_{TQDJS} If the memory attributes cannot be determined and the resultant memory region could be Device memory, then when an attempt to access that region generates an MMU fault, no memory access occurs.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D5.10.1.1 Translation fault

R_{DYNYQ} If descriptor bit[0] is 0 in any translation table entry, the descriptor is invalid. When a translation table lookup returns an invalid descriptor, a Translation fault is generated and descriptor bits[63:1] are ignored.

R_{KRMJZ} If descriptor bit[1] is 0 at a lookup level that does not support Block descriptors, then the descriptor encoding is reserved. When a translation table lookup returns that descriptor, a Translation fault is generated.

R_{FDQJL} If FEAT_BBML1 is implemented, and the Block descriptor has the nT bit set, then the implementation is permitted to generate a Translation fault.

I_{RRSLQ} For any translation lookup level, when a Translation fault is generated, the reported fault code indicates the lookup level.

R_{VZZSZ} When one or more of the following apply, a level 0 Translation fault is generated on the relevant translation stage:

- The IA does not map onto a TTBR_ELx address range.
- If the IA maps onto the TTBR0_ELx address range and the IA contains any one bits above the configured IA size as determined by TCR_ELx.T0SZ.
- If the IA maps onto the TTBR1_ELx address range and the IA contains any zero bits above the configured IA size as determined by TCR_ELx.T1SZ.
- When a TLB miss occurs, the corresponding TCR_ELx.EPD*n* field prevents a translation table walk using TTBR*n*_ELx.
- When FEAT_E0PD is implemented, the corresponding TCR_ELx.E0PD*n* field prevents unprivileged access to an address translated by TTBR*n*_ELx.

R_{MLNTS} A translation table entry that generates a Translation fault is not cached in a TLB.

I_{XFTPJ} When a Translation fault is generated, the fault handler does not have to perform TLB maintenance to remove the faulting entry.

I_{PXJFV} For more information, see MMU faults generated by cache maintenance operations.

D5.10.1.2 Address size fault

R_{CVSBH} For a translation stage, if an address in one of the following has nonzero address bits above the configured OA size, then an Address size fault is generated:

- The TTBR_ELx used in the translation.
- A translation table entry.
- The translation OA.

R_{FTZHB} An Address size fault can be generated at any translation lookup level.

R_{WDZFC} For the 64KB translation granule, if the implementation does not support 52-bit PAs, then all of the following apply:

- It is IMPLEMENTATION DEFINED whether descriptor bits[15:12] being nonzero generates an Address size fault.
- For this case, it is deprecated to not generate an Address size fault.

R_{BFHQH} When an Address size fault is generated, the reported fault code indicates one of the following:

- If the fault was generated due to the TTBR_ELx used in the translation having nonzero address bits above the OA size, then a fault at level 0.
- If the fault was not generated due to the TTBR_ELx used in the translation, then the lookup level at which the fault occurred.

R_{GGQPR} When an Address size fault is generated, the translation table entry causing the fault is not cached in a TLB.

I_{PBYZQ} When an Address size fault is generated, the fault handler does not have to perform TLB maintenance to remove the faulting entry.

I_{WWYQH} An implementation is required to ensure that the Contiguous bit does not prevent generation of Address size faults. For more information, see Architectural guarantees when the Contiguous bit is misprogrammed.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I_{JTTDF} For more information, see:

- MMU faults generated by cache maintenance operations.
- Output address size configuration.

D5.10.1.3 External abort on a translation table walk

R_{YLGBV} If an External abort on a translation table walk is generated, then it is reported in one of the following ways:

- If the External abort is synchronous, then it is reported as one of the following:
  - If the translation table walk is due to an instruction fetch, then a synchronous Instruction Abort exception.
  - If the translation table walk is due to a data access, an address translation instruction, or a cache maintenance instruction operating by VA, then a synchronous Data Abort exception.
- If the External abort is asynchronous, then it is reported using the SError exception.

I_{JVVQN} A TLB or intermediate TLB caching structure might support:

- An arbitrary number of translation table lookup levels.
- One or more translation stages that might not correspond to an address translation lookup stage.

R_{BGPQR} If a synchronous External abort is generated due to a TLB or intermediate TLB caching structure, including parity or ECC errors, then all of the following are permitted:

- If the PE cannot precisely determine the translation stage at which the error occurred, then it is reported and prioritized as a stage 1 fault.
- If the PE cannot precisely determine the lookup level at which the error occurred, then the lookup level is reported and prioritized as one of the following:
  - The lowest-numbered lookup level that could have caused the error.
  - If the PE cannot determine any information about the lookup level, then level 0.

D5.10.1.4 Access flag fault

I_{BMSDD} For an implementation that does not manage the AF in hardware, when and only when a non-speculative access is made to an address and an attempt is made to translate that address using a descriptor with an AF of 0, an Access flag fault is generated.

R_{LFGXS} For a translation lookup of a Block descriptor or Page descriptor, when an Access flag fault is generated, the reported fault code indicates the lookup level.

I_{PNQBP} When an Access flag fault is generated, the translation table entry causing the fault is not cached in a TLB.

I_{TQXPT} When an Access flag fault is generated, the fault handler does not have to perform TLB maintenance to remove the faulting entry.

I_{RGFRF} For more information, see:

- MMU faults generated by cache maintenance operations.
- Software management of the Access flag.

D5.10.1.5 Permission fault

R_{CSRQR} When a Permission fault is generated, the reported fault code indicates the lookup level of the Block or Page descriptor used in the translation, even if the lack of permission was caused by hierarchical permission controls.

R_{JVXRH} A translation table entry that generates a Permission fault is permitted to be cached in a TLB.

I_{WJLXV} If software updates a stage 1 translation table due to a Permission fault, then the software is required to invalidate the appropriate TLB entry to prevent stale information in a TLB from being used by a subsequent memory access.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I_{BXJNT} For more information, see:

- Prioritization of Permission faults.
- MMU faults generated by cache maintenance operations.
- Memory access control.
- The Protected System Memory Architecture.

D5.10.1.6 TLB conflict abort

I_{CNNYQ} When a TLB has not been properly invalidated, such as when architecturally required TLB invalidation is not done, an address lookup might hit multiple TLB entries.

R_{ZQNWZ} When a lookup address hits multiple TLB entries, it is IMPLEMENTATION DEFINED whether a TLB conflict abort is generated.

R_{WJMZJ} When a TLB conflict abort is generated, it is reported as one of the following:

- On an instruction fetch it is reported as an Instruction Abort.
- On a data access or a cache management instruction, it is reported as a Data Abort.
- For an `AT S1E0*` or `AT S1E1*` instruction executed from EL1, when a TLB conflict abort is generated on a stage 2 translation, it is reported as a Data Abort.

I_{DHRWD} For an `AT` instruction other than an `AT S1E0*` or `AT S1E1*` instruction executed from EL1, a TLB conflict does not generate an abort.

R_{QWTKL} For the EL1&0 regime, when a TLB conflict abort is generated and both stages of translation are enabled, then one of the following applies:

- If FEAT_BBML1 is implemented and the TLB conflict abort is generated due to changing the table or block size or Contiguous bit, then the abort is reported to EL2.
- Otherwise, it is IMPLEMENTATION DEFINED whether it is reported to EL1 or EL2.

R_{ZMVZT} A TLB Conflict abort cannot be generated for a disabled stage of translation.

I_{JYDXJ} When a TLB conflict abort is generated, all of the following are reported:

- A `0b110000` Fault status code.
- The lookup address that caused the fault.

D5.10.2 MMU faults generated by address translation instructions

R_{XGWVV} An address translation instruction uses the translation system and can generate all of the following faults:

- Translation fault.
- Address size fault.
- Synchronous External abort on a translation table walk.
- Access flag fault.
- Permission fault.
- TLB conflict abort.

D5.10.2.1 Exceptions to reporting the fault in PAR_EL1

R_{QBSVM} For an address translation instruction executed at a particular Exception level, ELx, if a synchronous External abort is generated on a stage 1 translation table walk, then the Data Abort exception is taken to the Exception level to which a synchronous External abort on a stage 1 translation table walk for a memory access from ELx would be taken.

R_{FDJKZ} When an address translation instruction causes a synchronous External abort that is reported as an exception, all of the following apply:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- PAR_EL1 is UNKNOWN.
- The ESR_ELx of the target Exception level indicates that the fault was generated by a translation table walk due to a cache maintenance operation or address translation instruction.
- The FAR_ELx of the target Exception level holds the VA supplied to the address translation instruction.

D5.10.3 MMU faults generated by cache maintenance operations

I_{QZTRG} There are no alignment requirements in cache maintenance instructions and execution of these instructions cannot generate an Alignment fault.

I_{BDCCY} Cache maintenance instructions treated as a NOP cannot generate MMU faults.

R_{TRTWX} It is IMPLEMENTATION DEFINED whether execution of any cache maintenance instruction by VA that is not treated as a NOP can generate an Access flag fault.

I_{ZNSBH} When an implementation can generate MMU faults on execution of cache maintenance operations, Permission faults are generated according to the type of cache maintenance operation and system register configuration.

R_{JYWZL} If a DC Invalidate by address instruction, for example, DC IVAC, DC IGVAC, or DC IGDVAC is not treated as a NOP and does not have write permission to the location it invalidates, then a Permission fault is generated.

I_{XQZJB} DC ZVA is not a cache maintenance instruction.

I_{LJLSP} For more information, see:

- Data and unified caches.
- Instruction caches.
- Memory aborts.
- Permission fault.
- A64 Cache maintenance instructions.

D5.10.4 MMU fault-checking sequence

I_{NTFDN} For a translation stage, when an IA is translated to an OA, the fault checking sequence is done using all of the following steps:

1. If the IA is subject to an alignment check, then check the alignment and do one of the following:
   - If the IA is not aligned, then an Alignment fault is generated.
   - If the IA is aligned, then continue to the next step.
2. Check that the IA maps to a translation table base address register, TTBR, and do one of the following:
   - If the IA does not map to a TTBR, then a Translation fault is generated.
   - If the IA maps to a TTBR and translation using that TTBR is disabled, then a Translation fault is generated.
   - If the IA maps to a TTBR, then get the translation table base address and continue to the next step.
3. Check that the translation table base address size is valid and do one of the following:
   - If the translation table base address size is not valid, then an Address size fault is generated.
   - If the translation table base address size is valid, then continue to the next step.
4. Fetch the descriptor, using all of the following steps:
   - The descriptor address is a PA from a stage 1 translation, then all of the following are done:
     - The fault checking sequence is done by the EL2 MPU, using the PA as an IA.
     - The OA from the MPU access is the PA.
5. Check that the descriptor is valid and do one of the following:
   - If the descriptor is not valid, then a Translation fault is generated.
   - If the descriptor is valid, then continue to the next step.
6. Check that the descriptor address size is valid and do one of the following:
   - If the descriptor address size is not valid, then an Address size fault is generated.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- If the descriptor address size is valid, then continue to the next step.

7. Check the descriptor type and do one of the following:
   - For a Table descriptor, get the descriptor address, get the hierarchical permissions and attributes that apply to subsequent lookup levels, and go back to step 4 to fetch the next descriptor.
   - For a Block descriptor or Page descriptor, continue to the next step.
8. If FEAT_BBML1 is implemented, and the fetched descriptor is a block descriptor with the nT bit set, then the implementation can generate a Translation fault.
9. If AF hardware management is disabled or not implemented, check the descriptor AF bit and do one of the following:
   - If AF is 0, then an Access flag fault is generated.
   - If AF is 1, then continue to the next step.
10. If AF hardware management is enabled, then the hardware attempts to update the AF and that might result in a Permission fault from the EL2 MPU, or a Synchronous External abort.
11. Get the OA and OA space from the Block descriptor or Page descriptor returned by the translation table walk.
12. Check the alignment required for the output memory type and do one of the following:
    - If the OA alignment is not valid, then an Alignment fault is generated.
    - If the OA alignment is valid, then continue to the next step.
13. Check the OA space access permissions and do one of the following:
    - If the OA space access is not permitted, then a Permission fault is generated.
    - If the OA space access is permitted, then continue to the next step.
14. If dirty state hardware management is enabled, then the hardware attempts to update the dirty state and that might result in a Permission fault at stage 2, or a Synchronous External abort.
15. The translation stage returns the OA and region attributes.

I_{MDJYB} For a translation stage, the following figure illustrates the MMU fault checking sequence.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

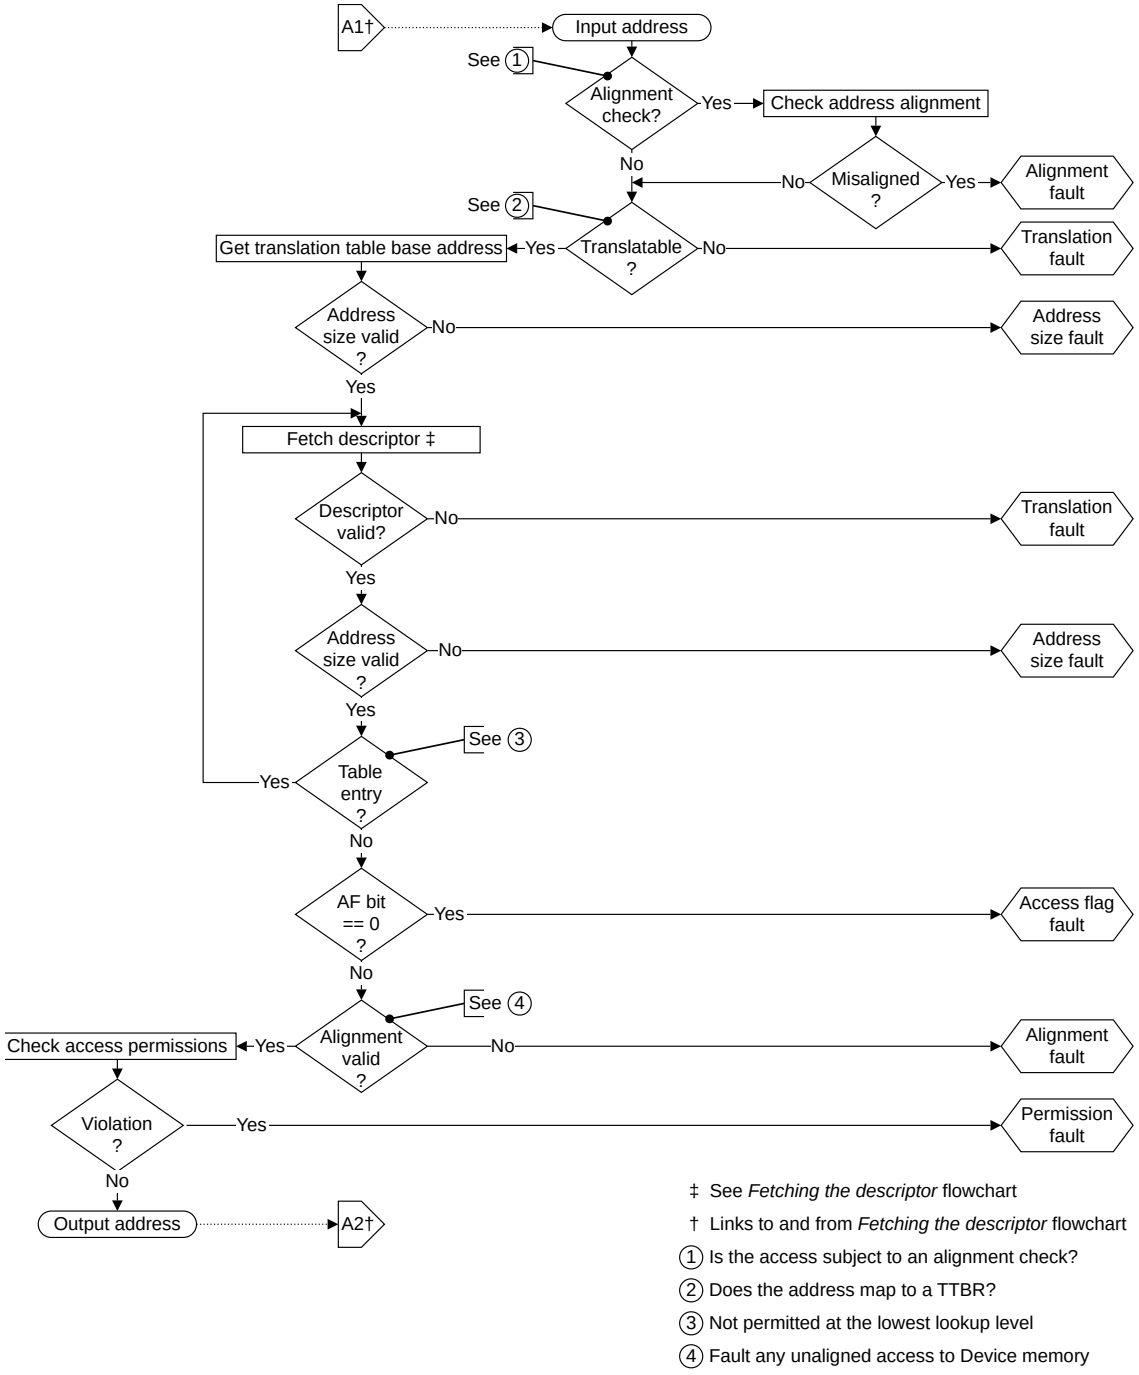

Figure D5-11 MMU fault checking sequence

I_{GFKXY} For a translation stage, the following figure illustrates the steps taken to fetch a descriptor during a translation table walk.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

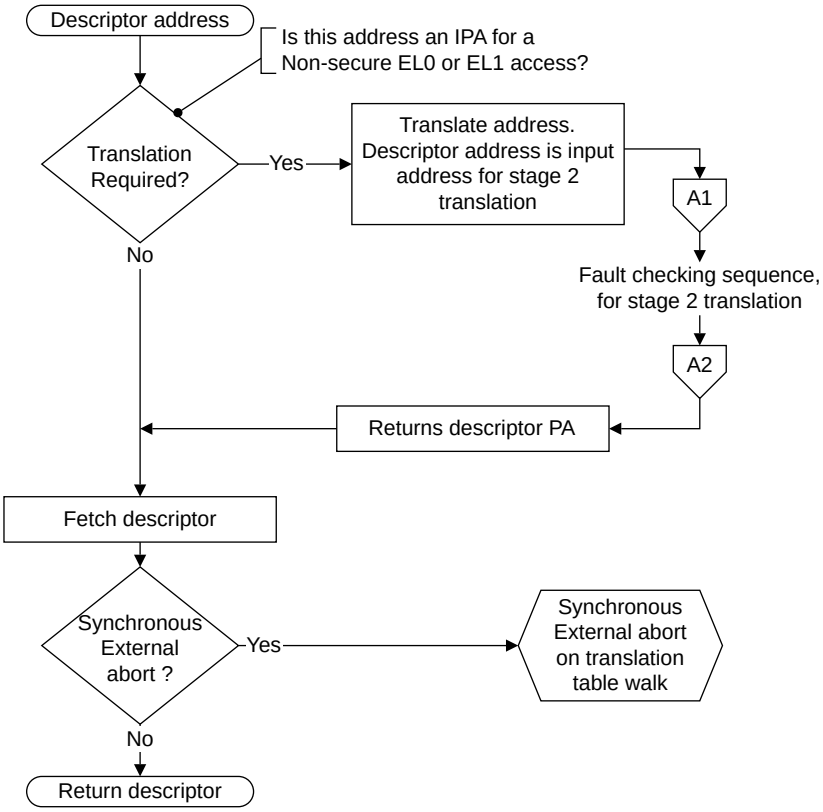

Figure D5-12 Fetching a descriptor during a translation table walk

I_{GLRRS} For more information, see Permission fault.

D5.10.4.1 The lookup level associated with MMU faults

I_{XCCCM} For MMU faults, the *Data Fault Status Code* (DFSC) and *Instruction Fault Status Code* (IFSC) in the ESR_ELx report the translation lookup level associated with a given MMU fault type.

I_{CRKPZ} When an MMU fault is generated, all of the following determine the lookup level associated with the fault:

- For a fault generated by a translation table walk, the lookup level at which the fault occurred.
- For a Translation fault, one of the following:
  - The lookup level at which the fault occurred.
  - If a fault is generated because translation table walks are disabled by TCR_ELx.EPD*n*, the IA is outside the range specified by the associated TTBR_ELx, or FEAT_E0PD is enabled and prevents access to addresses translated by TTBRn_ELx, then the fault is reported as a level 0 fault.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- For an Access flag fault, the lookup level at which the fault occurred.
- For a Permission fault, including a Permission fault generated by hierarchical permissions, the final lookup level that returned the Block descriptor or Page descriptor.

I_{CJZVP} For more information, see Permission fault.

D5.10.5 MMU fault prioritization from a single address translation stage

R_{JNVJY} For a single translation stage in a VMSAv8-64 translation regime, the following list shows the possible MMU faults on a memory access, from highest priority to lowest priority, and includes where stage 2 faults that are generated within a stage 1 translation table walk are prioritized:

1. For a stage 1 translation, an Alignment fault not caused by memory type.
2. If one or more of the following is true, then a Translation fault:
   - The IA out of the translated address range.
   - For a stage 1 translation, the IA requiring a TTBR_ELx that is disabled.
3. If one or more of the following is true, an Address size fault on the address in TTBR_ELx:
   - The address size check on TCR_EL1.IPS, TCR_EL2.{I}PS or VTCR_EL2.PS fails.
   - The programmed address is outside the implemented range.
4. If stage 2 address translation is enabled, then a stage 2 MMU fault on a level -1 memory access during a stage 1 table walk, including an Address size fault caused by a PA outside the implemented range.
5. A synchronous parity or ECC error on a level -1 lookup of a translation table walk.
6. A synchronous External abort on a level -1 lookup of a translation table walk.
7. Translation fault on a level -1 translation table entry.
8. If one or more of the following is true, an Address size fault on the address in a level -1 lookup translation table entry:
   - The address size check on TCR_EL1.IPS, TCR_EL2.{I}PS or VTCR_EL2.PS fails.
   - The OA is out of the implemented range.
9. A synchronous parity or ECC error on a level 0 lookup of a translation table walk.
10. A synchronous External abort on a level 0 lookup of a translation table walk.
11. Translation fault on a level 0 translation table entry.
12. If one or more of the following is true, an Address size fault on the address in a level 0 lookup translation table entry:
    - The address size check on TCR_EL1.IPS, TCR_EL2.{I}PS or VTCR_EL2.PS fails.
    - The OA is out of the implemented range.
13. A synchronous parity or ECC error on a level 1 lookup of a translation table walk.
14. A synchronous External abort on a level 1 lookup of a translation table walk.
15. Translation fault on a level 1 translation table entry.
16. If one or more of the following is true, an Address size fault on the address in a level 1 lookup translation table entry:
    - The address size check on TCR_EL1.IPS, TCR_EL2.{I}PS or VTCR_EL2.PS fails.
    - The OA is out of the implemented range.
17. A synchronous parity or ECC error on a level 2 lookup of a translation table walk.
18. A synchronous External abort on a level 2 lookup of a translation table walk.
19. Translation fault on a level 2 translation table entry.
20. If one or more of the following is true, an Address size fault on the address in a level 2 lookup translation table entry:
    - The address size check on TCR_EL1.IPS, TCR_EL2.{I}PS or VTCR_EL2.PS fails.
    - The OA is out of the implemented range.
21. A synchronous parity or ECC error on a level 3 lookup of a translation table walk.
22. A synchronous External abort on a level 3 lookup of a translation table walk.
23. Translation fault on a level 3 translation table entry.
24. If one or more of the following is true, an Address size fault on the address in a level 3 lookup translation table entry:
    - The address size check on TCR_EL1.IPS, TCR_EL2.{I}PS or VTCR_EL2.PS fails.
    - The OA is out of the implemented range.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

25. Access flag fault.
26. Alignment fault caused by the memory type.
    For an Alignment fault generated as a result of the conditions specified in Crossing a page boundary with different memory types or Shareability attributes or Crossing a peripheral boundary with a Device access, the prioritization of the Alignment fault is IMPLEMENTATION DEFINED, at a point between here and above Synchronous External abort on the memory access.
27. Permission fault. For more information, see Prioritization of Permission faults.
28. Synchronous parity or ECC error on the memory access.
29. Synchronous External abort on the memory access.

R_{WLJCM} For a TLB conflict abort, all of the following apply:

- The priority of the abort is IMPLEMENTATION DEFINED.
- The priority of the abort is required to be higher than any abort that depends on a value held in a TLB.

I_{HGZXP} The cause of a TLB conflict abort depends on the TLB implementation.

R_{CSFKV} For an IMPLEMENTATION DEFINED MMU fault caused by an unsupported combination of memory access type and memory type and reported with ESR_ELx.DFSC value `0b110101`, the priority is IMPLEMENTATION DEFINED.

R_{KYXHT} For an MMU fault at a translation stage caused by an unsupported atomic hardware update, the priority of this fault lies at an IMPLEMENTATION DEFINED point between all of the following:

- A priority immediately higher than an Access flag fault generated by the same translation stage as this MMU fault.
- A priority immediately lower than a Permission fault generated by the same translation stage as this MMU fault.

D5.10.5.1 Prioritization of Permission faults

R_{NRVMH} The following list shows the priority order of stage 1 Permission faults, from highest priority to lowest priority:

1. Fault due to stage 1 Base permissions.
2. Fault due to write of an Allocation Tag to a Canonically Tagged memory location.
3. Fault due to the dirty state.

D5.11 Translation Lookaside Buffers

I_{ZVNKM} The Arm architecture does not specify any structure of *Translation Lookaside Buffers* (TLBs), and permits any structure that complies with the requirements described in this section.

R_{XCLRD} Translation table entries that generate a Translation fault, an Address size fault, or an Access flag fault are never cached in a TLB.

R_{SQBCS} When address translation is enabled, a translation table entry for an in-context translation regime that does not cause a Translation fault, an Address size fault, or an Access flag fault is permitted to be cached in a TLB or intermediate TLB caching structure as the result of an explicit or speculative access.

R_{ZVMQM} A translation table entry is not permitted to be cached in a TLB or intermediate caching structure if a synchronous external abort on the translation table walk prevents the PE from determining if the translation table entry would otherwise cause a Translation fault, an Address size fault, or an Access flag fault.

I_{RCGCH} When address translation is enabled, if a translation table entry meets all of the following requirements, then that translation table entry is permitted to be cached in a TLB or intermediate TLB caching structure at any time:

- The translation table entry itself does not generate a Translation fault, an Address size fault, or an Access flag fault.
- The translation table entry is not from a translation regime configured by an Exception level that is lower than the current Exception level.

I_{LBGNR} The Arm architecture permits TLBs to cache certain information from System control registers, including when any or all translation stages are disabled. The individual register descriptions specify System control register fields are permitted to be cached in a TLB.
For more information, see AArch64 System Register Descriptions.

R_{JBNTF} For any System register field that is described as being permitted to be cached in a TLB, if that field takes an Effective value as a result of a System register control field at a higher Exception level, then the Effective value is also permitted to be cached in a TLB.

R_{WVTXJ} When executing at EL2 the TLB entries associated with the EL1&0 translation regime are out-of-context.

I_{RLTGW} The VMSA provides TLB maintenance instructions for the management of TLB contents.

R_{NDCMB} When a translation stage is disabled and then re-enabled, TLB entries are not corrupted.

D5.11.1 TLB behavior at reset

I_{GWZWM} When a reset occurs, an implementation is not required to automatically invalidate a TLB.

R_{BQCDZ} When a reset occurs, a TLB is affected in all of the following ways:

- All TLBs reset to an IMPLEMENTATION DEFINED state that might be UNKNOWN.
- It is IMPLEMENTATION DEFINED whether a specific TLB invalidation routine is required to invalidate a TLB before translation is enabled after a reset.

R_{HPBWC} For the ELx reset is taken to, when a reset occurs, SCTLR_EL1, System Control Register (EL1).M is reset to 0. For the translation regime controlled by that SCTLR_EL1, System Control Register (EL1).M bit, when SCTLR_EL1, System Control Register (EL1).M is 0 and SCTLR_EL2.BR is 1, the background region for the EL2 MPU is used.

R_{QNFHZ} If an implementation requires a specific TLB invalidation routine, then all of the following apply:

- The routine is IMPLEMENTATION DEFINED.
- The implementation documentation is required to clearly document the routine.
- Arm recommends that the routine is based on the TLB maintenance instructions.

I_{WVKXW} On a Cold reset or Warm reset, an implementation might require TLBs to maintain their contents from before the reset, including one or more of the following reasons:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- Power management.
- Debug requirements.

I_{WZHDM} For more information on the TLB maintenance instructions used in a TLB invalidation routine, see TLB maintenance instructions.

D5.11.2 TLB lockdown

R_{SSQZC} TLB lockdown support is IMPLEMENTATION DEFINED.

R_{XXDPS} If an implementation supports TLB lockdown, then all of the following apply:

- The lockdown mechanism is IMPLEMENTATION DEFINED.
- The implementation documentation is required to clearly document the interaction of the TLB lockdown mechanism with the architecture.
- A locked TLB entry is guaranteed to remain in the TLB, unless the locked TLB entry is affected by a TLB maintenance operation.
- An unlocked TLB entry is not guaranteed to remain in the TLB.
- If a translation table entry is modified, then it is not guaranteed that a locked TLB entry remains coherent with the modified translation table entry.

