8 March 2024

Confidentiality Status

This document is Non-Confidential. The right to use, copy and disclose this document may be subject to license restrictions in accordance with the terms of the agreement entered into by Arm and the party that Arm delivered this document to.

Product Status

The information in this document is final, that is for a developed product.

The information in this manual is at EAC quality, which means that all features of the specification are described in the manual.

Web Address

https://www.arm.com

Limitations of this issue of the Manual

This issue of the Arm Architecture Reference Manual contains many improvements and corrections.

The features implemented by the R-profile architecture are described in R-profile Architecture Extensions, and this manual should be interpreted in accordance with those features. The following sections make reference to features that cannot be implemented within an Armv8-R compliant PE:

- The Ordering requirements defined by the formal concurrency model. This is to ensure that the memory model is conformant with the formal concurrency model.
- The PMU Event Descriptions.

Validation of this document has identified the following issues that Arm will address in future issues:

- Some diagrams in the register descriptions chapter have long field names that split over several lines. These are not wrong, and the descriptions list the field name correctly.
- Arm Pseudocode Definition requires further review and update. Since this appendix is informative, rather than being part of the architecture specification, this does not affect the quality status of this release.
- For a list of the known issues in the most recent Register and Instruction XML releases, please refer to the Release Notes on Developer.

Arm® Architecture Reference Manual, for R-profile AArch64 architecture

Preface

About this Manual xviii

Using this Manual xxi

Conventions xxvi

Additional reading xxx

Feedback xxxiii

Part A Arm Architecture Introduction and Overview

Chapter A1 Introduction to the Arm Architecture

A1.1 About the Arm architecture 38

A1.2 Architecture profiles 41

A1.3 Arm architectural concepts 43

A1.4 Supported data types 47

A1.5 Floating-point support 56

A1.6 The Arm memory model 67

A1.7 Reliability, Availability, and Serviceability 69

Chapter A2 R-profile Architecture Extensions

A2.1 About the Armv8-R AArch64 architecture extensions 74

A2.2 Armv8-R AArch64 architecture extensions 76

Part B The AArch64 Application Level Architecture

Chapter B1 The AArch64 Application Level Programmers' Model

B1.1 About the Application level programmers' model 111

B1.2 Registers in AArch64 Execution state 113

B1.3 Process state, PSTATE 117

B1.4 Software control features and EL0 120

B1.5 Memory barriers 124

B1.6 Caches and memory hierarchy 132

B1.7 Alignment support 138

B1.8 Endian support 142

B1.9 Memory types and attributes 146

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

B1.10 Mismatched memory attributes 158
B1.11 Synchronization and semaphores 162

Part C The AArch64 Instruction Set

Chapter C1 The A64 Instruction Set

C1.1 About the A64 instruction set 176
C1.2 Structure of the A64 assembler language 178
C1.3 Address generation 185
C1.4 Instruction aliases 189

Chapter C2 About the A64 Instruction Descriptions

C2.1 Understanding the A64 instruction descriptions 192
C2.2 General information about the A64 instruction descriptions 196

Chapter C3 A64 Instruction Set Overview

C3.1 Branches, Exception generating, and System instructions 201
C3.2 Loads and stores 213
C3.3 Data processing - immediate 230
C3.4 Data processing - register 236
C3.5 Data processing - SIMD and floating-point 246

Chapter C4 A64 Instruction Set Encoding

C4.1 A64 instruction set encoding 272

Chapter C5 The A64 System Instruction Class

C5.1 The System instruction class encoding space 358
C5.2 Special-purpose registers 370
C5.3 A64 System instructions for cache maintenance 418
C5.4 A64 System instructions for address translation 444
C5.5 A64 System instructions for TLB maintenance 460
C5.6 A64 System instructions for prediction restriction 651
C5.7 A64 IMPLEMENTATION DEFINED System instructions 662

Chapter C6 A64 Base Instruction Descriptions

C6.1 About the A64 base instructions 667
C6.2 Alphabetical list of A64 base instructions 671

Chapter C7 A64 Advanced SIMD and Floating-point Instruction Descriptions

C7.1 About the A64 Advanced SIMD and floating-point instructions 1169
C7.2 Alphabetical list of A64 Advanced SIMD and floating-point instructions 1173

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Part D The AArch64 System Level Architecture

Chapter D1 The AArch64 System Level Programmers' Model

D1.1 Exception levels 2037
D1.2 Registers for instruction processing and exception handling 2040
D1.3 Exceptions 2043
D1.4 Process state, PSTATE 2065
D1.5 Resets and power domains 2068
D1.6 Mechanisms for entering a low-power state 2072
D1.7 Self-hosted debug 2078
D1.8 Event monitors 2081

Chapter D2 AArch64 Self-hosted Debug

D2.1 About self-hosted debug 2084
D2.2 Routing debug exceptions 2088
D2.3 The debug exception enable controls 2090
D2.4 The effect of powerdown on debug exceptions 2093
D2.5 Summary of the routing and enabling of debug exceptions 2095
D2.6 Pseudocode description of debug exceptions 2098
D2.7 Breakpoint Instruction exceptions 2100
D2.8 Breakpoint exceptions 2103
D2.9 Watchpoint exceptions 2119
D2.10 Software Step exceptions 2135
D2.11 Synchronization and debug exceptions 2147

Chapter D3 AArch64 Self-hosted Trace

D3.1 About self-hosted trace 2150
D3.2 Prohibited regions in self-hosted trace 2152
D3.3 Self-hosted trace timestamps 2155
D3.4 Synchronization in self-hosted trace 2157

Chapter D4 The AArch64 System Level Memory Model

D4.1 About the memory system architecture 2160
D4.2 Address space 2162
D4.3 Mixed-endian support in AArch64 2164
D4.4 Cache support 2166
D4.5 External aborts 2191
D4.6 Memory barrier instructions 2194
D4.7 Pseudocode description of general memory System instructions 2196

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Chapter D5 **The AArch64 Virtual Memory System Architecture**

D5.1 Address translation 2201
D5.2 Translation process 2210
D5.3 Translation table descriptor formats 2228
D5.4 Memory access control 2237
D5.5 Hardware updates to the translation tables 2244
D5.6 Memory region attributes 2252
D5.7 Other descriptor fields 2255
D5.8 Address tagging 2257
D5.9 Pointer authentication 2259
D5.10 Memory aborts 2265
D5.11 Translation Lookaside Buffers 2276
D5.12 TLB maintenance 2281
D5.13 Caches 2295
D5.14 Pseudocode description of VMSA address translation 2298

Chapter D6 **The AArch64 Protected Memory System Architecture**

D6.1 About the Protected Memory System Architecture 2302
D6.2 Memory Protection Unit 2304
D6.3 Address translation regimes 2306
D6.4 Default memory map 2308
D6.5 MPU memory translations and faults 2310
D6.6 Protection region attributes and access permissions 2319
D6.7 MPU fault encodings 2325
D6.8 PMSAv8-64 implications for caches 2327
D6.9 Address tagging and pointer authentication support 2329
D6.10 Security model 2331
D6.11 Virtualization 2334

Chapter D7 **The Generic Timer in AArch64 state**

D7.1 About the Generic Timer 2337
D7.2 The AArch64 view of the Generic Timer 2342

Chapter D8 **The Performance Monitors Extension**

D8.1 About the Performance Monitors 2348
D8.2 Accuracy of the Performance Monitors 2352
D8.3 Behavior on overflow 2355
D8.4 Attributability 2358
D8.5 Controlling the PMU counters 2360

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D8.6 Multithreaded implementations 2364
D8.7 Event filtering 2366
D8.8 Performance Monitors and Debug state 2369
D8.9 Counter access 2371
D8.10 Performance Monitors Extension registers 2374

Chapter D9 PMU Event Descriptions

D9.1 Definitions 2377
D9.2 The PMU event number space and common events 2387
D9.3 Common event numbers 2432
D9.4 Cycle event counting 2581
D9.5 Meaningful combinations of common events 2584
D9.6 Required events 2590
D9.7 Synchronous events 2593
D9.8 IMPLEMENTATION DEFINED event numbers 2595

Chapter D10 RAS PE Architecture

D10.1 About the RAS Extension 2598
D10.2 PE error handling 2600
D10.3 Generating error exceptions 2606
D10.4 Taking error exceptions 2608
D10.5 Error synchronization event 2617
D10.6 Virtual SError exceptions and delegated SError exceptions 2623
D10.7 Error records in the PE 2625

Chapter D11 AArch64 System Register Encoding

D11.1 The System register encoding space 2630
D11.2 Moves to and from debug and trace System registers 2632
D11.3 Moves to and from non-debug System registers, Special-purpose registers 2635

Chapter D12 AArch64 System Register Descriptions

D12.1 About the AArch64 System registers 2646
D12.2 General system control registers 2657
D12.3 Debug registers 2981
D12.4 Trace registers 3052
D12.5 Performance Monitors registers 3060
D12.6 PMSA registers 3116
D12.7 RAS registers 3140
D12.8 Generic Timer registers 3174

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Part E External Debug

Chapter E1 About External Debug

E1.1 Introduction to external debug 3212
E1.2 External debug 3214
E1.3 Required debug authentication 3216

Chapter E2 Debug State

E2.1 About Debug state 3219
E2.2 Halting the PE on debug events 3221
E2.3 Entering Debug state 3228
E2.4 Behavior in Debug state 3232
E2.5 Exiting Debug state 3252

Chapter E3 Halting Debug Events

E3.1 Introduction to Halting debug events 3256
E3.2 Halting Step debug events 3259
E3.3 Halt Instruction debug event 3269
E3.4 Exception Catch debug event 3271
E3.5 External Debug Request debug event 3275
E3.6 OS Unlock Catch debug event 3278
E3.7 Reset Catch debug events 3280
E3.8 Software Access debug event 3282
E3.9 Synchronization and Halting debug events 3284

Chapter E4 The Debug Communication Channel and Instruction Transfer Register

E4.1 Introduction 3287
E4.2 DCC and ITR registers 3289
E4.3 DCC and ITR access modes 3292
E4.4 Flow control of the DCC and ITR registers 3297
E4.5 Synchronization of DCC and ITR accesses 3302
E4.6 Interrupt-driven use of the DCC 3309
E4.7 Pseudocode description of the operation of the DCC and ITR registers 3311

Chapter E5 The Embedded Cross-Trigger Interface

E5.1 About the Embedded Cross-Trigger 3314
E5.2 Basic operation on the ECT 3317
E5.3 Cross-triggers on a PE in an Arm R-profile implementation 3322
E5.4 Description and allocation of CTI triggers 3324
E5.5 CTI registers programmers' model 3329

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

E5.6 Examples 3331

Chapter E6 Debug Reset and Powerdown Support

E6.1 About Debug over powerdown 3336
E6.2 Power domains and debug 3338
E6.3 Core power domain power states 3340
E6.4 Powerup request mechanism 3343
E6.5 Emulating low-power states 3346
E6.6 Debug OS Save and Restore sequences 3349
E6.7 Reset and debug 3356

Chapter E7 The PC Sample-based Profiling Extension

E7.1 About the PC Sample-based Profiling Extension 3360

Chapter E8 About the External Debug Registers

E8.1 Relationship between external debug and System registers 3365
E8.2 Endianness and supported access sizes 3367
E8.3 Synchronization of changes to the external debug registers 3369
E8.4 Memory-mapped accesses to the external debug interface 3374
E8.5 External debug interface register access permissions 3377
E8.6 External debug interface registers 3381
E8.7 Cross-trigger interface registers 3387
E8.8 External debug register resets 3390

Chapter E9 External Debug Register Descriptions

E9.1 About the external debug registers 3395
E9.2 External debug registers 3397
E9.3 External trace registers 3503
E9.4 Cross-Trigger Interface registers 3505

Part F Memory-mapped Components of the Arm Architecture

Chapter F1 Requirements for Memory-mapped Components

F1.1 Supported access sizes 3566
F1.2 Synchronization of memory-mapped registers 3569
F1.3 Access requirements for reserved and unallocated registers 3572

Chapter F2 System Level Implementation of the Generic Timer

F2.1 About the Generic Timer specification 3575
F2.2 Memory-mapped counter module 3578
F2.3 Memory-mapped timer components 3583

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Chapter F3 **Recommended External Interface to the Performance Monitors**

F3.1 About the external interface to the Performance Monitors registers 3589

Chapter F4 **External System Control Register Descriptions**

F4.1 About the external system control register descriptions 3595

F4.2 External Performance Monitors registers summary 3597

F4.3 Performance Monitors external register descriptions 3601

F4.4 Generic Timer memory-mapped registers overview....3678

F4.5 Generic Timer memory-mapped register descriptions 3680

Part G Architectural Pseudocode

Chapter G1 **R-profile Architecture Pseudocode**

G1.1 Pseudocode for AArch64 operation 3731

G1.2 Shared pseudocode....3863

Part H Appendixes

Appendix H1 **Architectural Constraints on UNPREDICTABLE Behaviors**

H1.1 AArch64 CONSTRAINED UNPREDICTABLE behaviors....4032

Appendix H2 **Recommendations for Reporting Memory Attributes on an Interconnect**

H2.1 Arm recommendations for reporting memory attributes on an interconnect 4051

Appendix H3 **Arm Pseudocode Definition**

H3.1 About the Arm pseudocode....4054

H3.2 Pseudocode for instruction descriptions....4056

H3.3 Data types 4059

H3.4 Operators 4065

H3.5 Statements and control structures....4072

H3.6 Built-in functions 4079

H3.7 Miscellaneous helper procedures and functions 4083

H3.8 Arm pseudocode definition index 4087

Appendix H4 **Registers Index**

H4.1 Introduction and register disambiguation....4092

H4.2 Alphabetical index of AArch64 registers and System instructions 4095

H4.3 Functional index of AArch64 registers and System instructions 4106

H4.4 Alphabetical index of memory-mapped registers 4117

H4.5 Functional index of memory-mapped registers....4125

Preface

This preface introduces the *Arm Architecture Reference Manual, for A-profile architecture*. It contains the following sections:

- About this Manual.
- Using this Manual.
- Conventions.
- Additional reading.
- Feedback.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

About this Manual

This Manual describes the Arm® architecture v8, Armv8. The architecture describes the operation of an Armv8-R AArch64 Processing element (PE), and this Manual includes descriptions of:

- The AArch64 Execution state.
- The A64 instruction set for AArch64 state.
- The Exception model.
- The memory model, that defines memory ordering and memory management. This Manual covers the Arm R architecture profile for AArch64 state, that defines a *Virtual Memory System Architecture* (VMSA) and a *Protected Memory System Architecture* (PMSA).
- The programmers' model, and its interfaces to System registers that control most PE and memory system features, and provide status information.
- The Advanced SIMD and floating-point instructions, which provide high-performance:
  - Single-precision, half-precision, and double-precision floating-point operations.
  - Conversions between double-precision, single-precision, and half-precision floating-point values.
  - Integer, single-precision floating-point, and half-precision floating-point vector operations in all instruction sets.
  - Double-precision floating-point vector operations in the A64 instruction set.
- The security model, which provides up to four Security states to support Secure applications and confidential computing.
- The virtualization model.
- The Debug architecture, which provides software access to debug features.

This Manual gives the assembler syntax for the instructions it describes, meaning that it describes instructions in textual form. However, this Manual is not a tutorial for Arm assembler language, nor does it describe Arm assembler language, except at a basic level. To make effective use of Arm assembler language, read the documentation supplied with the assembler being used.

This Manual is organized into parts:

Part A Provides an introduction to the Arm architecture, and an overview of the AArch64 state.

Part B Describes the application level view of the AArch64 Execution state, meaning the view from EL0. It describes the application level view of the programmers' model and the memory model.

Part C Describes the A64 instruction set, which is available in the AArch64 Execution state. The descriptions for each instruction also include the precise effects of each instruction when executed at EL0, described as *unprivileged* execution, including any restrictions on its use, and how the effects of the instruction differ at higher Exception levels. This information is of primary importance to authors and users of compilers, assemblers, and other programs that generate Arm machine code.

Part D Describes the system level view of the AArch64 Execution state. It includes details of the System registers, most of which are not accessible from EL0, and the system level view of the programmers' model and the memory model. This part includes the description of self-hosted debug.

Part E Describes the Debug architecture for external debug. This provides configuration, breakpoint and watchpoint support, and a *Debug Communications Channel* (DCC) to a debug host.

Part F Describes additional features of the architecture that are not closely coupled to a PE, and therefore are accessed through memory-mapped interfaces. Some of these features are OPTIONAL.

Part G Provides pseudocode that describes various features of the Arm architecture.

Part H, Appendixes

Provide additional information.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Glossary Defines terms used in this Manual that have a specialized meaning.

Note

Terms that are generally well understood in the microelectronics industry are not included in the Glossary.

Using this Manual

The information in this Manual is organized into parts, as described in this section.

Part A, Introduction and Architecture Overview

Part A gives an overview of the Armv8-R for AArch64 architecture profile, including its relationship to the other Arm PE architectures. It introduces the terminology used to describe the architecture.

It contains the following chapters:

Introduction to the Arm Architecture

Read this for an introduction to the Arm architecture.

R-profile Architecture Extensions

Read this for an introduction to the R-profile architecture extensions and features.

Part B, The AArch64 Application Level Architecture

Part B describes the AArch64 state application level view of the architecture. It contains the following chapters:

The AArch64 Application Level Programmers' Model

Read this for an application level description of the programmers' model for software executing in AArch64 state. It describes execution at EL0 when EL0 is using AArch64 state.

The AArch64 Application Level Memory Model

Read this for an application level description of the memory model for software executing in AArch64 state. It describes the memory model for execution in EL0 when EL0 is using AArch64 state. It includes information about Arm memory types, attributes, and memory access controls.

Part C, The A64 Instruction Set

Part C describes the A64 instruction set, which is used in AArch64 state. It contains the following chapters:

The A64 Instruction Set

Read this for a description of the A64 instruction set and common instruction operation details.

About the A64 Instruction Descriptions

Read this to understand the format of the A64 instruction descriptions.

A64 Instruction Set Overview

Read this for an overview of the A64 instructions.

A64 Instruction Set Encoding

Read this for a description of the A64 instruction set encoding.

The A64 System Instruction Class

Read this for a description of the AArch64 System instructions and register descriptions, and the System instruction class encoding space.

A64 Base Instruction Descriptions

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Read this for information on key aspects of the A64 base instructions and for descriptions of the individual instructions, which are listed in alphabetical order.

A64 Advanced SIMD and Floating-point Instruction Descriptions

Read this for information on key aspects of the A64 Advanced SIMD and floating-point instructions and for descriptions of the individual instructions, which are listed in alphabetical order.

Part D, The AArch64 System Level Architecture

Part D describes the AArch64 state system level view of the architecture. It contains the following chapters:

The AArch64 System Level Programmers' Model

Read this for a description of the AArch64 state system level view of the programmers' model.

AArch64 Self-hosted Debug

Read this for an introduction to, and a description of, self-hosted debug in AArch64 state.

AArch64 Self-hosted Trace

Read this for an introduction to, and a description of, self-hosted trace in AArch64 state.

The AArch64 System Level Memory Model

Read this for a description of the AArch64 state system level view of the general features of the memory system.

The AArch64 Virtual Memory System Architecture

Read this for a system level view of the AArch64 *Virtual Memory System Architecture* (VMSA), the memory system architecture of an R-profile architecture implementation executing in AArch64 state.

The AArch64 Protected Memory System Architecture

Read this for a system level view of the AArch64 *Protected Memory System Architecture* (PMSA), the memory system architecture of an R-profile architecture implementation executing in AArch64 state.

The Generic Timer in AArch64 state

Read this for a description of the AArch64 view of the Arm Generic Timer.

The Performance Monitors Extension

Read this for a description of the Arm Performance Monitors, an optional non-invasive debug component.

RAS PE Architecture

Read this for a description of the RAS Extension PE architecture.

AArch64 System Register Encoding

Read this for a description of the encoding of the AArch64 System registers, and the other uses of the AArch64 System registers encoding space.

AArch64 System Register Descriptions

Read this for an introduction to, and description of, each of the AArch64 System registers.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Part E, External Debug

Part E describes the architecture for external debug. It contains the following chapters:

About External Debug

Read this for an introduction to external debug, and a definition of the scope of this part of the Manual.

Debug State

Read this for a description of Debug state, which the PE might enter as the result of a Halting debug event.

Halting Debug Events

Read this for a description of the external debug events referred to as Halting debug events.

The Debug Communication Channel and Instruction Transfer Register

Read this for a description of the communication between a debugger and the PE debug logic using the Debug Communications Channel and the Instruction Transfer register.

The Embedded Cross-Trigger Interface

Read this for a description of the Embedded Cross-Trigger Interface.

Debug Reset and Powerdown Support

Read this for a description of reset and powerdown support in the Debug architecture.

The PC Sample-based Profiling Extension

Read this for a description of the PC Sample-based Profiling Extension that is an OPTIONAL extension to an Armv8 or Armv9 implementation.

About the External Debug Registers

Read this for some additional information about the external debug registers.

External Debug Register Descriptions

Read this for a description of each external debug register.

Part F, Memory-mapped Components of the Arm architecture

Part F describes the memory-mapped components in the architecture. It contains the following chapters:

Requirements for Memory-mapped Components

Read this for descriptions of some general requirements for memory-mapped components within a system that complies with the Arm architecture.

System Level Implementation of the Generic Timer

Read this for a definition of a system level implementation of the Generic Timer.

Recommended External Interface to the Performance Monitors

Read this for a description of the recommended memory-mapped and external debug interfaces to the Performance Monitors.

External System Control Register Descriptions

Read this for a description of each memory-mapped system control register.

Part G, Architectural Pseudocode

Part G contains pseudocode that describes various features of the Arm architecture. It contains the following chapter:

R-profile Architecture Pseudocode

Read this for the pseudocode definitions that describe various features of the Arm architecture, for operation in AArch64 state.

Part H, Appendixes

Note

Some of the descriptions in the following appendixes are not part of the Arm architecture specification. They are included here as supplementary information, for the convenience of developers and users who might require this information.

This Manual contains the following appendixes:

Architectural Constraints on UNPREDICTABLE Behaviors

Read this for a description of the architecturally-required constraints on UNPREDICTABLE behaviors in the Arm architecture.

Arm Pseudocode Definition

Read this for definitions of the Arm pseudocode.

Registers Index

Read this for an alphabetic and functional index of AArch64 registers, and memory-mapped registers.

Glossary

Defines terms used in this Manual that have a specialized meaning.

Note

Terms that are well understood in the microelectronics industry are not included in the Glossary.

Conventions

The following sections describe conventions that this book can use:

- Typographic conventions.
- Rules-based writing.
- Signals.
- Numbers.
- Pseudocode descriptions.
- Assembler syntax descriptions.

Typographic conventions

The typographical conventions are:

italic Introduces special terminology, and denotes citations.

bold Denotes signal names, and is used for terms in descriptive lists, where appropriate.

`monospace` Used for assembler syntax descriptions, pseudocode, and source code examples.

Also used in the main text for instruction mnemonics and for references to other items appearing in assembler syntax descriptions, pseudocode, and source code examples.

SMALL CAPITALS

Used in body text for a few terms that have specific technical meanings, and are defined in the Glossary.

Colored text Indicates a link. This can be:

- A URL, for example https://developer.arm.com.
- A cross-reference that includes the page number of the referenced information if it is not on the current page, for example, Assembler syntax descriptions.
- A link, to a chapter or appendix, or to a glossary entry, or to the section of the Manual that defines the colored term, for example Simple sequential execution or SCTLR.

{ and } Braces, { and }, have two distinct uses:

Optional items

In syntax descriptions braces enclose optional items. In the following example they indicate that the `<shift>`parameter is optional:

```
ADD <Wd|WSP>, <Wn|WSP>, #<imm>{, <shift>}
```

Similarly, they can be used in generalized field descriptions, for example TCR_ELx.{I}PS refers to a field in the TCR_ELx registers that is called either IPS or PS.

Sets of items

Braces can be used to enclose sets. For example, HCR_EL2.{E2H, TGE} refers to a set of two register fields, HCR_EL2.E2H and HCR_EL2.TGE.

Notes Notes are formatted as:

Note

This is a Note.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

In this Manual, Notes are used only to provide additional information, usually to help understanding of the text. While a Note might repeat architectural information given elsewhere in the Manual, a Note never provides any part of the definition of the architecture.

Rules-based writing

Some sections of this Manual use rules-based writing. Rules-based writing consists of a set of individual content items. A content item is classified as one of the following:

- Rule.
- Information.
- Software usage.
- Declaration.

Rules are normative statements. An implementation that is compliant with this specification must conform to all Rules in this Manual that apply to that implementation.

Rules must not be read in isolation. Where a particular feature is specified by multiple Rules, these are generally grouped into sections and subsections that provide context. Where appropriate, these sections begin with a short introduction.

Arm strongly recommends that implementers read all chapters and sections of this Manual to ensure that an implementation is compliant.

Content items other than Rules are informative statements. These are provided as an aid to understanding this Manual.

Content item identifiers

A content item may have an associated identifier which is unique among content items in this Manual. After content reaches beta status, a given content item has the same identifier across subsequent versions of this Manual.

Content item rendering

In this Manual, a content item is rendered with a token of the following format in the left margin: L_{iiii}. L is a label that indicates the content class of the content item. iiii is the identifier of the content item.

Content item classes

Each of the content item classes has a different function in this Manual.

Rule

A Rule is a statement that describes the behavior of a compliant implementation.

A Rule explains what happens in a particular situation.

A Rule does not define concepts or terminology.

A Rule is rendered with the label R.

Information

An Information statement provides information and guidance as an aid to understanding the Manual.

An Information statement is rendered with the label I.

Software usage

A Software usage statement provides guidance on how software can make use of the features defined by the specification.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

A Software usage statement is rendered with the label S.

Declaration

A Declaration statement introduces concepts or terminology.

A Declaration does not describe behavior.

A Declaration is rendered with the label D.

Signals

In general this specification does not define hardware signals, but it does include some signal examples and recommendations. The signal conventions are:

Signal level The level of an asserted signal depends on whether the signal is active-HIGH or active-LOW. Asserted means:

- HIGH for active-HIGH signals.
- LOW for active-LOW signals.

Lowercase n At the start or end of a signal name denotes an active-LOW signal.

Numbers

Numbers are normally written in decimal. Binary numbers are preceded by `0b`, and hexadecimal numbers by `0x`. In both cases, the prefix and the associated value are written in a `monospace` font, for example `0xFFFF_0000`. To improve readability, long numbers can be written with an underscore separator between every four characters, for example `0xFFFF_0000_0000_0000`. Ignore any underscores when interpreting the value of a number.

Pseudocode descriptions

This Manual uses a form of pseudocode to provide precise descriptions of the specified functionality. This pseudocode is written in `monospace` font, and is described in Arm Pseudocode Definition.

Assembler syntax descriptions

This Manual contains numerous syntax descriptions for assembler instructions and for components of assembler instructions. These are shown in a `monospace` font, and use the conventions described in Structure of the A64 assembler language, and Arm Pseudocode Definition.

Feedback

Arm welcomes feedback on its documentation.

Feedback on this Manual

If you have any comments or queries about this Manual, create a ticket at https://support.developer.arm.com.

As part of the ticket, include:

- The title, Arm® Architecture Reference Manual, for R-profile AArch64 architecture.
- The number, DDI 0628 A.a.
- The section name to which your comments refer.
- The page number(s) to which your comments refer.
- The rule identifier(s) to which your comments refer, if applicable.
- A concise explanation of your comments.

Arm also welcomes general suggestions for additions and improvements.

Note

Arm tests PDFs only in Adobe Acrobat and Acrobat Reader, and cannot guarantee the appearance or behavior of any document when viewed with any other PDF reader. Search performance may be significantly improved by increasing the Fast Find Maximum Cache Size under Search in Preferences.
If using Google Chrome™ or Microsoft Edge™, load time is significantly improved since the April 2025 release of these browsers.
Users may find, on some systems, that PDF viewers such as Okular or Foxit™ give good performance.

Inclusive terminology commitment

Arm values inclusive communities. Arm recognizes that we and our industry have used terms that can be offensive. Arm strives to lead the industry and create change.

Previous issues of this document included language that can be offensive. We have replaced this language. To report offensive language in this document, email `terms@arm.com`.

Chapter A1
Introduction to the Arm Architecture

This chapter introduces the Arm architecture. It contains the following sections:

- About the Arm architecture.
- Architecture profiles.
- Arm architectural concepts.
- Supported data types.
- Floating-point support.
- The Arm memory model.
- Reliability, Availability, and Serviceability.

A1.1 About the Arm architecture

The Arm architecture described in this Architecture Reference Manual defines the behavior of an abstract machine, referred to as a *processing element*, often abbreviated to *PE*. Implementations compliant with the Arm architecture must conform to the described behavior of the processing element. It is not intended to describe how to build an implementation of the PE, nor to limit the scope of such implementations beyond the defined behaviors.

Except where the architecture specifies differently, the programmer-visible behavior of an implementation that is compliant with the Arm architecture must be the same as a simple sequential execution of the program on the processing element. The programmer-visible behavior does not include a specified execution time for any instruction but requires each instruction to execute in finite time, as long as another observer is not continually modifying any Location associated with a Memory Effect, other than an Explicit Memory Effect, that is architecturally required for execution of the instruction. In cases where another observer is continually modifying a Location associated with a Memory Effect, other than an Explicit Memory Effect, at least one of the observers must make forward progress in finite time. Unless otherwise specified, the architecturally defined effects of each instruction also complete in finite time.

The Arm Architecture Reference Manual also describes rules for software to use the PE.

The Arm architecture includes definitions of:

- An associated debug architecture, see:
  - AArch64 Self-hosted Debug.
  - AArch32 Self-hosted Debug, AArch32 state is not described in this Manual.
  - External Debug.
- Associated trace architectures that define trace units that implementers can implement with the associated processor hardware. For more information, see:
  - The *Arm® Embedded Trace Macrocell Architecture Specification, ETMv4* (ARM IHI 0064).
  - AArch64 Self-hosted Trace.

Arm also provides system architecture specifications for systems aimed at particular product categories, such as servers, or personal computers, *Arm® Server Base System Architecture* (ARM DEN 0029) and *Arm® Base System Architecture* (ARM DEN 0094). These specifications build on the architecture specification in this Manual, restricting, as defined in those specifications, some of the optional and IMPLEMENTATION DEFINED features defined in this specification, as well as specifying additional features applicable at the system level.

The Arm architecture is a *Reduced Instruction Set Computer* (RISC) architecture with the following RISC architecture features:

- A large uniform register file.
- A *load/store* architecture, where data-processing operations only operate on register contents, not directly on memory contents.
- Simple addressing modes, with all load/store addresses determined from register contents and instruction fields only.

The architecture defines the interaction of the PE with memory, including caches, and includes a memory translation system. It also describes how multiple PEs interact with each other and with other observers in a system.

This document defines version 8of the R-profile architecture.

See Architecture profiles for more information.

The Arm architecture supports implementations across a wide range of performance points. Implementation size, performance, and very low power consumption are key attributes of the Arm architecture.

An important feature of the Arm architecture is backward compatibility, combined with the freedom for optimal implementation in a wide range of standard and more specialized use cases.

Features that are optional are explicitly defined as such in this Manual.

Note

The presence of an ID register field for a feature does not imply that the feature is optional.

Both Execution states support floating-point instructions:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- AArch64 state provides:
  - Advanced SIMD instructions that operate on registers in the SIMD&FP register file.
  - Scalar floating-point instructions that operate on registers in the SIMD&FP register file.

    Note

    The A64 instruction set does not include SIMD instructions that operate on the general-purpose registers, therefore, some AArch64 instructions descriptions use SIMD as a synonym for Advanced SIMD.

Note

See Conventions for information about conventions used in this Manual, including the use of SMALL CAPITALS for particular terms that have Arm-specific meanings that are defined in the Glossary.

A1.2 Architecture profiles

The Arm architecture has evolved significantly since its introduction, and Arm continues to develop it. Nine major versions of the architecture have been defined to date, denoted by the version numbers 1 to 9. Of these, the first three versions are now obsolete.

The generic names AArch64 and AArch32 describe the 64-bit and 32-bit Execution states:

AArch64 Is the 64-bit Execution state, meaning addresses are held in 64-bit registers, and instructions in the base instruction set can use 64-bit registers for their processing. AArch64 state supports the A64 instruction set.

AArch32 Is the 32-bit Execution state, meaning addresses are held in 32-bit registers, and instructions in the base instruction sets use 32-bit registers for their processing. AArch32 state supports the T32 and A32 instruction sets. AArch32 is not described in this Manual.

Note

The *Base instruction set* comprises the supported instructions other than the floating-point instructions.

See sections Execution state and The instruction sets for more information.

Arm defines three architecture profiles:

A Application profile, described in this Manual:

- Supports a *Virtual Memory System Architecture* (VMSA) based on a *Memory Management Unit* (MMU).

  Note

  An Armv8-A implementation can be called an AArchv8-A implementation and an Armv9-A implementation can be called an AArchv9-A implementation.

- Supports the A64, A32, and T32 instruction sets. The T32 and A32 instruction sets are not described in this Manual.

R Real-time profile:

- Supports a *Protected Memory System Architecture* (PMSA) based on a *Memory Protection Unit* (MPU).
- Supports an optional VMSA based on an MMU.
- Supports the A64, or the A32 and T32 instruction sets.

M Microcontroller profile:

- Implements a programmers' model designed for low-latency interrupt processing, with hardware stacking of registers and support for writing interrupt handlers in high-level languages.
- Supports a PMSA based on an MPU.
- Supports a variant of the T32 instruction set.

This Manual describes only Armv8-R AArch64. For information about the A and M architecture profiles, and earlier Arm architecture versions, see:

- The *Arm® Architecture Reference Manual, for A-profile architecture*.
- The *ARM® Architecture Reference Manual Supplement - ARMv8, for the ARMv8-R AArch32 architecture profile.*
- The *ARM® Architecture Reference Manual ARMv7-A and ARMv7-R edition*.
- The *Armv8-M Architecture Reference Manual*.
- The *Armv7-M Architecture Reference Manual*.
- The *ARMv6-M Architecture Reference Manual*.

A1.3 Arm architectural concepts

This section introduces architectural concepts and the associated terminology.

The following subsections describe key architectural concepts. Each section introduces the corresponding terms that are used to describe the architecture:

- Execution state.
- The instruction sets.
- System registers.
- Arm Debug.

A1.3.1 Execution state

The Execution state defines the PE execution environment, including:

- The supported register widths.
- The supported instruction sets.
- Significant aspects of:
  - The Exception model.
  - The *Virtual Memory System Architecture* (VMSA).
  - The programmers' model.

The Execution states are:

AArch64 The 64-bit Execution state. This Execution state:

- Provides 31 64-bit general-purpose registers, of which X30 is used as the procedure link register.
- Provides a 64-bit *Program Counter* (PC), *stack pointers* (SPs), and *Exception Link Registers* (ELRs).
- Provides 32 128-bit registers for Advanced SIMD vector and scalar floating-point support.
- Provides a single instruction set, A64. For more information, see The instruction sets.
- Defines the Armv8 Exception model, with three Exception levels, EL0 to EL2 that provide an *execution privilege* hierarchy, see Exception levels.
- Provides support for 64-bit *virtual addressing*. For more information, including the limits on address ranges, see The AArch64 Virtual Memory System Architecture.
- Defines a number of *Process state* (PSTATE) elements that hold PE state. The A64 instruction set includes instructions that operate directly on various PSTATE elements.
- Names each System register using a suffix that indicates the lowest Exception level at which the register can be accessed.

AArch32 AArch32 state is not described in this Manual.

A1.3.2 The instruction sets

The possible instruction sets depend on the Execution state:

AArch64 AArch64 state supports a single instruction set, called A64. This is a fixed-length instruction set that uses 32-bit instruction encodings.

For information on the A64 instruction set, see A64 Instruction Set Overview.

The instruction sets support SIMD and scalar floating-point instructions. See Floating-point support.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

A1.3.3 System registers

System registers provide control and status information of architected features.

The System registers use a standard naming format: <register_name>.<bit_field_name> to identify specific registers as well as control and status bits within a register.

Bits can also be described by their numerical position in the form <register_name>[x:y] or the generic form bits[x:y].

In addition, in AArch64 state, most register names include the lowest Exception level that can access the register as a suffix to the register name:

- <register_name>_ELx, where x is 0, 1, or 2.

For information about Exception levels, see Exception levels.

The System registers comprise:

- The following registers that are described in this Manual:
  - General system control registers.
  - Debug registers.
  - RAS registers.
  - Generic Timer registers.
  - Optionally, Performance Monitor registers.
- Optionally, one or more of the following groups of registers that are defined in other Arm architecture specifications:
  - Trace System registers, as defined in the *Arm® Embedded Trace Macrocell Architecture Specification, ETMv4*.
  - *Generic Interrupt Controller* (GIC) System registers, see The Arm Generic Interrupt Controller System registers.

For information about the AArch64 System registers, see AArch64 System Register Descriptions.

A1.3.3.1 The Arm Generic Interrupt Controller System registers

From version 3 of the Arm Generic Interrupt Controller architecture, GICv3, the GIC architecture specification defines a System register interface to some of its functionality. The System register summaries in this Manual include these registers, see:

- About the GIC System registers, for more information about the AArch64 GIC System registers.

These sections give only short overviews of the GIC System registers. For more information, including descriptions of the registers, see the *ARM® Generic Interrupt Controller Architecture Specification, GIC architecture version 3.0 and version 4.0* (ARM IHI 0069).

Note

The programmers' model for earlier versions of the GIC architecture is wholly memory-mapped.

A1.3.4 Arm Debug

Armv8 and later architectures support the following:

Self-hosted debug

In this model, the PE generates *debug exceptions*. Debug exceptions are part of the Armv8 Exception model.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

External debug

In this model, *debug events* cause the PE to enter *Debug state*. In Debug state, the PE is controlled by an external debugger.

All Armv8 and later implementations support both models. The model chosen by a particular user depends on the debug requirements during different stages of the design and development life cycle of the product. For example, external debug might be used during debugging of the hardware implementation and OS bring-up, and self-hosted debug might be used during application development.

For more information about self-hosted debug:

- In AArch64 state, see AArch64 Self-hosted Debug.

For more information about external debug, see External Debug.

A1.4 Supported data types

The Arm architecture supports the following integer data types:

Byte 8 bits.

Halfword 16 bits.

Word 32 bits.

Doubleword 64 bits.

Quadword 128 bits.

The architecture also supports the following floating-point data types:

- Half-precision. See Half-precision floating-point formats.
- Single-precision. See Single-precision floating-point format.
- Double-precision. See Double-precision floating-point format.

It also supports vectors, where a register holds a vector of multiple elements, each the same size and data type. See Advanced SIMD vector formats

The architecture provides the following:

- A general-purpose register file.
- A SIMD&FP register file.

In each of these, the possible register widths depend on the Execution state.

In AArch64 state:

- The general-purpose register file contains 64-bit registers:
  - Many instructions can access these registers as 64-bit registers, or as 32-bit registers using only the bottom 32 bits.
- The SIMD&FP register file contains 128-bit registers:
  - While the AArch64 vector registers support 128-bit vectors, the effective vector length can be 64-bits or 128-bits depending on the A64 instruction encoding used, see Instruction Mnemonics.

For more information on the register files in AArch64 state, see Registers in AArch64 Execution state.

A1.4.1 Advanced SIMD vector formats

In an implementation that includes the Advanced SIMD instructions that operate on the SIMD&FP register file, a register can hold one or more packed elements, all of the same size and type. In AArch64 state, the explicit combination of a register, number of elements, and element size describes a vector of elements. The vector is considered to be a one-dimensional array of elements of the data type specified in the instruction.

Vector indices are in the range 0 to (number of elements - 1). An index of 0 refers to the least significant bits of the vector.

A1.4.1.1 Advanced SIMD vector formats in AArch64 state

In AArch64 state, the SIMD&FP registers can be referred to as V*n*, where *n* is a value from 0 to 31.

The SIMD&FP registers support the following data formats for loads, stores, and data-processing operations:

- A single, scalar, element in the least significant bits of the register. See Registers in AArch64 Execution state.
- A 128-bit vector of byte, halfword, word, or doubleword elements. See Figure A1-1.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- A 64-bit vector of byte, halfword, word, or doubleword elements. See Figure A1-1.

For vectors, the element sizes are defined in Table A1-1, with the vector format described as:

- For a 128-bit vector: Vn.{2D, 4S, 8H, 16B}.
- For a 64-bit vector: Vn.{1D, 2S, 4H, 8B}.

Table A1-1 SIMD elements in AArch64 state

Mnemonic	Size
B	8 bits
H	16 bits
S	32 bits
D	64 bits

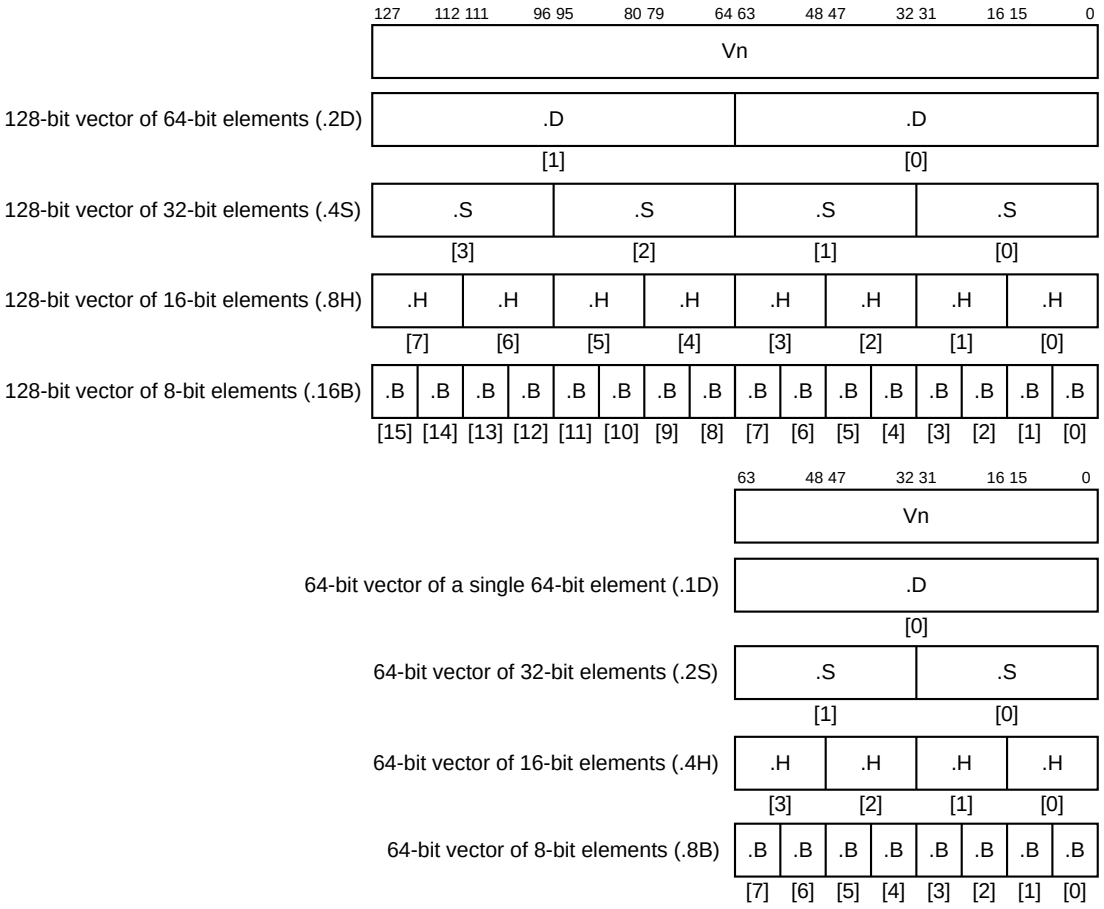

Figure A1-1 SIMD vectors in AArch64 state

A1.4.2 Half-precision floating-point formats

The Arm architecture supports two half-precision floating-point formats:

- IEEE half-precision, as described in the IEEE 754-2008 standard.

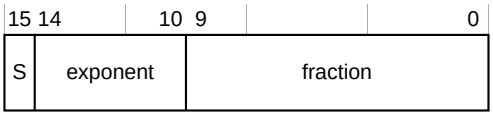
Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- Arm *alternative half-precision* format.

Both formats can be used for conversions to and from other floating-point formats. FPCR.AHP controls the format in AArch64 state. FEAT_FP16 adds half-precision data-processing instructions, which always use the IEEE format. These instructions ignore the value of the relevant AHP field, and behave as if it has an Effective value of 0.

The description of IEEE half-precision includes Arm-specific details that are left open by the standard, and is only an introduction to the formats and to the values they can contain. For more information, especially on the handling of infinities, NaNs, and signed zeros, see the IEEE 754 standard.

For both half-precision floating-point formats, the layout of the 16-bit format is the same. The format is:



The interpretation of the format depends on the value of the exponent field, bits[14:10] and on which half-precision format is being used.

0 < exponent < `0x1F`

The value is a normalized number and is equal to:

$(-1)^S \times 2^{(exponent-15)} \times (1.fraction)$

The minimum positive normalized number is 2^{-14}, or approximately 6.104×10^{-5}.

The maximum positive normalized number is $(2 - 2^{-10}) \times 2^{15}$, or 65504.

Larger normalized numbers can be expressed using the alternative format when the exponent == `0x1F`.

exponent == 0

The value is either a zero or a denormalized number, depending on the fraction bits:

fraction == 0

The value is a zero. There are two distinct zeros:

+0 when S==0.

-0 when S==1.

fraction != 0

The value is a denormalized number and is equal to:

$(-1)^S \times 2^{-14} \times (0.fraction)$

The minimum positive denormalized number is 2^{-24}, or approximately 5.960×10^{-8}.

Half-precision denormalized numbers are not flushed to zero by default. When FEAT_FP16 is implemented, the FPCR.FZ16 bit controls whether flushing denormalized numbers to zero is enabled for half-precision data-processing instructions. For details, see Flushing denormalized numbers to zero.

exponent == `0x1F`

The value depends on which half-precision format is being used:

IEEE half-precision

The value is either an infinity or a Not a Number (NaN), depending on the fraction bits:

fraction == 0

The value is an infinity. There are two distinct infinities:

+infinity When S==0. This represents all positive numbers that are too big to be represented accurately as a normalized number.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

-infinity When S==1. This represents all negative numbers with an absolute value that is too big to be represented accurately as a normalized number.

fraction != 0

The value is a NaN, and is either a *quiet NaN* or a *signaling NaN*.

The two types of NaN are distinguished by their most significant fraction bit, bit[9]:

bit[9] == 0 The NaN is a signaling NaN. The sign bit can take any value, and the remaining fraction bits can take any value except all zeros.

bit[9] == 1 The NaN is a quiet NaN. The sign bit and remaining fraction bits can take any value.

Alternative half-precision

The value is a normalized number and is equal to:

$-1^{S} \times 2^{16} \times (1.\text{fraction})$

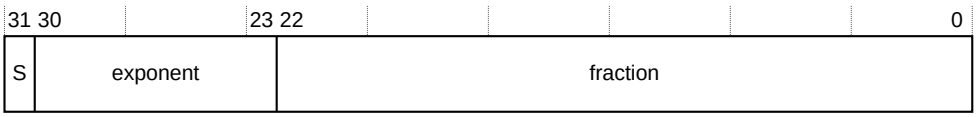
The maximum positive normalized number is $(2-2^{-10}) \times 2^{16}$ or 131008.

A1.4.3 Single-precision floating-point format

The single-precision floating-point format is as defined by the IEEE 754 standard.

This description includes Arm-specific details that are left open by the standard. It is only intended as an introduction to the formats and to the values they can contain. For full details, especially of the handling of infinities, NaNs, and signed zeros, see the IEEE 754 standard.

A single-precision value is a 32-bit word with the format:



The interpretation of the format depends on the value of the exponent field, bits[30:23]:

0 < exponent < `0xFF`

The value is a normalized number and is equal to:

$(-1)^{S} \times 2^{(\text{exponent} - 127)} \times (1.\text{fraction})$

The minimum positive normalized number is 2^{-126}, or approximately 1.175×10^{-38}.

The maximum positive normalized number is $(2 - 2^{-23}) \times 2^{127}$, or approximately 3.403×10^{38}.

exponent == 0

The value is either a zero or a denormalized number, depending on the fraction bits:

fraction == 0

The value is a zero. There are two distinct zeros:

+0 When S==0.

-0 When S==1.

These usually behave identically. In particular, the result is *equal* if +0 and -0 are compared as floating-point numbers. However, they yield different results in some circumstances. For example, the sign of the infinity produced as the result of dividing

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

by zero depends on the sign of the zero. The two zeros can be distinguished from each other by performing an integer comparison of the two words.

fraction != 0

The value is a denormalized number and is equal to:

$(-1)^S \times 2^{-126} \times (0.\text{fraction})$

The minimum positive denormalized number is 2^{-149}, or approximately 1.401×10^{-45}.

Denormalized numbers are optionally flushed to zero in floating-point processing and in Advanced SIMD processing in AArch64 state. For details, see Flushing denormalized numbers to zero.

exponent == `0xFF`

The value is either an *infinity* or a *Not a Number* (NaN), depending on the fraction bits:

fraction == 0

The value is an infinity. There are two distinct infinities:

+infinity When S==0. This represents all positive numbers that are too big to be represented accurately as a normalized number.

-infinity When S==1. This represents all negative numbers with an absolute value that is too big to be represented accurately as a normalized number.

fraction != 0

The value is a NaN, and is either a *quiet NaN* or a *signaling NaN*.

The two types of NaN are distinguished by their most significant fraction bit, bit[22]:

bit[22] == 0

The NaN is a signaling NaN. The sign bit can take any value, and the remaining fraction bits can take any value except all zeros.

bit[22] == 1

The NaN is a quiet NaN. The sign bit and remaining fraction bits can take any value.

For details of the *default NaN*, see Default NaN.

Note

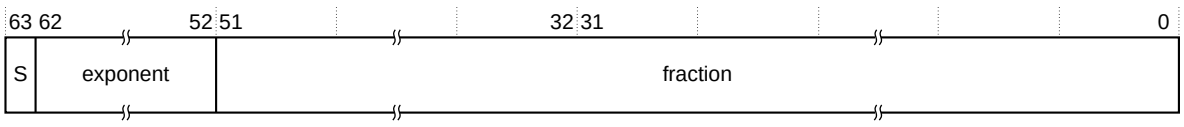
NaNs with different sign or fraction bits are distinct NaNs, but this does not mean software can use floating-point comparison instructions to distinguish them. This is because the IEEE 754 standard specifies that a NaN compares as *unordered* with everything, including itself.

A1.4.4 Double-precision floating-point format

The double-precision floating-point format is as defined by the IEEE 754 standard. Double-precision floating-point is supported by both SIMD and floating-point instructions in AArch64 state.

This description includes IMPLEMENTATION SPECIFIC details that are left open by the standard. It is only intended as an introduction to the formats and to the values they can contain. For full details, especially of the handling of infinities, nabs, and signed zeros, see the IEEE 754 standard.

A double-precision value is a 64-bit doubleword, with the format:



Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Double-precision values represent numbers, infinities, and NaNs in a similar way to single-precision values, with the interpretation of the format depending on the value of the exponent:

0 < exponent < `0x7FF`

The value is a normalized number and is equal to:

$(-1)^S \times 2^{(\text{exponent}-1023)} \times (1.\text{fraction})$

The minimum positive normalized number is 2^{-1022}, or approximately 2.225×10^{-308}.

The maximum positive normalized number is $(2 - 2^{-52}) \times 2^{1023}$, or approximately 1.798×10^{308}.

exponent == 0

The value is either a zero or a denormalized number, depending on the fraction bits:

fraction == 0

The value is a zero. There are two distinct zeros that behave in the same way as the two single-precision zeros:

+0 when S==0.

-0 when S==1.

fraction != 0

The value is a denormalized number and is equal to:

$(-1)^S \times 2^{-1022} \times (0.\text{fraction})$

The minimum positive denormalized number is 2^{-1074}, or approximately 4.941×10^{-324}.

Optionally, denormalized numbers are flushed to zero in floating-point calculations. For details, see Flushing denormalized numbers to zero.

exponent == `0x7FF`

The value is either an infinity or a NaN, depending on the fraction bits:

fraction == 0

The value is an infinity. As for single-precision, there are two infinities:

+infinity When S==0.

-infinity When S==1.

fraction != 0

The value is a NaN, and is either a *quiet NaN* or a *signaling NaN*.

The two types of NaN are distinguished by their most significant fraction bit, bit[51] of the doubleword:

bit[51] == 0

The NaN is a signaling NaN. The sign bit can take any value, and the remaining fraction bits can take any value except all zeros.

bit[51] == 1

The NaN is a quiet NaN. The sign bit and the remaining fraction bits can take any value.

For details of the *default NaN*, see Default NaN.

Note

NaNs with different sign or fraction bits are distinct NaNs, but this does not mean software can use floating-point comparison instructions to distinguish them. This is because the IEEE 754 standard specifies that a NaN compares as *unordered* with everything, including itself.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

A1.4.5 Conversion between floating-point and fixed-point values

The Arm architecture supports the conversion of a scalar floating-point value to or from a signed or unsigned fixed-point value in a general-purpose register. Conversion instructions take an argument, #fbits, that specifies the number of fraction bits in the fixed-point number. That is, #fbits indicates that the general-purpose register holds a fixed-point number with fbits bits after the binary point, where fbits is in the range 1 to 64 for a 64-bit general-purpose register, or 1 to 32 for a 32-bit general-purpose register:

- For a 64-bit register X_d:
  - The integer part is $X_d[63:\#fbits]$.
  - The fractional part is $X_d[(\#fbits-1):0]$.
- For a 32-bit register W_d or R_d:
  - The integer part is $W_d[31:\#fbits]$ or $R_d[31:\#fbits]$.
  - The fractional part is $W_d[(\#fbits-1):0]$ or $R_d[(\#fbits-1):0]$.

These instructions can cause the following floating-point exceptions:

Invalid Operation When the floating-point input is NaN or Infinity or when a numerical value cannot be represented within the destination register.

Inexact When the numeric result differs from the input value.

Input Denormal When flushing denormalized numbers to zero is enabled and the denormal input is replaced by a zero, see Flushing denormalized numbers to zero and Input Denormal exceptions.

Note

An out of range fixed-point result is saturated to the destination size.

For more information, see Floating-point exceptions and exception traps.

A1.4.6 Polynomial arithmetic over {0, 1}

Some SIMD instructions that operate on SIMD&FP registers can operate on polynomials over {0, 1}, see Supported data types. The polynomial data type represents a polynomial in x of the form $b_{n-1}x^{n-1} + \ldots + b_1x + b_0$ where b_k is bit[k] of the value.

The coefficients 0 and 1 are manipulated using the rules of Boolean arithmetic:

- $0 + 0 = 1 + 1 = 0$.
- $0 + 1 = 1 + 0 = 1$.
- $0 \times 0 = 0 \times 1 = 1 \times 0 = 0$.
- $1 \times 1 = 1$.

That is:

- Adding two polynomials over {0, 1} is the same as a bitwise exclusive-OR.
- Multiplying two polynomials over {0, 1} is the same as integer multiplication except that partial products are exclusive-ORed instead of being added.

A64 provides instructions for performing polynomial multiplication of 8-bit values, see PMUL and PMULL, PMULL2.

The Cryptographic Extension adds the ability to perform long polynomial multiplies of 64-bit values. See PMULL, PMULL2.

Non-Confidential

A1.4.6.1 Pseudocode description of polynomial multiplication

In pseudocode, polynomial addition is described by the EOR operation on bitstrings.

Polynomial multiplication is described by the `PolynomialMult()` function defined in R-profile Architecture Pseudocode.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

A1.5 Floating-point support

The architecture includes the following types of floating-point instructions:

- Scalar floating-point instructions that operate on the lowest numbered element of the SIMD&FP registers.
- Advanced SIMD floating-point instructions that operate on multiple elements of the SIMD&FP registers.

The architecture can provide the following levels of floating-point support:

- No floating-point support. This option is licensed only for implementations targeting specialized markets.
- Advanced SIMD and floating-point support.

The architecture supports the following floating-point formats:

Table A1-2 Floating-point formats

	AArch64 state
IEEE 754 half-precision	Conversion instructions to and from IEEE 754 half-precision.
	Supported for data processing if FEAT_FP16 is implemented.
Arm *alternative half-precision*	Conversion instructions to and from non-IEEE 754 Arm alternative half-precision.
IEEE 754 single-precision	Supported for scalar and vector data processing.
IEEE 754 double-precision	Supported for scalar and vector data processing.

For many floating-point instructions, there are configurable behaviors, such as:

- Configurable rounding modes. See Rounding.
- Configurable trapping of floating-point exceptions. See Floating-point exceptions and exception traps.
- Configurable non-IEEE 754 *Default NaN* behavior. See NaN handling and the Default NaN.
- Configurable non-IEEE 754 flushing to zero of denormalized numbers. See Flushing denormalized numbers to zero.

If floating-point exception trapping is supported, then unless stated otherwise, when a floating-point exception is not trapped, that exception causes a cumulative status register bit to be set to 1 and the operation produces a default result. For more information, see Floating-point exceptions and exception traps.

In AArch64 state, the Floating-point Control Register, FPCR, controls floating-point operation, and the Floating-point Status Register, FPSR, returns floating-point status information.

In AArch64 state, the PSTATE.{N,Z,C,V} condition flags are updated by floating-point comparison operations.

The remainder of this section contains:

- Instruction support.
- Floating-point standards, and terminology.
- Arm standard floating-point input and output values.
- Flushing denormalized numbers to zero.
- NaN handling and the Default NaN
- Rounding

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- Floating-point exceptions and exception traps

A1.5.1 Instruction support

The floating-point instructions support:

- Load and store for single elements and vectors of multiple elements.

  Note
  Single elements are also referred to as scalar elements.

- Data processing on single and multiple elements.
- Complex number arithmetic.
- Floating-point conversion between different levels of precision.
- Conversion between floating-point and integer types.
- Floating-point rounding.
- Atomic floating-point in-memory operations.

For more information on floating-point instructions in AArch64 state, see A64 Instruction Set Overview.

A1.5.2 Floating-point standards, and terminology

The Arm architecture includes support for all the required features of ANSI/IEEE Std 754-2008, *IEEE Standard for Binary Floating-Point Arithmetic*, referred to as IEEE 754-2008. However, some terms in this Manual are based on the 1985 version of this standard, referred to as IEEE 754-1985:

- Arm floating-point terminology generally uses the IEEE 754-1985 terms. This section summarizes how IEEE 754-2008 changes these terms.
- References to IEEE 754 that do not include the issue year apply to either issue of the standard.

Table A1-3 shows how the terminology in this Manual differs from that used in IEEE 754-2008.

Table A1-3 Floating-point terminology

This manual	IEEE 754-2008
Normalized[a]	Normal
Denormal, or denormalized	Subnormal
Round towards Minus Infinity (RM)	roundTowardsNegative
Round towards Plus Infinity (RP)	roundTowardsPositive
Round towards Zero (RZ)	roundTowardZero
Round to Nearest (RN)	roundTiesToEven
Round to Nearest with Ties to Away	roundTiesToAway
Rounding mode	Rounding-direction attribute

a. *Normalized number* is used in preference to *normal number*, because of the other specific uses of *normal* in this Manual.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

A1.5.3 Arm standard floating-point input and output values

The Arm architecture provides full IEEE 754 floating-point arithmetic support.

Arm standard floating-point arithmetic supports the following input formats defined by the IEEE 754 floating-point standard:

- Zeros.
- Normalized numbers.
- Denormalized numbers are flushed to 0 before floating-point operations, see Flushing denormalized numbers to zero.
- NaNs.
- Infinities.

Arm standard floating-point arithmetic supports the Round to Nearest (roundTiesToEven) rounding mode defined by the IEEE 754 standard.

Arm standard floating-point arithmetic supports the following output result formats defined by the IEEE 754 standard:

- Zeros.
- Normalized numbers.
- Results with an absolute value less than the minimum normalized number are flushed to zero, see Flushing denormalized numbers to zero.
- NaNs produced in floating-point operations are always the default NaN, see Default NaN.
- Infinities.

Note

AArch64 Advanced SIMD floating-point arithmetic is performed using the rounding mode selected by the FPCR.

A1.5.4 Flushing denormalized numbers to zero

Calculations involving denormalized numbers and Underflow exceptions can reduce the performance of floating-point processing. For many algorithms, replacing the denormalized operands and intermediate results with zeros can recover this performance, without significantly affecting the accuracy of the final result. Arm floating-point implementations allow denormalized numbers to be flushed to zero to permit this optimization.

If a number `value` satisfies the condition `0 < Abs(value) < MinNorm`, it is treated as a denormalized number.

`MinNorm` is defined as follows:

- For OFP8 E4M3 numbers, `MinNorm` is 2^{-6}.
- For half-precision and OFP8 E5M2 numbers, `MinNorm` is 2^{-14}.
- For single-precision and BFloat16 numbers, `MinNorm` is 2^{-126}.
- For double-precision numbers, `MinNorm` is 2^{-1022}.

Flushing denormals to zero is incompatible with the IEEE 754 standard, and must not be used when IEEE 754 compatibility is a requirement. Enabling flushing of denormals to zero must be done with care. Although it can improve performance on some algorithms, there are significant limitations on its use. These are application-dependent:

- On many algorithms, it has no noticeable effect, because the algorithm does not usually process denormalized numbers.
- On other algorithms, it can cause exceptions to occur and can seriously reduce the accuracy of the results of the algorithm.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

A1.5.4.1 Flushing denormalized inputs to zero

If flushing denormalized inputs to zero is enabled for an instruction and a data type, and an input to that instruction is a denormalized number of that data type, the input operand is flushed to zero, and its sign bit is not changed.

If a floating-point operation has a denormalized input that is flushed to zero, for all purposes within the instruction other than calculating Input Denormal floating-point exceptions, all inputs that are denormalized numbers are treated as though they were zero with the same sign as the input.

For floating-point instructions, if the instruction processes half-precision inputs, flushing denormalized inputs to zero can be controlled as follows:

- If FPCR.FZ16 == 0, denormalized half-precision inputs are not flushed to zero.
- If FPCR.FZ16 == 1:
  - Denormalized half-precision inputs to data processing instructions are flushed to zero.
  - Denormalized half-precision inputs to convert instructions are not flushed to zero.

If FPCR.FZ == 0, for all inputs other than half-precision, FPCR.FZ does not cause denormalized inputs to be flushed to zero, although other factors might cause denormalized inputs to be flushed to zero.

A1.5.4.2 Flushing denormalized outputs to zero

If a denormalized output is flushed to zero, the output is returned as zero with the same sign bit as the denormalized output value.

If FPCR.FZ == 0, then unless otherwise specified, for all outputs other than half-precision, FPCR.FZ does not cause denormalized outputs to be flushed to zero, although other factors might cause denormalized outputs to be flushed to zero.

If FPCR.FZ == 1, for all outputs other than half-precision, for floating-point instructions other than `FABS`, `FNEG`, `FMAX`, `FMAXP`, `FMAXV`, `FMIN`, `FMINP`, `FMINV`, `BFMIN`, and `BFMAX`, denormalized outputs are flushed to zero.

If FPCR.FZ16 == 0, denormalized half-precision outputs are not flushed to zero.

If FPCR.FZ16 == 1, for floating-point instructions other than `FABS`, `FNEG`, `FMAX`, `FMAXP`, `FMAXV`, `FMIN`, `FMINP`, `FMINV`, `BFMIN`, and `BFMAX`, denormalized half-precision outputs are flushed to zero.

A1.5.5 NaN handling and the Default NaN

The IEEE 754 standard defines a NaN as a number with all exponent bits set to 1 and a nonzero number in the mantissa, and specifies that the sign bit of a NaN has no significance.

The Arm architecture additionally defines the following in Table A1-4:

- A *Default NaN*, compliant with the IEEE 754 standard.
- A BFloat16 NaN, that follows the encoding in BFloat16 floating-point format.
- OFP8 NaN, that follow the encodings in FP8 floating-point formats.

For a quiet NaN output derived from a signaling NaN operand, the most significant fraction bit is set to 1.

A PE is forbidden to generate a NaN whose value is strongly correlated to the values of non-NaN inputs as a speculative result of a floating-point calculation not involving NaN inputs.

A1.5.5.1 Default NaN

A Default NaN is encoded as described in Table A1-4.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Table A1-4 Default NaN encodings

	Half-precision, IEEE Format	Single-precision	Double-precision	BFloat16	OFP8 E4M3	OFP8 E5M2
Exponent	`0x1F`	`0xFF`	`0x7FF`	`0xFF`	`0xF`	`0x1F`
Fraction	Bit[9] == '1', bits[8:0] == 0	Bit[22] == '1', bits[21:0] == 0	Bit[51] == '1', bits[50:0] == 0	Bit[6] == '1', bits[5:0] == 0	Bits[2:0] == '111'	Bit[1] == '1', bit[0] == '0'

When FPCR.DN == 1, if any input to a floating-point operation is a NaN, the output is a Default NaN.

Floating-point instructions that detect an Invalid Operation condition for a reason other than one of its inputs being a NaN, produce a Default NaN as the result.

A1.5.5.2 NaN handling

The IEEE 754 standard does not specify which input NaN is used as the output NaN. Therefore, where the Arm architecture specifies which input NaN to use, this is an addition to the requirements in the IEEE 754 standard.

Depending on the operation, the exact value of a derived quiet NaN output might have both a different sign and different fraction bits from its source. See individual instruction descriptions for details.

A1.5.5.3 NaN propagation

For NaN propagation rules for:

- BFDOT and BFMMLA, see BFloat16 behaviors for instructions that compute sum-of-products.
- FP8 instructions, see Summary of FP8 instruction behaviors.

Otherwise, behavior is as described in this section.

If an output NaN is derived from one of the operands, how the input NaN propagates to the output depends on the instruction and the number of operands.

If an output NaN is derived from an input NaN and if the size of the output format is the same as the input format, then all of the following apply:

- If the input NaN is a quiet NaN, the output NaN is derived from the input NaN.
- If the input NaN is a signaling NaN, the output NaN is derived as follows:
  - If the handling of a signaling NaN by the instruction detects an Invalid Operation condition, the output NaN is derived from a quietened version of the input NaN.
  - If the handling of a signaling NaN by the instruction does not detect an Invalid Operation condition, the output NaN is derived from the input NaN.

If an output NaN is derived from an input NaN and if the size of the output format is larger than the input format, all of the following apply:

- If the input NaN is a quiet NaN, the output NaN is the same as the input NaN except that the mantissa is zero-extended in the low-order bit to fit the output format, and the exponent field is set to all ones.
- If the input NaN is a signaling NaN, the output NaN is the quieted version of the input NaN, except that the mantissa is zero-extended in the low-order bits and the exponent field is set to all ones.

If an output NaN is derived from an input NaN and if the size of the output format is smaller than the input format, all of the following apply:

- If the input NaN is a quiet NaN, the output NaN is the same as the input NaN except that the mantissa is truncated in the lower-order bits to fit the output format, and the exponent field is set to all ones.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- If the input NaN is a signaling NaN, the output NaN is the quieted version of the input NaN except that the mantissa is truncated in the lower-order bits to fit the output format, and the exponent field is set to all ones.

For the following descriptions, the term “first operand” and “second operand” relate to the left-to-right ordering of the arguments of the pseudocode function that describes the operation.

A1.5.6 Rounding

The rounding mode specifies how the exact result of a floating-point operation is rounded to a value in the destination format.

The rounding mode is either determined by the rounding mode control field FPCR.RMode or by the instruction.

FPCR.RMode can select one of:

- Round to Nearest (RN) mode.
- Round towards Plus Infinity (RP) mode.
- Round towards Minus Infinity (RM) mode.
- Round towards Zero (RZ) mode.

The following additional rounding behaviors are not selected by FPCR.RMode, but are used by some instructions:

- Round to Odd.
- Round to Nearest with Ties to Away.

A1.5.6.1 Round to Nearest (RN) mode

Round to Nearest rounding mode rounds the exact result of a floating-point operation to a value that is representable in the destination format as follows:

- If the value before rounding has an absolute value that is too large to represent in the output format, the rounded value is an Infinity. The sign of the rounded value is the same as the sign of the value before rounding.
- If the value before rounding has an absolute value that is not too large to represent in the output format, the result is calculated as follows:
  - If the two nearest floating-point numbers bracketing the value before rounding are equally near, the result is the number with an even least significant digit.
  - If the two nearest floating-point numbers bracketing the value before rounding are not equally near, the result is the floating-point number nearest to the value before rounding.

A1.5.6.2 Round towards Plus Infinity (RP) mode

Round towards Plus Infinity rounding mode rounds the exact result of a floating-point operation to a value that is representable in the destination format. The result is the floating-point number in the output format that is closest to and not less than the value before rounding. The result can be plus infinity.

A1.5.6.3 Round towards Minus Infinity (RM) mode

Round towards Minus Infinity rounding mode rounds the exact result of a floating-point operation to a value that is representable in the destination format. The result is the number in the output format that is closest to and not greater than the value before rounding. The result can be minus infinity.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

A1.5.6.4 Round towards Zero (RZ) mode

Round towards Zero rounding mode rounds the exact result of a floating-point operation to a value that is representable in the destination format. The result is the floating-point number in the output format that is closest to and not greater in absolute value than the value before rounding.

A1.5.6.5 Round to Nearest with Ties to Away

Round to Nearest with Ties to Away rounds the exact result of a floating-point operation to a value that is representable in the destination format. The result is calculated as follows:

- If the two nearest floating-point numbers bracketing the value before rounding are equally near, the result is the number with the largest absolute value.
- If the two nearest floating-point numbers bracketing the value before rounding are not equally near, the result is the floating-point number nearest to the value before rounding.

Round to Nearest with Ties to Away rounding is used by FCVTAS (scalar), FCVTAS (vector), FCVTAU (scalar), FCVTAU (vector), FRINTA (scalar), and FRINTA (vector).

A1.5.6.6 Round to Odd

Round to Odd is not defined by IEEE 754.

Round to Odd rounds the exact result of a floating-point operation to a value that is representable in the destination format. If the result of the rounding is inexact, the least significant bit of the mantissa is forced to 1.

FCVTXN, FCVTXN2 for which Round to Odd rounding can avoid double rounding errors when a floating-point value is converted to a lower precision destination format through an intermediate precision format.

Example A1-1 Converting 64-bit floating-point format to 16-bit floating-point format

A 64-bit floating-point value can be converted to a correctly rounded 16-bit floating-point value using the following steps:

1. Use an `FCVTXN` instruction to produce a 32-bit value.
2. Use another instruction with the required rounding mode to convert the 32-bit value to the final 16-bit floating-point value.

A1.5.7 Floating-point exceptions and exception traps

Execution of a floating-point instruction, or execution of an Advanced SIMD instruction that performs floating-point operations, can generate an exceptional condition, called a *floating-point exception*.

Note

In AArch64 state, an Advanced SIMD instruction that operates on floating-point values can perform multiple floating-point operations. Therefore, this section describes the handling of a floating-point exception on an *operation*, rather than on an *instruction*.

The architecture does not support asynchronous reporting of floating-point exceptions.

For each of the following floating-point exceptions, it is IMPLEMENTATION DEFINED whether an implementation includes synchronous exception generation:

- Input Denormal.
- Inexact.
- Underflow.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- Overflow.
- Divide by Zero.
- Invalid Operation.

If an implementation does not support synchronous exception generation from a floating-point exception, then that synchronous exception is never generated and all statements about synchronous exception generation from that floating-point exception do not apply to the implementation.

Synchronous exception generation by floating-point exceptions is enabled using the FPCR as follows:

- For each floating-point exception that supports synchronous exception generation, the relevant control bit chosen from FPCR.{IDE, IXE, UFE, OFE, DZE, IOE} is used to enable synchronous exception generation.
- For each floating-point exception that does not support synchronous exception generation, the relevant bit chosen from FPCR.{IDE, IXE, UFE, OFE, DZE, IOE} is RAZ/WI.

For information about FP8 instruction behaviors, see Summary of FP8 instruction behaviors.

A1.5.7.1 Inexact exceptions

The cumulative floating-point exception bit FPSR.IXC and the trap enable bit FPCR.IXE both relate to Inexact exceptions.

If a result is not flushed to zero, and the result does not equal the result computed with unbounded exponent range and unbounded precision, then an Inexact exception is generated.

A1.5.7.2 Underflow exceptions

The cumulative floating-point exception bit FPSR.UFC, and the trap enable bit FPCR.UFE both relate to Underflow exceptions.

If the result of a floating-point operation is a denormalized number that is not flushed to zero, then:

- If the result is exact, an Underflow floating-point exception is generated only if FPCR.UFE is 1.
- If the result is inexact, an Underflow floating-point exception is always generated.

If the result of a floating-point operation is a denormalized number that is flushed to zero, then the Underflow floating-point exception is generated, however this floating-point exception is not trapped regardless of the value of FPCR.UFE.

A1.5.7.3 Overflow exceptions

The cumulative floating-point exception bit FPSR.OFC, and the trap enable bit FPCR.OFE both relate to Overflow exceptions.

If the output of an instruction rounded with an unbounded exponent is greater than the maximum normalized number for the output precision, an Overflow exception is generated.

If an untrapped Overflow exception is generated, the result is determined by the selected rounding behavior and the sign of the result before rounding, as follows:

- Round to Nearest carries all overflows to infinity with the sign of the result before rounding.
- Round towards Plus Infinity carries negative overflows to the most negative finite number of the output precision, and carries positive overflows to plus infinity.
- Round towards Minus Infinity carries positive overflows to the largest finite number of the output precision, and carries negative overflows to minus infinity.
- Round towards Zero carries all overflows to the output precision's largest finite number with the sign of the result before rounding.
- Round to Nearest Ties to Away carries all overflows to infinity with the sign of the result before rounding.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- Round to Odd, when used by convert instructions, carries all overflows to the output precision's largest finite number with the sign of the result before rounding.
- Round to Odd, when used by some BFloat16 instructions, carries all overflows to infinity with the sign of the result before rounding.

A1.5.7.4 Divide by Zero exceptions

The cumulative floating-point exception bit FPSR.DZC, and the trap enable bit FPCR.DZE both relate to Divide by Zero exceptions.

If a floating-point operation divides a finite nonzero number by zero, a Divide by Zero exception is generated.

If a floating-point operation divides a finite nonzero number by zero, and the Divide by Zero exception is untrapped, the result is a correctly signed infinity.

A1.5.7.5 Invalid Operation exceptions

The cumulative floating-point exception bit FPSR.IOC, and the trap enable bit FPCR.IOE both relate to Invalid Operation exceptions.

For any floating-point instruction that performs a floating-point operation, if any of the following apply, the instruction generates an Invalid Operation exception:

- At least one operand is a signaling NaN.
- Subtracting two equal-magnitude infinities that are of the same sign.
- Multiplying a zero by an infinity.
- Dividing a zero by a zero.
- Dividing an infinity by an infinity.
- Taking the square root of an operand that is less than zero.

If the input is one of: a quiet NaN, an infinity, or a number that overflows the values that can be represented in the output format, and if another exception is not generated to signal the condition, then a conversion from floating-point to either integer or fixed-point format, generates an Invalid Operation exception.

For the signaling compare instructions FCMPE, if either of the source operands is any type of NaN, the instruction generates an Invalid Operation floating-point exception.

A1.5.7.6 Handling floating-point exceptions

If an implementation supports synchronous exception generation for floating-point exceptions, the synchronous exceptions generated by the floating-point exception traps are taken to the lowest Exception level that can handle such an exception and that is not at a lower Exception level than where the exception was generated.

If an implementation supports synchronous exception generation for floating-point exceptions in AArch64 state, all of the following apply:

- The registers that are presented to the exception handler are consistent with the state of the PE immediately before the instruction that caused the exception, except that an implementation is permitted to not restore the cumulative floating-point exception bits in the event of such an exception.
- When the execution of separate operations in separate SIMD elements causes multiple floating-point exceptions, the ESR_ELx reports one exception associated with one element that the instruction uses. The architecture does not specify which element is reported.

The `AArch64.FPTrappedException()` and `FPProcessException()` pseudocode functions describe the handling of trapped floating-point exceptions generated in AArch64 state.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

A1.5.7.7 Combinations of floating-point exceptions

More than one floating-point exception might occur on the same operation. The architecture permits only the following combinations of floating-point exceptions:

- Overflow with Inexact.
- Underflow with Inexact.

If two floating-point exceptions occur on the same operation, the Input Denormal exception is treated as highest priority and the Inexact exception is treated as lowest priority.

Some floating-point instructions specify more than one floating-point operation, this is indicated by the pseudocode descriptions of the instruction. In these cases, it is possible for one instruction to generate multiple exceptions. Multiple exceptions from one instruction are prioritized as follows:

- If an exception generating operation outputs a result that is used by a second exception generating operation, the exception generated by the operation that outputs the result is treated as higher priority than the exception generated by the second operation that uses the result.
- If exception generating operations do not use the outputs of other exception generating operations, it is CONSTRAINED UNPREDICTABLE which floating-point exception is treated as higher priority. The exception prioritized might differ between different instances of the same two floating-point exceptions being generated on the same operation during execution of the instruction.
- A trapped Underflow exception has priority over a trapped Inexact exception.

If none of the floating-point exceptions caused by an operation is trapped, any floating-point exception that occurs causes the associated cumulative exception flag bit in the FPSR to be set to 1.

When FPCR.AH is 1, if the result of a floating-point operation is a denormalized number that is flushed to zero, both an untrapped Underflow floating-point exception and an Inexact floating-point exception are generated, which always sets the cumulative Underflow exception flag FPSR.UFC to 1 regardless of whether the Inexact floating-point exception is trapped. Otherwise, when a trapped floating-point exception is taken, it is IMPLEMENTATION DEFINED whether the FPSR is restored to the value it had immediately before the instruction that generated the trapped floating-point exception. If the IMPLEMENTATION DEFINED choice is that the FPSR is not restored, it is CONSTRAINED UNPREDICTABLE which trapped floating-point exceptions, if any, are indicated by the corresponding FPSR cumulative exception flag bits being set to 1.

When a trapped floating-point exception is taken, then in the ESR_ELx, all of the following apply:

- The highest priority trapped floating-point exception has a floating-point exception trapped bit set to 1.
- If any other untrapped floating-point exceptions are generated by the same operation, each untrapped exception has a floating-point exception trapped bit set to 0. This applies to both higher priority and lower priority untrapped floating-point exceptions.
- If any lower priority trapped floating-point exceptions are generated by the same operation, for each exception, it is CONSTRAINED UNPREDICTABLE whether the floating-point exception trapped bit is set to 1.

The architectural requirements for floating-point exception prioritization apply only to multiple floating-point exceptions generated on the same element of an Advanced SIMD operation. For trapped floating-point exceptions from Advanced SIMD the architecture does not define the floating-point exception prioritization between different elements of the instruction.

A1.6 The Arm memory model

The Arm memory model supports:

- Generating an exception on an unaligned memory access.
- Restricting access by applications to specified areas of memory.
- Translating *virtual addresses* (VAs) provided by executing instructions to *physical addresses* (PAs).
- Altering the interpretation of multi-byte data between big-endian and little-endian.
- Controlling the order of accesses to memory.
- Controlling caches and address translation structures.
- Synchronizing access to shared memory by multiple PEs.
- Barriers that control and prevent speculative access to memory.

AArch64 state VA supports 64-bit virtual addressing, with the Translation Control Register determining the supported VA range. Execution at EL1 and EL0 supports two independent VA ranges, each with its own translation controls.

Regardless of the Execution state, the *Virtual Memory System Architecture* (VMSA) can translate VAs to blocks or pages of memory anywhere within the supported PA space.

For more information, see:

For execution in AArch64 state

- The AArch64 Application Level Memory Model.
- The AArch64 System Level Memory Model.
- The AArch64 Virtual Memory System Architecture.
- The AArch64 Protected Memory System Architecture

A1.7 Reliability, Availability, and Serviceability

A1.7.1 Introduction

I_{LMHPD} RAS are three aspects of the *dependability* of a system:

- Reliability, that is, the continuity of correct service.
- Availability, that is, the readiness for correct service.
- Serviceability, that is, the ability to undergo modifications and repairs.

I_{HWHJM} RAS techniques reduce unplanned outages because:

- Transient errors can be detected and corrected before they cause application or system failure.
- Failing components can be identified and replaced.
- Failure can be predicted ahead-of-time to allow replacement during planned maintenance.

A1.7.2 Faults, errors, and failures

R_{NVNNC} Correct service is delivered when the service implements the system function.

I_{QWSVK} Correct service might include:

- Producing correct results.
- Producing results within the time allotted to the task.
- Not divulging secret or secure information.

R_{KRTSC} For the purpose of describing the RAS Extension and RAS System Architecture, deviation from correct service is defined using the following terms:

- A failure is the event of deviation from correct service. This includes data corruption, data loss, and service loss.
- An error is the deviation from correct service. An incorrect value that has an error is corrupt.
- A fault is the cause of the error.

R_{JNBDX} Errors that are present but not detected are latent errors or undetected errors.

I_{TNQPK} In a system with no error detection, all errors are latent errors and are silently propagated by components until they are either masked or cause failure.

I_{GRYKV} The severity of a failure can range from minor to catastrophic:

- The harmful consequences of a minor failure are of a similar cost to the benefits provided by correct service delivery.
- The harmful consequences of a catastrophic failure are orders of magnitude, or even incommensurably, higher than the benefit provided by correct service delivery.

I_{NMGPQ} There are many sources of faults in a system, including both software and hardware faults:

- *Hardware faults* originate in, or affect, hardware.
- *Software faults* affect software, that is programs or data.

The RAS Extension and RAS System Architecture primarily address errors produced from hardware faults. These fall into two main areas:

- Transient faults.
- Non-transient or *persistent faults*.

A1.7.3 General taxonomy of errors

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

A1.7.3.1 Error detection

R_{FHXWP} When a component accesses memory or other state, an error might be detected in that memory or state.

I_{WKPVR} The error might be corrected or deferred by the component, or signaled to another component as either a Deferred error or a Detected error.

A1.7.3.2 Error propagation

R_{LRZDN} A transaction occurs when a producer of the transaction passes a value or other signal to a consumer of the transaction.

I_{VYCCX} Transactions are part of the service provided by the producer for the consumer.

I_{RHGDL} In many protocols and service interface definitions, a high-level transaction consists of a sequence of operations, for instance between a *Requester* and a *Completer*.

For the purposes of this manual, the most basic form of a unidirectional transfer between a *producer* and *consumer* is considered as a transaction.

That is, each one of the sequence of operations is considered a separate transaction. For some operations, such as a request, the Requester is producer and the Completer is the consumer. For other operations, such as a response, the Completer is producer and the Requester is the consumer.

R_{SKZZG} An error is propagated by the producer of a transaction when the service interface is incorrect because of the error. The error is propagated to the consumer.

R_{CHCCV} An error is propagated by deviations from correct service, including when any of the following occurs that would not have been permitted to occur had the fault not been activated:

- A corrupt value is passed from producer to consumer.
- A transaction or other operation occurs that should not have occurred.
- A transaction or other operation that should have occurred does not occur.
- A loss of uniprocessor semantics or any other loss of coherency in a multiprocessor coherent system is observed.
- Changing the timing and/or order of transactions or other operations such that the timing and/or order of those transactions or operations is incorrect. In this case, the service interface defines acceptable timings and/or orders for transactions and other operations.

R_{YFBRV} The service interface for a transaction might include means to signal that the transaction is propagating either of the following:

- A Detected error.
- A Deferred error.

R_{BHWVX} An error is silently propagated by the producer of a transaction if the consumer of the transaction cannot detect the error and consumes an undetected error because of the transaction. This might be because of one of the following:

- The error is present on the transaction, but was not detected by the producer. The error is silently propagated by the producer.
- The error is present on the transaction, but was not signaled to the consumer as an error. For example, a corrupt value was passed in the transaction with no indication that it was corrupt. The error is silently propagated by the producer.

R_{FPBYS} A latent, possibly detectable, error is silently propagated by the consumer of an otherwise correct transaction if the transaction causes the error to become undetectable.

Example A1-2

A partial write to a protection granule removes poison, leaving the unchanged portion of the location corrupt. To implement a partial write, the consumer logically reads the current value of the location, modifies the value, and then writes the modified value back. These are internal transactions in the consumer that silently propagate the error. In this example there was no error at the producer nor on the transaction.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I_{QXRLB} Errors might be propagated by components in a system until one of the following occurs:

- They are masked and do not affect the outcome of the system.
  The error might be masked because a corrupt value is discarded or overwritten, or the error is detected and removed.
- They affect the service interface of the system and possibly cause failure. If the error has been silently propagated to the service interface, then:
  - This is a Silent Data Corruption, SDC.
  - The rate of such failures, measured as the number of failures per billion device-hours of operation, is called the Silent Data Corruption Failure-in-Time rate, SDC FIT rate.

  Alternatively, the error might have been detected, causing the system to invoke error handling and recovery. For more information, see *Arm® Reliability, Availability, and Serviceability (RAS) System Architecture, for A-profile architecture* (ARM IHI 0100).

A1.7.3.3 Infected and poisoned

R_{KNHWB} The state of a component becomes infected when the component consumes an Uncorrected error that updates the state.

R_{TZBSW} A value is poisoned in the state of a component if it is marked as being in error, such that a subsequent access of the state will detect the value is so marked and is treated as a Detected error.

I_{YBMFK} Poison is used to defer an error.

A1.7.3.4 Containable and uncontainable

R_{DXQRD} An undetected error is uncontained at the component that failed to detect it.

R_{RJYRQ} A silently propagated error is uncontained at the component that silently propagated it.

R_{GJQNR} A Detected Uncorrected error is uncontainable at the component if it might be uncontained at the component. A Detected Uncorrected error is containable at the component if it is not uncontainable at the component. If the component cannot determine whether a Detected Uncorrected error is uncontainable at the component or containable at the component, then the component treats the Detected Uncorrected error as uncontainable at the component.

I_{MRDMR} An error that is uncontainable at the component might be containable at the system level.

I_{NWZGB} Reporting an error as containable allows software to contain the error. This does not mean that hardware has contained the error.

Chapter A2
R-profile Architecture Extensions

This chapter introduces the Arm R-profile architecture extensions. It contains the following sections:

- About the R-profile architecture extensions.
- Armv8-R architecture extensions.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.

A2.1 About the Armv8-R AArch64 architecture extensions

An architecture extension adds a set of features that are when implemented can make an implementation compliant with the version of the architecture.

Each feature description includes:

- A feature name.
- A brief description of the feature.
- The Execution state the feature is supported in.
- Whether the implementation of the feature is mandatory or OPTIONAL.
- Dependencies on the implementation of other features if any.
- The register field that identifies the presence of the feature.

A2.1.1 Permitted implementation of subsets of the Armv8-R AArch64 architectural features

When a feature is introduced, the architecture specifies when the feature can be implemented. Typically, a feature introduced as part of Armv8.*x* is permitted to be built in Armv8.(*x*-1), subject only to those constraints that require that certain features be implemented together.

An implementation of the Armv8-R AArch64 architecture is based on the Armv8.4 architecture extensions.

A2.2 Armv8-R AArch64 architecture extensions

A2.2.1 The Armv8.0 architecture extension

The original Armv8-R architecture is called Armv8.0. It contains mandatory and optional architectural features. Some features must be implemented together. An implementation is Armv8.0 compliant if it includes all of the Armv8.0 architectural features that are mandatory.

An Armv8.0 compliant implementation can additionally include:

- Armv8.0 features that are optional.
- Any arbitrary subset of the architectural features of Armv8.1, subject only to those constraints that require that certain features be implemented together.

FEAT_AA64, PE uses AArch64 after last reboot

This feature is mandatory.

FEAT_AA64EL0, Support for AArch64 at EL0

This feature is mandatory.

FEAT_AA64EL1, Support for AArch64 at EL1

This feature is mandatory.

FEAT_AA64EL2, Support for AArch64 at EL2

This feature is mandatory.

FEAT_AES, Advanced SIMD AES instructions

FEAT_AES provides the AES* instructions to support AES encryption and decryption, AESD, AESE, AESMC, and AESIMC.

FEAT_AES is OPTIONAL from Armv8.0.

If FEAT_AES is implemented, then FEAT_Crypto is implemented.

The following field identifies the presence of FEAT_AES:

- ID_AA64ISAR0_EL1.AES.

FEAT_ASID16, 16 bit ASID

FEAT_ASID16 is OPTIONAL from Armv8.0.

The following field identifies the presence of FEAT_ASID16:

- ID_AA64MMFR0_EL1.ASIDBits.

FEAT_AdvSIMD, Advanced SIMD Extension

FEAT_AdvSIMD includes support for the SISD and SIMD operations. All Armv8-A systems that support standard operating systems with rich application environments also provide hardware support for Advanced SIMD instructions.

FEAT_AdvSIMD is OPTIONAL from Armv8.0.

If FEAT_AdvSIMD is implemented, then FEAT_FP is implemented.

The following fields identify the presence of FEAT_AdvSIMD:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- ID_AA64PFR0_EL1.AdvSIMD.
- EDPFR.AdvSIMD.

For more information, see:

- Supported data types.
- A64 Advanced SIMD and Floating-point Instruction Descriptions.

FEAT_BigEnd, Support for big-endian at EL1 and above

FEAT_BigEnd is OPTIONAL from Armv8.0.

If FEAT_BigEnd is implemented, then FEAT_BigEndEL0 is implemented.

If FEAT_MixedEnd is implemented, then FEAT_BigEnd is implemented.

FEAT_BigEndEL0, Support for big-endian at EL0

FEAT_BigEndEL0 is OPTIONAL from Armv8.0.

If FEAT_MixedEndEL0 is implemented, then FEAT_BigEndEL0 is implemented.

FEAT_CRC32, CRC32 instructions

FEAT_CRC32 introduces the support for the CRC32* instructions that perform cyclic redundancy check calculations.

FEAT_CRC32 is mandatory from Armv8.0.

The following field identifies the presence of FEAT_CRC32:

- ID_AA64ISAR0_EL1.CRC32.

FEAT_CSV2_1p1, Cache Speculation Variant 2

For FEAT_CSV2_1p1, within a hardware-described context, branch targets trained for branches situated at one address can control speculative execution of branches situated at different addresses only in a hard-to-determine way.

FEAT_CSV2_1p1 does not support the SCXTNUM_ELx registers.

FEAT_CSV2_1p1 is OPTIONAL from Armv8.0.

If FEAT_CSV2_1p1 is implemented, then FEAT_CSV2 is implemented.

The following fields identify the presence of FEAT_CSV2_1p1:

- ID_AA64PFR1_EL1.CSV2_frac.
- ID_AA64PFR0_EL1.CSV2.

For more information, see:

- For AArch64, ‘Restrictions on the effects of speculation’.

FEAT_CSV2_1p2, Cache Speculation Variant 2 version 1.2

For FEAT_CSV2_1p2, within a hardware-described context, branch targets trained for branches situated at one address can control speculative execution of branches situated at different addresses only in a hard-to-determine way.

FEAT_CSV2_1p2 introduces the SCXTNUM_ELx registers, but the contexts do not include the SCXTNUM_ELx register contexts.

FEAT_CSV2_1p2 is OPTIONAL from Armv8.0.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

If FEAT_CSV2_1p2 is implemented, then FEAT_CSV2_1p1 is implemented.

The following fields identify the presence of FEAT_CSV2_1p2:

- ID_AA64PFR1_EL1.CSV2_frac.
- ID_AA64PFR0_EL1.CSV2.

For more information, see:

- For AArch64, ‘Restrictions on the effects of speculation’.

FEAT_CSV2_2, Cache Speculation Variant 2 version 2

FEAT_CSV2_2 introduces the SCXTNUM_ELx registers, which provide a number that can be used to separate out different context numbers within their respective Exception levels for the purpose of protecting against speculative attacks through prediction resources.

FEAT_CSV2_2 is OPTIONAL from Armv8.0.

If FEAT_CSV2_2 is implemented, then FEAT_CSV2 is implemented.

If FEAT_CSV2_2 is implemented, then FEAT_CSV2_1p1 is not implemented.

The following field identifies the presence of FEAT_CSV2_2:

- ID_AA64PFR0_EL1.CSV2.

For more information, see:

- For AArch64, ‘Restrictions on the effects of speculation’.

FEAT_CSV2_3, Cache Speculation Variant 2 version 3

FEAT_CSV2_3 introduces a mechanism to identify if hardware cannot disclose information about whether prediction resources based on branch history trained in one hardware described context can control speculative execution in a different hardware described context.

FEAT_CSV2_3 is OPTIONAL from Armv8.0.

If FEAT_CSV2_3 is implemented, then FEAT_CSV2_2 is implemented.

The following field identifies the presence of FEAT_CSV2_3:

- ID_AA64PFR0_EL1.CSV2.

For more information, see:

- For AArch64, ‘Restrictions on the effects of speculation’.

FEAT_Crypto, Cryptographic Extension

The Arm Cryptographic Extension provides instructions for the acceleration of encryption and decryption. The presence of the Cryptographic Extension in an implementation is subject to export license controls.

The Cryptographic Extension is an extension of the SIMD support and operates on the vector register file. It also provides multiply instructions that operate on long polynomials.

If FEAT_Crypto is implemented, then FEAT_AES or FEAT_SHA1 is implemented.

In an Armv8.2 implementation, if FEAT_Crypto is implemented, FEAT_PMULL, FEAT_SHA256, FEAT_SM3, or FEAT_SM4 is implemented.

For more information, see:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- The Cryptographic Extension in AArch64 state.

FEAT_DoubleLock, Double Lock

FEAT_DoubleLock is the mnemonic used for the OS Double Lock.

FEAT_DoubleLock is OPTIONAL from Armv8.0.

The following field identifies the presence of FEAT_DoubleLock:

- ID_AA64DFR0_EL1.DoubleLock.

FEAT_EL0, Support for execution at EL0

This feature is mandatory.

FEAT_EL1, Support for execution at EL1

This feature is mandatory.

FEAT_EL2, Support for execution at EL2

This feature is mandatory.

FEAT_ETMv4, Embedded Trace Macrocell version 4

FEAT_ETMv4 indicates support for the Embedded Trace Macrocell architecture ETMv4.

FEAT_ETMv4 is OPTIONAL from Armv8.0.

If FEAT_ETMv4 is implemented, then FEAT_TRC_SR or FEAT_TRC_EXT is implemented.

For more information, see the Arm® Embedded Trace Macrocell Architecture Specification, ETMv4(ARM IHI 0064).

FEAT_FP, Floating Point extensions

FEAT_FP includes support for single-precision and double-precision floating-point types. All Armv8-A systems that support standard operating systems with rich application environments also provide hardware support for floating-point instructions.

FEAT_FP is OPTIONAL from Armv8.0.

If FEAT_FP is implemented, then FEAT_AdvSIMD is implemented.

The following fields identify the presence of FEAT_FP:

- ID_AA64PFR0_EL1.FP.
- EDPFR.FP.

For more information, see:

- Supported data types.
- Floating-point support.
- A64 Advanced SIMD and Floating-point Instruction Descriptions.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

FEAT_IVIPT, The IVIPT Extension

FEAT_IVIPT describes any permitted instruction cache implementation. This includes Virtual Index, Physical tag (VIPT) cache policy and Physical Index, Physical Tag (PIPT) cache policy.

FEAT_IVIPT is mandatory from Armv8.0.

.

For more information, see:

- Instruction caches.
- ‘Instruction caches’.

FEAT_LittleEnd, Support for little-endian at EL1 and above

FEAT_LittleEnd is OPTIONAL from Armv8.0.

If FEAT_LittleEnd is implemented, then FEAT_LittleEndEL0 is implemented.

If FEAT_MixedEnd is implemented, then FEAT_LittleEnd is implemented.

FEAT_LittleEndEL0, Support for little-endian at EL0

FEAT_LittleEndEL0 is OPTIONAL from Armv8.0.

If FEAT_MixedEndEL0 is implemented, then FEAT_LittleEndEL0 is implemented.

FEAT_MixedEnd, Mixed-endian support

FEAT_MixedEnd provides support for mixed-endian configuration.

FEAT_MixedEnd is OPTIONAL from Armv8.0.

If FEAT_MixedEnd is implemented, then FEAT_MixedEndEL0 is implemented.

The following field identifies the presence of FEAT_MixedEnd:

- ID_AA64MMFR0_EL1.BigEnd.

For more information see Mixed-endian support in AArch64.

FEAT_MixedEndEL0, Mixed-endian support at EL0

FEAT_MixedEndEL0 provides support for mixed-endian at EL0.

FEAT_MixedEndEL0 is OPTIONAL from Armv8.0.

The following fields identify the presence of FEAT_MixedEndEL0:

- ID_AA64MMFR0_EL1.BigEndEL0.
- ID_AA64MMFR0_EL1.BigEnd.

For more information see Mixed-endian support in AArch64.

FEAT_PMSAv64, Protected Memory System Architecture v8-64

For more information, see The AArch64 Protected Memory System Architecture

FEAT_PMULL, Advanced SIMD PMULL instructions

FEAT_PMULL provides the AES* instructions that support multiplication of 64-bit polynomials, PMULL, PMULL2.

FEAT_PMULL is OPTIONAL from Armv8.0.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

If FEAT_PMULL is implemented, then FEAT_AES is implemented.

The following field identifies the presence of FEAT_PMULL:

- ID_AA64ISAR0_EL1.AES.

FEAT_PMUv3, PMU extension version 3

The Performance Monitors Extension, FEAT_PMUv3, is an optional non-invasive debug component.

FEAT_PMUv3 is OPTIONAL from Armv8.0.

The following fields identify the presence of FEAT_PMUv3:

- ID_AA64DFR0_EL1.PMUVer.
- EDDFR.PMUVer.

For more information, see The Performance Monitors Extension.

FEAT_PMUv3_EXT, External interface to the Performance Monitors

FEAT_PMUv3_EXT indicates support for external access to the FEAT_PMUv3 and/or FEAT_PCSRv8p2 registers.

FEAT_PMUv3_EXT is OPTIONAL from Armv8.0.

If FEAT_PMUv3_EXT is implemented, then FEAT_PMUv3 or FEAT_PCSRv8p2 is implemented.

If FEAT_PMUv3_EXT is implemented, then FEAT_PMUv3_EXT32 is implemented.

FEAT_PMUv3_EXT32, 32-bit external interface to the Performance Monitors

FEAT_PMUv3_EXT32 indicates the external Performance Monitors and CoreSight registers are implemented as mostly 32-bit registers.

FEAT_PMUv3_EXT32 is OPTIONAL from Armv8.0.

If FEAT_PMUv3_EXT32 is implemented, then FEAT_PMUv3_EXT is implemented.

The following field identifies the presence of FEAT_PMUv3_EXT32:

- PMDEVARCH.ARCHPART.

For more information, see Recommended External Interface to the Performance Monitors.

FEAT_SHA1, Advanced SIMD SHA1 instructions

FEAT_SHA1 implements the SHA1* instructions.

FEAT_SHA1 is OPTIONAL from Armv8.0.

If FEAT_SHA1 is implemented, then FEAT_Crypto is implemented.

The following field identifies the presence of FEAT_SHA1:

- ID_AA64ISAR0_EL1.SHA1.

FEAT_SHA256, Advanced SIMD SHA256 instructions

FEAT_SHA256 implements the SHA256* instructions.

FEAT_SHA256 is OPTIONAL from Armv8.0.

If FEAT_SHA256 is implemented, then FEAT_SHA1 is implemented.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The following field identifies the presence of FEAT_SHA256:

- ID_AA64ISAR0_EL1.SHA2.

FEAT_Secure, Support for Secure state

FEAT_Secure adds support for Secure state.

FEAT_Secure is OPTIONAL from Armv8.0.

FEAT_SpecSEI, SError interrupt exceptions from speculative reads of memory

Describes whether the PE can generate SError interrupt exceptions from speculative reads of memory, including speculative instruction fetches.

FEAT_SpecSEI is OPTIONAL from Armv8.0.

The following field identifies the presence of FEAT_SpecSEI:

- ID_AA64MMFR1_EL1.SpecSEI.

FEAT_TGran16K, Support for 16KB memory translation granule size at stage 1

FEAT_TGran16K is OPTIONAL from Armv8.0.

The following field identifies the presence of FEAT_TGran16K:

- ID_AA64MMFR0_EL1.TGran16.

FEAT_TGran4K, Support for 4KB memory translation granule size at stage 1

FEAT_TGran4K is OPTIONAL from Armv8.0.

The following field identifies the presence of FEAT_TGran4K:

- ID_AA64MMFR0_EL1.TGran4.

FEAT_TGran64K, Support for 64KB memory translation granule size at stage 1

FEAT_TGran64K is OPTIONAL from Armv8.0.

The following field identifies the presence of FEAT_TGran64K:

- ID_AA64MMFR0_EL1.TGran64.

FEAT_TRC_EXT, Trace external registers

FEAT_TRC_EXT indicates support for external access to the ETMv4 or ETE registers.

FEAT_TRC_EXT is OPTIONAL from Armv8.0.

If FEAT_TRC_EXT is implemented, then FEAT_ETMv4 is implemented.

FEAT_TRC_SR, Trace System registers

FEAT_TRC_SR indicates support for System registers for ETMv4 or ETE.

FEAT_TRC_SR is OPTIONAL from Armv8.0.

If FEAT_TRC_SR is implemented, then FEAT_ETMv4 is implemented.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The following fields identify the presence of FEAT_TRC_SR:

- ID_AA64DFR0_EL1.TraceVer.
- EDDFR.TraceVer.

FEAT_nTLBPA, Intermediate caching of translation table walks

FEAT_nTLBPA introduces a mechanism to identify if the intermediate caching of translation table walks does not include non-coherent caches of previous valid translation table entries since the last completed TLBI applicable to the PE.

FEAT_nTLBPA is OPTIONAL from Armv8.0.

The following field identifies the presence of FEAT_nTLBPA:

- ID_AA64MMFR1_EL1.nTLBPA.

For more information, see:

- TLB maintenance.

A2.2.1.1 Features added to the Armv8.0 extension in later releases

- FEAT_CSV2.
- FEAT_CSV3.
- FEAT_DGH.
- FEAT_RAS.
- FEAT_SB.
- FEAT_SPECRES.
- FEAT_SSBS2.
- FEAT_SSBS.

A2.2.2 The Armv8.1 architecture extension

The Armv8.1 architecture extension is an extension to Armv8.0. It adds mandatory and optional architectural features. Some features must be implemented together. An implementation is Armv8.1 compliant if all of the following apply:

- It is Armv8.0 compliant.
- It includes all of the Armv8.1 architectural features that are mandatory.

An Armv8.1 compliant implementation can additionally include:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- Armv8.1 features that are optional.
- Any arbitrary subset of the architectural features of Armv8.2, subject only to those constraints that require that certain features be implemented together.

FEAT_Debugv8p1, Debug v8.1

FEAT_Debugv8p1 is OPTIONAL from Armv8.0.

The following fields identify the presence of FEAT_Debugv8p1:

- ID_AA64DFR0_EL1.DebugVer.
- EDDEVARCH.ARCHVER.

FEAT_HAFDBS, Hardware management of the Access flag and dirty state

In Armv8.0, all updates to the translation tables are performed by software. From Armv8.1, for the VMSAv8-64 translation regimes only, hardware can perform updates to the translation tables in two contexts:

- Hardware management of the Access flag.
- Hardware management of dirty state, with updates to a dirty state in the translation tables.

The dirty state is introduced in Armv8.1.

Hardware management of dirty state can be enabled only when hardware management of the Access flag is also enabled.

FEAT_HAFDBS is OPTIONAL from Armv8.0.

The following field identifies the presence of FEAT_HAFDBS:

- ID_AA64MMFR1_EL1.HAFDBS.

For more information, see:

- Hardware management of the Access flag.
- Hardware management of the dirty state.

FEAT_HPDS, Hierarchical permission disables in translations tables

FEAT_HPDS introduces the facility to disable the hierarchical permissions, APTable, PXNTable, and UXNTable, in the translation tables. This disable has no effect on the NSTable bit.

FEAT_HPDS is OPTIONAL from Armv8.0.

FEAT_HPDS is mandatory from Armv8.1.

The following field identifies the presence of FEAT_HPDS:

- ID_AA64MMFR1_EL1.HPDS.

This feature is added only to the VMSAv8-64 translation regimes. Armv8.2 extends this to the AArch32 translation regimes, see FEAT_AA32HPD.

FEAT_LSE, Large System Extensions

FEAT_LSE introduces a set of atomic instructions:

- Compare and Swap instructions, `CAS` and `CASP`.
- Atomic memory operation instructions, LD<OP> and ST<OP>, where <OP> is one of ADD, CLR, EOR, SET, SMAX, SMIN, UMAX, and UMIN.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- Swap instruction, SWP.

FEAT_LSE is OPTIONAL from Armv8.0.

FEAT_LSE is mandatory from Armv8.1.

The following field identifies the presence of FEAT_LSE:

- ID_AA64ISAR0_EL1.Atomic.

For more information, see:

- 'Atomic integer memory operations'.
- 'Swap operations'.
- 'Compare and Swap operations'.

FEAT_PAN, Privileged access never

FEAT_PAN introduces a bit to PSTATE. When the value of this PAN state bit is 1, any privileged data access from EL1, or EL2 when the Effective value of HCR_EL2.E2H is 1, to a virtual memory address that is accessible to data accesses at EL0, generates a Permission fault.

FEAT_PAN is OPTIONAL from Armv8.0.

FEAT_PAN is mandatory from Armv8.1.

The following field identifies the presence of FEAT_PAN:

- ID_AA64MMFR1_EL1.PAN.

For more information, see:

- PSTATE.PAN.
- 'About the PAN bit'.

FEAT_PMUv3p1, Armv8.1 PMU extensions

FEAT_PMUv3p1 introduces the following:

- The event number space is extended to 16 bits.
- The HPMD bit is added to MDCR_EL2. This bit disables event counting at EL2.
- The STALL_FRONTEND and STALL_BACKEND events are required to be implemented.

FEAT_PMUv3p1 is OPTIONAL from Armv8.0.

In an Armv8.1 implementation, if FEAT_PMUv3 is implemented, FEAT_PMUv3p1 is implemented.

If FEAT_PMUv3p1 is implemented, then FEAT_PMUv3 is implemented.

The following fields identify the presence of FEAT_PMUv3p1:

- ID_AA64DFR0_EL1.PMUVer.
- EDDFR.PMUVer.

For more information, see 'Required events'.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

FEAT_RDM, Advanced SIMD rounding double multiply-accumulate instructions

FEAT_RDM introduces Rounding Double Multiply Add/Subtract Advanced SIMD instructions. For more information, see:

For the A64 instruction set

- SQRDMLAH (by element).
- SQRDMLAH (vectors).
- SQRDMLSH (by element).
- SQRDMLSH (vector).

FEAT_RDM is OPTIONAL from Armv8.0.

In an Armv8.1 implementation, if FEAT_AdvSIMD is implemented, FEAT_RDM is implemented.

The following field identifies the presence of FEAT_RDM:

- ID_AA64ISAR0_EL1.RDM.

FEAT_VMID16, 16-bit VMID

In an Armv8.1 implementation, when EL2 is using AArch64, the virtual machine identifier (VMID) size is an IMPLEMENTATION DEFINED choice of 8 bits or 16 bits.

FEAT_VMID16 is OPTIONAL from Armv8.0.

The following field identifies the presence of FEAT_VMID16:

- ID_AA64MMFR1_EL1.VMIDBits.

For more information, see ‘VMID size’.

A2.2.2.1 Features added to the Armv8.1 extension in later releases

- FEAT_DPB2.
- FEAT_DotProd.
- FEAT_FHM.
- FEAT_FlagM.

A2.2.3 The Armv8.2 architecture extension

The Armv8.2 architecture extension is an extension to Armv8.1. It adds mandatory and optional architectural features. Some features must be implemented together. An implementation is Armv8.2 compliant if all of the following apply:

- It is Armv8.1 compliant.
- It includes all of the Armv8.2 architectural features that are mandatory.

An Armv8.2 compliant implementation can additionally include:

- Armv8.2 features that are optional.
- Any arbitrary subset of the architectural features of Armv8.3, subject only to those constraints that require that certain features be implemented together.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

FEAT_ASMv8p2, Armv8.2 changes to the A64 ISA

FEAT_ASMv8p2 introduces the BFC instruction to the A64 instruction set as an alias of BFM. It also requires that the BFC instruction and the A64 pseudo-instruction REV64 are implemented by assemblers.

In Armv8.0 and Armv8.1, the A64 pseudo-instruction REV64 is OPTIONAL.

FEAT_ASMv8p2 is OPTIONAL from Armv8.1.

FEAT_ASMv8p2 is mandatory from Armv8.2.

For more information, see:

- BFC.
- REV64.

FEAT_DPB, DC CVAP instruction

FEAT_DPB introduces a mechanism to identify and manage persistent memory locations in a shared memory hierarchy, including adding the DC CVAP instruction.

FEAT_DPB is OPTIONAL from Armv8.1.

FEAT_DPB is mandatory from Armv8.2.

The following field identifies the presence of FEAT_DPB:

- ID_AA64ISAR1_EL1.DPB.

For more information, see Memory hierarchy.

FEAT_Debugv8p2, Debug v8.2

FEAT_Debugv8p2 provides the following changes:

- If the Core power domain is powered up and DoubleLockStatus() == TRUE, EDPRSR.{DLK,SPD,PU} is only permitted to read {UNKNOWN, 0, 0}.
- The definition of Exception Catch debug events is extended to include reset entry.
- All CONSTRAINED UNPREDICTABLE cases that generate Exception Catch debug events are removed.
- Controls are added to EDECCR to control Exception Catch debug event generation on exception return.
- All IMPLEMENTATION DEFINED control of external debug accesses to OSLAR_EL1 is removed.
- ExternalSecureNoninvasiveDebugEnabled() cannot override software controls of counting attributable events in Secure state.

FEAT_Debugv8p2 is OPTIONAL from Armv8.1.

FEAT_Debugv8p2 is mandatory from Armv8.2.

If FEAT_Debugv8p2 is implemented, then FEAT_Debugv8p1 is implemented.

The following fields identify the presence of FEAT_Debugv8p2:

- ID_AA64DFR0_EL1.DebugVer.
- EDDEVARCH.ARCHVER.

For more information, see:

- Exception Catch debug event.
- EDPRSR.{DLK, SPD, PU} and the Core power domain.
- ‘Interaction with EL3’.
- External access disabled.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

FEAT_FP16, Half-precision floating-point data processing

FEAT_FP16 supports:

- Half-precision data-processing instructions for Advanced SIMD and floating-point.

FPCR.FZ16 enables flushing of denormalized numbers to zero for half-precision data-processing instructions.

FEAT_FP16 is OPTIONAL from Armv8.2.

In an Armv8.4 implementation, if FEAT_FHM is not implemented, then FEAT_FP16 is not implemented.

In an Armv8.2 implementation, if FEAT_FHM is implemented, FEAT_FP16 is implemented.

The following fields identify the presence of FEAT_FP16:

- ID_AA64PFR0_EL1.FP.
- ID_AA64PFR0_EL1.AdvSIMD.

For more information, see:

- Half-precision floating-point formats.
- Flushing denormalized numbers to zero.
- Modified immediate constants in A64 floating-point instructions.

FEAT_HPDS2, Hierarchical permission disables

FEAT_HPDS2 provides a mechanism to allow operating systems or hypervisors to make up to four bits of Translation Table final-level descriptors available for IMPLEMENTATION DEFINED hardware use.

FEAT_HPDS2 is OPTIONAL from Armv8.1.

If FEAT_HPDS2 is implemented, then FEAT_HPDS is implemented.

The following field identifies the presence of FEAT_HPDS2:

- ID_AA64MMFR1_EL1.HPDS.

For more information, see:

- ‘Page Based Hardware attributes’.
- ‘Attribute fields in VMSAv8-32 Long-descriptor translation table format descriptors’.

FEAT_IESB, Implicit Error Synchronization event

FEAT_IESB introduces control for an implicit error synchronization event at exception entry and return.

The implicit error synchronization events affect the same synchronizable asynchronous events that are synchronized by the ESB instruction. This means that if an implementation has either no sources of SError exceptions, or all SError exceptions are not synchronizable errors, then the controls added by this feature have no effect.

FEAT_IESB is OPTIONAL from Armv8.1.

If FEAT_IESB is implemented, then FEAT_RAS is implemented.

The following field identifies the presence of FEAT_IESB:

- ID_AA64MMFR2_EL1.IESB.

For more information, see Error synchronization event.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

FEAT_LPA, Large PA and IPA support

FEAT_LPA:

- Allows a larger physical address (PA) and intermediate physical address (IPA) space of up to 52 bits when using the 64KB translation granule.
- Allows a level 1 block size where the block covers a 4TB address range for the 64KB translation granule if the implementation support 52 bits of PA.

FEAT_LPA is OPTIONAL from Armv8.1.

The following field identifies the presence of FEAT_LPA:

- ID_AA64MMFR0_EL1.PARange.

For more information about FEAT_LPA, see:

- Implemented physical address size.
- Output address size configuration.
- Intermediate physical address size configuration
- Translation using the 64KB granule
- 'Table descriptor format'
- Block descriptor and Page descriptor formats

FEAT_LVA, Large VA support

FEAT_LVA supports a *virtual address* (VA) space for each translation table base register of up to 52 bits when using VMSAv8-64 translation format with the 64KB translation granule.

FEAT_LVA is OPTIONAL from Armv8.1.

The following field identifies the presence of FEAT_LVA:

- ID_AA64MMFR2_EL1.VARange.

For more information about FEAT_LVA, see:

- Supported virtual address ranges.
- Input address size configuration.
- Translation using the 64KB granule.

FEAT_PAN2, AT S1E1R and AT S1E1W instruction variants affected by PSTATE.PAN

FEAT_PAN2 introduces variants of the AT S1E1R and AT S1E1W instructions. These instructions factor in the PSTATE.PAN bit when determining whether or not the location will generate a Permission fault for a privileged access, as is reported in the PAR. For more information, see:

For the AArch64 System instructions:

- AT S1E1RP, Address Translate Stage 1 EL1 Read PAN.
- AT S1E1RP, Address Translate Stage 1 EL1 Write PA.

FEAT_PAN2 is OPTIONAL from Armv8.1.

FEAT_PAN2 is mandatory from Armv8.2.

If FEAT_PAN2 is implemented, then FEAT_PAN is implemented.

The following field identifies the presence of FEAT_PAN2:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- ID_AA64MMFR1_EL1.PAN.

For more information, see:

- Address translation instructions.
- Address translation instructions.
- ATS1C**, Address translation stage 1, current security state.
- Encoding and availability of the address translation instructions.

FEAT_PCSRv8p2, PC Sample-based Profiling Extension

FEAT_PCSRv8p2 moves the control and implementation of the OPTIONAL PC Sample-based Profiling Extension from the ED*SR Debug registers to PM*SR registers in the Performance Monitors address space.

FEAT_PCSRv8p2 is OPTIONAL from Armv8.1.

The following field identifies the presence of FEAT_PCSRv8p2:

- PMDEVID.PCSample.

For more information, see The PC Sample-based Profiling Extension.

FEAT_RAS, Reliability, Availability and Serviceability (RAS) Extension

FEAT_RAS introduces the following:

- The Error Synchronization Barrier (ESB) instruction for the A32, T32, and A64 instruction sets.
- Error records.
- The Error synchronization event.
- Additional syndrome information on External Aborts.

FEAT_RAS is OPTIONAL from Armv8.0.

FEAT_RAS is mandatory from Armv8.2.

The following field identifies the presence of FEAT_RAS:

- ID_AA64PFR0_EL1.RAS.

For more information, see:

- Reliability, Availability, and Serviceability.
- RAS PE Architecture.
- *Arm® Reliability Availability and Serviceability (RAS) System Architecture, for A-profile architecture* (ARM IHI 0100).

FEAT_SHA3, Advanced SIMD SHA3 instructions

FEAT_SHA3 introduces Advanced SIMD instructions that support SHA3 functionality.

FEAT_SHA3 is OPTIONAL from Armv8.1.

If FEAT_SHA3 is implemented, then FEAT_Crypto is implemented.

If FEAT_SHA3 is implemented, then FEAT_SHA256 and FEAT_SHA1 are implemented.

The following field identifies the presence of FEAT_SHA3:

- ID_AA64ISAR0_EL1.SHA3.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

For more information, see FEAT_SHA3, SHA3 functionality.

FEAT_SHA512, Advanced SIMD SHA512 instructions

FEAT_SHA512 introduces Advanced SIMD instructions that support SHA2-512 functionality.

FEAT_SHA512 is OPTIONAL from Armv8.1.

If FEAT_SHA512 is implemented, then FEAT_Crypto is implemented.

If FEAT_SHA512 is implemented, then FEAT_SHA256 and FEAT_SHA1 are implemented.

The following field identifies the presence of FEAT_SHA512:

- ID_AA64ISAR0_EL1.SHA2.

For more information, see FEAT_SHA512, SHA2-512 functionality.

FEAT_SM3, Advanced SIMD SM3 instructions

FEAT_SM3 introduces Advanced SIMD instructions that support the Chinese cryptography algorithm SM3.

FEAT_SM3 is OPTIONAL from Armv8.1.

If FEAT_SM3 is implemented, then FEAT_Crypto is implemented.

The following field identifies the presence of FEAT_SM3:

- ID_AA64ISAR0_EL1.SM3.

For more information, see FEAT_SM3, SM3 functionality.

FEAT_SM4, Advanced SIMD SM4 instructions

FEAT_SM4 introduces Advanced SIMD instructions that support the Chinese cryptography algorithm SM4.

FEAT_SM4 is OPTIONAL from Armv8.1.

If FEAT_SM4 is implemented, then FEAT_Crypto is implemented.

The following field identifies the presence of FEAT_SM4:

- ID_AA64ISAR0_EL1.SM4.

For more information, see FEAT_SM4, SM4 functionality.

FEAT_TTCNP, Translation table Common not private translations

FEAT_TTCNP permits multiple PEs in the same Inner Shareable domain to use the same translation tables for a given stage of address translation.

This facility is available for all VMSAv8-64 translation regimes and for VMSAv8-32 translation stages that use the Long descriptor Translation Table format.

FEAT_TTCNP is OPTIONAL from Armv8.1.

FEAT_TTCNP is mandatory from Armv8.2.

The following field identifies the presence of FEAT_TTCNP:

- ID_AA64MMFR2_EL1.CnP.

For more information, see:

- Common not private translations.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- ‘Common not private translations in VMSAv8-32’.

FEAT_UAO, Unprivileged Access Override control

FEAT_UAO introduces the UAO bit to PSTATE. When the Effective value of UAO is 1, if memory accesses that are described as unprivileged are made by the unprivileged memory access instructions, they are privileged.

FEAT_UAO is OPTIONAL from Armv8.1.

FEAT_UAO is mandatory from Armv8.2.

The following field identifies the presence of FEAT_UAO:

- ID_AA64MMFR2_EL1.UAO.

For more information, see:

- PSTATE.UAO.
- Load/store unprivileged.
- UAO.

FEAT_XNX, Translation table stage 2 Unprivileged Execute-never

FEAT_XNX extends the stage 2 translation table access permissions to provide control of whether memory is executable at EL0 independent of whether it is executable at EL1.

This facility is available for stage 2 translation stages in VMSAv8-64 and VMSAv8-32.

FEAT_XNX is OPTIONAL from Armv8.1.

FEAT_XNX is mandatory from Armv8.2.

The following field identifies the presence of FEAT_XNX:

- ID_AA64MMFR1_EL1.XNX.

For more information, see:

- ‘Stage 2 instruction execution using Direct permissions’.

A2.2.3.1 Features added to the Armv8.2 extension in later releases

- FEAT_LRCPC2.
- FEAT_LSE2.
- FEAT_PAuth2.
- FEAT_RASSAv1p1.
- FEAT_RASv1p1.

A2.2.4 The Armv8.3 architecture extension

The Armv8.3 architecture extension is an extension to Armv8.2. It adds mandatory and optional architectural features. Some features must be implemented together. An implementation is Armv8.3 compliant if all of the following apply:

- It is Armv8.2 compliant.
- It includes all of the Armv8.3 architectural features that are mandatory.

An Armv8.3 compliant implementation can additionally include:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- Armv8.3 features that are optional.
- Any arbitrary subset of the architectural features of Armv8.4, subject only to those constraints that require that certain features be implemented together.

FEAT_CCIDX, Extended cache index

FEAT_CCIDX introduces the following registers to allow caches to be described with greater numbers of sets and greater associativity:

- A 64-bit format of CCSIDR_EL1.
- CCSIDR2_EL1.

FEAT_CCIDX is OPTIONAL from Armv8.2.

The following field identifies the presence of FEAT_CCIDX:

- ID_AA64MMFR2_EL1.CCIDX.

For more information, see:

- Possible formats of the Cache Size Identification Register, CCSIDR_EL1.

FEAT_CONSTPACFIELD, PAC algorithm enhancement

FEAT_CONSTPACFIELD introduces functionality that permits an implementation with pointer authentication to use the value of bit[55] in the virtual address to determine the size of the PAC field when adding a PAC to the virtual address, even when the top byte is not being ignored.

FEAT_CONSTPACFIELD is OPTIONAL from Armv8.2.

If FEAT_CONSTPACFIELD is implemented, then FEAT_PAuth2 is implemented.

The following field identifies the presence of FEAT_CONSTPACFIELD:

- ID_AA64ISAR2_EL1.PAC_frac.

For more information, see PAC field.

FEAT_DoPD, Debug over Powerdown

FEAT_DoPD provides a debug programmers' model where all debug and PMU registers are in the Core power domain and all CTI registers are in the Debug power domain. Power control is provided by an OPTIONAL external powerup request mechanism.

When FEAT_DoPD is implemented:

- The optional Software Lock is not implemented by the architecturally defined debug components in the PE Core power domain.
- If an ETMv4 trace unit is implemented, the ETM must implement:
  - ETMv4.2 or later.
  - The Unified Power Domain Model.
- If FEAT_ETE is implemented, the trace unit always implements a single power domain.

FEAT_DoPD is OPTIONAL from Armv8.2.

If FEAT_DoPD is implemented, then FEAT_DoubleLock is not implemented.

If FEAT_DoPD is implemented, then FEAT_Debugv8p2 is implemented.

The following field identifies the presence of FEAT_DoPD:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- EDDEVID.DebugPower.

For more information, see Debug Reset and Powerdown Support.

FEAT_EPAC, Enhanced pointer authentication

FEAT_EPAC introduces functionality that permits setting the Pointer Authentication Code (PAC) field to 0 on performing a PAC operation on a non-canonical address.

FEAT_EPAC is OPTIONAL from Armv8.2.

If FEAT_EPAC is implemented, then FEAT_PAuth is implemented.

If FEAT_EPAC is implemented, then FEAT_PAuth2 is not implemented.

The following fields identify the presence of FEAT_EPAC:

- ID_AA64ISAR1_EL1.APA.
- ID_AA64ISAR1_EL1.API.
- ID_AA64ISAR2_EL1.APA3.

For more information, see Pointer authentication.

FEAT_FCMA, Floating-point complex number instructions

FEAT_FCMA introduces instructions for floating-point multiplication and addition of complex numbers.

FEAT_FCMA is OPTIONAL from Armv8.2.

In an Armv8.3 implementation, if FEAT_FP is implemented, FEAT_FCMA is implemented.

If FEAT_FCMA is implemented, then FEAT_FP is implemented.

The following field identifies the presence of FEAT_FCMA:

- ID_AA64ISAR1_EL1.FCMA.

For more information, see:

- AArch64 Advanced SIMD complex number arithmetic instructions.

FEAT_FPAC, Faulting on AUT* instructions

FEAT_FPAC introduces faulting on an AUT* instruction.

FEAT_FPAC is added as a further extension to FEAT_PAuth2.

FEAT_FPAC is OPTIONAL from Armv8.2.

If FEAT_FPAC is implemented, then FEAT_PAuth2 is implemented.

The following fields identify the presence of FEAT_FPAC:

- ID_AA64ISAR1_EL1.APA.
- ID_AA64ISAR1_EL1.API.
- ID_AA64ISAR2_EL1.APA3.

For more information, see Faulting on pointer authentication.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

FEAT_FPACCOMBINE, Faulting on combined pointer authentication instructions

FEAT_FPACCOMBINE introduces faulting on the combined instructions that perform pointer authentication.

FEAT_FPACCOMBINE is added as a further extension to FEAT_FPAC.

FEAT_FPACCOMBINE is OPTIONAL from Armv8.2.

If FEAT_FPACCOMBINE is implemented, then FEAT_FPAC is implemented.

The following fields identify the presence of FEAT_FPACCOMBINE:

- ID_AA64ISAR1_EL1.APA.
- ID_AA64ISAR1_EL1.API.
- ID_AA64ISAR2_EL1.APA3.

For more information, see Faulting on pointer authentication.

FEAT_FPACC_SPEC, Speculative behavior of pointer authentication instructions

FEAT_FPACC_SPEC introduces consistent impact of speculation for instructions that perform authentication.

FEAT_FPACC_SPEC is added as a further extension to FEAT_FPACCOMBINE.

FEAT_FPACC_SPEC is OPTIONAL from Armv8.2.

If FEAT_FPACC_SPEC is implemented, then FEAT_FPACCOMBINE is implemented.

The following field identifies the presence of FEAT_FPACC_SPEC:

- ID_AA64MMFR3_EL1.Spec_FPACC.

For more information, see Faulting on pointer authentication.

FEAT_JSCVT, JavaScript conversion instructions

FEAT_JSCVT introduces JavaScript convert instructions that truncate a double-precision value to a 32-bit signed integer, setting the condition flags to indicate whether the converted value was in range.

FEAT_JSCVT is OPTIONAL from Armv8.2.

In an Armv8.3 implementation, if FEAT_FP is implemented, FEAT_JSCVT is implemented.

If FEAT_JSCVT is implemented, then FEAT_FP is implemented.

The following field identifies the presence of FEAT_JSCVT:

- ID_AA64ISAR1_EL1.JSCVT.

For more information, see:

- Floating-point conversion.
- About the A64 Advanced SIMD and floating-point instructions.
- Advanced SIMD and floating-point instructions.
- Floating-point data-processing instructions.

FEAT_LRCPC, Load-Acquire RCpc instructions

FEAT_LRCPC introduces instructions that support the weaker Release Consistency processor consistent (RCpc) model that enables the reordering of a Store-Release followed by a Load-Acquire to a different address.

FEAT_LRCPC is OPTIONAL from Armv8.2.

FEAT_LRCPC is mandatory from Armv8.3.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The following field identifies the presence of FEAT_LRCPC:

- ID_AA64ISAR1_EL1.LRCPC.

For more information, see:

- Load-Acquire, Load-AcquirePC, and Store-Release.
- Load-Acquire/Store-Release.

FEAT_PACIMP, Pointer authentication - IMPLEMENTATION DEFINED algorithm

FEAT_PACIMP permits an IMPLEMENTATION DEFINED cryptographic algorithm to be used for PAC calculation.

FEAT_PACIMP is OPTIONAL from Armv8.2.

If FEAT_PACIMP is implemented, then FEAT_PAuth is implemented.

If FEAT_PACIMP is implemented, then FEAT_PACQARMA5 is not implemented.

If FEAT_PACIMP is implemented, then FEAT_PACQARMA3 is not implemented.

The following fields identify the presence of FEAT_PACIMP:

- ID_AA64ISAR1_EL1.GPI.
- ID_AA64ISAR1_EL1.API.

For more information, see Pointer authentication.

FEAT_PACQARMA3, Pointer authentication - QARMA3 algorithm

FEAT_PACQARMA3 introduces the QARMA3 cryptographic algorithm for PAC calculation.

FEAT_PACQARMA3 is OPTIONAL from Armv8.2.

If FEAT_PACQARMA3 is implemented, then FEAT_PAuth is implemented.

If FEAT_PACQARMA3 is implemented, then FEAT_PACQARMA5 is not implemented.

If FEAT_PACQARMA3 is implemented, then FEAT_PACIMP is not implemented.

The following fields identify the presence of FEAT_PACQARMA3:

- ID_AA64ISAR2_EL1.GPA3.
- ID_AA64ISAR2_EL1.APA3.

For more information, see Pointer authentication.

FEAT_PACQARMA5, Pointer authentication - QARMA5 algorithm

FEAT_PACQARMA5 introduces the QARMA5 cryptographic algorithm for PAC calculation.

FEAT_PACQARMA5 is OPTIONAL from Armv8.2.

If FEAT_PACQARMA5 is implemented, then FEAT_PAuth is implemented.

If FEAT_PACQARMA5 is implemented, then FEAT_PACQARMA3 is not implemented.

If FEAT_PACQARMA5 is implemented, then FEAT_PACIMP is not implemented.

The following fields identify the presence of FEAT_PACQARMA5:

- ID_AA64ISAR1_EL1.GPA.
- ID_AA64ISAR1_EL1.APA.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

For more information, see Pointer authentication.

FEAT_PAuth, Pointer authentication

FEAT_PAuth introduces functionality that supports address authentication of the contents of a register before that register is used as the target of an indirect branch, or as a load.

When FEAT_PAuth is implemented, all of the following must be true:

- Exactly one of the PAC algorithms is implemented.
- The PACGA instruction and other Pointer authentication instructions use the same algorithm.

The PAC algorithm features are:

- FEAT_PACQARMA5.
- FEAT_PACIMP.
- FEAT_PACQARMA3.

FEAT_PAuth is OPTIONAL from Armv8.2.

FEAT_PAuth is mandatory from Armv8.3.

If FEAT_PAuth is implemented, then FEAT_PACQARMA5, FEAT_PACIMP, or FEAT_PACQARMA3 is implemented.

For more information, see Pointer authentication.

FEAT_PAuth2, Enhancements to pointer authentication

FEAT_PAuth2 introduces enhanced pointer authentication functionality that changes the mechanism by which a PAC is added to the pointer.

FEAT_PAuth2 is OPTIONAL from Armv8.2.

If FEAT_PAuth2 is implemented, then FEAT_PAuth is implemented.

If FEAT_PAuth2 is implemented, then FEAT_EPAC is not implemented.

The following fields identify the presence of FEAT_PAuth2:

- ID_AA64ISAR1_EL1.APA.
- ID_AA64ISAR1_EL1.API.
- ID_AA64ISAR2_EL1.APA3.

For more information, see Pointer authentication.

A2.2.5 The Armv8.4 architecture extension

The Armv8.4 architecture extension is an extension to Armv8.3. It adds mandatory and optional architectural features. Some features must be implemented together. An implementation is Armv8.4 compliant if all of the following apply:

- It is Armv8.3 compliant.
- It includes all of the Armv8.4 architectural features that are mandatory.

An Armv8.4 compliant implementation can additionally include:

- Armv8.4 features that are optional.
- Any arbitrary subset of the architectural features of Armv8.5, subject only to those constraints that require that certain features be implemented together.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

FEAT_BBML1, Translation table break-before-make level 1

FEAT_BBML1 provides support for reducing the requirements for following a break-before-make sequence when changing between table or block sizes for a translation.

FEAT_BBML1 is OPTIONAL from Armv8.3.

The following field identifies the presence of FEAT_BBML1:

- ID_AA64MMFR2_EL1.BBM.

For more information, see:

- Block descriptor and Page descriptor formats.
- 'Block translation entry'.
- Support levels for changing block size.

FEAT_BBML2, Translation table break-before-make level 2

FEAT_BBML2 provides support for further reducing the requirements for following a break-before-make sequences when changing between table or block sizes for a translation.

FEAT_BBML2 is OPTIONAL from Armv8.3.

If FEAT_BBML2 is implemented, then FEAT_BBML1 is implemented.

The following field identifies the presence of FEAT_BBML2:

- ID_AA64MMFR2_EL1.BBM.

For more information, see FEAT_BBML1.

FEAT_CNTSC, Generic Counter Scaling

FEAT_CNTSC introduces a scaling register to the memory-mapped counter module that allows the frequency of the counter that is generated to be scaled from the basic frequency reported in the counter ID mechanisms.

FEAT_CNTSC is OPTIONAL from Armv8.3.

The following field identifies the presence of FEAT_CNTSC:

- CNTID.CNTSC.

For more information, see CNTCR.

FEAT_CSV2, Cache Speculation Variant 2

FEAT_CSV2 introduces a mechanism to identify if hardware cannot disclose information about whether any prediction resource, such as branch target, data-value, or cache prefetch, trained in one hardware described context can control speculative execution in a different hardware described context.

FEAT_CSV2 is OPTIONAL from Armv8.0.

The following field identifies the presence of FEAT_CSV2:

- ID_AA64PFR0_EL1.CSV2.

For more information, see:

- For AArch64, 'Restrictions on the effects of speculation'.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

FEAT_CSV3, Cache Speculation Variant 3

FEAT_CSV3 introduces a mechanism to identify whether data loaded or read from a register under speculation where the data load or register read would not be permitted architecturally, can be used by instructions newer than the load or register read in a manner that allows the value of the inaccessible data to be recovered by code architecturally executed.

FEAT_CSV3 is OPTIONAL from Armv8.0.

The following field identifies the presence of FEAT_CSV3:

- ID_AA64PFR0_EL1.CSV3.

FEAT_DGH, Data Gathering Hint

FEAT_DGH introduces the Data Gathering Hint instruction to the hint space.

FEAT_DGH is OPTIONAL from Armv8.0.

The following field identifies the presence of FEAT_DGH:

- ID_AA64ISAR1_EL1.DGH.

For more information, see Hint instructions.

FEAT_DIT, Data Independent Timing instructions

FEAT_DIT provides a mechanism for software to indicate that a sequence of code is intended to be independent from data values from certain instructions within the sequence.

FEAT_DIT is OPTIONAL from Armv8.3.

FEAT_DIT is mandatory from Armv8.4.

The following field identifies the presence of FEAT_DIT:

- ID_AA64PFR0_EL1.DIT.

For more information, see:

- About PSTATE.DIT.
- About the DIT bit.

FEAT_DPB2, DC CVADP instruction

FEAT_DPB2 allows two levels of cache clean to the Point of Persistence by:

- Redefining Point of Persistence, which changes the scope of DC CVAP.
- Defining a Point of Deep Persistence.
- Adding the DC CVADP System instruction.

FEAT_DPB2 is OPTIONAL from Armv8.1.

If FEAT_DPB2 is implemented, then FEAT_DPB is implemented.

The following field identifies the presence of FEAT_DPB2:

- ID_AA64ISAR1_EL1.DPB.

For more information, see Terminology for Clean, Invalidate, and Clean and Invalidate instructions.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

FEAT_Debugv8p4, Debug v8.4

FEAT_Debugv8p4 provides the following mandatory changes:

- The fields MDCR_EL3.{EPMAD, EDAD} control Non-secure access to the debug and PMU registers. The bus Requester is responsible for other debug authentication.
- The Software Lock is obsolete.
- Non-invasive Debug controls are relaxed.
- Secure and Non-secure views of the debug registers are enabled.

FEAT_Debugv8p4 is OPTIONAL from Armv8.3.

FEAT_Debugv8p4 is mandatory from Armv8.4.

If FEAT_Debugv8p4 is implemented, then FEAT_Debugv8p2 is implemented.

If FEAT_SEL2 is implemented, then FEAT_Debugv8p4 is implemented.

The following fields identify the presence of FEAT_Debugv8p4:

- ID_AA64DFR0_EL1.DebugVer.
- EDDEVARCH.ARCHVER.

For more information, see:

- Definition and constraints of a debugger in the context of external debug.
- External debug interface register access permissions.

FEAT_DotProd, Advanced SIMD dot product instructions

FEAT_DotProd provides instructions to perform a four-way vector dot product of 8-bit integers, accumulating each sum of four products into a 32-bit integer. Each 8-bit input can be treated as a signed or unsigned value.

FEAT_DotProd is OPTIONAL from Armv8.1.

In an Armv8.4 implementation, if FEAT_AdvSIMD is implemented, FEAT_DotProd is implemented.

The following field identifies the presence of FEAT_DotProd:

- ID_AA64ISAR0_EL1.DP.

For more information, see:

- SIMD integer dot product.

FEAT_E0PD, Preventing EL0 access to halves of address maps

FEAT_E0PD prevents access at EL0 to half of the addresses in the memory map.

FEAT_E0PD is OPTIONAL from Armv8.4.

If FEAT_E0PD is implemented, then FEAT_CSV3 is implemented.

The following field identifies the presence of FEAT_E0PD:

- ID_AA64MMFR2_EL1.E0PD.

For more information, see Preventing EL0 access to halves of the address map.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

FEAT_FHM, Floating-point half-precision to single-precision multiply-add instructions

FEAT_FHM introduces half-precision to single-precision fused multiply-add instructions.

FEAT_FHM is OPTIONAL from Armv8.1.

In an Armv8.4 implementation, if FEAT_FP16 is implemented, FEAT_FHM is implemented.

In an Armv8.2 implementation, if FEAT_FHM is implemented, FEAT_FP16 is implemented.

The following field identifies the presence of FEAT_FHM:

- ID_AA64ISAR0_EL1.FHM.

For more information, see:

- SIMD arithmetic.
- SIMD by element arithmetic.

FEAT_FlagM, Condition flag manipulation instructions

FEAT_FlagM provides instructions that manipulate the PSTATE.{N,Z,C,V} flags.

FEAT_FlagM is OPTIONAL from Armv8.1.

FEAT_FlagM is mandatory from Armv8.4.

The following field identifies the presence of FEAT_FlagM:

- ID_AA64ISAR0_EL1.TS.

For more information, see Flag manipulation instructions.

FEAT_IDST, ID space trap handling

FEAT_IDST causes all AArch64 read accesses to the feature ID space when exceptions are generated to be reported in ESR_ELx using the EC code `0x18`.

FEAT_IDST is OPTIONAL from Armv8.3.

FEAT_IDST is mandatory from Armv8.4.

The following field identifies the presence of FEAT_IDST:

- ID_AA64MMFR2_EL1.IDS.

FEAT_LRCPC2, Load-Acquire RCpc instructions version 2

FEAT_LRCPC2 provides versions of `LDAPR` and `STLR` with a 9-bit unscaled signed immediate offset.

FEAT_LRCPC2 is OPTIONAL from Armv8.2.

FEAT_LRCPC2 is mandatory from Armv8.4.

If FEAT_LRCPC2 is implemented, then FEAT_LRCPC is implemented.

The following field identifies the presence of FEAT_LRCPC2:

- ID_AA64ISAR1_EL1.LRCPC.

For more information, see:

- ‘Changes to single-copy atomicity in Armv8.4’.
- Load-Acquire/Store-Release.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- A64 instructions that are changed in Debug state.

FEAT_LSE2, Large System Extensions version 2

FEAT_LSE2 introduces changes to single-copy atomicity requirements for loads and stores, and changes to alignment requirements for loads and stores.

FEAT_LSE2 is OPTIONAL from Armv8.2.

FEAT_LSE2 is mandatory from Armv8.4.

The following field identifies the presence of FEAT_LSE2:

- ID_AA64MMFR2_EL1.AT.

For more information, see:

- 'Requirements for single-copy atomicity'.
- Alignment of data accesses.

FEAT_PMUv3p4, Arm8.4 PMU extensions

FEAT_PMUv3p4 introduces:

- PMMIR_EL1

FEAT_PMUv3p4 is OPTIONAL from Armv8.3.

If FEAT_PMUv3p4 is implemented, then FEAT_PMUv3p1 is implemented.

The following fields identify the presence of FEAT_PMUv3p4:

- ID_AA64DFR0_EL1.PMUVer.
- EDDFR.PMUVer.

For more information, see PMU Event Descriptions.

FEAT_RASSAv1p1, RAS version 1.1 System Architecture

FEAT_RASSAv1p1 implements the RAS System Architecture v1.1, including support for the following:

- Additional ERR<n>MISC<m> registers.
- The optional RAS Common Fault Injection Model Extension.

FEAT_RASSAv1p1 is OPTIONAL from Armv8.2.

In an Armv8.4 implementation, if FEAT_RAS is implemented, FEAT_RASSAv1p1 is implemented.

If FEAT_RASv1p1 is implemented, then FEAT_RASSAv1p1 is implemented.

FEAT_RASv1p1, RAS extension v1.1

FEAT_RASv1p1 introduces support for System register access to the following RAS System Architecture v1.1 features:

- Additional ERR<n>MISC<m> registers.
- The optional RAS Common Fault Injection Model Extension.

FEAT_RASv1p1 is OPTIONAL from Armv8.2.

In an Armv8.4 implementation, if FEAT_RAS is implemented, FEAT_RASv1p1 is implemented.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

If FEAT_RASv1p1 is implemented, then FEAT_RAS is implemented.

If FEAT_RASv1p1 is implemented, then FEAT_RASSAv1p1 is implemented.

The following fields identify the presence of FEAT_RASv1p1:

- ID_AA64PFR0_EL1.RAS.
- ID_AA64PFR1_EL1.RAS_frac.

For more information, see *Arm® Reliability Availability and Serviceability (RAS) System Architecture, for A-profile architecture* (ARM IHI 0100).

FEAT_S2FWB, Stage 2 forced Write-Back

FEAT_S2FWB reduces the requirement of additional cache maintenance instructions in systems where the data Cacheability attributes used by the Guest operating system are different from those expected by the Hypervisor. If this feature is implemented, there is no meaningful distinction between the Inner and Outer Shareability domains for Normal Cacheable accesses to Conventional memory.

FEAT_S2FWB is OPTIONAL from Armv8.3.

FEAT_S2FWB is mandatory from Armv8.4.

The following field identifies the presence of FEAT_S2FWB:

- ID_AA64MMFR2_EL1.FWB.

For more information, see:

- Block descriptor and Page descriptor formats.
- ‘Stage 2 memory type and Cacheability attributes when FEAT_S2FWB is enabled’.

FEAT_SB, Speculation Barrier

Speculation Barrier FEAT_SB introduces a barrier to control speculation.

FEAT_SB is OPTIONAL from Armv8.0.

The following field identifies the presence of FEAT_SB:

- ID_AA64ISAR1_EL1.SB.

For more information, see:

- Speculation Barrier (SB).
- Barriers and CLREX instructions.

FEAT_SEL2, Secure EL2

FEAT_SEL2 permits EL2 to be implemented in Secure state. When Secure EL2 is enabled, a translation regime is introduced that follows the same format as the other Secure translation regimes.

FEAT_SEL2 is OPTIONAL from Armv8.3.

In an Armv8.4 implementation, if FEAT_Secure is implemented, FEAT_SEL2 is implemented.

If FEAT_SEL2 is implemented, then FEAT_TTST is implemented.

If FEAT_SEL2 is implemented, then FEAT_Secure is implemented.

The following field identifies the presence of FEAT_SEL2:

- ID_AA64PFR0_EL1.SEL2.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

For more information, see:

- Security states
- Translation regimes.

FEAT_SPECRES, Speculation restriction instructions

FEAT_SPECRES introduces System instructions that prevent predictions based on information gathered from earlier execution within a particular execution context from affecting the later speculative execution within that context, to the extent that the speculative execution is observable through side channels.

FEAT_SPECRES is OPTIONAL from Armv8.0.

The following field identifies the presence of FEAT_SPECRES:

- ID_AA64ISAR1_EL1.SPECRES.

For more information, see:

- ‘Prediction restriction instructions’.
- ‘Execution, data prediction and prefetching restriction System instructions’.

FEAT_SSBS, Speculative Store Bypass Safe

FEAT_SSBS allows software to indicate whether hardware is permitted to load or store speculatively in a manner that could give rise to a cache timing side channel, which in turn could be used to derive an address from values loaded to a register from memory.

FEAT_SSBS is OPTIONAL from Armv8.0.

The following field identifies the presence of FEAT_SSBS:

- ID_AA64PFR1_EL1.SSBS.

For more information, see:

- AArch64 Speculative Store Bypass Safe.

FEAT_SSBS2, MRS and MSR instructions for SSBS version 2

FEAT_SSBS2 provides controls for the MSR and MRS instructions to read and write the PSTATE.SSBS field.

FEAT_SSBS2 is OPTIONAL from Armv8.0.

If FEAT_SSBS2 is implemented, then FEAT_SSBS is implemented.

The following field identifies the presence of FEAT_SSBS2:

- ID_AA64PFR1_EL1.SSBS.

For more information, see:

- AArch64 Speculative Store Bypass Safe.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

FEAT_TLBIOS, TLB invalidate instructions in Outer Shareable domain

FEAT_TLBIOS provides TLBI maintenance instructions that extend to the Outer Shareable domain.

FEAT_TLBIOS is OPTIONAL from Armv8.3.

FEAT_TLBIOS is mandatory from Armv8.4.

The following field identifies the presence of FEAT_TLBIOS:

- ID_AA64ISAR0_EL1.TLB.

For more information, see TLB maintenance instructions.

FEAT_TLBIRANGE, TLB invalidate range instructions

FEAT_TLBIRANGE provides TLBI maintenance instructions that apply to a range of input addresses.

FEAT_TLBIRANGE is OPTIONAL from Armv8.3.

FEAT_TLBIRANGE is mandatory from Armv8.4.

If FEAT_TLBIRANGE is implemented, then FEAT_TLBIOS is implemented.

The following field identifies the presence of FEAT_TLBIRANGE:

- ID_AA64ISAR0_EL1.TLB.

For more information, see:

- TLB maintenance instructions.
- TLB maintenance instructions that do not apply to a range of addresses.

FEAT_TRF, Self-hosted Trace extensions

FEAT_TRF introduces control of trace in a self-hosted system through System registers.

The feature provides:

- Control of Exception levels and Security states where trace generation is prohibited.
- Control of whether an offset is used for the timestamp recorded with trace information.
- A context synchronization instruction, TSB CSYNC, that can be used to prevent reordering of trace operation accesses with respect to other accesses of the same System registers.

FEAT_TRF is OPTIONAL from Armv8.3.

In an Armv8.4 implementation, if FEAT_ETMv4 is implemented, FEAT_TRF is implemented.

If FEAT_TRF is implemented, then FEAT_TRC_SR is implemented.

The following fields identify the presence of FEAT_TRF:

- ID_AA64DFR0_EL1.TraceFilt.
- EDDFR.TraceFilt.

For more information on FEAT_TRF, see:

- AArch64 Self-hosted Trace.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

FEAT_TTL, Translation Table Level

FEAT_TTL provides the TTL field to indicate the level of translation table walk holding the leaf entry for the address that is being invalidated. This field is provided in all TLB maintenance instructions that take a VA or an IPA argument.

FEAT_TTL is OPTIONAL from Armv8.3.

FEAT_TTL is mandatory from Armv8.4.

The following field identifies the presence of FEAT_TTL:

- ID_AA64MMFR2_EL1.TTL.

For more information, see:

- TLB maintenance instructions.
- TLB maintenance instructions that do not apply to a range of addresses.

FEAT_TTST, Small translation tables

FEAT_TTST relaxes the lower limit on the size of translation tables, by increasing the maximum permitted value of the T1SZ and T0SZ fields in TCR_EL1, TCR_EL2, TCR_EL3, VTCR_EL2 and VSTCR_EL2.

FEAT_TTST is OPTIONAL from Armv8.3.

If FEAT_SEL2 is implemented, then FEAT_TTST is implemented.

The following field identifies the presence of FEAT_TTST:

- ID_AA64MMFR2_EL1.ST.

For more information, see:

- Input address size configuration.
- Translation using the 4KB granule.
- Translation using the 16KB granule.
- Translation using the 64KB granule.

Chapter B1
The AArch64 Application Level Programmers' Model

This chapter describes the AArch64 application level programmers' model. It contains the following sections:

- About the Application level programmers' model.
- Registers in AArch64 Execution state.
- Process state, PSTATE.
- Software control features and EL0.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

B1.1 About the Application level programmers' model

This chapter contains the programmers' model information required for application development.

The information in this chapter is distinct from the system information required to service and support application execution under an operating system, or higher level of system software. However, some knowledge of the system information is needed to put the Application level programmers' model into context.

Depending on the implementation choices, the architecture supports multiple levels of execution privilege, indicated by different *Exception levels* that number upwards from EL0 to EL2. EL0 corresponds to the lowest privilege level and is often described as unprivileged. The Application level programmers' model is the programmers' model for software executing at EL0. For more information, see Exception levels.

System software determines the Exception level, and therefore the level of privilege, at which software runs. When an operating system supports execution at both EL1 and EL0, an application usually runs unprivileged at EL0. This:

- Permits the operating system to allocate system resources to an application in a unique or shared manner.
- Provides a degree of protection from other processes, and so helps protect the operating system from malfunctioning software.

This chapter indicates where some system level understanding is necessary, and where relevant it gives a reference to the system level description.

Execution at any Exception level above EL0 is often referred to as privileged execution.

For more information on the system level view of the architecture refer to The AArch64 System Level Programmers' Model.

B1.2 Registers in AArch64 Execution state

The following registers are visible at EL0 using AArch64:

R0-R30 31 general-purpose registers, R0 to R30. Each can be accessed as:

- A 64-bit general-purpose register named X0 to X30.
- A 32-bit general-purpose register named W0 to W30.

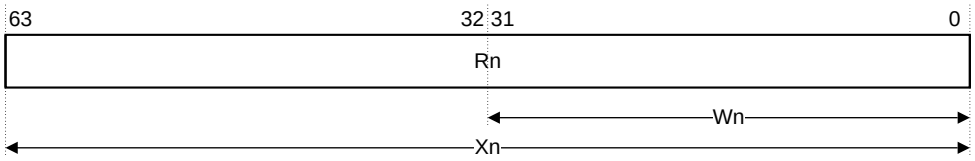

Figure B1-1 General-purpose register naming

The X30 general-purpose register is used as the procedure call link register.

SP A 64-bit dedicated Stack Pointer register. The least significant 32 bits of the stack pointer can be accessed using the register name WSP.

The use of SP as an operand in an instruction, indicates the use of the current stack pointer.

Note

Stack pointer alignment to a 16-byte boundary is configurable at EL1. For more information, see the *Procedure Call Standard for the Arm 64-bit Architecture*.

PC A 64-bit Program Counter holding the address of the current instruction.

Software cannot write directly to the PC. It can be updated only on a branch, exception entry or exception return.

Note

Attempting to execute an A64 instruction that is not word-aligned generates a PC alignment fault, see PC alignment checking.

V0-V31 32 SIMD&FP registers, V0 to V31. Each can be accessed as:

- A 128-bit register named Q0 to Q31.
- A 64-bit register named D0 to D31.
- A 32-bit register named S0 to S31.
- A 16-bit register named H0 to H31.
- An 8-bit register named B0 to B31.

Where the number of bits described by a register name does not occupy an entire SIMD&FP register, it refers to the least significant bits. See Figure B1-2.

For more information about data types and vector formats, see Supported data types.

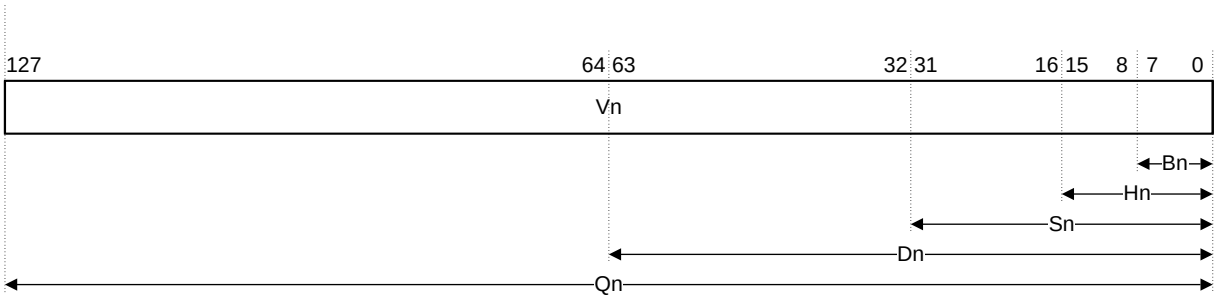

Figure B1-2 SIMD and floating-point register naming

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

FPCR, FPSR The FPCR is the floating-point control register. The FPSR is the floating-point status register.

See also:

- System registers.
- Pseudocode description of registers in AArch64 state.
- Registers for instruction processing and exception handling.

B1.2.1 System registers

System registers provide support for execution control, status and general system configuration. The majority of the System registers are not accessible at EL0.

However, some System registers can be configured to allow access from software executing at EL0. Any access from EL0 to a System register without access permission causes the instruction to be trapped. The registers that can be accessed from EL0 are:

Debug registers A Debug Communications Channel is supported by the MDCCSR_EL0, DBGDTR_EL0, DBGDTRRX_EL0, DBGDTRTX_EL0, DLR_EL0 and DSPSR_EL0 registers.

General system control registers

- The CTR_EL0 and DCZID_EL0 registers provide implementation parameters for EL0 cache management support.
- The SCXTNUM_EL0 register provides a number that can be used to separate out different context numbers.
- The POR_EL0 Permission Overlay register determines the unprivileged stage 1 overlay permissions for the EL1&0 and EL2&0 translation regimes.
- The TPIDR_EL0 and TPIDRRO_EL0 registers provide locations where software can store thread identifying information.

Generic timer registers

- Read access to the system counter effective frequency using CNTFRQ_EL0.
- Physical and virtual timer count registers, CNTPCT_EL0, CNTVCT_EL0, CNTPCTSS_EL0 and CNTVCTSS_EL0.
- Physical up-count comparison, down-count value and timer control registers, CNTP_CVAL_EL0, CNTP_TVAL_EL0, and CNTP_CTL_EL0.
- Virtual up-count comparison, down-count value and timer control registers, CNTV_CVAL_EL0, CNTV_TVAL_EL0, and CNTV_CTL_EL0.

Performance Monitors registers

The Performance Monitors Extension provides counters and configuration registers. Software executing at EL1 or a higher Exception level can configure some of these registers to be accessible at EL0.

For more details, see The Performance Monitors Extension.

B1.2.2 Pseudocode description of registers in AArch64 state

The AArch64 pseudocode uses getter and setter accessor functions to read and write register files that are visible at EL0:

- The setter or assignment accessor, for example "`X[num, width] = result`", is used for register writes.
- The getter or non-assignment accessor, "`operand = X[num, width]`", is used for register reads.
- The *num* parameter specifies the register number to be accessed within the named register file, and *width* specifies the bit width of the register access.
- For the general-purpose register `X[]` accessor, register number 31 accesses the zero register, ZR, which reads as zero and ignores writes.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- For other register accessors, such as the SIMD&FP `V[]` accessors, there is no special interpretation of the register number.

Other special AArch64 accessors include:

- The `SP[]` accessors have no parameters and are used to read or write the currently selected 64-bit stack pointer at the current Exception level.
- The `PC64[]` accessor has no parameter list and is used to read the 64-bit Program Counter.
- The `Vpart[]` accessors are used to perform a partial read or write of an Advanced SIMD vector register, using an additional *part* parameter to select which half of the vector register to access.
- The `V[]`, and `Vpart[]` accessors read and write the same underlying vector register file.

Other register accessors are defined as required by other architectural features. See R-profile Architecture Pseudocode, sections aarch64/functions/registers/.

B1.3 Process state, PSTATE

Process state, or PSTATE, is an abstraction of process state information. All of the instruction sets provide instructions that operate on elements of PSTATE.

For the system level view of PSTATE, see Process state, PSTATE in The AArch64 System Level Programmers' Model.

The following PSTATE information is accessible at EL0:

The Condition flags

Flag-setting instructions set these. They are:

N Negative Condition flag. If the result of the instruction is regarded as a two's complement signed integer, the PE sets this to:

- 1 if the result is negative.
- 0 if the result is positive or zero.

Z Zero Condition flag. Set to:

- 1 if the result of the instruction is zero.
- 0 otherwise.

A result of zero often indicates an equal result from a comparison.

C Carry Condition flag. Set to:

- 1 if the instruction results in a carry condition, for example an unsigned overflow that is the result of an addition.
- 0 otherwise.

V Overflow Condition flag. Set to:

- 1 if the instruction results in an overflow condition, for example a signed overflow that is the result of an addition.
- 0 otherwise.

Conditional instructions test the N, Z, C and V Condition flags, combining them with the Condition code for the instruction to determine whether the instruction must be executed. In this way, execution of the instruction is conditional on the result of a previous operation. For more information about conditional execution, see Condition flags and related instructions.

The exception masking bits

D Debug exception mask bit. When EL0 is enabled to modify the mask bits, this bit is visible and can be modified. However, this bit is architecturally ignored at EL0.

A SError mask bit.

I IRQ interrupt mask bit.

F FIQ interrupt mask bit.

For each bit, the values are:

0 Exception not masked.

1 Exception masked.

Access at EL0 using AArch64 state depends on SCTLR_EL1.UMA.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

B1.3.1 Accessing PSTATE fields at EL0

At EL0 using AArch64 state, PSTATE fields can be accessed using Special-purpose registers that can be directly read using the MRS instruction and directly written using the MSR (register) instructions. Table B1-1 shows the Special-purpose registers that access the PSTATE fields that hold AArch64 state when the PE is at EL0 using AArch64. All other PSTATE fields do not have direct read and write access at EL0.

Table B1-1 Accessing PSTATE fields at EL0 using MRS and MSR (register)

Special-purpose register	PSTATE fields
NZCV	N, Z, C, V
DAIF	D, A, I, F
SSBS	SSBS
DIT	DIT

Software can also use the MSR (immediate) instruction to directly write to PSTATE.{D, A, I, F, SSBS, DIT}. Table B1-2 shows the MSR (immediate) operands that can directly write to PSTATE.{D, A, I, F, SSBS, DIT} when the PE is at EL0 using AArch64 state.

Table B1-2 Accessing PSTATE.{D, A, I, F, SSBS, DIT} at EL0 using MSR (immediate)

Operand	PSTATE fields	Notes
DAIFSet	D, A, I, F	Directly sets any of the PSTATE.{D,A, I, F} bits to 1
DAIFClr	D, A, I, F	Directly clears any of the PSTATE.{D, A, I, F} bits to 0
SSBS	SSBS	Directly sets the PSTATE.SSBS bit to CRm<0>
DIT	DIT	Directly sets the PSTATE.DIT bit to CRm<0>

Access to the PSTATE.{D, A, I, F} fields at EL0 using AArch64 state depends on SCTLR_EL1.UMA.

Writes to the PSTATE fields have side-effects on various aspects of the PE operation. All of these side-effects, are guaranteed:

- Not to be visible to earlier instructions in the execution stream.
- To be visible to later instructions in the execution stream.

B1.4 Software control features and EL0

The following sections describe the EL0 view of the software control features:

- Exception handling.
- Wait for Interrupt and Wait for Event.
- The YIELD instruction.
- Application level cache management.
- Instructions relating to Debug.
- About PSTATE.DIT.

B1.4.1 Exception handling

In the Arm architecture, an *exception* causes a change of program flow. Execution of an exception handler starts, at an Exception level higher than EL0, from a defined vector that relates to the exception taken.

Exceptions include:

- Interrupts.
- Memory system aborts.
- Exceptions generated by attempting to execute an instruction that is UNDEFINED.
- System calls.
- Secure monitor or Hypervisor traps.
- Debug exceptions.

Most details of exception handling are not visible to application level software, and are described in The AArch64 System Level Programmers' Model.

The `SVC` instruction causes a Supervisor Call exception. This provides a mechanism for unprivileged software to make a system call to an operating system.

The `BRK` instruction generates a Breakpoint Instruction exception. This provides a mechanism for debugging software using debugger executing on the same PE, see Breakpoint Instruction exceptions.

Note

The `BRK` instruction is supported only in the A64 instruction set.

B1.4.2 Wait for Interrupt and Wait for Event

Issuing a `WFI` instruction indicates that no further execution is required until a WFI wakeup event occurs, see Wait for Interrupt mechanism. This permits entry to a low-power state.

Issuing a `WFE` instruction indicates that no further execution is required until a WFE wakeup event occurs, see Wait for Event. This permits entry to a low-power state.

B1.4.3 The YIELD instruction

The `YIELD` instruction provides a hint that the task performed by a thread is of low importance so that it could yield, see YIELD. This mechanism can be used to improve overall performance in a *Symmetric Multithreading* (SMT) or *Symmetric Multiprocessing* (SMP) system.

Examples of when the `YIELD` instruction might be used include a thread that is sitting in a spin-lock, or where the arbitration priority of the snoop bit in an SMP system is modified. The `YIELD` instruction permits binary compatibility between SMT and SMP systems.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The `YIELD` instruction is a `NOP` hint instruction.

The `YIELD` instruction has no effect in a single-threaded system, but developers of such systems can use the instruction to flag its intended use for future migration to a multiprocessor or multithreading system. Operating systems can use `YIELD` in places where a yield hint is wanted, knowing that it will be treated as a NOP if there is no implementation benefit.

B1.4.4 Application level cache management

A small number of cache maintenance instructions can be enabled at EL0 from higher levels of privilege using the SCTLR_EL1 System register. Any access from EL0 to an operation without access permission causes the instruction to be trapped.

About the available operations, see Application level access to functionality related to caches.

B1.4.5 Instructions relating to Debug

Exception handling refers to the `BRK` instruction, which generates a Breakpoint Instruction exception. In addition, in AArch64 state, the `HLT` instruction causes the PE to halt execution and enter Debug state. This provides a mechanism for debugging software using a debugger that is external to the PE, see About External Debug.

B1.4.6 About PSTATE.DIT

A *data-independent-time sequence of code* is the sequence of instructions executed from the first instruction executed after a change of PSTATE.DIT from 0 to 1 through the last instruction executed before a change of PSTATE.DIT from 1 to 0, inclusive. Instructions speculatively executed between the change of PSTATE.DIT from 0 to 1 and the change of PSTATE.DIT from 1 to 0 are considered part of the data-independent-time sequence of code.

A *data-independent-time resource* is any of:

- a general-purpose register other than the zero register (ZR)
- Stack Pointer register
- SIMD&FP register

Note

- The data value prediction applies to all prediction resources that use some form of training to speculate data values as part of an execution.
- The cache allocation applies to all instruction and data caches, and TLB prefetching hardware used by the executing PE that applies to the supplied context.

The context information is passed as a register argument, and is restricted so that:

- Execution of the System instruction at EL0 only applies to the current hardware defined context.
- Execution of the System instruction at EL1only applies to the current VMID and Security state, and does not apply to EL2.
- Execution of the System instruction at EL2 can only apply to the current Security state.

If the System instruction is specified to apply to a combination of Security state and Exception level that is not implemented, or an Exception level which is higher than the Exception level that the System instruction is executed at, then the System instruction is treated as a `NOP`.

When the System instruction is complete and synchronized, no predictions of the restricted type for the affected context are influenced by the execution of the program before the System instruction in a manner that can be observed by the use of any side channels.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

- Prediction restriction System instructions do not require the invalidation of prediction structures so long as the behavior described for completion is met by an implementation.
- Prediction restriction System instructions are permitted to invalidate more prediction information than is defined by the supplied execution context.

These System instructions are guaranteed to be complete following a DSB that covers both read and write behavior on the same PE that executed the original instruction. A subsequent Context synchronization event is required to ensure that the effect of the completion of the instructions is synchronized to the current execution.

In AArch64 state, EL0 access to the System instructions is controlled by SCTLR_EL1.EnRCTX.

Non-Confidential

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

B1.5 Memory barriers

Memory barrier is the general term applied to an instruction, or sequence of instructions, that forces synchronization events by a PE with respect to retiring load/store instructions. The memory barriers defined by the Arm architecture provide a range of functionality, including:

- Ordering of load/store instructions.
- Completion of load/store instructions.
- Context synchronization.

The following subsections describe the Arm memory barrier instructions:

- Instruction Synchronization Barrier.
- Data Memory Barrier.
- Speculation Barrier.
- Consumption of Speculative Data Barrier.
- Speculative Store Bypass Barrier.
- Physical Speculative Store Bypass Barrier.
- Data Synchronization Barrier.
- Shareability and access limitations on the data barrier operations.
- Load-Acquire, Load-AcquirePC, and Store-Release.

Note

Depending on the required synchronization, a program might use memory barriers on their own, or it might use them in conjunction with cache maintenance and memory management instructions that in general are available only when software execution is at EL1 or higher.

`DMB` and `DSB` instructions affect reads and writes to the memory system generated by load/store instructions and data or unified cache maintenance instructions being executed by the PE.

B1.5.1 Instruction Synchronization Barrier

An `ISB` instruction ensures that all instructions that come after the `ISB` instruction in program order are fetched from the cache or memory after the `ISB` instruction has completed. Using an `ISB` ensures that the effects of context-changing operations executed before the `ISB` are visible to the instructions fetched after the `ISB` instruction. Examples of context-changing operations that require the insertion of an `ISB` instruction to ensure the effects of the operation are visible to instructions fetched after the `ISB` instruction are:

- Completed cache and TLB maintenance instructions.
- Changes to System registers.

Any context-changing operations appearing in program order after the `ISB` instruction take effect only after the `ISB` has been executed.

The pseudocode function for the operation of an `ISB` is `InstructionSynchronizationBarrier()`.

See also Memory barriers.

B1.5.2 Data Memory Barrier

The `DMB` instruction is a memory barrier instruction that ensures the relative order of memory accesses before the barrier with memory accesses after the barrier. The `DMB` instruction does not ensure the completion of any of the memory accesses for which it ensures relative order.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The full definition of the DMB instruction is covered formally in the Ordering requirements defined by the formal concurrency model and this introduction to the DMB instruction is not intended to contradict that section.

The basic principle of a DMB instruction is to introduce order between memory accesses that are specified to be affected by the DMB options supplied as arguments to the DMB instruction. The DMB instruction ensures that all affected memory accesses by the PE executing the DMB instruction that appear in program order before the DMB instruction and those which originate from a different PE, to the extent required by the DMB options, which have been observed by the PE before the DMB instruction is executed, are observed by each PE, to the extent required by the DMB options, before any affected memory accesses that appear in program order after the DMB instruction are observed by that PE.

The use of a DMB instruction creates order between the Memory effects of instructions as described in the definition of Barrier-ordered-before.

The DMB instruction affects only memory accesses and the operation of data cache and unified cache maintenance instructions, see A64 Cache maintenance instructions. It has no effect on the ordering of any other instructions executing on the PE.

The pseudocode function for the operation of a DMB instruction is `DataMemoryBarrier()`.

B1.5.3 Speculation Barrier

An SB instruction is a memory barrier that prevents speculative execution of instructions until after the barrier has completed when those instructions could be observed through side-channels.

Until the barrier completes, the speculative execution of any instruction appearing later in the program order than the barrier cannot be performed to the extent that such speculation can be observed through side-channels as a result of control flow speculation or data value speculation. An example is speculative allocation into any caching structure where the allocation of that entry could indicate any data value present in memory or in the registers.

- Cannot be performed to the extent that such speculation can be observed through side-channels as a result of control flow speculation or data value speculation.
- Can be performed when predicting that a instruction that could generate an exception does not generate an exception.

The speculative execution of an SB instruction cannot be as a result of any of the following:

- Control flow speculation.
- Data value speculation.
- Can be as a result of predicting that an instruction that could generate an exception does not generate an exception.

An SB instruction can complete when all of the following apply:

- It is known that it is not speculative, or it is speculative only as a result of either:
  - Speculating that an instruction that could generate an exception does not generate an exception.
  - Speculating past the point in the Execution stream where a precise asynchronous exception is taken.
- All the data values generated by instructions appearing in program order before the SB instruction are architecturally resolved, and so are not speculative.

Note

The SB instruction has no effect on the use of prediction resources to predict the instruction stream that is being fetched, so long as the prediction of the instruction stream is not informed by data taken from the register outputs of the speculative execution of instructions appearing in program order after the SB instruction.

B1.5.4 Consumption of Speculative Data Barrier

The CSDB instruction is a memory barrier instruction that controls speculative execution arising from data value prediction.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Any instruction, other than a branch instruction, that appears in program order after the CSDB cannot be speculatively executed using the results of any of the following predictions if those predictions come from instructions that appear in program order before the CSDB and have not been architecturally resolved:

- Data value predictions of any instructions.
- `PSTATE.{N,Z,C,V}` predictions of any instructions other than conditional branch instructions appearing in program order before the `CSDB` that have not been architecturally resolved.

Note

For purposes of the definition of CSDB, `PSTATE.{N,Z,C,V}` are not considered data values. This definition permits:

- Control flow speculation before and after the `CSDB` instruction.
- Speculative execution of conditional data processing instructions after the `CSDB` instruction, unless they use the results of data value, or `PSTATE.{N,Z,C,V}` predictions of instructions appearing in program order before the `CSDB` instruction that have not been architecturally resolved.

B1.5.5 Speculative Store Bypass Barrier

The `SSBB` instruction is a memory barrier that prevents speculative loads from bypassing earlier stores to the same virtual address under certain conditions.

The semantics of the Speculative Store Bypass Barrier are:

- When a load to a location appears in program order after the `SSBB` instruction, then the load does not speculatively read an entry earlier in the coherence order for that location than the entry generated by the latest store satisfying all of the following conditions:
  - The store is to the same location as the load.
  - The store uses the same virtual address as the load.
  - The store appears in program order before the `SSBB` instruction.

B1.5.6 Physical Speculative Store Bypass Barrier

The `PSSBB` instruction is a memory barrier that prevents speculative loads from bypassing earlier stores to the same physical address under certain conditions.

The semantics of the Physical Speculative Store Bypass Barrier are:

- When a load to a location appears in program order after the `PSSBB` instruction, then the load does not speculatively read an entry earlier in the coherence order for that location than the entry generated by the latest store satisfying all of the following conditions:
  - The store is to the same location as the load.
  - The store appears in program order before the `PSSBB` instruction.

Note

The effect of this barrier applies to accesses to the same location even if they are accessed with different virtual addresses and from different Exception levels.

B1.5.7 Trace Synchronization Barrier

The `TSB` instruction is a barrier instruction that preserves the relative order of accesses to System registers due to trace operations and other accesses to the same registers.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

A trace operation is an operation of the trace unit generating trace for an instruction when FEAT_TRF is implemented and enabled.

A `TSB` instruction is not required to execute in program order with respect to other instructions. This includes being reordered with respect to other trace instructions. One or more Context synchronization events are required to ensure that `TSB` instruction is executed in the necessary order.

If trace is generated between a Context synchronization event and a `TSB` operation, these trace operations may be reordered with respect to the `TSB` operation, and therefore may not be synchronized.

The following situations are synchronized using a `TSB` operation:

- A direct write B to a System register is ordered after an indirect read or indirect write of the same register by a trace operation of a traced instruction A, if all of the following are true:
  - A is executed in program order before a Context synchronization event C.
  - C appears in program order before a `TSB` operation T.
  - B is executed in program order after T.
- A direct read B of a System register is ordered after an indirect write to the same register by a trace operation of a traced instruction A if all the following are true:
  - A is executed in program order before a Context synchronization event C1.
  - C1 appears in program order before `TSB` operation T.
  - T is executed in program order before a second Context synchronization event C2.
  - B is executed in program order after C2.

A `TSB` operation is not needed to ensure a direct write B to a System register is ordered before an indirect read or indirect write of the same register by a trace operation of a traced instruction A, if all the following are true:

- A is executed in program order after a Context synchronization event C.
- B is executed in program order before C.

See Synchronization and the Trace Buffer Unit.

The pseudocode function for the operation of a `TSB` instruction is `TraceSynchronizationBarrier()`.

B1.5.8 Data Synchronization Barrier

A `DSB` instruction is a memory barrier that ensures that memory accesses that occur before the `DSB` instruction have completed before the completion of the `DSB` instruction. In doing this, it acts as a stronger barrier than a `DMB` and all ordering that is created by a `DMB` with specific options is also generated by a `DSB` with the same options.

Execution of a `DSB` instruction at EL2 ensures that any memory accesses caused by Speculative translation table walks from the EL1&0 translation regime have been observed.

For more information, see Out-of-context translation regimes.

A `DSB` instruction executed by a PE completes when all of the following are complete for the set of observers in the required shareability domain:

- If the required access types of the `DSB` is reads, all of the following:
  - All Explicit Memory Read Effects generated by instructions in program order before the `DSB`.
  - If FEAT_GCS is implemented, all GCS Memory Read Effects that appear in program order before a GCSB instruction that appears in program order before the `DSB`.
  - If FEAT_MTE2 is implemented, all Implicit Tag Memory Read Effects generated by instructions in program order before the `DSB`.
- If the required access types of the `DSB` is writes, all of the following:
  - All Explicit Memory Write Effects generated by instructions in program order before the `DSB`.
  - If FEAT_GCS is implemented, all GCS Memory Write Effects that appear in program order before a GCSB instruction that appears in program order before the `DSB`.
- If the required access types of the `DSB` is reads and writes, all of the following:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- All Explicit Memory Effects generated by instructions in program order before the DSB.
- All Implicit TTD Memory Effects generated by instructions in program order before the DSB.
- All Implicit Instruction Memory Read Effects generated by instructions in program order before the DSB.
- All cache maintenance instructions in program order before the DSB.
- If FEAT_MTE2 is implemented, all Implicit Tag Memory Read Effects generated by instructions in program order before the DSB.
- If FEAT_SPMU is implemented, all Direct System Register Write Effects to a System PMU register generated by instructions in program order before the DSB.
- If FEAT_SPE is implemented, all PSB CSYNC instructions in program order before the DSB.
- If FEAT_XS is implemented and the DSB has the nXS qualifier, all of the following:
  - All TLBInXS maintenance operations generated by AArch64 TLB maintenance instructions with the nXS qualifier in program order before the DSB.
  - If HCRX_EL2.FnXS is 1, all TLBInXS maintenance operations generated by AArch32 or AArch64 TLB maintenance instructions executed at EL1 in program order before the DSB.
- If FEAT_XS is not implemented or the DSB does not have the nXS qualifier, all of the following:
  - All TLBI maintenance operations generated by TLB maintenance instructions in program order before the DSB.
- If FEAT_HDBSS is implemented and the DSB is executed at EL2 or EL3, all HDBSS Memory Write Effects generated by instructions in program order before the DSB.
- If FEAT_TRBE is implemented, all TSB CSYNC instructions in program order before the DSB.
- All CFP RCTX, COSP RCTX, CPP RCTX, DVP RCTX instructions in program order before the DSB.
- If FEAT_MTE_ASYNC is implemented, all Indirect System Register Write Effects to the Tag Fault Status Register accessible at ELx generated by instructions in program order before the DSB.
- If FEAT_GCS is implemented, all GCS Memory Effects that appear in program order before a GCSB instruction that appears in program order before the DSB.

In addition, no instruction that appears in program order after the DSB instruction can alter any state of the system or perform any part of its functionality until the DSB completes other than:

- Being fetched from memory and decoded, or any change to architectural or microarchitectural state resulting from being fetched or decoded.
- Indirectly or directly reading any of the following, so long as the reading of these resources does not cause a change in architectural state:
  - General-purpose registers
  - SIMD&FP registers
  - The Stack Pointer register
  - The Program Counter
  - Special-purpose registers
  - System registers other than CNTPCTSS_EL0 and CNTVCTSS_EL0

A DSB instruction ordered after a direct write to a System PMU register does not complete until all observers observe the direct write with following ordering requirements:

- EL1 and EL0 memory accesses are ordered only with respect to memory accesses using the same VMID.
- EL2 memory accesses are ordered only with respect to other EL2 memory accesses.

A Context synchronization event is required to create the order between the direct write and the DSB instruction.

If the R-profile architecture is implemented the execution of a DFB at EL2 orders memory accesses irrespective of their Exception level or associated VMID. If executed at EL1 or EL0 the instruction behaves as a DSB SY.

The pseudocode function for the operation of a DSB is DataSynchronizationBarrier().

See also:

- Memory barriers.
- Ordering and completion of TLB maintenance instructions.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

B1.5.9 Shareability and access limitations on the data barrier operations

The `DMB` and `DSB` instructions take an argument that specifies:

- The shareability domain over which the instruction must operate. This is one of:
  - Full system.
  - Outer Shareable.
  - Inner Shareable.
  - Non-shareable.

  Full system applies to all the observers in the system and, as such, encompasses the Inner and Outer Shareable domains of the processor.

  Note

  The distinction between Full system and Outer Shareable is applicable only for Normal Non-cacheable memory accesses and Device memory accesses.

- The accesses for which the instruction operates. This is one of:
  - Read and write accesses, both before and after the barrier instruction.
  - Write accesses only, before and after the barrier instruction.
  - Read accesses before the barrier instruction, and read and write accesses after the barrier instruction.

    Note

    This form of a `DMB` or `DSB` instruction can be described as a load-load/store barrier.

For more information on whether an access is before or after a barrier instruction, see Data Memory Barrier or Data Synchronization Barrier.

Table B1-3 shows how these options are encoded in the `<option>` field of the instruction:

Table B1-3 Encoding of the `DMB` and `DSB` `<option>` parameter

Accesses		Shareability domain			
Before the barrier	**After the barrier**	**Full system**	**Outer Shareable**	**Inner Shareable**	**Non-shareable**
Reads and writes	Reads and writes	`SY`	`OSH`	`ISH`	`NSH`
Writes	Writes	`ST`	`OSHST`	`ISHST`	`NSHST`
Reads	Reads and writes	`LD`	`OSHLD`	`ISHLD`	`NSHLD`

Note

Table B1-3 specifies the memory ordering requirements of DMB and DSB based on the `<option>` parameter. DSB has additional requirements with respect to execution of instructions appearing in program order after the DSB as described in the section Data Synchronization Barrier. These additional requirements create the effect of additional memory ordering beyond what is specified in the table.

See the instruction descriptions for more information:

- DMB.
- DSB.

Note

`ISB` also supports an optional limitation argument that can contain only one value that corresponds to full system operation, see ISB.

Non-Confidential

B1.5.10 Load-Acquire, Load-AcquirePC, and Store-Release

Arm provides a set of instructions with Acquire semantics for loads, and Release semantics for stores. These instructions support the *Release Consistency sequentially consistent* (RCsc) model. In addition, FEAT_LRCPC provides Load-AcquirePC instructions. The combination of Load-AcquirePC and Store-Release can be use to support the weaker *Release Consistency processor consistent* (RCpc) model.

The full definitions of the Load-Acquire and Load-AcquirePC instructions are covered formally in the Ordering requirements defined by the formal concurrency model. This introduction to the Load-Acquire and Load-AcquirePC instructions is not intended to contradict that section.

The basic principle of both Load-Acquire and Load-AcquirePC instructions is to introduce order between:

- The memory access generated by the Load-Acquire or Load-AcquirePC instruction.
- The memory accesses appearing in program order after the Load-Acquire or Load-AcquirePC instruction, such that the memory access generated by the Load-Acquire or Load-AcquirePC instruction is observed by each PE to the extent that the PE is required to observe the access coherently, before any of the memory accesses appearing in program order after the Load-Acquire or Load-AcquirePC instruction are observed by that PE to the extent that the PE is required to observe the accesses coherently.

The use of a Load-Acquire or Load-AcquirePC instruction creates order between the Memory effects of instructions as described in the definition of Barrier-ordered-before.

The full definition of the Store-Release instruction is covered formally in the Ordering requirements defined by the formal concurrency model and this introduction to the Store-Release instruction is not intended to contradict that section.

The basic principle of a Store-Release instruction is to introduce order between the following:

- A set of memory accesses, RWx, that are generated by the PE executing the Store-Release instruction and that appear in program order before the Store-Release instruction, together with those that originate from a different PE to the extent that the PE is required to observe them coherently, observed by the PE before executing the Store-release.
- The memory access generated by the Store-Release (Wrel), such that all of the memory accesses, RWx, are observed by each PE to the extent that the PE is required to observe those accesses coherently, before Wrel is observed by that PE to the extent that the PE is required to observe that access coherently.

The use of a Store-Release instruction creates order between the Memory effects of instructions as described in the definition of Barrier-ordered-before.

Where a Load-Acquire appears in program order after a Store-Release, the memory access generated by the Store-Release instruction is observed by each PE to the extent that PE is required to observe the access coherently, before the memory access generated by the Load-Acquire instruction is observed by that PE, to the extent that the PE is required to observe the access coherently. In addition, the use of a Load-Acquire, Load-AcquirePC or a Store-Release instruction on accesses to a Memory-mapped peripheral introduces order between the Memory effects of the instructions that access that peripheral, as described in the definition of Peripheral arrival order.

Load-Acquire, Load-AcquirePC and Store-Release, other than Load-Acquire Exclusive Pair and Store-Release-Exclusive Pair, access only a single data element.

Load-Acquire Exclusive Pair and Store-Release Exclusive Pair access two data elements.

A Store-Release Exclusive instruction has the release semantics only if the store is successful.

Note

- Each Load-Acquire Exclusive and Store-Release Exclusive instruction is essentially a variant of the equivalent Load-Exclusive or Store-Exclusive instruction. All usage restrictions and single-copy atomicity properties:
  - That apply to the Load-Exclusive instructions also apply to the Load-Acquire Exclusive instructions.
  - That apply to the Store-Exclusive instructions also apply to the Store-Release Exclusive instructions.
- The Load-Acquire, Load-AcquirePC, and Store-Release instructions can remove the requirement to use the explicit `DMB` instruction.

B1.6 Caches and memory hierarchy

The implementation of a memory system depends heavily on the microarchitecture and therefore many details of the memory system are IMPLEMENTATION DEFINED. The Arm architecture defines the application level interface to the memory system, including a hierarchical memory system with multiple levels of cache. This section describes an application level view of this system. It contains the subsections:

- Introduction to caches.
- Memory hierarchy.
- Application level access to functionality related to caches
- Implication of caches for the application programmer.
- Prefetching into cache.

B1.6.1 Introduction to caches

A cache is a block of high-speed memory that contains a number of entries, each consisting of:

- Main memory address information, commonly known as a *tag*.
- The associated data.

Caches increase the average speed of a memory access. Caching takes account of two principles of locality:

Spatial locality

An access to one Location is likely to be followed by accesses to adjacent Locations. Examples of this principle are:

- Sequential instruction execution.
- Accessing a data structure.

Temporal locality

An access to an area of memory is likely to be repeated in a short time period. An example of this principle is the execution of a software loop.

To minimize the quantity of control information stored, the spatial locality property groups several locations together under the same tag. This logical block is commonly known as a *cache line*. When data is loaded into a cache, access times for subsequent loads and stores are reduced, resulting in overall performance benefits. An access to information already in a cache is known as a *cache hit*, and other accesses are called *cache misses*.

Normally, caches are self-managing, with the updates occurring automatically. Whenever the PE accesses a cacheable memory location, the cache is checked. If the access is a cache hit, the access occurs in the cache. Otherwise, the access is made to memory. Typically, when making this access, a cache location is allocated and the cache line loaded from memory. The Arm architecture permits different cache topologies and access policies, provided they comply with the memory coherency model described in this manual.

Caches introduce a number of potential problems, mainly because:

- Memory accesses can occur at times other than when the programmer would expect them.
- A data item can be held in multiple physical locations.

B1.6.2 Memory hierarchy

Typically memory close to a PE has very low latency, but is limited in size and expensive to implement. Further from the PE it is common to implement larger blocks of memory but these have increased latency. To optimize overall performance, an Armv8 memory system can include multiple levels of cache in a hierarchical memory system that exploits this trade-off between size and latency. Figure B1-3 shows an example of such a system in an Armv8-R system that supports virtual addressing.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

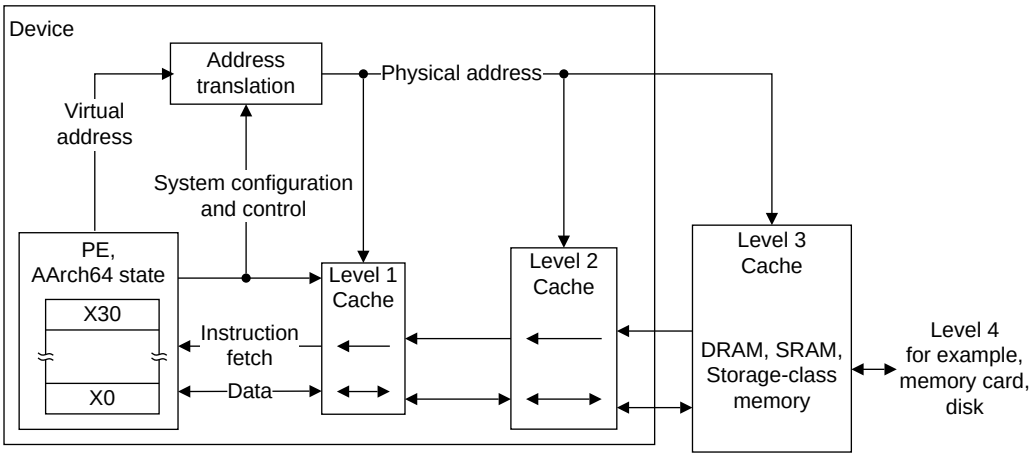

Figure B1-3 Multiple levels of cache in a memory hierarchy

Note

In this manual, in a hierarchical memory system, Level 1 refers to the level closest to the processing element, as shown in Figure B1-3.

Instructions and data can be held in separate caches or in a unified cache. A cache hierarchy can have one or more levels of separate instruction and data caches, with one or more unified caches that are located at the levels closest to the main memory. Memory coherency for cache topologies can be defined using the conceptual points Point of Unification (PoU), Point of Coherency (PoC), Point of Persistence (PoP), and Point of Deep Persistence (PoDP).

For more information, including the definitions of PoU, PoC, PoP, and PoDP, see About cache maintenance in AArch64 state.

B1.6.2.1 The cacheability and shareability memory attributes

Cacheability and shareability are two attributes that describe the memory hierarchy in a multiprocessing system:

Cacheability This attribute defines whether memory locations are allowed to be allocated into a cache or not. Cacheability is defined independently for Inner and Outer Cacheability locations.

Shareability This attribute defines whether memory locations are shareable between different agents in a system. Marking a memory location as shareable for a particular domain requires hardware to ensure that the location is coherent for all agents in that domain. Shareability is defined independently for Inner and Outer Shareability domains.

For more information about Cacheability and Shareability, see Memory types and attributes.

B1.6.3 Application level access to functionality related to caches

As indicated in About the Application level programmers' model, the application level corresponds to execution at EL0. The architecture defines a set of cache maintenance instructions that software can use to manage cache coherency. Software executing at a higher Exception level can enable use of some of this functionality from EL0, as follows:

When the value of SCTLR_EL1.UCI is 1

Software executing at EL0 can access:

- The data cache maintenance instructions, `DC CVAU`, `DC CVAC`, `DC CVAP`, `DC CVADP`, and `DC CIVAC`. See The data cache maintenance instruction (DC).
- The instruction cache maintenance instruction `IC IVAU`. See The instruction cache maintenance instruction (IC).

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Attempted execution of these instructions might generate a Permission fault as described in Permission fault.

When the value of SCTLR_EL1.UCT is 1

Software executing at EL0 can access the cache type register. See CTR_EL0.

When the value of SCTLR_EL1.DZE is 1

Software executing at EL0 can access the data cache zero instruction `DC ZVA`. See Data cache zero instruction.

The SCTLR_EL1.{UCI, UCT, DZE} control fields are accessible only by software executing at EL1 or higher.

When the Effective value of HCR_EL2.{E2H, TGE} is {1, 1}, the controls {UCI, UCT and DZE} are found in SCTLR_EL2.

This functionality is UNDEFINED at EL0 when the value of the corresponding SCTLR_EL1 control field is 0.

B1.6.4 Implication of caches for the application programmer

In normal operation, the caches are largely invisible to the application programmer. However they can become visible when there is a breakdown in the coherency of the caches. Such a breakdown can occur:

- When memory locations are updated by other agents in the system that do not use hardware management of coherency.
- When memory updates made from the application software must be made visible to other agents in the system, without the use of hardware management of coherency.

For example:

- In the absence of hardware management of coherency of DMA accesses, in a system with a DMA controller that reads memory locations that are held in the data cache of a PE, a breakdown of coherency occurs when the PE has written new data in the data cache, but the DMA controller reads the old data held in memory.
- In a Harvard cache implementation, where there are separate instruction and data caches, a breakdown of coherency occurs when new instruction data has been written into the data cache, but the instruction cache still contains the old instruction data.

B1.6.4.1 Data coherency issues

Software can ensure the data coherency of caches in the following ways:

- By not using the caches in situations where coherency issues can arise. This can be achieved by:
  - Using Non-cacheable or, in some cases, Write-Through Cacheable memory.
  - Not enabling caches in the system.
- By using cache maintenance instructions to manage the coherency issues in software. See Application level access to functionality related to caches.
- By using hardware coherency mechanisms to ensure the coherency of data accesses to memory for cacheable locations by observers within the different shareability domains, see Non-shareable Normal memory and Shareable, Inner Shareable, and Outer Shareable Normal memory.

Note

The performance of these hardware coherency mechanisms is highly IMPLEMENTATION SPECIFIC. In some implementations, the mechanism suppresses the ability to cache shareable locations. In other implementations, cache coherency hardware can hold data in caches while managing coherency between observers within the shareability domains.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

Not all these mechanisms are directly available to software operating at EL0 and might involve interaction with software operating at a higher Exception level.

B1.6.4.2 Synchronization and coherency issues between data and instruction accesses

How far ahead of the current point of execution instructions are fetched from is IMPLEMENTATION DEFINED. Such prefetching can be either a fixed or a dynamically varying number of instructions, and can follow any or all possible future execution paths. For all types of memory:

- The PE might have fetched the instructions from memory at any time since the last Context Synchronization event on that PE.
- Any instructions fetched in this way might be executed multiple times, if this is required by the execution of the program, without being refetched from memory. In the absence of a Context Synchronization event, there is no limit on the number of times such an instruction might be executed without being refetched from memory.

The Arm architecture requires the hardware to ensure coherency between instruction caches and memory, even for locations of shared memory. A write has been made coherent with an instruction fetch of a shareability domain when:

CTR_EL0.{DIC, IDC} == {0, 0} The location written to has been cleaned to the Point of unification (PoU) from the data cache, and that clean is complete for the shareability domain. Subsequently the location has been invalidated to the Point of unification (PoU) from the instruction cache, and that invalidation is complete for the shareability domain.

CTR_EL0.{DIC, IDC} == {0, 1} The write is complete for the shareability domain. Subsequently the location has been invalidated to the Point of unification (PoU) from the instruction cache, and that invalidation is complete for the shareability domain.

CTR_EL0.{DIC, IDC} == {1, 1} The write is complete for the shareability domain.

Note

Microarchitecturally, this means that these situations cannot both be true in an implementation:

- After delays in fetching from memory, the instruction queue can have entries written into it out of order.
- For an implementation:
  - When CTR_EL0.DIC == 0, if there is an outstanding entry in the instruction queue, then later entries in the instruction queue are not impacted by the IC IVAU instructions of a different core.
  - When CTR_EL0.DIC == 1, if there is a write to the location that is held in the queue when there is an outstanding entry in the instruction queue for an older entry, then the instruction queue does not have entries invalidated from it.

The full definition of the ordering implications of CTR_EL0.{DIC, IDC} is covered formally in the Ordering requirements defined by the formal concurrency model and the information in this section is not intended to contradict that section.

If software requires coherency between instruction execution and memory, it must manage this coherency using Context Synchronization events and cache maintenance instructions. The following code sequence can be used to allow a PE to execute code that the same PE has written.

```
; Coherency example for data and instruction accesses within the same Inner Shareable domain.
; Enter this code with <Wt> containing a new 32-bit instruction,
; to be held in Cacheable space at a location pointed to by Xn.
        STR Wt, [Xn]
        DC CVAU, Xn         ; Clean data cache by VA to point of unification (PoU)
        DSB ISH             ; Ensure visibility of the data cleaned from cache
        IC IVAU, Xn         ; Invalidate instruction cache by VA to PoU
        DSB ISH             ; Ensure completion of the invalidations
        ISB                 ; Synchronize the fetched instruction stream
```

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

- If this sequence is not executed between writing data to a location and executing the instruction at that location, the lack of coherency between instruction caches and memory means that the instructions that are executed might be the old instruction or the updated instruction, and which is used can arbitrarily vary during execution. It must not be assumed by software, before the synchronization sequence is executed, that when the updated instruction has been seen, the old instruction will not be seen again.
- For Non-cacheable or Write-Through accesses, the clean data cache by VA instruction is not required. However, the invalidate instruction cache instruction is required because the Armv8 AArch64 architecture allows Non-cacheable accesses to be held in an instruction cache. See Non-cacheable accesses and instruction caches.
- This code can be used when the thread of execution modifying the code is the same thread of execution that is executing the code. The Arm architecture limits the set of instructions that can be executed by one thread of execution as they are being modified by another thread of execution without requiring explicit synchronization. See Concurrent modification and execution of instructions.
- The system software controls whether these cache maintenance instructions are available to the application level by setting SCTLR_EL1.UCI.

B1.6.5 Prefetching into cache

The Arm architecture provides memory system hints `PRFM`, `PRFUM`, `LDNP`, and `STNP` that software can use to communicate the expected use of memory locations to the hardware. The memory system can respond by taking actions that are expected to speed up the memory accesses if they occur. The effect of these memory system hints is IMPLEMENTATION DEFINED. Typically, implementations use this information to bring the data or instruction locations into caches.

The Prefetch instructions are hints, and so implementations can treat them as `NOP`s without affecting the functional behavior of the device. The instructions cannot generate synchronous Data Abort exceptions, but the resulting memory system operations might, under exceptional circumstances, generate an asynchronous External abort, which is taken using an SError exception. For more information, see ISS encoding for an exception from a Data Abort.

`PrefetchHint {}` defines the prefetch hint types.

The `Hint_Prefetch()` function signals to the memory system that memory accesses of the type `hint` to or from the specified `address` are likely to occur in the near future. The memory system might take some action to speed up the memory accesses when they do occur, such as prefetching the specified address into one or more caches as indicated by the innermost cache level `target` and non-temporal hint `stream`.

For more information on `PRFM`, `PRFUM` and load/store instructions that provide hints to the memory system, see Prefetch memory and Load/store SIMD and floating-point non-temporal pair.

B1.7 Alignment support

This section describes alignment support. It contains the following subsections:

- Instruction alignment.
- Alignment of data accesses.

B1.7.1 Instruction alignment

A64 instructions must be word-aligned.

Attempting to fetch an instruction from a misaligned location results in a PC alignment fault. See PC alignment checking.

B1.7.2 Alignment of data accesses

When instructions that load or store single or multiple registers are executed, if the value of SCTLR_ELx.A applicable to the current Exception level is 1, an Alignment fault is generated if any of the following apply:

- For Load-Exclusive, Store-Exclusive, and Atomic instructions, the address that is accessed is not aligned to the overall access size.
- For all other instructions, the address that is accessed is not aligned to the size of the data element being accessed.

If FEAT_LSE2 is implemented, Load-Acquire/Store-Release instructions without exclusive or atomic behavior generate an Alignment fault if all of the following apply:

- Not all bytes of the memory access lie within a 16-byte quantity aligned to 16 bytes.
- The value of SCTLR_ELx.nAA applicable to the current Exception level is 0.

For an unaligned access to any type of Device memory:

- If the memory location cannot support unaligned accesses then an Alignment fault is generated.
- If the memory location supports unaligned accesses, then it is IMPLEMENTATION DEFINED whether the access generates an Alignment fault if the location would not generate an Alignment fault if the same access were made to Normal memory.

B1.7.2.1 Unaligned accesses to Normal memory

The behavior of unaligned accesses to Normal memory is dependent on all of the following:

- The instruction causing the memory access.
- The memory attributes of the accessed memory.
- The value of SCTLR_ELx.{A, nAA}.
- Whether or not FEAT_LSE2 is implemented.

B1.7.2.1.1 Load or Store of Single or Multiple registers

For all instructions that load or store single or multiple registers, but not Load-Exclusive, Store-Exclusive, Load-Acquire/Store-Release, and Atomic instructions, if the address that is accessed is not aligned to the size of the data element being accessed, then:

When the value of SCTLR_ELx.A applicable to the current Exception level is 1, an Alignment fault is generated.

When the value of SCTLR_ELx.A applicable to the current Exception level is 0:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- An unaligned access is performed.
- If FEAT_LSE2 is not implemented, the access is not guaranteed to be single-copy atomic except at the byte access level.
- If FEAT_LSE2 is implemented:
  - If all the bytes of the memory access lie within a 16-byte quantity aligned to 16 bytes and are to Normal Inner Write-Back, Outer Write-Back Cacheable, Shareable memory, the memory access is single-copy atomic. For `LDNP`, `LDP`, or `STP` instructions, the entire memory access will be single-copy atomic.
  - If all the bytes of the memory accessed do not lie within a 16-byte quantity aligned to 16 bytes, or the access is not to Normal Inner Write-Back, Outer Write-Back Cacheable, Shareable memory, the access is not guaranteed to be single-copy atomic except at the byte access level.

For these instructions, the definition of an unaligned access is based on the size of the accessed elements, not the overall size of the memory access. This affects SIMD loads and stores, and also load/store pair instructions.

B1.7.2.1.2 Load-Exclusive/ Store-Exclusive and Atomic instructions

If FEAT_LSE2 is not implemented and the value of SCTLR_ELx.A applicable to the current Exception level is 0, Load-Exclusive/Store-Exclusive and Atomic instructions, including those with acquire or release semantics, generate an alignment fault when the address being accessed is not aligned to the overall size of the access.

If FEAT_LSE2 is implemented, then:

- If all the bytes of the memory access lie within a 16-byte quantity aligned to 16 bytes and are to Normal Inner Write-Back, Outer Write-Back Cacheable, Shareable memory, an unaligned access is performed.
- If all the bytes of the memory access do not lie within a 16-byte quantity aligned to 16-bytes, or the memory access is not to Normal Inner Write-Back, Outer Write-Back Cacheable, Shareable memory, then it is a CONSTRAINED UNPREDICTABLE choice of either of the following:
  - An unaligned access is performed meeting all of the semantics of the instruction.
  - An Alignment fault is generated.

Where memory access is performed, then it is single-copy atomic.

For these instructions, the definition of an unaligned access is based on the overall access size.

If FEAT_LS64 is implemented, when a single-copy atomic 64-byte instruction accesses a memory location that is not aligned to 64 bytes, an Alignment fault always occurs, regardless of the value of SCTLR_ELx.A.

B1.7.2.1.3 Non-atomic Load-Acquire/Store-Release instructions

For Load-Acquire/Store-Release instructions that do not have exclusive or atomic behaviors, when the address being accessed is not aligned to the size of the data element being accessed and the value of SCTLR_ELx.A applicable to the current Exception level is 0:

If FEAT_LSE2 is not implemented, then these instructions generate an Alignment fault.

If FEAT_LSE2 is implemented, then:

- If the memory access is not to Normal Inner Write-Back, Outer Write-Back Cacheable, Shareable memory, then it is a CONSTRAINED UNPREDICTABLE choice of either of the following:
  - An unaligned access is performed which is not guaranteed to be single-copy atomic except at the byte access level.
  - An Alignment fault is generated.
- If all of the bytes of the memory access do not lie within a 16-byte quantity aligned to 16 bytes and SCTLR_ELx.nAA applicable to the current Exception level is 1, then an unaligned access is performed which is not guaranteed to be single-copy atomic except at the byte access level.

In this case, when an access is performed it meets all the semantics of the instruction, but the architecture does not define the order of the different transactions of the access defined by the single instructions relative to each other.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- If all the bytes of the memory access lie within a 16-byte quantity aligned to 16 bytes and are to Normal Inner Write-Back, Outer Write-Back Cacheable, Shareable memory, an unaligned access meeting all the semantics of the instruction is performed.

Note

- Unaligned accesses typically take additional cycles to complete compared to a naturally-aligned access.
- An operation that is not single-copy atomic above the byte level can abort on any memory access that it makes and can abort on more than one access. This means that an unaligned access that occurs across a page boundary can generate an abort on either side of the page boundary.

B1.8 Endian support

General description of endianness in the Arm architecture describes the relationship between endianness and memory addressing in the Arm architecture.

The following subsections then describe the endianness schemes supported by the architecture:

- Instruction endianness.
- Data endianness.
- Endianness of memory-mapped peripherals.

B1.8.1 General description of endianness in the Arm architecture

This section describes only memory addressing and the effects of endianness for data elements up to quadwords of 128 bits. However, this description can be extended to apply to larger data elements.

For an address A, Figure B1-4 shows, for big-endian and little-endian memory systems, the relationship between:

- The quadword at address A.
- The doubleword at address A and A+8.
- The words at addresses A, A+4, A+8, and A+12.
- The halfwords at addresses A, A+2, A+4, A+6, A+8, A+10, A+12, and A+14.
- The bytes at addresses A, A+1, A+2, A+3, A+4, A+5, A+6, A+7, A+8, A+9, A+10, A+11, A+12, A+13, A+14, and A+15.

The terms in Figure B1-4 have the following definitions:

B_A Byte at address A.

HW_A Halfword at address A.

MSByte Most significant byte.

LSByte Least significant byte.

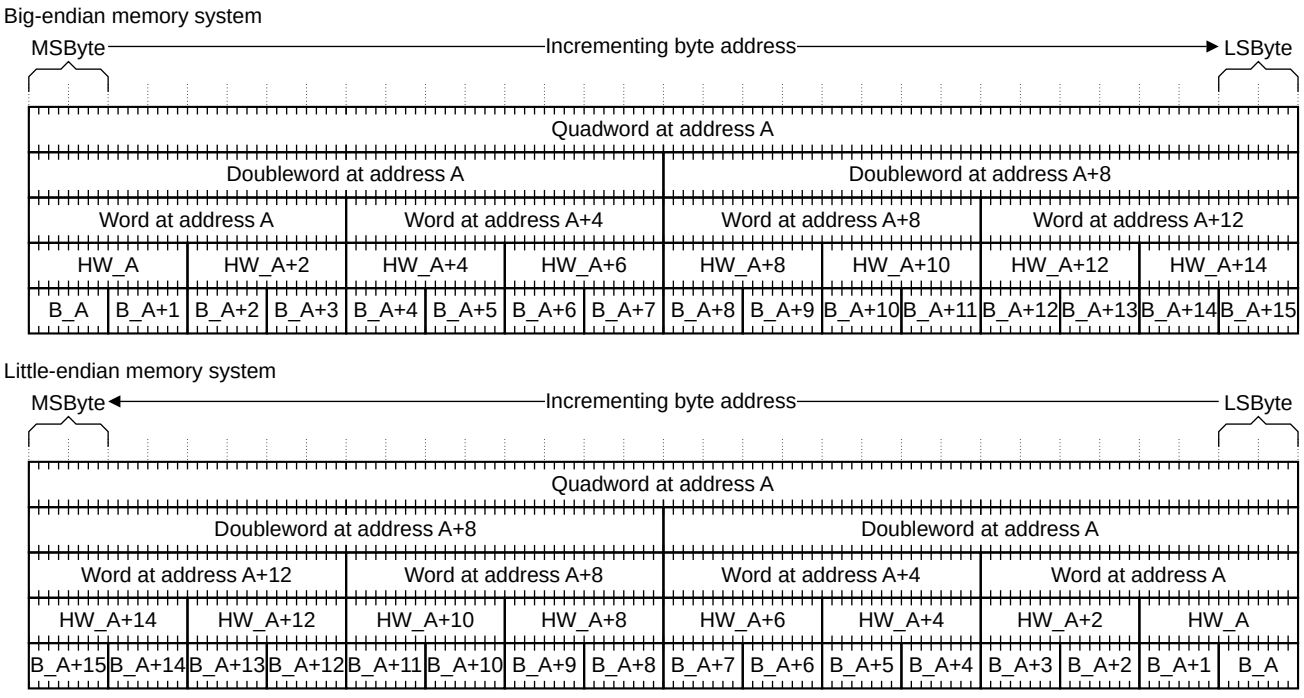

Figure B1-4 Endianness relationships

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The big-endian and little-endian mapping schemes determine the order in which the bytes of a quadword, doubleword, word, or halfword are interpreted. For example, a load of a word from address `0x1000` always results in an access to the bytes at memory locations `0x1000`, `0x1001`, `0x1002`, and `0x1003`. The endianness mapping scheme determines the significance of these 4 bytes.

B1.8.2 Instruction endianness

A64 instructions have a fixed length of 32 bits and are always little-endian.

B1.8.3 Data endianness

SCTLR_EL1.E0E, configurable at EL1 or higher, determines the data endianness for execution at EL0. When the Effective value of HCR_EL2.{E2H,TGE} is {1, 1}, the control is from SCTLR_EL2.E0E.

The data size used for endianness conversions:

- Is the size of the data value that is loaded or stored for SIMD and floating-point register and general-purpose register loads and stores.
- Is the size of the data element that is loaded or stored for SIMD element and data structure loads and stores. For more information, see Endianness in SIMD operations.

Note

This means the Armv8 architecture introduces a requirement for 128-bit endian conversions.

B1.8.3.1 Instructions to reverse bytes in a general-purpose register, a SIMD and floating-point register

An application or device driver might have to interface to memory-mapped peripheral registers or shared memory structures that are not the same endianness as the internal data structures. Similarly, the endianness of the operating system might not match that of the peripheral registers or shared memory. In these cases, the PE requires an efficient method to transform explicitly the endianness of the data.

Table B1-4 shows the instructions that provide this functionality:

Table B1-4 Byte reversal instructions

Function	Instructions	Notes
Reverse bytes in 32-bit word or words[a]	REV32	For use with general-purpose registers
Reverse bytes in whole register	REV	For use with general-purpose registers
Reverse bytes in 16-bit halfwords	REV16	For use with general-purpose registers
Reverse elements in doublewords, vector	REV64	For use with SIMD and floating-point registers
Reverse elements in words, vector	REV32	For use with SIMD and floating-point registers
Reverse elements in halfwords, vector	REV16	For use with SIMD and floating-point registers

a. Can operate on multiple words.

B1.8.3.2 Endianness in SIMD operations

SIMD element load/store instructions transfer vectors of elements between memory and the SIMD and floating-point register file. An instruction specifies both the length of the transfer and the size of the data elements being transferred. This information is used to load and store data correctly in both big-endian and little-endian systems.

For example:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

```
LD1 {V0.4H}, [X1]
```

This loads a 64-bit register with four 16-bit values. The four elements appear in the register in array order, with the lowest indexed element fetched from the lowest address. The order of bytes in the elements depends on the endianness configuration, as shown in Figure B1-5. Therefore, the order of the elements in the registers is the same regardless of the endianness configuration.

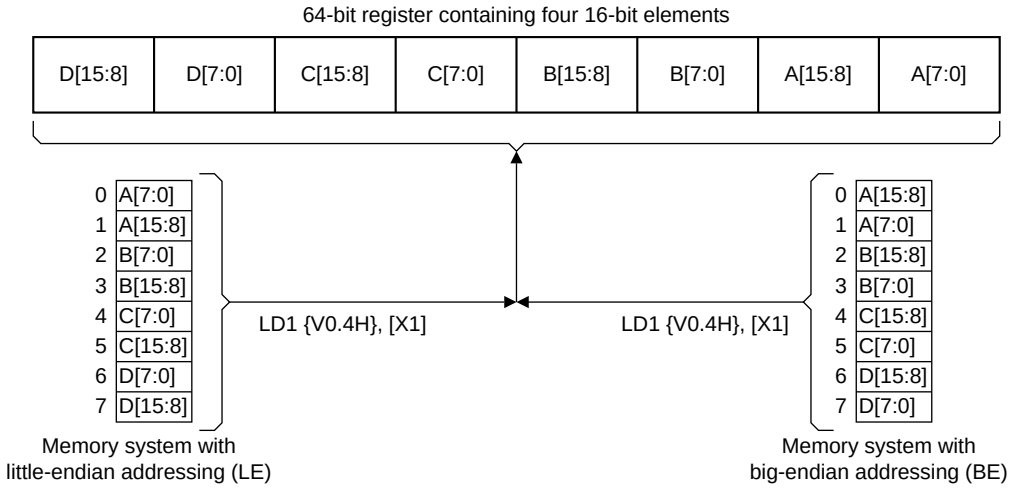

Figure B1-5 SIMD byte order example

The `BigEndian()` pseudocode function determines the current endianness of the data.

The `BigEndianReverse()` pseudocode function reverses the endianness of a bitstring.

The `BigEndian()` and `BigEndianReverse()` functions are defined in A-profile Architecture Pseudocode.

B1.8.4 Endianness of memory-mapped peripherals

All memory-mapped peripherals defined in the Arm architecture must be little-endian.

Peripherals to which this requirement applies include:

- Memory-mapped register interfaces to a debugger, or to a Cross Trigger Interface, see About the External Debug Registers.
- The memory-mapped register interface to the system level implementation of the Generic Timer, see System Level Implementation of the Generic Timer.
- A memory-mapped register interface to the Performance Monitors, see Recommended External Interface to the Performance Monitors.
- Memory-mapped register interfaces to an Arm Generic Interface Controller, see the *ARM® Generic Interrupt Controller Architecture Specification, GIC architecture version 3.0 and version 4.0.*
- The memory-mapped register interface to an Arm trace component. See, for example, the *Arm® Embedded Trace Macrocell Architecture Specification, ETMv4.*

B1.9 Memory types and attributes

The ordering of accesses for addresses in memory, referred to as the memory order model, is defined by the memory attributes. The following sections describe this model:

- Normal memory.
- Device memory.
- Memory access restrictions.

B1.9.1 Normal memory

The Normal memory type attribute applies to most memory in a system. It indicates that the hardware is permitted by the architecture to perform Speculative data read accesses to these locations, regardless of the access permissions for these locations.

The Normal memory type has the following properties:

- An Explicit Memory Write Effect to a memory location with the Normal attribute completes in finite time.
- Explicit Memory Write Effects to a memory location with the Normal memory type that is either Non-cacheable or Write-Through cacheable for both the Inner and Outer cacheability must reach the endpoint for that location in the memory system in finite time. Two writes to the same location, where at least one is using the Normal memory type, might be merged before they reach the endpoint unless there is an ordered-before relationship between the two writes. For the purposes of this requirement, the endpoint for a location in Conventional memory is the PoC.
- Unaligned memory accesses can access Normal memory if the system is configured to generate such accesses.
- There is no requirement for the memory system beyond the PE to be able to identify the elements accessed by multi-register load/store instructions. See Multi-register loads and stores that access Normal memory.
- Where a load or store instruction performs a sequence of memory accesses, as opposed to one single-copy atomic access as defined in the rules for single-copy atomicity, these accesses might occur multiple times as a result of executing the load or store instruction.

Note

Write speculation that is visible to other observers is prohibited for all memory types.

Note

- The Normal memory attribute is appropriate for locations of memory that are idempotent, meaning that they exhibit all of the following properties:
  - Read accesses can be repeated with no side effects.
  - Repeated read accesses return the last value written to the resource being read.
  - Read accesses can fetch additional memory locations with no side-effects.
  - Write accesses can be repeated with no side-effects if the contents of the location accessed are unchanged between the repeated writes or as the result of an exception, as described in this section.
  - Unaligned accesses can be supported.
  - Accesses can be merged before accessing the target memory system.
- Normal memory allows speculative reads and may be affected by intermediate buffering and forwarding of data. If non-idempotent memory locations are mapped as Normal memory, the following may occur:
  - Memory accesses return UNKNOWN values.
  - UNPREDICTABLE effects on memory-mapped peripherals.
- An instruction that generates a sequence of accesses as described in Atomicity in the Arm architecture might be abandoned as a result of an exception being taken during the sequence of accesses. On return from the exception the instruction is restarted, and therefore, one or more of the memory locations might be accessed multiple times. This can result in repeated write accesses to a location that has been changed between the write accesses.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

For accesses to Normal memory, a DMB instruction is required to ensure the required ordering.

The following sections describe the other attributes for Normal memory:

- Shareable Normal memory.
- Non-shareable Normal memory.
- Cacheability attributes for Normal memory.

See also:

- Multi-register loads and stores that access Normal memory.
- Atomicity in the Arm architecture.
- Memory barriers.
- Concurrent modification and execution of instructions.

B1.9.1.1 Shareable Normal memory

A Normal memory location has a Shareability attribute that is one of:

- Inner Shareable, meaning it applies across the Inner Shareable shareability domain.
- Outer Shareable, meaning it applies across both the Inner Shareable and the Outer Shareable shareability domains.
- Non-shareable.

The shareability attributes define the data coherency requirements of the location, which hardware must enforce. They do not affect the coherency requirements of instruction fetches, see Synchronization and coherency issues between data and instruction accesses.

Note

- System designers can use the shareability attribute to specify the locations in Normal memory for which coherency must be maintained. However, software developers must not assume that specifying a memory location as Non-shareable permits software to make assumptions about the incoherency of the location between different PEs in a shared memory system. Such assumptions are not portable between different multiprocessing implementations that might use the shareability attribute. Any multiprocessing implementation might implement caches that are shared, inherently, between different processing elements.
- This architecture assumes that all PEs that use the same operating system or hypervisor are in the same Inner Shareable shareability domain.

B1.9.1.1.1 Shareable, Inner Shareable, and Outer Shareable Normal memory

The Arm architecture abstracts the system as a series of Inner and Outer Shareability domains.

Each Inner Shareability domain contains a set of observers that are data coherent for each member of that set for data accesses with the Inner Shareable attribute made by any member of that set.

Each Outer Shareability domain contains a set of observers that are data coherent for each member of that set for data accesses with the Outer Shareable attribute made by any member of that set.

The following properties also hold:

- Each observer is a member of only a single Inner Shareability domain.
- Each observer is a member of only a single Outer Shareability domain.
- All observers in an Inner Shareability domain are always members of the same Outer Shareability domain. This means that an Inner Shareability domain is a subset of an Outer Shareability domain, although it is not required to be a proper subset.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

- Because all data accesses to Non-cacheable locations are data coherent to all observers, Non-cacheable locations are always treated as Outer Shareable.
- The Inner Shareable domain is expected to be the set of PEs controlled by a single hypervisor or operating system.

The details of the use of the shareability attributes are system-specific. Example B1-1 shows how they might be used.

Example B1-1 Use of shareability attributes

In an implementation, a particular subsystem with two clusters of PEs has the requirement that:

- In each cluster, the data caches or unified caches of the PEs in the cluster are transparent for all data accesses to memory locations with the Inner Shareable attribute.
- However, between the two clusters, the caches:
  - Are not required to be coherent for data accesses that have only the Inner Shareable attribute.
  - Are coherent for data accesses that have the Outer Shareable attribute.

In this system, each cluster is in a different shareability domain for the Inner Shareable attribute, but all components of the subsystem are in the same shareability domain for the Outer Shareable attribute.
A system might implement two such subsystems. If the data caches or unified caches of one subsystem are not transparent to the accesses from the other subsystem, this system has two Outer Shareable shareability domains.

Having two levels of shareability means system designers can reduce the performance and power overhead for shared memory locations that do not need to be part of the Outer Shareable shareability domain.

For shareable Normal memory, the Load-Exclusive and Store-Exclusive synchronization primitives take account of the possibility of accesses by more than one observer in the same Shareability domain.

B1.9.1.2 Non-shareable Normal memory

For Normal memory locations, the Non-shareable attribute identifies Normal memory that is likely to be accessed only by a single PE.

A location in Normal memory with the Non-shareable attribute does not require the hardware to make data accesses by different observers coherent, unless the memory is Non-cacheable. For a Non-shareable location, if other observers share the memory system, software must use cache maintenance instructions, if the presence of caches might lead to coherency issues when communicating between the observers. This cache maintenance requirement is in addition to the barrier operations that are required to ensure memory ordering.

For Non-shareable Normal memory, it is IMPLEMENTATION DEFINED whether the Load-Exclusive and Store-Exclusive synchronization primitives take account of the possibility of accesses by more than one observer.

B1.9.1.3 Cacheability attributes for Normal memory

In addition to being Outer Shareable, Inner Shareable or Non-shareable, each region of Normal memory is assigned a Cacheability attribute that is one of:

- Write-Through Cacheable.
- Write-Back Cacheable.
- Non-cacheable.

Also, for Write-Through Cacheable and Write-Back Cacheable Normal memory regions:

- A region might be assigned cache allocation hints for read and write accesses.
- It is IMPLEMENTATION DEFINED whether the cache allocation hints can have an additional attribute of Transient or Non-transient.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

For more information, see Cacheability, cache allocation hints, and cache transient hints.

A memory location can be marked as having different cacheability attributes, for example when using aliases in a VA to PA mapping:

- If the attributes differ only in the cache allocation hint, this does not affect the behavior of accesses to that location.
- For other cases, see Mismatched memory attributes.

The cacheability attributes provide a mechanism of coherency control with observers that lie outside the shareability domain of a region of memory. In some cases, the use of Write-Through Cacheable or Non-cacheable regions of memory might provide a better mechanism for controlling coherency than the use of hardware coherency mechanisms or the use of cache maintenance routines. To this end, the architecture requires the following properties for Non-cacheable or Write-Through Cacheable memory:

- A completed write to a memory location that is Non-cacheable or Write-Through Cacheable for a level of cache made by an observer accessing the memory system inside the level of cache is visible to all observers accessing the memory system outside the level of cache without the need of explicit cache maintenance.
- A completed write to a memory location that is Non-cacheable for a level of cache made by an observer accessing the memory system outside the level of cache is visible to all observers accessing the memory system inside the level of cache without the need of explicit cache maintenance.
- For accesses to Normal memory that is Non-cacheable, a DMB instruction introduces a Barrier-ordered-before relation on all accesses to a single peripheral or block of memory that is of IMPLEMENTATION DEFINED size. For more information, see Ordering relations.

Note

Implementations can use the cache allocation hints to indicate a probable performance benefit of caching. For example, a programmer might know that a piece of memory is not going to be accessed again and would be better treated as Non-cacheable. The distinction between memory regions with attributes that differ only in the cache allocation hints exists only as a hint for performance.

For Normal memory, the Arm architecture provides cacheability attributes that are defined independently for each of two conceptual levels of cache, the *inner* and the *outer* cache. The relationship between these conceptual levels of cache and the implemented physical levels of cache is IMPLEMENTATION DEFINED, and can differ from the boundaries between the Inner and Outer Shareability domains. However:

- Inner refers to the innermost caches, meaning the caches that are closest to the PE, and always includes the lowest level of cache.
- No cache that is controlled by the Inner cacheability attributes can lie outside a cache that is controlled by the Outer cacheability attributes.
- An implementation might not have any outer cache.

Example B1-2, Example B1-3, and Example B1-4 describe the possible ways of implementing a system with three levels of cache, *level 1* (L1) to *level 3* (L3).

Note

- L1 cache is the level closest to the PE, see Memory hierarchy.
- When managing coherency, system designs must consider both the inner and outer cacheability attributes, as well as the shareability attributes. This is because hardware might have to manage the coherency of caches at one conceptual level, even when another conceptual level has the Non-cacheable attribute.

Example B1-2 Implementation with two inner and one outer cache levels

Implement the three levels of cache in the system, L1 to L3, with:

- The Inner cacheability attribute applied to L1 and L2 cache.
- The Outer cacheability attribute applied to L3 cache.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Example B1-3 Implementation with three inner and no outer cache levels

Implement the three levels of cache in the system, L1 to L3, with the Inner cacheability attribute applied to L1, L2, and L3 cache. Do not use the Outer cacheability attribute.

Example B1-4 Implementation with one inner and two outer cache levels

Implement the three levels of cache in the system, L1 to L3, with:

- The Inner cacheability attribute applied to L1 cache.
- The Outer cacheability attribute applied to L2 and L3 cache.

B1.9.1.4 Multi-register loads and stores that access Normal memory

For all instructions that load or store more than one general-purpose register from an Exception level there is no requirement for the memory system beyond the PE to be able to identify the size of the elements accessed by these load or store instructions.

For all instructions that load or store more than one general-purpose register from an Exception level the order in which the registers are accessed is not defined by the architecture.

For all instructions that load or store one or more Advanced SIMD&FP registers from an Exception level, there is no requirement for the memory system beyond the PE to be able to identify the size of the element accessed by these load or store instructions.

B1.9.2 Device memory

The Device memory type attributes define memory locations where an access to the location can cause side-effects, or where the value returned for a load can vary depending on the number of loads performed. Typically, the Device memory attributes are used for memory-mapped peripherals and similar locations.

The attributes for Armv8 Device memory are:

Gathering Identified as G or nG, see Gathering.

Reordering Identified as R or nR, see Reordering.

Early Write Acknowledgement

Identified as E or nE, see Early Write Acknowledgement.

The Armv8 Device memory types are:

Device-nGnRnE Device non-Gathering, non-Reordering, No Early Write Acknowledgement.

Equivalent to the Strongly-ordered memory type in earlier versions of the architecture.

Device-nGnRE Device non-Gathering, non-Reordering, Early Write Acknowledgement.

Equivalent to the Device memory type in earlier versions of the architecture.

Device-nGRE Device non-Gathering, Reordering, Early Write Acknowledgement.

Armv8 adds this memory type to the translation table formats found in earlier versions of the architecture. The use of barriers is required to order accesses to Device-nGRE memory.

Device-GRE Device Gathering, Reordering, Early Write Acknowledgement.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Armv8 adds this memory type to the translation table formats found in earlier versions of the architecture. Device-GRE memory has the fewest constraints. It behaves similar to Normal memory, with the restriction that Speculative accesses to Device-GRE memory is forbidden.

Collectively these are referred to as *any Device memory type*. Going down the list, the memory types are described as getting *weaker*; conversely the going up the list the memory types are described as getting *stronger*.

Note

- As the list of types shows, these additional attributes are hierarchical. For example, a memory location that permits Gathering must also permit Reordering and Early Write Acknowledgement.
- The architecture does not require an implementation to distinguish between each of these memory types and Arm recognizes that not all implementations will do so. The subsection that describes each of the attributes, describes the implementation rules for the attribute.

All of these memory types have the following properties:

- Speculative data accesses are not permitted to any memory location with any Device memory attribute. This means that each memory access to any Device memory type must be one that would be generated by a simple sequential execution of the program.

  The following exception to this applies:

  — Reads generated by the SIMD and floating-point instructions can access bytes that are not explicitly accessed by the instruction if the bytes accessed are in a 16-byte window, aligned to 16-bytes, that contains at least one byte that is explicitly accessed by the instruction.

  — For Device memory with the Gathering attribute, reads generated by the `LDNP` instructions are permitted to access bytes that are not explicitly accessed by the instruction, provided that the bytes accessed are in a 128-byte window, aligned to 128-bytes, that contains at least one byte that is explicitly accessed by the instruction.

  — Where a load or store instruction performs a sequence of memory accesses, as opposed to one single-copy atomic access as defined in the rules for single-copy atomicity, these accesses might occur multiple times as a result of executing the load or store instruction. See Properties of single-copy atomic accesses.

  — An `LDRAA` or `LDRAB` instruction that fails the pointer authentication check and loads from a location in Device memory is permitted to cause one read access to that location if all of the other requirements for accessing that Device location are met.

  Note

  — An instruction that generates a sequence of accesses as described in Atomicity in the Arm architecture might be abandoned as a result of an exception being taken during the sequence of accesses. On return from the exception, the instruction is restarted, and therefore, one or more of the memory locations might be accessed multiple times. This can result in repeated accesses to a location where the program defines only a single access. For this reason, Arm strongly recommends that no accesses to Device memory are performed from a single instruction that spans the boundary of a translation granule or which in some other way could lead to some of the accesses being aborted.

  — Write speculation that is visible to other observers is prohibited for all memory types.

- An Explicit Memory Write Effect to a memory location with any Device memory type completes in finite time.
- If a value that would be returned from a read of a memory location with the Device memory type changes without an explicit Memory Write effect by an observer, this change must also be globally observed for all observers in the system in finite time. Such a change might occur in a peripheral location that holds status information.
- Data accesses to memory locations are coherent for all observers in the system, and correspondingly are treated as being Outer Shareable.
- A memory location with any Device memory attribute cannot be allocated into a cache.
- Explicit Memory Write Effects to a memory location with any Device memory attribute must reach the endpoint for that address in the memory system in finite time. Two Explicit Memory Write Effects of Device memory type to the same location might be merged before they reach the endpoint, unless both Explicit Memory Write Effects have the non-Gathering attribute or there is an ordered-before relationship between the two Explicit Memory Write Effects.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- For accesses to any Device memory type, a DMB instruction introduces a Barrier-ordered-before relation on all accesses to a single peripheral or block of memory that is of IMPLEMENTATION DEFINED size. For more information, see Ordering relations.
- If a memory location is not capable of supporting unaligned memory accesses, then an unaligned access to that memory location generates an Alignment fault at the first stage of translation that defined the location as being Device.
- If a memory location is capable of supporting unaligned memory accesses, and such a memory location is marked as Device, then it is IMPLEMENTATION DEFINED whether an unaligned access to that memory location generates an Alignment fault at the first stage of translation that defined the location as being Device.
- Hardware does not prevent speculative instruction fetches from a memory location with any of the Device memory attributes unless the memory location is also marked as execute-never for all Exception levels.

  Note

  This means that to prevent speculative instruction fetches from memory locations with Device memory attributes, any location that is assigned any Device memory type must also be marked as execute-never for all Exception levels. Failure to mark a memory location with any Device memory attribute as execute-never for all Exception levels is a programming error.

Note

In the EL1&0 translation regime in systems where HCR_EL2.TGE == 1 and HCR_EL2.DC == 0, any Alignment fault that results from the fact that all locations are treated as Device is a fault at the first stage of translation. This causes ESR_EL2.ISS[24] to be 0.

See also Memory access restrictions.

The memory types for translation table walks cannot be defined as any Device memory type within the TCR_ELx. For the EL1&0 translation regime, the memory accesses made during a stage 1 translation table walk are subject to a stage 2 translation, and as a result of this second stage of translation, the accesses from the first stage translation table walk might be made to memory locations with any Device memory type. These accesses might be made speculatively. When the value of the HCR_EL2.PTW bit is 1, a stage 2 Permission fault is generated if a first stage translation table walk is made to any Device memory type.

Note

In general, making a translation table walk to any Device memory type is the result of a programming error.

For an instruction fetch from a memory location with the Device attribute that is not marked as execute-never for the current Exception level, an implementation can either:

- Treat the instruction fetch as if it were to a memory location with the Normal Non-cacheable attribute.
- Take a Permission fault.

B1.9.2.1 Gathering

In the Device memory attribute:

G Indicates that the location has the Gathering attribute.

nG Indicates that the location does not have the Gathering attribute, meaning it is non-Gathering.

The Gathering attribute determines whether it is permissible for either:

- Multiple memory accesses of the same type, read or write, to the same memory location to be merged into a single transaction.
- Multiple memory accesses of the same type, read or write, to different memory locations to be merged into a single memory transaction on an interconnect.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

This also applies to writebacks from the cache, whether caused by a Natural eviction or as a result of a cache maintenance instruction.

For memory types with the Gathering attribute, either of these behaviors is permitted, provided that the ordering and coherency rules of the memory location are followed.

For memory types with the non-Gathering attribute, neither of these behaviors is permitted. As a result:

- The number of memory accesses that are made corresponds to the number that would be generated by a simple sequential execution of the program.
- All accesses occur at their single-copy atomic sizes, except that there is no requirement for the memory system beyond the PE to be able to identify the single-copy atomic sizes accessed by multi-register load/store instructions that generate more than one single-copy atomic access. See Multi-register loads and stores that access Device memory.

Gathering between two accesses, where one access is barrier-ordered-before the other access, is not permitted.

A read from a memory location with the non-Gathering attribute cannot come from a cache or a buffer, but must come from the endpoint for that address in the memory system. Typically this is a peripheral or physical memory.

Note

- A read from a memory location with the Gathering attribute can come from intermediate buffering of a previous write, provided that:
  - The accesses are not separated by a `DMB` or `DSB` barrier that affects both of the accesses.
  - The accesses are not separated by other ordering constructions that require that the accesses are in order. Such a construction might be a combination of Load-Acquire and Store-Release.
  - The accesses are not generated by a Store-Release instruction.
- The Arm architecture defines only programmer visible behavior. Therefore, gathering can be performed if a programmer cannot tell whether gathering has occurred.

An implementation is permitted to perform an access with the Gathering attribute in a manner consistent with the requirements specified by the non-Gathering attribute.

An implementation is not permitted to perform an access with the non-Gathering attribute in a manner consistent with the relaxations allowed by the Gathering attribute.

B1.9.2.2 Reordering

In the Device memory attribute:

R Indicates that the location has the Reordering attribute. Accesses to the location can be reordered within the same rules that apply to accesses to Normal Non-cacheable memory. All memory types with the Reordering attribute have the same ordering rules as accesses to Normal Non-cacheable memory, see Ordering relations.

nR Indicates that the location does not have the Reordering attribute, meaning it is non-Reordering.

Note

Some interconnect fabrics, such as PCIe, perform very limited reordering, which is not important for the software usage. It is outside the scope of the Arm architecture to prohibit the use of a non-Reordering memory type with these interconnects.

For all memory types with the non-Reordering attribute, the order of memory accesses arriving at a single peripheral of IMPLEMENTATION DEFINED size, as defined by the peripheral, must be the same order that occurs in a simple sequential execution of the program. That is, the accesses appear in program order. This ordering applies to all accesses using any of the memory types with the non-Reordering attribute. As a result, if there is a mixture of Device-nGnRE and Device-nGnRnE accesses to the same peripheral, these occur in program order. If the memory accesses are not to a peripheral, then this attribute imposes no restrictions.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

- The IMPLEMENTATION DEFINED size of the single peripheral is the same as applies for the ordering guarantee provided by the DMB instruction.
- The Arm architecture defines only programmer visible behavior. Therefore, reordering can be performed if a programmer cannot tell whether reordering has occurred.
- The non-Reordering property is only required by the architecture to apply the order of arrival of accesses to a single memory-mapped peripheral of an IMPLEMENTATION DEFINED size, and is not required to have an impact on the order of observation of memory accesses to SDRAM. For this reason, there is no effect of the non-Reordering attribute on the ordering relations between accesses to different locations described in Ordering relations as part of the formal definition of the memory model. It does have an effect on the Peripheral arrival order described in Peripheral arrival order.
- If the same memory location is mapped with different aliases, and different attribute values, these are a type of mismatched attribute. The different attributes could be:
  - A different Reordering attribute value.
  - A different Device memory attribute value.

For information about the effects of accessing memory with mismatched attributes, see Mismatched memory attributes.

An implementation:

- Is permitted to perform an access with the Reordering attribute in a manner consistent with the requirements specified by the non-Reordering attribute.
- Is not permitted to perform an access with the non-Reordering attribute in a manner consistent with the relaxations allowed by the Reordering attribute.

The non-Reordering attribute does not require any additional ordering, other than that which applies to Normal memory, between:

- Accesses to one physical address with the non-Reordering attribute and accesses to a different physical address with the Reordering attribute.
- Access to one physical address with the non-Reordering attribute and access to a different physical address to Normal memory.
- Accesses with the non-Reordering attribute and accesses to different peripherals of IMPLEMENTATION DEFINED size.

The non-Reordering attribute has no effect on the ordering of cache maintenance instructions, even if the memory location specified in the instruction has the non-Reordering attribute.

B1.9.2.3 Early Write Acknowledgement

In the Device memory attribute:

E Indicates that the location has the Early Write Acknowledgement attribute.

nE Indicates that the location has the No Early Write Acknowledgement attribute.

If the No Early Write Acknowledgement attribute is assigned for a Device memory location:

- For memory system endpoints where the system architecture in which the PE is operating requires that acknowledgment of a write comes from the endpoint, it is guaranteed that:
  - Only the endpoint of the write access returns a write acknowledgment of the access.
  - No earlier point in the memory system returns a write acknowledgment.
- For memory system endpoints where the system architecture in which the PE is operating does not require that acknowledgment of a write comes from the endpoint, the acknowledgment of a write is not required to come from the endpoint.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

A write with the No Early Write Acknowledgement attribute assigned for a Device memory location is not expected to generate an abort in any situation where the equivalent write to the same location without the No Early Write Acknowledgement attribute assigned does not generate an abort.

This means that a `DSB` barrier instruction, executed by the PE that performed the write to the No Early Write Acknowledgement Location, completes only after the write has reached its endpoint in the memory system if that is required by the system architecture.

Peripherals are an example of system endpoints that require that the acknowledgment of a write comes from the endpoint.

Note

- The Early Write Acknowledgement attribute only affects where the endpoint acknowledgment is returned from, and does not affect the ordering of arrival at the endpoint between accesses, which is determined by either the Device Reordering attribute, or the use of barriers to create order.
- The areas of the physical memory map for which write acknowledgment from the endpoint is required is outside the scope of the Arm Architecture definition and must be defined as part of the system architecture in which the PE is operating. In particular, regions of memory handled as PCIe configuration writes are expected to support write acknowledgment from the endpoint.
- Arm recognizes that not all areas of a physical memory map will be capable of supporting write acknowledgment from the endpoint. In particular, Arm expects that regions of memory handled as posted writes under PCIe will not support write acknowledgment from the endpoint.
- For maximum software compatibility, Arm strongly recommends that all peripherals for which standard software drivers expect that the use of a `DSB` instruction will determine that a write has reached its endpoint are placed in areas of the physical memory map that support write acknowledgment from the endpoint.

B1.9.2.4 Multi-register loads and stores that access Device memory

For all instructions that load or store more than one general-purpose register and generate more than one single-copy atomic access for that load or store, there is no requirement for the memory system beyond the PE to be able to identify the single-copy atomic sizes accessed by these load or store instructions.

For all instructions that load or store more than one general-purpose register, the order in which the registers are accessed is not defined by the architecture. This applies even to accesses to any type of Device memory.

For all instructions that load or store one or more Advanced SIMD&FP, and generate more than one single-copy atomic access for that load or store, there is no requirement for the memory system beyond the PE to be able to identify the single-copy atomic sizes accessed by these load or store instructions, even for access to any type of Device memory.

The architecture permits that the non-speculative execution of an instruction that loads or stores more than one general-purpose or SIMD and floating-point register might result in repeated accesses to the same address, even if the resulting accesses are to any type of Device memory.

B1.9.3 Memory access restrictions

The following restrictions apply to memory accesses:

- For two explicit Memory Read effects to any two adjacent bytes in memory, p and $p+1$, generated by the same instruction, and for two explicit Memory Write effects to any two adjacent bytes in memory, p and $p+1$, that are generated by the same instruction:
  - The bytes p and $p+1$ must have the same memory type and Shareability attributes, otherwise the results are CONSTRAINED UNPREDICTABLE. For example, an `LD1`, `ST1`, or an unaligned load or store that spans the boundary between Normal memory and Device memory is CONSTRAINED UNPREDICTABLE.
  - Except for possible differences in the cache allocation hints, Arm deprecates having different cacheability attributes for bytes p and $p+1$.

  For the permitted CONSTRAINED UNPREDICTABLE behavior, see Crossing a page boundary with different memory types or Shareability attributes.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- If the accesses of an instruction that causes multiple accesses to any type of Device memory cross an address boundary that corresponds to the smallest implemented translation granule, then behavior is CONSTRAINED UNPREDICTABLE, and Crossing a peripheral boundary with a Device access describes the permitted behaviors. For this reason, it is important that an access to a volatile memory device is not made using a single instruction that crosses an address boundary of the size of the smallest implemented translation granule.

Note

— The boundary referred to is between two Device memory regions that are both of the size of the smallest implemented translation granule and aligned to the size of the smallest implemented translation granule.

— This restriction means it is important that an access to a volatile memory device is not made using a single instruction that crosses an address boundary of the size of the smallest implemented translation granule.

— Arm expects this restriction to constrain the placing of volatile memory devices in the system memory map, rather than expecting a compiler to be aware of the alignment of memory accesses.

B1.10 Mismatched memory attributes

Memory attributes are controlled by privileged software. For more information, see The AArch64 Virtual Memory System Architecture.

Physical memory locations are accessed with *mismatched attributes* if all accesses to the location do not use a common definition of all of the following attributes of that location:

- Memory type: Device-nGnRnE, Device-nGnRE, Device-nGRE, Device-GRE or Normal.
- Shareability.
- Cacheability, for the same level of the inner or outer cache, but excluding any cache allocation hints.

Collectively these are referred to as memory attributes.

Note

In this document, the terms *location* and *memory location* refer to any byte within the current coherency granule and are used interchangeably.

When a memory Location is accessed with mismatched attributes, the only software visible effects are one or more of the following:

- Uniprocessor semantics for reads and writes to that memory Location might be lost. This means:
  - A read of the memory Location by one agent might not return the value most recently written to that memory Location by the same agent.
  - Multiple writes to the memory Location by one agent with different memory attributes might not be ordered in program order.
- There might be a loss of coherency when multiple agents attempt to access a memory Location.
- There might be a loss of properties derived from the memory type, as described in later bullets in this section.
- If all Load-Exclusive/Store-Exclusive instructions executed across all threads to access a given memory Location do not use consistent memory attributes, the Exclusives monitor state becomes UNKNOWN.
- Bytes written without the Write-Back cacheable attribute within the same Write-Back granule as bytes written with the Write-Back cacheable attribute might have their values reverted to the old values as a result of cache Write-Back.

The loss of properties associated with mismatched memory type attributes refers only to the following properties of Device memory that are additional to the properties of Normal memory:

- Prohibition of Speculative read accesses.
- Prohibition on Gathering.
- Prohibition on reordering.

For the following situations, when a physical memory Location is accessed with mismatched attributes, a more restrictive set of behaviors applies. The description of each situation also describes the behaviors that apply:

1. Any agent that reads that memory Location using the same common definition of the Memory type, Shareability and Cacheability attributes is guaranteed to access it coherently, to the extent required by that common definition of the memory attributes, only if all the following conditions are met:
   - All writes are performed to an alias of the memory Location that uses the same definition of the Memory type, Shareability and Cacheability attributes.
   - All aliases with write permission have the Inner Cacheability attribute the same as the Outer Cacheability attribute.
   - Either:
     - All writes are performed to an alias of the memory Location that has Inner Cacheability and Outer Cacheability attributes both as Non-cacheable.
     - All aliases to a memory Location use a definition of the Shareability attributes that encompasses all the agents with permission to access the Location.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

2. The possible software-visible effects caused by mismatched attributes for a memory Location are defined more precisely if all of the mismatched attributes define the memory Location as one of:
   - Any Device memory type.
   - Inner Non-cacheable, Outer Non-cacheable Normal memory.

   In these cases, the only permitted software-visible effects of the mismatched attributes are one or more of the following:
   - Possible loss of properties derived from the memory type when multiple agents attempt to access the memory Location.
   - Possible reordering of memory transactions to the same memory Location with different memory attributes, potentially leading to a loss of coherency or uniprocessor semantics. Any possible loss of coherency or uniprocessor semantics can be avoided by inserting DMB barrier instructions between accesses to the same memory Location that might use different attributes.

Where there is a loss of the uniprocessor semantics, ordering, or coherency, the following approaches can be used:

1. If the mismatched attributes for a memory location all assign the same shareability attribute to a Location that has a cacheable attribute, any loss of uniprocessor semantics, ordering, or coherency within a shareability domain can be avoided by use of software cache management. To do so, software must use the techniques that are required for the software management of the ordering or coherency of cacheable Locations between agents in different shareability domains. This means:
   - Before writing to a cacheable Location not using the Write-Back attribute, software must invalidate, or clean, a Location from the caches if any agent might have written to the Location with the Write-Back attribute. This avoids the possibility of overwriting the Location with stale data.
   - After writing to a cacheable Location with the Write-Back attribute, software must clean the Location from the caches, to make the write visible to external memory.
   - Before reading the Location with a cacheable attribute, software must invalidate, or clean and invalidate, the Location from the caches, to ensure that any value held in the caches reflects the last value made visible in external memory.
   - Executing a DMB barrier instruction, with scope that applies to the common shareability of the accesses, between any accesses to the same cacheable Location that use different attributes.

   In all cases:
   - Location refers to any byte within the current coherency granule.
   - A clean and invalidate instruction can be used instead of a clean instruction, or instead of an invalidate instruction.
   - In the sequences outlined in this section, all cache maintenance instructions and memory transactions must be completed, or ordered by the use of barrier operations, if they are not naturally ordered by the use of a common address, see Ordering and completion of data and instruction cache instructions.

   Note

   With software management of coherency, race conditions can cause loss of data. A race condition occurs when different agents write simultaneously to bytes that are in the same Location, and the invalidate, write, clean sequence of one agent overlaps with the equivalent sequence of another agent. A race condition also occurs if the first operation of either sequence is a clean, rather than an invalidate.

2. If the mismatched attributes for a Location mean that multiple cacheable accesses to the Location might be made with different shareability attributes, then uniprocessor semantics, ordering, and coherency are guaranteed only if:
   - Software running on a PE cleans and invalidates a Location from cache before and after each read or write to that Location by that PE.
   - A DMB barrier with scope that covers the full shareability of the accesses is placed between any accesses to the same memory Location that use different attributes.

   Note

   The Note in rule 1 of this list, about possible race conditions, also applies to this rule.

In addition, if multiple agents attempt to use Load-Exclusive or Store-Exclusive instructions to access a Location, and the accesses from the different agents have different memory attributes associated with the Location, the Exclusives monitor state becomes UNKNOWN.

Arm strongly recommends that software does not use mismatched attributes for aliases of the same Location. An implementation might not optimize the performance of a system that uses mismatched aliases.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

As described in Non-cacheable accesses and instruction caches, a non-cacheable access is permitted to be cached in an instruction cache, despite the fact that a non-cacheable access is not permitted to be cached in a unified cache. Despite this, when cacheable and non-cacheable aliases exist for memory which is executable, these must be treated as mismatched aliases to avoid coherency issues from the data or unified caches that might hold entries that will be brought into the instruction caches.

B1.11 Synchronization and semaphores

Armv8 provides non-blocking synchronization of shared memory, using *synchronization primitives*. The information in this section about memory accesses by synchronization primitives applies to accesses to both Normal memory and to any type of Device memory.

Note

Use of the Armv8 synchronization primitives scales for multiprocessing system designs.

Table B1-5 shows the synchronization primitives and the associated `CLREX` instruction.

Table B1-5 Synchronization primitives and associated instruction, A64 instruction set

Transaction size	Additional semantics	Load-Exclusive[a]	Store-Exclusive[a]	Other[a]
Byte	-	`LDXRB`	`STXRB`	-
	Load-Acquire/Store-Release	`LDAXRB`	`STLXRB`	-
Halfword	-	`LDXRH`	`STXRH`	-
	Load-Acquire/Store-Release	`LDAXRH`	`STLXRH`	-
Register[b]	-	`LDXR`	`STXR`	-
	Load-Acquire/Store-Release	`LDAXR`	`STLXR`	-
Pair[b]	-	`LDXP`	`STXP`	-
	Load-Acquire/Store-Release	`LDAXP`	`STLXP`	-
None	Clear-Exclusive	-	-	`CLREX`

a. Instruction in the A64 instruction set.

b. A register instruction operates on a doubleword if accessing an X register, or on a word if accessing a W register A pair instruction operates on two doublewords if access X registers, or on two words if accessing W registers.

Except for the row showing the `CLREX` instruction, the two instructions in a single row are a Load-Exclusive/Store-Exclusive instruction pair. The model for the use of a Load-Exclusive/Store-Exclusive instruction pair accessing a non-aborting memory address *x* is:

- The Load-Exclusive instruction reads a value from memory address *x*.
- The corresponding Store-Exclusive instruction succeeds in writing back to memory address *x* only if no other observer, process, or thread has performed a more recent store to address *x*. The Store-Exclusive instruction returns a status bit that indicates whether the Write Memory succeeded.

A Load-Exclusive instruction marks a small block of memory for exclusive access. The size of the marked block is IMPLEMENTATION DEFINED, see Marking and the size of the marked memory block. A Store-Exclusive instruction to any address in the marked block clears the marking.

Note

In this section, the term PE includes any observer that can generate a Load-Exclusive or a Store-Exclusive instruction.

The following sections give more information:

- Exclusive access instructions and Non-shareable memory locations.
- Exclusive access instructions and Shareable memory locations.
- Marking and the size of the marked memory block.
- Context switch support.
- Load-Exclusive and Store-Exclusive instruction usage restrictions.
- Use of WFE and SEV instructions by spin-locks.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

B1.11.1 Exclusive access instructions and Non-shareable memory locations

For memory locations for which the shareability attribute is Non-shareable, the exclusive access instructions rely on a *local Exclusives monitor*, or *local monitor*, that marks the address of the Explicit Memory Read effect generated by any Load-Exclusive instruction executed by the PE.

A Load-Exclusive instruction performs a load from memory, and:

- The executing PE marks the physical memory address for exclusive access.
- The local monitor of the executing PE transitions to the Exclusive Access state.

A Store-Exclusive instruction performs a conditional store to memory that depends on the state of the local monitor:

If the local monitor is in the Exclusive Access state

- If the address of the Explicit Memory Write effect of the Store-Exclusive instruction is the same as the address that has been marked in the monitor due to the execution of an earlier Load-Exclusive instruction, then the store occurs. Otherwise, it is IMPLEMENTATION DEFINED whether the store occurs.
- A status value is returned to a register:
  - — If the store took place, the status value is 0.
  - — Otherwise, the status value is 1.
- The local monitor of the executing PE transitions to the Open Access state.

When an Exclusives monitor is in the Exclusive Access state, the monitor is *set.*

If the local monitor is in the Open Access state

- No store takes place.
- A status value of 1 is returned to a register.
- The local monitor remains in the Open Access state.

When an Exclusives monitor is in the Open Access state, the monitor is *clear*.

The Store-Exclusive instruction defines the register to which the status value is returned.

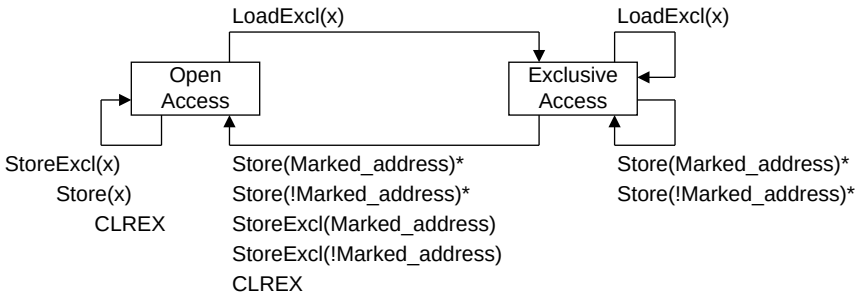
When a PE writes using any instruction other than a Store-Exclusive instruction:

- If the write is to a PA that is not marked as Exclusive Access by its local monitor and that local monitor is in the Exclusive Access state, it is IMPLEMENTATION DEFINED whether the write affects the state of the local monitor.
- If the write is to a PA that is marked as Exclusive Access by its local monitor, it is IMPLEMENTATION DEFINED whether the write affects the state of the local monitor.

It is IMPLEMENTATION DEFINED whether a store to a marked PA causes a mark in the local monitor to be cleared if that store is by an observer other than the one that caused the PA to be marked.

Figure B1-6 shows the state machine for the local monitor and the effect of each of the operations shown in the figure.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential



Operations marked * are possible alternative IMPLEMENTATION DEFINED options.
In the diagram: LoadExcl represents any Load-Exclusive instruction
StoreExcl represents any Store-Exclusive instruction
Store represents any other store instruction.

Any LoadExcl operation updates the marked address to the most significant bits of the address x used for the operation.

Figure B1-6 Local monitor state machine diagram

For more information about marking, see Marking and the size of the marked memory block.

Note

For the local monitor state machine, as shown in Figure B1-6:

- The IMPLEMENTATION DEFINED options for the local monitor are consistent with the local monitor being constructed so that it does not hold any PA, but instead treats any access as matching the address of the previous Load-Exclusive instruction.
- A local monitor implementation can be unaware of Load-Exclusive and Store-Exclusive instructions from other PEs.
- The architecture does not require a load instruction by another PE, that is not a Load-Exclusive instruction, to have any effect on the local monitor.
- It is IMPLEMENTATION DEFINED whether the transition from Exclusive Access to Open Access state occurs when the `Store` or `StoreExcl` is from another observer.

B1.11.1.1 Changes to the local monitor state resulting from speculative execution

The architecture permits a local monitor to transition to the Open Access state as a result of speculation, or from some other cause. This is in addition to the transitions to Open Access state caused by the architectural execution of an operation shown in Figure B1-6.

An implementation must ensure that:

- The local monitor cannot be seen to transition to the Exclusive Access state except as a result of the architectural execution of one of the operations shown in Figure B1-6.
- Any transition of the local monitor to the Open Access state not caused by the architectural execution of an operation shown in Figure B1-6 must not indefinitely delay forward progress of execution.

B1.11.2 Exclusive access instructions and Shareable memory locations

In the context of this section, a shareable memory location is a memory location that has, or is treated as if it has, a Shareability attribute of Inner Shareable or Outer Shareable.

For shareable memory locations, exclusive access instructions rely on:

- A *local monitor* for each PE in the system, which marks any address from which the PE executes a Load-Exclusive. The local monitor operates as described in Exclusive access instructions and Non-shareable memory locations, except that for shareable memory any Store-Exclusive is then subject to checking by the global monitor if it is described in that section as doing at least one of the following:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

— Updating memory.
— Returning a status value of 0.

The local monitor can ignore accesses from other PEs in the system.

- A *global monitor* that marks a PA as exclusive access for a particular PE. This marking is used later to determine whether a Store-Exclusive to that address that has not been failed by the local monitor can occur. Any successful write to the marked block by any other observer in the shareability domain of the memory location is guaranteed to clear the marking. For each PE in the system, the global monitor:

  — Can hold at least one marked block.
  — Maintains a state machine for each marked block it can hold.

  Note

  For each PE, the architecture only requires global monitor support for a single marked address. Any situation that might benefit from the use of multiple marked addresses on a single PE is UNPREDICTABLE or CONSTRAINED UNPREDICTABLE, see Load-Exclusive and Store-Exclusive instruction usage restrictions.

Note

The global monitor can either reside within the PE, or exist as a secondary monitor at the memory interfaces. The IMPLEMENTATION DEFINED aspects of the monitors mean that the global monitor and local monitor can be combined into a single unit, provided that the unit performs the global monitor and local monitor functions defined in this manual.

For shareable memory locations, in some implementations and for some memory types, the properties of the global monitor require functionality outside the PE. Some system implementations might not implement this functionality for all locations of memory. In particular, this can apply to:

- Any type of memory in the system implementation that does not support hardware cache coherency.
- Non-cacheable memory, or memory treated as Non-cacheable, in an implementation that does support hardware cache coherency.

In such a system, it is defined by the system:

- Whether the global monitor is implemented.
- If the global monitor is implemented, which address ranges or memory types it monitors.

Note

To support the use of the Load-Exclusive/Store-Exclusive mechanism when address translation is disabled, a system might define at least one location of memory, of at least the size of the translation granule, in the system memory map to support the global monitor for all Arm PEs within a common Inner Shareable domain. However, this is not an architectural requirement. Therefore, architecturally-compliant software that requires mutual exclusion must not rely on using the Load-Exclusive/Store-Exclusive mechanism, and must instead use a software algorithm such as Lamport's Bakery algorithm to achieve mutual exclusion.

Because implementations can choose which memory types are treated as Non-cacheable, the only memory types for which it is architecturally guaranteed that a global Exclusives monitor is implemented are:

- Inner Shareable, Inner Write-Back, Outer Write-Back Normal memory.
- Outer Shareable, Inner Write-Back, Outer Write-Back Normal memory.

The architecture only requires that Conventional memory mapped in this way supports this functionality.

If the global monitor is not implemented for an address range or memory type, then performing a Load-Exclusive or a Store-Exclusive instruction to such a location has one or more of the following effects:

- The instruction generates an External abort.
- The instruction generates an IMPLEMENTATION DEFINED MMU fault. This is reported using the Data Abort Fault status code of ESR_ELx.DFSC = `110101`.

  If the IMPLEMENTATION DEFINED MMU fault is generated for the EL1&0 translation regime then:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

  - If the fault is generated because of the memory type defined in the first stage of translation, or if the second stage of translation is disabled, then this is a first stage fault and the exception is taken to EL1.
  - Otherwise, the fault is an MPU fault and the exception is taken to EL2.

  The priority of this fault is IMPLEMENTATION DEFINED.
- The instruction is treated as a NOP.
- The Load-Exclusive instruction is treated as if it were accessing a Non-shareable location, but the state of the local monitor becomes UNKNOWN.
- The Store-Exclusive instruction is treated as if it were accessing a Non-shareable location, but the state of the local monitor becomes UNKNOWN. In this case, if the store exclusive instruction is a store exclusive pair of 64-bit quantities, then the two quantities being stored might not be stored atomically.
- The value held in the result register of the Store-Exclusive instruction becomes UNKNOWN.

In addition, for write transactions generated by non-PE observers that do not implement exclusive accesses or other atomic access mechanisms, the effect that writes have on the global and local monitors used by Arm PEs is IMPLEMENTATION DEFINED. The writes might not clear the global monitors of other PEs for:

- Some address ranges.
- Some memory types.

B1.11.2.1 Operation of the global Exclusives monitor

A Load-Exclusive instruction from shareable memory performs a load from memory, and causes the PA of the access to be marked as exclusive access for the requesting PE. This access can also cause the exclusive access mark to be removed from any other PA that has been marked by the requesting PE.

Note

The global monitor supports only a single outstanding exclusive access to shareable memory per PE.

A Load-Exclusive instruction by one PE has no effect on the global monitor state for any other PE.

A Store-Exclusive instruction performs a conditional store to memory:

- The store is guaranteed to succeed only if the PA accessed is marked as exclusive access for the requesting PE and both the local monitor and the global monitor state machines for the requesting PE are in the Exclusive Access state. In this case:
  - A status value of 0 is returned to a register to acknowledge the successful store.
  - The final state of the global monitor state machine for the requesting PE is IMPLEMENTATION DEFINED.
  - If the address accessed is marked for exclusive access in the global monitor state machine for any other PE, then that state machine transitions to Open Access state.
- If no address is marked as exclusive access for the requesting PE, the store does not succeed:
  - A status value of 1 is returned to a register to indicate that the store failed.
  - The global monitor is not affected and remains in Open Access state for the requesting PE.
- If a different PA is marked as exclusive access for the requesting PE, it is IMPLEMENTATION DEFINED whether the store succeeds or not:
  - If the store succeeds a status value of 0 is returned to a register, otherwise a value of 1 is returned.
  - If the global monitor state machine for the PE was in the Exclusive Access state before the Store-Exclusive instruction it is IMPLEMENTATION DEFINED whether that state machine transitions to the Open Access state.

The Store-Exclusive instruction defines the register to which the status value is returned.

In a shared memory system, the global monitor implements a separate state machine for each PE in the system. The state machine for accesses to shareable memory by PE(n) can respond to all the shareable memory accesses visible to it. This means that it responds to:

- Accesses generated by PE(n).

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- Accesses generated by the other observers in the shareability domain of the memory location. These accesses are identified as (!n).

In a shared memory system, the global monitor implements a separate state machine for each observer that can generate a Load-Exclusive or a Store-Exclusive instruction in the system.

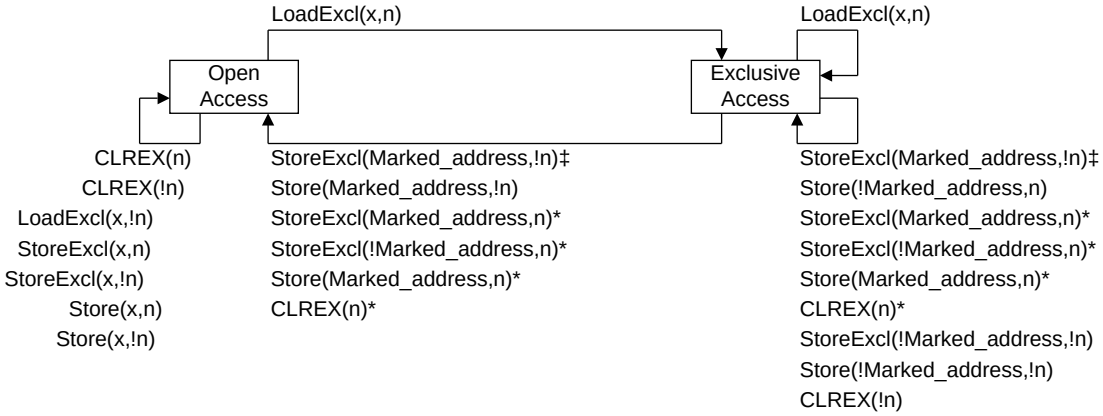
A global monitor:

- In the Exclusive Access state is *set*.
- In the Open Access state is *clear*.

B1.11.2.1.1 Clear global monitor event

Whenever the global monitor state for a PE changes from Exclusive access to Open access, an event is generated and held in the Event register for that PE. This register is used by the Wait for Event mechanism, see Mechanisms for entering a low-power state.

Figure B1-7 shows the state machine for PE(n) in a global monitor.



‡StoreExcl(Marked_address,!n) clears the monitor only if the StoreExcl updates memory
Operations marked * are possible alternative IMPLEMENTATION DEFINED options.
In the diagram: LoadExcl represents any Load-Exclusive instruction
StoreExcl represents any Store-Exclusive instruction
Store represents any other store instruction.

Any LoadExcl operation updates the marked address to the most significant bits of the address x used for the operation.

Figure B1-7 Global monitor state machine diagram for PE(n) in a multiprocessor system

For more information about marking, see Marking and the size of the marked memory block.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

For the global monitor state machine, as shown in Figure B1-7:

- The architecture does not require a load instruction by another PE, that is not a Load-Exclusive instruction, to have any effect on the global monitor.
- Whether a Store-Exclusive instruction successfully updates memory or not depends on whether the address accessed matches the marked shareable memory address for the PE issuing the Store-Exclusive instruction, and whether the local and global monitors are in the exclusive state. For this reason, Figure B1-7 shows only how the operations by (!n) cause state transitions of the state machine for PE(n).
- A Load-Exclusive instruction can only update the marked shareable memory address for the PE issuing the Load-Exclusive instruction.
- When the global monitor is in the Exclusive Access state, it is IMPLEMENTATION DEFINED whether a `CLREX` instruction causes the global monitor to transition from Exclusive Access to Open Access state.
- It is IMPLEMENTATION DEFINED:
  - Whether a modification to a Non-shareable memory location can cause a global monitor to transition from Exclusive Access to Open Access state.
  - Whether a Load-Exclusive instruction to a Non-shareable memory location can cause a global monitor to transition from Open Access to Exclusive Access state.

B1.11.3 Marking and the size of the marked memory block

When a Load-Exclusive instruction is executed, the resulting marked block ignores the least significant bits of the 64-bit memory address.

When a Load-Exclusive instruction is executed, a marked block of size 2^a bytes is created by ignoring the least significant bits of the memory address. A marked address is any address within this marked block. The size of the marked memory block is called the *Exclusives reservation granule*. The Exclusives reservation granule is IMPLEMENTATION DEFINED in the range 4-512 words.

Note

This definition means that the Exclusives reservation granule is:

- 4 words in an implementation where *a* is 4.
- 512 words in an implementation where *a* is 11.

For example, in an implementation where *a* is 4, a successful `LDXRB` of address `0x341B4` defines a marked block using bits[47:4] of the address. This means that the four words of memory from `0x341B0` to `0x341BF` are marked for exclusive access.

In some implementations the CTR identifies the Exclusives reservation granule, see CTR_EL0. Otherwise, software must assume that the maximum Exclusives reservation granule, 512 words, is implemented.

B1.11.4 Context switch support

An exception return clears the local monitor. As a result, performing a `CLREX` instruction as part of a context switch is not required in most situations.

Note

Context switching is not an application level operation. However, this information is included here to complete the description of the exclusive operations.

B1.11.5 Load-Exclusive and Store-Exclusive instruction usage restrictions

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The Load-Exclusive and Store-Exclusive instructions are intended to work together as a pair, for example a `LDXP/STXP` pair or a `LDXR/STXR` pair, executed as part of a loop that contains only a single Load-Exclusive and Store-Exclusive pair. To support different implementations of these functions, software must follow the notes and restrictions given here.

The following notes describe the use of a `LoadExcl/StoreExcl` instruction pair, to indicate the use of any of the Load-Exclusive/Store-Exclusive instruction pairs shown in Table B1-5. In this context, a `LoadExcl/StoreExcl` pair comprises two instructions in the same thread of execution:

- The exclusives support a single outstanding exclusive access for each PE thread that is executed. The architecture makes use of this by not requiring an address or size check as part of the `IsExclusiveLocal()` function. If the target VA of a `StoreExcl` is different from the VA of the preceding `LoadExcl` instruction in the same thread of execution, behavior can be CONSTRAINED UNPREDICTABLE with the following behavior:
  - The `StoreExcl` either passes or fails, the status value returned by the `StoreExcl` is UNKNOWN, and the states of the local and global monitors for that PE are UNKNOWN.

    Note

    This means the `StoreExcl` might pass for some instances of a `LoadExcl/StoreExcl` pair with mismatched addresses, and fail for other instances of a `LoadExcl/StoreExcl` pair with mismatched addresses.

  - The data at the address accessed by the `LoadExcl`, and at the address accessed by the `StoreExcl`, is UNKNOWN.

  This means software can rely on a `LoadExcl/StoreExcl` pair to eventually succeed only if the `LoadExcl` and the `StoreExcl` are executed with the same VA.
- An implementation of the Load-Exclusive and Store-Exclusive instructions can require that, in any thread of execution, the transaction size of a `StoreExcl` instruction is the same as the transaction size of the preceding `LoadExcl` instruction executed in that thread. If the transaction size of a `StoreExcl` instruction is different from the preceding `LoadExcl` instruction in the same thread of execution, behavior can be CONSTRAINED UNPREDICTABLE with the following behavior:
  - The `StoreExcl` either passes or fails, and the status value returned by the `StoreExcl` is UNKNOWN.

    Note

    This means the `StoreExcl` might pass for some instances of a `LoadExcl/StoreExcl` pair with mismatched transaction sizes, and fail for other instances of a `LoadExcl/StoreExcl` pair with mismatched transaction sizes.

  - The block of data of the size of the larger of the transaction sizes used by the `LoadExcl/StoreExcl` pair at the address accessed by the `LoadExcl/StoreExcl` pair, is UNKNOWN.

  This means software can rely on a `LoadExcl/StoreExcl` pair to eventually succeed only if the `LoadExcl` and the `StoreExcl` have the same transaction size.
- An implementation of the `LoadExcl` and `StoreExcl` instructions can require that, in any thread of execution, the `StoreExcl` instruction accesses the same number of registers as the preceding `LoadExcl` instruction executed in that thread. If the `StoreExcl` instruction accesses a different number of registers than the preceding `LoadExcl` instruction in the same thread of execution, behavior is CONSTRAINED UNPREDICTABLE. As a result, software can rely on an `LoadExcl/StoreExcl` pair to eventually succeed only if they access the same number of registers. For more information, see CONSTRAINED UNPREDICTABLE behavior when Load-Exclusive/Store-Exclusive access a different number of registers.
- If FEAT_LSE is not implemented, `LoadExcl/StoreExcl` loops are guaranteed to make forward progress only if, for any `LoadExcl/StoreExcl` loop within a single thread of execution, the software meets all of the following conditions. If FEAT_LSE is implemented, software can maximize the likelihood that `LoadExcl/StoreExcl` loops make forward progress, for any `LoadExcl/StoreExcl` loop within a single thread of execution, by meeting all of the following conditions:

  1 Between the Load-Exclusive and the Store-Exclusive, there are no explicit memory effects, software prefetches, direct or indirect System register writes, address translation instructions, cache or TLB maintenance instructions, exception generating instructions, exception returns, `ISB` barriers, indirect branches, or Branch with Link instructions.

  2 Between the Store-Exclusive returning a failing result and the retry of the corresponding Load-Exclusive:
  - There are no stores or `PRFM` or `RPRFM` instructions to any address within the Exclusives reservation granule accessed by the Store-Exclusive. This includes VA aliases to those addresses.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

— There are no loads or prefetches to any address within the Exclusives reservation granule accessed by the Store-Exclusive that use a different VA alias to that address.

— There are no other Store-Exclusive instructions to any other address.

— There are no direct or indirect System register writes, address translation instructions, cache or TLB maintenance instructions, exception generating instructions, exception returns, indirect branches, or Branch with Link instructions.

— All loads and stores are to a block of contiguous virtual memory of not more than 512 bytes in size.

The Exclusives monitor can be cleared at any time without an application-related cause, provided that such clearing is not systematically repeated so as to prevent the forward progress in finite time of at least one of the threads that is accessing the Exclusives monitor. However, it is permissible for the `LoadExcl`/`StoreExcl` loop not to make forward progress if a different thread is repeatedly doing any of the following in a tight loop:

— Performing stores to a PA covered by the Exclusives monitor.

— Prefetching with intent to write to a PA covered by the Exclusives monitor.

— Executing data cache clean, data cache invalidate, or data cache clean and invalidate instructions to a PA covered by the Exclusives monitor.

— Executing instruction cache invalidate all instructions.

— Executing instruction cache invalidate by VA instructions to a PA covered by the Exclusives monitor.

— Executing TLB maintenance to a PA covered by the Exclusives monitor.

- Implementations can benefit from keeping the `LoadExcl` and `StoreExcl` operations close together in a single thread of execution. This minimizes the likelihood of the Exclusives monitor state being cleared between the `LoadExcl` instruction and the `StoreExcl` instruction. Therefore, for best performance, Arm strongly recommends a limit of 128 bytes between `LoadExcl` and `StoreExcl` instructions in a single thread of execution.
- The architecture sets an upper limit of 2048 bytes on the Exclusives reservation granule that can be marked as exclusive. For performance reasons, Arm recommends that objects that are accessed by exclusive accesses are separated by the size of the Exclusives reservation granule. This is a performance guideline rather than a functional requirement.
- After taking a Data Abort exception, the state of the Exclusives monitors is UNKNOWN.
- For the memory location accessed by a `LoadExcl`/`StoreExcl` pair, if the memory attributes for a `StoreExcl` instruction are different from the memory attributes for the preceding `LoadExcl` instruction in the same thread of execution, behavior is CONSTRAINED UNPREDICTABLE. Where this occurs because the translation of the accessed address changes between the `LoadExcl` instruction and the `StoreExcl` instruction, the CONSTRAINED UNPREDICTABLE behavior is as follows:

  — The `StoreExcl` either passes or fails, and the status value returned by the `StoreExcl` is UNKNOWN.

  Note

  This means the `StoreExcl` might pass for some instances of a `LoadExcl`/`StoreExcl` pair with changed memory attributes, and fail for other instances of a `LoadExcl`/`StoreExcl` pair with changed memory attributes.

  — The data at the address accessed by the `StoreExcl` is UNKNOWN.

  Note

  Another bullet point in this list covers the case where the memory attributes of a `LoadExcl`/`StoreExcl` pair differ as a result of using different VAs with different attributes that point to the same PA.

- The effect of a data or unified cache invalidate, clean, or clean and invalidate instruction on a local or global Exclusives monitor that is in the Exclusive Access state is CONSTRAINED UNPREDICTABLE, and the instruction might clear the monitor, or it might leave it in the Exclusive Access state. For address-based maintenance instructions, this also applies to the monitors of other PEs in the same shareability domain as the PE executing the cache maintenance instruction, as determined by the shareability domain of the address being maintained.

  Note

  Arm strongly recommends that implementations ensure that the use of such maintenance instructions by a PE in one Security state cannot cause a denial of service on a PE in another Security state.

- If the mapping of the VA to PA is changed between the `LoadExcl` instruction and the `StoreExcl` instruction, and the change is performed using a break-before-make sequence as described in Using break-before-make when

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

updating translation table entries, if the `StoreExcl` is performed after another write to the same PA as the `StoreExcl`, and that other write was performed after the old translation was properly invalidated and that invalidation was properly synchronized, then the `StoreExcl` will not pass its monitor check.

Note

Arm expects that, in many implementations, either:

— The TLB invalidation will clear either the local or global monitor.

— The PA will be checked between the `LoadExcl` and `StoreExcl`.

B1.11.5.1 CONSTRAINED UNPREDICTABLE behavior when Load-Exclusive/Store-Exclusive access a different number of registers

As stated in this section, an implementation can require that the instructions of a Load-Exclusive/Store-Exclusive pair access the same number of registers. In such an implementation, this means behavior is CONSTRAINED UNPREDICTABLE if, in a single thread of execution, either:

- An `LDXP` instruction of two 32-bit quantities is followed by an `STXR` instruction of one 64-bit quantity at the same address.
- An `LDXR` instruction of one 64-bit quantity is followed by an `STXP` instruction of two 32-bit quantities at the same address.

In these cases, the CONSTRAINED UNPREDICTABLE behavior must be one of:

- The `STXP` or `STXR` instruction generates an external Data Abort.
- The `STXP` or `STXR` instruction generates an IMPLEMENTATION DEFINED MMU fault reported using the Data Abort Fault status code of ESR_ELx.DFSC = `0b110101`.
- The `STXP` or `STXR` instruction always fails, returning a status of 1.
- The `STXP` or `STXR` instruction always passes, returning a status of 0.
- This `STXP` or `STXR` instruction has the same pass or fail behavior that it would have had if the instruction had used the same size and number of registers as the preceding `LDXR` or `LDXP` instruction.

B1.11.6 Use of WFE and SEV instructions by spin-locks

Armv8 provides Wait For Event, Send Event, and Send Event Local instructions, `WFE`, `SEV`, and `SEVL`, that can assist with reducing power consumption and bus contention caused by PEs repeatedly attempting to obtain a spin-lock. These instructions can be used at the application level, but a complete understanding of what they do depends on a system level understanding of exceptions. They are described in Wait for Event. However, in Armv8, when the global monitor for a PE changes from Exclusive Access state to Open Access state, an event is generated.

Note

This is equivalent to issuing an `SEVL` instruction on the PE for which the monitor state has changed. It removes the need for spinlock code to include an `SEV` instruction after clearing a spinlock.

Chapter C1
The A64 Instruction Set

This chapter describes the A64 instruction set. It contains the following sections:

- About the A64 instruction set.
- Structure of the A64 assembler language.
- Address generation.
- Instruction aliases.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C1.1 About the A64 instruction set

The A64 instruction set is the instruction set supported in the AArch64 Execution state. All A64 instructions have a width of 32 bits.

The following chapters contain alphabetical lists of A64 instructions:

- A64 Base Instruction Descriptions lists all of:
  - Branch instructions, exception generating instructions, system instructions.
  - Load, store, and data-processing instructions associated with the general-purpose registers.
- A64 Advanced SIMD and Floating-point Instruction Descriptions lists the load, store, and data-processing instructions associated with Advanced SIMD and floating-point support.

When an instruction supports more than one syntax, each syntax is an *instruction variant*. Instruction variants can occur because of differences in:

- The size or format of the operands.
- The register file used for the operands.
- The addressing mode used for load/load/store memory operands.

Instruction variants might also arise as the result of other factors.

Instruction variants are described in the instruction description for the individual instructions.

A64 instruction set encoding describes the A64 encoding structure. A64 instructions have a regular bit encoding structure:

- 5-bit register operand fields at fixed positions within the instruction. For general-purpose register operands, the values 0-30 select one of 31 registers. The value 31 is used as a special case that can:
  - Indicate use of the current stack pointer, when identifying a load/store base register or in a limited set of data-processing instructions. See The stack pointer registers.
  - Indicate the value zero when used as a source register operand.
  - Indicate discarding the result when used as a destination register operand.
- For Advanced SIMD and floating-point register access, a 5-bit register operand field selects one of 32 registers of the appropriate type.
- Certain Advanced SIMD instructions have a register operand field smaller than 5 bits when specifying an indexed vector element or multi-vector operand, which restricts the number of vector registers that can be accessed by those operands.
- Immediate bits that provide constant data-processing values or address offsets are placed in contiguous bitfields. Some computed values in instruction variants use one or more immediate bitfields together with the secondary encoding bitfields.

All encodings that are not fully defined are described as unallocated. An attempt to execute an unallocated instruction is UNDEFINED, unless the behavior is otherwise defined in this Manual.

C1.2 Structure of the A64 assembler language

The following sections describe the A64 assembler syntax:

- General requirements.
- Common syntax terms.
- Instruction Mnemonics.
- Condition code.
- Register names.

C1.2.1 General requirements

The letter `W` denotes a general-purpose register holding a 32-bit word, and `X` denotes a general-purpose register holding a 64-bit doubleword.

An A64 assembler recognizes both uppercase and lowercase variants of the instruction mnemonics and register names, but not mixed case variants. An A64 disassembler can output either uppercase or lowercase mnemonics and register names. Program and data labels are case-sensitive.

The A64 assembly language does not require the # character to introduce constant immediate operands, but an assembler must allow immediate values introduced with or without the # character.

In Example C1-1, the sequence // is used as a comment leader and A64 assemblers are encouraged to accept this syntax.

C1.2.2 Common syntax terms

The following syntax terms are used frequently throughout the A64 instruction set description.

`UPPER` Text in upper-case letters is fixed. Text in lower-case letters is variable. This means that register name `Xn` indicates that the `X` is required, followed by a variable register number, for example `X29`.

`< >` Any text enclosed by angle braces, < >, is a value that the user supplies. Subsequent text might supply additional information.

`{ }` Any item enclosed by curly brackets, { }, is optional. A description of the item and how its presence or absence affects the instruction is normally supplied by subsequent text. In some cases curly braces are actual symbols in the syntax, for example when they surround a register list. These cases are called out in the surrounding text.

`[ ]` Any items enclosed by square brackets, [ ], constitute a list of alternative characters. A single one of the characters can be used in that position and the subsequent text describes the meaning of the alternatives. In some case the square brackets are part of the syntax itself, such as addressing modes or vector elements. These cases are called out in the surrounding text.

`a|b` Alternative words are separated by a vertical bar, |, and can be surrounded by parentheses to delimit them. For example, `U(ADD|SUB)W` represents `UADDW` or `USUBW`.

`±` This indicates an optional + or - sign. If neither is used then + is assumed.

`uimmn` An *n*-bit unsigned, positive, immediate value.

`simmn` An *n*-bit two's complement, signed immediate value, where *n* includes the sign bit.

`SP` See Register names.

`Wn` See Register names.

`WSP` See Register names.

`WZR` See Register names.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

`Xn`	See Register names.
`XZR`	See Register names

C1.2.3 Instruction Mnemonics

The A64 assembly language overloads instruction mnemonics and distinguishes between the different forms of an instruction based on the operand types. For example, the following `ADD` instructions all have different opcodes. However, the programmer must remember only one mnemonic, as the assembler automatically chooses the correct opcode based on the operands. The disassembler follows the same procedure in reverse.

Example C1-1 ADD instructions with different opcodes

```
ADD W0, W1, W2          // add 32-bit register
ADD X0, X1, X2          // add 64-bit register
ADD X0, X1, W2, SXTW    // add 64-bit extended register
ADD X0, X1, #42         // add 64-bit immediate
```

C1.2.4 Condition code

The A64 ISA has some instructions that set Condition flags or test Condition codes or both. For information about instructions that set the Condition flags or use the condition mnemonics, see Condition flags and related instructions.

Table C1-1 shows the available Condition codes.

Table C1-1 Condition codes

cond	Mnemonic	Meaning (integer)	Meaning (floating-point)[a]	Condition flags
0000	EQ	Equal	Equal	Z == 1
0001	NE	Not equal	Not equal or unordered	Z == 0
0010	CS or HS	Carry set	Greater than, equal, or unordered	C == 1
0011	CC or LO	Carry clear	Less than	C == 0
0100	MI	Minus, negative	Less than	N == 1
0101	PL	Plus, positive or zero	Greater than, equal, or unordered	N == 0
0110	VS	Overflow	Unordered	V == 1
0111	VC	No overflow	Ordered	V == 0
1000	HI	Unsigned higher	Greater than, or unordered	C ==1 && Z == 0
1001	LS	Unsigned lower or same	Less than or equal	!(C ==1 && Z ==0)
1010	GE	Signed greater than or equal	Greater than or equal	N == V
1011	LT	Signed less than	Less than, or unordered	N != V
1100	GT	Signed greater than	Greater than	Z == 0 && N == V
1101	LE	Signed less than or equal	Less than, equal, or unordered	!(Z == 0 && N == V)
1110	AL	Always	Always	Any
1111	NV[b]	Always	Always	Any

a. Unordered means at least one NaN operand.

b. The Condition code `NV` exists only to provide a valid disassembly of the `0b1111` encoding, otherwise its behavior is identical to `AL`.

C1.2.5 Register names

See:

- General-purpose register file and zero register and stack pointer.
- Advanced SIMD and floating-point register file.
- Advanced SIMD and floating-point scalar register names.
- SIMD vector register names.
- SIMD vector element names.

C1.2.5.1 General-purpose register file and zero register and stack pointer

The 31 general-purpose registers in the general-purpose register file are named R0-R30 and encoded in the instruction register fields with values 0-30. In a general-purpose register field the value 31 represents either the current stack pointer or the zero register, depending on the instruction and the operand position.

When the registers are used in a specific instruction variant, they must be qualified to indicate the operand data size, 32 bits or 64 bits, and the data size of the instruction.

When the data size is 32 bits, the lower 32 bits of the register are used and the upper 32 bits are ignored on a read and cleared to zero on a write.

Table C1-2 shows the qualified names for registers, where *n* is a register number 0-30.

Table C1-2 Naming of general-purpose registers, the zero register, and the stack pointer

Name	Size	Encoding	Description
Wn	32 bits	0-30	General-purpose register 0-30
Xn	64 bits	0-30	General-purpose register 0-30
WZR	32 bits	31	Zero register
XZR	64 bits	31	Zero register
WSP	32 bits	31	Current stack pointer
SP	64 bits	31	Current stack pointer

This list gives more information about the instruction arguments shown in Table C1-2:

- The names Xn and Wn both refer to the same general-purpose register, Rn.
- There is no register named W31 or X31.
- The name SP represents the stack pointer for 64-bit operands where an encoding of the value 31 in the corresponding register field is interpreted as a read or write of the current stack pointer. When instructions do not interpret this operand encoding as the stack pointer, use of the name SP is an error.
- The name WSP represents the current stack pointer in a 32-bit context.
- The name XZR represents the zero register for 64-bit operands where an encoding of the value 31 in the corresponding register field is interpreted as returning zero when read or discarding the result when written. When instructions do not interpret this operand encoding as the zero register, use of the name XZR is an error.
- The name WZR represents the zero register in a 32-bit context.
- The architecture does not define a specific name for general-purpose register R30 to reflect its role as the link register on procedure calls. However, an A64 assembler must always use W30 and X30 for this purpose, and additional software names might be defined as part of the Procedure Call Standard, see *Procedure Call Standard for the Arm 64-bit Architecture*.

Non-Confidential

C1.2.5.2 Advanced SIMD and floating-point register file

The 32 registers in the Advanced SIMD and floating-point register file, V0-V31, hold floating-point operands for the scalar floating-point instructions, and both scalar and vector operands for the Advanced SIMD instructions. When they are used in a specific instruction form, the names must be further qualified to indicate the data shape, that is the data element size and the number of elements or lanes within the register. A similar requirement is placed on the general-purpose registers. See General-purpose register file and zero register and stack pointer.

Note

The data type is described by the instruction mnemonics that operate on the data. The data type is not described by the register name. The data type is the interpretation of bits within each register or vector element, whether these are integers, floating-point values, polynomials, or cryptographic hashes.

C1.2.5.3 Advanced SIMD and floating-point scalar register names

Advanced SIMD and floating-point instructions that operate on scalar data only access the lower bits of an Advanced SIMD and floating-point register. The unused high bits are ignored on a read and cleared to 0 on a write.

Table C1-3 shows the qualified names for accessing scalar Advanced SIMD and floating-point registers. The letter *n* denotes a register number between 0 and 31.

Table C1-3 Advanced SIMD and floating-point scalar register names

Size	Name
8 bits	`Bn`
16 bits	`Hn`
32 bits	`Sn`
64 bits	`Dn`
128 bits	`Qn`

C1.2.5.4 SIMD vector register names

If a register holds multiple data elements on which arithmetic is performed in a parallel, SIMD manner, then a qualifier describes the vector shape. The vector shape is the element size and the number of elements or lanes. If the element size in bits multiplied by the number of lanes does not equal 128, then the upper 64 bits of the register are ignored on a read and cleared to zero on a write.

Table C1-4 shows the SIMD vector register names. The letter *n* denotes a register number between 0 and 31.

Table C1-4 SIMD vector register names

Shape	Name
8 bits × 8 lanes	`Vn.8B`
8 bits × 16 lanes	`Vn.16B`
16 bits × 4 lanes	`Vn.4H`
16 bits × 8 lanes	`Vn.8H`
32 bits × 2 lanes	`Vn.2S`
32 bits × 4 lanes	`Vn.4S`

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Shape	Name
64 bits × 1 lane	`Vn.1D`
64 bits × 2 lanes	`Vn.2D`

C1.2.5.5 SIMD vector element names

Appending a constant, zero-based element index to the register name inside square brackets indicates that a single element from a SIMD and floating-point register is used as a scalar operand. The number of lanes is not represented, as it is not encoded in the instruction and can only be inferred from the index value.

Table C1-5 shows the vector register names and the element index. The letter *i* denotes the element index.

Table C1-5 Vector register names with element index

Size	Name
8 bits	`Vn.B[i]`
16 bits	`Vn.H[i]`
32 bits	`Vn.S[i]`
64 bits	`Vn.D[i]`

An assembler must accept a fully qualified SIMD register name if the number of lanes is greater than the index value. See SIMD vector register names. For example, an assembler must accept all of the following forms as the name for the 32-bit element in bits [63:32] of the SIMD and floating-point register V9:

```
V9.S[1]     //standard disassembly
V9.2S[1]    //optional number of lanes
V9.4S[1]    //optional number of lanes
```

Note

The SIMD and floating-point register element name `Vn.S[0]` is not equivalent to the scalar SIMD and floating-point register name `Sn`. Although they represent the same bits in the register, they select different instruction encoding forms, either the vector element or the scalar form.

C1.2.5.5.1 SIMD vector register list

Where an instruction operates on multiple SIMD&FP, for example vector load/store structure and table lookup operations, the registers are specified as a list enclosed by curly braces. This list consists of either a sequence of registers separated by commas, or a register range separated by a hyphen. The registers must be numbered in increasing order, modulo 32, in increments of one. The hyphenated form is preferred for disassembly if there are more than two registers in the list and the register numbers are increasing by 1. The following examples are equivalent representations of a set of four registers `V4` to `V7`, each holding four lanes of 32-bit elements:

```
{ V4.4S - V7.4S }              //standard disassembly
{ V4.4S, V5.4S, V6.4S, V7.4S } //alternative representation
```

C1.2.5.5.2 SIMD vector element list

Registers in a list can also have a vector element form. For example, the `LD4` instruction can load one element into each of four registers, and in this case the index is appended to the list as follows:

```
{ V4.S - V7.S }[3]                //standard disassembly
{ V4.4S, V5.4S, V6.4S, V7.4S }[3] //alternative with optional number of lanes
```

C1.3 Address generation

The A64 instruction set supports 64-bit virtual addresses (VAs). The valid VA range is determined by the following factors:

- The size of the implemented virtual address space.
- *Memory Management Unit* (MMU) configuration settings.
- *Memory Protection Unit* (MPU) configuration settings.

Limits on the VA size mean that the most significant bits of the virtual address do not hold valid address bits. These unused bits can hold:

- A tag, see Address tagging.
- If FEAT_PAuth is implemented, a Pointer authentication code (PAC), see Pointer authentication.

For more information on memory management and address translation, see The AArch64 Virtual Memory System Architectureand The AArch64 Protected Memory System Architecture.

C1.3.1 Register indexed addressing

The A64 instruction set allows a 64-bit index register to be added to the 64-bit base register, with optional scaling of the index by the access size. Additionally it allows for sign-extension or zero-extension of a 32-bit value within an index register, followed by optional scaling.

C1.3.2 PC-relative addressing

The A64 instruction set has support for position-independent code and data addressing:

- PC-relative literal loads have an offset range of ± 1MB.
- Process state flag and compare based conditional branches have a range of ± 1MB. Test bit conditional branches have a restricted range of ± 32KB.
- Unconditional branches, including branch and link, have a range of ± 128MB.

PC-relative load/store operations, and address generation with a range of ± 4GB can be performed using two instructions.

C1.3.3 Load/store addressing modes

Load/store addressing modes in the A64 instruction set require a 64-bit base address from a general-purpose register X0-X30 or the current stack pointer, `SP`, with an optional immediate or register offset. Table C1-6 shows the assembler syntax for the complete set of load/store addressing modes.

Table C1-6 A64 Load/store addressing modes

Addressing Mode	Offset		
	Immediate	Register	Extended Register
Base register only (no offset)	`[base{, #0}]`	-	-
Base plus offset	`[base{, #imm}]`	`[base, Xm{, LSL #imm}]`	`[base, Wm, (S|U)XT(X|W) {#imm}]`
Pre-indexed	`[base, #imm]!`	-	-

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Addressing Mode	Offset		
	Immediate	Register	Extended Register
Post-indexed	`[base], #imm`	`[base], Xm`[a]	-
Literal (PC-relative)	`label`	-	-

a. The post-indexed by register offset mode can be used with the SIMD load/store structure instructions described in Load/store Advanced SIMD. Otherwise the post-indexed by register offset mode is not available.

Some types of load/store instruction support only a subset of the load/store addressing modes listed in Table C1-6. Details of the supported modes are as follows:

- Base plus offset addressing means that the address is the value in the 64-bit base register plus an offset.
- Pre-indexed addressing means that the address is the sum of the value in the 64-bit base register and an offset, and the address is then written back to the base register.
- Post-indexed addressing means that the address is the value in the 64-bit base register, and the sum of the address and the offset is then written back to the base register.
- Literal addressing means that the address is the value of the 64-bit program counter for this instruction plus a 19-bit signed word offset. This means that it is a 4 byte aligned address within ±1MB of the address of this instruction with no offset. Literal addressing can be used only for loads of at least 32 bits and for prefetch instructions. The PC cannot be referenced using any other addressing modes. The syntax for labels is specific to individual toolchains.
- An immediate offset can be unsigned or signed, and scaled or unscaled, depending on the type of load/store instruction. When the immediate offset is scaled it is encoded as a multiple of the transfer size, although the assembly language always uses a byte offset, and the assembler or disassembler performs the necessary conversion. The usable byte offsets therefore depend on the type of load/store instruction and the transfer size. Table C1-7 shows the offset and the type of load/store instruction.

Table C1-7 Immediate offsets and the type of load/store instruction

Offset bits	Sign	Scaling	Write-Back	Load/store type
0	-	-	-	Exclusive/acquire/release
7	Signed	Scaled	Optional	Register pair
9	Signed	Unscaled	Optional	Single register
12	Unsigned	Scaled	No	Single register

- A register offset means that the offset is the 64 bits from a general-purpose register, Xm, optionally scaled by the transfer size, in bytes, if `LSL #imm` is present and where `imm` must be equal to $\log_2$(transfer_size). The `SXTX` extend/shift option is functionally equivalent to `LSL`, but the `LSL` option is preferred in source code.
- An extended register offset means that offset is the bottom 32 bits from a general-purpose register Wm, sign-extended or zero-extended to 64 bits, and then scaled by the transfer size if so indicated by `#imm`, where imm must be equal to $\log_2$(transfer_size). An assembler must accept Wm or Xm as an extended register offset, but Wm is preferred for disassembly.
- Generating an address lower than the value in the base register requires a negative signed immediate offset or a register offset holding a negative value.
- When stack alignment checking is enabled by system software and the base register is the SP, the current stack pointer must be initially quadword aligned, that is aligned to 16 bytes. Misalignment generates a Stack Alignment fault. The offset does not have to be a multiple of 16 bytes unless the specific load/store instruction requires this. SP cannot be used as a register offset.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C1.3.3.1 Address calculation

General-purpose arithmetic instructions can calculate the result of most addressing modes and write the address to a general-purpose register or, in most cases, to the current stack pointer.

Table C1-8 shows the arithmetic instructions that can compute addressing modes.

Table C1-8 Arithmetic instructions to compute addressing modes

Addressing Form	Offset		
	Immediate	Register	Extended Register
Base register (no offset)	`MOV Xd|SP, base`	-	-
Base plus offset	`ADD Xd|SP, base, #imm` or `SUB Xd|SP, base, #imm`	`ADD <Xd|SP>, base, Xm{,LSL#imm}`	`ADD <Xd|SP>, base, Wm,(S|U)XT(W|H|B|X) {#imm}`
Pre-indexed	-	-	-
Post-indexed	-	-	-
Literal (PC-relative)	`ADR Xd, label`	-	-

Note

- For the 64-bit base plus register offset form, the `UXTX` mnemonic is an alias for the `LSL` shift option, but `LSL` is preferred for disassembly. Similarly the `SXTX` extend/shift option is functionally equivalent to the `LSL` option, but the `LSL` option is preferred in source code.
- To calculate a base plus immediate offset the `ADD` instructions defined in Arithmetic (immediate) accept an unsigned 12-bit immediate offset, with an optional left shift by 12. This means that a single `ADD` instruction cannot support the full range of byte offsets available to a single register load/store with a scaled 12-bit immediate offset. For example, a quadword `LDR` effectively has a 16-bit byte offset. To calculate an address with a byte offset that requires more than 12 bits it is necessary to use two `ADD` instructions. The following example shows this:

```
ADD Xd, base, #(imm & 0xFFF)
ADD Xd, Xd, #(imm>>12), LSL #12
```

- To calculate a base plus extended register offset, the `ADD` instructions defined in Arithmetic (extended register) provide a superset of the addressing mode that also supports sign-extension or zero-extension of a byte or halfword value with any shift amount between 0 and 4, for example:

```
ADD  Xd, base, Wm, SXTW #3   // Xd = base + (SignExtend(Wm) LSL 3)
ADD  Xd, base, Wm, UXTH #4   // Xd = base + (ZeroExtend(Wm<15:0>) LSL 4)
```

- If the same extended register offset is used by more than one load/store instruction, then, depending on the implementation, it might be more efficient to calculate the extended and scaled intermediate result just once, and then reuse it as a simple register offset. The extend and scale calculation can be performed using the `SBFIZ` and `UBFIZ` bitfield instructions defined in Bitfield move, for example:

```
SBFIZ Xd, Xm, #3, #32   //Xd = "Wm, SXTW #3"
UBFIZ Xd, Xm, #4, #16   //Xd = "Wm, UXTH #4"
```

C1.4 Instruction aliases

Some instructions have an associated *architecture alias* that is used for disassembly of the encoding when the associated conditions are met. Architecture alias instructions are included in the alphabetic lists of instruction types and clearly presented as an alias form in descriptions for the individual instructions.

Chapter C2
About the A64 Instruction Descriptions

This chapter describes the *instruction descriptions* contained in A64 Base Instruction Descriptions, and A64 Advanced SIMD and Floating-point Instruction Descriptions.

It contains the following sections:

- Understanding the A64 instruction descriptions.
- General information about the A64 instruction descriptions.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C2.1 Understanding the A64 instruction descriptions

Each instruction description in A64 Base Instruction Descriptions and A64 Advanced SIMD and Floating-point Instruction Descriptions has the following content:

1. A title.
2. An introduction to the instruction.
3. The instruction encoding or encodings.
4. Any alias conditions.
5. A list of the assembler symbols for the instruction.
6. Pseudocode describing how the instruction operates.
7. Notes, if applicable.

The following sections describe each of these.

C2.1.1 The title

The title of an instruction description includes the base mnemonic for the instruction.

If different forms of an instruction use the same base mnemonic, each form has its own description. In this case, the title is the mnemonic followed by a short description of the instruction form in parentheses. This is most often used when an operand is an immediate value in one instruction form, but is a register in another form.

For example, in A64 Base Instruction Descriptions there are the following titles for different forms of the `ADD` instruction:

- ADD (extended register).
- ADD (immediate).
- ADD (shifted register).

C2.1.2 An introduction to the instruction

This briefly describes the function of the instruction. The introduction is not a complete description of the instruction, and it is not definitive. If there is any conflict between it and the more detailed information that follows it, the more detailed information takes priority.

C2.1.3 The instruction encoding or encodings

This shows the instruction encoding diagram, or if the instruction has more than one encoding, shows all of the encoding diagrams. Each diagram has a subheading.

For example, for load and store instructions, the subheadings might be:

- Post-index.
- Pre-index.
- Unsigned offset.

Each diagram numbers the bits from 31 to 0. The diagram for an instruction at address *A* shows, from left to right, the bytes at addresses *A*+3, *A*+2, *A*+1, and *A*.

There might be variants of an encoding, if the *assembler syntax prototype* differs depending on the value in one or more of the encoding fields. In this case, each variant has a subheading that describes the variant and shows the distinguishing field value or values in parentheses. For example, in A64 Base Instruction Descriptions there are the following subheadings for variants of the `ADC` instruction encoding:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- 32-bit variant (sf = 0).
- 64-bit variant (sf = 1).

The assembler syntax prototype for an encoding or variant of an encoding shows how to form a complete assembler source code instruction that assembles to the encoding. Unless otherwise stated, the prototype is also the preferred syntax for a disassembler to disassemble the encoding to. Disassemblers are permitted to omit optional symbols that represent the default value of a field or set of fields, to produce more readable disassembled code, provided that the output re-assembles to the same encoding.

Each encoding diagram, and its associated assembler syntax prototypes, is followed by encoding-specific pseudocode that translates the fields of that encoding into inputs for the encoding-independent pseudocode that describes the operation of the instruction. See Pseudocode describing how the instruction operates.

C2.1.4 Any alias conditions, if applicable

This is an optional part of an instruction description. If included, it describes the set of conditions for which an alternative mnemonic and its associated assembler syntax prototypes are preferred for disassembly by a disassembler. It includes a link to the alias instruction description that defines the alternative syntax. The alias syntax and the original syntax can be used interchangeably in the assembler source code.

Arm recommends that if a disassembler outputs the alias syntax, it consistently outputs the alias syntax.

C2.1.5 A list of the assembler symbols for the instruction

The *Assembler symbols* subsection of the instruction description contains a list of the symbols that the assembler syntax prototype or prototypes use, if any.

In assembler syntax prototypes, the following conventions are used:

`< >` Angle brackets. Any symbol enclosed by these is a name or a value that the user supplies. For each symbol, there is a description of what the symbol represents. The description usually also specifies which encoding field or fields encodes the symbol.

`{ }` Brace brackets. Any symbols enclosed by these are optional. For each optional symbol, there is a description of what the symbol represents and how its presence or absence is encoded.

In some assembler syntax prototypes, some brace brackets are mandatory, for example if they surround a register list. When the use of brace brackets is mandatory, they are separated from other syntax items by one or more spaces.

`#` This usually precedes a numeric constant. All uses of # are optional in A64 assembler source code. Arm recommends that disassemblers output the # where the assembler syntax prototype includes it.

`+/-` This indicates an optional + or – sign. If neither is coded, + is assumed.

Single spaces are used for clarity, to separate syntax items. Where a space is mandatory, the assembler syntax prototype shows two or more consecutive spaces.

Any characters not shown in this conventions list must be coded exactly as shown in the assembler syntax prototype. Apart from brace brackets, the characters shown are used as part of a meta-language to define the architectural assembler syntax for an instruction encoding or alias, but have no architecturally defined significance in the input to an assembler or in the output from a disassembler.

The following symbol conventions are used:

`<Xn>` The 64-bit name of a general-purpose register (X0-X30) or the zero register (XZR).

`<Wn>` The 32-bit name of a general-purpose register (W0-W30) or the zero register (WZR).

`<Xn|SP>` The 64-bit name of a general-purpose register (X0-X30) or the current stack pointer (SP).

`<Wn|WSP>` The 32-bit name of a general-purpose register (W0-W30) or the current stack pointer (WSP).

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

`<Bn>, <Hn>, <Sn>, <Dn>, <Qn>`

The 8, 16, 32, 64, or 128-bit name of a SIMD and floating-point register in a scalar context, as described in Register names.

`<Vn>` The name of a SIMD and floating-point register in a vector context, as described in Register names.

If the description of a symbol specifies that the symbol is a register, the description might also specify that the range of permitted registers is extended or restricted. It also specifies any differences from the default rules for such fields.

Note

Register names provides the A64 register names.

C2.1.6 Pseudocode describing how the instruction operates

The *Operation* subsection of the instruction description contains this pseudocode.

It is encoding-independent pseudocode that provides a precise description of what the instruction does.

Note

For a description of Arm pseudocode, see Arm Pseudocode Definition. This appendix also describes the execution model for an instruction.

C2.1.7 Notes, if applicable

If applicable, other notes about the instruction appear under additional subheadings.

C2.2 General information about the A64 instruction descriptions

This section provides general information about the A64 instruction descriptions. Some of this information also applies to System register descriptions, for example the terms defined in Fixed values in AArch64 instruction and System register descriptions apply to the AArch64 descriptions throughout this manual. The following subsections provide this information:

- Execution of instructions in Debug state.
- Fixed values in AArch64 instruction and System register descriptions.
- Modified immediate constants in A64 floating-point instructions.

C2.2.1 Execution of instructions in Debug state

In general, except for the instructions described in Debug state, the A64 instruction descriptions do not indicate any differences in the behavior of the instruction if it is executed in Debug state. For this information, see Executing instructions in Debug state.

Note

For many instructions, execution is unchanged in Debug state. Executing instructions in Debug state identifies these instructions,

C2.2.2 Fixed values in AArch64 instruction and System register descriptions

This section summarizes the terms used to describe fixed values in AArch64 register and instruction descriptions. The Glossary gives full descriptions of these terms, and each entry in this section includes a link to the corresponding Glossary entry.

Note

In register descriptions, the meaning of some bits depends on the PE state. This affects the definitions of RES0 and RES1, as shown in the Glossary.

The following terms are used to describe bits or fields with fixed values:

RAZ Read-As-Zero. See Read-As-Zero (RAZ).

In diagrams, a RAZ bit can be shown as 0.

(0), RES0 Reserved, Should-Be-Zero (SBZ) or RES0.

In instruction encoding diagrams, and sometimes in other descriptions, `(0)` indicates an SBZ bit. If the bit is set to 1, behavior is CONSTRAINED UNPREDICTABLE, and must be one of the following:

- The instruction is UNDEFINED.
- The instruction is treated as a NOP.
- The instruction executes as if the value of the bit was 0.
- Any destination registers of the instruction become UNKNOWN.

This notation can be expanded for fields, so a three-bit field can be shown as either `(0)(0)(0)` or as `(000)`.

In register diagrams, but not in the A64 encoding and instruction descriptions, bits or fields can be shown as RES0. See the Glossary definition of RES0 for more information.

Note

Some of the System instruction descriptions in this chapter are based on the *field description* of the input value for the instruction. These are register descriptions and therefore can include RES0 fields,

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The (0) and RES0 descriptions can be applied to bits or bit fields that are read-only, or are write-only. The Glossary definitions cover these cases.

RAO Read-As-One. See Read-As-One (RAO).

In diagrams, a RAO bit can be shown as 1.

(1), RES1 Reserved, Should-Be-One (SBO) or RES1.

In instruction encoding diagrams, and sometimes in other descriptions, (1) indicates an SBO bit. If the bit is set to 0, behavior is CONSTRAINED UNPREDICTABLE, and must be one of the following:

- The instruction is UNDEFINED.
- The instruction is treated as a NOP.
- The instruction executes as if the value of the bit was 1.
- Any destination registers of the instruction become UNKNOWN.

This notation can be expanded for fields, so a three-bit field can be shown as either (1)(1)(1) or as (111).

In register diagrams, but not in the A64 encoding and instruction descriptions, bits or fields can be shown as RES1. See the Glossary definition of *RES1* for more information.

Note

Some of the System instruction descriptions in this chapter are based on the *field description* of the input value for the instruction. These are register descriptions and therefore can include RES1 fields,

The (1) and RES1 descriptions can be applied to bits or bit fields that are read-only, or are write-only. The Glossary definitions cover these cases.

C2.2.3 Modified immediate constants in A64 floating-point instructions

Table C2-1 shows the immediate constants available in FMOV (scalar, immediate) and FMOV (vector, immediate) floating-point instructions.

Table C2-1 A64 Floating-point modified immediate constants

Data type	immediate	Constant[a]
F16	abcdefgh	aBbbcdef gh000000
F32	abcdefgh	aBbbbbbc defgh000 00000000 00000000
F64	abcdefgh	aBbbbbbb bbcdefgh 00000000 00000000 00000000 00000000 00000000 00000000

a. In this column, B = NOT(b). The bit pattern represents the floating-point number $(-1)^S \times 2^{exp} \times$ mantissa, where S = UInt(a), exp = UInt(NOT(b):c:d)-3 and mantissa = (16+UInt(e:f:g:h))/16.

The immediate value shown in the table is either:

- The value of the imm8 field for an FMOV (scalar, immediate) instruction, see FMOV (scalar, immediate).
- The value obtained by concatenating the a:b:c:d:e:f:g:h fields for an FMOV (vector, immediate) instruction, see FMOV (vector, immediate).

Table C2-2 shows the floating-point constant values encoded in the b:c:d:e:f:g:h fields of the FMOV (vector, immediate) instruction.

Chapter C3
A64 Instruction Set Overview

This chapter provides an overview of the A64 instruction set. It contains the following sections:

- Branches, Exception generating, and System instructions.
- Loads and stores.
- Data processing - immediate.
- Data processing - register.
- Data processing - SIMD and floating-point.

For a structured breakdown of instruction groups by encoding, see A64 Instruction Set Encoding.

C3.1 Branches, Exception generating, and System instructions

This section describes the branch, exception generating, and System instructions. It contains the following subsections:

- Conditional branch.
- Unconditional branch (immediate).
- Unconditional branch (register).
- Direct and indirect branch.
- Exception generation and return.
- System register instructions.
- System instructions.
- Hint instructions.
- Barriers and CLREX instructions.
- Pointer authentication instructions.

Note

Software must:

- Use only `BLR` or `BL` to perform a nested subroutine call when that subroutine is expected to return to the immediately following instruction, that is, the instruction with the address of the `BLR` or `BL` instruction incremented by four.
- Use only `RET` to perform a subroutine return, when that subroutine is expected to have been entered by a `BL` or `BLR` instruction.
- Use only `B`, `BR`, or the instructions listed in Table C3-1 to perform a control transfer that is not a subroutine call or subroutine return described in this *Note*.

C3.1.1 Conditional branch

Conditional branches change the flow of execution depending on the following:

- The current state of the Condition flags.
- The result of comparison between 0 and a value or a bit in a general purpose register.
- The result of comparison between values in two general purpose registers.
- The result of comparison between an immediate value and a value in a general purpose register.

See Table C1-1 for a list of the Condition codes that can be used for `cond`.

Table C3-1 shows the Conditional branch instructions.

Table C3-1 Conditional branch instructions

Mnemonic	Instruction	Branch offset range from the PC	See
`B.cond`	Branch conditionally	±1MB	B.cond
`CBNZ`	Compare and branch if nonzero	±1MB	CBNZ
`CBZ`	Compare and branch if zero	±1MB	CBZ
`TBNZ`	Test bit and branch if nonzero	±32KB	TBNZ
`TBZ`	Test bit and branch if zero	±32KB	TBZ

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C3.1.2 Unconditional branch (immediate)

Unconditional branch (immediate) instructions change the flow of execution unconditionally by adding an immediate offset with a range of ±128MB to the value of the program counter that fetched the instruction. The `BL` instruction also writes the address of the sequentially following instruction to general-purpose register, X30.

Table C3-2 shows the Unconditional branch instructions with an immediate branch offset.

Table C3-2 Unconditional branch instructions (immediate)

Mnemonic	Instruction	Immediate branch offset range from the PC	See
`B`	Branch unconditionally	±128MB	B
`BL`	Branch with link	±128MB	BL

C3.1.3 Unconditional branch (register)

Unconditional branch (register) instructions change the flow of execution unconditionally by setting the program counter to the value in a general-purpose register. The `BLR` instruction also writes the address of the sequentially following instruction to general-purpose register X30. The `RET` instruction behaves identically to `BR`, but provides an additional hint to the PE that this is a return from a subroutine. Table C3-3 shows Unconditional branch instructions that jump directly to an address held in a general-purpose register.