I_{DXXYV} If a translation table entry is modified, then it is not guaranteed that a locked TLB entry remains incoherent with the modified translation table entry because the lockdown mechanism might permit a TLB maintenance instruction to trigger an update of the locked TLB entry.
For more information, see The interaction of TLB lockdown with TLB maintenance instructions.

R_{DSQQW} The implementation is permitted to use the reserved IMPLEMENTATION DEFINED register encodings to implement TLB lockdown functions.

I_{LSKYV} TLB lockdown functions might include, but are not limited to, all of the following:

- Unlock all locked TLB entries.
- Prefetch a translation table entry into a specific TLB level.

R_{DSLVY} If an implementation supports TLB lockdown and EL2 is enabled, then when executing at EL1 or EL0, an exception due to TLB lockdown can be routed to one of the following:

- EL1, as a Data Abort exception.
- EL2, as a Hyp Trap exception.

D5.11.3 Use of ASIDs to reduce TLB maintenance requirements

I_{LHWHR} TLB maintenance can be reduced during context switches by associating the translation table lookups from some translation regimes with an *address space identifier* (ASID).

R_{JHDZC} The rules in this section apply only to translation regimes that support two privilege levels.

R_{QRRHL} The rules in this section refer to the *controlling ELx*, in an R-Profile implementation the controlling ELx is EL1 for stage 1 translations in the E1&0 translation regime.

D5.11.3.1 Global and process-specific translation table entries

I_{FRDGD} For translation regimes that use an ASID, it is possible to mark translations as global or non-global.

R_{XXNPZ} A TLB entry associated with a specific ASID value, or a specific ASID and a VMID value, can only be used to translate a VA in a context that is associated with the same ASID value.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

R_{WTVTJ} For stage 1 of a translation regime that supports two privilege levels, non-global TLB entries are associated with a specific ASID.

I_{LCNWN} For stage 1 of a translation regime that can support two privilege levels, Arm expects that software configures translations specific to a process to be associated with a specific ASID.

I_{HGKKC} The ASID permits software to switch between process-specific translation table mappings without removing previous mappings cached for another ASID from a TLB.

I_{LQMXG} For stage 1 of a translation regime that can support two privilege levels, each TTBR0_ELx and TTBR1_ELx has an ASID field.

R_{SCBSR} All the following values of TCR_ELx.A1 determine the ASID value that is used by the translations of both the lower VA range and upper VA range:

- If the value is 0, then the TTBR0_ELx.ASID is used.
- If the value is 1, then the TTBR1_ELx.ASID is used.

R_{PYWKY} For stage 1 of a translation regime that supports two privilege levels, TCR2_ELx.A2 determines all of the following:

- If the value is 0, then the one ASID selected by TCR_ELx.A1 is used.
- If the value is 1, then two ASIDs are used.

R_{XPSGZ} For a controlling ELx, if two concurrent ASIDs are used, then TCR_ELx.A1 does not select which ASID field is used for the purpose of caching translations in a TLB, and instead all of the following apply:

- Any non-global translation of an address in the TTBR0_ELx VA range is associated with TTBR0_ELx.ASID.
- Any non-global translation of an address in the TTBR1_ELx VA range is associated with TTBR1_ELx.ASID.

I_{NWLMM} The scope of `TLBI` operations is not affected by the Effective value of TCR2_ELx.A2.
This means that a `TLBI ASIDE1*` operation removes TLB entries associated with the specified ASID, regardless of which half of the VA range those entries would be used to translate, and would not be required to remove any other TLB entries.

I_{QYCVK} For execution at EL0, if FEAT_CSV2 is implemented, and the EL1&0 translation regime is used, the architecture defines a hardware-defined context as including an ASID. However, for execution at EL1 or at EL2 when using this translation regime, the hardware-defined context does not include an ASID.
For more information see Restrictions on the effects of speculation.

R_{SCLCL} For a controlling ELx, if two concurrent ASIDs are used, then for the purposes of FEAT_CSV2, the ASID used in the hardware-defined context when executing at EL0 is one of the following:

- If TCR_ELx.A1 is 0, then TTBR0_ELx.ASID.
- If TCR_ELx.A1 is 1, then TTBR1_ELx.ASID.

R_{QGKGF} The nG bit in a Block descriptor and Page descriptor indicates one of the following:

- If the value is 0, the translation is global and the TLB entry applies to all ASID values.
- If the value is 1, the translation is non-global and the TLB entry applies to only the current ASID value.

R_{CHVGJ} For a translation regime that supports global and non-global translations, translation table entries from lookup levels other than the final lookup level are treated as non-global, regardless of the value of the nG bit in the final lookup level.

R_{JYHZR} For a translation in Secure state, if the NSTable bit in a Table descriptor is 1 at any level of the translation table walk, then the resulting translation is treated as non-global, regardless of the nG bit value in the Block descriptor or Page descriptor for the translation.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D5.11.3.2 ASID size

R_{KHXQX} The ASID size is an IMPLEMENTATION DEFINED choice of 8 bits or 16 bits.

I_{NHTBK} The maximum supported ASID size is indicated by ID_AA64MMFR0_EL1.ASIDBits.

I_{BZXYN} For an implementation that supports 16-bit ASIDs, all of the following values of TCR_ELx.AS specify whether TTBRn_ELx.ASID[15:8] are used:

- If TCR_ELx.AS is 0, then TTBRn_ELx.ASID[15:8] are not used and are treated in all of the following ways:
  - For every purpose other than direct reads of TTBR0_ELx.ASID and TTBR1_ELx.ASID, the bits are ignored by hardware.
  - When used for allocating and matching entries in a TLB, the bits are treated as if they are all zeros.
- If TCR_ELx.AS is 1, then TTBRn_ELx.ASID[15:8] are used for allocating and matching entries in a TLB.

I_{ZRWYC} Bits[15:8] of the ASID field in `TLBI{P}` instructions are considered by hardware regardless of the value of TCR_ELx.AS.

D5.11.3.3 Common not private translations

I_{XJYLH} FEAT_TTCNP allows multiple PEs in the same Inner Shareable domain and operating in the same translation regime to use the same translation table entries in a given translation stage.

R_{FWQJZ} If all of the following conditions are met, translation table entries pointed to by TTBR_ELx are shared with all other PEs in the Inner Shareable domain, and are referred to as common not private translation tables:

- For the PEs that share the translation tables, the Effective value of the corresponding TTBR_ELx.CnP is 1.
- For the PEs that share the translation tables, the same translation regime in the same Security state applies to the corresponding TTBR_ELx.
- If an ASID applies to the corresponding translation stage, then all of the PEs that share non-global translation table entries are required to have the same current ASID.

R_{LGDJT} For a common not private translation table, if a System register field with all of the following characteristics is set by a particular PE to a value that is different than the value set by the other PEs, then it is CONSTRAINED UNPREDICTABLE whether the System register field is interpreted using the value of the particular PE or the value of one of the other PEs that are sharing the translation table entry:

- The register field applies to the translation stage.
- The register field is permitted to be cached in a TLB.

I_{YVLVD} The TTBR_ELx.CnP bit is permitted to be cached in a TLB.

R_{QLGWZ} For a common not private translation table, if a TTBR_ELx does not point to the same translation table as the other TTBR_ELx registers, then the system is misconfigured and an address translation using that TTBR_ELx causes one of the following to occur:

- Multiple hits in a TLB, which is permitted to generate a TLB conflict abort.
- A CONSTRAINED UNPREDICTABLE result due to caching of control or data values.

For more information, see TLB conflict abort and CONSTRAINED UNPREDICTABLE behaviors due to caching of control or data values.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D5.12 TLB maintenance

R_{RVJDB} For the purpose of TLB maintenance, a TLB entry is any structure that holds a translation table entry, including intermediate TLB caching structures and temporary working registers in translation table walk hardware.

I_{NDFND} When a translation table walk occurs, translation table entries that are permitted to be cached in a TLB might be held in TLB caching structures.

R_{PDGZY} Entries held in a TLB are distinguished by all of the following context information:

- The Security state.
- The translation regime.
- If applicable to the translation regime, then whether the translation is global or non-global.
- If the translation is non-global, then the ASID.

R_{FFWJK} TLBs, or TLB caching structures, are not guaranteed to remain coherent with changes to translation table entries, and are therefore distinct from data caches.

R_{ZYZYK} Indexing an intermediate TLB structure by the IA is permitted.

R_{BKKRB} If FEAT_nTLBPA is not implemented, then indexing an intermediate TLB structure by all of the following is also permitted:

- The PA of the location holding the translation table entry.
- For stage 1 translations, the IPA of the location holding the translation table entry.

R_{TJQVP} If FEAT_nTLBPA is not implemented, any TLB maintenance instruction that applies to a PE with the context information that is relevant to the translation table entry ensures cached copies of translation table entries are invalidated for that PE in all of the following implementations of intermediate TLB structures:

- Indexing the TLB using the PA of the location holding the translation table entry.
- For stage 1 translations, indexing the TLB using the IPA of the location holding the translation table entry.

I_{PFNFJ} FEAT_nTLBPA permits software to determine the existence of intermediate TLB caching structures that are indexed by PA or IPA and perform TLB maintenance accordingly when it would otherwise not be required.

R_{LGSCG} When a TLB maintenance instruction targets only stage 1 entries, all of the following apply:

- The maintenance applies to any entries in caching structures that include stage 1 information used to translate the address or range of addresses being invalidated.
- If the TLB maintenance targets a specific ASID, then entries in caching structures that are not tagged with the specific ASID are not invalidated.
- If the stage 1 translation information contained in a single Block or Page has been collectively cached as one or more smaller TLB entries, for example as the result of splintering, then all entries containing that stage 1 information are invalidated, regardless of whether the entry would be used to translate the address being invalidated.

R_{KVQYF} It is permissble to cache stage 1 VMSAv8-64 and stage 2 PMSAv8-64 attributes as a common entry for the Secure EL1&0 translation regime.

R_{GYQRW} Visibility of stage 2 PMSAv8-64 MPU updates for stage 1 VMSAv8-64 contexts requires the associated TLB invalidation for stage 2. The stage 2 invalidation is not required to apply caching structures that combine stage 1 and stage 2 attributes.

R_{GPPYH} When a translation table entry associated with a specific ASID is modified, software is required to invalidate the corresponding TLB entry to ensure that the modified translation table entry is visible to subsequent execution, including speculative execution.

R_{VNRFW} When a System register field is modified and that field is permitted to be cached in a TLB, software is required to invalidate all TLB entries that might be affected by the field, at any address translation stage in the translation regime even if the translation stage is disabled, using the appropriate ASID, after any required System register synchronization. For more information, see Synchronization requirements for AArch64 System registers.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I_{WZCBG} When a translation table entry that generates a Translation fault, Address size fault, or Access flag fault is changed to one that does not fault, all of the following apply to software:

- TLB invalidation is not required because an entry that generates one of the listed faults is never cached in a TLB.
- A Context synchronization event is required to ensure that the completed change to the translation table entry affects subsequent instruction fetches.

D5.12.1 Using break-before-make when updating translation table entries

R_{VSPZR} If multiple execution threads use the same translation tables, then when a translation table entry is modified in one or more of the following ways, the architecture requires software to use a break-before-make sequence:

- A change to the memory type, Shareability or Cacheability.
- The translation OA is changed and one or more of the following apply:
  - Either or both of the old and new translations grant write permission, including cases where the DBM bit is set and hardware updates of the dirty state is enabled.
  - The memory contents at the new OA do not match the memory contents at the previous OA.
- A global entry is created that might overlap with non-global entries in a TLB.

I_{WZRHR} A change to the translation OA space is considered a change to the translation OA.

I_{THWDH} Use of a break-before-make sequence to ensure that old and new translation table entries are never simultaneously visible to different execution threads is guaranteed to prevent all of the following problems:

- Creating multiple TLB entries that apply to the same address.
- The effects of TLB caching breaking coherency.
- The effects of TLB caching breaking single-copy atomicity properties.
- The effects of TLB caching breaking ordering guarantees or uniprocessor semantics.
- The effects of TLB caching causing a failure to clear the Exclusives monitors.

R_{DDMVT} A break-before-make sequence requires all of the following steps:

1. Replace the old translation table entry with an invalid entry.
2. Execute a DSB instruction to ensure the invalid entry is visible.
3. Invalidate TLB entries based on the translation table entry with a broadcast TLB invalidation instruction.
4. Execute a DSB instruction to ensure the invalidation completes.
5. Write the new translation table entry
6. Execute a DSB instruction to ensure the new entry is visible.

I_{GXGZY} For a translation stage with AF hardware management enabled, if a translation table entry is modified and the break-before-make sequence is not followed, then all of the following failures associated with AF hardware updates can occur:

- When a memory location associated with that translation table entry is accessed, the AF is not set.
- When hardware updates to that translation table entry are followed by stores appearing later in program order, the ordering required is not followed.

R_{RTBRL} For a translation stage with dirty state hardware management enabled, if a translation table entry is modified and the break-before-make sequence is not followed, then all of the following failures associated with dirty state hardware updates can occur:

- When a memory location associated with that translation table entry is not written, hardware modifies the AP[2] descriptor bit.
- When a memory location associated with that translation table entry is written, hardware does not modify the AP[2] descriptor bit.
- When hardware updates to that translation table entry are followed by stores appearing later in program order, the ordering required is not followed.

R_{LGRYM} If translation table entries are changed without appropriate TLB maintenance operations, including in the case where use of the break-before-make sequence is required but software does not follow the break-before-make sequence, it is possible that TLBs concurrently hold multiple different copies of those translation table entries.
In this situation, the following behaviors are permitted for a speculative or architectural access to the address resolved by those TLB entries:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- Use of the address matches multiple entries in a TLB, and a TLB conflict abort is detected. In this case, no access is made to memory based on those TLB entries. If the access is architectural, then the TLB conflict abort is reported as an exception.
- The resulting behavior is CONSTRAINED UNPREDICTABLE, and gives a behavior consistent with translation using one of the matching entries, or an amalgamation of more than one of the matching entries, but cannot permit access to memory regions with permissions or attributes that would not be possible in the current Security state at the current Exception level. This includes, for example, insufficient TLB maintenance by Non-secure state must not permit it to access any memory in Secure PA space.

I_{HLHBH} For more information, see CONSTRAINED UNPREDICTABLE behaviors due to caching of control or data values.

D5.12.2 Support levels for changing table or block size

R_{PVTFW} All statements in this section apply only to changing table or block sizes without changing any other property requiring break-before-make as specified in the rule R_{WHZWS} in Using break-before-make when updating translation table entries.

R_{KFLJB} When a translation table entry is modified to change the table or block size, the hardware provides one of the following possible implementations affecting the break-before-make requirement to avoid breaking coherency, ordering guarantees or uniprocessor semantics, or failing to clear the Exclusives monitors:

- If FEAT_BBML1 is not implemented, then software is required to use the break-before-make sequence.
- If FEAT_BBML1 is implemented, then software can use all of the following:
  - The break-before-make sequence.
  - The nT bit in the Table descriptor or Block descriptor.
- If FEAT_BBML2 is implemented, then software can change table or block size without breaking coherency, ordering guarantees or uniprocessor semantics, or failing to clear the Exclusives monitors.

For more information, see Block translation entry.

R_{HHCXC} When using a Table descriptor or Block descriptor with the nT bit set to 1, any accesses translated do not break coherency, ordering guarantees or uniprocessor semantics, or fail to clear the Exclusives monitors.

I_{HYQMB} If the TLB entries are not invalidated after the writes that modified the translation table entries are completed, then a TLB conflict abort can be generated because in a TLB there might be multiple translation table entries that all translate the same IA.

For Table descriptors, this also applies to intermediate TLB caching structures.

For more information, see TLB conflict abort.

I_{GYJBJ} When an MMU fault is reported while changing table or block sizes but before completing the required TLBI to invalidate the old translation table entry, the syndrome information reported for the fault is consistent with one of the following:

- The old translation table structure.
- The new translation table structure.

R_{KHRBC} If FEAT_BBML1 is implemented, then changing the Contiguous bit in a set of Block descriptors or Page descriptors can be done without breaking coherency, ordering guarantees or uniprocessor semantics, or failing to clear the Exclusives monitors.

R_{FCPSG} If FEAT_BBML1 is implemented and the Contiguous bit in a set of Block descriptors or Page descriptors is changed, then a TLB conflict abort can be generated because multiple translation table entries might exist within a TLB that translates the same IA.

I_{CFFVK} If FEAT_BBML1 is implemented and a TLB conflict abort is generated, then TLB maintenance is required to remove the multiple TLB entries that translate the same address.

For Table descriptors, this also applies to intermediate TLB caching structures.

For more information, see TLB maintenance due to TLB conflict.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D5.12.3 TLB maintenance due to TLB conflict

R_{BLRKC} If multiple TLB entries translate the same address, then the `ALL` or `VMALL` form of a TLB maintenance instruction that targets the given translation regime is guaranteed to remove all TLB entries within that regime.

I_{CNGYR} The following instructions are guaranteed to remove the TLB entries associated with a conflict:

- `VMALLE1`.
- `ALLE1`.

R_{GRVDR} If multiple TLB entries translate the same address, then the minimum set of TLB maintenance operations required to guarantee all TLB entries associated with that address and translation regime have been invalidated is IMPLEMENTATION DEFINED.

D5.12.4 The interaction of TLB lockdown with TLB maintenance instructions

R_{VGPNS} If a TLB entry is locked and a TLB invalidate all instruction is executed and, if that entry was not locked the TLB invalidate all instruction would invalidate that entry, then one of the following IMPLEMENTATION DEFINED behaviors occur:

- The locked TLB entry is not affected.
- If the TLB entry is locked or might be locked, an IMPLEMENTATION DEFINED Data Abort exception is generated.

I_{FRJSL} The IMPLEMENTATION DEFINED Data Abort on a TLB invalidate all instruction permits TLB invalidation routines to choose to invalidate a large range of addresses, without considering whether any TLB entries are locked, or to not affect locked TLB entries.

R_{BMHZW} If a TLB entry is locked and a TLB invalidate by VA or invalidate by ASID instruction is executed and, if that entry was not locked the TLB invalidate by VA or invalidate by ASID instruction would invalidate that entry, then one of the following IMPLEMENTATION DEFINED behaviors occur:

- The locked TLB entry is invalidated.
- The locked TLB entry is not affected.
- If the TLB entry is locked or might be locked, an IMPLEMENTATION DEFINED Data Abort exception is generated.

I_{FXBBY} The exception syndrome definitions include a fault code for cache and TLB lockdown faults.

R_{BCLPC} If an implementation uses an abort mechanism when entries that can be locked down are not actually locked down, then all of the following are required:

- The IMPLEMENTATION DEFINED instruction sequences that perform the required operations on entries that are not locked down are documented.
- An IMPLEMENTATION DEFINED mechanism is documented that ensures no TLB entries are locked.
- For locked entries, one of the other specified alternatives is implemented.

I_{DRZHY} If an implementation supports TLB lockdown, then Arm recommends that IMPLEMENTATION DEFINED TLB maintenance instruction sequences use the architecturally-defined operations to minimize the number of customized operations required.

I_{PNDQN} For more information on TLB lockdown, see TLB lockdown.

D5.12.5 TLB maintenance instructions

I_{HMJDP} For a given translation regime, the architecture defines TLB maintenance instructions that provide all of the following functions:

- Invalidate all corresponding entries in a TLB.
- Invalidate a corresponding single TLB entry by ASID for a non-global entry.
- Invalidate all corresponding TLB entries that match a specific ASID.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- Invalidate all corresponding TLB entries that match a specific VA, regardless of the ASID.
- Invalidate all corresponding TLB entries within a range of addresses.

I_{XMWNR} Each TLB maintenance instruction can be applied to one of the following:

- Only the PE that executes the instruction
- All PEs in the same Shareability domain as the PE that executes the instruction.

I_{JFCRF} The A64 assembly language syntax of a TLB maintenance instruction is `TLBI{P} <operation>{, <Xt>}`.

I_{KTDKY} All of the following apply to the TLB maintenance instructions:

- The `TLBI` operations take zero or one register arguments, for cases where 64 bits or fewer of scope information is required.
- The `TLBIP` operations take a pair of register arguments, for cases where more than 64 bits of scope information is required.

I_{NDJSJ} The `<operation>` in `TLBI{P} <operation>{, <Xt>}` is one of the following:

- For `TLBI` instructions:
  - `ALLE1{NXS}`, `ALLE2{NXS}`, `ALLE3{NXS}`, `ALLE1IS{NXS}`, `ALLE2IS{NXS}`, `ALLE3IS{NXS}`, `ALLE1OS{NXS}`, `ALLE2OS{NXS}`, or `ALLE3OS{NXS}`.
  - `VMALLE1{NXS}`, `VMALLE1IS{NXS}`, `VMALLE1OS{NXS}`, `VMALLS12E1{NXS}`, `VMALLS12E1IS{NXS}`, `VMALLS12E1OS{NXS}`, `VMALLWS2E1{NXS}`, `VMALLWS2E1IS{NXS}`, or `VMALLWS2E1OS{NXS}`.
  - `ASIDE1{NXS}`, `ASIDE1IS{NXS}`, or `ASIDE1OS{NXS}`.
- For `TLBI` and `TLBIP` instructions:
  - `{R}VA{L}E1{NXS}`, `{R}VA{L}E2{NXS}`, `{R}VA{L}E3{NXS}`, `{R}VA{L}E1IS{NXS}`, `{R}VA{L}E2IS{NXS}`, `{R}VA{L}E3IS{NXS}`, `{R}VA{L}E1OS{NXS}`, `{R}VA{L}E2OS{NXS}`, or `{R}VA{L}E3OS{NXS}`.
  - `{R}VAA{L}E1{NXS}`, `{R}VAA{L}E1IS{NXS}`, or `{R}VAA{L}E1OS{NXS}`.
  - `{R}IPAS2{L}E1{NXS}`, `{R}IPAS2{L}E1IS{NXS}`, or `{R}IPAS2{L}E1OS{NXS}`.

I_{YBNHL} The `<operation>` in `TLBI{P} <operation>{, <Xt>}` has a structure of `{R}<type><regime><shareability>{NXS}` with all of the following components:

- `R` is optional and determines one of the following:
  - When present, the instruction applies to all TLB entries translating addresses within the address range.
  - When not present, the instruction applies to all TLB entries translating a single address that could be used by the PE that executes the TLB maintenance instruction.
- `<type>` is one of the following:
  - `ALL` specifies all translations at `<regime>`.
  - `VMALL` specifies all stage 1 translations for the affected translation regime, and if applicable, matching the current VMID.
  - `VMALLS12` specifies all stage 1 and stage 2 translations at EL1 with the current VMID.
  - `VMALLWS2` specifies all writable-dirty stage 2 translations at EL1 with the current VMID.
  - `ASID` specifies all non-global translations for the affected translation regime with the supplied ASID.
  - `VA{L}` specifies all translations at `<regime>` using the supplied address and, if an ASID is supplied, the supplied ASID or global entries.
  - `VAA{L}` specifies all global entries and non-global entries, regardless of the ASID value, for the affected translation regime using the supplied address.
  - `IPAS2{L}` specifies all stage 2 translations using the supplied IPA.
- For the `VA{L}`, `VAA{L}`, and `IPAS2{L}` types, `L` is an optional parameter specifying that the invalidation applies only to cached entries containing translation information returned by the final lookup level of the translation table walk.
- `<regime>` is one of the following Exception levels:
  - If `E1`, then EL1.
  - If `E2`, then EL2.
- `<shareability>` is one of the following:
  - `IS` indicates that the instruction applies to all TLBs in the Inner Shareable domain.
  - `OS` indicates that the instruction applies to all TLBs in the Outer Shareable domain.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

— The parameter is optional, and no value indicates that the instruction applies to all TLBs that could be used by the PE that executes the instruction.

I_{YKBMJ} If `<regime>` is higher than the current Exception level, then the TLB maintenance instruction is UNDEFINED.

I_{DJQYS} All TLB maintenance instructions are UNDEFINED at EL0.

I_{LQDRK} In an R-profile implementation, all of the following TLB instructions are UNDEFINED:

- `TLBI ALLE3`.
- `TLBI ALLE3{I}{O}S`.
- `TLBI VAE3{I}{O}{S}`.
- `TLBI VALE3{I}{O}{S}`.

I_{BWGVK} When a TLB entry is invalidated by one PE, it is inconsistent with the architecture to allow another PE to refill that TLB entry so that the new entry gives the appearance to software that the invalidation did not occur.

I_{BNSBV} The `<Xt>` in `TLBI{P} <operation>{, <Xt>}` has all of the following properties:

- It specifies a register that passes one or both of an address and an ASID as an argument.
- For operations that include a VA, if FEAT_TTL is implemented, then the register passes the level hint.
- For range-based TLB maintenance operations, then the register passes information about the address range.
- It is required by the `TLBI ASID`, `TLBI{P} {R}VA{L}`, `TLBI{P} {R}VAA{L}`, and `TLBI{P} {R}IPAS2{L}` instructions.

D5.12.5.1 TLB maintenance instructions that do not apply to a range of addresses

I_{ZVNJG} For TLB maintenance instructions that take a VA, an ASID, or both as an argument, and that do not apply to a range of addresses, the register specified by the `Xt` argument has the following format:

- Register bits[63:48] are one of the following:
  - If the instruction requires an ASID argument, the ASID.
  - If the instruction does not require an ASID argument, RES0.
- If FEAT_TTL is not implemented, then register bits[47:44] are RES0.
- If FEAT_TTL is implemented, then register bits[47:44] are one of the following:
  - If the instruction requires a VA argument, the translation table level hint, TTL.
  - If the instruction does not require a VA argument, RES0.
- Register bits[43:0] are one of the following:
  - If the instruction requires a VA argument, VA[55:12].
  - If the instruction does not require a VA argument, RES0.

R_{JGGKN} For TLB maintenance instructions that take a VA, hardware interprets VA[63:56] as each having the same value as VA[55].

I_{LHKCP} If the implementation supports 16-bit ASIDs, then software is required to set the upper 8 bits of the ASID to 0 when the context being invalidated uses only 8 bits.

I_{KTQZV} For TLB maintenance instructions that take a register argument that holds an IPA and that do not apply to a range of addresses, the register specified by the `Xt` argument has the following format:

- Register bit[63] is the NS bit specifying the Secure or Non-secure IPA space.
- If FEAT_TTL is not implemented, then register bits[62:40] are RES0.
- If FEAT_TTL is implemented, then all of the following apply:
  - Register bits[62:48] are RES0.
  - Register bits[47:44] are the translation table level hint, TTL.
  - Register bits[43:40] are RES0.
- Register bits[39:36] are one of the following:
  - If 52-bit addresses are supported, IPA[51:48].
  - If 52-bit addresses are not supported, RES0.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- Register bits[35:0] are IPA[47:12].

I_{HQTLK} For TLB maintenance instructions that take a register argument that holds a VA or an IPA, register bits that hold the address have all of the following properties:

- If the 4KB granule size is used, all address bits in the register bits are used by the invalidation instruction.
- If the 16KB granule size is used, register bits[1:0] are ignored because address bits[13:12] have no effect on the invalidation instruction.
- If the 64KB granule size is used, register bits[3:0] are ignored because address bits[15:12] have no effect on the invalidation instruction.

D5.12.5.2 TLB maintenance instructions that apply to a range of addresses

I_{QPHNP} For TLB maintenance instructions that take a VA, or a VA and an ASID, and that apply to a range of addresses, the register specified by the `Xt` argument has the following format:

- Register bits[63:48] are one of the following:
  - If the instruction requires an ASID argument, the ASID.
  - If the instruction does not require an ASID argument, RES0.
- Register bits[47:46] are the translation granule size, TG.
- Register bits[45:44] are the SCALE field that is the exponent element of the calculation that produces the upper range.
- Register bits[43:39] are the NUM field that is the base element of the calculation that produces the upper range.
- If FEAT_TTL is not implemented, then register bits[38:37] are RES0.
- If FEAT_TTL is implemented, then register bits[38:37] are the translation table level hint, TTL.
- Register bits[36:0] give the starting address of the range of addresses, BaseADDR.

I_{DKWRD} For TLB maintenance instructions that take a register argument that holds an IPA and that apply to a range of addresses, the register specified by the `Xt` argument has the following format:

- Register bit[63] is the NS bit specifying the Secure or Non-secure IPA space.
- Register bits[62:48] are RES0.
- Register bits[47:46] are the translation granule size, TG.
- Register bits[45:44] are the SCALE field that is the exponent element of the calculation that produces the upper range.
- Register bits[43:39] are the NUM field that is the base element of the calculation that produces the upper range.
- If FEAT_TTL is not implemented, then register bits[38:37] are RES0.
- If FEAT_TTL is implemented, then register bits[38:37] are the translation table level hint, TTL.
- Register bits[36:0] specify the starting address of the range of addresses, BaseADDR.

R_{PVVXP} For TLB instructions that apply to a range of addresses, the following table shows the TG field encodings that define the translation granule size for the translations that are being invalidated, and the Translation_Granule_Size in bytes used in determining the address range.