Table C3-3 Unconditional branch instructions (register)

Mnemonic	Instruction	See
`BLR`	Branch with link to register	BLR
`BR`	Branch to register	BR
`RET`	Return from subroutine	RET

C3.1.4 Direct and indirect branch

Table C3-4 and Table C3-5 shows the Direct branch and Indirect branch instructions.

Table C3-4 Direct branch instructions

Mnemonic	Instruction	See
`B`	Unconditional branch	B
`B.cond`	Conditional branch	B.cond
`BC.cond`	Branch consistent conditionally	BC.cond
`BL`	Branch with link	BL

C3.1.5 Exception generation and return

This section describes the following exceptions:

- Exception generating.
- Exception return.
- Debug state.

C3.1.5.1 Exception generating

Table C3-8 shows the Exception generating instructions.

Table C3-8 Exception generating instructions

Table C3-14 Barriers and CLREX instructions

Mnemonic	Instruction	See
CLREX	Clear Exclusives monitor	CLREX
DFB	Data full barrier	DFB
DMB	Data memory barrier	DMB
DSB	Data synchronization barrier	DSB
ISB	Instruction synchronization barrier	ISB

For more information about DSB, DMB, and ISB, see Memory barriers.

Table C3-15 shows the speculation and synchronization barriers. If these instructions are not implemented, then these instructions execute as a NOP.

Table C3-15 Speculation and synchronization barriers

Mnemonic	Instruction	See
CSDB	Consumption of Speculative Data Barrier	CSDB
ESB	Error synchronization barrier	ESB
PSSBB	Physical Speculative Store Bypass Barrier	PSSBB
SB	Speculation Barrier	SB
SSBB	Speculative Store Bypass Barrier	SSBB
TSB	Trace Synchronization Barrier	TSB

For more information about:

- CSDB, PSSBB, SB, SSBB, TSB, see Memory barriers.
- ESB, see Error synchronization event.

C3.1.10 Pointer authentication instructions

FEAT_PAuth adds support for pointer authentication, see Pointer authentication. This functionality includes the A64 instructions described in this section. These instructions fall into two groups, see:

- Basic pointer authentication instructions.
- Combined instructions that include pointer authentication.

C3.1.10.1 Basic pointer authentication instructions

Each of these instructions only performs an operation that supports pointer authentication.

Table C3-17 shows the instructions that add a *Pointer Authentication Code* (PAC) to the address in a register:

Table C3-16 shows the instructions that authenticate a PAC in a register:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.

C3.2 Loads and stores

This section describes the load/store instructions. It contains the following subsections:

- Load/store register.
- Load/store register (unscaled offset).
- Load/store pair.
- Load/store non-temporal pair.
- Load/store unprivileged.
- Load-Exclusive/Store-Exclusive.
- Load-Acquire/Store-Release.
- Load/store scalar SIMD and floating-point.
- Load/store Advanced SIMD.
- Prefetch memory.
- Atomic instructions.

The requirements for the alignment of data memory accesses are strict. For more information, see Alignment of data accesses.

The additional control bits SCTLR_ELx.SA and SCTLR_EL1.SA0 control whether the stack pointer must be quadword aligned when used as a base register. See SP alignment checking. Using a misaligned stack pointer generates an SP alignment fault exception.

Note

In some cases, load/store instructions can lead to CONSTRAINED UNPREDICTABLE behavior. See AArch64 CONSTRAINED UNPREDICTABLE behaviors.

C3.2.1 Load/store register

The load/store register instructions support the following addressing modes:

- Base plus a scaled 12-bit unsigned immediate offset or base plus an unscaled 9-bit signed immediate offset.
- Base plus a 64-bit register offset, optionally scaled.
- Base plus a 32-bit extended register offset, optionally scaled.
- Pre-indexed by an unscaled 9-bit signed immediate offset.
- Post-indexed by an unscaled 9-bit signed immediate offset.
- PC-relative literal for loads of 32 bits or more.

See also Load/store addressing modes.

If a Load instruction specifies writeback and the register being loaded is also the base register, then behavior is CONSTRAINED UNPREDICTABLE and one of the following behaviors must occur:

- The instruction is treated as UNDEFINED.
- The instruction is treated as a NOP.
- The instruction performs the load using the specified addressing mode and the base register becomes UNKNOWN. In addition, if an exception occurs during the execution of such an instruction, the base address might be corrupted so that the instruction cannot be repeated.

If a Store instruction performs a writeback and the register that is stored is also the base register, then behavior is CONSTRAINED UNPREDICTABLE and one of the following behaviors must occur:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- The instruction is treated as UNDEFINED.
- The instruction is treated as a NOP.
- The instruction performs the store to the designated register using the specified addressing mode, but the value stored is UNKNOWN.

Table C3-21 shows the load/store register instructions.

Table C3-21 Load/store register instructions

Mnemonic	Instruction	See
LDR	Load register (register offset)	LDR (register)
	Load register (immediate offset)	LDR (immediate)

STRB	Store byte (register offset)	STRB (register)
	Store byte (immediate offset)	STRB (immediate)
STRH	Store halfword (register offset)	STRH (register)
	Store halfword (immediate offset)	STRH (immediate)

C3.2.2 Load/store register (unscaled offset)

The load/store register instructions with an unscaled offset support only one addressing mode:

- Base plus an unscaled 9-bit signed immediate offset.

See Load/store addressing modes.

The load/store register (unscaled offset) instructions are required to disambiguate this instruction class from the load/store register instruction forms that support an addressing mode of base plus a scaled, unsigned 12-bit immediate offset, because that can represent some offset values in the same range.

The ambiguous immediate offsets are byte offsets that are both:

- In the range 0-255, inclusive.
- Naturally aligned to the access size.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Other byte offsets in the range -256 to 255 inclusive are unambiguous. An assembler program translating a load/store instruction, for example `LDR`, is required to encode an unambiguous offset using the unscaled 9-bit offset form, and to encode an ambiguous offset using the scaled 12-bit offset form. A programmer might force the generation of the unscaled 9-bit form by using one of the mnemonics in Table C3-22. Arm recommends that a disassembler outputs all unscaled 9-bit offset forms using one of these mnemonics, but unambiguous offsets can be output using a load/store single register mnemonic, for example, `LDR`.

Table C3-22 shows the load/store register instructions with an unscaled offset.

Table C3-22 Load/store register (unscaled offset) instructions

Mnemonic	Instruction	See
`LDUR`	Load register (unscaled offset)	LDUR
`LDURB`	Load byte (unscaled offset)	LDURB
`LDURSB`	Load signed byte (unscaled offset)	LDURSB
`LDURH`	Load halfword (unscaled offset)	LDURH
`LDURSH`	Load signed halfword (unscaled offset)	LDURSH
`LDURSW`	Load signed word (unscaled offset)	LDURSW
`STUR`	Store register (unscaled offset)	STUR
`STURB`	Store byte (unscaled offset)	STURB
`STURH`	Store halfword (unscaled offset)	STURH

C3.2.3 Load/store pair

The load/store pair instructions support the following addressing modes:

- Base plus a scaled 7-bit signed immediate offset.
- Pre-indexed by a scaled 7-bit signed immediate offset.
- Post-indexed by a scaled 7-bit signed immediate offset.

See also Load/store addressing modes.

If a Load Pair instruction specifies the same register for the two registers that are being loaded, then behavior is CONSTRAINED UNPREDICTABLE and one of the following behaviors must occur:

- The instruction is treated as UNDEFINED.
- The instruction is treated as a `NOP`.
- The instruction performs all the loads using the specified addressing mode and the register that is loaded takes an UNKNOWN value.

If a Load Pair instruction specifies writeback and one of the registers being loaded is also the base register, then behavior is CONSTRAINED UNPREDICTABLE and one of the following behaviors must occur:

- The instruction is treated as UNDEFINED.
- The instruction is treated as a `NOP`.
- The instruction performs all of the loads using the specified addressing mode, and the base register becomes UNKNOWN. In addition, if an exception occurs during the instruction, the base address might be corrupted so that the instruction cannot be repeated.

If a Store Pair instruction performs a writeback and one of the registers being stored is also the base register, then behavior is CONSTRAINED UNPREDICTABLE and one of the following behaviors must occur:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- The instruction is treated as UNDEFINED.
- The instruction is treated as a NOP.
- The instruction performs all the stores of the registers indicated by the specified addressing mode, but the value stored for the base register is UNKNOWN.

Table C3-23 shows the load/store pair instructions.

Table C3-23 Load/store pair instructions

Mnemonic	Instruction	See
LDP	Load Pair	LDP
LDPSW	Load Pair signed words	LDPSW
STP	Store Pair	STP

C3.2.4 Load/store non-temporal pair

The load/store non-temporal pair instructions support only one addressing mode:

- Base plus a scaled 7-bit signed immediate offset.

See Load/store addressing modes.

The load/store non-temporal pair instructions provide a hint to the memory system that an access is non-temporal, and unlikely to be repeated in the near future. This means that data caching is not required. However, depending on the memory type, the instructions might permit memory reads to be prefetched and memory writes to be gathered to accelerate bulk memory transfers.

In addition, there is an exception to the usual memory ordering rules. If an address dependency exists between two memory reads, and a Load Non-temporal Pair instruction generated the second read, then in the absence of any other barrier mechanism to achieve order, the memory accesses can be observed in any order by the other observers within the shareability domain of the memory addresses being accessed.

If a Load Non-Temporal Pair instruction specifies the same register for the two registers that are being loaded, then behavior is CONSTRAINED UNPREDICTABLE and one of the following must occur:

- The instruction is treated as UNDEFINED.
- The instruction is treated as a NOP.
- The instruction performs all the loads using the specified addressing mode and the register that is loaded takes an UNKNOWN value.

Table C3-24 shows the load/store non-temporal pair instructions.

Table C3-24 Load/store non-temporal pair instructions

Mnemonic	Instruction	See
LDNP	Load Non-temporal Pair	LDNP
STNP	Store Non-temporal Pair	STNP

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C3.2.5 Load/store unprivileged

The load/store unprivileged instructions support only one addressing mode:

- Base plus an unscaled 9-bit signed immediate offset.

See Load/store addressing modes.

The access permissions that apply to accesses made at EL0 apply to the memory accesses made by a load/store unprivileged instruction that is executed either:

- At EL1 when the Effective value of PSTATE.UAO is 0.
- At EL2 when both the Effective value of HCR_EL2.{E2H, TGE} is {1, 1} and the Effective value of PSTATE.UAO is 0.

Otherwise, memory accesses made by a load/store unprivileged instruction are subject to the access permissions that apply to the Exception level at which the instruction is executed. These are the permissions that apply to the corresponding load/store register instruction, see Load/store register.

Note

This means that when the value of PSTATE.UAO is 1 the access permissions for a load/store unprivileged instruction are always the same as those for the corresponding load/store register instruction.

Table C3-25 shows the load/store unprivileged instructions.

Table C3-25 Load-Store unprivileged instructions

Mnemonic	Instruction	See
LDTR	Load unprivileged register	LDTR
LDTRB	Load unprivileged byte	LDTRB

LDTRSW	Load unprivileged signed word	LDTRSW
STTR	Store unprivileged register	STTR
STTRB	Store unprivileged byte	STTRB
STTRH	Store unprivileged halfword	STTRH

C3.2.6 Load-Exclusive/Store-Exclusive

The Load-Exclusive/Store-Exclusive instructions support only one addressing mode:

- Base register with no offset.

See Load/store addressing modes.

The Load-Exclusive instructions mark the physical address being accessed as an exclusive access. This exclusive access mark is checked by the Store-Exclusive instruction, permitting the construction of atomic read-modify-write operations on shared memory variables, semaphores, mutexes, and spinlocks. See Synchronization and semaphores.

If FEAT_LSE2 is not implemented then:.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- The Load-Exclusive/Store-Exclusive instructions other than Load-Exclusive pair and Store-Exclusive pair require natural alignment, and an unaligned address generates an Alignment fault.
- Memory accesses generated by Load-Exclusive pair or Store-Exclusive pair instructions must be aligned to the size of the pair, otherwise the access generates an Alignment fault.

  For more information on alignment requirements and behaviors, see Load-Exclusive/ Store-Exclusive and Atomic instructions.

When a Store-Exclusive pair succeeds, it causes a single-copy atomic update of the entire memory location being stored to.

Table C3-26 shows the Load-Exclusive/Store-Exclusive instructions.

Table C3-26 Load-Exclusive/Store-Exclusive instructions

STXRH	Store Exclusive halfword	STXRH
STXP	Store Exclusive pair	STXP

C3.2.7 Load-Acquire/Store-Release

The Load-Acquire, Load-AcquirePC and Store-Release instructions are added as part of the FEAT_LRCPC, FEAT_LRCPC2, and FEAT_LRCPC3 architecture features.

If FEAT_LSE2 is not implemented, then:

- The Load-Acquire, Load-AcquirePC, and Store-Release instructions other than Load-Acquire pair and Store-Release pair require natural alignment, and an unaligned address generates an Alignment fault.
- Memory accesses generated by Load-Acquire pair or Store-Release pair instructions must be aligned to the size of the accessed element in the pair, otherwise the access generates an Alignment fault.

For more information on alignment requirements and behaviors, see Non-atomic Load-Acquire/Store-Release instructions.

The Load-Acquire, Load-AcquirePC, and Store-Release instructions can remove the requirement to use the explicit DMB memory barrier instruction. For more information about the ordering of Load-Acquire, Load-AcquirePC, and Store-Release, see Load-Acquire, Load-AcquirePC, and Store-Release.

A Store-Release Exclusive instruction has the Release semantics only if the store is successful.

Armv8.1 adds more instructions with load-acquire and store-release mechanisms, see LoadLOAcquire/StoreLORelease.

Table C3-27 shows the Non-exclusive Load-Acquire/Store-Release instructions.

C3.2.8 Load/store scalar SIMD and floating-point

The load/store scalar SIMD and floating-point instructions operate on scalar values in the SIMD and floating-point register file as described in Advanced SIMD and floating-point scalar register names. The memory addressing modes

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

available, described in Load/store addressing modes, are identical to the general-purpose register load/store instructions, and like those instructions permit arbitrary address alignment unless strict alignment checking is enabled. However, unlike the load/store instructions that transfer general-purpose registers, load/store scalar SIMD and floating-point instructions make no guarantee of atomicity, even when the address is naturally aligned to the size of the data.

C3.2.8.1 Load/store scalar SIMD and floating-point register

The load/store scalar SIMD and floating-point register instructions support the following addressing modes:

- Base plus a scaled 12-bit unsigned immediate offset or base plus unscaled 9-bit signed immediate offset.
- Base plus 64-bit register offset, optionally scaled.
- Base plus 32-bit extended register offset, optionally scaled.
- Pre-indexed by an unscaled 9-bit signed immediate offset.
- Post-indexed by an unscaled 9-bit signed immediate offset.
- PC-relative literal for loads of 32 bits or more.

For more information on the addressing modes, see Load/store addressing modes.

Note

The unscaled 9-bit signed immediate offset address mode requires its own instruction form, see Load/store scalar SIMD and floating-point register (unscaled offset).

Table C3-29 shows the load/store instructions for a single SIMD and floating-point register.

Table C3-29 Load/store single SIMD and floating-point register instructions

Mnemonic	Instruction	See
LDR	Load scalar SIMD&FP register (register offset)	LDR (register, SIMD&FP)
	Load scalar SIMD&FP register (immediate offset)	LDR (immediate, SIMD&FP)
	Load scalar SIMD&FP register (PC-relative literal)	LDR (literal, SIMD&FP)
STR	Store scalar SIMD&FP register (register offset)	STR (register, SIMD&FP)
	Store scalar SIMD&FP register (immediate offset)	STR (immediate, SIMD&FP)

C3.2.8.2 Load/store scalar SIMD and floating-point register (unscaled offset)

The load /store scalar SIMD and floating-point register instructions support only one addressing mode:

- Base plus an unscaled 9-bit signed immediate offset.

See also Load/store addressing modes.

The load/store scalar SIMD and floating-point register (unscaled offset) instructions are required to disambiguate this instruction class from the load/store single SIMD and floating-point instruction forms that support an addressing mode of base plus a scaled, unsigned 12-bit immediate offset. This is similar to the load/store register (unscaled offset) instructions, that disambiguate this instruction class from the load/store register instruction, see Load/store register (unscaled offset).

Table C3-30 shows the load/store SIMD and floating-point register instructions with an unscaled offset.

Non-Confidential

Table C3-30 Load/store SIMD and floating-point register instructions

Mnemonic	Instruction	See
LDUR	Load scalar SIMD&FP register (unscaled offset)	LDUR (SIMD&FP)
STUR	Store scalar SIMD&FP register (unscaled offset)	STUR (SIMD&FP)

C3.2.8.3 Load/store SIMD and floating-point register pair

The load/store SIMD and floating-point register pair instructions support the following addressing modes:

- Base plus a scaled 7-bit signed immediate offset.
- Pre-indexed by a scaled 7-bit signed immediate offset.
- Post-indexed by a scaled 7-bit signed immediate offset.

See also Load/store addressing modes.

If a Load pair instruction specifies the same register for the two registers that are being loaded, then behavior is CONSTRAINED UNPREDICTABLE and one of the following behaviors must occur:

- The instruction is treated as UNDEFINED.
- The instruction is treated as a NOP.
- The instruction performs all of the loads using the specified addressing mode and the register being loaded takes an UNKNOWN value.

Table C3-31 shows the load/store SIMD and floating-point register pair instructions.

Table C3-31 Load/store SIMD and floating-point register pair instructions

Mnemonic	Instruction	See
LDP	Load pair of scalar SIMD&FP registers	LDP (SIMD&FP)
STP	Store pair of scalar SIMD&FP registers	STP (SIMD&FP)

C3.2.8.4 Load/store SIMD and floating-point non-temporal pair

The load/store SIMD and floating-point non-temporal pair instructions support only one addressing mode:

- Base plus a scaled 7-bit signed immediate offset.

See also Load/store addressing modes.

The load/store non-temporal pair instructions provide a hint to the memory system that an access is non-temporal or streaming, and unlikely to be repeated in the near future. This means that data caching is not required. However, depending on the memory type, the instructions might permit memory reads to be prefetched and memory writes to be gathered to accelerate bulk memory transfers.

In addition, there is an exception to the usual memory ordering rules. If an address dependency exists between two memory reads, and a load non-temporal pair instruction generated the second read, then in the absence of any other barrier mechanism to achieve order, those memory accesses can be observed in any order by the other observers within the shareability domain of the memory addresses being accessed.

If a load non-temporal pair instruction specifies the same register for the two registers that are being loaded, then behavior is CONSTRAINED UNPREDICTABLE and one of the following behaviors must occur:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- The instruction is treated as UNDEFINED.
- The instruction is treated as a NOP.
- The instruction performs all the loads using the specified addressing mode and the register that is loaded takes an UNKNOWN value.

Table C3-32 shows the load/store SIMD and floating-point Non-temporal pair instructions.

Table C3-32 Load/store SIMD and floating-point non-temporal pair instructions

Mnemonic	Instruction	See
LDNP	Load pair of scalar SIMD&FP registers	LDNP (SIMD&FP)
STNP	Store pair of scalar SIMD&FP registers	STNP (SIMD&FP)

C3.2.9 Load/store Advanced SIMD

The Advanced SIMD load/store structure instructions support the following addressing modes:

- Base register only.
- Post-indexed by a 64-bit register.
- Post-indexed by an immediate, equal to the number of bytes transferred.

Load/store vector instructions, like other load/store instructions, allow any address alignment, unless strict alignment checking is enabled. If strict alignment checking is enabled, then alignment checking to the size of the element is performed. However, unlike the load/store instructions that transfer general-purpose registers, the load/store vector instructions do not guarantee atomicity, even when the address is naturally aligned to the size of the element.

C3.2.9.1 Load/store structures

Table C3-33 shows the load/store structure instructions. A post-increment immediate offset, if present, must be 8, 16, 24, 32, 48, or 64, depending on the number of elements transferred.

Table C3-33 Load/store multiple structures instructions

C3.2.9.2 Load single structure and replicate

Table C3-34 shows the Load single structure and replicate instructions. A post-increment immediate offset, if present, must be 1, 2, 3, 4, 6, 8, 12, 16, 24, or 32, depending on the number of elements transferred.

Table C3-34 Load single structure and replicate instructions

Mnemonic	Instruction	See
LD1R	Load single 1-element structure and replicate to all lanes of one register	LD1R
LD2R	Load single 2-element structure and replicate to all lanes of two registers	LD2R
LD3R	Load single 3-element structure and replicate to all lanes of three registers	LD3R
LD4R	Load single 4-element structure and replicate to all lanes of four registers	LD4R

C3.2.10 Prefetch memory

The Prefetch memory instructions support the following addressing modes:

- Base register with no offset.
- Base plus a scaled 12-bit unsigned immediate offset or base plus an unscaled 9-bit signed immediate offset.
- Base plus a 64-bit register offset. This can be optionally scaled by 8-bits, for example LSL#3.
- Base plus a 32-bit extended register offset. This can be optionally scaled by 8-bits.
- PC-relative literal.

The Prefetch memory instructions signal to the memory system that memory accesses from a specified address or range of addresses are likely to occur in the near future. The memory system can respond by taking actions that are expected to speed up the memory access when they do occur, such as prefetching the specified address or range of addresses into one or more caches. Because these signals are only hints, it is valid for the PE to treat any or all prefetch instructions as a NOP.

Because they are hints to the memory system, the operation of a prefetch memory instruction cannot cause a synchronous exception. However, a memory operation performed as a result of one of these memory system hints might in exceptional cases trigger an asynchronous event, and thereby influence the execution of the PE. An example of an asynchronous event that might be triggered is an SError exception.

A prefetch memory instruction can only have an effect on software visible structures as defined in the translation regime of the current Exception level, such as caches and translation lookaside buffers associated with memory locations that can be accessed by reads, writes, or execution.

A PRFM, PRFUM, or RPRFM instruction is guaranteed not to access Device memory.

A PRFM or PRFUM instruction using a PLI hint cannot result in any access that could not be performed by the PE speculatively fetching an instruction. Therefore, if all associated MMUs and MPUs are disabled, a PLI hint can only access memory locations consistent with instruction fetches permitted by The effects of disabling an address translation stage.

Arm recommends that when a PRFM or a PRFUM instruction describes a particular cache level, then the memory location described at that cache level should be made available at that same cache level, even if the line had previously been at a level of the cache that is closer to the PE than the specified cache level.

Note

For a PRFM PST instruction, this might result in the demotion of a cache line from a level that was closer to the cache.

Table C3-35 shows the Prefetch memory instructions.

	Prefetch memory (immediate offset)	PRFM (immediate)
	Prefetch memory (PC-relative offset)	PRFM (literal)
PRFUM	Prefetch memory (unscaled offset)	PRFUM

C3.2.11 Atomic instructions

The atomic instructions perform atomic read and write operations on a memory location such that the architecture guarantees that no modification of that memory location by another observer can occur between the read and the write defined by that instruction.

This section describes the following operations:

- Atomic integer memory operations.
- Atomic floating-point memory operations.
- Swap operations.
- Compare and Swap operations.

The atomic instructions support only one addressing mode:

- Base register only.

See also Load/store addressing modes.

For the purpose of permission checking, and for watchpoints, all of the Atomic memory operation instructions are treated as performing both a load and a store.

The instructions are provided with ordering options, which map to the acquire and release definitions used in the architecture. The atomic instructions with release semantics have the same rules as Store-Release instructions regarding multi-copy atomicity. These operations map to the acquire and release definitions, and are counted as Load-Acquire and Store-Release operations respectively.

C3.2.11.1 Atomic integer memory operations

The address accessed by the 128-bit atomic instructions must be aligned to 128-bits, otherwise the instructions generate an Alignment fault.

For the LD<OP> instructions, where the source and destination registers are the same, if the instruction generates a synchronous Data Abort, then the source register is restored to the value it held before the instruction was executed.

The ST<OP> instructions, and LD<OP> instructions where the destination register is WZR or XZR, are not regarded as doing a read for the purpose of a DMB LD barrier.

For information on alignment requirements and behaviors, see Load-Exclusive/ Store-Exclusive and Atomic instructions.

C3.2.11.2 Swap operations

For the SWP instructions, where the source and destination registers are the same, if the instruction generates a synchronous Data Abort, then the source register is restored to the value it held before the instruction was executed.

If the destination register Rt is WZR or XZR, this is not regarded as doing a read for the purpose of a DMB LD barrier.

For information on alignment requirements and behaviors, see Load-Exclusive/ Store-Exclusive and Atomic instructions.

Table C3-37 Swap instructions

Mnemonic	Instruction	See
SWP	Swap	SWP, SWPA, SWPAL, SWPL
SWPB	Swap byte	SWPB, SWPAB, SWPALB, SWPLB
SWPH	Swap halfword	SWPH, SWPAH, SWPALH, SWPLH

C3.2.11.3 Compare and Swap operations

If FEAT_LSE2 is not implemented then:

- The CAS instructions require natural alignment.
- The CASP instructions require alignment to the total size of the memory being accessed.

If a compare and swap instruction does not perform a store, then the instruction does not have release semantics, regardless of the instruction ordering options.

For the CAS and CASP instructions, the architecture permits that a data read clears any Exclusives monitors associated with that location, even if the compare subsequently fails. If these instructions generate a synchronous Data Abort, the registers which are compared and loaded are restored to the values held in the registers before the instruction was executed.

If the destination register Rs is WZR or XZR, this is not regarded as doing a read for the purpose of a DMB LD barrier.

For more information on alignment requirements and behaviors, see Load-Exclusive/ Store-Exclusive and Atomic instructions.

C3.3 Data processing - immediate

This section describes the instruction groups for data processing with immediate operands. It contains the following subsections:

- Arithmetic (immediate).
- Logical (immediate).
- Move (wide immediate).
- Move (immediate).
- PC-relative address calculation.
- Bitfield move.
- Bitfield insert and extract
- Extract register.
- Shift (immediate).
- Sign-extend and Zero-extend.

C3.3.1 Arithmetic (immediate)

The Arithmetic (immediate) instructions accept a 12-bit unsigned immediate value, optionally shifted left by 12 bits.

The Arithmetic (immediate) instructions that do not set Condition flags can read from and write to the current stack pointer. The flag setting instructions can read from the stack pointer, but they cannot write to it.

Table C3-39 shows the Arithmetic instructions with an immediate offset.

Table C3-39 Arithmetic instructions with an immediate

Mnemonic	Instruction	See
ADD	Add	ADD (immediate)
ADDS	Add and set flags	ADDS (immediate)
SUB	Subtract	SUB (immediate)
SUBS	Subtract and set flags	SUBS (immediate)
CMP	Compare	CMP (immediate)
CMN	Compare negative	CMN (immediate)

C3.3.2 Logical (immediate)

The Logical (immediate) instructions accept a bitmask immediate value that is a 32-bit pattern or a 64-bit pattern viewed as a vector of identical elements of size e = 2, 4, 8, 16, 32 or, 64 bits. Each element contains the same sub-pattern, that is a single run of 1 to (e - 1) nonzero bits from bit 0 followed by zero bits, then rotated by 0 to (e - 1) bits. This mechanism can generate 5334 unique 64-bit patterns as 2667 pairs of pattern and their bitwise inverse.

Note

Values that consist of only zeros or only ones cannot be described in this way.

The Logical (immediate) instructions that do not set the Condition flags can write to the current stack pointer, for example to align the stack pointer in a function prologue.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

Apart from ANDS and its TST alias, Logical (immediate) instructions do not set the Condition flags. However, the final results of a bitwise operation can be tested by a CBZ, CBNZ, TBZ, or TBNZ conditional branch.

Table C3-40 shows the Logical immediate instructions.

Table C3-40 Logical immediate instructions

Mnemonic	Instruction	See
AND	Bitwise AND	AND (immediate)
ANDS	Bitwise AND and set flags	ANDS (immediate)
EOR	Bitwise exclusive OR	EOR (immediate)
ORR	Bitwise inclusive OR	ORR (immediate)
TST	Test bits	TST (immediate)

C3.3.3 Move (wide immediate)

The Move (wide immediate) instructions insert a 16-bit immediate, or inverted immediate, into a 16-bit aligned position in the destination register. The value of the other bits in the destination register depends on the variant used. The optional shift amount can be any multiple of 16 that is smaller than the register size.

Table C3-41 shows the Move (wide immediate) instructions.

Table C3-41 Move (wide immediate) instructions

Mnemonic	Instruction	See
MOVZ	Move wide with zero	MOVZ
MOVN	Move wide with NOT	MOVN
MOVK	Move wide with keep	MOVK

C3.3.4 Move (immediate)

The Move (immediate) instructions are aliases for a single MOVZ, MOVN, or ORR (immediate with zero register), instruction to load an immediate value into the destination register. An assembler must permit a signed or unsigned immediate, as long as its binary representation can be generated using one of these instructions, and an assembler error results if the immediate cannot be generated in this way. On disassembly, it is unspecified whether the immediate is output as a signed or an unsigned value.

If there is a choice between the MOVZ, MOVN, and ORR instruction to encode the immediate, then an assembler must prefer MOVZ to MOVN, and MOVZ or MOVN to ORR, to ensure reversability. A disassembler must output ORR (immediate with zero register) MOVZ, and MOVN, as a MOV mnemonic except that the underlying instruction must be used when:

- ORR has an immediate that can be generated by a MOVZ or MOVN instruction.
- A MOVN instruction has an immediate that can be encoded by MOVZ.
- MOVZ #0 or MOVN #0 have a shift amount other than LSL #0.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Table C3-42 shows the Move (immediate) instructions.

Table C3-42 Move (immediate) instructions

Mnemonic	Instruction	See
MOV	Move (inverted wide immediate)	MOV (inverted wide immediate)
	Move (wide immediate)	MOV (wide immediate)
	Move (bitmask immediate)	MOV (bitmask immediate)

C3.3.5 PC-relative address calculation

The ADR instruction adds a signed, 21-bit immediate to the value of the program counter that fetched this instruction, and then writes the result to a general-purpose register. This permits the calculation of any byte address within ±1MB of the current PC.

The ADRP instruction shifts a signed, 21-bit immediate left by 12 bits, adds it to the value of the program counter with the bottom 12 bits cleared to zero, and then writes the result to a general-purpose register. This permits the calculation of the address at a 4KB aligned memory region. In conjunction with an ADD (immediate) instruction, or a load/store instruction with a 12-bit immediate offset, this allows for the calculation of, or access to, any address within ±4GB of the current PC.

Note

The term *page* used in the ADRP description is short-hand for the 4KB memory region, and is not related to the virtual memory translation granule size.

Table C3-43 shows the instructions used for PC-relative address calculations are as follows:

Table C3-43 PC-relative address calculation instructions

Mnemonic	Instruction	See
ADRP	Compute address of 4KB page at a PC-relative offset	ADRP
ADR	Compute address of label at a PC-relative offset.	ADR

C3.3.6 Bitfield move

The Bitfield move instructions copy a field of constant width from bit 0 in the source register to a constant bit position in the destination register, or from a constant bit position in the source register to bit 0 in the destination register. The remaining bits in the destination register are set as follows:

- For BFM, the remaining bits are unchanged.
- For UBFM the lower bits, if any, and upper bits, if any, are set to zero.
- For SBFM, the lower bits, if any, are set to zero, and the upper bits, if any, are set to a copy of the most-significant bit in the copied field.

Table C3-44 shows the Bitfield move instructions.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.

Table C3-44 Bitfield move instructions

Mnemonic	Instruction	See
BFM	Bitfield move	BFM
SBFM	Signed bitfield move	SBFM
UBFM	Unsigned bitfield move (32-bit)	UBFM

C3.3.7 Bitfield insert and extract

The Bitfield insert and extract instructions are implemented as aliases of the Bitfield move instructions. Table C3-45 shows the Bitfield insert and extract aliases.

Table C3-45 Bitfield insert and extract instructions

Mnemonic	Instruction	See
BFC	Bitfield clear	BFC
BFI	Bitfield insert	BFI
BFXIL	Bitfield extract and insert low	BFXIL
SBFIZ	Signed bitfield insert in zero	SBFIZ
SBFX	Signed bitfield extract	SBFX
UBFIZ	Unsigned bitfield insert in zero	UBFIZ
UBFX	Unsigned bitfield extract	UBFX

C3.3.8 Extract register

Depending on the register width of the operands, the Extract register instruction copies a 32-bit or 64-bit field from a constant bit position within a double-width value formed by the concatenation of a pair of source registers to a destination register.

Table C3-46 shows the Extract (immediate) instructions.

Table C3-46 Extract register instructions

Mnemonic	Instruction	See
EXTR	Extract register from pair	EXTR

C3.3.9 Shift (immediate)

Shifts and rotates by a constant amount are implemented as aliases of the Bitfield move or Extract register instructions. The shift or rotate amount must be in the range 0 to one less than the register width of the instruction, inclusive.

Table C3-47 shows the aliases that can be used as immediate shift and rotate instructions.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Table C3-47 Aliases for immediate shift and rotate instructions

Mnemonic	Instruction	See
ASR	Arithmetic shift right	ASR (immediate)
LSL	Logical shift left	LSL (immediate)
LSR	Logical shift right	LSR (immediate)
ROR	Rotate right	ROR (immediate)

C3.3.10 Sign-extend and Zero-extend

The Sign-extend and Zero-extend instructions are implemented as aliases of the Bitfield move instructions.

Table C3-48 shows the aliases that can be used as zero-extend and sign-extend instructions.

Table C3-48 Zero-extend and sign-extend instructions

Mnemonic	Instruction	See
SXTB	Sign-extend byte	SXTB
SXTH	Sign-extend halfword	SXTH
SXTW	Sign-extend word	SXTW
UXTB	Unsigned extend byte	UXTB
UXTH	Unsigned extend halfword	UXTH

C3.4 Data processing - register

This section describes the instruction groups for data processing with all register operands. It contains the following subsections:

- Arithmetic (shifted register).
- Arithmetic (extended register).
- Arithmetic with carry.
- Flag manipulation instructions.
- Logical (shifted register).
- Move (register).
- Shift (register).
- Multiply and divide.
- CRC32.
- Bit operation.
- Conditional select.
- Conditional comparison.

C3.4.1 Arithmetic (shifted register)

The Arithmetic (shifted register) instructions apply an optional shift operator to the second source register value before performing the arithmetic operation. The register width of the instruction controls whether the new bits are fed into the intermediate result on a right shift or rotate at bit[63] or bit[31].

The shift operators `LSL`, `ASR`, and `LSR` accept an immediate shift amount in the range 0 to one less than the register width of the instruction, inclusive.

Omitting the shift operator implies `LSL #0`, which means that there is no shift. A disassembler must not output `LSL #0`. However, a disassembler must output all other shifts by zero.

The current stack pointer, SP or WSP, cannot be used with this class of instructions. See Arithmetic (extended register) for arithmetic instructions that can operate on the current stack pointer.

Table C3-49 shows the Arithmetic (shifted register) instructions.

Table C3-49 Arithmetic (shifted register) instructions

Mnemonic	Instruction	See
`ADD`	Add	ADD (shifted register)
`ADDS`	Add and set flags	ADDS (shifted register)
`SUB`	Subtract	SUB (shifted register)
`SUBS`	Subtract and set flags	SUBS (shifted register)
`CMN`	Compare negative	CMN (shifted register)
`CMP`	Compare	CMP (shifted register)
`NEG`	Negate	NEG (shifted register)
`NEGS`	Negate and set flags	NEGS

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C3.4.2 Arithmetic (extended register)

The extended register instructions provide an optional sign-extension or zero-extension of a portion of the second source register value, followed by an optional left shift by a constant amount of 1-4, inclusive.

The extended shift is described by the mandatory extend operator `SXTB`, `SXTH`, `SXTW`, `UXTB`, `UXTH`, or `UXTW` . This is followed by an optional left shift amount. If the shift amount is not specified, the default shift amount is zero. A disassembler must not output a shift amount of zero.

For 64-bit instruction forms, the additional operators `UXTX` and `SXTX` use all 64 bits of the second source register with an optional shift. In that case, Arm recommends `UXTX` as the operator. If and only if at least one register is SP, Arm recommends use of the `LSL` operator name, rather than `UXTX`, and when the shift amount is also zero then both the operator and the shift amount can be omitted. `UXTW` and `SXTW` both use all 32 bits of the second source register with an optional shift. In that case Arm recommends `UXTW` as the operator. If and only if at least one register is WSP, Arm recommends use of the `LSL` operator name, rather than `UXTW`, and when the shift amount is also zero then both the operator and the shift amount can be omitted.

For 32-bit instruction forms, the operators `UXTW` and `SXTW` both use all 32 bits of the second source register with an optional shift. In that case, Arm recommends `UXTW` as the operator. If and only if at least one register is WSP, Arm recommends use of the `LSL` operator name, rather than `UXTW`, and when the shift amount is also zero then both the operator and the shift amount can be omitted.

The non-flag setting variants of the extended register instruction permit the use of the current stack pointer as either the destination register and the first source register. The flag setting variants only permit the stack pointer to be used as the first source register.

In the 64-bit form of these instructions, the final register operand is written as `Wm` for all except the `UXTX`/`LSL` and `SXTX` extend operators. For example:

```
CMP X4, W5, SXTW
ADD X1, X2, W3, UXTB #2
SUB SP, SP, X1              // SUB SP, SP, X1, UXTX #0
```

Table C3-50 shows the Arithmetic (extended register) instructions.

Table C3-50 Arithmetic (extended register) instructions

Mnemonic	Instruction	See
`ADD`	Add	ADD (extended register)
`ADDS`	Add and set flags	ADDS (extended register)
`SUB`	Subtract	SUB (extended register)
`SUBS`	Subtract and set flags	SUBS (extended register)
`CMN`	Compare negative	CMN (extended register)
`CMP`	Compare	CMP (extended register)

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C3.4.3 Arithmetic with carry

The Arithmetic with carry instructions accept two source registers, with the carry flag as an additional input to the calculation. They do not support shifting of the second source register.

Table C3-51 shows the Arithmetic with carry instructions

Table C3-51 Arithmetic with carry instructions

Mnemonic	Instruction	See
ADC	Add with carry	ADC
ADCS	Add with carry and set flags	ADCS
SBC	Subtract with carry	SBC
SBCS	Subtract with carry and set flags	SBCS
NGC	Negate with carry	NGC
NGCS	Negate with carry and set flags	NGCS

C3.4.4 Flag manipulation instructions

The Flag manipulation instructions set the value of the NZCV condition flags directly.

The instructions SETF8 and SETF16 accept one source register and set the NZV condition flags based on the value of the input register. The instruction RMIF accepts one source register and two immediate values, rotating the first source register using the first immediate value and setting the NZCV condition flags masked by the second immediate value.

The instructions XAFLAG and AXFLAG convert PSTATE condition flags between the FCMP instruction format and an alternative format. See Table C6-1 for more information.

Table C3-52 shows the Flag manipulation instructions.

Table C3-52 Flag manipulation instructions

Mnemonic	Instruction	See
CFINV	Invert value of the PSTATE.C bit	CFINV
RMIF	Rotate, mask insert flags	RMIF
SETF8	Evaluation of 8-bit flags	SETF8, SETF16
SETF16	Evaluation of 16-bit flags	SETF8, SETF16

C3.4.5 Logical (shifted register)

The Logical (shifted register) instructions apply an optional shift operator to the second source register value before performing the main operation. The register width of the instruction controls whether the new bits are fed into the intermediate result on a right shift or rotate at bit[63] or bit[31].

The shift operators LSL, ASR, LSR, and ROR accept a constant immediate shift amount in the range 0 to one less than the register width of the instruction, inclusive.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Omitting the shift operator and amount implies `LSL #0`, which means that there is no shift. A disassembler must not output `LSL #0`. However, a disassembler must output all other shifts by zero.

Note

Apart from `ANDS`, `TST`, and `BICS`, the logical instructions do not set the Condition flags, but the final result of a bit operation can usually directly control a `CBZ`, `CBNZ`, `TBZ`, or `TBNZ` conditional branch.

Table C3-53 shows the Logical (shifted register) instructions.

Table C3-53 Logical (shifted register) instructions

Mnemonic	Instruction	See
`AND`	Bitwise AND	AND (shifted register)
`ANDS`	Bitwise AND and set flags	ANDS (shifted register)
`BIC`	Bitwise bit clear	BIC (shifted register)
`BICS`	Bitwise bit clear and set flags	BICS (shifted register)
`EON`	Bitwise exclusive-OR NOT	EON (shifted register)
`EOR`	Bitwise exclusive-OR	EOR (shifted register)
`ORR`	Bitwise inclusive OR	ORR (shifted register)
`MVN`	Bitwise NOT	MVN
`ORN`	Bitwise inclusive OR NOT	ORN (shifted register)
`TST`	Test bits	TST (shifted register)

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C3.4.6 Move (register)

The Move (register) instructions are aliases for other data processing instructions. They copy a value from a general-purpose register to another general-purpose register or the current stack pointer, or from the current stack pointer to a general-purpose register.

Table C3-54 MOV register instructions

Mnemonic	Instruction	See
MOV	Move register	MOV (register)
	Move register to SP or move SP to register	MOV (to/from SP)

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C3.4.7 Shift (register)

In the Shift (register) instructions, the shift amount is the positive value in the second source register modulo the register size. The register width of the instruction controls whether the new bits are fed into the result on a right shift or rotate at bit[63] or bit[31].

Table C3-55 shows the Shift (register) instructions.

Table C3-55 Shift (register) instructions

Mnemonic	Instruction	See
ASRV	Arithmetic shift right variable	ASRV
LSLV	Logical shift left variable	LSLV
LSRV	Logical shift right variable	LSRV
RORV	Rotate right variable	RORV

However, the Shift (register) instructions have a preferred set of aliases that match the shift immediate aliases described in Shift (immediate).

Table C3-56 shows the aliases for Shift (register) instructions.

Table C3-56 Aliases for Variable shift instructions

Mnemonic	Instruction	See
ASR	Arithmetic shift right	ASR (register)
LSL	Logical shift left	LSL (register)
LSR	Logical shift right	LSR (register)
ROR	Rotate right	ROR (register)

C3.4.8 Multiply and divide

This section describes the instructions used for integer multiplication and division. It contains the following subsections:

- Multiply.
- Divide.

C3.4.8.1 Multiply

The Multiply instructions write to a single 32-bit or 64-bit destination register, and are built around the fundamental four operand multiply-add and multiply-subtract operation, together with 32-bit to 64-bit widening variants. A 64-bit to 128-bit widening multiple can be constructed with two instructions, using SMULH or UMULH to generate the upper 64 bits. Table C3-57 shows the Multiply instructions.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Table C3-57 Multiply integer instructions

Mnemonic	Instruction	See
MADD	Multiply-add	MADD
MSUB	Multiply-subtract	MSUB
MNEG	Multiply-negate	MNEG
MUL	Multiply	MUL
SMADDL	Signed multiply-add long	SMADDL
SMSUBL	Signed multiply-subtract long	SMSUBL
SMNEGL	Signed multiply-negate long	SMNEGL
SMULL	Signed multiply long	SMULL
SMULH	Signed multiply high	SMULH
UMADDL	Unsigned multiply-add long	UMADDL
UMSUBL	Unsigned multiply-subtract long	UMSUBL
UMNEGL	Unsigned multiply-negate long	UMNEGL
UMULL	Unsigned multiply long	UMULL
UMULH	Unsigned multiply high	UMULH

C3.4.8.2 Divide

The Divide instructions compute the quotient of a division, rounded towards zero. The remainder can then be computed as (numerator - (quotient × denominator)), using the MSUB instruction.

If a signed integer division (INT_MIN / -1) is performed where INT_MIN is the most negative integer value representable in the selected register size, then the result overflows the signed integer range. No indication of this overflow is produced and the result that is written to the destination register is INT_MIN.

A division by zero results in a zero being written to the destination register, without any indication that the division by zero occurred.

Table C3-58 shows the Divide instructions.

Table C3-58 Divide instructions

Mnemonic	Instruction	See
SDIV	Signed divide	SDIV
UDIV	Unsigned divide	UDIV

C3.4.9 CRC32

The CRC32 instructions operate on the general-purpose register file to update a 32-bit CRC value from an input value comprising 1, 2, 4, or 8 bytes. There are two different classes of CRC instructions, CRC32, and CRC32C, that support two commonly used 32-bit polynomials, known as CRC-32 and CRC-32C.

To fit with common usage, the bit order of the values is reversed as part of the operation.

When bits[19:16] of ID_AA64ISAR0_EL1 are set to 0b0001, the CRC instructions are implemented.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

These instructions are optional in an Armv8.0 implementation.

All implementations of Armv8.1 architecture and later are required to implement the `CRC32` instructions.

Table C3-59 shows the `CRC` instructions.

Table C3-59 CRC32 instructions

Mnemonic	Instruction	See
`CRC32B`	CRC-32 sum from byte	CRC32B, CRC32H, CRC32W, CRC32X
`CRC32H`	CRC-32 sum from halfword	CRC32B, CRC32H, CRC32W, CRC32X
`CRC32W`	CRC-32 sum from word	CRC32B, CRC32H, CRC32W, CRC32X
`CRC32X`	CRC-32 sum from doubleword	CRC32B, CRC32H, CRC32W, CRC32X
`CRC32CB`	CRC-32C sum from byte	CRC32CB, CRC32CH, CRC32CW, CRC32CX
`CRC32CH`	CRC-32C sum from halfword	CRC32CB, CRC32CH, CRC32CW, CRC32CX
`CRC32CW`	CRC-32C sum from word	CRC32CB, CRC32CH, CRC32CW, CRC32CX
`CRC32CX`	CRC-32C sum from doubleword	CRC32CB, CRC32CH, CRC32CW, CRC32CX

C3.4.10 Bit operation

Table C3-60 shows the Bit operation instructions.

Table C3-60 Bit operation instructions

Mnemonic	Instruction	See
`CLS`	Count leading sign bits	CLS
`CLZ`	Count leading zero bits	CLZ
`RBIT`	Reverse bit order	RBIT
`REV`	Reverse bytes in register	REV
`REV16`	Reverse bytes in halfwords	REV16
`REV32`	Reverse bytes in words	REV32
`REV64`	Reverse bytes in register	REV64

C3.4.11 Conditional select

The Conditional select instructions select between the first or second source register, depending on the current state of the Condition flags. When the named condition is true, the first source register is selected and its value is copied without modification to the destination register. When the condition is false the second source register is selected and its value might be optionally inverted, negated, or incremented by one, before writing to the destination register.

Other useful conditional set and conditional unary operations are implemented as aliases of the four Conditional select instructions.

Table C3-61 shows the Conditional select instructions.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Table C3-61 Conditional select instructions

Mnemonic	Instruction	See
CSEL	Conditional select	CSEL
CSINC	Conditional select increment	CSINC
CSINV	Conditional select inversion	CSINV
CSNEG	Conditional select negation	CSNEG
CSET	Conditional set	CSET
CSETM	Conditional set mask	CSETM
CINC	Conditional increment	CINC
CINV	Conditional invert	CINV
CNEG	Conditional negate	CNEG

C3.4.12 Conditional comparison

The Conditional comparison instructions provide a conditional select for the NZCV Condition flags, setting the flags to the result of an arithmetic comparison of its two source register values if the named input condition is true, or to an immediate value if the input condition is false. There are register and immediate forms. The immediate form compares the source register to a small 5-bit unsigned value.

Table C3-62 shows the Conditional comparison instructions.

Table C3-62 Conditional comparison instructions

Mnemonic	Instruction	See
CCMN	Conditional compare negative (register)	CCMN (register)
CCMN	Conditional compare negative (immediate)	CCMN (immediate)

C3.5 Data processing - SIMD and floating-point

This section describes the instruction groups for data processing with SIMD and floating-point register operands.

Common features of SIMD instructions gives general information about SIMD instructions.

The following subsections describe the scalar floating-point data processing instructions:

- Floating-point move (register).
- Floating-point move (immediate).
- Floating-point conversion.
- Floating-point round to integral value.
- Floating-point multiply-add.
- Floating-point arithmetic (one source).
- Floating-point arithmetic (two sources).
- Floating-point minimum and maximum.
- Floating-point comparison.
- Floating-point conditional select.

The following subsections describe the SIMD data processing instructions:

- SIMD move.
- SIMD arithmetic.
- SIMD compare.
- SIMD widening and narrowing arithmetic.
- SIMD unary arithmetic.
- SIMD by element arithmetic.
- SIMD permute.
- SIMD immediate.
- SIMD shift (immediate).
- SIMD conversions.
- SIMD reduce (across vector lanes).
- SIMD pairwise arithmetic.
- SIMD dot product.
- SIMD table lookup.
- SIMD complex number arithmetic instructions.
- SIMD multiply-accumulate.
- The Cryptographic Extension in AArch64 state.

For information about the floating-point exceptions, see Floating-point exceptions and exception traps.

C3.5.1 Common features of SIMD instructions

A number of SIMD instructions come in three forms:

Wide Indicated by the suffix *W*. The element width of the destination register and the first source operand is double that of the second source operand.

Long Indicated by the suffix *L*. The element width of the destination register is double that of both source operands.

Narrow Indicated by the suffix *N*. The element width of the destination register is half that of both source operands.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

In addition, each vector form of the instruction is part of a pair, with a second and upper part suffix of *2*, to identify the variant of the instruction:

- Where a SIMD operation widens or lengthens a 64-bit vector to a 128-bit vector, the instruction provides a second part operation that can extract the source from the upper 64 bits of the source registers.
- Where a SIMD operation narrows a 128-bit vector to a 64-bit vector, the instruction provides a second-part operation that can pack the result of a second operation into the upper part of the same destination register.

Note

This is referred to as a *lane set specifier*.

C3.5.2 Floating-point move (register)

The Floating-point move (register) instructions copy a scalar floating-point value from one register to another register without performing any conversion.

Some of the Floating-point move (register) instructions overlap with the functionality provided by the Advanced SIMD instructions `DUP`, `INS`, and `UMOV`. However, Arm recommends using the `FMOV` instructions when operating on scalar floating-point data to avoid the creation of scalar floating-point code that depends on the availability of the Advanced SIMD instruction set.

Table C3-63 shows the Floating-point move (register) instructions.

Table C3-63 Floating-point move (register) instructions

Mnemonic	Instruction	See
`FMOV`	Floating-point move register without conversion	FMOV (register)
	Floating-point move to or from general-purpose register without conversion	FMOV (general)

C3.5.3 Floating-point move (immediate)

The Floating-point move (immediate) instructions convert a small constant immediate floating-point value into a half-precision, single-precision, or double-precision scalar floating-point value in a SIMD and floating-point register.

The floating-point constant can be specified either in decimal notation, such as 12.0 or -1.2e1, or as a string beginning with `0x` followed by a hexadecimal representation of the IEEE 754 half-precision, single-precision, or double-precision encoding. Arm recommends that a disassembler uses the decimal notation, provided that this displays the value precisely.

Note

When FEAT_FP16 is not implemented, the only half-precision instructions that are supported are floating-point conversions between half-precision, single-precision, and double-precision.

The floating-point value must be expressible as $(\pm n/16 \times 2^r)$, where n is an integer in the range $16 \le n \le 31$ and r is an integer in the range of $-3 \le r \le 4$, that is a normalized binary floating-point encoding with one sign bit, four bits of fraction, and a 3-bit exponent.

Table C3-64 shows the Floating-point move (immediate) instruction:

Mnemonic	Instruction	See
FMOV	Floating-point move immediate	FMOV (scalar, immediate)

C3.5.4 Floating-point conversion

The following subsections describe the conversion of floating-point values:

- Convert floating-point precision.
- Convert from floating-point single-precision to BFloat16.
- Convert from floating-point to integer or fixed-point.
- Convert from integer or fixed-point to floating-point.

C3.5.4.1 Convert floating-point precision

These instructions convert a floating-point scalar with one precision to a floating-point scalar with a different precision, using the current rounding mode as specified by FPCR.RMode.

Table C3-65 shows the Floating-point precision conversion instruction.

Table C3-65 Floating-point precision conversion instruction

Mnemonic	Instruction	See
FCVT	Floating-point convert precision (scalar)	FCVT

C3.5.4.2 Convert from floating-point single-precision to BFloat16

The BFCVT instruction is provided by FEAT_BF16. This instruction converts a single-precision floating-point input to BFloat16 format, honoring the FPCR rounding mode controls to give a more accurate conversion than simply removing the bottom 16 bits of the input.

Table C3-66 shows this instruction.

Table C3-66 Floating-point single-precision to BFloat16 conversion instruction

Mnemonic	Instruction	See
BFCVT	BFloat16 floating-point convert from single-precision to BFloat16 format (scalar)	BFCVT

C3.5.4.3 Convert from floating-point to integer or fixed-point

Floating-point to integer or fixed-point conversion is supported by the following instruction variants:

- Scalar instruction variant, which converts a floating-point value in a SIMD and floating-point source register to an integer or fixed-point value in a general-purpose destination register.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- Scalar SIMD&FP instruction variant, which converts a floating-point value in a SIMD and floating-point source register to an integer value in a SIMD and floating-point destination register.

For a fixed-point value, a final immediate operand indicates that the general-purpose register holds a fixed-point number and `fbits` indicates the number of bits after the binary point. `fbits` is in the range 1- 32 inclusive for a 32-bit general-purpose register name, and 1-64 inclusive for a 64-bit general-purpose register name.

Table C3-67 shows the floating-point to integer or fixed-point conversion instructions.

Table C3-67 Floating-point to integer or fixed-point conversion instructions

	Floating-point scalar convert to unsigned fixed-point, rounding toward zero (scalar form)	FCVTZU (scalar, fixed-point)
FJCVTZS	Floating-point Javascript convert to signed fixed-point, rounding toward zero (scalar form)	FJCVTZS

C3.5.4.4 Convert from integer or fixed-point to floating-point

The integer or fixed-point to floating-point conversion is supported by the following instruction variants:

- Scalar instruction variant, which converts an integer or fixed-point value in a general-purpose register to a floating-point value in a SIMD and floating-point destination register.
- Scalar SIMD&FP variant, which converts an integer value in a SIMD and floating-point source register to a floating-point value in a SIMD and floating-point destination register.

For a fixed-point value, a final immediate operand indicates that the general-purpose register holds a fixed-point number and `fbits` indicates the number of bits after the binary point. `fbits` is in the range 1- 32 inclusive for a 32-bit general-purpose register name, and 1-64 inclusive for a 64-bit general-purpose register name.

	Unsigned fixed-point convert to floating-point, using the current rounding mode (scalar form)	UCVTF (scalar, fixed-point)

C3.5.5 Floating-point round to integral value

The following subsections describe instructions which round a floating-point number to an integral valued floating-point number in the same format:

- Floating-point round to an integer of the same size as the register
- Floating-point round to 32-bit or 64-bit integer

C3.5.5.1 Floating-point round to an integer of the same size as the register

The following instructions round a floating-point value to an integer floating-point value of the same size.

For these instructions:

- A zero input gives a zero result with the same sign.
- An infinite input gives an infinite result with the same sign.
- A NaN is propagated as in normal floating-point arithmetic.

These instructions can cause floating-point exceptions, for more information see Floating-point exceptions and exception traps.

Table C3-69 shows the Floating-point round to integer instructions.

Table C3-69 Floating-point round to integer instructions

Mnemonic	Instruction	See

FMUL	Floating-point scalar multiply	FMUL (scalar)
FNMUL	Floating-point scalar multiply-negate	FNMUL (scalar)
FSUB	Floating-point scalar subtract	FSUB (scalar)

C3.5.9 Floating-point minimum and maximum

The `min(x,y)` and `max(x,y)` operations return a quiet NaN when either x or y is NaN.

As described in Flushing denormalized numbers to zero, if flushing denormalized inputs to zero is enabled, denormal operands are flushed to zero before comparison, and if the result of the comparison is the flushed value, then a zero value

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

is returned. Where both *x* and *y* are zero, or denormal values flushed to zero, with different signs, then +0.0 is returned by `max()` and -0.0 by `min()`.

The `minNum(x,y)` and `maxNum(x,y)` operations follow the IEEE 754-2008 standard and return the numerical operand when one operand is numerical and the other a quiet NaN. Apart from this additional handling of a single quiet NaN, the result is then identical to `min(x,y)` and `max(x,y)`.

Table C3-73 shows the Floating-point instructions that can perform floating-point minimum and maximum operations.

Table C3-73 Floating-point minimum and maximum instructions

Mnemonic	Instruction	See
FMAX	Floating-point scalar maximum	FMAX (scalar)
FMAXNM	Floating-point scalar maximum number	FMAXNM (scalar)
FMIN	Floating-point scalar minimum	FMIN (scalar)
FMINNM	Floating-point scalar minimum number	FMINNM (scalar)

C3.5.10 Floating-point comparison

These instructions set the NZCV Condition flags in PSTATE, based on the result of a comparison of two operands. If the floating-point comparisons are *unordered*, where one or both operands are a form of NaN, the C and V bits are set to 1 and the N and Z bits are cleared to 0.

Note

The A64 floating-point comparison instructions do not change the Condition flags in the FPSR.

For the conditional Floating-point comparison instructions, if the condition is TRUE, the flags are updated to the result of the comparison, otherwise the flags are updated to the immediate value that is defined in the instruction encoding.

The quiet compare instructions generate an Invalid Operation floating-point exception if either of the source operands is a signaling NaN. The signaling compare instructions generate an Invalid Operation floating-point exception if either of the source operands is any type of NaN.

Table C3-74 shows the Floating-point comparison instructions.

C3.5.14 SIMD compare

The SIMD compare instructions compare vector or scalar elements according to the specified condition and set the destination vector element to all ones if the condition holds, or to zero if the condition does not hold.

Note

Some of the comparisons, such as LS, LE, LO, and LT, can be made by reversing the operands and using the opposite comparison, HS, GE, HI, or GT.

Table C3-78 shows that SIMD compare instructions.

C3.5.22 SIMD reduce (across vector lanes)

The SIMD reduce (across vector lanes) instructions perform arithmetic operations horizontally, that is across all lanes of the input vector. They deliver a single scalar result.

Table C3-87 shows the SIMD reduce (across vector lanes) instructions.

Table C3-87 SIMD reduce (across vector lanes) instructions

Mnemonic	Instruction	See
ADDV	Add (across vector)	ADDV
FMAXNMV	Floating-point maximum number (across vector)	FMAXNMV
FMAXV	Floating-point maximum (across vector)	FMAXV
FMINNMV	Floating-point minimum number (across vector)	FMINNMV
FMINV	Floating-point minimum (across vector)	FMINV
SADDLV	Signed add long (across vector)	SADDLV
SMAXV	Signed maximum (across vector)	SMAXV
SMINV	Signed minimum (across vector)	SMINV
UADDLV	Unsigned add long (across vector)	UADDLV
UMAXV	Unsigned maximum (across vector)	UMAXV
UMINV	Unsigned minimum (across vector)	UMINV

C3.5.23 SIMD pairwise arithmetic

The SIMD pairwise arithmetic instructions perform operations on pairs of adjacent elements and deliver a vector result.

Table C3-88 shows the SIMD pairwise arithmetic instructions.

Table C3-88 SIMD pairwise arithmetic instructions

Mnemonic	Instruction	See
ADDP	Add pairwise (vector and scalar form)	ADDP (vector) ADDP (scalar)
FADDP	Floating-point add pairwise (vector and scalar form)	FADDP (vector) FADDP (scalar)
FMAXNMP	Floating-point maximum number pairwise (vector and scalar form)	FMAXNMP (vector) FMAXNMP (scalar)

UMAXP	Unsigned maximum pairwise	UMAXP
UMINP	Unsigned minimum pairwise	UMINP

C3.5.24 SIMD dot product

C3.5.24.1 Integer dot product

FEAT_DotProd provides SIMD instructions that perform the dot product of the four 8-bit subelements of the 32-bit elements of one vector with the four 8-bit subelements of a second vector. It provides two forms of the instructions, each with signed and unsigned versions:

Vector form The dot product is calculated for each element of the first vector with the corresponding element of the second vector.

Indexed form The dot product is calculated for each element of the first vector with the element of the second vector that is indicated by the index argument to the instruction.

Note

That is, a single element from the second vector is used, and the dot product is calculated between each element of the first vector and this single element from the second vector.

Table C3-89 shows the SIMD integer dot product instructions.

Table C3-89 SIMD integer dot product instructions

Mnemonic	Instruction	See
SDOT	Signed dot product (vector form)	SDOT (vector)
UDOT	Unsigned dot product (vector form)	UDOT (vector)
SDOT	Signed dot product (indexed form)	SDOT (by element)
UDOT	Unsigned dot product (indexed form)	UDOT (by element)

C3.5.25 SIMD table lookup

C3.5.25.1 Table vector lookup

Table C3-90 shows the SIMD table vector lookup instructions.

Mnemonic	Instruction	See
TBL	Table vector lookup	TBL
TBX	Table vector lookup extension	TBX

C3.5.26 SIMD complex number arithmetic instructions

FEAT_FCMA provides SIMD instructions that perform arithmetic on complex numbers held in element pairs in vector registers, where the less significant element of the pair contains the real component and the more significant element contains the imaginary component.

These instructions provide double-precision and single-precision versions. If FEAT_FP16 is implemented they also provide half-precision versions, otherwise the half-precision encodings are UNDEFINED.

Table C3-91 shows the FEAT_FCMA SIMD instructions.

Table C3-91 SIMD complex number arithmetic instructions

Mnemonic	Instruction	See
FCADD	Floating-point complex add	FCADD
FCMLA	Floating-point complex multiply accumulate (vector form)	FCMLA
FCMLA	Floating-point complex multiply accumulate (indexed form)	FCMLA (by element)

A pair of FCMLA instructions can be used to perform a complex number multiplication. This is demonstrated in Complex multiplication.

C3.5.27 SIMD multiply-accumulate

C3.5.27.1 Floating-point fused multiply-accumulate

The SIMD floating-point fused multiply-accumulate instructions multiply the vector elements in the first source SIMD&FP register by the corresponding value in the second source SIMD&FP register, and accumulate or subtract the product in the vector elements of the destination SIMD&FP register.

Table C3-92 shows these instructions.

Table C3-92 SIMD floating-point fused multiply-accumulate instructions

Mnemonic	Instruction	See
FMLA	Floating-point fused multiply-add (vector form)	FMLA (vector)
FMLAL, FMLAL2	Floating-point fused multiply-add long (vector form)	FMLAL, FMLAL2 (vector)
FMLS	Floating-point fused multiply-subtract (vector form)	FMLS (vector)

C3.5.28 The Cryptographic Extension in AArch64 state

C3.5.28.1 The Armv8.0 Cryptographic Extension

The instructions provided by the OPTIONAL Armv8.0 Cryptographic Extension use the SIMD and floating-point register file. For more information about the functions they provide, see:

- *Advanced Encryption Standard (AES)*.
- *Secure Hash Algorithm (SHA)*.
- *The Galois/Counter Mode of Operation*.

Table C3-93 shows the Armv8.0 Cryptographic Extension instructions.

Table C3-93 Cryptographic Extension instructions

Mnemonic	Instruction	See
AESD	AES single round decryption	AESD
AESE	AES single round encryption	AESE
AESIMC	AES inverse mix columns	AESIMC
AESMC	AES mix columns	AESMC
PMULL	Polynomial multiply long	PMULL, PMULL2 [a]
SHA1C	SHA1 hash update (choose)	SHA1C
SHA1H	SHA1 fixed rotate	SHA1H
SHA1M	SHA1 hash update (majority)	SHA1M
SHA1P	SHA1 hash update (parity)	SHA1P
SHA1SU0	SHA1 schedule update 0	SHA1SU0
SHA1SU1	SHA1 schedule update 1	SHA1SU1
SHA256H	SHA256 hash update, part 1	SHA256H
SHA256H2	SHA256 hash update, part 2	SHA256H2
SHA256SU0	SHA256 schedule update 0	SHA256SU0
SHA256SU1	SHA256 schedule update 1	SHA256SU1

a. The Cryptographic Extension adds the variant of the instruction that operates on two 64-bit polynomials.

C3.5.28.2 Armv8.2 extensions to the Cryptographic Extension

Armv8.2 supports the following OPTIONAL extensions to the Cryptographic Extension:

- FEAT_SHA512, SHA2-512 functionality.
- FEAT_SHA3, SHA3 functionality.
- FEAT_SM3, SM3 functionality.
- FEAT_SM4, SM4 functionality.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C3.5.28.2.1 FEAT_SHA512, SHA2-512 functionality

FEAT_SHA512 provides instructions to accelerate the SHA-2 hash algorithm using a digest that is larger than 256 bits. The relevant standards are SHA-384, SHA-512, SHA-512|224 and SHA-512|256. These are all based on the SHA-512 computation, and therefore this set of instructions is described as the *SHA512 instructions*.

Implementation of FEAT_SHA512 requires the implementation of the SHA1 and SHA2-256 instructions from the Armv8.0 Cryptographic Extension.

Note

Implementation of FEAT_SHA512 does not require the implementation of the AES instructions, and the 64-bit polynomial variants of the `PMULL` instructions, from the Armv8.0 Cryptographic Extension.

When FEAT_SHA512 is implemented, the value of ID_AA64ISAR0_EL1.SHA2 is `0b0010`, indicating support for the SHA512 instructions.

Table C3-94 shows the FEAT_SHA512 instructions:

Table C3-94 FEAT_SHA512 instructions

Mnemonic	Instruction	See
`SHA512H`	SHA512 Hash update part 1	SHA512H
`SHA512H2`	SHA512 Hash update part 2	SHA512H2
`SHA512SU0`	SHA512 Schedule Update 0	SHA512SU0
`SHA512SU1`	SHA512 Schedule Update 1	SHA512SU1

Use of the SHA512 instructions shows an example of the use of these instructions to calculate a SHA512 hash iteration. This example code is not part of the architectural definition of these instructions.

C3.5.28.2.2 FEAT_SHA3, SHA3 functionality

FEAT_SHA3 provides instructions to accelerate the SHA-3 hash algorithm. This set of instructions is described as the *SHA3 instructions.*

Note

Implementation of FEAT_SHA3 does not require the implementation of the AES instructions, and the 64-bit polynomial variants of the `PMULL` instructions, from the Armv8.0 Cryptographic Extension.

When FEAT_SHA3 is implemented, the value of ID_AA64ISAR0_EL1.SHA3 is `0b0001`, indicating support for the SHA3 instructions.

Table C3-95 shows the FEAT_SHA3 instructions. The SHA-3 hash algorithm is based on a running digest of 1600 bytes, arranged as a five by five array of 64-bit registers. The Arm acceleration of these instructions is based on mapping the 25 64-bit values into 25 vector registers, with each 64-bit value occupying the same 64-bit element in each vector. A series of transformations is performed on these registers as part of a round of the SHA-3 hash calculation.

The SIMD nature of the vector registers means the acceleration can compute two parallel SHA3 hash calculations, where one calculation is performed using the zeroth 64-bit element of each vector, and the other calculation is performed using the first 64-bit element of each vector.

To provide acceleration where the SIMD calculation is not required, the instructions provide variants that operate only on the zeroth 64-bit elements. These are provided as a power optimization.

Non-Confidential

Table C3-95 FEAT_SHA3 instructions

Mnemonic	Instruction	See
BCAX	Bit Clear and Exclusive OR	BCAX
EOR3	Three-way Exclusive OR	EOR3
RAX1	Rotate and Exclusive OR	RAX1
XAR	Exclusive OR and Rotate	XAR

Use of the SHA3 instructions shows an example of the use of these instructions to calculate the combined theta, phi, rho and chi operations of a SHA3 iteration. This example code is not part of the architectural definition of these instructions.

C3.5.28.2.3 FEAT_SM3, SM3 functionality

FEAT_SM3 provides instructions to accelerate the SM3 hash algorithm, the standard Chinese hash algorithm. These are described as the *SM3 instructions*.

FEAT_SM3 can be implemented independently of any part of the Armv8.0 Cryptographic Extension, and independently of FEAT_SHA512.

Note

This means that Armv8.2 permits an implementation of the Cryptographic Extension that provides only the FEAT_SM3 functionality.

When FEAT_SM3 is implemented, the value of ID_AA64ISAR0_EL1.SM3 is 0b0001, indicating support for the SM3 instructions.

Table C3-96 shows the FEAT_SM3 instructions. The SM3 algorithm computes a digest of 256 bits, which can be held in two vector registers. The SM3 instructions include instructions to accelerate the computation of the hash and the schedule update.

Note

The SM3 instruction names refer to intermediate variables defined as part of the *SM3 Cryptographic Hash Algorithm* specification.

Table C3-96 FEAT_SM3 instructions

Mnemonic	Instruction	See
SM3SS1	SM3 SS1 calculation	SM3SS1
SM3TT1A	SM3 TT1 calculation, part A	SM3TT1A
SM3TT1B	SM3 TT1 calculation, part B	SM3TT1B
SM3TT2A	SM3 TT2 calculation, part A	SM3TT2A
SM3TT2B	SM3 TT2 calculation, part B	SM3TT2B
SM3PARTW1	SM3 PARTW calculation, part 1	SM3PARTW1
SM3PARTW2	SM3 PARTW calculation, part 1	SM3PARTW2

Use of the SM3 instructions shows an example of the use of these instructions to generate an SM3 hash. This example code is not part of the architectural definition of these instructions.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C3.5.28.2.4 FEAT_SM4, SM4 functionality

FEAT_SM4 provides instruction to accelerate the SM4 encryption algorithm, the standard Chinese encryption algorithm. This set of instructions is described as the *SM4 instructions*.

FEAT_SM4 can be implemented independently of any part of the Armv8.0 Cryptographic Extension, and independently of FEAT_SHA3.

Note

This means that Armv8.2 permits an implementation of the Cryptographic Extension that provides only the FEAT_SM4 functionality.

When FEAT_SM4 is implemented, the value of ID_AA64ISAR0_EL1.SM4 is `0b0001`, indicating support for the SM4 instructions.

Table C3-97 shows the FEAT_SM4 instructions. The SM4 algorithm is 128-bit wide block cipher. The `SM4E` instruction accelerates a single round of encryption or decryption, and the `SM4EKEY` instruction accelerates a single round of key generation:

Table C3-97 FEAT_SM4 instructions

Mnemonic	Instruction	See
`SM4E`	SM4 Encrypt	SM4E
`SM4EKEY`	SM4 Key	SM4EKEY

Use of the SM4 instructions shows an example of the use of these instructions to perform SM4 encryption and decryption. This example code is not part of the architectural definition of these instructions.

Chapter C4
A64 Instruction Set Encoding

This chapter describes the encoding of the A64 instruction set. It contains the following section:

- A64 instruction set encoding.

In this chapter:

- In the decode tables, an entry of - for a field value means the value of the field does not affect the decoding.
- In the decode diagrams, a shaded field indicates that the bits in that field are not used in that level of decode.

Chapter C5
The A64 System Instruction Class

This chapter describes the A64 System instruction class, and the System instruction class encoding space, that is a subset of the System registers encoding space. It contains the following sections:

- The System instruction class encoding space.
- Special purpose registers.
- A64 System instructions for cache maintenance.
- A64 System instructions for address translation.
- A64 System instructions for TLB maintenance.
- A64 System instructions for prediction restriction.
- A64 IMPLEMENTATION DEFINED System instructions.

See General information about the A64 instruction descriptions for information about entries used in the instruction encoding descriptions.

Non-Confidential

C5.1 The System instruction class encoding space

Part of the A64 instruction encoding space is assigned to instructions that access the System register encoding space. These instructions provide:

- Access to *System registers*, including the debug registers, that provide system control, and system status information.
- Access to Special-purpose registers such as SPSR_ELx, ELR_ELx, and the equivalent fields of the Process State.
- The cache and TLB maintenance instructions and address translation instructions.
- Barriers and the `CLREX` instruction.
- Architectural hint instructions.

This section describes the general model for accessing this functionality.

Note

- See Fixed values in AArch64 instruction and System register descriptions for information about abbreviations used in the System instruction descriptions.

Principles of the System instruction class encoding describes some general properties of these encodings. System instruction class encoding overview then describes the top-level encoding of these instructions, and the following sections then describe the next level of the encoding hierarchy of System instructions and Special-purpose registers:

- op0 == `0b00`, architectural hints, barriers and CLREX, and PSTATE access.
- op0 == `0b01`, cache maintenance, TLB maintenance, address translation and prediction restriction instructions.
- op0 == `0b11`, Moves to and from Special-purpose registers.

For the description of the next level of encoding hierarchy of System registers, see:

- Moves to and from debug and trace System registers.
- Moves to and from non-debug System registers, Special-purpose registers.
- Reserved encodings for IMPLEMENTATION DEFINED registers.

C5.1.1 Principles of the System instruction class encoding

An encoding in the System instruction space is identified by a set of arguments,{`op0`, `op1`, `CRn`, `CRm`, `op2`}. These form an encoding hierarchy, where:

`op0` Defines the top-level division of the encoding space, see System instruction class encoding overview.

`op1` Identifies the lowest Exception level at which the encoding is accessible, as follows:

Accessible at EL0 `op1` has the value `0b011`.

Accessible at EL1 `op1` has the value 0, 1, or 2..

Accessible at Secure EL1 `op1` has the value `0b111`.

Accessible at EL2 `op1` has the value `0b100`.

Arm strongly recommends that implementers adopt this use of `op1` when using the IMPLEMENTATION DEFINED regions of the encoding space described in Reserved encodings for IMPLEMENTATION DEFINED registers.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

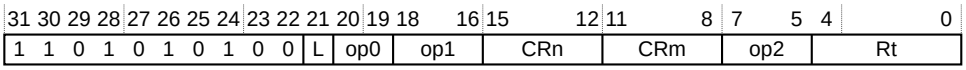
C5.1.2 System instruction class encoding overview

The encoding of the System instruction class describes each instruction as being either:

- A transfer to a System register. This is a System instruction with the semantics of a write.
- A transfer from a System register. This is a System instruction with the semantics of a read.

A System instruction that initiates an operation operates as if it was making a transfer to a register.

In the AArch64 instruction set, the decode structure for the System instruction class is:



The value of `L` indicates the transfer direction:

0 Transfer to System register.

1 Transfer from System register.

The `op0` field is the top-level encoding of the System instruction type. Its possible values are:

`0b00` These encodings provide:

- Instructions with an immediate field for accessing PSTATE, the current PE state.
- The architectural hint instructions.
- Barriers and the `CLREX` instruction.

For more information about these encodings, see op0 == `0b00`, architectural hints, barriers and CLREX, and PSTATE access.

`0b01` These encodings provide:

- Cache maintenance instructions.
- TLB maintenance instructions.
- Address translation instructions.
- Prediction restriction instructions.

For more information, see op0 == `0b01`, cache maintenance, TLB maintenance, address translation and prediction restriction instructions.

`0b10` These encodings provide moves to and from:

- Debug and trace registers.

For more information, see Moves to and from debug and trace System registers.

`0b11` These encodings provide:

- Moves to and from Non-debug System registers. The accessed registers provide system control, and system status information.
- Access to Special-purpose registers.

For more information, see Instructions for accessing Special-purpose registers and Instructions for accessing non-debug System registers.

C5.1.2.1 UNDEFINED behaviors

In the System register instruction encoding space, the following principles apply:

- All unallocated encodings are treated as UNDEFINED.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- All encodings with `L` == 1 and `op0` == `0b0x` are UNDEFINED, except for encodings in the area reserved for IMPLEMENTATION DEFINED use, see Reserved encoding space for IMPLEMENTATION DEFINED instructions.

For registers and operations that are accessible from a particular Exception level, any attempt to access those registers from a lower Exception level is UNDEFINED.

If a particular Exception level:

- Defines a register to be RO, then any attempt to write to that register, at that Exception level, is UNDEFINED. This means that any access to that register with `L` == 0 is UNDEFINED.
- Defines a register to be WO, then any attempt to read from that register, at that Exception level, is UNDEFINED. This means that any access to that register with `L` == 1 is UNDEFINED.

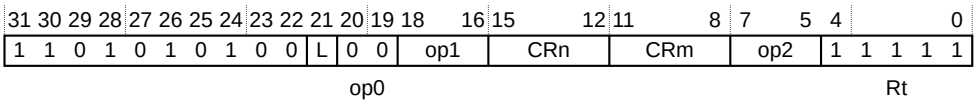
For IMPLEMENTATION DEFINED encoding spaces, the treatment of the encodings is IMPLEMENTATION DEFINED, but see the recommendation in Principles of the System instruction class encoding.

C5.1.3 `op0`== `0b00`, architectural hints, barriers and `CLREX`, and PSTATE access

The different groups of System register instructions with `op0`== `0b00`:

- Are identified by the value of `CRn`.
- Are always encoded with a value of `0b11111` in the `Rt` field.

The encoding of these instructions is:



The encoding of the `CRn` field is as follows:

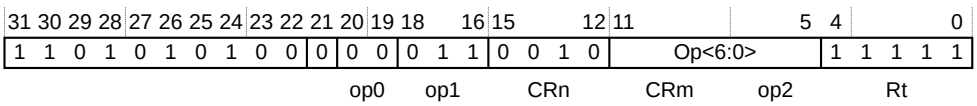
`0b0010` See Architectural hint instructions.

`0b0011` See Barriers and CLREX.

`0b0100` See Instructions for accessing the PSTATE fields.

C5.1.3.1 Architectural hint instructions

Within the `op0==0b00` encodings, the architectural hint instructions are identified by `CRn` having the value `0b0010`. The encoding of these instructions is:



The value of `op<6:0>`, formed by concatenating the `CRm` and `op2` fields, determines the hint instruction as follows:

`0b0000000` `NOP` instruction.

`0b0000001` `YIELD` instruction.

`0b0000010` `WFE` instruction.

`0b0000011` `WFI` instruction.

`0b0000100` `SEV` instruction.

`0b0000101` `SEVL` instruction.

0b0001110 AUTIB, AUTIB1716, AUTIBSP, AUTIBZ, AUTIZB instruction, AUTIB1716 variant.

0b0010000 ESB instruction.

0b0010001

: TSB instruction.

0b0010100 CSDB instruction.

0b0011000 PACIA, PACIA1716, PACIASP, PACIAZ, PACIZA instruction, PACIAZ variant.

0b0011001 PACIA, PACIA1716, PACIASP, PACIAZ, PACIZA instruction, PACIASP variant.

0b0011010 PACIB, PACIB1716, PACIBSP, PACIBZ, PACIZB instruction, PACIBZ variant.

0b0011011 PACIB, PACIB1716, PACIBSP, PACIBZ, PACIZB instruction, PACIBSP variant.

0b0011100 AUTIA, AUTIA1716, AUTIASP, AUTIAZ, AUTIZA instruction, AUTIAZ variant.

0b0011101 AUTIA, AUTIA1716, AUTIASP, AUTIAZ, AUTIZA instruction, AUTIASP variant.

0b0011110 AUTIB, AUTIB1716, AUTIBSP, AUTIBZ, AUTIZB instruction, AUTIBZ variant.

0b0011111 AUTIB, AUTIB1716, AUTIBSP, AUTIBZ, AUTIZB instruction, AUTIBSP variant.

These instructions are described in A64 Base Instruction Descriptions.

Note

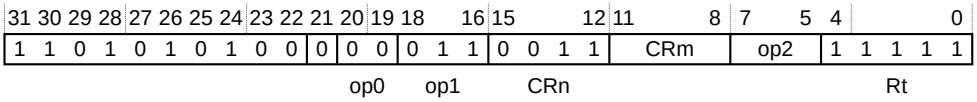
Instruction encodings with bits[4:0] not set to 0b11111 are UNDEFINED.

For more information about:

- The WFE, WFI, SEV, and SEVL instructions, see Mechanisms for entering a low-power state.
- The YIELD instruction, see Software control features and EL0.

C5.1.3.2 Barriers and CLREX

Within the op0==0b00 encodings, the barriers and CLREX instructions are identified by CRn having the value 0b0011. The encoding of these instructions is:



The value of op2 determines the instruction, as follows.

0b001 DSB instruction, Memory nXS barrier variant.

0b010 CLREX instruction.

0b100 DSB instruction, Memory barrier variant.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

`0b101` `DMB` instruction.

`0b110` `ISB` instruction.

`0b111` `SB` instruction.

`0b000`; `0b011` UNDEFINED.

These instructions are described in A64 Base Instruction Descriptions.

Note

- Instruction encodings with bits[4:0] not set to `0b11111` are UNDEFINED.

For more information about:

- The barrier instructions, see Memory barriers.
- The `CLREX` instruction, see Synchronization and semaphores.

C5.1.3.3 Instructions for accessing the PSTATE fields

Within the `op0==0b00` encodings, the instructions that can be used to modify PSTATE fields directly are identified by `CRn` having the value `0b0100`. The encoding of these instructions is shown in Figure C5-1 and Figure C5-2:

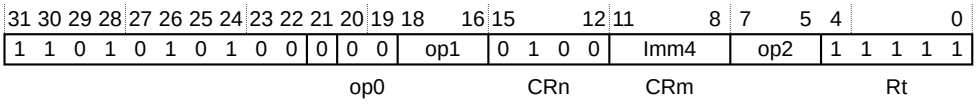


Figure C5-1 Instructions using `#Imm4`

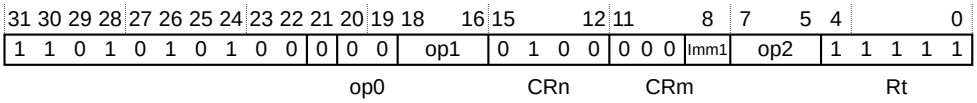

Figure C5-2 Instructions using `#Imm1`

These instructions are:

```
CFINV                ; Inverts the value of PSTATE.C
MSR DAIFSet, #Imm4   ; Used to set any or all of DAIF to 1
MSR DAIFClr, #Imm4   ; Used to clear any or all of DAIF to 0
MSR SPSel, #Imm4     ; Used to select the Stack Pointer, between SP_EL0 and SP_ELx
MSR UAO, #Imm4       ; Used to set the value of PSTATE.UAO
MSR PAN, #Imm4       ; Used to set the value of PSTATE.PAN
MSR DIT, #Imm4       ; Used to set the value of PSTATE.DIT
MSR SSBS, #Imm4      ; Used to set the value of PSTATE.SSBS
```

The value of `op2` selects the instruction form, which defines the constraints on the values of the `op1` and `Imm4` or `Imm1` arguments, as follows:

`op2` == `0b000` Selects the `CFINV` instruction.

`op2` == `0b011` Selects the `MSR UAO` instruction.

`op2` == `0b100` Selects the `MSR PAN` instruction.

`op2` == `0b101` Selects the `MSR SPSel` instruction.

`op2` == `0b001` Selects the `MSR SSBS` instruction.

`op2` == `0b010` Selects the `MSR DIT` instruction.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

`op2` == `0b100` Reserved.

`op2` == `0b110` Selects the `MSR DAIFSet` instruction, that sets the specified PSTATE.{D, A, I, F} bits to 1.

`op2` == `0b111` Selects the `MSR DAIFClr` instruction, that clears the specified PSTATE.{D, A, I, F} bits to 0.

`op2` == `0b000` Reserved.

All other combinations of `op1` and `op2` are reserved, and the corresponding instructions are UNDEFINED.

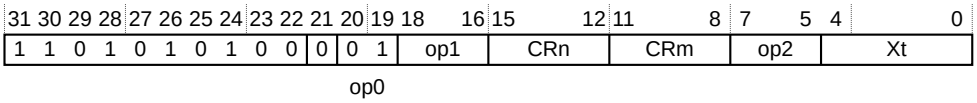
Note

For PSTATE updates, instruction encodings with bits[4:0] not set to `0b11111` are UNDEFINED.

Writes to PSTATE occur in program order without the need for additional synchronization. Changing PSTATE.SP to use SP_EL0 synchronizes any updates to SP_EL0 that have been written by an `MSR` to SP_EL0, without the need for additional synchronization.

C5.1.4 `op0`== `0b01`, cache maintenance, TLB maintenance, address translation and prediction restriction instructions

The System instructions are encoded with `op0`== `0b01`. The different groups of System instructions are identified by the values of `CRn` and `CRm`, except that some of this encoding space is reserved for IMPLEMENTATION DEFINED functionality. The encoding of these instructions is:



The grouping of these instructions depending on the `CRn` and `CRm` fields is as follows:

`CRn` == `0b0111` The instruction group is determined by the value of `CRm`, as follows:

`CRm` == {`0b0001`, `0b0101`} Instruction cache maintenance instructions.

See Cache maintenance instructions, and data cache zero operations.

`CRm` == `0b0011` Prediction restriction instructions.

See Prediction restriction instructions.

`CRm` == `0b0100` Data cache zero operations.

See Cache maintenance instructions, and data cache zero operations.

`CRm` == {`0b0110`, `0b1010`, `0b1011`, `0b1100`, `0b1101`, `0b1110`} Data cache maintenance instructions.

See Cache maintenance instructions, and data cache zero operations.

`CRm` == `0b1000` See Address translation instructions.

`CRn` == {`0b1000`, `0b1001`} See TLB maintenance instructions.

`CRn` == {`0b1011`, `0b1111`} See Reserved encoding space for IMPLEMENTATION DEFINED instructions.

C5.1.4.1 Cache maintenance instructions, and data cache zero operations

Table C5-1 lists the Cache maintenance instructions and their encodings. Instructions that take an argument include `Xt` in the instruction syntax. For instructions that do not take an argument, the Xt field is encoded as `0b11111`. For these instructions, if the Xt field is not set to `0b11111`, it is CONSTRAINED UNPREDICTABLE whether:

- The instruction is UNDEFINED.
- The instruction behaves as if the Xt field is set to `0b11111`.

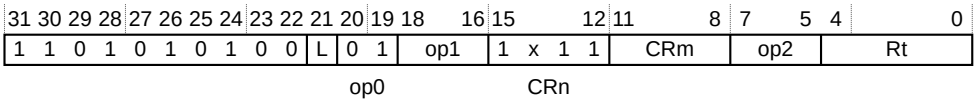
For more information about these instructions, see TLB maintenance instructions.

C5.1.4.4 Reserved encoding space for IMPLEMENTATION DEFINED instructions

The A64 instruction set reserves the following encoding space for IMPLEMENTATION DEFINED instructions:



The value of `L` defines the use of `Rt` as follows:

0 `Rt` is an argument supplied to the instruction.

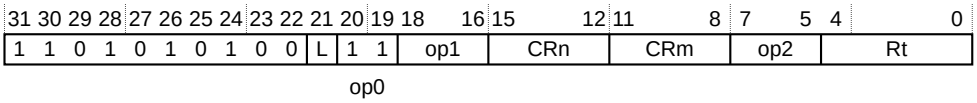
1 `Rt` is a result returned by the instruction.

IMPLEMENTATION DEFINED instructions in this encoding space are accessed using the `SYS` and `SYSL`.

See also Reserved encodings for IMPLEMENTATION DEFINED registers.

C5.1.5 `op0`== `0b11`, Moves to and from Special-purpose registers

The instructions that move data to and from non-debug System registers are encoded with `op0`== `0b11`, except that some of this encoding space is reserved for IMPLEMENTATION DEFINED functionality. The encoding of these instructions is:



C5.1.5.1 Instructions for accessing Special-purpose registers

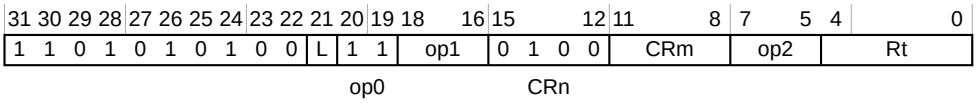
The value of `CRn` provides the next level of decode of these instructions. For Special-purpose registers, the value of CRn is 4.

The A64 instructions for accessing Special-purpose registers are:

```
MSR <Special-purpose_register>, Xt    ; Write to Special-purpose register
MRS Xt, <Special-purpose_register>    ; Read from Special-purpose register
```

Where `<Special-purpose_register>` is the register name, for example SP_EL0.

For these accesses, `CRn` has the value `0b0100`. The encoding for Special-purpose register accesses is:



Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The full list of Special-purpose registers is in Table C5-4. The characteristic of a Special-purpose register is that all direct and indirect reads and writes to the register appear to occur in program order relative to other instructions, without the need for any explicit synchronization.

Table C5-4 lists the encodings for `op1`, `CRm`, and `op2` fields for accesses to the Special-purpose registers in AArch64.

Table C5-4 Instruction encodings for Special-purpose register accesses

C5.2 Special-purpose registers

This section describes the following Special-purpose registers:

- CurrentEL, that holds PSTATE.EL, and that software can read to determine the current Exception level.
- DAIF, that holds the current PSTATE.{D, A, I, F} interrupt mask bits.
- DIT, that holds the PSTATE.DIT bit.
- ELR_EL1, that holds the address to return to for an exception return from EL1.
- ELR_EL2, that holds the address to return to for an exception return from EL2.
- FPCR, that provides control of floating-point operation.
- FPSR, that provides floating-point status information.
- NZCV, that holds the PSTATE.{N, Z, C, V} condition flags.
- PAN, that holds the PSTATE.PAN state bit.
- SP_EL0, that holds the stack pointer for EL0.
- SP_EL1, that holds the stack pointer for EL1.
- SP_EL2, that holds the stack pointer for EL2.
- SPSel, that holds PSTATE.SP, that at EL1 or higher selects the current SP.
- SPSR_EL1, that holds process state on taking an exception to AArch64 EL1.
- SPSR_EL2, that holds process state on taking an exception to AArch64 EL2.
- SSBS, that holds the PSTATE.SSBS bit.
- UAO, that holds the PSTATE.UAO bit.

The following registers are also Special-purpose registers:

- DLR_EL0, that holds the address to return to for a return from Debug state.
- DSPSR_EL0, that holds process state on entry to Debug state.

C5.2.1 CurrentEL, Current Exception Level

The CurrentEL characteristics are:

Purpose

Holds the current Exception level.

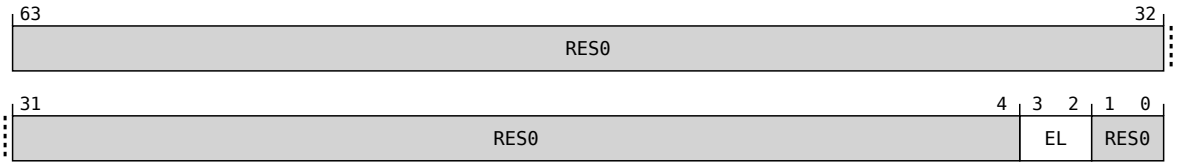
Configuration

There are no configuration notes.

Attributes

CurrentEL is a 64-bit register.

Field descriptions



Bits [63:4]

Reserved, RES0.

EL, bits [3:2]

Current Exception level.

EL	Meaning
0b00	EL0.
0b01	EL1.
0b10	EL2.
0b11	EL3.

When the Effective value of HCR_EL2.NV is 1, EL1 read accesses to the CurrentEL register return the value of 0b10 in this field.

The reset behavior of this field is:

- On a Warm reset, this field resets to '10'.

Bits [1:0]

Reserved, RES0.

Accessing CurrentEL

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, CurrentEL

op0	op1	CRn	CRm	op2
0b11	0b000	0b0100	0b0010	0b010

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

```
if PSTATE.EL == EL0 then
    UNDEFINED;
elsif PSTATE.EL == EL1 then
    X[t, 64] = Zeros(60):PSTATE.EL:Zeros(2);
elsif PSTATE.EL == EL2 then
    X[t, 64] = Zeros(60):PSTATE.EL:Zeros(2);
```

Non-Confidential

C5.2.2 DAIF, Interrupt Mask Bits

The DAIF characteristics are:

Purpose

Allows access to the interrupt mask bits.

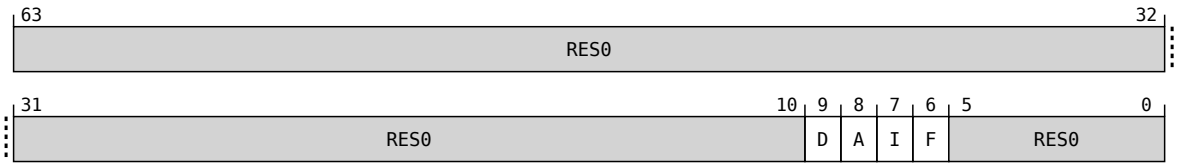
Configuration

There are no configuration notes.

Attributes

DAIF is a 64-bit register.

Field descriptions



Bits [63:10]

Reserved, RES0.

D, bit [9]

Process state D mask.

D	Meaning
0b0	Watchpoint, Breakpoint, and Software Step exceptions targeted at the current Exception level are not masked.
0b1	Watchpoint, Breakpoint, and Software Step exceptions targeted at the current Exception level are masked.

When the target Exception level of the debug exception is higher than the current Exception level, the exception is not masked by this bit.

The reset behavior of this field is:

- On a Warm reset, this field resets to '1'.

A, bit [8]

SError exception mask bit.

A	Meaning
0b0	Exception not masked.
0b1	Exception masked.

The reset behavior of this field is:

- On a Warm reset, this field resets to '1'.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I, bit [7]

IRQ mask bit.

I	Meaning
0b0	Exception not masked.
0b1	Exception masked.

The reset behavior of this field is:

- On a Warm reset, this field resets to '1'.

F, bit [6]

FIQ mask bit.

F	Meaning
0b0	Exception not masked.
0b1	Exception masked.

The reset behavior of this field is:

- On a Warm reset, this field resets to '1'.

Bits [5:0]

Reserved, RES0.

Accessing DAIF

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, DAIF

op0	op1	CRn	CRm	op2
0b11	0b011	0b0100	0b0010	0b001

```
if PSTATE.EL == EL0 then

C5.2.3 DIT, Data Independent Timing

The DIT characteristics are:

Purpose

Allows access to the Data Independent Timing bit.

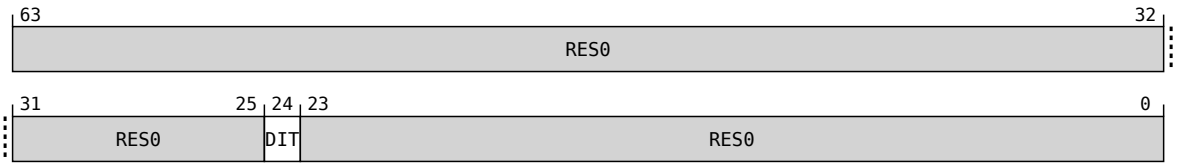
Configuration

This register is present only when FEAT_DIT is implemented. Otherwise, direct accesses to DIT are UNDEFINED.

Attributes

DIT is a 64-bit register.

Field descriptions



Bits [63:25]

Reserved, RES0.

DIT, bit [24]

Data Independent Timing.

DIT	Meaning
0b0	The architecture makes no statement about the timing properties of any instructions.
0b1	The architecture requires that the execution time of a data-independent-time sequence of code must be independent of all data-independent-time values. For more information, see About PSTATE.DIT.

The list of data-independent-time instructions is:

- Flag Manipulation: CFINV.
- Data Processing – Immediate:
  - Add/subtract (immediate): ADD, ADDS, SUB, and SUBS.
  - Bitfield: BFM, SBFM, and UBFM.
  - Extract: EXTR.
  - Logical (immediate): AND, ANDS, EOR, and ORR.
  - Min/max (immediate): SMAX, SMIN, UMAX, and UMIN.
- Data Processing – Register:
  - Add/subtract (extended register): ADD, ADDS, SUB, and SUBS.
  - Add/subtract (shifted register): ADD, ADDS, SUB, and SUBS.
  - Add/subtract (with carry): ADC, ADCS, SBC, and SBCS.
  - Conditional compare (immediate): CCMN, and CCMP.
  - Conditional compare (register): CCMN, and CCMP.
  - Conditional select: CSEL, CSINC, CSINV, and CSNEG.
  - Data-processing (1 source): ABS, CLS, CLZ, CNT, CTZ, RBIT, REV16, REV32, and REV.
  - Data-processing (2 source): ASRV, CRC32B, CRC32CB, CRC32CH, CRC32CW, CRC32CX, CRC32H, CRC32W, CRC32X, LSLV, LSRV, RORV, SMAX, SMIN, UMAX, and UMIN.
  - Data-processing (3 source): MADD, MSUB, SMADDL, SMSUBL, SMULH, UMADDL, UMSUBL, and UMULH.
  - Evaluate into flags: SETF16, and SETF8.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

  - Logical (shifted register): AND, ANDS, BIC, BICS, EON, EOR, ORN, and ORR.
  - Rotate right into flags: RMIF.
- Data Processing – Scalar Floating-Point and Advanced SIMD:
  - Advanced SIMD across lanes: ADDV, SADDLV, SMAXV, SMINV, UADDLV, UMAXV, and UMINV.
  - Advanced SIMD copy: DUP, INS, SMOV, and UMOV.
  - Advanced SIMD extract: EXT.
  - Advanced SIMD modified immediate: BIC, and ORR.
  - Advanced SIMD permute: TRN1, TRN2, UZP1, UZP2, ZIP1, and ZIP2.
  - Advanced SIMD scalar copy: DUP.
  - Advanced SIMD scalar pairwise: ADDP.
  - Advanced SIMD scalar shift by immediate: Advanced SIMD scalar shift by immediate: SHL, SLI, SRSHR, SRI, SRSRA, SSHR, SSRA, URSHR, URSRA, USHR, and USRA.
  - Advanced SIMD scalar three same: ADD, CMEQ, CMGE, CMGT, CMHI, CMHS, CMTST, SQDMULH, SQRDMULH, SSHL, SUB, and USHL.
  - Advanced SIMD scalar three same extra: SQRDMLAH.
  - Advanced SIMD scalar two-register miscellaneous: ABS, CMEQ, CMGE, CMGT, CMLE, CMLT, and NEG.
  - Advanced SIMD scalar x indexed element: SQDMULH, SQRDMLAH, and SQRDMULH.
  - Advanced SIMD shift by immediate: RSHRN2, RSHRN, SHL, SHRN2, SHRN, SLI, SRI, SSHLL2, SSHLL, SSHR, SSRA, USHLL2, USHLL, USHR, and USRA.
  - Advanced SIMD table lookup: LUTI2, LUTI4, TBL, and TBX.
  - Advanced SIMD three different: ADDHN2, ADDHN, PMULL2, PMULL, RADDHN2, RADDHN, RSUBHN2, RSUBHN, SABAL2, SABAL, SABDL2, SABDL, SADDL2, SADDL, SADDW2, SADDW, SMLAL2, SMLAL, SMLSL2, SMLSL, SMULL2, SMULL, SSUBL2, SSUBL, SSUBW2, SSUBW, SUBHN2, SUBHN, UABAL2, UABAL, UABDL2, UABDL, UADDL2, UADDL, UADDW2, UADDW, UMLAL2, UMLAL, UMLSL2, UMLSL, UMULL2, UMULL, USUBL2, USUBL, USUBW2, and USUBW.
  - Advanced SIMD three same: ADD, ADDP, AND, BIC, BIF, BIT, BSL, CMEQ, CMGE, CMGT, CMHI, CMHS, CMTST, EOR, MLA, MLS, MUL, ORN, ORR, PMUL, SABA, SABD, SHADD, SHSUB, SMAX, SMAXP, SMIN, SMINP, SQDMULH, SQRDMULH, SSHL, SUB, UABA, UABD, UHADD, UHSUB, UMAX, UMAXP, UMIN, UMINP, and USHL.
  - Advanced SIMD three-register extension: SDOT, SMMLA, SQRDMLAH, UDOT, UMMLA, USDOT, and USMMLA.
  - Advanced SIMD two-register miscellaneous: ABS, CLS, CLZ, CMEQ, CMGE, CMGT, CMLE, CMLT, CNT, NEG, NOT, RBIT, REV16, REV32, REV64, SADALP, SADDLP, SHLL2, SHLL, UADALP, UADDLP, XTN2, and XTN.
  - Advanced SIMD vector x indexed element: MLA, MLS, MUL, SDOT, SMLAL2, SMLAL, SMLSL2, SMLSL, SMULL2, SMULL, SQDMULH, SQRDMLAH, SQRDMULH, SUDOT, UDOT, UMLAL2, UMLAL, UMLSL2, UMLSL, UMULL2, UMULL, and USDOT.
  - Cryptographic AES: AESD, AESE, AESIMC, and AESMC.
  - Cryptographic four-register: BCAX, EOR3, and SM3SS1.
  - Cryptographic three-register SHA: SHA1C, SHA1M, SHA1P, SHA1SU0, SHA256H2, SHA256H, and SHA256SU1.
  - Cryptographic three-register SHA 512: RAX1, SHA512H2, SHA512H, SHA512SU1, SM3PARTW1, SM3PARTW2, and SM4EKEY.
  - Cryptographic three-register, imm2: SM3TT1A, SM3TT1B, SM3TT2A, and SM3TT2B.
  - Cryptographic three-register, imm6: XAR.
  - Cryptographic two-register SHA: SHA1H, SHA1SU1, and SHA256SU0.
  - Cryptographic two-register SHA 512: SHA512SU0, and SM4E.
  - Floating-point conditional select: FCSEL.
- Loads and Stores:
  - 128-bit atomic memory operations: LDCLRP, LDCLRPA, LDCLRPAL, LDCLRPL, LDSETP, LDSETPA, LDSETPAL, LDSETPL, SWPP, SWPPA, SWPPAL, and SWPPL.
  - Advanced SIMD load/store multiple structures: LD1, LD2, LD3, LD4, ST1, ST2, ST3, and ST4.
  - Advanced SIMD load/store multiple structures (post-indexed): LD1, LD2, LD3, LD4, ST1, ST2, ST3, and ST4.
  - Advanced SIMD load/store single structure: LD1, LD1R, LD2, LD2R, LD3, LD3R, LD4, LD4R, LDAP1, ST1, ST2, ST3, ST4, and STL1.
  - Advanced SIMD load/store single structure (post-indexed): LD1, LD1R, LD2, LD2R, LD3, LD3R, LD4, LD4R, ST1, ST2, ST3, and ST4.
  - Atomic memory operations: LDADD, LDADDA, LDADDAB, LDADDAH, LDADDAL, LDADDALB, LDADDALH, LDADDB, LDADDH, LDADDL, LDADDLB, LDADDLH, LDAPR, LDAPRB, LDAPRH, LDCLR, LDCLRA, LDCLRAB, LDCLRAH, LDCLRAL, LDCLRALB, LDCLRALH, LDCLRB, LDCLRH, LDCLRL, LDCLRLB, LDCLRLH, LDEOR, LDEORA, LDEORAB, LDEORAH, LDEORAL, LDEORALB, LDEORALH, LDEORB, LDEORH, LDEORL, LDEORLB, LDEORLH, LDSET, LDSETA, LDSETAB, LDSETAH, LDSETAL, LDSETALB, LDSETALH, LDSETB, LDSETH, LDSETL, LDSETLB, LDSETLH, LDSMAX, LDSMAXA, LDSMAXAB, LDSMAXAH, LDSMAXAL, LDSMAXALB, LDSMAXALH, LDSMAXB, LDSMAXH, LDSMAXL, LDSMAXLB, LDSMAXLH, LDSMIN, LDSMINA, LDSMINAB, LDSMINAH, LDSMINAL, LDSMINALB, LDSMINALH, LDSMINB, LDSMINH, LDSMINL, LDSMINLB, LDSMINLH, LDUMAX, LDUMAXA, LDUMAXAB, LDUMAXAH, LDUMAXAL, LDUMAXALB, LDUMAXALH, LDUMAXB, LDUMAXH, LDUMAXL, LDUMAXLB, LDUMAXLH, LDUMIN, LDUMINA, LDUMINAB, LDUMINAH, LDUMINAL, LDUMINALB, LDUMINALH, LDUMINB, LDUMINH, LDUMINL, LDUMINLB, and LDUMINLH.
  - LDAPR/STLR (SIMD&FP): LDAPUR, and STLUR.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- LDAPR/STLR (unscaled immediate): LDAPUR, LDAPURB, LDAPURH, LDAPURSB, LDAPURSH, LDAPURSW, STLUR, STLURB, and STLURH.
- LDAPR/STLR (writeback): LDAPR, and STLR.
- LDIAPP/STILP: LDIAPP, and STILP.
- Load/store exclusive pair: LDAXP, LDXP, STLXP, and STXP.
- Load/store exclusive register: LDAXR, LDAXRB, LDAXRH, LDXR, LDXRB, LDXRH, STLXR, STLXRB, STLXRH, STXR, STXRB and STXRH.
- Load/store no-allocate pair (offset): LDNP, and STNP.
- Load/store ordered: LDAR, LDARB, LDARH, LDLAR, LDLARB, LDLARH, STLLR, STLLRB, STLLRH, STLR, STLRB, and STLRH.
- Load/store register (immediate post-indexed): LDR, LDRB, LDRH, LDRSB, LDRSH, LDRSW, STR, STRB, and STRH.
- Load/store register (immediate pre-indexed): LDR, LDRB, LDRH, LDRSB, LDRSH, LDRSW, STR, STRB, and STRH.
- Load/store register (pac): LDRAA, and LDRAB.
- Load/store register (register offset): LDR, LDRB, LDRH, LDRSB, LDRSH, LDRSW, STR, STRB, and STRH.
- Load/store register (unprivileged): LDTR, LDTRB, LDTRH, LDTRSB, LDTRSH, LDTRSW, STTR, STTRB, and STTRH.
- Load/store register (unscaled immediate): LDUR, LDURB, LDURH, LDURSB, LDURSH, LDURSW, STUR, STURB, and STURH.
- Load/store register (unsigned immediate): LDR, LDRB, LDRH, LDRSB, LDRSH, LDRSW, STR, STRB, and STRH.
- Load/store register pair (offset): LDP, LDPSW, and STP.
- Load/store register pair (post-indexed): LDP, LDPSW, and STP.
- Load/store register pair (pre-indexed): LDP, LDPSW, and STP.

The reset behavior of this field is:

- On a Warm reset, this field resets to '0'.

Bits [23:0]

Reserved, RES0.

C5.2.4 ELR_EL1, Exception Link Register (EL1)

The ELR_EL1 characteristics are:

Purpose

When taking an exception to EL1, holds the address to return to.

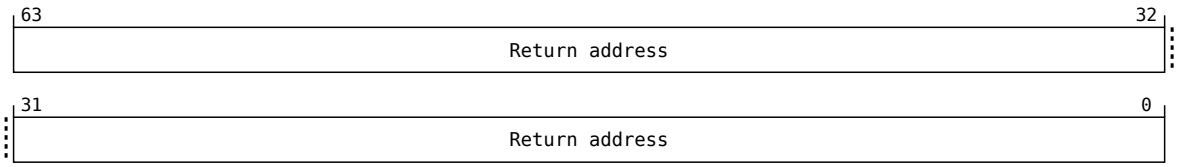
Configuration

There are no configuration notes.

Attributes

ELR_EL1 is a 64-bit register.

Field descriptions



ADDR, bits [63:0]

Return address.

An exception return from EL1 using AArch64 makes ELR_EL1 become UNKNOWN.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing ELR_EL1

Accesses to this register use the following encodings in the System register encoding space:

`MRS <Xt>, ELR_EL1`

op0	op1	CRn	CRm	op2
0b11	0b000	0b0100	0b0000	0b001

```
if PSTATE.EL == EL0 then
    UNDEFINED;
elsif PSTATE.EL == EL1 then
    X[t, 64] = ELR_EL1;
elsif PSTATE.EL == EL2 then
    X[t, 64] = ELR_EL1;
```

C5.2.5 ELR_EL2, Exception Link Register (EL2)

The ELR_EL2 characteristics are:

Purpose

When taking an exception to EL2, holds the address to return to.

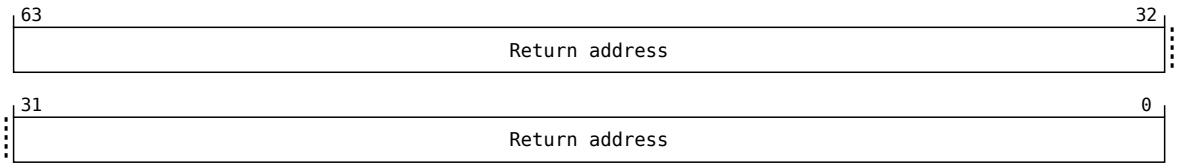
Configuration

There are no configuration notes.

Attributes

ELR_EL2 is a 64-bit register.

Field descriptions



ADDR, bits [63:0]

Return address.

An exception return from EL2 using AArch64 makes ELR_EL2 become UNKNOWN.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing ELR_EL2

Accesses to this register use the following encodings in the System register encoding space:

`MRS <Xt>, ELR_EL2`

op0	op1	CRn	CRm	op2
0b11	0b100	0b0100	0b0000	0b001

```
if PSTATE.EL == EL0 then
    UNDEFINED;

C5.2.6 FPCR, Floating-point Control Register

The FPCR characteristics are:

Purpose

Controls behavior of the floating-point instructions.

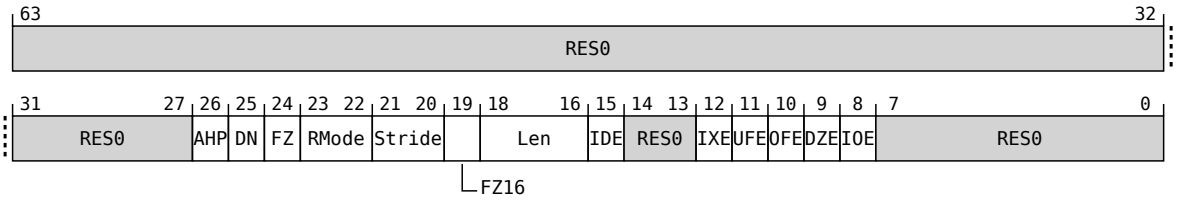
Configuration

There are no configuration notes.

Attributes

FPCR is a 64-bit register.

Field descriptions



Bits [63:27]

Reserved, RES0.

AHP, bit [26]

Alternative half-precision control bit.

AHP	Meaning
0b0	IEEE half-precision format selected.
0b1	Alternative half-precision format selected.

This bit is used only for conversions between half-precision floating-point and other floating-point formats.

The data-processing instructions added as part of the FEAT_FP16 extension always use the IEEE half-precision format, and ignore the value of this bit.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

DN, bit [25]

Default NaN use for NaN propagation.

DN	Meaning
0b0	NaN operands propagate through to the output of a floating-point operation.
0b1	Any operation involving one or more NaNs returns the Default NaN. This bit has no effect on the output of the FABS and FNEG instructions. This bit has no effect on the output of the FMAX, FMAXP, FMAXV, FMIN, FMINP, and FMINV instructions when FPCR.AH is 1.

The reset behavior of this field is:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

FZ, bit [24]

Flushing denormalized numbers to zero control bit.

FZ	Meaning
0b0	Flushing denormalized numbers to zero disabled.
0b1	Flushing denormalized numbers to zero enabled.

For more information, see 'Flushing denormalized numbers to zero' and the pseudocode of the floating-point instructions.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

RMode, bits [23:22]

Rounding Mode control field.

RMode	Meaning
0b00	Round to Nearest (RN) mode.
0b01	Round towards Plus Infinity (RP) mode.
0b10	Round towards Minus Infinity (RM) mode.
0b11	Round towards Zero (RZ) mode.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Stride, bits [21:20]

This field has no function in AArch64 state, and nonzero values are ignored during execution in AArch64 state.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

When an implementation implements FPSCR.LEN,STRIDE as RAZ, access to this field is RAZ/WI.

FZ16, bit [19]

When FEAT_FP16 is implemented:

Flushing denormalized numbers to zero control bit on half-precision data-processing instructions.

FZ16	Meaning
0b0	For some instructions, this bit disables flushing to zero of inputs and outputs that are half-precision denormalized numbers.
0b1	Flushing denormalized numbers to zero enabled.

For more information, see 'Flushing denormalized numbers to zero' and the pseudocode of the floating-point instructions.

The reset behavior of this field is:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Len, bits [18:16]

This field has no function in AArch64 state, and nonzero values are ignored during execution in AArch64 state.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

When an implementation implements FPSCR.LEN,STRIDE as RAZ, access to this field is RAZ/WI.

IDE, bit [15]

Input Denormal floating-point exception trap enable.

IDE	Meaning
0b0	Untrapped exception handling selected. If the floating-point exception occurs, the FPSR.IDC bit is set to 1.
0b1	Trapped exception handling selected. If the floating-point exception occurs, the PE does not update the FPSR.IDC bit.

The value of this bit controls both scalar and vector floating-point arithmetic.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

When an implementation does not implement trapping of Input Denormal floating-point exceptions, access to this field is RAZ/WI.

Bits [14:13]

Reserved, RES0.

IXE, bit [12]

Inexact floating-point exception trap enable.

IXE	Meaning
0b0	Untrapped exception handling selected. If the floating-point exception occurs, the FPSR.IXC bit is set to 1.
0b1	Trapped exception handling selected. If the floating-point exception occurs, the PE does not update the FPSR.IXC bit.

The value of this bit controls both scalar and vector floating-point arithmetic.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

When an implementation does not implement trapping of Inexact floating-point exceptions, access to this field is RAZ/WI.

UFE, bit [11]

Underflow floating-point exception trap enable.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

UFE	Meaning
0b0	Untrapped exception handling selected. If the floating-point exception occurs, the FPSR.UFC bit is set to 1.
0b1	Trapped exception handling selected. If the floating-point exception occurs and Flush-to-zero is not enabled, the PE does not update the FPSR.UFC bit.

The value of this bit controls both scalar and vector floating-point arithmetic.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

When an implementation does not implement trapping of Underflow floating-point exceptions, access to this field is RAZ/WI.

OFE, bit [10]

Overflow floating-point exception trap enable.

OFE	Meaning
0b0	Untrapped exception handling selected. If the floating-point exception occurs, the FPSR.OFC bit is set to 1.
0b1	Trapped exception handling selected. If the floating-point exception occurs, the PE does not update the FPSR.OFC bit.

The value of this bit controls both scalar and vector floating-point arithmetic.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

When an implementation does not implement trapping of Overflow floating-point exceptions, access to this field is RAZ/WI.

DZE, bit [9]

Divide by Zero floating-point exception trap enable.

DZE	Meaning
0b0	Untrapped exception handling selected. If the floating-point exception occurs, the FPSR.DZC bit is set to 1.
0b1	Trapped exception handling selected. If the floating-point exception occurs, the PE does not update the FPSR.DZC bit.

The value of this bit controls both scalar and vector floating-point arithmetic.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

When an implementation does not implement trapping of Divide by Zero floating-point exceptions, access to this field is RAZ/WI.

IOE, bit [8]

Invalid Operation floating-point exception trap enable.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

IOE	Meaning
0b0	Untrapped exception handling selected. If the floating-point exception occurs, the FPSR.IOC bit is set to 1.
0b1	Trapped exception handling selected. If the floating-point exception occurs, the PE does not update the FPSR.IOC bit.

The value of this bit controls both scalar and vector floating-point arithmetic.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

When an implementation does not implement trapping of Invalid Operation floating-point exceptions, access to this field is RAZ/WI.

Bits [7:0]

Reserved, RES0.

Accessing FPCR

Accesses to this register use the following encodings in the System register encoding space:

`MRS <Xt>, FPCR`

op0	op1	CRn	CRm	op2
0b11	0b011	0b0100	0b0100	0b000

C5.2.7 FPSR, Floating-point Status Register

The FPSR characteristics are:

Purpose

Provides floating-point system status information.

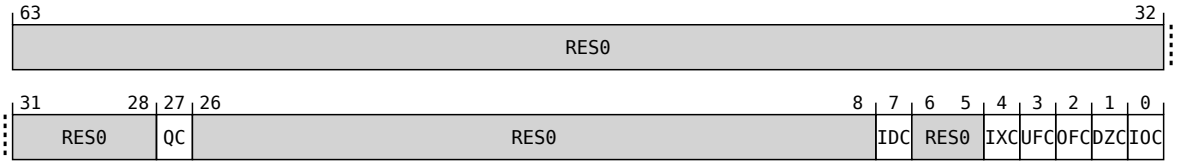
Configuration

There are no configuration notes.

Attributes

FPSR is a 64-bit register.

Field descriptions



Bits [63:28]

Reserved, RES0.

QC, bit [27]

Cumulative saturation bit, Advanced SIMD only. This bit is set to 1 to indicate that an Advanced SIMD integer operation has saturated since 0 was last written to this bit.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [26:8]

Reserved, RES0.

IDC, bit [7]

Input Denormal cumulative floating-point exception bit. This bit is set to 1 to indicate that the Input Denormal floating-point exception has occurred since 0 was last written to this bit.

How scalar and Advanced SIMD floating-point instructions update this bit depends on the value of the FPCR.IDE bit. This bit is set to 1 to indicate a floating-point exception only if FPCR.IDE is 0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [6:5]

Reserved, RES0.

IXC, bit [4]

Inexact cumulative floating-point exception bit. This bit is set to 1 to indicate that the Inexact floating-point exception has occurred since 0 was last written to this bit.

How scalar and Advanced SIMD floating-point instructions update this bit depends on the value of the FPCR.IXE bit. This bit is set to 1 to indicate a floating-point exception only if FPCR.IXE is 0.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The criteria for the Inexact floating-point exception to occur are affected by whether denormalized numbers are flushed to zero and by the value of the FPCR.AH bit. For more information, see 'Floating-point exceptions and exception traps'.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

UFC, bit [3]

Underflow cumulative floating-point exception bit. This bit is set to 1 to indicate that the Underflow floating-point exception has occurred since 0 was last written to this bit.

How scalar and Advanced SIMD floating-point instructions update this bit depends on the value of the FPCR.UFE bit. This bit is set to 1 to indicate a floating-point exception only if FPCR.UFE is 0 or if flushing denormalized numbers to zero is enabled.

The criteria for the Underflow floating-point exception to occur are affected by whether denormalized numbers are flushed to zero and by the value of the FPCR.AH bit. For more information, see 'Floating-point exceptions and exception traps'.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

OFC, bit [2]

Overflow cumulative floating-point exception bit. This bit is set to 1 to indicate that the Overflow floating-point exception has occurred since 0 was last written to this bit.

How scalar and Advanced SIMD floating-point instructions update this bit depends on the value of the FPCR.OFE bit. This bit is set to 1 to indicate a floating-point exception only if FPCR.OFE is 0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

DZC, bit [1]

Divide by Zero cumulative floating-point exception bit. This bit is set to 1 to indicate that the Divide by Zero floating-point exception has occurred since 0 was last written to this bit.

How scalar and Advanced SIMD floating-point instructions update this bit depends on the value of the FPCR.DZE bit. This bit is set to 1 to indicate a floating-point exception only if FPCR.DZE is 0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

IOC, bit [0]

Invalid Operation cumulative floating-point exception bit. This bit is set to 1 to indicate that the Invalid Operation floating-point exception has occurred since 0 was last written to this bit.

How scalar and Advanced SIMD floating-point instructions update this bit depends on the value of the FPCR.IOE bit. This bit is set to 1 to indicate a floating-point exception only if FPCR.IOE is 0.

The criteria for the Invalid Operation floating-point exception to occur are affected by the value of the FPCR.AH bit. For more information, see 'Floating-point exceptions and exception traps'.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

C5.2.8 NZCV, Condition Flags

The NZCV characteristics are:

Purpose

Allows access to the condition flags.

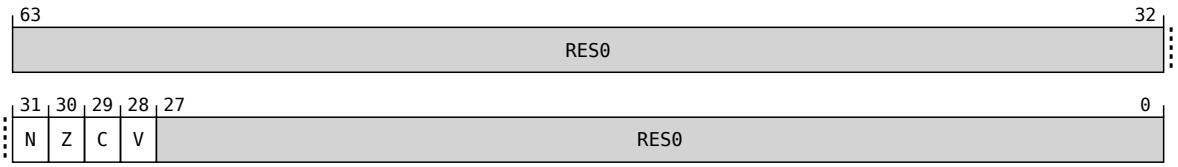
Configuration

There are no configuration notes.

Attributes

NZCV is a 64-bit register.

Field descriptions



Bits [63:32]

Reserved, RES0.

N, bit [31]

Negative condition flag. Set to 1 if the result of the last flag-setting instruction was negative.

Z, bit [30]

Zero condition flag. Set to 1 if the result of the last flag-setting instruction was zero, and to 0 otherwise. A result of zero often indicates an equal result from a comparison.

C, bit [29]

Carry condition flag. Set to 1 if the last flag-setting instruction resulted in a carry condition, for example an unsigned overflow on an addition.

V, bit [28]

Overflow condition flag. Set to 1 if the last flag-setting instruction resulted in an overflow condition, for example a signed overflow on an addition.

Bits [27:0]

Reserved, RES0.

Accessing NZCV

Accesses to this register use the following encodings in the System register encoding space:

```
MRS <Xt>, NZCV
```

op0	op1	CRn	CRm	op2
0b11	0b011	0b0100	0b0010	0b000

C5.2.9 PAN, Privileged Access Never

The PAN characteristics are:

Purpose

Allows access to the Privileged Access Never bit.

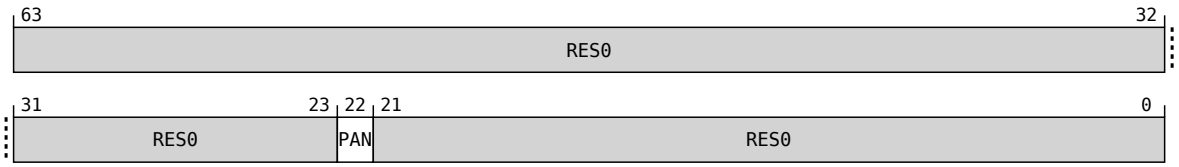
Configuration

This register is present only when FEAT_PAN is implemented. Otherwise, direct accesses to PAN are UNDEFINED.

Attributes

PAN is a 64-bit register.

Field descriptions



Bits [63:23]

Reserved, RES0.

PAN, bit [22]

Privileged Access Never.

PAN	Meaning
0b0	Privileged reads and write are not disabled by this mechanism.
0b1	Disables privileged read and write accesses to addresses accessible at EL0 for an enabled stage 1 translation regime that defines the EL0 permissions.

When the target of the exception is EL1 and the value of the SCTLR_EL1.SPAN bit is 0, this bit is set to 1. Otherwise, the value of this bit is preserved on taking an exception.

Bits [21:0]

Reserved, RES0.

Accessing PAN

Accesses to this register use the following encodings in the System register encoding space:

```
MRS <Xt>, PAN
```

op0	op1	CRn	CRm	op2
0b11	0b000	0b0100	0b0010	0b011

C5.2.10 SP_EL0, Stack Pointer (EL0)

The SP_EL0 characteristics are:

Purpose

Holds the stack pointer associated with EL0. At higher Exception levels, this is used as the current stack pointer when the value of SPSel.SP is 0.

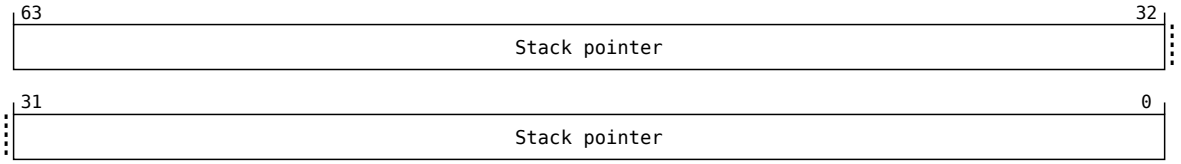
Configuration

There are no configuration notes.

Attributes

SP_EL0 is a 64-bit register.

Field descriptions



StackPointer, bits [63:0]

Stack pointer.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing SP_EL0

When the value of PSTATE.SP is 0, this register is accessible at all Exception levels as the current stack pointer.

Accesses to this register use the following encodings in the System register encoding space:

`MRS <Xt>, SP_EL0`

op0	op1	CRn	CRm	op2
0b11	0b000	0b0100	0b0001	0b000

```
if PSTATE.EL == EL0 then

C5.2.11 SP_EL1, Stack Pointer (EL1)

The SP_EL1 characteristics are:

Purpose

Holds the stack pointer associated with EL1. The value of SPSel.SP determines the current stack pointer.

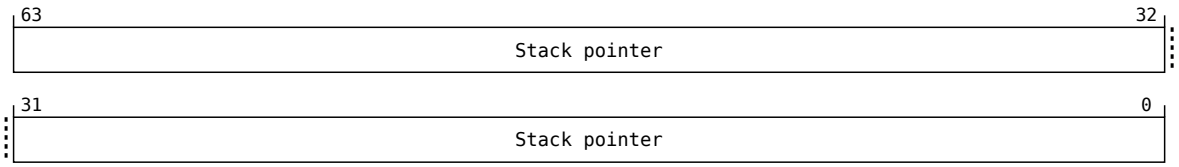
Configuration

There are no configuration notes.

Attributes

SP_EL1 is a 64-bit register.

Field descriptions



StackPointer, bits [63:0]

Stack pointer.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing SP_EL1

This accessibility information only applies to accesses using the MRS or MSR instructions.

When the value of SPSel.SP is 1, this register is also accessible at EL1 as the current stack pointer.

Note

When the value of SPSel.SP is 0, SP_EL0 is used as the current stack pointer at all Exception levels.

Accesses to this register use the following encodings in the System register encoding space:

`MRS <Xt>, SP_EL1`

op0	op1	CRn	CRm	op2
0b11	0b100	0b0100	0b0001	0b000

```
if PSTATE.EL == EL0 then

C5.2.12 SP_EL2, Stack Pointer (EL2)

The SP_EL2 characteristics are:

Purpose

Holds the stack pointer associated with EL2. The value of SPSel.SP determines the current stack pointer.

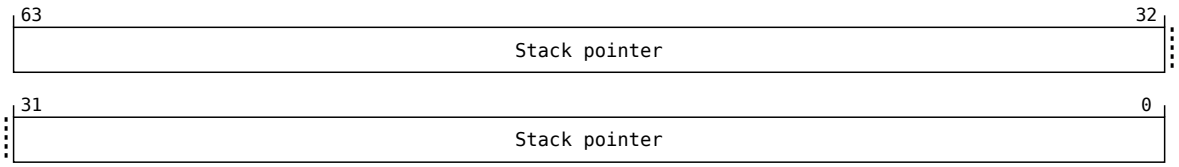
Configuration

There are no configuration notes.

Attributes

SP_EL2 is a 64-bit register.

Field descriptions



StackPointer, bits [63:0]

Stack pointer.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing SP_EL2

This accessibility information only applies to accesses using the MRS or MSR instructions.

When the value of SPSel.SP is 1, this register is also accessible at EL2 as the current stack pointer.

Note

When the value of SPSel.SP is 0, SP_EL0 is used as the current stack pointer at all Exception levels.

This system instruction encoding is Undefined()

Accesses to this register use the following encodings in the System register encoding space:

```
MRS <Xt>, SP_EL2
```

op0	op1	CRn	CRm	op2
0b11	0b110	0b0100	0b0001	0b000

C5.2.13 SPSel, Stack Pointer Select

The SPSel characteristics are:

Purpose

Allows the Stack Pointer to be selected between SP_EL0 and SP_ELx.

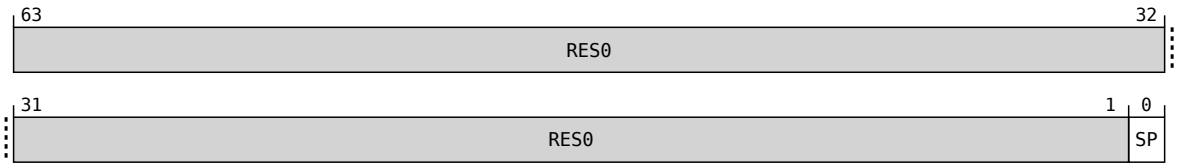
Configuration

There are no configuration notes.

Attributes

SPSel is a 64-bit register.

Field descriptions



Bits [63:1]

Reserved, RES0.

SP, bit [0]

Stack pointer to use. Possible values of this bit are:

SP	Meaning
0b0	Use SP_EL0 at all Exception levels.
0b1	Use SP_ELx for Exception level ELx.

The reset behavior of this field is:

- On a Warm reset, this field resets to '1'.

Accessing SPSel

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, SPSel

op0	op1	CRn	CRm	op2

C5.2.14 SPSR_EL1, Saved Program Status Register (EL1)

The SPSR_EL1 characteristics are:

Purpose

Holds the saved process state when an exception is taken to EL1.

Configuration

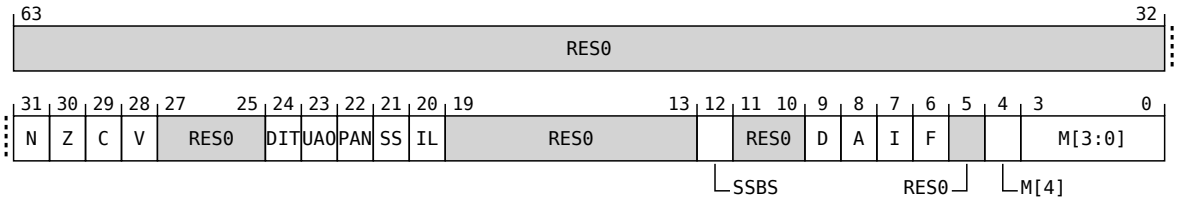
There are no configuration notes.

Attributes

SPSR_EL1 is a 64-bit register.

Field descriptions

When exception taken from AArch64 state:



An exception return from EL1 using AArch64 makes SPSR_EL1 become UNKNOWN.

Bits [63:32]

Reserved, RES0.

N, bit [31]

Negative Condition flag. Set to the value of PSTATE.N on taking an exception to EL1, and copied to PSTATE.N on executing an exception return operation in EL1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Z, bit [30]

Zero Condition flag. Set to the value of PSTATE.Z on taking an exception to EL1, and copied to PSTATE.Z on executing an exception return operation in EL1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

C, bit [29]

Carry Condition flag. Set to the value of PSTATE.C on taking an exception to EL1, and copied to PSTATE.C on executing an exception return operation in EL1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

V, bit [28]

Overflow Condition flag. Set to the value of PSTATE.V on taking an exception to EL1, and copied to PSTATE.V on executing an exception return operation in EL1.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [27:25]

Reserved, RES0.

DIT, bit [24]

When FEAT_DIT is implemented:

Data Independent Timing. Set to the value of PSTATE.DIT on taking an exception to EL1, and copied to PSTATE.DIT on executing an exception return operation in EL1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

UAO, bit [23]

When FEAT_UAO is implemented:

User Access Override. Set to the value of PSTATE.UAO on taking an exception to EL1, and copied to PSTATE.UAO on executing an exception return operation in EL1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

PAN, bit [22]

When FEAT_PAN is implemented:

Privileged Access Never. Set to the value of PSTATE.PAN on taking an exception to EL1, and copied to PSTATE.PAN on executing an exception return operation in EL1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

SS, bit [21]

Software Step. Set to the value of PSTATE.SS on taking an exception to EL1, and conditionally copied to PSTATE.SS on executing an exception return operation in EL1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

IL, bit [20]

Illegal Execution state. Set to the value of PSTATE.IL on taking an exception to EL1, and copied to PSTATE.IL on executing an exception return operation in EL1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Bits [19:13]

Reserved, RES0.

SSBS, bit [12]

When FEAT_SSBS is implemented:

Speculative Store Bypass. Set to the value of PSTATE.SSBS on taking an exception to EL1, and copied to PSTATE.SSBS on executing an exception return operation in EL1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bits [11:10]

Reserved, RES0.

D, bit [9]

Debug exception mask. Set to the value of PSTATE.D on taking an exception to EL1, and copied to PSTATE.D on executing an exception return operation in EL1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

A, bit [8]

SError exception mask. Set to the value of PSTATE.A on taking an exception to EL1, and copied to PSTATE.A on executing an exception return operation in EL1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

I, bit [7]

IRQ interrupt mask. Set to the value of PSTATE.I on taking an exception to EL1, and copied to PSTATE.I on executing an exception return operation in EL1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

F, bit [6]

FIQ interrupt mask. Set to the value of PSTATE.F on taking an exception to EL1, and copied to PSTATE.F on executing an exception return operation in EL1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [5]

Reserved, RES0.

M[4], bit [4]

Execution state. Set to `0b0`, the value of PSTATE.nRW, on taking an exception to EL1 from AArch64 state, and copied to PSTATE.nRW on executing an exception return operation in EL1.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

M[4]	Meaning
0b0	AArch64 execution state.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

M[3:0], bits [3:0]

AArch64 Exception level and selected Stack Pointer.

M[3:0]	Meaning
0b0000	EL0.
0b0100	EL1 with SP_EL0 (EL1t).
0b0101	EL1 with SP_EL1 (EL1h).
0b1000	EL1 with SP_EL0 (EL1t) and either HCR_EL2.{NV, NV1} is {1,0} or HCR_EL2.{NV, NV2} is {1,1}.
0b1001	EL1 with SP_EL1 (EL1h) and either HCR_EL2.{NV, NV1} is {1,0} or HCR_EL2.{NV, NV2} is {1,1}.

Other values are reserved. If SPSR_EL1.M[3:0] has a Reserved value, or a value for an unimplemented Exception level, executing an exception return operation in EL1 is an illegal return event, as described in 'Illegal return events from AArch64 state'.

The bits in this field are interpreted as follows:

- M[3:2]: On an exception to EL1:
  - If the exception is taken from EL0:
    - M[3:2] is set to the value of PSTATE.EL on taking an exception to EL1.
  - If the exception is taken from EL1:
    - If the Effective value of HCR_EL2.{NV, NV1} is not {1,0} and the Effective value of HCR_EL2.{NV, NV2} is not {1,1}, then M[3:2] is set to the value of PSTATE.EL on taking an exception to EL1.
    - If the Effective value of HCR_EL2.{NV, NV1} is {1,0} or if the Effective value of HCR_EL2.{NV, NV2} is {1,1}, then M[3:2] is set to 0b10.
  - M[3:2] is copied to PSTATE.EL on executing a legal exception return operation in EL1.
- M[1] is unused and is 0 for all non-reserved values.
- M[0] is set to the value of PSTATE.SP on taking an exception to EL1 and copied to PSTATE.SP on executing an exception return operation in EL1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing SPSR_EL1

Accesses to this register use the following encodings in the System register encoding space:

```
MRS <Xt>, SPSR_EL1
```

op0	op1	CRn	CRm	op2
0b11	0b000	0b0100	0b0000	0b000

```
if PSTATE.EL == EL0 then
    UNDEFINED;
elsif PSTATE.EL == EL1 then
    X[t, 64] = SPSR_EL1;
elsif PSTATE.EL == EL2 then
    X[t, 64] = SPSR_EL1;
```

C5.2.15 SPSR_EL2, Saved Program Status Register (EL2)

The SPSR_EL2 characteristics are:

Purpose

Holds the saved process state when an exception is taken to EL2.

Configuration

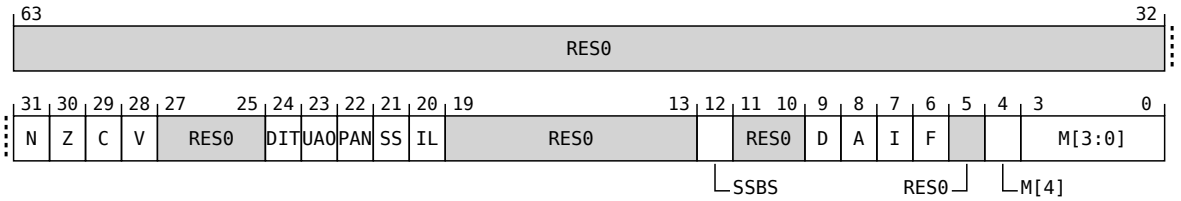
There are no configuration notes.

Attributes

SPSR_EL2 is a 64-bit register.

Field descriptions

When exception taken from AArch64 state:



An exception return from EL2 using AArch64 makes SPSR_EL2 become UNKNOWN.

Bits [63:32]

Reserved, RES0.

N, bit [31]

Negative Condition flag. Set to the value of PSTATE.N on taking an exception to EL2, and copied to PSTATE.N on executing an exception return operation in EL2.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Z, bit [30]

Zero Condition flag. Set to the value of PSTATE.Z on taking an exception to EL2, and copied to PSTATE.Z on executing an exception return operation in EL2.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

C, bit [29]

Carry Condition flag. Set to the value of PSTATE.C on taking an exception to EL2, and copied to PSTATE.C on executing an exception return operation in EL2.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

V, bit [28]

Overflow Condition flag. Set to the value of PSTATE.V on taking an exception to EL2, and copied to PSTATE.V on executing an exception return operation in EL2.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [27:25]

Reserved, RES0.

DIT, bit [24]

When FEAT_DIT is implemented:

Data Independent Timing. Set to the value of PSTATE.DIT on taking an exception to EL2, and copied to PSTATE.DIT on executing an exception return operation in EL2.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

UAO, bit [23]

When FEAT_UAO is implemented:

User Access Override. Set to the value of PSTATE.UAO on taking an exception to EL2, and copied to PSTATE.UAO on executing an exception return operation in EL2.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

PAN, bit [22]

When FEAT_PAN is implemented:

Privileged Access Never. Set to the value of PSTATE.PAN on taking an exception to EL2, and copied to PSTATE.PAN on executing an exception return operation in EL2.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

SS, bit [21]

Software Step. Set to the value of PSTATE.SS on taking an exception to EL2, and conditionally copied to PSTATE.SS on executing an exception return operation in EL2.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

IL, bit [20]

Illegal Execution state. Set to the value of PSTATE.IL on taking an exception to EL2, and copied to PSTATE.IL on executing an exception return operation in EL2.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Bits [19:13]

Reserved, RES0.

SSBS, bit [12]

When FEAT_SSBS is implemented:

Speculative Store Bypass. Set to the value of PSTATE.SSBS on taking an exception to EL2, and copied to PSTATE.SSBS on executing an exception return operation in EL2.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bits [11:10]

Reserved, RES0.

D, bit [9]

Debug exception mask. Set to the value of PSTATE.D on taking an exception to EL2, and copied to PSTATE.D on executing an exception return operation in EL2.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

A, bit [8]

SError exception mask. Set to the value of PSTATE.A on taking an exception to EL2, and copied to PSTATE.A on executing an exception return operation in EL2.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

I, bit [7]

IRQ interrupt mask. Set to the value of PSTATE.I on taking an exception to EL2, and copied to PSTATE.I on executing an exception return operation in EL2.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

F, bit [6]

FIQ interrupt mask. Set to the value of PSTATE.F on taking an exception to EL2, and copied to PSTATE.F on executing an exception return operation in EL2.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [5]

Reserved, RES0.

M[4], bit [4]

Execution state. Set to `0b0`, the value of PSTATE.nRW, on taking an exception to EL2 from AArch64 state, and copied to PSTATE.nRW on executing an exception return operation in EL2.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

M[4]	Meaning
0b0	AArch64 execution state.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

M[3:0], bits [3:0]

AArch64 Exception level and selected Stack Pointer.

M[3:0]	Meaning
0b0000	EL0.
0b0100	EL1 with SP_EL0 (EL1t).
0b0101	EL1 with SP_EL1 (EL1h).
0b1000	EL2 with SP_EL0 (EL2t).
0b1001	EL2 with SP_EL2 (EL2h).

Other values are reserved. If SPSR_EL2.M[3:0] has a Reserved value, or a value for an unimplemented Exception level, executing an exception return operation in EL2 is an illegal return event, as described in 'Illegal return events from AArch64 state'.

The bits in this field are interpreted as follows:

- M[3:2] is set to the value of PSTATE.EL on taking an exception to EL2 and copied to PSTATE.EL on executing an exception return operation in EL2.
- M[1] is unused and is 0 for all non-reserved values.
- M[0] is set to the value of PSTATE.SP on taking an exception to EL2 and copied to PSTATE.SP on executing an exception return operation in EL2.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing SPSR_EL2

Accesses to this register use the following encodings in the System register encoding space:

`MRS <Xt>, SPSR_EL2`

op0	op1	CRn	CRm	op2
0b11	0b100	0b0100	0b0000	0b000

```
if PSTATE.EL == EL0 then
    UNDEFINED;
elsif PSTATE.EL == EL1 then
    UNDEFINED;
elsif PSTATE.EL == EL2 then
    X[t, 64] = SPSR_EL2;
```

`MSR SPSR_EL2, <Xt>`

C5.2.16 SSBS, Speculative Store Bypass Safe

The SSBS characteristics are:

Purpose

Allows access to the Speculative Store Bypass Safe bit.

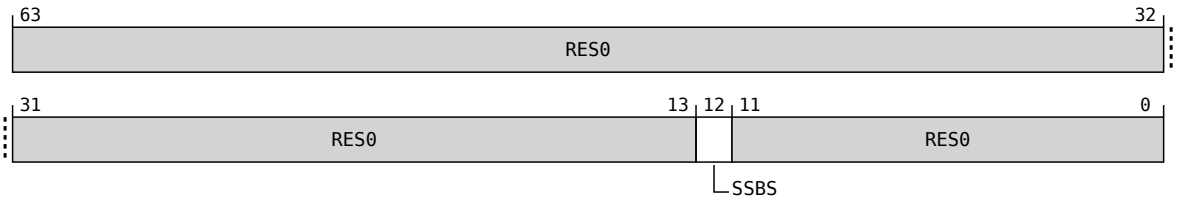
Configuration

This register is present only when FEAT_SSBS2 is implemented. Otherwise, direct accesses to SSBS are UNDEFINED.

Attributes

SSBS is a 64-bit register.

Field descriptions



Bits [63:13]

Reserved, RES0.

SSBS, bit [12]

Speculative Store Bypass Safe.

Prohibits speculative loads or stores which might practically allow a cache timing side channel.

A speculative value in a register is used in a potentially speculatively exploitable manner if it is used to form an address, generate condition codes, or generate SVE predicate values to be used by other instructions in the speculative sequence or if the execution timing of any other instructions in the speculative sequence is a function of the data loaded under speculation.

SSBS	Meaning
0b0	Hardware is not permitted to use speculative register values in a potentially speculatively exploitable manner if the speculative read that loads the register is from earlier in the coherence order than the entry generated by the latest store to that location using the same virtual address as the load instruction.
0b1	When the value of PSTATE.SSBS is 1, hardware is permitted to use speculative register values in a potentially speculatively exploitable manner if the speculative read that loads the register is from earlier in the coherence order than the entry generated by the latest store to that location using the same virtual address as the load instruction.

The value of this bit is set to the value in the SCTLR_ELx.DSSBS field on taking an exception to ELx.

The reset behavior of this field is:

- On a Warm reset, this field resets to an IMPLEMENTATION DEFINED value.

Bits [11:0]

Reserved, RES0.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Accessing SSBS

Accesses to this register use the following encodings in the System register encoding space:

`MRS <Xt>, SSBS`

op0	op1	CRn	CRm	op2
0b11	0b011	0b0100	0b0010	0b110

```
if !IsFeatureImplemented(FEAT_SSBS2) then
    UNDEFINED;
elsif PSTATE.EL == EL0 then
    X[t, 64] = Zeros(51):PSTATE.SSBS:Zeros(12);
elsif PSTATE.EL == EL1 then
    X[t, 64] = Zeros(51):PSTATE.SSBS:Zeros(12);
elsif PSTATE.EL == EL2 then
    X[t, 64] = Zeros(51):PSTATE.SSBS:Zeros(12);
```

C5.3 A64 System instructions for cache maintenance

This section lists the A64 System instructions for cache maintenance.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C5.3.1 DC CISW, Data or unified Cache line Clean and Invalidate by Set/Way

The DC CISW characteristics are:

Purpose

Clean and Invalidate data cache by set/way.

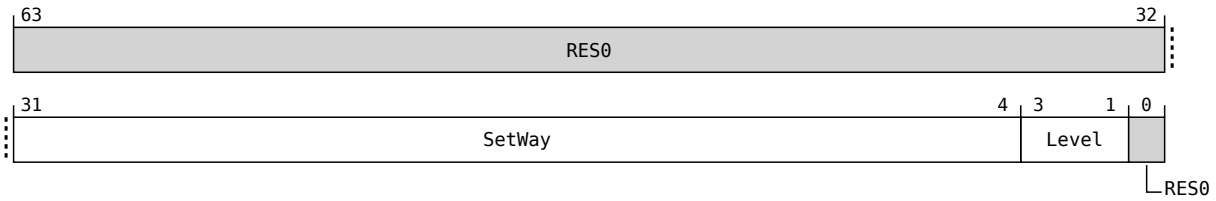
Configuration

There are no configuration notes.

Attributes

DC CISW is a 64-bit System instruction.

Field descriptions



Bits [63:32]

Reserved, RES0.

SetWay, bits [31:4]

Contains two fields:

- Way, bits[31:32-A], the number of the way to operate on.
- Set, bits[B-1:L], the number of the set to operate on.

Bits[L-1:4] are RES0.

$A = Log_2(ASSOCIATIVITY)$, $L = Log_2(LINELEN)$, $B = (L + S)$, $S = Log_2(NSETS)$.

ASSOCIATIVITY, LINELEN (line length, in bytes), and NSETS (number of sets) have their usual meanings and are the values for the cache level being operated on. The values of A and S are rounded up to the next integer.

Level, bits [3:1]

Cache level to operate on, minus 1. For example, this field is 0 for operations on L1 cache, or 1 for operations on L2 cache.

Bit [0]

Reserved, RES0.

Executing DC CISW

If this instruction is executed with a set, way or level argument that is larger than the value supported by the implementation then the behavior is CONSTRAINED UNPREDICTABLE and one of the following occurs:

- The instruction is UNDEFINED.
- The instruction performs cache maintenance on one of:
  - No cache lines.
  - A single arbitrary cache line.
  - Multiple arbitrary cache lines.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

This system instruction is an alias of the SYS instruction.

Accesses to this instruction use the following encodings in the System instruction encoding space:

`DC CISW, <Xt>`

op0	op1	CRn	CRm	op2
0b01	0b000	0b0111	0b1110	0b010

```
if PSTATE.EL == EL0 then
    UNDEFINED;
elsif PSTATE.EL == EL1 then
    if HCR_EL2.TSW == '1' then
        AArch64.SystemAccessTrap(EL2, 0x18);
    else
        AArch64.DC(X[t, 64], CacheType_Data, CacheOp_CleanInvalidate, CacheOpScope_SetWay);
elsif PSTATE.EL == EL2 then
    AArch64.DC(X[t, 64], CacheType_Data, CacheOp_CleanInvalidate, CacheOpScope_SetWay);
```

C5.3.2 DC CIVAC, Data or unified Cache line Clean and Invalidate by VA to PoC

The DC CIVAC characteristics are:

Purpose

Clean and Invalidate data cache by address to Point of Coherency.

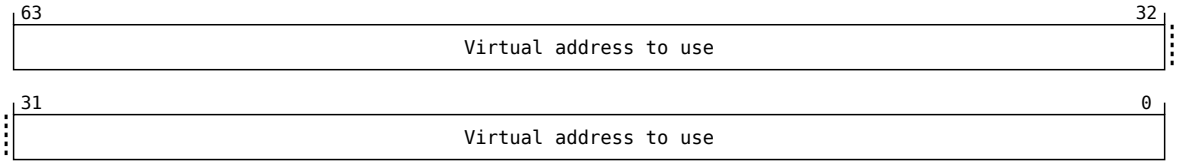
Configuration

There are no configuration notes.

Attributes

DC CIVAC is a 64-bit System instruction.

Field descriptions



VA, bits [63:0]

Virtual address to use. No alignment restrictions apply to this VA.

Executing DC CIVAC

If EL0 access is enabled, when executed at EL0, the instruction may generate a Permission fault, subject to the constraints described in 'MMU faults generated by cache maintenance operations'.

Execution of this instruction might require an address translation from VA to PA, and that translation might fault. For more information, see 'The data cache maintenance instruction (DC)'.

This system instruction is an alias of the SYS instruction.

Accesses to this instruction use the following encodings in the System instruction encoding space:

`DC CIVAC, <Xt>`

op0	op1	CRn	CRm	op2
0b01	0b011	0b0111	0b1110	0b001

```
if PSTATE.EL == EL0 then

C5.3.3 DC CSW, Data or unified Cache line Clean by Set/Way

The DC CSW characteristics are:

Purpose

Clean data cache by set/way.

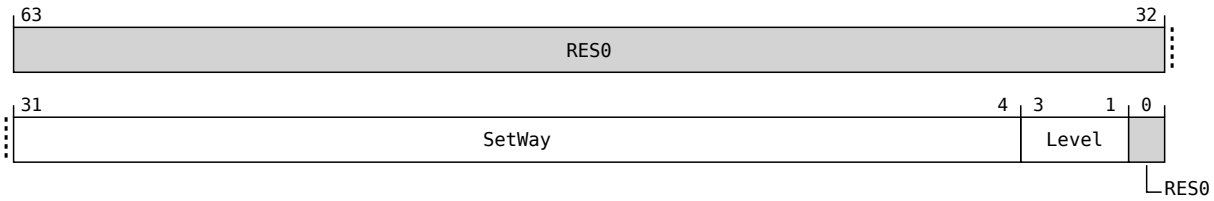
Configuration

There are no configuration notes.

Attributes

DC CSW is a 64-bit System instruction.

Field descriptions



Bits [63:32]

Reserved, RES0.

SetWay, bits [31:4]

Contains two fields:

- Way, bits[31:32-A], the number of the way to operate on.
- Set, bits[B-1:L], the number of the set to operate on.

Bits[L-1:4] are RES0.

$A = Log_2(ASSOCIATIVITY)$, $L = Log_2(LINELEN)$, $B = (L + S)$, $S = Log_2(NSETS)$.

ASSOCIATIVITY, LINELEN (line length, in bytes), and NSETS (number of sets) have their usual meanings and are the values for the cache level being operated on. The values of A and S are rounded up to the next integer.

Level, bits [3:1]

Cache level to operate on, minus 1. For example, this field is 0 for operations on L1 cache, or 1 for operations on L2 cache.

Bit [0]

Reserved, RES0.

Executing DC CSW

If this instruction is executed with a set, way or level argument that is larger than the value supported by the implementation then the behavior is CONSTRAINED UNPREDICTABLE and one of the following occurs:

- The instruction is UNDEFINED.
- The instruction performs cache maintenance on one of:
  - No cache lines.
  - A single arbitrary cache line.
  - Multiple arbitrary cache lines.

C5.3.4 DC CVAC, Data or unified Cache line Clean by VA to PoC

The DC CVAC characteristics are:

Purpose

Clean data cache by address to Point of Coherency.

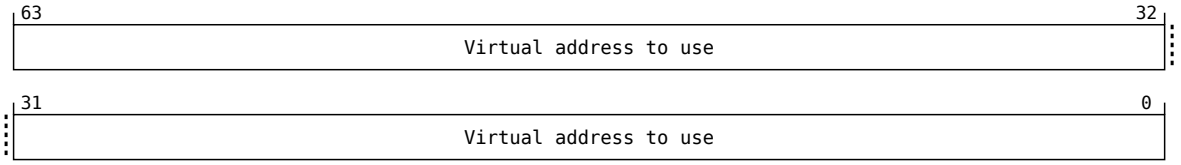
Configuration

There are no configuration notes.

Attributes

DC CVAC is a 64-bit System instruction.

Field descriptions



VA, bits [63:0]

Virtual address to use. No alignment restrictions apply to this VA.

Executing DC CVAC

If EL0 access is enabled, when executed at EL0, the instruction may generate a Permission fault, subject to the constraints described in 'MMU faults generated by cache maintenance operations'.

Execution of this instruction might require an address translation from VA to PA, and that translation might fault. For more information, see 'The data cache maintenance instruction (DC)'.

This system instruction is an alias of the SYS instruction.

Accesses to this instruction use the following encodings in the System instruction encoding space:

C5.3.5 DC CVADP, Data or unified Cache line Clean by VA to PoDP

The DC CVADP characteristics are:

Purpose

Clean data cache by address to Point of Deep Persistence.

If the memory system does not identify a Point of Deep Persistence, then this instruction behaves as a DC CVAP.

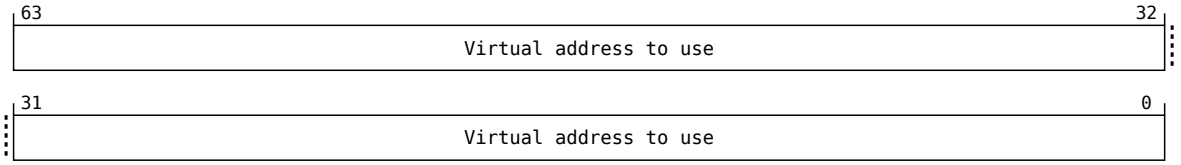
Configuration

This system instruction is present only when FEAT_DPB2 is implemented. Otherwise, direct accesses to DC CVADP are UNDEFINED.

Attributes

DC CVADP is a 64-bit System instruction.

Field descriptions



VA, bits [63:0]

Virtual address to use. No alignment restrictions apply to this VA.

Executing DC CVADP

If EL0 access is enabled, when executed at EL0, the instruction may generate a Permission fault, subject to the constraints described in 'MMU faults generated by cache maintenance operations'.

Execution of this instruction might require an address translation from VA to PA, and that translation might fault. For more information, see 'The data cache maintenance instruction (DC)'.

This system instruction is an alias of the SYS instruction.

Accesses to this instruction use the following encodings in the System instruction encoding space:

`DC CVADP, <Xt>`

op0	op1	CRn	CRm	op2
0b01	0b011	0b0111	0b1101	0b001

```

C5.3.8 DC ISW, Data or unified Cache line Invalidate by Set/Way

The DC ISW characteristics are:

Purpose

Invalidate data cache by set/way.

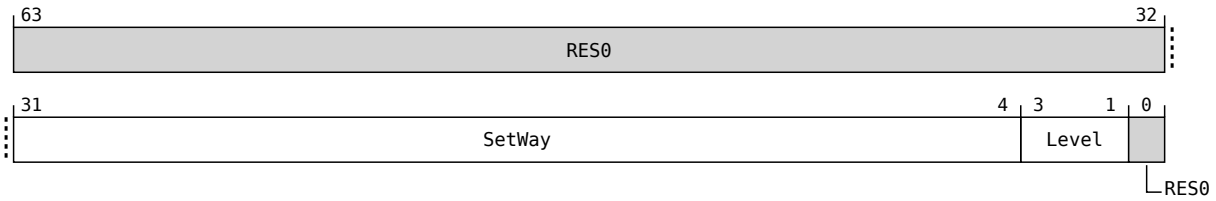
Configuration

There are no configuration notes.

Attributes

DC ISW is a 64-bit System instruction.

Field descriptions



Bits [63:32]

Reserved, RES0.

SetWay, bits [31:4]

Contains two fields:

- Way, bits[31:32-A], the number of the way to operate on.
- Set, bits[B-1:L], the number of the set to operate on.

Bits[L-1:4] are RES0.

$A = Log_2(ASSOCIATIVITY)$, $L = Log_2(LINELEN)$, $B = (L + S)$, $S = Log_2(NSETS)$.

ASSOCIATIVITY, LINELEN (line length, in bytes), and NSETS (number of sets) have their usual meanings and are the values for the cache level being operated on. The values of A and S are rounded up to the next integer.

Level, bits [3:1]

Cache level to operate on, minus 1. For example, this field is 0 for operations on L1 cache, or 1 for operations on L2 cache.

Bit [0]

Reserved, RES0.

Executing DC ISW

If this instruction is executed with a set, way or level argument that is larger than the value supported by the implementation then the behavior is CONSTRAINED UNPREDICTABLE and one of the following occurs:

- The instruction is UNDEFINED.
- The instruction performs cache maintenance on one of:
  - No cache lines.
  - A single arbitrary cache line.
  - Multiple arbitrary cache lines.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

This system instruction is an alias of the SYS instruction.

Accesses to this instruction use the following encodings in the System instruction encoding space:

`DC ISW, <Xt>`

op0	op1	CRn	CRm	op2
0b01	0b000	0b0111	0b0110	0b010

C5.3.9 DC IVAC, Data or unified Cache line Invalidate by VA to PoC

The DC IVAC characteristics are:

Purpose

Invalidate data cache by address to Point of Coherency.

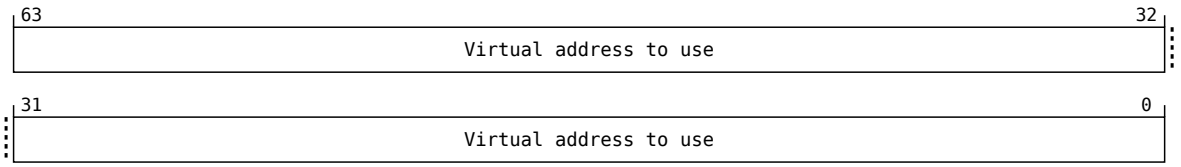
Configuration

There are no configuration notes.

Attributes

DC IVAC is a 64-bit System instruction.

Field descriptions



VA, bits [63:0]

Virtual address to use. No alignment restrictions apply to this VA.

Executing DC IVAC

When the instruction is executed, it can generate a watchpoint, which is prioritized in the same way as other watchpoints. If a watchpoint is generated, the CM bit in the ESR_ELx.ISS field is set to 1.

This instruction requires write access permission to the VA, otherwise it generates a Permission fault, subject to the constraints described in 'MMU faults generated by cache maintenance operations'.

Execution of this instruction might require an address translation from VA to PA, and that translation might fault. For more information, see 'The data cache maintenance instruction (DC)'.

This system instruction is an alias of the SYS instruction.

Accesses to this instruction use the following encodings in the System instruction encoding space:

```
DC IVAC, <Xt>
```

op0	op1	CRn	CRm	op2
0b01	0b000	0b0111	0b0110	0b001

```

C5.3.10 DC ZVA, Data Cache Zero by VA

The DC ZVA characteristics are:

Purpose

Zero data cache by address. Zeroes a naturally aligned block of N bytes, where the size of N is identified in DCZID_EL0.

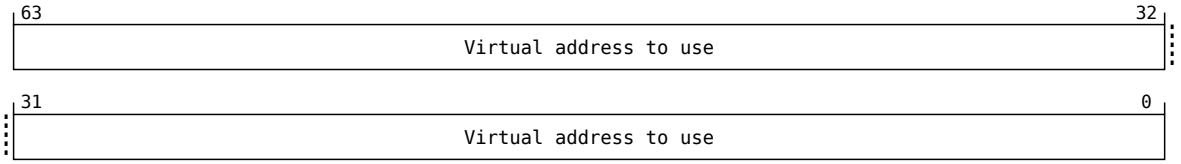
Configuration

There are no configuration notes.

Attributes

DC ZVA is a 64-bit System instruction.

Field descriptions



VA, bits [63:0]

Virtual address to use. There is no alignment restriction on the address within the block of N bytes that is used.

Executing DC ZVA

When this instruction is executed, it can generate memory faults or watchpoints which are prioritized in the same way as other memory-related faults or watchpoints. If a synchronous Data Abort fault or a watchpoint is generated, the CM bit in the ESR_ELx.ISS field is set to 0.

If the memory region being zeroed is any type of Device memory, this instruction generates an Alignment fault which is prioritized in the same way as other Alignment faults that are determined by the memory type.

This instruction applies to Normal memory regardless of cacheability attributes.

This instruction behaves as a set of Stores to each byte within the block being accessed, and so it:

- Generates a Permission fault if the translation system does not permit writes to the locations.
- Requires the same considerations for ordering and the management of coherency as any other store instructions.

This system instruction is an alias of the SYS instruction.

Accesses to this instruction use the following encodings in the System instruction encoding space:

```
DC ZVA, <Xt>
```

op0	op1	CRn	CRm	op2
0b01	0b011	0b0111	0b0100	0b001

```

C5.3.11 IC IALLU, Instruction Cache Invalidate All to PoU

The IC IALLU characteristics are:

Purpose

Invalidate all instruction caches of the PE executing the instruction to the Point of Unification.

Configuration

There are no configuration notes.

Attributes

IC IALLU is a 64-bit System instruction.

Field descriptions

This instruction has no applicable fields.

The value in the register specified by <Xt> is ignored.

Executing IC IALLU

The Rt field should be set to `0b11111`. If the Rt field is not set to `0b11111`, it is CONSTRAINED UNPREDICTABLE whether:

- The instruction is UNDEFINED.
- The instruction behaves as if the Rt field is set to `0b11111`.

This system instruction is an alias of the SYS instruction.

Accesses to this instruction use the following encodings in the System instruction encoding space:

```

C5.3.13 IC IVAU, Instruction Cache line Invalidate by VA to PoU

The IC IVAU characteristics are:

Purpose

Invalidate instruction cache by address to Point of Unification.

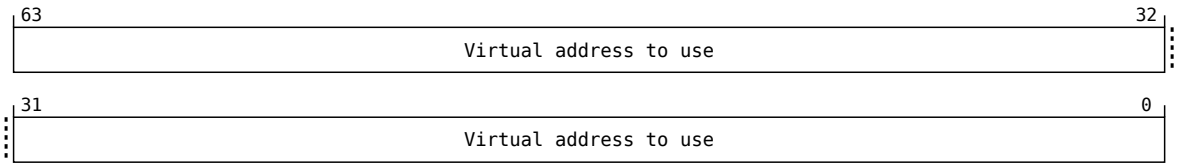
Configuration

There are no configuration notes.

Attributes

IC IVAU is a 64-bit System instruction.

Field descriptions



VA, bits [63:0]

Virtual address to use. No alignment restrictions apply to this VA.

Executing IC IVAU

If EL0 access is enabled, when executed at EL0, the instruction may generate a Permission fault, subject to the constraints described in 'MMU faults generated by cache maintenance operations'.

Execution of this instruction might require an address translation from VA to PA, and that translation might fault. For more information, see 'The instruction cache maintenance instruction (IC)'.

This system instruction is an alias of the SYS instruction.

Accesses to this instruction use the following encodings in the System instruction encoding space:

`IC IVAU{, <Xt>}`

op0	op1	CRn	CRm	op2

C5.4 A64 System instructions for address translation

This section lists the A64 System instructions for address translation.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C5.4.1 AT S12E0R, Address Translate Stages 1 and 2 EL0 Read

The AT S12E0R characteristics are:

Purpose

Performs stage 1 and 2 address translations from EL0, with permissions as if reading from the given virtual address from EL0, using the EL1&0 translation regime.

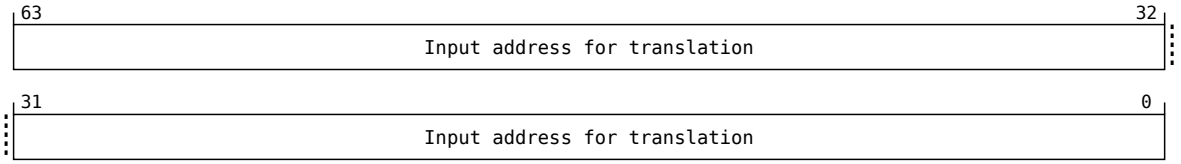
Configuration

There are no configuration notes.

Attributes

AT S12E0R is a 64-bit System instruction.

Field descriptions



IA, bits [63:0]

Input address for translation. The resulting address can be read from the PAR_EL1.

Executing AT S12E0R

This system instruction is an alias of the SYS instruction.

Accesses to this instruction use the following encodings in the System instruction encoding space:

`AT S12E0R, <Xt>`

op0	op1	CRn	CRm	op2
0b01	0b100	0b0111	0b1000	0b110

```
if PSTATE.EL == EL0 then
    UNDEFINED;
elsif PSTATE.EL == EL1 then
    UNDEFINED;
elsif PSTATE.EL == EL2 then
    if HCR_EL2.<DC,VM> == '00' then
        AArch64.AT(X[t, 64], TranslationStage_1, EL0, ATAccess_Read);
    else
        AArch64.AT(X[t, 64], TranslationStage_12, EL0, ATAccess_Read);
```

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C5.4.2 AT S12E0W, Address Translate Stages 1 and 2 EL0 Write

The AT S12E0W characteristics are:

Purpose

Performs stage 1 and 2 address translations from EL0, with permissions as if writing to the given virtual address from EL0, using the EL1&0 translation regime.

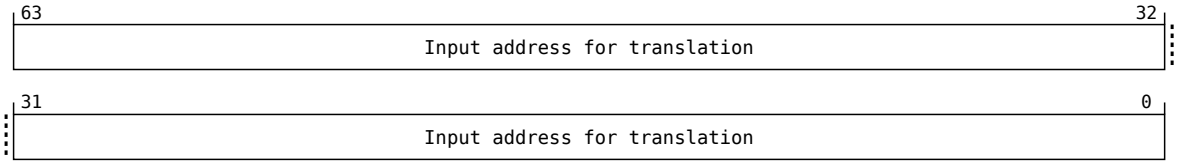
Configuration

There are no configuration notes.

Attributes

AT S12E0W is a 64-bit System instruction.

Field descriptions



IA, bits [63:0]

Input address for translation. The resulting address can be read from the PAR_EL1.

Executing AT S12E0W

This system instruction is an alias of the SYS instruction.

Accesses to this instruction use the following encodings in the System instruction encoding space:

`AT S12E0W, <Xt>`

op0	op1	CRn	CRm	op2
0b01	0b100	0b0111	0b1000	0b111

```
if PSTATE.EL == EL0 then
    UNDEFINED;
elsif PSTATE.EL == EL1 then
    UNDEFINED;
elsif PSTATE.EL == EL2 then
    if HCR_EL2.<DC,VM> == '00' then
        AArch64.AT(X[t, 64], TranslationStage_1, EL0, ATAccess_Write);
    else
        AArch64.AT(X[t, 64], TranslationStage_12, EL0, ATAccess_Write);
```

Non-Confidential

C5.4.3 AT S12E1R, Address Translate Stages 1 and 2 EL1 Read

The AT S12E1R characteristics are:

Purpose

Performs stage 1 and 2 address translation, with permissions as if reading from the given virtual address from EL1, using the EL1&0 translation regime.

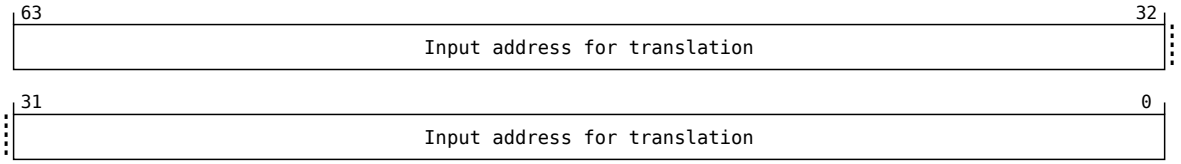
Configuration

There are no configuration notes.

Attributes

AT S12E1R is a 64-bit System instruction.

Field descriptions



IA, bits [63:0]

Input address for translation. The resulting address can be read from the PAR_EL1.

Executing AT S12E1R

This system instruction is an alias of the SYS instruction.

Accesses to this instruction use the following encodings in the System instruction encoding space:

`AT S12E1R, <Xt>`

op0	op1	CRn	CRm	op2
0b01	0b100	0b0111	0b1000	0b100

```
if PSTATE.EL == EL0 then
    UNDEFINED;
elsif PSTATE.EL == EL1 then
    UNDEFINED;
elsif PSTATE.EL == EL2 then
    if HCR_EL2.<DC,VM> == '00' then
        AArch64.AT(X[t, 64], TranslationStage_1, EL1, ATAccess_Read);
    else
        AArch64.AT(X[t, 64], TranslationStage_12, EL1, ATAccess_Read);
```

Non-Confidential

C5.4.4 AT S12E1W, Address Translate Stages 1 and 2 EL1 Write

The AT S12E1W characteristics are:

Purpose

Performs stage 1 and 2 address translation, with permissions as if writing to the given virtual address from EL1, using the EL1&0 translation regime.

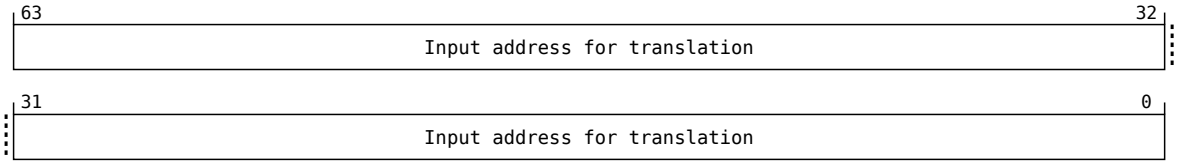
Configuration

There are no configuration notes.

Attributes

AT S12E1W is a 64-bit System instruction.

Field descriptions



IA, bits [63:0]

Input address for translation. The resulting address can be read from the PAR_EL1.

Executing AT S12E1W

This system instruction is an alias of the SYS instruction.

Accesses to this instruction use the following encodings in the System instruction encoding space:

`AT S12E1W, <Xt>`

op0	op1	CRn	CRm	op2
0b01	0b100	0b0111	0b1000	0b101

```
if PSTATE.EL == EL0 then
    UNDEFINED;
elsif PSTATE.EL == EL1 then
    UNDEFINED;
elsif PSTATE.EL == EL2 then
    if HCR_EL2.<DC,VM> == '00' then
        AArch64.AT(X[t, 64], TranslationStage_1, EL1, ATAccess_Write);
    else
        AArch64.AT(X[t, 64], TranslationStage_12, EL1, ATAccess_Write);
```

C5.4.5 AT S1E0R, Address Translate Stage 1 EL0 Read

The AT S1E0R characteristics are:

Purpose

Performs stage 1 address translation from EL0, with permissions as if reading from the given virtual address from EL0, using the EL1&0 translation regime.

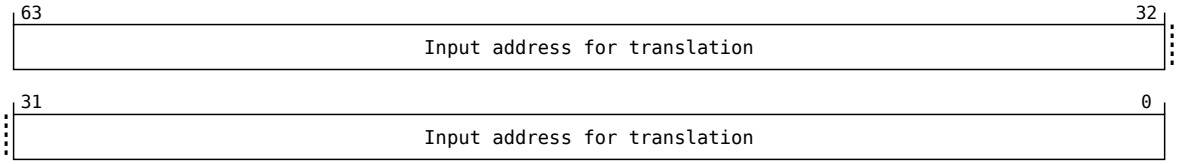
Configuration

There are no configuration notes.

Attributes

AT S1E0R is a 64-bit System instruction.

Field descriptions



IA, bits [63:0]

Input address for translation. The resulting address can be read from the PAR_EL1.

Executing AT S1E0R

This system instruction is an alias of the SYS instruction.

Accesses to this instruction use the following encodings in the System instruction encoding space:

`AT S1E0R, <Xt>`

op0	op1	CRn	CRm	op2
0b01	0b000	0b0111	0b1000	0b010

```
if PSTATE.EL == EL0 then
    UNDEFINED;
elsif PSTATE.EL == EL1 then
    AArch64.AT(X[t, 64], TranslationStage_1, EL0, ATAccess_Read);
elsif PSTATE.EL == EL2 then
    AArch64.AT(X[t, 64], TranslationStage_1, EL0, ATAccess_Read);
```

C5.4.6 AT S1E0W, Address Translate Stage 1 EL0 Write

The AT S1E0W characteristics are:

Purpose

Performs stage 1 address translation from EL0, with permissions as if writing to the given virtual address from EL0, using the EL1&0 translation regime.

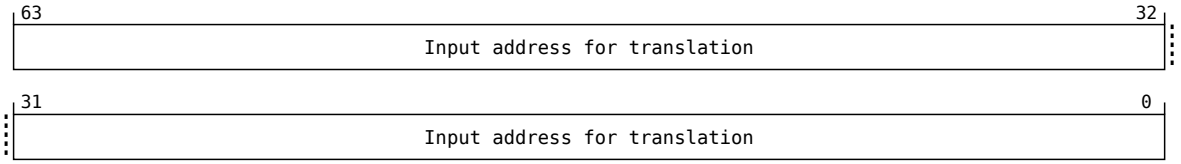
Configuration

There are no configuration notes.

Attributes

AT S1E0W is a 64-bit System instruction.

Field descriptions



IA, bits [63:0]

Input address for translation. The resulting address can be read from the PAR_EL1.

Executing AT S1E0W

This system instruction is an alias of the SYS instruction.

Accesses to this instruction use the following encodings in the System instruction encoding space:

`AT S1E0W, <Xt>`

op0	op1	CRn	CRm	op2
0b01	0b000	0b0111	0b1000	0b011

C5.4.7 AT S1E1R, Address Translate Stage 1 EL1 Read

The AT S1E1R characteristics are:

Purpose

Performs stage 1 address translation, with permissions as if reading from the given virtual address from EL1, using the EL1&0 translation regime.

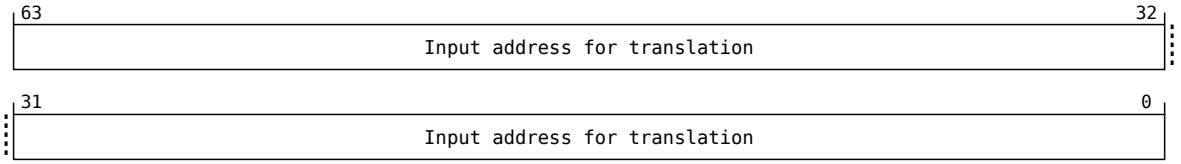
Configuration

There are no configuration notes.

Attributes

AT S1E1R is a 64-bit System instruction.

Field descriptions



IA, bits [63:0]

Input address for translation. The resulting address can be read from the PAR_EL1.

Executing AT S1E1R

This system instruction is an alias of the SYS instruction.

Accesses to this instruction use the following encodings in the System instruction encoding space:

`AT S1E1R, <Xt>`

op0	op1	CRn	CRm	op2
0b01	0b000	0b0111	0b1000	0b000

```
if PSTATE.EL == EL0 then
    UNDEFINED;
elsif PSTATE.EL == EL1 then
    AArch64.AT(X[t, 64], TranslationStage_1, EL1, ATAccess_Read);
elsif PSTATE.EL == EL2 then
    AArch64.AT(X[t, 64], TranslationStage_1, EL1, ATAccess_Read);
```

C5.4.8 AT S1E1RP, Address Translate Stage 1 EL1 Read PAN

The AT S1E1RP characteristics are:

Purpose

Performs a stage 1 address translation, where the value of PSTATE.PAN determines if a read from a location will generate a Permission fault for a privileged access, using the EL1&0 translation regime, accessed from EL1.

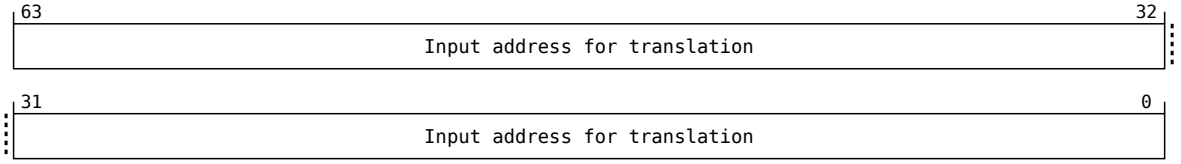
Configuration

This system instruction is present only when FEAT_PAN2 is implemented. Otherwise, direct accesses to AT S1E1RP are UNDEFINED.

Attributes

AT S1E1RP is a 64-bit System instruction.

Field descriptions



IA, bits [63:0]

Input address for translation. The resulting address can be read from the PAR_EL1.

Executing AT S1E1RP

This system instruction is an alias of the SYS instruction.

Accesses to this instruction use the following encodings in the System instruction encoding space:

`AT S1E1RP, <Xt>`

op0	op1	CRn	CRm	op2
0b01	0b000	0b0111	0b1001	0b000

```
if !IsFeatureImplemented(FEAT_PAN2) then
    UNDEFINED;
elsif PSTATE.EL == EL0 then
    UNDEFINED;
elsif PSTATE.EL == EL1 then
    AArch64.AT(X[t, 64], TranslationStage_1, EL1, ATAccess_ReadPAN);
elsif PSTATE.EL == EL2 then
    AArch64.AT(X[t, 64], TranslationStage_1, EL1, ATAccess_ReadPAN);
```

C5.4.9 AT S1E1W, Address Translate Stage 1 EL1 Write

The AT S1E1W characteristics are:

Purpose

Performs stage 1 address translation, with permissions as if writing to the given virtual address from EL1, using the EL1&0 translation regime.

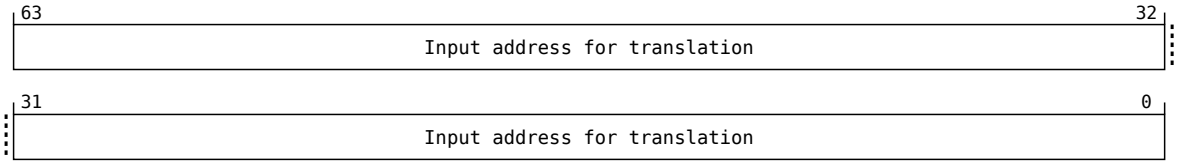
Configuration

There are no configuration notes.

Attributes

AT S1E1W is a 64-bit System instruction.

Field descriptions



IA, bits [63:0]

Input address for translation. The resulting address can be read from the PAR_EL1.

Executing AT S1E1W

This system instruction is an alias of the SYS instruction.

Accesses to this instruction use the following encodings in the System instruction encoding space:

`AT S1E1W, <Xt>`

op0	op1	CRn	CRm	op2
0b01	0b000	0b0111	0b1000	0b001

```
if PSTATE.EL == EL0 then
    UNDEFINED;
elsif PSTATE.EL == EL1 then
    AArch64.AT(X[t, 64], TranslationStage_1, EL1, ATAccess_Write);
elsif PSTATE.EL == EL2 then
    AArch64.AT(X[t, 64], TranslationStage_1, EL1, ATAccess_Write);
```

Non-Confidential

C5.4.10 AT S1E1WP, Address Translate Stage 1 EL1 Write PAN

The AT S1E1WP characteristics are:

Purpose

Performs a stage 1 address translation, where the value of PSTATE.PAN determines if a write to a location will generate a Permission fault for a privileged access, using the EL1&0 translation regime, accessed from EL1.

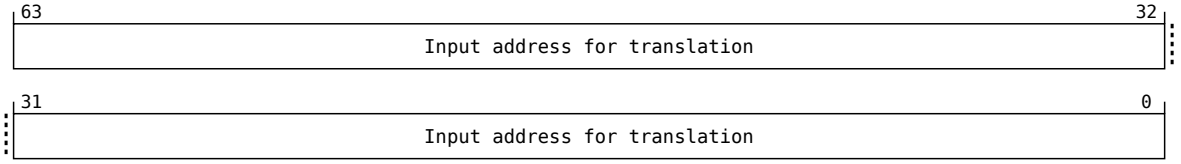
Configuration

This system instruction is present only when FEAT_PAN2 is implemented. Otherwise, direct accesses to AT S1E1WP are UNDEFINED.

Attributes

AT S1E1WP is a 64-bit System instruction.

Field descriptions



IA, bits [63:0]

Input address for translation. The resulting address can be read from the PAR_EL1.

Executing AT S1E1WP

This system instruction is an alias of the SYS instruction.

Accesses to this instruction use the following encodings in the System instruction encoding space:

`AT S1E1WP, <Xt>`

op0	op1	CRn	CRm	op2
0b01	0b000	0b0111	0b1001	0b001

```
if !IsFeatureImplemented(FEAT_PAN2) then
    UNDEFINED;
elsif PSTATE.EL == EL0 then
    UNDEFINED;
elsif PSTATE.EL == EL1 then
    AArch64.AT(X[t, 64], TranslationStage_1, EL1, ATAccess_WritePAN);
elsif PSTATE.EL == EL2 then
    AArch64.AT(X[t, 64], TranslationStage_1, EL1, ATAccess_WritePAN);
```

C5.4.11 AT S1E2R, Address Translate Stage 1 EL2 Read

The AT S1E2R characteristics are:

Purpose

Performs stage 1 address translation as defined for EL2, with permissions as if reading from the given virtual address.

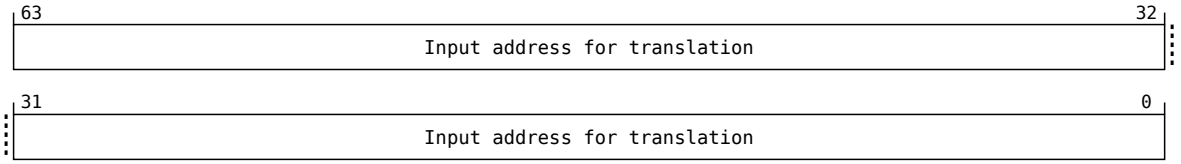
Configuration

There are no configuration notes.

Attributes

AT S1E2R is a 64-bit System instruction.

Field descriptions



IA, bits [63:0]

Input address for translation. The resulting address can be read from the PAR_EL1.

Executing AT S1E2R

This system instruction is an alias of the SYS instruction.

Accesses to this instruction use the following encodings in the System instruction encoding space:

`AT S1E2R, <Xt>`

op0	op1	CRn	CRm	op2
0b01	0b100	0b0111	0b1000	0b000

```
if PSTATE.EL == EL0 then
    UNDEFINED;
elsif PSTATE.EL == EL1 then

C5.4.12 AT S1E2W, Address Translate Stage 1 EL2 Write

The AT S1E2W characteristics are:

Purpose

Performs stage 1 address translation as defined for EL2, with permissions as if writing to the given virtual address.

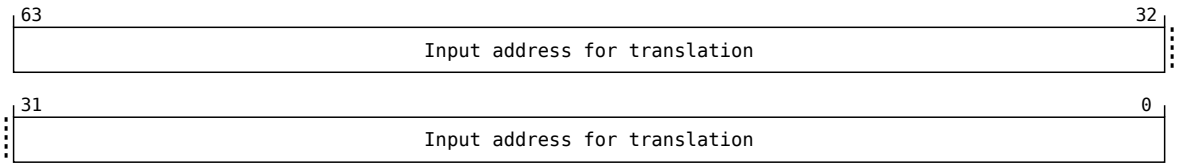
Configuration

There are no configuration notes.

Attributes

AT S1E2W is a 64-bit System instruction.

Field descriptions



IA, bits [63:0]

Input address for translation. The resulting address can be read from the PAR_EL1.

Executing AT S1E2W

This system instruction is an alias of the SYS instruction.

Accesses to this instruction use the following encodings in the System instruction encoding space:

`AT S1E2W, <Xt>`

op0	op1	CRn	CRm	op2
0b01	0b100	0b0111	0b1000	0b001

```

C5.4.13 AT S1E3R, Address Translate Stage 1 EL3 Read

The AT S1E3R characteristics are:

Purpose

Performs stage 1 address translation as defined for EL3, with permissions as if reading from the given virtual address.

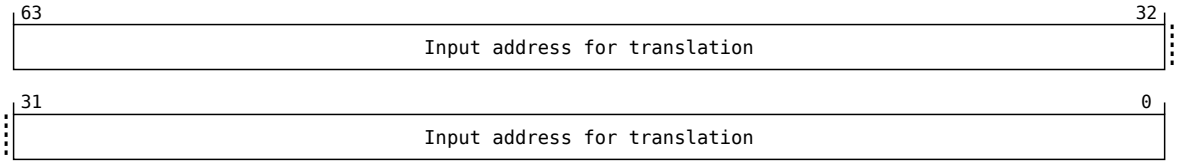
Configuration

There are no configuration notes.

Attributes

AT S1E3R is a 64-bit System instruction.

Field descriptions



IA, bits [63:0]

Input address for translation. The resulting address can be read from the PAR_EL1.

Executing AT S1E3R

This system instruction is an alias of the SYS instruction.

This system instruction encoding is Undefined()

Accesses to this instruction use the following encodings in the System instruction encoding space:

`AT S1E3R, <Xt>`

op0	op1	CRn	CRm	op2
0b01	0b110	0b0111	0b1000	0b000

C5.4.14 AT S1E3W, Address Translate Stage 1 EL3 Write

The AT S1E3W characteristics are:

Purpose

Performs stage 1 address translation as defined for EL3, with permissions as if writing to the given virtual address.

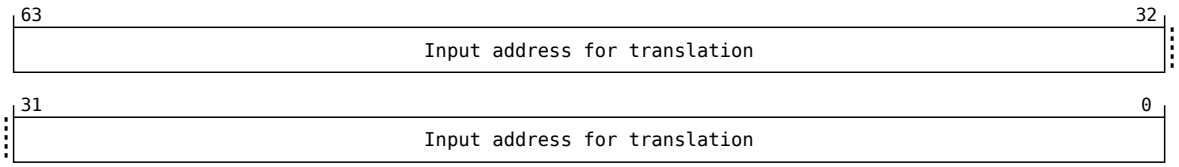
Configuration

There are no configuration notes.

Attributes

AT S1E3W is a 64-bit System instruction.

Field descriptions



IA, bits [63:0]

Input address for translation. The resulting address can be read from the PAR_EL1.

Executing AT S1E3W

This system instruction is an alias of the SYS instruction.

This system instruction encoding is Undefined()

Accesses to this instruction use the following encodings in the System instruction encoding space:

`AT S1E3W, <Xt>`

op0	op1	CRn	CRm	op2
0b01	0b110	0b0111	0b1000	0b001

C5.5 A64 System instructions for TLB maintenance

This section lists the A64 System instructions for TLB maintenance.

For more information about these instructions see TLB maintenance instructions. In particular, for the full description of the scope of each instruction see TLB maintenance instruction scope.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C5.5.1 TLBI ALLE1, TLB Invalidate All, EL1

The TLBI ALLE1 characteristics are:

Purpose

Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 or stage 2 translation table entry, from any level of the translation table walk.
- The entry would be required to translate an address using the EL1&0 translation regime.

The invalidation applies to entries with any VMID.

The invalidation only applies to the PE that executes this System instruction.

Note

For the EL1&0 translation regimes, the invalidation applies to both global entries and non-global entries with any ASID.

Configuration

There are no configuration notes.

Attributes

TLBI ALLE1 is a 64-bit System instruction.

Field descriptions

This instruction has no applicable fields.

The value in the register specified by <Xt> is ignored.

Executing TLBI ALLE1

The Rt field should be set to `0b11111`. If the Rt field is not set to `0b11111`, it is CONSTRAINED UNPREDICTABLE whether:

- The instruction is UNDEFINED.
- The instruction behaves as if the Rt field is set to `0b11111`.

This system instruction is an alias of the SYS instruction.

Accesses to this instruction use the following encodings in the System instruction encoding space:

```
TLBI ALLE1{, <Xt>}
```

op0	op1	CRn	CRm	op2
0b01	0b100	0b1000	0b0111	0b100

```
if PSTATE.EL == EL0 then
    UNDEFINED;
elsif PSTATE.EL == EL1 then
    UNDEFINED;
elsif PSTATE.EL == EL2 then
    AArch64.TLBI_ALL(SecurityStateAtEL(EL1), Regime_EL10, Broadcast_NSH, TLBI_AllAttr, X[t, 64]);
```

Non-Confidential

C5.5.2 TLBI ALLE1IS, TLB Invalidate All, EL1, Inner Shareable

The TLBI ALLE1IS characteristics are:

Purpose

Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 or stage 2 translation table entry, from any level of the translation table walk.
- The entry would be required to translate an address using the EL1&0 translation regime.

The invalidation applies to entries with any VMID.

The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that executes this System instruction.

Note

For the EL1&0 translation regimes, the invalidation applies to both global entries and non-global entries with any ASID.

Configuration

There are no configuration notes.

Attributes

TLBI ALLE1IS is a 64-bit System instruction.

Field descriptions

This instruction has no applicable fields.

The value in the register specified by <Xt> is ignored.

Executing TLBI ALLE1IS

The Rt field should be set to `0b11111`. If the Rt field is not set to `0b11111`, it is CONSTRAINED UNPREDICTABLE whether:

- The instruction is UNDEFINED.
- The instruction behaves as if the Rt field is set to `0b11111`.

This system instruction is an alias of the SYS instruction.

Accesses to this instruction use the following encodings in the System instruction encoding space:

```
TLBI ALLE1IS{, <Xt>}
```

op0	op1	CRn	CRm	op2
0b01	0b100	0b1000	0b0011	0b100

```
if PSTATE.EL == EL0 then
    UNDEFINED;
elsif PSTATE.EL == EL1 then
    UNDEFINED;
elsif PSTATE.EL == EL2 then
    AArch64.TLBI_ALL(SecurityStateAtEL(EL1), Regime_EL10, Broadcast_ISH, TLBI_AllAttr, X[t, 64]);
```

C5.5.3 TLBI ALLE1OS, TLB Invalidate All, EL1, Outer Shareable

The TLBI ALLE1OS characteristics are:

Purpose

Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 or stage 2 translation table entry, from any level of the translation table walk.
- The entry would be required to translate an address using the EL1&0 translation regime.

The invalidation applies to entries with any VMID.

The invalidation applies to all PEs in the same Outer Shareable shareability domain as the PE that executes this System instruction.

Note

For the EL1&0 translation regimes, the invalidation applies to both global entries and non-global entries with any ASID.

Configuration

This system instruction is present only when FEAT_TLBIOS is implemented. Otherwise, direct accesses to TLBI ALLE1OS are UNDEFINED.

Attributes

TLBI ALLE1OS is a 64-bit System instruction.

Field descriptions

This instruction has no applicable fields.

The value in the register specified by <Xt> is ignored.

Executing TLBI ALLE1OS

The Rt field should be set to `0b11111`. If the Rt field is not set to `0b11111`, it is CONSTRAINED UNPREDICTABLE whether:

- The instruction is UNDEFINED.
- The instruction behaves as if the Rt field is set to `0b11111`.

This system instruction is an alias of the SYS instruction.

Accesses to this instruction use the following encodings in the System instruction encoding space:

```
TLBI ALLE1OS{, <Xt>}
```

op0	op1	CRn	CRm	op2
0b01	0b100	0b1000	0b0001	0b100

```

Non-Confidential

C5.5.4 TLBI ALLE2, TLB Invalidate All, EL2

The TLBI ALLE2 characteristics are:

Purpose

If EL2 is implemented and enabled in the current Security state, invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry, from any level of the translation table walk.
- The entry would be required to translate any address using the EL2&0 or EL2 translation regime.

The invalidation only applies to the PE that executes this System instruction.

Configuration

There are no configuration notes.

Attributes

TLBI ALLE2 is a 64-bit System instruction.

Field descriptions

This instruction has no applicable fields.

The value in the register specified by <Xt> is ignored.

Executing TLBI ALLE2

The Rt field should be set to `0b11111`. If the Rt field is not set to `0b11111`, it is CONSTRAINED UNPREDICTABLE whether:

- The instruction is UNDEFINED.
- The instruction behaves as if the Rt field is set to `0b11111`.

This system instruction is an alias of the SYS instruction.

Accesses to this instruction use the following encodings in the System instruction encoding space:

```
TLBI ALLE2{, <Xt>}
```

op0	op1	CRn	CRm	op2
0b01	0b100	0b1000	0b0111	0b000

```
if PSTATE.EL == EL0 then
    UNDEFINED;
elsif PSTATE.EL == EL1 then
    UNDEFINED;
elsif PSTATE.EL == EL2 then
    AArch64.TLBI_ALL(SecurityStateAtEL(EL2), Regime_EL2, Broadcast_NSH, TLBI_AllAttr, X[t, 64]);

C5.5.5 TLBI ALLE2IS, TLB Invalidate All, EL2, Inner Shareable

The TLBI ALLE2IS characteristics are:

Purpose

If EL2 is implemented and enabled in the current Security state, invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry, from any level of the translation table walk.
- The entry would be required to translate any address using the EL2&0 or EL2 translation regime.

The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that executes this System instruction.

Configuration

There are no configuration notes.

Attributes

TLBI ALLE2IS is a 64-bit System instruction.

Field descriptions

This instruction has no applicable fields.

The value in the register specified by <Xt> is ignored.

Executing TLBI ALLE2IS

The Rt field should be set to `0b11111`. If the Rt field is not set to `0b11111`, it is CONSTRAINED UNPREDICTABLE whether:

- The instruction is UNDEFINED.
- The instruction behaves as if the Rt field is set to `0b11111`.

This system instruction is an alias of the SYS instruction.

Accesses to this instruction use the following encodings in the System instruction encoding space:

```
TLBI ALLE2IS{, <Xt>}
```

op0	op1	CRn	CRm	op2
0b01	0b100	0b1000	0b0011	0b000

```
if PSTATE.EL == EL0 then
    UNDEFINED;
elsif PSTATE.EL == EL1 then
    UNDEFINED;
elsif PSTATE.EL == EL2 then
    AArch64.TLBI_ALL(SecurityStateAtEL(EL2), Regime_EL2, Broadcast_ISH, TLBI_AllAttr, X[t, 64]);
```

C5.5.6 TLBI ALLE2OS, TLB Invalidate All, EL2, Outer Shareable

The TLBI ALLE2OS characteristics are:

Purpose

If EL2 is implemented and enabled in the current Security state, invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry, from any level of the translation table walk.
- The entry would be required to translate any address using the EL2&0 or EL2 translation regime.

The invalidation applies to all PEs in the same Outer Shareable shareability domain as the PE that executes this System instruction.

Configuration

This system instruction is present only when FEAT_TLBIOS is implemented. Otherwise, direct accesses to TLBI ALLE2OS are UNDEFINED.

Attributes

TLBI ALLE2OS is a 64-bit System instruction.

Field descriptions

This instruction has no applicable fields.

The value in the register specified by <Xt> is ignored.

Executing TLBI ALLE2OS

The Rt field should be set to `0b11111`. If the Rt field is not set to `0b11111`, it is CONSTRAINED UNPREDICTABLE whether:

- The instruction is UNDEFINED.
- The instruction behaves as if the Rt field is set to `0b11111`.

This system instruction is an alias of the SYS instruction.

Accesses to this instruction use the following encodings in the System instruction encoding space:

```
TLBI ALLE2OS{, <Xt>}
```

op0	op1	CRn	CRm	op2
0b01	0b100	0b1000	0b0001	0b000

```
if !IsFeatureImplemented(FEAT_TLBIOS) then

C5.5.7 TLBI ALLE3, TLB Invalidate All, EL3

The TLBI ALLE3 characteristics are:

Purpose

If EL3 is implemented, invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry, from any level of the translation table walk.
- The entry would be required to translate an address using the EL3 translation regime.

The invalidation applies to the PE that executes this System instruction.

Configuration

There are no configuration notes.

Attributes

TLBI ALLE3 is a 64-bit System instruction.

Field descriptions

This instruction has no applicable fields.

The value in the register specified by <Xt> is ignored.

Executing TLBI ALLE3

The Rt field should be set to `0b11111`. If the Rt field is not set to `0b11111`, it is CONSTRAINED UNPREDICTABLE whether:

- The instruction is UNDEFINED.
- The instruction behaves as if the Rt field is set to `0b11111`.

This system instruction is an alias of the SYS instruction.

This system instruction encoding is Undefined()

Accesses to this instruction use the following encodings in the System instruction encoding space:

```

C5.5.10 TLBI ASIDE1, TLB Invalidate by ASID, EL1

The TLBI ASIDE1 characteristics are:

Purpose

Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be used for the specified ASID, and either:
  - Is from a level of lookup above the final level.
  - Is a non-global entry from the final level of lookup.

The entry would be used with the current VMID and would be required to translate an address using the EL1&0 translation regime for the Security state.

The invalidation applies to the PE that executes this System instruction.

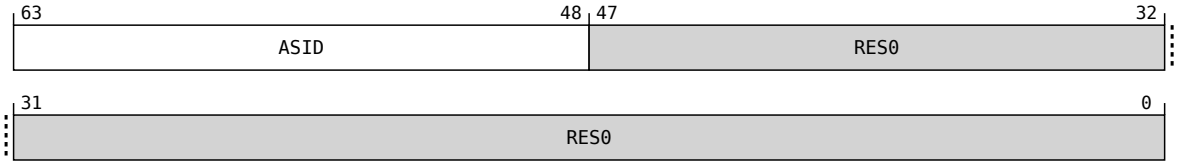
Configuration

There are no configuration notes.

Attributes

TLBI ASIDE1 is a 64-bit System instruction.

Field descriptions



ASID, bits [63:48]

ASID value to match. Any appropriate TLB entries that match the ASID values will be affected by this System instruction.

If the implementation supports 16 bits of ASID, then the upper 8 bits of the ASID must be written to 0 by software when the context being invalidated only uses 8 bits.

Bits [47:0]

Reserved, RES0.

Executing TLBI ASIDE1

This system instruction is an alias of the SYS instruction.

Accesses to this instruction use the following encodings in the System instruction encoding space:

```
TLBI ASIDE1{, <Xt>}
```

op0	op1	CRn	CRm	op2

C5.5.13 TLBI IPAS2E1, TLB Invalidate by Intermediate Physical Address, Stage 2, EL1

The TLBI IPAS2E1 characteristics are:

Purpose

If EL2 is implemented and enabled in the current Security state, invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 2 only translation table entry, from any level of the translation table walk.
- The entry would be required to translate the specified IPA using the EL1&0 translation regime.
- The entry would be used with the current VMID.

The invalidation is not required to apply to caching structures that combine stage 1 and stage 2 translation table entries.

The invalidation applies to the PE that executes this System instruction.

For more information about the architectural requirements for this System instruction, see 'Invalidating TLB entries from stage 2 translations'.

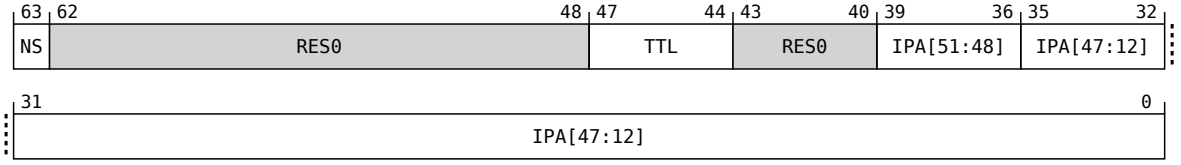
Configuration

There are no configuration notes.

Attributes

TLBI IPAS2E1 is a 64-bit System instruction.

Field descriptions



NS, bit [63]

When FEAT_SEL2 is implemented:

Not Secure. Specifies the IPA space.

NS	Meaning
0b0	IPA is in the Secure IPA space.
0b1	IPA is in the Non-secure IPA space.

Otherwise:

Reserved, RES0.

Bits [62:48]

Reserved, RES0.

TTL, bits [47:44]

When FEAT_TTL is implemented:

Translation Table Level. Indicates the level of the translation table walk that holds the leaf entry for the address being invalidated.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

TTL	Meaning
0b00xx	No information supplied as to the translation table level. Hardware must assume that the entry can be from any level. In this case, TTL<1:0> is RES0.
0b01xx	The entry comes from a 4KB translation granule. The level of walk for the leaf level 0bxx is encoded as: 0b00 : Reserved. Treat as if TTL<3:2> is 0b00. 0b01 : Level 1. 0b10 : Level 2. 0b11 : Level 3.
0b10xx	The entry comes from a 16KB translation granule. The level of walk for the leaf level 0bxx is encoded as: 0b00 : Reserved. Treat as if TTL<3:2> is 0b00. 0b01 : Reserved. Treat as if TTL<3:2> is 0b00. 0b10 : Level 2. 0b11 : Level 3.
0b11xx	The entry comes from a 64KB translation granule. The level of walk for the leaf level 0bxx is encoded as: 0b00 : Reserved. Treat as if TTL<3:2> is 0b00. 0b01 : Level 1. 0b10 : Level 2. 0b11 : Level 3.

If an incorrect value of the TTL field is specified for the entry being invalidated by the instruction, then no entries are required by the architecture to be invalidated from the TLB.

Otherwise:

Reserved, RES0.

Bits [43:40]

Reserved, RES0.

IPA[51:48], bits [39:36]

When FEAT_LPA is implemented:

Extension to IPA[47:12]. For more information, see IPA[47:12].

Otherwise:

Reserved, RES0.

IPA[47:12], bits [35:0]

Bits[47:12] of the intermediate physical address to match. For implementations with fewer than 48 bits, the upper bits of this field are RES0.

If ID_AA64MMFR0_EL1.PARange is 0b0110, bits IPA[51:48] form the upper part of the address value. Otherwise and bits IPA[51:48] are RES0.

Executing TLBI IPAS2E1

This system instruction is an alias of the SYS instruction.

Accesses to this instruction use the following encodings in the System instruction encoding space:

```
TLBI IPAS2E1{, <Xt>}
```

C5.5.15 TLBI IPAS2E1OS, TLB Invalidate by Intermediate Physical Address, Stage 2, EL1, Outer Shareable

The TLBI IPAS2E1OS characteristics are:

Purpose

If EL2 is implemented and enabled in the current Security state, invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 2 only translation table entry, from any level of the translation table walk.
- The entry would be required to translate the specified IPA using the EL1&0 translation regime.
- The entry would be used with the current VMID.

The invalidation is not required to apply to caching structures that combine stage 1 and stage 2 translation table entries.

The invalidation applies to all PEs in the same Outer Shareable shareability domain as the PE that executes this System instruction.

For more information about the architectural requirements for this System instruction, see ‘Invalidating TLB entries from stage 2 translations’.

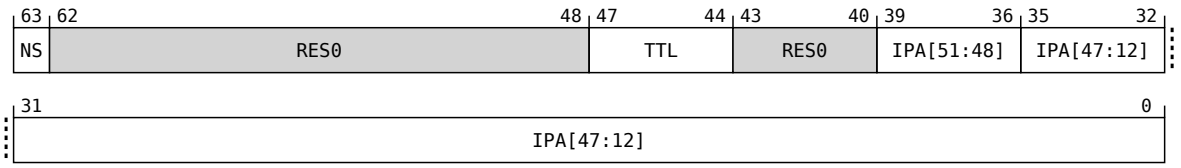
Configuration

This system instruction is present only when FEAT_TLBIOS is implemented. Otherwise, direct accesses to TLBI IPAS2E1OS are UNDEFINED.

Attributes

TLBI IPAS2E1OS is a 64-bit System instruction.

Field descriptions



NS, bit [63]

When FEAT_SEL2 is implemented:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

When FEAT_TTL is implemented:

Translation Table Level. Indicates the level of the translation table walk that holds the leaf entry for the address being invalidated.

TTL	Meaning
0b00xx	No information supplied as to the translation table level. Hardware must assume that the entry can be from any level. In this case, TTL<1:0> is RES0.
0b01xx	The entry comes from a 4KB translation granule. The level of walk for the leaf level 0bxx is encoded as: 0b00 : Reserved. Treat as if TTL<3:2> is 0b00. 0b01 : Level 1. 0b10 : Level 2. 0b11 : Level 3.
0b10xx	The entry comes from a 16KB translation granule. The level of walk for the leaf level 0bxx is encoded as: 0b00 : Reserved. Treat as if TTL<3:2> is 0b00. 0b01 : Reserved. Treat as if TTL<3:2> is 0b00. 0b10 : Level 2. 0b11 : Level 3.
0b11xx	The entry comes from a 64KB translation granule. The level of walk for the leaf level 0bxx is encoded as: 0b00 : Reserved. Treat as if TTL<3:2> is 0b00. 0b01 : Level 1. 0b10 : Level 2. 0b11 : Level 3.

If an incorrect value of the TTL field is specified for the entry being invalidated by the instruction, then no entries are required by the architecture to be invalidated from the TLB.

Otherwise:

Reserved, RES0.

Bits [43:40]

Reserved, RES0.

IPA[51:48], bits [39:36]

Extension to IPA[47:12]. For more information, see IPA[47:12].

IPA[47:12], bits [35:0]

Bits[47:12] of the intermediate physical address to match. For implementations with fewer than 48 bits, the upper bits of this field are RES0.

If ID_AA64MMFR0_EL1.PARange is 0b0110, bits IPA[51:48] form the upper part of the address value. Otherwise and bits IPA[51:48] are RES0.

Executing TLBI IPAS2E1OS

This system instruction is an alias of the SYS instruction.

Accesses to this instruction use the following encodings in the System instruction encoding space:

C5.5.16 TLBI IPAS2LE1, TLB Invalidate by Intermediate Physical Address, Stage 2, Last level, EL1

The TLBI IPAS2LE1 characteristics are:

Purpose

If EL2 is implemented and enabled in the current Security state, invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 2 only translation table entry, from the final level of the translation table walk.
- The entry would be required to translate the specified IPA using the EL1&0 translation regime.
- The entry would be used with the current VMID.

The invalidation is not required to apply to caching structures that combine stage 1 and stage 2 translation table entries.

The invalidation applies to the PE that executes this System instruction.

For more information about the architectural requirements for this System instruction, see 'Invalidating TLB entries from stage 2 translations'.

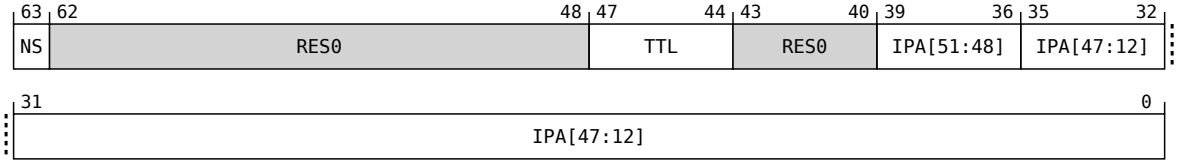
Configuration

There are no configuration notes.

Attributes

TLBI IPAS2LE1 is a 64-bit System instruction.

Field descriptions



NS, bit [63]

C5.5.19 TLBI RIPAS2E1, TLB Range Invalidate by Intermediate Physical Address, Stage 2, EL1

The TLBI RIPAS2E1 characteristics are:

Purpose

If EL2 is implemented and enabled in the current Security state, invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 2 only translation table entry, from any level of the translation table walk up to the level indicated in the TTL hint.
- The entry would be required to translate any IPA in the specified address range using the EL1&0 translation regime.
- The entry would be used with the current VMID.
- The entry is within the address range determined by the formula [BaseADDR <= VA < BaseADDR + ((NUM +1)*$2^{(5*SCALE+1)}$ * Translation_Granule_Size)].

The invalidation is not required to apply to caching structures that combine stage 1 and stage 2 translation table entries.

The invalidation applies to the PE that executes this System instruction.

For translation table entry, the range of addresses invalidated is UNPREDICTABLE when:

- For the 4K translation granule:
  - If TTL==01 and BaseADDR[29:12] is not equal to 0000000000000000.
  - If TTL==10 and BaseADDR[20:12] is not equal to 000000000.
- For the 16K translation granule:
  - If TTL==10 and BaseADDR[24:14] is not equal to 00000000000.
- For the 64K translation granule:
  - If TTL==01 and BaseADDR[41:16] is not equal to 00000000000000000000000000.
  - If TTL==10 and BaseADDR[28:16] is not equal to 0000000000000.

For more information about the architectural requirements for this System instruction, see ‘Invalidating TLB entries from stage 2 translations’.

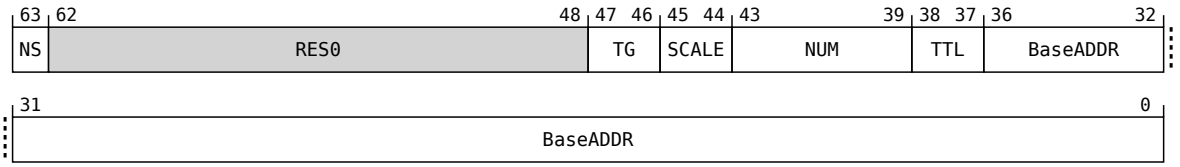
Configuration

This system instruction is present only when FEAT_TLBIRANGE is implemented. Otherwise, direct accesses to TLBI RIPAS2E1 are UNDEFINED.

Attributes

TLBI RIPAS2E1 is a 64-bit System instruction.

Field descriptions



NS, bit [63]

When FEAT_SEL2 is implemented:

Not Secure. Specifies the IPA space.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

NS	Meaning
0b0	IPA is in the Secure IPA space.
0b1	IPA is in the Non-secure IPA space.

Otherwise:

Reserved, RES0.

Bits [62:48]

Reserved, RES0.

TG, bits [47:46]

Translation granule size.

TG	Meaning
0b00	Reserved.
0b01	4K translation granule.
0b10	16K translation granule.
0b11	64K translation granule.

The instruction takes a translation granule size for the translations that are being invalidated. If the translations used a different translation granule size than the one being specified, then the architecture does not require that the instruction invalidates any entries.

SCALE, bits [45:44]

The exponent element of the calculation that is used to produce the upper range.

NUM, bits [43:39]

The base element of the calculation that is used to produce the upper range.

TTL, bits [38:37]

TTL Level hint. The TTL hint is only guaranteed to invalidate:

- Non-leaf-level entries in the range up to but not including the level described by the TTL hint.
- Leaf-level entries in the range that match the level described by the TTL hint.

TTL	Meaning
0b00	The entries in the range can be using any level for the translation table entries.
0b01	When using a 4KB or 64KB translation granule, all entries to invalidate are Level 1 translation table entries. When using a 16KB translation granule, this value is reserved and hardware should treat this field as 0b00.
0b10	The TTL hint indicates level 2.
0b11	The TTL hint indicates level 3.

BaseADDR, bits [36:0]

The starting address for the range of the maintenance instruction.

When using a 4KB translation granule, this field is BaseADDR[48:12].

When using a 16KB translation granule, this field is BaseADDR[50:14].

When using a 64KB translation granule, this field is BaseADDR[52:16].

C5.5.20 TLBI RIPAS2E1IS, TLB Range Invalidate by Intermediate Physical Address, Stage 2, EL1, Inner Shareable

The TLBI RIPAS2E1IS characteristics are:

Purpose

If EL2 is implemented and enabled in the current Security state, invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 2 only translation table entry, from any level of the translation table walk up to the level indicated in the TTL hint.
- The entry would be required to translate any IPA in the specified address range using the EL1&0 translation regime.
- The entry would be used with the current VMID.
- The entry is within the address range determined by the formula [BaseADDR <= VA < BaseADDR + ((NUM +1)*$2^{(5*SCALE+1)}$ * Translation_Granule_Size)].

The invalidation is not required to apply to caching structures that combine stage 1 and stage 2 translation table entries.

The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that executes this System instruction.

For translation table entry, the range of addresses invalidated is UNPREDICTABLE when:

- For the 4K translation granule:
  - If TTL==01 and BaseADDR[29:12] is not equal to 000000000000000000.
  - If TTL==10 and BaseADDR[20:12] is not equal to 000000000.
- For the 16K translation granule:
  - If TTL==10 and BaseADDR[24:14] is not equal to 00000000000.
- For the 64K translation granule:
  - If TTL==01 and BaseADDR[41:16] is not equal to 000000000000000000000000000000.
  - If TTL==10 and BaseADDR[28:16] is not equal to 0000000000000.

For more information about the architectural requirements for this System instruction, see ‘Invalidating TLB entries from stage 2 translations’.

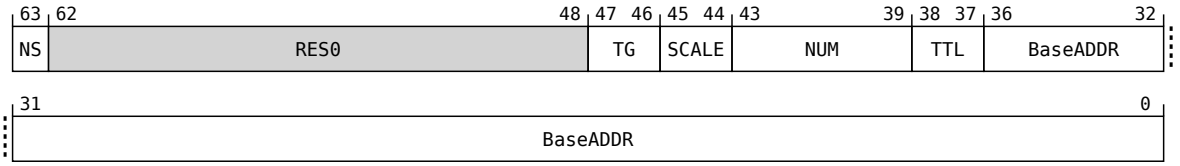
Configuration

This system instruction is present only when FEAT_TLBIRANGE is implemented. Otherwise, direct accesses to TLBI RIPAS2E1IS are UNDEFINED.

Attributes

TLBI RIPAS2E1IS is a 64-bit System instruction.

Field descriptions



NS, bit [63]

When FEAT_SEL2 is implemented:

Not Secure. Specifies the IPA space.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

NS	Meaning
0b0	IPA is in the Secure IPA space.
0b1	IPA is in the Non-secure IPA space.

Otherwise:

Reserved, RES0.

Bits [62:48]

Reserved, RES0.

TG, bits [47:46]

Translation granule size.

TG	Meaning
0b00	Reserved.
0b01	4K translation granule.
0b10	16K translation granule.
0b11	64K translation granule.

The instruction takes a translation granule size for the translations that are being invalidated. If the translations used a different translation granule size than the one being specified, then the architecture does not require that the instruction invalidates any entries.

SCALE, bits [45:44]

The exponent element of the calculation that is used to produce the upper range.

NUM, bits [43:39]

The base element of the calculation that is used to produce the upper range.

TTL, bits [38:37]

TTL Level hint. The TTL hint is only guaranteed to invalidate:

- Non-leaf-level entries in the range up to but not including the level described by the TTL hint.
- Leaf-level entries in the range that match the level described by the TTL hint.

TTL	Meaning
0b00	The entries in the range can be using any level for the translation table entries.
0b01	When using a 4KB or 64KB translation granule, all entries to invalidate are Level 1 translation table entries. When using a 16KB translation granule, this value is reserved and hardware should treat this field as 0b00.
0b10	The TTL hint indicates level 2.
0b11	The TTL hint indicates level 3.

BaseADDR, bits [36:0]

The starting address for the range of the maintenance instruction.

When using a 4KB translation granule, this field is BaseADDR[48:12].

When using a 16KB translation granule, this field is BaseADDR[50:14].

When using a 64KB translation granule, this field is BaseADDR[52:16].

C5.5.21 TLBI RIPAS2E1OS, TLB Range Invalidate by Intermediate Physical Address, Stage 2, EL1, Outer Shareable

The TLBI RIPAS2E1OS characteristics are:

Purpose

If EL2 is implemented and enabled in the current Security state, invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 2 only translation table entry, from any level of the translation table walk up to the level indicated in the TTL hint.
- The entry would be required to translate any IPA in the specified address range using the EL1&0 translation regime.
- The entry would be used with the current VMID.
- The entry is within the address range determined by the formula [BaseADDR <= VA < BaseADDR + ((NUM +1)*$2^{(5*SCALE+1)}$ * Translation_Granule_Size)].

The invalidation is not required to apply to caching structures that combine stage 1 and stage 2 translation table entries.

The invalidation applies to all PEs in the same Outer Shareable shareability domain as the PE that executes this System instruction.

For translation table entry, the range of addresses invalidated is UNPREDICTABLE when:

- For the 4K translation granule:
  - If TTL==01 and BaseADDR[29:12] is not equal to 000000000000000000.
  - If TTL==10 and BaseADDR[20:12] is not equal to 000000000.
- For the 16K translation granule:
  - If TTL==10 and BaseADDR[24:14] is not equal to 00000000000.
- For the 64K translation granule:
  - If TTL==01 and BaseADDR[41:16] is not equal to 000000000000000000000000000000.
  - If TTL==10 and BaseADDR[28:16] is not equal to 0000000000000.

For more information about the architectural requirements for this System instruction, see ‘Invalidating TLB entries from stage 2 translations’.

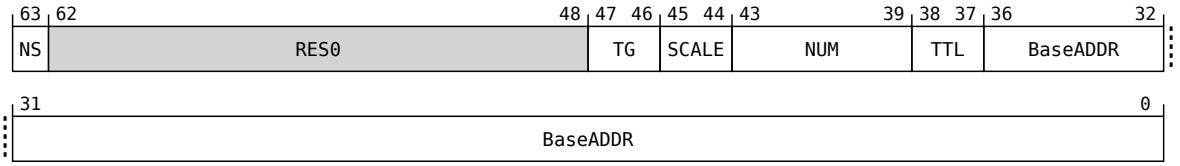
Configuration

This system instruction is present only when FEAT_TLBIRANGE is implemented and FEAT_TLBIOS is implemented. Otherwise, direct accesses to TLBI RIPAS2E1OS are UNDEFINED.

Attributes

TLBI RIPAS2E1OS is a 64-bit System instruction.

Field descriptions



NS, bit [63]

When FEAT_SEL2 is implemented:

Not Secure. Specifies the IPA space.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

NS	Meaning
0b0	IPA is in the Secure IPA space.
0b1	IPA is in the Non-secure IPA space.

Otherwise:

Reserved, RES0.

Bits [62:48]

Reserved, RES0.

TG, bits [47:46]

Translation granule size.

TG	Meaning
0b00	Reserved.
0b01	4K translation granule.
0b10	16K translation granule.
0b11	64K translation granule.

The instruction takes a translation granule size for the translations that are being invalidated. If the translations used a different translation granule size than the one being specified, then the architecture does not require that the instruction invalidates any entries.

SCALE, bits [45:44]

The exponent element of the calculation that is used to produce the upper range.

NUM, bits [43:39]

The base element of the calculation that is used to produce the upper range.

TTL, bits [38:37]

TTL Level hint. The TTL hint is only guaranteed to invalidate:

- Non-leaf-level entries in the range up to but not including the level described by the TTL hint.
- Leaf-level entries in the range that match the level described by the TTL hint.

TTL	Meaning
0b00	The entries in the range can be using any level for the translation table entries.
0b01	When using a 4KB or 64KB translation granule, all entries to invalidate are Level 1 translation table entries. When using a 16KB translation granule, this value is reserved and hardware should treat this field as 0b00.
0b10	The TTL hint indicates level 2.
0b11	The TTL hint indicates level 3.

BaseADDR, bits [36:0]

The starting address for the range of the maintenance instruction.

When using a 4KB translation granule, this field is BaseADDR[48:12].

When using a 16KB translation granule, this field is BaseADDR[50:14].

When using a 64KB translation granule, this field is BaseADDR[52:16].

C5.5.22 TLBI RIPAS2LE1, TLB Range Invalidate by Intermediate Physical Address, Stage 2, Last level, EL1

The TLBI RIPAS2LE1 characteristics are:

Purpose

If EL2 is implemented and enabled in the current Security state, invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 2 only translation table entry, from the leaf level of the translation table walk, indicated by the TTL hint.
- The entry would be required to translate any IPA in the specified address range using the EL1&0 translation regime.
- The entry would be used with the current VMID.
- The entry is within the address range determined by the formula [BaseADDR <= VA < BaseADDR + ((NUM +1)*$2^{(5*SCALE+1)}$ * Translation_Granule_Size)].

The invalidation is not required to apply to caching structures that combine stage 1 and stage 2 translation table entries.

The invalidation only applies to the PE that executes this System instruction.

For translation table entry, the range of addresses invalidated is UNPREDICTABLE when:

- For the 4K translation granule:
  - If TTL==01 and BaseADDR[29:12] is not equal to 0000000000000000.
  - If TTL==10 and BaseADDR[20:12] is not equal to 000000000.
- For the 16K translation granule:
  - If TTL==10 and BaseADDR[24:14] is not equal to 00000000000.
- For the 64K translation granule:
  - If TTL==01 and BaseADDR[41:16] is not equal to 00000000000000000000000000.
  - If TTL==10 and BaseADDR[28:16] is not equal to 0000000000000.

For more information about the architectural requirements for this System instruction, see ‘Invalidating TLB entries from stage 2 translations’.

Configuration

This system instruction is present only when FEAT_TLBIRANGE is implemented. Otherwise, direct accesses to TLBI RIPAS2LE1 are UNDEFINED.

Attributes

TLBI RIPAS2LE1 is a 64-bit System instruction.

C5.5.23 TLBI RIPAS2LE1IS, TLB Range Invalidate by Intermediate Physical Address, Stage 2, Last level, EL1, Inner Shareable

The TLBI RIPAS2LE1IS characteristics are:

Purpose

If EL2 is implemented and enabled in the current Security state, invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 2 only translation table entry, from the leaf level of the translation table walk, indicated by the TTL hint.
- The entry would be required to translate any IPA in the specified address range using the EL1&0 translation regime.
- The entry would be used with the current VMID.
- The entry is within the address range determined by the formula [BaseADDR <= VA < BaseADDR + ((NUM +1)*$2^{(5*SCALE+1)}$ * Translation_Granule_Size)].

The invalidation is not required to apply to caching structures that combine stage 1 and stage 2 translation table entries.

The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that executes this System instruction.

For translation table entry, the range of addresses invalidated is UNPREDICTABLE when:

- For the 4K translation granule:
  - If TTL==01 and BaseADDR[29:12] is not equal to 000000000000000000.
  - If TTL==10 and BaseADDR[20:12] is not equal to 000000000.
- For the 16K translation granule:
  - If TTL==10 and BaseADDR[24:14] is not equal to 00000000000.
- For the 64K translation granule:
  - If TTL==01 and BaseADDR[41:16] is not equal to 000000000000000000000000000000.
  - If TTL==10 and BaseADDR[28:16] is not equal to 0000000000000.

For more information about the architectural requirements for this System instruction, see ‘Invalidating TLB entries from stage 2 translations’.

Configuration

This system instruction is present only when FEAT_TLBIRANGE is implemented. Otherwise, direct accesses to TLBI RIPAS2LE1IS are UNDEFINED.

Attributes

TLBI RIPAS2LE1IS is a 64-bit System instruction.

C5.5.24 TLBI RIPAS2LE1OS, TLB Range Invalidate by Intermediate Physical Address, Stage 2, Last level, EL1, Outer Shareable

The TLBI RIPAS2LE1OS characteristics are:

Purpose

If EL2 is implemented and enabled in the current Security state, invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 2 only translation table entry, from the leaf level of the translation table walk, indicated by the TTL hint.
- The entry would be required to translate any IPA in the specified address range using the EL1&0 translation regime.
- The entry would be used with the current VMID.
- The entry is within the address range determined by the formula [BaseADDR <= VA < BaseADDR + ((NUM +1)*$2^{(5*SCALE+1)}$ * Translation_Granule_Size)].

Note

When a TLB maintenance instruction is generated to the Secure EL1&0 translation regime and is defined to pass a VMID argument, then:

- A PE is architecturally required to invalidate all relevant entries in the Secure EL1&0 translation of a System MMU in the same required shareability domain with a VMID of 0.

The invalidation is not required to apply to caching structures that combine stage 1 and stage 2 translation table entries.

The invalidation applies to all PEs in the same Outer Shareable shareability domain as the PE that executes this System instruction.

For translation table entry, the range of addresses invalidated is UNPREDICTABLE when:

- For the 4K translation granule:
  - If TTL==01 and BaseADDR[29:12] is not equal to 000000000000000000.
  - If TTL==10 and BaseADDR[20:12] is not equal to 000000000.
- For the 16K translation granule:
  - If TTL==10 and BaseADDR[24:14] is not equal to 00000000000.
- For the 64K translation granule:
  - If TTL==01 and BaseADDR[41:16] is not equal to 000000000000000000000000000.
  - If TTL==10 and BaseADDR[28:16] is not equal to 0000000000000.

For more information about the architectural requirements for this System instruction, see ‘Invalidating TLB entries from stage 2 translations’.

Configuration

This system instruction is present only when FEAT_TLBIRANGE is implemented and FEAT_TLBIOS is implemented. Otherwise, direct accesses to TLBI RIPAS2LE1OS are UNDEFINED.

Attributes

TLBI RIPAS2LE1OS is a 64-bit System instruction.

C5.5.25 TLBI RVAAE1, TLB Range Invalidate by VA, All ASID, EL1

The TLBI RVAAE1 characteristics are:

Purpose

Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry, from any level of the translation table walk up to the level indicated in the TTL hint.
- The entry is within the address range determined by the formula [BaseADDR <= VA < BaseADDR + ((NUM +1)*$2^{(5*SCALE+1)}$ * Translation_Granule_Size)].

The entry would be used with the current VMID and would be required to translate any of the VAs in the specified address range using the EL1&0 translation regime for the Security state.

The invalidation applies to the PE that executes this System instruction.

Note

For the EL1&0 translation regimes, the invalidation applies to both global entries and non-global entries with any ASID.

For translation table entry, the range of addresses invalidated is UNPREDICTABLE when:

- For the 4K translation granule:
  - If TTL==01 and BaseADDR[29:12] is not equal to 000000000000000000.
  - If TTL==10 and BaseADDR[20:12] is not equal to 000000000.
- For the 16K translation granule:

C5.5.26 TLBI RVAAE1IS, TLB Range Invalidate by VA, All ASID, EL1, Inner Shareable

The TLBI RVAAE1IS characteristics are:

Purpose

Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry, from any level of the translation table walk up to the level indicated in the TTL hint.
- The entry is within the address range determined by the formula [BaseADDR <= VA < BaseADDR + ((NUM +1)*$2^{(5*SCALE+1)}$ * Translation_Granule_Size)].

The entry would be used with the current VMID and would be required to translate any of the VAs in the specified address range using the EL1&0 translation regime for the Security state.

The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that executes this System instruction.

Note

When a TLB maintenance instruction is generated to the Secure EL1&0 translation regime and is defined to pass a VMID argument, then:

- A PE is architecturally required to invalidate all relevant entries in the Secure EL1&0 translation of a System MMU in the same required shareability domain with a VMID of 0.

Note

For the EL1&0 translation regimes, the invalidation applies to both global entries and non-global entries with any ASID.

For translation table entry, the range of addresses invalidated is UNPREDICTABLE when:

- For the 4K translation granule:
  - If TTL==01 and BaseADDR[29:12] is not equal to 000000000000000000.
  - If TTL==10 and BaseADDR[20:12] is not equal to 000000000.
- For the 16K translation granule:
  - If TTL==10 and BaseADDR[24:14] is not equal to 00000000000.
- For the 64K translation granule:
  - If TTL==01 and BaseADDR[41:16] is not equal to 00000000000000000000000000.
  - If TTL==10 and BaseADDR[28:16] is not equal to 0000000000000.

Configuration

This system instruction is present only when FEAT_TLBIRANGE is implemented. Otherwise, direct accesses to TLBI RVAAE1IS are UNDEFINED.

Attributes

TLBI RVAAE1IS is a 64-bit System instruction.

TG, bits [47:46]

Translation granule size.

TG	Meaning
0b00	Reserved.
0b01	4K translation granule.
0b10	16K translation granule.
0b11	64K translation granule.

The instruction takes a translation granule size for the translations that are being invalidated. If the translations used a different translation granule size than the one being specified, then the architecture does not require that the instruction invalidates any entries.

SCALE, bits [45:44]

The exponent element of the calculation that is used to produce the upper range.

NUM, bits [43:39]

The base element of the calculation that is used to produce the upper range.

TTL, bits [38:37]

TTL Level hint. The TTL hint is only guaranteed to invalidate:

- Non-leaf-level entries in the range up to but not including the level described by the TTL hint.
- Leaf-level entries in the range that match the level described by the TTL hint.

TTL	Meaning
0b00	The entries in the range can be using any level for the translation table entries.
0b01	When using a 4KB or 64KB translation granule, all entries to invalidate are Level 1 translation table entries. When using a 16KB translation granule, this value is reserved and hardware should treat this field as 0b00.
0b10	The TTL hint indicates level 2.
0b11	The TTL hint indicates level 3.

BaseADDR, bits [36:0]

The starting address for the range of the maintenance instruction.

When using a 4KB translation granule, this field is BaseADDR[48:12].

When using a 16KB translation granule, this field is BaseADDR[50:14].

When using a 64KB translation granule, this field is BaseADDR[52:16].

Executing TLBI RVAAE1IS

C5.5.27 TLBI RVAAE1OS, TLB Range Invalidate by VA, All ASID, EL1, Outer Shareable

The TLBI RVAAE1OS characteristics are:

Purpose

Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry, from any level of the translation table walk up to the level indicated in the TTL hint.
- The entry is within the address range determined by the formula [BaseADDR <= VA < BaseADDR + ((NUM +1)*$2^{(5*SCALE+1)}$ * Translation_Granule_Size)].

The entry would be used with the current VMID and would be required to translate any of the VAs in the specified address range using the EL1&0 translation regime for the Security state.

The invalidation applies to all PEs in the same Outer Shareable shareability domain as the PE that executes this System instruction.

Note

When a TLB maintenance instruction is generated to the Secure EL1&0 translation regime and is defined to pass a VMID argument, then:

- A PE is architecturally required to invalidate all relevant entries in the Secure EL1&0 translation of a System MMU in the same required shareability domain with a VMID of 0.

Note

For the EL1&0 translation regimes, the invalidation applies to both global entries and non-global entries with any ASID.

For translation table entry, the range of addresses invalidated is UNPREDICTABLE when:

- For the 4K translation granule:
  - If TTL==01 and BaseADDR[29:12] is not equal to 000000000000000000.
  - If TTL==10 and BaseADDR[20:12] is not equal to 000000000.
- For the 16K translation granule:
  - If TTL==10 and BaseADDR[24:14] is not equal to 00000000000.
- For the 64K translation granule:
  - If TTL==01 and BaseADDR[41:16] is not equal to 00000000000000000000000000.
  - If TTL==10 and BaseADDR[28:16] is not equal to 0000000000000.

Configuration

This system instruction is present only when FEAT_TLBIRANGE is implemented and FEAT_TLBIOS is implemented. Otherwise, direct accesses to TLBI RVAAE1OS are UNDEFINED.

Attributes

TLBI RVAAE1OS is a 64-bit System instruction.

C5.5.28 TLBI RVAALE1, TLB Range Invalidate by VA, All ASID, Last level, EL1

The TLBI RVAALE1 characteristics are:

Purpose

Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry, from the leaf level of the translation table walk, indicated by the TTL hint.
- The entry is within the address range determined by the formula [BaseADDR <= VA < BaseADDR + ((NUM +1)*$2^{(5*SCALE+1)}$ * Translation_Granule_Size)].

The entry would be used with the current VMID and would be required to translate any of the VAs in the specified address range using the EL1&0 translation regime for the Security state.

The invalidation applies to the PE that executes this System instruction.

Note

For the EL1&0 translation regimes, the invalidation applies to both global entries and non-global entries with any ASID.

For translation table entry, the range of addresses invalidated is UNPREDICTABLE when:

- For the 4K translation granule:
  - If TTL==01 and BaseADDR[29:12] is not equal to 0000000000000000.
  - If TTL==10 and BaseADDR[20:12] is not equal to 000000000.
- For the 16K translation granule:
  - If TTL==10 and BaseADDR[24:14] is not equal to 00000000000.
- For the 64K translation granule:
  - If TTL==01 and BaseADDR[41:16] is not equal to 00000000000000000000000000.
  - If TTL==10 and BaseADDR[28:16] is not equal to 0000000000000.

Configuration

This system instruction is present only when FEAT_TLBIRANGE is implemented. Otherwise, direct accesses to TLBI RVAALE1 are UNDEFINED.

Attributes

TLBI RVAALE1 is a 64-bit System instruction.

C5.5.29 TLBI RVAALE1IS, TLB Range Invalidate by VA, All ASID, Last Level, EL1, Inner Shareable

The TLBI RVAALE1IS characteristics are:

Purpose

Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry, from the leaf level of the translation table walk, indicated by the TTL hint.
- The entry is within the address range determined by the formula [BaseADDR <= VA < BaseADDR + ((NUM +1)*$2^{(5*SCALE+1)}$ * Translation_Granule_Size)].

The entry would be used with the current VMID and would be required to translate any of the VAs in the specified address range using the EL1&0 translation regime for the Security state.

The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that executes this System instruction.

Note

When a TLB maintenance instruction is generated to the Secure EL1&0 translation regime and is defined to pass a VMID argument, then:

- A PE is architecturally required to invalidate all relevant entries in the Secure EL1&0 translation of a System MMU in the same required shareability domain with a VMID of 0.

Note

For the EL1&0 translation regimes, the invalidation applies to both global entries and non-global entries with any ASID.

For translation table entry, the range of addresses invalidated is UNPREDICTABLE when:

- For the 4K translation granule:
  - If TTL==01 and BaseADDR[29:12] is not equal to 000000000000000000.
  - If TTL==10 and BaseADDR[20:12] is not equal to 000000000.
- For the 16K translation granule:
  - If TTL==10 and BaseADDR[24:14] is not equal to 00000000000.
- For the 64K translation granule:
  - If TTL==01 and BaseADDR[41:16] is not equal to 00000000000000000000000000.
  - If TTL==10 and BaseADDR[28:16] is not equal to 0000000000000.

Configuration

This system instruction is present only when FEAT_TLBIRANGE is implemented. Otherwise, direct accesses to TLBI RVAALE1IS are UNDEFINED.

Attributes

TLBI RVAALE1IS is a 64-bit System instruction.

C5.5.30 TLBI RVAALE1OS, TLB Range Invalidate by VA, All ASID, Last Level, EL1, Outer Shareable

The TLBI RVAALE1OS characteristics are:

Purpose

Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry, from the leaf level of the translation table walk, indicated by the TTL hint.
- The entry is within the address range determined by the formula [BaseADDR <= VA < BaseADDR + ((NUM +1)*$2^{(5*SCALE+1)}$ * Translation_Granule_Size)].

The entry would be used with the current VMID and would be required to translate any of the VAs in the specified address range using the EL1&0 translation regime for the Security state.

The invalidation applies to all PEs in the same Outer Shareable shareability domain as the PE that executes this System instruction.

Note

When a TLB maintenance instruction is generated to the Secure EL1&0 translation regime and is defined to pass a VMID argument, then:

- A PE is architecturally required to invalidate all relevant entries in the Secure EL1&0 translation of a System MMU in the same required shareability domain with a VMID of 0.

Note

For the EL1&0 translation regimes, the invalidation applies to both global entries and non-global entries with any ASID.

For translation table entry, the range of addresses invalidated is UNPREDICTABLE when:

- For the 4K translation granule:
  - If TTL==01 and BaseADDR[29:12] is not equal to 000000000000000000.
  - If TTL==10 and BaseADDR[20:12] is not equal to 000000000.
- For the 16K translation granule:
  - If TTL==10 and BaseADDR[24:14] is not equal to 00000000000.
- For the 64K translation granule:
  - If TTL==01 and BaseADDR[41:16] is not equal to 00000000000000000000000000.
  - If TTL==10 and BaseADDR[28:16] is not equal to 0000000000000.

Configuration

This system instruction is present only when FEAT_TLBIRANGE is implemented and FEAT_TLBIOS is implemented. Otherwise, direct accesses to TLBI RVAALE1OS are UNDEFINED.

Attributes

TLBI RVAALE1OS is a 64-bit System instruction.

C5.5.31 TLBI RVAE1, TLB Range Invalidate by VA, EL1

The TLBI RVAE1 characteristics are:

Purpose

Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry, from any level of the translation table walk up to the level indicated in the TTL hint.
- The entry would be used to translate any of the VAs in the specified address range, and one of the following applies:
  - The entry is from a level of lookup above the final level and matches the specified ASID.
  - The entry is a global entry from the final level of lookup.
  - The entry is a non-global entry from the final level of lookup that matches the specified ASID.
- The entry is within the address range determined by the formula [BaseADDR <= VA < BaseADDR + ((NUM +1)*$2^{(5*SCALE+1)}$ * Translation_Granule_Size)].

The entry would be used with the current VMID and would be required to translate any of the VAs in the specified address range using the EL1&0 translation regime for the Security state.

The invalidation applies to the PE that executes this System instruction.

For translation table entry, the range of addresses invalidated is UNPREDICTABLE when:

- For the 4K translation granule:
  - If TTL==01 and BaseADDR[29:12] is not equal to 000000000000000000.
  - If TTL==10 and BaseADDR[20:12] is not equal to 000000000.
- For the 16K translation granule:
  - If TTL==10 and BaseADDR[24:14] is not equal to 00000000000.
- For the 64K translation granule:
  - If TTL==01 and BaseADDR[41:16] is not equal to 000000000000000000000000000000.
  - If TTL==10 and BaseADDR[28:16] is not equal to 0000000000000.

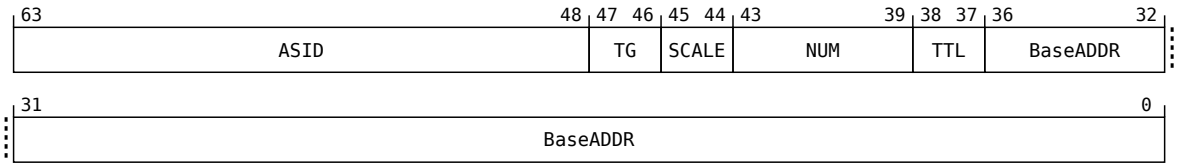
Configuration

This system instruction is present only when FEAT_TLBIRANGE is implemented. Otherwise, direct accesses to TLBI RVAE1 are UNDEFINED.

Attributes

TLBI RVAE1 is a 64-bit System instruction.

Field descriptions



ASID, bits [63:48]

ASID value to match. Any TLB entries that match the ASID value and VA value will be affected by this System instruction.

Global TLB entries that match the VA value will be affected by this System instruction, regardless of the value of the ASID field.

If the implementation supports 16 bits of ASID, then the upper 8 bits of the ASID must be written to 0 by software when the context being invalidated only uses 8 bits.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

TG, bits [47:46]

Translation granule size.

TG	Meaning
0b00	Reserved.
0b01	4K translation granule.
0b10	16K translation granule.
0b11	64K translation granule.

The instruction takes a translation granule size for the translations that are being invalidated. If the translations used a different translation granule size than the one being specified, then the architecture does not require that the instruction invalidates any entries.

SCALE, bits [45:44]

The exponent element of the calculation that is used to produce the upper range.

NUM, bits [43:39]

The base element of the calculation that is used to produce the upper range.

TTL, bits [38:37]

TTL Level hint. The TTL hint is only guaranteed to invalidate:

- Non-leaf-level entries in the range up to but not including the level described by the TTL hint.
- Leaf-level entries in the range that match the level described by the TTL hint.

TTL	Meaning
0b00	The entries in the range can be using any level for the translation table entries.
0b01	When using a 4KB or 64KB translation granule, all entries to invalidate are Level 1 translation table entries. When using a 16KB translation granule, this value is reserved and hardware should treat this field as 0b00.
0b10	The TTL hint indicates level 2.
0b11	The TTL hint indicates level 3.

BaseADDR, bits [36:0]

The starting address for the range of the maintenance instruction.

When using a 4KB translation granule, this field is BaseADDR[48:12].

When using a 16KB translation granule, this field is BaseADDR[50:14].

When using a 64KB translation granule, this field is BaseADDR[52:16].

Executing TLBI RVAE1

C5.5.32 TLBI RVAE1IS, TLB Range Invalidate by VA, EL1, Inner Shareable

The TLBI RVAE1IS characteristics are:

Purpose

Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry, from any level of the translation table walk up to the level indicated in the TTL hint.
- The entry would be used to translate any of the VAs in the specified address range, and one of the following applies:
  - The entry is from a level of lookup above the final level and matches the specified ASID.
  - The entry is a global entry from the final level of lookup.
  - The entry is a non-global entry from the final level of lookup that matches the specified ASID.
- The entry is within the address range determined by the formula [BaseADDR <= VA < BaseADDR + ((NUM +1)*$2^{(5*SCALE+1)}$ * Translation_Granule_Size)].

The entry would be used with the current VMID and would be required to translate any of the VAs in the specified address range using the EL1&0 translation regime for the Security state.

The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that executes this System instruction.

Note

When a TLB maintenance instruction is generated to the Secure EL1&0 translation regime and is defined to pass a VMID argument, then:

- A PE is architecturally required to invalidate all relevant entries in the Secure EL1&0 translation of a System MMU in the same required shareability domain with a VMID of 0.

For translation table entry, the range of addresses invalidated is UNPREDICTABLE when:

- For the 4K translation granule:
  - If TTL==01 and BaseADDR[29:12] is not equal to 000000000000000000.
  - If TTL==10 and BaseADDR[20:12] is not equal to 000000000.
- For the 16K translation granule:
  - If TTL==10 and BaseADDR[24:14] is not equal to 00000000000.
- For the 64K translation granule:
  - If TTL==01 and BaseADDR[41:16] is not equal to 000000000000000000000000000000.
  - If TTL==10 and BaseADDR[28:16] is not equal to 0000000000000.

Configuration

This system instruction is present only when FEAT_TLBIRANGE is implemented. Otherwise, direct accesses to TLBI RVAE1IS are UNDEFINED.

Attributes

TLBI RVAE1IS is a 64-bit System instruction.

Field descriptions

Non-Confidential

ASID, bits [63:48]

ASID value to match. Any TLB entries that match the ASID value and VA value will be affected by this System instruction.

Global TLB entries that match the VA value will be affected by this System instruction, regardless of the value of the ASID field.

If the implementation supports 16 bits of ASID, then the upper 8 bits of the ASID must be written to 0 by software when the context being invalidated only uses 8 bits.

TG, bits [47:46]

Translation granule size.

TG	Meaning
0b00	Reserved.
0b01	4K translation granule.
0b10	16K translation granule.
0b11	64K translation granule.

The instruction takes a translation granule size for the translations that are being invalidated. If the translations used a different translation granule size than the one being specified, then the architecture does not require that the instruction invalidates any entries.

SCALE, bits [45:44]

The exponent element of the calculation that is used to produce the upper range.

NUM, bits [43:39]

The base element of the calculation that is used to produce the upper range.

TTL, bits [38:37]

TTL Level hint. The TTL hint is only guaranteed to invalidate:

- Non-leaf-level entries in the range up to but not including the level described by the TTL hint.
- Leaf-level entries in the range that match the level described by the TTL hint.

TTL	Meaning
0b00	The entries in the range can be using any level for the translation table entries.
0b01	When using a 4KB or 64KB translation granule, all entries to invalidate are Level 1 translation table entries. When using a 16KB translation granule, this value is reserved and hardware should treat this field as 0b00.
0b10	The TTL hint indicates level 2.
0b11	The TTL hint indicates level 3.

BaseADDR, bits [36:0]

The starting address for the range of the maintenance instruction.

When using a 4KB translation granule, this field is BaseADDR[48:12].

When using a 16KB translation granule, this field is BaseADDR[50:14].

When using a 64KB translation granule, this field is BaseADDR[52:16].

C5.5.33 TLBI RVAE1OS, TLB Range Invalidate by VA, EL1, Outer Shareable

The TLBI RVAE1OS characteristics are:

Purpose

Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry, from any level of the translation table walk up to the level indicated in the TTL hint.
- The entry would be used to translate any of the VAs in the specified address range, and one of the following applies:
  - The entry is from a level of lookup above the final level and matches the specified ASID.
  - The entry is a global entry from the final level of lookup.
  - The entry is a non-global entry from the final level of lookup that matches the specified ASID.
- The entry is within the address range determined by the formula [BaseADDR <= VA < BaseADDR + ((NUM +1)*$2^{(5*SCALE+1)}$ * Translation_Granule_Size)].

The entry would be used with the current VMID and would be required to translate any of the VAs in the specified address range using the EL1&0 translation regime for the Security state.

The invalidation applies to all PEs in the same Outer Shareable shareability domain as the PE that executes this System instruction.

Note

When a TLB maintenance instruction is generated to the Secure EL1&0 translation regime and is defined to pass a VMID argument, then:

- A PE is architecturally required to invalidate all relevant entries in the Secure EL1&0 translation of a System MMU in the same required shareability domain with a VMID of 0.

For translation table entry, the range of addresses invalidated is UNPREDICTABLE when:

- For the 4K translation granule:
  - If TTL==01 and BaseADDR[29:12] is not equal to 000000000000000000.
  - If TTL==10 and BaseADDR[20:12] is not equal to 000000000.
- For the 16K translation granule:
  - If TTL==10 and BaseADDR[24:14] is not equal to 00000000000.
- For the 64K translation granule:
  - If TTL==01 and BaseADDR[41:16] is not equal to 000000000000000000000000000000.
  - If TTL==10 and BaseADDR[28:16] is not equal to 0000000000000.

Configuration

This system instruction is present only when FEAT_TLBIRANGE is implemented and FEAT_TLBIOS is implemented. Otherwise, direct accesses to TLBI RVAE1OS are UNDEFINED.

Attributes

TLBI RVAE1OS is a 64-bit System instruction.

C5.5.34 TLBI RVAE2, TLB Range Invalidate by VA, EL2

The TLBI RVAE2 characteristics are:

Purpose

When EL2 is implemented and enabled in the current Security state, invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry, from any level of the translation table walk up to the level indicated in the TTL hint.
- The entry would be used to translate any VA in the range determined by the formula [BaseADDR <= VA < BaseADDR + ((NUM +1)*$2^{(5*SCALE+1)}$ * Translation_Granule_Size)] using the EL2 translation regime for the Security state.
- The entry is from any level of the translation table walk.

The invalidation applies to the PE that executes this System instruction.

For translation table entry, the range of addresses invalidated is UNPREDICTABLE when:

- For the 4K translation granule:
  - If TTL==01 and BaseADDR[29:12] is not equal to 0000000000000000.
  - If TTL==10 and BaseADDR[20:12] is not equal to 000000000.
- For the 16K translation granule:
  - If TTL==10 and BaseADDR[24:14] is not equal to 00000000000.
- For the 64K translation granule:
  - If TTL==01 and BaseADDR[41:16] is not equal to 00000000000000000000000000.
  - If TTL==10 and BaseADDR[28:16] is not equal to 0000000000000.

Configuration

This system instruction is present only when FEAT_TLBIRANGE is implemented. Otherwise, direct accesses to TLBI RVAE2 are UNDEFINED.

Attributes

TLBI RVAE2 is a 64-bit System instruction.

C5.5.37 TLBI RVAE3, TLB Range Invalidate by VA, EL3

The TLBI RVAE3 characteristics are:

Purpose

If EL3 is implemented, invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry, from any level of the translation table walk up to the level indicated in the TTL hint.
- The entry would be used to translate any of the VAs in the specified address range using the EL3 translation regime.
- The entry is within the address range determined by the formula [BaseADDR <= VA < BaseADDR + ((NUM +1)*$2^{(5*SCALE+1)}$ * Translation_Granule_Size)].

The invalidation applies to the PE that executes this System instruction.

For translation table entry, the range of addresses invalidated is UNPREDICTABLE when:

- For the 4K translation granule:
  - If TTL==01 and BaseADDR[29:12] is not equal to 00000000000000000.
  - If TTL==10 and BaseADDR[20:12] is not equal to 000000000.
- For the 16K translation granule:
  - If TTL==10 and BaseADDR[24:14] is not equal to 00000000000.
- For the 64K translation granule:
  - If TTL==01 and BaseADDR[41:16] is not equal to 000000000000000000000000000.
  - If TTL==10 and BaseADDR[28:16] is not equal to 0000000000000.

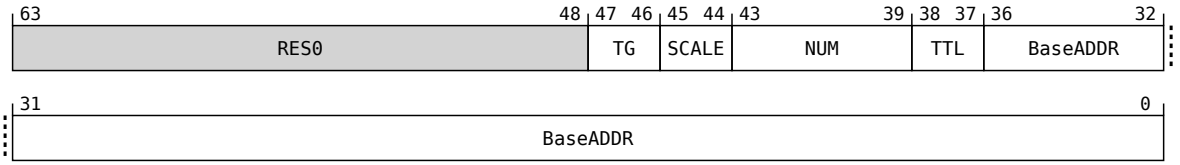
Configuration

This system instruction is present only when FEAT_TLBIRANGE is implemented. Otherwise, direct accesses to TLBI RVAE3 are UNDEFINED.

Attributes

TLBI RVAE3 is a 64-bit System instruction.

Field descriptions



Bits [63:48]

Reserved, RES0.

TG, bits [47:46]

Translation granule size.

TG	Meaning
0b00	Reserved.
0b01	4K translation granule.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

TG	Meaning
0b10	16K translation granule.
0b11	64K translation granule.

The instruction takes a translation granule size for the translations that are being invalidated. If the translations used a different translation granule size than the one being specified, then the architecture does not require that the instruction invalidates any entries.

SCALE, bits [45:44]

The exponent element of the calculation that is used to produce the upper range.

NUM, bits [43:39]

The base element of the calculation that is used to produce the upper range.

TTL, bits [38:37]

TTL Level hint. The TTL hint is only guaranteed to invalidate:

- Non-leaf-level entries in the range up to but not including the level described by the TTL hint.
- Leaf-level entries in the range that match the level described by the TTL hint.

TTL	Meaning
0b00	The entries in the range can be using any level for the translation table entries.
0b01	When using a 4KB or 64KB translation granule, all entries to invalidate are Level 1 translation table entries. When using a 16KB translation granule, this value is reserved and hardware should treat this field as 0b00.
0b10	The TTL hint indicates level 2.
0b11	The TTL hint indicates level 3.

BaseADDR, bits [36:0]

The starting address for the range of the maintenance instruction.

When using a 4KB translation granule, this field is BaseADDR[48:12].

When using a 16KB translation granule, this field is BaseADDR[50:14].

When using a 64KB translation granule, this field is BaseADDR[52:16].

C5.5.38 TLBI RVAE3IS, TLB Range Invalidate by VA, EL3, Inner Shareable

The TLBI RVAE3IS characteristics are:

Purpose

If EL3 is implemented, invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry, from any level of the translation table walk up to the level indicated in the TTL hint.
- The entry would be used to translate any of the VAs in the specified address range using the EL3 translation regime.
- The entry is within the address range determined by the formula [BaseADDR <= VA < BaseADDR + ((NUM +1)*$2^{(5*SCALE+1)}$ * Translation_Granule_Size)].

The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that executes this System instruction.

For translation table entry, the range of addresses invalidated is UNPREDICTABLE when:

- For the 4K translation granule:
  - If TTL==01 and BaseADDR[29:12] is not equal to 000000000000000000.
  - If TTL==10 and BaseADDR[20:12] is not equal to 000000000.
- For the 16K translation granule:
  - If TTL==10 and BaseADDR[24:14] is not equal to 00000000000.
- For the 64K translation granule:
  - If TTL==01 and BaseADDR[41:16] is not equal to 000000000000000000000000000000.
  - If TTL==10 and BaseADDR[28:16] is not equal to 0000000000000.

C5.5.40 TLBI RVALE1, TLB Range Invalidate by VA, Last level, EL1

The TLBI RVALE1 characteristics are:

Purpose

Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry, from any level of the translation table walk up to the level indicated in the TTL hint.
- The entry would be used to translate any of the VAs in the specified address range, and one of the following applies:
  - The entry is a global entry from the final level of lookup.
  - The entry is a non-global entry from the final level of lookup that matches the specified ASID.
- The entry is within the address range determined by the formula [BaseADDR <= VA < BaseADDR + ((NUM +1)*$2^{(5*SCALE+1)}$ * Translation_Granule_Size)].

The entry would be used with the current VMID and would be required to translate any of the VAs in the specified address range using the EL1&0 translation regime for the Security state.

The invalidation applies to the PE that executes this System instruction.

For translation table entry, the range of addresses invalidated is UNPREDICTABLE when:

- For the 4K translation granule:
  - If TTL==01 and BaseADDR[29:12] is not equal to 000000000000000000.
  - If TTL==10 and BaseADDR[20:12] is not equal to 000000000.
- For the 16K translation granule:
  - If TTL==10 and BaseADDR[24:14] is not equal to 00000000000.
- For the 64K translation granule:
  - If TTL==01 and BaseADDR[41:16] is not equal to 000000000000000000000000000000.
  - If TTL==10 and BaseADDR[28:16] is not equal to 0000000000000.

For more information about the architectural requirements for this System instruction, see ‘Invalidating TLB entries from stage 2 translations’.

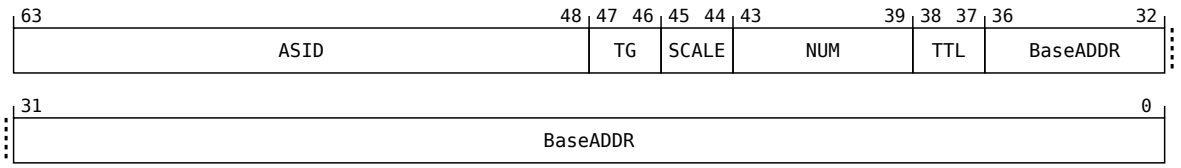
Configuration

This system instruction is present only when FEAT_TLBIRANGE is implemented. Otherwise, direct accesses to TLBI RVALE1 are UNDEFINED.

Attributes

TLBI RVALE1 is a 64-bit System instruction.

Field descriptions



ASID, bits [63:48]

ASID value to match. Any TLB entries that match the ASID value and VA value will be affected by this System instruction.

Global TLB entries that match the VA value will be affected by this System instruction, regardless of the value of the ASID field.

If the implementation supports 16 bits of ASID, then the upper 8 bits of the ASID must be written to 0 by software when the context being invalidated only uses 8 bits.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

TG, bits [47:46]

Translation granule size.

TG	Meaning
0b00	Reserved.
0b01	4K translation granule.
0b10	16K translation granule.
0b11	64K translation granule.

The instruction takes a translation granule size for the translations that are being invalidated. If the translations used a different translation granule size than the one being specified, then the architecture does not require that the instruction invalidates any entries.

C5.5.41 TLBI RVALE1IS, TLB Range Invalidate by VA, Last level, EL1, Inner Shareable

The TLBI RVALE1IS characteristics are:

Purpose

Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry, from any level of the translation table walk up to the level indicated in the TTL hint.
- The entry would be used to translate any of the VAs in the specified address range, and one of the following applies:
  - The entry is a global entry from the final level of lookup.
  - The entry is a non-global entry from the final level of lookup that matches the specified ASID.
- The entry is within the address range determined by the formula [BaseADDR <= VA < BaseADDR + ((NUM +1)*$2^{(5*SCALE+1)}$ * Translation_Granule_Size)].

The entry would be used with the current VMID and would be required to translate any of the VAs in the specified address range using the EL1&0 translation regime for the Security state.

The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that executes this System instruction.

Note

When a TLB maintenance instruction is generated to the Secure EL1&0 translation regime and is defined to pass a VMID argument, then:

- A PE is architecturally required to invalidate all relevant entries in the Secure EL1&0 translation of a System MMU in the same required shareability domain with a VMID of 0.

For translation table entry, the range of addresses invalidated is UNPREDICTABLE when:

- For the 4K translation granule:
  - If TTL==01 and BaseADDR[29:12] is not equal to 000000000000000000.
  - If TTL==10 and BaseADDR[20:12] is not equal to 000000000.
- For the 16K translation granule:
  - If TTL==10 and BaseADDR[24:14] is not equal to 00000000000.
- For the 64K translation granule:
  - If TTL==01 and BaseADDR[41:16] is not equal to 000000000000000000000000000000.
  - If TTL==10 and BaseADDR[28:16] is not equal to 0000000000000.

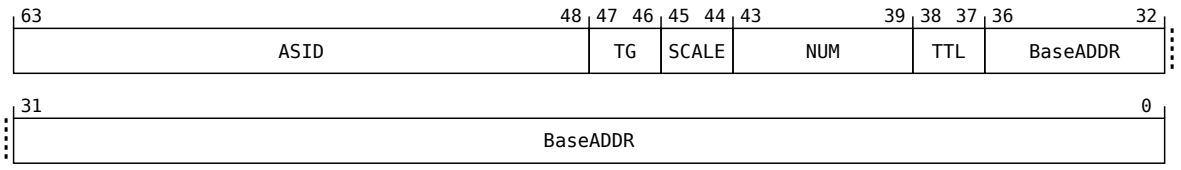
Configuration

This system instruction is present only when FEAT_TLBIRANGE is implemented. Otherwise, direct accesses to TLBI RVALE1IS are UNDEFINED.

Attributes

TLBI RVALE1IS is a 64-bit System instruction.

Field descriptions



ASID, bits [63:48]

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

ASID value to match. Any TLB entries that match the ASID value and VA value will be affected by this System instruction.

Global TLB entries that match the VA value will be affected by this System instruction, regardless of the value of the ASID field.

If the implementation supports 16 bits of ASID, then the upper 8 bits of the ASID must be written to 0 by software when the context being invalidated only uses 8 bits.

TG, bits [47:46]

Translation granule size.

TG	Meaning
0b00	Reserved.
0b01	4K translation granule.
0b10	16K translation granule.
0b11	64K translation granule.

The instruction takes a translation granule size for the translations that are being invalidated. If the translations used a different translation granule size than the one being specified, then the architecture does not require that the instruction invalidates any entries.

SCALE, bits [45:44]

The exponent element of the calculation that is used to produce the upper range.

NUM, bits [43:39]

The base element of the calculation that is used to produce the upper range.

TTL, bits [38:37]

TTL Level hint. The TTL hint is only guaranteed to invalidate:

- Non-leaf-level entries in the range up to but not including the level described by the TTL hint.
- Leaf-level entries in the range that match the level described by the TTL hint.

TTL	Meaning
0b00	The entries in the range can be using any level for the translation table entries.
0b01	When using a 4KB or 64KB translation granule, all entries to invalidate are Level 1 translation table entries. When using a 16KB translation granule, this value is reserved and hardware should treat this field as 0b00.
0b10	The TTL hint indicates level 2.
0b11	The TTL hint indicates level 3.

BaseADDR, bits [36:0]

The starting address for the range of the maintenance instruction.

When using a 4KB translation granule, this field is BaseADDR[48:12].

When using a 16KB translation granule, this field is BaseADDR[50:14].

When using a 64KB translation granule, this field is BaseADDR[52:16].

C5.5.42 TLBI RVALE1OS, TLB Range Invalidate by VA, Last level, EL1, Outer Shareable

The TLBI RVALE1OS characteristics are:

Purpose

Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry, from any level of the translation table walk up to the level indicated in the TTL hint.
- The entry would be used to translate any of the VAs in the specified address range, and one of the following applies:
  - The entry is a global entry from the final level of lookup.
  - The entry is a non-global entry from the final level of lookup that matches the specified ASID.
- The entry is within the address range determined by the formula [BaseADDR <= VA < BaseADDR + ((NUM +1)*$2^{(5*SCALE+1)}$ * Translation_Granule_Size)].

The entry would be used with the current VMID and would be required to translate any of the VAs in the specified address range using the EL1&0 translation regime for the Security state.

The invalidation applies to all PEs in the same Outer Shareable shareability domain as the PE that executes this System instruction.

Note

When a TLB maintenance instruction is generated to the Secure EL1&0 translation regime and is defined to pass a VMID argument, then:

- A PE is architecturally required to invalidate all relevant entries in the Secure EL1&0 translation of a System MMU in the same required shareability domain with a VMID of 0.

For translation table entry, the range of addresses invalidated is UNPREDICTABLE when:

- For the 4K translation granule:
  - If TTL==01 and BaseADDR[29:12] is not equal to 000000000000000000.
  - If TTL==10 and BaseADDR[20:12] is not equal to 000000000.
- For the 16K translation granule:
  - If TTL==10 and BaseADDR[24:14] is not equal to 00000000000.
- For the 64K translation granule:
  - If TTL==01 and BaseADDR[41:16] is not equal to 000000000000000000000000000000.
  - If TTL==10 and BaseADDR[28:16] is not equal to 0000000000000.

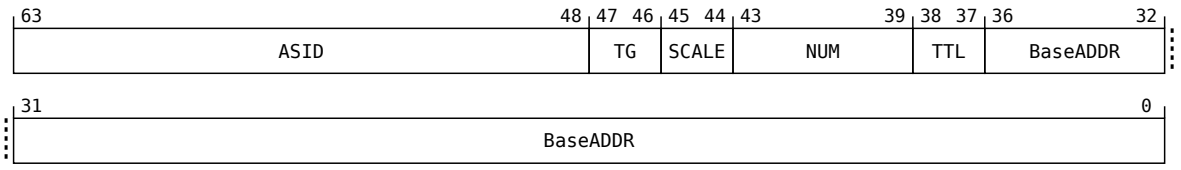
Configuration

This system instruction is present only when FEAT_TLBIRANGE is implemented and FEAT_TLBIOS is implemented. Otherwise, direct accesses to TLBI RVALE1OS are UNDEFINED.

Attributes

TLBI RVALE1OS is a 64-bit System instruction.

Field descriptions



ASID, bits [63:48]

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

ASID value to match. Any TLB entries that match the ASID value and VA value will be affected by this System instruction.

Global TLB entries that match the VA value will be affected by this System instruction, regardless of the value of the ASID field.

If the implementation supports 16 bits of ASID, then the upper 8 bits of the ASID must be written to 0 by software when the context being invalidated only uses 8 bits.

TG, bits [47:46]

Translation granule size.

TG	Meaning
0b00	Reserved.
0b01	4K translation granule.
0b10	16K translation granule.
0b11	64K translation granule.

The instruction takes a translation granule size for the translations that are being invalidated. If the translations used a different translation granule size than the one being specified, then the architecture does not require that the instruction invalidates any entries.

SCALE, bits [45:44]

The exponent element of the calculation that is used to produce the upper range.

NUM, bits [43:39]

The base element of the calculation that is used to produce the upper range.

TTL, bits [38:37]

TTL Level hint. The TTL hint is only guaranteed to invalidate:

- Non-leaf-level entries in the range up to but not including the level described by the TTL hint.
- Leaf-level entries in the range that match the level described by the TTL hint.

TTL	Meaning
0b00	The entries in the range can be using any level for the translation table entries.
0b01	When using a 4KB or 64KB translation granule, all entries to invalidate are Level 1 translation table entries. When using a 16KB translation granule, this value is reserved and hardware should treat this field as 0b00.
0b10	The TTL hint indicates level 2.
0b11	The TTL hint indicates level 3.

BaseADDR, bits [36:0]

The starting address for the range of the maintenance instruction.

When using a 4KB translation granule, this field is BaseADDR[48:12].

When using a 16KB translation granule, this field is BaseADDR[50:14].

When using a 64KB translation granule, this field is BaseADDR[52:16].

C5.5.43 TLBI RVALE2, TLB Range Invalidate by VA, Last level, EL2

The TLBI RVALE2 characteristics are:

Purpose

When EL2 is implemented and enabled in the current Security state, invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry, from any level of the translation table walk up to the level indicated in the TTL hint.
- The entry would be used to translate any VA in the range determined by the formula [BaseADDR <= VA < BaseADDR + ((NUM +1)*$2^{(5*SCALE+1)}$ * Translation_Granule_Size)] using the EL2 translation regime for the Security state.
- The entry is from the final level of the translation table walk.

The invalidation applies to the PE that executes this System instruction.

For translation table entry, the range of addresses invalidated is UNPREDICTABLE when:

- For the 4K translation granule:
  - If TTL==01 and BaseADDR[29:12] is not equal to 0000000000000000.
  - If TTL==10 and BaseADDR[20:12] is not equal to 000000000.
- For the 16K translation granule:
  - If TTL==10 and BaseADDR[24:14] is not equal to 00000000000.
- For the 64K translation granule:
  - If TTL==01 and BaseADDR[41:16] is not equal to 00000000000000000000000000.
  - If TTL==10 and BaseADDR[28:16] is not equal to 0000000000000.

Configuration

This system instruction is present only when FEAT_TLBIRANGE is implemented. Otherwise, direct accesses to TLBI RVALE2 are UNDEFINED.

Attributes

TLBI RVALE2 is a 64-bit System instruction.

The TLBI RVALE3OS characteristics are:

Purpose

If EL3 is implemented, invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry, from the final level of the translation table walk up to the level indicated in the TTL hint.
- The entry would be used to translate any of the VAs in the specified address range using the EL3 translation regime.
- The entry is within the address range determined by the formula [BaseADDR <= VA < BaseADDR + ((NUM +1)*$2^{(5*SCALE+1)}$ * Translation_Granule_Size)].

The invalidation applies to all PEs in the same Outer Shareable shareability domain as the PE that executes this System instruction.

For translation table entry, the range of addresses invalidated is UNPREDICTABLE when:

- For the 4K translation granule:
  - If TTL==01 and BaseADDR[29:12] is not equal to 000000000000000000.
  - If TTL==10 and BaseADDR[20:12] is not equal to 000000000.
- For the 16K translation granule:
  - If TTL==10 and BaseADDR[24:14] is not equal to 00000000000.
- For the 64K translation granule:
  - If TTL==01 and BaseADDR[41:16] is not equal to 000000000000000000000000000000.
  - If TTL==10 and BaseADDR[28:16] is not equal to 0000000000000.

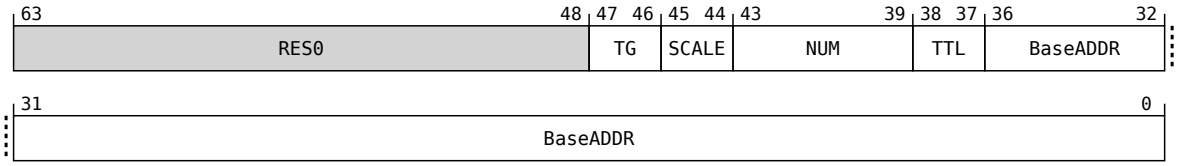
Configuration

This system instruction is present only when FEAT_TLBIRANGE is implemented and FEAT_TLBIOS is implemented. Otherwise, direct accesses to TLBI RVALE3OS are UNDEFINED.

Attributes

TLBI RVALE3OS is a 64-bit System instruction.

Field descriptions



Bits [63:48]

Reserved, RES0.

TG, bits [47:46]

Translation granule size.

TG	Meaning
0b00	Reserved.
0b01	4K translation granule.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

TG	Meaning
0b10	16K translation granule.
0b11	64K translation granule.

The instruction takes a translation granule size for the translations that are being invalidated. If the translations used a different translation granule size than the one being specified, then the architecture does not require that the instruction invalidates any entries.

SCALE, bits [45:44]

The exponent element of the calculation that is used to produce the upper range.

NUM, bits [43:39]

The base element of the calculation that is used to produce the upper range.

TTL, bits [38:37]

TTL Level hint. The TTL hint is only guaranteed to invalidate:

- Non-leaf-level entries in the range up to but not including the level described by the TTL hint.
- Leaf-level entries in the range that match the level described by the TTL hint.

TTL	Meaning
0b00	The entries in the range can be using any level for the translation table entries.
0b01	When using a 4KB or 64KB translation granule, all entries to invalidate are Level 1 translation table entries. When using a 16KB translation granule, this value is reserved and hardware should treat this field as 0b00.
0b10	The TTL hint indicates level 2.
0b11	The TTL hint indicates level 3.

BaseADDR, bits [36:0]

The starting address for the range of the maintenance instruction.

When using a 4KB translation granule, this field is BaseADDR[48:12].

When using a 16KB translation granule, this field is BaseADDR[50:14].

When using a 64KB translation granule, this field is BaseADDR[52:16].

Executing TLBI RVALE3OS

This system instruction is an alias of the SYS instruction.

This system instruction encoding is Undefined()

Accesses to this instruction use the following encodings in the System instruction encoding space:

```
TLBI RVALE3OS{, <Xt>}
```

op0	op1	CRn	CRm	op2
0b01	0b110	0b1000	0b0101	0b101

```

C5.5.49 TLBI VAAE1, TLB Invalidate by VA, All ASID, EL1

The TLBI VAAE1 characteristics are:

Purpose

Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry, from any level of the translation table walk.

The entry would be used with the current VMID and would be required to translate the specified VA using the EL1&0 translation regime for the Security state.

The invalidation applies to the PE that executes this System instruction.

Note

For the EL1&0 translation regimes, the invalidation applies to both global entries and non-global entries with any ASID.

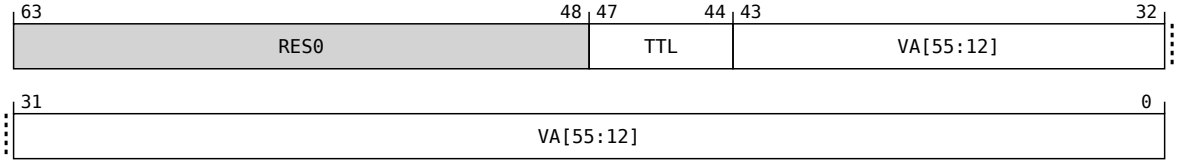
Configuration

There are no configuration notes.

Attributes

TLBI VAAE1 is a 64-bit System instruction.

Field descriptions



Bits [63:48]

Reserved, RES0.

TTL, bits [47:44]

When FEAT_TTL is implemented:

Translation Table Level. Indicates the level of the translation table walk that holds the leaf entry for the address being invalidated.

TTL	Meaning
0b00xx	No information supplied as to the translation table level. Hardware must assume that the entry can be from any level. In this case, TTL<1:0> is RES0.
0b01xx	The entry comes from a 4KB translation granule. The level of walk for the leaf level 0bxx is encoded as: 0b00 : Reserved. Treat as if TTL<3:2> is 0b00. 0b01 : Level 1. 0b10 : Level 2. 0b11 : Level 3.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

TTL	Meaning
0b10xx	The entry comes from a 16KB translation granule. The level of walk for the leaf level 0bxx is encoded as: 0b00 : Reserved. Treat as if TTL<3:2> is 0b00. 0b01 : Reserved. Treat as if TTL<3:2> is 0b00. 0b10 : Level 2. 0b11 : Level 3.
0b11xx	The entry comes from a 64KB translation granule. The level of walk for the leaf level 0bxx is encoded as: 0b00 : Reserved. Treat as if TTL<3:2> is 0b00. 0b01 : Level 1. 0b10 : Level 2. 0b11 : Level 3.

If an incorrect value of the TTL field is specified for the entry being invalidated by the instruction, then no entries are required by the architecture to be invalidated from the TLB.

Otherwise:

Reserved, RES0.

VA[55:12], bits [43:0]

Bits[55:12] of the virtual address to match. Any appropriate TLB entries that match the VA will be affected by this System instruction, regardless of the ASID.

The treatment of the low-order bits of this field depends on the translation granule size, as follows:

- Where a 4KB translation granule is being used, all bits are valid and used for the invalidation.
- Where a 16KB translation granule is being used, bits [1:0] of this field are RES0 and ignored when the instruction is executed, because VA[13:12] have no effect on the operation of the instruction.
- Where a 64KB translation granule is being used, bits [3:0] of this field are RES0 and ignored when the instruction is executed, because VA[15:12] have no effect on the operation of the instruction.

Executing TLBI VAAE1

This system instruction is an alias of the SYS instruction.

Accesses to this instruction use the following encodings in the System instruction encoding space:

`TLBI VAAE1{, <Xt>}`

op0	op1	CRn	CRm	op2
0b01	0b000	0b1000	0b0111	0b011

```
if PSTATE.EL == EL0 then
    UNDEFINED;
elsif PSTATE.EL == EL1 then
    if HCR_EL2.TTLB == '1' then
        AArch64.SystemAccessTrap(EL2, 0x18);
    elsif HCR_EL2.FB == '1' then
        AArch64.TLBI_VAA(SecurityStateAtEL(EL1), Regime_EL10, VMID[], Broadcast_ForcedISH,
            ↪TLBILevel_Any, TLBI_AllAttr, X[t, 64]);
    else
        AArch64.TLBI_VAA(SecurityStateAtEL(EL1), Regime_EL10, VMID[], Broadcast_NSH, TLBILevel_Any,
            ↪TLBI_AllAttr, X[t, 64]);
elsif PSTATE.EL == EL2 then
    AArch64.TLBI_VAA(SecurityStateAtEL(EL1), Regime_EL10, VMID[], Broadcast_NSH, TLBILevel_Any,
        ↪TLBI_AllAttr, X[t, 64]);
```

C5.5.50 TLBI VAAE1IS, TLB Invalidate by VA, All ASID, EL1, Inner Shareable

The TLBI VAAE1IS characteristics are:

Purpose

Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry, from any level of the translation table walk.

The entry would be used with the current VMID and would be required to translate the specified VA using the EL1&0 translation regime for the Security state.

The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that executes this System instruction.

Note

From Armv8.4, when a TLB maintenance instruction is generated to the Secure EL1&0 translation regime and is defined to pass a VMID argument, then:

- A PE is architecturally required to invalidate all relevant entries in the Secure EL1&0 translation of a System MMU in the same required shareability domain with a VMID of 0.

Note

For the EL1&0 translation regimes, the invalidation applies to both global entries and non-global entries with any ASID.

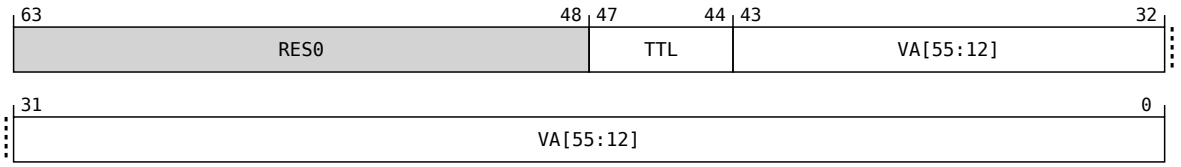
Configuration

There are no configuration notes.

Attributes

TLBI VAAE1IS is a 64-bit System instruction.

Field descriptions



Bits [63:48]

Reserved, RES0.

TTL, bits [47:44]

When FEAT_TTL is implemented:

Translation Table Level. Indicates the level of the translation table walk that holds the leaf entry for the address being invalidated.

TTL	Meaning
0b00xx	No information supplied as to the translation table level. Hardware must assume that the entry can be from any level. In this case, TTL<1:0> is RES0.

C5.5.54 TLBI VAALE1OS, TLB Invalidate by VA, All ASID, Last Level, EL1, Outer Shareable

The TLBI VAALE1OS characteristics are:

Purpose

Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry, from the final level of the translation table walk.

The entry would be used with the current VMID and would be required to translate the specified VA using the EL1&0 translation regime for the Security state.

The invalidation applies to all PEs in the same Outer Shareable shareability domain as the PE that executes this System instruction.

Note

When a TLB maintenance instruction is generated to the Secure EL1&0 translation regime and is defined to pass a VMID argument, then:

- A PE is architecturally required to invalidate all relevant entries in the Secure EL1&0 translation of a System MMU in the same required shareability domain with a VMID of 0.

Note

For the EL1&0 translation regimes, the invalidation applies to both global entries and non-global entries with any ASID.

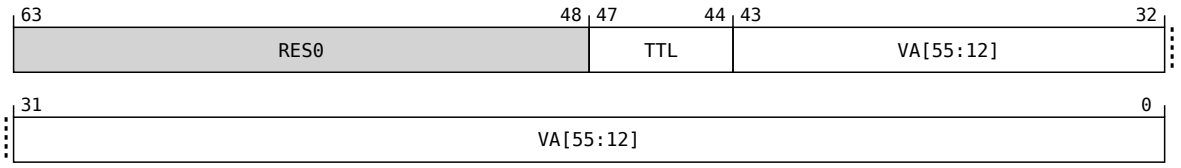
Configuration

This system instruction is present only when FEAT_TLBIOS is implemented. Otherwise, direct accesses to TLBI VAALE1OS are UNDEFINED.

Attributes

TLBI VAALE1OS is a 64-bit System instruction.

Field descriptions



Bits [63:48]

Reserved, RES0.

TTL, bits [47:44]

When FEAT_TTL is implemented:

Translation Table Level. Indicates the level of the translation table walk that holds the leaf entry for the address being invalidated.

TTL	Meaning
0b00xx	No information supplied as to the translation table level. Hardware must assume that the entry can be from any level. In this case, TTL<1:0> is RES0.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

TTL	Meaning
0b01xx	The entry comes from a 4KB translation granule. The level of walk for the leaf level 0bxx is encoded as: 0b00 : Reserved. Treat as if TTL<3:2> is 0b00. 0b01 : Level 1. 0b10 : Level 2. 0b11 : Level 3.
0b10xx	The entry comes from a 16KB translation granule. The level of walk for the leaf level 0bxx is encoded as: 0b00 : Reserved. Treat as if TTL<3:2> is 0b00. 0b01 : Reserved. Treat as if TTL<3:2> is 0b00. 0b10 : Level 2. 0b11 : Level 3.
0b11xx	The entry comes from a 64KB translation granule. The level of walk for the leaf level 0bxx is encoded as: 0b00 : Reserved. Treat as if TTL<3:2> is 0b00. 0b01 : Level 1. 0b10 : Level 2. 0b11 : Level 3.

If an incorrect value of the TTL field is specified for the entry being invalidated by the instruction, then no entries are required by the architecture to be invalidated from the TLB.

Otherwise:

Reserved, RES0.

VA[55:12], bits [43:0]

Bits[55:12] of the virtual address to match. Any appropriate TLB entries that match the VA will be affected by this System instruction, regardless of the ASID.

The treatment of the low-order bits of this field depends on the translation granule size, as follows:

- Where a 4KB translation granule is being used, all bits are valid and used for the invalidation.
- Where a 16KB translation granule is being used, bits [1:0] of this field are RES0 and ignored when the instruction is executed, because VA[13:12] have no effect on the operation of the instruction.
- Where a 64KB translation granule is being used, bits [3:0] of this field are RES0 and ignored when the instruction is executed, because VA[15:12] have no effect on the operation of the instruction.

Executing TLBI VAALE1OS

This system instruction is an alias of the SYS instruction.

Accesses to this instruction use the following encodings in the System instruction encoding space:

`TLBI VAALE1OS{, <Xt>}`

op0	op1	CRn	CRm	op2
0b01	0b000	0b1000	0b0001	0b111

```
if !IsFeatureImplemented(FEAT_TLBIOS) then

C5.5.55 TLBI VAE1, TLB Invalidate by VA, EL1

The TLBI VAE1 characteristics are:

Purpose

Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be used to translate the specified VA, and one of the following applies:
  - The entry is from a level of lookup above the final level and matches the specified ASID.
  - The entry is a global entry from the final level of lookup.
  - The entry is a non-global entry from the final level of lookup that matches the specified ASID.

The entry would be used with the current VMID and would be required to translate the specified VA using the EL1&0 translation regime for the Security state.

The invalidation applies to the PE that executes this System instruction.

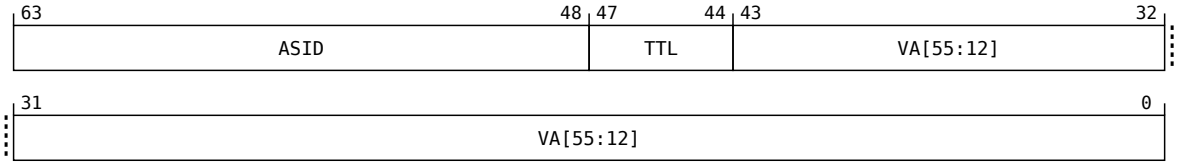
Configuration

There are no configuration notes.

Attributes

TLBI VAE1 is a 64-bit System instruction.

Field descriptions



ASID, bits [63:48]

ASID value to match. Any TLB entries that match the ASID value and VA value will be affected by this System instruction.

Global TLB entries that match the VA value will be affected by this System instruction, regardless of the value of the ASID field.

If the implementation supports 16 bits of ASID, then the upper 8 bits of the ASID must be written to 0 by software when the context being invalidated only uses 8 bits.

TTL, bits [47:44]

When FEAT_TTL is implemented:

Translation Table Level. Indicates the level of the translation table walk that holds the leaf entry for the address being invalidated.

TTL	Meaning
0b00xx	No information supplied as to the translation table level. Hardware must assume that the entry can be from any level. In this case, TTL<1:0> is RES0.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

TTL	Meaning
0b01xx	The entry comes from a 4KB translation granule. The level of walk for the leaf level 0bxx is encoded as: 0b00 : Reserved. Treat as if TTL<3:2> is 0b00. 0b01 : Level 1. 0b10 : Level 2. 0b11 : Level 3.
0b10xx	The entry comes from a 16KB translation granule. The level of walk for the leaf level 0bxx is encoded as: 0b00 : Reserved. Treat as if TTL<3:2> is 0b00. 0b01 : Reserved. Treat as if TTL<3:2> is 0b00. 0b10 : Level 2. 0b11 : Level 3.
0b11xx	The entry comes from a 64KB translation granule. The level of walk for the leaf level 0bxx is encoded as: 0b00 : Reserved. Treat as if TTL<3:2> is 0b00. 0b01 : Level 1. 0b10 : Level 2. 0b11 : Level 3.

If an incorrect value of the TTL field is specified for the entry being invalidated by the instruction, then no entries are required by the architecture to be invalidated from the TLB.

Otherwise:

Reserved, RES0.

VA[55:12], bits [43:0]

Bits[55:12] of the virtual address to match. Any appropriate TLB entries that match the ASID value (if appropriate) and VA will be affected by this System instruction.

The treatment of the low-order bits of this field depends on the translation granule size, as follows:

- Where a 4KB translation granule is being used, all bits are valid and used for the invalidation.
- Where a 16KB translation granule is being used, bits [1:0] of this field are RES0 and ignored when the instruction is executed, because VA[13:12] have no effect on the operation of the instruction.
- Where a 64KB translation granule is being used, bits [3:0] of this field are RES0 and ignored when the instruction is executed, because VA[15:12] have no effect on the operation of the instruction.

Executing TLBI VAE1

This system instruction is an alias of the SYS instruction.

Accesses to this instruction use the following encodings in the System instruction encoding space:

`TLBI VAE1{, <Xt>}`

op0	op1	CRn	CRm	op2
0b01	0b000	0b1000	0b0111	0b001

```

C5.5.56 TLBI VAE1IS, TLB Invalidate by VA, EL1, Inner Shareable

The TLBI VAE1IS characteristics are:

Purpose

Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be used to translate the specified VA, and one of the following applies:
  - The entry is from a level of lookup above the final level and matches the specified ASID.
  - The entry is a global entry from the final level of lookup.
  - The entry is a non-global entry from the final level of lookup that matches the specified ASID.

The entry would be used with the current VMID and would be required to translate the specified VA using the EL1&0 translation regime for the Security state.

The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that executes this System instruction.

Note

From Armv8.4, when a TLB maintenance instruction is generated to the Secure EL1&0 translation regime and is defined to pass a VMID argument, then:

- A PE is architecturally required to invalidate all relevant entries in the Secure EL1&0 translation of a System MMU in the same required shareability domain with a VMID of 0.

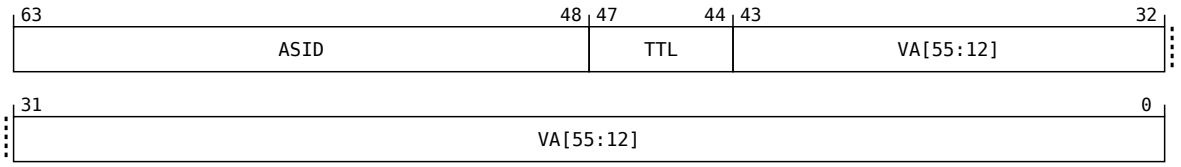
Configuration

There are no configuration notes.

Attributes

TLBI VAE1IS is a 64-bit System instruction.

Field descriptions



ASID, bits [63:48]

ASID value to match. Any TLB entries that match the ASID value and VA value will be affected by this System instruction.

Global TLB entries that match the VA value will be affected by this System instruction, regardless of the value of the ASID field.

If the implementation supports 16 bits of ASID, then the upper 8 bits of the ASID must be written to 0 by software when the context being invalidated only uses 8 bits.

TTL, bits [47:44]

When FEAT_TTL is implemented:

Translation Table Level. Indicates the level of the translation table walk that holds the leaf entry for the address being invalidated.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

TTL	Meaning
0b00xx	No information supplied as to the translation table level. Hardware must assume that the entry can be from any level. In this case, TTL<1:0> is RES0.
0b01xx	The entry comes from a 4KB translation granule. The level of walk for the leaf level 0bxx is encoded as: 0b00 : Reserved. Treat as if TTL<3:2> is 0b00. 0b01 : Level 1. 0b10 : Level 2. 0b11 : Level 3.
0b10xx	The entry comes from a 16KB translation granule. The level of walk for the leaf level 0bxx is encoded as: 0b00 : Reserved. Treat as if TTL<3:2> is 0b00. 0b01 : Reserved. Treat as if TTL<3:2> is 0b00. 0b10 : Level 2. 0b11 : Level 3.
0b11xx	The entry comes from a 64KB translation granule. The level of walk for the leaf level 0bxx is encoded as: 0b00 : Reserved. Treat as if TTL<3:2> is 0b00. 0b01 : Level 1. 0b10 : Level 2. 0b11 : Level 3.

If an incorrect value of the TTL field is specified for the entry being invalidated by the instruction, then no entries are required by the architecture to be invalidated from the TLB.

Otherwise:

Reserved, RES0.

VA[55:12], bits [43:0]

Bits[55:12] of the virtual address to match. Any appropriate TLB entries that match the ASID value (if appropriate) and VA will be affected by this System instruction.

The treatment of the low-order bits of this field depends on the translation granule size, as follows:

- Where a 4KB translation granule is being used, all bits are valid and used for the invalidation.
- Where a 16KB translation granule is being used, bits [1:0] of this field are RES0 and ignored when the instruction is executed, because VA[13:12] have no effect on the operation of the instruction.
- Where a 64KB translation granule is being used, bits [3:0] of this field are RES0 and ignored when the instruction is executed, because VA[15:12] have no effect on the operation of the instruction.

Executing TLBI VAE1IS

This system instruction is an alias of the SYS instruction.

Accesses to this instruction use the following encodings in the System instruction encoding space:

`TLBI VAE1IS{, <Xt>}`

C5.5.57 TLBI VAE1OS, TLB Invalidate by VA, EL1, Outer Shareable

The TLBI VAE1OS characteristics are:

Purpose

Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be used to translate the specified VA, and one of the following applies:
  - The entry is from a level of lookup above the final level and matches the specified ASID.
  - The entry is a global entry from the final level of lookup.
  - The entry is a non-global entry from the final level of lookup that matches the specified ASID.

The entry would be used with the current VMID and would be required to translate the specified VA using the EL1&0 translation regime for the Security state.

The invalidation applies to all PEs in the same Outer Shareable shareability domain as the PE that executes this System instruction.

Note

When a TLB maintenance instruction is generated to the Secure EL1&0 translation regime and is defined to pass a VMID argument, then:

- A PE is architecturally required to invalidate all relevant entries in the Secure EL1&0 translation of a System MMU in the same required shareability domain with a VMID of 0.

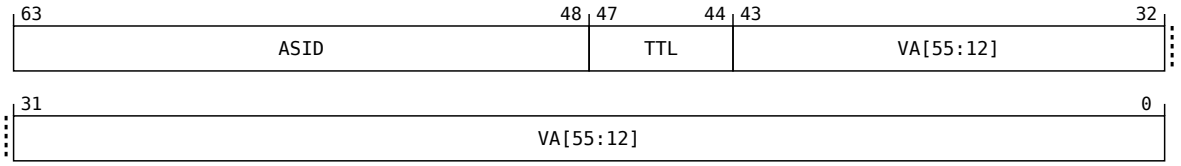
Configuration

This system instruction is present only when FEAT_TLBIOS is implemented. Otherwise, direct accesses to TLBI VAE1OS are UNDEFINED.

Attributes

TLBI VAE1OS is a 64-bit System instruction.

Field descriptions



ASID, bits [63:48]

ASID value to match. Any TLB entries that match the ASID value and VA value will be affected by this System instruction.

Global TLB entries that match the VA value will be affected by this System instruction, regardless of the value of the ASID field.

If the implementation supports 16 bits of ASID, then the upper 8 bits of the ASID must be written to 0 by software when the context being invalidated only uses 8 bits.

TTL, bits [47:44]

When FEAT_TTL is implemented:

Translation Table Level. Indicates the level of the translation table walk that holds the leaf entry for the address being invalidated.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

TTL	Meaning
0b00xx	No information supplied as to the translation table level. Hardware must assume that the entry can be from any level. In this case, TTL<1:0> is RES0.
0b01xx	The entry comes from a 4KB translation granule. The level of walk for the leaf level 0bxx is encoded as: 0b00 : Reserved. Treat as if TTL<3:2> is 0b00. 0b01 : Level 1. 0b10 : Level 2. 0b11 : Level 3.
0b10xx	The entry comes from a 16KB translation granule. The level of walk for the leaf level 0bxx is encoded as: 0b00 : Reserved. Treat as if TTL<3:2> is 0b00. 0b01 : Reserved. Treat as if TTL<3:2> is 0b00. 0b10 : Level 2. 0b11 : Level 3.
0b11xx	The entry comes from a 64KB translation granule. The level of walk for the leaf level 0bxx is encoded as: 0b00 : Reserved. Treat as if TTL<3:2> is 0b00. 0b01 : Level 1. 0b10 : Level 2. 0b11 : Level 3.

If an incorrect value of the TTL field is specified for the entry being invalidated by the instruction, then no entries are required by the architecture to be invalidated from the TLB.

Otherwise:

Reserved, RES0.

VA[55:12], bits [43:0]

Bits[55:12] of the virtual address to match. Any appropriate TLB entries that match the ASID value (if appropriate) and VA will be affected by this System instruction.

The treatment of the low-order bits of this field depends on the translation granule size, as follows:

- Where a 4KB translation granule is being used, all bits are valid and used for the invalidation.
- Where a 16KB translation granule is being used, bits [1:0] of this field are RES0 and ignored when the instruction is executed, because VA[13:12] have no effect on the operation of the instruction.
- Where a 64KB translation granule is being used, bits [3:0] of this field are RES0 and ignored when the instruction is executed, because VA[15:12] have no effect on the operation of the instruction.

Executing TLBI VAE1OS

This system instruction is an alias of the SYS instruction.

Accesses to this instruction use the following encodings in the System instruction encoding space:

C5.5.58 TLBI VAE2, TLB Invalidate by VA, EL2

The TLBI VAE2 characteristics are:

Purpose

When EL2 is implemented and enabled in the current Security state, invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be required to translate the specified VA using the EL2 translation regime for the Security state.
- The entry is from any level of the translation table walk.

The invalidation applies to the PE that executes this System instruction.

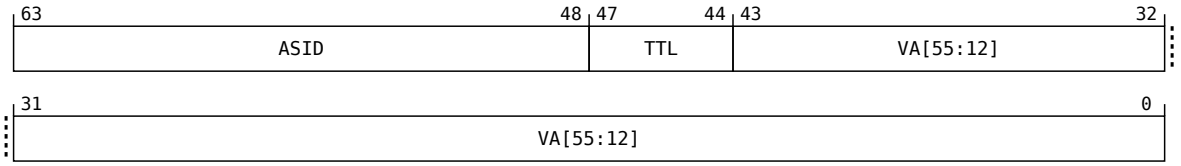
Configuration

There are no configuration notes.

Attributes

TLBI VAE2 is a 64-bit System instruction.

Field descriptions



ASID, bits [63:48]

ASID value to match. Any TLB entries that match the ASID value and VA value will be affected by this System instruction.

Global TLB entries that match the VA value will be affected by this System instruction, regardless of the value of the ASID field.

If the implementation supports 16 bits of ASID, then the upper 8 bits of the ASID must be written to 0 by software when the context being invalidated only uses 8 bits.

TTL, bits [47:44]

When FEAT_TTL is implemented:

Translation Table Level. Indicates the level of the translation table walk that holds the leaf entry for the address being invalidated.

TTL	Meaning
0b00xx	No information supplied as to the translation table level. Hardware must assume that the entry can be from any level. In this case, TTL<1:0> is RES0.
0b01xx	The entry comes from a 4KB translation granule. The level of walk for the leaf level 0bxx is encoded as: 0b00 : Reserved. Treat as if TTL<3:2> is 0b00. 0b01 : Level 1. 0b10 : Level 2. 0b11 : Level 3.

TTL	Meaning
0b01xx	The entry comes from a 4KB translation granule. The level of walk for the leaf level 0bxx is encoded as: 0b00 : Reserved. Treat as if TTL<3:2> is 0b00. 0b01 : Level 1. 0b10 : Level 2. 0b11 : Level 3.
0b10xx	The entry comes from a 16KB translation granule. The level of walk for the leaf level 0bxx is encoded as: 0b00 : Reserved. Treat as if TTL<3:2> is 0b00. 0b01 : Reserved. Treat as if TTL<3:2> is 0b00. 0b10 : Level 2. 0b11 : Level 3.
0b11xx	The entry comes from a 64KB translation granule. The level of walk for the leaf level 0bxx is encoded as: 0b00 : Reserved. Treat as if TTL<3:2> is 0b00. 0b01 : Level 1. 0b10 : Level 2. 0b11 : Level 3.

If an incorrect value of the TTL field is specified for the entry being invalidated by the instruction, then no entries are required by the architecture to be invalidated from the TLB.

Otherwise:

Reserved, RES0.

VA[55:12], bits [43:0]

Bits[55:12] of the virtual address to match. Any appropriate TLB entries that match the ASID value (if appropriate) and VA will be affected by this System instruction.

The treatment of the low-order bits of this field depends on the translation granule size, as follows:

- Where a 4KB translation granule is being used, all bits are valid and used for the invalidation.
- Where a 16KB translation granule is being used, bits [1:0] of this field are RES0 and ignored when the instruction is executed, because VA[13:12] have no effect on the operation of the instruction.
- Where a 64KB translation granule is being used, bits [3:0] of this field are RES0 and ignored when the instruction is executed, because VA[15:12] have no effect on the operation of the instruction.

Executing TLBI VAE2IS

This system instruction is an alias of the SYS instruction.

Accesses to this instruction use the following encodings in the System instruction encoding space:

`TLBI VAE2IS{, <Xt>}`

op0	op1	CRn	CRm	op2
0b01	0b100	0b1000	0b0011	0b001

```

C5.5.60 TLBI VAE2OS, TLB Invalidate by VA, EL2, Outer Shareable

The TLBI VAE2OS characteristics are:

Purpose

When EL2 is implemented and enabled in the current Security state, invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be required to translate the specified VA using the EL2 translation regime for the Security state.
- The entry is from any level of the translation table walk.

The invalidation applies to all PEs in the same Outer Shareable shareability domain as the PE that executes this System instruction.

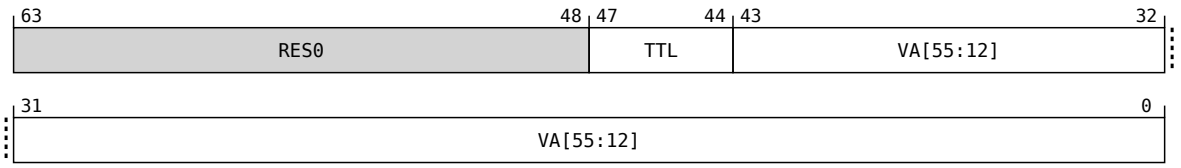
Configuration

This system instruction is present only when FEAT_TLBIOS is implemented. Otherwise, direct accesses to TLBI VAE2OS are UNDEFINED.

Attributes

TLBI VAE2OS is a 64-bit System instruction.

Field descriptions



Bits [63:48]

Reserved, RES0.

TTL, bits [47:44]

When FEAT_TTL is implemented:

Translation Table Level. Indicates the level of the translation table walk that holds the leaf entry for the address being invalidated.

TTL	Meaning
0b00xx	No information supplied as to the translation table level. Hardware must assume that the entry can be from any level. In this case, TTL<1:0> is RES0.
0b01xx	The entry comes from a 4KB translation granule. The level of walk for the leaf level 0bxx is encoded as: 0b00 : Reserved. Treat as if TTL<3:2> is 0b00. 0b01 : Level 1. 0b10 : Level 2. 0b11 : Level 3.

C5.5.61 TLBI VAE3, TLB Invalidate by VA, EL3

The TLBI VAE3 characteristics are:

Purpose

If EL3 is implemented, invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry, from any level of the translation table walk.
- The entry would be used to translate the specified VA using the EL3 translation regime.

The invalidation applies to the PE that executes this System instruction.

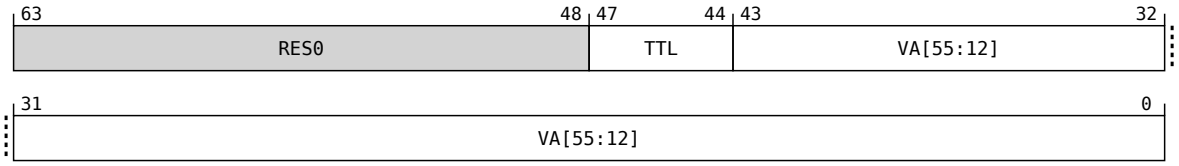
Configuration

There are no configuration notes.

Attributes

TLBI VAE3 is a 64-bit System instruction.

Field descriptions



Bits [63:48]

Reserved, RES0.

TTL, bits [47:44]

When FEAT_TTL is implemented:

Translation Table Level. Indicates the level of the translation table walk that holds the leaf entry for the address being invalidated.

TTL	Meaning
0b00xx	No information supplied as to the translation table level. Hardware must assume that the entry can be from any level. In this case, TTL<1:0> is RES0.
0b01xx	The entry comes from a 4KB translation granule. The level of walk for the leaf level 0bxx is encoded as: 0b00 : Reserved. Treat as if TTL<3:2> is 0b00. 0b01 : Level 1. 0b10 : Level 2. 0b11 : Level 3.
0b10xx	The entry comes from a 16KB translation granule. The level of walk for the leaf level 0bxx is encoded as: 0b00 : Reserved. Treat as if TTL<3:2> is 0b00. 0b01 : Reserved. Treat as if TTL<3:2> is 0b00. 0b10 : Level 2. 0b11 : Level 3.

C5.5.62 TLBI VAE3IS, TLB Invalidate by VA, EL3, Inner Shareable

The TLBI VAE3IS characteristics are:

Purpose

If EL3 is implemented, invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry, from any level of the translation table walk.
- The entry would be used to translate the specified VA using the EL3 translation regime.

The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that executes this System instruction.

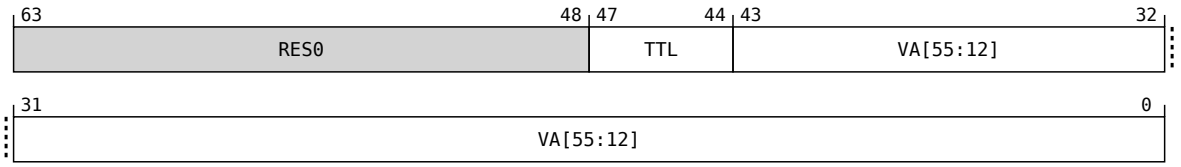
Configuration

There are no configuration notes.

Attributes

TLBI VAE3IS is a 64-bit System instruction.

Field descriptions



Bits [63:48]

Reserved, RES0.

TTL, bits [47:44]

When FEAT_TTL is implemented:

Translation Table Level. Indicates the level of the translation table walk that holds the leaf entry for the address being invalidated.

TTL	Meaning
0b00xx	No information supplied as to the translation table level. Hardware must assume that the entry can be from any level. In this case, TTL<1:0> is RES0.
0b01xx	The entry comes from a 4KB translation granule. The level of walk for the leaf level 0bxx is encoded as: 0b00 : Reserved. Treat as if TTL<3:2> is 0b00. 0b01 : Level 1. 0b10 : Level 2. 0b11 : Level 3.
0b10xx	The entry comes from a 16KB translation granule. The level of walk for the leaf level 0bxx is encoded as: 0b00 : Reserved. Treat as if TTL<3:2> is 0b00. 0b01 : Reserved. Treat as if TTL<3:2> is 0b00. 0b10 : Level 2. 0b11 : Level 3.

C5.5.64 TLBI VALE1, TLB Invalidate by VA, Last level, EL1

The TLBI VALE1 characteristics are:

Purpose

Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be used to translate the specified VA, and one of the following applies:
  - The entry is a global entry from the final level of lookup.
  - The entry is a non-global entry from the final level of lookup that matches the specified ASID.

The entry would be used with the current VMID and would be required to translate the specified VA using the EL1&0 translation regime for the Security state.

The invalidation applies to the PE that executes this System instruction.

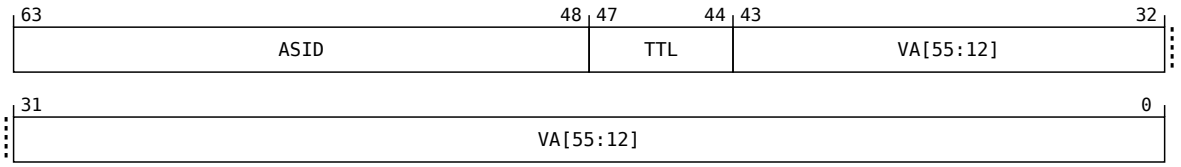
Configuration

There are no configuration notes.

Attributes

TLBI VALE1 is a 64-bit System instruction.

Field descriptions



ASID, bits [63:48]

ASID value to match. Any TLB entries that match the ASID value and VA value will be affected by this System instruction.

Global TLB entries that match the VA value will be affected by this System instruction, regardless of the value of the ASID field.

If the implementation supports 16 bits of ASID, then the upper 8 bits of the ASID must be written to 0 by software when the context being invalidated only uses 8 bits.

TTL, bits [47:44]

When FEAT_TTL is implemented:

Translation Table Level. Indicates the level of the translation table walk that holds the leaf entry for the address being invalidated.

TTL	Meaning
0b00xx	No information supplied as to the translation table level. Hardware must assume that the entry can be from any level. In this case, TTL<1:0> is RES0.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

TTL	Meaning
0b01xx	The entry comes from a 4KB translation granule. The level of walk for the leaf level 0bxx is encoded as: 0b00 : Reserved. Treat as if TTL<3:2> is 0b00. 0b01 : Level 1. 0b10 : Level 2. 0b11 : Level 3.
0b10xx	The entry comes from a 16KB translation granule. The level of walk for the leaf level 0bxx is encoded as: 0b00 : Reserved. Treat as if TTL<3:2> is 0b00. 0b01 : Reserved. Treat as if TTL<3:2> is 0b00. 0b10 : Level 2. 0b11 : Level 3.
0b11xx	The entry comes from a 64KB translation granule. The level of walk for the leaf level 0bxx is encoded as: 0b00 : Reserved. Treat as if TTL<3:2> is 0b00. 0b01 : Level 1. 0b10 : Level 2. 0b11 : Level 3.

If an incorrect value of the TTL field is specified for the entry being invalidated by the instruction, then no entries are required by the architecture to be invalidated from the TLB.

Otherwise:

Reserved, RES0.

VA[55:12], bits [43:0]

Bits[55:12] of the virtual address to match. Any appropriate TLB entries that match the ASID value (if appropriate) and VA will be affected by this System instruction.

The treatment of the low-order bits of this field depends on the translation granule size, as follows:

- Where a 4KB translation granule is being used, all bits are valid and used for the invalidation.
- Where a 16KB translation granule is being used, bits [1:0] of this field are RES0 and ignored when the instruction is executed, because VA[13:12] have no effect on the operation of the instruction.
- Where a 64KB translation granule is being used, bits [3:0] of this field are RES0 and ignored when the instruction is executed, because VA[15:12] have no effect on the operation of the instruction.

Executing TLBI VALE1

This system instruction is an alias of the SYS instruction.

Accesses to this instruction use the following encodings in the System instruction encoding space:

`TLBI VALE1{, <Xt>}`

op0	op1	CRn	CRm	op2
0b01	0b000	0b1000	0b0111	0b101

```
if PSTATE.EL == EL0 then
    UNDEFINED;

C5.5.65 TLBI VALE1IS, TLB Invalidate by VA, Last level, EL1, Inner Shareable

The TLBI VALE1IS characteristics are:

Purpose

Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be used to translate the specified VA, and one of the following applies:
  - The entry is a global entry from the final level of lookup.
  - The entry is a non-global entry from the final level of lookup that matches the specified ASID.

The entry would be used with the current VMID and would be required to translate the specified VA using the EL1&0 translation regime for the Security state.

The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that executes this System instruction.

Note

From Armv8.4, when a TLB maintenance instruction is generated to the Secure EL1&0 translation regime and is defined to pass a VMID argument, then:

- A PE is architecturally required to invalidate all relevant entries in the Secure EL1&0 translation of a System MMU in the same required shareability domain with a VMID of 0.

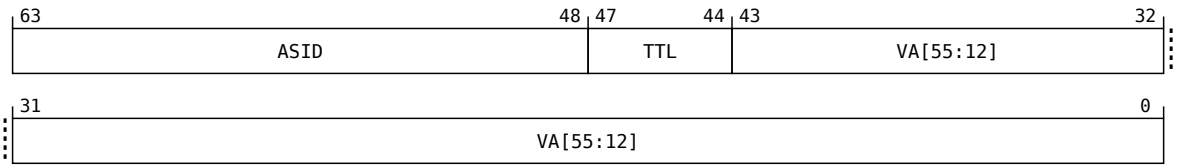
Configuration

There are no configuration notes.

Attributes

TLBI VALE1IS is a 64-bit System instruction.

Field descriptions



ASID, bits [63:48]

ASID value to match. Any TLB entries that match the ASID value and VA value will be affected by this System instruction.

Global TLB entries that match the VA value will be affected by this System instruction, regardless of the value of the ASID field.

If the implementation supports 16 bits of ASID, then the upper 8 bits of the ASID must be written to 0 by software when the context being invalidated only uses 8 bits.