Table D5-29 TG field encodings in TLB instructions that apply to a range of addresses

TG	Translation granule size	Translation_Granule_Size
00	Reserved	N/A
01	4KB translation granule	4096
10	16KB translation granule	16384
11	64KB translation granule	65536

R_{XKMMX} For TLB instructions that apply to a range of addresses, if the translations use a different translation granule size than the one specified by the TG field, then the architecture does not require that the instruction invalidate those entries.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

R_{QKRKL} For all TLB range maintenance instructions, TLB entries that translate one or more addresses within the address range determined by the following formula are invalidated:

`[BaseADDR <= input_address < BaseADDR + ((NUM +1)*2^(5*SCALE +1) * Translation_Granule_Size)].`

R_{QNPXY} For a translation regime that supports two VA ranges, if a TLB range maintenance instruction is issued with an address in the TTBR1_ELx half of the VA space, and the SCALE and NUM values cause the range to exceed the top of the address space, then the address is not considered to wrap on overflow and the PE is not required to invalidate any entries inserted for the corresponding TTBR0_ELx half of the VA space.

I_{HKYNQ} For a TLBI range maintenance instruction, `BaseADDR` is derived from bits[36:0] in the register specified by the `Xt` argument as one of the following:

- For the 4KB granule size, one of the following:
  - If the Effective value of TCR_EL1.DS is 0, then `BaseADDR[48:12]`.
  - If the Effective value of TCR_EL1.DS is 1, then `BaseADDR[52:16]`. In this case, `BaseADDR[15:12]` is treated as all zero.
- For the 16KB granule size, one of the following:
  - If the Effective value of TCR_EL1.DS is 0, then `BaseADDR[50:14]`.
  - If the Effective value of TCR_EL1.DS is 1, then `BaseADDR[52:16]`. In this case, `BaseADDR[15:14]` is treated as all zero.
- For the 64KB granule size, `BaseADDR[52:16]`.

I_{XGGRD} For all of the following, the invalidated address range is UNPREDICTABLE:

- For the 4KB translation granule, one of the following:
  - The TTL field is `0b01` and `BaseADDR[29:12]` are not all zero.
  - The TTL field is `0b10` and `BaseADDR[20:12]` are not all zero.
- For the 16KB translation granule, one of the following:
  - The TTL field is `0b10` and BaseADDR[24:14] are not all zero.
- For the 64KB translation granule, one of the following:
  - The TTL field is `0b01` and `BaseADDR[41:16]` are not all zero.
  - The TTL field is `0b10` and `BaseADDR[28:16]` are not all zero.

I_{ZNXDY} For more information, see Broadcast TLB maintenance.

D5.12.5.3 Translation table level hint

R_{BLDQZ} All statements in this section require implementation of FEAT_TTL.

I_{LTZBK} For the address being invalidated by a TLB maintenance instruction, the TTL field in the register specified by `Xt` indicates the lookup level of the translation table walk holding the leaf entry.

I_{WVDLN} Hardware can use the TTL field to determine if the page might have been splintered into multiple TLB entries.

R_{SQXYZ} For an entry being invalidated by a TLB maintenance instruction, if an incorrect TTL value is specified, then the architecture does not require any entries to be invalidated from a TLB.

I_{VWPQL} For TLB instructions that apply to a single address, the following table shows the 4-bit TTL field encodings.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Table D5-30 TTL field encodings in TLB instructions that apply to a single address

TTL[3:2]	Translation granule	TTL[1:0]	Information supplied
00	-	RES0	No information supplied about the translation level. Hardware assumes that the leaf entry can be from any level.
01	4KB	00	If FEAT_LPA2 is not implemented, then this value is reserved, and hardware treats this as if TTL[3:2] is `0b00`. If FEAT_LPA2 is implemented, then the leaf entry for the address being invalidated is on level 0 of the translation table walk.
		01	The leaf entry for the address being invalidated is on level 1 of the translation table walk.
		10	The leaf entry for the address being invalidated is on level 2 of the translation table walk.
		11	The leaf entry for the address being invalidated is on level 3 of the translation table walk.
10	16KB	00	This value is reserved, and hardware treats this as if TTL[3:2] is `0b00`.
		01	If FEAT_LPA2 is not implemented, then this value is reserved, and hardware treats this as if TTL[3:2] is `0b00`. If FEAT_LPA2 is implemented, then the leaf entry for the address being invalidated is on level 1 of the translation table walk.
		10	The leaf entry for the address being invalidated is on level 2 of the translation table walk.
		11	The leaf entry for the address being invalidated is on level 3 of the translation table walk.
11	64KB	00	This value is reserved, and hardware treats this as if TTL[3:2] is `0b00`.
		01	The leaf entry for the address being invalidated is on level 1 of the translation table walk.
		10	The leaf entry for the address being invalidated is on level 2 of the translation table walk.
		11	The leaf entry for the address being invalidated is on level 3 of the translation table walk.

I_VNDBJ For TLB instructions that apply to a range of addresses, the following table shows the 2-bit TTL field encodings.

Table D5-31 TTL field encodings in TLB instructions that apply to a range of addresses

TTL	Information supplied
00	The leaf entries in the range can be using any level for the translation table entries.
01	When the 4KB or 64KB translation granule is used, all leaf entries to invalidate are level 1 translation table entries. If FEAT_LPA2 is not implemented, then when using a 16KB translation granule, this value is reserved, and hardware treats this as if TTL is `0b00`. If FEAT_LPA2 is implemented, then when using a 16KB translation granule, all leaf entries to invalidate are level 1 translation table entries.
10	All leaf entries to invalidate are level 2 translation table entries.
11	All leaf entries to invalidate are level 3 translation table entries.

D5.12.5.4 TLB maintenance instruction scope

R_YPJSC If `<type>` is `ALL` in a TLB maintenance instruction, then all of the following apply:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- For all values of `<regime>`, the instruction exists.
- For entries from the EL1&0 translation regime the instruction applies to cached copies of translation table entries with any VMID.
- For entries from a translation regime in which an ASID is valid, the instruction applies to all of the following cached copies of translation table entries from any lookup level in the translation table walk:
  - Global entries.
  - Non-global entries with any ASID.

R_{DNPQC} If `<type>` is `VMALL` in a TLB maintenance instruction, then all of the following apply:

- If and only if the value of `<regime>` is E1, then the instruction applies to the EL1&0 translation regime.
- The instruction applies to all cached copies of the stage 1 translation table entries from any lookup level in the translation table walk required to translate any address at the specified Exception level.
- For entries from the EL1&0 translation regime the instruction applies only to cached copies of translation table entries with the current VMID.
- For entries from a translation regime in which an ASID is valid, the instruction applies to all of the following cached copies of translation table entries from any lookup level in the translation table walk:
  - Global entries.
  - Non-global entries with any ASID.

R_{TBTPJ} If `<type>` is `VMALLS12` in a TLB maintenance instruction, then all of the following apply:

- If and only if the value of `<regime>` is E1, then the instruction applies to the EL1&0 translation regime.
- The instruction applies only to cached copies of translation table entries with the current VMID.
- For entries from a translation regime in which an ASID is valid, the instruction applies to all of the following cached copies of translation table entries from any lookup level in the translation table walk:
  - Global entries.
  - Non-global entries with any ASID.

R_{NMXFR} If `<type>` is `ASID` in a TLB maintenance instruction, then all of the following apply:

- If and only if the value of `<regime>` is E1, then the instruction applies to the EL1&0 translation regime when executing at EL1.
- The instruction applies to all cached copies of the stage 1 translation table entries from any lookup level in the translation table walk required to translate any address at the specified Exception level.
- The instruction applies only to non-global entries from the final lookup level that matches the specified ASID.

R_{WJWNN} If `<type>` is `VA` in a TLB maintenance instruction, then all of the following apply:

- For all values of `<regime>`, the instruction exists.
- The instruction applies to all cached copies of the stage 1 translation table entries from any lookup level in the translation table walk required to translate the address at the specified Exception level.
- For entries from a translation regime in which an ASID is valid, the instruction applies only to all of the following cached copies of translation table entries:
  - A non-global entry from any lookup level that matches the specified ASID.
  - A global entry from the final lookup level.

R_{PGHBM} If `<type>` is `VAL` in a TLB maintenance instruction, then all of the following apply:

- For all values of `<regime>`, the instruction exists.
- The instruction applies to all cached copies of the stage 1 translation table entries from the final lookup level in the translation table walk required to translate the address at the specified Exception level.
- The instruction applies only to cached copies of translation table entries from the final lookup level with the current VMID.
- For entries from a translation regime in which an ASID is valid, the instruction applies only to all of the following cached copies of translation table entries:
  - A non-global entry from the final lookup level that matches the specified ASID.
  - A global entry from the final lookup level.

R_{GKRKF} If `<type>` is `VAA` in a TLB maintenance instruction, then all of the following apply:

- If and only if the value of `<regime>` is E1, then the instruction applies to the EL1&0 translation regime when executing at EL1.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- The instruction applies to all cached copies of the stage 1 translation table entries from any lookup level in the translation table walk required to translate the address at the specified Exception level.
- The instruction applies only to cached copies of translation table entries with the current VMID.
- The instruction applies to all of the following cached copies of translation table entries from any lookup level in the translation table walk:
  - Global entries.
  - Non-global entries with any ASID.

R_{CBRLG} If `<type>` is `VAAL` in a TLB maintenance instruction, then all of the following apply:

- If and only if the value of `<regime>` is E1, then the instruction applies to the EL1&0 translation regime when executing at EL1.
- The instruction applies to all cached copies of the stage 1 translation table entries from the final lookup level in the translation table walk required to translate the address at the specified Exception level.
- The instruction applies to all of the following cached copies of translation table entries from the final lookup level in the translation table walk:
  - Global entries.
  - Non-global entries with any ASID.

D5.12.6 Operation of the TLB maintenance instructions

R_{XQBCL} A TLB maintenance instruction applies whether a translation stage is enabled or disabled.

R_{KKDKL} A TLB maintenance instruction can affect any TLB entries that are not locked down.

I_{YGYRY} There is no guarantee that an unlocked TLB entry remains in the cache. Therefore, it is not possible to determine architecturally whether a TLB maintenance instruction has affected any TLB entries that were not specified by the instruction.

I_{LMGTM} The TLB maintenance instructions specify the Exception level of the translation regime to which they apply.

R_{TBLDD} A TLB maintenance instruction never generates an MMU abort.

I_{FNJXC} A TLB maintenance instruction is not affected by the current state of all of the following control bits involved in the translation process:

- In AArch64 state, all of the following:
  - SCTLR_EL1.M.
  - SCTLR_EL2.M.
  - HCR_EL2.{VM, RW}.
  - TCR_EL1.{TG1, EPD1, T1SZ, TG0, EPD0, T0SZ, AS, A1}.
  - TCR_EL2.{TG0, T0SZ}.
  - VTCR_EL2.{SL0, T0SZ}.
  - TTBR0_EL1.ASID.
  - TTBR1_EL1.ASID.

R_{FZTHY} Address-based TLB maintenance instructions are applied to the extent of the `<shareability>` specified by the instruction regardless of the Shareability assigned by any translation of the IA or Shareability attribute stored in TLB entries.

R_{LQLSD} When a TLB maintenance instruction is executed, all of the following apply:

- The minimum size of a TLB entry that is required to be invalidated from the TLB is at least the size specified by the corresponding translation table entry.
- The Contiguous bit does not affect the minimum size of a TLB entry that is required to be invalidated from the TLB.

I_{JQPNP} When invalidating a mapping greater than a translation granule size or block size, for example a mapping that is specified using the Contiguous bit, software is required to issue a TLB maintenance instruction for each block or granule within the configured contiguous region size to invalidate the entire mapping.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

R_{MMZTY} An implementation is permitted to invalidate more than the minimum required TLB entries.

I_{ZWTPG} Arm recommends not invalidating entries that are not required to be invalidated to minimize the performance impact.

I_{RTRQB} Arm expects software to mostly use address-based TLB invalidation instructions that apply to entries cached from the last level of a stage 1 translation table walk to avoid unnecessary loss of the cached intermediate translation table entries.

D5.12.7 Broadcast TLB maintenance

R_{GYPWS} In all of the following cases, a broadcast TLB maintenance instruction is not required to perform any invalidation on the recipient PE within the target Shareability domain:

- A TLB maintenance instruction specifying a VA and affecting the EL1&0 translation regime is broadcast from a PE using a stage 1 translation granule size for that translation regime to a PE using EL1 and a different stage 1 translation granule size for that VA.
- A TLB maintenance instruction specifying a range of VAs or IPAs is broadcast from one PE to a PE that does not support the TLB range-based operations.

R_{YNPVV} The set of Requesters containing TLBs that support TLB range-based operations is defined by the system architecture.

I_{WHFDZ} Arm strongly recommends that within an Inner Shareable domain, all PEs support the same set of broadcast TLB range maintenance instructions.

R_{TVMHK} If an Armv7 PE is in the same Inner Shareable domain as an Armv8 PE, and the Armv8 PE issues a broadcast TLB maintenance instruction that is not defined in Armv7, then that instruction is not required to affect the TLBs of the Armv7 PE.

D5.12.8 Ordering and completion of TLB maintenance instructions

R_{TGVWD} For all of the following instructions, the effects of a TLB maintenance instruction can be observed in any order relative to that instruction unless a DSB is executed between the instructions:

- Any load or store instruction.
- Another TLB maintenance instruction.
- A data or instruction cache maintenance instruction.

R_{QRNJC} A TLB maintenance instruction executed by a PE causes a TLB maintenance operation to occur on each PE within the Shareability domain specified by the instruction.

R_{WWQZZ} When a TLB maintenance instruction is executed, *in-scope old translation information* is any translation information related to addresses within the scope of that instruction that is not consistent with one or more of the following:

- The architectural translation information held in the translation tables.
- Any architecture translation information that is Coherence-after the information held in the translation tables.

I_{YMDMJ} In-scope old translation information might be held in TLBs or other non-coherent caching structures.

R_{STPSQ} For a PE that handles a TLB maintenance operation the TLB maintenance operation is finished when all of the following apply:

- All memory accesses generated by that PE using in-scope old translation information are complete.
- All memory accesses, RWx, generated by that PE are complete, where RWx is the set of all memory accesses generated by instructions for that PE that appear in program order before an instruction I1 executed by that PE, where all of the following apply:
  - I1 uses the in-scope old translation information.
  - The use of the in-scope old translation information generates a synchronous Data Abort.
  - If I1 did not generate an abort from use of the in-scope old translation information, I1 would generate a memory access that RWx would be locally-ordered-before.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

R_{DCJQM} When the TLB maintenance operations specified by a TLB maintenance instruction are finished for all PEs, the TLB maintenance instruction is complete.

R_{LXHLD} If a TLB maintenance instruction is complete, then no new memory accesses using the in-scope old translation information are architecturally performed by any observer that is affected by the TLB maintenance instruction.

I_{CPZSM} If it is impossible for software running on any observer to determine that the memory accesses have been performed, then speculative memory accesses can be performed using in-scope old translation information.

R_{PSMWS} When a DSB instruction is used to ensure the completion of TLB maintenance instructions, all of the following apply:

- The DSB is required to apply to both loads and stores.
- A DSB `NSH` is sufficient to ensure completion of TLB maintenance instructions that apply to a single PE.
- A DSB `ISH` is sufficient to ensure completion of TLB maintenance instructions that apply to PEs in the same Inner Shareable domain.

R_{YNJCP} When a PE, PEx, executes a TLB maintenance instruction, the instruction can complete at any time after it is issued, but the instruction is only guaranteed to be finished for a PE other than PEx after the execution of DSB by the PEx.

R_{RBWPQ} For the TLB of a PE that issues a TLB maintenance instruction, the instruction is guaranteed to be complete after the execution of DSB by that PE, followed by a Context synchronizatrion event.

I_{MGRRK} For more information, see Ordering requirements defined by the formal concurrency model.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D5.13 Caches

D5.13.1 Data and unified caches

R_{JHVQL} For data and unified caches, if all data accesses to an address do not use mismatched memory attributes, then the use of address translation is transparent to any data access to the address.
For more information, see Mismatched memory attributes.

R_{CTGML} For data accesses from the same observer to different VAs, if the accesses are translated to the same PA with the same memory attributes, then they are coherent and all of the following behaviors are guaranteed without requiring the use of barrier or cache maintenance instructions:

- Two writes to the same PA occur in program order.
- A read of a PA returns the value of the last successful write to that PA.
- A write to a PA that occurs, in program order, after a read of that PA, has no effect on the value returned by that read.

R_{NGPVX} When cache maintenance is done to a memory location, the effect of that cache maintenance is visible to all VA or IPA aliases of that physical memory location.

I_{FHPPX} The properties of data and unified caches are consistent with implementing the caches as physically-indexed, physically-tagged caches.

D5.13.2 Instruction caches

R_{GXBMD} An instruction cache has all of the following properties:

- An instruction cache is accessed only as a result of an instruction fetch.
- An instruction cache is never written to by a load or store instruction.
- Cache invalidation is the only cache maintenance that can be done on an instruction cache.

R_{XBHSB} The Arm architecture permits all of the following instruction cache implementations:

- *Physically-indexed, physically-tagged* (PIPT) instruction cache.
- *Virtually-indexed, physically-tagged* (VIPT) instruction cache.

I_{XSPPH} The CTR_EL0.L1Ip field identifies the form of the instruction caches.

R_{WNDVG} If CTR_EL0.DIC is 1, instruction cache maintenance is not required after overwriting instructions, including for different VA aliases of the affected Locations, regardless of the value of CTR_EL0.L1Ip.

R_{XLZJK} For all permitted instruction cache implementations, the Arm IVIPT Extension is also implemented, which reduces instruction cache maintenance requirements to requiring maintenance only after writing new data to a PA that holds an instruction.

I_{QNJPN} Previous versions of the Arm architecture permitted an instruction cache option that does not implement the Arm IVIPT Extension.

I_{GWSPL} For software to be portable between implementations that might use any of the permitted instruction cache implementations, that software is required to invalidate the instruction cache whenever any condition occurs that requires instruction cache maintenance on at least one of the instruction cache types.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D5.13.2.1 Physically-indexed, physically-tagged instruction caches

R_{YXNGL} For PIPT instruction caches, all of the following apply:

- If all instruction fetches to an address do not use mismatched memory attributes, then the use of address translation is transparent to any instruction fetch to the address.
- If instruction cache maintenance is done on a memory location, then the effect of that instruction cache maintenance is visible to all VA or IPA aliases of that physical memory location.

D5.13.2.2 Virtually-indexed, physically-tagged instruction caches

R_{LYZYY} For VIPT instruction caches, all of the following apply:

- If all instruction fetches to an address do not use mismatched memory attributes, then the use of address translation is transparent to any instruction fetch to the address.
- If instruction cache maintenance by address is done on a memory location, then the effect of that instruction cache maintenance is visible only to the VA supplied with the operation, and the effect of the invalidation might not be visible to any other VA or IPA aliases of that physical memory location.
- The only architecturally-guaranteed way to invalidate all VA or IPA aliases of a PA from a VIPT instruction cache is to invalidate the entire instruction cache.

D5.13.3 Cache maintenance requirements due to changing memory region attributes

I_{VPPPM} If changes are made to the memory region attributes in translation table entries, TLB maintenance might be required. For more information, see TLB maintenance.

I_{ZDQCY} The behaviors caused by mismatched memory attributes mean that if any of the following changes are made to the Inner Cacheability or Outer Cacheability attributes in translation table entries, then software is required to ensure that any cached copies of affected locations are removed from the caches, typically by cleaning and invalidating the locations from the cache levels that might hold copies of the locations affected by the attribute change:

- A change from Write-Back to Write-Through.
- A change from Write-Back to Non-cacheable.
- A change from Write-Through to Non-cacheable.
- A change from Write-Through to Write-Back.

For more information, see Mismatched memory attributes and Using break-before-make when updating translation table entries.

R_{ZNPYM} If the Shareability attributes in translation table entries are changed, then software is required to execute the following sequence to prevent possible coherency errors caused by mismatched memory attributes:

1. Make the memory location Non-cacheable, Outer Shareable.
2. Clean and invalidate the memory location from caches in the appropriate Shareability domain.
3. Change the Shareability attributes to the new values.

D5.14 Pseudocode description of VMSA address translation

I_{ZMHCV} The Arm architecture defines pseudocode that describes the translation table walk.

I_{STKYL} **Full Physical Address**

A complete PA necessary to identify a location in physical memory is captured by the type `FullAddress`. This is composed of:

- A bitstring `address`, which identifies the PA.
- An enumeration `paspace` which identifies the PA space.

I_{MXLCQ} **Address translation**

`AArch64.TranslateAddress()` acts as the entry point to VMSA and performs the required address translation based on the provided parameters and System register configurations. The function returns an `AddressDescriptor` structure holding valid data for either of the following:

- Target memory address and attributes for a non-faulting translation.
- Fault details holding data to be populated in syndrome registers.

I_{LTNYC} `AArch64.S1DisabledOutput()` assigns the appropriate memory attributes and flat maps the input address to the output address.

I_{KKVJD} **Translation table walk**

Stage 1 of translation has a separate walk function, `AArch64.S1Walk()`. Each use walk parameters extracted from related System registers. Parameters are collected based on the active translation regime.

I_{YMSFF} For a non-faulting walk, three items are returned by a translation table walk:

- The final walk state.
- The final descriptor fetched.
- The address of the final descriptor.

I_{KGLCH} The final descriptor and its address are used to update the descriptor as specified by Hardware management of the Access flag and Hardware management of the dirty state.

I_{RQKNH} A faulting walk could report one of the following at a specified level:

- Translation Fault.
- Address size Fault.
- Access flag Fault.

I_{DNSWC} **Hardware update of Translation Table descriptors**

The walk parameters collected from System registers indicate the ability to update the access flag or set write permissions within descriptors. This is controlled by the Dirty Bit Modifier, and the conditions specified in Hardware management of the Access flag and Hardware management of the dirty state. The translation function `AArch64.S1Translate()` set the appropriate descriptor bits returned by the walk functions and call `AArch64.MemSwapTableDesc()` to swap the old descriptor for the updated one in an atomic fashion.

I_{DKMRY} **Address decoding and calculation**

The walk state is initialized to hold the base address of the first translation table. For stage 1, the base address is acquired using `AArch64.S1TTBaseAddress()`, which decodes TTBR0_ELx and TTBR1_ELx registers depending on the regime and the range the VA corresponds to.

Indexing at the start level is shown in `AArch64.S1SLTTEntryAddress()` for stage 1. The final walk state would hold the base address for the output block or page; this is extracted from the Leaf descriptor in `AArch64.S1LeafBase()` for stage 1.

I_{GDTNP} **Memory attribute decoding**

If a stage of translation is enabled, fetched descriptors that are blocks or pages encode memory attributes assigned to the output of translation. Stage 1 memory attributes are decoded by the function `S1DecodeMemAttrs()`. The combination of stage 1 and stage 2 attributes by the function `S2CombineS1MemAttrs()` is presented to the MPU for the stage 2 translation. However, if FEAT_S2FWB is enabled, this behavior is overridden and memory attributes are decoded as specified in Stage 2 memory type and Cacheability attributes when FWB is enabled. This is captured by the function `AArch64.S2ApplyFWBMemAttrs()`.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I_{HGFRX} **Fault detection**

As soon as translation is invoked a reserve `FaultRecord` accompanies the process capturing the stage and level of translation as it proceeds. When a fault is detected, it is reflected in the `FaultRecord` and reported back as the result of translation with the most recent state to be reported already captured within. The following functions detect a certain type of fault:

- The `AArch64.S1CheckPermissions()` function checks permissions for stage 1.
- The `AArch64.S2HasAlignmentFaultDueToMemType()` functions detect an alignment fault for stage 1 and stage 2 respectively.
- The `AArch64.S1TxSZFaults()` function detects a Translation fault caused by erroneous configuration of TCR_ELx.T*n*SZ field.
- `AArch64.VAIsOutOfRange()` detects a stage 1 Translation fault caused by VAs larger than the address input size configured.

I_{PJBNQ} For more information, see function descriptions in aarch64/translation.

Chapter D6
The AArch64 Protected Memory System Architecture

This chapter provides a system-level view of the Protected Memory System Architecture for any implementation that is compliant with the Armv8-R AArch64 architecture. It contains the following sections:

- About the Protected Memory System Architecture .
- Memory Protection Unit.
- Address translation regimes.
- Default memory map.
- MPU memory translations and faults.
- Protection region attributes and access permissions.
- MPU fault encodings.
- PMSAv8-64 implications for caches.
- Address tagging and pointer authentication support.
- Security model.
- Virtualization.

D6.1 About the Protected Memory System Architecture

R_{CCSZJ} The Armv8-R AArch64 architecture supports the *Protected Memory System Architecture* (PMSAv8-64) at EL1 and EL2.

I_{KFQTT} The PMSAv8-64 is based on *Memory Protection Units* (MPUs) that provide a memory protection scheme by defining *protection regions* in the address space.
The PMSAv8-64:

- Supports a unified memory protection scheme where an MPU manages instruction and data access. The MPUs defined by the architecture do not provide separate instruction protection regions and data protection regions in the address map.
- Defines MPU faults that are consistent with VMSAv8-64 fault definitions and reuses IFSC and DFSC fault encodings.
- Does not support virtual addressing and flat maps an input address to an output address.

D6.1.1 Protection regions

R_{LGFYG} The MPUs divide the address map into protection regions.

I_{MTLWF} A protection region is a contiguous memory region for which the MPU defines the memory attributes and the access permissions.

R_{DLWYC} Protection regions have all of the following properties:

- Are defined by a pair of registers, a Base Address Register, and a Limit Address Register for each Exception level:
  - PRBAR_ELx.
  - PRBAR<n>_ELx.
  - PRLAR_ELx.
  - PLBAR<n>_ELx.
- Have a minimum size of 64 bytes.
- Have a maximum size of the entire address map.
- Must not overlap.

R_{YNGFT} Memory attributes are provided by the Memory Attributes Indirection Registers:

- MAIR_ELx.
- AMAIR_ELx.

R_{QMXQS} The Memory Attribute Indirection Registers are indexed by the Base Address and Limit Address Registers to define the attributes for the Protection region.

I_{LFRRK} The definition of a protection region specifies the base and the limit of the region, the access permissions, and the memory attributes for the Protection region.

I_{GFSTP} If the MPU is disabled the PE uses an IMPLEMENTATION DEFINED default memory map. For more information see Default Memory Map.

D6.1.2 Address range

R_{RNZPF} The maximum supported address bit size is 48, or 52 if FEAT_LPA is enabled.

R_{HRWYX} A PE can choose to implement a smaller PA range and the actual implemented physical address range is defined by the ID_AA64MMFR0_EL1.PARange field.

R_{SVYSG} Any access to physical memory address outside the address range results in a memory fault.
For more information, see MPU memory translations and faults

D6.2 Memory Protection Unit

I_{FQPST} An MPU checks whether the address used by a memory access matches all of the following:

- A memory protection region.
- The memory access permissions defined by the associated memory protection region.
- The memory attributes defined by the associated memory protection region.
- The Security state defined by the associated memory protection region.

R_{BQGDB} The PMSAv8-64 defines two MPUs:

EL1 MPU

The EL1 MPU can be configured from EL1 or EL2. The EL1 MPU controls the stage 1 of the Secure EL1&0 translation regime that defines the protection regions for accesses from EL1 and EL0.

EL2 MPU

The EL2 MPU can be configured only from EL2. The EL2 MPU controls:

- Stage 1 of the Secure EL2 translation regime that defines the protection regions for accesses from EL2.
- Stage 2 of the Secure EL1 &0 translation regime that defines the protection regions for accesses from EL1 and EL0.

Note

When HCR_EL2.VM is 1 and SCTLR_EL2.M is 1, then EL2 MPU modifies the access permissions and memory attributes that are assigned by the EL1 MPU.

R_{QLGWV} The PMSAv8-64 uses SCTLR_EL1.M to enable and disable the EL1 MPU. The EL1 MPU also supports a Background region, controlled by SCTLR_EL1.BR.

R_{GNWJH} The PMSAv8-64 uses SCTLR_EL2.M to enable and disable the EL2 MPU. The EL2 MPU also supports a Background region, controlled by SCTLR_EL2.BR.

For more information, see:

- Protection regions.
- Protection region attributes and access permissions.
- Default memory map.

D6.2.1 Default Cacheability

I_{CWZLJ} The PMSAv8-64 supports Default Cacheability for the stage 1 of the Secure EL1&0 translation regime access. For more information, see Memory region attributes.

D6.3 Address translation regimes

I_{WKVZH} In PMSAv8-64:

- Address translation describes the process of flat mapping the VA used by the PE, to the PA accessed in the memory system, and determining the access permissions and memory attributes of the target PA.
- A translation regime maps a VA to a PA using 1 or 2 stages of address translation to assign the access permissions and memory attributes of the target PA. When 2 translation stages are used, the intermediate address is called as an IPA.

R_{PPLTJ} The PMSAv8-64 architecture supports two translation regimes:

- Secure EL1&0 translation regime.
- Secure EL2 translation regime.

D6.3.1 Secure EL1&0 translation regime

R_{RSZBF} The Secure EL1&0 translation regime assigns the access permissions and memory attributes for any access from EL1 or EL0.

R_{JHPRR} This translation regime has 1 or 2 stages of translation:

- All accesses from EL1 or EL0 are translated by the EL1 MPU.
- When the value of HCR_EL2.VM is 1 and SCTLR_EL2.M is 1, the accesses are further translated by the EL2 MPU. This translation is a stage 2 translation, and can modify the access permissions and memory attributes that are assigned by the stage 1 translation.

R_{VHLGJ} For the EL1&0 stage 1 translation, an ADDRESS is in the protection region *n* if and only if:

- PRBAR<n>_EL1.BASE:'000000' <= ADDRESS <= PRLAR<n>_EL1.LIMIT:'111111'.

D6.3.2 Secure EL2 translation regime

R_{CTLZJ} The Secure EL2 translation regime assigns the access permissions and memory attributes for any access from EL2.

R_{CFQHD} This translation regime has a single stage of translation, stage 1, that is performed by the EL2 MPU.

R_{BWBJW} For the EL2 translation, an ADDRESS is in the protection region *n* if and only if:

- PRBAR<n>_EL2.BASE:'000000' <= ADDRESS <= PRLAR<n>_EL2.LIMIT:'111111'.

For more information, see Protection regions and Protection region attributes and access permissions.

D6.4 Default memory map

R_{XVXND} The default memory map of the Armv8-R AArch64 architecture is IMPLEMENTATION DEFINED.

R_{ZTGTY} The memory attributes, access permissions, and Security state of the memory regions in the default memory map are IMPLEMENTATION DEFINED.

R_{LHZQT} The default memory map is same for EL1 and EL2 MPUs.

R_{PCHLR} For PMSAv8-64, the Background region is enabled and disabled using SCTLR_ELx.BR.

R_{ZQBYD} If the revelant MPU is disabled and the Background region is enabled (SCTLR_ELx.{BR,M} == {1,0}) then the default memory map is used to determine the memory attributes, access permissions and Security state for the Background region.

I_{WYVJN} The Armv8-R AArch64 architecture defines only the conditions required to access the default memory map, but not the memory map itself.

R_{SSMPX} Any access outside the implemented physical address range in the default memory map results in a fault.

R_{QVBFB} If the IMPLEMENTATION DEFINED default memory map is discontinuous, then the implementation must also define a generic permission and attribute to be used for memory access to all memory regions that are not covered by the default memory map. However, an implementation can also select a default memory map so that the accesses to these discontinuous memory regions, where no memory attributes are allocated, always result in memory faults.

D6.5 MPU memory translations and faults

I_{TBZYB} This section provides information on memory attributes and the MPU faults for the stage 1 Secure EL1&0, stage 1 Secure EL2, and the stage 2 Secure EL1&0 translation regimes.

For the EL1 MPU memory translations, this section describes the following:

- Table D6-1.
- Table D6-2.
- Table D6-3.
- Table D6-4.
- Figure D6-1.

For the EL2 MPU memory translations, this section describes the following:

- Table D6-5.
- Table D6-6.
- Table D6-7.
- Table D6-8.
- Table D6-9.
- Figure D6-2.
- Figure D6-3.

D6.5.1 EL1 MPU memory translations

I_{FTMQV} The EL1 MPU controls the stage 1 of the Secure EL1&0 translation regime.

R_{ZPLQC} Based on the values of HCR_EL2.DC and SCTLR_EL1.{M, BR}, the stage 1 of the Secure EL1&0 translation regime can have the following configurations for memory attributes, as described in Table D6-1.

Table D6-1 Stage 1 EL1&0 memory attributes

HCR_EL2	SCTLR_EL1		MPU hit	Memory attribute
DC	M	BR		
1	x	x	-	Default Cacheability
0	0	0	-	Accesses permitted
0	0	1	-	Default memory map
0	1	0	No	Not applicable, MPU Fault
0	1	0	Yes	MPU memory map
0	1	1	No	Default memory map
0	1	1	Yes	MPU memory map

R_{HFKTS} Based on the values of HCR_EL2.DC and SCTLR_EL1.{M, BR}, the stage 1 of the Secure EL1&0 translation regime can result in MPU faults for EL1 accesses, as described in Table D6-2.

Table D6-2 Stage 1 MPU faults for EL1 access

HCR_EL2	SCTLR_EL1		MPU hit	MPU faults
DC	M	BR		
1	x	x	-	No Fault or Address size fault
0	0	0	-	No Fault or Address size fault

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

HCR_EL2	SCTLR_EL1		MPU hit	MPU faults
DC	M	BR		
0	0	1	-	No Fault, or Background region Translation fault, or Background region Permission fault
0	1	0	No	Translation fault
0	1	0	Yes	No Fault or Permission fault
0	1	1	No	No Fault, or Background region Translation fault, or Background region Permission fault
0	1	1	Yes	No Fault or Permission fault

R_{ZSPZK} Based on the values of HCR_EL2.DC and SCTLR_EL1.{M, BR}, the stage 1 of the Secure EL1&0 translation regime can result in MPU faults for EL0 accesses, as described in Table D6-3.

Table D6-3 Stage 1 MPU faults for EL0 access

HCR_EL2	SCTLR_EL1		MPU hit	MPU faults
DC	M	BR		
1	x	x	-	No Fault or Address size fault
0	0	0	-	No Fault or Address size fault
0	0	1	-	No Fault, or Background region Translation fault, or Background region Permission fault
0	1	x	No	Translation fault
0	1	x	Yes	No Fault or Permission fault

R_{QMPWZ} If HCR_EL2.{DC, TGE} is not {0, 0}, then the PE behaves as if the value of the SCTLR_EL1.BR is 0 for all purposes other than returning the value of a direct read of the field.

D6.5.2 EL1 MPU faults

I_{RBZDF} Each EL1 MPU protection region is defined using the PRBAR_EL1 and PRLAR_EL1 registers.

R_{YFYJN} The MPU checks the input address with each protection region, and an address is considered to match a region if:

```
Address >= PRBAR_EL1.BASE:'000000' && Address <= PRLAR_EL1.LIMIT:'111111'
```

R_{HTZMK} Based on MPU protection region checks, the EL1 MPU can raise the following responses as described in Table D6-4.

Table D6-4 EL1 MPU fault types

Protection region match	Permission	MPU response
No match	-	Translation fault
Multiple	-	Translation fault
Single	Denied	Permission fault
	Allowed	Valid

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

R_{DFBZT} If the EL1 MPU is disabled and the input address is larger than the implemented PA size, then a level 0 address size fault is generated.

R_{GSYFG} If the EL1 MPU is enabled and the input address is larger than the implemented PA size, then a level 0 translation fault is generated.

R_{GHZRY} Transactions permitted by the EL1 MPU are presented to stage 2 permission checks by the EL2 MPU.

I_{JBNSP} Depending on the configuration in the PMSAv8-64 registers, the memory attributes of an address can be defined by an MPU protection region or a Background region.

D6.5.3 MPU fault check for the stage 1 Secure EL1&0 translation

I_{TSMHY} Figure D6-1 shows the MPU fault check sequence for the stage 1 of the Secure EL1&0 translation regime.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

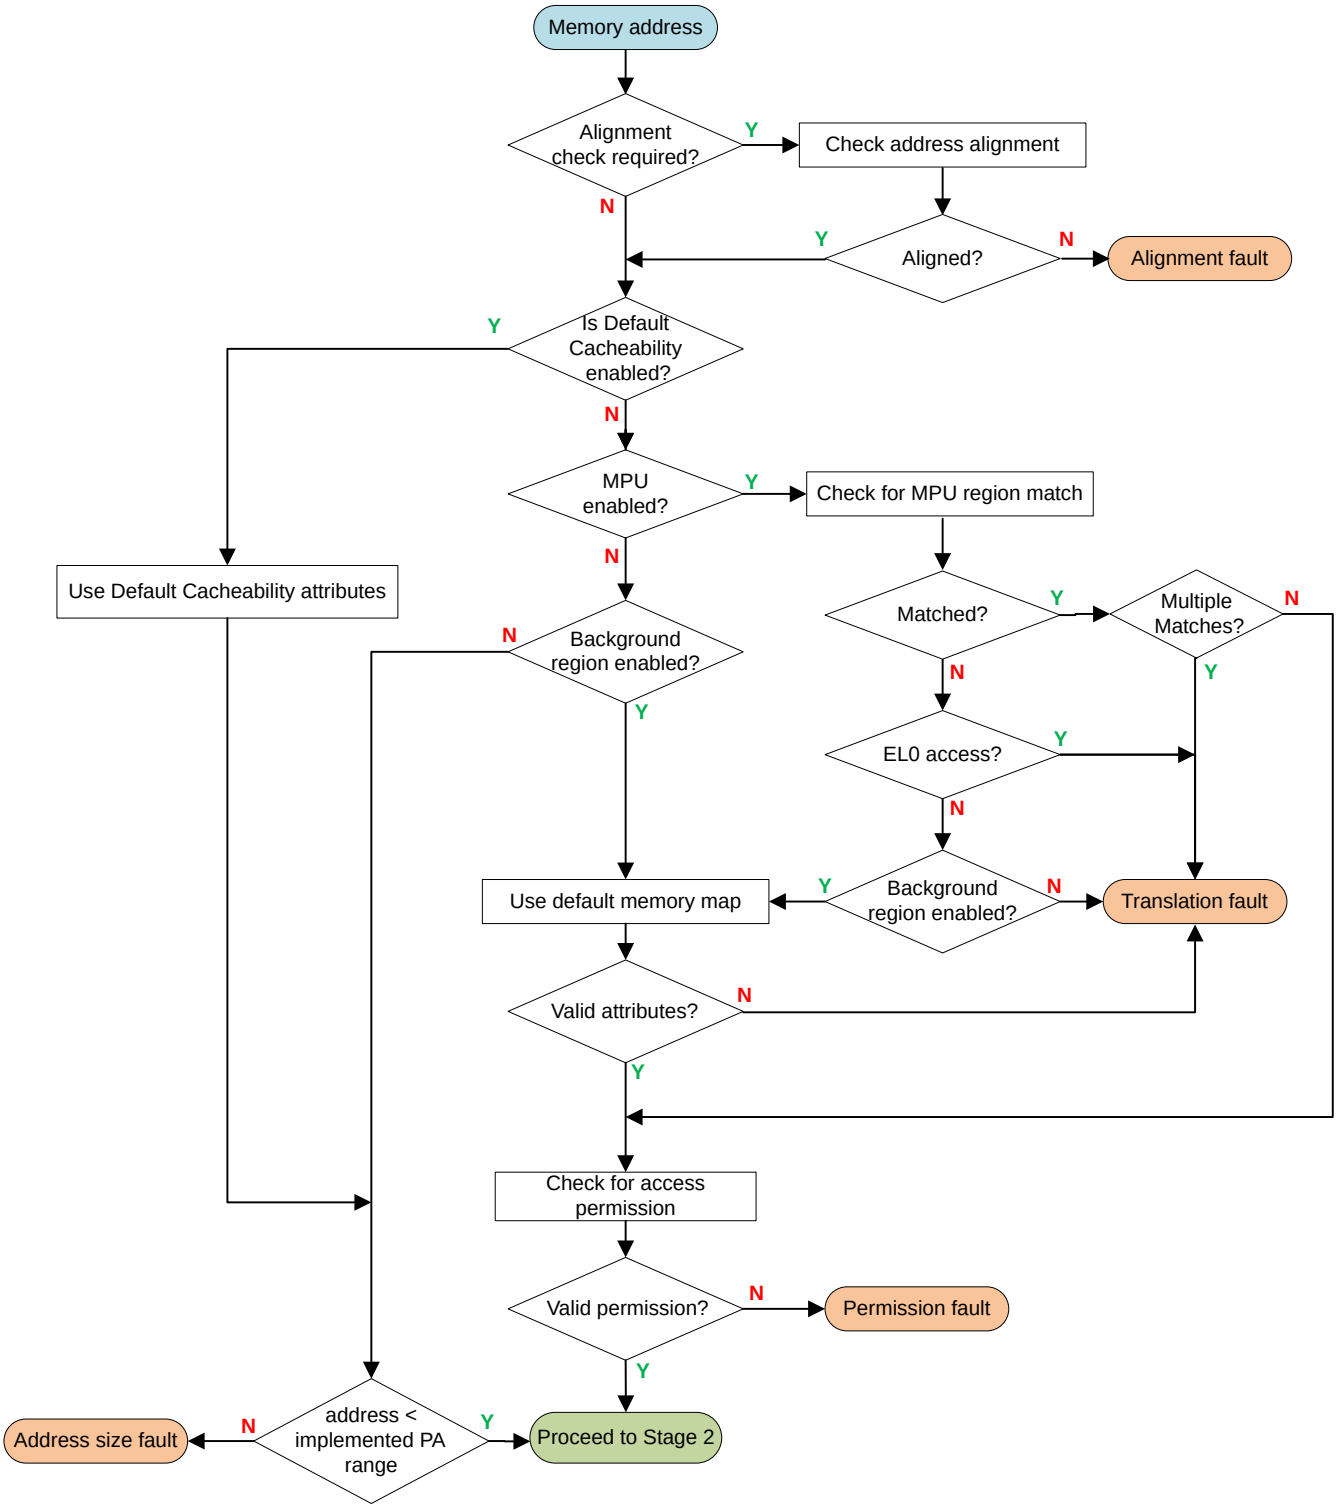

Figure D6-1 MPU fault check sequence for the stage 1 Secure EL1&0 translation

D6.5.4 EL2 MPU memory translations

R_{FJDCZ} Based on the values of SCTLR_EL2.{M, BR}, the stage 1 of the Secure EL2 translation regime can have the following configurations for memory attributes, as described in Table D6-5.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Table D6-5 Stage 1 EL2 memory attributes

SCTLR_EL2		MPU hit	Memory attributes
M	BR		
0	0	-	Accesses permitted
0	1	-	Default memory map
1	0	No	Not applicable. MPU Fault.
1	0	Yes	MPU memory map
1	1	No	Default memory map
1	1	Yes	MPU memory map

Table D6-6 lists the configurations for stage 1 MPU faults for EL2 access.

Table D6-6 Stage 1 MPU faults for EL2 access

SCTLR_EL2		MPU hit	MPU faults
M	BR		
0	0	-	No Fault or Address size fault
0	1	-	No Fault, or Background region Translation fault, or Background region Permission fault
1	0	No	Translation fault
1	0	Yes	No Fault or Permission fault
1	1	No	No Fault, or Background region Translation fault, or Background region Permission fault
1	1	Yes	No Fault or Permission fault

R_{CZDBJ} Based on HCR_EL2.VM and SCTLR_EL2.{M, BR}, the stage 2 of the Secure EL1&0 translation regime can have the following configurations for memory attributes, as described in Table D6-7.

Table D6-7 Stage 2 EL1&0 memory attributes

HCR_EL2	SCTLR_EL2		MPU hit	Memory attribute
VM	M	BR		
0	x	x	-	Stage 2 translation disabled
1	0	0	-	CONSTRAINED UNPREDICTABLE
1	0	1	-	Default memory map
1	1	x	No	Not applicable. MPU Fault.
1	1	x	Yes	MPU memory map

Table D6-8 lists the configurations for MPU faults for the stage 2 of the Secure EL1&0 translation regime.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Table D6-8 Stage 2 EL1&0 MPU faults

HCR_EL2	SCTLR_EL2		MPU hit	MPU faults
VM	M	BR		
0	x	x	-	No Fault
1	0	0	-	CONSTRAINED UNPREDICTABLE
1	0	1	-	No Fault, or Background region Translation fault, or Background region Permission fault, or Translation fault due to Secure Check, if enabled.
1	1	x	No	Translation fault
1	1	x	Yes	No Fault, or Permission fault, or Translation fault due to Secure Check, if enabled.

R_{XTWMV} There are no separate configurations for the protection regions for the stage 1 of the Secure EL2 and the stage 2 of the Secure EL1&0 translations. Memory accesses for both translations are controlled by the same MPU configuration registers, PRBAR_EL2 and PRLAR_EL2.

Note

In Armv8-A, there are separate translation table base registers for the stage 1 of the Secure EL2 and the stage 2 of the Secure EL1&0 translation regimes.

D6.5.5 EL2 MPU faults

I_{QVJVG} Each EL2 MPU protection region is defined using PRBAR_EL2 and PRLAR_EL2.

R_{YHTXR} The MPU checks the input address with each protection region and an address is considered to match a region if:

```
Address >= PRBAR_EL2.BASE:'000000' && Address <= PRLAR_EL2.LIMIT:'111111'
```

R_{FXSQK} Based on MPU protection region checks, the EL2 MPU can raise the following responses as described in Table D6-9.

Table D6-9 EL2 MPU fault types

Protection region match	Permission	MPU response
No match	-	Translation fault
Multiple	-	Translation fault
Single	Denied	Permission fault
Single	Allowed	Valid

R_{JGXXQ} If the EL2 MPU is disabled for the stage 1 of the Secure EL2 translation regime, then any access to an address outside the implemented PA range raises a level 0 address size fault.

R_{SLNZH} If the EL2 MPU is enabled for the stage 1 of the Secure EL2 translation regime, and the input address is larger than the implemented PA range, then a level 0 translation fault is generated.

D6.5.6 MPU fault check for the stage 1 Secure EL2 translation

I_{BMMTX} Figure D6-2 shows the MPU fault check sequence for the stage 1 of the Secure EL2 translation regime.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.

D6.6 Protection region attributes and access permissions

R_{HJQLL} The protection region attribute fields control the Memory type, Cacheability, and Shareability attributes of the region. PMSAv8-64 uses the same memory types and memory attributes as VMSAv8-64.

R_{ZDXDJ} The memory attributes and access permissions for a protection region are defined by:

- The PRBAR_EL1 and PRLAR_EL1 registers, or the PRBAR_EL2 and PRLAR_EL2 registers that define the protection region.
- The MAIR_EL1.Attr<*n*> or MAIR_EL2.Attr<*n*> field that is indexed by PRLAR_EL1.AttrIndx or PRLAR_EL2.AttrIndx, respectively.

For the Secure EL1&0 translation regime, when HCR_EL2.VM is 1, the stage 1 memory attribute and access permission assignments are combined with the stage 2 assignments, as described in Combining memory attributes and access permissions.

For more information, see Memory attributes and access permission mappings.

D6.6.1 Protection region attributes

R_{MJDVK} The PMSAv8-64 uses the same memory attributes defined by the VMSAv8-64, and the MPU enables configuration of the attributes for each protection region using MAIR_EL1 and MAIR_EL2 for the stage 1 EL1&0 and EL2 translations.

R_{NJQMD} The PMSAv8-64 also enables configuration of each protection region to map to Secure or Non-secure address space using the NS bit in the EL1 and EL2 MPU configuration registers.

R_{GRFHL} Writes to MPU registers are only guaranteed to be visible following a *Context synchronization event* and DSB operation.

R_{ZYCWG} If there are multiple protection regions allocated to the same coherency granule, then PMSAv8-64 follows the mismatched memory attributes rules to access any byte within that coherency granule.

R_{VMRLQ} If the Security states of protection regions are different, then implementation must ensure that these regions are not allocated to the same coherency granule. For the stage 2 EL1&0 translations, memory attributes encoding in the MAIR_EL2 register is defined in Table D6-10.

Table D6-10 Meaning of Attr[7:4]

Attr [7:6]	Attr [5:4]	Memory type	Outer cache policy
00	00	Device memory	Not Applicable (NA)
00	!=00	Normal memory	Write-Through (WT)
01	00	Normal memory	Non Cacheable (NC)
01	!=00	Normal memory	Write-Back (WB)
10	xx	Normal memory	Write-Through (WT)
11	xx	Normal memory	Write-Back (WB)

R_{BQYGF} When Attr[7:4] is 0b0000, Attr[3:0] defines the type of Device memory. In this case, Attr[1:0] != 0b00 gives UNPREDICTABLE behavior as defined by Armv8-A. Table D6-11 describes the meaning of Attr<3.0> when Attr[7:4] is 0b0000.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Table D6-11 Attr<3.0> Meaning when Attr[7:4] is `0b0000`

Attr [3:2]	Attr [1:0]	Memory type
`00`	`00`	Device-nGnRnE
`01`	`00`	Device-nGnRE
`10`	`00`	Device-nGRE
`11`	`00`	Device-GRE

R_{TMGLY} When Attr[7:4] is not `0b0000`, Attr[3:0] defines the Inner Cache Policy, and Attr[3:0] = `0b0000` gives UNPREDICTABLE behavior as defined by Armv8-A. Table D6-12 describes the meaning of Attr<3.0> when Attr[7:4] is not `0b0000`.

Table D6-12 Attr<3.0> Meaning when Attr[7:4] is not `0b0000`

Attr [3:2]	Attr [1:0]	Memory type	Inner Cache Policy
`00`	!=`00`	Normal memory	Write-Through (WT)
`01`	`00`	Normal memory	Non Cacheable (NC)
`01`	!=`00`	Normal memory	Write-Back (WB)
`10`	`xx`	Normal memory	Write-Through (WT)
`11`	`xx`	Normal memory	Write-Back (WB)

For more information, see The AArch64 Virtual Memory System Architecture.

D6.6.2 Access control

I_{VXZDW} The Base and Limit registers in the PMSAv8-64 contain the same access permission and security control bits present in the VMSAv8-64 translation table desciptors.

R_{MCJFK} PMSAv8-64 also does not support Privileged execute-never (PXN) and Unprivileged execute-never (UXN) bits. PMSAv8-64 behaves as if PXN = XN and UXN = XN, and follows the same rule defined by VMSAv8-64 in combining permission attributes.

R_{XHFGG} The following table lists the stage 1 permissions and the access type that is permitted when that permission is present. If the stage 1 permission is not present, that access type is not permitted.

Table D6-13 Stage 1 permissions

Stage 1 permission	Access type permitted
UnprivRead	Unprivileged data read in the EL1&0 translation regime.
UnprivWrite	Unprivileged data write in the EL1&0 translation regime.
PrivRead	Privileged data read in the EL1&0, and EL2 translation regimes.
PrivWrite	Privileged data write in the EL1&0, and EL2 translation regimes.
Execute	Instruction execution in the EL1&0, and EL2 translation regimes.

R_{PBTCW} The following table shows the possible data access permissions at EL0 and the corresponding higher Exception level.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Table D6-14 Data access permissions for a stage 1 translation supporting two Exception levels

AP[2:1]	Permissions
00	PrivRead, PrivWrite
01	PrivRead, PrivWrite, UnprivRead, UnprivWrite
10	PrivRead
11	PrivRead, UnprivRead

I_{HKLTT} All of the following controls can ensure that memory locations are not both writable and executable:

- For privileged accesses in all translation regimes, PrivWXN.
- For unprivileged accesses in the EL1&0 translation regime, UnprivWXN.

I_{TNLPM} In an MPU controlled memory access that applies to EL0 and a higher Exception level, then the following table shows the possible stage 1 memory access permissions, using all of the following notations:

- XN is in the applicable PRBAR<n>_ELx register at the higher Exception level to which the translation regime applies.
- AP[2:1] is the Effective value of AP[2:1].
- WXN is in the SCTLR_ELx register at the higher Exception level to which the translation regime applies.

Table D6-15 Summary of possible memory access permissions using Direct permissions for a stage 1 translation supporting two Exception levels

XN	AP[2:1]	WXN	Permission
0	00	0	PrivRead, PrivWrite, Execute
0	00	1	PrivRead, PrivWrite, PrivWXN, Execute
0	01	0	PrivRead, PrivWrite, UnprivRead, UnprivWrite, Execute
0	01	1	PrivRead, PrivWrite, UnprivRead, UnprivWrite, UnprivWXN
0	10	x	PrivRead, Execute
0	11	x	PrivRead, Execute, UnprivRead, Execute
0	00	x	PrivRead, PrivWrite, Execute
1	00	0	PrivRead, PrivWrite,
1	00	1	PrivRead, PrivWrite, PrivWXN
1	01	x	PrivRead, PrivWrite, UnprivRead, UnprivWrite
1	10	x	PrivRead
1	11	x	PrivRead, UnprivRead
1	00	x	PrivRead, PrivWrite
1	01	x	PrivRead, PrivWrite, UnprivRead, UnprivWrite
1	10	x	PrivRead
1	11	x	PrivRead, UnprivRead

R_{JCKXP} If the values of SCTLR_EL1.{WXN, M} is {1,1} then in the in EL1&0 translation regime a memory region that is marked as PrivWrite will be Execute-never at EL1 and if marked as UnprivWrite will be Execute-never at EL0.

R_{NJNYR} If the value of SCTLR_EL1.{M, BR} is {0, 1}, then for the Secure EL1&0 translation regime, any memory region that is writable at EL0, is also executable from EL1 if that address is marked as executable by the Background region.

R_{SCNQL} Access granted in the stage 1 of the Secure EL1&0 translation regime by the EL1 MPU is subject to further qualification by the EL2 MPU in the stage 2 of the Secure EL1&0 translation regime.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I_{FZDRR} For selecting memory attributes and defining access permissions, PMSAv8-64 follows the same prioritization rules defined by VMSAv8-64.

R_{PCXZQ} PMSAv8-64 does not support hierarchical control bits defined in the VMSAv8-64 table descriptors.

R_{PVRXB} Armv8-R AArch64 supports FEAT_PAN. If the value of SCTLR_EL1.M is 1, FEAT_PAN is applied to the stage 1 of the Secure EL1&0 translation regime.

D6.6.3 Memory attributes and access permission mappings

R_{LXGMJ} Memory attributes, Security states, and access permission information present in the translation table descriptors of VMSAv8-64 are mapped to MPU configuration registers in PMSAv8-64, as described in Table D6-16.

Table D6-16 Memory attributes and access permission mappings

Attributes and permissions	MPU register fields	Description
Non-secure (NS)	PRLAR_EL1.NS PRLAR_EL2.NS	Specifies whether the translated address is in the Secure or Non-secure address space.
Access Permission (AP)	PRBAR_EL1.AP PRBAR_EL2.AP	Defines the Access permissions for the protection region.
Execute Never (XN)	PRBAR_EL1.XN PRBAR_EL2.XN	Defines the Execute-never attribute for the protection region.
Shareability (SH)	PRBAR_EL1.SH PRBAR_EL2.SH	Defines the Shareability for a Normal memory region. For any type of Device memory or Normal Non-cacheable memory, the value of the SH[1:0] field is IGNORED.
Attribute Index (AttrIndx)	PRLAR_EL1.AttrIndx PRLAR_EL2.AttrIndx	Indexes an Attr<n> field in the MAIR_EL1 or MAIR_EL2 register, which gives the memory type and memory attributes.

D6.6.4 Combining memory attributes and access permissions

I_{YPVNH} The PMSAv8-64 uses the same architecture rules as Armv8-A for combining stage 1 and stage 2 memory attributes and the access permissions for the Secure EL1&0 translation regime.

For more information see Combining stage 1 and stage 2 memory type attributes.

D6.6.4.1 Stage 2 forced Write-Back Feature

R_{BTHTX} If FEAT_S2FWB is enabled (HCR_EL2.FWB=1), the Inner and Outer Memory attributes for the stage 2 of the Secure EL1&0 translation regime must be the same with the same encoding, otherwise the combined attribute is UNKNOWN.

- If FEAT_S2FWB is enabled and the memory attributes for the stage 2 of the Secure EL1&0 translation regime are Write-Back (WB) with Attr[7:6] = 0b11, then the combined attribute is WB. If the memory attribute is assigned by the MPU, the attribute encoding is derived from MAIR_EL2.Attr[7:6]. If the memory attribute is assigned from Background region, then the encoding is derived from the memory region configuration in the Background region.
- If FEAT_S2FWB is not enabled, then stage 1 and stage 2 memory attributes of the Secure EL1&0 translation regime are combined using Armv8-A rule for combining memory attributes when FEAT_S2FWB is not enabled.

R_{CWSCK} In Armv8-A, the memory attribute encoding that enables FEAT_S2FWB is MemAttr[4:2] = 0b110 in stage 2 block or page descriptor of the Secure EL1&0 translation regime, while in Armv8-R AArch64, it is MAIR_EL2.Attr[7:6] = 0b11. Therefore, FEAT_S2FWB architecture rules defined for the 0b110 encoding in Armv8-A must be applied to the 0b11 encoding in Armv8-R AArch64.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I_{RWXST} For more information, see Stage 2 memory type and Cacheability attributes when FEAT_S2FWB is enabled.

D6.6.5 Enabling and disabling the caching of memory accesses

I_{TLWNZ} The Armv8-R AArch64 architecture follows the same rule as the Armv8-A AArch64 architecture for enabling and disabling cache, and can force all memory locations with the Normal memory type to be treated as Non-cacheable regardless of their assigned Cacheability attribute using SCTLR_ELx.{I,C} and HCR_EL2.{ID,CD}.
For more information, see Cacheability attributes for Normal memory.

R_{HDGGS} For a PMSAv8-64 based address translation, Armv8-R AArch64 extends the functionality of SCTLR_ELx.{I,C} and HCR_EL2.{ID,CD} for accesses to Background region also.

D6.6.6 Enabling and disabling stages in translation regimes

R_{FQGZD} The EL1 MPU controls the stage 1 of the Secure EL1&0 translation regime.

R_{GGQSJ} The EL2 MPU controls the stage 2 of the Secure EL1&0 translation regime and the stage 1 of the Secure EL2 translation regime.

R_{ZNDLM} For the Secure EL1&0 translation regime:

- If SCTLR_EL1.{M, BR} is {0, 0}, then stage 1 translation is disabled.
- If HCR_EL2.VM is 0, then stage 2 translation is disabled.
- If HCR_EL2.VM is 1 and SCTLR_EL2.{M, BR} is {0, 0}, then the behavior is CONSTRAINED UNPREDICTABLE with the following permitted values:
  - The stage 2 memory attribute becomes UNKNOWN.
  - Raise stage 2 level 0 translation fault.