TTL, bits [47:44]

When FEAT_TTL is implemented:

Translation Table Level. Indicates the level of the translation table walk that holds the leaf entry for the address being invalidated.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

TTL	Meaning
0b00xx	No information supplied as to the translation table level. Hardware must assume that the entry can be from any level. In this case, TTL<1:0> is RES0.
0b01xx	The entry comes from a 4KB translation granule. The level of walk for the leaf level 0bxx is encoded as: 0b00 : Reserved. Treat as if TTL<3:2> is 0b00. 0b01 : Level 1. 0b10 : Level 2. 0b11 : Level 3.
0b10xx	The entry comes from a 16KB translation granule. The level of walk for the leaf level 0bxx is encoded as: 0b00 : Reserved. Treat as if TTL<3:2> is 0b00. 0b01 : Reserved. Treat as if TTL<3:2> is 0b00. 0b10 : Level 2. 0b11 : Level 3.
0b11xx	The entry comes from a 64KB translation granule. The level of walk for the leaf level 0bxx is encoded as: 0b00 : Reserved. Treat as if TTL<3:2> is 0b00. 0b01 : Level 1. 0b10 : Level 2. 0b11 : Level 3.

If an incorrect value of the TTL field is specified for the entry being invalidated by the instruction, then no entries are required by the architecture to be invalidated from the TLB.

Otherwise:

Reserved, RES0.

VA[55:12], bits [43:0]

Bits[55:12] of the virtual address to match. Any appropriate TLB entries that match the ASID value (if appropriate) and VA will be affected by this System instruction.

The treatment of the low-order bits of this field depends on the translation granule size, as follows:

- Where a 4KB translation granule is being used, all bits are valid and used for the invalidation.
- Where a 16KB translation granule is being used, bits [1:0] of this field are RES0 and ignored when the instruction is executed, because VA[13:12] have no effect on the operation of the instruction.
- Where a 64KB translation granule is being used, bits [3:0] of this field are RES0 and ignored when the instruction is executed, because VA[15:12] have no effect on the operation of the instruction.

Executing TLBI VALE1IS

This system instruction is an alias of the SYS instruction.

Accesses to this instruction use the following encodings in the System instruction encoding space:

`TLBI VALE1IS{, <Xt>}`

op0	op1	CRn	CRm	op2

C5.5.66 TLBI VALE1OS, TLB Invalidate by VA, Last level, EL1, Outer Shareable

The TLBI VALE1OS characteristics are:

Purpose

Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be used to translate the specified VA, and one of the following applies:
  - The entry is a global entry from the final level of lookup.
  - The entry is a non-global entry from the final level of lookup that matches the specified ASID.

The entry would be used with the current VMID and would be required to translate the specified VA using the EL1&0 translation regime for the Security state.

The invalidation applies to all PEs in the same Outer Shareable shareability domain as the PE that executes this System instruction.

Note

When a TLB maintenance instruction is generated to the Secure EL1&0 translation regime and is defined to pass a VMID argument, then:

- A PE is architecturally required to invalidate all relevant entries in the Secure EL1&0 translation of a System MMU in the same required shareability domain with a VMID of 0.

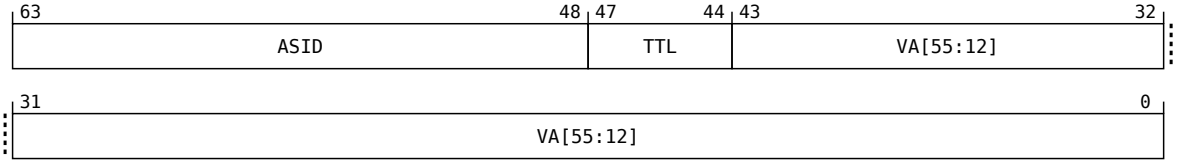
Configuration

This system instruction is present only when FEAT_TLBIOS is implemented. Otherwise, direct accesses to TLBI VALE1OS are UNDEFINED.

Attributes

TLBI VALE1OS is a 64-bit System instruction.

Field descriptions



ASID, bits [63:48]

ASID value to match. Any TLB entries that match the ASID value and VA value will be affected by this System instruction.

Global TLB entries that match the VA value will be affected by this System instruction, regardless of the value of the ASID field.

If the implementation supports 16 bits of ASID, then the upper 8 bits of the ASID must be written to 0 by software when the context being invalidated only uses 8 bits.

TTL, bits [47:44]

When FEAT_TTL is implemented:

Translation Table Level. Indicates the level of the translation table walk that holds the leaf entry for the address being invalidated.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

TTL	Meaning
0b00xx	No information supplied as to the translation table level. Hardware must assume that the entry can be from any level. In this case, TTL<1:0> is RES0.
0b01xx	The entry comes from a 4KB translation granule. The level of walk for the leaf level 0bxx is encoded as: 0b00 : Reserved. Treat as if TTL<3:2> is 0b00. 0b01 : Level 1. 0b10 : Level 2. 0b11 : Level 3.
0b10xx	The entry comes from a 16KB translation granule. The level of walk for the leaf level 0bxx is encoded as: 0b00 : Reserved. Treat as if TTL<3:2> is 0b00. 0b01 : Reserved. Treat as if TTL<3:2> is 0b00. 0b10 : Level 2. 0b11 : Level 3.
0b11xx	The entry comes from a 64KB translation granule. The level of walk for the leaf level 0bxx is encoded as: 0b00 : Reserved. Treat as if TTL<3:2> is 0b00. 0b01 : Level 1. 0b10 : Level 2. 0b11 : Level 3.

If an incorrect value of the TTL field is specified for the entry being invalidated by the instruction, then no entries are required by the architecture to be invalidated from the TLB.

Otherwise:

Reserved, RES0.

VA[55:12], bits [43:0]

Bits[55:12] of the virtual address to match. Any appropriate TLB entries that match the ASID value (if appropriate) and VA will be affected by this System instruction.

The treatment of the low-order bits of this field depends on the translation granule size, as follows:

- Where a 4KB translation granule is being used, all bits are valid and used for the invalidation.
- Where a 16KB translation granule is being used, bits [1:0] of this field are RES0 and ignored when the instruction is executed, because VA[13:12] have no effect on the operation of the instruction.
- Where a 64KB translation granule is being used, bits [3:0] of this field are RES0 and ignored when the instruction is executed, because VA[15:12] have no effect on the operation of the instruction.

Executing TLBI VALE1OS

This system instruction is an alias of the SYS instruction.

Accesses to this instruction use the following encodings in the System instruction encoding space:

`TLBI VALE1OS{, <Xt>}`

op0	op1	CRn	CRm	op2

C5.5.67 TLBI VALE2, TLB Invalidate by VA, Last level, EL2

The TLBI VALE2 characteristics are:

Purpose

When EL2 is implemented and enabled in the current Security state, invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be used to translate the specified VA using the EL2 translation regime for the Security state.
- The entry is from the final level of the translation table walk.

The invalidation applies to the PE that executes this System instruction.

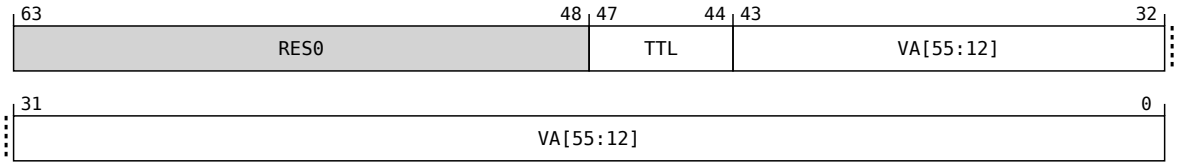
Configuration

There are no configuration notes.

Attributes

TLBI VALE2 is a 64-bit System instruction.

Field descriptions



Bits [63:48]

Reserved, RES0.

TTL, bits [47:44]

When FEAT_TTL is implemented:

Translation Table Level. Indicates the level of the translation table walk that holds the leaf entry for the address being invalidated.

TTL	Meaning
0b00xx	No information supplied as to the translation table level. Hardware must assume that the entry can be from any level. In this case, TTL<1:0> is RES0.
0b01xx	The entry comes from a 4KB translation granule. The level of walk for the leaf level 0bxx is encoded as: 0b00 : Reserved. Treat as if TTL<3:2> is 0b00. 0b01 : Level 1. 0b10 : Level 2. 0b11 : Level 3.
0b10xx	The entry comes from a 16KB translation granule. The level of walk for the leaf level 0bxx is encoded as: 0b00 : Reserved. Treat as if TTL<3:2> is 0b00. 0b01 : Reserved. Treat as if TTL<3:2> is 0b00. 0b10 : Level 2. 0b11 : Level 3.

C5.5.70 TLBI VALE3, TLB Invalidate by VA, Last level, EL3

The TLBI VALE3 characteristics are:

Purpose

If EL3 is implemented, invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry, from the final level of the translation table walk.
- The entry would be used to translate the specified VA using the EL3 translation regime.

The invalidation applies to the PE that executes this System instruction.

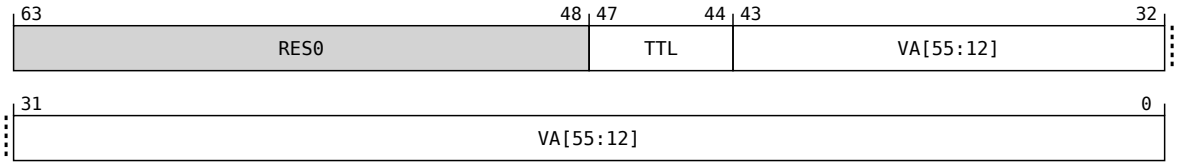
Configuration

There are no configuration notes.

Attributes

TLBI VALE3 is a 64-bit System instruction.

Field descriptions



Bits [63:48]

Reserved, RES0.

TTL, bits [47:44]

When FEAT_TTL is implemented:

Translation Table Level. Indicates the level of the translation table walk that holds the leaf entry for the address being invalidated.

TTL	Meaning
0b00xx	No information supplied as to the translation table level. Hardware must assume that the entry can be from any level. In this case, TTL<1:0> is RES0.
0b01xx	The entry comes from a 4KB translation granule. The level of walk for the leaf level 0bxx is encoded as: 0b00 : Reserved. Treat as if TTL<3:2> is 0b00. 0b01 : Level 1. 0b10 : Level 2. 0b11 : Level 3.
0b10xx	The entry comes from a 16KB translation granule. The level of walk for the leaf level 0bxx is encoded as: 0b00 : Reserved. Treat as if TTL<3:2> is 0b00. 0b01 : Reserved. Treat as if TTL<3:2> is 0b00. 0b10 : Level 2. 0b11 : Level 3.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.

C5.5.72 TLBI VALE3OS, TLB Invalidate by VA, Last level, EL3, Outer Shareable

The TLBI VALE3OS characteristics are:

Purpose

If EL3 is implemented, invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry, from the final level of the translation table walk.
- The entry would be used to translate the specified VA using the EL3 translation regime.

The invalidation applies to all PEs in the same Outer Shareable shareability domain as the PE that executes this System instruction.

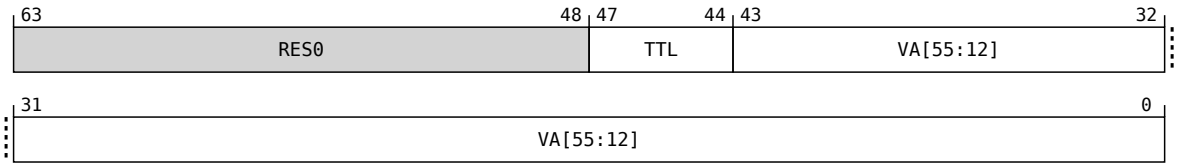
Configuration

This system instruction is present only when FEAT_TLBIOS is implemented. Otherwise, direct accesses to TLBI VALE3OS are UNDEFINED.

Attributes

TLBI VALE3OS is a 64-bit System instruction.

Field descriptions



Bits [63:48]

Reserved, RES0.

TTL, bits [47:44]

When FEAT_TTL is implemented:

Translation Table Level. Indicates the level of the translation table walk that holds the leaf entry for the address being invalidated.

TTL	Meaning
0b00xx	No information supplied as to the translation table level. Hardware must assume that the entry can be from any level. In this case, TTL<1:0> is RES0.
0b01xx	The entry comes from a 4KB translation granule. The level of walk for the leaf level 0bxx is encoded as: 0b00 : Reserved. Treat as if TTL<3:2> is 0b00. 0b01 : Level 1. 0b10 : Level 2. 0b11 : Level 3.
0b10xx	The entry comes from a 16KB translation granule. The level of walk for the leaf level 0bxx is encoded as: 0b00 : Reserved. Treat as if TTL<3:2> is 0b00. 0b01 : Reserved. Treat as if TTL<3:2> is 0b00. 0b10 : Level 2. 0b11 : Level 3.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

TTL	Meaning
0b11xx	The entry comes from a 64KB translation granule. The level of walk for the leaf level 0bxx is encoded as: 0b00 : Reserved. Treat as if TTL<3:2> is 0b00. 0b01 : Level 1. 0b10 : Level 2. 0b11 : Level 3.

If an incorrect value of the TTL field is specified for the entry being invalidated by the instruction, then no entries are required by the architecture to be invalidated from the TLB.

Otherwise:

Reserved, RES0.

VA[55:12], bits [43:0]

Bits[55:12] of the virtual address to match. Any appropriate TLB entries that match the ASID value (if appropriate) and VA will be affected by this System instruction.

The treatment of the low-order bits of this field depends on the translation granule size, as follows:

- Where a 4KB translation granule is being used, all bits are valid and used for the invalidation.
- Where a 16KB translation granule is being used, bits [1:0] of this field are RES0 and ignored when the instruction is executed, because VA[13:12] have no effect on the operation of the instruction.
- Where a 64KB translation granule is being used, bits [3:0] of this field are RES0 and ignored when the instruction is executed, because VA[15:12] have no effect on the operation of the instruction.

Executing TLBI VALE3OS

This system instruction is an alias of the SYS instruction.

This system instruction encoding is Undefined()

Accesses to this instruction use the following encodings in the System instruction encoding space:

```
TLBI VALE3OS{, <Xt>}
```

op0	op1	CRn	CRm	op2
0b01	0b110	0b1000	0b0001	0b101

```
if !IsFeatureImplemented(FEAT_TLBIOS) then

C5.5.73 TLBI VMALLE1, TLB Invalidate by VMID, All at stage 1, EL1

The TLBI VMALLE1 characteristics are:

Purpose

Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry, from any level of the translation table walk.

The entry would be used with the current VMID and would be required to translate the specified VA using the EL1&0 translation regime for the Security state.

The invalidation applies to the PE that executes this System instruction.

Note

For the EL1&0 translation regimes, the invalidation applies to both global entries and non-global entries with any ASID.

Configuration

There are no configuration notes.

Attributes

TLBI VMALLE1 is a 64-bit System instruction.

Field descriptions

This instruction has no applicable fields.

The value in the register specified by <Xt> is ignored.

Executing TLBI VMALLE1

The Rt field should be set to `0b11111`. If the Rt field is not set to `0b11111`, it is CONSTRAINED UNPREDICTABLE whether:

- The instruction is UNDEFINED.
- The instruction behaves as if the Rt field is set to `0b11111`.

This system instruction is an alias of the SYS instruction.

Accesses to this instruction use the following encodings in the System instruction encoding space:

```
TLBI VMALLE1{, <Xt>}
```

op0	op1	CRn	CRm	op2
0b01	0b000	0b1000	0b0111	0b000

```
if PSTATE.EL == EL0 then
    UNDEFINED;
elsif PSTATE.EL == EL1 then
    if HCR_EL2.TTLB == '1' then
        AArch64.SystemAccessTrap(EL2, 0x18);
    elsif HCR_EL2.FB == '1' then
        AArch64.TLBI_VMALL(SecurityStateAtEL(EL1), Regime_EL10, VMID[], Broadcast_ForcedISH,
            ↪TLBI_AllAttr, X[t, 64]);
    else
        AArch64.TLBI_VMALL(SecurityStateAtEL(EL1), Regime_EL10, VMID[], Broadcast_NSH, TLBI_AllAttr,
            ↪X[t, 64]);
elsif PSTATE.EL == EL2 then
    AArch64.TLBI_VMALL(SecurityStateAtEL(EL1), Regime_EL10, VMID[], Broadcast_NSH, TLBI_AllAttr, X[t,

C5.5.74 TLBI VMALLE1IS, TLB Invalidate by VMID, All at stage 1, EL1, Inner Shareable

The TLBI VMALLE1IS characteristics are:

Purpose

Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry, from any level of the translation table walk.

The entry would be used with the current VMID and would be required to translate the specified VA using the EL1&0 translation regime for the Security state.

The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that executes this System instruction.

Note

From Armv8.4, when a TLB maintenance instruction is generated to the Secure EL1&0 translation regime and is defined to pass a VMID argument, then:

- A PE is architecturally required to invalidate all relevant entries in the Secure EL1&0 translation of a System MMU in the same required shareability domain with a VMID of 0.

Note

For the EL1&0 translation regimes, the invalidation applies to both global entries and non-global entries with any ASID.

Configuration

There are no configuration notes.

Attributes

TLBI VMALLE1IS is a 64-bit System instruction.

Field descriptions

This instruction has no applicable fields.

The value in the register specified by <Xt> is ignored.

Executing TLBI VMALLE1IS

The Rt field should be set to `0b11111`. If the Rt field is not set to `0b11111`, it is CONSTRAINED UNPREDICTABLE whether:

- The instruction is UNDEFINED.
- The instruction behaves as if the Rt field is set to `0b11111`.

This system instruction is an alias of the SYS instruction.

Accesses to this instruction use the following encodings in the System instruction encoding space:

```

C5.5.75 TLBI VMALLE1OS, TLB Invalidate by VMID, All at stage 1, EL1, Outer Shareable

The TLBI VMALLE1OS characteristics are:

Purpose

Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry, from any level of the translation table walk.

The entry would be used with the current VMID and would be required to translate the specified VA using the EL1&0 translation regime for the Security state.

The invalidation applies to all PEs in the same Outer Shareable shareability domain as the PE that executes this System instruction.

Note

When a TLB maintenance instruction is generated to the Secure EL1&0 translation regime and is defined to pass a VMID argument, then:

- A PE is architecturally required to invalidate all relevant entries in the Secure EL1&0 translation of a System MMU in the same required shareability domain with a VMID of 0.

Note

For the EL1&0 translation regimes, the invalidation applies to both global entries and non-global entries with any ASID.

Configuration

This system instruction is present only when FEAT_TLBIOS is implemented. Otherwise, direct accesses to TLBI VMALLE1OS are UNDEFINED.

Attributes

TLBI VMALLE1OS is a 64-bit System instruction.

Field descriptions

This instruction has no applicable fields.

The value in the register specified by <Xt> is ignored.

Executing TLBI VMALLE1OS

The Rt field should be set to `0b11111`. If the Rt field is not set to `0b11111`, it is CONSTRAINED UNPREDICTABLE whether:

C5.5.76 TLBI VMALLS12E1, TLB Invalidate by VMID, All at Stage 1 and 2, EL1

The TLBI VMALLS12E1 characteristics are:

Purpose

Invalidates cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 or stage 2 translation table entry, from any level of the translation table walk.
- The entry would be required to translate an address using the EL1&0 translation regime.
- The entry would be used with the current VMID.

The invalidation applies to the PE that executes this System instruction.

Note

For the EL1&0 translation regimes, the invalidation applies to both global entries and non-global entries with any ASID.

Configuration

There are no configuration notes.

Attributes

TLBI VMALLS12E1 is a 64-bit System instruction.

Field descriptions

This instruction has no applicable fields.

The value in the register specified by <Xt> is ignored.

Executing TLBI VMALLS12E1

The Rt field should be set to `0b11111`. If the Rt field is not set to `0b11111`, it is CONSTRAINED UNPREDICTABLE whether:

- The instruction is UNDEFINED.
- The instruction behaves as if the Rt field is set to `0b11111`.

C5.6 A64 System instructions for prediction restriction

This section lists the A64 System instructions for prediction restriction.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C5.6.1 CFP RCTX, Control Flow Prediction Restriction by Context

The CFP RCTX characteristics are:

Purpose

Control Flow Prediction Restriction by Context applies to all Control Flow Prediction Resources that predict execution based on information gathered within the target execution context or contexts.

Control flow predictions determined by the actions of code in the target execution context or contexts appearing in program order before the instruction cannot exploitatively control speculative execution occurring after the instruction is complete and synchronized.

This instruction is guaranteed to be complete following a DSB that covers both read and write behavior on the same PE as executed the original restriction instruction, and a subsequent context synchronization event is required to ensure that the effect of the completion of the instructions is synchronized to the current execution.

Note

This instruction does not require the invalidation of prediction structures so long as the behavior described for completion of this instruction is met by the implementation.
On some implementations the instruction is likely to take a significant number of cycles to execute. This instruction is expected to be used very rarely, such as on the roll-over of an ASID or VMID, but should not be used on every context switch.

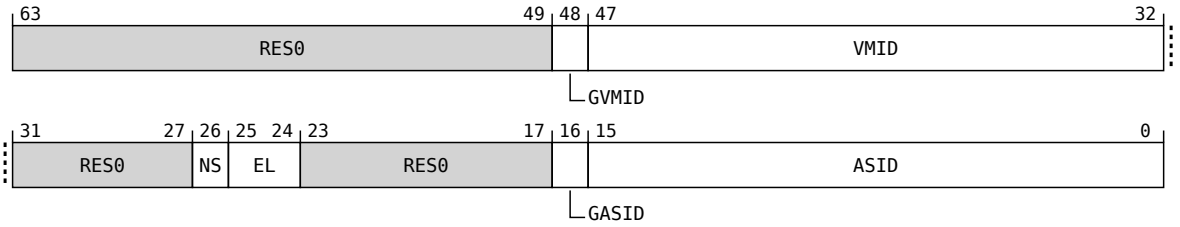
Configuration

This system instruction is present only when FEAT_SPECRES is implemented. Otherwise, direct accesses to CFP RCTX are UNDEFINED.

Attributes

CFP RCTX is a 64-bit System instruction.

Field descriptions



Bits [63:49]

Reserved, RES0.

GVMID, bit [48]

Execution of this instruction applies to all VMIDs or a specified VMID.

GVMID	Meaning
0b0	Applies to specified VMID for an EL0 or EL1 target execution context.
0b1	Applies to all VMIDs for an EL0 or EL1 target execution context.

For target execution contexts other than EL0 or EL1, this field is RES0.

If the instruction is executed at EL0 or EL1, this field has an Effective value of 0.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

VMID, bits [47:32]

Only applies when bit[48] is 0 and the target execution context is either:

- EL1.
- EL0.

Otherwise this field is RES0.

When the instruction is executed at EL1, this field is treated as the current VMID.

When the instruction is executed at EL0, this field is treated as the current VMID.

If the implementation supports 16 bits of VMID, then the upper 8 bits of the VMID must be written to 0 by software when the context being affected only uses 8 bits.

Bits [31:27]

Reserved, RES0.

NS, bit [26]

Security State.

NS	Meaning
0b0	Secure state.
0b1	Non-secure state.

When executed in Non-secure state, the Effective value of NS is 1.

EL, bits [25:24]

Exception Level. Indicates the Exception level of the target execution context.

EL	Meaning
0b00	EL0.
0b01	EL1
0b10	EL2

If the instruction is executed at an Exception level lower than the specified level, or is specified to apply to a combination of Exception level and Security state that is not implemented, this instruction is treated as a NOP.

Bits [23:17]

Reserved, RES0.

GASID, bit [16]

Execution of this instruction applies to all ASIDs or a specified ASID.

GASID	Meaning
0b0	Applies to specified ASID for an EL0 target execution context.
0b1	Applies to all ASIDs for an EL0 target execution context.

For target execution contexts other than EL0, this field is RES0.

If the instruction is executed at EL0, this field has an Effective value of 0.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

ASID, bits [15:0]

Only applies for an EL0 target execution context and when bit[16] is 0.

Otherwise, this field is RES0.

When the instruction is executed at EL0, this field is treated as the current ASID.

If the implementation supports 16 bits of ASID, then the upper 8 bits of the ASID must be written to 0 by software when the context being affected only uses 8 bits.

Executing CFP RCTX

This system instruction is an alias of the SYS instruction.

Accesses to this instruction use the following encodings in the System instruction encoding space:

`CFP RCTX, <Xt>`

op0	op1	CRn	CRm	op2
0b01	0b011	0b0111	0b0011	0b100

```
if !IsFeatureImplemented(FEAT_SPECRES) then
    UNDEFINED;
elsif PSTATE.EL == EL0 then
    if !ELIsInHost(EL0) && SCTLR_EL1.EnRCTX == '0' then
        if HCR_EL2.TGE == '1' then
            AArch64.SystemAccessTrap(EL2, 0x18);
        else
            AArch64.SystemAccessTrap(EL1, 0x18);
    else
        AArch64.RestrictPrediction(X[t, 64], RestrictType_ControlFlow);
elsif PSTATE.EL == EL1 then
    AArch64.RestrictPrediction(X[t, 64], RestrictType_ControlFlow);
elsif PSTATE.EL == EL2 then
    AArch64.RestrictPrediction(X[t, 64], RestrictType_ControlFlow);
```

Non-Confidential

C5.6.2 CPP RCTX, Cache Prefetch Prediction Restriction by Context

The CPP RCTX characteristics are:

Purpose

Cache Prefetch Prediction Restriction by Context applies to all Cache Allocation Resources that predict cache allocations based on information gathered within the target execution context or contexts.

The actions of code in the target execution context or contexts appearing in program order before the instruction cannot exploitatively control cache prefetch predictions occurring after the instruction is complete and synchronized.

This instruction applies to all:

- Instruction caches.
- Data caches.
- TLB prefetching hardware used by the executing PE that applies to the supplied context or contexts.

This instruction is guaranteed to be complete following a DSB that covers both read and write behavior on the same PE as executed the original restriction instruction, and a subsequent context synchronization event is required to ensure that the effect of the completion of the instructions is synchronized to the current execution.

Note

This instruction does not require the invalidation of Cache Allocation Resources so long as the behavior described for completion of this instruction is met by the implementation.
On some implementations the instruction is likely to take a significant number of cycles to execute. This instruction is expected to be used very rarely, such as on the roll-over of an ASID or VMID, but should not be used on every context switch.

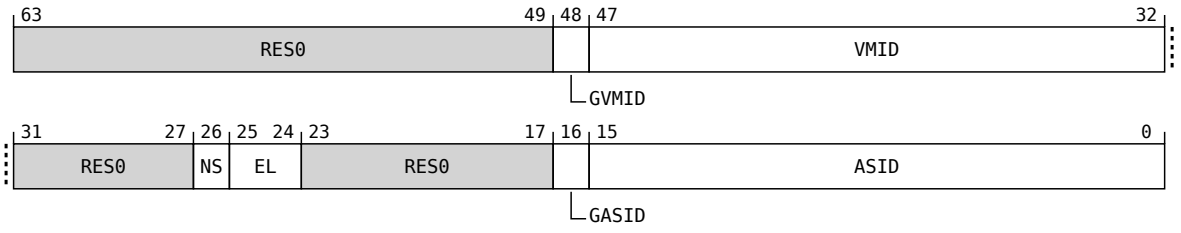
Configuration

This system instruction is present only when FEAT_SPECRES is implemented. Otherwise, direct accesses to CPP RCTX are UNDEFINED.

Attributes

CPP RCTX is a 64-bit System instruction.

Field descriptions



Bits [63:49]

Reserved, RES0.

GVMID, bit [48]

Execution of this instruction applies to all VMIDs or a specified VMID.

GVMID	Meaning
0b0	Applies to specified VMID for an EL0 or EL1 target execution context.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

GVMID	Meaning
0b1	Applies to all VMIDs for an EL0 or EL1 target execution context.

For target execution contexts other than EL0 and EL1, this field is RES0.

If the instruction is executed at EL0 or EL1, this field has an Effective value of 0.

VMID, bits [47:32]

Only applies when bit[48] is 0 and the target execution context is either:

- EL1.
- EL0.

Otherwise this field is RES0.

When the instruction is executed at EL1, this field is treated as the current VMID.

When the instruction is executed at EL0, this field is treated as the current VMID.

If the implementation supports 16 bits of VMID, then the upper 8 bits of the VMID must be written to 0 by software when the context being affected only uses 8 bits.

Bits [31:27]

Reserved, RES0.

NS, bit [26]

Security State.

NS	Meaning
0b0	Secure state.
0b1	Non-secure state.

When executed in Non-secure state, the Effective value of NS is 1.

EL, bits [25:24]

Exception Level. Indicates the Exception level of the target execution context.

EL	Meaning
0b00	EL0.
0b01	EL1
0b10	EL2

If the instruction is executed at an Exception level lower than the specified level, or is specified to apply to a combination of Exception level and Security state that is not implemented, this instruction is treated as a NOP.

Bits [23:17]

Reserved, RES0.

GASID, bit [16]

Execution of this instruction applies to all ASIDs or a specified ASID.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

GASID	Meaning
0b0	Applies to specified ASID for an EL0 target execution context.
0b1	Applies to all ASIDs for an EL0 target execution context.

For target execution contexts other than EL0, this field is RES0.

If the instruction is executed at EL0, this field has an Effective value of 0.

ASID, bits [15:0]

Only applies for an EL0 target execution context and when bit[16] is 0.

Otherwise, this field is RES0.

When the instruction is executed at EL0, this field is treated as the current ASID.

If the implementation supports 16 bits of ASID, then the upper 8 bits of the ASID must be written to 0 by software when the context being affected only uses 8 bits.

Executing CPP RCTX

This system instruction is an alias of the SYS instruction.

Accesses to this instruction use the following encodings in the System instruction encoding space:

`CPP RCTX, <Xt>`

op0	op1	CRn	CRm	op2
0b01	0b011	0b0111	0b0011	0b111

```
if !IsFeatureImplemented(FEAT_SPECRES) then
    UNDEFINED;
elsif PSTATE.EL == EL0 then
    if !ELIsInHost(EL0) && SCTLR_EL1.EnRCTX == '0' then
        if HCR_EL2.TGE == '1' then
            AArch64.SystemAccessTrap(EL2, 0x18);
        else
            AArch64.SystemAccessTrap(EL1, 0x18);
    else
        AArch64.RestrictPrediction(X[t, 64], RestrictType_CachePrefetch);
elsif PSTATE.EL == EL1 then
    AArch64.RestrictPrediction(X[t, 64], RestrictType_CachePrefetch);
elsif PSTATE.EL == EL2 then
    AArch64.RestrictPrediction(X[t, 64], RestrictType_CachePrefetch);
```

C5.6.3 DVP RCTX, Data Value Prediction Restriction by Context

The DVP RCTX characteristics are:

Purpose

Data Value Prediction Restriction by Context applies to all Data Value Prediction Resources that predict execution based on information gathered within the target execution context or contexts.

Note

The prediction of the PSTATE.{N,Z,C,V} values is not considered a data value for this purpose.

Data value predictions determined by the actions of code in the target execution context or contexts appearing in program order before the instruction cannot exploitatively control speculative execution occurring after the instruction is complete and synchronized.

This instruction is guaranteed to be complete following a DSB that covers both read and write behavior on the same PE as executed the original restriction instruction, and a subsequent context synchronization event is required to ensure that the effect of the completion of the instructions is synchronized to the current execution.

Note

This instruction does not require the invalidation of prediction structures so long as the behavior described for completion of this instruction is met by the implementation.
On some implementations the instruction is likely to take a significant number of cycles to execute. This instruction is expected to be used very rarely, such as on the roll-over of an ASID or VMID, but should not be used on every context switch.

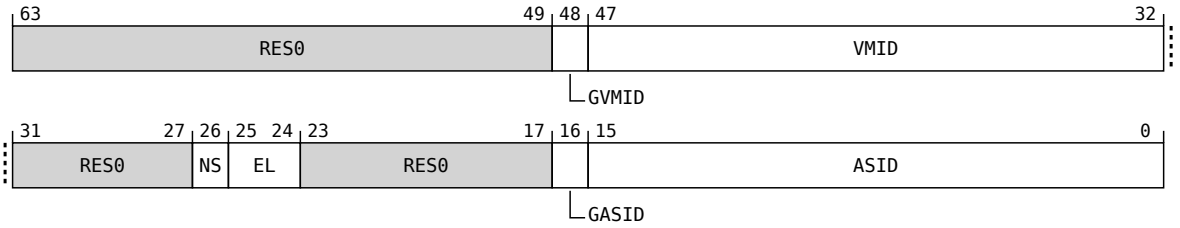
Configuration

This system instruction is present only when FEAT_SPECRES is implemented. Otherwise, direct accesses to DVP RCTX are UNDEFINED.

Attributes

DVP RCTX is a 64-bit System instruction.

Field descriptions



Bits [63:49]

Reserved, RES0.

GVMID, bit [48]

Execution of this instruction applies to all VMIDs or a specified VMID.

GVMID	Meaning
0b0	Applies to specified VMID for an EL0 or EL1 target execution context.
0b1	Applies to all VMIDs for an EL0 or EL1 target execution context.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

For target execution contexts other than EL0 or EL1, this field is RES0.

If the instruction is executed at EL0 or EL1, then this field has an Effective value of 0.

VMID, bits [47:32]

Only applies when bit[48] is 0 and the target execution context is either:

- EL1.
- EL0.

Otherwise this field is RES0.

When the instruction is executed at EL1, this field is treated as the current VMID.

When the instruction is executed at EL0, this field is treated as the current VMID.

If the implementation supports 16 bits of VMID, then the upper 8 bits of the VMID must be written to 0 by software when the context being affected only uses 8 bits.

Bits [31:27]

Reserved, RES0.

NS, bit [26]

Security State.

NS	Meaning
0b0	Secure state.
0b1	Non-secure state.

When executed in Non-secure state, the Effective value of NS is 1.

EL, bits [25:24]

Exception Level. Indicates the Exception level of the target execution context.

EL	Meaning
0b00	EL0.
0b01	EL1
0b10	EL2

If the instruction is executed at an Exception level lower than the specified level, or is specified to apply to a combination of Exception level and Security state that is not implemented, this instruction is treated as a NOP.

Bits [23:17]

Reserved, RES0.

GASID, bit [16]

Execution of this instruction applies to all ASIDs or a specified ASID.

GASID	Meaning
0b0	Applies to specified ASID for an EL0 target execution context.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

0b1	Applies to all ASIDs for an EL0 target execution context.

For target execution contexts other than EL0, this field is RES0.

If the instruction is executed at EL0, this field has an Effective value of 0.

ASID, bits [15:0]

Only applies for an EL0 target execution context and when bit[16] is 0.

Otherwise this field is RES0.

When the instruction is executed at EL0, this field is treated as the current ASID.

If the implementation supports 16 bits of ASID, then the upper 8 bits of the ASID must be written to 0 by software when the context being affected only uses 8 bits.

Executing DVP RCTX

This system instruction is an alias of the SYS instruction.

Accesses to this instruction use the following encodings in the System instruction encoding space:

`DVP RCTX, <Xt>`

op0	op1	CRn	CRm	op2
0b01	0b011	0b0111	0b0011	0b101

```
if !IsFeatureImplemented(FEAT_SPECRES) then
    UNDEFINED;
elsif PSTATE.EL == EL0 then
    if !ELIsInHost(EL0) && SCTLR_EL1.EnRCTX == '0' then
        if HCR_EL2.TGE == '1' then
            AArch64.SystemAccessTrap(EL2, 0x18);
        else
            AArch64.SystemAccessTrap(EL1, 0x18);
    else
        AArch64.RestrictPrediction(X[t, 64], RestrictType_DataValue);
elsif PSTATE.EL == EL1 then
    AArch64.RestrictPrediction(X[t, 64], RestrictType_DataValue);
elsif PSTATE.EL == EL2 then
    AArch64.RestrictPrediction(X[t, 64], RestrictType_DataValue);
```

C5.7 A64 IMPLEMENTATION DEFINED System instructions

This section lists the A64 IMPLEMENTATION DEFINED System instructions.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C5.7.1 SYS|SYSL S1_<op1>_<Cn>_<Cm>_<op2>, IMPLEMENTATION DEFINED System instructions

The SYS|SYSL S1_<op1><*Cn*><Cm>_<op2> characteristics are:

Purpose

This area of the System instruction encoding space is reserved for IMPLEMENTATION DEFINED System instructions.

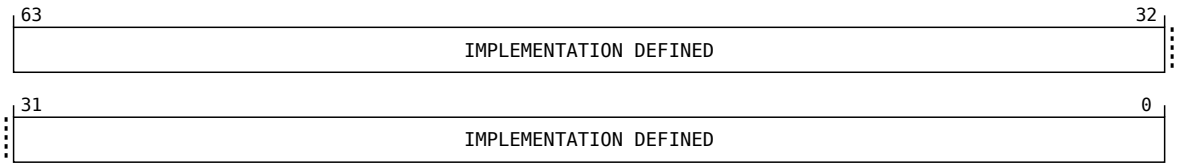
Configuration

There are no configuration notes.

Attributes

SYS|SYSL S1_<op1><*Cn*><Cm>_<op2> is a 64-bit System instruction.

Field descriptions



IMPLEMENTATION DEFINED, bits [63:0]

IMPLEMENTATION DEFINED.

Executing SYS|SYSL S1_<op1>_<Cn>_<Cm>_<op2>

Accesses to this instruction use the following encodings in the System instruction encoding space:

`SYS #<op1>, <Cn>, <Cm>, #<op2>{, <Xt>}`

op0	op1	CRn	CRm	op2
0b01	op1[2:0]	0b1x11	Cm[3:0]	op2[2:0]

```
if PSTATE.EL == EL0 then
    AArch64.ImpDefSysInstr(op0, op1, CRn, CRm, op2, t);
elsif PSTATE.EL == EL1 then
    if HCR_EL2.TIDCP == '1' then
        AArch64.SystemAccessTrap(EL2, 0x18);
    else
        AArch64.ImpDefSysInstr(op0, op1, CRn, CRm, op2, t);
elsif PSTATE.EL == EL2 then
    AArch64.ImpDefSysInstr(op0, op1, CRn, CRm, op2, t);
```

`SYSL <Xt>, #<op1>, <Cn>, <Cm>, #<op2>`

op0	op1	CRn	CRm	op2
0b01	op1[2:0]	0b1x11	Cm[3:0]	op2[2:0]

```
if PSTATE.EL == EL0 then
    AArch64.ImpDefSysInstrWithResult(op0, op1, CRn, CRm, op2, t);
elsif PSTATE.EL == EL1 then
    if HCR_EL2.TIDCP == '1' then
        AArch64.SystemAccessTrap(EL2, 0x18);
```

Chapter C6
A64 Base Instruction Descriptions

This chapter describes the A64 base instructions.

It contains the following sections:

- About the A64 base instructions.
- Alphabetical list of A64 base instructions.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C6.1 About the A64 base instructions

Alphabetical list of A64 base instructions gives full descriptions of the A64 instructions that are in the following instruction groups:

- Branch, Exception generation, and System instructions.
- Loads and stores associated with the general-purpose registers.
- Data processing (immediate).
- Data processing (register).

A64 instruction set encoding provides an overview of the instruction encodings as well as of the instruction classes within their functional groups.

The rest of this section is general description of the base instructions. It contains the following subsections:

- Register size.
- Use of the PC.
- Use of the stack pointer.
- Condition flags and related instructions.

C6.1.1 Register size

Most data processing, comparison, and conversion instructions that use the general-purpose registers as the source or destination operand have two instruction variants that operate on either a 32-bit or a 64-bit value.

Where a 32-bit instruction form is selected, the following holds:

- The upper 32 bits of the source registers are ignored.
- The upper 32 bits of the destination register are set to zero.
- Right shifts and right rotates inject at bit[31], not at bit[63].
- The Condition flags, where set by the instruction, are computed from the lower 32 bits.

This distinction applies even when the results of a 32-bit instruction form are indistinguishable from the lower 32 bits computed by the equivalent 64-bit instruction form. For example, a 32-bit bitwise `ORR` could be performed using a 64-bit `ORR` and simply ignoring the top 32 bits of the result. However, the A64 instruction set includes separate 32-bit and 64-bit forms of the `ORR` instruction.

As well as distinct sign-extend or zero-extend instructions, the A64 instruction set also provides the ability to extend and shift the final source register of an `ADD`, `SUB`, `ADDS`, `or SUBS` instruction and the index register of a load/store instruction. This enables array index calculations involving a 64-bit array pointer and a 32-bit array index to be implemented efficiently.

The assembly language notation enables the distinct identification of registers holding 32-bit values and registers holding 64-bit values. See Register names and Register indexed addressing.

C6.1.2 Use of the PC

A64 instructions have limited access to the PC. The only instructions that can read the PC are those that generate a PC relative address:

- ADR and ADRP.
- The Load register (literal) instruction class.
- Direct branches that use an immediate offset.
- The unconditional branch with link instructions, BL and BLR, that use the PC to create the return link address.

Only explicit control flow instructions can modify the PC:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- Conditional and unconditional branch and return instructions.
- Exception generation and exception return instructions.

For more details of instructions that can modify the PC, see Branches, Exception generating, and System instructions.

C6.1.3 Use of the stack pointer

A64 instructions can use the stack pointer only in a limited number of cases:

- Load/store instructions use the current stack pointer as the base address:
  - When stack alignment checking is enabled by system software and the base register is SP, the current stack pointer must be initially quadword aligned, That is, it must be aligned to 16 bytes. Misalignment generates an SP alignment fault. See SP alignment checking for more information.
- Add and subtract data processing instructions in their immediate and extended register forms, use the current stack pointer as a source register or the destination register or both.
- Logical data processing instructions in their immediate form use the current stack pointer as the destination register.

C6.1.4 Condition flags and related instructions

The A64 base instructions that use the Condition flags as an input are:

- Conditional branch. The conditional branch instruction is `B.cond`.
- Add or subtract with carry. These instruction types include instructions to perform multi-precision arithmetic and calculate checksums. The add or subtract with carry instructions are `ADC`, `ADCS`, `SBC`, and `SBCS`, or an architectural alias for these instructions.
- Conditional select with increment, negate, or invert. This instruction type conditionally selects between one source register and a second, incremented, negated, inverted, or unmodified source register. The conditional select with increment, negate, or invert instructions are `CSINC`, `CSINV`, and `CSNEG`.

  These instructions also implement:
  - Conditional select or move. The Condition flags select one of two source registers as the destination register. Short conditional sequences can be replaced by unconditional instructions followed by a conditional select, `CSEL`.
  - Conditional set. Conditionally selects between 0 and 1, or 0 and -1. This can be used to convert the Condition flags to a Boolean value or mask in a general-purpose register, for example. These instructions include `CSET` and `CSETM`.
- Conditional compare. This instruction type sets the Condition flags to the result of a comparison if the original condition is true, otherwise it sets the Condition flags to an immediate value. It permits the flattening of nested conditional expressions without using conditional branches or performing Boolean arithmetic within the general-purpose registers. The conditional compare instructions are `CCMP` and `CCMN`.

The A64 base instructions that update the Condition flags as an output are:

- Flag-setting data processing instructions, such as `ADCS`, `ADDS`, `ANDS`, `BICS`, `RMIF`, `SBCS`, `SETF8`,`SETF16`, and `SUBS`, and the aliases `CMN`, `CMP`, and `TST`.
- Conditional compare instructions such as `CCMN`, `CCMP`.
- The random number generation instructions `MRS RNDR` and `MRS RNDRRS`, see Effect of random number generation instructions on Condition flags.

The A64 base instructions that manipulate the Condition flags are:

- The flag manipulation instruction `CFINV`, which inverts the value of the Carry flag.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- If FEAT_FlagM2 is implemented, the base instructions `AXFLAG` and `XAFLAG`. These instructions convert between the Arm floating point comparison PSTATE condition flag format and an alternative format shown in Table C6-1.

Table C6-1 Relationship between ARM format and alternative format PSTATE condition flags

	ARM format				Alternative format			
Result	N	Z	C	V	N	Z	C	V
Greater than	0	0	1	0	0	0	1	0
Less than	1	0	0	0	0	0	0	0
Equal	0	1	1	0	0	1	1	0
Unordered	0	0	1	1	0	1	0	0

The flags can be directly accessed for a read/write using the NZCV.

The A64 base instructions also include conditional branch instructions that do not manipulate the Condition flags:

- Compare and branch if a register is zero or nonzero, `CBZ` and `CBNZ`.
- Test a single bit in a register and branch if the bit is zero or nonzero, `TBZ` and `TBNZ`.
- Compare and branch instructions, `CB<cc>` (immediate), `CB<cc>` (register), `CBB<cc>`, and `CBH<cc>`.

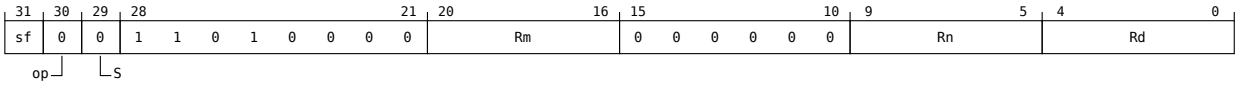
C6.2.1 ADC

Add with carry

This instruction adds two register values and the Carry flag value, and writes the result to the destination register.



Encoding for the 32-bit variant Applies when `(sf == 0)`

```
ADC <Wd>, <Wn>, <Wm>
```

Encoding for the 64-bit variant Applies when `(sf == 1)`

```
ADC <Xd>, <Xn>, <Xm>
```

Decode for all variants of this encoding

```
constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer m = UInt(Rm);
constant integer datasize = 32 << UInt(sf);
```

Assembler Symbols

<**Wd**> Is the 32-bit name of the general-purpose destination register, encoded in the “Rd” field.

<**Wn**> Is the 32-bit name of the first general-purpose source register, encoded in the “Rn” field.

<**Wm**> Is the 32-bit name of the second general-purpose source register, encoded in the “Rm” field.

<**Xd**> Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

<**Xn**> Is the 64-bit name of the first general-purpose source register, encoded in the “Rn” field.

<**Xm**> Is the 64-bit name of the second general-purpose source register, encoded in the “Rm” field.

Operation

```
constant bits(datasize) operand1 = X[n, datasize];
constant bits(datasize) operand2 = X[m, datasize];
bits(datasize) result;

(result, -) = AddWithCarry(operand1, operand2, PSTATE.C);

X[d, datasize] = result;
```

Operational information

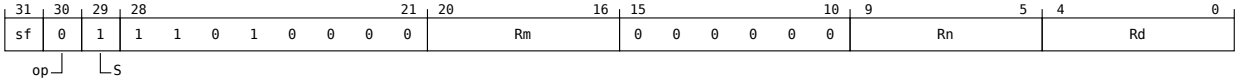
This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.2 ADCS

Add with carry, setting flags

This instruction adds two register values and the Carry flag value, and writes the result to the destination register. It updates the condition flags based on the result.



Encoding for the 32-bit variant Applies when `(sf == 0)`

```
ADCS <Wd>, <Wn>, <Wm>
```

Encoding for the 64-bit variant Applies when `(sf == 1)`

```
ADCS <Xd>, <Xn>, <Xm>
```

Decode for all variants of this encoding

```
constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer m = UInt(Rm);
constant integer datasize = 32 << UInt(sf);
```

Assembler Symbols

<**Wd**> Is the 32-bit name of the general-purpose destination register, encoded in the “Rd” field.

<**Wn**> Is the 32-bit name of the first general-purpose source register, encoded in the “Rn” field.

<**Wm**> Is the 32-bit name of the second general-purpose source register, encoded in the “Rm” field.

<**Xd**> Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

<**Xn**> Is the 64-bit name of the first general-purpose source register, encoded in the “Rn” field.

<**Xm**> Is the 64-bit name of the second general-purpose source register, encoded in the “Rm” field.

Operation

```
constant bits(datasize) operand1 = X[n, datasize];
constant bits(datasize) operand2 = X[m, datasize];
bits(datasize) result;
bits(4) nzcv;

(result, nzcv) = AddWithCarry(operand1, operand2, PSTATE.C);

X[d, datasize] = result;
PSTATE.<N,Z,C,V> = nzcv;
```

Operational information

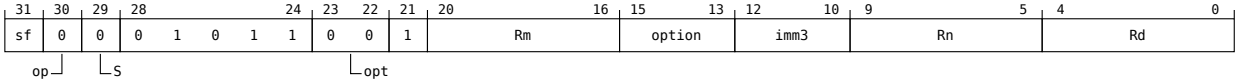
This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.3 ADD (extended register)

Add extended and scaled register

This instruction adds a register value and a sign or zero-extended register value, followed by an optional left shift amount, and writes the result to the destination register. The argument that is extended from the <Rm> register can be a byte, halfword, word, or doubleword.



Encoding for the 32-bit variant Applies when `(sf == 0)`

```
ADD <Wd|WSP>, <Wn|WSP>, <Wm>{, <extend> {#<amount>}}
```

Encoding for the 64-bit variant Applies when `(sf == 1)`

```
ADD <Xd|SP>, <Xn|SP>, <R><m>{, <extend> {#<amount>}}
```

Decode for all variants of this encoding

```
if imm3 IN {'101', '110', '111'} then EndOfDecode(Decode_UNDEF);
constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer m = UInt(Rm);
constant integer shift = UInt(imm3);
constant integer datasize = 32 << UInt(sf);
constant ExtendType extend_type = DecodeRegExtend(option);
```

Assembler Symbols

<**Wd**|**WSP**> Is the 32-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.

<**Wn**|**WSP**> Is the 32-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn" field.

<**Wm**> Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.

<**extend**> For the "32-bit" variant: is the extension to be applied to the second source operand, encoded in "option":

option	<extend>
000	UXTB
001	UXTH
010	LSL|UXTW
011	UXTX
100	SXTB
101	SXTH
110	SXTW
111	SXTX

If "Rd" or "Rn" is '11111' (WSP) and "option" is '010' then LSL is preferred, but may be omitted when "imm3" is '000'. In all other cases <extend> is required and must be UXTW when "option" is '010'.

For the "64-bit" variant: is the extension to be applied to the second source operand, encoded in "option":

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

option	<extend>
000	UXTB
001	UXTH
010	UXTW
011	LSL|UXTX
100	SXTB
101	SXTH
110	SXTW
111	SXTX

If “Rd” or “Rn” is ’11111’ (SP) and “option” is ’011’ then LSL is preferred, but may be omitted when “imm3” is ’000’. In all other cases <extend> is required and must be UXTX when “option” is ’011’.

<**amount**> Is the left shift amount to be applied after extension in the range 0 to 4, defaulting to 0, encoded in the “imm3” field. It must be absent when <extend> is absent, is required when <extend> is LSL, and is optional when <extend> is present but not LSL.

<**Xd|SP**> Is the 64-bit name of the destination general-purpose register or stack pointer, encoded in the “Rd” field.

<**Xn|SP**> Is the 64-bit name of the first source general-purpose register or stack pointer, encoded in the “Rn” field.

<**R**> Is a width specifier, encoded in “option”:

option	<R>
00x	W
010	W
x11	X
10x	W
110	W

<**m**> Is the number [0-30] of the second general-purpose source register or the name ZR (31), encoded in the “Rm” field.

Operation

```
constant bits(datasize) operand1 = if n == 31 then SP[datasize] else X[n, datasize];
constant bits(datasize) operand2 = ExtendReg(m, extend_type, shift, datasize);
bits(datasize) result;

(result, -) = AddWithCarry(operand1, operand2, '0');

if d == 31 then
    SP[64] = ZeroExtend(result, 64);
else
    X[d, datasize] = result;
```

Operational information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

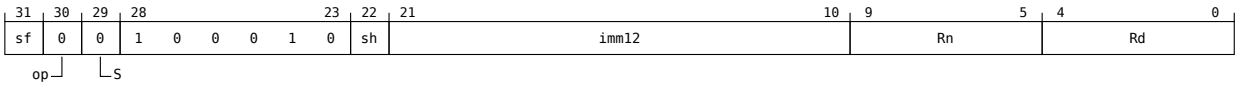
Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.4 ADD (immediate)

Add immediate value

This instruction adds a register value and an optionally-shifted immediate value, and writes the result to the destination register.

This instruction is used by the alias MOV (to/from SP).



Encoding for the 32-bit variant Applies when `(sf == 0)`

```
ADD <Wd|WSP>, <Wn|WSP>, #<imm>{, <shift>}
```

Encoding for the 64-bit variant Applies when `(sf == 1)`

```
ADD <Xd|SP>, <Xn|SP>, #<imm>{, <shift>}
```

Decode for all variants of this encoding

```
constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer datasize = 32 << UInt(sf);

constant bits(24) imm = if sh == '0' then Zeros(12):imm12 else imm12:Zeros(12);
```

Assembler Symbols

<**Wd**|**WSP**> Is the 32-bit name of the destination general-purpose register or stack pointer, encoded in the “Rd” field.

<**Wn**|**WSP**> Is the 32-bit name of the source general-purpose register or stack pointer, encoded in the “Rn” field.

<**imm**> Is an unsigned immediate, in the range 0 to 4095, encoded in the “imm12” field.

<**shift**> Is the optional left shift to apply to the immediate, defaulting to LSL #0 and encoded in “sh”:

sh	<shift>
0	LSL #0
1	LSL #12

<**Xd**|**SP**> Is the 64-bit name of the destination general-purpose register or stack pointer, encoded in the “Rd” field.

<**Xn**|**SP**> Is the 64-bit name of the source general-purpose register or stack pointer, encoded in the “Rn” field.

Alias Conditions

Alias	Is preferred when
MOV (to/from SP)	`sh == '0' && imm12 == '000000000000' && (Rd == '11111' || Rn == '11111')`

Operation

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

```
constant bits(datasize) operand1 = if n == 31 then SP[datasize] else X[n, datasize];
constant bits(datasize) operand2 = ZeroExtend(imm, datasize);
bits(datasize) result;
(result, -) = AddWithCarry(operand1, operand2, '0');

if d == 31 then
    SP[64] = ZeroExtend(result, 64);
else
    X[d, datasize] = result;
```

Operational information

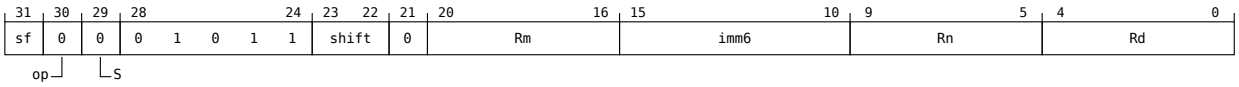
This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.5 ADD (shifted register)

Add optionally-shifted register

This instruction adds a register value and an optionally-shifted register value, and writes the result to the destination register.



Encoding for the 32-bit variant Applies when `(sf == 0)`

```
ADD <Wd>, <Wn>, <Wm>{, <shift> #<amount>}
```

Encoding for the 64-bit variant Applies when `(sf == 1)`

```
ADD <Xd>, <Xn>, <Xm>{, <shift> #<amount>}
```

Decode for all variants of this encoding

```
if shift == '11' then EndOfDecode(Decode_UNDEF);
if sf == '0' && imm6<5> == '1' then EndOfDecode(Decode_UNDEF);

constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer m = UInt(Rm);
constant integer datasize = 32 << UInt(sf);
constant ShiftType shift_type = DecodeShift(shift);
constant integer shift_amount = UInt(imm6);
```

Assembler Symbols

<**Wd**> Is the 32-bit name of the general-purpose destination register, encoded in the “Rd” field.

<**Wn**> Is the 32-bit name of the first general-purpose source register, encoded in the “Rn” field.

<**Wm**> Is the 32-bit name of the second general-purpose source register, encoded in the “Rm” field.

<**shift**> Is the optional shift type to be applied to the second source operand, defaulting to LSL and encoded in “shift”:

shift	<shift>
00	LSL
01	LSR
10	ASR
11	RESERVED

<**amount**> For the “32-bit” variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the “imm6” field.

For the “64-bit” variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the “imm6” field.

<**Xd**> Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

<**Xn**> Is the 64-bit name of the first general-purpose source register, encoded in the “Rn” field.

<**Xm**> Is the 64-bit name of the second general-purpose source register, encoded in the “Rm” field.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Operation

```
constant bits(datasize) operand1 = X[n, datasize];
constant bits(datasize) operand2 = ShiftReg(m, shift_type, shift_amount, datasize);
bits(datasize) result;

(result, -) = AddWithCarry(operand1, operand2, '0');

X[d, datasize] = result;
```

Operational information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

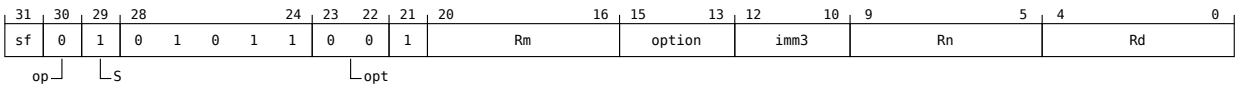
Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.6 ADDS (extended register)

Add extended and scaled register, setting flags

This instruction adds a register value and a sign or zero-extended register value, followed by an optional left shift amount, and writes the result to the destination register. The argument that is extended from the <Rm> register can be a byte, halfword, word, or doubleword. It updates the condition flags based on the result.

This instruction is used by the alias CMN (extended register).



Encoding for the 32-bit variant Applies when `(sf == 0)`

```
ADDS <Wd>, <Wn|WSP>, <Wm>{, <extend> {#<amount>}}
```

Encoding for the 64-bit variant Applies when `(sf == 1)`

```
ADDS <Xd>, <Xn|SP>, <R><m>{, <extend> {#<amount>}}
```

Decode for all variants of this encoding

```
if imm3 IN {'101', '110', '111'} then EndOfDecode(Decode_UNDEF);
constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer m = UInt(Rm);
constant integer shift = UInt(imm3);
constant integer datasize = 32 << UInt(sf);
constant ExtendType extend_type = DecodeRegExtend(option);
```

Assembler Symbols

<Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Wn|WSP> Is the 32-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn" field.

<Wm> Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.

<extend> For the "32-bit" variant: is the extension to be applied to the second source operand, encoded in "option":

option	<extend>
000	UXTB
001	UXTH
010	LSL|UXTW
011	UXTX
100	SXTB
101	SXTH
110	SXTW
111	SXTX

If "Rn" is '11111' (WSP) and "option" is '010' then LSL is preferred, but may be omitted when "imm3" is '000'. In all other cases <extend> is required and must be UXTW when "option" is '010'.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

For the “64-bit” variant: is the extension to be applied to the second source operand, encoded in “option”:

option	<extend>
000	UXTB
001	UXTH
010	UXTW
011	LSL|UXTX
100	SXTB
101	SXTH
110	SXTW
111	SXTX

If “Rn” is ’11111’ (SP) and “option” is ’011’ then LSL is preferred, but may be omitted when “imm3” is ’000’. In all other cases <extend> is required and must be UXTX when “option” is ’011’.

<**amount**> Is the left shift amount to be applied after extension in the range 0 to 4, defaulting to 0, encoded in the “imm3” field. It must be absent when <extend> is absent, is required when <extend> is LSL, and is optional when <extend> is present but not LSL.

<**Xd**> Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

<**Xn|SP**> Is the 64-bit name of the first source general-purpose register or stack pointer, encoded in the “Rn” field.

<**R**> Is a width specifier, encoded in “option”:

option	<R>
00x	W
010	W
x11	X
10x	W
110	W

<**m**> Is the number [0-30] of the second general-purpose source register or the name ZR (31), encoded in the “Rm” field.

Alias Conditions

Alias	Is preferred when
CMN (extended register)	Rd == '11111'

Operation

```
constant bits(datasize) operand1 = if n == 31 then SP[datasize] else X[n, datasize];
constant bits(datasize) operand2 = ExtendReg(m, extend_type, shift, datasize);
bits(datasize) result;
bits(4) nzcv;

(result, nzcv) = AddWithCarry(operand1, operand2, '0');

X[d, datasize] = result;
PSTATE.<N,Z,C,V> = nzcv;
```

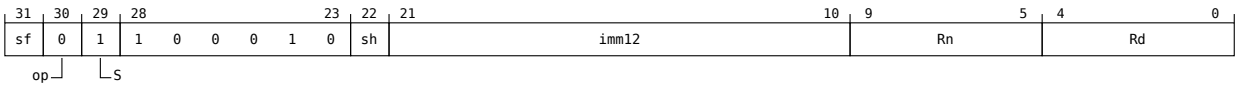
C6.2.7 ADDS (immediate)

Add immediate value, setting flags

This instruction adds a register value and an optionally-shifted immediate value, and writes the result to the destination register. It updates the condition flags based on the result.

This instruction is used by the alias CMN (immediate).



Encoding for the 32-bit variant Applies when `(sf == 0)`

```
ADDS <Wd>, <Wn|WSP>, #<imm>{, <shift>}
```

Encoding for the 64-bit variant Applies when `(sf == 1)`

```
ADDS <Xd>, <Xn|SP>, #<imm>{, <shift>}
```

Decode for all variants of this encoding

```
constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer datasize = 32 << UInt(sf);

constant bits(24) imm = if sh == '0' then Zeros(12):imm12 else imm12:Zeros(12);
```

Assembler Symbols

<**Wd**> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

<**Wn|WSP**> Is the 32-bit name of the source general-purpose register or stack pointer, encoded in the "Rn" field.

<**imm**> Is an unsigned immediate, in the range 0 to 4095, encoded in the "imm12" field.

<**shift**> Is the optional left shift to apply to the immediate, defaulting to LSL #0 and encoded in "sh":

sh	<shift>
0	LSL #0
1	LSL #12

<**Xd**> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<**Xn|SP**> Is the 64-bit name of the source general-purpose register or stack pointer, encoded in the "Rn" field.

Alias Conditions

Alias	Is preferred when
CMN (immediate)	Rd == '11111'

Operation

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

```
constant bits(datasize) operand1 = if n == 31 then SP[datasize] else X[n, datasize];
constant bits(datasize) operand2 = ZeroExtend(imm, datasize);
bits(datasize) result;
bits(4) nzcv;

(result, nzcv) = AddWithCarry(operand1, operand2, '0');

X[d, datasize] = result;
PSTATE.<N,Z,C,V> = nzcv;
```

Operational information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

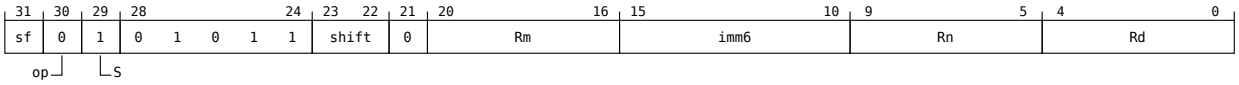
Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.8 ADDS (shifted register)

Add optionally-shifted register, setting flags

This instruction adds a register value and an optionally-shifted register value, and writes the result to the destination register. It updates the condition flags based on the result.

This instruction is used by the alias CMN (shifted register).



Encoding for the 32-bit variant Applies when `(sf == 0)`

```
ADDS <Wd>, <Wn>, <Wm>{, <shift> #<amount>}
```

Encoding for the 64-bit variant Applies when `(sf == 1)`

```
ADDS <Xd>, <Xn>, <Xm>{, <shift> #<amount>}
```

Decode for all variants of this encoding

```
if shift == '11' then EndOfDecode(Decode_UNDEF);
if sf == '0' && imm6<5> == '1' then EndOfDecode(Decode_UNDEF);

constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer m = UInt(Rm);
constant integer datasize = 32 << UInt(sf);
constant ShiftType shift_type = DecodeShift(shift);
constant integer shift_amount = UInt(imm6);
```

Assembler Symbols

<**Wd**> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

<**Wn**> Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.

<**Wm**> Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.

<**shift**> Is the optional shift type to be applied to the second source operand, defaulting to LSL and encoded in "shift":

shift	<shift>
00	LSL
01	LSR
10	ASR
11	RESERVED

<**amount**> For the "32-bit" variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.

For the "64-bit" variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field.

<**Xd**> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<**Xn**> Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

<**Xm**> Is the 64-bit name of the second general-purpose source register, encoded in the “Rm” field.

Alias Conditions

Alias	Is preferred when
CMN (shifted register)	Rd == '11111'

Operation

```
constant bits(datasize) operand1 = X[n, datasize];
constant bits(datasize) operand2 = ShiftReg(m, shift_type, shift_amount, datasize);
bits(datasize) result;
bits(4) nzcv;

(result, nzcv) = AddWithCarry(operand1, operand2, '0');

X[d, datasize] = result;
PSTATE.<N,Z,C,V> = nzcv;
```

Operational information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

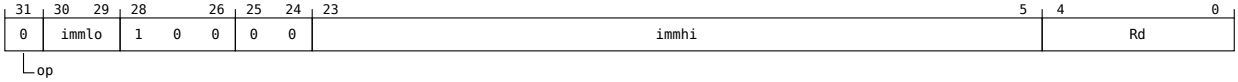
C6.2.9 ADR

Form PC-relative address

This instruction adds an immediate value to the PC value to form a PC-relative address, and writes the result to the destination register.



Encoding

```
ADR <Xd>, <label>
```

Decode for this encoding

```
constant integer d = UInt(Rd);
constant bits(64) imm = SignExtend(immhi:immlo, 64);
```

Assembler Symbols

<**Xd**> Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

<**label**> Is the program label whose address is to be calculated. Its offset from the address of this instruction, in the range +/-1MB, is encoded in “immhi:immlo”.

Operation

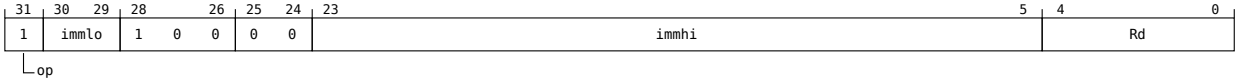
```
X[d, 64] = PC64 + imm;
```

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.10 ADRP

Form PC-relative address to 4KB page

This instruction adds an immediate value that is shifted left by 12 bits, to the PC value to form a PC-relative address, with the bottom 12 bits masked out, and writes the result to the destination register.



Encoding

```
ADRP <Xd>, <label>
```

Decode for this encoding

```
constant integer d = UInt(Rd);
constant bits(64) imm = SignExtend(immhi:immlo:Zeros(12), 64);
```

Assembler Symbols

<**Xd**> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<**label**> Is the program label whose 4KB page address is to be calculated. Its offset from the page address of this instruction, in the range +/-4GB, is encoded as "immhi:immlo" times 4096.

Operation

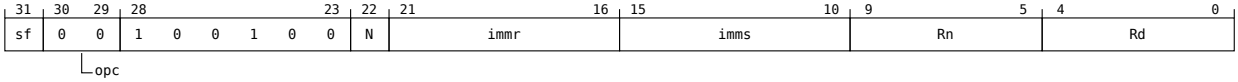
```
constant bits(64) base = PC64<63:12>:Zeros(12);
X[d, 64] = base + imm;
```

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.11 AND (immediate)

Bitwise AND (immediate)

This instruction performs a bitwise AND of a register value and an immediate value, and writes the result to the destination register.



Encoding for the 32-bit variant Applies when `(sf == 0 && N == 0)`

```
AND <Wd|WSP>, <Wn>, #<imm>
```

Encoding for the 64-bit variant Applies when `(sf == 1)`

```
AND <Xd|SP>, <Xn>, #<imm>
```

Decode for all variants of this encoding

```
if sf == '0' && N != '0' then EndOfDecode(Decode_UNDEF);
constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer datasize = 32 << UInt(sf);
bits(datasize) imm;
(imm, -) = DecodeBitMasks(N, imms, immr, TRUE, datasize);
```

Assembler Symbols

<**Wd|WSP**> Is the 32-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.

<**Wn**> Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.

<**imm**> For the "32-bit" variant: is the bitmask immediate, encoded in "imms:immr".

For the "64-bit" variant: is the bitmask immediate, encoded in "N:imms:immr".

<**Xd|SP**> Is the 64-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.

<**Xn**> Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.

Operation

```
constant bits(datasize) operand1 = X[n, datasize];
constant bits(datasize) operand2 = imm;

constant bits(datasize) result = operand1 AND operand2;

if d == 31 then
    SP[64] = ZeroExtend(result, 64);
else
    X[d, datasize] = result;
```

Operational information

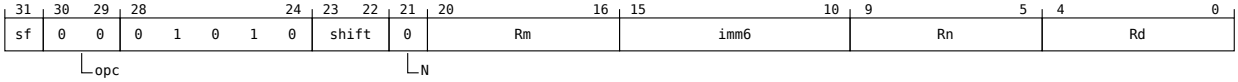
This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.12 AND (shifted register)

Bitwise AND (shifted register)

This instruction performs a bitwise AND of a register value and an optionally-shifted register value, and writes the result to the destination register.



Encoding for the 32-bit variant Applies when `(sf == 0)`

```
AND <Wd>, <Wn>, <Wm>{, <shift> #<amount>}
```

Encoding for the 64-bit variant Applies when `(sf == 1)`

```
AND <Xd>, <Xn>, <Xm>{, <shift> #<amount>}
```

Decode for all variants of this encoding

```
if sf == '0' && imm6<5> == '1' then EndOfDecode(Decode_UNDEF);
constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer m = UInt(Rm);
constant integer datasize = 32 << UInt(sf);
constant ShiftType shift_type = DecodeShift(shift);
constant integer shift_amount = UInt(imm6);
```

Assembler Symbols

<**Wd**> Is the 32-bit name of the general-purpose destination register, encoded in the “Rd” field.

<**Wn**> Is the 32-bit name of the first general-purpose source register, encoded in the “Rn” field.

<**Wm**> Is the 32-bit name of the second general-purpose source register, encoded in the “Rm” field.

<**shift**> Is the optional shift to be applied to the final source, defaulting to LSL and encoded in “shift”:

shift	<shift>
00	LSL
01	LSR
10	ASR
11	ROR

<**amount**> For the “32-bit” variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the “imm6” field.

For the “64-bit” variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the “imm6” field.

<**Xd**> Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

<**Xn**> Is the 64-bit name of the first general-purpose source register, encoded in the “Rn” field.

<**Xm**> Is the 64-bit name of the second general-purpose source register, encoded in the “Rm” field.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Operation

```
constant bits(datasize) operand1 = X[n, datasize];
constant bits(datasize) operand2 = ShiftReg(m, shift_type, shift_amount, datasize);

X[d, datasize] = operand1 AND operand2;
```

Operational information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

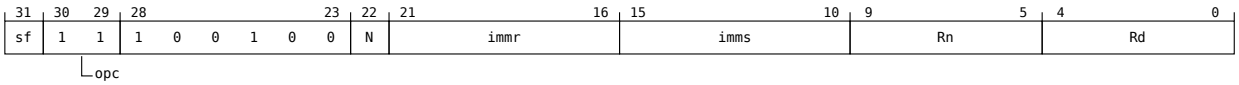
Non-Confidential

C6.2.13 ANDS (immediate)

Bitwise AND (immediate), setting flags

This instruction performs a bitwise AND of a register value and an immediate value, and writes the result to the destination register. It updates the condition flags based on the result.

This instruction is used by the alias TST (immediate).



Encoding for the 32-bit variant Applies when `(sf == 0 && N == 0)`

```
ANDS <Wd>, <Wn>, #<imm>
```

Encoding for the 64-bit variant Applies when `(sf == 1)`

```
ANDS <Xd>, <Xn>, #<imm>
```

Decode for all variants of this encoding

```
if sf == '0' && N != '0' then EndOfDecode(Decode_UNDEF);
constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer datasize = 32 << UInt(sf);
bits(datasize) imm;
(imm, -) = DecodeBitMasks(N, imms, immr, TRUE, datasize);
```

Assembler Symbols

<**Wd**> Is the 32-bit name of the general-purpose destination register, encoded in the “Rd” field.

<**Wn**> Is the 32-bit name of the general-purpose source register, encoded in the “Rn” field.

<**imm**> For the “32-bit” variant: is the bitmask immediate, encoded in “imms:immr”.

For the “64-bit” variant: is the bitmask immediate, encoded in “N:imms:immr”.

<**Xd**> Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

<**Xn**> Is the 64-bit name of the general-purpose source register, encoded in the “Rn” field.

Alias Conditions

Alias	Is preferred when
TST (immediate)	`Rd == '11111'`

Operation

```
constant bits(datasize) operand1 = X[n, datasize];
constant bits(datasize) operand2 = imm;

constant bits(datasize) result = operand1 AND operand2;

X[d, datasize] = result;
PSTATE.<N,Z,C,V> = result<datasize-1>:IsZeroBit(result):'00';
```

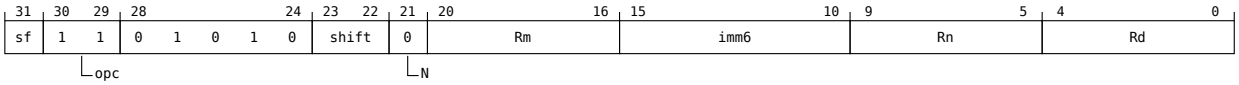
C6.2.14 ANDS (shifted register)

Bitwise AND (shifted register), setting flags

This instruction performs a bitwise AND of a register value and an optionally-shifted register value, and writes the result to the destination register. It updates the condition flags based on the result.

This instruction is used by the alias TST (shifted register).



Encoding for the 32-bit variant Applies when `(sf == 0)`

```
ANDS <Wd>, <Wn>, <Wm>{, <shift> #<amount>}
```

Encoding for the 64-bit variant Applies when `(sf == 1)`

```
ANDS <Xd>, <Xn>, <Xm>{, <shift> #<amount>}
```

Decode for all variants of this encoding

```
if sf == '0' && imm6<5> == '1' then EndOfDecode(Decode_UNDEF);
constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer m = UInt(Rm);
constant integer datasize = 32 << UInt(sf);
constant ShiftType shift_type = DecodeShift(shift);
constant integer shift_amount = UInt(imm6);
```

Assembler Symbols

<**Wd**> Is the 32-bit name of the general-purpose destination register, encoded in the “Rd” field.

<**Wn**> Is the 32-bit name of the first general-purpose source register, encoded in the “Rn” field.

<**Wm**> Is the 32-bit name of the second general-purpose source register, encoded in the “Rm” field.

<**shift**> Is the optional shift to be applied to the final source, defaulting to LSL and encoded in “shift”:

shift	<shift>
00	LSL
01	LSR
10	ASR
11	ROR

<**amount**> For the “32-bit” variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the “imm6” field.

For the “64-bit” variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the “imm6” field.

<**Xd**> Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

<**Xn**> Is the 64-bit name of the first general-purpose source register, encoded in the “Rn” field.

<**Xm**> Is the 64-bit name of the second general-purpose source register, encoded in the “Rm” field.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Alias Conditions

Alias	Is preferred when
TST (shifted register)	Rd == '11111'

Operation

```
constant bits(datasize) operand1 = X[n, datasize];
constant bits(datasize) operand2 = ShiftReg(m, shift_type, shift_amount, datasize);

constant bits(datasize) result = operand1 AND operand2;
X[d, datasize] = result;
PSTATE.<N,Z,C,V> = result<datasize-1>:IsZeroBit(result):'00';
```

Operational information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

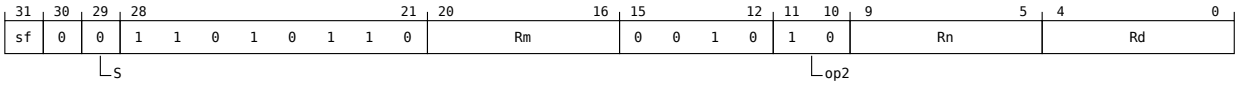
C6.2.15 ASR (register)

Arithmetic shift right (register)

This instruction shifts a register value right by a variable number of bits, shifting in copies of its sign bit, and writes the result to the destination register. The value of the second source register modulo the register size in bits gives the number of bits by which the first source register is right-shifted.

This is an alias of ASRV. This means:

- The encodings in this description are named to match the encodings of ASRV.
- The description of ASRV gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.



Encoding for the 32-bit variant Applies when `(sf == 0)`

```
ASR <Wd>, <Wn>, <Wm>
```

is equivalent to

```
ASRV <Wd>, <Wn>, <Wm>
```

and is always the preferred disassembly.

Encoding for the 64-bit variant Applies when `(sf == 1)`

```
ASR <Xd>, <Xn>, <Xm>
```

is equivalent to

```
ASRV <Xd>, <Xn>, <Xm>
```

and is always the preferred disassembly.

Assembler Symbols

<**Wd**> Is the 32-bit name of the general-purpose destination register, encoded in the “Rd” field.

<**Wn**> Is the 32-bit name of the first general-purpose source register, encoded in the “Rn” field.

<**Wm**> Is the 32-bit name of the second general-purpose source register holding a shift amount from 0 to 31 in its bottom 5 bits, encoded in the “Rm” field.

<**Xd**> Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

<**Xn**> Is the 64-bit name of the first general-purpose source register, encoded in the “Rn” field.

<**Xm**> Is the 64-bit name of the second general-purpose source register holding a shift amount from 0 to 63 in its bottom 6 bits, encoded in the “Rm” field.

Operation

The description of ASRV gives the operational pseudocode for this instruction.

Operational Information

The description of ASRV gives the operational information for this instruction.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

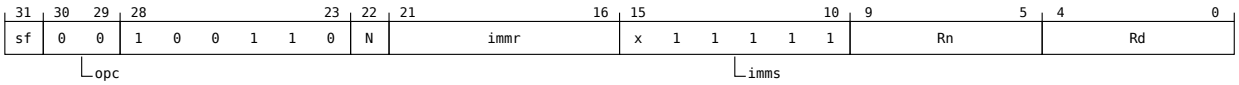
C6.2.16 ASR (immediate)

Arithmetic shift right (immediate)

This instruction shifts a register value right by an immediate number of bits, shifting in copies of the sign bit in the upper bits and zeros in the lower bits, and writes the result to the destination register.

This is an alias of SBFM. This means:

- The encodings in this description are named to match the encodings of SBFM.
- The description of SBFM gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.



Encoding for the 32-bit variant Applies when `(sf == 0 && N == 0 && imms == 011111)`

```
ASR <Wd>, <Wn>, #<shift>
```

is equivalent to

```
SBFM <Wd>, <Wn>, #<shift>, #31
```

and is always the preferred disassembly.

Encoding for the 64-bit variant Applies when `(sf == 1 && N == 1 && imms == 111111)`

```
ASR <Xd>, <Xn>, #<shift>
```

is equivalent to

```
SBFM <Xd>, <Xn>, #<shift>, #63
```

and is always the preferred disassembly.

Assembler Symbols

<**Wd**> Is the 32-bit name of the general-purpose destination register, encoded in the “Rd” field.

<**Wn**> Is the 32-bit name of the general-purpose source register, encoded in the “Rn” field.

<**shift**> For the “32-bit” variant: is the shift amount, in the range 0 to 31, encoded in the “immr” field.

For the “64-bit” variant: is the shift amount, in the range 0 to 63, encoded in the “immr” field.

<**Xd**> Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

<**Xn**> Is the 64-bit name of the general-purpose source register, encoded in the “Rn” field.

Operation

The description of SBFM gives the operational pseudocode for this instruction.

Operational Information

The description of SBFM gives the operational information for this instruction.

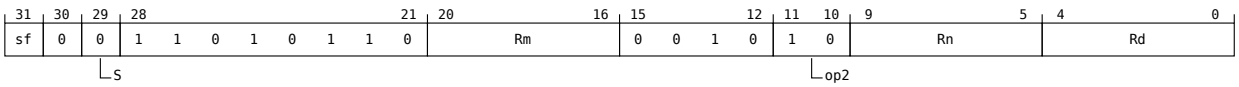
Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.17 ASRV

Arithmetic shift right variable

This instruction shifts a register value right by a variable number of bits, shifting in copies of its sign bit, and writes the result to the destination register. The value of the second source register modulo the register size in bits gives the number of bits by which the first source register is right-shifted.

This instruction is used by the alias ASR (register).



Encoding for the 32-bit variant Applies when `(sf == 0)`

```
ASRV <Wd>, <Wn>, <Wm>
```

Encoding for the 64-bit variant Applies when `(sf == 1)`

```
ASRV <Xd>, <Xn>, <Xm>
```

Decode for all variants of this encoding

```
constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer m = UInt(Rm);
constant integer datasize = 32 << UInt(sf);
constant ShiftType shift_type = DecodeShift(op2);
```

Assembler Symbols

<Wd> Is the 32-bit name of the general-purpose destination register, encoded in the “Rd” field.

<Wn> Is the 32-bit name of the first general-purpose source register, encoded in the “Rn” field.

<Wm> Is the 32-bit name of the second general-purpose source register holding a shift amount from 0 to 31 in its bottom 5 bits, encoded in the “Rm” field.

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

<Xn> Is the 64-bit name of the first general-purpose source register, encoded in the “Rn” field.

<Xm> Is the 64-bit name of the second general-purpose source register holding a shift amount from 0 to 63 in its bottom 6 bits, encoded in the “Rm” field.

Operation

```
constant bits(datasize) operand2 = X[m, datasize];

X[d, datasize] = ShiftReg(n, shift_type, UInt(operand2) MOD datasize, datasize);
```

Operational information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

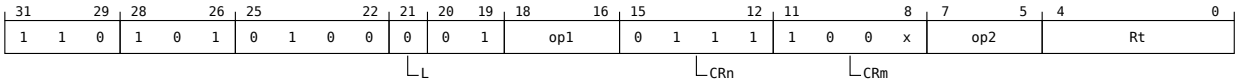
C6.2.18 AT

Address translate

For more information, see op0==0b01, cache maintenance, TLB maintenance, and address translation instructions.

This is an alias of SYS. This means:

- The encodings in this description are named to match the encodings of SYS.
- The description of SYS gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.



Encoding

```
AT <at_op>, <Xt>
```

is equivalent to

```
SYS #<op1>, C7, <Cm>, #<op2>, <Xt>
```

and is the preferred disassembly when `SysOp(op1, '0111', CRm, op2) == Sys_AT`.

Assembler Symbols

<at_op> Is an AT operation name, as listed for the AT system instruction group, encoded in "op1:CRm:op2":

op1	CRm	op2	<at_op>	Architectural Feature
000	1000	000	S1E1R	-
000	1000	001	S1E1W	-
000	1000	010	S1E0R	-
000	1000	011	S1E0W	-
000	1001	000	S1E1RP	FEAT_PAN2
000	1001	001	S1E1WP	FEAT_PAN2
100	1000	000	S1E2R	-
100	1000	001	S1E2W	-
100	1000	100	S12E1R	-
100	1000	101	S12E1W	-
100	1000	110	S12E0R	-
100	1000	111	S12E0W	-
110	1000	000	S1E3R	-
110	1000	001	S1E3W	-

<Xt> Is the 64-bit name of the general-purpose source register, encoded in the "Rt" field.

Operation

The description of SYS gives the operational pseudocode for this instruction.

C6.2.19 AUTDA, AUTDZA

Authenticate data address, using key A

This instruction authenticates a data address, using a modifier and key A.

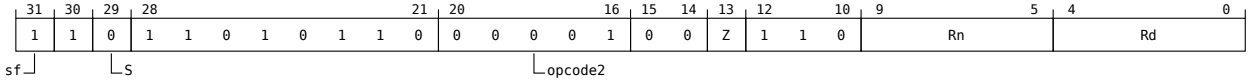
The address is in the general-purpose register that is specified by <Xd>.

The modifier is:

- In the general-purpose register or stack pointer that is specified by <Xn|SP>, for AUTDA.
- The value zero, for AUTDZA.

If the authentication passes, the upper bits of the address are restored to enable subsequent use of the address. For information on behavior if the authentication fails, see Faulting on pointer authentication.

Integer
(FEAT_PAuth)



Encoding for the AUTDA variant Applies when (Z == 0)

```
AUTDA <Xd>, <Xn|SP>
```

Encoding for the AUTDZA variant Applies when (Z == 1 && Rn == 11111)

```
AUTDZA <Xd>
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_PAuth) then EndOfDecode(Decode_UNDEF);
if Z == '1' && Rn != '11111' then EndOfDecode(Decode_UNDEF);
constant boolean auth_combined = FALSE;

constant integer d = UInt(Rd);
constant integer n = UInt(Rn);

constant boolean source_is_sp = Z == '0' && n == 31;
```

Assembler Symbols

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Xn|SP> Is the 64-bit name of the general-purpose source register or stack pointer, encoded in the "Rn" field.

Operation

```
if source_is_sp then
    X[d, 64] = AuthDA(X[d, 64], SP[64], auth_combined);
else
    X[d, 64] = AuthDA(X[d, 64], X[n, 64], auth_combined);
```

C6.2.20 AUTDB, AUTDZB

Authenticate data address, using key B

This instruction authenticates a data address, using a modifier and key B.

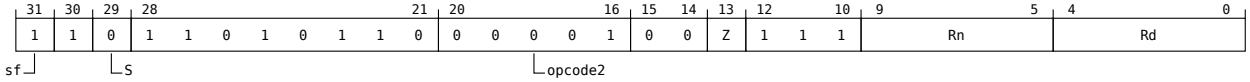
The address is in the general-purpose register that is specified by <Xd>.

The modifier is:

- In the general-purpose register or stack pointer that is specified by <Xn|SP> for AUTDB.
- The value zero, for AUTDZB.

If the authentication passes, the upper bits of the address are restored to enable subsequent use of the address. For information on behavior if the authentication fails, see Faulting on pointer authentication.

Integer
(FEAT_PAuth)



Encoding for the AUTDB variant Applies when (Z == 0)

```
AUTDB <Xd>, <Xn|SP>
```

Encoding for the AUTDZB variant Applies when (Z == 1 && Rn == 11111)

```
AUTDZB <Xd>
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_PAuth) then EndOfDecode(Decode_UNDEF);
if Z == '1' && Rn != '11111' then EndOfDecode(Decode_UNDEF);
constant boolean auth_combined = FALSE;

constant integer d = UInt(Rd);
constant integer n = UInt(Rn);

constant boolean source_is_sp = Z == '0' && n == 31;
```

Assembler Symbols

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Xn|SP> Is the 64-bit name of the general-purpose source register or stack pointer, encoded in the "Rn" field.

Operation

```
if source_is_sp then
    X[d, 64] = AuthDB(X[d, 64], SP[64], auth_combined);
else
    X[d, 64] = AuthDB(X[d, 64], X[n, 64], auth_combined);
```

C6.2.21 AUTIA, AUTIA1716, AUTIASP, AUTIAZ, AUTIZA

Authenticate instruction address, using key A

This instruction authenticates an instruction address, using a modifier and key A.

If the authentication passes, the upper bits of the address are restored to enable subsequent use of the address. For information on behavior if the authentication fails, see Faulting on pointer authentication.

The address is:

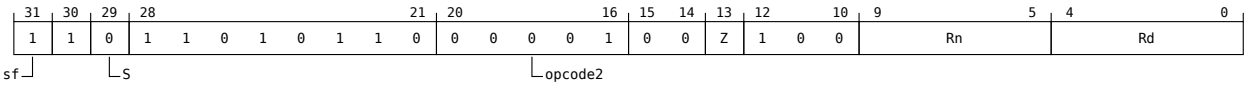
- In the general-purpose register that is specified by <Xd> for AUTIA and AUTIZA.
- In X17, for AUTIA1716.
- In X30, for AUTIASP and AUTIAZ.

The modifier is:

- In the general-purpose register or stack pointer that is specified by <Xn|SP> for AUTIA.
- The value zero, for AUTIZA and AUTIAZ.
- In X16, for AUTIA1716.
- In SP, for AUTIASP.

It has encodings from 2 classes: Integer and System

Integer
(FEAT_PAuth)



Encoding for the AUTIA variant Applies when `(Z == 0)`

```
AUTIA <Xd>, <Xn|SP>
```

Encoding for the AUTIZA variant Applies when `(Z == 1 && Rn == 11111)`

```
AUTIZA <Xd>
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_PAuth) then EndOfDecode(Decode_UNDEF);
if Z == '1' && Rn != '11111' then EndOfDecode(Decode_UNDEF);
constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant boolean auth_combined = FALSE;

constant boolean source_is_sp = Z == '0' && n == 31;
```

System
(FEAT_PAuth)

Encoding for the AUTIA1716 variant Applies when `(CRm == 0001 && op2 == 100)`

```
AUTIA1716
```

Encoding for the AUTIASP variant Applies when `(CRm == 0011 && op2 == 101)`

```
AUTIASP
```

Encoding for the AUTIAZ variant Applies when `(CRm == 0011 && op2 == 100)`

```
AUTIAZ
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_PAuth) then EndOfDecode(Decode_NOP);
integer d;
integer n;
boolean source_is_sp = FALSE;
constant boolean auth_combined = FALSE;

case CRm:op2 of
    when '0011 100' // AUTIAZ
        d = 30;
        n = 31;
    when '0011 101' // AUTIASP
        d = 30;
        source_is_sp = TRUE;
    when '0001 100' // AUTIA1716
        d = 17;
        n = 16;
```

Assembler Symbols

<**Xd**> Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

<**Xn**|**SP**> Is the 64-bit name of the general-purpose source register or stack pointer, encoded in the “Rn” field.

Operation

```
if source_is_sp then
    X[d, 64] = AuthIA(X[d, 64], SP[64], auth_combined);
else
    X[d, 64] = AuthIA(X[d, 64], X[n, 64], auth_combined);
```

C6.2.22 AUTIB, AUTIB1716, AUTIBSP, AUTIBZ, AUTIZB

Authenticate instruction address, using key B

This instruction authenticates an instruction address, using a modifier and key B.

If the authentication passes, the upper bits of the address are restored to enable subsequent use of the address. For information on behavior if the authentication fails, see Faulting on pointer authentication.

The address is:

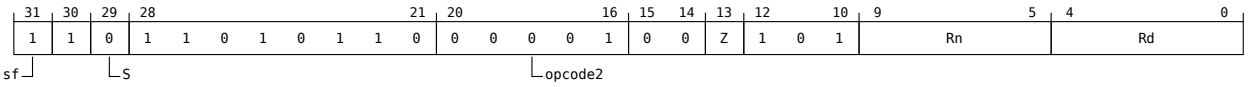
- In the general-purpose register that is specified by <Xd> for AUTIB and AUTIZB.
- In X17, for AUTIB1716.
- In X30, for AUTIBSP and AUTIBZ.

The modifier is:

- In the general-purpose register or stack pointer that is specified by <Xn|SP> for AUTIB.
- The value zero, for AUTIZB and AUTIBZ.
- In X16, for AUTIB1716.
- In SP, for AUTIBSP.

It has encodings from 2 classes: Integer and System

Integer
(FEAT_PAuth)



Encoding for the AUTIB variant Applies when (Z == 0)

```
AUTIB <Xd>, <Xn|SP>
```

Encoding for the AUTIZB variant Applies when (Z == 1 && Rn == 11111)

```
AUTIZB <Xd>
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_PAuth) then EndOfDecode(Decode_UNDEF);
if Z == '1' && Rn != '11111' then EndOfDecode(Decode_UNDEF);
constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant boolean auth_combined = FALSE;

constant boolean source_is_sp = Z == '0' && n == 31;
```

System
(FEAT_PAuth)

Non-Confidential

Encoding for the AUTIB1716 variant Applies when `(CRm == 0001 && op2 == 110)`

```
AUTIB1716
```

Encoding for the AUTIBSP variant Applies when `(CRm == 0011 && op2 == 111)`

```
AUTIBSP
```

Encoding for the AUTIBZ variant Applies when `(CRm == 0011 && op2 == 110)`

```
AUTIBZ
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_PAuth) then EndOfDecode(Decode_NOP);
integer d;
integer n;
boolean source_is_sp = FALSE;
constant boolean auth_combined = FALSE;

case CRm:op2 of
    when '0011 110' // AUTIBZ
        d = 30;
        n = 31;
    when '0011 111' // AUTIBSP
        d = 30;
        source_is_sp = TRUE;
    when '0001 110' // AUTIB1716
        d = 17;
        n = 16;
```

Assembler Symbols

<**Xd**> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<**Xn**|**SP**> Is the 64-bit name of the general-purpose source register or stack pointer, encoded in the "Rn" field.

Operation

```
if source_is_sp then
    X[d, 64] = AuthIB(X[d, 64], SP[64], auth_combined);
else
    X[d, 64] = AuthIB(X[d, 64], X[n, 64], auth_combined);

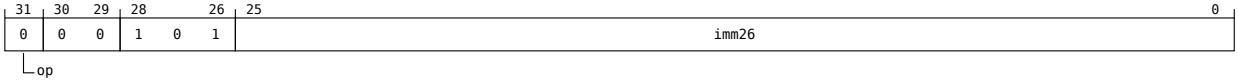
C6.2.23 B

Branch

This instruction branches unconditionally to a label at a PC-relative offset. This instruction provides a hint that this is not a subroutine call or return.



Encoding

```
B <label>
```

Decode for this encoding

```
constant bits(64) offset = SignExtend(imm26:'00', 64);
```

Assembler Symbols

<label> Is the program label to be unconditionally branched to. Its offset from the address of this instruction, in the range +/-128MB, is encoded as “imm26” times 4.

Operation

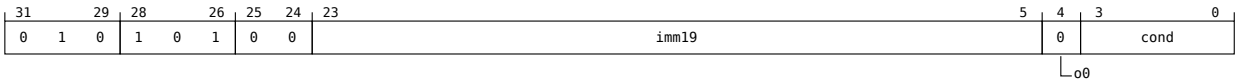
```
constant boolean branch_conditional = FALSE;
BranchTo(PC64 + offset, BranchType_DIR, branch_conditional);
```

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.24 B.cond

Branch conditionally

This instruction branches conditionally to a label at a PC-relative offset. This instruction provides a hint that this is not a subroutine call or return.



Encoding

```
B.<cond> <label>
```

Decode for this encoding

```
constant bits(64) offset = SignExtend(imm19:'00', 64);
constant bits(4) condition = cond;
```

Assembler Symbols

<**cond**> Is one of the standard conditions, encoded in the standard way, and encoded in "cond":

cond	<cond>
0000	EQ
0001	NE
0010	CS
0011	CC
0100	MI
0101	PL
0110	VS
0111	VC
1000	HI
1001	LS
1010	GE
1011	LT
1100	GT
1101	LE
1110	AL
1111	NV

<**label**> Is the program label to be conditionally branched to. Its offset from the address of this instruction, in the range +/-1MB, is encoded as "imm19" times 4.

Operation

```
constant boolean branch_conditional = TRUE;
if ConditionHolds(condition) then
    BranchTo(PC64 + offset, BranchType_DIR, branch_conditional);
```

C6.2.25 BFC

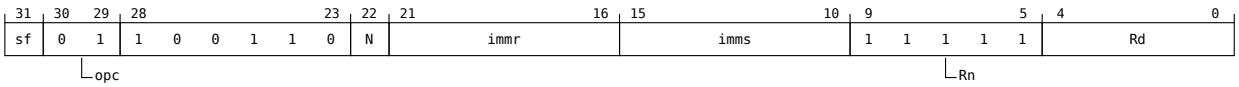
Bitfield clear

This instruction sets a bitfield of <width> bits at bit position <lsb> of the destination register to zero, leaving the other destination bits unchanged.

This is an alias of BFM. This means:

- The encodings in this description are named to match the encodings of BFM.
- The description of BFM gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

Leaving other bits unchanged
(FEAT_ASMv8p2)



Encoding for the 32-bit variant Applies when `(sf == 0 && N == 0)`

```
BFC <Wd>, #<lsb>, #<width>
```

is equivalent to

```
BFM <Wd>, WZR, #(-<lsb> MOD 32), #(<width>-1)
```

and is the preferred disassembly when `UInt(imms) < UInt(immr)`.

Encoding for the 64-bit variant Applies when `(sf == 1 && N == 1)`

```
BFC <Xd>, #<lsb>, #<width>
```

is equivalent to

```
BFM <Xd>, XZR, #(-<lsb> MOD 64), #(<width>-1)
```

and is the preferred disassembly when `UInt(imms) < UInt(immr)`.

Assembler Symbols

<**Wd**> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

<**lsb**> For the "32-bit" variant: is the bit number of the lsb of the destination bitfield, in the range 0 to 31.

For the "64-bit" variant: is the bit number of the lsb of the destination bitfield, in the range 0 to 63.

<**width**> For the "32-bit" variant: is the width of the bitfield, in the range 1 to 32-<lsb>.

For the "64-bit" variant: is the width of the bitfield, in the range 1 to 64-<lsb>.

<**Xd**> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

Operation

The description of BFM gives the operational pseudocode for this instruction.

Operational Information

The description of BFM gives the operational information for this instruction.

Non-Confidential

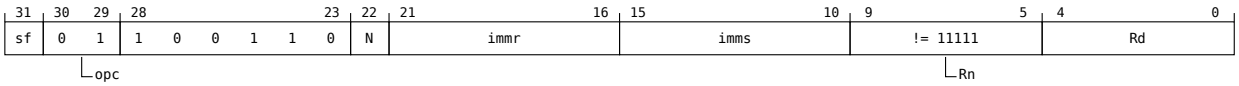
C6.2.26 BFI

Bitfield insert

This instruction copies a bitfield of <width> bits from the least significant bits of the source register to bit position <lsb> of the destination register, leaving the other destination bits unchanged.

This is an alias of BFM. This means:

- The encodings in this description are named to match the encodings of BFM.
- The description of BFM gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.



Encoding for the 32-bit variant Applies when `(sf == 0 && N == 0)`

```
BFI <Wd>, <Wn>, #<lsb>, #<width>
```

is equivalent to

```
BFM <Wd>, <Wn>, #(-<lsb> MOD 32), #(<width>-1)
```

and is the preferred disassembly when `UInt(imms) < UInt(immr)`.

Encoding for the 64-bit variant Applies when `(sf == 1 && N == 1)`

```
BFI <Xd>, <Xn>, #<lsb>, #<width>
```

is equivalent to

```
BFM <Xd>, <Xn>, #(-<lsb> MOD 64), #(<width>-1)
```

and is the preferred disassembly when `UInt(imms) < UInt(immr)`.

Assembler Symbols

<**Wd**> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

<**Wn**> Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.

<**lsb**> For the "32-bit" variant: is the bit number of the lsb of the destination bitfield, in the range 0 to 31.

For the "64-bit" variant: is the bit number of the lsb of the destination bitfield, in the range 0 to 63.

<**width**> For the "32-bit" variant: is the width of the bitfield, in the range 1 to 32-<lsb>.

For the "64-bit" variant: is the width of the bitfield, in the range 1 to 64-<lsb>.

<**Xd**> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<**Xn**> Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.

Operation

The description of BFM gives the operational pseudocode for this instruction.

Operational Information

The description of BFM gives the operational information for this instruction.

Non-Confidential

C6.2.27 BFM

Bitfield move

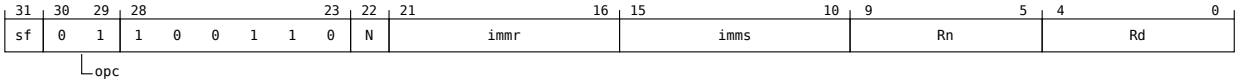
This instruction is usually accessed via one of its aliases, which are always preferred for disassembly.

If <imms> is greater than or equal to <immr>, this copies a bitfield of (<imms>-<immr>+1) bits starting from bit position <immr> in the source register to the least significant bits of the destination register.

If <imms> is less than <immr>, this copies a bitfield of (<imms>+1) bits from the least significant bits of the source register to bit position (regsize-<immr>) of the destination register, where regsize is the destination register size of 32 or 64 bits.

In both cases, the other bits of the destination register remain unchanged.

This instruction is used by the aliases BFC, BFI, and BFXIL.



Encoding for the 32-bit variant Applies when `(sf == 0 && N == 0)`

```
BFM <Wd>, <Wn>, #<immr>, #<imms>
```

Encoding for the 64-bit variant Applies when `(sf == 1 && N == 1)`

```
BFM <Xd>, <Xn>, #<immr>, #<imms>
```

Decode for all variants of this encoding

```
if sf == '1' && N != '1' then EndOfDecode(Decode_UNDEF);
if sf == '0' && (N != '0' || immr<5> != '0' || imms<5> != '0') then EndOfDecode(Decode_UNDEF);

constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer datasize = 32 << UInt(sf);
constant integer s = UInt(imms);
constant integer r = UInt(immr);

bits(datasize) wmask;
bits(datasize) tmask;
(wmask, tmask) = DecodeBitMasks(N, imms, immr, FALSE, datasize);
```

Assembler Symbols

<**Wd**> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

<**Wn**> Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.

<**immr**> For the "32-bit" variant: is the right rotate amount, in the range 0 to 31, encoded in the "immr" field.

For the "64-bit" variant: is the right rotate amount, in the range 0 to 63, encoded in the "immr" field.

<**imms**> For the "32-bit" variant: is the leftmost bit number to be moved from the source, in the range 0 to 31, encoded in the "imms" field.

For the "64-bit" variant: is the leftmost bit number to be moved from the source, in the range 0 to 63, encoded in the "imms" field.

<**Xd**> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

<**Xn**> Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.

Alias Conditions

Alias	Is preferred when
BFC	`Rn == '11111' && UInt(imms) < UInt(immr)`
BFI	`Rn != '11111' && UInt(imms) < UInt(immr)`
BFXIL	`UInt(imms) >= UInt(immr)`

Operation

```
constant bits(datasize) dst = X[d, datasize];
constant bits(datasize) src = X[n, datasize];

// Perform bitfield move on low bits
constant bits(datasize) bot = (dst AND NOT(wmask)) OR (ROR(src, r) AND wmask);

// Combine extension bits and result bits
X[d, datasize] = (dst AND NOT(tmask)) OR (bot AND tmask);
```

Operational information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

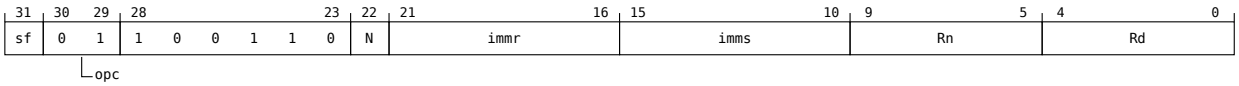
C6.2.28 BFXIL

Bitfield extract and insert at low end

This instruction copies a bitfield of <width> bits starting from bit position <lsb> in the source register to the least significant bits of the destination register, leaving the other destination bits unchanged.

This is an alias of BFM. This means:

- The encodings in this description are named to match the encodings of BFM.
- The description of BFM gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.



Encoding for the 32-bit variant Applies when `(sf == 0 && N == 0)`

```
BFXIL <Wd>, <Wn>, #<lsb>, #<width>
```

is equivalent to

```
BFM <Wd>, <Wn>, #<lsb>, #(<lsb>+<width>-1)
```

and is the preferred disassembly when `UInt(imms) >= UInt(immr)`.

Encoding for the 64-bit variant Applies when `(sf == 1 && N == 1)`

```
BFXIL <Xd>, <Xn>, #<lsb>, #<width>
```

is equivalent to

```
BFM <Xd>, <Xn>, #<lsb>, #(<lsb>+<width>-1)
```

and is the preferred disassembly when `UInt(imms) >= UInt(immr)`.

Assembler Symbols

<**Wd**> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

<**Wn**> Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.

<**lsb**> For the "32-bit" variant: is the bit number of the lsb of the source bitfield, in the range 0 to 31.

For the "64-bit" variant: is the bit number of the lsb of the source bitfield, in the range 0 to 63.

<**width**> For the "32-bit" variant: is the width of the bitfield, in the range 1 to 32-<lsb>.

For the "64-bit" variant: is the width of the bitfield, in the range 1 to 64-<lsb>.

<**Xd**> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<**Xn**> Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.

Operation

The description of BFM gives the operational pseudocode for this instruction.

Operational Information

The description of BFM gives the operational information for this instruction.

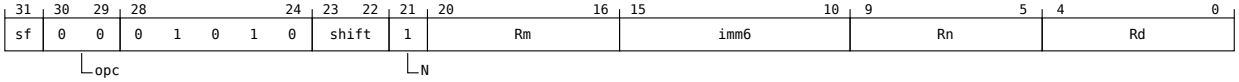
C6.2.29 BIC (shifted register)

Bitwise bit clear (shifted register)

This instruction performs a bitwise AND of a register value and the complement of an optionally-shifted register value, and writes the result to the destination register.



Encoding for the 32-bit variant Applies when `(sf == 0)`

```
BIC <Wd>, <Wn>, <Wm>{, <shift> #<amount>}
```

Encoding for the 64-bit variant Applies when `(sf == 1)`

```
BIC <Xd>, <Xn>, <Xm>{, <shift> #<amount>}
```

Decode for all variants of this encoding

```
if sf == '0' && imm6<5> == '1' then EndOfDecode(Decode_UNDEF);
constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer m = UInt(Rm);
constant integer datasize = 32 << UInt(sf);
constant ShiftType shift_type = DecodeShift(shift);
constant integer shift_amount = UInt(imm6);
```

Assembler Symbols

<**Wd**> Is the 32-bit name of the general-purpose destination register, encoded in the “Rd” field.

<**Wn**> Is the 32-bit name of the first general-purpose source register, encoded in the “Rn” field.

<**Wm**> Is the 32-bit name of the second general-purpose source register, encoded in the “Rm” field.

<**shift**> Is the optional shift to be applied to the final source, defaulting to LSL and encoded in “shift”:

shift	<shift>
00	LSL
01	LSR
10	ASR
11	ROR

<**amount**> For the “32-bit” variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the “imm6” field.

For the “64-bit” variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the “imm6” field.

<**Xd**> Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

<**Xn**> Is the 64-bit name of the first general-purpose source register, encoded in the “Rn” field.

<**Xm**> Is the 64-bit name of the second general-purpose source register, encoded in the “Rm” field.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Operation

```
constant bits(datasize) operand1 = X[n, datasize];
constant bits(datasize) operand2 = ShiftReg(m, shift_type, shift_amount, datasize);

X[d, datasize] = operand1 AND NOT(operand2);
```

Operational information

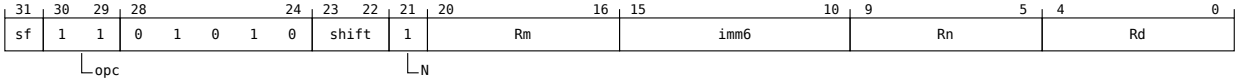
This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.30 BICS (shifted register)

Bitwise bit clear (shifted register), setting flags

This instruction performs a bitwise AND of a register value and the complement of an optionally-shifted register value, and writes the result to the destination register. It updates the condition flags based on the result.



Encoding for the 32-bit variant Applies when `(sf == 0)`

```
BICS <Wd>, <Wn>, <Wm>{, <shift> #<amount>}
```

Encoding for the 64-bit variant Applies when `(sf == 1)`

```
BICS <Xd>, <Xn>, <Xm>{, <shift> #<amount>}
```

Decode for all variants of this encoding

```
if sf == '0' && imm6<5> == '1' then EndOfDecode(Decode_UNDEF);
constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer m = UInt(Rm);
constant integer datasize = 32 << UInt(sf);
constant ShiftType shift_type = DecodeShift(shift);
constant integer shift_amount = UInt(imm6);
```

Assembler Symbols

<**Wd**> Is the 32-bit name of the general-purpose destination register, encoded in the “Rd” field.

<**Wn**> Is the 32-bit name of the first general-purpose source register, encoded in the “Rn” field.

<**Wm**> Is the 32-bit name of the second general-purpose source register, encoded in the “Rm” field.

<**shift**> Is the optional shift to be applied to the final source, defaulting to LSL and encoded in “shift”:

shift	<shift>
00	LSL
01	LSR
10	ASR
11	ROR

<**amount**> For the “32-bit” variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the “imm6” field.

For the “64-bit” variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the “imm6” field.

<**Xd**> Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

<**Xn**> Is the 64-bit name of the first general-purpose source register, encoded in the “Rn” field.

<**Xm**> Is the 64-bit name of the second general-purpose source register, encoded in the “Rm” field.

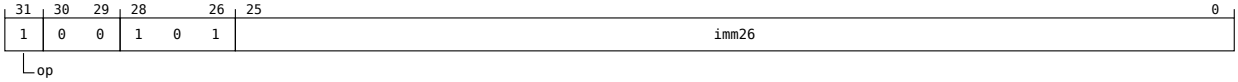
C6.2.31 BL

Branch with link

This instruction branches to a PC-relative offset, setting register X30 to PC+4. This instruction provides a hint that this is a subroutine call.



Encoding

```
BL <label>
```

Decode for this encoding

```
constant bits(64) offset = SignExtend(imm26:'00', 64);
constant integer d = 30;
```

Assembler Symbols

<label> Is the program label to be unconditionally branched to. Its offset from the address of this instruction, in the range +/-128MB, is encoded as "imm26" times 4.

Operation

```
X[d, 64] = PC64 + 4;

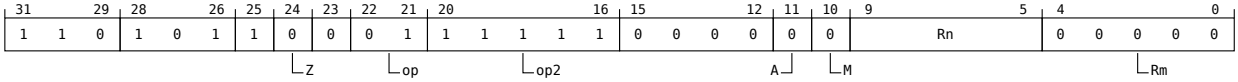
constant boolean branch_conditional = FALSE;
BranchTo(PC64 + offset, BranchType_DIRCALL, branch_conditional);
```

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.32 BLR

Branch with link to register

This instruction calls a subroutine at an address in a register, setting register X30 to PC+4. This instruction provides a hint that this is a subroutine call.



Encoding

BLR <Xn>

Decode for this encoding

```
constant integer n = UInt(Rn);
```

Assembler Symbols

<Xn> Is the 64-bit name of the general-purpose register holding the address to be branched to, encoded in the "Rn" field.

Operation

```
constant bits(64) target = X[n, 64];

X[30, 64] = PC64 + 4;

constant boolean branch_conditional = FALSE;
BranchTo(target, BranchType_INDCALL, branch_conditional);
```

C6.2.33 BLRAA, BLRAAZ, BLRAB, BLRABZ

Branch with link to register, with pointer authentication

This instruction authenticates the address in the general-purpose register that is specified by <Xn>, using a modifier and the specified key, and calls a subroutine at the authenticated address, setting register X30 to PC+4.

The modifier is:

- In the general-purpose register or stack pointer that is specified by <Xm|SP>, for BLRAA and BLRAB.
- The value zero, for BLRAAZ and BLRABZ.

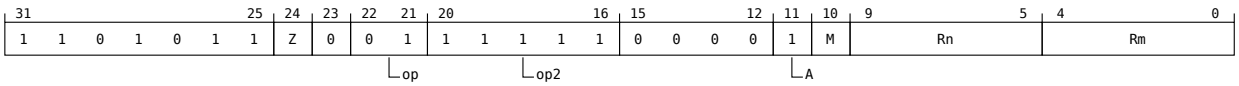
Key A is used for BLRAA and BLRAAZ. Key B is used for BLRAB and BLRABZ.

If the authentication passes, the PE continues execution at the target of the branch. For information on behavior if the authentication fails, see Faulting on pointer authentication.

The authenticated address is not written back to the general-purpose register.

This instruction provides a hint that this is a subroutine call.

Integer
(FEAT_PAuth)



Encoding for the Key A, register modifier variant Applies when `(Z == 1 && M == 0)`

```
BLRAA <Xn>, <Xm|SP>
```

Encoding for the Key A, zero modifier variant Applies when `(Z == 0 && M == 0 && Rm == 11111)`

```
BLRAAZ <Xn>
```

Encoding for the Key B, register modifier variant Applies when `(Z == 1 && M == 1)`

```
BLRAB <Xn>, <Xm|SP>
```

Encoding for the Key B, zero modifier variant Applies when `(Z == 0 && M == 1 && Rm == 11111)`

```
BLRABZ <Xn>
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_PAuth) then EndOfDecode(Decode_UNDEF);
if Z == '0' && Rm != '11111' then EndOfDecode(Decode_UNDEF);

constant integer n = UInt(Rn);
constant integer m = UInt(Rm);
constant boolean use_key_a = (M == '0');
constant boolean source_is_sp = ((Z == '1') && (m == 31));
constant boolean auth_then_branch = TRUE;
```

Assembler Symbols

<Xn> Is the 64-bit name of the general-purpose register holding the address to be branched to, encoded in the "Rn" field.

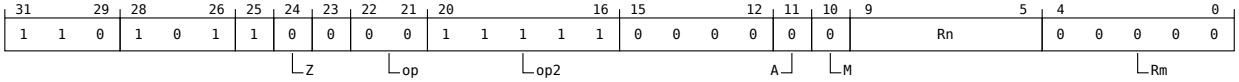
C6.2.34 BR

Branch to register

This instruction branches unconditionally to an address in a register. This instruction provides a hint that this is not a subroutine call or return.



Encoding

```
BR <Xn>
```

Decode for this encoding

```
constant integer n = UInt(Rn);
```

Assembler Symbols

<**Xn**> Is the 64-bit name of the general-purpose register holding the address to be branched to, encoded in the "Rn" field.

Operation

```
constant bits(64) target = X[n, 64];

constant boolean branch_conditional = FALSE;
BranchTo(target, BranchType_INDIR, branch_conditional);
```

C6.2.35 BRAA, BRAAZ, BRAB, BRABZ

Branch to register, with pointer authentication

This instruction authenticates the address in the general-purpose register that is specified by <Xn>, using a modifier and the specified key, and branches to the authenticated address.

The modifier is:

- In the general-purpose register or stack pointer that is specified by <Xm|SP>, for BRAA and BRAB.
- The value zero, for BRAAZ and BRABZ.

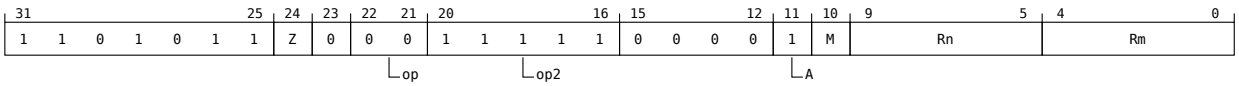
Key A is used for BRAA and BRAAZ. Key B is used for BRAB and BRABZ.

If the authentication passes, the PE continues execution at the target of the branch. For information on behavior if the authentication fails, see Faulting on pointer authentication.

The authenticated address is not written back to the general-purpose register.

This instruction provides a hint that this is not a subroutine call or return.

Integer
(FEAT_PAuth)



Encoding for the Key A, register modifier variant Applies when (Z == 1 && M == 0)

```
BRAA <Xn>, <Xm|SP>
```

Encoding for the Key A, zero modifier variant Applies when (Z == 0 && M == 0 && Rm == 11111)

```
BRAAZ <Xn>
```

Encoding for the Key B, register modifier variant Applies when (Z == 1 && M == 1)

```
BRAB <Xn>, <Xm|SP>
```

Encoding for the Key B, zero modifier variant Applies when (Z == 0 && M == 1 && Rm == 11111)

```
BRABZ <Xn>
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_PAuth) then EndOfDecode(Decode_UNDEF);
if Z == '0' && Rm != '11111' then EndOfDecode(Decode_UNDEF);

constant integer n = UInt(Rn);
constant integer m = UInt(Rm);
constant boolean use_key_a = (M == '0');
constant boolean source_is_sp = ((Z == '1') && (m == 31));
constant boolean auth_then_branch = TRUE;
```

Assembler Symbols

<**Xn**> Is the 64-bit name of the general-purpose register holding the address to be branched to, encoded in the "Rn" field.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

<Xm|SP> Is the 64-bit name of the general-purpose source register or stack pointer holding the modifier, encoded in the "Rm" field.

Operation

```
bits(64) target = X[n, 64];
constant bits(64) modifier = if source_is_sp then SP[64] else X[m, 64];

if use_key_a then
    target = AuthIA(target, modifier, auth_then_branch);
else
    target = AuthIB(target, modifier, auth_then_branch);

constant boolean branch_conditional = FALSE;
BranchTo(target, BranchType_INDIR, branch_conditional);
```

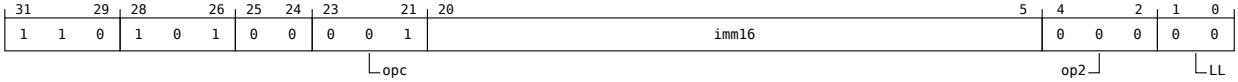
C6.2.36 BRK

Breakpoint instruction

This instruction generates a Breakpoint Instruction exception. The PE records the exception in ESR_ELx, using the EC value 0x3C, and captures the value of the immediate argument in ESR_ELx.ISS.



Encoding

```
BRK #<imm>
```

Decode for this encoding

```
constant bits(16) comment = imm16;
```

Assembler Symbols

<**imm**> Is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the “imm16” field.

Operation

```
AArch64.SoftwareBreakpoint(comment);
```

C6.2.37 CAS, CASA, CASAL, CASL

Compare and swap word or doubleword in memory

This instruction reads a 32-bit word or 64-bit doubleword from memory, and compares it against the value held in a first register. If the comparison is equal, the value in a second register is written to memory. If the comparison is not equal, the architecture permits writing the value read from the location to memory. If the write is performed, the read and write occur atomically such that no other modification of the memory location can take place between the read and write.

- If the destination register is not one of WZR or XZR, CASA and CASAL load from memory with acquire semantics.
- CASL and CASAL store to memory with release semantics.
- CAS has neither acquire nor release semantics.

The architecture permits that the data read clears any exclusive monitors associated with that location, even if the compare subsequently fails.

If the instruction generates a synchronous Data Abort, the register which is compared and loaded, that is <Ws>, or <Xs>, is restored to the value held in the register before the instruction was executed.

For a CAS or CASA instruction, when <Ws> or <Xs> specifies the same register as <Wt> or <Xt>, this signals to the memory system that an additional subsequent CAS, CASA, CASAL, or CASL access to the specified location is expected to occur in the near future in the absence of taking an exception or exceptional software conditions. The memory system can respond by taking actions that are expected to enable the subsequent CAS, CASA, CASAL, or CASL access to succeed when it does occur.

A code sequence starting with a CAS or CASA instruction for which <Ws> or <Xs> specifies the same register as <Wt> or <Xt>, and ending with a subsequent CAS, CASA, CASAL, or CASL to the same location, exhibits the following properties for best performance when the location may be accessed concurrently, on one or more other PEs:

- The sequence does not contain any direct system register writes, address translation instructions, cache or TLB maintenance operations, exception producing instructions, exception returns, or ISB barriers.
- The execution of the sequence includes 32 or fewer instructions.
- The value provided in <Ws> or <Xs> of the first CAS or CASA is a value likely to result in the comparison failing. A failing comparison result may lead to better performance due to the hardware not performing a write to memory.

Note

For a CAS or CASA instruction, when <Ws> or <Xs> specifies the same register as <Wt> or <Xt>, the value in memory is not modified, because the CAS or CASA either fails its compare or writes the same value back to memory.

For performance reasons, software is advised to not use a CAS or CASA where <Ws> or <Xs> specify the same register as <Wt> or <Xt> in a routine which includes a subsequent CAS, CASA, CASAL, or CASL for any of the following purposes:

- To load the value that will be compared to conditionally determine whether or not to execute the subsequent CAS, CASA, CASAL, or CASL.
- As a form of prefetch executed between the instruction loading the value that will be compared and the subsequent compare instruction which conditionally determines whether or not to execute the subsequent CAS, CASA, CASAL, or CASL.

This guidance does not apply in cases where the compare between the CAS or CASA, where <Ws> or <Xs> specify the same register as <Wt> or <Xt>, and the subsequent CAS, CASA, CASAL, or CASL is intended to detect an exceptional software condition such that the result of the compare does not prevent the subsequent CAS, CASA, CASAL, or CASL from executing under normal operating conditions.

For more information about memory ordering semantics, see Load-Acquire, Store-Release.

For information about addressing modes, see Load/Store addressing modes.

C6.2.38 CASB, CASAB, CASALB, CASLB

Compare and swap byte in memory

This instruction reads an 8-bit byte from memory, and compares it against the value held in a first register. If the comparison is equal, the value in a second register is written to memory. If the comparison is not equal, the architecture permits writing the value read from the location to memory. If the write is performed, the read and write occur atomically such that no other modification of the memory location can take place between the read and write.

- If the destination register is not one of WZR or XZR, CASAB and CASALB load from memory with acquire semantics.
- CASLB and CASALB store to memory with release semantics.
- CASB has neither acquire nor release semantics.

The architecture permits that the data read clears any exclusive monitors associated with that location, even if the compare subsequently fails.

If the instruction generates a synchronous Data Abort, the register which is compared and loaded, that is <Ws>, is restored to the values held in the register before the instruction was executed.

For a CASB or CASAB instruction, when <Ws> or <Xs> specifies the same register as <Wt> or <Xt>, this signals to the memory system that an additional subsequent CASB, CASAB, CASALB, or CASLB access to the specified location is expected to occur in the near future in the absence of taking an exception or exceptional software conditions. The memory system can respond by taking actions that are expected to enable the subsequent CASB, CASAB, CASALB, or CASLB access to succeed when it does occur.

A code sequence starting with a CASB or CASAB instruction for which <Ws> or <Xs> specifies the same register as <Wt> or <Xt>, and ending with a subsequent CASB, CASAB, CASALB, or CASLB to the same location, exhibits the following properties for best performance when the location may be accessed concurrently, on one or more other PEs:

- The sequence does not contain any direct system register writes, address translation instructions, cache or TLB maintenance operations, exception producing instructions, exception returns, or ISB barriers.
- The execution of the sequence includes 32 or fewer instructions.
- The value provided in <Ws> or <Xs> of the first CASB or CASAB is a value likely to result in the comparison failing. A failing comparison result may lead to better performance due to the hardware not performing a write to memory.

Note

For a CASB or CASAB instruction, when <Ws> or <Xs> specifies the same register as <Wt> or <Xt>, the value in memory is not modified, because the CASB or CASAB either fails its compare or writes the same value back to memory.

For performance reasons, software is advised to not use a CASB or CASAB where <Ws> or <Xs> specify the same register as <Wt> or <Xt> in a routine which includes a subsequent CASB, CASAB, CASALB, or CASLB for any of the following purposes:

- To load the value that will be compared to conditionally determine whether or not to execute the subsequent CASB, CASAB, CASALB, or CASLB.
- As a form of prefetch executed between the instruction loading the value that will be compared and the subsequent compare instruction which conditionally determines whether or not to execute the subsequent CASB, CASAB, CASALB, or CASLB.

This guidance does not apply in cases where the compare between the CASB or CASAB, where <Ws> or <Xs> specify the same register as <Wt> or <Xt>, and the subsequent CASB, CASAB, CASALB, or CASLB is intended to detect an exceptional software condition such that the result of the compare does not prevent the subsequent CASB, CASAB, CASALB, or CASLB from executing under normal operating conditions.

C6.2.39 CASH, CASAH, CASALH, CASLH

Compare and swap halfword in memory

This instruction reads a 16-bit halfword from memory, and compares it against the value held in a first register. If the comparison is equal, the value in a second register is written to memory. If the comparison is not equal, the architecture permits writing the value read from the location to memory. If the write is performed, the read and write occur atomically such that no other modification of the memory location can take place between the read and write.

- If the destination register is not one of WZR or XZR, CASAH and CASALH load from memory with acquire semantics.
- CASLH and CASALH store to memory with release semantics.
- CASH has neither acquire nor release semantics.

The architecture permits that the data read clears any exclusive monitors associated with that location, even if the compare subsequently fails.

If the instruction generates a synchronous Data Abort, the register which is compared and loaded, that is <Ws>, is restored to the values held in the register before the instruction was executed.

For a CASH or CASAH instruction, when <Ws> or <Xs> specifies the same register as <Wt> or <Xt>, this signals to the memory system that an additional subsequent CASH, CASAH, CASALH, or CASLH access to the specified location is expected to occur in the near future in the absence of taking an exception or exceptional software conditions. The memory system can respond by taking actions that are expected to enable the subsequent CASH, CASAH, CASALH, or CASLH access to succeed when it does occur.

A code sequence starting with a CASH or CASAH instruction for which <Ws> or <Xs> specifies the same register as <Wt> or <Xt>, and ending with a subsequent CASH, CASAH, CASALH, or CASLH to the same location, exhibits the following properties for best performance when the location may be accessed concurrently, on one or more other PEs:

- The sequence does not contain any direct system register writes, address translation instructions, cache or TLB maintenance operations, exception producing instructions, exception returns, or ISB barriers.
- The execution of the sequence includes 32 or fewer instructions.
- The value provided in <Ws> or <Xs> of the first CASH or CASAH is a value likely to result in the comparison failing. A failing comparison result may lead to better performance due to the hardware not performing a write to memory.

Note

For a CASH or CASAH instruction, when <Ws> or <Xs> specifies the same register as <Wt> or <Xt>, the value in memory is not modified, because the CASH or CASAH either fails its compare or writes the same value back to memory.

For performance reasons, software is advised to not use a CASH or CASAH where <Ws> or <Xs> specify the same register as <Wt> or <Xt> in a routine which includes a subsequent CASH, CASAH, CASALH, or CASLH for any of the following purposes:

- To load the value that will be compared to conditionally determine whether or not to execute the subsequent CASH, CASAH, CASALH, or CASLH.
- As a form of prefetch executed between the instruction loading the value that will be compared and the subsequent compare instruction which conditionally determines whether or not to execute the subsequent CASH, CASAH, CASALH, or CASLH.

This guidance does not apply in cases where the compare between the CASH or CASAH, where <Ws> or <Xs> specify the same register as <Wt> or <Xt>, and the subsequent CASH, CASAH, CASALH, or CASLH is intended to detect an exceptional software condition such that the result of the compare does not prevent the subsequent CASH, CASAH, CASALH, or CASLH from executing under normal operating conditions.

C6.2.40 CASP, CASPA, CASPAL, CASPL

Compare and swap pair of words or doublewords in memory

This instruction reads a pair of 32-bit words or 64-bit doublewords from memory, and compares them against the values held in the first pair of registers. If the comparison is equal, the values in the second pair of registers are written to memory. If the comparison is not equal, the architecture permits writing the value read from the location to memory. If the writes are performed, the reads and writes occur atomically such that no other modification of the memory location can take place between the reads and writes.

- CASPA and CASPAL load from memory with acquire semantics.
- CASPL and CASPAL store to memory with release semantics.
- CASP has neither acquire nor release semantics.

The architecture permits that the data read clears any exclusive monitors associated with that location, even if the compare subsequently fails.

If the instruction generates a synchronous Data Abort, the registers which are compared and loaded, that is <Ws> and <W(s+1)>, or <Xs> and <X(s+1)>, are restored to the values held in the registers before the instruction was executed.

For a CASP or CASPA instruction, when <Ws> or <Xs> specifies the same register as <Wt> or <Xt>, this signals to the memory system that an additional subsequent CASP, CASPA, CASPAL, or CASPL access to the specified location is expected to occur in the near future in the absence of taking an exception or exceptional software conditions. The memory system can respond by taking actions that are expected to enable the subsequent CASP, CASPA, CASPAL, or CASPL access to succeed when it does occur.

A code sequence starting with a CASP or CASPA instruction for which <Ws> or <Xs> specifies the same register as <Wt> or <Xt>, and ending with a subsequent CASP, CASPA, CASPAL, or CASPL to the same location, exhibits the following properties for best performance when the location may be accessed concurrently, on one or more other PEs:

- The sequence does not contain any direct system register writes, address translation instructions, cache or TLB maintenance operations, exception producing instructions, exception returns, or ISB barriers.
- The execution of the sequence includes 32 or fewer instructions.
- The value provided in <Ws> or <Xs> of the first CASP or CASPA is a value likely to result in the comparison failing. A failing comparison result may lead to better performance due to the hardware not performing a write to memory.

Note

For a CASP or CASPA instruction, when <Ws> or <Xs> specifies the same register as <Wt> or <Xt>, the value in memory is not modified, because the CASP or CASPA either fails its compare or writes the same value back to memory.

For performance reasons, software is advised to not use a CASP or CASPA where <Ws> or <Xs> specify the same register as <Wt> or <Xt> in a routine which includes a subsequent CASP, CASPA, CASPAL, or CASPL for any of the following purposes:

- To load the value that will be compared to conditionally determine whether or not to execute the subsequent CASP, CASPA, CASPAL, or CASPL.
- As a form of prefetch executed between the instruction loading the value that will be compared and the subsequent compare instruction which conditionally determines whether or not to execute the subsequent CASP, CASPA, CASPAL, or CASPL.

This guidance does not apply in cases where the compare between the CASP or CASPA, where <Ws> or <Xs> specify the same register as <Wt> or <Xt>, and the subsequent CASP, CASPA, CASPAL, or CASPL is intended to detect an exceptional software condition such that the result of the compare does not prevent the subsequent CASP, CASPA, CASPAL, or CASPL from executing under normal operating conditions.

For more information about memory ordering semantics, see Load-Acquire, Store-Release.

For information about addressing modes, see Load/Store addressing modes.

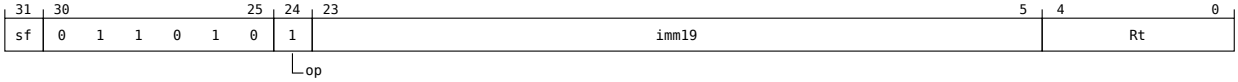
C6.2.41 CBNZ

Compare and branch on nonzero

This instruction compares the value in a register with zero, and conditionally branches to a label at a PC-relative offset if the comparison is not equal. This instruction provides a hint that this is not a subroutine call or return. This instruction does not affect the condition flags.



Encoding for the 32-bit variant Applies when `(sf == 0)`

```
CBNZ <Wt>, <label>
```

Encoding for the 64-bit variant Applies when `(sf == 1)`

```
CBNZ <Xt>, <label>
```

Decode for all variants of this encoding

```
constant integer t = UInt(Rt);
constant integer datasize = 32 << UInt(sf);
constant bits(64) offset = SignExtend(imm19:'00', 64);
```

Assembler Symbols

<**Wt**> Is the 32-bit name of the general-purpose register to be tested, encoded in the "Rt" field.

<**label**> Is the program label to be conditionally branched to. Its offset from the address of this instruction, in the range +/-1MB, is encoded as "imm19" times 4.

<**Xt**> Is the 64-bit name of the general-purpose register to be tested, encoded in the "Rt" field.

Operation

```
constant boolean branch_conditional = TRUE;
constant bits(datasize) operand1 = X[t, datasize];
if !IsZero(operand1) then
    BranchTo(PC64 + offset, BranchType_DIR, branch_conditional);
```

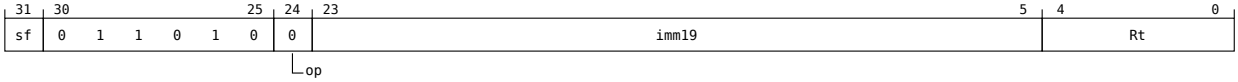
C6.2.42 CBZ

Compare and branch on zero

This instruction compares the value in a register with zero, and conditionally branches to a label at a PC-relative offset if the comparison is equal. This instruction provides a hint that this is not a subroutine call or return. This instruction does not affect condition flags.



Encoding for the 32-bit variant Applies when `(sf == 0)`

```
CBZ <Wt>, <label>
```

Encoding for the 64-bit variant Applies when `(sf == 1)`

```
CBZ <Xt>, <label>
```

Decode for all variants of this encoding

```
constant integer t = UInt(Rt);
constant integer datasize = 32 << UInt(sf);
constant bits(64) offset = SignExtend(imm19:'00', 64);
```

Assembler Symbols

<**Wt**> Is the 32-bit name of the general-purpose register to be tested, encoded in the "Rt" field.

<**label**> Is the program label to be conditionally branched to. Its offset from the address of this instruction, in the range +/-1MB, is encoded as "imm19" times 4.

<**Xt**> Is the 64-bit name of the general-purpose register to be tested, encoded in the "Rt" field.

Operation

```
constant boolean branch_conditional = TRUE;
constant bits(datasize) operand1 = X[t, datasize];
if IsZero(operand1) then
    BranchTo(PC64 + offset, BranchType_DIR, branch_conditional);
```

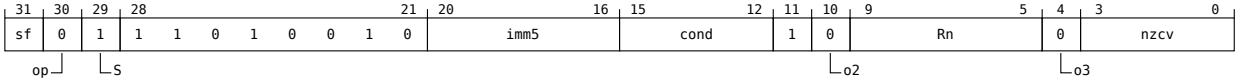
C6.2.43 CCMN (immediate)

Conditional compare negative (immediate)

This instruction sets the value of the condition flags to the result of the comparison of a register value and a negated immediate value if the condition is TRUE, and an immediate value otherwise.



Encoding for the 32-bit variant Applies when `(sf == 0)`

```
CCMN <Wn>, #<imm>, #<nzcv>, <cond>
```

Encoding for the 64-bit variant Applies when `(sf == 1)`

```
CCMN <Xn>, #<imm>, #<nzcv>, <cond>
```

Decode for all variants of this encoding

```
constant integer n = UInt(Rn);
constant integer datasize = 32 << UInt(sf);
constant bits(4) condition = cond;
bits(4) flags = nzcv;
constant bits(datasize) imm = ZeroExtend(imm5, datasize);
```

Assembler Symbols

<**Wn**> Is the 32-bit name of the general-purpose source register, encoded in the “Rn” field.

<**imm**> Is a five bit unsigned (positive) immediate encoded in the “imm5” field.

<**nzcv**> Is the flag bit specifier, an immediate in the range 0 to 15, giving the alternative state for the 4-bit NZCV condition flags, encoded in the “nzcv” field.

<**cond**> Is one of the standard conditions, encoded in the standard way, and encoded in “cond”:

cond	<cond>
0000	EQ
0001	NE
0010	CS
0011	CC
0100	MI
0101	PL
0110	VS
0111	VC
1000	HI
1001	LS
1010	GE
1011	LT
1100	GT

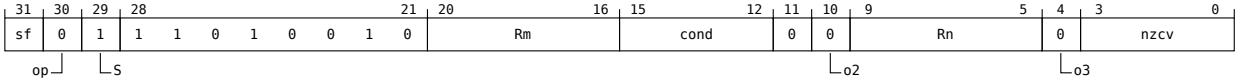
C6.2.44 CCMN (register)

Conditional compare negative (register)

This instruction sets the value of the condition flags to the result of the comparison of a register value and the inverse of another register value if the condition is TRUE, and an immediate value otherwise.



Encoding for the 32-bit variant Applies when `(sf == 0)`

```
CCMN <Wn>, <Wm>, #<nzcv>, <cond>
```

Encoding for the 64-bit variant Applies when `(sf == 1)`

```
CCMN <Xn>, <Xm>, #<nzcv>, <cond>
```

Decode for all variants of this encoding

```
constant integer n = UInt(Rn);
constant integer m = UInt(Rm);
constant integer datasize = 32 << UInt(sf);
constant bits(4) condition = cond;
bits(4) flags = nzcv;
```

Assembler Symbols

<**Wn**> Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.

<**Wm**> Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.

<**nzcv**> Is the flag bit specifier, an immediate in the range 0 to 15, giving the alternative state for the 4-bit NZCV condition flags, encoded in the "nzcv" field.

<**cond**> Is one of the standard conditions, encoded in the standard way, and encoded in "cond":

cond	<cond>
0000	EQ
0001	NE

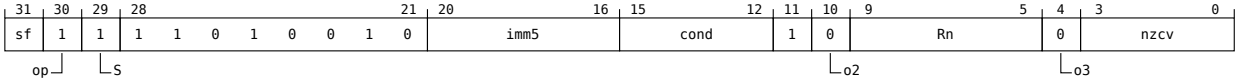
C6.2.45 CCMP (immediate)

Conditional compare (immediate)

This instruction sets the value of the condition flags to the result of the comparison of a register value and an immediate value if the condition is TRUE, and an immediate value otherwise.



Encoding for the 32-bit variant Applies when `(sf == 0)`

```
CCMP <Wn>, #<imm>, #<nzcv>, <cond>
```

Encoding for the 64-bit variant Applies when `(sf == 1)`

```
CCMP <Xn>, #<imm>, #<nzcv>, <cond>
```

Decode for all variants of this encoding

```
constant integer n = UInt(Rn);
constant integer datasize = 32 << UInt(sf);
constant bits(4) condition = cond;
bits(4) flags = nzcv;
constant bits(datasize) imm = ZeroExtend(imm5, datasize);
```

Assembler Symbols

<**Wn**> Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.

<**imm**> Is a five bit unsigned (positive) immediate encoded in the "imm5" field.

<**nzcv**> Is the flag bit specifier, an immediate in the range 0 to 15, giving the alternative state for the 4-bit NZCV condition flags, encoded in the "nzcv" field.

<**cond**> Is one of the standard conditions, encoded in the standard way, and encoded in "cond":

C6.2.48 CFP

Control flow prediction restriction by context

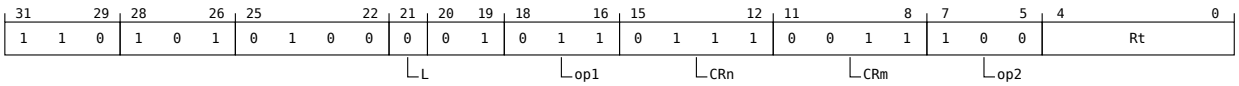
This instruction prevents control flow predictions that predict execution addresses based on information gathered from earlier execution within a particular execution context. Control flow predictions determined by the actions of code in the target execution context or contexts appearing in program order before the instruction cannot be used to exploitatively control speculative execution occurring after the instruction is complete and synchronized.

For more information, see CFP RCTX, Control Flow Prediction Restriction by Context.

This is an alias of SYS. This means:

- The encodings in this description are named to match the encodings of SYS.
- The description of SYS gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

System
(FEAT_SPECRES)



Encoding

```
CFP RCTX, <Xt>
```

is equivalent to

```
SYS #3, C7, C3, #4, <Xt>
```

and is always the preferred disassembly.

Assembler Symbols

<Xt> Is the 64-bit name of the general-purpose source register, encoded in the "Rt" field.

Operation

The description of SYS gives the operational pseudocode for this instruction.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

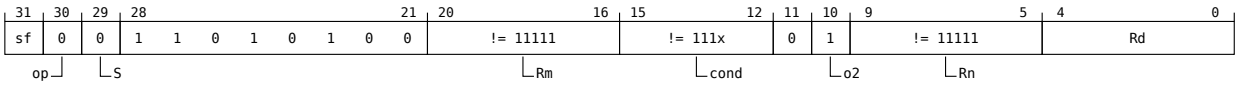
C6.2.49 CINC

Conditional increment

This instruction returns, in the destination register, the value of the source register incremented by 1 if the condition is TRUE, and otherwise returns the value of the source register.

This is an alias of CSINC. This means:

- The encodings in this description are named to match the encodings of CSINC.
- The description of CSINC gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.



Encoding for the 32-bit variant Applies when `(sf == 0)`

```
CINC <Wd>, <Wn>, <invcond>
```

is equivalent to

```
CSINC <Wd>, <Wn>, <Wm>, <cond>
```

and is the preferred disassembly when `Rn == Rm`.

Encoding for the 64-bit variant Applies when `(sf == 1)`

```
CINC <Xd>, <Xn>, <invcond>
```

is equivalent to

```
CSINC <Xd>, <Xn>, <Xm>, <cond>
```

and is the preferred disassembly when `Rn == Rm`.

Assembler Symbols

<**Wd**> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

<**Wn**> Is the 32-bit name of the general-purpose source register, encoded in the "Rn" and "Rm" fields.

<**invcond**> Is one of the standard conditions, excluding AL and NV, encoded with its least significant bit inverted, and encoded in "cond":

cond	<invcond>	Description
0000	NE	Maps to <cond> EQ.
0001	EQ	Maps to <cond> NE.
0010	CC	Maps to <cond> CS.
0011	CS	Maps to <cond> CC.

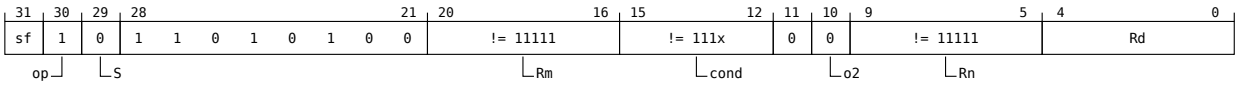
C6.2.50 CINV

Conditional invert

This instruction returns, in the destination register, the bitwise inversion of the value of the source register if the condition is TRUE, and otherwise returns the value of the source register.

This is an alias of CSINV. This means:

- The encodings in this description are named to match the encodings of CSINV.
- The description of CSINV gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.



Encoding for the 32-bit variant Applies when `(sf == 0)`

```
CINV <Wd>, <Wn>, <invcond>
```

is equivalent to

```
CSINV <Wd>, <Wn>, <Wm>, <cond>
```

and is the preferred disassembly when `Rn == Rm`.

Encoding for the 64-bit variant Applies when `(sf == 1)`

```
CINV <Xd>, <Xn>, <invcond>
```

is equivalent to

```
CSINV <Xd>, <Xn>, <Xm>, <cond>
```

and is the preferred disassembly when `Rn == Rm`.

Assembler Symbols

<**Wd**> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

<**Wn**> Is the 32-bit name of the general-purpose source register, encoded in the "Rn" and "Rm" fields.

<**invcond**> Is one of the standard conditions, excluding AL and NV, encoded with its least significant bit inverted, and encoded in "cond":

cond	<invcond>	Description
0000	NE	Maps to <cond> EQ.
0001	EQ	Maps to <cond> NE.
0010	CC	Maps to <cond> CS.
0011	CS	Maps to <cond> CC.
0100	PL	Maps to <cond> MI.
0101	MI	Maps to <cond> PL.
0110	VC	Maps to <cond> VS.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

cond	<invcond>	Description
0111	VS	Maps to <cond> VC.
1000	LS	Maps to <cond> HI.
1001	HI	Maps to <cond> LS.
1010	LT	Maps to <cond> GE.
1011	GE	Maps to <cond> LT.
1100	LE	Maps to <cond> GT.
1101	GT	Maps to <cond> LE.

<**Xd**> Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

<**Xn**> Is the 64-bit name of the general-purpose source register, encoded in the “Rn” and “Rm” fields.

Operation

The description of CSINV gives the operational pseudocode for this instruction.

Operational Information

The description of CSINV gives the operational information for this instruction.

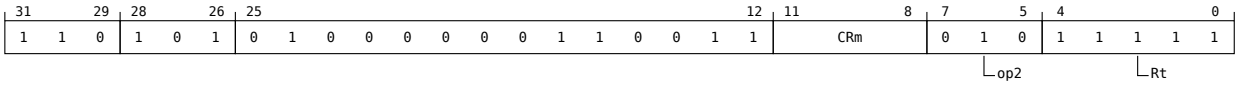
C6.2.51 CLREX

Clear exclusive

This instruction clears the local monitor of the executing PE.



Encoding

```
CLREX {#<imm>}
```

Decode for this encoding

```
// CRm field is ignored
```

Assembler Symbols

<**imm**> Is an optional 4-bit unsigned immediate, in the range 0 to 15, defaulting to 15 and encoded in the “CRm” field.

Operation

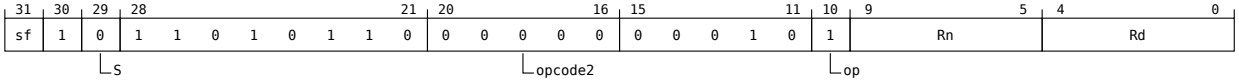
```
ClearExclusiveLocal(ProcessorID());
```

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.52 CLS

Count leading sign bits

This instruction determines the number of leading bits of the source register that have the same value as the most significant bit of the register, and writes the result to the destination register. The result does not include the most significant bit of the source register.



Encoding for the 32-bit variant Applies when `(sf == 0)`

```
CLS <Wd>, <Wn>
```

Encoding for the 64-bit variant Applies when `(sf == 1)`

```
CLS <Xd>, <Xn>
```

Decode for all variants of this encoding

```
constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer datasize = 32 << UInt(sf);
```

Assembler Symbols

<**Wd**> Is the 32-bit name of the general-purpose destination register, encoded in the “Rd” field.

<**Wn**> Is the 32-bit name of the general-purpose source register, encoded in the “Rn” field.

<**Xd**> Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

<**Xn**> Is the 64-bit name of the general-purpose source register, encoded in the “Rn” field.

Operation

```
constant bits(datasize) operand1 = X[n, datasize];
constant integer result = CountLeadingSignBits(operand1);

X[d, datasize] = result<datasize-1:0>;
```

Operational information

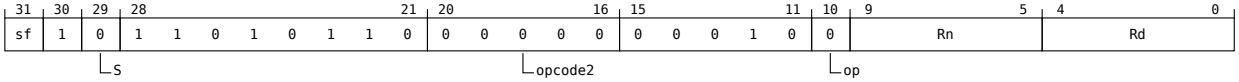
This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.53 CLZ

Count leading zeros

This instruction determines the number of consecutive binary zero bits, starting from the most significant bit in the source register, and places the result in the destination register.



Encoding for the 32-bit variant Applies when `(sf == 0)`

```
CLZ <Wd>, <Wn>
```

Encoding for the 64-bit variant Applies when `(sf == 1)`

```
CLZ <Xd>, <Xn>
```

Decode for all variants of this encoding

```
constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer datasize = 32 << UInt(sf);
```

Assembler Symbols

<**Wd**> Is the 32-bit name of the general-purpose destination register, encoded in the “Rd” field.

<**Wn**> Is the 32-bit name of the general-purpose source register, encoded in the “Rn” field.

<**Xd**> Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

<**Xn**> Is the 64-bit name of the general-purpose source register, encoded in the “Rn” field.

Operation

```
constant bits(datasize) operand1 = X[n, datasize];
constant integer result = CountLeadingZeroBits(operand1);

X[d, datasize] = result<datasize-1:0>;
```

Operational information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

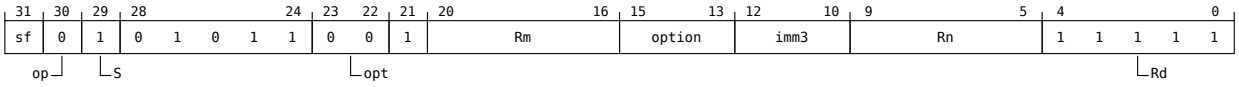
C6.2.54 CMN (extended register)

Compare negative (extended register)

This instruction adds a register value and a sign or zero-extended register value, followed by an optional left shift amount. The argument that is extended from the <Rm> register can be a byte, halfword, word, or doubleword. It updates the condition flags based on the result, and discards the result.

This is an alias of ADDS (extended register). This means:

- The encodings in this description are named to match the encodings of ADDS (extended register).
- The description of ADDS (extended register) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.



Encoding for the 32-bit variant Applies when `(sf == 0)`

```
CMN <Wn|WSP>, <Wm>{, <extend> {#<amount>}}
```

is equivalent to

```
ADDS WZR, <Wn|WSP>, <Wm>{, <extend> {#<amount>}}
```

and is always the preferred disassembly.

Encoding for the 64-bit variant Applies when `(sf == 1)`

```
CMN <Xn|SP>, <R><m>{, <extend> {#<amount>}}
```

is equivalent to

```
ADDS XZR, <Xn|SP>, <R><m>{, <extend> {#<amount>}}
```

and is always the preferred disassembly.

Assembler Symbols

<Wn|WSP> Is the 32-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn" field.

<Wm> Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.

<extend> For the "32-bit" variant: is the extension to be applied to the second source operand, encoded in "option":

option	<extend>
000	UXTB
001	UXTH
010	LSL|UXTW
011	UXTX
100	SXTB
101	SXTH
110	SXTW

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

option	<extend>
111	SXTX

If “Rn” is ’11111’ (WSP) and “option” is ’010’ then LSL is preferred, but may be omitted when “imm3” is ’000’. In all other cases <extend> is required and must be UXTW when “option” is ’010’.

For the “64-bit” variant: is the extension to be applied to the second source operand, encoded in “option”:

option	<extend>
000	UXTB
001	UXTH
010	UXTW
011	LSL|UXTX
100	SXTB
101	SXTH
110	SXTW
111	SXTX

If “Rn” is ’11111’ (SP) and “option” is ’011’ then LSL is preferred, but may be omitted when “imm3” is ’000’. In all other cases <extend> is required and must be UXTX when “option” is ’011’.

<**amount**> Is the left shift amount to be applied after extension in the range 0 to 4, defaulting to 0, encoded in the “imm3” field. It must be absent when <extend> is absent, is required when <extend> is LSL, and is optional when <extend> is present but not LSL.

<**Xn**|**SP**> Is the 64-bit name of the first source general-purpose register or stack pointer, encoded in the “Rn” field.

<**R**> Is a width specifier, encoded in “option”:

option	<R>
00x	W
010	W
x11	X
10x	W
110	W

<**m**> Is the number [0-30] of the second general-purpose source register or the name ZR (31), encoded in the “Rm” field.

Operation

The description of ADDS (extended register) gives the operational pseudocode for this instruction.

Operational Information

The description of ADDS (extended register) gives the operational information for this instruction.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

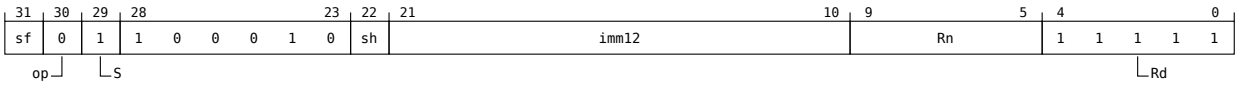
C6.2.55 CMN (immediate)

Compare negative (immediate)

This instruction adds a register value and an optionally-shifted immediate value. It updates the condition flags based on the result, and discards the result.

This is an alias of ADDS (immediate). This means:

- The encodings in this description are named to match the encodings of ADDS (immediate).
- The description of ADDS (immediate) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.



Encoding for the 32-bit variant Applies when `(sf == 0)`

```
CMN <Wn|WSP>, #<imm>{, <shift>}
```

is equivalent to

```
ADDS WZR, <Wn|WSP>, #<imm>{, <shift>}
```

and is always the preferred disassembly.

Encoding for the 64-bit variant Applies when `(sf == 1)`

```
CMN <Xn|SP>, #<imm>{, <shift>}
```

is equivalent to

```
ADDS XZR, <Xn|SP>, #<imm>{, <shift>}
```

and is always the preferred disassembly.

Assembler Symbols

<**Wn|WSP**> Is the 32-bit name of the source general-purpose register or stack pointer, encoded in the "Rn" field.

<**imm**> Is an unsigned immediate, in the range 0 to 4095, encoded in the "imm12" field.

<**shift**> Is the optional left shift to apply to the immediate, defaulting to LSL #0 and encoded in "sh":

sh	<shift>
0	LSL #0
1	LSL #12

<**Xn|SP**> Is the 64-bit name of the source general-purpose register or stack pointer, encoded in the "Rn" field.

Operation

The description of ADDS (immediate) gives the operational pseudocode for this instruction.

Operational Information

The description of ADDS (immediate) gives the operational information for this instruction.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

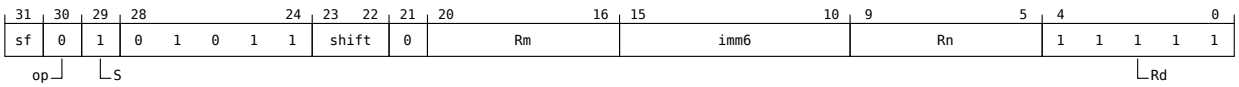
C6.2.56 CMN (shifted register)

Compare negative (shifted register)

This instruction adds a register value and an optionally-shifted register value. It updates the condition flags based on the result, and discards the result.

This is an alias of ADDS (shifted register). This means:

- The encodings in this description are named to match the encodings of ADDS (shifted register).
- The description of ADDS (shifted register) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.



Encoding for the 32-bit variant Applies when `(sf == 0)`

```
CMN <Wn>, <Wm>{, <shift> #<amount>}
```

is equivalent to

```
ADDS WZR, <Wn>, <Wm>{, <shift> #<amount>}
```

and is always the preferred disassembly.

Encoding for the 64-bit variant Applies when `(sf == 1)`

```
CMN <Xn>, <Xm>{, <shift> #<amount>}
```

is equivalent to

```
ADDS XZR, <Xn>, <Xm>{, <shift> #<amount>}
```

and is always the preferred disassembly.

Assembler Symbols

<**Wn**> Is the 32-bit name of the first general-purpose source register, encoded in the “Rn” field.

<**Wm**> Is the 32-bit name of the second general-purpose source register, encoded in the “Rm” field.

<**shift**> Is the optional shift type to be applied to the second source operand, defaulting to LSL and encoded in “shift”:

shift	<**shift**>
00	LSL
01	LSR
10	ASR
11	RESERVED

<**amount**> For the “32-bit” variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the “imm6” field.

For the “64-bit” variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the “imm6” field.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

<Xn> Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.

<Xm> Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.

Operation

The description of ADDS (shifted register) gives the operational pseudocode for this instruction.

Operational Information

The description of ADDS (shifted register) gives the operational information for this instruction.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.