R_{RRRVB} For the Secure EL2 translation regime if SCTLR_EL2.{M, BR} is {0, 0}, then translation is disabled.

D6.7 MPU fault encodings

R_{VSGFD} PMSAv8-64 defines MPU faults that are consistent with the VMSAv8-64 fault definitions and reuses the ELR_ELx.{IFSC, DFSC} fault encodings.

R_{WKWLY} Each MPU raises faults on invalid memory accesses, including accesses to memory regions outside address ranges and the accesses without sufficient permissions. Table D6-17 describes the MPU fault encodings mapped from VMSAv8-64.

Table D6-17 PMSAv8-64 fault encodings

Memory faults	MPU fault encodings mapped from VMSAv8-64	Description
Alignment fault	Alignment fault	Unaligned memory access.
Translation fault	Translation fault, level 0	Invalid input address. There is no valid mapping or valid memory attributes for the input address.
Permission fault	Permission fault, level 0 (`0b001100`)	Insufficient access permissions.
Address size fault	Address size fault, level 0	Generated output address is out of range of the implemented physical address.
Access flag fault		Not applicable for PMSAv8-64.
TLB conflict abort		Not applicable for PMSAv8-64.
Synchronous abort (translation table walk)		Not applicable for PMSAv8-64.

For more information, see The AArch64 System Level Programmers' Model.

D6.8 PMSAv8-64 implications for caches

I_{KJCWD} Enabling, reconfiguring, or reprogramming any memory region can result in new and different memory attributes for a previously accessed or speculatively accessed address. In this case, the rules for mismatched memory attributes apply.

See Mismatched memory attributes for more information.

D6.8.1 Cache line length

R_{RLGGC} The PMSAv8-64 permits the definition of memory regions that might be smaller than a cache line in the implementation. Therefore, the following rules apply:

- If the MPU is configured so that multiple differing attributes apply to a single cache line, then for any access to that cache line, the rules for mismatched memory attributes apply.
- Marking any part of a cache line as Write-Back permits the entire line to be treated as Write-Back.

D6.9 Address tagging and pointer authentication support

R_{QSMRT} The Armv8-R AArch64 architecture supports Address tagging.

R_{YGVMZ} The Armv8-R AArch64 architecture supports FEAT_PAuth2 feature that is defined in the Armv8-A architecture with a modified definition of PAC field as described below:

- When Address tagging is used, the PAC field is Xn[54:bottom_PAC_bit].
- When Address tagging is not used, the PAC field is Xn[63:56, 54:bottom_PAC_bit].

R_{FJJMS} In PMSAv8-64, the bottom_PAC_bit is the maximum physical address size as indicated by ID_AA64MMFR0_EL1.PARange.

For more information, see:

- Pointer authentication.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D6.10 Security model

R_{JHBHB} The Armv8-R AArch64 architecture always executes code in Secure state with EL2 as the highest Exception level and:

- It is not possible to switch to Non-secure state.
- EL0, EL1, and EL2, all run in Secure state.

D6.10.1 Secure EL2

I_{DPDGZ} The Armv8-R AArch64 architecture adopts FEAT_SEL2 feature from Armv8.4-A architecture extension and introduces it as PMSAv8-64 based architecture feature.

I_{SBSHY} The protection region configuration registers for EL1 and EL2 MPUs, PRLAR_EL1 and PRLAR_EL2, are extended to include the NS bit that has the same behavior as NS bit in the translation table descriptor of VMSAv8-64.

R_{XNFXC} Security controls for translation table walks are not supported in PMSAv8-64.

R_{BJMVG} The NS bit in the PRLAR_EL1 and PRLAR_EL2 specifies whether the output address is in the Secure or Non-secure address space. Each protection region can be independently configured to the Secure or Non-secure address space.

R_{PTBZB} The configuration bits required to implement Secure and Non-secure states in VMSAv8-64 are mapped to PMSAv8-64 as described in Table D6-18.

Table D6-18 VMSAv8-64 and PMSAv8-64 security configuration

VMSAv8-64	PMSAv8-64
NS bit in translation table	PRLAR_EL1.NS/PRLAR_EL2.NS
NSTable bit in translation table	Not Applicable
VSTCR_EL2.SW	Not Applicable
VSTCR_EL2.SA	VSTCR_EL2.SA
VTCR_EL2.NSW	Not Applicable
VTCR_EL2.NSA	VTCR_EL2.NSA

For more information, see:

- Address translation.
- Translation table descriptor formats.
- Security state of translation table lookups.
- Translation process.

D6.10.1.1 Secure EL1&0 translation

R_{PDXNY} As the stage 2 of the Secure EL1&0 translation regime is controlled by the EL2 MPU and there is no page-based address translation or translation table walk, the following modifications are added to FEAT_SEL2:

- VTCR_EL2.NSW and VSTCR_EL2.SW control bits are RES0.
- VSTTBR_EL2 register is not present.
- Adds a secure check control, VSTCR_EL2.SC.

R_{ZXXGF} VSTCR_EL2.SA and VTCR_EL2.NSA controls are supported and have the same functionality as FEAT_SEL2 but are applied to PA in the Secure EL1&0 translation regime.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

R_{WXGLD} VSTCR_EL2.SC has no effect on the Secure EL2 translation regime. Table D6-19 describes the behavior of VSTCR_EL2.SC for the Secure EL1&0 translation regime.

Table D6-19 Secure check behavior in the Secure EL1&0 translation regime

VA	EL1 MPU NS attribute	IPA	EL2 MPU NS attribute	SC	PA
Secure	0	Secure	0	x	Secure
Secure	1	Non-secure	1	x	Non-secure
Secure	0	Secure	1	0	Non-secure
Secure	0	Secure	1	1	Fault
Secure	1	Non-secure	0	0	Non-secure
Secure	1	Non-secure	0	1	Fault

R_{TYJWG} EL1 and EL0 access is further subjected to VSTCR_EL2.SA and VTCR_EL2.NSA controls as defined by Armv8.4-A. Table D6-20 describes the behavior of VSTCR_EL2.SA and VTCR_EL2.NSA in the Secure EL1&0 translation regime.

Table D6-20 VSTCR_EL2.SA and VTCR_EL2.NSA behavior in the Secure EL1&0 translation regime

PA.NS	VSTCR_EL2.SA	VTCR_EL2.NSA	PA.NS (final)
0	0	x	0
0	1	Behaves as 1	1
1	0	0	0
1	0	1	1
1	1	x	1

R_{TBFFN} The Armv8-R AArch64 architecture follows the Armv8-A architecture rules on whether VSTCR_EL2.SA and VTCR_EL2.NSA controls should be applied.

- If HCR_EL2.VM=1 and SCTLR_EL2.M=1 or SCTLR_EL2.BR=1, then stage 2 Secure EL1&0 translation is enabled.
- If HCR_EL2.VM=0, then stage 2 Secure EL1&0 translation is disabled.

For more information, see The AArch64 System Level Programmers' Model.

D6.10.2 Secure EL2 translation

R_{JNLSG} The Armv8-R AArch64 architecture implements PMSAv8-64 at stage 1 of the Secure EL2 translation regime. Therefore, there is no translation table walk and address mapping.

R_{JPBSD} The NS bit in the EL2 MPU protection region register determines whether the output address must be looked for in either the Secure or Non-secure address space.

D6.11 Virtualization

R_{SYWRQ} Armv8-R AArch64 implements a permission-based containerization by introducing a stage 2 translation.

I_{XTHJL} The stage 2 translation uses an MPU controlled by a hypervisor running at EL2.

R_{PPJMB} The MPU does not perform address mapping and only checks permissions.

I_{NBZNG} Therefore, Armv8-R AArch64 relies on hypervisor configured permission attributes of the memory region to implement containerization.
For more information, see The AArch64 System Level Programmers' Model.

D6.11.1 Support for Guest operating systems

R_{LHPVJ} The hypervisor supports Guest operating systems using PMSAv8-64 on a per guest basis.

R_{CWHFT} Memory accesses by PMSAv8-64 guests are further validated by the EL2 MPU, controlled by the hypervisor.

R_{JNZKY} PMSAv8-64 guests have access to the EL1 MPU for isolating individual tasks.

I_{SZSQD} If multiple PMSAv8-64 guests are present, then these guests must be configured to use non-conflicting physical memory addresses. Virtualization is supported by the EL2 MPU at stage 2 of the Secure EL1&0 translation regime.

Chapter D7
The Generic Timer in AArch64 state

This chapter describes the implementation of the Arm Generic Timer. It includes an overview of the AArch64 System register interface to an Arm Generic Timer.

It contains the following sections:

- About the Generic Timer.
- The AArch64 view of the Generic Timer.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D7.1 About the Generic Timer

Figure D7-1 shows an example System on Chip that uses the Generic Timer as a system timer. In this figure:

- This manual defines the architecture of the individual PEs in the multiprocessor blocks.
- The *Arm Generic Interrupt Controller Architecture Specification* defines a possible architecture for the interrupt controllers.
- Generic Timer functionality is distributed across multiple components.

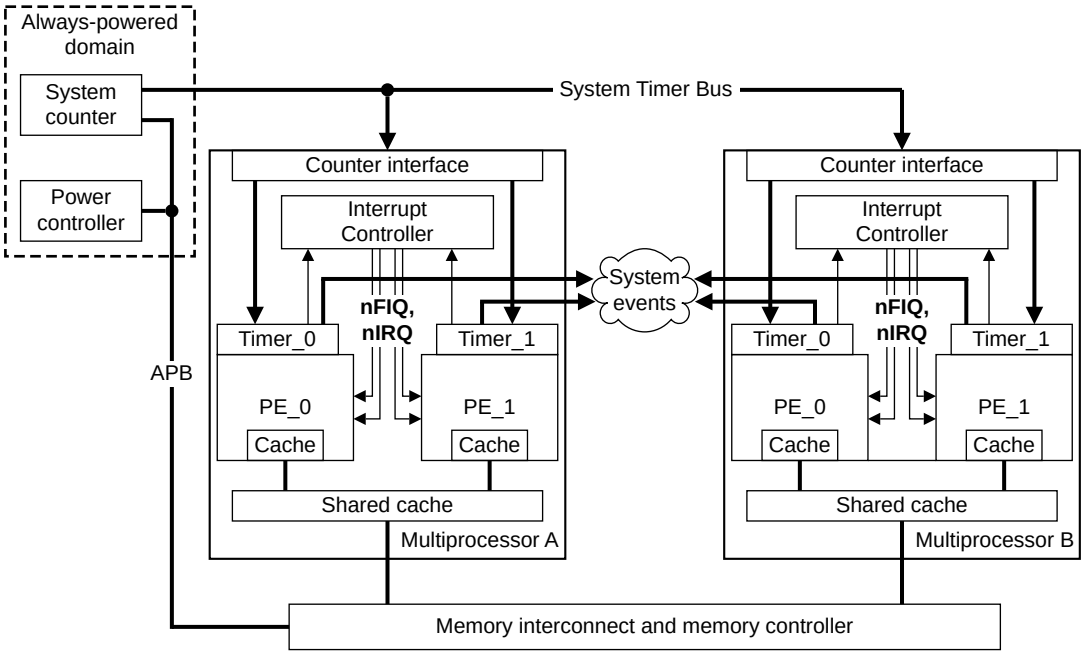

Figure D7-1 Generic Timer example

The Generic Timer:

- Provides a system counter that measures the passing of time in real-time.

  Note

  The Generic Timer can also provide other components at a system level, but Figure D7-1 does not show any such components.

- Supports *virtual counters* that measure the passing of virtual-time. That is, a virtual counter can measure the passing of time on a particular virtual machine.
- Can trigger events after a period of time has passed. The timers:
  - Can be used as count-up or as count-down timers.
  - Can operate in real-time or in virtual-time.

This chapter describes an instance of the Generic Timer component that Figure D7-1 shows as Timer_0 or Timer_1 within the Multiprocessor A or Multiprocessor B block.

A Generic Timer implementation must also include a memory-mapped system component. This component:

- Must provide the System counter shown in Figure D7-1.
- Optionally, can provide timer components for use at a system level.

System Level Implementation of the Generic Timer describes this memory-mapped component.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D7.1.1 The full set of Generic Timer components

Within a system that might include multiple PEs, a full set of Generic Timer components is as follows:

The system counter

This provides a uniform view of system time, see The system counter. Because this must be implemented at the system level, it is accessed through The system level memory-mapped implementation of the Generic Timer. However, during initialization, a status register in each implemented timer in the system must be programmed with the frequency of the system counter, so that software can read this frequency.

PE implementations of the Generic Timer

Each PE implementation of the Generic Timer provides the following components:

- A physical counter, which gives access to the count value of the system counter.
- A virtual counter, which gives access to virtual time. In AArch64 state, the CNTVOFF_EL2 register defines the offset between physical time, as defined by the value of the system counter, and virtual time.
- A number of timers. In an implementation where all Exception levels are implemented and can use AArch64 state, the timers that are accessible from AArch64 state are:
  - An EL1 physical timer.
  - A Secure EL2 physical timer.

The AArch64 view of the Generic Timer describes these components.

The system level memory-mapped implementation of the Generic Timer

The memory-mapped registers that control the components of the system level implementation of the Generic Timer are grouped into *frames*. The Generic Timer architecture defines the offset of each register within its frame, but the base address of each frame is IMPLEMENTATION DEFINED, and defined by the system.

Each system level component has one or two register frames. The possible system level components are:

The memory-mapped counter module, required

This module controls the system counter. It has two frames:

- A control frame, CNTControlBase.
- A status frame, CNTReadBase.

The memory-mapped timer control module, required

The system level implementation of the Generic Timer can provide up to eight timers, and the memory-mapped timer control module identifies:

- Which timers are implemented.
- The features of each implemented timer.

This module has a single frame, CNTCTLBase.

Memory-mapped timers, optional

An implemented memory-mapped timer:

- Must provide a privileged view of the timer, in the CNTBase*N* frame.
- Optionally. provides an unprivileged view of the timer in the CNTEL0Base*N* frame.

N is the timer number, and the corresponding frame number, in the range 0 - 7.

System Level Implementation of the Generic Timer describes these components.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D7.1.2 The system counter

The Generic Timer provides a system counter with the following specification:

Width

From Armv8.0 to Armv8.5 inclusive, at least 56 bits wide. The value returned by any 64-bit read of the counter is zero-extended to 64 bits.

Effective frequency

This indicates the amount of time each unit of the counter represents. For example:

- An effective frequency of 50MHz means each unit of the counter represents 20ns.
- An effective frequency of 1GHz means each unit of the counter represents 1ns.
- The effective frequency is indicated in the CNTFRQ_EL0 register.

From Armv8.0 to Armv8.5 inclusive, the effective frequency is a fixed value, typically in the range 1-50MHz.

Roll-over

Roll-over time of not less than 40 years.

Counter resolution

The counter resolution is a representation of how frequently the counter is updated.

For example, a counter might have an effective frequency of 1GHz, but the actual clock runs at 125MHz and therefore the counter resolution is 125Mhz.

The counter resolution might vary over time, to accommodate different operating modes of the system such as lower power modes. Such variation might be invisible to the programmer and be system specific, or might be controllable by the programmer through the frequency modes table.

Accuracy

Arm does not specify a required accuracy, but recommends that the counter does not gain or lose more than ten seconds in a 24-hour period.

Use of different counter resolutions must not affect the implemented accuracy.

Start-up

Starts operating from zero.

The system counter, once configured and running, must provide a uniform view of system time. More precisely, it must be impossible for the following sequence of events to show system time going backwards:

1. Device A reads the time from the system counter.
2. Device A communicates with another agent in the system, Device B.
3. After recognizing the communication from Device A, Device B reads the time from the system counter.

The system counter must be implemented in an always-on power domain.

To support lower-power operating modes in architectures from Armv8.0 to Armv8.5, the counter can operate with a lower counter resolution by incrementing by larger amounts at a lower actual clock frequency. For example, a system counter with an effective frequency of 10MHz might either increment:

- By 1 at 10MHz.
- By 500 at 20kHz, when the system lowers the actual clock frequency, to reduce power consumption.

In this case, the counter must support transitions between higher resolution operation and lower resolution operation, without any impact on the required accuracy of the counter.

The CNTFRQ_EL0 register is intended to hold a copy of the effective frequency to allow fast reference to this frequency by software running on the PE. For more information, see Initializing and reading the system effective frequency.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The mechanism by which the count from the system counter is distributed to system components is IMPLEMENTATION DEFINED, but each PE with a System register interface to the system counter must have a counter input that can capture each increment of the counter.

Note

So that the system counter can be clocked independently from the PE hardware, the count value might be distributed using a Gray code sequence. Gray count scheme for timer distribution scheme gives more information about this possibility.

D7.1.2.1 Initializing and reading the system effective frequency

The CNTFRQ_EL0 register must be programmed to the effective frequency of the system counter. Typically, this is done only during the system boot process, by using the System register interface to write the effective frequency to the CNTFRQ_EL0 register. Only software executing at the highest implemented Exception level can write to CNTFRQ_EL0.

Note

The CNTFRQ_EL0 register is UNKNOWN at reset, and therefore the effective frequency must be set as part of the system boot process.

Software can read the CNTFRQ_EL0 register, to determine the effective frequency, from EL2.

D7.1.2.2 Memory-mapped controls of the system counter

Some system counter controls are accessible only through the memory-mapped interface to the system counter. These controls are:

- Enabling and disabling the counter.
- Setting the counter value.
- Changing the operating mode, to change the counter resolution.
- Enabling Halt-on-debug, which a debugger can then use to suspend counting.

For descriptions of these controls, see System Level Implementation of the Generic Timer.

Non-Confidential

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D7.2 The AArch64 view of the Generic Timer

The following sections describe the components and features of a PE implementation of the Generic Timer, as seen from AArch64 state:

- The physical counter.
- The virtual counter.
- Event streams.
- Timers.

D7.2.1 The physical counter

The PE includes a physical counter that contains the count value of the system counter. The CNTPCT_EL0 register holds the current physical counter value. This is defined as the pseudocode function `PhysicalCountInt`().Reads of CNTPCT_EL0 register at EL2 return the current value of `PhysicalCountInt`().

For more information, see The physical offset register.

Reads of CNTPCT_EL0 can occur speculatively and out of order relative to other instructions executed on the same PE.

D7.2.2 The virtual counter

An implementation of the Generic Timer always includes a virtual counter, which indicates virtual time.

The virtual counter contains the value of the physical counter minus a 64-bit virtual offset. When executing at EL1 or EL0, the virtual offset value relates to the current virtual machine.

The CNTVOFF_EL2 register contains the virtual offset, see The virtual offset register.

The CNTVCT_EL0 register holds the current virtual counter value.

Reads of CNTVCT_EL0 can occur speculatively and out of order relative to other instructions executed on the same PE.

D7.2.2.1 The virtual offset register

The virtual counter is a counter that has a *virtual offset* relative to the physical counter as viewed from EL2. This virtual offset is held in the register CNTVOFF_EL2. The virtual counter value is the count compared by the EL1 virtual timer.

If EL2 is not implemented, then the virtual counter uses a fixed offset of zero.

D7.2.3 Event streams

An implementation that includes the Generic Timer can use the system counter to generate one or more *event streams*, to generate periodic wakeup events as part of the mechanism described in Wait for Event.

Note

An event stream might be used:

- To impose a time-out on a Wait For Event polling loop.
- To safeguard against any programming error that means an expected event is not generated.

The CNTKCTL_EL1.{EVNTEN, EVNTDIR, EVNTI} fields define an event stream that is generated from the virtual counter.

In all implementations, the CNTHCTL_EL2.{EVNTEN, EVNTDIR, EVNTI} fields define an event stream that is generated from the physical counter.

The event stream is configured as follows:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- EVNTI selects the counter bit that triggers the event.
- EVNTI selects between bits[0:15].
- EVNTDIR selects whether the event is generated on each 0 to 1 transition, or each 1 to 0 transition, of the selected counter bit.

Note

If the event stream is configured to produce events from the low order bits of the counter when the effective frequency is very high (for example 1GHz), then the practical update rate of the counter might mean that the event stream is not generated as the low order bit might not change. Software can rely on an event stream rate of at least 1MHz in normal operation.

The pseudocode descriptions of the operation of an event stream are `SetEventRegister`, `TestEventCNTV`, and `TestEventCNTP`.

D7.2.4 Timers

In an implementation of the Generic Timer the following timers are implemented:

- An EL1 physical timer, which can be accessed from EL1.
  When this timer can be accessed from EL1, an EL1 control determines whether it can be accessed from EL0.
- As FEAT_SEL2 is always implemented, a Secure EL2 physical timer.

The output of each implemented timer:

- Provides an output signal to the system.
- If the PE interfaces to a *Generic Interrupt Controller* (GIC), signals a *Private Peripheral Interrupt* (PPI) to that GIC. In a multiprocessor implementation, each PE must use the same interrupt number for each timer.

Each timer:

- Is based around a 64-bit CompareValue that provides a 64-bit unsigned upcounter.
- Provides an alternative view of the CompareValue, called the TimerValue, that appears to operate as a 32-bit downcounter.
- Has, in addition, a 32-bit Control register.

Table D7-1 Physical timer registers summary for the Generic Timer

Timer[a] register	EL1 physical timer	Secure EL2 physical timer
CV	CNTP_CVAL_EL0	CNTHPS_CVAL_EL2
TV	CNTP_TVAL_EL0	CNTHPS_TVAL_EL2
Control	CNTP_CTL_EL0	CNTHPS_CTL_EL2

a. In this column, CV indicates the CompareValue register, and TV indicates the TimerValue register.

Table D7-2 Virtual timer register summary for the Generic Timer

Timer[a] register	EL1 virtual timer
CV	CNTV_CVAL_EL0
TV	CNTV_TVAL_EL0
Control	CNTV_CTL_EL0

a. In this column, CV indicates the CompareValue register, and TV indicates the TimerValue register.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D7.2.4.1 Operation of the CompareValue views of the timers

The CompareValue view of a timer operates as a 64-bit upcounter. The timer condition is met when the appropriate counter reaches the value programmed into its CompareValue register.

When the timer condition is met, an interrupt is generated if the interrupt is not masked in the corresponding timer control register, CNTP_CTL_EL0, or CNTV_CTL_EL0.

The operation of this view of a timer is:

```
TimerConditionMet = (((PhysicalCountInt() - Offset)[63:0] - CompareValue[63:0]) >= 0)
```

Where:

`TimerConditionMet` Is TRUE if the timer condition for this counter is met, and FALSE otherwise.

`PhysicalCountInt()` The physical counter value, which can be read from the CNTPCT_EL0 register when read from EL2.

`Offset` For the EL1 and EL2 physical timer, offset value of the EL1 physical timer is zero.

`CompareValue` The value of the appropriate CompareValue register, CNTP_CVAL_EL0, CNTHPS_CVAL_EL2 or CNTV_CVAL_EL0.

In this view of a timer, `PhysicalCountInt`(), `Offset`, and `CompareValue` are all 64-bit unsigned values.

Note

This means that a timer with a `CompareValue` of, or close to, `0xFFFF_FFFF_FFFF_FFFF` might never meet its timer condition. However, there is no practical requirement to use values close to the counter wrap value.
Software can observe the counter value by the offset in some situations by reading CNTVCT_EL0.

D7.2.4.2 Operation of the TimerValue views of the timers

The TimerValue view of a timer appears to operate as a signed 32-bit downcounter. A TimerValue register is programmed with a count value. This value decrements on each increment of the appropriate counter, and the timer condition is met when the value reaches zero. When the timer condition is met, an interrupt is generated if the interrupt is not masked in the corresponding timer control register, CNTP_CTL_EL0, CNTHP_CTL_EL2, CNTHPS_CTL_EL2, CNTPS_CTL_EL1, or CNTV_CTL_EL0.

This view of a timer depends on the following behavior of accesses to TimerValue registers:

Reads

```
TimerValue = (CompareValue[63:0] - (PhysicalCountInt()[63:0] - Offset[63:0]))[31:0]
```

Writes

```
CompareValue = ((PhysicalCountInt()[63:0] - Offset[63:0])[63:0] +
    ↪SignExtend(TimerValue[31:0]))[63:0]
```

Where the arguments other than `TimerValue` have the definitions used in Operation of the CompareValue views of the timers, and in addition:

`TimerValue` The value of a TimerValue register, CNTP_TVAL_EL0, CNTHP_TVAL_EL2, CNTHPS_TVAL_EL2, CNTPS_TVAL_EL1, or CNTV_TVAL_EL0.

In this view of a timer, values are signed in standard two's complement form.

A read of a TimerValue register after the timer condition has been met indicates the time since the timer condition was met.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

- Operation of the CompareValue views of the timers gives a strict definition of `TimerConditionMet`. However, provided that the TimerValue is not expected to wrap as a 32-bit signed value when decremented from `0x8000_0000`, the TimerValue view can be used as giving an effect equivalent to:

  `TimerConditionMet = (TimerValue ≤ 0)`

- Programming TimerValue to a negative number with magnitude greater than (Counter - Offset) can lead to an arithmetic overflow that causes the CompareValue to be a large positive value. This potentially delays meeting the timer condition for a long period of time.

Chapter D8
The Performance Monitors Extension

This chapter describes the implementation of the Arm Performance Monitors, which are an optional non-invasive debug component. It describes version 3 of the *Performance Monitor Unit* (PMU) architecture, FEAT_PMUv3. It contains the following sections:

- About the Performance Monitors.
- Accuracy of the Performance Monitors.
- Behavior on overflow.
- Attributability.
- Controlling the PMU counters.
- Multithreaded implementations.
- Event filtering.
- Performance Monitors and Debug state.
- Counter access.
- Performance Monitors Extension registers.

Non-Confidential

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D8.1 About the Performance Monitors

The Performance Monitors Extension is an OPTIONAL feature of an implementation, but Arm strongly recommends that implementations include version 3 of the Performance Monitors Extension, FEAT_PMUv3.

Note

No previous versions of the Performance Monitors Extension can be implemented in architectures from Armv8.0.

The Performance Monitors Extension provides:

- The 64-bit cycle counter, PMCCNTR_EL0. The cycle counter is always implemented.
- The 64-bit instruction counter, PMICNTR_EL0. The instruction counter is an optional feature, FEAT_PMUv3_ICNTR.
- The event counters, PMEVCNTR<n>_EL0. Between 0 and 31 event counters are implemented.
  The event counters are either 64 or 32 bit counters:
  - If FEAT_PMUv3p5 is implemented and the highest Exception level is using AArch64, then the event counters are 64 bit.
  - If FEAT_PMUv3p5 is not implemented, the event counters are 32 bit.
- EL2 has controls to partition the implemented event counters into the following ranges:
  - A first range which is available for use by the guest operating system accessible at all Exception levels.
  - A second range which is available for use by the hypervisor accessible EL2.

  For more information see Interaction with EL2.
- Controls for:
  - Enabling counters. See Enabling PMU counters.
  - Resetting counters. Resetting counters.
  - Flagging overflows. See Behavior on overflow.
  - Enabling interrupts on overflow. See Generating overflow interrupt requests.
  - Freezing counters. See Freezing PMU counters.
  - Prohibiting counting. See Prohibiting counting.

The PMU architecture uses event numbers to identify an event. It:

- Defines event numbers for common events, for use across many architectures and microarchitectures. See Common event numbers.

  Note

  Implementations that include FEAT_PMUv3 must, as a minimum requirement, implement a subset of the common events. See Common event numbers.
- Reserves a large event number space for IMPLEMENTATION DEFINED events. See IMPLEMENTATION DEFINED event numbers.

The full set of events for an implementation is IMPLEMENTATION DEFINED. Arm recommends that implementations include all of the events that are appropriate to the architecture profile and microarchitecture of the implementation. For more information, see PMU Event Descriptions.

When an implementation includes the Performance Monitors Extension, the architecture defines the following possible interfaces to the Performance Monitors Extension registers:

- A System register interface. This interface is mandatory.
- An external debug interface which optionally supports memory-mapped accesses. Implementation of this interface is OPTIONAL. See Recommended External Interface to the Performance Monitors.

An operating system can use the System registers to access the counters.

Also, if required, the operating system can enable application software to access the counters. This enables an application to monitor its own performance with fine-grain control without requiring operating system support. For example, an application might implement per-function performance monitoring.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

To enable interaction with external monitoring, an implementation might consider additional enhancements, such as providing:

- A set of events, from which a selection can be exported onto a bus for use as external events.
- The ability to count external events. This enhancement requires the implementation to include a set of external event input signals.

The Performance Monitors Cycle Count Register is accessible as PMCCNTR_EL0.

D8.1.1 Interaction with EL2

Software executing at or EL2 can program MDCR_EL2, Monitor Debug Configuration Register (EL2).HPMN to partition the event counters into two ranges:

- If MDCR_EL2, Monitor Debug Configuration Register (EL2).HPMN is not 0 and is less-than PMCR_EL0, Performance Monitors Control Register.N, MDCR_EL2, Monitor Debug Configuration Register (EL2).HPMN divides the event counters into a first range [0..(MDCR_EL2, Monitor Debug Configuration Register (EL2).HPMN-1)], and a second range [MDCR_EL2, Monitor Debug Configuration Register (EL2).HPMN..(PMCR_EL0, Performance Monitors Control Register.N-1)].
- If FEAT_HPMN0 is implemented and MDCR_EL2, Monitor Debug Configuration Register (EL2).HPMN is 0, all event counters are in the second range and none are in the first range.
- If MDCR_EL2, Monitor Debug Configuration Register (EL2).HPMN is equal to PMCR_EL0, Performance Monitors Control Register.N, all event counters are in the first range and none are in the second range.

Each range of event counters has its own global controls.

Counters in the second range are also described as *reserved by EL2*.

Software executing at EL2 can:

- Trap an access at EL0 or EL1 to the PMU. This means the hypervisor can identify which Guest OSs are using the PMU and intelligently employ switching of the PMU state. There is a separate trap for the PMCR_EL0, Performance Monitors Control Register register.
- If FEAT_PMUv3p1 is implemented, prohibit counting of events Attributable to EL2 by the event counters in the first range.

When EL2 is implemented and enabled in the current Security state, software executing at EL1 and, if enabled by PMUSERENR_EL0, Performance Monitors User Enable Register, EL0:

- Will read the value of MDCR_EL2, Monitor Debug Configuration Register (EL2).HPMN for PMCR_EL0, Performance Monitors Control Register.N.
- Cannot access the event counters in the second range, or the controls associated with them.

For more information, see:

- Enabling PMU counters.
- Counter access.
- Controlling the PMU counters.
- Multithreaded implementations.

D8.1.2 Interaction with trace

When FEAT_ETE is implemented, the trace unit uses the PMU events as External Inputs. See External inputs.

When FEAT_ETMv4 is implemented, it is IMPLEMENTATION DEFINED whether the implementation exports PMU events to the ETM trace unit, and the form of any exporting is also IMPLEMENTATION DEFINED. If implemented, this exporting is controlled by PMCR.X.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

For more information about when the trace unit is permitted to observe PMU events, see Controls to prohibit trace at Exception levels and External inputs.

When FEAT_ETE is implemented, the PMU implements a set of events for importing external events from the trace unit and the cross-trigger interface. See Required events. Arm recommends similar functionality is implemented when FEAT_ETMv4 is implemented, and further recommends reusing the events defined for FEAT_ETE. When implemented, this functionality enables the trace unit to pass in events to be counted.

D8.2 Accuracy of the Performance Monitors

The Performance Monitors:

- Are a non-invasive debug component. See Non-invasive behavior.
- Must provide broadly accurate and statistically useful count information.

However, the Performance Monitors allow for:

- A reasonable degree of inaccuracy in the counts to keep the implementation and validation cost low. See A reasonable degree of inaccuracy.
- IMPLEMENTATION DEFINED controls, such as those in ACTLR registers, that software must configure before using certain PMU events. For example, to configure how the PE generates PMU events for components such as external caches and external memory.
- Other IMPLEMENTATION DEFINED controls, such as those in ACTLR registers, to optionally put the PE in an operating state that might do one or both of the following:
  - Change the level of non-invasiveness of the Performance Monitors so that enabling an event counter can impact the performance or behavior of the PE.
  - Allow inaccurate counts. This includes, but is not limited to, cycle counts.

D8.2.1 Non-invasive behavior

The Performance Monitors are a non-invasive debug feature. A non-invasive debug feature permits the observation of data and program flow. Performance Monitors, PC Sample-based Profiling and Trace are non-invasive debug features.

Non-invasive debug components do not guarantee that they do not make any changes to the behavior or performance of the processor. Any changes that do occur must not be severe however, as this will reduce the usefulness of event counters for performance measurement and profiling. This does not include any change to program behavior that results from the same program being instrumented to use the Performance Monitors, or from some other performance monitoring process being run concurrently with the process being profiled in a multitasking operating system. As such, a reasonable variation in performance is permissible.

Note

Power consumption is one measure of performance. Therefore, a reasonable variation in power consumption is permissible.

Arm does not define a *reasonable variation in performance*, but recommends that such a variation is kept within 5% of normal operating performance, when averaged across a suite of code that is representative of the application workload.

For some common architectural events, this requirement to be non-invasive can conflict with the requirement to present an accurate value of the count under normal operating conditions. Should an implementation require more performance-invasive techniques to accurately count an event, there are the following options:

- If the event is optional, define an alternative IMPLEMENTATION DEFINED event that accurately counts the event and document the impact on performance of enabling the event.
- Provide an IMPLEMENTATION DEFINED control that disables accurate counting of the event to restore broadly accurate performance, and document the impact on performance of accurate counting.

Note

The IMPLEMENTATION DEFINED invasiveness might include the PE disabling one or more performance optimizations such as multi-issue, out-of-order execution, and pipelining.
A software implication is that the performance invasiveness is proportional to the sampling interval. This can disproportionately affect profiling of rare events, because the population is smaller and therefore the interval will tend to be smaller.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D8.2.2 A reasonable degree of inaccuracy

The Performance Monitors provide broadly accurate and statistically useful count information. To keep the implementation, validation, and performance overhead costs low, a reasonable degree of inaccuracy in the counts and the detection of overflow is acceptable. Arm does not define a *reasonable degree of inaccuracy* but recommends the following guidelines:

- Under normal operating conditions the counters must present an accurate value of the count.
- In exceptional circumstances, such as enabling or disabling the counter, a change in Security state, or other boundary condition, it is acceptable for the count to be inaccurate.
- In exceptional microarchitectural circumstances, including when the event occurs rapidly in close succession, the overflow of a counter in synchronous mode might only be observed by a later instruction that also generates the event.

  This means that there might be temporal inaccuracy in the generation of the PMU exception. This is also known as the shadow effect.
- Under very unusual, non-repeating pathological cases, the counts can be inaccurate. These cases are likely to occur as a result of asynchronous exceptions, such as interrupts, where the chance of a systematic error in the count is very unlikely.

Note

An implementation must not introduce inaccuracies that can be triggered systematically by the execution of normal pieces of software. For example, it is not reasonable for the count of branch behavior to be inaccurate when caused by a systematic error generated by the loop structure producing a dropping in branch count.
However, dropping a single branch count as the result of a rare interaction with an interrupt is acceptable.

The architecture does not permit these behaviors for events that specifically count architectural exceptional circumstances, such as a change in Exception level, for example, EXC_TAKEN.

The permitted inaccuracy limits the possible uses of the Performance Monitors. In particular, the architecture does not define the point in a pipeline where the event counter is incremented, relative to the point where a read of the event counters is made. This means that pipelining effects can cause some imprecision, and can affect which events are counted.

This applies to both architectural and microarchitectural events, and can apply differently to different events. Arm recommends that is applied consistently between counters. For example, any boundary condition effects that apply to an event counter counting the CPU_CYCLES event should apply in the same way to the cycle counter PMCCNTR_EL0. However, this is not required.

Inaccuracies around exceptional events, such as enabling or disabling the counter, should be such that the inaccuracy is reduced by lengthening the sampling period.

Where a direct write to a Performance Monitors control register disables a counter, and is followed by a Context Synchronization event, any subsequent indirect read of the control register by the Performance Monitors to determine whether the counter is enabled will return the updated value. Any subsequent direct read of the counter or counter overflow status flags will return the value at the point the counter was disabled.

Note

The imprecision means that the counter might have counted an event around the time the counter was disabled, but does not allow the event to be observed as counted after the counter was disabled.

In addition to this, entry to and exit from Debug state can disturb the normal running of the PE, causing further inaccuracy in the Performance Monitors. Disabling the counters while in Debug state limits the extent of this inaccuracy. An implementation can employ methods to limit this inaccuracy, for example by promptly disabling the counters during the Debug state entry sequence.

An implementation must document any particular scenarios where significant inaccuracies are expected.

D8.3 Behavior on overflow

The event counters, PMEVCNTR<n>_EL0, Performance Monitors Event Count Registers, n = 0 - 30 are 32-bit unsigned counters that overflow if incrementing PMEVCNTR<n>_EL0, Performance Monitors Event Count Registers, n = 0 - 30 causes an unsigned overflow of an event counter, the PE sets PMOVSCLR_EL0, Performance Monitors Overflow Flag Status Clear Register[*n*] to 1.

The cycle counter, PMCCNTR_EL0, Performance Monitors Cycle Count Register, is a 64-bit unsigned counter, f incrementing PMCCNTR_EL0, Performance Monitors Cycle Count Register causes an unsigned overflow of bits [31:0] of the cycle counter, the PE sets PMOVSCLR_EL0, Performance Monitors Overflow Flag Status Clear Register[31] to 1.

When any overflow occurs, an interrupt request is generated if the PE is configured to generate counter overflow interrupts. For more information, see Generating overflow interrupt requests.

The update of PMOVSCLR_EL0, Performance Monitors Overflow Flag Status Clear Register occurs synchronously with the update of the counter.

A PMU overflow can be used as an input trigger event to the *Cross Trigger Interface* (CTI) for the PE. For more information, see Performance Monitors overflow trigger event.

D8.3.1 Generating overflow interrupt requests

Software can program the Performance Monitors so that an overflow interrupt request is generated when a counter overflows. See PMINTENSET_EL1, Performance Monitors Interrupt Enable Set Register and PMINTENCLR_EL1, Performance Monitors Interrupt Enable Clear Register.

A PMU interrupt request is always taken asynchronously.

Note

- The mechanism by which an interrupt request from the Performance Monitors generates an FIQ or IRQ exception is IMPLEMENTATION DEFINED.
- Arm recommends that the overflow interrupt requests:
  - Translate into a **PMUIRQ** signal, so that they are observable to external devices.
  - Connect to inputs on an IMPLEMENTATION DEFINED Generic Interrupt Controller as a *Private Peripheral Interrupt* (PPI) for the originating processor. See the *ARM Generic Interrupt Controller Architecture Specification* for information about PPIs.
  - Connect to a CTI, see The Embedded Cross-Trigger Interface.
- Arm strongly discourages implementations from connecting overflow interrupt requests from multiple PEs to the same *System Peripheral Interrupt* (SPI) identifier.
- From GICv3, the *ARM® Generic Interrupt Controller Architecture Specification* recommends that the *Private Peripheral Interrupt* (PPI) with ID 23 is used for overflow interrupt requests.

Software can write to the counters to control the frequency at which interrupt requests occur. For example, software might set a 32-bit counter to `0xFFFF_0000`, to generate another counter overflow after 65 536 increments, and reset it to this value every time an overflow interrupt occurs.

Note

If an event can occur multiple times in a single clock cycle, then counter overflow can occur without the counter registering a value of zero.

The overflow interrupt request is a level-sensitive request. The PE signals a request for:

- Any implemented PMEVCNTR<n>_EL0, Performance Monitors Event Count Registers, n = 0 - 30 counter, when the global enable control for the event counter is 1, the value of PMOVSSET_EL0, Performance Monitors Overflow Flag Status Set Register[*n*] is 1, and the value of PMINTENSET_EL1, Performance Monitors Interrupt Enable Set Register[*n*] is 1.
- The cycle counter, when the values of PMCR_EL0.E, PMOVSSET_EL0, Performance Monitors Overflow Flag

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Status Set Register[31] and PMINTENSET_EL1, Performance Monitors Interrupt Enable Set Register[31] are all 1.

- The instruction counter, when the values of PMCR_EL0.E, PMOVSSET_EL0.F0, and PMINTENSET_EL1.F0, are all 1.

The overflow interrupt request is active in all Security states.

The interrupt handler for the counter overflow request must cancel the interrupt request, by writing 1 to PMOVSCLR_EL0, Performance Monitors Overflow Flag Status Clear Register[*n*] to clear the overflow bit to 0.

D8.3.1.1 Pseudocode description of overflow interrupt requests

See R-profile Architecture Pseudocode for a pseudocode description of overflow interrupt requests. The `CheckForPMUOverflow()` pseudocode function signal PMU overflow interrupt requests to an interrupt controller and PMU overflow trigger events to the cross-trigger interface.

Non-Confidential

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D8.4 Attributability

An event caused by the PE counting the event is *Attributable*. If an agent other than the PE that is counting the events causes an event, these events are Unattributable.

An event is defined as being either Attributable or Unattributable. If the event is Attributable, it is further defined whether it is Attributable to:

- The current Security state of the PE.
- The current Exception level of the PE.
- When the PE is in Debug state, operations issued to the PE by the debugger through the external debug interface.

In a multithreaded implementation, an event might be generated by another PE with the same values for affinity level 1 and higher. This event is further defined as Attributable to:

- The current Security state of that PE.
- The current Exception level of that PE.
- When that PE is in Debug state, operations issued to that PE by the debugger through the external debug interface.

See Multithreaded implementations for information about enabling and restricting counting events in a multithreaded implementation.

Note

An implementation is described as multithreaded when the lowest level of affinity, as reported by MPIDR_EL1{Aff3, Aff2, Aff1, Aff0}, consists of logical PEs that are implemented using a multithreading type approach. In this section, when referring to a multithreaded implementation, *thread* is used to mean processing elements with:

- MPIDR_EL1.MT set to 1,
- Different values for affinity level 0.
- The same values for affinity level 1 and higher.

An event can be defined as the combination of multiple subevents, which can be either Attributable or Unattributable.

All architecturally defined events are Attributable, unless otherwise stated.

Unattributable events might be counted when Attributable events are not counted. See:

- Event filtering.
- Performance Monitors and Debug state.
- Counting events from shared components.

These sections are summarized by Table D8-1 for events Attributable to the processor, and Unattributable events. Table D8-1 entries apply when the counter and PMU are enabled and not frozen. Otherwise, events are not counted.

Table D8-1 Counting events

State	Allowed or prohibited	Filtered	Event type		
			If Attributable to:	Then	Else
Non- debug	Allowed	Not filtered	X	Count	Count
		Filtered	Current Exception level	Do not count	IMPLEMENTATION DEFINED
	Prohibited	X	Current Security state	Do not count	IMPLEMENTATION DEFINED
Debug	X	X	Debugger operations or raw cycles	Do not count	IMPLEMENTATION DEFINED

D8.5 Controlling the PMU counters

This section describes the mechanisms available for controlling the PMU event and cycle counters. The following sections describe those mechanisms:

- Enabling PMU counters.
- Freezing PMU counters.
- Prohibiting counting.

D8.5.1 Enabling PMU counters

Counters are enabled by a combination of the *global enable control* for the counter and a counter enable control, PMCNTENSET_EL0, Performance Monitors Count Enable Set Register, as described in the following sections.

D8.5.1.1 Enabling the event counters

PMCNTENSET_EL0, Performance Monitors Count Enable Set Register.P<n> is the counter enable control for event counter *n*.

The counters are controlled by the following:

- For an event counter *n* reserved by EL2, the global enable control is MDCR_EL2, Monitor Debug Configuration Register (EL2).HPME.
- For all other event counters, the global enable control is PMCR_EL0, Performance Monitors Control Register.E.

For more information, see Interaction with EL2.

Table D8-2 shows the combined effect of all the counter enable controls.

Table D8-2 Event counter enables when an implementation includes EL2

MDCR_EL2.HPME	PMCR_EL0.E	PMCNTENSET_EL0.P[*n*] == 0	PMCNTENSET_EL0.P[*n*] == 1	
			n < MDCR_EL2.HPMN	*n* ≥ MDCR_EL2.HPMN
0	0	PMEVCNTR<n>_EL0 disabled	PMEVCNTR<n>_EL0 disabled	PMEVCNTR<n>_EL0 disabled
0	1	PMEVCNTR<n>_EL0 disabled	PMEVCNTR<n>_EL0 enabled	PMEVCNTR<n>_EL0 disabled
1	0	PMEVCNTR<n>_EL0 disabled	PMEVCNTR<n>_EL0 disabled	PMEVCNTR<n>_EL0 enabled
1	1	PMEVCNTR<n>_EL0 disabled	PMEVCNTR<n>_EL0 enabled	PMEVCNTR<n>_EL0 enabled

D8.5.1.2 Enabling the cycle counter

For the cycle counter, PMCCNTR_EL0, Performance Monitors Cycle Count Register, the global enable control is PMCR_EL0, Performance Monitors Control Register.E.

For the cycle counter, the counter enable control is PMCNTENSET_EL0, Performance Monitors Count Enable Set Register.C.

PMCR_EL0, Performance Monitors Control Register.DP controls whether the cycle counter is disabled when event counting is prohibited, as described in Prohibiting counting.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D8.5.1.3 Enabling the instruction counter

When FEAT_PMUv3_ICNTR is implemented, for the instruction counter, PMICNTR_EL0, the global enable control is PMCR_EL0, Performance Monitors Control Register.E and the counter enable control is PMCNTENSET_EL0.F0.

D8.5.2 Freezing PMU counters

The cycle counter, PMCCNTR_EL0, is disabled when an unsigned overflow occurs, PMCR_EL0.FZO is 1, and PMCR_EL0.DP is 1.

Note

The architecture does not define when PMU events are counted relative to the instructions that caused the event. Events caused by an instruction might be counted before or after the instruction becomes architecturally executed, and events might be counted for operations that are not architecturally executed. Events can be counted speculatively, out-of-order, or both with respect to the simple sequential execution of the program. Events might also be counted simultaneously by other event counters when the overflow occurs, including events from different instructions. Multiple instances of an event might occur simultaneously, thus an event counter unsigned overflow can yield a nonzero value in the event counter. Arm recommends that such counting anomalies are minimized when software uses the freeze on overflow feature. When the freeze on overflow feature is being used, software cannot assume that the event counter stops counting at zero when an overflow occurs.

To freeze the PMU counter values on taking a synchronous PMU exception, software should configure the relevant PMU counters to not count at the Exception level where the PMU exception is taken to and higher Exception levels. This has the effect of stopping counting when the PMU exception is taken.

Note

This mechanism can only be used when profiling software that only executes at lower Exception levels.

If an event counter *n* overflows, where *n* is even and event counter *n*+1 is configured to count the CHAIN event, it is CONSTRAINED UNPREDICTABLE whether the CHAIN event observes the overflow event when the applicable PMCR_EL0.FZO or MDCR_EL2.HPMFZO bit is 1 and the corresponding PMCR_EL0.LP or MDCR_EL2.HLP bit is 0.

If a direct read of PMOVSCLR_EL0 returns a nonzero value for a subset of the overflow flags, which means an event counter *n* should not count, then a sequence of direct reads of PMEVCNTR<n>_EL0 ordered after the read of PMOVSCLR_EL0 and before the PMOVSCLR_EL0 flags are cleared to zero, will return the same value for each read, because the event counter has stopped counting.

Note

Direct reads of System registers require explicit synchronization for following direct reads of other System registers to be ordered after the first direct read.

D8.5.3 Resetting counters

Software can reset all the event counters and/or the cycle counter in a single operation by writing 1 to PMCR_EL0, Performance Monitors Control Register.C and/or PMCR_EL0, Performance Monitors Control Register.P.

If FEAT_PMUv3p9 is implemented, then counters can be individually reset together in a single operation using PMZR_EL0.

D8.5.4 Prohibiting counting

Counting Attributable events is prohibited at EL2 unless any of the following is true:

- FEAT_PMUv3p1 is not implemented.
- MDCR_EL2, Monitor Debug Configuration Register (EL2).HPMD is 0.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- MDCR_EL2.HPMN is less than PMCR_EL0.N, the event is being counted by event counter *n*, and *n* is in the range [MDCR_EL2.HPMN .. (PMCR_EL0.N-1)].

If FEAT_SEL2 is implemented, counting Attributable events at Secure EL2 is allowed if and only if counting events is allowed in Secure state, and counting events is allowed at EL2.

For each Unattributable event, it is IMPLEMENTATION DEFINED whether it is counted when counting Attributable events is prohibited.

The accessibility of Performance Monitors registers is unaffected by whether event counting is enabled or prohibited.

All of the following apply to the instruction counter, PMICNTR_EL0:

- Counting is prohibited at EL2 unless MDCR_EL2.HPMD is 0.

The cycle counter, PMCCNTR_EL0, Performance Monitors Cycle Count Register, counts unless any of the following is true:

- The cycle counter is disabled by PMCR_EL0.E or PMCNTENSET_EL0.C.
- PMCR_EL0, Performance Monitors Control Register.DP is 1 and one of the following is true:
  - Event counting by event counters in the range [0 .. (MDCR_EL2, Monitor Debug Configuration Register (EL2).HPMN-1)] is prohibited.
  - Event counting by event counters in the range [0 .. (MDCR_EL2, Monitor Debug Configuration Register (EL2).HPMN-1)] is frozen by PMCR_EL0, Performance Monitors Control Register.FZO.
- The PE is in Debug state.

See `CountPMUEvents()` in R-profile Architecture Pseudocode for more information. The `CountPMUEvents(n)` function returns TRUE if PMEVCNTR<n>_EL0, Performance Monitors Event Count Registers, n = 0 - 30 is enabled and allowed to count events at the current Exception level or state, and FALSE otherwise. The function `CountPMUEvents(31)` returns TRUE if the cycle counter is enabled and allowed to count cycles at the current Exception level and state, and FALSE otherwise. The function `CountPMUEvents(32)` returns TRUE if the instruction counter is enabled and allowed to count instructions at the current Exception level and state, and FALSE otherwise. However, these functions do not completely describe the behavior for Unattributable events.

The Performance Monitors are intended to be broadly accurate and statistically useful, see Accuracy of the Performance Monitors. Some inaccuracy is permitted at the point of changing between a state where counting is prohibited and a state where counting is allowed, however. To avoid the leaking of information, the permitted inaccuracy is that transactions that are not prohibited can be uncounted. Where possible, prohibited transactions must not be counted, but if they are counted, then that counting must not degrade security.

D8.6 Multithreaded implementations

If an implementation is multithreaded and the Effective value of PMEVTYPER<n>.MT is 1, then, unless otherwise stated, the counter counts the sum of all events across all PEs with the same level 1 Affinity. A pair of PEs have the same level 1 Affinity if they have the same values for all fields in MPIDR_EL1or MPIDR except the Aff0 field.

See also Cycle event counting in multithreaded implementations for additional requirements for events that count cycles.

Events on other PEs are not counted when the Effective value of PMEVTYPER<n>_EL0, Performance Monitors Event Type Registers, n = 0 - 30.MT is 0.

If the CPU implements multithreading, it is IMPLEMENTATION DEFINED whether PMEVTYPER<n>_EL0, Performance Monitors Event Type Registers, n = 0 - 30.MT is implemented as RW or RES0.

When the current configuration is not multithreaded, and PEA prohibits counting of events Attributable to Secure state when PEA is in Secure state, it is IMPLEMENTATION DEFINED whether:

- Counting events Attributable to Secure state when PEA is in Non-secure state is permitted.
- Counting Unattributable events related to other Secure operations in the system when PEA is in Non-secure state is permitted.

Otherwise, counting events in Non-secure state is permitted.

When the current configuration is not multithreaded, and PEA prohibits counting of events Attributable to EL2 when PEA is at EL2, it is IMPLEMENTATION DEFINED whether:

- Counting events Attributable to EL2 when PEA is using another Exception level is permitted.
- Counting Unattributable events related to EL2 when PEA is using another Exception level is permitted.

Otherwise, counting events at another Exception level is permitted.

When the current configuration is not multithreaded, and PEA prohibits counting of events Attributable to a Security state and an Exception level when FEAT_PMUv3p7 is implemented, it is IMPLEMENTATION DEFINED whether:

- Counting events Attributable to EL2 when PEA is using another Exception level is permitted.
- Counting Unattributable events related to EL2 when PEA is using another Exception level is permitted.

See Time as measured by the Performance Monitors cycle counter.

D8.7 Event filtering

The PMU can filter events by various combinations of Exception level and Security state. This gives software the flexibility to count events across multiple processes.

D8.7.1 Filtering by Exception level and Security state

In AArch64 state:

- For each event counter, PMEVTYPER<n>_EL0 specifies the Exception levels in which the counter counts events Attributable to Exception levels.
- PMCCFILTR_EL0 specifies the Exception levels in which the cycle counter counts.

For an event that is Attributable to an Exception level, in a multithreaded implementation:

- When the Effective value of PMEVTYPER<n>_EL0.MT is 1, the specified filtering is evaluated using the current Exception level and Security state of the thread to which the event is Attributable. See Example D8-1.
- When the Effective value of PMEVTYPER<n>_EL0.MT is 0, the event is only counted if it is Attributable to the counting thread, and the filtering is evaluated using the Exception level and Security state of the counting thread.

Example D8-1 Example of the effect of the PMEVTYPER<*n*>_EL0.MT control

In a multithreaded implementation, if the Effective value of PMEVTYPER<n>_EL0.MT is 1 and the value of PMEVTYPER<n>_EL0.U is 1 on the counting thread, then event counter *n* does not count events Attributable to EL0 on another thread, even if the counting thread is not executing at EL0.

For each Unattributable event, it is IMPLEMENTATION DEFINED whether the filtering applies. In a multithreaded implementation, if the filtering applies to an Unattributable event, then the filtering is evaluated using the Exception level and Security state of the counting thread.

For more information, see the individual register descriptions and Multithreaded implementations.

D8.7.2 Accuracy of event filtering

For most events, it is acceptable that, during a transition between states, events generated by instructions executed in one state are counted in the other state. The following sections describe the cases where event counts must not be counted in the wrong state:

- Exception-related events.
- Software increment events.

D8.7.2.1 Exception-related events

The PMU must filter events related to exceptions and exception handling according to the Exception level in which the event occurred. These events are:

- EXC_TAKEN, Exception taken.
- EXC_RETURN, Instruction architecturally executed, Condition code check pass, exception return.
- CID_WRITE_RETIRED, Instruction architecturally executed, Condition code check pass, write to CONTEXTIDR_EL1, Context ID Register (EL1).
- TTBR_WRITE_RETIRED, Instruction architecturally executed, Condition code check pass, write to translation table base.
- EXC_UNDEF, Exception taken, other synchronous.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- EXC_SVC, Exception taken, Supervisor Call.
- EXC_PABORT, Exception taken, Instruction Abort.
- EXC_DABORT, Exception taken, Data Abort or SError.
- EXC_IRQ, Exception taken, IRQ.
- EXC_FIQ, Exception taken, FIQ.
- EXC_SMC, Exception taken, Secure Monitor Call.
- EXC_HVC, Exception taken, Hypervisor Call.
- EXC_TRAP_PABORT, Exception taken, Instruction Abort not Taken locally.
- EXC_TRAP_DABORT, Exception taken, Data Abort or SError not Taken locally.
- EXC_TRAP_OTHER, Exception taken, other traps not Taken locally.
- EXC_TRAP_IRQ, Exception taken, IRQ not Taken locally.
- BRB_FILTRATE, Branch record captured.

The PMU must not count an exception after it has been taken because this could systematically report a result of zero exceptions at EL0. Similarly, it is not acceptable for the PMU to count exception returns or writes to CONTEXTIDR_EL1, Context ID Register (EL1) after the return from the exception.

If FEAT_SEBEP is implemented, then when any precise exception is taken, including PMU exceptions, the value of all event counters counting at-retirement events and the instruction counter are precise. See R_{TNVSL} in Definition of a precise exception and imprecise exception.

D8.7.2.2 Software increment events

The PMU must filter software increment events according to the Exception level in which the software increment occurred. Software increment counting must also be precise, meaning the PMU must count every architecturally executed software increment event, and must not count any Speculatively executed software increment.

If the PE performs two architecturally executed writes to the PMSWINC_EL0 register without an intervening Context Synchronization event, then the counter is incremented twice.

For more information, see SW_INCR.

D8.7.3 Pseudocode description of event filtering

See `CountPMUEvents()` in R-profile Architecture Pseudocode for a pseudocode description of event filtering. However, this function does not completely describe the behavior for Unattributable events.

Non-Confidential

D8.8 Performance Monitors and Debug state

Events that count cycles are not counted in Debug state.

Events Attributable to the operations issued by the debugger through the external debug interface are not counted in Debug state.

In an implementation that supports multithreading, when the Effective value of PMEVTYPER<n>_EL0.MT is 1, if an event is Attributable to an operation issued by the debugger through the external debug interface to another thread that is in Debug state, then the event is not counted, and it is IMPLEMENTATION DEFINED whether the event is counted when the counting thread is in Debug state.

For each Unattributable event, it is IMPLEMENTATION DEFINED whether it is counted when the counting PE is in Debug state. If the event might be counted, then the rules in Filtering by Exception level and Security state apply for the current Security state in Debug state.

Non-Confidential

D8.9 Counter access

All implemented event counters are accessible in EL2. If EL2 is implemented the hypervisor uses MDCR_EL2, Monitor Debug Configuration Register (EL2).HPMN to reserve an event counter, with the effect that if EL2 is enabled in the current Security state, software cannot access that counter and its associated state from EL0 or EL1.

Note

Whether software can access an event counter at an Exception level does not affect whether the counter counts events at that Exception level. For more information, see Controlling the PMU counters and Enabling PMU counters.

D8.9.1 PMEVCNTR<*n*> event counters

Table D8-3 shows how the number of implemented event counters, PMCR_EL0, Performance Monitors Control Register.N, and if EL2 is implemented, the value of the MDCR_EL2, Monitor Debug Configuration Register (EL2).HPMN field affects the behavior of permitted accesses to the PMEVCNTR<n>_EL0, Performance Monitors Event Count Registers, n = 0 - 30 event counter registers for values of *n* from 0 to 30.