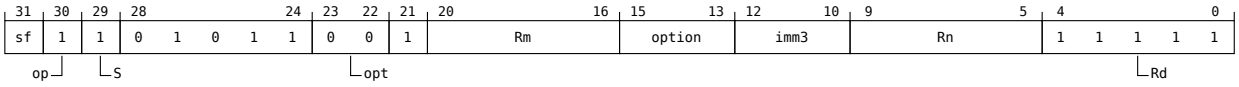
C6.2.57 CMP (extended register)

Compare (extended register)

This instruction subtracts a sign or zero-extended register value, followed by an optional left shift amount, from a register value. The argument that is extended from the <Rm> register can be a byte, halfword, word, or doubleword. It updates the condition flags based on the result, and discards the result.

This is an alias of SUBS (extended register). This means:

- The encodings in this description are named to match the encodings of SUBS (extended register).
- The description of SUBS (extended register) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.



Encoding for the 32-bit variant Applies when `(sf == 0)`

```
CMP <Wn|WSP>, <Wm>{, <extend> {#<amount>}}
```

is equivalent to

```
SUBS WZR, <Wn|WSP>, <Wm>{, <extend> {#<amount>}}
```

and is always the preferred disassembly.

Encoding for the 64-bit variant Applies when `(sf == 1)`

```
CMP <Xn|SP>, <R><m>{, <extend> {#<amount>}}
```

is equivalent to

```
SUBS XZR, <Xn|SP>, <R><m>{, <extend> {#<amount>}}
```

and is always the preferred disassembly.

Assembler Symbols

<Wn|WSP> Is the 32-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn" field.

<Wm> Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.

<extend> For the "32-bit" variant: is the extension to be applied to the second source operand, encoded in "option":

option	<extend>
000	UXTB
001	UXTH
010	LSL|UXTW
011	UXTX
100	SXTB
101	SXTH
110	SXTW

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

option	<extend>
111	SXTX

If “Rn” is ’11111’ (WSP) and “option” is ’010’ then LSL is preferred, but may be omitted when “imm3” is ’000’. In all other cases <extend> is required and must be UXTW when “option” is ’010’.

For the “64-bit” variant: is the extension to be applied to the second source operand, encoded in “option”:

option	<extend>
000	UXTB
001	UXTH
010	UXTW
011	LSL|UXTX
100	SXTB
101	SXTH
110	SXTW
111	SXTX

If “Rn” is ’11111’ (SP) and “option” is ’011’ then LSL is preferred, but may be omitted when “imm3” is ’000’. In all other cases <extend> is required and must be UXTX when “option” is ’011’.

<**amount**> Is the left shift amount to be applied after extension in the range 0 to 4, defaulting to 0, encoded in the “imm3” field. It must be absent when <extend> is absent, is required when <extend> is LSL, and is optional when <extend> is present but not LSL.

<**Xn|SP**> Is the 64-bit name of the first source general-purpose register or stack pointer, encoded in the “Rn” field.

<**R**> Is a width specifier, encoded in “option”:

option	<R>
00x	W
010	W
x11	X
10x	W
110	W

<**m**> Is the number [0-30] of the second general-purpose source register or the name ZR (31), encoded in the “Rm” field.

Operation

The description of SUBS (extended register) gives the operational pseudocode for this instruction.

Operational Information

The description of SUBS (extended register) gives the operational information for this instruction.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.

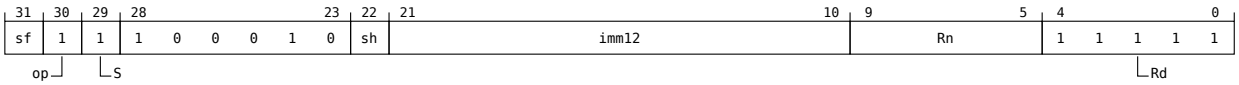
C6.2.58 CMP (immediate)

Compare (immediate)

This instruction subtracts an optionally-shifted immediate value from a register value. It updates the condition flags based on the result, and discards the result.

This is an alias of SUBS (immediate). This means:

- The encodings in this description are named to match the encodings of SUBS (immediate).
- The description of SUBS (immediate) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.



Encoding for the 32-bit variant Applies when `(sf == 0)`

```
CMP <Wn|WSP>, #<imm>{, <shift>}
```

is equivalent to

```
SUBS WZR, <Wn|WSP>, #<imm>{, <shift>}
```

and is always the preferred disassembly.

Encoding for the 64-bit variant Applies when `(sf == 1)`

```
CMP <Xn|SP>, #<imm>{, <shift>}
```

is equivalent to

```
SUBS XZR, <Xn|SP>, #<imm>{, <shift>}
```

and is always the preferred disassembly.

Assembler Symbols

<**Wn**|**WSP**> Is the 32-bit name of the source general-purpose register or stack pointer, encoded in the "Rn" field.

<**imm**> Is an unsigned immediate, in the range 0 to 4095, encoded in the "imm12" field.

<**shift**> Is the optional left shift to apply to the immediate, defaulting to LSL #0 and encoded in "sh":

sh	<shift>
0	LSL #0
1	LSL #12

<**Xn**|**SP**> Is the 64-bit name of the source general-purpose register or stack pointer, encoded in the "Rn" field.

Operation

The description of SUBS (immediate) gives the operational pseudocode for this instruction.

Operational Information

The description of SUBS (immediate) gives the operational information for this instruction.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

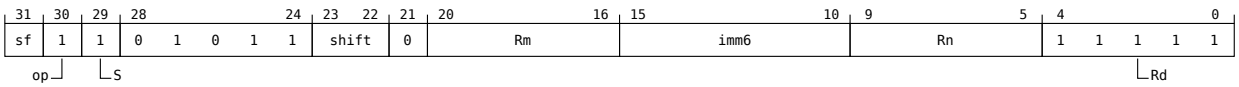
C6.2.59 CMP (shifted register)

Compare (shifted register)

This instruction subtracts an optionally-shifted register value from a register value. It updates the condition flags based on the result, and discards the result.

This is an alias of SUBS (shifted register). This means:

- The encodings in this description are named to match the encodings of SUBS (shifted register).
- The description of SUBS (shifted register) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.



Encoding for the 32-bit variant Applies when `(sf == 0)`

```
CMP <Wn>, <Wm>{, <shift> #<amount>}
```

is equivalent to

```
SUBS WZR, <Wn>, <Wm>{, <shift> #<amount>}
```

and is always the preferred disassembly.

Encoding for the 64-bit variant Applies when `(sf == 1)`

```
CMP <Xn>, <Xm>{, <shift> #<amount>}
```

is equivalent to

```
SUBS XZR, <Xn>, <Xm>{, <shift> #<amount>}
```

and is always the preferred disassembly.

Assembler Symbols

<**Wn**> Is the 32-bit name of the first general-purpose source register, encoded in the “Rn” field.

<**Wm**> Is the 32-bit name of the second general-purpose source register, encoded in the “Rm” field.

<**shift**> Is the optional shift type to be applied to the second source operand, defaulting to LSL and encoded in “shift”:

shift	<**shift**>
00	LSL
01	LSR
10	ASR
11	RESERVED

<**amount**> For the “32-bit” variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the “imm6” field.

For the “64-bit” variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the “imm6” field.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

<Xn> Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.

<Xm> Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.

Operation

The description of SUBS (shifted register) gives the operational pseudocode for this instruction.

Operational Information

The description of SUBS (shifted register) gives the operational information for this instruction.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.

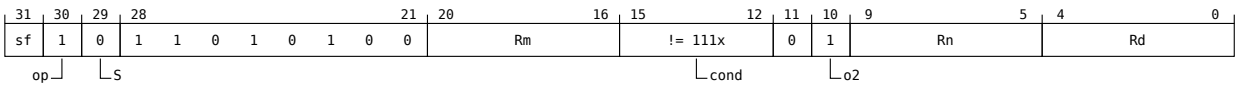
C6.2.60 CNEG

Conditional negate

This instruction returns, in the destination register, the negated value of the source register if the condition is TRUE, and otherwise returns the value of the source register.

This is an alias of CSNEG. This means:

- The encodings in this description are named to match the encodings of CSNEG.
- The description of CSNEG gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.



Encoding for the 32-bit variant Applies when `(sf == 0)`

```
CNEG <Wd>, <Wn>, <invcond>
```

is equivalent to

```
CSNEG <Wd>, <Wn>, <Wm>, <cond>
```

and is the preferred disassembly when `Rn == Rm`.

Encoding for the 64-bit variant Applies when `(sf == 1)`

```
CNEG <Xd>, <Xn>, <invcond>
```

is equivalent to

```
CSNEG <Xd>, <Xn>, <Xm>, <cond>
```

and is the preferred disassembly when `Rn == Rm`.

Assembler Symbols

<**Wd**> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

<**Wn**> Is the 32-bit name of the general-purpose source register, encoded in the "Rn" and "Rm" fields.

<**invcond**> Is one of the standard conditions, excluding AL and NV, encoded with its least significant bit inverted, and encoded in "cond":

cond	<invcond>	Description
0000	NE	Maps to <cond> EQ.
0001	EQ	Maps to <cond> NE.
0010	CC	Maps to <cond> CS.
0011	CS	Maps to <cond> CC.
0100	PL	Maps to <cond> MI.
0101	MI	Maps to <cond> PL.
0110	VC	Maps to <cond> VS.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

cond	<invcond>	Description
0111	VS	Maps to <cond> VC.
1000	LS	Maps to <cond> HI.
1001	HI	Maps to <cond> LS.
1010	LT	Maps to <cond> GE.
1011	GE	Maps to <cond> LT.
1100	LE	Maps to <cond> GT.
1101	GT	Maps to <cond> LE.

<**Xd**> Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

<**Xn**> Is the 64-bit name of the general-purpose source register, encoded in the “Rn” and “Rm” fields.

Operation

The description of CSNEG gives the operational pseudocode for this instruction.

Operational Information

The description of CSNEG gives the operational information for this instruction.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.61 CPP

Cache prefetch prediction restriction by context

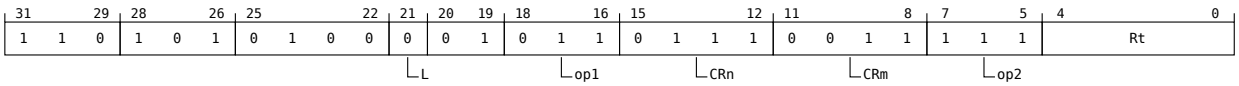
This instruction prevents cache allocation predictions that predict execution addresses based on information gathered from earlier execution within a particular execution context. The actions of code in the target execution context or contexts appearing in program order before the instruction cannot exploitatively control cache prefetch predictions occurring after the instruction is complete and synchronized.

For more information, see CPP RCTX, Cache Prefetch Prediction Restriction by Context.

This is an alias of SYS. This means:

- The encodings in this description are named to match the encodings of SYS.
- The description of SYS gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

System
(FEAT_SPECRES)



Encoding

```
CPP RCTX, <Xt>
```

is equivalent to

```
SYS #3, C7, C3, #7, <Xt>
```

and is always the preferred disassembly.

Assembler Symbols

<Xt> Is the 64-bit name of the general-purpose source register, encoded in the "Rt" field.

Operation

The description of SYS gives the operational pseudocode for this instruction.

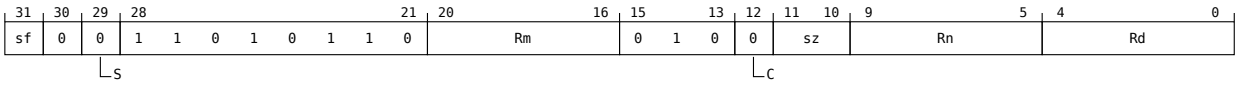
Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.62 CRC32B, CRC32H, CRC32W, CRC32X

CRC32 checksum

This instruction performs a cyclic redundancy check (CRC) calculation on a value held in a general-purpose register. It takes an input CRC value in the first source operand, performs a CRC on the input value in the second source operand, and returns the output CRC value. The second source operand can be 8, 16, 32, or 64 bits. To align with common usage, the bit order of the values is reversed as part of the operation, and the polynomial 0x04C11DB7 is used for the CRC calculation.

CRC
(FEAT_CRC32)



Encoding for the CRC32B variant Applies when `(sf == 0 && sz == 00)`

```
CRC32B <Wd>, <Wn>, <Wm>
```

Encoding for the CRC32H variant Applies when `(sf == 0 && sz == 01)`

```
CRC32H <Wd>, <Wn>, <Wm>
```

Encoding for the CRC32W variant Applies when `(sf == 0 && sz == 10)`

```
CRC32W <Wd>, <Wn>, <Wm>
```

Encoding for the CRC32X variant Applies when `(sf == 1 && sz == 11)`

```
CRC32X <Wd>, <Wn>, <Xm>
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_CRC32) then EndOfDecode(Decode_UNDEF);
constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer m = UInt(Rm);
if sf == '1' && sz != '11' then EndOfDecode(Decode_UNDEF);
if sf == '0' && sz == '11' then EndOfDecode(Decode_UNDEF);
constant integer size = 8 << UInt(sz);
```

Assembler Symbols

<Wd> Is the 32-bit name of the general-purpose accumulator output register, encoded in the “Rd” field.

<Wn> Is the 32-bit name of the general-purpose accumulator input register, encoded in the “Rn” field.

<Wm> Is the 32-bit name of the general-purpose data source register, encoded in the “Rm” field.

<Xm> Is the 64-bit name of the general-purpose data source register, encoded in the “Rm” field.

Operation

```
constant bits(32)      acc     = X[n, 32];     // accumulator
constant bits(size)    val     = X[m, size];   // input value
constant bits(32)      poly    = 0x04C11DB7<31:0>;

constant bits(32+size) tempacc = BitReverse(acc):Zeros(size);
```

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

```
constant bits(size+32) tempval = BitReverse(val):Zeros(32);

// Poly32Mod2 on a bitstring does a polynomial Modulus over {0,1} operation
X[d, 32] = BitReverse(Poly32Mod2(tempacc EOR tempval, poly));
```

Operational information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

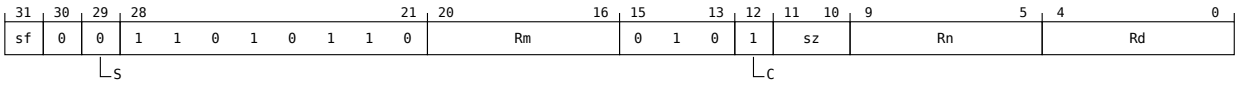
Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.63 CRC32CB, CRC32CH, CRC32CW, CRC32CX

CRC32C checksum

This instruction performs a cyclic redundancy check (CRC) calculation on a value held in a general-purpose register. It takes an input CRC value in the first source operand, performs a CRC on the input value in the second source operand, and returns the output CRC value. The second source operand can be 8, 16, 32, or 64 bits. To align with common usage, the bit order of the values is reversed as part of the operation, and the polynomial 0x1EDC6F41 is used for the CRC calculation.

CRC
(FEAT_CRC32)



Encoding for the CRC32CB variant Applies when `(sf == 0 && sz == 00)`

```
CRC32CB <Wd>, <Wn>, <Wm>
```

Encoding for the CRC32CH variant Applies when `(sf == 0 && sz == 01)`

```
CRC32CH <Wd>, <Wn>, <Wm>
```

Encoding for the CRC32CW variant Applies when `(sf == 0 && sz == 10)`

```
CRC32CW <Wd>, <Wn>, <Wm>
```

Encoding for the CRC32CX variant Applies when `(sf == 1 && sz == 11)`

```
CRC32CX <Wd>, <Wn>, <Xm>
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_CRC32) then EndOfDecode(Decode_UNDEF);
constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer m = UInt(Rm);
if sf == '1' && sz != '11' then EndOfDecode(Decode_UNDEF);
if sf == '0' && sz == '11' then EndOfDecode(Decode_UNDEF);
constant integer size = 8 << UInt(sz);
```

Assembler Symbols

<Wd> Is the 32-bit name of the general-purpose accumulator output register, encoded in the "Rd" field.

<Wn> Is the 32-bit name of the general-purpose accumulator input register, encoded in the "Rn" field.

<Wm> Is the 32-bit name of the general-purpose data source register, encoded in the "Rm" field.

<Xm> Is the 64-bit name of the general-purpose data source register, encoded in the "Rm" field.

Operation

```
constant bits(32)      acc     = X[n, 32];     // accumulator
constant bits(size)    val     = X[m, size];   // input value
constant bits(32)      poly    = 0x1EDC6F41<31:0>;

constant bits(32+size) tempacc = BitReverse(acc):Zeros(size);
```

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

```
constant bits(size+32) tempval = BitReverse(val):Zeros(32);

// Poly32Mod2 on a bitstring does a polynomial Modulus over {0,1} operation
X[d, 32] = BitReverse(Poly32Mod2(tempacc EOR tempval, poly));
```

Operational information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

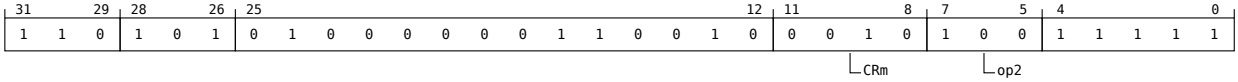
Non-Confidential

C6.2.64 CSDB

Consumption of speculative data barrier

This instruction is a memory barrier that controls speculative execution arising from data value prediction. For more information and details of the semantics, see Consumption of Speculative Data Barrier (CSDB).



Encoding

CSDB

Decode for this encoding

```
// Empty.
```

Operation

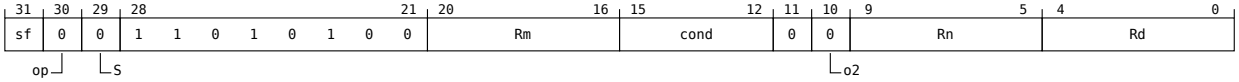
```
ConsumptionOfSpeculativeDataBarrier();
```

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.65 CSEL

Conditional select

This instruction writes the value of the first source register to the destination register if the condition is TRUE. If the condition is FALSE, it writes the value of the second source register to the destination register.



Encoding for the 32-bit variant Applies when `(sf == 0)`

```
CSEL <Wd>, <Wn>, <Wm>, <cond>
```

Encoding for the 64-bit variant Applies when `(sf == 1)`

```
CSEL <Xd>, <Xn>, <Xm>, <cond>
```

Decode for all variants of this encoding

```
constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer m = UInt(Rm);
constant integer datasize = 32 << UInt(sf);
constant bits(4) condition = cond;
```

Assembler Symbols

<**Wd**> Is the 32-bit name of the general-purpose destination register, encoded in the “Rd” field.

<**Wn**> Is the 32-bit name of the first general-purpose source register, encoded in the “Rn” field.

<**Wm**> Is the 32-bit name of the second general-purpose source register, encoded in the “Rm” field.

<**cond**> Is one of the standard conditions, encoded in the standard way, and encoded in “cond”:

cond	<cond>
0000	EQ
0001	NE
0010	CS
0011	CC
0100	MI
0101	PL
0110	VS
0111	VC
1000	HI
1001	LS
1010	GE
1011	LT
1100	GT

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

cond	<cond>
1101	LE
1110	AL
1111	NV

<**Xd**> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<**Xn**> Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.

<**Xm**> Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.

Operation

```
bits(datasize) result;
if ConditionHolds(condition) then
    result = X[n, datasize];
else
    result = X[m, datasize];

X[d, datasize] = result;
```

Operational information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

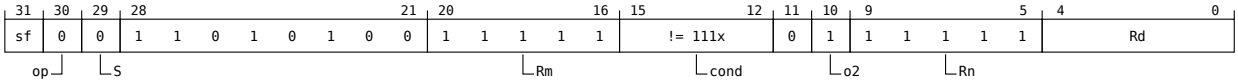
C6.2.66 CSET

Conditional set

This instruction sets the destination register to 1 if the condition is TRUE, and otherwise sets it to 0.

This is an alias of CSINC. This means:

- The encodings in this description are named to match the encodings of CSINC.
- The description of CSINC gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.



Encoding for the 32-bit variant Applies when `(sf == 0)`

```
CSET <Wd>, <invcond>
```

is equivalent to

```
CSINC <Wd>, WZR, WZR, <cond>
```

and is always the preferred disassembly.

Encoding for the 64-bit variant Applies when `(sf == 1)`

```
CSET <Xd>, <invcond>
```

is equivalent to

```
CSINC <Xd>, XZR, XZR, <cond>
```

and is always the preferred disassembly.

Assembler Symbols

<**Wd**> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

<**invcond**> Is one of the standard conditions, excluding AL and NV, encoded with its least significant bit inverted, and encoded in "cond":

cond	<invcond>	Description
0000	NE	Maps to <cond> EQ.
0001	EQ	Maps to <cond> NE.
0010	CC	Maps to <cond> CS.
0011	CS	Maps to <cond> CC.
0100	PL	Maps to <cond> MI.
0101	MI	Maps to <cond> PL.
0110	VC	Maps to <cond> VS.
0111	VS	Maps to <cond> VC.
1000	LS	Maps to <cond> HI.

1010	LT	Maps to <cond> GE.
1011	GE	Maps to <cond> LT.
1100	LE	Maps to <cond> GT.
1101	GT	Maps to <cond> LE.

<**Xd**> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

Operation

The description of CSINC gives the operational pseudocode for this instruction.

Operational Information

The description of CSINC gives the operational information for this instruction.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

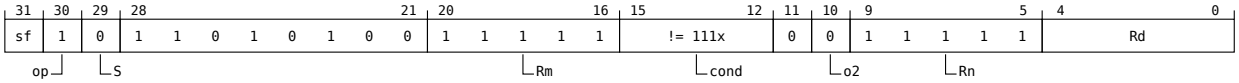
C6.2.67 CSETM

Conditional set mask

This instruction sets all bits of the destination register to 1 if the condition is TRUE, and otherwise sets all bits to 0.

This is an alias of CSINV. This means:

- The encodings in this description are named to match the encodings of CSINV.
- The description of CSINV gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.



Encoding for the 32-bit variant Applies when `(sf == 0)`

```
CSETM <Wd>, <invcond>
```

is equivalent to

```
CSINV <Wd>, WZR, WZR, <cond>
```

and is always the preferred disassembly.

Encoding for the 64-bit variant Applies when `(sf == 1)`

```
CSETM <Xd>, <invcond>
```

is equivalent to

```
CSINV <Xd>, XZR, XZR, <cond>
```

and is always the preferred disassembly.

Assembler Symbols

<**Wd**> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

<**invcond**> Is one of the standard conditions, excluding AL and NV, encoded with its least significant bit inverted, and encoded in "cond":

cond	<invcond>	Description
0000	NE	Maps to <cond> EQ.
0001	EQ	Maps to <cond> NE.
0010	CC	Maps to <cond> CS.
0011	CS	Maps to <cond> CC.

Non-Confidential

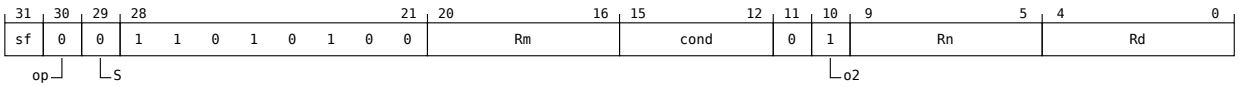
C6.2.68 CSINC

Conditional select increment

This instruction returns, in the destination register, the value of the first source register if the condition is TRUE, and otherwise returns the value of the second source register incremented by 1.

This instruction is used by the aliases CINC, and CSET.



Encoding for the 32-bit variant Applies when `(sf == 0)`

```
CSINC <Wd>, <Wn>, <Wm>, <cond>
```

Encoding for the 64-bit variant Applies when `(sf == 1)`

```
CSINC <Xd>, <Xn>, <Xm>, <cond>
```

Decode for all variants of this encoding

```
constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer m = UInt(Rm);
constant integer datasize = 32 << UInt(sf);
constant bits(4) condition = cond;
```

Assembler Symbols

<**Wd**> Is the 32-bit name of the general-purpose destination register, encoded in the “Rd” field.

<**Wn**> Is the 32-bit name of the first general-purpose source register, encoded in the “Rn” field.

<**Wm**> Is the 32-bit name of the second general-purpose source register, encoded in the “Rm” field.

<**cond**> Is one of the standard conditions, encoded in the standard way, and encoded in “cond”:

cond	<cond>
0000	EQ
0001	NE
0010	CS
0011	CC
0100	MI
0101	PL
0110	VS
0111	VC
1000	HI
1001	LS
1010	GE
1011	LT

Non-Confidential

cond	<cond>
1100	GT
1101	LE
1110	AL
1111	NV

<**Xd**> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<**Xn**> Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.

<**Xm**> Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.

Alias Conditions

Alias	Is preferred when
CINC	Rm != '11111' && Rn != '11111' && !(cond IN {'111x'}) && Rn == Rm
CSET	Rm == '11111' && Rn == '11111' && !(cond IN {'111x'})

Operation

```
bits(datasize) result;
if ConditionHolds(condition) then
    result = X[n, datasize];
else
    result = X[m, datasize] + 1;

X[d, datasize] = result;
```

Operational information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

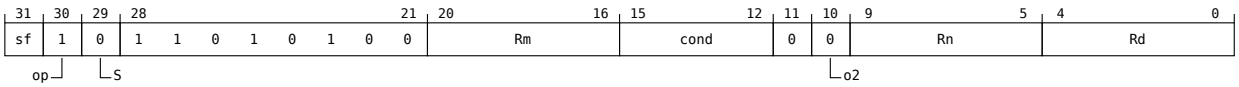
Non-Confidential

C6.2.69 CSINV

Conditional select invert

This instruction returns, in the destination register, the value of the first source register if the condition is TRUE, and otherwise returns the bitwise inversion value of the second source register.

This instruction is used by the aliases CINV, and CSETM.



Encoding for the 32-bit variant Applies when `(sf == 0)`

```
CSINV <Wd>, <Wn>, <Wm>, <cond>
```

Encoding for the 64-bit variant Applies when `(sf == 1)`

```
CSINV <Xd>, <Xn>, <Xm>, <cond>
```

Decode for all variants of this encoding

```
constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer m = UInt(Rm);
constant integer datasize = 32 << UInt(sf);
constant bits(4) condition = cond;
```

Assembler Symbols

<**Wd**> Is the 32-bit name of the general-purpose destination register, encoded in the “Rd” field.

<**Wn**> Is the 32-bit name of the first general-purpose source register, encoded in the “Rn” field.

<**Wm**> Is the 32-bit name of the second general-purpose source register, encoded in the “Rm” field.

<**cond**> Is one of the standard conditions, encoded in the standard way, and encoded in “cond”:

cond	<cond>
0000	EQ
0001	NE
0010	CS
0011	CC
0100	MI
0101	PL
0110	VS
0111	VC
1000	HI
1001	LS
1010	GE
1011	LT

Non-Confidential

cond	<cond>
1100	GT
1101	LE
1110	AL
1111	NV

<**Xd**> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<**Xn**> Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.

<**Xm**> Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.

Alias Conditions

Alias	Is preferred when
CINV	Rm != '11111' && Rn != '11111' && !(cond IN {'111x'}) && Rn == Rm
CSETM	Rm == '11111' && Rn == '11111' && !(cond IN {'111x'})

Operation

```
bits(datasize) result;
if ConditionHolds(condition) then
    result = X[n, datasize];
else
    result = NOT(X[m, datasize]);

X[d, datasize] = result;
```

Operational information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

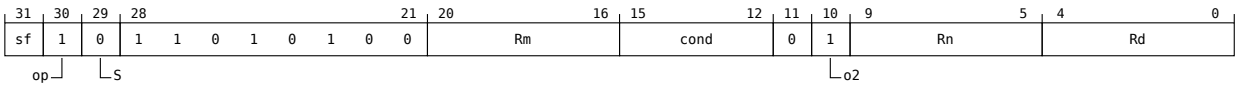
C6.2.70 CSNEG

Conditional select negation

This instruction returns, in the destination register, the value of the first source register if the condition is TRUE, and otherwise returns the negated value of the second source register.

This instruction is used by the alias CNEG.



Encoding for the 32-bit variant Applies when `(sf == 0)`

```
CSNEG <Wd>, <Wn>, <Wm>, <cond>
```

Encoding for the 64-bit variant Applies when `(sf == 1)`

```
CSNEG <Xd>, <Xn>, <Xm>, <cond>
```

Decode for all variants of this encoding

```
constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer m = UInt(Rm);
constant integer datasize = 32 << UInt(sf);
constant bits(4) condition = cond;
```

Assembler Symbols

<**Wd**> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

<**Wn**> Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.

<**Wm**> Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.

<**cond**> Is one of the standard conditions, encoded in the standard way, and encoded in "cond":

cond	<cond>
0000	EQ
0001	NE
0010	CS
0011	CC
0100	MI
0101	PL
0110	VS
0111	VC
1000	HI
1001	LS
1010	GE
1011	LT

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

cond	<cond>
1100	GT
1101	LE
1110	AL
1111	NV

<**Xd**> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<**Xn**> Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.

<**Xm**> Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.

Alias Conditions

Alias	Is preferred when
CNEG	!(cond IN {'111x'}) && Rn == Rm

Operation

```
bits(datasize) result;
if ConditionHolds(condition) then
    result = X[n, datasize];
else
    result = NOT(X[m, datasize]) + 1;

X[d, datasize] = result;
```

Operational information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

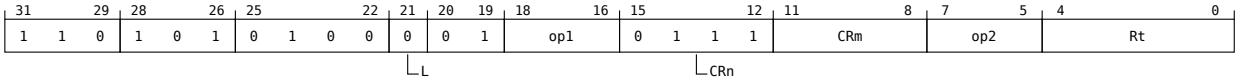
C6.2.71 DC

Data cache operation

For more information, see op0==0b01, cache maintenance, TLB maintenance, and address translation instructions.

This is an alias of SYS. This means:

- The encodings in this description are named to match the encodings of SYS.
- The description of SYS gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.



Encoding

```
DC <dc_op>, <Xt>
```

is equivalent to

```
SYS #<op1>, C7, <Cm>, #<op2>, <Xt>
```

and is the preferred disassembly when `SysOp(op1, '0111', CRm, op2) == Sys_DC`.

Assembler Symbols

<**dc_op**> Is a DC operation name, as listed for the DC system instruction group, encoded in "op1:CRm:op2":

op1	CRm	op2	<dc_op>	Architectural Feature
000	0110	001	IVAC	-
000	0110	010	ISW	-
000	1010	010	CSW	-
000	1110	010	CISW	-
011	0100	001	ZVA	-
011	1010	001	CVAC	-
011	1011	001	CVAU	-
011	1100	001	CVAP	FEAT_DPB
011	1101	001	CVADP	FEAT_DPB2
011	1110	001	CIVAC	-

<**Xt**> Is the 64-bit name of the general-purpose source register, encoded in the "Rt" field.

Operation

The description of SYS gives the operational pseudocode for this instruction.

Non-Confidential

C6.2.72 DCPS1

Debug change PE state to EL1

This instruction, when executed in Debug state:

- If executed at EL0, changes the current Exception level and SP to EL1 using SP_EL1.
- Otherwise, if executed at ELx, selects SP_ELx.

The target Exception level of a DCPS1 instruction is:

- EL1 if the instruction is executed at EL0.
- Otherwise, the Exception level at which the instruction is executed.

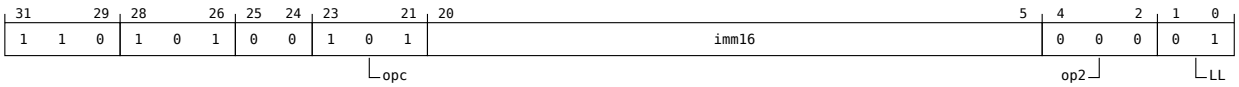
When the target Exception level of a DCPS1 instruction is ELx, on executing this instruction:

- ELR_ELx becomes UNKNOWN.
- SPSR_ELx becomes UNKNOWN.
- ESR_ELx becomes UNKNOWN.
- DLR_EL0 and DSPSR_EL0 become UNKNOWN.
- The endianness is set according to SCTLR_ELx.EE.

This instruction is always UNDEFINED in Non-debug state.

This instruction is UNDEFINED at EL0 if HCR_EL2.TGE == 1.

For more information on the operation of the DCPS<n> instructions, see DCPS.



Encoding

```
DCPS1 {#<imm>}
```

Decode for this encoding

```
// Empty.
```

Assembler Symbols

<imm> Is an optional 16-bit unsigned immediate, in the range 0 to 65535, defaulting to 0 and encoded in the "imm16" field.

Operation

```
if !Halted() then UNDEFINED;
DCPSInstruction(EL1);
```

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.73 DCPS2

Debug change PE state to EL2

This instruction, when executed in Debug state:

- If executed at EL0 or EL1, changes the current Exception level and SP to EL2 using SP_EL2.
- Otherwise, if executed at ELx, selects SP_ELx.

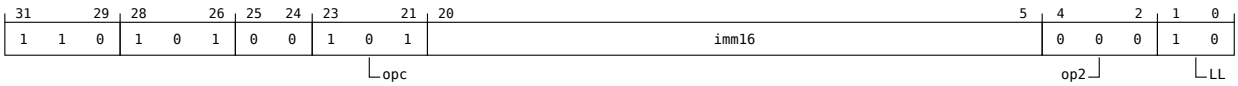
The target Exception level of a DCPS2 instruction is EL2.

When the target Exception level of a DCPS2 instruction is ELx, on executing this instruction:

- ELR_ELx becomes UNKNOWN.
- SPSR_ELx becomes UNKNOWN.
- ESR_ELx becomes UNKNOWN.
- DLR_EL0 and DSPSR_EL0 become UNKNOWN.
- The endianness is set according to SCTLR_ELx.EE.

This instruction is always UNDEFINED in Non-debug state.

For more information on the operation of the DCPS<n> instructions, see DCPS.



Encoding

```
DCPS2 {#<imm>}
```

Decode for this encoding

```
// Empty.
```

Assembler Symbols

<imm> Is an optional 16-bit unsigned immediate, in the range 0 to 65535, defaulting to 0 and encoded in the "imm16" field.

Operation

```
if !Halted() then UNDEFINED;
DCPSInstruction(EL2);
```

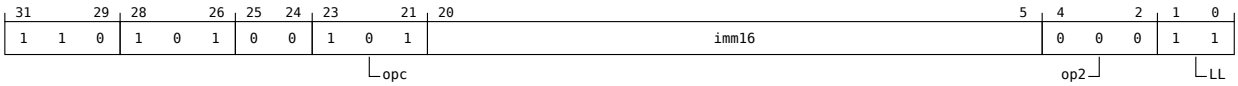
Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.74 DCPS3

Debug change PE state to EL3

This instruction is UNDEFINED.

For more information on the operation of the DCPS<n> instructions, see DCPS.



Encoding

```
DCPS3 {#<imm>}
```

Decode for this encoding

```
// Empty.
```

Assembler Symbols

<imm> Is an optional 16-bit unsigned immediate, in the range 0 to 65535, defaulting to 0 and encoded in the "imm16" field.

Operation

```
if !Halted() then UNDEFINED;
DCPSInstruction(EL3);
```

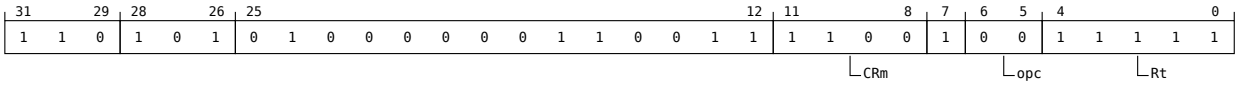
C6.2.75 DFB

Data full barrier

This instruction is a memory barrier that ensures the completion of memory accesses. If executed at EL2, this instruction orders memory accesses irrespective of their Exception level or associated VMID. If executed at EL1 or EL0, this instruction behaves as DSB SY.

This is an alias of DSB. This means:

- The encodings in this description are named to match the encodings of DSB.
- The description of DSB gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.



Encoding

```
DFB
```

is equivalent to

```
DSB #12
```

and is always the preferred disassembly.

Operation

The description of DSB gives the operational pseudocode for this instruction.

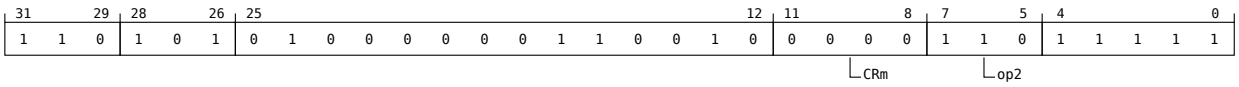
Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.76 DGH

Data gathering hint

This instruction is a hint instruction that indicates that it is not expected to be performance optimal to merge memory accesses with Normal Non-cacheable or Device-GRE attributes appearing in program order before the hint instruction with any memory accesses appearing after the hint instruction into a single memory transaction on an interconnect.

System
(FEAT_DGH)



Encoding

DGH

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_DGH) then EndOfDecode(Decode_NOP);
```

Operation

```
Hint_DGH();
```

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

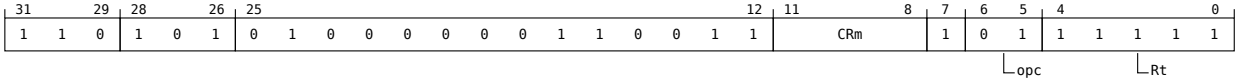
C6.2.77 DMB

Data memory barrier

This instruction is a memory barrier that ensures the ordering of observations of memory accesses, see Data Memory Barrier.

The ordering requirements of Data Memory Barrier instruction is as follows:

- EL1 and EL0 memory accesses are ordered only with respect to memory accesses using the same VMID.
- EL2 memory accesses are ordered only with respect to other EL2 memory accesses.



Encoding

```
DMB (<option>|#<imm>)
```

Decode for this encoding

```
MBReqDomain domain;
MBReqTypes types;
case CRm<3:2> of
    when '00' domain = MBReqDomain_OuterShareable;
    when '01' domain = MBReqDomain_Nonshareable;
    when '10' domain = MBReqDomain_InnerShareable;
    when '11' domain = MBReqDomain_FullSystem;
case CRm<1:0> of
    when '00' types = MBReqTypes_All; domain = MBReqDomain_FullSystem;
    when '01' types = MBReqTypes_Reads;
    when '10' types = MBReqTypes_Writes;
    when '11' types = MBReqTypes_All;

boolean vmid_sensitive = CRm<1:0> != '00';
```

Assembler Symbols

<**option**> Specifies the limitation on the barrier operation. Values are:

SY Full system is the required shareability domain, reads and writes are the required access types, both before and after the barrier instruction. This option is referred to as the full system barrier. Encoded as CRm = 0b1111.

ST Full system is the required shareability domain, writes are the required access type, both before and after the barrier instruction. Encoded as CRm = 0b1110.

LD Full system is the required shareability domain, reads are the required access type before the barrier instruction, and reads and writes are the required access types after the barrier instruction. Encoded as CRm = 0b1101.

ISH Inner Shareable is the required shareability domain, reads and writes are the required access types, both before and after the barrier instruction. Encoded as CRm = 0b1011.

ISHST Inner Shareable is the required shareability domain, writes are the required access type, both before and after the barrier instruction. Encoded as CRm = 0b1010.

ISHLD Inner Shareable is the required shareability domain, reads are the required access type before the barrier instruction, and reads and writes are the required access types after the barrier instruction. Encoded as CRm = 0b1001.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

NSH Non-shareable is the required shareability domain, reads and writes are the required access, both before and after the barrier instruction. Encoded as CRm = 0b0111.

NSHST Non-shareable is the required shareability domain, writes are the required access type, both before and after the barrier instruction. Encoded as CRm = 0b0110.

NSHLD Non-shareable is the required shareability domain, reads are the required access type before the barrier instruction, and reads and writes are the required access types after the barrier instruction. Encoded as CRm = 0b0101.

OSH Outer Shareable is the required shareability domain, reads and writes are the required access types, both before and after the barrier instruction. Encoded as CRm = 0b0011.

OSHST Outer Shareable is the required shareability domain, writes are the required access type, both before and after the barrier instruction. Encoded as CRm = 0b0010.

OSHLD Outer Shareable is the required shareability domain, reads are the required access type before the barrier instruction, and reads and writes are the required access types after the barrier instruction. Encoded as CRm = 0b0001.

All other encodings of "CRm" that are not listed are reserved and can be encoded using the #<imm> syntax. All unsupported and reserved options must execute as a full system barrier operation, but software must not rely on this behavior. For more information on whether an access is before or after a barrier instruction, see Data Memory Barrier (DMB) or see Data Synchronization Barrier (DSB).

CRm	<option>
xx00	RESERVED
0001	OSHLD
0010	OSHST

C6.2.78 DRPS

Debug restore PE state

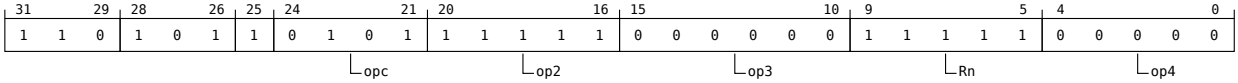
This instruction restores PSTATE from the SPSR.

The SPSR is checked for the current Exception level for an illegal return event. See Illegal exception returns from AArch64 state.

This instruction is UNDEFINED in Non-debug state.

This instruction is UNDEFINED at EL0.

For more information on the operation of DRPS, see DRPS.



Encoding

DRPS

Decode for this encoding

```
// Empty.
```

Operation

```
if !Halted() || PSTATE.EL == EL0 then UNDEFINED;
DRPSInstruction();
```

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.79 DSB

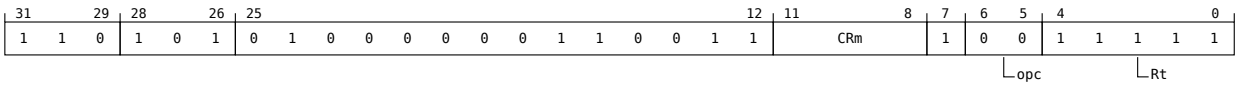
Data synchronization barrier

This instruction is a memory barrier that ensures the completion of memory accesses, see Data Synchronization Barrier.

The ordering requirements of Data Synchronization Barrier instruction is as follows:

- EL1 and EL0 memory accesses are ordered only with respect to memory accesses using the same VMID.
- EL2 memory accesses are ordered only with respect to other EL2 memory accesses.

This instruction is used by the aliases DFB, PSSBB, and SSBB.



Encoding

```
DSB (<option>|#<imm>)
```

Decode for this encoding

```
constant boolean nXS = FALSE;

MBReqDomain domain;
case CRm<3:2> of
    when '00' domain = MBReqDomain_OuterShareable;
    when '01' domain = MBReqDomain_Nonshareable;
    when '10' domain = MBReqDomain_InnerShareable;
    when '11' domain = MBReqDomain_FullSystem;

MBReqTypes types;
case CRm<1:0> of
    when '00' types = MBReqTypes_All; domain = MBReqDomain_FullSystem;
    when '01' types = MBReqTypes_Reads;
    when '10' types = MBReqTypes_Writes;
    when '11' types = MBReqTypes_All;
```

Assembler Symbols

<**option**> Specifies the limitation on the barrier operation. Values are:

SY Full system is the required shareability domain, reads and writes are the required access types, both before and after the barrier instruction. This option is referred to as the full system barrier. Encoded as CRm = 0b1111.

ST Full system is the required shareability domain, writes are the required access type, both before and after the barrier instruction. Encoded as CRm = 0b1110.

LD Full system is the required shareability domain, reads are the required access type before the barrier instruction, and reads and writes are the required access types after the barrier instruction. Encoded as CRm = 0b1101.

ISH Inner Shareable is the required shareability domain, reads and writes are the required access types, both before and after the barrier instruction. Encoded as CRm = 0b1011.

ISHST Inner Shareable is the required shareability domain, writes are the required access type, both before and after the barrier instruction. Encoded as CRm = 0b1010.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

ISHLD Inner Shareable is the required shareability domain, reads are the required access type before the barrier instruction, and reads and writes are the required access types after the barrier instruction. Encoded as CRm = 0b1001.

NSH Non-shareable is the required shareability domain, reads and writes are the required access, both before and after the barrier instruction. Encoded as CRm = 0b0111.

NSHST Non-shareable is the required shareability domain, writes are the required access type, both before and after the barrier instruction. Encoded as CRm = 0b0110.

NSHLD Non-shareable is the required shareability domain, reads are the required access type before the barrier instruction, and reads and writes are the required access types after the barrier instruction. Encoded as CRm = 0b0101.

OSH Outer Shareable is the required shareability domain, reads and writes are the required access types, both before and after the barrier instruction. Encoded as CRm = 0b0011.

OSHST Outer Shareable is the required shareability domain, writes are the required access type, both before and after the barrier instruction. Encoded as CRm = 0b0010.

OSHLD Outer Shareable is the required shareability domain, reads are the required access type before the barrier instruction, and reads and writes are the required access types after the barrier instruction. Encoded as CRm = 0b0001.

All other encodings of "CRm" that are not listed, other than the values 0b0000, 0b0100, and 0b1100, are reserved and can be encoded using the #<imm> syntax. All unsupported and reserved options must execute as a full system barrier operation, but software must not rely on this behavior. For more information on whether an access is before or after a barrier instruction, see Data Memory Barrier (DMB) or see Data Synchronization Barrier (DSB).

Note

The value 0b0000 is used to encode SSBB, the value 0b0100 is used to encode PSSBB, and the value 0b1100 is used to encode DFB.

CRm	<option>
0001	OSHLD
0010	OSHST

C6.2.80 DVP

Data value prediction restriction by context

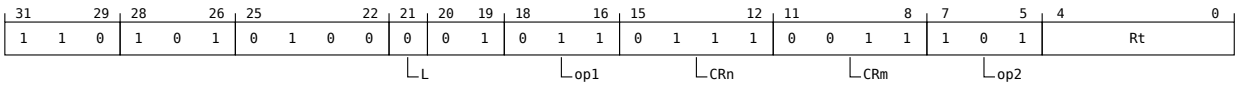
This instruction prevents data value predictions that predict execution addresses based on information gathered from earlier execution within a particular execution context. Data value predictions determined by the actions of code in the target execution context or contexts appearing in program order before the instruction cannot be used to exploitatively control speculative execution occurring after the instruction is complete and synchronized.

For more information, see DVP RCTX, Data Value Prediction Restriction by Context.

This is an alias of SYS. This means:

- The encodings in this description are named to match the encodings of SYS.
- The description of SYS gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

System
(FEAT_SPECRES)



Encoding

```
DVP RCTX, <Xt>
```

is equivalent to

```
SYS #3, C7, C3, #5, <Xt>
```

and is always the preferred disassembly.

Assembler Symbols

<Xt> Is the 64-bit name of the general-purpose source register, encoded in the "Rt" field.

Operation

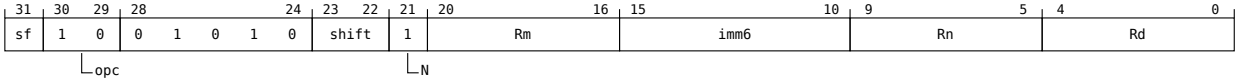
The description of SYS gives the operational pseudocode for this instruction.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.81 EON (shifted register)

Bitwise exclusive-OR NOT (shifted register)

This instruction performs a bitwise exclusive-OR NOT of a register value and an optionally-shifted register value, and writes the result to the destination register.



Encoding for the 32-bit variant Applies when `(sf == 0)`

```
EON <Wd>, <Wn>, <Wm>{, <shift> #<amount>}
```

Encoding for the 64-bit variant Applies when `(sf == 1)`

```
EON <Xd>, <Xn>, <Xm>{, <shift> #<amount>}
```

Decode for all variants of this encoding

```
if sf == '0' && imm6<5> == '1' then EndOfDecode(Decode_UNDEF);
constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer m = UInt(Rm);
constant integer datasize = 32 << UInt(sf);
constant ShiftType shift_type = DecodeShift(shift);
constant integer shift_amount = UInt(imm6);
```

Assembler Symbols

<**Wd**> Is the 32-bit name of the general-purpose destination register, encoded in the “Rd” field.

<**Wn**> Is the 32-bit name of the first general-purpose source register, encoded in the “Rn” field.

<**Wm**> Is the 32-bit name of the second general-purpose source register, encoded in the “Rm” field.

<**shift**> Is the optional shift to be applied to the final source, defaulting to LSL and encoded in “shift”:

shift	<shift>
00	LSL
01	LSR
10	ASR
11	ROR

<**amount**> For the “32-bit” variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the “imm6” field.

For the “64-bit” variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the “imm6” field.

<**Xd**> Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

<**Xn**> Is the 64-bit name of the first general-purpose source register, encoded in the “Rn” field.

<**Xm**> Is the 64-bit name of the second general-purpose source register, encoded in the “Rm” field.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Operation

```
constant bits(datasize) operand1 = X[n, datasize];
constant bits(datasize) operand2 = ShiftReg(m, shift_type, shift_amount, datasize);

X[d, datasize] = operand1 EOR NOT(operand2);
```

Operational information

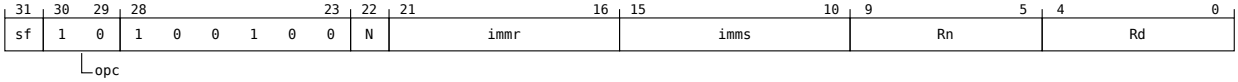
This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.82 EOR (immediate)

Bitwise exclusive-OR (immediate)

This instruction performs a bitwise exclusive-OR of a register value and an immediate value, and writes the result to the destination register.



Encoding for the 32-bit variant Applies when `(sf == 0 && N == 0)`

```
EOR <Wd|WSP>, <Wn>, #<imm>
```

Encoding for the 64-bit variant Applies when `(sf == 1)`

```
EOR <Xd|SP>, <Xn>, #<imm>
```

Decode for all variants of this encoding

```
if sf == '0' && N != '0' then EndOfDecode(Decode_UNDEF);
constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer datasize = 32 << UInt(sf);
bits(datasize) imm;
(imm, -) = DecodeBitMasks(N, imms, immr, TRUE, datasize);
```

Assembler Symbols

<**Wd|WSP**> Is the 32-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.

<**Wn**> Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.

<**imm**> For the "32-bit" variant: is the bitmask immediate, encoded in "imms:immr".

For the "64-bit" variant: is the bitmask immediate, encoded in "N:imms:immr".

<**Xd|SP**> Is the 64-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.

<**Xn**> Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.

Operation

```
constant bits(datasize) operand1 = X[n, datasize];
constant bits(datasize) operand2 = imm;

constant bits(datasize) result = operand1 EOR operand2;

if d == 31 then
    SP[64] = ZeroExtend(result, 64);
else
    X[d, datasize] = result;
```

Operational information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

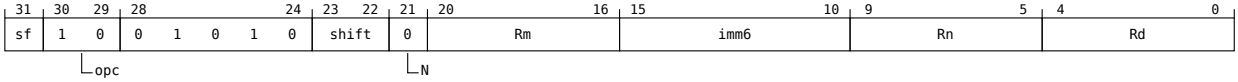
Non-Confidential

C6.2.83 EOR (shifted register)

Bitwise exclusive-OR (shifted register)

This instruction performs a bitwise exclusive-OR of a register value and an optionally-shifted register value, and writes the result to the destination register.



Encoding for the 32-bit variant Applies when `(sf == 0)`

```
EOR <Wd>, <Wn>, <Wm>{, <shift> #<amount>}
```

Encoding for the 64-bit variant Applies when `(sf == 1)`

```
EOR <Xd>, <Xn>, <Xm>{, <shift> #<amount>}
```

Decode for all variants of this encoding

```
if sf == '0' && imm6<5> == '1' then EndOfDecode(Decode_UNDEF);
constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer m = UInt(Rm);
constant integer datasize = 32 << UInt(sf);
constant ShiftType shift_type = DecodeShift(shift);
constant integer shift_amount = UInt(imm6);
```

Assembler Symbols

<**Wd**> Is the 32-bit name of the general-purpose destination register, encoded in the “Rd” field.

<**Wn**> Is the 32-bit name of the first general-purpose source register, encoded in the “Rn” field.

<**Wm**> Is the 32-bit name of the second general-purpose source register, encoded in the “Rm” field.

<**shift**> Is the optional shift to be applied to the final source, defaulting to LSL and encoded in “shift”:

shift	<shift>
00	LSL
01	LSR
10	ASR
11	ROR

<**amount**> For the “32-bit” variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the “imm6” field.

For the “64-bit” variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the “imm6” field.

<**Xd**> Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

<**Xn**> Is the 64-bit name of the first general-purpose source register, encoded in the “Rn” field.

<**Xm**> Is the 64-bit name of the second general-purpose source register, encoded in the “Rm” field.

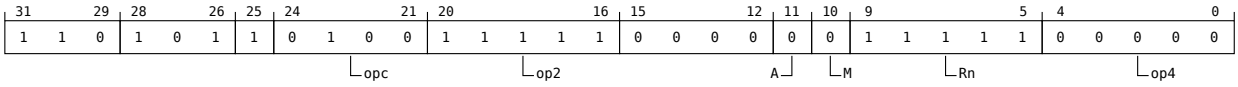
C6.2.84 ERET

Exception return

This instruction restores PSTATE from the SPSR, and branches to the address held in the ELR.

The SPSR is checked for the current Exception level for an illegal return event. See Illegal exception returns from AArch64 state.

ERET is UNDEFINED at EL0.



Encoding

ERET

Decode for this encoding

```
constant boolean pac = FALSE;
constant boolean use_key_a = TRUE;
```

Operation

```
if PSTATE.EL == EL0 then UNDEFINED;
constant bits(64) target = ELR_ELx[];

AArch64.ExceptionReturn(target, SPSR_ELx[]);
```

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.85 ERETAA, ERETAB

Exception return, with pointer authentication

This instruction authenticates the address in ELR, using SP as the modifier and the specified key, restores PSTATE from the SPSR for the current Exception level, and branches to the authenticated address.

Key A is used for `ERETAA`. Key B is used for `ERETAB`.

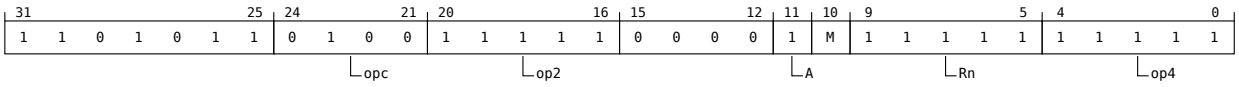
If the authentication passes, the PE continues execution at the target of the branch. For information on behavior if the authentication fails, see Faulting on pointer authentication.

The authenticated address is not written back to ELR.

The SPSR is checked for the current Exception level for an illegal return event. See Illegal exception returns from AArch64 state.

`ERETAA` and `ERETAB` are UNDEFINED at EL0.

Integer
(FEAT_PAuth)



Encoding for the ERETAA variant Applies when `(M == 0)`

`ERETAA`

Encoding for the ERETAB variant Applies when `(M == 1)`

`ERETAB`

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_PAuth) then EndOfDecode(Decode_UNDEF);

constant boolean pac = TRUE;
constant boolean use_key_a = (M == '0');
constant boolean auth_then_branch = TRUE;
```

Operation

```
if PSTATE.EL == EL0 then UNDEFINED;
bits(64) target = ELR_ELx[];
constant bits(64) modifier = SP[64];

if use_key_a then
    target = AuthIA(target, modifier, auth_then_branch);
else
    target = AuthIB(target, modifier, auth_then_branch);

AArch64.ExceptionReturn(target, SPSR_ELx[]);
```

Non-Confidential

C6.2.86 ESB

Error synchronization barrier

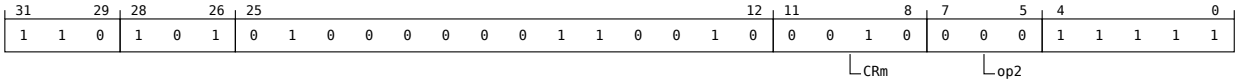
This instruction is an error synchronization event that might also update DISR_EL1 and VDISR_EL2.

This instruction can be used at all Exception levels and in Debug state.

In Debug state, this instruction behaves as if SError interrupts are masked at all Exception levels. For more information, see RAS PE architecture and Arm® Reliability, Availability, and Serviceability (RAS) System Architecture, for A-profile architecture (ARM IHI 0100).

If FEAT_RAS is not implemented, this instruction executes as a `NOP`.

System
(FEAT_RAS)



Encoding

```
ESB
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_RAS) then EndOfDecode(Decode_NOP);
```

Operation

```
SynchronizeErrors();
AArch64.ESBOperation();
if PSTATE.EL IN {EL0, EL1} && EL2Enabled() then
    AArch64.vESBOperation();
TakeUnmaskedSErrorInterrupts();
```

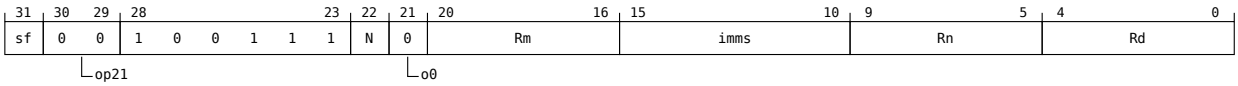
Non-Confidential

C6.2.87 EXTR

Extract register

This instruction extracts a register from a pair of registers.

This instruction is used by the alias ROR (immediate).



Encoding for the 32-bit variant Applies when `(sf == 0 && N == 0 && imms == 0xxxxx)`

```
EXTR <Wd>, <Wn>, <Wm>, #<lsb>
```

Encoding for the 64-bit variant Applies when `(sf == 1 && N == 1)`

```
EXTR <Xd>, <Xn>, <Xm>, #<lsb>
```

Decode for all variants of this encoding

```
if N != sf then EndOfDecode(Decode_UNDEF);
if sf == '0' && imms<5> == '1' then EndOfDecode(Decode_UNDEF);

constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer m = UInt(Rm);
constant integer datasize = 32 << UInt(sf);
constant integer lsb = UInt(imms);
```

Assembler Symbols

<**Wd**> Is the 32-bit name of the general-purpose destination register, encoded in the “Rd” field.

<**Wn**> Is the 32-bit name of the first general-purpose source register, encoded in the “Rn” field.

<**Wm**> Is the 32-bit name of the second general-purpose source register, encoded in the “Rm” field.

<**lsb**> For the “32-bit” variant: is the least significant bit position from which to extract, in the range 0 to 31, encoded in the “imms” field.

For the “64-bit” variant: is the least significant bit position from which to extract, in the range 0 to 63, encoded in the “imms” field.

<**Xd**> Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

<**Xn**> Is the 64-bit name of the first general-purpose source register, encoded in the “Rn” field.

<**Xm**> Is the 64-bit name of the second general-purpose source register, encoded in the “Rm” field.

Alias Conditions

Alias	Is preferred when
ROR (immediate)	Rn == Rm

Operation

C6.2.88 HINT

Hint instruction

This instruction is for the instruction set space that is reserved for architectural hint instructions.

Some encodings described here are not allocated in this revision of the architecture, and behave as NOPs. These encodings might be allocated to other hint functionality in future revisions of the architecture and therefore must not be used by software.

Encoding

```
HINT #<imm>
```

Decode for this encoding

```
SystemHintOp op;

case CRm:op2 of
    when '0000 000' op = SystemHintOp_NOP;
    when '0000 001' op = SystemHintOp_YIELD;
    when '0000 010' op = SystemHintOp_WFE;
    when '0000 011' op = SystemHintOp_WFI;
    when '0000 100' op = SystemHintOp_SEV;
    when '0000 101' op = SystemHintOp_SEVL;
    when '0000 110'
        if !IsFeatureImplemented(FEAT_DGH) then EndOfDecode(Decode_NOP);
        op = SystemHintOp_DGH;
    when '0000 111' SEE "XPACLRI";
    when '0001 xxx'
        case op2 of
            when '000' SEE "PACIA1716";
            when '010' SEE "PACIB1716";
            when '100' SEE "AUTIA1716";
            when '110' SEE "AUTIB1716";
            otherwise EndOfDecode(Decode_NOP);
    when '0010 000'
        if !IsFeatureImplemented(FEAT_RAS) then EndOfDecode(Decode_NOP);
        op = SystemHintOp_ESB;
    when '0010 010'
        if !IsFeatureImplemented(FEAT_TRF) then EndOfDecode(Decode_NOP);
        op = SystemHintOp_TSB;
    when '0010 100'
        op = SystemHintOp_CSDB;
    when '0011 xxx'
        case op2 of
            when '000' SEE "PACIAZ";
            when '001' SEE "PACIASP";
            when '010' SEE "PACIBZ";
            when '011' SEE "PACIBSP";

            when '101' SEE "AUTIASP";
            when '110' SEE "AUTIBZ";
            when '111' SEE "AUTIBSP";
    otherwise EndOfDecode(Decode_NOP);
```

Assembler Symbols

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

<**imm**> Is a 7-bit unsigned immediate, in the range 0 to 127, encoded in the “CRm:op2” field.

The encodings that are allocated to architectural hint functionality are described in the ’Hints’ table in the ’Index by Encoding’.

Note

For allocated encodings of “CRm:op2”:

- A disassembler will disassemble the allocated instruction, rather than the `HINT` instruction.
- An assembler may support assembly of allocated encodings using `HINT` with the corresponding <imm> value, but it is not required to do so.

Operation

```
case op of
    when SystemHintOp_YIELD
        Hint_Yield();

    when SystemHintOp_DGH
        Hint_DGH();

    when SystemHintOp_WFE
        Hint_WFE();

    when SystemHintOp_WFI
        Hint_WFI();

    when SystemHintOp_SEV
        SendEvent();

    when SystemHintOp_SEVL
        SendEventLocal();

    when SystemHintOp_ESB
        SynchronizeErrors();
        AArch64.ESBOperation();
        if PSTATE.EL IN {EL0, EL1} && EL2Enabled() then
            AArch64.vESBOperation();
        TakeUnmaskedSErrorInterrupts();

    when SystemHintOp_TSB

        TraceSynchronizationBarrier();

    when SystemHintOp_CSDB
        ConsumptionOfSpeculativeDataBarrier();

    when SystemHintOp_NOP
        return; // Do nothing

    otherwise
        Unreachable();
```

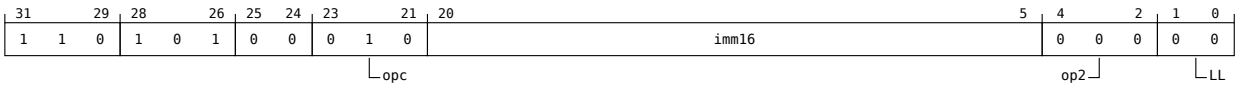
C6.2.89 HLT

Halt instruction

This instruction can generate a Halt Instruction debug event, which causes entry into Debug state.



Encoding

```
HLT #<imm>
```

Decode for this encoding

```
if EDSCR.HDE == '0' || !HaltingAllowed() then
    EndOfDecode(Decode_UNDEF);
```

Assembler Symbols

<imm> Is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm16" field.

Operation

```
constant boolean is_async = FALSE;
Halt(DebugHalt_HaltInstruction, is_async);
```

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.90 HVC

Hypervisor call

This instruction causes an exception to EL2. Software executing at EL1 can use this instruction to call the hypervisor to request a service.

The HVC instruction is UNDEFINED:

- When HCR_EL2.HCD is set to 1.
- At EL1 if EL2 is not enabled.
- At EL0.

On executing an HVC instruction, the PE records the exception as a Hypervisor Call exception in ESR_ELx, using the EC syndrome value 0x16, and the value of the immediate argument.

Encoding

```
HVC #<imm>
```

Decode for this encoding

```
if !HaveEL(EL2) then EndOfDecode(Decode_UNDEF);
constant bits(16) imm = imm16;
```

Assembler Symbols

<imm> Is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm16" field.

Operation

```
if PSTATE.EL == EL0 then UNDEFINED;
if PSTATE.EL == EL1 && !EL2Enabled() then UNDEFINED;
if HCR_EL2.HCD == '1' then UNDEFINED;

AArch64.CallHypervisor(imm);
```

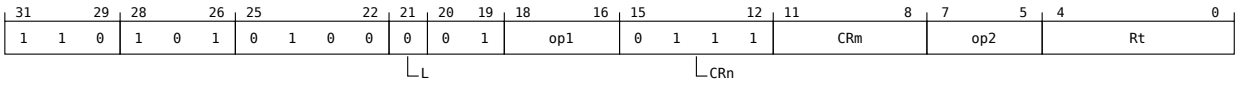
C6.2.91 IC

Instruction cache operation

For more information, see op0==0b01, cache maintenance, TLB maintenance, and address translation instructions.

This is an alias of SYS. This means:

- The encodings in this description are named to match the encodings of SYS.
- The description of SYS gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.



Encoding

```
IC <ic_op>{, <Xt>}
```

is equivalent to

```
SYS #<op1>, C7, <Cm>, #<op2>{, <Xt>}
```

and is the preferred disassembly when `SysOp(op1, '0111', CRm, op2) == Sys_IC`.

Assembler Symbols

<ic_op> Is an IC operation name, as listed for the IC system instruction pages, encoded in "op1:CRm:op2":

op1	CRm	op2	<ic_op>
000	0001	000	IALLUIS
000	0101	000	IALLU
011	0101	001	IVAU

<Xt> Is the 64-bit name of the optional general-purpose source register, defaulting to '11111', encoded in the "Rt" field.

Operation

The description of SYS gives the operational pseudocode for this instruction.

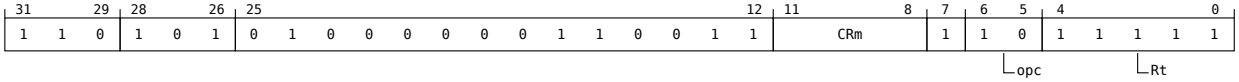
Non-Confidential

C6.2.92 ISB

Instruction synchronization barrier

This instruction flushes the pipeline in the PE and is a context synchronization event. For more information, see Instruction Synchronization Barrier (ISB).



Encoding

```
ISB {<option>|#<imm>}
```

Decode for this encoding

```
// no additional decoding required
```

Assembler Symbols

<**option**> Specifies an optional limitation on the barrier operation. Values are:

SY Full system barrier operation, encoded as CRm = 0b1111. Can be omitted.

All other encodings of "CRm" are reserved. The corresponding instructions execute as full system barrier operations, but must not be relied upon by software.

<**imm**> Is an optional 4-bit unsigned immediate, in the range 0 to 15, defaulting to 15 and encoded in the "CRm" field.

Operation

```
InstructionSynchronizationBarrier();
```

C6.2.93 LDADD, LDADDA, LDADDAL, LDADDL

Atomic add on word or doubleword

This instruction atomically loads a 32-bit word or 64-bit doubleword from memory, adds the value held in a register to it, and stores the result back to memory. The value initially loaded from memory is returned in the destination register.

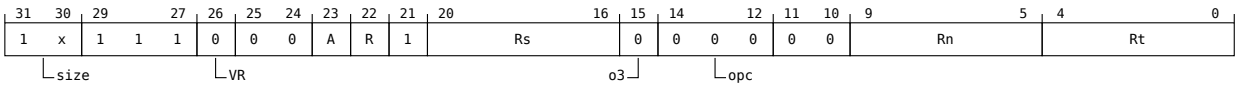
- If the destination register is not one of WZR or XZR, `LDADDA` and `LDADDAL` load from memory with acquire semantics.
- `LDADDL` and `LDADDAL` store to memory with release semantics.
- `LDADD` has neither acquire nor release semantics.

For more information about memory ordering semantics, see Load-Acquire, Store-Release.

For information about addressing modes, see Load/Store addressing modes.

This instruction is used by the alias STADD, STADDL.

Integer
(FEAT_LSE)



Encoding for the 32-bit no memory ordering variant Applies when `(size == 10 && A == 0 && R == 0)`

```
LDADD <Ws>, <Wt>, [<Xn|SP>]
```

Encoding for the 32-bit acquire variant Applies when `(size == 10 && A == 1 && R == 0)`

```
LDADDA <Ws>, <Wt>, [<Xn|SP>]
```

Encoding for the 32-bit acquire-release variant Applies when `(size == 10 && A == 1 && R == 1)`

```
LDADDAL <Ws>, <Wt>, [<Xn|SP>]
```

Encoding for the 32-bit release variant Applies when `(size == 10 && A == 0 && R == 1)`

```
LDADDL <Ws>, <Wt>, [<Xn|SP>]
```

Encoding for the 64-bit no memory ordering variant Applies when `(size == 11 && A == 0 && R == 0)`

```
LDADD <Xs>, <Xt>, [<Xn|SP>]
```

Encoding for the 64-bit acquire variant Applies when `(size == 11 && A == 1 && R == 0)`

```
LDADDA <Xs>, <Xt>, [<Xn|SP>]
```

Encoding for the 64-bit acquire-release variant Applies when `(size == 11 && A == 1 && R == 1)`

```
LDADDAL <Xs>, <Xt>, [<Xn|SP>]
```

Encoding for the 64-bit release variant Applies when `(size == 11 && A == 0 && R == 1)`

```
LDADDL <Xs>, <Xt>, [<Xn|SP>]
```

Decode for all variants of this encoding

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

```
if !IsFeatureImplemented(FEAT_LSE) then EndOfDecode(Decode_UNDEF);
constant integer s = UInt(Rs);
constant integer t = UInt(Rt);
constant integer n = UInt(Rn);

constant integer datasize = 8 << UInt(size);
constant integer regsize = if datasize == 64 then 64 else 32;

constant boolean acquire = A == '1' && Rt != '11111';
constant boolean release = R == '1';
```

Assembler Symbols

<Ws> Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.

<Wt> Is the 32-bit name of the general-purpose register to be loaded, encoded in the "Rt" field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<Xs> Is the 64-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.

<Xt> Is the 64-bit name of the general-purpose register to be loaded, encoded in the "Rt" field.

Alias Conditions

Alias	Is preferred when
STADD, STADDL	A == '0' && Rt == '11111'

Operation

```
bits(64) address;

constant boolean privileged = PSTATE.EL != EL0;
constant AccessDescriptor accdesc = CreateAccDescAtomicOp(MemAtomicOp_ADD, acquire,
                                                          release, privileged, t, s);

if n == 31 then
    CheckSPAlignment();
    address = SP[64];
else
    address = X[n, 64];

constant bits(datasize) comparevalue = bits(datasize) UNKNOWN; // Irrelevant when not executing CAS
constant bits(datasize) value = X[s, datasize];
constant bits(datasize) data = MemAtomic(address, comparevalue, value, accdesc);

if t != 31 then
    X[t, regsize] = ZeroExtend(data, regsize);
```

Operational information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

C6.2.94 LDADDB, LDADDAB, LDADDALB, LDADDLB

Atomic add on byte

This instruction atomically loads an 8-bit byte from memory, adds the value held in a register to it, and stores the result back to memory. The value initially loaded from memory is returned in the destination register.

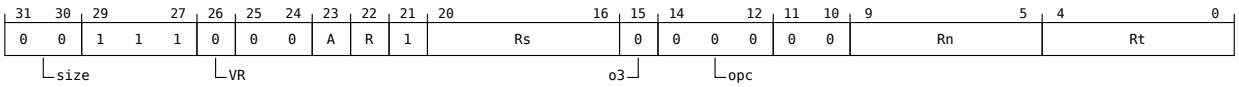
- If the destination register is not WZR, LDADDAB and LDADDALB load from memory with acquire semantics.
- LDADDLB and LDADDALB store to memory with release semantics.
- LDADDB has neither acquire nor release semantics.

For more information about memory ordering semantics, see Load-Acquire, Store-Release.

For information about addressing modes, see Load/Store addressing modes.

This instruction is used by the alias STADDB, STADDLB.

Integer
(FEAT_LSE)



Encoding for the No memory ordering variant Applies when (A == 0 && R == 0)

```
LDADDB <Ws>, <Wt>, [<Xn|SP>]
```

Encoding for the Acquire variant Applies when (A == 1 && R == 0)

```
LDADDAB <Ws>, <Wt>, [<Xn|SP>]
```

Encoding for the Acquire-release variant Applies when (A == 1 && R == 1)

```
LDADDALB <Ws>, <Wt>, [<Xn|SP>]
```

Encoding for the Release variant Applies when (A == 0 && R == 1)

```
LDADDLB <Ws>, <Wt>, [<Xn|SP>]
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_LSE) then EndOfDecode(Decode_UNDEF);
constant integer s = UInt(Rs);
constant integer t = UInt(Rt);
constant integer n = UInt(Rn);

constant boolean acquire = A == '1' && Rt != '11111';
constant boolean release = R == '1';
```

Assembler Symbols

<**Ws**> Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.

<**Wt**> Is the 32-bit name of the general-purpose register to be loaded, encoded in the "Rt" field.

<**Xn|SP**> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

C6.2.96 LDAPR

Load-acquire RCpc register

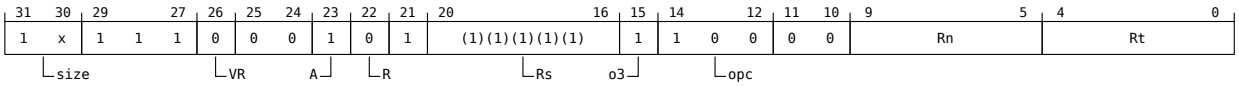
This instruction derives an address from a base register value, loads a 32-bit word or 64-bit doubleword from the derived address in memory, and writes it to a register.

If the destination register is not one of WZR or XZR, `LDAPR` loads from memory with AcquirePC semantics.

For more information about memory ordering semantics, see Load-Acquire, Load-AcquirePC, and Store-Release.

For information about addressing modes, see Load/Store addressing modes.

No offset
(FEAT_LRCPC)



Encoding for the 32-bit variant Applies when `(size == 10)`

```
LDAPR <Wt>, [<Xn|SP> {, #0}]
```

Encoding for the 64-bit variant Applies when `(size == 11)`

```
LDAPR <Xt>, [<Xn|SP> {, #0}]
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_LRCPC) then EndOfDecode(Decode_UNDEF);
constant integer t = UInt(Rt);
constant integer n = UInt(Rn);
constant boolean wback = FALSE;
constant integer offset = 0;
constant boolean wb_unknown = FALSE;
constant integer elsize = 8 << UInt(size);
constant integer regsize = if elsize == 64 then 64 else 32;
constant integer datasize = elsize;
constant boolean acquirepc = t != 31;
```

Assembler Symbols

<Wt> Is the 32-bit name of the general-purpose register to be loaded, encoded in the "Rt" field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<Xt> Is the 64-bit name of the general-purpose register to be loaded, encoded in the "Rt" field.

Operation

```
bits(64) address;
bits(datasize) data;
constant integer dbytes = datasize DIV 8;

constant AccessDescriptor accdesc = CreateAccDescLDAcqPC(acquirepc, t);

if n == 31 then
    CheckSPAlignment();
    address = SP[64];
else
    address = X[n, 64];
```

C6.2.97 LDAPRB

Load-acquire RCpc register byte

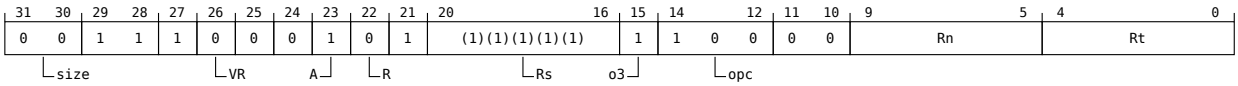
This instruction derives an address from a base register value, loads a byte from the derived address in memory, zero-extends it and writes it to a register.

If the destination register is not one of WZR or XZR, `LDAPRB` loads from memory with AcquirePC semantics.

For more information about memory ordering semantics, see Load-Acquire, Load-AcquirePC, and Store-Release.

For information about addressing modes, see Load/Store addressing modes.

Integer
(FEAT_LRCPC)



Encoding

```
LDAPRB <Wt>, [<Xn|SP> {, #0}]
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_LRCPC) then EndOfDecode(Decode_UNDEF);
constant integer t = UInt(Rt);
constant integer n = UInt(Rn);
constant boolean acquirepc = t != 31;
```

Assembler Symbols

<Wt> Is the 32-bit name of the general-purpose register to be loaded, encoded in the "Rt" field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

```
bits(64) address;
bits(8) data;

constant AccessDescriptor accdesc = CreateAccDescLDAcqPC(acquirepc, t);

if n == 31 then
    CheckSPAlignment();
    address = SP[64];
else
    address = X[n, 64];

data = Mem[address, 1, accdesc];
X[t, 32] = ZeroExtend(data, 32);
```

C6.2.98 LDAPRH

Load-acquire RCpc register halfword

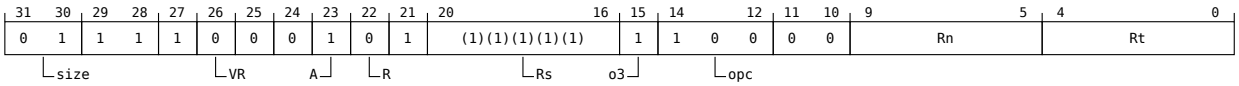
This instruction derives an address from a base register value, loads a halfword from the derived address in memory, zero-extends it and writes it to a register.

If the destination register is not one of WZR or XZR, `LDAPRH` loads from memory with AcquirePC semantics.

For more information about memory ordering semantics, see Load-Acquire, Load-AcquirePC, and Store-Release.

For information about addressing modes, see Load/Store addressing modes.

Integer
(FEAT_LRCPC)



Encoding

```
LDAPRH <Wt>, [<Xn|SP> {, #0}]
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_LRCPC) then EndOfDecode(Decode_UNDEF);
constant integer t = UInt(Rt);
constant integer n = UInt(Rn);
constant boolean acquirepc = t != 31;
```

Assembler Symbols

<Wt> Is the 32-bit name of the general-purpose register to be loaded, encoded in the "Rt" field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

```
bits(64) address;
bits(16) data;

constant AccessDescriptor accdesc = CreateAccDescLDAcqPC(acquirepc, t);

if n == 31 then
    CheckSPAlignment();
    address = SP[64];
else
    address = X[n, 64];

data = Mem[address, 2, accdesc];
X[t, 32] = ZeroExtend(data, 32);
```

C6.2.103 LDAPURSH

Load-acquire RCpc register signed halfword (unscaled)

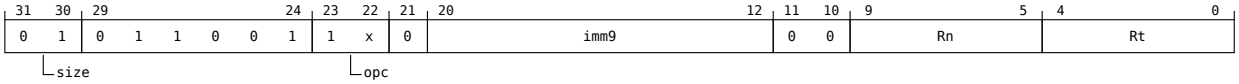
This instruction calculates an address from a base register and an immediate offset, loads a signed halfword from memory, sign-extends it, and writes it to a register.

If the destination register is not one of WZR or XZR, `LDAPURSH` loads from memory with AcquirePC semantics.

For more information about memory ordering semantics, see Load-Acquire, Load-AcquirePC, and Store-Release.

For information about addressing modes, see Load/Store addressing modes.

Unscaled offset
(FEAT_LRCPC2)



Encoding for the 32-bit variant Applies when `(opc == 11)`

C6.2.104 LDAPURSW

Load-acquire RCpc register signed word (unscaled)

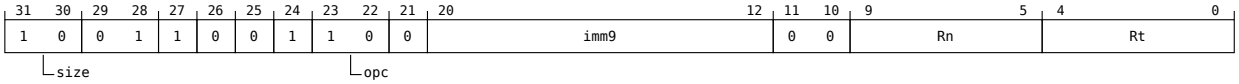
This instruction calculates an address from a base register and an immediate offset, loads a signed word from memory, sign-extends it, and writes it to a register.

If the destination register is not one of WZR or XZR, `LDAPURSW` loads from memory with AcquirePC semantics.

For more information about memory ordering semantics, see Load-Acquire, Load-AcquirePC, and Store-Release.

For information about addressing modes, see Load/Store addressing modes.

Unscaled offset
(FEAT_LRCPC2)



Encoding

```
LDAPURSW <Xt>, [<Xn|SP>{, #<simm>}]
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_LRCPC2) then EndOfDecode(Decode_UNDEF);
constant bits(64) offset = SignExtend(imm9, 64);
```

Assembler Symbols

<Xt> Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<simm> Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the "imm9" field.

Shared Decode

```
constant integer t = UInt(Rt);
constant integer n = UInt(Rn);
constant integer datasize = 32;
constant boolean acquirepc = t != 31;
```

Operation

```
bits(64) address;

constant AccessDescriptor accdesc = CreateAccDescLDAcqPC(acquirepc, t);

if n == 31 then
    CheckSPAlignment();
    address = SP[64];
else
    address = X[n, 64];

address = AddressAdd(address, offset, accdesc);

constant bits(datasize) data = Mem[address, datasize DIV 8, accdesc];

C6.2.105 LDAR

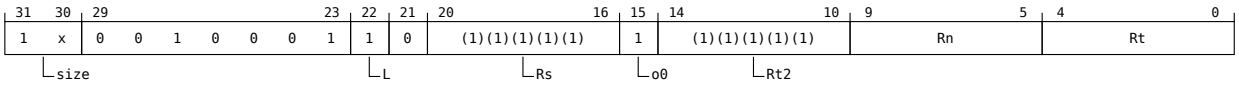
Load-acquire register

This instruction derives an address from a base register value, loads a 32-bit word or 64-bit doubleword from memory, and writes it to a register.

If the destination register is not one of WZR or XZR, `LDAR` loads from memory with Acquire semantics.

For more information about memory ordering semantics, see Load-Acquire, Load-AcquirePC, and Store-Release.

For information about addressing modes, see Load/Store addressing modes.



Encoding for the 32-bit variant Applies when `(size == 10)`

```
LDAR <Wt>, [<Xn|SP>{, #0}]
```

Encoding for the 64-bit variant Applies when `(size == 11)`

```
LDAR <Xt>, [<Xn|SP>{, #0}]
```

Decode for all variants of this encoding

```
constant integer t = UInt(Rt);
constant integer n = UInt(Rn);
constant integer elsize = 8 << UInt(size);
constant integer regsize = if elsize == 64 then 64 else 32;
constant boolean acquire = t != 31;
```

Assembler Symbols

<Wt> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<Xt> Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

Operation

```
bits(64) address;
constant integer dbytes = elsize DIV 8;

constant AccessDescriptor accdesc = CreateAccDescAcqRel(MemOp_LOAD, acquire, t);

if n == 31 then
    CheckSPAlignment();
    address = SP[64];
else
    address = X[n, 64];

constant bits(elsize) data = Mem[address,  dbytes, accdesc];
X[t, regsize] = ZeroExtend(data, regsize);
```

C6.2.106 LDARB

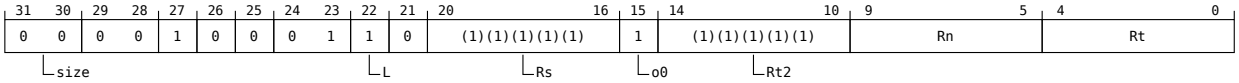
Load-acquire register byte

This instruction derives an address from a base register value, loads a byte from memory, zero-extends it and writes it to a register.

If the destination register is not one of WZR or XZR, `LDARB` loads from memory with Acquire semantics.

For more information about memory ordering semantics, see Load-Acquire, Load-AcquirePC, and Store-Release.

For information about addressing modes, see Load/Store addressing modes.



Encoding

```
LDARB <Wt>, [<Xn|SP>{, #0}]
```

Decode for this encoding

```
constant integer t = UInt(Rt);
constant integer n = UInt(Rn);
constant boolean acquire = t != 31;
```

Assembler Symbols

<Wt> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

```
bits(64) address;

constant AccessDescriptor accdesc = CreateAccDescAcqRel(MemOp_LOAD, acquire, t);

if n == 31 then
    CheckSPAlignment();
    address = SP[64];
else
    address = X[n, 64];

constant bits(8) data = Mem[address,  1, accdesc];
X[t, 32] = ZeroExtend(data, 32);
```

Operational information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

Non-Confidential

C6.2.107 LDARH

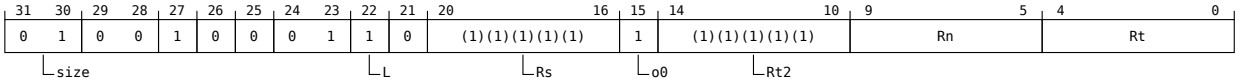
Load-acquire register halfword

This instruction derives an address from a base register value, loads a halfword from memory, zero-extends it, and writes it to a register.

If the destination register is not one of WZR or XZR, `LDARH` loads from memory with Acquire semantics.

For more information about memory ordering semantics, see Load-Acquire, Load-AcquirePC, and Store-Release.

For information about addressing modes, see Load/Store addressing modes.



Encoding

```
LDARH <Wt>, [<Xn|SP>{, #0}]
```

Decode for this encoding

```
constant integer t = UInt(Rt);
constant integer n = UInt(Rn);
constant boolean acquire = t != 31;
```

Assembler Symbols

<Wt> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

```
bits(64) address;

constant AccessDescriptor accdesc = CreateAccDescAcqRel(MemOp_LOAD, acquire, t);

if n == 31 then
    CheckSPAlignment();
    address = SP[64];
else
    address = X[n, 64];

constant bits(16) data = Mem[address,  2, accdesc];
X[t, 32] = ZeroExtend(data, 32);
```

Operational information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

Non-Confidential

C6.2.108 LDAXP

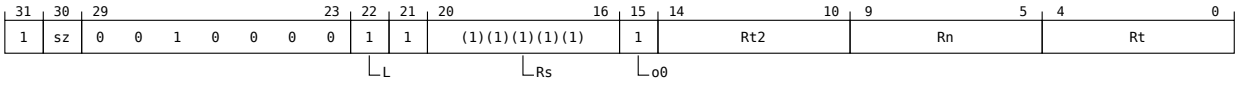
Load-acquire exclusive pair of registers

This instruction derives an address from a base register value, loads two 32-bit words or two 64-bit doublewords from memory, and writes them to two registers. For information on single-copy atomicity and alignment requirements, see Requirements for single-copy atomicity and Alignment of data accesses. The PE marks the physical address being accessed as an exclusive access. This exclusive access mark is checked by Store Exclusive instructions. See Synchronization and semaphores.

If the destination registers are not both WZR or not both XZR, `LDAXP` loads from memory with Acquire semantics.

For more information about memory ordering semantics, see Load-Acquire, Load-AcquirePC, and Store-Release.

For information about addressing modes, see Load/Store addressing modes.



Encoding for the 32-bit variant Applies when `(sz == 0)`

```
LDAXP <Wt1>, <Wt2>, [<Xn|SP>{, #0}]
```

Encoding for the 64-bit variant Applies when `(sz == 1)`

```
LDAXP <Xt1>, <Xt2>, [<Xn|SP>{, #0}]
```

Decode for all variants of this encoding

```
constant integer t = UInt(Rt);
constant integer t2 = UInt(Rt2);
constant integer n = UInt(Rn);

constant integer elsize = 32 << UInt(sz);
constant integer datasize = elsize * 2;
constant boolean acqrel = t != 31 && t2 != 31;

boolean rt_unknown = FALSE;
if t == t2 then
    constant Constraint c = ConstrainUnpredictable(Unpredictable_LDPOVERLAP);
    assert c IN {Constraint_UNKNOWN, Constraint_UNDEF, Constraint_NOP};
    case c of
        when Constraint_UNKNOWN    rt_unknown = TRUE;    // result is UNKNOWN
        when Constraint_UNDEF      EndOfDecode(Decode_UNDEF);
        when Constraint_NOP        EndOfDecode(Decode_NOP);
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Architectural Constraints on UNPREDICTABLE behaviors, and particularly LDAXP.

Assembler Symbols

<**Wt1**> Is the 32-bit name of the first general-purpose register to be transferred, encoded in the “Rt” field.

<**Wt2**> Is the 32-bit name of the second general-purpose register to be transferred, encoded in the “Rt2” field.

<**Xn|SP**> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the “Rn” field.

<**Xt1**> Is the 64-bit name of the first general-purpose register to be transferred, encoded in the “Rt” field.

<**Xt2**> Is the 64-bit name of the second general-purpose register to be transferred, encoded in the “Rt2” field.

C6.2.109 LDAXR

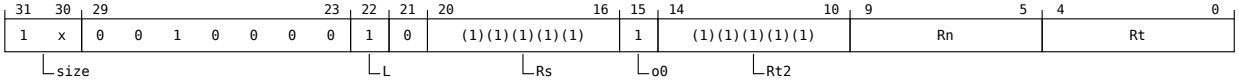
Load-acquire exclusive register

This instruction derives an address from a base register value, loads a 32-bit word or 64-bit doubleword from memory, and writes it to a register. The memory access is atomic. The PE marks the physical address being accessed as an exclusive access. This exclusive access mark is checked by Store Exclusive instructions. See Synchronization and semaphores.

If the destination register is not one of WZR or XZR, `LDAXR` loads from memory with Acquire semantics.

For more information about memory ordering semantics, see Load-Acquire, Load-AcquirePC, and Store-Release.

For information about addressing modes, see Load/Store addressing modes.



Encoding for the 32-bit variant Applies when `(size == 10)`

```
LDAXR <Wt>, [<Xn|SP>{, #0}]
```

Encoding for the 64-bit variant Applies when `(size == 11)`

```
LDAXR <Xt>, [<Xn|SP>{, #0}]
```

Decode for all variants of this encoding

```
constant integer t = UInt(Rt);
constant integer n = UInt(Rn);

constant integer elsize = 8 << UInt(size);
constant integer regsize = if elsize == 64 then 64 else 32;
constant boolean acqrel = t != 31;
```

Assembler Symbols

<Wt> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<Xt> Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

Operation

```
bits(64) address;
bits(elsize) data;

constant integer dbytes = elsize DIV 8;
constant boolean privileged = PSTATE.EL != EL0;
constant AccessDescriptor accdesc = CreateAccDescExLDST(MemOp_LOAD, acqrel, privileged, t);

if n == 31 then
    CheckSPAlignment();
    address = SP[64];
else
    address = X[n, 64];

AArch64.SetExclusiveMonitors(address, dbytes, accdesc);

data = Mem[address, dbytes, accdesc];
X[t, regsize] = ZeroExtend(data, regsize);

C6.2.110 LDAXRB

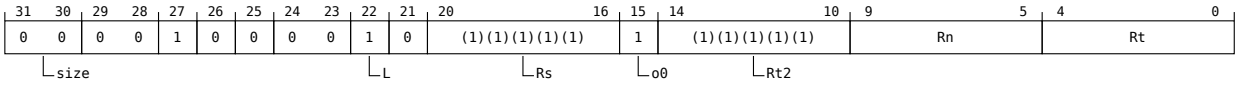
Load-acquire exclusive register byte

This instruction derives an address from a base register value, loads a byte from memory, zero-extends it and writes it to a register. The memory access is atomic. The PE marks the physical address being accessed as an exclusive access. This exclusive access mark is checked by Store Exclusive instructions. See Synchronization and semaphores.

If the destination register is not one of WZR or XZR, `LDAXRB` loads from memory with Acquire semantics.

For more information about memory ordering semantics, see Load-Acquire, Load-AcquirePC, and Store-Release.

For information about addressing modes, see Load/Store addressing modes.



Encoding

```
LDAXRB <Wt>, [<Xn|SP>{, #0}]
```

Decode for this encoding

```
constant integer t = UInt(Rt);
constant integer n = UInt(Rn);

constant boolean acqrel = t != 31;
```

Assembler Symbols

<Wt> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

```
bits(64) address;
bits(8) data;

constant boolean privileged = PSTATE.EL != EL0;
constant AccessDescriptor accdesc = CreateAccDescExLDST(MemOp_LOAD, acqrel, privileged, t);

if n == 31 then
    CheckSPAlignment();
    address = SP[64];
else
    address = X[n, 64];

AArch64.SetExclusiveMonitors(address, 1, accdesc);

data = Mem[address, 1, accdesc];
X[t, 32] = ZeroExtend(data, 32);
```

C6.2.111 LDAXRH

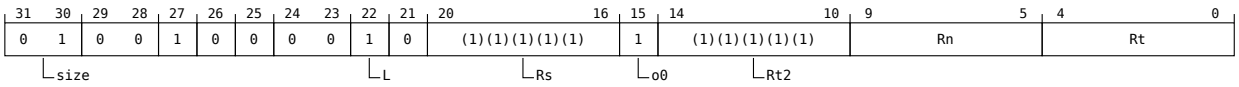
Load-acquire exclusive register halfword

This instruction derives an address from a base register value, loads a halfword from memory, zero-extends it and writes it to a register. The memory access is atomic. The PE marks the physical address being accessed as an exclusive access. This exclusive access mark is checked by Store Exclusive instructions. See Synchronization and semaphores.

If the destination register is not one of WZR or XZR, `LDAXRH` loads from memory with Acquire semantics.

For more information about memory ordering semantics, see Load-Acquire, Load-AcquirePC, and Store-Release.

For information about addressing modes, see Load/Store addressing modes.



Encoding

```
LDAXRH <Wt>, [<Xn|SP>{, #0}]
```

Decode for this encoding

```
constant integer t = UInt(Rt);
constant integer n = UInt(Rn);

constant boolean acqrel = t != 31;
```

Assembler Symbols

<Wt> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

```
bits(64) address;
bits(16) data;

constant boolean privileged = PSTATE.EL != EL0;
constant AccessDescriptor accdesc = CreateAccDescExLDST(MemOp_LOAD, acqrel, privileged, t);

if n == 31 then
    CheckSPAlignment();
    address = SP[64];
else
    address = X[n, 64];

AArch64.SetExclusiveMonitors(address, 2, accdesc);

data = Mem[address, 2, accdesc];
X[t, 32] = ZeroExtend(data, 32);
```

C6.2.112 LDCLR, LDCLRA, LDCLRAL, LDCLRL

Atomic bit clear on word or doubleword

This instruction atomically loads a 32-bit word or 64-bit doubleword from memory, performs a bitwise AND with the complement of the value held in a register on it, and stores the result back to memory. The value initially loaded from memory is returned in the destination register.

- If the destination register is not one of WZR or XZR, `LDCLRA` and `LDCLRAL` load from memory with acquire semantics.
- `LDCLRL` and `LDCLRAL` store to memory with release semantics.
- `LDCLR` has neither acquire nor release semantics.

For more information about memory ordering semantics, see Load-Acquire, Store-Release.

For information about addressing modes, see Load/Store addressing modes.

This instruction is used by the alias STCLR, STCLRL.

C6.2.114 LDCLRH, LDCLRAH, LDCLRALH, LDCLRLH

Atomic bit clear on halfword

This instruction atomically loads a 16-bit halfword from memory, performs a bitwise AND with the complement of the value held in a register on it, and stores the result back to memory. The value initially loaded from memory is returned in the destination register.

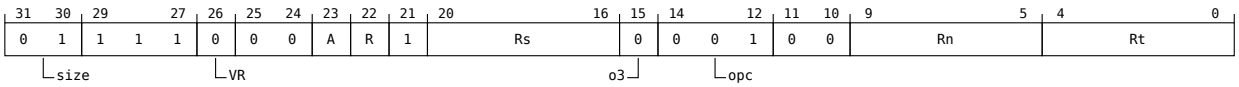
- If the destination register is not WZR, `LDCLRAH` and `LDCLRALH` load from memory with acquire semantics.
- `LDCLRLH` and `LDCLRALH` store to memory with release semantics.
- `LDCLRH` has neither acquire nor release semantics.

For more information about memory ordering semantics, see Load-Acquire, Store-Release.

For information about addressing modes, see Load/Store addressing modes.

This instruction is used by the alias STCLRH, STCLRLH.

Integer
(FEAT_LSE)



Encoding for the No memory ordering variant Applies when `(A == 0 && R == 0)`

```
LDCLRH <Ws>, <Wt>, [<Xn|SP>]
```

Encoding for the Acquire variant Applies when `(A == 1 && R == 0)`

```
LDCLRAH <Ws>, <Wt>, [<Xn|SP>]
```

Encoding for the Acquire-release variant Applies when `(A == 1 && R == 1)`

```
LDCLRALH <Ws>, <Wt>, [<Xn|SP>]
```

Encoding for the Release variant Applies when `(A == 0 && R == 1)`

```
LDCLRLH <Ws>, <Wt>, [<Xn|SP>]
```

Decode for all variants of this encoding

C6.2.115 LDEOR, LDEORA, LDEORAL, LDEORL

Atomic exclusive-OR on word or doubleword

This instruction atomically loads a 32-bit word or 64-bit doubleword from memory, performs an exclusive-OR with the value held in a register on it, and stores the result back to memory. The value initially loaded from memory is returned in the destination register.

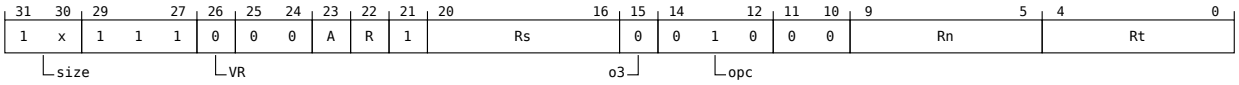
- If the destination register is not one of WZR or XZR, `LDEORA` and `LDEORAL` load from memory with acquire semantics.
- `LDEORL` and `LDEORAL` store to memory with release semantics.
- `LDEOR` has neither acquire nor release semantics.

For more information about memory ordering semantics, see Load-Acquire, Store-Release.

For information about addressing modes, see Load/Store addressing modes.

This instruction is used by the alias STEOR, STEORL.

Integer
(FEAT_LSE)



Encoding for the 32-bit no memory ordering variant Applies when `(size == 10 && A == 0 && R == 0)`

```
LDEOR <Ws>, <Wt>, [<Xn|SP>]
```

Encoding for the 32-bit acquire variant Applies when `(size == 10 && A == 1 && R == 0)`

```
LDEORA <Ws>, <Wt>, [<Xn|SP>]
```

Encoding for the 32-bit acquire-release variant Applies when `(size == 10 && A == 1 && R == 1)`

```
LDEORAL <Ws>, <Wt>, [<Xn|SP>]
```

Encoding for the 32-bit release variant Applies when `(size == 10 && A == 0 && R == 1)`

```
LDEORL <Ws>, <Wt>, [<Xn|SP>]
```

Encoding for the 64-bit no memory ordering variant Applies when `(size == 11 && A == 0 && R == 0)`

```
LDEOR <Xs>, <Xt>, [<Xn|SP>]
```

Encoding for the 64-bit acquire variant Applies when `(size == 11 && A == 1 && R == 0)`

```
LDEORA <Xs>, <Xt>, [<Xn|SP>]
```

Encoding for the 64-bit acquire-release variant Applies when `(size == 11 && A == 1 && R == 1)`

```
LDEORAL <Xs>, <Xt>, [<Xn|SP>]
```

Encoding for the 64-bit release variant Applies when `(size == 11 && A == 0 && R == 1)`

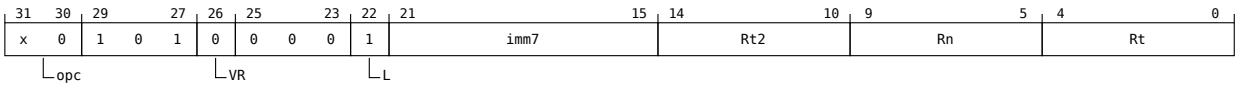
C6.2.118 LDNP

Load pair of registers, with non-temporal hint

This instruction calculates an address from a base register value and an immediate offset, loads two 32-bit words or two 64-bit doublewords from memory, and writes them to two registers.

For information about addressing modes, see Load/Store addressing modes. For information about non-temporal pair instructions, see Load/Store non-temporal pair.



Encoding for the 32-bit variant Applies when `(opc == 00)`

```
LDNP <Wt1>, <Wt2>, [<Xn|SP>{, #<imm>}]
```

Encoding for the 64-bit variant Applies when `(opc == 10)`

```
LDNP <Xt1>, <Xt2>, [<Xn|SP>{, #<imm>}]
```

Decode for all variants of this encoding

```
constant integer t = UInt(Rt);
constant integer t2 = UInt(Rt2);
constant integer n = UInt(Rn);
constant boolean nontemporal = TRUE;
constant integer scale = 2 + UInt(opc<1>);
constant integer datasize = 8 << scale;
constant bits(64) offset = LSL(SignExtend(imm7, 64), scale);

boolean rt_unknown = FALSE;
if t == t2 then
    constant Constraint c = ConstrainUnpredictable(Unpredictable_LDPOVERLAP);
    assert c IN {Constraint_UNKNOWN, Constraint_UNDEF, Constraint_NOP};
    case c of
        when Constraint_UNKNOWN    rt_unknown = TRUE;    // Result is UNKNOWN
        when Constraint_UNDEF      EndOfDecode(Decode_UNDEF);
        when Constraint_NOP        EndOfDecode(Decode_NOP);
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Architectural Constraints on UNPREDICTABLE behaviors, and particularly LDNP.

Assembler Symbols

<**Wt1**> Is the 32-bit name of the first general-purpose register to be transferred, encoded in the "Rt" field.

<**Wt2**> Is the 32-bit name of the second general-purpose register to be transferred, encoded in the "Rt2" field.

<**Xn|SP**> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<**imm**> For the "32-bit" variant: is the optional signed immediate byte offset, a multiple of 4 in the range -256 to 252, defaulting to 0 and encoded in the "imm7" field as <imm>/4.

For the "64-bit" variant: is the optional signed immediate byte offset, a multiple of 8 in the range -512 to 504, defaulting to 0 and encoded in the "imm7" field as <imm>/8.

<**Xt1**> Is the 64-bit name of the first general-purpose register to be transferred, encoded in the "Rt" field.

<**Xt2**> Is the 64-bit name of the second general-purpose register to be transferred, encoded in the "Rt2" field.

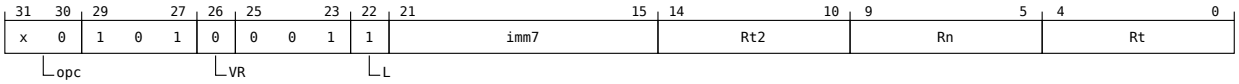
C6.2.119 LDP

Load pair of registers

This instruction calculates an address from a base register value and an immediate offset, loads two 32-bit words or two 64-bit doublewords from memory, and writes them to two registers. For information about addressing modes, see Load/Store addressing modes.

It has encodings from 3 classes: Post-index , Pre-index and Signed offset

Post-index



Encoding for the 32-bit variant Applies when `(opc == 00)`

```
LDP <Wt1>, <Wt2>, [<Xn|SP>], #<imm>
```

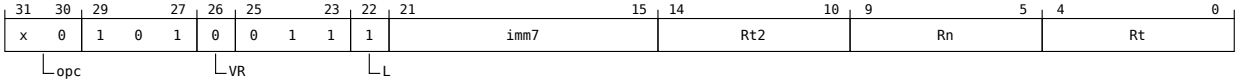
Encoding for the 64-bit variant Applies when `(opc == 10)`

```
LDP <Xt1>, <Xt2>, [<Xn|SP>], #<imm>
```

Decode for all variants of this encoding

```
boolean wback = TRUE;
constant boolean postindex = TRUE;
```

Pre-index



Encoding for the 32-bit variant Applies when `(opc == 00)`

```
LDP <Wt1>, <Wt2>, [<Xn|SP>, #<imm>]!
```

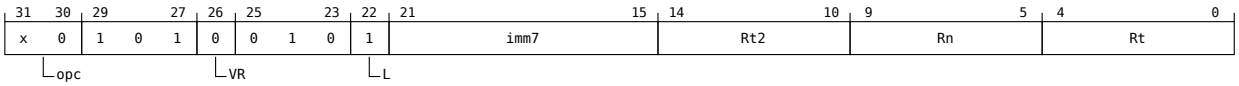
Encoding for the 64-bit variant Applies when `(opc == 10)`

```
LDP <Xt1>, <Xt2>, [<Xn|SP>, #<imm>]!
```

Decode for all variants of this encoding

```
boolean wback = TRUE;
constant boolean postindex = FALSE;
```

Signed offset



Encoding for the 32-bit variant Applies when `(opc == 00)`

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

```
LDP <Wt1>, <Wt2>, [<Xn|SP>{, #<imm>}]
```

Encoding for the 64-bit variant Applies when `(opc == 10)`

```
LDP <Xt1>, <Xt2>, [<Xn|SP>{, #<imm>}]
```

Decode for all variants of this encoding

```
boolean wback = FALSE;
constant boolean postindex = FALSE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Architectural Constraints on UNPREDICTABLE behaviors, and particularly LDP.

Assembler Symbols

<**Wt1**> Is the 32-bit name of the first general-purpose register to be transferred, encoded in the "Rt" field.

<**Wt2**> Is the 32-bit name of the second general-purpose register to be transferred, encoded in the "Rt2" field.

<**Xn|SP**> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<**imm**> For the "Post-index 32-bit" and "Pre-index 32-bit" variants: is the signed immediate byte offset, a multiple of 4 in the range -256 to 252, encoded in the "imm7" field as <imm>/4.

For the "Post-index 64-bit" and "Pre-index 64-bit" variants: is the signed immediate byte offset, a multiple of 8 in the range -512 to 504, encoded in the "imm7" field as <imm>/8.

For the "Signed offset 32-bit" variant: is the optional signed immediate byte offset, a multiple of 4 in the range -256 to 252, defaulting to 0 and encoded in the "imm7" field as <imm>/4.

For the "Signed offset 64-bit" variant: is the optional signed immediate byte offset, a multiple of 8 in the range -512 to 504, defaulting to 0 and encoded in the "imm7" field as <imm>/8.

<**Xt1**> Is the 64-bit name of the first general-purpose register to be transferred, encoded in the "Rt" field.

<**Xt2**> Is the 64-bit name of the second general-purpose register to be transferred, encoded in the "Rt2" field.

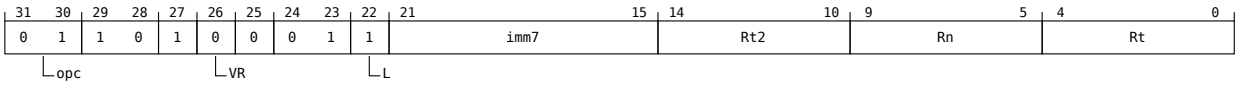
C6.2.120 LDPSW

Load pair of registers signed word

This instruction calculates an address from a base register value and an immediate offset, loads two 32-bit words from memory, sign-extends them, and writes them to two registers. For information about addressing modes, see Load/Store addressing modes.

It has encodings from 3 classes: Post-index , Pre-index and Signed offset

Post-index



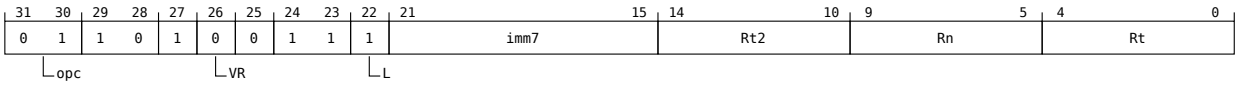
Encoding

```
LDPSW <Xt1>, <Xt2>, [<Xn|SP>], #<imm>
```

Decode for this encoding

```
boolean wback = TRUE;
constant boolean postindex = TRUE;
```

Pre-index



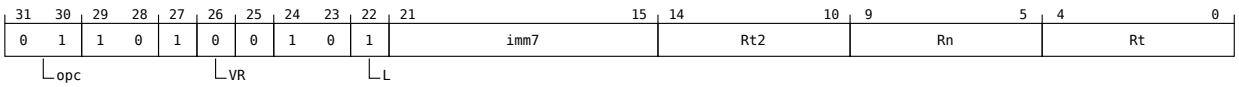
Encoding

```
LDPSW <Xt1>, <Xt2>, [<Xn|SP>, #<imm>]!
```

Decode for this encoding

```
boolean wback = TRUE;
constant boolean postindex = FALSE;
```

Signed offset



Encoding

```
LDPSW <Xt1>, <Xt2>, [<Xn|SP>{, #<imm>}]
```

Decode for this encoding

```
boolean wback = FALSE;
constant boolean postindex = FALSE;
```

Assembler Symbols

<**Xt1**> Is the 64-bit name of the first general-purpose register to be transferred, encoded in the "Rt" field.

<**Xt2**> Is the 64-bit name of the second general-purpose register to be transferred, encoded in the "Rt2" field.

<**Xn|SP**> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<**imm**> For the "Post-index" and "Pre-index" variants: is the signed immediate byte offset, a multiple of 4 in the range -256 to 252, encoded in the "imm7" field as <imm>/4.

For the "Signed offset" variant: is the optional signed immediate byte offset, a multiple of 4 in the range -256 to 252, defaulting to 0 and encoded in the "imm7" field as <imm>/4.

Shared Decode

```
constant integer t = UInt(Rt);
constant integer t2 = UInt(Rt2);
constant integer n = UInt(Rn);
constant boolean nontemporal = FALSE;
constant integer scale = 2 + UInt(opc<1>);
constant integer datasize = 32;
constant bits(64) offset = LSL(SignExtend(imm7, 64), scale);

boolean rt_unknown = FALSE;
boolean wb_unknown = FALSE;

if wback && (t == n || t2 == n) && n != 31 then
    constant Constraint c = ConstrainUnpredictable(Unpredictable_WBOVERLAPLD);
    assert c IN {Constraint_WBSUPPRESS, Constraint_UNKNOWN, Constraint_UNDEF, Constraint_NOP};
    case c of
        when Constraint_WBSUPPRESS wback = FALSE;        // Writeback is suppressed
        when Constraint_UNKNOWN    wb_unknown = TRUE;    // Writeback is UNKNOWN
        when Constraint_UNDEF      EndOfDecode(Decode_UNDEF);
        when Constraint_NOP        EndOfDecode(Decode_NOP);

if t == t2 then
    constant Constraint c = ConstrainUnpredictable(Unpredictable_LDPOVERLAP);
    assert c IN {Constraint_UNKNOWN, Constraint_UNDEF, Constraint_NOP};
    case c of
        when Constraint_UNKNOWN    rt_unknown = TRUE;    // Result is UNKNOWN
        when Constraint_UNDEF      EndOfDecode(Decode_UNDEF);
        when Constraint_NOP        EndOfDecode(Decode_NOP);
```

Operation

```

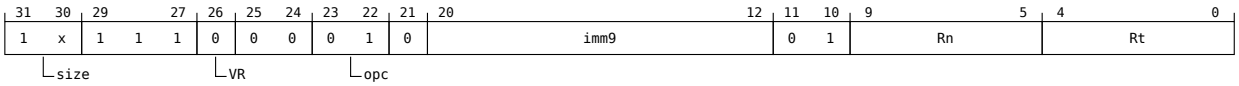
C6.2.121 LDR (immediate)

Load register (immediate)

This instruction loads a word or doubleword from memory and writes it to a register. The address that is used for the load is calculated from a base register and an immediate offset. For information about addressing modes, see Load/Store addressing modes. The Unsigned offset variant scales the immediate offset value by the size of the value accessed before adding it to the base register value.

It has encodings from 3 classes: Post-index , Pre-index and Unsigned offset

Post-index



Encoding for the 32-bit variant Applies when `(size == 10)`

```
LDR <Wt>, [<Xn|SP>], #<simm>
```

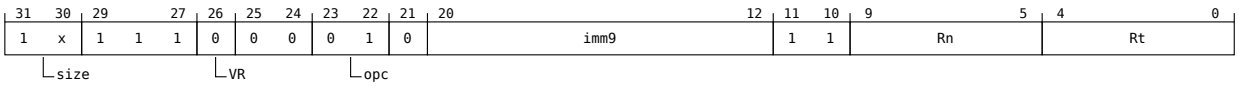
Encoding for the 64-bit variant Applies when `(size == 11)`

```
LDR <Xt>, [<Xn|SP>], #<simm>
```

Decode for all variants of this encoding

```
boolean wback = TRUE;
constant boolean postindex = TRUE;
constant integer scale = UInt(size);
constant bits(64) offset = SignExtend(imm9, 64);
```

Pre-index



Encoding for the 32-bit variant Applies when `(size == 10)`

```
LDR <Wt>, [<Xn|SP>, #<simm>]!
```

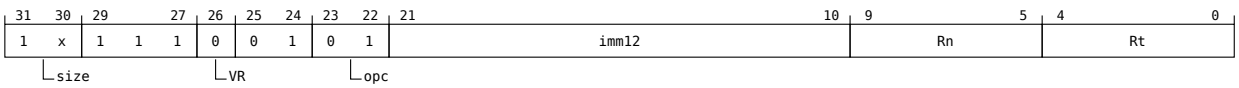
Encoding for the 64-bit variant Applies when `(size == 11)`

```
LDR <Xt>, [<Xn|SP>, #<simm>]!
```

Decode for all variants of this encoding

```
boolean wback = TRUE;
constant boolean postindex = FALSE;
constant integer scale = UInt(size);
constant bits(64) offset = SignExtend(imm9, 64);
```

Unsigned offset



Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Encoding for the 32-bit variant Applies when `(size == 10)`

```
LDR <Wt>, [<Xn|SP>{, #<pimm>}]
```

Encoding for the 64-bit variant Applies when `(size == 11)`

```
LDR <Xt>, [<Xn|SP>{, #<pimm>}]
```

Decode for all variants of this encoding

```
boolean wback = FALSE;
constant boolean postindex = FALSE;
constant integer scale = UInt(size);
constant bits(64) offset = LSL(ZeroExtend(imm12, 64), scale);
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Architectural Constraints on UNPREDICTABLE behaviors, and particularly LDR (immediate).

Assembler Symbols

<**Wt**> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

<**Xn|SP**> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<**simm**> Is the signed immediate byte offset, in the range -256 to 255, encoded in the "imm9" field.

<**Xt**> Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

<**pimm**> For the "32-bit" variant: is the optional positive immediate byte offset, a multiple of 4 in the range 0 to 16380, defaulting to 0 and encoded in the "imm12" field as <pimm>/4.

For the "64-bit" variant: is the optional positive immediate byte offset, a multiple of 8 in the range 0 to 32760, defaulting to 0 and encoded in the "imm12" field as <pimm>/8.

Shared Decode

```
constant integer t = UInt(Rt);
constant integer n = UInt(Rn);
constant integer datasize = 8 << scale;
constant integer regsize = if datasize == 64 then 64 else 32;
constant boolean nontemporal = FALSE;

Constraint c;
boolean wb_unknown = FALSE;
if wback && n == t && n != 31 then
    c = ConstrainUnpredictable(Unpredictable_WBOVERLAPLD);
    assert c IN {Constraint_WBSUPPRESS, Constraint_UNKNOWN, Constraint_UNDEF, Constraint_NOP};
    case c of
        when Constraint_WBSUPPRESS wback = FALSE;       // Writeback is suppressed
        when Constraint_UNKNOWN    wb_unknown = TRUE;   // Writeback is UNKNOWN
        when Constraint_UNDEF      EndOfDecode(Decode_UNDEF);
        when Constraint_NOP        EndOfDecode(Decode_NOP);
```

Operation

```
bits(64) address;

constant boolean privileged = PSTATE.EL != EL0;
constant AccessDescriptor accdesc = CreateAccDescGPR(MemOp_LOAD, nontemporal, privileged, t);

if n == 31 then
    CheckSPAlignment();
    address = SP[64];
else
    address = X[n, 64];
```

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

```
if !postindex then
    address = AddressAdd(address, offset, accdesc);

constant bits(datasize) data = Mem[address, datasize DIV 8, accdesc];
X[t, regsize] = ZeroExtend(data, regsize);

if wback then
    if wb_unknown then
        address = bits(64) UNKNOWN;
    elsif postindex then
        address = AddressAdd(address, offset, accdesc);
    if n == 31 then
        SP[64] = address;
    else
        X[n, 64] = address;
```

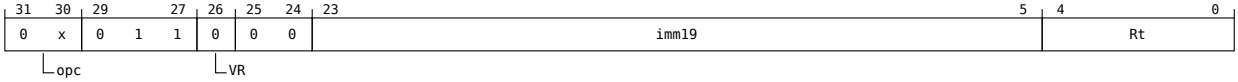
C6.2.122 LDR (literal)

Load register (literal)

This instruction calculates an address from the PC value and an immediate offset, loads a word from memory, and writes it to a register. For information about addressing modes, see Load/Store addressing modes.



Encoding for the 32-bit variant Applies when `(opc == 00)`

```
LDR <Wt>, <label>
```

Encoding for the 64-bit variant Applies when `(opc == 01)`

```
LDR <Xt>, <label>
```

Decode for all variants of this encoding

```
constant integer t = UInt(Rt);
constant integer size = 4 << UInt(opc<0>);
constant boolean nontemporal = FALSE;
constant boolean tagchecked = FALSE;

constant bits(64) offset = SignExtend(imm19:'00', 64);
```

Assembler Symbols

<**Wt**> Is the 32-bit name of the general-purpose register to be loaded, encoded in the "Rt" field.

<**label**> Is the program label from which the data is to be loaded. Its offset from the address of this instruction, in the range +/-1MB, is encoded as "imm19" times 4.

<**Xt**> Is the 64-bit name of the general-purpose register to be loaded, encoded in the "Rt" field.

Operation

```
constant bits(64) address = PC64 + offset;
constant boolean privileged = PSTATE.EL != EL0;
constant AccessDescriptor accdesc = CreateAccDescGPR(MemOp_LOAD, nontemporal, privileged, t);

X[t, size * 8] = Mem[address, size, accdesc];
```

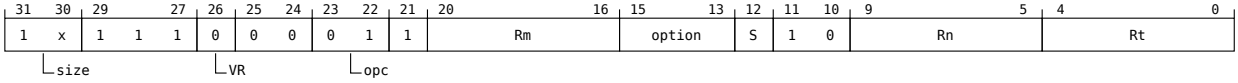
Non-Confidential

C6.2.123 LDR (register)

Load register (register)

This instruction calculates an address from a base register value and an offset register value, loads a word from memory, and writes it to a register. The offset register value can optionally be shifted and extended. For information about addressing modes, see Load/Store addressing modes.



Encoding for the 32-bit variant Applies when `(size == 10)`

```
LDR <Wt>, [<Xn|SP>, (<Wm>|<Xm>){, <extend> {<amount>}}]
```

Encoding for the 64-bit variant Applies when `(size == 11)`

```
LDR <Xt>, [<Xn|SP>, (<Wm>|<Xm>){, <extend> {<amount>}}]
```

Decode for all variants of this encoding

```
if option<1> == '0' then EndOfDecode(Decode_UNDEF);             // sub-word index
constant ExtendType extend_type = DecodeRegExtend(option);
constant integer scale = UInt(size);
constant integer shift = if S == '1' then scale else 0;
```

Assembler Symbols

<**Wt**> Is the 32-bit name of the general-purpose register to be transferred, encoded in the “Rt” field.

<**Xn|SP**> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the “Rn” field.

<**Wm**> When option<0> is set to 0, is the 32-bit name of the general-purpose index register, encoded in the “Rm” field.

<**Xm**> When option<0> is set to 1, is the 64-bit name of the general-purpose index register, encoded in the “Rm” field.

<**extend**> Is the index extend/shift specifier, defaulting to LSL, and which must be omitted for the LSL option when <amount> is omitted, encoded in “option”:

option	<extend>
010	UXTW
011	LSL
110	SXTW
111	SXTX

<**amount**> For the “32-bit” variant: is the index shift amount, optional only when <extend> is not LSL. Where it is permitted to be optional, it defaults to #0. It is encoded in “S”:

S	<amount>
0	#0

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

S	<amount>
1	#2

For the “64-bit” variant: is the index shift amount, optional only when <extend> is not LSL. Where it is permitted to be optional, it defaults to #0. It is encoded in “S”:

S	<amount>
0	#0
1	#3

<Xt> Is the 64-bit name of the general-purpose register to be transferred, encoded in the “Rt” field.

Shared Decode

```
constant integer t = UInt(Rt);
constant integer n = UInt(Rn);
constant integer m = UInt(Rm);
constant integer datasize = 8 << scale;
constant integer regsize = if datasize == 64 then 64 else 32;
constant boolean nontemporal = FALSE;
```

Operation

```
constant bits(64) offset = ExtendReg(m, extend_type, shift, 64);
bits(64) address;

constant boolean privileged = PSTATE.EL != EL0;
constant AccessDescriptor accdesc = CreateAccDescGPR(MemOp_LOAD, nontemporal, privileged, t);

if n == 31 then
    CheckSPAlignment();
    address = SP[64];
else
    address = X[n, 64];

address = AddressAdd(address, offset, accdesc);

constant bits(datasize) data = Mem[address, datasize DIV 8, accdesc];
X[t, regsize] = ZeroExtend(data, regsize);
```

Operational information

C6.2.124 LDRAA, LDRAB

Load register, with pointer authentication

This instruction authenticates an address from a base register using a modifier of zero and the specified key, adds an immediate offset to the authenticated address, and loads a 64-bit doubleword from memory at this resulting address into a register.

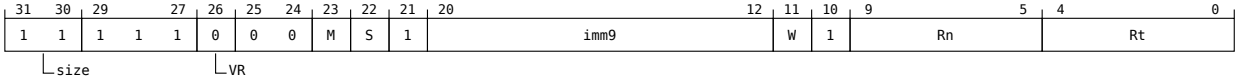
Key A is used for `LDRAA`. Key B is used for `LDRAB`.

If the authentication passes, the PE behaves the same as for an `LDR` instruction. For information on behavior if the authentication fails, see Faulting on pointer authentication.

The authenticated address is not written back to the base register, unless the pre-indexed variant of the instruction is used. In this case, the address that is written back to the base register does not include the pointer authentication code.

For information about addressing modes, see Load/Store addressing modes.

PAC
(FEAT_PAuth)



Encoding for the Key A, offset variant Applies when `(M == 0 && W == 0)`

```
LDRAA <Xt>, [<Xn|SP>{, #<simm>}]
```

Encoding for the Key A, pre-indexed variant Applies when `(M == 0 && W == 1)`

```
LDRAA <Xt>, [<Xn|SP>{, #<simm>}]!
```

Encoding for the Key B, offset variant Applies when `(M == 1 && W == 0)`

```
LDRAB <Xt>, [<Xn|SP>{, #<simm>}]
```

Encoding for the Key B, pre-indexed variant Applies when `(M == 1 && W == 1)`

```
LDRAB <Xt>, [<Xn|SP>{, #<simm>}]!
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_PAuth) then EndOfDecode(Decode_UNDEF);
constant integer t = UInt(Rt);
constant integer n = UInt(Rn);
boolean wback = W == '1';
constant boolean use_key_a = M == '0';
constant bits(10) S10 = S:imm9;
constant bits(64) offset = LSL(SignExtend(S10, 64), 3);
constant boolean nontemporal = FALSE;

boolean wb_unknown = FALSE;
if wback && n == t && n != 31 then
    constant Constraint c = ConstrainUnpredictable(Unpredictable_WBOVERLAPLD);
    assert c IN {Constraint_WBSUPPRESS, Constraint_UNKNOWN, Constraint_UNDEF, Constraint_NOP};
    case c of
        when Constraint_WBSUPPRESS wback = FALSE;       // writeback is suppressed
        when Constraint_UNKNOWN    wb_unknown = TRUE;   // writeback is UNKNOWN
        when Constraint_UNDEF      EndOfDecode(Decode_UNDEF);
        when Constraint_NOP        EndOfDecode(Decode_NOP);
```

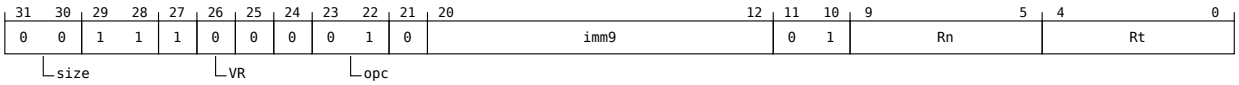
C6.2.125 LDRB (immediate)

Load register byte (immediate)

This instruction loads a byte from memory, zero-extends it, and writes the result to a register. The address that is used for the load is calculated from a base register and an immediate offset. For information about addressing modes, see Load/Store addressing modes.

It has encodings from 3 classes: Post-index , Pre-index and Unsigned offset

Post-index



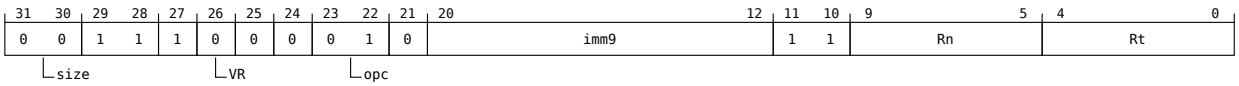
Encoding

```
LDRB <Wt>, [<Xn|SP>], #<simm>
```

Decode for this encoding

```
boolean wback = TRUE;
constant boolean postindex = TRUE;
constant bits(64) offset = SignExtend(imm9, 64);
```

Pre-index



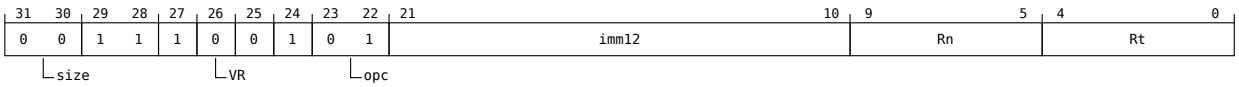
Encoding

```
LDRB <Wt>, [<Xn|SP>, #<simm>]!
```

Decode for this encoding

```
boolean wback = TRUE;
constant boolean postindex = FALSE;
constant bits(64) offset = SignExtend(imm9, 64);
```

Unsigned offset



Encoding

```
LDRB <Wt>, [<Xn|SP>{, #<pimm>}]
```

Decode for this encoding

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

```
boolean wback = FALSE;
constant boolean postindex = FALSE;
constant bits(64) offset = LSL(ZeroExtend(imm12, 64), 0);
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Architectural Constraints on UNPREDICTABLE behaviors, and particularly LDRH (immediate).

Assembler Symbols

<**Wt**> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

<**Xn|SP**> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<**simm**> Is the signed immediate byte offset, in the range -256 to 255, encoded in the "imm9" field.

<**pimm**> Is the optional positive immediate byte offset, in the range 0 to 4095, defaulting to 0 and encoded in the "imm12" field.

Shared Decode

```
constant integer t = UInt(Rt);
constant integer n = UInt(Rn);
constant boolean nontemporal = FALSE;

Constraint c;
boolean wb_unknown = FALSE;
if wback && n == t && n != 31 then
    c = ConstrainUnpredictable(Unpredictable_WBOVERLAPLD);
    assert c IN {Constraint_WBSUPPRESS, Constraint_UNKNOWN, Constraint_UNDEF, Constraint_NOP};
    case c of
        when Constraint_WBSUPPRESS wback = FALSE;       // Writeback is suppressed
        when Constraint_UNKNOWN    wb_unknown = TRUE;   // Writeback is UNKNOWN
        when Constraint_UNDEF      EndOfDecode(Decode_UNDEF);
        when Constraint_NOP        EndOfDecode(Decode_NOP);
```

Operation

```
bits(64) address;

constant boolean privileged = PSTATE.EL != EL0;
constant AccessDescriptor accdesc = CreateAccDescGPR(MemOp_LOAD, nontemporal, privileged, t);

if n == 31 then
    CheckSPAlignment();
    address = SP[64];
else
    address = X[n, 64];

if !postindex then
    address = AddressAdd(address, offset, accdesc);

constant bits(8) data = Mem[address, 1, accdesc];
X[t, 32] = ZeroExtend(data, 32);

if wback then
    if wb_unknown then
        address = bits(64) UNKNOWN;
    elsif postindex then
        address = AddressAdd(address, offset, accdesc);
    if n == 31 then
        SP[64] = address;
    else

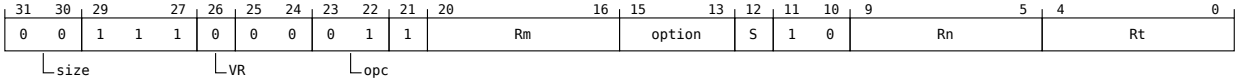
C6.2.126 LDRB (register)

Load register byte (register)

This instruction calculates an address from a base register value and an offset register value, loads a byte from memory, zero-extends it, and writes it to a register. For information about addressing modes, see Load/Store addressing modes.



Encoding for the Extended register variant Applies when `(option != 011)`

```
LDRB <Wt>, [<Xn|SP>, (<Wm>|<Xm>), <extend> {<amount>}]
```

Encoding for the Shifted register variant Applies when `(option == 011)`

```
LDRB <Wt>, [<Xn|SP>, <Xm>{, LSL <amount>}]
```

Decode for all variants of this encoding

```
if option<1> == '0' then EndOfDecode(Decode_UNDEF);             // sub-word index
constant ExtendType extend_type = DecodeRegExtend(option);
constant integer shift = 0;
```

Assembler Symbols

<**Wt**> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

<**Xn|SP**> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<**Wm**> When option<0> is set to 0, is the 32-bit name of the general-purpose index register, encoded in the "Rm" field.

<**Xm**> When option<0> is set to 1, is the 64-bit name of the general-purpose index register, encoded in the "Rm" field.

<**extend**> Is the index extend specifier, encoded in "option":

option	<extend>
010	UXTW
110	SXTW
111	SXTX

<**amount**> Is the index shift amount, it must be #0, encoded in "S" as 0 if omitted, or as 1 if present.

Shared Decode

```
constant integer t = UInt(Rt);
constant integer n = UInt(Rn);
constant integer m = UInt(Rm);
constant boolean nontemporal = FALSE;
```

Operation

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

```
constant bits(64) offset = ExtendReg(m, extend_type, shift, 64);
bits(64) address;

constant boolean privileged = PSTATE.EL != EL0;
constant AccessDescriptor accdesc = CreateAccDescGPR(MemOp_LOAD, nontemporal, privileged, t);

if n == 31 then
    CheckSPAlignment();
    address = SP[64];
else
    address = X[n, 64];

address = AddressAdd(address, offset, accdesc);

constant bits(8) data = Mem[address, 1, accdesc];
X[t, 32] = ZeroExtend(data, 32);
```

Operational information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

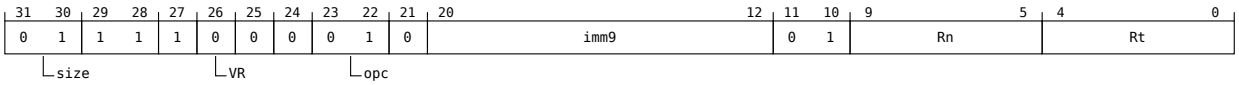
C6.2.127 LDRH (immediate)

Load register halfword (immediate)

This instruction loads a halfword from memory, zero-extends it, and writes the result to a register. The address that is used for the load is calculated from a base register and an immediate offset. For information about addressing modes, see Load/Store addressing modes.

It has encodings from 3 classes: Post-index , Pre-index and Unsigned offset

Post-index



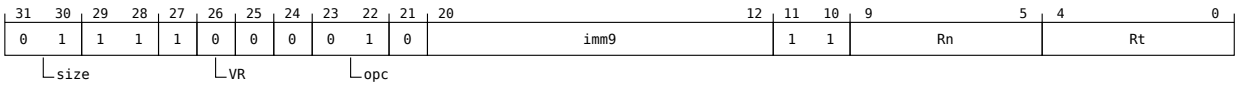
Encoding

```
LDRH <Wt>, [<Xn|SP>], #<simm>
```

Decode for this encoding

```
boolean wback = TRUE;
constant boolean postindex = TRUE;
constant bits(64) offset = SignExtend(imm9, 64);
```

Pre-index



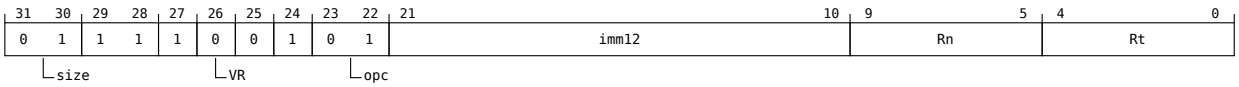
Encoding

```
LDRH <Wt>, [<Xn|SP>, #<simm>]!
```

Decode for this encoding

```
boolean wback = TRUE;
constant boolean postindex = FALSE;
constant bits(64) offset = SignExtend(imm9, 64);
```

Unsigned offset



Encoding

```
LDRH <Wt>, [<Xn|SP>{, #<pimm>}]
```

Decode for this encoding

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

```
boolean wback = FALSE;
constant boolean postindex = FALSE;
constant bits(64) offset = LSL(ZeroExtend(imm12, 64), 1);
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Architectural Constraints on UNPREDICTABLE behaviors, and particularly LDRH (immediate).

Assembler Symbols

<**Wt**> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

<**Xn|SP**> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<**simm**> Is the signed immediate byte offset, in the range -256 to 255, encoded in the "imm9" field.

<**pimm**> Is the optional positive immediate byte offset, a multiple of 2 in the range 0 to 8190, defaulting to 0 and encoded in the "imm12" field as <pimm>/2.

Shared Decode

```
constant integer t = UInt(Rt);
constant integer n = UInt(Rn);
constant boolean nontemporal = FALSE;

Constraint c;
boolean wb_unknown = FALSE;
if wback && n == t && n != 31 then
    c = ConstrainUnpredictable(Unpredictable_WBOVERLAPLD);
    assert c IN {Constraint_WBSUPPRESS, Constraint_UNKNOWN, Constraint_UNDEF, Constraint_NOP};
    case c of
        when Constraint_WBSUPPRESS wback = FALSE;       // Writeback is suppressed
        when Constraint_UNKNOWN    wb_unknown = TRUE;   // Writeback is UNKNOWN
        when Constraint_UNDEF      EndOfDecode(Decode_UNDEF);
        when Constraint_NOP        EndOfDecode(Decode_NOP);
```

Operation

```
bits(64) address;

constant boolean privileged = PSTATE.EL != EL0;
constant AccessDescriptor accdesc = CreateAccDescGPR(MemOp_LOAD, nontemporal, privileged, t);

if n == 31 then
    CheckSPAlignment();
    address = SP[64];
else
    address = X[n, 64];

if !postindex then
    address = AddressAdd(address, offset, accdesc);

constant bits(16) data = Mem[address, 2, accdesc];
X[t, 32] = ZeroExtend(data, 32);

if wback then
    if wb_unknown then
        address = bits(64) UNKNOWN;
    elsif postindex then
        address = AddressAdd(address, offset, accdesc);
    if n == 31 then
        SP[64] = address;
    else
        X[n, 64] = address;
```

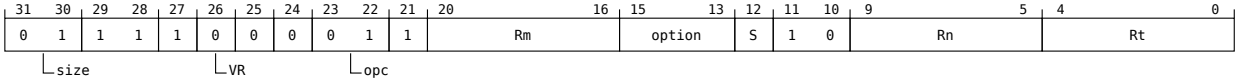
C6.2.128 LDRH (register)

Load register halfword (register)

This instruction calculates an address from a base register value and an offset register value, loads a halfword from memory, zero-extends it, and writes it to a register. For information about addressing modes, see Load/Store addressing modes.



Encoding

```
LDRH <Wt>, [<Xn|SP>, (<Wm>|<Xm>){, <extend> {<amount>}}]
```

Decode for this encoding

```
if option<1> == '0' then EndOfDecode(Decode_UNDEF);             // sub-word index
constant ExtendType extend_type = DecodeRegExtend(option);
constant integer shift = if S == '1' then 1 else 0;
```

Assembler Symbols

<Wt> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<Wm> When option<0> is set to 0, is the 32-bit name of the general-purpose index register, encoded in the "Rm" field.

<Xm> When option<0> is set to 1, is the 64-bit name of the general-purpose index register, encoded in the "Rm" field.

<extend> Is the index extend/shift specifier, defaulting to LSL, and which must be omitted for the LSL option when <amount> is omitted, encoded in "option":

option	<extend>
010	UXTW
011	LSL
110	SXTW
111	SXTX

<amount> Is the index shift amount, optional only when <extend> is not LSL. Where it is permitted to be optional, it defaults to #0. It is encoded in "S":

S	<amount>
0	#0
1	#1

Shared Decode

Non-Confidential

```
constant integer t = UInt(Rt);
constant integer n = UInt(Rn);
constant integer m = UInt(Rm);
constant boolean nontemporal = FALSE;
```

Operation

```
constant bits(64) offset = ExtendReg(m, extend_type, shift, 64);
bits(64) address;

constant boolean privileged = PSTATE.EL != EL0;
constant AccessDescriptor accdesc = CreateAccDescGPR(MemOp_LOAD, nontemporal, privileged, t);

if n == 31 then
    CheckSPAlignment();
    address = SP[64];
else
    address = X[n, 64];

address = AddressAdd(address, offset, accdesc);

constant bits(16) data = Mem[address, 2, accdesc];
X[t, 32] = ZeroExtend(data, 32);
```

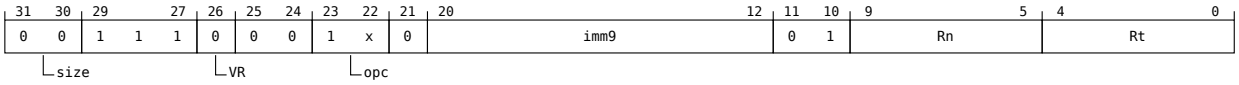
C6.2.129 LDRSB (immediate)

Load register signed byte (immediate)

This instruction loads a byte from memory, sign-extends it to either 32 bits or 64 bits, and writes the result to a register. The address that is used for the load is calculated from a base register and an immediate offset. For information about addressing modes, see Load/Store addressing modes.

It has encodings from 3 classes: Post-index , Pre-index and Unsigned offset

Post-index



Encoding for the 32-bit variant Applies when `(opc == 11)`

```
LDRSB <Wt>, [<Xn|SP>], #<simm>
```

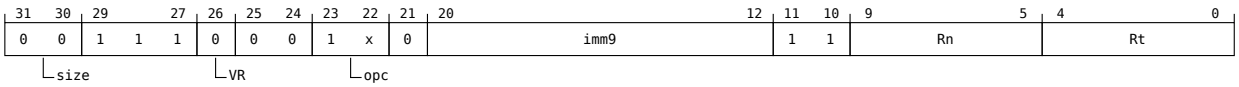
Encoding for the 64-bit variant Applies when `(opc == 10)`

```
LDRSB <Xt>, [<Xn|SP>], #<simm>
```

Decode for all variants of this encoding

```
boolean wback = TRUE;
constant boolean postindex = TRUE;
constant bits(64) offset = SignExtend(imm9, 64);
```

Pre-index



Encoding for the 32-bit variant Applies when `(opc == 11)`

```
LDRSB <Wt>, [<Xn|SP>, #<simm>]!
```

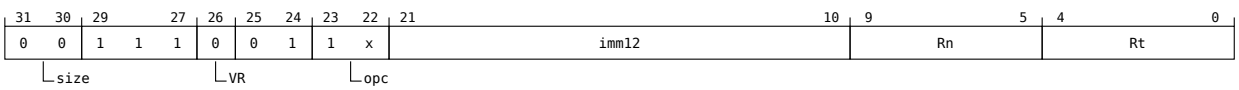
Encoding for the 64-bit variant Applies when `(opc == 10)`

```
LDRSB <Xt>, [<Xn|SP>, #<simm>]!
```

Decode for all variants of this encoding

```
boolean wback = TRUE;
constant boolean postindex = FALSE;
constant bits(64) offset = SignExtend(imm9, 64);
```

Unsigned offset



Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Encoding for the 32-bit variant Applies when `(opc == 11)`

```
LDRSB <Wt>, [<Xn|SP>{, #<pimm>}]
```

Encoding for the 64-bit variant Applies when `(opc == 10)`

```
LDRSB <Xt>, [<Xn|SP>{, #<pimm>}]
```

Decode for all variants of this encoding

```
boolean wback = FALSE;
constant boolean postindex = FALSE;
constant bits(64) offset = LSL(ZeroExtend(imm12, 64), 0);
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Architectural Constraints on UNPREDICTABLE behaviors, and particularly LDRSB (immediate).

Assembler Symbols

<**Wt**> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

<**Xn|SP**> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<**simm**> Is the signed immediate byte offset, in the range -256 to 255, encoded in the "imm9" field.

<**Xt**> Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

<**pimm**> Is the optional positive immediate byte offset, in the range 0 to 4095, defaulting to 0 and encoded in the "imm12" field.

Shared Decode

```
constant integer t = UInt(Rt);
constant integer n = UInt(Rn);
constant integer regsize = 64 >> UInt(opc<0>);
constant boolean nontemporal = FALSE;

Constraint c;
boolean wb_unknown = FALSE;
if wback && n == t && n != 31 then
    c = ConstrainUnpredictable(Unpredictable_WBOVERLAPLD);
    assert c IN {Constraint_WBSUPPRESS, Constraint_UNKNOWN, Constraint_UNDEF, Constraint_NOP};
    case c of
        when Constraint_WBSUPPRESS wback = FALSE;       // Writeback is suppressed
        when Constraint_UNKNOWN    wb_unknown = TRUE;   // Writeback is UNKNOWN
        when Constraint_UNDEF      EndOfDecode(Decode_UNDEF);
        when Constraint_NOP        EndOfDecode(Decode_NOP);
```

Operation

```
bits(64) address;

constant boolean privileged = PSTATE.EL != EL0;
constant AccessDescriptor accdesc = CreateAccDescGPR(MemOp_LOAD, nontemporal, privileged, t);

if n == 31 then
    CheckSPAlignment();
    address = SP[64];
else
    address = X[n, 64];

if !postindex then
    address = AddressAdd(address, offset, accdesc);

constant bits(8) data = Mem[address, 1, accdesc];
X[t, regsize] = SignExtend(data, regsize);
```

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

```
if wback then
    if wb_unknown then
        address = bits(64) UNKNOWN;
    elsif postindex then
        address = AddressAdd(address, offset, accdesc);
    if n == 31 then
        SP[64] = address;
    else
        X[n, 64] = address;
```

Operational information

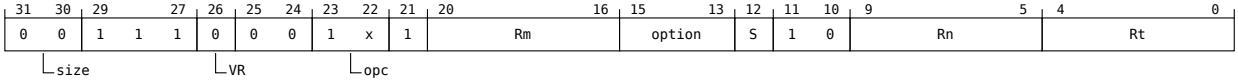
C6.2.130 LDRSB (register)

Load register signed byte (register)

This instruction calculates an address from a base register value and an offset register value, loads a byte from memory, sign-extends it, and writes it to a register. For information about addressing modes, see Load/Store addressing modes.



Encoding for the 32-bit with extended register offset variant Applies when `(opc == 11 && option != 011)`

```
LDRSB <Wt>, [<Xn|SP>, (<Wm>|<Xm>), <extend> {<amount>}]
```

Encoding for the 32-bit with shifted register offset variant Applies when `(opc == 11 && option == 011)`

```
LDRSB <Wt>, [<Xn|SP>, <Xm>{, LSL <amount>}]
```

Encoding for the 64-bit with extended register offset variant Applies when `(opc == 10 && option != 011)`

```
LDRSB <Xt>, [<Xn|SP>, (<Wm>|<Xm>), <extend> {<amount>}]
```

Encoding for the 64-bit with shifted register offset variant Applies when `(opc == 10 && option == 011)`

```
LDRSB <Xt>, [<Xn|SP>, <Xm>{, LSL <amount>}]
```

Decode for all variants of this encoding

```
if option<1> == '0' then EndOfDecode(Decode_UNDEF);             // sub-word index
constant ExtendType extend_type = DecodeRegExtend(option);
constant integer shift = 0;
```

Assembler Symbols

<**Wt**> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

<**Xn|SP**> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<**Wm**> When option<0> is set to 0, is the 32-bit name of the general-purpose index register, encoded in the "Rm" field.

<**Xm**> When option<0> is set to 1, is the 64-bit name of the general-purpose index register, encoded in the "Rm" field.

<**extend**> Is the index extend specifier, encoded in "option":

option	<extend>
010	UXTW
110	SXTW
111	SXTX

<**amount**> Is the index shift amount, it must be #0, encoded in "S" as 0 if omitted, or as 1 if present.

<**Xt**> Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Shared Decode

```
constant integer t = UInt(Rt);
constant integer n = UInt(Rn);
constant integer m = UInt(Rm);
constant integer regsize = 64 >> UInt(opc<0>);
constant boolean nontemporal = FALSE;
```

Operation

```
constant bits(64) offset = ExtendReg(m, extend_type, shift, 64);
bits(64) address;

constant boolean privileged = PSTATE.EL != EL0;
constant AccessDescriptor accdesc = CreateAccDescGPR(MemOp_LOAD, nontemporal, privileged, t);

if n == 31 then
    CheckSPAlignment();
    address = SP[64];
else
    address = X[n, 64];

address = AddressAdd(address, offset, accdesc);

constant bits(8) data = Mem[address, 1, accdesc];
X[t, regsize] = SignExtend(data, regsize);
```

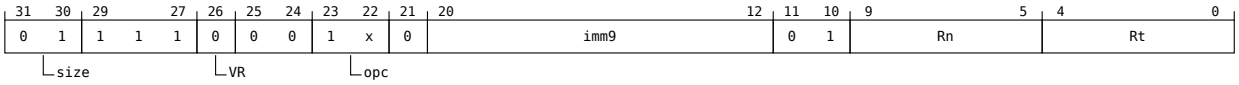
C6.2.131 LDRSH (immediate)

Load register signed halfword (immediate)

This instruction loads a halfword from memory, sign-extends it to 32 bits or 64 bits, and writes the result to a register. The address that is used for the load is calculated from a base register and an immediate offset. For information about addressing modes, see Load/Store addressing modes.

It has encodings from 3 classes: Post-index , Pre-index and Unsigned offset

Post-index



Encoding for the 32-bit variant Applies when `(opc == 11)`

```
LDRSH <Wt>, [<Xn|SP>], #<simm>
```

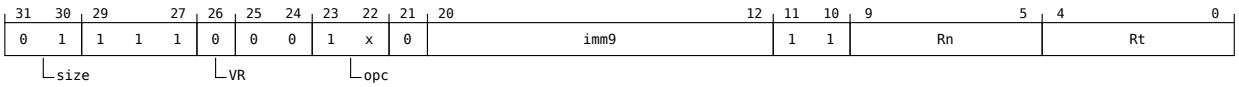
Encoding for the 64-bit variant Applies when `(opc == 10)`

```
LDRSH <Xt>, [<Xn|SP>], #<simm>
```

Decode for all variants of this encoding

```
boolean wback = TRUE;
constant boolean postindex = TRUE;
constant bits(64) offset = SignExtend(imm9, 64);
```

Pre-index



Encoding for the 32-bit variant Applies when `(opc == 11)`

```
LDRSH <Wt>, [<Xn|SP>, #<simm>]!
```

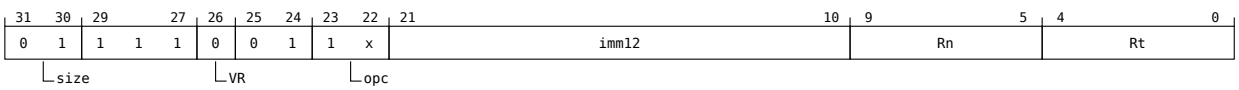
Encoding for the 64-bit variant Applies when `(opc == 10)`

```
LDRSH <Xt>, [<Xn|SP>, #<simm>]!
```

Decode for all variants of this encoding

```
boolean wback = TRUE;
constant boolean postindex = FALSE;
constant bits(64) offset = SignExtend(imm9, 64);
```

Unsigned offset



Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Encoding for the 32-bit variant Applies when `(opc == 11)`

```
LDRSH <Wt>, [<Xn|SP>{, #<pimm>}]
```

Encoding for the 64-bit variant Applies when `(opc == 10)`

```
LDRSH <Xt>, [<Xn|SP>{, #<pimm>}]
```

Decode for all variants of this encoding

```
boolean wback = FALSE;
constant boolean postindex = FALSE;
constant bits(64) offset = LSL(ZeroExtend(imm12, 64), 1);
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Architectural Constraints on UNPREDICTABLE behaviors, and particularly LDRSH (immediate).

Assembler Symbols

<**Wt**> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

<**Xn|SP**> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<**simm**> Is the signed immediate byte offset, in the range -256 to 255, encoded in the "imm9" field.

<**Xt**> Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

<**pimm**> Is the optional positive immediate byte offset, a multiple of 2 in the range 0 to 8190, defaulting to 0 and encoded in the "imm12" field as <pimm>/2.

Shared Decode

```
constant integer t = UInt(Rt);
constant integer n = UInt(Rn);
constant integer regsize = 64 >> UInt(opc<0>);
constant boolean nontemporal = FALSE;

Constraint c;
boolean wb_unknown = FALSE;
if wback && n == t && n != 31 then

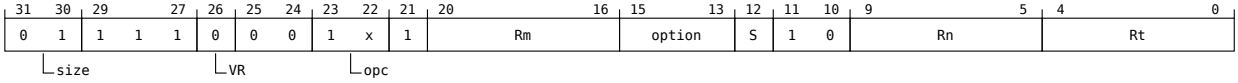
C6.2.132 LDRSH (register)

Load register signed halfword (register)

This instruction calculates an address from a base register value and an offset register value, loads a halfword from memory, sign-extends it, and writes it to a register. For information about addressing modes, see Load/Store addressing modes.



Encoding for the 32-bit variant Applies when `(opc == 11)`

```
LDRSH <Wt>, [<Xn|SP>, (<Wm>|<Xm>){, <extend> {<amount>}}]
```

Encoding for the 64-bit variant Applies when `(opc == 10)`

```
LDRSH <Xt>, [<Xn|SP>, (<Wm>|<Xm>){, <extend> {<amount>}}]
```

Decode for all variants of this encoding

```
if option<1> == '0' then EndOfDecode(Decode_UNDEF);             // sub-word index
constant ExtendType extend_type = DecodeRegExtend(option);
constant integer shift = if S == '1' then 1 else 0;
```

Assembler Symbols

<**Wt**> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

<**Xn|SP**> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<**Wm**> When option<0> is set to 0, is the 32-bit name of the general-purpose index register, encoded in the "Rm" field.

<**Xm**> When option<0> is set to 1, is the 64-bit name of the general-purpose index register, encoded in the "Rm" field.

<**extend**> Is the index extend/shift specifier, defaulting to LSL, and which must be omitted for the LSL option when <amount> is omitted, encoded in "option":

option	<extend>
010	UXTW
011	LSL
110	SXTW
111	SXTX

<**amount**> Is the index shift amount, optional only when <extend> is not LSL. Where it is permitted to be optional, it defaults to #0. It is encoded in "S":

S	<amount>
0	#0
1	#1

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

<**Xt**> Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

Shared Decode

```
constant integer t = UInt(Rt);
constant integer n = UInt(Rn);
constant integer m = UInt(Rm);
constant integer regsize = 64 >> UInt(opc<0>);
constant boolean nontemporal = FALSE;
```

Operation

```
constant bits(64) offset = ExtendReg(m, extend_type, shift, 64);
bits(64) address;

constant boolean privileged = PSTATE.EL != EL0;
constant AccessDescriptor accdesc = CreateAccDescGPR(MemOp_LOAD, nontemporal, privileged, t);

if n == 31 then
    CheckSPAlignment();
    address = SP[64];
else
    address = X[n, 64];

address = AddressAdd(address, offset, accdesc);

constant bits(16) data = Mem[address, 2, accdesc];
X[t, regsize] = SignExtend(data, regsize);
```

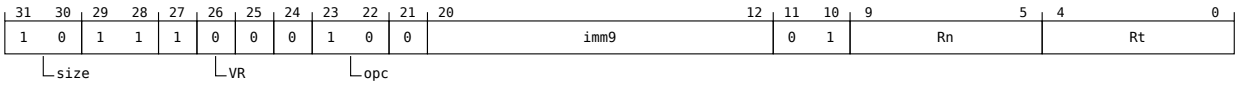
C6.2.133 LDRSW (immediate)

Load register signed word (immediate)

This instruction loads a word from memory, sign-extends it to 64 bits, and writes the result to a register. The address that is used for the load is calculated from a base register and an immediate offset. For information about addressing modes, see Load/Store addressing modes.

It has encodings from 3 classes: Post-index , Pre-index and Unsigned offset

Post-index



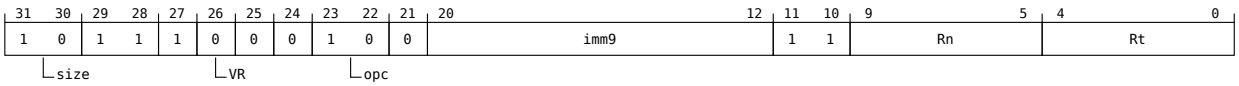
Encoding

```
LDRSW <Xt>, [<Xn|SP>], #<simm>
```

Decode for this encoding

```
boolean wback = TRUE;
constant boolean postindex = TRUE;
constant bits(64) offset = SignExtend(imm9, 64);
```

Pre-index



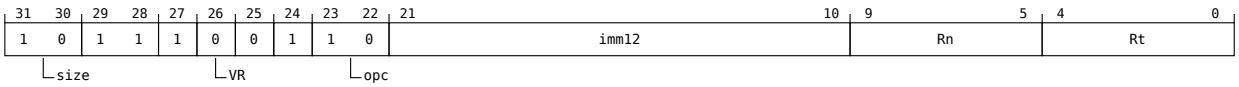
Encoding

```
LDRSW <Xt>, [<Xn|SP>, #<simm>]!
```

Decode for this encoding

```
boolean wback = TRUE;
constant boolean postindex = FALSE;
constant bits(64) offset = SignExtend(imm9, 64);
```

Unsigned offset



Encoding

```
LDRSW <Xt>, [<Xn|SP>{, #<pimm>}]
```

Decode for this encoding

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

```
boolean wback = FALSE;
constant boolean postindex = FALSE;
constant bits(64) offset = LSL(ZeroExtend(imm12, 64), 2);
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Architectural Constraints on UNPREDICTABLE behaviors, and particularly LDRSW (immediate).