Table D8-3 Result of PMEVCNTR<n> event counter accesses

Condition	Access at Exception level		
	EL2	EL1	EL0
n < HDCR.HPMN and EL2 is implemented and enabled in the current Security state	Succeeds	Succeeds	Succeeds
n ≥ MDCR_EL2, Monitor Debug Configuration Register (EL2).HPMN and *n* < PMCR_EL0, Performance Monitors Control Register.N and EL2 is implemented and enabled in the current Security state	Succeeds	No access	No access
n ≥ PMCR_EL0, Performance Monitors Control Register.N	No access	No access	No access

Where Table D8-3 shows access succeeds for an event counter *n*, the access might be UNDEFINED or generate a trap exception. See the descriptions of PMEVCNTR<n>_EL0, Performance Monitors Event Count Registers, n = 0 - 30 and PMXEVCNTR_EL0, Performance Monitors Selected Event Count Register for details.

Where Table D8-3 shows no access for an event counter *n*:

- When PMSELR_EL0, Performance Monitors Event Counter Selection Register.SEL is *n*, the PE prevents direct reads and direct writes of PMXEVTYPER_EL0, Performance Monitors Selected Event Type Register or PMXEVCNTR_EL0, Performance Monitors Selected Event Count Register. See the register descriptions for more information.
- The PE prevents direct reads and direct writes of PMEVTYPER<n>_EL0, Performance Monitors Event Type Registers, n = 0 - 30 or PMEVCNTR<n>_EL0, Performance Monitors Event Count Registers, n = 0 - 30. See the register descriptions for more information.
- If FEAT_PMUv3_SS is implemented, the PE prevents direct reads and direct writes of PMEVCNTSVR<n>_EL1. See the register descriptions for more information.
- Direct reads and direct writes of the following register fields are RAZ/WI: PMOVSCLR_EL0, Performance Monitors Overflow Flag Status Clear Register[*n*], PMOVSSET_EL0, Performance Monitors Overflow Flag Status Set Register[*n*], PMCNTENSET_EL0, Performance Monitors Count Enable Set Register[*n*], PMCNTENCLR_EL0, Performance Monitors Count Enable Clear Register[*n*], PMINTENSET_EL1, Performance Monitors Interrupt Enable Set Register[*n*], PMINTENCLR_EL1, Performance Monitors Interrupt Enable Clear Register[*n*], and, when FEAT_PMUv3p9 is implemented, PMUACR_EL1[n].
- Direct writes to PMSWINC_EL0, Performance Monitors Software Increment Register[*n*] are ignored, and, when FEAT_PMUv3p9 is implemented, direct writes to PMZR_EL0[n] are ignored.
- A direct write of 1 to PMCR_EL0, Performance Monitors Control Register.P does not reset PMEVCNTR<n>_EL0, Performance Monitors Event Count Registers, n = 0 - 30.

D8.9.2 Cycle and instruction counters

The PMU does not provide any control that a hypervisor can use to reserve the cycle counter for its own use. However, access to the PMU registers are subject to the access permissions described in Configurable instruction controls.

Chapter D9
PMU Event Descriptions

This chapter describes the PMU events that can be counted, their associated event numbers, and the mnemonics for the events. It contains the following sections:

- Definitions.
- The PMU event number space and common events.
- Common event numbers.
- Cycle event counting.
- Meaningful combinations of common events.
- Required events.
- Synchronous events.
- IMPLEMENTATION DEFINED event numbers.

D9.1 Definitions

The following subsections give more information about terms used in the event definitions:

- Definition of terms.
- Levels of caches and TLBs.
- Counting events from shared components.
- Counting exceptions taken locally or not taken locally.

D9.1.1 Definition of terms

This section describes terms used by PMU events as they relate to the implementation of the PMU. For more definitions, see Glossary.

Architectural event

An architectural event is an event which gives the same result for the same program on any implementation of the Arm architecture, subject to the program having the same inputs, including asynchronous events triggered by the system, any IMPLEMENTATION DEFINED or UNPREDICTABLE variation permitted by the event definition, and the reasonable degree of inaccuracy described in A reasonable degree of inaccuracy. INST_RETIRED is an example of an architectural event.

An architectural event should not be confused with an event defined by the architecture, which is referred to as a Common event.

Note: Do not confuse Architectural events and Common events. An Architectural event can be either Common or IMPLEMENTATION DEFINED. See also Common event and IMPLEMENTATION DEFINED event.

At-retirement event

An at-retirement event is generated by an Architecturally executed instruction that does not generate an exception, unless specified otherwise. This includes SVC, HVC, and SMC exceptions.

For cache and TLB events:

- The event counts each architecturally-executed instruction that generates the event.
- The event is only counted once, by the first instruction that causes it. This might not be the first instruction in program order.

  Note

  Consider two loads that execute out of order that access the same cache line granule which is not in the cache. The second instruction in program order causes the miss, and the first instruction fetches data from the same cache miss result. Only the second instruction counts the cache miss event. Also, the second instruction might be speculative and the first instruction retired, meaning the cache miss is not counted at all.

- The population counts for the events are the architecturally-executed instruction counts.

Common event

An event that is defined by the Performance Monitors Extension. For more information, see Common event numbers.

Note: Do not confuse Common events and Architectural events. A Common event can be either Architectural or Microarchitectural. See also Architectural event and Microarchitectural event.

CSIZE

Container size, in bits, that corresponds to the largest non-overlapping Advanced SIMD vector element size or scalar register size that is encoded in the instruction opcode.

Event in progress

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Some events count when another event or condition is *in progress*. This might mean that the event counts the occupancy of a queue or other microarchitectural structure tracking the event. It is usually IMPLEMENTATION DEFINED when an event is in progress.

For example, the MEM_ACCESS_RD_PERCYC event counts when the MEM_ACCESS_RD event is in progress, meaning on each Processor cycle, the counter increments by the number of Memory-read operations that are in progress.

These events can be used to calculate the average number of events in progress. In the case of the MEM_ACCESS_RD_PERCYC event, this is also the average read latency. However, the definition of *in progress* might not include all parts of the operation.

Example D9-1 Stages of an operation not included in the definition of event in progress

In an example implementation, a Memory-read operation generated by a load instruction occupies three pipeline stages in the PE before generating a MEM_ACCESS_RD event when the PE starts to access memory. The event is then considered to be *in progress* until the data is returned to the PE. In the case of a Normal Cacheable access, the PE first looks in the Level 1 data cache, and if the address is cached, returns data in two cycles. Once the data is returned, it is another cycle before the result can be forwarded to any other instruction.
In this example, if all loads hit in the Level 1 cache, the average read latency calculated using the MEM_ACCESS_RD_PERCYC and MEM_ACCESS_RD events might be two cycles. Although this value is correct for the IMPLEMENTATION SPECIFIC definition of this event, it has to be adjusted by a constant four additional cycles to match the more commonly understood definition of Level 1 cache access latency, which for this example would be quoted as six cycles.

Instruction architecturally executed

An instruction that is part of the Execution stream. See also Architecturally executed.

A reasonable degree of inaccuracy allows for counts to be inaccurate in exceptional circumstances. For an event that counts instructions architecturally executed, this allows an implementation to count instructions that do not form part of the Execution stream because of an exceptional event, such as if the instruction generates a synchronous exception or entry to Debug state.

Instructions that have no visible effect on the architectural state of the PE are architecturally executed and counted even if they form part of the Execution stream.

Examples of instructions that have no visible effect are:

- A `NOP`.
- A conditional instruction that fails its Condition code check.
- A Compare and Branch on Zero, `CBZ`, instruction that does not branch.
- A Compare and Branch on Nonzero, `CBNZ`, instruction that does not branch.

However, for events that count only the execution of instructions that update System registers, such as CID_WRITE_RETIRED, if such an instruction is executed twice without an intervening Context Synchronization event, it is constrained unpredictable whether the first instruction is counted.

Instruction architecturally executed, Condition code check pass

Instruction architecturally executed, Condition code check pass is a class of events that explicitly do not occur for:

- A conditional instruction that fails its Condition code check.
- A Compare and Branch on Zero, `CBZ`, instruction that does not branch.
- A Compare and Branch on Nonzero, `CBNZ`, instruction that does not branch.
- A Test and Branch on Zero, `TBZ`, instruction that does not branch.
- A Test and Branch on Nonzero, `TBNZ`, instruction that does not branch.
- A Store-Exclusive instruction that does not write to memory.

Otherwise, the definition of architecturally executed is the same as for Instruction architecturally executed.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

A branch that is architecturally executed, with condition code check pass is also described as a branch taken.

Instruction memory access

A PE acquires instructions for execution through instruction fetches. Instruction fetches might be due to:

- Fetching instructions that are architecturally executed.
- The result of the execution of an instruction prefetch instruction, `PLI`.
- Speculation that a particular instruction might be executed in the future.

The relationship between the fetch of an individual instruction and an instruction memory access is IMPLEMENTATION DEFINED. For example, an implementation might fetch many instructions including a non-integer number of instructions in a single instruction memory access.

IMPLEMENTATION DEFINED event

An event that is defined by the implementation. For more information, see IMPLEMENTATION DEFINED event numbers.

Note: Do not confuse IMPLEMENTATION DEFINED events and Microarchitectural events. An IMPLEMENTATION DEFINED event can be either Architectural or Microarchitectural. See also Architectural event and Microarchitectural event.

Memory-read operations

A PE accesses memory through memory-read operations and Memory-write operations. A memory-read operation might be due to:

- The result of an architecturally executed Memory-reading instructions.
- The result of a Speculatively executed memory-reading instructions.
- A translation table walk.

For levels of cache hierarchy beyond the Level 1 caches, memory-read operations also include accesses made as part of a refill of another cache closer to the PE. Such refills might be due to:

- Memory-read operations or Memory-write operations that miss in the cache
- The execution of a data prefetch instruction.
- The execution of a cache maintenance instruction.

  Note

  A prefetch instruction or cache maintenance instruction is not, in itself, an access to that cache. However, it might generate cache refills which are then treated as memory-read operations beyond that cache.

- Speculation that a future instruction might access the memory location.
- Instruction memory accesses to a unified cache, when the cache does not implement the L<n>I_CACHE event.

This list is not exhaustive.

The relationship between memory-read instructions and memory-read operations is IMPLEMENTATION DEFINED. For example, for some implementations an `LDP` instruction that reads two 64-bit registers might generate one memory-read operation if the address is quadword-aligned, but for other addresses it generates two or more memory-read operations.

Memory-reading instructions

An instruction with explicit Memory read effects. Loads and atomic instructions that return a value to the PE are counted as Memory-reading instructions.

Unless otherwise specified, this includes instructions that can have a Memory read effect, even if the instruction does not actually read from memory for some other reason. For example, a load that generates an MMU fault.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

It is IMPLEMENTATION DEFINED whether the prefetch instructions PRFM, PLD, PLDW, and PLI count as integer data-processing instructions or Memory-reading instructions. Arm recommends that if the instruction is not implemented as a NOP then it is counted as a Memory-reading instruction.

Memory-writing instructions, other than atomics, that return a result in a PE register other than data from the location being accessed are not counted as Memory-reading instructions. This includes Store-exclusive instructions.

Atomic instructions that do not return a value to the PE are not counted as Memory-reading instructions.

Memory-write operations

Memory-write operations might be due to:

- The result of an architecturally executed Memory-writing instructions.
- The result of a Speculatively executed Memory-writing instructions.
- A hardware update of a translation table entry.

Note

Speculatively executed Memory-writing instructions that do not become architecturally executed must not alter the architecturally defined view of memory. They can, however, generate a Memory-write operation that is later undone in some IMPLEMENTATION SPECIFIC way.

For levels of cache hierarchy beyond the Level 1 caches, Memory-write operations also include accesses made as part of a write-back from another cache closer to the PE. Such write-backs might be due to:

- Evicting a dirty line from the cache, to allocate a cache line for a cache refill, see Memory-read operations.
- The execution of a cache maintenance instruction.

  Note

  A cache maintenance instruction is not in itself an access to that cache. However, it might generate write-backs which are then treated as Memory-write operations beyond that cache.

- The result of a coherency request from another PE.

This list is not exhaustive.

DC ZVA is counted as a Memory-write operation.

The relationship between Memory-writing instructions and Memory-write operations is IMPLEMENTATION DEFINED. For example, for some implementations an STP instruction that writes two 64-bit registers might generate one Memory-write operation if the address is quadword-aligned, but for other addresses it generates two or more Memory-write operations. In some implementations, the result of two STR instructions that write to adjacent memory might be merged into a single Memory-write operation.

Note

The data written back from a cache that is shared with other PEs might not be data that was written by the PE that performs the operation that leads to the write-back. Nevertheless, the event is counted as a write-back event for that PE.

Memory-writing instructions

Are instructions with explicit Memory write effects, including Tag-write effects. Stores and atomic instructions are counted as Memory-writing instructions.

Unless otherwise specified, this includes instructions that can have a Memory write effect, even if the instruction does not actually write to memory for some other reason. For example, a CAS or Store-exclusive that does not update memory, or a store that generates an MMU fault.

DC ZVA is counted as Memory-writing instructions.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Microarchitectural event

A microarchitectural event is any event which is not architectural. That is, it will give different results for the same program on two different implementations of the Arm architecture, due to microarchitectural differences in the implementations. L1D_CACHE_REFILL is an example of a microarchitectural event.

A microarchitectural event should not be confused with an event defined by the implementation, which is referred to as an IMPLEMENTATION DEFINED event.

Note: Do not confuse Microarchitectural events and IMPLEMENTAION DEFINED events. A Microarchitectural event can be either Common or IMPLEMENTATION DEFINED. See also Common event and IMPLEMENTATION DEFINED event.

MSIZE

Memory element access size, in bits, that corresponds to a load or store instruction mnemonic suffix, where B=8, H=16, W=32 and D=64. When an instruction mnemonic does not end with B, H, W or D, the memory access size is implied by the scalar transfer register size or SIMD transfer register element size.

Operation

An instruction might create one or more microarchitectural operations (µ-ops) at any point in the execution pipeline. Depending on the event definition, the µ-ops might be counted instead of instructions. The definition of a µ-op is IMPLEMENTATION SPECIFIC. An architecture instruction might create more than one µ-op for each instruction. µ-ops might also be removed or merged in the execution stream, so an architecture instruction might create no µ-ops for an instruction. Any arbitrary translation of instructions to an equivalent sequence of µ-ops is permitted.

This means the relationship between a µ-op and an architecturally executed instruction is IMPLEMENTATION DEFINED.

Note

The architecture does not require that an implementation that generates µ-ops must count µ-ops for operations. An implementation can choose to interpret operation as instruction.

The counting of operations can indicate the workload on the PE. However, there is no requirement for operations to represent similar amounts of work, and direct comparisons between different microarchitectures are not meaningful.

Operations might be defined with reference to a particular instruction or type of instruction. In the case of operations this means operations with semantics that map to that type of instruction.

Operation speculatively executed

An Operation that is Speculatively executed.

There is no architecturally guaranteed relationship between a Speculatively executed micro-op and an architecturally executed instruction.

The results of such an operation can also be discarded, if it transpires that the operation was not required, such as following a mispredicted branch. Therefore, the architecture defines these events as *operations speculatively executed*, where appropriate.

Many PMU events count operations that are speculatively executed. This means that the PMU can observe and record the behavior of operations executed under the effects of speculation. However, the PMU must not count an event that might be used to infer values that cannot be accessed or used by the operation, as defined by Restrictions on the effects of speculation.

For example:

- An address that is not permitted to be used by the operation might be inferred by whether it is present in a cache or TLB.
- A condition code that is not permitted to be used by the operation can be inferred by whether a branch was taken or not taken.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- A predicate value that is not permitted to be used by the operation can be inferred by whether a predicate value is empty or not.

Note

In some events, operation has a more specific meaning described in the event.

Processor cycle

For a non-multithreaded implementation, this means a cycle of the processor. For a multithreaded implementation, processor cycle means each cycle of the multithreaded processor, not just those cycles for which the PE counting the event is active.

Slot

An implementation of a PE might be able to execute multiple micro-ops in a single processor cycle. The maximum number of micro-ops that can be executed might vary at different points in the execution pipeline.

To allow profiling of the utilization of the resource of the PE, an IMPLEMENTATION SPECIFIC point in the execution pipeline is chosen where the maximum number of micro-ops that can be executed is an IMPLEMENTATION DEFINED fixed value.

Each possible micro-op that can be executed at that point in a cycle is called a Slot. The maximum number of micro-ops that can be executed is defined by PMMIR.SLOTS.

Software change of the PC

All of the following are treated as a software change of the PC:

- Branch instructions.
- Memory-reading instructions that explicitly write to the PC.
- Data-processing instructions that explicitly write to the PC.
- Exception return instructions.

It is IMPLEMENTATION DEFINED whether any or all of the following are treated as software changes of the PC:

- `BRK` instructions.
- An exception generated because an instruction is UNDEFINED.
- The exception-generating instructions, `SVC` and `HVC`.
- Context synchronization barrier `ISB` instructions.

Speculatively executed

An instruction or operation that is counted by an event when it might be Speculative.

The architecture does not define the point in a pipeline where an event is counted. For some events, this means the operation or instruction is counted when the operation or instruction is Speculative. The results of such an operation or instruction might later be discarded, if it transpires that the operation was not required, such as following a mispredicted branch, or might be later resolved to be Architecturally executed.

Different groups of events might be counted at different points in the pipeline and so can have different IMPLEMENTATION DEFINED definitions of speculatively executed. Such groups share a common base type, which the event name denotes. Each of the events in the previous example is of the base type, operation speculatively executed.

For groups of events with a common base type, speculatively executed operations are all counted on the same basis, which normally means at the same point in the pipeline. It is possible to compare the counts and make meaningful observations about the program being profiled.

Taken locally

Taken locally is a qualifier that determines which instances of an exception are counted by particular PMU events. See Counting exceptions taken locally or not taken locally.

In this context, an exception that is *Taken locally* means an exception that is one of:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- Taken to the current Exception level.

  Note

  This is not possible when the current Exception level is EL0.

- Taken from EL0 to EL1.
- Taken from EL0 to EL2 because the Effective value of HCR_EL2.{E2H, TGE} is {1, 1}.

  Note

  An exception taken from EL0 to EL2 is not *Taken locally*.

D9.1.2 Levels of caches and TLBs

The mapping of levels of cache and TLB to the PMU events is IMPLEMENTATION DEFINED. Although CLIDR_EL1 and CLIDR define the implemented levels of cache, these are not required to correspond with the levels of cache defined for PMU events. The architecture does not provide any way of determining implemented levels of TLB. Also, many implementations include structures that provide some caching at a higher level than the level 1 caches or TLBs. Typically, these structures, that might be called Level 0 caches, or mini caches, or microcaches, are invisible to software. The IMPLEMENTATION SPECIFIC nature of cache and TLB implementations mean that, in general, PMU event counts cannot be used reliably to make direct comparisons between different implementations, and Arm recommends the following implementation guidelines:

- If L3D_CACHE events are implemented, then L2D_CACHE and if applicable L2I_CACHE events should be implemented.
- If L2D_CACHE events are implemented, then L1D_CACHE and if applicable L1I_CACHE events should be implemented.
- If L2I_CACHE events are implemented, then L1I_CACHE events should be implemented.
- Where the Last Level of cache is also the Level 3 or Level 2 unified cache, the LL_CACHE events should be implemented in preference to the L3D_CACHE or L2D_CACHE events as applicable.
- For the Level <n> cache, where <n> = 1 or <n> = 2:
  - If the Level <n> cache is unified, but the cache can disambiguate between Data and Instruction accesses to the cache, then both the L<n>D_CACHE and L<n>I_CACHE events should be implemented.
  - If the cache is unified and the cache cannot disambiguate between Data and Instruction accesses, then only the L<n>D_CACHE should be implemented, counting all accesses.

This final property is IMPLEMENTATION DEFINED.

N1_*, N2_*, N3_*, and N4_* events are defined for identifying the *non-uniform memory access* (NUMA) distance for data returned directly from caches and memory, with support for:

- Up to four NUMA distance levels.
- Up to three cache types at each level.
- Up to three memory types at each level.
- Cache snoop responses at each level.

The NUMA distance indicates the relative distance that the return data has traveled. The NUMA distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have different levels of hierarchy. The interpretation of NUMA distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system.

The mapping of NUMA distance values to LOCAL and REMOTE events is IMPLEMENTATION DEFINED.

The definition of memory types in the system is IMPLEMENTATION DEFINED, but must be broadly similar for all devices in the system.

D9.1.3 Counting events from shared components

There is no architectural concept of a *shared* component. However, when a cache, a bus, or any other system component that might generate countable events is implemented, and:

- The extent of the first-order effects due to an event from that component are only applicable to a single PE, then the event is not shared.
- Otherwise, the event is shared.

Second-order effects are not considered when determining if an event is shared.

If the cache is shared and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is `0b0`, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the cache is shared by PEs other than the PEs in the multithreaded processor and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is `0b1`, the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted and might depend on the Effective value of PMEVTYPER<n>_EL0.MT.

Example D9-2 First and second order effects of a cache miss in a multiple-PE implementation

In an implementation that consists of two PEs, each with its own L1 cache, a cache miss by one of the PEs is a first-order effect of an access to its cache. Any snoop that is performed on the L1 cache of the other PE in the implementation as a result of that cache miss is a second order effect.

Note

Shared events are inherently linked to microarchitectures and so the implementer must make an informed decision about how such events are implemented.

D9.1.4 Counting exceptions taken locally or not taken locally

Table D9-1 shows the events for exceptions taken to an Exception level using AArch64.

Table D9-1 Events for exceptions taken to an Exception level using AArch64

ESR.EC	Description	Event number and classification for exceptions	
		Taken locally	Not Taken locally
`0x00`	Unknown or uncategorized	`0x0081`, EXC_UNDEF	`0x008D`, EXC_TRAP_OTHER
`0x01`	`WF*` traps	`0x0081`, EXC_UNDEF	`0x008D`, EXC_TRAP_OTHER
`0x07`	Advanced SIMD or FP traps	`0x0081`, EXC_UNDEF	`0x008D`, EXC_TRAP_OTHER
`0x15`	AArch64 `SVC`	`0x0082`, EXC_SVC	`0x008D`, EXC_TRAP_OTHER
`0x16`	AArch64 `HVC` that is not disabled	`0x008A`, EXC_HVC	`0x008A`, EXC_HVC
`0x17`	-	-	-
`0x18`	AArch64 `MSR`, `MRS` and System instruction traps	`0x0081`, EXC_UNDEF	`0x008D`, EXC_TRAP_OTHER
`0x19`	-	-	-
`0x1E`	-	-	-
`0x1F`	-	-	-
`0x20`	Instruction Abort from below	`0x0083`, EXC_PABORT	`0x008B`, EXC_TRAP_PABORT

D9.2 The PMU event number space and common events

In Armv8.0, the event number space is 10 bits. Armv8.1 extends the event number space, and therefore the PMEVTYPER<n>_EL0.evtCount field, to 16 bits, and is allocated as Table D9-2 shows. For more information about the entries in the Allocation column see the text that follows this table:

Table D9-2 Allocation of the PMU event number space

Event numbers	Allocation
In all versions from Armv8.0	
0x0000 - 0x003F	Common architectural and microarchitectural events.
0x0040 - 0x00BF	When FEAT_PMUv3p8 is implemented, common architectural and microarchitectural events. Previously Arm-recommended common architectural and microarchitectural events.
0x00C0 - 0x03FF	IMPLEMENTATION DEFINED events.
From Armv8.1	
0x0400 - 0x3FFF	IMPLEMENTATION DEFINED events.
0x4000 - 0x403F	Common architectural and microarchitectural events.
0x4040 - 0x40BF	When FEAT_PMUv3p8 is implemented, common architectural and microarchitectural events. Previously Arm-recommended common architectural and microarchitectural events.
0x40C0 - 0x7FFF	IMPLEMENTATION DEFINED events.
0x8000 -0x80FF	Common architectural and microarchitectural events.
0x8100 - 0xC0BF	Reserved.
0xC0C0 - 0xFFFF	IMPLEMENTATION DEFINED events.

See PMEVTYPER<n>.evtCount for details of the PE behavior when an event number for a reserved or unimplemented PMU event is written to evtCount.

Table D9-3 lists the number, mnemonic, and description of PMU events.

Table D9-3 Event index

Number	Mnemonic	Description
0x0000	SW_INCR	Instruction architecturally executed, Condition code check pass, software increment.
0x0001	L1I_CACHE_REFILL	Level 1 instruction cache refill.
0x0002	L1I_TLB_REFILL	Level 1 instruction TLB refill.
0x0003	L1D_CACHE_REFILL	Level 1 data cache refill.
0x0004	L1D_CACHE	Level 1 data cache access.
0x0005	L1D_TLB_REFILL	Level 1 data TLB refill.
0x0006	LD_RETIRED	Instruction architecturally executed, Condition code check pass, load.
0x0007	ST_RETIRED	Instruction architecturally executed, Condition code check pass, store.
0x0008	INST_RETIRED	Instruction architecturally executed.
0x0009	EXC_TAKEN	Exception taken.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Number	Mnemonic	Description
0x000A	EXC_RETURN	Instruction architecturally executed, Condition code check pass, exception return.
0x000B	CID_WRITE_RETIRED	Instruction architecturally executed, Condition code check pass, write to CONTEXTIDR.
0x000C	PC_WRITE_RETIRED	Instruction architecturally executed, Condition code check pass, Software change of the PC.
0x000D	BR_IMMED_RETIRED	Branch instruction architecturally executed, immediate.
0x000E	BR_RETURN_RETIRED	Branch instruction architecturally executed, procedure return, taken.
0x000F	UNALIGNED_LDST_RETIRED	Instruction architecturally executed, Condition code check pass, unaligned load or store.
0x0010	BR_MIS_PRED	Branch instruction speculatively executed, mispredicted or not predicted.
0x0011	CPU_CYCLES	Cycle.
0x0012	BR_PRED	Predictable branch instruction speculatively executed.
0x0013	MEM_ACCESS	Data memory access.
0x0014	L1I_CACHE	Level 1 instruction cache access.
0x0015	L1D_CACHE_WB	Level 1 data cache write-back.
0x0016	L2D_CACHE	Level 2 data cache access.
0x0017	L2D_CACHE_REFILL	Level 2 data cache refill.
0x0018	L2D_CACHE_WB	Level 2 data cache write-back.
0x0019	BUS_ACCESS	Bus access.
0x001A	MEMORY_ERROR	Local memory error.
0x001B	INST_SPEC	Operation speculatively executed.
0x001C	TTBR_WRITE_RETIRED	Instruction architecturally executed, Condition code check pass, write to TTBR.
0x001D	BUS_CYCLES	Bus cycle.
0x001E	CHAIN	Chain a pair of event counters.
0x001F	L1D_CACHE_ALLOCATE	Level 1 data cache allocation without refill.
0x0020	L2D_CACHE_ALLOCATE	Level 2 data cache allocation without refill.
0x0021	BR_RETIRED	Instruction architecturally executed, branch.
0x0022	BR_MIS_PRED_RETIRED	Branch instruction architecturally executed, mispredicted.
0x0023	STALL_FRONTEND	No operation sent for execution due to the frontend.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Number	Mnemonic	Description
0x0024	STALL_BACKEND	No operation sent for execution due to the backend.
0x0025	L1D_TLB	Level 1 data TLB access.
0x0026	L1I_TLB	Level 1 instruction TLB access.
0x0027	L2I_CACHE	Level 2 instruction cache access.
0x0028	L2I_CACHE_REFILL	Level 2 instruction cache refill.
0x0029	L3D_CACHE_ALLOCATE	Level 3 data cache allocation without refill.
0x002A	L3D_CACHE_REFILL	Level 3 data cache refill.
0x002B	L3D_CACHE	Level 3 data cache access.
0x002C	L3D_CACHE_WB	Level 3 data cache write-back.
0x002D	L2D_TLB_REFILL	Level 2 data TLB refill.
0x002E	L2I_TLB_REFILL	Level 2 instruction TLB refill.
0x002F	L2D_TLB	Level 2 data TLB access.
0x0030	L2I_TLB	Level 2 instruction TLB access.
0x0031	REMOTE_ACCESS	Access to a remote device.
0x0032	LL_CACHE	Last level cache access.
0x0033	LL_CACHE_MISS	Last level cache miss.
0x0034	DTLB_WALK	Data TLB access with at least one translation table walk.
0x0035	ITLB_WALK	Instruction TLB access with at least one translation table walk.
0x0036	LL_CACHE_RD	Last level cache access, read.
0x0037	LL_CACHE_MISS_RD	Last level cache miss, read.
0x0038	REMOTE_ACCESS_RD	Access to a remote device, read.
0x0039	L1D_CACHE_LMISS_RD	Level 1 data cache long-latency read miss.
0x003A	OP_RETIRED	Micro-operation architecturally executed.
0x003B	OP_SPEC	Micro-operation speculatively executed.
0x003C	STALL	No operation sent for execution.
0x003D	STALL_SLOT_BACKEND	No operation sent for execution on a Slot due to the backend.
0x003E	STALL_SLOT_FRONTEND	No operation sent for execution on a Slot due to the frontend.
0x003F	STALL_SLOT	No operation sent for execution on a Slot.
0x0040	L1D_CACHE_RD	Level 1 data cache access, read.
0x0041	L1D_CACHE_WR	Level 1 data cache access, write.
0x0042	L1D_CACHE_REFILL_RD	Level 1 data cache refill, read.
0x0043	L1D_CACHE_REFILL_WR	Level 1 data cache refill, write.
0x0044	L1D_CACHE_REFILL_INNER	Level 1 data cache refill, inner.