Assembler Symbols

<**Xt**> Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

<**Xn|SP**> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<**simm**> Is the signed immediate byte offset, in the range -256 to 255, encoded in the "imm9" field.

<**pimm**> Is the optional positive immediate byte offset, a multiple of 4 in the range 0 to 16380, defaulting to 0 and encoded in the "imm12" field as <pimm>/4.

Shared Decode

```
constant integer t = UInt(Rt);
constant integer n = UInt(Rn);
constant boolean nontemporal = FALSE;

Constraint c;
boolean wb_unknown = FALSE;
if wback && n == t && n != 31 then
    c = ConstrainUnpredictable(Unpredictable_WBOVERLAPLD);
    assert c IN {Constraint_WBSUPPRESS, Constraint_UNKNOWN, Constraint_UNDEF, Constraint_NOP};
    case c of
        when Constraint_WBSUPPRESS wback = FALSE;       // Writeback is suppressed
        when Constraint_UNKNOWN    wb_unknown = TRUE;   // Writeback is UNKNOWN
        when Constraint_UNDEF      EndOfDecode(Decode_UNDEF);
        when Constraint_NOP        EndOfDecode(Decode_NOP);
```

Operation

```
bits(64) address;

constant boolean privileged = PSTATE.EL != EL0;
constant AccessDescriptor accdesc = CreateAccDescGPR(MemOp_LOAD, nontemporal, privileged, t);

if n == 31 then
    CheckSPAlignment();
    address = SP[64];
else
    address = X[n, 64];

if !postindex then
    address = AddressAdd(address, offset, accdesc);

constant bits(32) data = Mem[address, 4, accdesc];
X[t, 64] = SignExtend(data, 64);

if wback then
    if wb_unknown then
        address = bits(64) UNKNOWN;
    elsif postindex then
        address = AddressAdd(address, offset, accdesc);
    if n == 31 then
        SP[64] = address;
    else
        X[n, 64] = address;
```

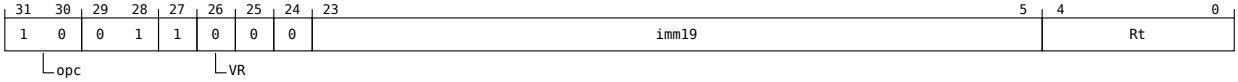
C6.2.134 LDRSW (literal)

Load register signed word (literal)

This instruction calculates an address from the PC value and an immediate offset, loads a word from memory, and writes it to a register. For information about addressing modes, see Load/Store addressing modes.



Encoding

```
LDRSW <Xt>, <label>
```

Decode for this encoding

```
constant integer t = UInt(Rt);
constant boolean nontemporal = FALSE;
constant boolean tagchecked = FALSE;

constant bits(64) offset = SignExtend(imm19:'00', 64);
```

Assembler Symbols

<Xt> Is the 64-bit name of the general-purpose register to be loaded, encoded in the "Rt" field.

<label> Is the program label from which the data is to be loaded. Its offset from the address of this instruction, in the range +/-1MB, is encoded as "imm19" times 4.

Operation

```
constant bits(64) address = PC64 + offset;
constant boolean privileged = PSTATE.EL != EL0;
constant AccessDescriptor accdesc = CreateAccDescGPR(MemOp_LOAD, nontemporal, privileged, t);

constant bits(32) data = Mem[address, 4, accdesc];
X[t, 64] = SignExtend(data, 64);
```

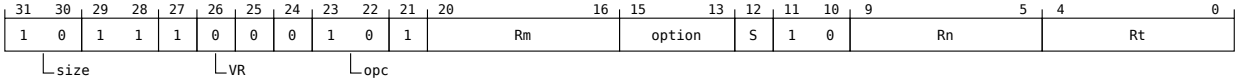
C6.2.135 LDRSW (register)

Load register signed word (register)

This instruction calculates an address from a base register value and an offset register value, loads a word from memory, sign-extends it to form a 64-bit value, and writes it to a register. The offset register value can be shifted left by 0 or 2 bits. For information about addressing modes, see Load/Store addressing modes.



Encoding

```
LDRSW <Xt>, [<Xn|SP>, (<Wm>|<Xm>){, <extend> {<amount>}}]
```

Decode for this encoding

```
if option<1> == '0' then EndOfDecode(Decode_UNDEF);             // sub-word index
constant ExtendType extend_type = DecodeRegExtend(option);
constant integer shift = if S == '1' then 2 else 0;
```

Assembler Symbols

<**Xt**> Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

<**Xn|SP**> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<**Wm**> When option<0> is set to 0, is the 32-bit name of the general-purpose index register, encoded in the "Rm" field.

<**Xm**> When option<0> is set to 1, is the 64-bit name of the general-purpose index register, encoded in the "Rm" field.

<**extend**> Is the index extend/shift specifier, defaulting to LSL, and which must be omitted for the LSL option when <amount> is omitted, encoded in "option":

option	<extend>
010	UXTW
011	LSL
110	SXTW
111	SXTX

<**amount**> Is the index shift amount, optional only when <extend> is not LSL. Where it is permitted to be optional, it defaults to #0. It is encoded in "S":

S	<amount>
0	#0
1	#2

C6.2.136 LDSET, LDSETA, LDSETAL, LDSETL

Atomic bit set on word or doubleword

This instruction atomically loads a 32-bit word or 64-bit doubleword from memory, performs a bitwise OR with the value held in a register on it, and stores the result back to memory. The value initially loaded from memory is returned in the destination register.

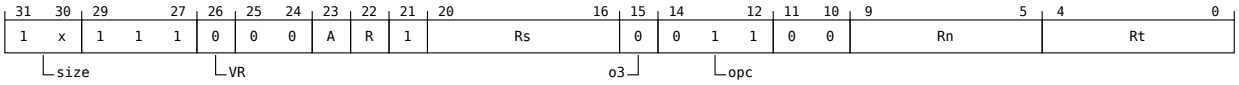
- If the destination register is not one of WZR or XZR, `LDSETA` and `LDSETAL` load from memory with acquire semantics.
- `LDSETL` and `LDSETAL` store to memory with release semantics.
- `LDSET` has neither acquire nor release semantics.

For more information about memory ordering semantics, see Load-Acquire, Store-Release.

For information about addressing modes, see Load/Store addressing modes.

This instruction is used by the alias STSET, STSETL.

Integer
(FEAT_LSE)



Encoding for the 32-bit no memory ordering variant Applies when `(size == 10 && A == 0 && R == 0)`

```
LDSET <Ws>, <Wt>, [<Xn|SP>]
```

Encoding for the 32-bit acquire variant Applies when `(size == 10 && A == 1 && R == 0)`

```
LDSETA <Ws>, <Wt>, [<Xn|SP>]
```

Encoding for the 32-bit acquire-release variant Applies when `(size == 10 && A == 1 && R == 1)`

```
LDSETAL <Ws>, <Wt>, [<Xn|SP>]
```

Encoding for the 32-bit release variant Applies when `(size == 10 && A == 0 && R == 1)`

```
LDSETL <Ws>, <Wt>, [<Xn|SP>]
```

Encoding for the 64-bit no memory ordering variant Applies when `(size == 11 && A == 0 && R == 0)`

```
LDSET <Xs>, <Xt>, [<Xn|SP>]
```

Encoding for the 64-bit acquire variant Applies when `(size == 11 && A == 1 && R == 0)`

```
LDSETA <Xs>, <Xt>, [<Xn|SP>]
```

Encoding for the 64-bit acquire-release variant Applies when `(size == 11 && A == 1 && R == 1)`

```
LDSETAL <Xs>, <Xt>, [<Xn|SP>]
```

Encoding for the 64-bit release variant Applies when `(size == 11 && A == 0 && R == 1)`

```
LDSETL <Xs>, <Xt>, [<Xn|SP>]
```

Decode for all variants of this encoding

C6.2.143 LDSMINB, LDSMINAB, LDSMINALB, LDSMINLB

Atomic signed minimum on byte

This instruction atomically loads an 8-bit byte from memory, compares it against the value held in a register, and stores the smaller value back to memory, treating the values as signed numbers. The value initially loaded from memory is returned in the destination register.

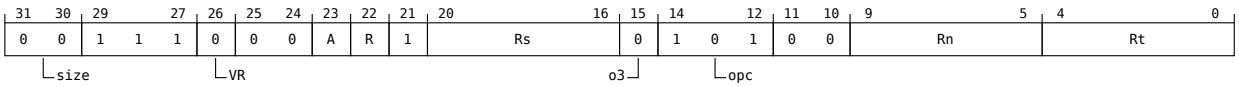
- If the destination register is not WZR, `LDSMINAB` and `LDSMINALB` load from memory with acquire semantics.
- `LDSMINLB` and `LDSMINALB` store to memory with release semantics.
- `LDSMINB` has neither acquire nor release semantics.

For more information about memory ordering semantics, see Load-Acquire, Store-Release.

For information about addressing modes, see Load/Store addressing modes.

This instruction is used by the alias STSMINB, STSMINLB.

Integer
(FEAT_LSE)



Encoding for the No memory ordering variant Applies when `(A == 0 && R == 0)`

```
LDSMINB <Ws>, <Wt>, [<Xn|SP>]
```

Encoding for the Acquire variant Applies when `(A == 1 && R == 0)`

```

C6.2.144 LDSMINH, LDSMINAH, LDSMINALH, LDSMINLH

Atomic signed minimum on halfword

This instruction atomically loads a 16-bit halfword from memory, compares it against the value held in a register, and stores the smaller value back to memory, treating the values as signed numbers. The value initially loaded from memory is returned in the destination register.

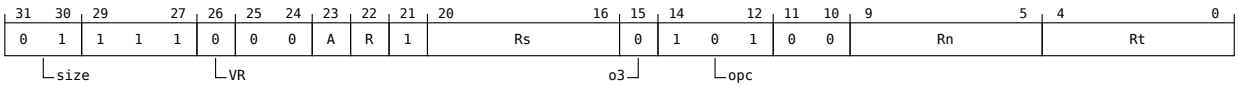
- If the destination register is not WZR, `LDSMINAH` and `LDSMINALH` load from memory with acquire semantics.
- `LDSMINLH` and `LDSMINALH` store to memory with release semantics.
- `LDSMINH` has neither acquire nor release semantics.

For more information about memory ordering semantics, see Load-Acquire, Store-Release.

For information about addressing modes, see Load/Store addressing modes.

This instruction is used by the alias STSMINH, STSMINLH.

Integer
(FEAT_LSE)



Encoding for the No memory ordering variant Applies when `(A == 0 && R == 0)`

```
LDSMINH <Ws>, <Wt>, [<Xn|SP>]
```

Encoding for the Acquire variant Applies when `(A == 1 && R == 0)`

```

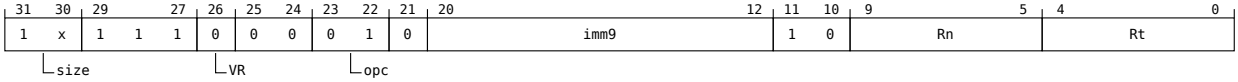
C6.2.145 LDTR

Load register (unprivileged)

This instruction loads a word or doubleword from memory, and writes it to a register. The address that is used for the load is calculated from a base register and an immediate offset.



Encoding for the 32-bit variant Applies when `(size == 10)`

```
LDTR <Wt>, [<Xn|SP>{, #<simm>}]
```

Encoding for the 64-bit variant Applies when `(size == 11)`

```
LDTR <Xt>, [<Xn|SP>{, #<simm>}]
```

Decode for all variants of this encoding

```
constant integer scale = UInt(size);
constant bits(64) offset = SignExtend(imm9, 64);
```

Assembler Symbols

<**Wt**> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

<**Xn|SP**> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<**simm**> Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the "imm9" field.

<**Xt**> Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

Shared Decode

```
constant integer t = UInt(Rt);
constant integer n = UInt(Rn);

constant integer datasize = 8 << scale;
constant integer regsize = if datasize == 64 then 64 else 32;
constant boolean nontemporal = FALSE;
```

Operation

```
bits(64) address;

constant boolean privileged = AArch64.IsUnprivAccessPriv();
constant AccessDescriptor accdesc = CreateAccDescGPR(MemOp_LOAD, nontemporal, privileged, t);

if n == 31 then
    CheckSPAlignment();
    address = SP[64];
else
    address = X[n, 64];

address = AddressAdd(address, offset, accdesc);

constant bits(datasize) data = Mem[address, datasize DIV 8, accdesc];
X[t, regsize] = ZeroExtend(data, regsize);
```

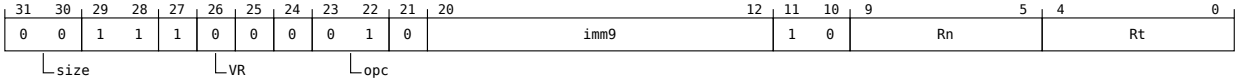
C6.2.146 LDTRB

Load register byte (unprivileged)

This instruction loads a byte from memory, zero-extends it, and writes the result to a register. The address that is used for the load is calculated from a base register and an immediate offset.



Encoding

```
LDTRB <Wt>, [<Xn|SP>{, #<simm>}]
```

Decode for this encoding

```
constant bits(64) offset = SignExtend(imm9, 64);
```

Assembler Symbols

<**Wt**> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

<**Xn|SP**> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<**simm**> Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the "imm9" field.

Shared Decode

```
constant integer t = UInt(Rt);
constant integer n = UInt(Rn);

constant integer datasize = 8;
constant boolean nontemporal = FALSE;
```

Operation

```
bits(64) address;

constant boolean privileged = AArch64.IsUnprivAccessPriv();
constant AccessDescriptor accdesc = CreateAccDescGPR(MemOp_LOAD, nontemporal, privileged, t);

if n == 31 then
    CheckSPAlignment();
    address = SP[64];
else
    address = X[n, 64];

address = AddressAdd(address, offset, accdesc);

constant bits(datasize) data = Mem[address, datasize DIV 8, accdesc];
X[t, 32] = ZeroExtend(data, 32);
```

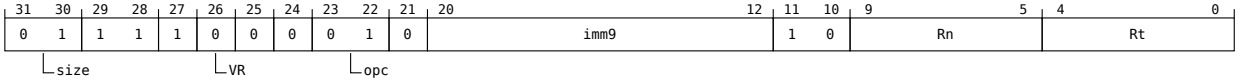
C6.2.147 LDTRH

Load register halfword (unprivileged)

This instruction loads a halfword from memory, zero-extends it, and writes the result to a register. The address that is used for the load is calculated from a base register and an immediate offset.



Encoding

```
LDTRH <Wt>, [<Xn|SP>{, #<simm>}]
```

Decode for this encoding

```
constant bits(64) offset = SignExtend(imm9, 64);
```

Assembler Symbols

<**Wt**> Is the 32-bit name of the general-purpose register to be transferred, encoded in the “Rt” field.

<**Xn|SP**> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the “Rn” field.

<**simm**> Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the “imm9” field.

Shared Decode

```
constant integer t = UInt(Rt);
constant integer n = UInt(Rn);

constant integer datasize = 16;
constant boolean nontemporal = FALSE;
```

Operation

```
bits(64) address;

constant boolean privileged = AArch64.IsUnprivAccessPriv();
constant AccessDescriptor accdesc = CreateAccDescGPR(MemOp_LOAD, nontemporal, privileged, t);

if n == 31 then
    CheckSPAlignment();
    address = SP[64];
else
    address = X[n, 64];

address = AddressAdd(address, offset, accdesc);

constant bits(datasize) data = Mem[address, datasize DIV 8, accdesc];
X[t, 32] = ZeroExtend(data, 32);
```

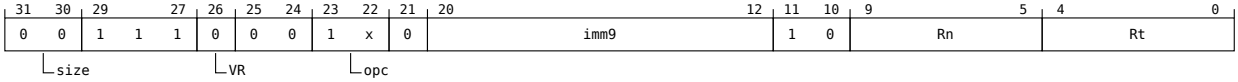
C6.2.148 LDTRSB

Load register signed byte (unprivileged)

This instruction loads a byte from memory, sign-extends it to 32 bits or 64 bits, and writes the result to a register. The address that is used for the load is calculated from a base register and an immediate offset.



Encoding for the 32-bit variant Applies when `(opc == 11)`

```
LDTRSB <Wt>, [<Xn|SP>{, #<simm>}]
```

Encoding for the 64-bit variant Applies when `(opc == 10)`

```
LDTRSB <Xt>, [<Xn|SP>{, #<simm>}]
```

Decode for all variants of this encoding

```
constant bits(64) offset = SignExtend(imm9, 64);
```

Assembler Symbols

<**Wt**> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

<**Xn|SP**> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<**simm**> Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the "imm9" field.

<**Xt**> Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

Shared Decode

```
constant integer t = UInt(Rt);
constant integer n = UInt(Rn);

constant integer datasize = 8;
constant integer regsize = 64 >> UInt(opc<0>);
constant boolean nontemporal = FALSE;
```

Operation

```
bits(64) address;

constant boolean privileged = AArch64.IsUnprivAccessPriv();
constant AccessDescriptor accdesc = CreateAccDescGPR(MemOp_LOAD, nontemporal, privileged, t);

if n == 31 then
    CheckSPAlignment();
    address = SP[64];
else
    address = X[n, 64];

address = AddressAdd(address, offset, accdesc);

constant bits(datasize) data = Mem[address, datasize DIV 8, accdesc];
X[t, regsize] = SignExtend(data, regsize);
```

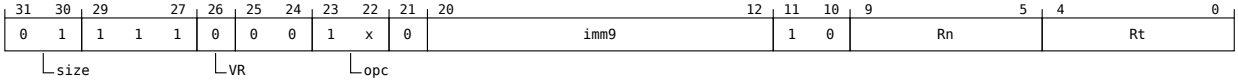
C6.2.149 LDTRSH

Load register signed halfword (unprivileged)

This instruction loads a halfword from memory, sign-extends it to 32 bits or 64 bits, and writes the result to a register. The address that is used for the load is calculated from a base register and an immediate offset.



Encoding for the 32-bit variant Applies when `(opc == 11)`

```
LDTRSH <Wt>, [<Xn|SP>{, #<simm>}]
```

Encoding for the 64-bit variant Applies when `(opc == 10)`

```
LDTRSH <Xt>, [<Xn|SP>{, #<simm>}]
```

Decode for all variants of this encoding

```
constant bits(64) offset = SignExtend(imm9, 64);
```

Assembler Symbols

<**Wt**> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

<**Xn|SP**> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<**simm**> Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the "imm9" field.

<**Xt**> Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

Shared Decode

```
constant integer t = UInt(Rt);
constant integer n = UInt(Rn);

constant integer datasize = 16;
constant integer regsize = 64 >> UInt(opc<0>);
constant boolean nontemporal = FALSE;
```

Operation

```
bits(64) address;

constant boolean privileged = AArch64.IsUnprivAccessPriv();
constant AccessDescriptor accdesc = CreateAccDescGPR(MemOp_LOAD, nontemporal, privileged, t);

if n == 31 then
    CheckSPAlignment();
    address = SP[64];
else
    address = X[n, 64];

address = AddressAdd(address, offset, accdesc);

constant bits(datasize) data = Mem[address, datasize DIV 8, accdesc];
X[t, regsize] = SignExtend(data, regsize);

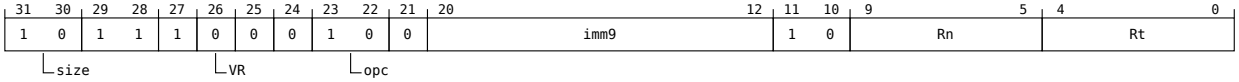
C6.2.150 LDTRSW

Load register signed word (unprivileged)

This instruction loads a word from memory, sign-extends it to 64 bits, and writes the result to a register. The address that is used for the load is calculated from a base register and an immediate offset.



Encoding

```
LDTRSW <Xt>, [<Xn|SP>{, #<simm>}]
```

Decode for this encoding

```
constant bits(64) offset = SignExtend(imm9, 64);
```

Assembler Symbols

<Xt> Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<simm> Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the "imm9" field.

Shared Decode

```
constant integer t = UInt(Rt);
constant integer n = UInt(Rn);

constant integer datasize = 32;
constant boolean nontemporal = FALSE;
```

Operation

```
bits(64) address;

constant boolean privileged = AArch64.IsUnprivAccessPriv();
constant AccessDescriptor accdesc = CreateAccDescGPR(MemOp_LOAD, nontemporal, privileged, t);

if n == 31 then
    CheckSPAlignment();
    address = SP[64];
else
    address = X[n, 64];

address = AddressAdd(address, offset, accdesc);

constant bits(datasize) data = Mem[address, datasize DIV 8, accdesc];
X[t, 64] = SignExtend(data, 64);
```

C6.2.151 LDUMAX, LDUMAXA, LDUMAXAL, LDUMAXL

Atomic unsigned maximum on word or doubleword

This instruction atomically loads a 32-bit word or 64-bit doubleword from memory, compares it against the value held in a register, and stores the larger value back to memory, treating the values as unsigned numbers. The value initially loaded from memory is returned in the destination register.

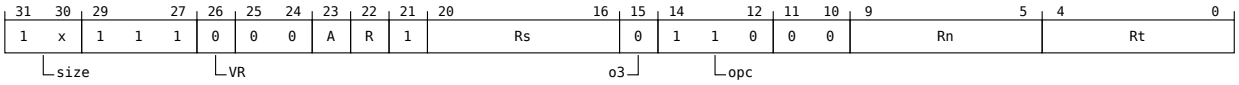
- If the destination register is not one of WZR or XZR, `LDUMAXA` and `LDUMAXAL` load from memory with acquire semantics.
- `LDUMAXL` and `LDUMAXAL` store to memory with release semantics.
- `LDUMAX` has neither acquire nor release semantics.

For more information about memory ordering semantics, see Load-Acquire, Store-Release.

For information about addressing modes, see Load/Store addressing modes.

This instruction is used by the alias STUMAX, STUMAXL.

Integer
(FEAT_LSE)



Encoding for the 32-bit no memory ordering variant Applies when `(size == 10 && A == 0 && R == 0)`

```

C6.2.153 LDUMAXH, LDUMAXAH, LDUMAXALH, LDUMAXLH

Atomic unsigned maximum on halfword

This instruction atomically loads a 16-bit halfword from memory, compares it against the value held in a register, and stores the larger value back to memory, treating the values as unsigned numbers. The value initially loaded from memory is returned in the destination register.

- If the destination register is not WZR, `LDUMAXAH` and `LDUMAXALH` load from memory with acquire semantics.
- `LDUMAXLH` and `LDUMAXALH` store to memory with release semantics.
- `LDUMAXH` has neither acquire nor release semantics.

For more information about memory ordering semantics, see Load-Acquire, Store-Release.

For information about addressing modes, see Load/Store addressing modes.

This instruction is used by the alias STUMAXH, STUMAXLH.

Integer
(FEAT_LSE)

C6.2.154 LDUMIN, LDUMINA, LDUMINAL, LDUMINL

Atomic unsigned minimum on word or doubleword

This instruction atomically loads a 32-bit word or 64-bit doubleword from memory, compares it against the value held in a register, and stores the smaller value back to memory, treating the values as unsigned numbers. The value initially loaded from memory is returned in the destination register.

- If the destination register is not one of WZR or XZR, `LDUMINA` and `LDUMINAL` load from memory with acquire semantics.
- `LDUMINL` and `LDUMINAL` store to memory with release semantics.
- `LDUMIN` has neither acquire nor release semantics.

For more information about memory ordering semantics, see Load-Acquire, Store-Release.

For information about addressing modes, see Load/Store addressing modes.

This instruction is used by the alias STUMIN, STUMINL.

Integer
(FEAT_LSE)

C6.2.155 LDUMINB, LDUMINAB, LDUMINALB, LDUMINLB

Atomic unsigned minimum on byte

This instruction atomically loads an 8-bit byte from memory, compares it against the value held in a register, and stores the smaller value back to memory, treating the values as unsigned numbers. The value initially loaded from memory is returned in the destination register.

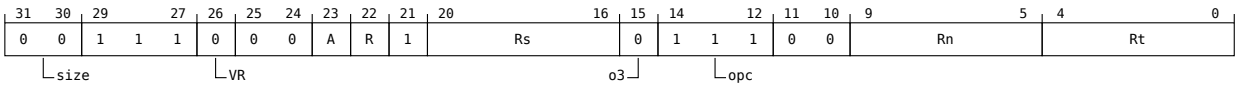
- If the destination register is not WZR, `LDUMINAB` and `LDUMINALB` load from memory with acquire semantics.
- `LDUMINLB` and `LDUMINALB` store to memory with release semantics.
- `LDUMINB` has neither acquire nor release semantics.

For more information about memory ordering semantics, see Load-Acquire, Store-Release.

For information about addressing modes, see Load/Store addressing modes.

This instruction is used by the alias STUMINB, STUMINLB.

Integer
(FEAT_LSE)



Encoding for the No memory ordering variant Applies when `(A == 0 && R == 0)`

```
LDUMINB <Ws>, <Wt>, [<Xn|SP>]
```

Encoding for the Acquire variant Applies when `(A == 1 && R == 0)`

```

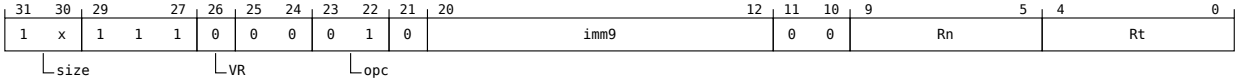
C6.2.157 LDUR

Load register (unscaled)

This instruction calculates an address from a base register and an immediate offset, loads a 32-bit word or 64-bit doubleword from memory, zero-extends it, and writes it to a register. For information about addressing modes, see Load/Store addressing modes.



Encoding for the 32-bit variant Applies when `(size == 10)`

```
LDUR <Wt>, [<Xn|SP>{, #<simm>}]
```

Encoding for the 64-bit variant Applies when `(size == 11)`

```
LDUR <Xt>, [<Xn|SP>{, #<simm>}]
```

Decode for all variants of this encoding

```
constant integer scale = UInt(size);
constant bits(64) offset = SignExtend(imm9, 64);
```

Assembler Symbols

<**Wt**> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

<**Xn|SP**> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<**simm**> Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the "imm9" field.

<**Xt**> Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

Shared Decode

```
constant integer n = UInt(Rn);
constant integer t = UInt(Rt);
constant integer datasize = 8 << scale;
constant integer regsize = if datasize == 64 then 64 else 32;
constant boolean nontemporal = FALSE;
```

Operation

```
bits(64) address;

constant boolean privileged = PSTATE.EL != EL0;
constant AccessDescriptor accdesc = CreateAccDescGPR(MemOp_LOAD, nontemporal, privileged, t);

if n == 31 then
    CheckSPAlignment();
    address = SP[64];
else
    address = X[n, 64];

address = AddressAdd(address, offset, accdesc);

constant bits(datasize) data = Mem[address, datasize DIV 8, accdesc];
X[t, regsize] = ZeroExtend(data, regsize);
```

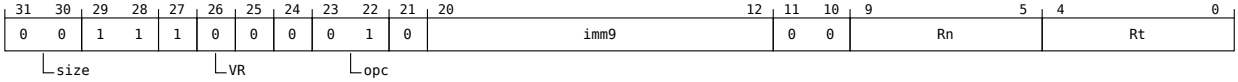
C6.2.158 LDURB

Load register byte (unscaled)

This instruction calculates an address from a base register and an immediate offset, loads a byte from memory, zero-extends it, and writes it to a register. For information about addressing modes, see Load/Store addressing modes.



Encoding

```
LDURB <Wt>, [<Xn|SP>{, #<simm>}]
```

Decode for this encoding

```
constant bits(64) offset = SignExtend(imm9, 64);
```

Assembler Symbols

<**Wt**> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

<**Xn|SP**> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<**simm**> Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the "imm9" field.

Shared Decode

```
constant integer n = UInt(Rn);
constant integer t = UInt(Rt);
constant integer datasize = 8;
constant boolean nontemporal = FALSE;
```

Operation

```
bits(64) address;

constant boolean privileged = PSTATE.EL != EL0;
constant AccessDescriptor accdesc = CreateAccDescGPR(MemOp_LOAD, nontemporal, privileged, t);

if n == 31 then
    CheckSPAlignment();
    address = SP[64];
else
    address = X[n, 64];

address = AddressAdd(address, offset, accdesc);

constant bits(datasize) data = Mem[address, datasize DIV 8, accdesc];
X[t, 32] = ZeroExtend(data, 32);
```

Operational information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

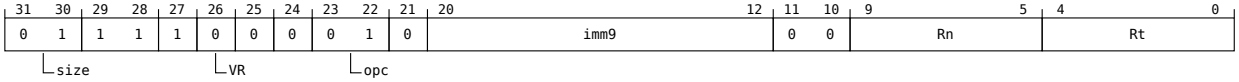
C6.2.159 LDURH

Load register halfword (unscaled)

This instruction calculates an address from a base register and an immediate offset, loads a halfword from memory, zero-extends it, and writes it to a register. For information about addressing modes, see Load/Store addressing modes.



Encoding

```
LDURH <Wt>, [<Xn|SP>{, #<simm>}]
```

Decode for this encoding

```
constant bits(64) offset = SignExtend(imm9, 64);
```

Assembler Symbols

<**Wt**> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

<**Xn|SP**> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<**simm**> Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the "imm9" field.

Shared Decode

```
constant integer n = UInt(Rn);
constant integer t = UInt(Rt);
constant integer datasize = 16;
constant boolean nontemporal = FALSE;
```

Operation

```
bits(64) address;

constant boolean privileged = PSTATE.EL != EL0;
constant AccessDescriptor accdesc = CreateAccDescGPR(MemOp_LOAD, nontemporal, privileged, t);

if n == 31 then
    CheckSPAlignment();
    address = SP[64];
else
    address = X[n, 64];

address = AddressAdd(address, offset, accdesc);

constant bits(datasize) data = Mem[address, datasize DIV 8, accdesc];
X[t, 32] = ZeroExtend(data, 32);
```

Operational information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

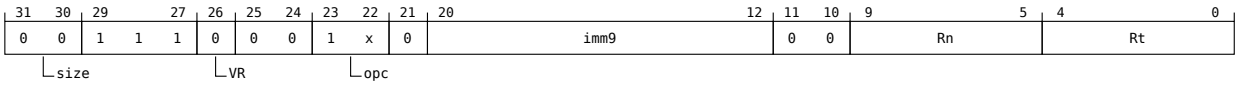
C6.2.160 LDURSB

Load register signed byte (unscaled)

This instruction calculates an address from a base register and an immediate offset, loads a signed byte from memory, sign-extends it, and writes it to a register. For information about addressing modes, see Load/Store addressing modes.



Encoding for the 32-bit variant Applies when `(opc == 11)`

```
LDURSB <Wt>, [<Xn|SP>{, #<simm>}]
```

Encoding for the 64-bit variant Applies when `(opc == 10)`

```
LDURSB <Xt>, [<Xn|SP>{, #<simm>}]
```

Decode for all variants of this encoding

```
constant bits(64) offset = SignExtend(imm9, 64);
```

Assembler Symbols

<Wt> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<simm> Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the "imm9" field.

<Xt> Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

Shared Decode

```
constant integer n = UInt(Rn);
constant integer t = UInt(Rt);
constant integer datasize = 8;
constant integer regsize = 64 >> UInt(opc<0>);
constant boolean nontemporal = FALSE;
```

Operation

```
bits(64) address;

constant boolean privileged = PSTATE.EL != EL0;
constant AccessDescriptor accdesc = CreateAccDescGPR(MemOp_LOAD, nontemporal, privileged, t);

if n == 31 then
    CheckSPAlignment();
    address = SP[64];
else
    address = X[n, 64];

address = AddressAdd(address, offset, accdesc);

constant bits(datasize) data = Mem[address, datasize DIV 8, accdesc];
X[t, regsize] = SignExtend(data, regsize);
```

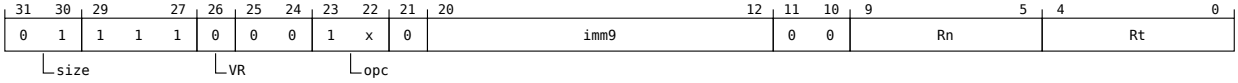
C6.2.161 LDURSH

Load register signed halfword (unscaled)

This instruction calculates an address from a base register and an immediate offset, loads a signed halfword from memory, sign-extends it, and writes it to a register. For information about addressing modes, see Load/Store addressing modes.



Encoding for the 32-bit variant Applies when `(opc == 11)`

```
LDURSH <Wt>, [<Xn|SP>{, #<simm>}]
```

Encoding for the 64-bit variant Applies when `(opc == 10)`

```
LDURSH <Xt>, [<Xn|SP>{, #<simm>}]
```

Decode for all variants of this encoding

```
constant bits(64) offset = SignExtend(imm9, 64);
```

Assembler Symbols

<**Wt**> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

<**Xn|SP**> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<**simm**> Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the "imm9" field.

<**Xt**> Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

Shared Decode

```
constant integer n = UInt(Rn);
constant integer t = UInt(Rt);
constant integer datasize = 16;
constant integer regsize = 64 >> UInt(opc<0>);
constant boolean nontemporal = FALSE;
```

Operation

```
bits(64) address;

constant boolean privileged = PSTATE.EL != EL0;
constant AccessDescriptor accdesc = CreateAccDescGPR(MemOp_LOAD, nontemporal, privileged, t);

if n == 31 then
    CheckSPAlignment();
    address = SP[64];
else
    address = X[n, 64];

address = AddressAdd(address, offset, accdesc);

constant bits(datasize) data = Mem[address, datasize DIV 8, accdesc];
X[t, regsize] = SignExtend(data, regsize);
```

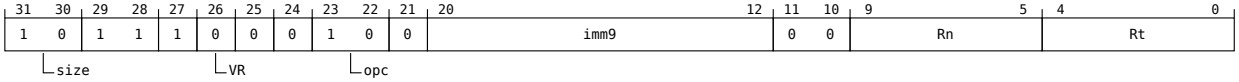
C6.2.162 LDURSW

Load register signed word (unscaled)

This instruction calculates an address from a base register and an immediate offset, loads a signed word from memory, sign-extends it, and writes it to a register. For information about addressing modes, see Load/Store addressing modes.



Encoding

```
LDURSW <Xt>, [<Xn|SP>{, #<simm>}]
```

Decode for this encoding

```
constant bits(64) offset = SignExtend(imm9, 64);
```

Assembler Symbols

<Xt> Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<simm> Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the "imm9" field.

Shared Decode

```
constant integer n = UInt(Rn);
constant integer t = UInt(Rt);
constant integer datasize = 32;
constant boolean nontemporal = FALSE;
```

Operation

```
bits(64) address;

constant boolean privileged = PSTATE.EL != EL0;
constant AccessDescriptor accdesc = CreateAccDescGPR(MemOp_LOAD, nontemporal, privileged, t);

if n == 31 then
    CheckSPAlignment();
    address = SP[64];
else
    address = X[n, 64];

address = AddressAdd(address, offset, accdesc);

constant bits(datasize) data = Mem[address, datasize DIV 8, accdesc];
X[t, 64] = SignExtend(data, 64);
```

Operational information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

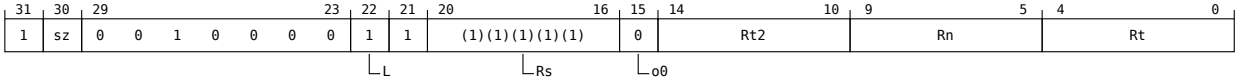
Non-Confidential

C6.2.163 LDXP

Load exclusive pair of registers

This instruction derives an address from a base register value, loads two 32-bit words or two 64-bit doublewords from memory, and writes them to two registers. For information on single-copy atomicity and alignment requirements, see Requirements for single-copy atomicity and Alignment of data accesses. The PE marks the physical address being accessed as an exclusive access. This exclusive access mark is checked by Store Exclusive instructions. See Synchronization and semaphores. For information about addressing modes, see Load/Store addressing modes.



Encoding for the 32-bit variant Applies when `(sz == 0)`

```
LDXP <Wt1>, <Wt2>, [<Xn|SP>{, #0}]
```

Encoding for the 64-bit variant Applies when `(sz == 1)`

```
LDXP <Xt1>, <Xt2>, [<Xn|SP>{, #0}]
```

Decode for all variants of this encoding

```
constant integer t = UInt(Rt);
constant integer t2 = UInt(Rt2);
constant integer n = UInt(Rn);

constant integer elsize = 32 << UInt(sz);
constant integer datasize = elsize * 2;
constant boolean acqrel = FALSE;

boolean rt_unknown = FALSE;
if t == t2 then
    constant Constraint c = ConstrainUnpredictable(Unpredictable_LDPOVERLAP);
    assert c IN {Constraint_UNKNOWN, Constraint_UNDEF, Constraint_NOP};
    case c of
        when Constraint_UNKNOWN    rt_unknown = TRUE;    // result is UNKNOWN
        when Constraint_UNDEF      EndOfDecode(Decode_UNDEF);
        when Constraint_NOP        EndOfDecode(Decode_NOP);
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Architectural Constraints on UNPREDICTABLE behaviors, and particularly LDXP.

Assembler Symbols

<**Wt1**> Is the 32-bit name of the first general-purpose register to be transferred, encoded in the “Rt” field.

<**Wt2**> Is the 32-bit name of the second general-purpose register to be transferred, encoded in the “Rt2” field.

<**Xn|SP**> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the “Rn” field.

<**Xt1**> Is the 64-bit name of the first general-purpose register to be transferred, encoded in the “Rt” field.

<**Xt2**> Is the 64-bit name of the second general-purpose register to be transferred, encoded in the “Rt2” field.

Operation

```
bits(64) address;
bits(datasize) data;
```

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

```
constant integer dbytes = datasize DIV 8;
constant boolean privileged = PSTATE.EL != EL0;
constant boolean ispair = elsize == 64;   // When elsize is 32, the access is single-copy atomic
constant AccessDescriptor accdesc = CreateAccDescExLDST(MemOp_LOAD, acqrel, privileged, ispair, t,
                                                        t2);

if n == 31 then
    CheckSPAlignment();
    address = SP[64];
else
    address = X[n, 64];

AArch64.SetExclusiveMonitors(address, dbytes, accdesc);

data = Mem[address, dbytes, accdesc];
if rt_unknown then
    // ConstrainedUNPREDICTABLE case
    X[t, datasize]  = bits(datasize) UNKNOWN;        // In this case t = t2
elsif BigEndian(accdesc.acctype) then
    X[t, elsize]  = data<elsize +: elsize>;
    X[t2, elsize] = data<0 +: elsize>;
else
    X[t, elsize]  = data<0 +: elsize>;
    X[t2, elsize] = data<elsize +: elsize>;
```

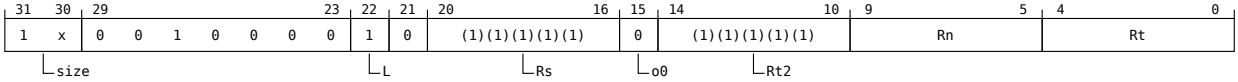
C6.2.164 LDXR

Load exclusive register

This instruction derives an address from a base register value, loads a 32-bit word or a 64-bit doubleword from memory, and writes it to a register. The memory access is atomic. The PE marks the physical address being accessed as an exclusive access. This exclusive access mark is checked by Store Exclusive instructions. See Synchronization and semaphores.

For information about addressing modes, see Load/Store addressing modes.



Encoding for the 32-bit variant Applies when `(size == 10)`

```
LDXR <Wt>, [<Xn|SP>{, #0}]
```

Encoding for the 64-bit variant Applies when `(size == 11)`

```
LDXR <Xt>, [<Xn|SP>{, #0}]
```

Decode for all variants of this encoding

```
constant integer t = UInt(Rt);
constant integer n = UInt(Rn);

constant integer elsize = 8 << UInt(size);
constant integer regsize = if elsize == 64 then 64 else 32;
constant boolean acqrel = FALSE;
```

Assembler Symbols

<Wt> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<Xt> Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

Operation

```
bits(64) address;
bits(elsize) data;

constant integer dbytes = elsize DIV 8;
constant boolean privileged = PSTATE.EL != EL0;
constant AccessDescriptor accdesc = CreateAccDescExLDST(MemOp_LOAD, acqrel, privileged, t);

if n == 31 then
    CheckSPAlignment();
    address = SP[64];
else
    address = X[n, 64];

AArch64.SetExclusiveMonitors(address, dbytes, accdesc);

data = Mem[address, dbytes, accdesc];
X[t, regsize] = ZeroExtend(data, regsize);
```

Operational information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

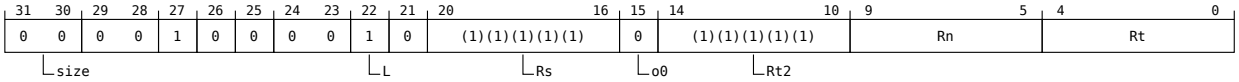
Non-Confidential

C6.2.165 LDXRB

Load exclusive register byte

This instruction derives an address from a base register value, loads a byte from memory, zero-extends it and writes it to a register. The memory access is atomic. The PE marks the physical address being accessed as an exclusive access. This exclusive access mark is checked by Store Exclusive instructions. See Synchronization and semaphores. For information about addressing modes, see Load/Store addressing modes.



Encoding

```
LDXRB <Wt>, [<Xn|SP>{, #0}]
```

Decode for this encoding

```
constant integer t = UInt(Rt);
constant integer n = UInt(Rn);

constant boolean acqrel = FALSE;
```

Assembler Symbols

<Wt> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

```
bits(64) address;
bits(8) data;

constant boolean privileged = PSTATE.EL != EL0;
constant AccessDescriptor accdesc = CreateAccDescExLDST(MemOp_LOAD, acqrel, privileged, t);

if n == 31 then
    CheckSPAlignment();
    address = SP[64];
else
    address = X[n, 64];

AArch64.SetExclusiveMonitors(address, 1, accdesc);

data = Mem[address, 1, accdesc];
X[t, 32] = ZeroExtend(data, 32);
```

Operational information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

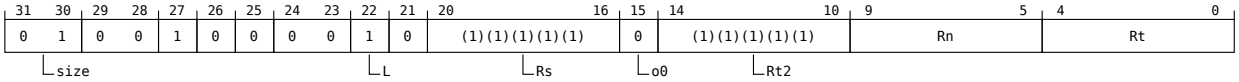
C6.2.166 LDXRH

Load exclusive register halfword

This instruction derives an address from a base register value, loads a halfword from memory, zero-extends it and writes it to a register. The memory access is atomic. The PE marks the physical address being accessed as an exclusive access. This exclusive access mark is checked by Store Exclusive instructions. See Synchronization and semaphores. For information about addressing modes, see Load/Store addressing modes.



Encoding

```
LDXRH <Wt>, [<Xn|SP>{, #0}]
```

Decode for this encoding

```
constant integer t = UInt(Rt);
constant integer n = UInt(Rn);

constant boolean acqrel = FALSE;
```

Assembler Symbols

<Wt> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

```
bits(64) address;
bits(16) data;

constant boolean privileged = PSTATE.EL != EL0;
constant AccessDescriptor accdesc = CreateAccDescExLDST(MemOp_LOAD, acqrel, privileged, t);

if n == 31 then
    CheckSPAlignment();
    address = SP[64];
else
    address = X[n, 64];

AArch64.SetExclusiveMonitors(address, 2, accdesc);

data = Mem[address, 2, accdesc];
X[t, 32] = ZeroExtend(data, 32);
```

Operational information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

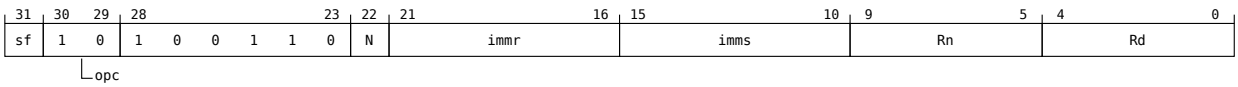
C6.2.167 LSL (immediate)

Logical shift left (immediate)

This instruction shifts a register value left by an immediate number of bits, shifting in zeros, and writes the result to the destination register.

This is an alias of UBFM. This means:

- The encodings in this description are named to match the encodings of UBFM.
- The description of UBFM gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.



Encoding for the 32-bit variant Applies when `(sf == 0 && N == 0 && imms != 011111)`

```
LSL <Wd>, <Wn>, #<shift>
```

is equivalent to

```
UBFM <Wd>, <Wn>, #(-<shift> MOD 32), #(31-<shift>)
```

and is the preferred disassembly when `UInt(imms) + 1 == UInt(immr)`.

Encoding for the 64-bit variant Applies when `(sf == 1 && N == 1 && imms != 111111)`

```
LSL <Xd>, <Xn>, #<shift>
```

is equivalent to

```
UBFM <Xd>, <Xn>, #(-<shift> MOD 64), #(63-<shift>)
```

and is the preferred disassembly when `UInt(imms) + 1 == UInt(immr)`.

Assembler Symbols

<**Wd**> Is the 32-bit name of the general-purpose destination register, encoded in the “Rd” field.

<**Wn**> Is the 32-bit name of the general-purpose source register, encoded in the “Rn” field.

<**shift**> For the “32-bit” variant: is the shift amount, in the range 0 to 31.

For the “64-bit” variant: is the shift amount, in the range 0 to 63.

<**Xd**> Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

<**Xn**> Is the 64-bit name of the general-purpose source register, encoded in the “Rn” field.

Operation

The description of UBFM gives the operational pseudocode for this instruction.

Operational Information

The description of UBFM gives the operational information for this instruction.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

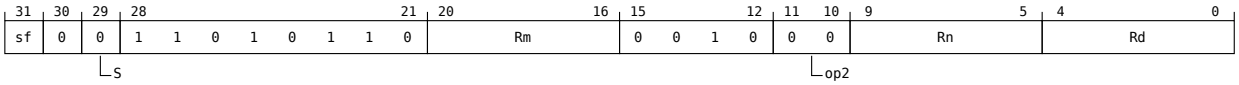
C6.2.168 LSL (register)

Logical shift left (register)

This instruction shifts a register value left by a variable number of bits, shifting in zeros, and writes the result to the destination register. The value of the second source register modulo the register size in bits gives the number of bits by which the first source register is left-shifted.

This is an alias of LSLV. This means:

- The encodings in this description are named to match the encodings of LSLV.
- The description of LSLV gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.



Encoding for the 32-bit variant Applies when `(sf == 0)`

```
LSL <Wd>, <Wn>, <Wm>
```

is equivalent to

```
LSLV <Wd>, <Wn>, <Wm>
```

and is always the preferred disassembly.

Encoding for the 64-bit variant Applies when `(sf == 1)`

```
LSL <Xd>, <Xn>, <Xm>
```

is equivalent to

```
LSLV <Xd>, <Xn>, <Xm>
```

and is always the preferred disassembly.

Assembler Symbols

<**Wd**> Is the 32-bit name of the general-purpose destination register, encoded in the “Rd” field.

<**Wn**> Is the 32-bit name of the first general-purpose source register, encoded in the “Rn” field.

<**Wm**> Is the 32-bit name of the second general-purpose source register holding a shift amount from 0 to 31 in its bottom 5 bits, encoded in the “Rm” field.

<**Xd**> Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

<**Xn**> Is the 64-bit name of the first general-purpose source register, encoded in the “Rn” field.

<**Xm**> Is the 64-bit name of the second general-purpose source register holding a shift amount from 0 to 63 in its bottom 6 bits, encoded in the “Rm” field.

Operation

The description of LSLV gives the operational pseudocode for this instruction.

Operational Information

The description of LSLV gives the operational information for this instruction.

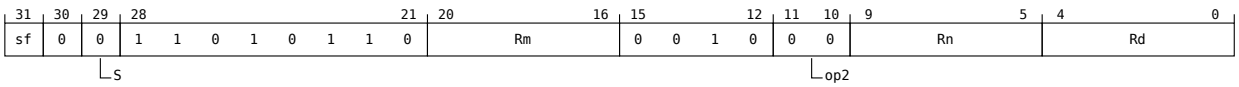
Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.169 LSLV

Logical shift left variable

This instruction shifts a register value left by a variable number of bits, shifting in zeros, and writes the result to the destination register. The value of the second source register modulo the register size in bits gives the number of bits by which the first source register is left-shifted.

This instruction is used by the alias LSL (register).



Encoding for the 32-bit variant Applies when `(sf == 0)`

```
LSLV <Wd>, <Wn>, <Wm>
```

Encoding for the 64-bit variant Applies when `(sf == 1)`

```
LSLV <Xd>, <Xn>, <Xm>
```

Decode for all variants of this encoding

```
constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer m = UInt(Rm);
constant integer datasize = 32 << UInt(sf);
constant ShiftType shift_type = DecodeShift(op2);
```

Assembler Symbols

<**Wd**> Is the 32-bit name of the general-purpose destination register, encoded in the “Rd” field.

<**Wn**> Is the 32-bit name of the first general-purpose source register, encoded in the “Rn” field.

<**Wm**> Is the 32-bit name of the second general-purpose source register holding a shift amount from 0 to 31 in its bottom 5 bits, encoded in the “Rm” field.

<**Xd**> Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

<**Xn**> Is the 64-bit name of the first general-purpose source register, encoded in the “Rn” field.

<**Xm**> Is the 64-bit name of the second general-purpose source register holding a shift amount from 0 to 63 in its bottom 6 bits, encoded in the “Rm” field.

Operation

```
constant bits(datasize) operand2 = X[m, datasize];

X[d, datasize] = ShiftReg(n, shift_type, UInt(operand2) MOD datasize, datasize);
```

Operational information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

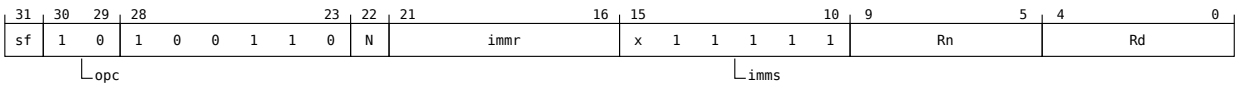
C6.2.170 LSR (immediate)

Logical shift right (immediate)

This instruction shifts a register value right by an immediate number of bits, shifting in zeros, and writes the result to the destination register.

This is an alias of UBFM. This means:

- The encodings in this description are named to match the encodings of UBFM.
- The description of UBFM gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.



Encoding for the 32-bit variant Applies when `(sf == 0 && N == 0 && imms == 011111)`

```
LSR <Wd>, <Wn>, #<shift>
```

is equivalent to

```
UBFM <Wd>, <Wn>, #<shift>, #31
```

and is always the preferred disassembly.

Encoding for the 64-bit variant Applies when `(sf == 1 && N == 1 && imms == 111111)`

```
LSR <Xd>, <Xn>, #<shift>
```

is equivalent to

```
UBFM <Xd>, <Xn>, #<shift>, #63
```

and is always the preferred disassembly.

Assembler Symbols

<**Wd**> Is the 32-bit name of the general-purpose destination register, encoded in the “Rd” field.

<**Wn**> Is the 32-bit name of the general-purpose source register, encoded in the “Rn” field.

<**shift**> For the “32-bit” variant: is the shift amount, in the range 0 to 31, encoded in the “immr” field.

For the “64-bit” variant: is the shift amount, in the range 0 to 63, encoded in the “immr” field.

<**Xd**> Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

<**Xn**> Is the 64-bit name of the general-purpose source register, encoded in the “Rn” field.

Operation

The description of UBFM gives the operational pseudocode for this instruction.

Operational Information

The description of UBFM gives the operational information for this instruction.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

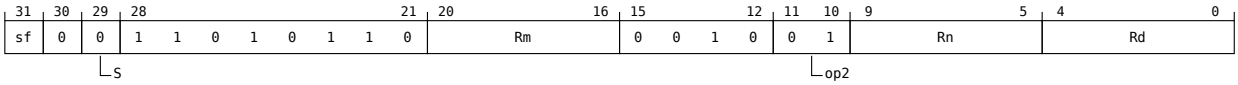
C6.2.171 LSR (register)

Logical shift right (register)

This instruction shifts a register value right by a variable number of bits, shifting in zeros, and writes the result to the destination register. The value of the second source register modulo the register size in bits gives the number of bits by which the first source register is right-shifted.

This is an alias of LSRV. This means:

- The encodings in this description are named to match the encodings of LSRV.
- The description of LSRV gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.



Encoding for the 32-bit variant Applies when `(sf == 0)`

```
LSR <Wd>, <Wn>, <Wm>
```

is equivalent to

```
LSRV <Wd>, <Wn>, <Wm>
```

and is always the preferred disassembly.

Encoding for the 64-bit variant Applies when `(sf == 1)`

```
LSR <Xd>, <Xn>, <Xm>
```

is equivalent to

```
LSRV <Xd>, <Xn>, <Xm>
```

and is always the preferred disassembly.

Assembler Symbols

<**Wd**> Is the 32-bit name of the general-purpose destination register, encoded in the “Rd” field.

<**Wn**> Is the 32-bit name of the first general-purpose source register, encoded in the “Rn” field.

<**Wm**> Is the 32-bit name of the second general-purpose source register holding a shift amount from 0 to 31 in its bottom 5 bits, encoded in the “Rm” field.

<**Xd**> Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

<**Xn**> Is the 64-bit name of the first general-purpose source register, encoded in the “Rn” field.

<**Xm**> Is the 64-bit name of the second general-purpose source register holding a shift amount from 0 to 63 in its bottom 6 bits, encoded in the “Rm” field.

Operation

The description of LSRV gives the operational pseudocode for this instruction.

Operational Information

The description of LSRV gives the operational information for this instruction.

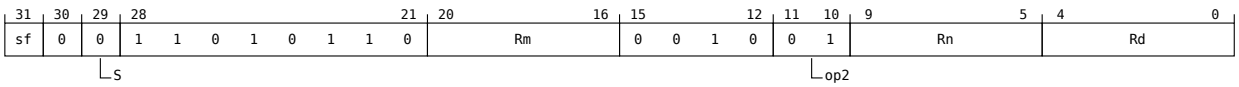
Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.172 LSRV

Logical shift right variable

This instruction shifts a register value right by a variable number of bits, shifting in zeros, and writes the result to the destination register. The value of the second source register modulo the register size in bits gives the number of bits by which the first source register is right-shifted.

This instruction is used by the alias LSR (register).



Encoding for the 32-bit variant Applies when `(sf == 0)`

```
LSRV <Wd>, <Wn>, <Wm>
```

Encoding for the 64-bit variant Applies when `(sf == 1)`

```
LSRV <Xd>, <Xn>, <Xm>
```

Decode for all variants of this encoding

```
constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer m = UInt(Rm);
constant integer datasize = 32 << UInt(sf);
constant ShiftType shift_type = DecodeShift(op2);
```

Assembler Symbols

<**Wd**> Is the 32-bit name of the general-purpose destination register, encoded in the “Rd” field.

<**Wn**> Is the 32-bit name of the first general-purpose source register, encoded in the “Rn” field.

<**Wm**> Is the 32-bit name of the second general-purpose source register holding a shift amount from 0 to 31 in its bottom 5 bits, encoded in the “Rm” field.

<**Xd**> Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

<**Xn**> Is the 64-bit name of the first general-purpose source register, encoded in the “Rn” field.

<**Xm**> Is the 64-bit name of the second general-purpose source register holding a shift amount from 0 to 63 in its bottom 6 bits, encoded in the “Rm” field.

Operation

```
constant bits(datasize) operand2 = X[m, datasize];

X[d, datasize] = ShiftReg(n, shift_type, UInt(operand2) MOD datasize, datasize);
```

Operational information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

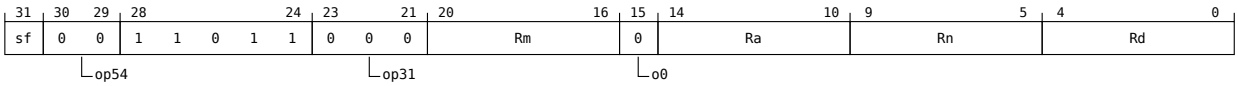
Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.173 MADD

Multiply-add

This instruction multiplies two register values, adds a third register value, and writes the result to the destination register.

This instruction is used by the alias MUL.



Encoding for the 32-bit variant Applies when `(sf == 0)`

```
MADD <Wd>, <Wn>, <Wm>, <Wa>
```

Encoding for the 64-bit variant Applies when `(sf == 1)`

```
MADD <Xd>, <Xn>, <Xm>, <Xa>
```

Decode for all variants of this encoding

```
constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer m = UInt(Rm);
constant integer a = UInt(Ra);
constant integer datasize = 32 << UInt(sf);
```

Assembler Symbols

<**Wd**> Is the 32-bit name of the general-purpose destination register, encoded in the “Rd” field.

<**Wn**> Is the 32-bit name of the first general-purpose source register holding the multiplicand, encoded in the “Rn” field.

<**Wm**> Is the 32-bit name of the second general-purpose source register holding the multiplier, encoded in the “Rm” field.

<**Wa**> Is the 32-bit name of the third general-purpose source register holding the addend, encoded in the “Ra” field.

<**Xd**> Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

<**Xn**> Is the 64-bit name of the first general-purpose source register holding the multiplicand, encoded in the “Rn” field.

<**Xm**> Is the 64-bit name of the second general-purpose source register holding the multiplier, encoded in the “Rm” field.

<**Xa**> Is the 64-bit name of the third general-purpose source register holding the addend, encoded in the “Ra” field.

Alias Conditions

Alias	Is preferred when
MUL	`Ra == '11111'`

Operation

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

```
constant bits(datasize) operand1 = X[n, datasize];
constant bits(datasize) operand2 = X[m, datasize];
constant bits(datasize) operand3 = X[a, datasize];

constant integer result = UInt(operand3) + (UInt(operand1) * UInt(operand2));

X[d, datasize] = result<datasize-1:0>;
```

Operational information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

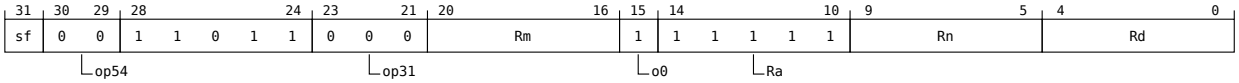
C6.2.174 MNEG

Multiply-negate

This instruction multiplies two register values, negates the product, and writes the result to the destination register.

This is an alias of MSUB. This means:

- The encodings in this description are named to match the encodings of MSUB.
- The description of MSUB gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.



Encoding for the 32-bit variant Applies when `(sf == 0)`

```
MNEG <Wd>, <Wn>, <Wm>
```

is equivalent to

```
MSUB <Wd>, <Wn>, <Wm>, WZR
```

and is always the preferred disassembly.

Encoding for the 64-bit variant Applies when `(sf == 1)`

```
MNEG <Xd>, <Xn>, <Xm>
```

is equivalent to

```
MSUB <Xd>, <Xn>, <Xm>, XZR
```

and is always the preferred disassembly.

Assembler Symbols

<**Wd**> Is the 32-bit name of the general-purpose destination register, encoded in the “Rd” field.

<**Wn**> Is the 32-bit name of the first general-purpose source register holding the multiplicand, encoded in the “Rn” field.

<**Wm**> Is the 32-bit name of the second general-purpose source register holding the multiplier, encoded in the “Rm” field.

<**Xd**> Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

<**Xn**> Is the 64-bit name of the first general-purpose source register holding the multiplicand, encoded in the “Rn” field.

<**Xm**> Is the 64-bit name of the second general-purpose source register holding the multiplier, encoded in the “Rm” field.

Operation

The description of MSUB gives the operational pseudocode for this instruction.

Operational Information

The description of MSUB gives the operational information for this instruction.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

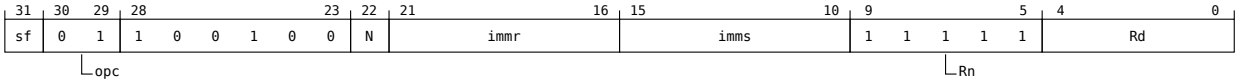
C6.2.175 MOV (bitmask immediate)

Move bitmask immediate value

This instruction writes a bitmask immediate value to a register.

This is an alias of ORR (immediate). This means:

- The encodings in this description are named to match the encodings of ORR (immediate).
- The description of ORR (immediate) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.



Encoding for the 32-bit variant Applies when `(sf == 0 && N == 0)`

```
MOV <Wd|WSP>, #<imm>
```

is equivalent to

```
ORR <Wd|WSP>, WZR, #<imm>
```

and is the preferred disassembly when `!MoveWidePreferred(sf, N, imms, immr)`.

Encoding for the 64-bit variant Applies when `(sf == 1)`

```
MOV <Xd|SP>, #<imm>
```

is equivalent to

```
ORR <Xd|SP>, XZR, #<imm>
```

and is the preferred disassembly when `!MoveWidePreferred(sf, N, imms, immr)`.

Assembler Symbols

<**Wd**|**WSP**> Is the 32-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.

<**imm**> For the "32-bit" variant: is the bitmask immediate, encoded in "imms:immr", but excluding values which could be encoded by MOVZ or MOVN.

For the "64-bit" variant: is the bitmask immediate, encoded in "N:imms:immr", but excluding values which could be encoded by MOVZ or MOVN.

<**Xd**|**SP**> Is the 64-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.

Operation

The description of ORR (immediate) gives the operational pseudocode for this instruction.

Operational Information

The description of ORR (immediate) gives the operational information for this instruction.

C6.2.176 MOV (inverted wide immediate)

Move inverted wide immediate value

This instruction moves an inverted 16-bit immediate value to a register.

This is an alias of MOVN. This means:

- The encodings in this description are named to match the encodings of MOVN.
- The description of MOVN gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

Encoding for the 32-bit variant Applies when `(sf == 0 && hw == 0x)`

```
MOV <Wd>, #<imm>
```

is equivalent to

```
MOVN <Wd>, #<imm16>, LSL #<shift>
```

and is the preferred disassembly when `!(IsZero(imm16) && hw != '00') && !IsOnes(imm16).`

Encoding for the 64-bit variant Applies when `(sf == 1)`

```
MOV <Xd>, #<imm>
```

is equivalent to

```
MOVN <Xd>, #<imm16>, LSL #<shift>
```

and is the preferred disassembly when `!(IsZero(imm16) && hw != '00').`

Assembler Symbols

<**Wd**> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

<**imm**> For the "32-bit" variant: is a 32-bit immediate, the bitwise inverse of which can be encoded in "imm16:hw", but excluding 0xFFFF0000 and 0x0000FFFF

For the "64-bit" variant: is a 64-bit immediate, the bitwise inverse of which can be encoded in "imm16:hw".

<**Xd**> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

Operation

The description of MOVN gives the operational pseudocode for this instruction.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

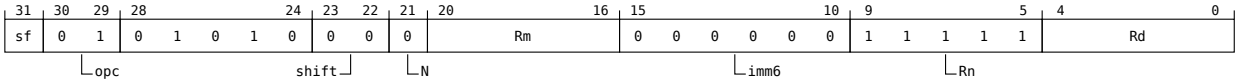
C6.2.177 MOV (register)

Move register value

This instruction copies the value in a source register to the destination register.

This is an alias of ORR (shifted register). This means:

- The encodings in this description are named to match the encodings of ORR (shifted register).
- The description of ORR (shifted register) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.



Encoding for the 32-bit variant Applies when `(sf == 0)`

```
MOV <Wd>, <Wm>
```

is equivalent to

```
ORR <Wd>, WZR, <Wm>
```

and is always the preferred disassembly.

Encoding for the 64-bit variant Applies when `(sf == 1)`

```
MOV <Xd>, <Xm>
```

is equivalent to

```
ORR <Xd>, XZR, <Xm>
```

and is always the preferred disassembly.

Assembler Symbols

<**Wd**> Is the 32-bit name of the general-purpose destination register, encoded in the “Rd” field.

<**Wm**> Is the 32-bit name of the general-purpose source register, encoded in the “Rm” field.

<**Xd**> Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

<**Xm**> Is the 64-bit name of the general-purpose source register, encoded in the “Rm” field.

Operation

The description of ORR (shifted register) gives the operational pseudocode for this instruction.

Operational Information

The description of ORR (shifted register) gives the operational information for this instruction.

Non-Confidential

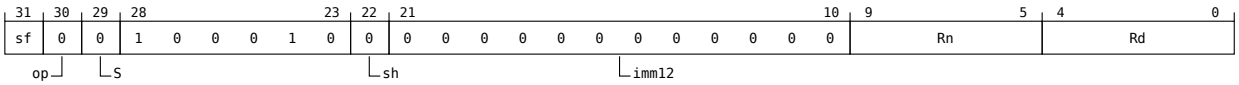
C6.2.178 MOV (to/from SP)

Move register value to or from SP

This instruction copies the value of a register to or from the stack pointer.

This is an alias of ADD (immediate). This means:

- The encodings in this description are named to match the encodings of ADD (immediate).
- The description of ADD (immediate) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.



Encoding for the 32-bit variant Applies when `(sf == 0)`

```
MOV <Wd|WSP>, <Wn|WSP>
```

is equivalent to

```
ADD <Wd|WSP>, <Wn|WSP>, #0
```

and is the preferred disassembly when `Rd == '11111' || Rn == '11111'`.

Encoding for the 64-bit variant Applies when `(sf == 1)`

```
MOV <Xd|SP>, <Xn|SP>
```

is equivalent to

```
ADD <Xd|SP>, <Xn|SP>, #0
```

and is the preferred disassembly when `Rd == '11111' || Rn == '11111'`.

Assembler Symbols

<**Wd**|**WSP**> Is the 32-bit name of the destination general-purpose register or stack pointer, encoded in the “Rd” field.

<**Wn**|**WSP**> Is the 32-bit name of the source general-purpose register or stack pointer, encoded in the “Rn” field.

<**Xd**|**SP**> Is the 64-bit name of the destination general-purpose register or stack pointer, encoded in the “Rd” field.

<**Xn**|**SP**> Is the 64-bit name of the source general-purpose register or stack pointer, encoded in the “Rn” field.

Operation

The description of ADD (immediate) gives the operational pseudocode for this instruction.

Operational Information

The description of ADD (immediate) gives the operational information for this instruction.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.179 MOV (wide immediate)

Move wide immediate value

This instruction moves a 16-bit immediate value to a register.

This is an alias of MOVZ. This means:

- The encodings in this description are named to match the encodings of MOVZ.
- The description of MOVZ gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

Encoding for the 32-bit variant Applies when `(sf == 0 && hw == 0x)`

```
MOV <Wd>, #<imm>
```

is equivalent to

```
MOVZ <Wd>, #<imm16>, LSL #<shift>
```

and is the preferred disassembly when `!(IsZero(imm16) && hw != '00')`.

Encoding for the 64-bit variant Applies when `(sf == 1)`

```
MOV <Xd>, #<imm>
```

is equivalent to

```
MOVZ <Xd>, #<imm16>, LSL #<shift>
```

and is the preferred disassembly when `!(IsZero(imm16) && hw != '00')`.

Assembler Symbols

<**Wd**> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

<**imm**> For the "32-bit" variant: is a 32-bit immediate which can be encoded in "imm16:hw".

For the "64-bit" variant: is a 64-bit immediate which can be encoded in "imm16:hw".

<**Xd**> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

Operation

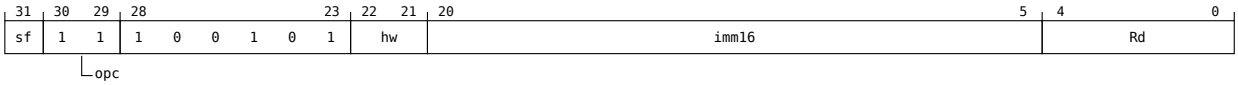
The description of MOVZ gives the operational pseudocode for this instruction.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.180 MOVK

Move wide with keep

This instruction moves an optionally-shifted 16-bit immediate value into a register, keeping other bits unchanged.



Encoding for the 32-bit variant Applies when `(sf == 0 && hw == 0x)`

```
MOVK <Wd>, #<imm>{, LSL #<shift>}
```

Encoding for the 64-bit variant Applies when `(sf == 1)`

```
MOVK <Xd>, #<imm>{, LSL #<shift>}
```

Decode for all variants of this encoding

```
if sf == '0' && hw<1> == '1' then EndOfDecode(Decode_UNDEF);

constant integer d = UInt(Rd);
constant integer datasize = 32 << UInt(sf);
constant bits(16) imm = imm16;
constant integer pos = UInt(hw) << 4;
```

Assembler Symbols

<**Wd**> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

<**imm**> Is the 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm16" field.

<**shift**> For the "32-bit" variant: is the amount by which to shift the immediate left, either 0 (the default) or 16, encoded in the "hw" field as <shift>/16.

For the "64-bit" variant: is the amount by which to shift the immediate left, either 0 (the default), 16, 32 or 48, encoded in the "hw" field as <shift>/16.

<**Xd**> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

Operation

```
bits(datasize) result = X[d, datasize];
result<pos+15:pos> = imm;
X[d, datasize] = result;
```

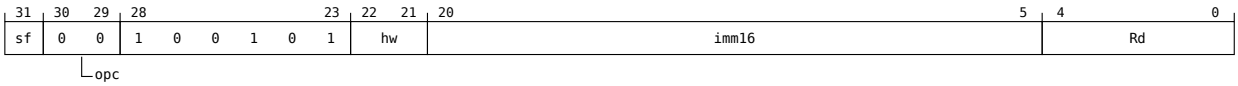
Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.181 MOVN

Move wide with NOT

This instruction moves the inverse of an optionally-shifted 16-bit immediate value to a register.

This instruction is used by the alias MOV (inverted wide immediate).



Encoding for the 32-bit variant Applies when `(sf == 0 && hw == 0x)`

```
MOVN <Wd>, #<imm>{, LSL #<shift>}
```

Encoding for the 64-bit variant Applies when `(sf == 1)`

```
MOVN <Xd>, #<imm>{, LSL #<shift>}
```

Decode for all variants of this encoding

```
if sf == '0' && hw<1> == '1' then EndOfDecode(Decode_UNDEF);

constant integer d = UInt(Rd);
constant integer datasize = 32 << UInt(sf);
constant bits(16) imm = imm16;
constant integer pos = UInt(hw) << 4;
```

Assembler Symbols

<**Wd**> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

<**imm**> Is the 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm16" field.

<**shift**> For the "32-bit" variant: is the amount by which to shift the immediate left, either 0 (the default) or 16, encoded in the "hw" field as <shift>/16.

For the "64-bit" variant: is the amount by which to shift the immediate left, either 0 (the default), 16, 32 or 48, encoded in the "hw" field as <shift>/16.

<**Xd**> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

Alias Conditions

Alias	Of variant	Is preferred when
MOV (inverted wide immediate)	32-bit	`!(IsZero(imm16) && hw != '00') && !IsOnes(imm16)`
MOV (inverted wide immediate)	64-bit	`!(IsZero(imm16) && hw != '00')`

Operation

```
bits(datasize) result = Zeros(datasize);
result<pos+15:pos> = imm;
X[d, datasize] = NOT(result);
```

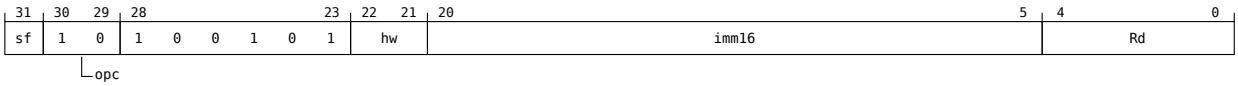
Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.182 MOVZ

Move wide with zero

This instruction moves an optionally-shifted 16-bit immediate value to a register.

This instruction is used by the alias MOV (wide immediate).



Encoding for the 32-bit variant Applies when `(sf == 0 && hw == 0x)`

```
MOVZ <Wd>, #<imm>{, LSL #<shift>}
```

Encoding for the 64-bit variant Applies when `(sf == 1)`

```
MOVZ <Xd>, #<imm>{, LSL #<shift>}
```

Decode for all variants of this encoding

```
if sf == '0' && hw<1> == '1' then EndOfDecode(Decode_UNDEF);

constant integer d = UInt(Rd);
constant integer datasize = 32 << UInt(sf);
constant bits(16) imm = imm16;
constant integer pos = UInt(hw) << 4;
```

Assembler Symbols

<**Wd**> Is the 32-bit name of the general-purpose destination register, encoded in the “Rd” field.

<**imm**> Is the 16-bit unsigned immediate, in the range 0 to 65535, encoded in the “imm16” field.

<**shift**> For the “32-bit” variant: is the amount by which to shift the immediate left, either 0 (the default) or 16, encoded in the “hw” field as <shift>/16.

For the “64-bit” variant: is the amount by which to shift the immediate left, either 0 (the default), 16, 32 or 48, encoded in the “hw” field as <shift>/16.

<**Xd**> Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

Alias Conditions

Alias	Is preferred when
MOV (wide immediate)	!(IsZero(imm16) && hw != '00')

Operation

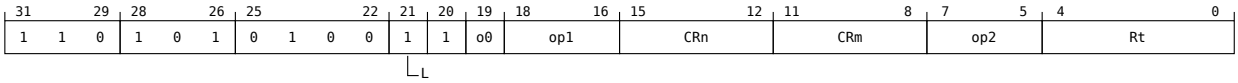
```
bits(datasize) result = Zeros(datasize);
result<pos+15:pos> = imm;
X[d, datasize] = result;
```

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.183 MRS

Move System register to general-purpose register

This instruction allows the PE to read an AArch64 System register into a general-purpose register.



Encoding

```
MRS <Xt>, (<systemreg>|S<op0>_<op1>_<Cn>_<Cm>_<op2>)
```

Decode for this encoding

```
constant integer t       = UInt(Rt);
constant bits(1) sys_L   = L;
constant bits(2) sys_op0 = '1' : o0;
constant bits(3) sys_op1 = op1;
constant bits(3) sys_op2 = op2;
constant bits(4) sys_crn = CRn;
constant bits(4) sys_crm = CRm;
```

Assembler Symbols

<Xt> Is the 64-bit name of the general-purpose destination register, encoded in the “Rt” field.

<systemreg> Is a System register name, encoded in “o0:op1:CRn:CRm:op2”.

The System register names are defined in AArch64 System Register Descriptions.

<op0> Is an unsigned immediate, encoded in “o0”:

o0	<op0>
0	2
1	3

<op1> Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the “op1” field.

<Cn> Is a name ’Cn’, with ’n’ in the range 0 to 15, encoded in the “CRn” field.

<Cm> Is a name ’Cm’, with ’m’ in the range 0 to 15, encoded in the “CRm” field.

<op2> Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the “op2” field.

Operation

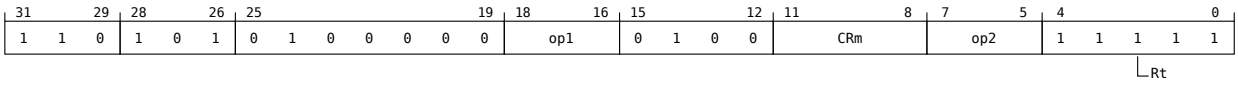
```
AArch64.SysRegRead(sys_op0, sys_op1, sys_crn, sys_crm, sys_op2, t);
```

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.184 MSR (immediate)

Move immediate value to special register

This instruction moves an immediate value to selected bits of the PSTATE. For more information, see Process state, PSTATE.



Encoding Applies when `(!(op1 == 000 && op2 IN {00x, 010}))`

```
MSR <pstatefield>, #<imm>
```

Decode for this encoding

```
if op1 == '000' && op2 == '000' then SEE "CFINV";

bits(2) min_EL;
boolean need_secure = FALSE;

case op1 of
    when '00x'
        min_EL = EL1;
    when '010'
        min_EL = EL1;
    when '011'
        min_EL = EL0;
    when '100'
        min_EL = EL2;
    when '101'
        EndOfDecode(Decode_UNDEF);
    when '110'
        min_EL = EL3;
    when '111'
        min_EL = EL1;
        need_secure = TRUE;

constant bits(4) operand = CRm;
PSTATEField field;
case op1:op2 of
    when '000 011'
        if !IsFeatureImplemented(FEAT_UAO) then EndOfDecode(Decode_UNDEF);
        field = PSTATEField_UAO;
    when '000 100'
        if !IsFeatureImplemented(FEAT_PAN) then EndOfDecode(Decode_UNDEF);
        field = PSTATEField_PAN;
    when '000 101' field = PSTATEField_SP;
    when '001 000'
        case CRm of
            otherwise
                EndOfDecode(Decode_UNDEF);
    when '011 010'
        if !IsFeatureImplemented(FEAT_DIT) then EndOfDecode(Decode_UNDEF);
        field = PSTATEField_DIT;
    when '011 110' field = PSTATEField_DAIFSet;
    when '011 111' field = PSTATEField_DAIFClr;
    when '011 001'
        if !IsFeatureImplemented(FEAT_SSBS) then EndOfDecode(Decode_UNDEF);
        field = PSTATEField_SSBS;
    otherwise      EndOfDecode(Decode_UNDEF);
```

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Assembler Symbols

<**pstatefield**> Is a PSTATE field name. For the MSR instruction, this is encoded in "op1:op2:op2":

op1	op2	<pstatefield>	Architectural Feature
000	011	UAO	FEAT_UAO
000	100	PAN	FEAT_PAN
000	101	SPSel	-
000	11x	RESERVED	-
001	xxx	RESERVED	-
010	xxx	RESERVED	-
011	000	RESERVED	-
011	001	SSBS	FEAT_SSBS
011	010	DIT	FEAT_DIT
011	011	RESERVED	-
011	10x	RESERVED	-
011	110	DAIFSet	-
011	111	DAIFClr	-
1xx	xxx	RESERVED	-

<**imm**> Is a 4-bit unsigned immediate, in the range 0 to 15, encoded in the "CRm" field.

Operation

```
if UInt(PSTATE.EL) < UInt(min_EL) then UNDEFINED;
if need_secure && CurrentSecurityState() != SS_Secure then UNDEFINED;

case field of
    when PSTATEField_SSBS
        PSTATE.SSBS = operand<0>;
    when PSTATEField_SP
        PSTATE.SP = operand<0>;
    when PSTATEField_DAIFSet
        AArch64.CheckDAIFAccess(PSTATEField_DAIFSet);
        PSTATE.D = PSTATE.D OR operand<3>;
        PSTATE.A = PSTATE.A OR operand<2>;
        PSTATE.I = PSTATE.I OR operand<1>;
        PSTATE.F = PSTATE.F OR operand<0>;
    when PSTATEField_DAIFClr
        AArch64.CheckDAIFAccess(PSTATEField_DAIFClr);
        PSTATE.D = PSTATE.D AND NOT(operand<3>);
        PSTATE.A = PSTATE.A AND NOT(operand<2>);
        PSTATE.I = PSTATE.I AND NOT(operand<1>);
        PSTATE.F = PSTATE.F AND NOT(operand<0>);
    when PSTATEField_PAN
        PSTATE.PAN = operand<0>;
    when PSTATEField_UAO
        PSTATE.UAO = operand<0>;
    when PSTATEField_DIT
        PSTATE.DIT = operand<0>;
```

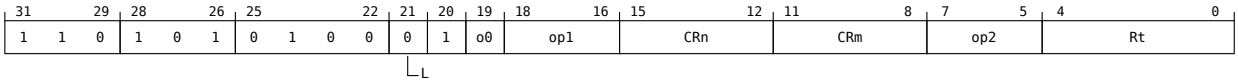
C6.2.185 MSR (register)

Move general-purpose register to System register

This instruction allows the PE to write an AArch64 System register from a general-purpose register.



Encoding

```
MSR (<systemreg>|S<op0>_<op1>_<Cn>_<Cm>_<op2>), <Xt>
```

Decode for this encoding

```
constant integer t       = UInt(Rt);
constant bits(1) sys_L   = L;
constant bits(2) sys_op0 = '1' : o0;
constant bits(3) sys_op1 = op1;
constant bits(3) sys_op2 = op2;
constant bits(4) sys_crn = CRn;
constant bits(4) sys_crm = CRm;
```

Assembler Symbols

<**systemreg**> Is a System register name, encoded in “o0:op1:CRn:CRm:op2”.

The System register names are defined in AArch64 System Register Descriptions.

<**op0**> Is an unsigned immediate, encoded in “o0”:

o0	<op0>
0	2
1	3

<**op1**> Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the “op1” field.

<**Cn**> Is a name ’Cn’, with ’n’ in the range 0 to 15, encoded in the “CRn” field.

<**Cm**> Is a name ’Cm’, with ’m’ in the range 0 to 15, encoded in the “CRm” field.

<**op2**> Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the “op2” field.

<**Xt**> Is the 64-bit name of the general-purpose source register, encoded in the “Rt” field.

Operation

```
AArch64.SysRegWrite(sys_op0, sys_op1, sys_crn, sys_crm, sys_op2, t);
```

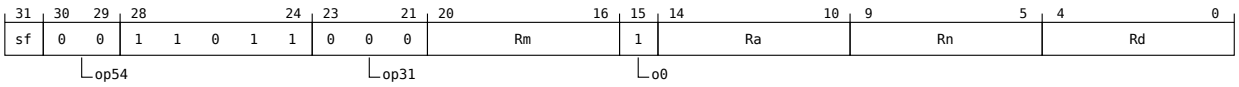
Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.186 MSUB

Multiply-subtract

This instruction multiplies two register values, subtracts the product from a third register value, and writes the result to the destination register.

This instruction is used by the alias MNEG.



Encoding for the 32-bit variant Applies when `(sf == 0)`

```
MSUB <Wd>, <Wn>, <Wm>, <Wa>
```

Encoding for the 64-bit variant Applies when `(sf == 1)`

```
MSUB <Xd>, <Xn>, <Xm>, <Xa>
```

Decode for all variants of this encoding

```
constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer m = UInt(Rm);
constant integer a = UInt(Ra);
constant integer datasize = 32 << UInt(sf);
```

Assembler Symbols

<**Wd**> Is the 32-bit name of the general-purpose destination register, encoded in the “Rd” field.

<**Wn**> Is the 32-bit name of the first general-purpose source register holding the multiplicand, encoded in the “Rn” field.

<**Wm**> Is the 32-bit name of the second general-purpose source register holding the multiplier, encoded in the “Rm” field.

<**Wa**> Is the 32-bit name of the third general-purpose source register holding the minuend, encoded in the “Ra” field.

<**Xd**> Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

<**Xn**> Is the 64-bit name of the first general-purpose source register holding the multiplicand, encoded in the “Rn” field.

<**Xm**> Is the 64-bit name of the second general-purpose source register holding the multiplier, encoded in the “Rm” field.

<**Xa**> Is the 64-bit name of the third general-purpose source register holding the minuend, encoded in the “Ra” field.

Alias Conditions

Alias	Is preferred when
MNEG	`Ra == '11111'`

Operation

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

```
constant bits(datasize) operand1 = X[n, datasize];
constant bits(datasize) operand2 = X[m, datasize];
constant bits(datasize) operand3 = X[a, datasize];

constant integer result = UInt(operand3) - (UInt(operand1) * UInt(operand2));

X[d, datasize] = result<datasize-1:0>;
```

Operational information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

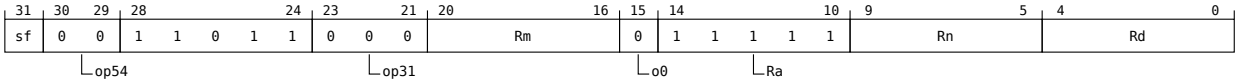
C6.2.187 MUL

Multiply

This instruction multiplies two register values and writes the result to the destination register.

This is an alias of MADD. This means:

- The encodings in this description are named to match the encodings of MADD.
- The description of MADD gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.



Encoding for the 32-bit variant Applies when `(sf == 0)`

```
MUL <Wd>, <Wn>, <Wm>
```

is equivalent to

```
MADD <Wd>, <Wn>, <Wm>, WZR
```

and is always the preferred disassembly.

Encoding for the 64-bit variant Applies when `(sf == 1)`

```
MUL <Xd>, <Xn>, <Xm>
```

is equivalent to

```
MADD <Xd>, <Xn>, <Xm>, XZR
```

and is always the preferred disassembly.

Assembler Symbols

<**Wd**> Is the 32-bit name of the general-purpose destination register, encoded in the “Rd” field.

<**Wn**> Is the 32-bit name of the first general-purpose source register holding the multiplicand, encoded in the “Rn” field.

<**Wm**> Is the 32-bit name of the second general-purpose source register holding the multiplier, encoded in the “Rm” field.

<**Xd**> Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

<**Xn**> Is the 64-bit name of the first general-purpose source register holding the multiplicand, encoded in the “Rn” field.

<**Xm**> Is the 64-bit name of the second general-purpose source register holding the multiplier, encoded in the “Rm” field.

Operation

The description of MADD gives the operational pseudocode for this instruction.

Operational Information

The description of MADD gives the operational information for this instruction.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

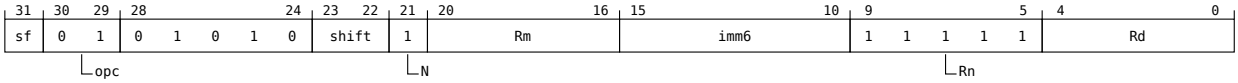
C6.2.188 MVN

Bitwise NOT

This instruction writes the bitwise inverse of a register value to the destination register.

This is an alias of ORN (shifted register). This means:

- The encodings in this description are named to match the encodings of ORN (shifted register).
- The description of ORN (shifted register) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.



Encoding for the 32-bit variant Applies when `(sf == 0)`

```
MVN <Wd>, <Wm>{, <shift> #<amount>}
```

is equivalent to

```
ORN <Wd>, WZR, <Wm>{, <shift> #<amount>}
```

and is always the preferred disassembly.

Encoding for the 64-bit variant Applies when `(sf == 1)`

```
MVN <Xd>, <Xm>{, <shift> #<amount>}
```

is equivalent to

```
ORN <Xd>, XZR, <Xm>{, <shift> #<amount>}
```

and is always the preferred disassembly.

Assembler Symbols

<**Wd**> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

<**Wm**> Is the 32-bit name of the general-purpose source register, encoded in the "Rm" field.

<**shift**> Is the optional shift to be applied to the final source, defaulting to LSL and encoded in "shift":

shift	<**shift**>
00	LSL
01	LSR
10	ASR
11	ROR

<**amount**> For the "32-bit" variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.

For the "64-bit" variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field.

<**Xd**> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

<**Xm**> Is the 64-bit name of the general-purpose source register, encoded in the “Rm” field.

Operation

The description of ORN (shifted register) gives the operational pseudocode for this instruction.

Operational Information

The description of ORN (shifted register) gives the operational information for this instruction.

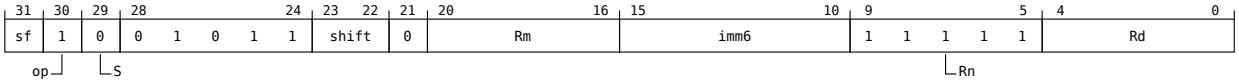
C6.2.189 NEG (shifted register)

Negate (shifted register)

This instruction negates an optionally-shifted register value, and writes the result to the destination register.

This is an alias of SUB (shifted register). This means:

- The encodings in this description are named to match the encodings of SUB (shifted register).
- The description of SUB (shifted register) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.



Encoding for the 32-bit variant Applies when `(sf == 0)`

```
NEG <Wd>, <Wm>{, <shift> #<amount>}
```

is equivalent to

```
SUB <Wd>, WZR, <Wm>{, <shift> #<amount>}
```

and is always the preferred disassembly.

Encoding for the 64-bit variant Applies when `(sf == 1)`

```
NEG <Xd>, <Xm>{, <shift> #<amount>}
```

is equivalent to

```
SUB <Xd>, XZR, <Xm>{, <shift> #<amount>}
```

and is always the preferred disassembly.

Assembler Symbols

<**Wd**> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

<**Wm**> Is the 32-bit name of the general-purpose source register, encoded in the "Rm" field.

<**shift**> Is the optional shift type to be applied to the second source operand, defaulting to LSL and encoded in "shift":

shift	<**shift**>
00	LSL
01	LSR
10	ASR
11	RESERVED

<**amount**> For the "32-bit" variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.

For the "64-bit" variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field.

<**Xd**> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

<Xm> Is the 64-bit name of the general-purpose source register, encoded in the “Rm” field.

Operation

The description of SUB (shifted register) gives the operational pseudocode for this instruction.

Operational Information

The description of SUB (shifted register) gives the operational information for this instruction.

Non-Confidential

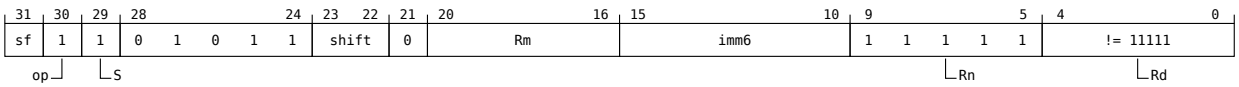
C6.2.190 NEGS

Negate, setting flags

This instruction negates an optionally-shifted register value, and writes the result to the destination register. It updates the condition flags based on the result.

This is an alias of SUBS (shifted register). This means:

- The encodings in this description are named to match the encodings of SUBS (shifted register).
- The description of SUBS (shifted register) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.



Encoding for the 32-bit variant Applies when `(sf == 0)`

```
NEGS <Wd>, <Wm>{, <shift> #<amount>}
```

is equivalent to

```
SUBS <Wd>, WZR, <Wm>{, <shift> #<amount>}
```

and is always the preferred disassembly.

Encoding for the 64-bit variant Applies when `(sf == 1)`

```
NEGS <Xd>, <Xm>{, <shift> #<amount>}
```

is equivalent to

```
SUBS <Xd>, XZR, <Xm>{, <shift> #<amount>}
```

and is always the preferred disassembly.

Assembler Symbols

<**Wd**> Is the 32-bit name of the general-purpose destination register, encoded in the “Rd” field.

<**Wm**> Is the 32-bit name of the general-purpose source register, encoded in the “Rm” field.

<**shift**> Is the optional shift type to be applied to the second source operand, defaulting to LSL and encoded in “shift”:

shift	<**shift**>
00	LSL
01	LSR
10	ASR
11	RESERVED

<**amount**> For the “32-bit” variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the “imm6” field.

For the “64-bit” variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the “imm6” field.

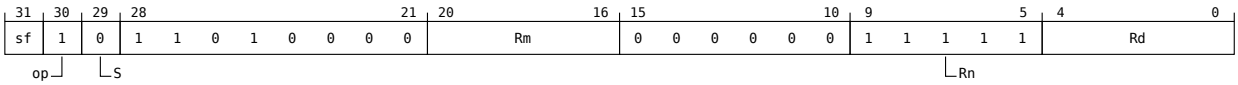
C6.2.191 NGC

Negate with carry

This instruction negates the sum of a register value and the value of NOT (Carry flag), and writes the result to the destination register.

This is an alias of SBC. This means:

- The encodings in this description are named to match the encodings of SBC.
- The description of SBC gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.



Encoding for the 32-bit variant Applies when `(sf == 0)`

```
NGC <Wd>, <Wm>
```

is equivalent to

```
SBC <Wd>, WZR, <Wm>
```

and is always the preferred disassembly.

Encoding for the 64-bit variant Applies when `(sf == 1)`

```
NGC <Xd>, <Xm>
```

is equivalent to

```
SBC <Xd>, XZR, <Xm>
```

and is always the preferred disassembly.

Assembler Symbols

<**Wd**> Is the 32-bit name of the general-purpose destination register, encoded in the “Rd” field.

<**Wm**> Is the 32-bit name of the general-purpose source register, encoded in the “Rm” field.

<**Xd**> Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

<**Xm**> Is the 64-bit name of the general-purpose source register, encoded in the “Rm” field.

Operation

The description of SBC gives the operational pseudocode for this instruction.

Operational Information

The description of SBC gives the operational information for this instruction.

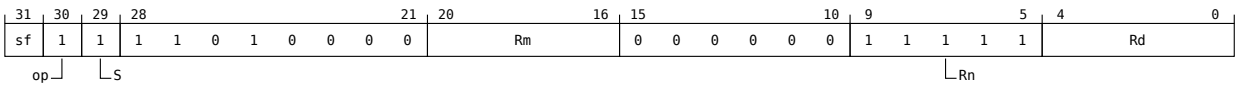
C6.2.192 NGCS

Negate with carry, setting flags

This instruction negates the sum of a register value and the value of NOT (Carry flag), and writes the result to the destination register. It updates the condition flags based on the result.

This is an alias of SBCS. This means:

- The encodings in this description are named to match the encodings of SBCS.
- The description of SBCS gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.



Encoding for the 32-bit variant Applies when `(sf == 0)`

```
NGCS <Wd>, <Wm>
```

is equivalent to

```
SBCS <Wd>, WZR, <Wm>
```

and is always the preferred disassembly.

Encoding for the 64-bit variant Applies when `(sf == 1)`

```
NGCS <Xd>, <Xm>
```

is equivalent to

```
SBCS <Xd>, XZR, <Xm>
```

and is always the preferred disassembly.

Assembler Symbols

<**Wd**> Is the 32-bit name of the general-purpose destination register, encoded in the “Rd” field.

<**Wm**> Is the 32-bit name of the general-purpose source register, encoded in the “Rm” field.

<**Xd**> Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

<**Xm**> Is the 64-bit name of the general-purpose source register, encoded in the “Rm” field.

Operation

The description of SBCS gives the operational pseudocode for this instruction.

Operational Information

The description of SBCS gives the operational information for this instruction.

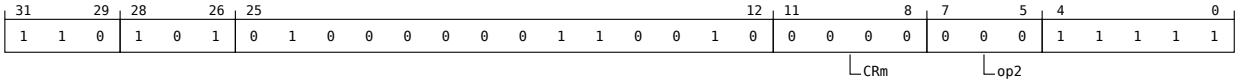
C6.2.193 NOP

No operation

This instruction does nothing, other than advance the value of the program counter by 4. This instruction can be used for instruction alignment purposes.

Note

The timing effects of including a NOP instruction in a program are not guaranteed. It can increase execution time, leave it unchanged, or even reduce it. Therefore, NOP instructions are not suitable for timing loops.



Encoding

NOP

Decode for this encoding

```
// Empty.
```

Operation

```
return; // Do nothing
```

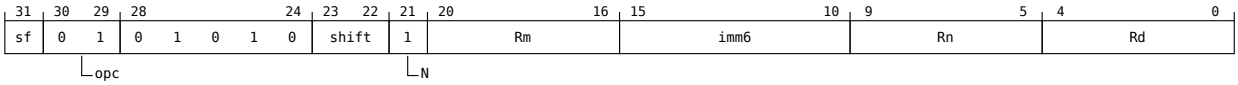
C6.2.194 ORN (shifted register)

Bitwise OR NOT (shifted register)

This instruction performs a bitwise (inclusive) OR of a register value and the complement of an optionally-shifted register value, and writes the result to the destination register.

This instruction is used by the alias MVN.



Encoding for the 32-bit variant Applies when `(sf == 0)`

```
ORN <Wd>, <Wn>, <Wm>{, <shift> #<amount>}
```

Encoding for the 64-bit variant Applies when `(sf == 1)`

```
ORN <Xd>, <Xn>, <Xm>{, <shift> #<amount>}
```

Decode for all variants of this encoding

```
if sf == '0' && imm6<5> == '1' then EndOfDecode(Decode_UNDEF);
constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer m = UInt(Rm);
constant integer datasize = 32 << UInt(sf);
constant ShiftType shift_type = DecodeShift(shift);
constant integer shift_amount = UInt(imm6);
```

Assembler Symbols

<**Wd**> Is the 32-bit name of the general-purpose destination register, encoded in the “Rd” field.

<**Wn**> Is the 32-bit name of the first general-purpose source register, encoded in the “Rn” field.

<**Wm**> Is the 32-bit name of the second general-purpose source register, encoded in the “Rm” field.

<**shift**> Is the optional shift to be applied to the final source, defaulting to LSL and encoded in “shift”:

shift	<**shift**>
00	LSL
01	LSR
10	ASR
11	ROR

<**amount**> For the “32-bit” variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the “imm6” field.

For the “64-bit” variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the “imm6” field.

<**Xd**> Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

<**Xn**> Is the 64-bit name of the first general-purpose source register, encoded in the “Rn” field.

<**Xm**> Is the 64-bit name of the second general-purpose source register, encoded in the “Rm” field.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Alias Conditions

Alias	Is preferred when
MVN	Rn == '11111'

Operation

```
constant bits(datasize) operand1 = X[n, datasize];
constant bits(datasize) operand2 = ShiftReg(m, shift_type, shift_amount, datasize);

X[d, datasize] = operand1 OR NOT(operand2);
```

Operational information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

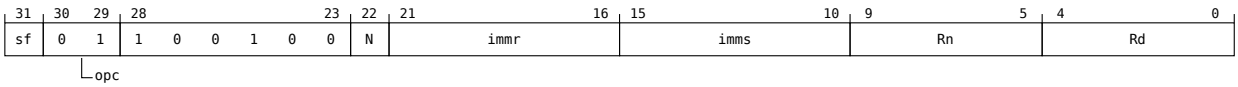
Non-Confidential

C6.2.195 ORR (immediate)

Bitwise OR (immediate)

This instruction performs a bitwise (inclusive) OR of a register value and an immediate value, and writes the result to the destination register.

This instruction is used by the alias MOV (bitmask immediate).



Encoding for the 32-bit variant Applies when `(sf == 0 && N == 0)`

```
ORR <Wd|WSP>, <Wn>, #<imm>
```

Encoding for the 64-bit variant Applies when `(sf == 1)`

```
ORR <Xd|SP>, <Xn>, #<imm>
```

Decode for all variants of this encoding

```
if sf == '0' && N != '0' then EndOfDecode(Decode_UNDEF);
constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer datasize = 32 << UInt(sf);
bits(datasize) imm;
(imm, -) = DecodeBitMasks(N, imms, immr, TRUE, datasize);
```

Assembler Symbols

<**Wd|WSP**> Is the 32-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.

<**Wn**> Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.

<**imm**> For the "32-bit" variant: is the bitmask immediate, encoded in "imms:immr".

For the "64-bit" variant: is the bitmask immediate, encoded in "N:imms:immr".

<**Xd|SP**> Is the 64-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.

<**Xn**> Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.

Alias Conditions

Alias	Is preferred when
MOV (bitmask immediate)	`Rn == '11111' && !MoveWidePreferred(sf, N, imms, immr)`

Operation

```
constant bits(datasize) operand1 = X[n, datasize];
constant bits(datasize) operand2 = imm;

constant bits(datasize) result = operand1 OR operand2;
```

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

```
if d == 31 then
    SP[64] = ZeroExtend(result, 64);
else
    X[d, datasize] = result;
```

Operational information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

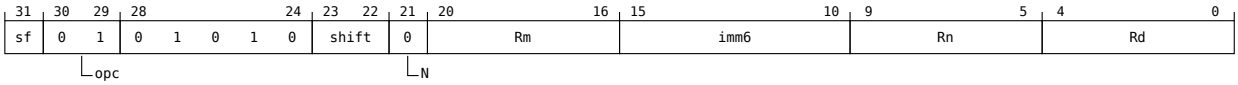
Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.196 ORR (shifted register)

Bitwise OR (shifted register)

This instruction performs a bitwise (inclusive) OR of a register value and an optionally-shifted register value, and writes the result to the destination register.

This instruction is used by the alias MOV (register).



Encoding for the 32-bit variant Applies when `(sf == 0)`

```
ORR <Wd>, <Wn>, <Wm>{, <shift> #<amount>}
```

Encoding for the 64-bit variant Applies when `(sf == 1)`

```
ORR <Xd>, <Xn>, <Xm>{, <shift> #<amount>}
```

Decode for all variants of this encoding

```
if sf == '0' && imm6<5> == '1' then EndOfDecode(Decode_UNDEF);
constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer m = UInt(Rm);
constant integer datasize = 32 << UInt(sf);
constant ShiftType shift_type = DecodeShift(shift);
constant integer shift_amount = UInt(imm6);
```

Assembler Symbols

<**Wd**> Is the 32-bit name of the general-purpose destination register, encoded in the “Rd” field.

<**Wn**> Is the 32-bit name of the first general-purpose source register, encoded in the “Rn” field.

<**Wm**> Is the 32-bit name of the second general-purpose source register, encoded in the “Rm” field.

<**shift**> Is the optional shift to be applied to the final source, defaulting to LSL and encoded in “shift”:

shift	<shift>
00	LSL
01	LSR
10	ASR
11	ROR

<**amount**> For the “32-bit” variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the “imm6” field.

For the “64-bit” variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the “imm6” field.

<**Xd**> Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

<**Xn**> Is the 64-bit name of the first general-purpose source register, encoded in the “Rn” field.

<**Xm**> Is the 64-bit name of the second general-purpose source register, encoded in the “Rm” field.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Alias Conditions

Alias	Is preferred when
MOV (register)	shift == '00' && imm6 == '000000' && Rn == '11111'

Operation

```
constant bits(datasize) operand1 = X[n, datasize];
constant bits(datasize) operand2 = ShiftReg(m, shift_type, shift_amount, datasize);

X[d, datasize] = operand1 OR operand2;
```

Operational information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

C6.2.197 PACDA, PACDZA

Pointer Authentication Code for data address, using key A

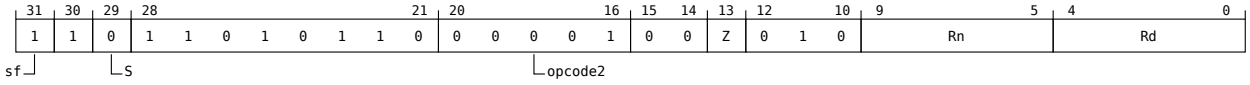
This instruction calculates and inserts a Pointer Authentication Code for a data address, using a modifier and key A.

The address is in the general-purpose register that is specified by <Xd>.

The modifier is:

- In the general-purpose register or stack pointer that is specified by <Xn|SP> for PACDA.
- The value zero, for PACDZA.

Integer
(FEAT_PAuth)



Encoding for the PACDA variant Applies when (Z == 0)

```
PACDA <Xd>, <Xn|SP>
```

Encoding for the PACDZA variant Applies when (Z == 1 && Rn == 11111)

```
PACDZA <Xd>
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_PAuth) then EndOfDecode(Decode_UNDEF);

boolean source_is_sp = FALSE;
constant integer d = UInt(Rd);
constant integer n = UInt(Rn);

if Z == '0' then // PACDA
    if n == 31 then source_is_sp = TRUE;
else // PACDZA
    if n != 31 then EndOfDecode(Decode_UNDEF);
```

Assembler Symbols

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Xn|SP> Is the 64-bit name of the general-purpose source register or stack pointer, encoded in the "Rn" field.

Operation

```
if source_is_sp then
    X[d, 64] = AddPACDA(X[d, 64], SP[64]);
else
    X[d, 64] = AddPACDA(X[d, 64], X[n, 64]);
```

C6.2.198 PACDB, PACDZB

Pointer Authentication Code for data address, using key B

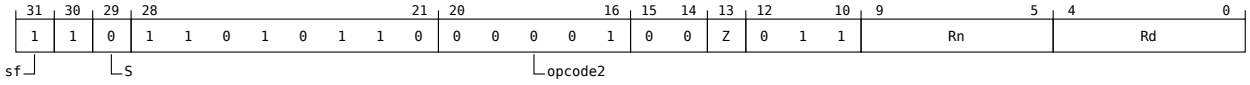
This instruction calculates and inserts a Pointer Authentication Code for a data address, using a modifier and key B.

The address is in the general-purpose register that is specified by <Xd>.

The modifier is:

- In the general-purpose register or stack pointer that is specified by <Xn|SP> for PACDB.
- The value zero, for PACDZB.

Integer
(FEAT_PAuth)



Encoding for the PACDB variant Applies when (Z == 0)

```
PACDB <Xd>, <Xn|SP>
```

Encoding for the PACDZB variant Applies when (Z == 1 && Rn == 11111)

```
PACDZB <Xd>
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_PAuth) then EndOfDecode(Decode_UNDEF);

boolean source_is_sp = FALSE;
constant integer d = UInt(Rd);
constant integer n = UInt(Rn);

if Z == '0' then // PACDB
    if n == 31 then source_is_sp = TRUE;
else // PACDZB
    if n != 31 then EndOfDecode(Decode_UNDEF);
```

Assembler Symbols

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Xn|SP> Is the 64-bit name of the general-purpose source register or stack pointer, encoded in the "Rn" field.

Operation

```
if source_is_sp then
    X[d, 64] = AddPACDB(X[d, 64], SP[64]);
else
    X[d, 64] = AddPACDB(X[d, 64], X[n, 64]);
```

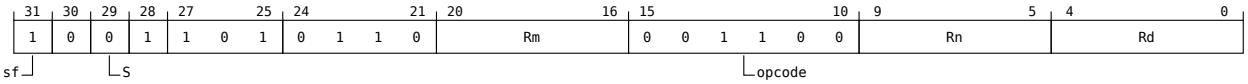
C6.2.199 PACGA

Pointer Authentication Code, using generic key

This instruction calculates the Pointer Authentication Code for a 64-bit value in the first source register, using a modifier in the second source register, and the generic key. The calculated Pointer Authentication Code is written to the most significant 32 bits of the destination register, and the least significant 32 bits of the destination register are set to zero.

Integer
(FEAT_PAuth)



Encoding

```
PACGA <Xd>, <Xn>, <Xm|SP>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_PAuth) then EndOfDecode(Decode_UNDEF);

boolean source_is_sp = FALSE;
constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer m = UInt(Rm);

if m == 31 then source_is_sp = TRUE;
```

Assembler Symbols

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Xn> Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.

<Xm|SP> Is the 64-bit name of the second general-purpose source register or stack pointer, encoded in the "Rm" field.

Operation

```
if source_is_sp then
    X[d, 64] = AddPACGA(X[n, 64], SP[64]);
else
    X[d, 64] = AddPACGA(X[n, 64], X[m, 64]);
```

C6.2.200 PACIA, PACIA1716, PACIASP, PACIAZ, PACIZA

Pointer Authentication Code for instruction address, using key A

This instruction calculates and inserts a Pointer Authentication Code for an instruction address, using a modifier and key A.

The address is:

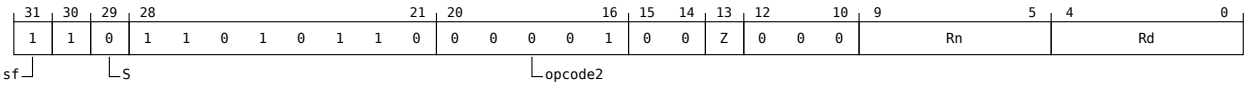
- In the general-purpose register that is specified by <Xd> for PACIA and PACIZA.
- In X17, for PACIA1716.
- In X30, for PACIASP and PACIAZ.

The modifier is:

- In the general-purpose register or stack pointer that is specified by <Xn|SP> for PACIA.
- The value zero, for PACIZA and PACIAZ.
- In X16, for PACIA1716.
- In SP, for PACIASP.

It has encodings from 2 classes: Integer and System

Integer
(FEAT_PAuth)



Encoding for the PACIA variant Applies when (Z == 0)

```
PACIA <Xd>, <Xn|SP>
```

Encoding for the PACIZA variant Applies when (Z == 1 && Rn == 11111)

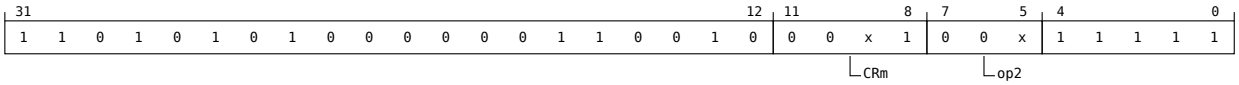
```
PACIZA <Xd>
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_PAuth) then EndOfDecode(Decode_UNDEF);
boolean source_is_sp = FALSE;
constant integer d = UInt(Rd);
constant integer n = UInt(Rn);

if Z == '0' then // PACIA
    if n == 31 then source_is_sp = TRUE;
else // PACIZA
    if n != 31 then EndOfDecode(Decode_UNDEF);
```

System
(FEAT_PAuth)



Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Encoding for the PACIA1716 variant Applies when `(CRm == 0001 && op2 == 000)`

```
PACIA1716
```

Encoding for the PACIASP variant Applies when `(CRm == 0011 && op2 == 001)`

```
PACIASP
```

Encoding for the PACIAZ variant Applies when `(CRm == 0011 && op2 == 000)`

```
PACIAZ
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_PAuth) then EndOfDecode(Decode_NOP);
integer d;
integer n;
boolean source_is_sp = FALSE;

case CRm:op2 of
    when '0011 000' // PACIAZ
        d = 30;
        n = 31;
    when '0011 001' // PACIASP
        d = 30;
        source_is_sp = TRUE;
    when '0001 000' // PACIA1716
        d = 17;
        n = 16;
```

Assembler Symbols

<**Xd**> Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

<**Xn**|**SP**> Is the 64-bit name of the general-purpose source register or stack pointer, encoded in the “Rn” field.

Operation

```
if source_is_sp then
    X[d, 64] = AddPACIA(X[d, 64], SP[64]);
else
    X[d, 64] = AddPACIA(X[d, 64], X[n, 64]);

C6.2.201 PACIB, PACIB1716, PACIBSP, PACIBZ, PACIZB

Pointer Authentication Code for instruction address, using key B

This instruction calculates and inserts a Pointer Authentication Code for an instruction address, using a modifier and key B.

The address is:

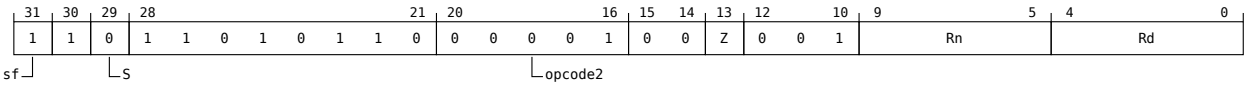
- In the general-purpose register that is specified by <Xd> for PACIB and PACIZB.
- In X17, for PACIB1716.
- In X30, for PACIBSP and PACIBZ.

The modifier is:

- In the general-purpose register or stack pointer that is specified by <Xn|SP> for PACIB.
- The value zero, for PACIZB and PACIBZ.
- In X16, for PACIB1716.
- In SP, for PACIBSP.

It has encodings from 2 classes: Integer and System

Integer
(FEAT_PAuth)



Encoding for the PACIB variant Applies when (Z == 0)

```
PACIB <Xd>, <Xn|SP>
```

Encoding for the PACIZB variant Applies when (Z == 1 && Rn == 11111)

```
PACIZB <Xd>
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_PAuth) then EndOfDecode(Decode_UNDEF);
boolean source_is_sp = FALSE;
constant integer d = UInt(Rd);
constant integer n = UInt(Rn);

if Z == '0' then // PACIB
    if n == 31 then source_is_sp = TRUE;
else // PACIZB
    if n != 31 then EndOfDecode(Decode_UNDEF);
```

System
(FEAT_PAuth)

    when '0011 010' // PACIBZ
        d = 30;
        n = 31;
    when '0011 011' // PACIBSP
        d = 30;
        source_is_sp = TRUE;
    when '0001 010' // PACIB1716
        d = 17;
        n = 16;
```

Assembler Symbols

<**Xd**> Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

<**Xn**|**SP**> Is the 64-bit name of the general-purpose source register or stack pointer, encoded in the “Rn” field.

Operation

```
if source_is_sp then
    X[d, 64] = AddPACIB(X[d, 64], SP[64]);
else
    X[d, 64] = AddPACIB(X[d, 64], X[n, 64]);
```

C6.2.202 PRFM (immediate)

Prefetch memory (immediate)

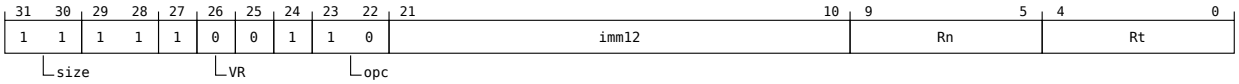
This instruction signals the memory system that data memory accesses from a specified address are likely to occur in the near future. The address for data memory accesses is calculated from a base register value and an immediate offset. The memory system can respond by taking actions that are expected to speed up the memory accesses when they do occur, such as making the cache line containing the specified address available at the level of cache specified by the instruction.

The <prfop> operand specifies the prefetch hint as follows:

- Access type:
  - PLD for prefetch for load.
  - PLI for prefetch for execute.
  - PST for prefetch for store.
- Target cache level:
  - L1 for Level 1 cache.
  - L2 for Level 2 cache.
  - L3 for Level 3 cache.
- Policy:
  - KEEP for retained or temporal prefetch, allocated in the cache normally.
  - STRM for streaming or non-temporal prefetch, for data that is used only once.

The effect of a `PRFM` instruction is IMPLEMENTATION DEFINED. For more information, see Prefetch memory.

For information about addressing modes, see Load/Store addressing modes.



Encoding

```
PRFM (<prfop>|#<imm5>), [<Xn|SP>{, #<pimm>}]
```

Decode for this encoding

```
constant bits(64) offset = LSL(ZeroExtend(imm12, 64), 3);
constant integer n = UInt(Rn);
constant integer t = UInt(Rt);
constant boolean nontemporal = FALSE;
```

Assembler Symbols

<prfop> Is the prefetch operation, encoded in "Rt":

Rt	<prfop>
00000	PLDL1KEEP
00001	PLDL1STRM
00010	PLDL2KEEP
00011	PLDL2STRM
00100	PLDL3KEEP

10010	PSTL2KEEP
10011	PSTL2STRM
10100	PSTL3KEEP
10101	PSTL3STRM

For other encodings of the “Rt” field, use <imm5>.

<**imm5**> Is the prefetch operation encoding as an immediate, in the range 0 to 31, encoded in the “Rt” field.

This syntax is only for encodings that are not accessible using <prfop>.

<**Xn|SP**> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the “Rn” field.

<**pimm**> Is the optional positive immediate byte offset, a multiple of 8 in the range 0 to 32760, defaulting to 0 and encoded in the “imm12” field as <pimm>/8.

Operation

```
bits(64) address;

constant boolean privileged = PSTATE.EL != EL0;
constant AccessDescriptor accdesc = CreateAccDescGPR(MemOp_PREFETCH, nontemporal, privileged, t);

if n == 31 then
    address = SP[64];
else
    address = X[n, 64];

address = AddressAdd(address, offset, accdesc);

Prefetch(address, t<4:0>);
```

C6.2.203 PRFM (literal)

Prefetch memory (literal)

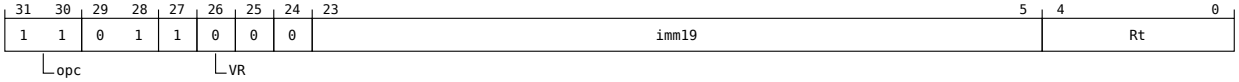
This instruction signals the memory system that data memory accesses from a specified address are likely to occur in the near future. The address for data memory accesses is calculated from the PC value and an immediate offset. The memory system can respond by taking actions that are expected to speed up the memory accesses when they do occur, such as making the cache line containing the specified address available at the level of cache specified by the instruction.

The <prfop> operand specifies the prefetch hint as follows:

- Access type:
  - PLD for prefetch for load.
  - PLI for prefetch for execute.
  - PST for prefetch for store.
- Target cache level:
  - L1 for Level 1 cache.
  - L2 for Level 2 cache.
  - L3 for Level 3 cache.
- Policy:
  - KEEP for retained or temporal prefetch, allocated in the cache normally.
  - STRM for streaming or non-temporal prefetch, for data that is used only once.

The effect of a `PRFM` instruction is IMPLEMENTATION DEFINED. For more information, see Prefetch memory.

For information about addressing modes, see Load/Store addressing modes.



Encoding

```
PRFM (<prfop>|#<imm5>), <label>
```

Decode for this encoding

```
constant integer t = UInt(Rt);

constant bits(64) offset = SignExtend(imm19:'00', 64);
```

Assembler Symbols

<prfop> Is the prefetch operation, encoded in "Rt":

Rt	<prfop>
00000	PLDL1KEEP
00001	PLDL1STRM

C6.2.204 PRFM (register)

Prefetch memory (register)

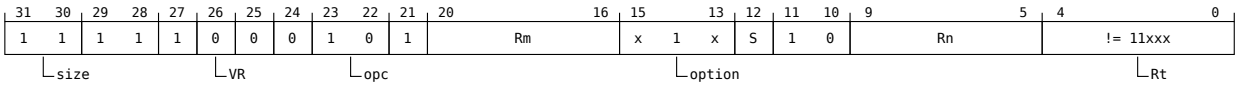
This instruction signals the memory system that data memory accesses from a specified address are likely to occur in the near future. The address for data memory accesses is calculated from a base register value and an offset register value. The offset register value can optionally be shifted and extended. The memory system can respond by taking actions that are expected to speed up the memory accesses when they do occur, such as making the cache line containing the specified address available at the level of cache specified by the instruction.

The <prfop> operand specifies the prefetch hint as follows:

- Access type:
  - PLD for prefetch for load.
  - PLI for prefetch for execute.
  - PST for prefetch for store.
- Target cache level:
  - L1 for Level 1 cache.
  - L2 for Level 2 cache.
  - L3 for Level 3 cache.
- Policy:
  - KEEP for retained or temporal prefetch, allocated in the cache normally.
  - STRM for streaming or non-temporal prefetch, for data that is used only once.

The effect of a PRFM instruction is IMPLEMENTATION DEFINED. For more information, see Prefetch memory.

For information about addressing modes, see Load/Store addressing modes.



Encoding

```
PRFM (<prfop>|#<imm5>), [<Xn|SP>, (<Wm>|<Xm>){, <extend> {<amount>}}]
```

Decode for this encoding

```
if option<1> == '0' then EndOfDecode(Decode_UNDEF);             // sub-word index
constant ExtendType extend_type = DecodeRegExtend(option);
constant integer shift = if S == '1' then 3 else 0;
constant integer n = UInt(Rn);
constant integer t = UInt(Rt);
constant integer m = UInt(Rm);
constant boolean nontemporal = FALSE;
```

Assembler Symbols

<prfop> Is the prefetch operation, encoded in "Rt":

Rt	<prfop>
00000	PLDL1KEEP
00001	PLDL1STRM
00010	PLDL2KEEP

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Rt	<prfop>
00011	PLDL2STRM
00100	PLDL3KEEP
00101	PLDL3STRM
01000	PLIL1KEEP
01001	PLIL1STRM
01010	PLIL2KEEP
01011	PLIL2STRM
01100	PLIL3KEEP
01101	PLIL3STRM
10000	PSTL1KEEP
10001	PSTL1STRM
10010	PSTL2KEEP
10011	PSTL2STRM
10100	PSTL3KEEP
10101	PSTL3STRM

For other encodings of the “Rt” field, use <imm5>.

<**imm5**> Is the prefetch operation encoding as an immediate, in the range 0 to 31, encoded in the “Rt” field.

This syntax is only for encodings that are not accessible using <prfop>.

<**Xn|SP**> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the “Rn” field.

<**Wm**> When option<0> is set to 0, is the 32-bit name of the general-purpose index register, encoded in the “Rm” field.

<**Xm**> When option<0> is set to 1, is the 64-bit name of the general-purpose index register, encoded in the “Rm” field.

<**extend**> Is the index extend/shift specifier, defaulting to LSL, and which must be omitted for the LSL option when <amount> is omitted, encoded in “option”:

option	<extend>
010	UXTW
011	LSL
110	SXTW
111	SXTX

<**amount**> Is the index shift amount, optional only when <extend> is not LSL. Where it is permitted to be optional, it defaults to #0. It is encoded in “S”:

S	<amount>
0	#0
1	#3

Operation

C6.2.205 PRFUM

Prefetch memory (unscaled offset)

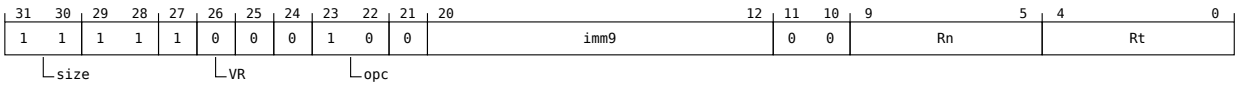
This instruction signals the memory system that data memory accesses from a specified address are likely to occur in the near future. The memory system can respond by taking actions that are expected to speed up the memory accesses when they do occur, such as making the cache line containing the specified address available at the level of cache specified by the instruction.

The <prfop> operand specifies the prefetch hint as follows:

- Access type:
  - PLD for prefetch for load.
  - PLI for prefetch for execute.
  - PST for prefetch for store.
  - L1 for Level 1 cache.
  - L2 for Level 2 cache.
  - L3 for Level 3 cache.
- Policy:
  - KEEP for retained or temporal prefetch, allocated in the cache normally.
  - STRM for streaming or non-temporal prefetch, for data that is used only once.

The effect of a `PRFUM` instruction is IMPLEMENTATION DEFINED. For more information, see Prefetch memory.

For information about addressing modes, see Load/Store addressing modes.



Encoding

```
PRFUM (<prfop>|#<imm5>), [<Xn|SP>{, #<simm>}]
```

Decode for this encoding

```
constant bits(64) offset = SignExtend(imm9, 64);
constant integer n = UInt(Rn);
constant integer t = UInt(Rt);
constant boolean nontemporal = FALSE;
```

Assembler Symbols

<prfop> Is the prefetch operation, encoded in "Rt":

Rt	<prfop>
00000	PLDL1KEEP
00001	PLDL1STRM
00010	PLDL2KEEP
00011	PLDL2STRM
00100	PLDL3KEEP
00101	PLDL3STRM

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.

Rt	<prfop>
01000	PLIL1KEEP
01001	PLIL1STRM
01010	PLIL2KEEP
01011	PLIL2STRM
01100	PLIL3KEEP
01101	PLIL3STRM
10000	PSTL1KEEP
10001	PSTL1STRM
10010	PSTL2KEEP
10011	PSTL2STRM
10100	PSTL3KEEP
10101	PSTL3STRM

For other encodings of the “Rt” field, use <imm5>.

<**imm5**> Is the prefetch operation encoding as an immediate, in the range 0 to 31, encoded in the “Rt” field.

This syntax is only for encodings that are not accessible using <prfop>.

<**Xn|SP**> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the “Rn” field.

<**simm**> Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the “imm9” field.

Operation

```
bits(64) address;

constant boolean privileged = PSTATE.EL != EL0;
constant AccessDescriptor accdesc = CreateAccDescGPR(MemOp_PREFETCH, nontemporal, privileged, t);

if n == 31 then
    address = SP[64];
else
    address = X[n, 64];

address = AddressAdd(address, offset, accdesc);

Prefetch(address, t<4:0>);
```

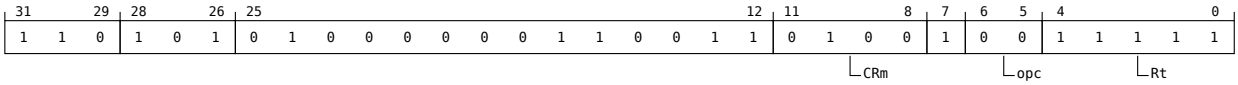
C6.2.206 PSSBB

Physical speculative store bypass barrier

This instruction is a memory barrier that prevents speculative loads from bypassing earlier stores to the same physical address under certain conditions. For more information and details of the semantics, see Physical Speculative Store Bypass Barrier (PSSBB).

This is an alias of DSB. This means:

- The encodings in this description are named to match the encodings of DSB.
- The description of DSB gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.



Encoding

```
PSSBB
```

is equivalent to

```
DSB #4
```

and is always the preferred disassembly.

Operation

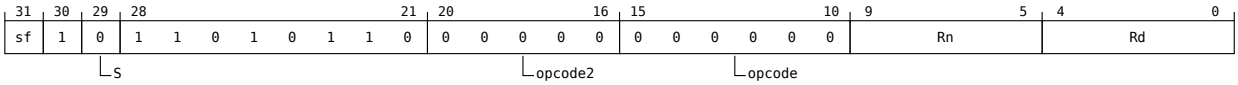
The description of DSB gives the operational pseudocode for this instruction.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.207 RBIT

Reverse bits

This instruction reverses the bit order in a register.



Encoding for the 32-bit variant Applies when `(sf == 0)`

```
RBIT <Wd>, <Wn>
```

Encoding for the 64-bit variant Applies when `(sf == 1)`

```
RBIT <Xd>, <Xn>
```

Decode for all variants of this encoding

```
constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer datasize = 32 << UInt(sf);
```

Assembler Symbols

<**Wd**> Is the 32-bit name of the general-purpose destination register, encoded in the “Rd” field.

<**Wn**> Is the 32-bit name of the general-purpose source register, encoded in the “Rn” field.

<**Xd**> Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

<**Xn**> Is the 64-bit name of the general-purpose source register, encoded in the “Rn” field.

Operation

```
constant bits(datasize) operand = X[n, datasize];
bits(datasize) result;

for i = 0 to datasize-1
    result<(datasize-1)-i> = operand<i>;

X[d, datasize] = result;
```

Operational information

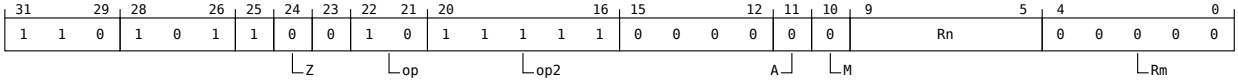
This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.208 RET

Return from subroutine

This instruction branches unconditionally to an address in a register. This instruction provides a hint that this is a subroutine return.



Encoding

```
RET {<Xn>}
```

Decode for this encoding

```
constant integer n = UInt(Rn);
```

Assembler Symbols

<Xn> Is the 64-bit name of the general-purpose register holding the address to be branched to, encoded in the "Rn" field. Defaults to X30 if absent.

Operation

```
constant bits(64) target = X[n, 64];

constant boolean branch_conditional = FALSE;
BranchTo(target, BranchType_RET, branch_conditional);
```

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.209 RETAA, RETAB

Return from subroutine, with pointer authentication

This instruction authenticates the address that is held in LR, using SP as the modifier and the specified key, and branches to the authenticated address.

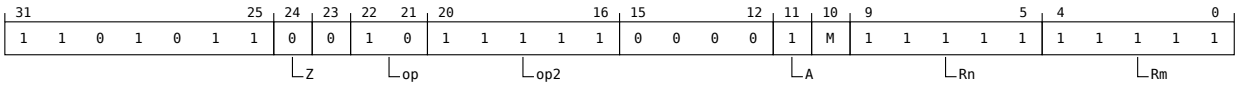
Key A is used for `RETAA`. Key B is used for `RETAB`.

If the authentication passes, the PE continues execution at the target of the branch. For information on behavior if the authentication fails, see Faulting on pointer authentication.

The authenticated address is not written back to LR.

This instruction provides a hint that this is a subroutine return.

Integer
(FEAT_PAuth)



Encoding for the RETAA variant Applies when `(M == 0)`

`RETAA`

Encoding for the RETAB variant Applies when `(M == 1)`

`RETAB`

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_PAuth) then EndOfDecode(Decode_UNDEF);

constant boolean use_key_a = (M == '0');
constant boolean auth_then_branch = TRUE;
```

Operation

```
bits(64) target = X[30, 64];

constant bits(64) modifier = SP[64];

if use_key_a then
    target = AuthIA(target, modifier, auth_then_branch);
else
    target = AuthIB(target, modifier, auth_then_branch);

constant boolean branch_conditional = FALSE;
BranchTo(target, BranchType_RET, branch_conditional);
```

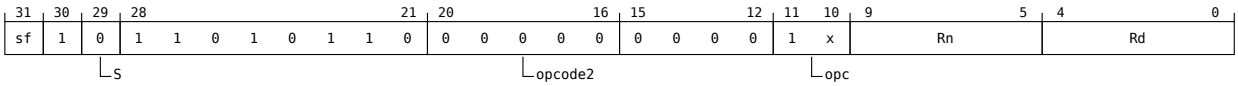
Non-Confidential

C6.2.210 REV

Reverse bytes

This instruction reverses the byte order in a register.

This instruction is used by the pseudo-instruction REV64.



Encoding for the 32-bit variant Applies when `(sf == 0 && opc == 10)`

```
REV <Wd>, <Wn>
```

Encoding for the 64-bit variant Applies when `(sf == 1 && opc == 11)`

```
REV <Xd>, <Xn>
```

Decode for all variants of this encoding

```
if opc == '11' && sf == '0' then EndOfDecode(Decode_UNDEF);

constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer datasize = 32 << UInt(sf);
constant integer container_size = 8 << UInt(opc);
```

Assembler Symbols

<**Wd**> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

<**Wn**> Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.

<**Xd**> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<**Xn**> Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.

Operation

```
constant bits(datasize) operand = X[n, datasize];
bits(datasize) result;

constant integer containers = datasize DIV container_size;
for c = 0 to containers-1
    constant bits(container_size) container = Elem[operand, c, container_size];
    Elem[result, c, container_size] = Reverse(container, 8);

X[d, datasize] = result;
```

Operational information

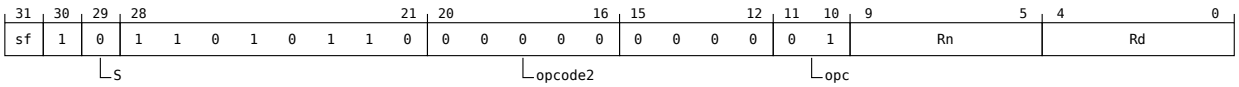
This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.211 REV16

Reverse bytes in 16-bit halfwords

This instruction reverses the byte order in each 16-bit halfword of a register.



Encoding for the 32-bit variant Applies when `(sf == 0)`

```
REV16 <Wd>, <Wn>
```

Encoding for the 64-bit variant Applies when `(sf == 1)`

```
REV16 <Xd>, <Xn>
```

Decode for all variants of this encoding

```
if opc == '11' && sf == '0' then EndOfDecode(Decode_UNDEF);

constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer datasize = 32 << UInt(sf);
constant integer container_size = 8 << UInt(opc);
```

Assembler Symbols

<**Wd**> Is the 32-bit name of the general-purpose destination register, encoded in the “Rd” field.

<**Wn**> Is the 32-bit name of the general-purpose source register, encoded in the “Rn” field.

<**Xd**> Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

<**Xn**> Is the 64-bit name of the general-purpose source register, encoded in the “Rn” field.

Operation

```
constant bits(datasize) operand = X[n, datasize];
bits(datasize) result;

constant integer containers = datasize DIV container_size;
for c = 0 to containers-1
    constant bits(container_size) container = Elem[operand, c, container_size];
    Elem[result, c, container_size] = Reverse(container, 8);

X[d, datasize] = result;
```

Operational information

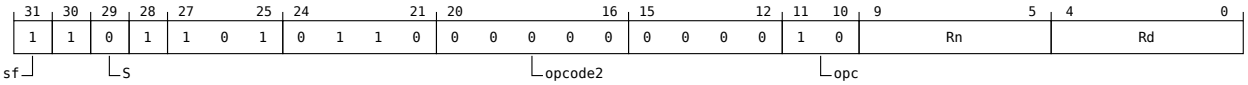
This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.212 REV32

Reverse bytes in 32-bit words

This instruction reverses the byte order in each 32-bit word of a register.



Encoding

```
REV32 <Xd>, <Xn>
```

Decode for this encoding

```
if opc == '11' && sf == '0' then EndOfDecode(Decode_UNDEF);

constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer datasize = 32 << UInt(sf);
constant integer container_size = 8 << UInt(opc);
```

Assembler Symbols

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Xn> Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.

Operation

```
constant bits(datasize) operand = X[n, datasize];
bits(datasize) result;

constant integer containers = datasize DIV container_size;
for c = 0 to containers-1
    constant bits(container_size) container = Elem[operand, c, container_size];
    Elem[result, c, container_size] = Reverse(container, 8);

X[d, datasize] = result;
```

Operational information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.

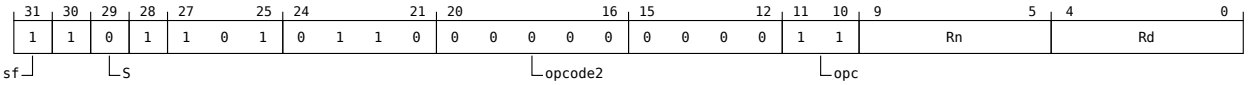
C6.2.213 REV64

Reverse bytes

This instruction reverses the byte order in a 64-bit general-purpose register.

This is a pseudo-instruction of REV. This means:

- The encodings in this description are named to match the encodings of REV.
- The assembler syntax is used only for assembly, and is not used on disassembly.
- The description of REV gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.



Encoding

```
REV64 <Xd>, <Xn>
```

is equivalent to

```
REV <Xd>, <Xn>
```

Assembler Symbols

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Xn> Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.

Operation

The description of REV gives the operational pseudocode for this instruction.

Operational Information

The description of REV gives the operational information for this instruction.

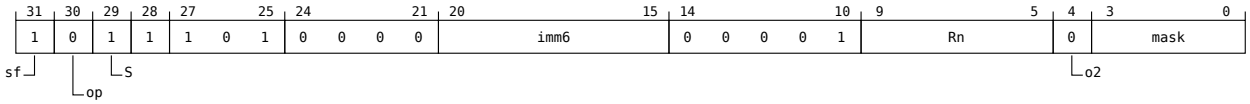
C6.2.214 RMIF

Rotate, mask insert flags

This instruction performs a rotation right of a value held in a general-purpose register by an immediate value, and then inserts a selection of the bottom four bits of the result of the rotation into the PSTATE flags, under the control of a second immediate mask.

Integer
(FEAT_FlagM)



Encoding

```
RMIF <Xn>, #<shift>, #<mask>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_FlagM) then EndOfDecode(Decode_UNDEF);
constant integer imm = UInt(imm6);
constant bits(4) flagmask = mask;
constant integer n = UInt(Rn);
```

Assembler Symbols

<**Xn**> Is the 64-bit name of the general-purpose source register, encoded in the “Rn” field.

<**shift**> Is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the “imm6” field.

<**mask**> Is the flag bit mask, an immediate in the range 0 to 15, which selects the bits that are inserted into the NZCV condition flags, encoded in the “mask” field.

Operation

```
constant bits(64) reg = X[n, 64];
constant bits(4) flags = (reg:reg)<imm+3:imm>;
if flagmask<3> == '1' then PSTATE.N = flags<3>;
if flagmask<2> == '1' then PSTATE.Z = flags<2>;
if flagmask<1> == '1' then PSTATE.C = flags<1>;
if flagmask<0> == '1' then PSTATE.V = flags<0>;
```

Operational information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

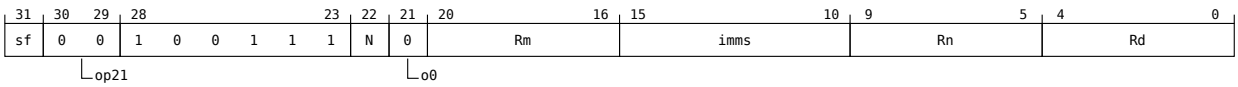
C6.2.215 ROR (immediate)

Rotate right (immediate)

This instruction provides the value of the contents of a register rotated by a variable number of bits. The bits that are rotated off the right end are inserted into the vacated bit positions on the left.

This is an alias of EXTR. This means:

- The encodings in this description are named to match the encodings of EXTR.
- The description of EXTR gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.



Encoding for the 32-bit variant Applies when `(sf == 0 && N == 0 && imms == 0xxxxx)`

```
ROR <Wd>, <Ws>, #<shift>
```

is equivalent to

```
EXTR <Wd>, <Ws>, <Ws>, #<shift>
```

and is the preferred disassembly when `Rn == Rm`.

Encoding for the 64-bit variant Applies when `(sf == 1 && N == 1)`

```
ROR <Xd>, <Xs>, #<shift>
```

is equivalent to

```
EXTR <Xd>, <Xs>, <Xs>, #<shift>
```

and is the preferred disassembly when `Rn == Rm`.

Assembler Symbols

<**Wd**> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

<**Ws**> Is the 32-bit name of the general-purpose source register, encoded in the "Rn" and "Rm" fields.

<**shift**> For the "32-bit" variant: is the amount by which to rotate, in the range 0 to 31, encoded in the "imms" field.

For the "64-bit" variant: is the amount by which to rotate, in the range 0 to 63, encoded in the "imms" field.

<**Xd**> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<**Xs**> Is the 64-bit name of the general-purpose source register, encoded in the "Rn" and "Rm" fields.

Operation

The description of EXTR gives the operational pseudocode for this instruction.

Operational Information

The description of EXTR gives the operational information for this instruction.

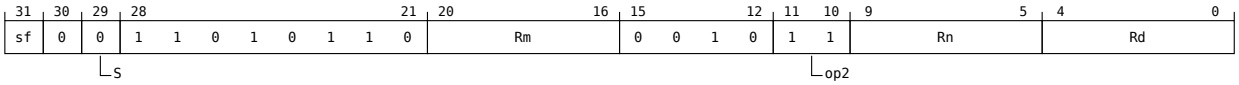
C6.2.216 ROR (register)

Rotate right (register)

This instruction provides the value of the contents of a register rotated by a variable number of bits. The bits that are rotated off the right end are inserted into the vacated bit positions on the left. The value of the second source register modulo the register size in bits gives the number of bits by which the first source register is right-shifted.

This is an alias of RORV. This means:

- The encodings in this description are named to match the encodings of RORV.
- The description of RORV gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.



Encoding for the 32-bit variant Applies when `(sf == 0)`

```
ROR <Wd>, <Wn>, <Wm>
```

is equivalent to

```
RORV <Wd>, <Wn>, <Wm>
```

and is always the preferred disassembly.

Encoding for the 64-bit variant Applies when `(sf == 1)`

```
ROR <Xd>, <Xn>, <Xm>
```

is equivalent to

```
RORV <Xd>, <Xn>, <Xm>
```

and is always the preferred disassembly.

Assembler Symbols

<**Wd**> Is the 32-bit name of the general-purpose destination register, encoded in the “Rd” field.

<**Wn**> Is the 32-bit name of the first general-purpose source register, encoded in the “Rn” field.

<**Wm**> Is the 32-bit name of the second general-purpose source register holding a shift amount from 0 to 31 in its bottom 5 bits, encoded in the “Rm” field.

<**Xd**> Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

<**Xn**> Is the 64-bit name of the first general-purpose source register, encoded in the “Rn” field.

<**Xm**> Is the 64-bit name of the second general-purpose source register holding a shift amount from 0 to 63 in its bottom 6 bits, encoded in the “Rm” field.

Operation

The description of RORV gives the operational pseudocode for this instruction.

Operational Information

The description of RORV gives the operational information for this instruction.

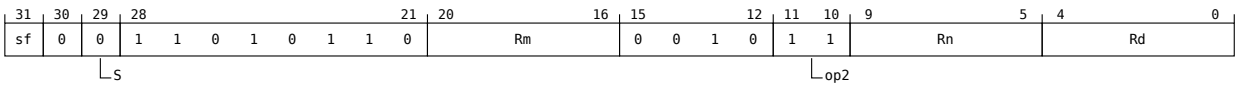
C6.2.217 RORV

Rotate right variable

This instruction provides the value of the contents of a register rotated by a variable number of bits. The bits that are rotated off the right end are inserted into the vacated bit positions on the left. The value of the second source register modulo the register size in bits gives the number of bits by which the first source register is right-shifted.

This instruction is used by the alias ROR (register).



Encoding for the 32-bit variant Applies when `(sf == 0)`

```
RORV <Wd>, <Wn>, <Wm>
```

Encoding for the 64-bit variant Applies when `(sf == 1)`

```
RORV <Xd>, <Xn>, <Xm>
```

Decode for all variants of this encoding

```
constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer m = UInt(Rm);
constant integer datasize = 32 << UInt(sf);
constant ShiftType shift_type = DecodeShift(op2);
```

Assembler Symbols

<**Wd**> Is the 32-bit name of the general-purpose destination register, encoded in the “Rd” field.

<**Wn**> Is the 32-bit name of the first general-purpose source register, encoded in the “Rn” field.

<**Wm**> Is the 32-bit name of the second general-purpose source register holding a shift amount from 0 to 31 in its bottom 5 bits, encoded in the “Rm” field.

<**Xd**> Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

<**Xn**> Is the 64-bit name of the first general-purpose source register, encoded in the “Rn” field.

<**Xm**> Is the 64-bit name of the second general-purpose source register holding a shift amount from 0 to 63 in its bottom 6 bits, encoded in the “Rm” field.

Operation

```
constant bits(datasize) operand2 = X[m, datasize];

X[d, datasize] = ShiftReg(n, shift_type, UInt(operand2) MOD datasize, datasize);
```

Operational information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

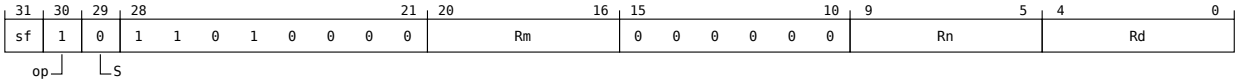
C6.2.219 SBC

Subtract with carry

This instruction subtracts a register value and the value of NOT (Carry flag) from a register value, and writes the result to the destination register.

This instruction is used by the alias NGC.



Encoding for the 32-bit variant Applies when `(sf == 0)`

```
SBC <Wd>, <Wn>, <Wm>
```

Encoding for the 64-bit variant Applies when `(sf == 1)`

```
SBC <Xd>, <Xn>, <Xm>
```

Decode for all variants of this encoding

```
constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer m = UInt(Rm);
constant integer datasize = 32 << UInt(sf);
```

Assembler Symbols

<**Wd**> Is the 32-bit name of the general-purpose destination register, encoded in the “Rd” field.

<**Wn**> Is the 32-bit name of the first general-purpose source register, encoded in the “Rn” field.

<**Wm**> Is the 32-bit name of the second general-purpose source register, encoded in the “Rm” field.

<**Xd**> Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

<**Xn**> Is the 64-bit name of the first general-purpose source register, encoded in the “Rn” field.

<**Xm**> Is the 64-bit name of the second general-purpose source register, encoded in the “Rm” field.

Alias Conditions

Alias	Is preferred when
NGC	`Rn == '11111'`

Operation

```
constant bits(datasize) operand1 = X[n, datasize];
constant bits(datasize) operand2 = NOT(X[m, datasize]);
bits(datasize) result;

(result, -) = AddWithCarry(operand1, operand2, PSTATE.C);

X[d, datasize] = result;
```

Operational information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

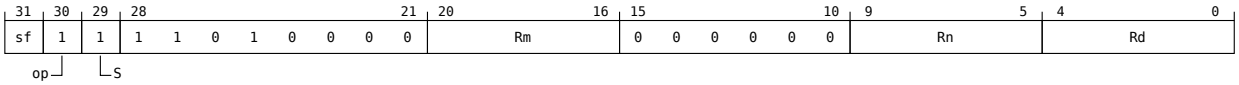
Non-Confidential

C6.2.220 SBCS

Subtract with carry, setting flags

This instruction subtracts a register value and the value of NOT (Carry flag) from a register value, and writes the result to the destination register. It updates the condition flags based on the result.

This instruction is used by the alias NGCS.



Encoding for the 32-bit variant Applies when `(sf == 0)`

```
SBCS <Wd>, <Wn>, <Wm>
```

Encoding for the 64-bit variant Applies when `(sf == 1)`

```
SBCS <Xd>, <Xn>, <Xm>
```

Decode for all variants of this encoding

```
constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer m = UInt(Rm);
constant integer datasize = 32 << UInt(sf);
```

Assembler Symbols

<**Wd**> Is the 32-bit name of the general-purpose destination register, encoded in the “Rd” field.

<**Wn**> Is the 32-bit name of the first general-purpose source register, encoded in the “Rn” field.

<**Wm**> Is the 32-bit name of the second general-purpose source register, encoded in the “Rm” field.

<**Xd**> Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

<**Xn**> Is the 64-bit name of the first general-purpose source register, encoded in the “Rn” field.

<**Xm**> Is the 64-bit name of the second general-purpose source register, encoded in the “Rm” field.

Alias Conditions

Alias	Is preferred when
NGCS	`Rn == '11111'`

Operation

```
constant bits(datasize) operand1 = X[n, datasize];
constant bits(datasize) operand2 = NOT(X[m, datasize]);
bits(datasize) result;
bits(4) nzcv;

(result, nzcv) = AddWithCarry(operand1, operand2, PSTATE.C);

X[d, datasize] = result;
PSTATE.<N,Z,C,V> = nzcv;
```

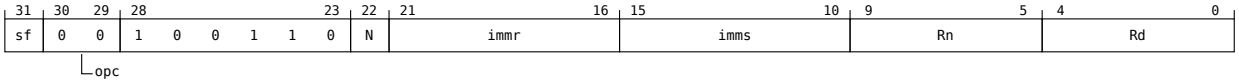
C6.2.221 SBFIZ

Signed bitfield insert in zeros

This instruction copies a bitfield of <width> bits from the least significant bits of the source register to bit position <lsb> of the destination register, setting the destination bits below the bitfield to zero, and the bits above the bitfield to a copy of the most significant bit of the bitfield.

This is an alias of SBFM. This means:

- The encodings in this description are named to match the encodings of SBFM.
- The description of SBFM gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.



Encoding for the 32-bit variant Applies when `(sf == 0 && N == 0)`

```
SBFIZ <Wd>, <Wn>, #<lsb>, #<width>
```

is equivalent to

```
SBFM <Wd>, <Wn>, #(-<lsb> MOD 32), #(<width>-1)
```

and is the preferred disassembly when `UInt(imms) < UInt(immr)`.

Encoding for the 64-bit variant Applies when `(sf == 1 && N == 1)`

```
SBFIZ <Xd>, <Xn>, #<lsb>, #<width>
```

is equivalent to

```
SBFM <Xd>, <Xn>, #(-<lsb> MOD 64), #(<width>-1)
```

and is the preferred disassembly when `UInt(imms) < UInt(immr)`.

Assembler Symbols

<**Wd**> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

<**Wn**> Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.

<**lsb**> For the "32-bit" variant: is the bit number of the lsb of the destination bitfield, in the range 0 to 31.

For the "64-bit" variant: is the bit number of the lsb of the destination bitfield, in the range 0 to 63.

<**width**> For the "32-bit" variant: is the width of the bitfield, in the range 1 to 32-<lsb>.

For the "64-bit" variant: is the width of the bitfield, in the range 1 to 64-<lsb>.

<**Xd**> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<**Xn**> Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.

Operation

The description of SBFM gives the operational pseudocode for this instruction.

Operational Information

The description of SBFM gives the operational information for this instruction.

Non-Confidential

C6.2.222 SBFM

Signed bitfield move

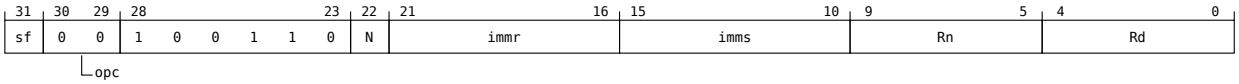
This instruction is usually accessed via one of its aliases, which are always preferred for disassembly.

If <imms> is greater than or equal to <immr>, this copies a bitfield of (<imms>-<immr>+1) bits starting from bit position <immr> in the source register to the least significant bits of the destination register.

If <imms> is less than <immr>, this copies a bitfield of (<imms>+1) bits from the least significant bits of the source register to bit position (regsize-<immr>) of the destination register, where regsize is the destination register size of 32 or 64 bits.

In both cases, the destination bits below the bitfield are set to zero, and the bits above the bitfield are set to a copy of the most significant bit of the bitfield.

This instruction is used by the aliases ASR (immediate), SBFIZ, SBFX, SXTB, SXTH, and SXTW.



Encoding for the 32-bit variant Applies when `(sf == 0 && N == 0)`

```
SBFM <Wd>, <Wn>, #<immr>, #<imms>
```

Encoding for the 64-bit variant Applies when `(sf == 1 && N == 1)`

```
SBFM <Xd>, <Xn>, #<immr>, #<imms>
```

Decode for all variants of this encoding

```
if sf == '1' && N != '1' then EndOfDecode(Decode_UNDEF);
if sf == '0' && (N != '0' || immr<5> != '0' || imms<5> != '0') then EndOfDecode(Decode_UNDEF);

constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer datasize = 32 << UInt(sf);
constant integer s = UInt(imms);
constant integer r = UInt(immr);

bits(datasize) wmask;
bits(datasize) tmask;
(wmask, tmask) = DecodeBitMasks(N, imms, immr, FALSE, datasize);
```

Assembler Symbols

<**Wd**> Is the 32-bit name of the general-purpose destination register, encoded in the “Rd” field.

<**Wn**> Is the 32-bit name of the general-purpose source register, encoded in the “Rn” field.

<**immr**> For the “32-bit” variant: is the right rotate amount, in the range 0 to 31, encoded in the “immr” field.

For the “64-bit” variant: is the right rotate amount, in the range 0 to 63, encoded in the “immr” field.

<**imms**> For the “32-bit” variant: is the leftmost bit number to be moved from the source, in the range 0 to 31, encoded in the “imms” field.

For the “64-bit” variant: is the leftmost bit number to be moved from the source, in the range 0 to 63, encoded in the “imms” field.

<**Xd**> Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

<Xn> Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.

Alias Conditions

Alias	Of variant	Is preferred when
ASR (immediate)	32-bit	imms == '011111'
ASR (immediate)	64-bit	imms == '111111'
SBFIZ		UInt(imms) < UInt(immr)
SBFX		BFXPreferred(sf, opc<1>, imms, immr)
SXTB		immr == '000000' && imms == '000111'
SXTH		immr == '000000' && imms == '001111'
SXTW		immr == '000000' && imms == '011111'

Operation

```
constant bits(datasize) src = X[n, datasize];

// Perform bitfield move on low bits
constant bits(datasize) bot = ROR(src, r) AND wmask;

constant bits(datasize) top = Replicate(src<s>, datasize);

// Combine extension bits and result bits
X[d, datasize] = (top AND NOT(tmask)) OR (bot AND tmask);
```

Operational information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

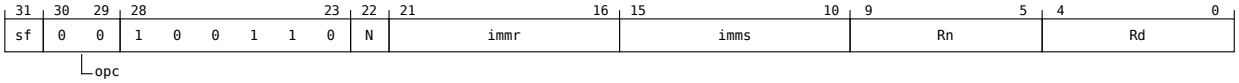
C6.2.223 SBFX

Signed bitfield extract

This instruction copies a bitfield of <width> bits starting from bit position <lsb> in the source register to the least significant bits of the destination register, and sets destination bits above the bitfield to a copy of the most significant bit of the bitfield.

This is an alias of SBFM. This means:

- The encodings in this description are named to match the encodings of SBFM.
- The description of SBFM gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.



Encoding for the 32-bit variant Applies when `(sf == 0 && N == 0)`

```
SBFX <Wd>, <Wn>, #<lsb>, #<width>
```

is equivalent to

```
SBFM <Wd>, <Wn>, #<lsb>, #(<lsb>+<width>-1)
```

and is the preferred disassembly when `BFXPreferred(sf, opc<1>, imms, immr)`.

Encoding for the 64-bit variant Applies when `(sf == 1 && N == 1)`

```
SBFX <Xd>, <Xn>, #<lsb>, #<width>
```

is equivalent to

```
SBFM <Xd>, <Xn>, #<lsb>, #(<lsb>+<width>-1)
```

and is the preferred disassembly when `BFXPreferred(sf, opc<1>, imms, immr)`.

Assembler Symbols

<**Wd**> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

<**Wn**> Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.

<**lsb**> For the "32-bit" variant: is the bit number of the lsb of the source bitfield, in the range 0 to 31.

For the "64-bit" variant: is the bit number of the lsb of the source bitfield, in the range 0 to 63.

<**width**> For the "32-bit" variant: is the width of the bitfield, in the range 1 to 32-<lsb>.

For the "64-bit" variant: is the width of the bitfield, in the range 1 to 64-<lsb>.

<**Xd**> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<**Xn**> Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.

Operation

The description of SBFM gives the operational pseudocode for this instruction.

Operational Information

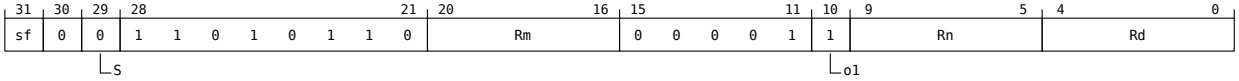
The description of SBFM gives the operational information for this instruction.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.224 SDIV

Signed divide

This instruction divides the first signed source register value by the second signed source register value, and writes the result to the destination register. Dividing by zero writes the value zero to the destination register. The condition flags are not affected.



Encoding for the 32-bit variant Applies when `(sf == 0)`

```
SDIV <Wd>, <Wn>, <Wm>
```

Encoding for the 64-bit variant Applies when `(sf == 1)`

```
SDIV <Xd>, <Xn>, <Xm>
```

Decode for all variants of this encoding

```
constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer m = UInt(Rm);
constant integer datasize = 32 << UInt(sf);
```

Assembler Symbols

<**Wd**> Is the 32-bit name of the general-purpose destination register, encoded in the “Rd” field.

<**Wn**> Is the 32-bit name of the first general-purpose source register, encoded in the “Rn” field.

<**Wm**> Is the 32-bit name of the second general-purpose source register, encoded in the “Rm” field.

<**Xd**> Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

<**Xn**> Is the 64-bit name of the first general-purpose source register, encoded in the “Rn” field.

<**Xm**> Is the 64-bit name of the second general-purpose source register, encoded in the “Rm” field.

Operation

```
constant bits(datasize) operand1 = X[n, datasize];
constant bits(datasize) operand2 = X[m, datasize];
constant integer dividend = SInt(operand1);
constant integer divisor  = SInt(operand2);
integer result;
if divisor == 0 then
    result = 0;
elsif (dividend < 0) == (divisor < 0) then
    result = Abs(dividend) DIV Abs(divisor);    // same signs - positive result
else
    result = -(Abs(dividend) DIV Abs(divisor)); // different signs - negative result
X[d, datasize] = result<datasize-1:0>;
```

Non-Confidential

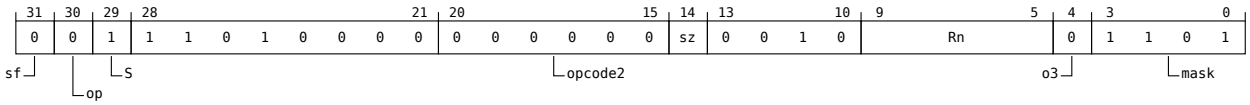
C6.2.225 SETF8, SETF16

Evaluation of 8-bit or 16-bit flag values

This instruction sets the PSTATE.NZV flags based on the value in the specified general-purpose register. `SETF8` treats the value as an 8-bit value. `SETF16` treats the value as a 16-bit value.

The PSTATE.C flag is not affected by these instructions.

Integer
(FEAT_FlagM)



Encoding for the SETF8 variant Applies when `(sz == 0)`

```
SETF8 <Wn>
```

Encoding for the SETF16 variant Applies when `(sz == 1)`

```
SETF16 <Wn>
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_FlagM) then EndOfDecode(Decode_UNDEF);
constant integer size = 8 << UInt(sz);
constant integer n = UInt(Rn);
```

Assembler Symbols

<Wn> Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.

Operation

```
constant bits(32) reg = X[n, 32];
PSTATE.N = reg<size-1>;
PSTATE.Z = if (reg<size-1:0> == Zeros(size)) then '1' else '0';
PSTATE.V = reg<size> EOR reg<size-1>;
//PSTATE.C unchanged;
```

Operational information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

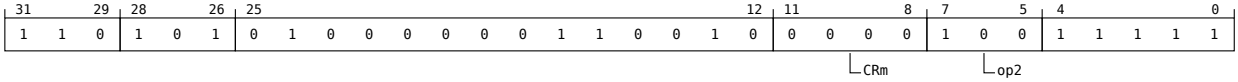
Non-Confidential

C6.2.226 SEV

Send event

This instruction is a hint instruction that causes an event to be signaled to all PEs in the multiprocessor system. For more information, see Wait for Event mechanism and Send event.



Encoding

```
SEV
```

Decode for this encoding

```
// Empty.
```

Operation

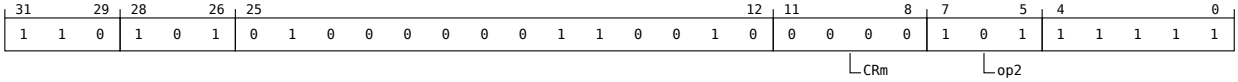
```
SendEvent();
```

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.227 SEVL

Send event local

This instruction is a hint instruction that causes an event to be signaled locally without requiring the event to be signaled to other PEs in the multiprocessor system. It can prime a wait-loop that starts with a `WFE` instruction.



Encoding

```
SEVL
```

Decode for this encoding

```
// Empty.
```

Operation

```
SendEventLocal();
```

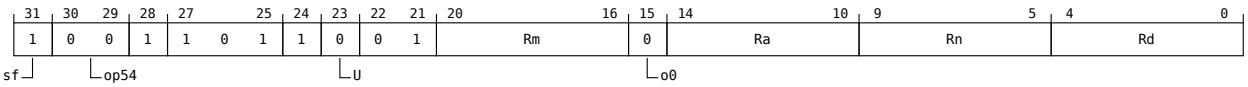
Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.228 SMADDL

Signed multiply-add long

This instruction multiplies two 32-bit register values, adds a 64-bit register value, and writes the result to the 64-bit destination register.

This instruction is used by the alias SMULL.



Encoding

```
SMADDL <Xd>, <Wn>, <Wm>, <Xa>
```

Decode for this encoding

```
constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer m = UInt(Rm);
constant integer a = UInt(Ra);
```

Assembler Symbols

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Wn> Is the 32-bit name of the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.

<Wm> Is the 32-bit name of the second general-purpose source register holding the multiplier, encoded in the "Rm" field.

<Xa> Is the 64-bit name of the third general-purpose source register holding the addend, encoded in the "Ra" field.

Alias Conditions

Alias	Is preferred when
SMULL	Ra == '11111'

Operation

```
constant bits(32) operand1 = X[n, 32];
constant bits(32) operand2 = X[m, 32];
constant bits(64) operand3 = X[a, 64];

constant integer result = SInt(operand3) + (SInt(operand1) * SInt(operand2));

X[d, 64] = result<63:0>;
```

Operational information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.229 SMC

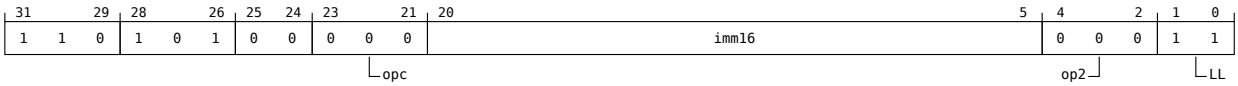
Secure monitor call

If execution of SMC is not trapped to EL2, this instruction is UNDEFINED.

SMC is available only for software executing at EL1. It is UNDEFINED at EL0.

If the value of HCR_EL2.TSC is 1, execution of an SMC instruction at EL1 generates a Secure Monitor Call exception, recording it in ESR_ELx, using the EC syndrome value 0x17, that is taken to EL2.

If the value of HCR_EL2.TSC is 0, the SMC instruction is UNDEFINED.



Encoding

```
SMC #<imm>
```

Decode for this encoding

```
constant bits(16) imm = imm16;
```

Assembler Symbols

<**imm**> Is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the “imm16” field.

Operation

```
if PSTATE.EL == EL0 then UNDEFINED;
AArch64.CheckForSMCUndefOrTrap(imm);
Unreachable();
```

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

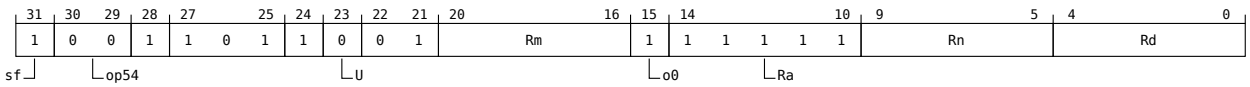
C6.2.230 SMNEGL

Signed multiply-negate long

This instruction multiplies two 32-bit register values, negates the product, and writes the result to the 64-bit destination register.

This is an alias of SMSUBL. This means:

- The encodings in this description are named to match the encodings of SMSUBL.
- The description of SMSUBL gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.



Encoding

SMNEGL <Xd>, <Wn>, <Wm>

is equivalent to

SMSUBL <Xd>, <Wn>, <Wm>, XZR

and is always the preferred disassembly.

Assembler Symbols

<**Xd**> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<**Wn**> Is the 32-bit name of the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.

<**Wm**> Is the 32-bit name of the second general-purpose source register holding the multiplier, encoded in the "Rm" field.

Operation

The description of SMSUBL gives the operational pseudocode for this instruction.

Operational Information

The description of SMSUBL gives the operational information for this instruction.

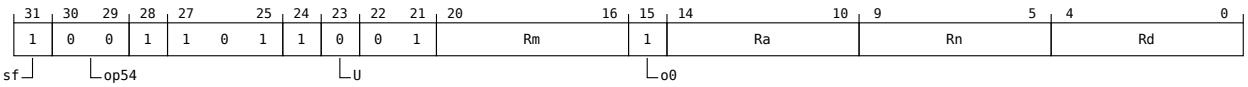
Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.231 SMSUBL

Signed multiply-subtract long

This instruction multiplies two 32-bit register values, subtracts the product from a 64-bit register value, and writes the result to the 64-bit destination register.

This instruction is used by the alias SMNEGL.



Encoding

```
SMSUBL <Xd>, <Wn>, <Wm>, <Xa>
```

Decode for this encoding

```
constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer m = UInt(Rm);
constant integer a = UInt(Ra);
```

Assembler Symbols

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Wn> Is the 32-bit name of the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.

<Wm> Is the 32-bit name of the second general-purpose source register holding the multiplier, encoded in the "Rm" field.

<Xa> Is the 64-bit name of the third general-purpose source register holding the minuend, encoded in the "Ra" field.

Alias Conditions

Alias	Is preferred when
SMNEGL	`Ra == '11111'`

Operation

```
constant bits(32) operand1 = X[n, 32];
constant bits(32) operand2 = X[m, 32];
constant bits(64) operand3 = X[a, 64];

constant integer result = SInt(operand3) - (SInt(operand1) * SInt(operand2));

X[d, 64] = result<63:0>;
```

Operational information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

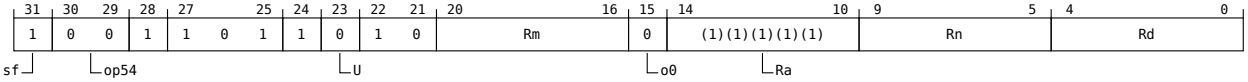
C6.2.232 SMULH

Signed multiply high

This instruction multiplies two 64-bit register values, and writes bits[127:64] of the 128-bit result to the 64-bit destination register.



Encoding

```
SMULH <Xd>, <Xn>, <Xm>
```

Decode for this encoding

```
constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer m = UInt(Rm);
```

Assembler Symbols

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Xn> Is the 64-bit name of the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.

<Xm> Is the 64-bit name of the second general-purpose source register holding the multiplier, encoded in the "Rm" field.

Operation

```
constant bits(64) operand1 = X[n, 64];
constant bits(64) operand2 = X[m, 64];

constant integer result = SInt(operand1) * SInt(operand2);

X[d, 64] = result<127:64>;
```

Operational information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

Non-Confidential

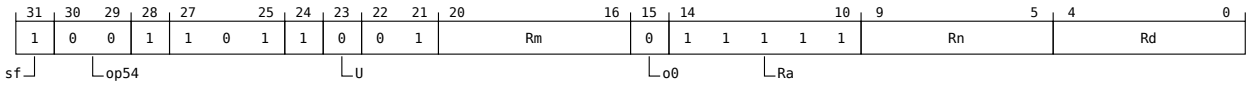
C6.2.233 SMULL

Signed multiply long

This instruction multiplies two 32-bit register values, and writes the result to the 64-bit destination register.

This is an alias of SMADDL. This means:

- The encodings in this description are named to match the encodings of SMADDL.
- The description of SMADDL gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.



Encoding

SMULL <Xd>, <Wn>, <Wm>

is equivalent to

SMADDL <Xd>, <Wn>, <Wm>, XZR

and is always the preferred disassembly.

Assembler Symbols

<**Xd**> Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

<**Wn**> Is the 32-bit name of the first general-purpose source register holding the multiplicand, encoded in the “Rn” field.

<**Wm**> Is the 32-bit name of the second general-purpose source register holding the multiplier, encoded in the “Rm” field.

Operation

The description of SMADDL gives the operational pseudocode for this instruction.

Operational Information

The description of SMADDL gives the operational information for this instruction.

Non-Confidential

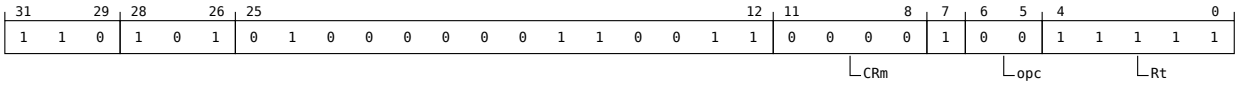
C6.2.234 SSBB

Speculative store bypass barrier

This instruction is a memory barrier that prevents speculative loads from bypassing earlier stores to the same virtual address under certain conditions. For more information and details of the semantics, see Speculative Store Bypass Barrier (SSBB).

This is an alias of DSB. This means:

- The encodings in this description are named to match the encodings of DSB.
- The description of DSB gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.



Encoding

```
SSBB
```

is equivalent to

```
DSB #0
```

and is always the preferred disassembly.

Operation

The description of DSB gives the operational pseudocode for this instruction.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.235 STCLR, STCLRL

Atomic bit clear on word or doubleword, without return

This instruction atomically loads a 32-bit word or 64-bit doubleword from memory, performs a bitwise AND with the complement of the value held in a register on it, and stores the result back to memory.

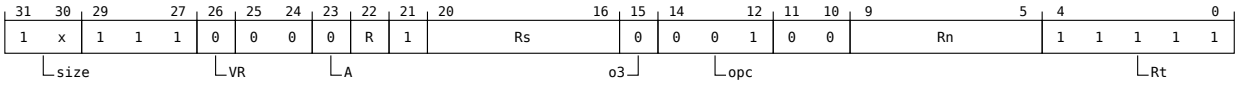
- `STCLR` does not have release semantics.
- `STCLRL` stores to memory with release semantics, as described in Load-Acquire, Store-Release.

For information about addressing modes, see Load/Store addressing modes.

This is an alias of LDCLR, LDCLRA, LDCLRAL, LDCLRL. This means:

- The encodings in this description are named to match the encodings of LDCLR, LDCLRA, LDCLRAL, LDCLRL.
- The description of LDCLR, LDCLRA, LDCLRAL, LDCLRL gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

Integer
(FEAT_LSE)



Encoding for the 32-bit no memory ordering variant Applies when `(size == 10 && R == 0)`

```
STCLR <Ws>, [<Xn|SP>]
```

is equivalent to

```
LDCLR <Ws>, WZR, [<Xn|SP>]
```

and is always the preferred disassembly.

Encoding for the 32-bit release variant Applies when `(size == 10 && R == 1)`

```
STCLRL <Ws>, [<Xn|SP>]
```

is equivalent to

```
LDCLRL <Ws>, WZR, [<Xn|SP>]
```

and is always the preferred disassembly.

Encoding for the 64-bit no memory ordering variant Applies when `(size == 11 && R == 0)`

```
STCLR <Xs>, [<Xn|SP>]
```

is equivalent to

```
LDCLR <Xs>, XZR, [<Xn|SP>]
```

and is always the preferred disassembly.

Encoding for the 64-bit release variant Applies when `(size == 11 && R == 1)`

```
STCLRL <Xs>, [<Xn|SP>]
```

C6.2.236 STCLRB, STCLRLB

Atomic bit clear on byte, without return

This instruction atomically loads an 8-bit byte from memory, performs a bitwise AND with the complement of the value held in a register on it, and stores the result back to memory.

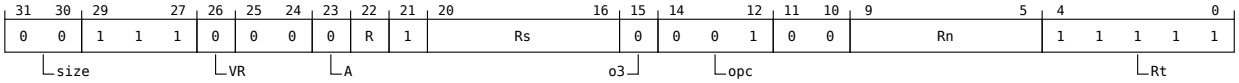
- `STCLRB` does not have release semantics.
- `STCLRLB` stores to memory with release semantics, as described in Load-Acquire, Store-Release.

For information about addressing modes, see Load/Store addressing modes.

This is an alias of LDCLRB, LDCLRAB, LDCLRALB, LDCLRLB. This means:

- The encodings in this description are named to match the encodings of LDCLRB, LDCLRAB, LDCLRALB, LDCLRLB.
- The description of LDCLRB, LDCLRAB, LDCLRALB, LDCLRLB gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

Integer
(FEAT_LSE)



Encoding for the No memory ordering variant Applies when `(R == 0)`

```
STCLRB <Ws>, [<Xn|SP>]
```

is equivalent to

```
LDCLRB <Ws>, WZR, [<Xn|SP>]
```

and is always the preferred disassembly.

C6.2.237 STCLRH, STCLRLH

Atomic bit clear on halfword, without return

This instruction atomically loads a 16-bit halfword from memory, performs a bitwise AND with the complement of the value held in a register on it, and stores the result back to memory.

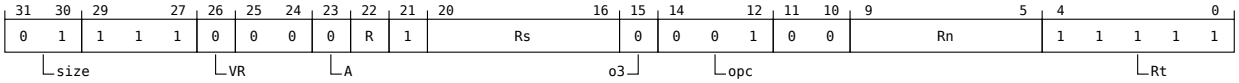
- `STCLRH` does not have release semantics.
- `STCLRLH` stores to memory with release semantics, as described in Load-Acquire, Store-Release.

For information about addressing modes, see Load/Store addressing modes.

This is an alias of LDCLRH, LDCLRAH, LDCLRALH, LDCLRLH. This means:

- The encodings in this description are named to match the encodings of LDCLRH, LDCLRAH, LDCLRALH, LDCLRLH.
- The description of LDCLRH, LDCLRAH, LDCLRALH, LDCLRLH gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

Integer
(FEAT_LSE)



Encoding for the No memory ordering variant Applies when `(R == 0)`

```
STCLRH <Ws>, [<Xn|SP>]
```

is equivalent to

```
LDCLRH <Ws>, WZR, [<Xn|SP>]
```

and is always the preferred disassembly.

Encoding for the Release variant Applies when `(R == 1)`

```
STCLRLH <Ws>, [<Xn|SP>]
```

is equivalent to

```
LDCLRLH <Ws>, WZR, [<Xn|SP>]
```

and is always the preferred disassembly.

C6.2.238 STEOR, STEORL

Atomic exclusive-OR on word or doubleword, without return

This instruction atomically loads a 32-bit word or 64-bit doubleword from memory, performs an exclusive-OR with the value held in a register on it, and stores the result back to memory.

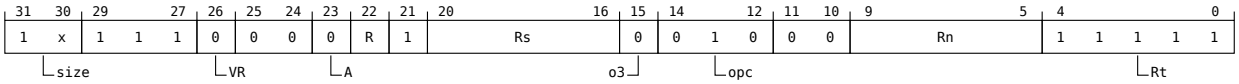
- `STEOR` does not have release semantics.
- `STEORL` stores to memory with release semantics, as described in Load-Acquire, Store-Release.

For information about addressing modes, see Load/Store addressing modes.

This is an alias of LDEOR, LDEORA, LDEORAL, LDEORL. This means:

- The encodings in this description are named to match the encodings of LDEOR, LDEORA, LDEORAL, LDEORL.
- The description of LDEOR, LDEORA, LDEORAL, LDEORL gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

Integer
(FEAT_LSE)



Encoding for the 32-bit no memory ordering variant Applies when `(size == 10 && R == 0)`

```
STEOR <Ws>, [<Xn|SP>]

C6.2.239 STEORB, STEORLB

Atomic exclusive-OR on byte, without return

This instruction atomically loads an 8-bit byte from memory, performs an exclusive-OR with the value held in a register on it, and stores the result back to memory.