Non-Confidential

Number	Mnemonic	Description
0x0045	L1D_CACHE_REFILL_OUTER	Level 1 data cache refill, outer.
0x0046	L1D_CACHE_WB_VICTIM	Level 1 data cache write-back, victim.
0x0047	L1D_CACHE_WB_CLEAN	Level 1 data cache write-back, cleaning and coherency.
0x0048	L1D_CACHE_INVAL	Level 1 data cache invalidate.
0x004C	L1D_TLB_REFILL_RD	Level 1 data TLB refill, read.
0x004D	L1D_TLB_REFILL_WR	Level 1 data TLB refill, write.
0x004E	L1D_TLB_RD	Level 1 data TLB access, read.
0x004F	L1D_TLB_WR	Level 1 data TLB access, write.
0x0050	L2D_CACHE_RD	Level 2 data cache access, read.
0x0051	L2D_CACHE_WR	Level 2 data cache access, write.
0x0052	L2D_CACHE_REFILL_RD	Level 2 data cache refill, read.
0x0053	L2D_CACHE_REFILL_WR	Level 2 data cache refill, write.
0x0056	L2D_CACHE_WB_VICTIM	Level 2 data cache write-back, victim.
0x0057	L2D_CACHE_WB_CLEAN	Level 2 data cache write-back, cleaning and coherency.
0x0058	L2D_CACHE_INVAL	Level 2 data cache invalidate.
0x005C	L2D_TLB_REFILL_RD	Level 2 data TLB refill, read.
0x005D	L2D_TLB_REFILL_WR	Level 2 data TLB refill, write.
0x005E	L2D_TLB_RD	Level 2 data TLB access, read.
0x005F	L2D_TLB_WR	Level 2 data TLB access, write.
0x0060	BUS_ACCESS_RD	Bus access, read.
0x0061	BUS_ACCESS_WR	Bus access, write.
0x0062	BUS_ACCESS_SHARED	Bus access, Normal, Cacheable, Shareable.
0x0063	BUS_ACCESS_NOT_SHARED	Bus access, not Normal, Cacheable, Shareable.
0x0064	BUS_ACCESS_NORMAL	Bus access, normal.
0x0065	BUS_ACCESS_PERIPH	Bus access, peripheral.
0x0066	MEM_ACCESS_RD	Data memory access, read.
0x0067	MEM_ACCESS_WR	Data memory access, write.
0x0068	UNALIGNED_LD_SPEC	Unaligned access, read.
0x0069	UNALIGNED_ST_SPEC	Unaligned access, write.
0x006A	UNALIGNED_LDST_SPEC	Unaligned access.
0x006C	LDREX_SPEC	Exclusive operation speculatively executed, Load-Exclusive.
0x006D	STREX_PASS_SPEC	Exclusive operation speculatively executed, Store-Exclusive pass.
0x006E	STREX_FAIL_SPEC	Exclusive operation speculatively executed, Store-Exclusive fail.
0x006F	STREX_SPEC	Exclusive operation speculatively executed, Store-Exclusive.

Number	Mnemonic	Description
0x0070	LD_SPEC	Operation speculatively executed, load.
0x0071	ST_SPEC	Operation speculatively executed, store.
0x0072	LDST_SPEC	Operation speculatively executed, load or store.
0x0073	DP_SPEC	Operation speculatively executed, integer data processing.
0x0074	ASE_SPEC	Operation speculatively executed, Advanced SIMD data processing.
0x0075	VFP_SPEC	Operation speculatively executed, scalar floating-point data processing.
0x0076	PC_WRITE_SPEC	Operation speculatively executed, Software change of the PC.
0x0077	CRYPTO_SPEC	Operation speculatively executed, cryptographic data processing.
0x0078	BR_IMMED_SPEC	Branch speculatively executed, immediate branch.
0x0079	BR_RETURN_SPEC	Branch speculatively executed, procedure return.
0x007A	BR_INDIRECT_SPEC	Branch speculatively executed, indirect branch.
0x007C	ISB_SPEC	Barrier speculatively executed, ISB.
0x007D	DSB_SPEC	Barrier speculatively executed, DSB.
0x007E	DMB_SPEC	Barrier speculatively executed, DMB.
0x007F	CSDB_SPEC	Barrier speculatively executed, CSDB.
0x0081	EXC_UNDEF	Exception taken, other synchronous.
0x0082	EXC_SVC	Exception taken, Supervisor Call.
0x0083	EXC_PABORT	Exception taken, Instruction Abort.
0x0084	EXC_DABORT	Exception taken, Data Abort or SError.
0x0086	EXC_IRQ	Exception taken, IRQ.
0x0087	EXC_FIQ	Exception taken, FIQ.
0x0088	EXC_SMC	Exception taken, Secure Monitor Call.
0x008A	EXC_HVC	Exception taken, Hypervisor Call.
0x008B	EXC_TRAP_PABORT	Exception taken, Instruction Abort not Taken locally.
0x008C	EXC_TRAP_DABORT	Exception taken, Data Abort or SError not Taken locally.
0x008D	EXC_TRAP_OTHER	Exception taken, other traps not Taken locally.
0x008E	EXC_TRAP_IRQ	Exception taken, IRQ not Taken locally.
0x008F	EXC_TRAP_FIQ	Exception taken, FIQ not Taken locally.

Number	Mnemonic	Description
0x0090	RC_LD_SPEC	Release consistency operation speculatively executed, Load-Acquire.
0x0091	RC_ST_SPEC	Release consistency operation speculatively executed, Store-Release.
0x00A0	L3D_CACHE_RD	Level 3 data cache access, read.
0x00A1	L3D_CACHE_WR	Level 3 data cache access, write.
0x00A2	L3D_CACHE_REFILL_RD	Level 3 data cache refill, read.
0x00A3	L3D_CACHE_REFILL_WR	Level 3 data cache refill, write.
0x00A6	L3D_CACHE_WB_VICTIM	Level 3 data cache write-back, victim.
0x00A7	L3D_CACHE_WB_CLEAN	Level 3 data cache write-back, cleaning and coherency.
0x00A8	L3D_CACHE_INVAL	Level 3 data cache invalidate.
0x4000	SAMPLE_POP	Statistical Profiling sample population.
0x4001	SAMPLE_FEED	Statistical Profiling sample taken.
0x4002	SAMPLE_FILTRATE	Statistical Profiling sample taken and not removed by filtering.
0x4003	SAMPLE_COLLISION	Statistical Profiling sample collided with previous sample.
0x4004	CNT_CYCLES	Constant frequency cycles.
0x4005	STALL_BACKEND_MEM	Memory stall cycles.
0x4006	L1I_CACHE_LMISS	Level 1 instruction cache long-latency miss.
0x4009	L2D_CACHE_LMISS_RD	Level 2 data cache long-latency read miss.
0x400A	L2I_CACHE_LMISS	Level 2 instruction cache long-latency miss.
0x400B	L3D_CACHE_LMISS_RD	Level 3 data cache long-latency read miss.
0x400C	TRB_WRAP	Trace buffer current write pointer wrapped.
0x4010	TRCEXTOUT0	Trace unit external output 0.
0x4011	TRCEXTOUT1	Trace unit external output 1.
0x4012	TRCEXTOUT2	Trace unit external output 2.
0x4013	TRCEXTOUT3	Trace unit external output 3.
0x4018	CTI_TRIGOUT4	Cross-trigger Interface output trigger 4.
0x4019	CTI_TRIGOUT5	Cross-trigger Interface output trigger 5.
0x401A	CTI_TRIGOUT6	Cross-trigger Interface output trigger 6.
0x401B	CTI_TRIGOUT7	Cross-trigger Interface output trigger 7.

Number	Mnemonic	Description
0x4020	LDST_ALIGN_LAT	Access with additional latency from alignment.
0x4021	LD_ALIGN_LAT	Load with additional latency from alignment.
0x4022	ST_ALIGN_LAT	Store with additional latency from alignment.
0x4030	TSTART_RETIRED	Instruction architecturally executed, outer transaction TSTART.
0x4031	TCOMMIT_RETIRED	Instruction architecturally executed, outer transaction TCOMMIT.
0x4032	TME_TRANSACTION_FAILED	Transaction failed or was canceled.
0x4034	TME_INST_RETIRED_COMMITTED	Instruction architecturally executed, in a committed transaction.
0x4035	TME_CPU_CYCLES_COMMITTED	PE cycle, in a committed transaction.
0x4038	TME_FAILURE_CNCL	Transaction failed with CNCL cause.
0x4039	TME_FAILURE_NEST	Transaction failed with NEST cause.
0x403A	TME_FAILURE_ERR	Transaction failed with ERR cause.
0x403B	TME_FAILURE_IMP	Transaction failed with IMP cause.
0x403C	TME_FAILURE_MEM	Transaction failed with MEM cause.
0x403D	TME_FAILURE_SIZE	Transaction failed with SIZE cause.
0x403E	TME_FAILURE_TLBI	Transaction failed due to execution of TLBI by another PE.
0x403F	TME_FAILURE_WSET	Transaction failed due to transactional write set limit overflow.
0x8000	SIMD_INST_RETIRED	Instruction architecturally executed, SIMD.
0x8001	ASE_INST_RETIRED	Instruction architecturally executed, Advanced SIMD.
0x8003	ASE_SVE_INST_RETIRED	Instruction architecturally executed, Advanced SIMD or SVE.
0x8004	SIMD_INST_SPEC	Operation speculatively executed, SIMD.
0x8005	ASE_INST_SPEC	Operation speculatively executed, Advanced SIMD.
0x8007	ASE_SVE_INST_SPEC	Operation speculatively executed, Advanced SIMD or SVE.
0x8008	UOP_SPEC	Microarchitectural operation speculatively executed.
0x8009	ASE_UOP_SPEC	Microarchitectural operation speculatively executed, Advanced SIMD.
0x800B	ASE_SVE_UOP_SPEC	Microarchitectural operation speculatively executed, Advanced SIMD or SVE.
0x800C	SIMD_UOP_SPEC	Microarchitectural operation speculatively executed, SIMD.

Number	Mnemonic	Description
0x8010	FP_SPEC	Floating-point operation speculatively executed, including SIMD.
0x8011	ASE_FP_SPEC	Floating-point operation speculatively executed, Advanced SIMD.
0x8013	ASE_SVE_FP_SPEC	Floating-point operation speculatively executed, Advanced SIMD or SVE.
0x8014	FP_HP_SPEC	Floating-point operation speculatively executed, half-precision.
0x8015	ASE_FP_HP_SPEC	Floating-point operation speculatively executed, Advanced SIMD half-precision, data-processing.
0x8017	ASE_SVE_FP_HP_SPEC	Floating-point operation speculatively executed, Advanced SIMD or SVE half-precision.
0x8018	FP_SP_SPEC	Floating-point operation speculatively executed, single-precision.
0x8019	ASE_FP_SP_SPEC	Floating-point operation speculatively executed, Advanced SIMD single-precision, data-processing.
0x801B	ASE_SVE_FP_SP_SPEC	Floating-point operation speculatively executed, Advanced SIMD or SVE single-precision, data-processing.
0x801C	FP_DP_SPEC	Floating-point operation speculatively executed, double-precision, data-processing.
0x801D	ASE_FP_DP_SPEC	Floating-point operation speculatively executed, Advanced SIMD double-precision, data-processing.
0x801F	ASE_SVE_FP_DP_SPEC	Floating-point operation speculatively executed, Advanced SIMD or SVE double-precision, data-processing.
0x8020	FP_DIV_SPEC	Floating-point operation speculatively executed, divide.
0x8021	ASE_FP_DIV_SPEC	Floating-point operation speculatively executed, Advanced SIMD divide.
0x8023	ASE_SVE_FP_DIV_SPEC	Floating-point operation speculatively executed, Advanced SIMD or SVE divide.
0x8024	FP_SQRT_SPEC	Floating-point operation speculatively executed, square root.
0x8025	ASE_FP_SQRT_SPEC	Floating-point operation speculatively executed, Advanced SIMD square root.
0x8027	ASE_SVE_FP_SQRT_SPEC	Floating-point operation speculatively executed, Advanced SIMD or SVE square-root.
0x8028	FP_FMA_SPEC	Floating-point operation speculatively executed, FMA.
0x8029	ASE_FP_FMA_SPEC	Floating-point operation speculatively executed, Advanced SIMD FMA.

Number	Mnemonic	Description
0x802B	ASE_SVE_FP_FMA_SPEC	Floating-point operation speculatively executed, Advanced SIMD or SVE FMA.
0x802C	FP_MUL_SPEC	Floating-point operation speculatively executed, multiply.
0x802D	ASE_FP_MUL_SPEC	Floating-point operation speculatively executed, Advanced SIMD multiply.
0x802F	ASE_SVE_FP_MUL_SPEC	Floating-point operation speculatively executed, Advanced SIMD or SVE multiply.
0x8030	FP_ADDSUB_SPEC	Floating-point operation speculatively executed, add or subtract.
0x8031	ASE_FP_ADDSUB_SPEC	Floating-point operation speculatively executed, Advanced SIMD add or subtract.
0x8033	ASE_SVE_FP_ADDSUB_SPEC	Floating-point operation speculatively executed, Advanced SIMD or SVE add or subtract .
0x8034	FP_RECPE_SPEC	Floating-point operation speculatively executed, reciprocal estimate.
0x8035	ASE_FP_RECPE_SPEC	Floating-point operation speculatively executed, Advanced SIMD reciprocal estimate.
0x8037	ASE_SVE_FP_RECPE_SPEC	Floating-point operation speculatively executed, Advanced SIMD or SVE reciprocal estimate.
0x8038	FP_CVT_SPEC	Floating-point operation speculatively executed, convert.
0x8039	ASE_FP_CVT_SPEC	Floating-point operation speculatively executed, Advanced SIMD convert.
0x803B	ASE_SVE_FP_CVT_SPEC	Floating-point operation speculatively executed, Advanced SIMD or SVE convert.
0x803D	ASE_FP_PREDUCE_SPEC	Floating-point operation speculatively executed, Advanced SIMD pairwise add step or pairwise reduce step.
0x803F	ASE_SVE_FP_VREDUCE_SPEC	Floating-point operation speculatively executed, Advanced SIMD or SVE vector reduction.
0x8040	INT_SPEC	Integer operation speculatively executed.
0x8041	ASE_INT_SPEC	Integer operation speculatively executed, Advanced SIMD.
0x8043	ASE_SVE_INT_SPEC	Integer operation speculatively executed, Advanced SIMD or SVE.
0x8044	INT_DIV_SPEC	Integer operation speculatively executed, divide.
0x8045	INT_DIV64_SPEC	Integer operation speculatively executed, 64-bit divide.

Number	Mnemonic	Description
0x8048	INT_MUL_SPEC	Integer operation speculatively executed, multiply.
0x8049	ASE_INT_MUL_SPEC	Integer operation speculatively executed, Advanced SIMD multiply.
0x804B	ASE_SVE_INT_MUL_SPEC	Integer operation speculatively executed, Advanced SIMD or SVE multiply.
0x804C	INT_MUL64_SPEC	Integer operation speculatively executed, 64×64 multiply.
0x804E	INT_MULH64_SPEC	Integer operation speculatively executed, 64×64 multiply returning high part.
0x8053	ASE_SVE_FP_BF16_SPEC	Floating-point operation speculatively executed, SVE or Advanced SIMD BFloat16, data-processing.
0x8056	SVE_SPEC	Operation speculatively executed, SVE data processing.
0x8057	ASE_SVE_SPEC	Operation speculatively executed, Advanced SIMD data processing or SVE data processing.
0x8058	NONFP_SPEC	Non-floating-point operation speculatively executed.
0x8059	ASE_NONFP_SPEC	Non-floating-point operation speculatively executed, Advanced SIMD.
0x805B	ASE_SVE_NONFP_SPEC	Non-floating-point operation speculatively executed, Advanced SIMD or SVE.
0x805D	ASE_INT_VREDUCE_SPEC	Integer operation speculatively executed, Advanced SIMD reduction.
0x805F	ASE_SVE_INT_VREDUCE_SPEC	Integer operation speculatively executed, Advanced SIMD or SVE reduction.
0x8084	ASE_SVE_LDST_SPEC	Operation speculatively executed, Advanced SIMD or SVE load or store.
0x8085	ASE_SVE_LD_SPEC	Operation speculatively executed, Advanced SIMD or SVE load.
0x8086	ASE_SVE_ST_SPEC	Operation speculatively executed, Advanced SIMD or SVE store.
0x8087	PRF_SPEC	Operation speculatively executed, prefetch.
0x8088	BASE_LDST_REG_SPEC	Operation speculatively executed, general-purpose register load, store, or prefetch.
0x8089	BASE_LD_REG_SPEC	Operation speculatively executed, general-purpose register load.
0x808A	BASE_ST_REG_SPEC	Operation speculatively executed, general-purpose register store.

Number	Mnemonic	Description
0x808B	BASE_PRF_SPEC	Operation speculatively executed, general-purpose register prefetch.
0x808C	FPASE_LDST_REG_SPEC	Operation speculatively executed, SIMD&FP register load or store.
0x808D	FPASE_LD_REG_SPEC	Operation speculatively executed, SIMD&FP register load.
0x808E	FPASE_ST_REG_SPEC	Operation speculatively executed, SIMD&FP register store.
0x80A4	ASE_SVE_LDST_MULTI_SPEC	Operation speculatively executed, Advanced SIMD or SVE contiguous load or store multiple vector.
0x80A5	ASE_SVE_LD_MULTI_SPEC	Operation speculatively executed, Advanced SIMD or SVE contiguous load multiple vector.
0x80A6	ASE_SVE_ST_MULTI_SPEC	Operation speculatively executed, Advanced SIMD or SVE contiguous store multiple vector.
0x80B4	ASE_SVE_UNALIGNED_LDST_SPEC	Advanced SIMD or SVE unaligned access.
0x80B5	ASE_SVE_UNALIGNED_LD_SPEC	Advanced SIMD or SVE unaligned read.
0x80B6	ASE_SVE_UNALIGNED_ST_SPEC	Advanced SIMD or SVE unaligned write.
0x80B8	ASE_SVE_UNALIGNED_CONTIG_LDST_SPEC	Advanced SIMD or SVE unaligned contiguous access.
0x80B9	ASE_SVE_UNALIGNED_CONTIG_LD_SPEC	Advanced SIMD or SVE unaligned contiguous read.
0x80BA	ASE_SVE_UNALIGNED_CONTIG_ST_SPEC	Advanced SIMD or SVE unaligned contiguous write.
0x80C1	FP_FIXED_OPS_SPEC	Non-scalable element arithmetic operations speculatively executed, floating-point.
0x80C3	FP_HP_FIXED_OPS_SPEC	Non-scalable element arithmetic operations speculatively executed, largest type is half-precision floating-point.
0x80C5	FP_SP_FIXED_OPS_SPEC	Non-scalable element arithmetic operations speculatively executed, largest type is single-precision floating-point.
0x80C7	FP_DP_FIXED_OPS_SPEC	Non-scalable element arithmetic operations speculatively executed, largest type is double-precision floating-point.
0x80C9	INT_FIXED_OPS_SPEC	Non-scalable element arithmetic operations speculatively executed, integer.
0x80CB	LDST_FIXED_OPS_SPEC	Non-scalable load or store element operations speculatively executed.
0x80CD	LD_FIXED_OPS_SPEC	Non-scalable load element operations speculatively executed.

Number	Mnemonic	Description
0x80CF	ST_FIXED_OPS_SPEC	Non-scalable store element operations speculatively executed.
0x80DB	LDST_FIXED_BYTES_SPEC	Non-scalable load and store bytes speculatively executed.
0x80DD	LD_FIXED_BYTES_SPEC	Non-scalable load bytes speculatively executed.
0x80DF	ST_FIXED_BYTES_SPEC	Non-scalable store bytes speculatively executed.
0x80E1	ASE_INT8_SPEC	Integer operation speculatively executed, Advanced SIMD 8-bit.
0x80E3	ASE_SVE_INT8_SPEC	Integer operation speculatively executed, Advanced SIMD or SVE 8-bit.
0x80E5	ASE_INT16_SPEC	Integer operation speculatively executed, Advanced SIMD 16-bit.
0x80E7	ASE_SVE_INT16_SPEC	Integer operation speculatively executed, Advanced SIMD or SVE 16-bit.
0x80E9	ASE_INT32_SPEC	Integer operation speculatively executed, Advanced SIMD 32-bit.
0x80EB	ASE_SVE_INT32_SPEC	Integer operation speculatively executed, Advanced SIMD or SVE 32-bit.
0x80ED	ASE_INT64_SPEC	Integer operation speculatively executed, Advanced SIMD 64-bit.
0x80EF	ASE_SVE_INT64_SPEC	Integer operation speculatively executed, Advanced SIMD or SVE 64-bit.
0x80F1	ASE_FP_DOT_SPEC	Floating-point operation speculatively executed, Advanced SIMD dot-product.
0x80F3	ASE_SVE_FP_DOT_SPEC	Floating-point operation speculatively executed, Advanced SIMD or SVE dot-product.
0x80F5	ASE_FP_MMLA_SPEC	Floating-point operation speculatively executed, Advanced SIMD matrix multiply.
0x80F7	ASE_SVE_FP_MMLA_SPEC	Floating-point operation speculatively executed, Advanced SIMD or SVE matrix multiply.
0x80F9	ASE_INT_DOT_SPEC	Operation speculatively executed, Advanced SIMD integer dot-product.
0x80FB	ASE_SVE_INT_DOT_SPEC	Integer operation speculatively executed, Advanced SIMD or SVE dot-product.
0x80FD	ASE_INT_MMLA_SPEC	Integer operation speculatively executed, Advanced SIMD matrix multiply.
0x80FF	ASE_SVE_INT_MMLA_SPEC	Integer operation speculatively executed, Advanced SIMD or SVE matrix multiply.

Number	Mnemonic	Description
0x8107	BR_SKIP_RETIRED	Branch instruction architecturally executed, not taken.
0x8108	BR_IMMED_TAKEN_RETIRED	Branch instruction architecturally executed, immediate, taken.
0x810C	BR_INDNR_TAKEN_RETIRED	Branch instruction architecturally executed, indirect excluding procedure return, taken.
0x8110	BR_IMMED_PRED_RETIRED	Branch instruction architecturally executed, predicted immediate.
0x8111	BR_IMMED_MIS_PRED_RETIRED	Branch instruction architecturally executed, mispredicted immediate.
0x8112	BR_IND_PRED_RETIRED	Branch instruction architecturally executed, predicted indirect.
0x8113	BR_IND_MIS_PRED_RETIRED	Branch instruction architecturally executed, mispredicted indirect.
0x8114	BR_RETURN_PRED_RETIRED	Branch instruction architecturally executed, predicted procedure return.
0x8115	BR_RETURN_MIS_PRED_RETIRED	Branch instruction architecturally executed, mispredicted procedure return.
0x8116	BR_INDNR_PRED_RETIRED	Branch instruction architecturally executed, predicted indirect excluding procedure return.
0x8117	BR_INDNR_MIS_PRED_RETIRED	Branch instruction architecturally executed, mispredicted indirect excluding procedure return.
0x8118	BR_TAKEN_PRED_RETIRED	Branch instruction architecturally executed, predicted branch, taken.
0x8119	BR_TAKEN_MIS_PRED_RETIRED	Branch instruction architecturally executed, mispredicted branch, taken.
0x811A	BR_SKIP_PRED_RETIRED	Branch instruction architecturally executed, predicted branch, not taken.
0x811B	BR_SKIP_MIS_PRED_RETIRED	Branch instruction architecturally executed, mispredicted branch, not taken.
0x811C	BR_PRED_RETIRED	Branch instruction architecturally executed, predicted branch.
0x811D	BR_IND_RETIRED	Instruction architecturally executed, indirect branch.
0x811F	BRB_FILTRATE	Branch Record captured.
0x8120	INST_FETCH_PERCYC	Instruction fetches in progress.
0x8121	MEM_ACCESS_RD_PERCYC	Data memory reads in progress.
0x8122	SAMPLE_FEED_DS	Statistical Profiling sample taken, selected Data Source.
0x8123	SAMPLE_BUFFER_FULL	Profiling Buffer full.
0x8124	INST_FETCH	Instruction memory access.
0x8125	BUS_REQ_RD_PERCYC	Bus read transactions in progress.
0x8126	BUS_REQ_WR_PERCYC	Bus write transactions in progress.

Number	Mnemonic	Description
0x8127	PMU_SNAPSHOT	Successful PMU capture event.
0x8128	DTLB_WALK_PERCYC	Data translation table walks in progress.
0x8129	ITLB_WALK_PERCYC	Instruction translation table walks in progress.
0x8130	L1D_TLB_RW	Level 1 data TLB access, demand access.
0x8131	L1I_TLB_RD	Level 1 instruction TLB access, demand access.
0x8132	L1D_TLB_PRFM	Level 1 data TLB access, software prefetch.
0x8133	L1I_TLB_PRFM	Level 1 instruction TLB access, software prefetch.
0x8134	DTLB_HWUPD	Data TLB hardware update of translation table.
0x8135	ITLB_HWUPD	Instruction TLB hardware update of translation table.
0x8136	DTLB_STEP	Data TLB translation table walk, step.
0x8137	ITLB_STEP	Instruction TLB translation table walk, step.
0x8138	DTLB_WALK_LARGE	Data TLB large page translation table walk.
0x8139	ITLB_WALK_LARGE	Instruction TLB large page translation table walk.
0x813A	DTLB_WALK_SMALL	Data TLB small page translation table walk.
0x813B	ITLB_WALK_SMALL	Instruction TLB small page translation table walk.
0x813C	DTLB_WALK_RW	Data TLB demand access, with at least one translation table walk.
0x813D	ITLB_WALK_RD	Instruction TLB demand access, with at least one translation table walk.
0x813E	DTLB_WALK_PRFM	Data TLB software prefetch, with at least one translation table walk.
0x813F	ITLB_WALK_PRFM	Instruction TLB software prefetch, with at least one translation table walk.
0x8140	L1D_CACHE_RW	Level 1 data cache demand access.
0x8141	L1I_CACHE_RD	Level 1 instruction cache demand fetch.
0x8142	L1D_CACHE_PRFM	Level 1 data cache software prefetch.
0x8143	L1I_CACHE_PRFM	Level 1 instruction cache software prefetch.
0x8144	L1D_CACHE_MISS	Level 1 data cache demand access miss.
0x8145	L1I_CACHE_HWPRF	Level 1 instruction cache hardware prefetch.

Non-Confidential

Number	Mnemonic	Description
0x8146	L1D_CACHE_REFILL_PRFM	Level 1 data cache refill, software prefetch.
0x8147	L1I_CACHE_REFILL_PRFM	Level 1 instruction cache refill, software prefetch.
0x8148	L2D_CACHE_RW	Level 2 data cache demand access.
0x8149	L2I_CACHE_RD	Level 2 instruction cache demand fetch.
0x814A	L2D_CACHE_PRFM	Level 2 data cache software prefetch.
0x814B	L2I_CACHE_PRFM	Level 2 instruction cache software prefetch.
0x814C	L2D_CACHE_MISS	Level 2 data cache demand access miss.
0x814D	L2I_CACHE_HWPRF	Level 2 instruction cache hardware prefetch.
0x814E	L2D_CACHE_REFILL_PRFM	Level 2 data cache refill, software prefetch.
0x814F	L2I_CACHE_REFILL_PRFM	Level 2 instruction cache refill, software prefetch.
0x8150	L3D_CACHE_RW	Level 3 data cache demand access.
0x8151	L3D_CACHE_PRFM	Level 3 data cache software prefetch.
0x8152	L3D_CACHE_MISS	Level 3 data cache demand access miss.
0x8153	L3D_CACHE_REFILL_PRFM	Level 3 data cache refill, software prefetch.
0x8154	L1D_CACHE_HWPRF	Level 1 data cache hardware prefetch.
0x8155	L2D_CACHE_HWPRF	Level 2 data cache hardware prefetch.
0x8156	L3D_CACHE_HWPRF	Level 3 data cache hardware prefetch.
0x8157	LL_CACHE_HWPRF	Last level cache hardware prefetch.
0x8158	STALL_FRONTEND_MEMBOUND	Frontend stall cycles, memory bound.
0x8159	STALL_FRONTEND_L1I	Frontend stall cycles, level 1 instruction cache.
0x815A	STALL_FRONTEND_L2I	Frontend stall cycles, level 2 instruction cache.
0x815B	STALL_FRONTEND_MEM	Frontend stall cycles, last level PE cache or memory.
0x815C	STALL_FRONTEND_TLB	Frontend stall cycles, TLB.
0x8160	STALL_FRONTEND_CPUBOUND	Frontend stall cycles, processor bound.
0x8161	STALL_FRONTEND_FLOW	Frontend stall cycles, flow control.
0x8162	STALL_FRONTEND_FLUSH	Frontend stall cycles, flush recovery.
0x8163	STALL_FRONTEND_RENAME	Frontend stall cycles, rename full.
0x8164	STALL_BACKEND_MEMBOUND	Backend stall cycles, memory bound.
0x8165	STALL_BACKEND_L1D	Backend stall cycles, level 1 data cache.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Number	Mnemonic	Description
0x8166	STALL_BACKEND_L2D	Backend stall cycles, level 2 data cache.
0x8167	STALL_BACKEND_TLB	Backend stall cycles, TLB.