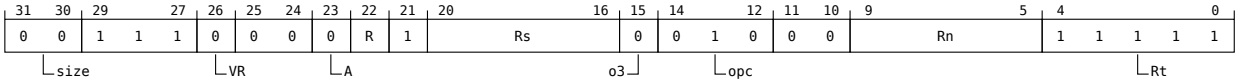
- STEORB does not have release semantics.
- STEORLB stores to memory with release semantics, as described in Load-Acquire, Store-Release.

For information about addressing modes, see Load/Store addressing modes.

This is an alias of LDEORB, LDEORAB, LDEORALB, LDEORLB. This means:

- The encodings in this description are named to match the encodings of LDEORB, LDEORAB, LDEORALB, LDEORLB.
- The description of LDEORB, LDEORAB, LDEORALB, LDEORLB gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

Integer
(FEAT_LSE)



Encoding for the No memory ordering variant Applies when (R == 0)

```
STEORB <Ws>, [<Xn|SP>]
```

is equivalent to

```
LDEORB <Ws>, WZR, [<Xn|SP>]
```

and is always the preferred disassembly.

Encoding for the Release variant Applies when (R == 1)

```
STEORLB <Ws>, [<Xn|SP>]
```

is equivalent to

```
LDEORLB <Ws>, WZR, [<Xn|SP>]
```

and is always the preferred disassembly.

Assembler Symbols

<**Ws**> Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.

<**Xn|SP**> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

The description of LDEORB, LDEORAB, LDEORALB, LDEORLB gives the operational pseudocode for this instruction.

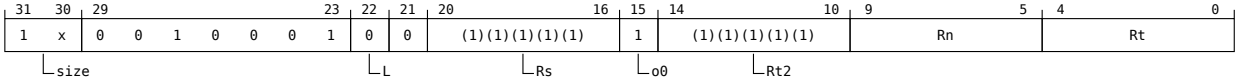
C6.2.241 STLR

Store-release register

This instruction stores a 32-bit word or a 64-bit doubleword to a memory location, from a register. The instruction also has memory ordering semantics as described in Load-Acquire, Store-Release. For information about addressing modes, see Load/Store addressing modes.



Encoding for the 32-bit variant Applies when `(size == 10)`

```
STLR <Wt>, [<Xn|SP>{, #0}]
```

Encoding for the 64-bit variant Applies when `(size == 11)`

```
STLR <Xt>, [<Xn|SP>{, #0}]
```

Decode for all variants of this encoding

```
constant integer t = UInt(Rt);
constant integer n = UInt(Rn);
constant boolean wback = FALSE;
constant integer offset = 0;
constant boolean rt_unknown = FALSE;

constant integer elsize = 8 << UInt(size);
constant integer datasize = elsize;
constant boolean acquire = FALSE;
```

Assembler Symbols

<Wt> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<Xt> Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

Operation

```
bits(64) address;
constant integer dbytes = datasize DIV 8;

constant AccessDescriptor accdesc = CreateAccDescAcqRel(MemOp_STORE, acquire, t);

if n == 31 then
    CheckSPAlignment();
    address = SP[64];
else
    address = X[n, 64];

address = AddressAdd(address, offset, accdesc);
bits(datasize) data;
if rt_unknown then
    data = bits(datasize) UNKNOWN;
else
    data = X[t, datasize];
Mem[address, dbytes, accdesc] = data;
if wback then
```

Non-Confidential

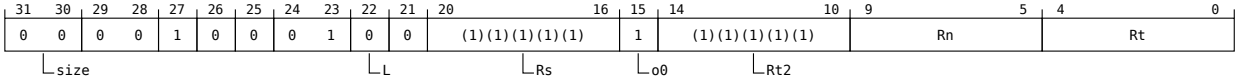
C6.2.242 STLRB

Store-release register byte

This instruction stores a byte from a 32-bit register to a memory location. The instruction also has memory ordering semantics as described in Load-Acquire, Store-Release. For information about addressing modes, see Load/Store addressing modes.



Encoding

```
STLRB <Wt>, [<Xn|SP>{, #0}]
```

Decode for this encoding

```
constant integer t = UInt(Rt);
constant integer n = UInt(Rn);
constant boolean acquire = FALSE;
```

Assembler Symbols

<Wt> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

```
bits(64) address;

constant AccessDescriptor accdesc = CreateAccDescAcqRel(MemOp_STORE, acquire, t);

if n == 31 then
    CheckSPAlignment();
    address = SP[64];
else
    address = X[n, 64];

address = AddressAdd(address, 0, accdesc);
Mem[address, 1, accdesc] = X[t, 8];
```

Operational information

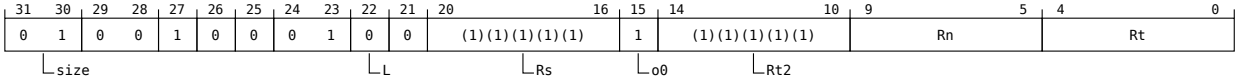
This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.243 STLRH

Store-release register halfword

This instruction stores a halfword from a 32-bit register to a memory location. The instruction also has memory ordering semantics as described in Load-Acquire, Store-Release. For information about addressing modes, see Load/Store addressing modes.



Encoding

```
STLRH <Wt>, [<Xn|SP>{, #0}]
```

Decode for this encoding

```
constant integer t = UInt(Rt);
constant integer n = UInt(Rn);
constant boolean acquire = FALSE;
```

Assembler Symbols

<Wt> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

```
bits(64) address;

constant AccessDescriptor accdesc = CreateAccDescAcqRel(MemOp_STORE, acquire, t);

if n == 31 then
    CheckSPAlignment();
    address = SP[64];
else
    address = X[n, 64];

address = AddressAdd(address, 0, accdesc);
Mem[address, 2, accdesc] = X[t, 16];
```

Operational information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

C6.2.244 STLUR

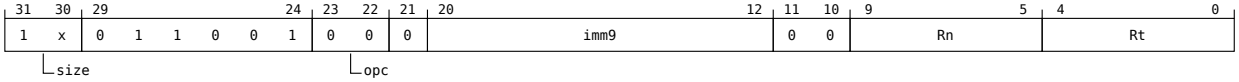
Store-release register (unscaled)

This instruction calculates an address from a base register value and an immediate offset, and stores a 32-bit word or a 64-bit doubleword to the calculated address, from a register.

The instruction has memory ordering semantics as described in Load-Acquire, Load-AcquirePC, and Store-Release

For information about addressing modes, see Load/Store addressing modes.

Unscaled offset
(FEAT_LRCPC2)



Encoding for the 32-bit variant Applies when `(size == 10)`

```
STLUR <Wt>, [<Xn|SP>{, #<simm>}]
```

Encoding for the 64-bit variant Applies when `(size == 11)`

```
STLUR <Xt>, [<Xn|SP>{, #<simm>}]
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_LRCPC2) then EndOfDecode(Decode_UNDEF);
constant integer scale = UInt(size);
constant bits(64) offset = SignExtend(imm9, 64);
constant integer n = UInt(Rn);
constant integer t = UInt(Rt);

constant integer datasize = 8 << scale;
constant boolean acquire = FALSE;
```

Assembler Symbols

<**Wt**> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

<**Xn|SP**> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<**simm**> Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the "imm9" field.

<**Xt**> Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

Operation

```
bits(64) address;

constant AccessDescriptor accdesc = CreateAccDescAcqRel(MemOp_STORE, acquire, t);

if n == 31 then
    CheckSPAlignment();
    address = SP[64];
else
    address = X[n, 64];

address = AddressAdd(address, offset, accdesc);

Mem[address, datasize DIV 8, accdesc] = X[t, datasize];
```

C6.2.245 STLURB

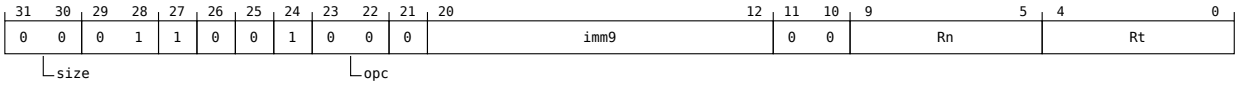
Store-release register byte (unscaled)

This instruction calculates an address from a base register value and an immediate offset, and stores a byte to the calculated address, from a 32-bit register.

The instruction has memory ordering semantics as described in Load-Acquire, Load-AcquirePC, and Store-Release

For information about addressing modes, see Load/Store addressing modes.

Unscaled offset
(FEAT_LRCPC2)



Encoding

```
STLURB <Wt>, [<Xn|SP>{, #<simm>}]
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_LRCPC2) then EndOfDecode(Decode_UNDEF);
constant bits(64) offset = SignExtend(imm9, 64);
constant integer n = UInt(Rn);
constant integer t = UInt(Rt);

constant integer datasize = 8;
constant boolean acquire = FALSE;
```

Assembler Symbols

<Wt> Is the 32-bit name of the general-purpose register to be transferred, encoded in the “Rt” field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the “Rn” field.

<simm> Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the “imm9” field.

Operation

```
bits(64) address;

constant AccessDescriptor accdesc = CreateAccDescAcqRel(MemOp_STORE, acquire, t);

if n == 31 then
    CheckSPAlignment();
    address = SP[64];
else
    address = X[n, 64];

address = AddressAdd(address, offset, accdesc);

Mem[address, datasize DIV 8, accdesc] = X[t, datasize];
```

Operational information

C6.2.246 STLURH

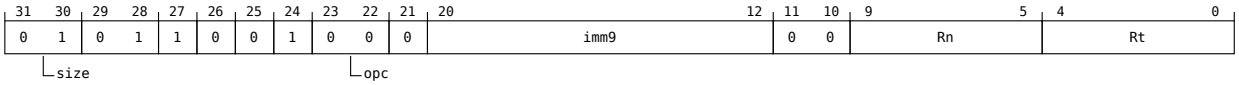
Store-release register halfword (unscaled)

This instruction calculates an address from a base register value and an immediate offset, and stores a halfword to the calculated address, from a 32-bit register.

The instruction has memory ordering semantics as described in Load-Acquire, Load-AcquirePC, and Store-Release

For information about addressing modes, see Load/Store addressing modes.

Unscaled offset
(FEAT_LRCPC2)



Encoding

```
STLURH <Wt>, [<Xn|SP>{, #<simm>}]
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_LRCPC2) then EndOfDecode(Decode_UNDEF);
constant bits(64) offset = SignExtend(imm9, 64);
constant integer n = UInt(Rn);
constant integer t = UInt(Rt);

constant integer datasize = 16;
constant boolean acquire = FALSE;
```

Assembler Symbols

<**Wt**> Is the 32-bit name of the general-purpose register to be transferred, encoded in the “Rt” field.

<**Xn|SP**> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the “Rn” field.

<**simm**> Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the “imm9” field.

Operation

```
bits(64) address;

constant AccessDescriptor accdesc = CreateAccDescAcqRel(MemOp_STORE, acquire, t);

if n == 31 then
    CheckSPAlignment();
    address = SP[64];
else
    address = X[n, 64];

address = AddressAdd(address, offset, accdesc);

Mem[address, datasize DIV 8, accdesc] = X[t, datasize];
```

Operational information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

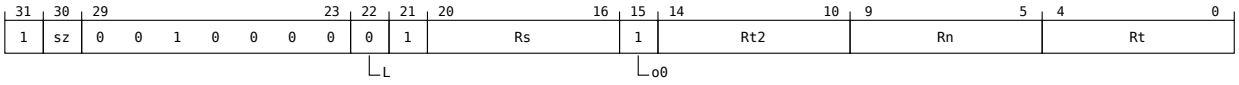
C6.2.247 STLXP

Store-release exclusive pair of registers

This instruction stores two 32-bit words or two 64-bit doublewords to a memory location if the PE has exclusive access to the memory address, from two registers, and returns a status value of 0 if the store was successful, or of 1 if no store was performed. See Synchronization and semaphores. For information on single-copy atomicity and alignment requirements, see Requirements for single-copy atomicity and Alignment of data accesses. If a 64-bit pair Store-Exclusive succeeds, it causes a single-copy atomic update of the 128-bit memory location being updated. The instruction also has memory ordering semantics, as described in Load-Acquire, Store-Release. For information about addressing modes, see Load/Store addressing modes.



Encoding for the 32-bit variant Applies when `(sz == 0)`

```
STLXP <Ws>, <Wt1>, <Wt2>, [<Xn|SP>{, #0}]
```

Encoding for the 64-bit variant Applies when `(sz == 1)`

```
STLXP <Ws>, <Xt1>, <Xt2>, [<Xn|SP>{, #0}]
```

Decode for all variants of this encoding

```
constant integer s = UInt(Rs);
constant integer t = UInt(Rt);
constant integer t2 = UInt(Rt2);
constant integer n = UInt(Rn);

constant integer elsize = 32 << UInt(sz);
constant integer datasize = elsize * 2;
constant boolean acqrel = TRUE;

boolean rt_unknown = FALSE;
boolean rn_unknown = FALSE;
if s == t || (s == t2) then
    constant Constraint c = ConstrainUnpredictable(Unpredictable_DATAOVERLAP);
    assert c IN {Constraint_UNKNOWN, Constraint_UNDEF, Constraint_NOP};
    case c of
        when Constraint_UNKNOWN    rt_unknown = TRUE;    // store UNKNOWN value
        when Constraint_UNDEF      EndOfDecode(Decode_UNDEF);
        when Constraint_NOP        EndOfDecode(Decode_NOP);
if s == n && n != 31 then
    constant Constraint c = ConstrainUnpredictable(Unpredictable_BASEOVERLAP);
    assert c IN {Constraint_UNKNOWN, Constraint_UNDEF, Constraint_NOP};
    case c of
        when Constraint_UNKNOWN    rn_unknown = TRUE;    // address is UNKNOWN
        when Constraint_UNDEF      EndOfDecode(Decode_UNDEF);
        when Constraint_NOP        EndOfDecode(Decode_NOP);
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Architectural Constraints on UNPREDICTABLE behaviors, and particularly STLXP.

Assembler Symbols

<**Ws**> Is the 32-bit name of the general-purpose register into which the status result of the store exclusive is written, encoded in the "Rs" field. The value returned is:

0 If the operation updates memory.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

1 If the operation fails to update memory.

<**Wt1**> Is the 32-bit name of the first general-purpose register to be transferred, encoded in the "Rt" field.

<**Wt2**> Is the 32-bit name of the second general-purpose register to be transferred, encoded in the "Rt2" field.

<**Xn|SP**> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<**Xt1**> Is the 64-bit name of the first general-purpose register to be transferred, encoded in the "Rt" field.

<**Xt2**> Is the 64-bit name of the second general-purpose register to be transferred, encoded in the "Rt2" field.

Aborts and alignment

If a synchronous Data Abort exception is generated by the execution of this instruction:

- Memory is not updated.
- <Ws> is not updated.

Accessing an address that is not aligned to the size of the data being accessed causes an Alignment fault Data Abort exception to be generated, subject to the following rules:

- If AArch64.ExclusiveMonitorsPass() returns TRUE, the exception is generated.
- Otherwise, it is IMPLEMENTATION DEFINED whether the exception is generated.

If AArch64.ExclusiveMonitorsPass() returns FALSE and the memory address, if accessed, would generate a synchronous Data Abort exception, it is IMPLEMENTATION DEFINED whether the exception is generated.

Operation

```
bits(64) address;
bits(datasize) data;

constant integer dbytes = datasize DIV 8;
constant boolean privileged = PSTATE.EL != EL0;
constant boolean ispair = FALSE;
constant AccessDescriptor accdesc = CreateAccDescExLDST(MemOp_STORE, acqrel, privileged, ispair, t,
                                                        t2);

if n == 31 then
    CheckSPAlignment();
    address = SP[64];
elsif rn_unknown then
    address = bits(64) UNKNOWN;
else
    address = X[n, 64];

if rt_unknown then
    data = bits(datasize) UNKNOWN;
else
    constant bits(datasize DIV 2) el1 = X[t, datasize DIV 2];
    constant bits(datasize DIV 2) el2 = X[t2, datasize DIV 2];
    data = if BigEndian(accdesc.acctype) then el1:el2 else el2:el1;
bit status = '1';
// Check whether the Exclusives monitors are set to include the
// physical memory locations corresponding to virtual address
// range [address, address+dbytes-1].
// If AArch64.ExclusiveMonitorsPass() returns FALSE and the memory address,
// if accessed, would generate a synchronous Data Abort exception, it is
// IMPLEMENTATION DEFINED whether the exception is generated.
// It is a limitation of this model that synchronous Data Aborts are never
// generated in this case, as Mem[] is not called.

if AArch64.ExclusiveMonitorsPass(address, dbytes, accdesc) then
    // This atomic write will be rejected if it does not refer
    // to the same physical locations after address translation.
```

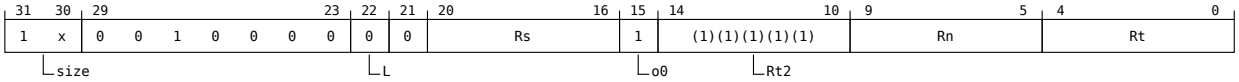
C6.2.248 STLXR

Store-release exclusive register

This instruction stores a 32-bit word or a 64-bit doubleword to memory if the PE has exclusive access to the memory address, and returns a status value of 0 if the store was successful, or of 1 if no store was performed. See Synchronization and semaphores. The memory access is atomic. The instruction also has memory ordering semantics as described in Load-Acquire, Store-Release. For information about addressing modes, see Load/Store addressing modes.



Encoding for the 32-bit variant Applies when `(size == 10)`

```
STLXR <Ws>, <Wt>, [<Xn|SP>{, #0}]
```

Encoding for the 64-bit variant Applies when `(size == 11)`

```
STLXR <Ws>, <Xt>, [<Xn|SP>{, #0}]
```

Decode for all variants of this encoding

```
constant integer s = UInt(Rs);
constant integer t = UInt(Rt);
constant integer n = UInt(Rn);

constant integer elsize = 8 << UInt(size);
constant boolean acqrel = TRUE;

boolean rt_unknown = FALSE;
boolean rn_unknown = FALSE;
if s == t then
    constant Constraint c = ConstrainUnpredictable(Unpredictable_DATAOVERLAP);
    assert c IN {Constraint_UNKNOWN, Constraint_UNDEF, Constraint_NOP};
    case c of
        when Constraint_UNKNOWN    rt_unknown = TRUE;    // store UNKNOWN value
        when Constraint_UNDEF      EndOfDecode(Decode_UNDEF);
        when Constraint_NOP        EndOfDecode(Decode_NOP);
if s == n && n != 31 then
    constant Constraint c = ConstrainUnpredictable(Unpredictable_BASEOVERLAP);
    assert c IN {Constraint_UNKNOWN, Constraint_UNDEF, Constraint_NOP};
    case c of
        when Constraint_UNKNOWN    rn_unknown = TRUE;    // address is UNKNOWN
        when Constraint_UNDEF      EndOfDecode(Decode_UNDEF);
        when Constraint_NOP        EndOfDecode(Decode_NOP);
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Architectural Constraints on UNPREDICTABLE behaviors, and particularly STLXR.

Assembler Symbols

<**Ws**> Is the 32-bit name of the general-purpose register into which the status result of the store exclusive is written, encoded in the “Rs” field. The value returned is:

0 If the operation updates memory.

1 If the operation fails to update memory.

<**Wt**> Is the 32-bit name of the general-purpose register to be transferred, encoded in the “Rt” field.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

<**Xn|SP**> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<**Xt**> Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

Aborts and alignment

If a synchronous Data Abort exception is generated by the execution of this instruction:

- Memory is not updated.
- <Ws> is not updated.

Accessing an address that is not aligned to the size of the data being accessed causes an Alignment fault Data Abort exception to be generated, subject to the following rules:

- If AArch64.ExclusiveMonitorsPass() returns TRUE, the exception is generated.
- Otherwise, it is IMPLEMENTATION DEFINED whether the exception is generated.

If AArch64.ExclusiveMonitorsPass() returns FALSE and the memory address, if accessed, would generate a synchronous Data Abort exception, it is IMPLEMENTATION DEFINED whether the exception is generated.

Operation

```
bits(64) address;
bits(elsize) data;

constant integer dbytes = elsize DIV 8;
constant boolean privileged = PSTATE.EL != EL0;
constant AccessDescriptor accdesc = CreateAccDescExLDST(MemOp_STORE, acqrel, privileged, t);

if n == 31 then
    CheckSPAlignment();
    address = SP[64];
elsif rn_unknown then
    address = bits(64) UNKNOWN;
else
    address = X[n, 64];

if rt_unknown then
    data = bits(elsize) UNKNOWN;
else
    data = X[t, elsize];
bit status = '1';
// Check whether the Exclusives monitors are set to include the
// physical memory locations corresponding to virtual address
// range [address, address+dbytes-1].
// If AArch64.ExclusiveMonitorsPass() returns FALSE and the memory address,
// if accessed, would generate a synchronous Data Abort exception, it is
// IMPLEMENTATION DEFINED whether the exception is generated.
// It is a limitation of this model that synchronous Data Aborts are never
// generated in this case, as Mem[] is not called.

if AArch64.ExclusiveMonitorsPass(address, dbytes, accdesc) then
    // This atomic write will be rejected if it does not refer
    // to the same physical locations after address translation.
    Mem[address, dbytes, accdesc] = data;
    status = ExclusiveMonitorsStatus();
X[s, 32] = ZeroExtend(status, 32);
```

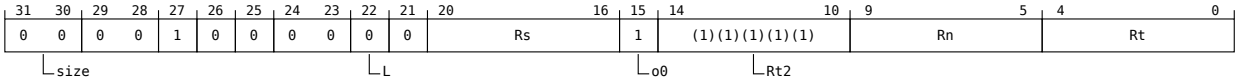
C6.2.249 STLXRB

Store-release exclusive register byte

This instruction stores a byte from a 32-bit register to memory if the PE has exclusive access to the memory address, and returns a status value of 0 if the store was successful, or of 1 if no store was performed. See Synchronization and semaphores. The memory access is atomic. The instruction also has memory ordering semantics as described in Load-Acquire, Store-Release. For information about addressing modes, see Load/Store addressing modes.



Encoding

```
STLXRB <Ws>, <Wt>, [<Xn|SP>{, #0}]
```

Decode for this encoding

```
constant integer s = UInt(Rs);
constant integer t = UInt(Rt);
constant integer n = UInt(Rn);

constant boolean acqrel = TRUE;

boolean rt_unknown = FALSE;
boolean rn_unknown = FALSE;
if s == t then
    constant Constraint c = ConstrainUnpredictable(Unpredictable_DATAOVERLAP);
    assert c IN {Constraint_UNKNOWN, Constraint_UNDEF, Constraint_NOP};
    case c of
        when Constraint_UNKNOWN    rt_unknown = TRUE;    // store UNKNOWN value
        when Constraint_UNDEF      EndOfDecode(Decode_UNDEF);
        when Constraint_NOP        EndOfDecode(Decode_NOP);
if s == n && n != 31 then
    constant Constraint c = ConstrainUnpredictable(Unpredictable_BASEOVERLAP);
    assert c IN {Constraint_UNKNOWN, Constraint_UNDEF, Constraint_NOP};
    case c of
        when Constraint_UNKNOWN    rn_unknown = TRUE;    // address is UNKNOWN
        when Constraint_UNDEF      EndOfDecode(Decode_UNDEF);
        when Constraint_NOP        EndOfDecode(Decode_NOP);
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Architectural Constraints on UNPREDICTABLE behaviors, and particularly STLXRB.

Assembler Symbols

<**Ws**> Is the 32-bit name of the general-purpose register into which the status result of the store exclusive is written, encoded in the "Rs" field. The value returned is:

0 If the operation updates memory.

1 If the operation fails to update memory.

<**Wt**> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

<**Xn|SP**> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Aborts

If a synchronous Data Abort exception is generated by the execution of this instruction:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- Memory is not updated.
- <Ws> is not updated.

If AArch64.ExclusiveMonitorsPass() returns FALSE and the memory address, if accessed, would generate a synchronous Data Abort exception, it is IMPLEMENTATION DEFINED whether the exception is generated.

Operation

```
bits(64) address;
bits(8) data;

constant boolean privileged = PSTATE.EL != EL0;
constant AccessDescriptor accdesc = CreateAccDescExLDST(MemOp_STORE, acqrel, privileged, t);

if n == 31 then
    CheckSPAlignment();
    address = SP[64];
elsif rn_unknown then
    address = bits(64) UNKNOWN;
else
    address = X[n, 64];

if rt_unknown then
    data = bits(8) UNKNOWN;
else
    data = X[t, 8];
bit status = '1';
// Check whether the Exclusives monitors are set to include the
// physical memory locations corresponding to virtual address
// range [address, address+dbytes-1].
// If AArch64.ExclusiveMonitorsPass() returns FALSE and the memory address,
// if accessed, would generate a synchronous Data Abort exception, it is
// IMPLEMENTATION DEFINED whether the exception is generated.
// It is a limitation of this model that synchronous Data Aborts are never
// generated in this case, as Mem[] is not called.

if AArch64.ExclusiveMonitorsPass(address, 1, accdesc) then
    // This atomic write will be rejected if it does not refer
    // to the same physical locations after address translation.
    Mem[address, 1, accdesc] = data;
    status = ExclusiveMonitorsStatus();
X[s, 32] = ZeroExtend(status, 32);
```

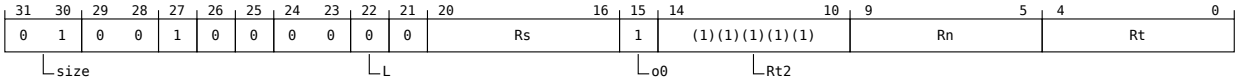
C6.2.250 STLXRH

Store-release exclusive register halfword

This instruction stores a halfword from a 32-bit register to memory if the PE has exclusive access to the memory address, and returns a status value of 0 if the store was successful, or of 1 if no store was performed. See Synchronization and semaphores. The memory access is atomic. The instruction also has memory ordering semantics as described in Load-Acquire, Store-Release. For information about addressing modes, see Load/Store addressing modes.



Encoding

```
STLXRH <Ws>, <Wt>, [<Xn|SP>{, #0}]
```

Decode for this encoding

```
constant integer s = UInt(Rs);
constant integer t = UInt(Rt);
constant integer n = UInt(Rn);

constant boolean acqrel = TRUE;

boolean rt_unknown = FALSE;
boolean rn_unknown = FALSE;
if s == t then
    constant Constraint c = ConstrainUnpredictable(Unpredictable_DATAOVERLAP);
    assert c IN {Constraint_UNKNOWN, Constraint_UNDEF, Constraint_NOP};
    case c of
        when Constraint_UNKNOWN    rt_unknown = TRUE;    // store UNKNOWN value
        when Constraint_UNDEF      EndOfDecode(Decode_UNDEF);
        when Constraint_NOP        EndOfDecode(Decode_NOP);
if s == n && n != 31 then
    constant Constraint c = ConstrainUnpredictable(Unpredictable_BASEOVERLAP);
    assert c IN {Constraint_UNKNOWN, Constraint_UNDEF, Constraint_NOP};
    case c of
        when Constraint_UNKNOWN    rn_unknown = TRUE;    // address is UNKNOWN
        when Constraint_UNDEF      EndOfDecode(Decode_UNDEF);
        when Constraint_NOP        EndOfDecode(Decode_NOP);
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Architectural Constraints on UNPREDICTABLE behaviors, and particularly STLXRH.

Assembler Symbols

<**Ws**> Is the 32-bit name of the general-purpose register into which the status result of the store exclusive is written, encoded in the "Rs" field. The value returned is:

0 If the operation updates memory.

1 If the operation fails to update memory.

<**Wt**> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

<**Xn|SP**> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Aborts and alignment

If a synchronous Data Abort exception is generated by the execution of this instruction:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- Memory is not updated.
- <Ws> is not updated.

A non halfword-aligned memory address causes an Alignment fault Data Abort exception to be generated, subject to the following rules:

- If AArch64.ExclusiveMonitorsPass() returns TRUE, the exception is generated.
- Otherwise, it is IMPLEMENTATION DEFINED whether the exception is generated.

If AArch64.ExclusiveMonitorsPass() returns FALSE and the memory address, if accessed, would generate a synchronous Data Abort exception, it is IMPLEMENTATION DEFINED whether the exception is generated.

Operation

```
bits(64) address;
bits(16) data;

constant boolean privileged = PSTATE.EL != EL0;
constant AccessDescriptor accdesc = CreateAccDescExLDST(MemOp_STORE, acqrel, privileged, t);

if n == 31 then
    CheckSPAlignment();
    address = SP[64];
elsif rn_unknown then
    address = bits(64) UNKNOWN;
else
    address = X[n, 64];

if rt_unknown then
    data = bits(16) UNKNOWN;
else
    data = X[t, 16];
bit status = '1';
// Check whether the Exclusives monitors are set to include the
// physical memory locations corresponding to virtual address
// range [address, address+dbytes-1].
// If AArch64.ExclusiveMonitorsPass() returns FALSE and the memory address,
// if accessed, would generate a synchronous Data Abort exception, it is
// IMPLEMENTATION DEFINED whether the exception is generated.
// It is a limitation of this model that synchronous Data Aborts are never
// generated in this case, as Mem[] is not called.

if AArch64.ExclusiveMonitorsPass(address, 2, accdesc) then
    // This atomic write will be rejected if it does not refer
    // to the same physical locations after address translation.
    Mem[address, 2, accdesc] = data;
    status = ExclusiveMonitorsStatus();
X[s, 32] = ZeroExtend(status, 32);
```

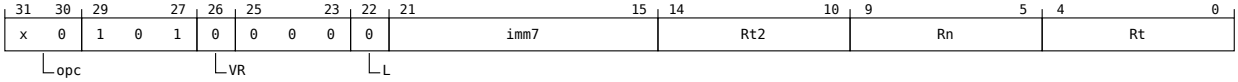
C6.2.251 STNP

Store pair of registers, with non-temporal hint

This instruction calculates an address from a base register value and an immediate offset, and stores two 32-bit words or two 64-bit doublewords to the calculated address, from two registers. For information about addressing modes, see Load/Store addressing modes. For information about non-temporal pair instructions, see Load/Store non-temporal pair.



Encoding for the 32-bit variant Applies when `(opc == 00)`

```
STNP <Wt1>, <Wt2>, [<Xn|SP>{, #<imm>}]
```

Encoding for the 64-bit variant Applies when `(opc == 10)`

```
STNP <Xt1>, <Xt2>, [<Xn|SP>{, #<imm>}]
```

Decode for all variants of this encoding

```
constant integer t = UInt(Rt);
constant integer t2 = UInt(Rt2);
constant integer n = UInt(Rn);
constant boolean nontemporal = TRUE;
constant integer scale = 2 + UInt(opc<1>);
constant integer datasize = 8 << scale;
constant bits(64) offset = LSL(SignExtend(imm7, 64), scale);
```

Assembler Symbols

<Wt1> Is the 32-bit name of the first general-purpose register to be transferred, encoded in the "Rt" field.

<Wt2> Is the 32-bit name of the second general-purpose register to be transferred, encoded in the "Rt2" field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<imm> For the "32-bit" variant: is the optional signed immediate byte offset, a multiple of 4 in the range -256 to 252, defaulting to 0 and encoded in the "imm7" field as <imm>/4.

For the "64-bit" variant: is the optional signed immediate byte offset, a multiple of 8 in the range -512 to 504, defaulting to 0 and encoded in the "imm7" field as <imm>/8.

<Xt1> Is the 64-bit name of the first general-purpose register to be transferred, encoded in the "Rt" field.

<Xt2> Is the 64-bit name of the second general-purpose register to be transferred, encoded in the "Rt2" field.

Operation

```
bits(64) address;
constant integer dbytes = datasize DIV 8;
constant boolean privileged = PSTATE.EL != EL0;
constant boolean ispair = TRUE;
constant AccessDescriptor accdesc = CreateAccDescGPR(MemOp_STORE, nontemporal, privileged, ispair,
                                                     t, t2);
if n == 31 then
    CheckSPAlignment();
    address = SP[64];
else
```

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

```
    address = X[n, 64];

address = AddressAdd(address, offset, accdesc);
constant bits(2*datasize) data = (if BigEndian(accdesc.acctype)
                                  then X[t,  datasize]:X[t2, datasize]
                                  else X[t2, datasize]:X[t,  datasize]);
Mem[address, 2 * dbytes, accdesc] = data;
```

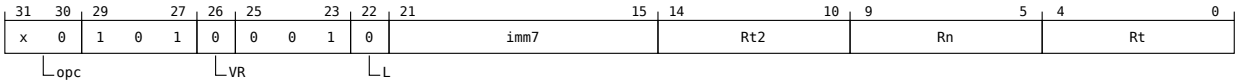
C6.2.252 STP

Store pair of registers

This instruction calculates an address from a base register value and an immediate offset, and stores two 32-bit words or two 64-bit doublewords to the calculated address, from two registers. For information about addressing modes, see Load/Store addressing modes.

It has encodings from 3 classes: Post-index , Pre-index and Signed offset

Post-index



Encoding for the 32-bit variant Applies when `(opc == 00)`

```
STP <Wt1>, <Wt2>, [<Xn|SP>], #<imm>
```

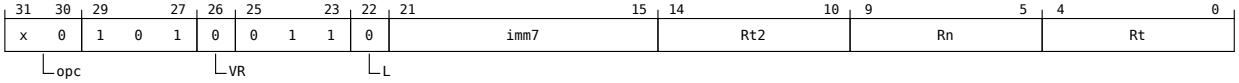
Encoding for the 64-bit variant Applies when `(opc == 10)`

```
STP <Xt1>, <Xt2>, [<Xn|SP>], #<imm>
```

Decode for all variants of this encoding

```
constant boolean wback = TRUE;
constant boolean postindex = TRUE;
```

Pre-index



Encoding for the 32-bit variant Applies when `(opc == 00)`

```
STP <Wt1>, <Wt2>, [<Xn|SP>, #<imm>]!
```

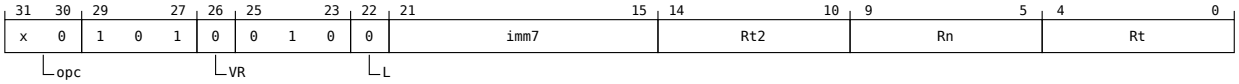
Encoding for the 64-bit variant Applies when `(opc == 10)`

```
STP <Xt1>, <Xt2>, [<Xn|SP>, #<imm>]!
```

Decode for all variants of this encoding

```
constant boolean wback = TRUE;
constant boolean postindex = FALSE;
```

Signed offset



Encoding for the 32-bit variant Applies when `(opc == 00)`

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

```
STP <Wt1>, <Wt2>, [<Xn|SP>{, #<imm>}]
```

Encoding for the 64-bit variant Applies when `(opc == 10)`

```
STP <Xt1>, <Xt2>, [<Xn|SP>{, #<imm>}]
```

Decode for all variants of this encoding

```
constant boolean wback = FALSE;
constant boolean postindex = FALSE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Architectural Constraints on UNPREDICTABLE behaviors, and particularly STP.

Assembler Symbols

<**Wt1**> Is the 32-bit name of the first general-purpose register to be transferred, encoded in the "Rt" field.

<**Wt2**> Is the 32-bit name of the second general-purpose register to be transferred, encoded in the "Rt2" field.

<**Xn|SP**> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<**imm**> For the "Post-index 32-bit" and "Pre-index 32-bit" variants: is the signed immediate byte offset, a multiple of 4 in the range -256 to 252, encoded in the "imm7" field as <imm>/4.

For the "Post-index 64-bit" and "Pre-index 64-bit" variants: is the signed immediate byte offset, a multiple of 8 in the range -512 to 504, encoded in the "imm7" field as <imm>/8.

For the "Signed offset 32-bit" variant: is the optional signed immediate byte offset, a multiple of 4 in the range -256 to 252, defaulting to 0 and encoded in the "imm7" field as <imm>/4.

For the "Signed offset 64-bit" variant: is the optional signed immediate byte offset, a multiple of 8 in the range -512 to 504, defaulting to 0 and encoded in the "imm7" field as <imm>/8.

<**Xt1**> Is the 64-bit name of the first general-purpose register to be transferred, encoded in the "Rt" field.

<**Xt2**> Is the 64-bit name of the second general-purpose register to be transferred, encoded in the "Rt2" field.

Shared Decode

```
constant integer t = UInt(Rt);
constant integer t2 = UInt(Rt2);
constant integer n = UInt(Rn);
constant boolean nontemporal = FALSE;
constant integer scale = 2 + UInt(opc<1>);
constant integer datasize = 8 << scale;
constant bits(64) offset = LSL(SignExtend(imm7, 64), scale);

boolean rt_unknown = FALSE;
if wback && (t == n || t2 == n) && n != 31 then
    constant Constraint c = ConstrainUnpredictable(Unpredictable_WBOVERLAPST);
    assert c IN {Constraint_NONE, Constraint_UNKNOWN, Constraint_UNDEF, Constraint_NOP};
    case c of
        when Constraint_NONE       rt_unknown = FALSE;   // Value stored is pre-writeback

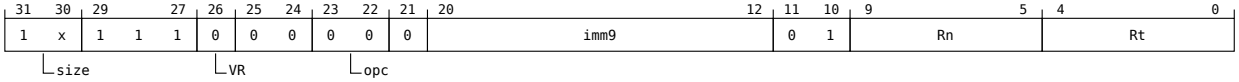
C6.2.253 STR (immediate)

Store register (immediate)

This instruction stores a word or a doubleword from a register to memory. The address that is used for the store is calculated from a base register and an immediate offset. For information about addressing modes, see Load/Store addressing modes.

It has encodings from 3 classes: Post-index , Pre-index and Unsigned offset

Post-index



Encoding for the 32-bit variant Applies when `(size == 10)`

```
STR <Wt>, [<Xn|SP>], #<simm>
```

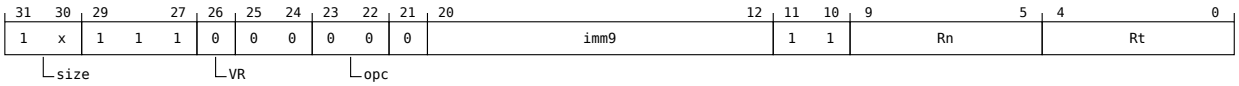
Encoding for the 64-bit variant Applies when `(size == 11)`

```
STR <Xt>, [<Xn|SP>], #<simm>
```

Decode for all variants of this encoding

```
constant boolean wback = TRUE;
constant boolean postindex = TRUE;
constant integer scale = UInt(size);
constant bits(64) offset = SignExtend(imm9, 64);
```

Pre-index



Encoding for the 32-bit variant Applies when `(size == 10)`

```
STR <Wt>, [<Xn|SP>, #<simm>]!
```

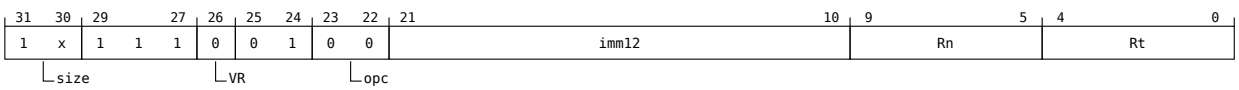
Encoding for the 64-bit variant Applies when `(size == 11)`

```
STR <Xt>, [<Xn|SP>, #<simm>]!
```

Decode for all variants of this encoding

```
constant boolean wback = TRUE;
constant boolean postindex = FALSE;
constant integer scale = UInt(size);
constant bits(64) offset = SignExtend(imm9, 64);
```

Unsigned offset



Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Encoding for the 32-bit variant Applies when `(size == 10)`

```
STR <Wt>, [<Xn|SP>{, #<pimm>}]
```

Encoding for the 64-bit variant Applies when `(size == 11)`

```
STR <Xt>, [<Xn|SP>{, #<pimm>}]
```

Decode for all variants of this encoding

```
constant boolean wback = FALSE;
constant boolean postindex = FALSE;
constant integer scale = UInt(size);
constant bits(64) offset = LSL(ZeroExtend(imm12, 64), scale);
```

Assembler Symbols

<**Wt**> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

<**Xn|SP**> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<**simm**> Is the signed immediate byte offset, in the range -256 to 255, encoded in the "imm9" field.

<**Xt**> Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

<**pimm**> For the "32-bit" variant: is the optional positive immediate byte offset, a multiple of 4 in the range 0 to 16380, defaulting to 0 and encoded in the "imm12" field as <pimm>/4.

For the "64-bit" variant: is the optional positive immediate byte offset, a multiple of 8 in the range 0 to 32760, defaulting to 0 and encoded in the "imm12" field as <pimm>/8.

Shared Decode

```
constant integer t = UInt(Rt);
constant integer n = UInt(Rn);
constant integer datasize = 8 << scale;
constant boolean nontemporal = FALSE;

Constraint c;
boolean rt_unknown = FALSE;
if wback && n == t && n != 31 then
    c = ConstrainUnpredictable(Unpredictable_WBOVERLAPST);
    assert c IN {Constraint_NONE, Constraint_UNKNOWN, Constraint_UNDEF, Constraint_NOP};
    case c of
        when Constraint_NONE    rt_unknown = FALSE;    // Value stored is original value
        when Constraint_UNKNOWN rt_unknown = TRUE;     // Value stored is UNKNOWN
        when Constraint_UNDEF   EndOfDecode(Decode_UNDEF);
        when Constraint_NOP     EndOfDecode(Decode_NOP);
```

Operation

```
bits(64) address;

constant boolean privileged = PSTATE.EL != EL0;
constant AccessDescriptor accdesc = CreateAccDescGPR(MemOp_STORE, nontemporal, privileged, t);

if n == 31 then
    CheckSPAlignment();
    address = SP[64];
else
    address = X[n, 64];

if !postindex then
    address = AddressAdd(address, offset, accdesc);

bits(datasize) data;
```

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

```
if rt_unknown then
    data = bits(datasize) UNKNOWN;
else
    data = X[t, datasize];

Mem[address, datasize DIV 8, accdesc] = data;

if wback then
    if postindex then
        address = AddressAdd(address, offset, accdesc);
    if n == 31 then
        SP[64] = address;
    else
        X[n, 64] = address;
```

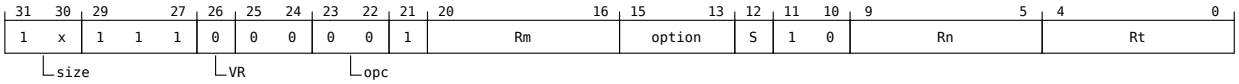
C6.2.254 STR (register)

Store register (register)

This instruction calculates an address from a base register value and an offset register value, and stores a 32-bit word or a 64-bit doubleword to the calculated address, from a register. For information about addressing modes, see Load/Store addressing modes.

The instruction uses an offset addressing mode, that calculates the address used for the memory access from a base register value and an offset register value. The offset can be optionally shifted and extended.



Encoding for the 32-bit variant Applies when `(size == 10)`

```
STR <Wt>, [<Xn|SP>, (<Wm>|<Xm>){, <extend> {<amount>}}]
```

Encoding for the 64-bit variant Applies when `(size == 11)`

```
STR <Xt>, [<Xn|SP>, (<Wm>|<Xm>){, <extend> {<amount>}}]
```

Decode for all variants of this encoding

```
if option<1> == '0' then EndOfDecode(Decode_UNDEF);             // sub-word index
constant ExtendType extend_type = DecodeRegExtend(option);
constant integer scale = UInt(size);
constant integer shift = if S == '1' then scale else 0;
```

Assembler Symbols

<**Wt**> Is the 32-bit name of the general-purpose register to be transferred, encoded in the “Rt” field.

<**Xn|SP**> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the “Rn” field.

<**Wm**> When option<0> is set to 0, is the 32-bit name of the general-purpose index register, encoded in the “Rm” field.

<**Xm**> When option<0> is set to 1, is the 64-bit name of the general-purpose index register, encoded in the “Rm” field.

<**extend**> Is the index extend/shift specifier, defaulting to LSL, and which must be omitted for the LSL option when <amount> is omitted, encoded in “option”:

option	<extend>
010	UXTW
011	LSL
110	SXTW
111	SXTX

<**amount**> For the “32-bit” variant: is the index shift amount, optional only when <extend> is not LSL. Where it is permitted to be optional, it defaults to #0. It is encoded in “S”:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

S	<amount>
0	#0
1	#2

For the “64-bit” variant: is the index shift amount, optional only when <extend> is not LSL. Where it is permitted to be optional, it defaults to #0. It is encoded in “S”:

S	<amount>
0	#0
1	#3

<Xt> Is the 64-bit name of the general-purpose register to be transferred, encoded in the “Rt” field.

Shared Decode

```
constant integer t = UInt(Rt);
constant integer n = UInt(Rn);
constant integer m = UInt(Rm);
constant integer datasize = 8 << scale;
constant boolean nontemporal = FALSE;
```

Operation

```
constant bits(64) offset = ExtendReg(m, extend_type, shift, 64);
bits(64) address;

constant boolean privileged = PSTATE.EL != EL0;
constant AccessDescriptor accdesc = CreateAccDescGPR(MemOp_STORE, nontemporal, privileged, t);

if n == 31 then
    CheckSPAlignment();
    address = SP[64];
else
    address = X[n, 64];

address = AddressAdd(address, offset, accdesc);

Mem[address, datasize DIV 8, accdesc] = X[t, datasize];
```

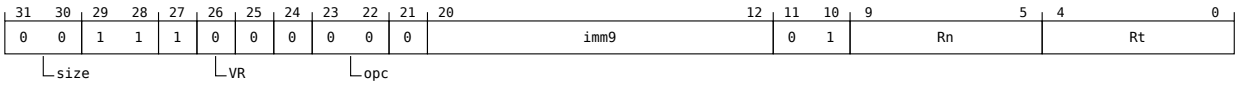
C6.2.255 STRB (immediate)

Store register byte (immediate)

This instruction stores the least significant byte of a 32-bit register to memory. The address that is used for the store is calculated from a base register and an immediate offset. For information about addressing modes, see Load/Store addressing modes.

It has encodings from 3 classes: Post-index , Pre-index and Unsigned offset

Post-index



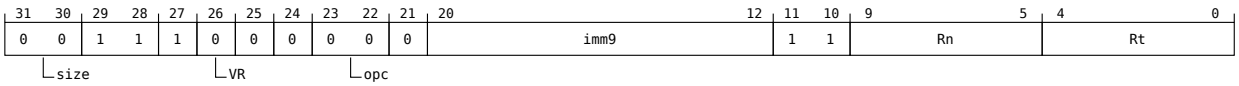
Encoding

```
STRB <Wt>, [<Xn|SP>], #<simm>
```

Decode for this encoding

```
constant boolean wback = TRUE;
constant boolean postindex = TRUE;
constant bits(64) offset = SignExtend(imm9, 64);
```

Pre-index



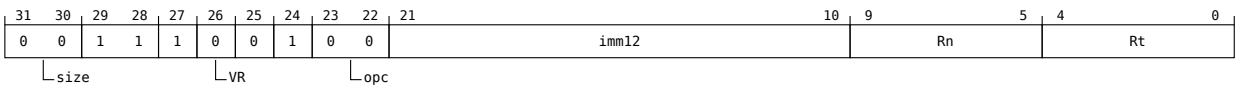
Encoding

```
STRB <Wt>, [<Xn|SP>, #<simm>]!
```

Decode for this encoding

```
constant boolean wback = TRUE;
constant boolean postindex = FALSE;
constant bits(64) offset = SignExtend(imm9, 64);
```

Unsigned offset



Encoding

```
STRB <Wt>, [<Xn|SP>{, #<pimm>}]
```

Decode for this encoding

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

```
constant boolean wback = FALSE;
constant boolean postindex = FALSE;
constant bits(64) offset = LSL(ZeroExtend(imm12, 64), 0);
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Architectural Constraints on UNPREDICTABLE behaviors, and particularly STRB (immediate).

Assembler Symbols

<**Wt**> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

<**Xn|SP**> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<**simm**> Is the signed immediate byte offset, in the range -256 to 255, encoded in the "imm9" field.

<**pimm**> Is the optional positive immediate byte offset, in the range 0 to 4095, defaulting to 0 and encoded in the "imm12" field.

Shared Decode

```
constant integer t = UInt(Rt);
constant integer n = UInt(Rn);
constant boolean nontemporal = FALSE;

Constraint c;
boolean rt_unknown = FALSE;
if wback && n == t && n != 31 then
    c = ConstrainUnpredictable(Unpredictable_WBOVERLAPST);
    assert c IN {Constraint_NONE, Constraint_UNKNOWN, Constraint_UNDEF, Constraint_NOP};
    case c of
        when Constraint_NONE    rt_unknown = FALSE;    // Value stored is original value
        when Constraint_UNKNOWN rt_unknown = TRUE;     // Value stored is UNKNOWN
        when Constraint_UNDEF   EndOfDecode(Decode_UNDEF);
        when Constraint_NOP     EndOfDecode(Decode_NOP);
```

Operation

```
bits(64) address;

constant boolean privileged = PSTATE.EL != EL0;
constant AccessDescriptor accdesc = CreateAccDescGPR(MemOp_STORE, nontemporal, privileged, t);

if n == 31 then
    CheckSPAlignment();
    address = SP[64];
else
    address = X[n, 64];

if !postindex then
    address = AddressAdd(address, offset, accdesc);

bits(8) data;
if rt_unknown then
    data = bits(8) UNKNOWN;
else
    data = X[t, 8];

Mem[address, 1, accdesc] = data;

if wback then
    if postindex then
        address = AddressAdd(address, offset, accdesc);
    if n == 31 then
        SP[64] = address;
    else
```

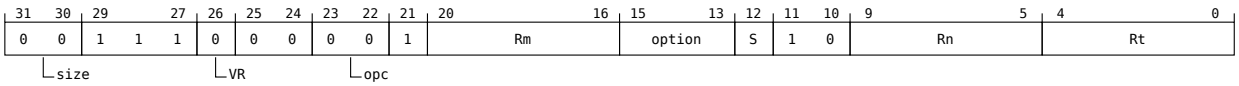
C6.2.256 STRB (register)

Store register byte (register)

This instruction calculates an address from a base register value and an offset register value, and stores a byte from a 32-bit register to the calculated address. For information about addressing modes, see Load/Store addressing modes.

The instruction uses an offset addressing mode, that calculates the address used for the memory access from a base register value and an offset register value. The offset can be optionally shifted and extended.



Encoding for the Extended register variant Applies when `(option != 011)`

```
STRB <Wt>, [<Xn|SP>, (<Wm>|<Xm>), <extend> {<amount>}]
```

Encoding for the Shifted register variant Applies when `(option == 011)`

```
STRB <Wt>, [<Xn|SP>, <Xm>{, LSL <amount>}]
```

Decode for all variants of this encoding

```
if option<1> == '0' then EndOfDecode(Decode_UNDEF);             // sub-word index
constant ExtendType extend_type = DecodeRegExtend(option);
constant integer shift = 0;
```

Assembler Symbols

<**Wt**> Is the 32-bit name of the general-purpose register to be transferred, encoded in the “Rt” field.

<**Xn|SP**> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the “Rn” field.

<**Wm**> When option<0> is set to 0, is the 32-bit name of the general-purpose index register, encoded in the “Rm” field.

<**Xm**> When option<0> is set to 1, is the 64-bit name of the general-purpose index register, encoded in the “Rm” field.

<**extend**> Is the index extend specifier, encoded in “option”:

option	<extend>
010	UXTW
110	SXTW
111	SXTX

<**amount**> Is the index shift amount, it must be #0, encoded in “S” as 0 if omitted, or as 1 if present.

Shared Decode

```
constant integer t = UInt(Rt);
constant integer n = UInt(Rn);
constant integer m = UInt(Rm);
constant boolean nontemporal = FALSE;
```

Operation

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

```
constant bits(64) offset = ExtendReg(m, extend_type, shift, 64);
bits(64) address;

constant boolean privileged = PSTATE.EL != EL0;
constant AccessDescriptor accdesc = CreateAccDescGPR(MemOp_STORE, nontemporal, privileged, t);

if n == 31 then
    CheckSPAlignment();
    address = SP[64];
else
    address = X[n, 64];

address = AddressAdd(address, offset, accdesc);

Mem[address, 1, accdesc] = X[t, 8];
```

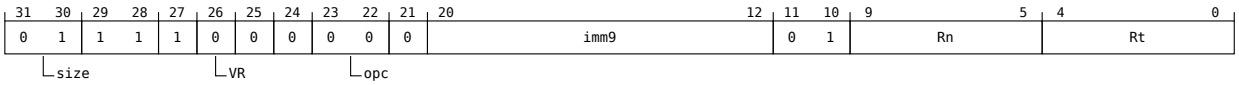
C6.2.257 STRH (immediate)

Store register halfword (immediate)

This instruction stores the least significant halfword of a 32-bit register to memory. The address that is used for the store is calculated from a base register and an immediate offset. For information about addressing modes, see Load/Store addressing modes.

It has encodings from 3 classes: Post-index , Pre-index and Unsigned offset

Post-index



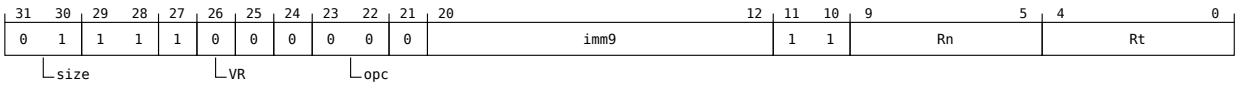
Encoding

```
STRH <Wt>, [<Xn|SP>], #<simm>
```

Decode for this encoding

```
constant boolean wback = TRUE;
constant boolean postindex = TRUE;
constant bits(64) offset = SignExtend(imm9, 64);
```

Pre-index



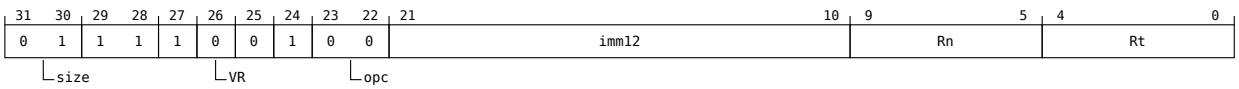
Encoding

```
STRH <Wt>, [<Xn|SP>, #<simm>]!
```

Decode for this encoding

```
constant boolean wback = TRUE;
constant boolean postindex = FALSE;
constant bits(64) offset = SignExtend(imm9, 64);
```

Unsigned offset



Encoding

```
STRH <Wt>, [<Xn|SP>{, #<pimm>}]
```

Decode for this encoding

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

```
constant boolean wback = FALSE;
constant boolean postindex = FALSE;
constant bits(64) offset = LSL(ZeroExtend(imm12, 64), 1);
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Architectural Constraints on UNPREDICTABLE behaviors, and particularly STRH (immediate).

Assembler Symbols

<**Wt**> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

<**Xn|SP**> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<**simm**> Is the signed immediate byte offset, in the range -256 to 255, encoded in the "imm9" field.

<**pimm**> Is the optional positive immediate byte offset, a multiple of 2 in the range 0 to 8190, defaulting to 0 and encoded in the "imm12" field as <pimm>/2.

Shared Decode

```
constant integer t = UInt(Rt);
constant integer n = UInt(Rn);
constant boolean nontemporal = FALSE;

Constraint c;
boolean rt_unknown = FALSE;
if wback && n == t && n != 31 then
    c = ConstrainUnpredictable(Unpredictable_WBOVERLAPST);
    assert c IN {Constraint_NONE, Constraint_UNKNOWN, Constraint_UNDEF, Constraint_NOP};
    case c of
        when Constraint_NONE    rt_unknown = FALSE;    // Value stored is original value
        when Constraint_UNKNOWN rt_unknown = TRUE;     // Value stored is UNKNOWN
        when Constraint_UNDEF   EndOfDecode(Decode_UNDEF);
        when Constraint_NOP     EndOfDecode(Decode_NOP);
```

Operation

```
bits(64) address;

constant boolean privileged = PSTATE.EL != EL0;
constant AccessDescriptor accdesc = CreateAccDescGPR(MemOp_STORE, nontemporal, privileged, t);

if n == 31 then
    CheckSPAlignment();
    address = SP[64];
else
    address = X[n, 64];

if !postindex then
    address = AddressAdd(address, offset, accdesc);

bits(16) data;
if rt_unknown then
    data = bits(16) UNKNOWN;

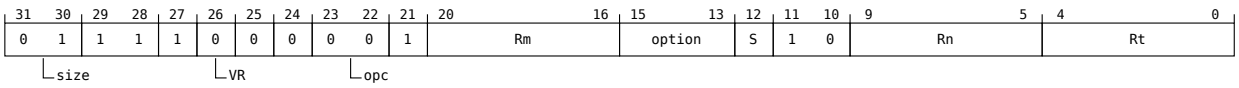
C6.2.258 STRH (register)

Store register halfword (register)

This instruction calculates an address from a base register value and an offset register value, and stores a halfword from a 32-bit register to the calculated address. For information about addressing modes, see Load/Store addressing modes.

The instruction uses an offset addressing mode, that calculates the address used for the memory access from a base register value and an offset register value. The offset can be optionally shifted and extended.



Encoding

```
STRH <Wt>, [<Xn|SP>, (<Wm>|<Xm>){, <extend> {<amount>}}]
```

Decode for this encoding

```
if option<1> == '0' then EndOfDecode(Decode_UNDEF);             // sub-word index
constant ExtendType extend_type = DecodeRegExtend(option);
constant integer shift = if S == '1' then 1 else 0;
```

Assembler Symbols

<Wt> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<Wm> When option<0> is set to 0, is the 32-bit name of the general-purpose index register, encoded in the "Rm" field.

<Xm> When option<0> is set to 1, is the 64-bit name of the general-purpose index register, encoded in the "Rm" field.

<extend> Is the index extend/shift specifier, defaulting to LSL, and which must be omitted for the LSL option when <amount> is omitted, encoded in "option":

option	<extend>
010	UXTW
011	LSL
110	SXTW
111	SXTX

<amount> Is the index shift amount, optional only when <extend> is not LSL. Where it is permitted to be optional, it defaults to #0. It is encoded in "S":

S	<amount>
0	#0
1	#1

Shared Decode

C6.2.259 STSET, STSETL

Atomic bit set on word or doubleword, without return

This instruction atomically loads a 32-bit word or 64-bit doubleword from memory, performs a bitwise OR with the value held in a register on it, and stores the result back to memory.

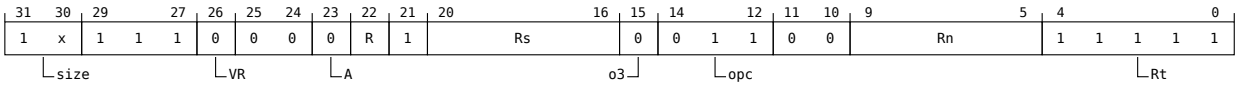
- `STSET` does not have release semantics.
- `STSETL` stores to memory with release semantics, as described in Load-Acquire, Store-Release.

For information about addressing modes, see Load/Store addressing modes.

This is an alias of LDSET, LDSETA, LDSETAL, LDSETL. This means:

- The encodings in this description are named to match the encodings of LDSET, LDSETA, LDSETAL, LDSETL.
- The description of LDSET, LDSETA, LDSETAL, LDSETL gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

Integer
(FEAT_LSE)



Encoding for the 32-bit no memory ordering variant Applies when `(size == 10 && R == 0)`

```
STSET <Ws>, [<Xn|SP>]
```

is equivalent to

```
LDSET <Ws>, WZR, [<Xn|SP>]
```

and is always the preferred disassembly.

Encoding for the 32-bit release variant Applies when `(size == 10 && R == 1)`

```
STSETL <Ws>, [<Xn|SP>]
```

is equivalent to

```
LDSETL <Ws>, WZR, [<Xn|SP>]
```

and is always the preferred disassembly.

Encoding for the 64-bit no memory ordering variant Applies when `(size == 11 && R == 0)`

```
STSET <Xs>, [<Xn|SP>]
```

is equivalent to

```
LDSET <Xs>, XZR, [<Xn|SP>]
```

and is always the preferred disassembly.

Encoding for the 64-bit release variant Applies when `(size == 11 && R == 1)`

```
STSETL <Xs>, [<Xn|SP>]
```

is equivalent to

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

```
LDSETL <Xs>, XZR, [<Xn|SP>]
```

and is always the preferred disassembly.

Assembler Symbols

<**Ws**> Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the “Rs” field.

<**Xn|SP**> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the “Rn” field.

<**Xs**> Is the 64-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the “Rs” field.

Operation

The description of LDSET, LDSETA, LDSETAL, LDSETL gives the operational pseudocode for this instruction.

Operational Information

The description of LDSET, LDSETA, LDSETAL, LDSETL gives the operational information for this instruction.

C6.2.260 STSETB, STSETLB

Atomic bit set on byte, without return

This instruction atomically loads an 8-bit byte from memory, performs a bitwise OR with the value held in a register on it, and stores the result back to memory.

- `STSETB` does not have release semantics.
- `STSETLB` stores to memory with release semantics, as described in Load-Acquire, Store-Release.

For information about addressing modes, see Load/Store addressing modes.

This is an alias of LDSETB, LDSETAB, LDSETALB, LDSETLB. This means:

- The encodings in this description are named to match the encodings of LDSETB, LDSETAB, LDSETALB, LDSETLB.
- The description of LDSETB, LDSETAB, LDSETALB, LDSETLB gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

Integer

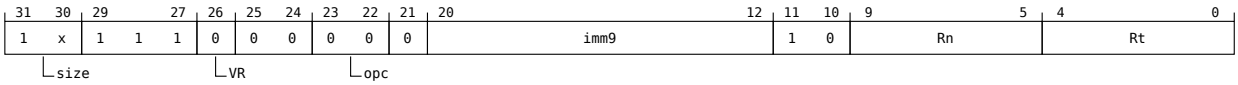
C6.2.268 STTR

Store register (unprivileged)

This instruction stores a word or doubleword from a register to memory. The address that is used for the store is calculated from a base register and an immediate offset.



Encoding for the 32-bit variant Applies when `(size == 10)`

```
STTR <Wt>, [<Xn|SP>{, #<simm>}]
```

Encoding for the 64-bit variant Applies when `(size == 11)`

```
STTR <Xt>, [<Xn|SP>{, #<simm>}]
```

Decode for all variants of this encoding

```
constant integer scale = UInt(size);
constant bits(64) offset = SignExtend(imm9, 64);
```

Assembler Symbols

<Wt> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<simm> Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the "imm9" field.

<Xt> Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

Shared Decode

```
constant integer t = UInt(Rt);
constant integer n = UInt(Rn);

constant integer datasize = 8 << scale;
constant boolean nontemporal = FALSE;
```

Operation

```
bits(64) address;

constant boolean privileged = AArch64.IsUnprivAccessPriv();
constant AccessDescriptor accdesc = CreateAccDescGPR(MemOp_STORE, nontemporal, privileged, t);

if n == 31 then
    CheckSPAlignment();
    address = SP[64];
else
    address = X[n, 64];

address = AddressAdd(address, offset, accdesc);

Mem[address, datasize DIV 8, accdesc] = X[t, datasize];
```

Operational information

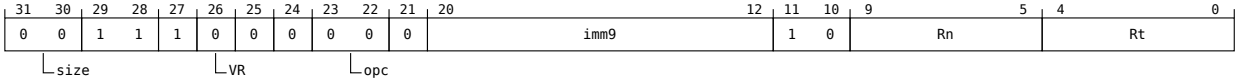
This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.269 STTRB

Store register byte (unprivileged)

This instruction stores a byte from a 32-bit register to memory. The address that is used for the store is calculated from a base register and an immediate offset.



Encoding

```
STTRB <Wt>, [<Xn|SP>{, #<simm>}]
```

Decode for this encoding

```
constant bits(64) offset = SignExtend(imm9, 64);
```

Assembler Symbols

<**Wt**> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

<**Xn|SP**> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<**simm**> Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the "imm9" field.

Shared Decode

```
constant integer t = UInt(Rt);
constant integer n = UInt(Rn);

constant integer datasize = 8;
constant boolean nontemporal = FALSE;
```

Operation

```
bits(64) address;

constant boolean privileged = AArch64.IsUnprivAccessPriv();
constant AccessDescriptor accdesc = CreateAccDescGPR(MemOp_STORE, nontemporal, privileged, t);

if n == 31 then
    CheckSPAlignment();
    address = SP[64];
else
    address = X[n, 64];

address = AddressAdd(address, offset, accdesc);

Mem[address, datasize DIV 8, accdesc] = X[t, datasize];
```

Operational information

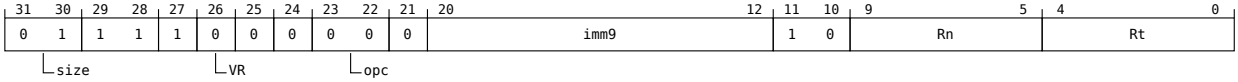
This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.270 STTRH

Store register halfword (unprivileged)

This instruction stores a halfword from a 32-bit register to memory. The address that is used for the store is calculated from a base register and an immediate offset.



Encoding

```
STTRH <Wt>, [<Xn|SP>{, #<simm>}]
```

Decode for this encoding

```
constant bits(64) offset = SignExtend(imm9, 64);
```

Assembler Symbols

<**Wt**> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

<**Xn|SP**> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<**simm**> Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the "imm9" field.

Shared Decode

```
constant integer t = UInt(Rt);
constant integer n = UInt(Rn);

constant integer datasize = 16;
constant boolean nontemporal = FALSE;
```

Operation

```
bits(64) address;

constant boolean privileged = AArch64.IsUnprivAccessPriv();
constant AccessDescriptor accdesc = CreateAccDescGPR(MemOp_STORE, nontemporal, privileged, t);

if n == 31 then
    CheckSPAlignment();
    address = SP[64];
else
    address = X[n, 64];

address = AddressAdd(address, offset, accdesc);

Mem[address, datasize DIV 8, accdesc] = X[t, datasize];
```

Operational information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

Encoding for the No memory ordering variant Applies when (R == 0)

```
STUMAXH <Ws>, [<Xn|SP>]
```

is equivalent to

```
LDUMAXH <Ws>, WZR, [<Xn|SP>]
```

and is always the preferred disassembly.

Encoding for the Release variant Applies when (R == 1)

```
STUMAXLH <Ws>, [<Xn|SP>]
```

is equivalent to

```
LDUMAXLH <Ws>, WZR, [<Xn|SP>]
```

and is always the preferred disassembly.

Assembler Symbols

<**Ws**> Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.

<**Xn|SP**> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

The description of LDUMAXH, LDUMAXAH, LDUMAXALH, LDUMAXLH gives the operational pseudocode for this instruction.

Operational Information

The description of LDUMAXH, LDUMAXAH, LDUMAXALH, LDUMAXLH gives the operational information for this instruction.

C6.2.274 STUMIN, STUMINL

Atomic unsigned minimum on word or doubleword, without return

This instruction atomically loads a 32-bit word or 64-bit doubleword from memory, compares it against the value held in a register, and stores the smaller value back to memory, treating the values as unsigned numbers.

- `STUMIN` does not have release semantics.
- `STUMINL` stores to memory with release semantics, as described in Load-Acquire, Store-Release.

For information about addressing modes, see Load/Store addressing modes.

This is an alias of LDUMIN, LDUMINA, LDUMINAL, LDUMINL. This means:

- The encodings in this description are named to match the encodings of LDUMIN, LDUMINA, LDUMINAL, LDUMINL.
- The description of LDUMIN, LDUMINA, LDUMINAL, LDUMINL gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

Integer

C6.2.275 STUMINB, STUMINLB

Atomic unsigned minimum on byte, without return

This instruction atomically loads an 8-bit byte from memory, compares it against the value held in a register, and stores the smaller value back to memory, treating the values as unsigned numbers.

- STUMINB does not have release semantics.
- STUMINLB stores to memory with release semantics, as described in Load-Acquire, Store-Release.

For information about addressing modes, see Load/Store addressing modes.

This is an alias of LDUMINB, LDUMINAB, LDUMINALB, LDUMINLB. This means:

- The encodings in this description are named to match the encodings of LDUMINB, LDUMINAB, LDUMINALB, LDUMINLB.
- The description of LDUMINB, LDUMINAB, LDUMINALB, LDUMINLB gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

C6.2.276 STUMINH, STUMINLH

Atomic unsigned minimum on halfword, without return

This instruction atomically loads a 16-bit halfword from memory, compares it against the value held in a register, and stores the smaller value back to memory, treating the values as unsigned numbers.

- STUMINH does not have release semantics.
- STUMINLH stores to memory with release semantics, as described in Load-Acquire, Store-Release.

For information about addressing modes, see Load/Store addressing modes.

This is an alias of LDUMINH, LDUMINAH, LDUMINALH, LDUMINLH. This means:

- The encodings in this description are named to match the encodings of LDUMINH, LDUMINAH, LDUMINALH, LDUMINLH.
- The description of LDUMINH, LDUMINAH, LDUMINALH, LDUMINLH gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

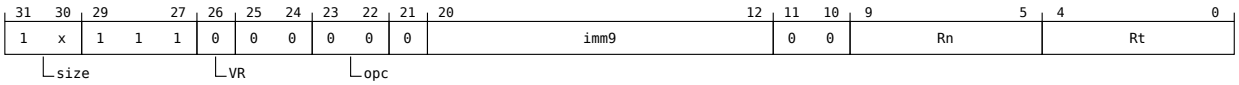
C6.2.277 STUR

Store register (unscaled)

This instruction calculates an address from a base register value and an immediate offset, and stores a 32-bit word or a 64-bit doubleword to the calculated address, from a register. For information about addressing modes, see Load/Store addressing modes.



Encoding for the 32-bit variant Applies when `(size == 10)`

```
STUR <Wt>, [<Xn|SP>{, #<simm>}]
```

Encoding for the 64-bit variant Applies when `(size == 11)`

```
STUR <Xt>, [<Xn|SP>{, #<simm>}]
```

Decode for all variants of this encoding

```
constant integer scale = UInt(size);
constant bits(64) offset = SignExtend(imm9, 64);
```

Assembler Symbols

<**Wt**> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

<**Xn|SP**> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<**simm**> Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the "imm9" field.

<**Xt**> Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

Shared Decode

```
constant integer n = UInt(Rn);
constant integer t = UInt(Rt);
constant integer datasize = 8 << scale;
constant boolean nontemporal = FALSE;
```

Operation

```
bits(64) address;

constant boolean privileged = PSTATE.EL != EL0;
constant AccessDescriptor accdesc = CreateAccDescGPR(MemOp_STORE, nontemporal, privileged, t);

if n == 31 then
    CheckSPAlignment();
    address = SP[64];
else
    address = X[n, 64];

address = AddressAdd(address, offset, accdesc);

Mem[address, datasize DIV 8, accdesc] = X[t, datasize];
```

Operational information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

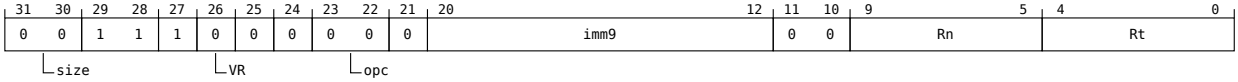
Non-Confidential

C6.2.278 STURB

Store register byte (unscaled)

This instruction calculates an address from a base register value and an immediate offset, and stores a byte to the calculated address, from a 32-bit register. For information about addressing modes, see Load/Store addressing modes.



Encoding

```
STURB <Wt>, [<Xn|SP>{, #<simm>}]
```

Decode for this encoding

```
constant bits(64) offset = SignExtend(imm9, 64);
```

Assembler Symbols

<**Wt**> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

<**Xn|SP**> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<**simm**> Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the "imm9" field.

Shared Decode

```
constant integer n = UInt(Rn);
constant integer t = UInt(Rt);
constant integer datasize = 8;
constant boolean nontemporal = FALSE;
```

Operation

```
bits(64) address;

constant boolean privileged = PSTATE.EL != EL0;
constant AccessDescriptor accdesc = CreateAccDescGPR(MemOp_STORE, nontemporal, privileged, t);

if n == 31 then
    CheckSPAlignment();
    address = SP[64];
else
    address = X[n, 64];

address = AddressAdd(address, offset, accdesc);

Mem[address, datasize DIV 8, accdesc] = X[t, datasize];
```

Operational information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

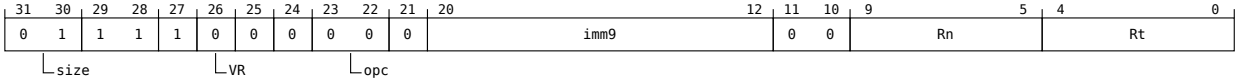
C6.2.279 STURH

Store register halfword (unscaled)

This instruction calculates an address from a base register value and an immediate offset, and stores a halfword to the calculated address, from a 32-bit register. For information about addressing modes, see Load/Store addressing modes.



Encoding

```
STURH <Wt>, [<Xn|SP>{, #<simm>}]
```

Decode for this encoding

```
constant bits(64) offset = SignExtend(imm9, 64);
```

Assembler Symbols

<**Wt**> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

<**Xn|SP**> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<**simm**> Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the "imm9" field.

Shared Decode

```
constant integer n = UInt(Rn);
constant integer t = UInt(Rt);
constant integer datasize = 16;
constant boolean nontemporal = FALSE;
```

Operation

```
bits(64) address;

constant boolean privileged = PSTATE.EL != EL0;
constant AccessDescriptor accdesc = CreateAccDescGPR(MemOp_STORE, nontemporal, privileged, t);

if n == 31 then
    CheckSPAlignment();
    address = SP[64];
else
    address = X[n, 64];

address = AddressAdd(address, offset, accdesc);

Mem[address, datasize DIV 8, accdesc] = X[t, datasize];
```

Operational information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

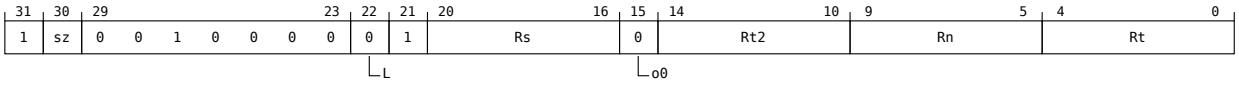
C6.2.280 STXP

Store exclusive pair of registers

This instruction stores two 32-bit words or two 64-bit doublewords from two registers to a memory location if the PE has exclusive access to the memory address, and returns a status value of 0 if the store was successful, or of 1 if no store was performed. See Synchronization and semaphores. For information on single-copy atomicity and alignment requirements, see Requirements for single-copy atomicity and Alignment of data accesses. If a 64-bit pair Store-Exclusive succeeds, it causes a single-copy atomic update of the 128-bit memory location being updated. For information about addressing modes, see Load/Store addressing modes.



Encoding for the 32-bit variant Applies when `(sz == 0)`

```
STXP <Ws>, <Wt1>, <Wt2>, [<Xn|SP>{, #0}]
```

Encoding for the 64-bit variant Applies when `(sz == 1)`

```
STXP <Ws>, <Xt1>, <Xt2>, [<Xn|SP>{, #0}]
```

Decode for all variants of this encoding

```
constant integer s = UInt(Rs);
constant integer t = UInt(Rt);
constant integer t2 = UInt(Rt2);
constant integer n = UInt(Rn);

constant integer elsize = 32 << UInt(sz);
constant integer datasize = elsize * 2;
constant boolean acqrel = FALSE;

boolean rt_unknown = FALSE;
boolean rn_unknown = FALSE;
if s == t || (s == t2) then
    constant Constraint c = ConstrainUnpredictable(Unpredictable_DATAOVERLAP);
    assert c IN {Constraint_UNKNOWN, Constraint_UNDEF, Constraint_NOP};
    case c of
        when Constraint_UNKNOWN    rt_unknown = TRUE;    // store UNKNOWN value
        when Constraint_UNDEF      EndOfDecode(Decode_UNDEF);
        when Constraint_NOP        EndOfDecode(Decode_NOP);
if s == n && n != 31 then
    constant Constraint c = ConstrainUnpredictable(Unpredictable_BASEOVERLAP);
    assert c IN {Constraint_UNKNOWN, Constraint_UNDEF, Constraint_NOP};
    case c of
        when Constraint_UNKNOWN    rn_unknown = TRUE;    // address is UNKNOWN
        when Constraint_UNDEF      EndOfDecode(Decode_UNDEF);
        when Constraint_NOP        EndOfDecode(Decode_NOP);
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Architectural Constraints on UNPREDICTABLE behaviors, and particularly STXP.

Assembler Symbols

<**Ws**> Is the 32-bit name of the general-purpose register into which the status result of the store exclusive is written, encoded in the "Rs" field. The value returned is:

0 If the operation updates memory.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

1 If the operation fails to update memory.

<**Wt1**> Is the 32-bit name of the first general-purpose register to be transferred, encoded in the "Rt" field.

<**Wt2**> Is the 32-bit name of the second general-purpose register to be transferred, encoded in the "Rt2" field.

<**Xn|SP**> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<**Xt1**> Is the 64-bit name of the first general-purpose register to be transferred, encoded in the "Rt" field.

<**Xt2**> Is the 64-bit name of the second general-purpose register to be transferred, encoded in the "Rt2" field.

Aborts and alignment

If a synchronous Data Abort exception is generated by the execution of this instruction:

- Memory is not updated.
- <Ws> is not updated.

Accessing an address that is not aligned to the size of the data being accessed causes an Alignment fault Data Abort exception to be generated, subject to the following rules:

- If AArch64.ExclusiveMonitorsPass() returns TRUE, the exception is generated.
- Otherwise, it is IMPLEMENTATION DEFINED whether the exception is generated.

If AArch64.ExclusiveMonitorsPass() returns FALSE and the memory address, if accessed, would generate a synchronous Data Abort exception, it is IMPLEMENTATION DEFINED whether the exception is generated.

Operation

```
bits(64) address;
bits(datasize) data;

constant integer dbytes = datasize DIV 8;
constant boolean privileged = PSTATE.EL != EL0;
constant boolean ispair = FALSE;
constant AccessDescriptor accdesc = CreateAccDescExLDST(MemOp_STORE, acqrel, privileged, ispair, t,
                                                        t2);

if n == 31 then
    CheckSPAlignment();
    address = SP[64];
elsif rn_unknown then
    address = bits(64) UNKNOWN;
else
    address = X[n, 64];

if rt_unknown then
    data = bits(datasize) UNKNOWN;
else
    constant bits(datasize DIV 2) el1 = X[t, datasize DIV 2];
    constant bits(datasize DIV 2) el2 = X[t2, datasize DIV 2];
    data = if BigEndian(accdesc.acctype) then el1:el2 else el2:el1;
bit status = '1';
// Check whether the Exclusives monitors are set to include the
// physical memory locations corresponding to virtual address
// range [address, address+dbytes-1].
// If AArch64.ExclusiveMonitorsPass() returns FALSE and the memory address,
// if accessed, would generate a synchronous Data Abort exception, it is
// IMPLEMENTATION DEFINED whether the exception is generated.
// It is a limitation of this model that synchronous Data Aborts are never
// generated in this case, as Mem[] is not called.

if AArch64.ExclusiveMonitorsPass(address, dbytes, accdesc) then
    // This atomic write will be rejected if it does not refer
    // to the same physical locations after address translation.
```

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

```
    Mem[address, dbytes, accdesc] = data;
    status = ExclusiveMonitorsStatus();
X[s, 32] = ZeroExtend(status, 32);
```

Operational information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.

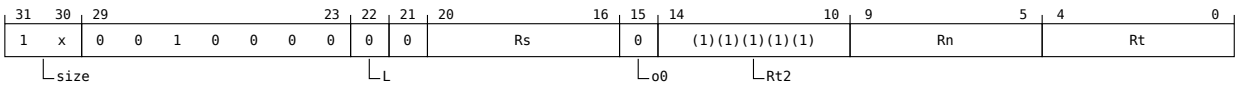
C6.2.281 STXR

Store exclusive register

This instruction stores a 32-bit word or a 64-bit doubleword from a register to memory if the PE has exclusive access to the memory address, and returns a status value of 0 if the store was successful, or of 1 if no store was performed. See Synchronization and semaphores.

For information about addressing modes, see Load/Store addressing modes.



Encoding for the 32-bit variant Applies when `(size == 10)`

```
STXR <Ws>, <Wt>, [<Xn|SP>{, #0}]
```

Encoding for the 64-bit variant Applies when `(size == 11)`

```
STXR <Ws>, <Xt>, [<Xn|SP>{, #0}]
```

Decode for all variants of this encoding

```
constant integer s = UInt(Rs);
constant integer t = UInt(Rt);
constant integer n = UInt(Rn);

constant integer elsize = 8 << UInt(size);
constant boolean acqrel = FALSE;

boolean rt_unknown = FALSE;
boolean rn_unknown = FALSE;
if s == t then
    constant Constraint c = ConstrainUnpredictable(Unpredictable_DATAOVERLAP);
    assert c IN {Constraint_UNKNOWN, Constraint_UNDEF, Constraint_NOP};
    case c of
        when Constraint_UNKNOWN    rt_unknown = TRUE;    // store UNKNOWN value
        when Constraint_UNDEF      EndOfDecode(Decode_UNDEF);
        when Constraint_NOP        EndOfDecode(Decode_NOP);
if s == n && n != 31 then
    constant Constraint c = ConstrainUnpredictable(Unpredictable_BASEOVERLAP);
    assert c IN {Constraint_UNKNOWN, Constraint_UNDEF, Constraint_NOP};
    case c of
        when Constraint_UNKNOWN    rn_unknown = TRUE;    // address is UNKNOWN
        when Constraint_UNDEF      EndOfDecode(Decode_UNDEF);
        when Constraint_NOP        EndOfDecode(Decode_NOP);
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Architectural Constraints on UNPREDICTABLE behaviors, and particularly STXR.

Assembler Symbols

<**Ws**> Is the 32-bit name of the general-purpose register into which the status result of the store exclusive is written, encoded in the "Rs" field. The value returned is:

0 If the operation updates memory.

1 If the operation fails to update memory.

<**Wt**> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

<**Xn|SP**> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<**Xt**> Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

Aborts and alignment

If a synchronous Data Abort exception is generated by the execution of this instruction:

- Memory is not updated.
- <Ws> is not updated.

Accessing an address that is not aligned to the size of the data being accessed causes an Alignment fault Data Abort exception to be generated, subject to the following rules:

- If AArch64.ExclusiveMonitorsPass() returns TRUE, the exception is generated.
- Otherwise, it is IMPLEMENTATION DEFINED whether the exception is generated.

If AArch64.ExclusiveMonitorsPass() returns FALSE and the memory address, if accessed, would generate a synchronous Data Abort exception, it is IMPLEMENTATION DEFINED whether the exception is generated.

Operation

```
bits(64) address;
bits(elsize) data;

constant integer dbytes = elsize DIV 8;
constant boolean privileged = PSTATE.EL != EL0;
constant AccessDescriptor accdesc = CreateAccDescExLDST(MemOp_STORE, acqrel, privileged, t);

if n == 31 then
    CheckSPAlignment();
    address = SP[64];
elsif rn_unknown then
    address = bits(64) UNKNOWN;
else
    address = X[n, 64];

if rt_unknown then
    data = bits(elsize) UNKNOWN;
else
    data = X[t, elsize];
bit status = '1';
// Check whether the Exclusives monitors are set to include the
// physical memory locations corresponding to virtual address
// range [address, address+dbytes-1].
// If AArch64.ExclusiveMonitorsPass() returns FALSE and the memory address,
// if accessed, would generate a synchronous Data Abort exception, it is
// IMPLEMENTATION DEFINED whether the exception is generated.
// It is a limitation of this model that synchronous Data Aborts are never
// generated in this case, as Mem[] is not called.

if AArch64.ExclusiveMonitorsPass(address, dbytes, accdesc) then
    // This atomic write will be rejected if it does not refer
    // to the same physical locations after address translation.
    Mem[address, dbytes, accdesc] = data;
    status = ExclusiveMonitorsStatus();
X[s, 32] = ZeroExtend(status, 32);
```

Operational information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

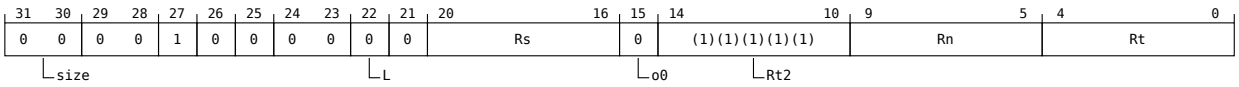
C6.2.282 STXRB

Store exclusive register byte

This instruction stores a byte from a register to memory if the PE has exclusive access to the memory address, and returns a status value of 0 if the store was successful, or of 1 if no store was performed. See Synchronization and semaphores. The memory access is atomic.

For information about addressing modes, see Load/Store addressing modes.



Encoding

```
STXRB <Ws>, <Wt>, [<Xn|SP>{, #0}]
```

Decode for this encoding

```
constant integer s = UInt(Rs);
constant integer t = UInt(Rt);
constant integer n = UInt(Rn);

constant boolean acqrel = FALSE;

boolean rt_unknown = FALSE;
boolean rn_unknown = FALSE;
if s == t then
    constant Constraint c = ConstrainUnpredictable(Unpredictable_DATAOVERLAP);
    assert c IN {Constraint_UNKNOWN, Constraint_UNDEF, Constraint_NOP};
    case c of
        when Constraint_UNKNOWN    rt_unknown = TRUE;    // store UNKNOWN value
        when Constraint_UNDEF      EndOfDecode(Decode_UNDEF);
        when Constraint_NOP        EndOfDecode(Decode_NOP);
if s == n && n != 31 then
    constant Constraint c = ConstrainUnpredictable(Unpredictable_BASEOVERLAP);
    assert c IN {Constraint_UNKNOWN, Constraint_UNDEF, Constraint_NOP};
    case c of
        when Constraint_UNKNOWN    rn_unknown = TRUE;    // address is UNKNOWN
        when Constraint_UNDEF      EndOfDecode(Decode_UNDEF);
        when Constraint_NOP        EndOfDecode(Decode_NOP);
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Architectural Constraints on UNPREDICTABLE behaviors, and particularly STXRB.

Assembler Symbols

<**Ws**> Is the 32-bit name of the general-purpose register into which the status result of the store exclusive is written, encoded in the "Rs" field. The value returned is:

0 If the operation updates memory.

1 If the operation fails to update memory.

<**Wt**> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

<**Xn|SP**> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Aborts

If a synchronous Data Abort exception is generated by the execution of this instruction:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- Memory is not updated.
- <Ws> is not updated.

If AArch64.ExclusiveMonitorsPass() returns FALSE and the memory address, if accessed, would generate a synchronous Data Abort exception, it is IMPLEMENTATION DEFINED whether the exception is generated.

Operation

```
bits(64) address;
bits(8) data;

constant boolean privileged = PSTATE.EL != EL0;
constant AccessDescriptor accdesc = CreateAccDescExLDST(MemOp_STORE, acqrel, privileged, t);

if n == 31 then
    CheckSPAlignment();
    address = SP[64];
elsif rn_unknown then
    address = bits(64) UNKNOWN;
else
    address = X[n, 64];

if rt_unknown then
    data = bits(8) UNKNOWN;
else
    data = X[t, 8];
bit status = '1';
// Check whether the Exclusives monitors are set to include the
// physical memory locations corresponding to virtual address
// range [address, address+dbytes-1].
// If AArch64.ExclusiveMonitorsPass() returns FALSE and the memory address,
// if accessed, would generate a synchronous Data Abort exception, it is
// IMPLEMENTATION DEFINED whether the exception is generated.
// It is a limitation of this model that synchronous Data Aborts are never
// generated in this case, as Mem[] is not called.

if AArch64.ExclusiveMonitorsPass(address, 1, accdesc) then
    // This atomic write will be rejected if it does not refer
    // to the same physical locations after address translation.
    Mem[address, 1, accdesc] = data;
    status = ExclusiveMonitorsStatus();
X[s, 32] = ZeroExtend(status, 32);
```

Operational information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

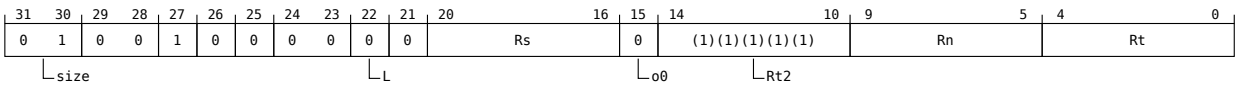
C6.2.283 STXRH

Store exclusive register halfword

This instruction stores a halfword from a register to memory if the PE has exclusive access to the memory address, and returns a status value of 0 if the store was successful, or of 1 if no store was performed. See Synchronization and semaphores. The memory access is atomic.

For information about addressing modes, see Load/Store addressing modes.



Encoding

```
STXRH <Ws>, <Wt>, [<Xn|SP>{, #0}]
```

Decode for this encoding

```
constant integer s = UInt(Rs);
constant integer t = UInt(Rt);
constant integer n = UInt(Rn);

constant boolean acqrel = FALSE;

boolean rt_unknown = FALSE;
boolean rn_unknown = FALSE;
if s == t then
    constant Constraint c = ConstrainUnpredictable(Unpredictable_DATAOVERLAP);
    assert c IN {Constraint_UNKNOWN, Constraint_UNDEF, Constraint_NOP};
    case c of
        when Constraint_UNKNOWN    rt_unknown = TRUE;    // store UNKNOWN value
        when Constraint_UNDEF      EndOfDecode(Decode_UNDEF);
        when Constraint_NOP        EndOfDecode(Decode_NOP);
if s == n && n != 31 then
    constant Constraint c = ConstrainUnpredictable(Unpredictable_BASEOVERLAP);
    assert c IN {Constraint_UNKNOWN, Constraint_UNDEF, Constraint_NOP};
    case c of
        when Constraint_UNKNOWN    rn_unknown = TRUE;    // address is UNKNOWN
        when Constraint_UNDEF      EndOfDecode(Decode_UNDEF);
        when Constraint_NOP        EndOfDecode(Decode_NOP);
```

Assembler Symbols

<Ws> Is the 32-bit name of the general-purpose register into which the status result of the store exclusive is written, encoded in the “Rs” field. The value returned is:

0 If the operation updates memory.

1 If the operation fails to update memory.

<Wt> Is the 32-bit name of the general-purpose register to be transferred, encoded in the “Rt” field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the “Rn” field.

Aborts and alignment

If a synchronous Data Abort exception is generated by the execution of this instruction:

- Memory is not updated.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- <Ws> is not updated.

A non halfword-aligned memory address causes an Alignment fault Data Abort exception to be generated, subject to the following rules:

- If AArch64.ExclusiveMonitorsPass() returns TRUE, the exception is generated.
- Otherwise, it is IMPLEMENTATION DEFINED whether the exception is generated.

If AArch64.ExclusiveMonitorsPass() returns FALSE and the memory address, if accessed, would generate a synchronous Data Abort exception, it is IMPLEMENTATION DEFINED whether the exception is generated.

Operation

```
bits(64) address;
bits(16) data;

constant boolean privileged = PSTATE.EL != EL0;
constant AccessDescriptor accdesc = CreateAccDescExLDST(MemOp_STORE, acqrel, privileged, t);

if n == 31 then
    CheckSPAlignment();
    address = SP[64];
elsif rn_unknown then
    address = bits(64) UNKNOWN;
else
    address = X[n, 64];

if rt_unknown then
    data = bits(16) UNKNOWN;
else
    data = X[t, 16];
bit status = '1';
// Check whether the Exclusives monitors are set to include the
// physical memory locations corresponding to virtual address
// range [address, address+dbytes-1].
// If AArch64.ExclusiveMonitorsPass() returns FALSE and the memory address,
// if accessed, would generate a synchronous Data Abort exception, it is
// IMPLEMENTATION DEFINED whether the exception is generated.
// It is a limitation of this model that synchronous Data Aborts are never
// generated in this case, as Mem[] is not called.

if AArch64.ExclusiveMonitorsPass(address, 2, accdesc) then
    // This atomic write will be rejected if it does not refer
    // to the same physical locations after address translation.
    Mem[address, 2, accdesc] = data;
    status = ExclusiveMonitorsStatus();
X[s, 32] = ZeroExtend(status, 32);
```

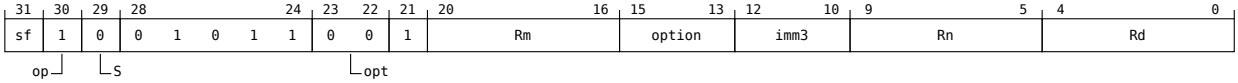
C6.2.284 SUB (extended register)

Subtract extended and scaled register

This instruction subtracts a sign or zero-extended register value, followed by an optional left shift amount, from a register value, and writes the result to the destination register. The argument that is extended from the <Rm> register can be a byte, halfword, word, or doubleword.



Encoding for the 32-bit variant Applies when `(sf == 0)`

```
SUB <Wd|WSP>, <Wn|WSP>, <Wm>{, <extend> {#<amount>}}
```

Encoding for the 64-bit variant Applies when `(sf == 1)`

```
SUB <Xd|SP>, <Xn|SP>, <R><m>{, <extend> {#<amount>}}
```

Decode for all variants of this encoding

```
if imm3 IN {'101', '110', '111'} then EndOfDecode(Decode_UNDEF);
constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer m = UInt(Rm);
constant integer shift = UInt(imm3);
constant integer datasize = 32 << UInt(sf);
constant ExtendType extend_type = DecodeRegExtend(option);
```

Assembler Symbols

<Wd|WSP> Is the 32-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.

<Wn|WSP> Is the 32-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn" field.

<Wm> Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.

<extend> For the "32-bit" variant: is the extension to be applied to the second source operand, encoded in "option":

option	<extend>
000	UXTB
001	UXTH
010	LSL|UXTW
011	UXTX
100	SXTB
101	SXTH
110	SXTW
111	SXTX

If "Rd" or "Rn" is '11111' (WSP) and "option" is '010' then LSL is preferred, but may be omitted when "imm3" is '000'. In all other cases <extend> is required and must be UXTW when "option" is '010'.

For the "64-bit" variant: is the extension to be applied to the second source operand, encoded in "option":

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

option	<extend>
000	UXTB
001	UXTH
010	UXTW
011	LSL|UXTX
100	SXTB
101	SXTH
110	SXTW
111	SXTX

If “Rd” or “Rn” is ’11111’ (SP) and “option” is ’011’ then LSL is preferred, but may be omitted when “imm3” is ’000’. In all other cases <extend> is required and must be UXTX when “option” is ’011’.

<**amount**> Is the left shift amount to be applied after extension in the range 0 to 4, defaulting to 0, encoded in the “imm3” field. It must be absent when <extend> is absent, is required when <extend> is LSL, and is optional when <extend> is present but not LSL.

<**Xd|SP**> Is the 64-bit name of the destination general-purpose register or stack pointer, encoded in the “Rd” field.

<**Xn|SP**> Is the 64-bit name of the first source general-purpose register or stack pointer, encoded in the “Rn” field.

<**R**> Is a width specifier, encoded in “option”:

option	<R>
00x	W
010	W
x11	X
10x	W
110	W

<**m**> Is the number [0-30] of the second general-purpose source register or the name ZR (31), encoded in the “Rm” field.

Operation

```
constant bits(datasize) operand1 = if n == 31 then SP[datasize] else X[n, datasize];
constant bits(datasize) operand2 = NOT(ExtendReg(m, extend_type, shift, datasize));
bits(datasize) result;

(result, -) = AddWithCarry(operand1, operand2, '1');

if d == 31 then
    SP[64] = ZeroExtend(result, 64);
else
    X[d, datasize] = result;
```

Operational information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

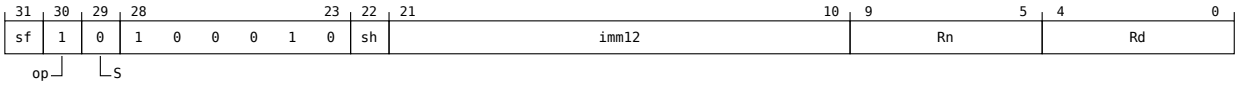
C6.2.285 SUB (immediate)

Subtract immediate value

This instruction subtracts an optionally-shifted immediate value from a register value, and writes the result to the destination register.



Encoding for the 32-bit variant Applies when `(sf == 0)`

```
SUB <Wd|WSP>, <Wn|WSP>, #<imm>{, <shift>}
```

Encoding for the 64-bit variant Applies when `(sf == 1)`

```
SUB <Xd|SP>, <Xn|SP>, #<imm>{, <shift>}
```

Decode for all variants of this encoding

```
constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer datasize = 32 << UInt(sf);

constant bits(24) imm = if sh == '0' then Zeros(12):imm12 else imm12:Zeros(12);
```

Assembler Symbols

<Wd|WSP> Is the 32-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.

<Wn|WSP> Is the 32-bit name of the source general-purpose register or stack pointer, encoded in the "Rn" field.

<imm> Is an unsigned immediate, in the range 0 to 4095, encoded in the "imm12" field.

<shift> Is the optional left shift to apply to the immediate, defaulting to LSL #0 and encoded in "sh":

sh	<shift>
0	LSL #0
1	LSL #12

<Xd|SP> Is the 64-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.

<Xn|SP> Is the 64-bit name of the source general-purpose register or stack pointer, encoded in the "Rn" field.

Operation

```
constant bits(datasize) operand1 = if n == 31 then SP[datasize] else X[n, datasize];
constant bits(datasize) operand2 = ZeroExtend(imm, datasize);
bits(datasize) result;
(result, -) = AddWithCarry(operand1, NOT(operand2), '1');

if d == 31 then
    SP[64] = ZeroExtend(result, 64);
else
    X[d, datasize] = result;
```

Operational information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

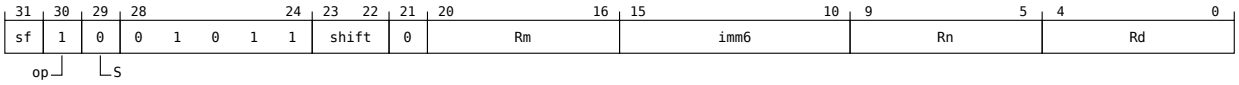
Non-Confidential

C6.2.286 SUB (shifted register)

Subtract optionally-shifted register

This instruction subtracts an optionally-shifted register value, and writes the result to the destination register.

This instruction is used by the alias NEG (shifted register).



Encoding for the 32-bit variant Applies when `(sf == 0)`

```
SUB <Wd>, <Wn>, <Wm>{, <shift> #<amount>}
```

Encoding for the 64-bit variant Applies when `(sf == 1)`

```
SUB <Xd>, <Xn>, <Xm>{, <shift> #<amount>}
```

Decode for all variants of this encoding

```
if shift == '11' then EndOfDecode(Decode_UNDEF);
if sf == '0' && imm6<5> == '1' then EndOfDecode(Decode_UNDEF);

constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer m = UInt(Rm);
constant integer datasize = 32 << UInt(sf);
constant ShiftType shift_type = DecodeShift(shift);
constant integer shift_amount = UInt(imm6);
```

Assembler Symbols

<**Wd**> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

<**Wn**> Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.

<**Wm**> Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.

<**shift**> Is the optional shift type to be applied to the second source operand, defaulting to LSL and encoded in "shift":

shift	<shift>
00	LSL
01	LSR
10	ASR
11	RESERVED

<**amount**> For the "32-bit" variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.

For the "64-bit" variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field.

<**Xd**> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<**Xn**> Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

<**Xm**> Is the 64-bit name of the second general-purpose source register, encoded in the “Rm” field.

Alias Conditions

Alias	Is preferred when
NEG (shifted register)	Rn == '11111'

Operation

```
constant bits(datasize) operand1 = X[n, datasize];
constant bits(datasize) operand2 = NOT(ShiftReg(m, shift_type, shift_amount, datasize));
bits(datasize) result;

(result, -) = AddWithCarry(operand1, operand2, '1');

X[d, datasize] = result;
```

Operational information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

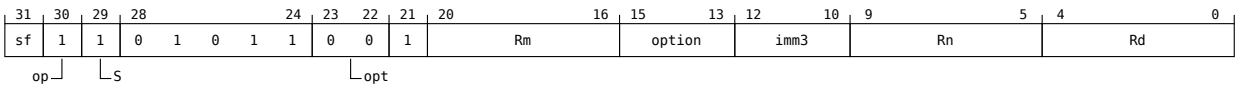
C6.2.287 SUBS (extended register)

Subtract extended and scaled register, setting flags

This instruction subtracts a sign or zero-extended register value, followed by an optional left shift amount, from a register value, and writes the result to the destination register. The argument that is extended from the <Rm> register can be a byte, halfword, word, or doubleword. It updates the condition flags based on the result.

This instruction is used by the alias CMP (extended register).



Encoding for the 32-bit variant Applies when `(sf == 0)`

```
SUBS <Wd>, <Wn|WSP>, <Wm>{, <extend> {#<amount>}}
```

Encoding for the 64-bit variant Applies when `(sf == 1)`

```
SUBS <Xd>, <Xn|SP>, <R><m>{, <extend> {#<amount>}}
```

Decode for all variants of this encoding

```
if imm3 IN {'101', '110', '111'} then EndOfDecode(Decode_UNDEF);
constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer m = UInt(Rm);
constant integer shift = UInt(imm3);
constant integer datasize = 32 << UInt(sf);
constant ExtendType extend_type = DecodeRegExtend(option);
```

Assembler Symbols

<Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Wn|WSP> Is the 32-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn" field.

<Wm> Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.

<extend> For the "32-bit" variant: is the extension to be applied to the second source operand, encoded in "option":

option	<extend>
000	UXTB
001	UXTH
010	LSL|UXTW
011	UXTX
100	SXTB
101	SXTH
110	SXTW
111	SXTX

If "Rn" is '11111' (WSP) and "option" is '010' then LSL is preferred, but may be omitted when "imm3" is '000'. In all other cases <extend> is required and must be UXTW when "option" is '010'.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

For the “64-bit” variant: is the extension to be applied to the second source operand, encoded in “option”:

option	<extend>
000	UXTB
001	UXTH
010	UXTW
011	LSL|UXTX
100	SXTB
101	SXTH
110	SXTW
111	SXTX

If “Rn” is ’11111’ (SP) and “option” is ’011’ then LSL is preferred, but may be omitted when “imm3” is ’000’. In all other cases <extend> is required and must be UXTX when “option” is ’011’.

<**amount**> Is the left shift amount to be applied after extension in the range 0 to 4, defaulting to 0, encoded in the “imm3” field. It must be absent when <extend> is absent, is required when <extend> is LSL, and is optional when <extend> is present but not LSL.

<**Xd**> Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

<**Xn|SP**> Is the 64-bit name of the first source general-purpose register or stack pointer, encoded in the “Rn” field.

<**R**> Is a width specifier, encoded in “option”:

option	<R>
00x	W
010	W
x11	X
10x	W
110	W

<**m**> Is the number [0-30] of the second general-purpose source register or the name ZR (31), encoded in the “Rm” field.

Alias Conditions

Alias	Is preferred when
CMP (extended register)	Rd == '11111'

Operation

```
constant bits(datasize) operand1 = if n == 31 then SP[datasize] else X[n, datasize];
constant bits(datasize) operand2 = NOT(ExtendReg(m, extend_type, shift, datasize));
bits(datasize) result;
bits(4) nzcv;

(result, nzcv) = AddWithCarry(operand1, operand2, '1');

X[d, datasize] = result;
PSTATE.<N,Z,C,V> = nzcv;
```

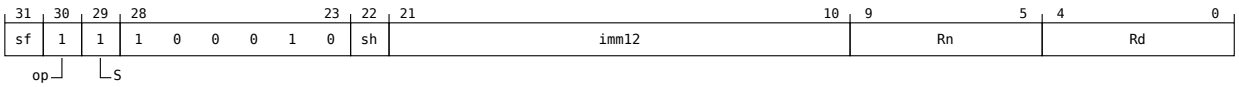
C6.2.288 SUBS (immediate)

Subtract immediate value, setting flags

This instruction subtracts an optionally-shifted immediate value from a register value, and writes the result to the destination register. It updates the condition flags based on the result.

This instruction is used by the alias CMP (immediate).



Encoding for the 32-bit variant Applies when `(sf == 0)`

```
SUBS <Wd>, <Wn|WSP>, #<imm>{, <shift>}
```

Encoding for the 64-bit variant Applies when `(sf == 1)`

```
SUBS <Xd>, <Xn|SP>, #<imm>{, <shift>}
```

Decode for all variants of this encoding

```
constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer datasize = 32 << UInt(sf);

constant bits(24) imm = if sh == '0' then Zeros(12):imm12 else imm12:Zeros(12);
```

Assembler Symbols

<**Wd**> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

<**Wn|WSP**> Is the 32-bit name of the source general-purpose register or stack pointer, encoded in the "Rn" field.

<**imm**> Is an unsigned immediate, in the range 0 to 4095, encoded in the "imm12" field.

<**shift**> Is the optional left shift to apply to the immediate, defaulting to LSL #0 and encoded in "sh":

sh	<shift>
0	LSL #0
1	LSL #12

<**Xd**> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<**Xn|SP**> Is the 64-bit name of the source general-purpose register or stack pointer, encoded in the "Rn" field.

Alias Conditions

Alias	Is preferred when
CMP (immediate)	Rd == '11111'

Operation

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

```
constant bits(datasize) operand1 = if n == 31 then SP[datasize] else X[n, datasize];
constant bits(datasize) operand2 = ZeroExtend(imm, datasize);
bits(datasize) result;
bits(4) nzcv;

(result, nzcv) = AddWithCarry(operand1, NOT(operand2), '1');

X[d, datasize] = result;
PSTATE.<N,Z,C,V> = nzcv;
```

Operational information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

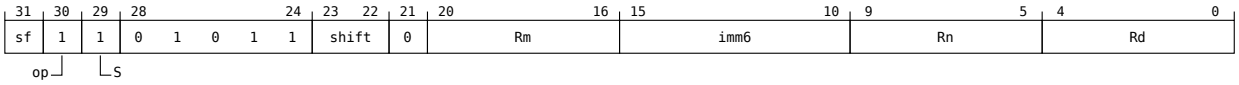
C6.2.289 SUBS (shifted register)

Subtract optionally-shifted register, setting flags

This instruction subtracts an optionally-shifted register value, and writes the result to the destination register. It updates the condition flags based on the result.

This instruction is used by the aliases CMP (shifted register), and NEGS.



Encoding for the 32-bit variant Applies when `(sf == 0)`

```
SUBS <Wd>, <Wn>, <Wm>{, <shift> #<amount>}
```

Encoding for the 64-bit variant Applies when `(sf == 1)`

```
SUBS <Xd>, <Xn>, <Xm>{, <shift> #<amount>}
```

Decode for all variants of this encoding

```
if shift == '11' then EndOfDecode(Decode_UNDEF);
if sf == '0' && imm6<5> == '1' then EndOfDecode(Decode_UNDEF);

constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer m = UInt(Rm);
constant integer datasize = 32 << UInt(sf);
constant ShiftType shift_type = DecodeShift(shift);
constant integer shift_amount = UInt(imm6);
```

Assembler Symbols

<**Wd**> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

<**Wn**> Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.

<**Wm**> Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.

<**shift**> Is the optional shift type to be applied to the second source operand, defaulting to LSL and encoded in "shift":

shift	<shift>
00	LSL
01	LSR
10	ASR
11	RESERVED

<**amount**> For the "32-bit" variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.

For the "64-bit" variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field.

<**Xd**> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<**Xn**> Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

<**Xm**> Is the 64-bit name of the second general-purpose source register, encoded in the “Rm” field.

Alias Conditions

Alias	Is preferred when
CMP (shifted register)	Rd == '11111'
NEGS	Rn == '11111' && Rd != '11111'

Operation

```
constant bits(datasize) operand1 = X[n, datasize];
constant bits(datasize) operand2 = NOT(ShiftReg(m, shift_type, shift_amount, datasize));
bits(datasize) result;
bits(4) nzcv;

(result, nzcv) = AddWithCarry(operand1, operand2, '1');

X[d, datasize] = result;
PSTATE.<N,Z,C,V> = nzcv;
```

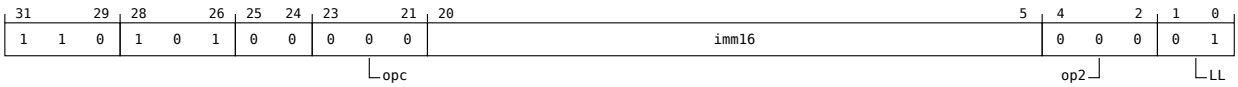
C6.2.290 SVC

Supervisor call

This instruction causes an exception to be taken to EL1.

On executing an `svc` instruction, the PE records the exception as a Supervisor Call exception in ESR_ELx, using the EC syndrome value 0x15, and the value of the immediate argument.



Encoding

```
SVC #<imm>
```

Decode for this encoding

```
constant bits(16) imm = imm16;
```

Assembler Symbols

<imm> Is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm16" field.

Operation

```
AArch64.CallSupervisor(imm);
```

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.291 SWP, SWPA, SWPAL, SWPL

Swap word or doubleword in memory

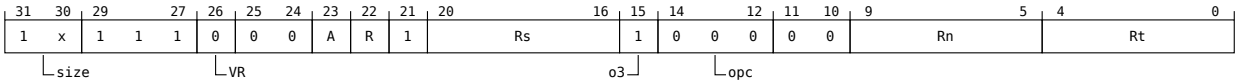
This instruction atomically loads a 32-bit word or 64-bit doubleword from a memory location, and stores the value held in a register back to the same memory location. The value initially loaded from memory is returned in the destination register.

- If the destination register is not one of WZR or XZR, `SWPA` and `SWPAL` load from memory with acquire semantics.
- `SWPL` and `SWPAL` store to memory with release semantics.
- `SWP` has neither acquire nor release semantics.

For more information about memory ordering semantics, see Load-Acquire, Store-Release.

For information about addressing modes, see Load/Store addressing modes.

Integer
(FEAT_LSE)



Encoding for the 32-bit SWP variant Applies when `(size == 10 && A == 0 && R == 0)`

```
SWP <Ws>, <Wt>, [<Xn|SP>]
```

Encoding for the 32-bit SWPA variant Applies when `(size == 10 && A == 1 && R == 0)`

```
SWPA <Ws>, <Wt>, [<Xn|SP>]
```

Encoding for the 32-bit SWPAL variant Applies when `(size == 10 && A == 1 && R == 1)`

```
SWPAL <Ws>, <Wt>, [<Xn|SP>]
```

Encoding for the 32-bit SWPL variant Applies when `(size == 10 && A == 0 && R == 1)`

```
SWPL <Ws>, <Wt>, [<Xn|SP>]
```

Encoding for the 64-bit SWP variant Applies when `(size == 11 && A == 0 && R == 0)`

```
SWP <Xs>, <Xt>, [<Xn|SP>]
```

Encoding for the 64-bit SWPA variant Applies when `(size == 11 && A == 1 && R == 0)`

```
SWPA <Xs>, <Xt>, [<Xn|SP>]
```

Encoding for the 64-bit SWPAL variant Applies when `(size == 11 && A == 1 && R == 1)`

```
SWPAL <Xs>, <Xt>, [<Xn|SP>]
```

Encoding for the 64-bit SWPL variant Applies when `(size == 11 && A == 0 && R == 1)`

```
SWPL <Xs>, <Xt>, [<Xn|SP>]
```

Decode for all variants of this encoding

Non-Confidential

```
if !IsFeatureImplemented(FEAT_LSE) then EndOfDecode(Decode_UNDEF);

constant integer s = UInt(Rs);
constant integer t = UInt(Rt);
constant integer n = UInt(Rn);

constant integer datasize = 8 << UInt(size);
constant integer regsize = if datasize == 64 then 64 else 32;
constant boolean acquire = A == '1' && Rt != '11111';
constant boolean release = R == '1';
```

Assembler Symbols

<Ws> Is the 32-bit name of the general-purpose register to be stored, encoded in the “Rs” field.

<Wt> Is the 32-bit name of the general-purpose register to be loaded, encoded in the “Rt” field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the “Rn” field.

<Xs> Is the 64-bit name of the general-purpose register to be stored, encoded in the “Rs” field.

<Xt> Is the 64-bit name of the general-purpose register to be loaded, encoded in the “Rt” field.

Operation

```
bits(64) address;
bits(datasize) data;
bits(datasize) store_value;

constant boolean privileged = PSTATE.EL != EL0;
constant AccessDescriptor accdesc = CreateAccDescAtomicOp(MemAtomicOp_SWP, acquire, release,
                                                          privileged, t, s);

if n == 31 then
    CheckSPAlignment();
    address = SP[64];
else
    address = X[n, 64];

store_value = X[s, datasize];

constant bits(datasize) comparevalue = bits(datasize) UNKNOWN; // Irrelevant when not executing CAS
data = MemAtomic(address, comparevalue, store_value, accdesc);

X[t, regsize] = ZeroExtend(data, regsize);
```

C6.2.292 SWPB, SWPAB, SWPALB, SWPLB

Swap byte in memory

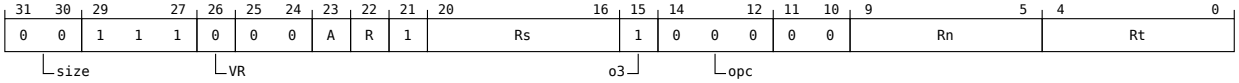
This instruction atomically loads an 8-bit byte from a memory location, and stores the value held in a register back to the same memory location. The value initially loaded from memory is returned in the destination register.

- If the destination register is not WZR, `SWPAB` and `SWPALB` load from memory with acquire semantics.
- `SWPLB` and `SWPALB` store to memory with release semantics.
- `SWPB` has neither acquire nor release semantics.

For more information about memory ordering semantics, see Load-Acquire, Store-Release.

For information about addressing modes, see Load/Store addressing modes.

Integer
(FEAT_LSE)



Encoding for the SWPB variant Applies when `(A == 0 && R == 0)`

```
SWPB <Ws>, <Wt>, [<Xn|SP>]
```

Encoding for the SWPAB variant Applies when `(A == 1 && R == 0)`

```
SWPAB <Ws>, <Wt>, [<Xn|SP>]
```

Encoding for the SWPALB variant Applies when `(A == 1 && R == 1)`

```
SWPALB <Ws>, <Wt>, [<Xn|SP>]
```

Encoding for the SWPLB variant Applies when `(A == 0 && R == 1)`

```
SWPLB <Ws>, <Wt>, [<Xn|SP>]
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_LSE) then EndOfDecode(Decode_UNDEF);

constant integer s = UInt(Rs);
constant integer t = UInt(Rt);
constant integer n = UInt(Rn);

constant boolean acquire = A == '1' && Rt != '11111';
constant boolean release = R == '1';
```

Assembler Symbols

<Ws> Is the 32-bit name of the general-purpose register to be stored, encoded in the “Rs” field.

<Wt> Is the 32-bit name of the general-purpose register to be loaded, encoded in the “Rt” field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the “Rn” field.

Operation

C6.2.293 SWPH, SWPAH, SWPALH, SWPLH

Swap halfword in memory

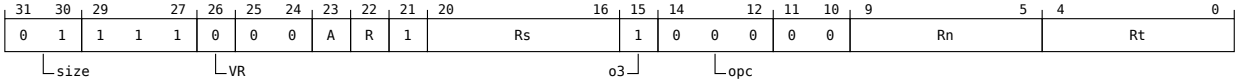
This instruction atomically loads a 16-bit halfword from a memory location, and stores the value held in a register back to the same memory location. The value initially loaded from memory is returned in the destination register.

- If the destination register is not WZR, `SWPAH` and `SWPALH` load from memory with acquire semantics.
- `SWPLH` and `SWPALH` store to memory with release semantics.
- `SWPH` has neither acquire nor release semantics.

For more information about memory ordering semantics, see Load-Acquire, Store-Release.

For information about addressing modes, see Load/Store addressing modes.

Integer
(FEAT_LSE)



Encoding for the SWPH variant Applies when `(A == 0 && R == 0)`

```
SWPH <Ws>, <Wt>, [<Xn|SP>]
```

Encoding for the SWPAH variant Applies when `(A == 1 && R == 0)`

```
SWPAH <Ws>, <Wt>, [<Xn|SP>]
```

Encoding for the SWPALH variant Applies when `(A == 1 && R == 1)`

```
SWPALH <Ws>, <Wt>, [<Xn|SP>]
```

Encoding for the SWPLH variant Applies when `(A == 0 && R == 1)`

```
SWPLH <Ws>, <Wt>, [<Xn|SP>]
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_LSE) then EndOfDecode(Decode_UNDEF);

constant integer s = UInt(Rs);
constant integer t = UInt(Rt);
constant integer n = UInt(Rn);

constant boolean acquire = A == '1' && Rt != '11111';
constant boolean release = R == '1';
```

Assembler Symbols

<Ws> Is the 32-bit name of the general-purpose register to be stored, encoded in the “Rs” field.

<Wt> Is the 32-bit name of the general-purpose register to be loaded, encoded in the “Rt” field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the “Rn” field.

Operation

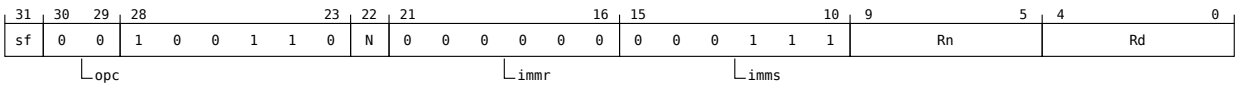
C6.2.294 SXTB

Signed extend byte

This instruction extracts an 8-bit value from a register, sign-extends it to the size of the register, and writes the result to the destination register.

This is an alias of SBFM. This means:

- The encodings in this description are named to match the encodings of SBFM.
- The description of SBFM gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.



Encoding for the 32-bit variant Applies when `(sf == 0 && N == 0)`

```
SXTB <Wd>, <Wn>
```

is equivalent to

```
SBFM <Wd>, <Wn>, #0, #7
```

and is always the preferred disassembly.

Encoding for the 64-bit variant Applies when `(sf == 1 && N == 1)`

```
SXTB <Xd>, <Wn>
```

is equivalent to

```
SBFM <Xd>, <Xn>, #0, #7
```

and is always the preferred disassembly.

Assembler Symbols

<**Wd**> Is the 32-bit name of the general-purpose destination register, encoded in the “Rd” field.

<**Wn**> Is the 32-bit name of the general-purpose source register, encoded in the “Rn” field.

<**Xd**> Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

Operation

The description of SBFM gives the operational pseudocode for this instruction.

Operational Information

The description of SBFM gives the operational information for this instruction.

Non-Confidential

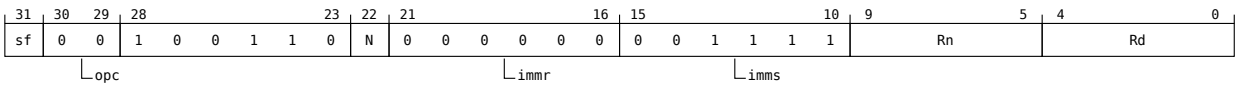
C6.2.295 SXTH

Sign extend halfword

This instruction extracts a 16-bit value, sign-extends it to the size of the register, and writes the result to the destination register.

This is an alias of SBFM. This means:

- The encodings in this description are named to match the encodings of SBFM.
- The description of SBFM gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.



Encoding for the 32-bit variant Applies when `(sf == 0 && N == 0)`

```
SXTH <Wd>, <Wn>
```

is equivalent to

```
SBFM <Wd>, <Wn>, #0, #15
```

and is always the preferred disassembly.

Encoding for the 64-bit variant Applies when `(sf == 1 && N == 1)`

```
SXTH <Xd>, <Wn>
```

is equivalent to

```
SBFM <Xd>, <Xn>, #0, #15
```

and is always the preferred disassembly.

Assembler Symbols

<**Wd**> Is the 32-bit name of the general-purpose destination register, encoded in the “Rd” field.

<**Wn**> Is the 32-bit name of the general-purpose source register, encoded in the “Rn” field.

<**Xd**> Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

Operation

The description of SBFM gives the operational pseudocode for this instruction.

Operational Information

The description of SBFM gives the operational information for this instruction.

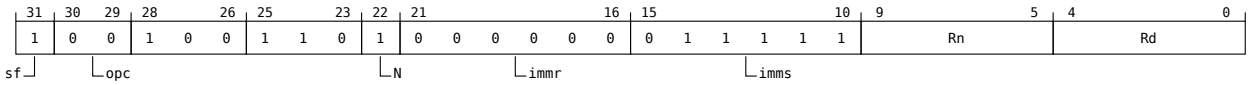
C6.2.296 SXTW

Sign extend word

This instruction sign-extends a word to the size of the register, and writes the result to the destination register.

This is an alias of SBFM. This means:

- The encodings in this description are named to match the encodings of SBFM.
- The description of SBFM gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.



Encoding

SXTW <Xd>, <Wn>

is equivalent to

SBFM <Xd>, <Xn>, #0, #31

and is always the preferred disassembly.

Assembler Symbols

<**Xd**> Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

<**Wn**> Is the 32-bit name of the general-purpose source register, encoded in the “Rn” field.

Operation

The description of SBFM gives the operational pseudocode for this instruction.

Operational Information

The description of SBFM gives the operational information for this instruction.

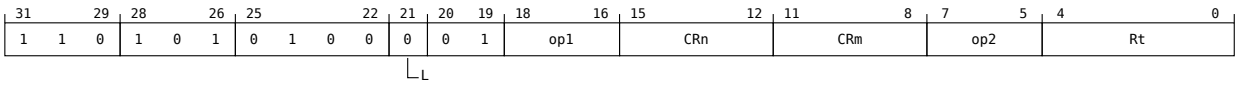
C6.2.297 SYS

System instruction

For more information, see Op0 equals 0b01, cache maintenance, TLB maintenance, and address translation instructions for the encodings of System instructions.

This instruction is used by the aliases AT, CFP, CPP, DC, DVP, IC, and TLBI.



Encoding

```
SYS #<op1>, <Cn>, <Cm>, #<op2>{, <Xt>}
```

Decode for this encoding

```
constant integer t       = UInt(Rt);
constant bits(1) sys_L   = L;
constant bits(2) sys_op0 = '01';
constant bits(3) sys_op1 = op1;
constant bits(3) sys_op2 = op2;
constant bits(4) sys_crn = CRn;
constant bits(4) sys_crm = CRm;
```

Assembler Symbols

<**op1**> Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the “op1” field.

<**Cn**> Is a name ’Cn’, with ’n’ in the range 0 to 15, encoded in the “CRn” field.

<**Cm**> Is a name ’Cm’, with ’m’ in the range 0 to 15, encoded in the “CRm” field.

<**op2**> Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the “op2” field.

<**Xt**> Is the 64-bit name of the optional general-purpose source register, defaulting to ’11111’, encoded in the “Rt” field.

Alias Conditions

Alias	Is preferred when
AT	`CRn == '0111' && CRm IN {'100x'} &&SysOp(op1, '0111', CRm, op2) == Sys_AT`
CFP	`op1 == '011' && CRn == '0111' && CRm == '0011' && op2 == '100'`
CPP	`op1 == '011' && CRn == '0111' && CRm == '0011' && op2 == '111'`
DC	`CRn == '0111' &&SysOp(op1, '0111', CRm, op2) == Sys_DC`
DVP	`op1 == '011' && CRn == '0111' && CRm == '0011' && op2 == '101'`
IC	`CRn == '0111' &&SysOp(op1, '0111', CRm, op2) == Sys_IC`

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Alias	Is preferred when
TLBI	CRn IN {'100x'} &&SysOp(op1, CRn, CRm, op2) == Sys_TLBI

Operation

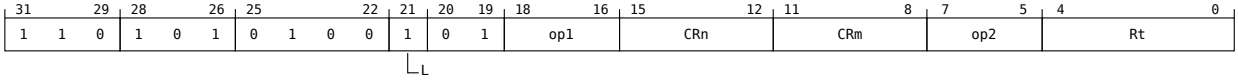
```
AArch64.SysInstr(sys_op0, sys_op1, sys_crn, sys_crm, sys_op2, t);
```

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.298 SYSL

System instruction with result

For more information, see Op0 equals 0b01, cache maintenance, TLB maintenance, and address translation instructions for the encodings of System instructions.



Encoding

```
SYSL <Xt>, #<op1>, <Cn>, <Cm>, #<op2>
```

Decode for this encoding

```
constant integer t       = UInt(Rt);
constant bits(1) sys_L   = L;
constant bits(2) sys_op0 = '01';
constant bits(3) sys_op1 = op1;
constant bits(3) sys_op2 = op2;
constant bits(4) sys_crn = CRn;
constant bits(4) sys_crm = CRm;
```

Assembler Symbols

<**Xt**> Is the 64-bit name of the general-purpose destination register, encoded in the “Rt” field.

<**op1**> Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the “op1” field.

<**Cn**> Is a name ’Cn’, with ’n’ in the range 0 to 15, encoded in the “CRn” field.

<**Cm**> Is a name ’Cm’, with ’m’ in the range 0 to 15, encoded in the “CRm” field.

<**op2**> Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the “op2” field.

Operation

```
AArch64.SysInstrWithResult(sys_op0, sys_op1, sys_crn, sys_crm, sys_op2, t);
```

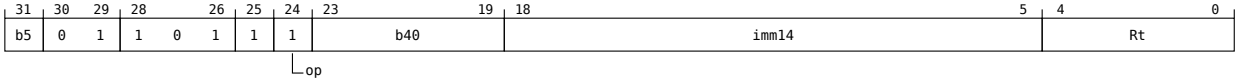
C6.2.299 TBNZ

Test bit and branch if nonzero

This instruction compares the value of a bit in a general-purpose register with zero, and conditionally branches to a label at a PC-relative offset if the comparison is not equal. This instruction provides a hint that this is not a subroutine call or return. This instruction does not affect condition flags.



Encoding

```
TBNZ <R><t>, #<imm>, <label>
```

Decode for this encoding

```
constant integer t = UInt(Rt);

constant integer datasize = 32 << UInt(b5);
constant integer bit_pos = UInt(b5:b40);
constant bits(64) offset = SignExtend(imm14:'00', 64);
```

Assembler Symbols

<**R**> Is a width specifier, encoded in “b5”:

b5	<R>
0	W
1	X

In assembler source code an ’X’ specifier is always permitted, but a ’W’ specifier is only permitted when the bit number is less than 32.

<**t**> Is the number [0-30] of the general-purpose register to be tested or the name ZR (31), encoded in the “Rt” field.

<**imm**> Is the bit number to be tested, in the range 0 to 63, encoded in “b5:b40”.

<**label**> Is the program label to be conditionally branched to. Its offset from the address of this instruction, in the range +/-32KB, is encoded as “imm14” times 4.

Operation

```
constant bits(datasize) operand = X[t, datasize];
constant boolean branch_conditional = TRUE;
if operand<bit_pos> != '0' then
    BranchTo(PC64 + offset, BranchType_DIR, branch_conditional);
```

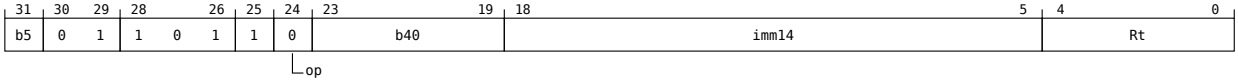
Non-Confidential

C6.2.300 TBZ

Test bit and branch if zero

This instruction compares the value of a test bit with zero, and conditionally branches to a label at a PC-relative offset if the comparison is equal. This instruction provides a hint that this is not a subroutine call or return. This instruction does not affect condition flags.



Encoding

```
TBZ <R><t>, #<imm>, <label>
```

Decode for this encoding

```
constant integer t = UInt(Rt);

constant integer datasize = 32 << UInt(b5);
constant integer bit_pos = UInt(b5:b40);
constant bits(64) offset = SignExtend(imm14:'00', 64);
```

Assembler Symbols

<**R**> Is a width specifier, encoded in “b5”:

b5	<R>
0	W
1	X

In assembler source code an ’X’ specifier is always permitted, but a ’W’ specifier is only permitted when the bit number is less than 32.

<**t**> Is the number [0-30] of the general-purpose register to be tested or the name ZR (31), encoded in the “Rt” field.

<**imm**> Is the bit number to be tested, in the range 0 to 63, encoded in “b5:b40”.

<**label**> Is the program label to be conditionally branched to. Its offset from the address of this instruction, in the range +/-32KB, is encoded as “imm14” times 4.

Operation

```
constant bits(datasize) operand = X[t, datasize];
constant boolean branch_conditional = TRUE;
if operand<bit_pos> == '0' then
    BranchTo(PC64 + offset, BranchType_DIR, branch_conditional);
```

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

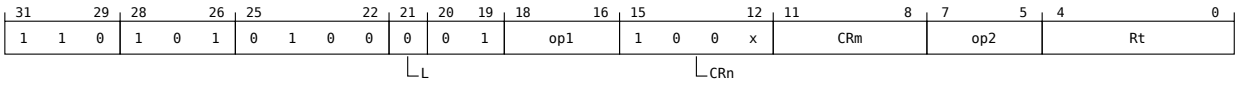
C6.2.301 TLBI

TLB invalidate operation

For more information, see op0==0b01, cache maintenance, TLB maintenance, and address translation instructions.

This is an alias of SYS. This means:

- The encodings in this description are named to match the encodings of SYS.
- The description of SYS gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.



Encoding

```
TLBI <tlbi_op>{, <Xt>}
```

is equivalent to

```
SYS #<op1>, <Cn>, <Cm>, #<op2>{, <Xt>}
```

and is the preferred disassembly when `SysOp(op1, CRn, CRm, op2) == Sys_TLBI`.

Assembler Symbols

<**tlbi_op**> Is a TLBI operation name, as listed for the TLBI system instruction group, encoded in "op1:CRn:CRm:op2":

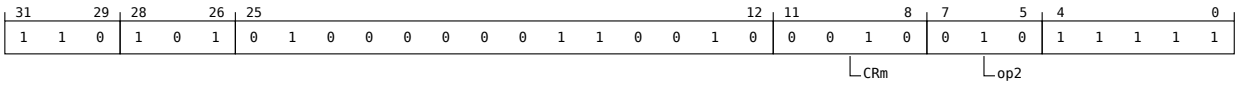
C6.2.302 TSB

Trace synchronization barrier

This instruction is a barrier that synchronizes the trace operations of instructions, see Trace Synchronization Barrier (TSB).

If FEAT_TRF is not implemented, this instruction executes as a `NOP`.

System
(FEAT_TRF)



Encoding

```
TSB CSYNC
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_TRF) then EndOfDecode(Decode_NOP);
```

Operation

```
TraceSynchronizationBarrier();
```

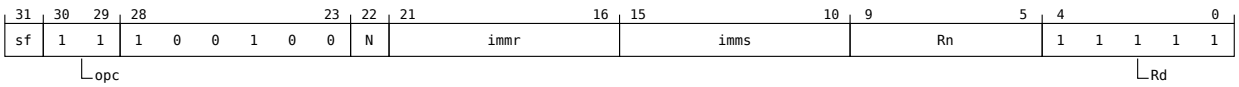
C6.2.303 TST (immediate)

Test bits (immediate)

This instruction performs a bitwise AND of a register value and an immediate value, and discards the results. It updates the condition flags based on the result.

This is an alias of ANDS (immediate). This means:

- The encodings in this description are named to match the encodings of ANDS (immediate).
- The description of ANDS (immediate) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.



Encoding for the 32-bit variant Applies when `(sf == 0 && N == 0)`

```
TST <Wn>, #<imm>
```

is equivalent to

```
ANDS WZR, <Wn>, #<imm>
```

and is always the preferred disassembly.

Encoding for the 64-bit variant Applies when `(sf == 1)`

```
TST <Xn>, #<imm>
```

is equivalent to

```
ANDS XZR, <Xn>, #<imm>
```

and is always the preferred disassembly.

Assembler Symbols

<**Wn**> Is the 32-bit name of the general-purpose source register, encoded in the “Rn” field.

<**imm**> For the “32-bit” variant: is the bitmask immediate, encoded in “imms:immr”.

For the “64-bit” variant: is the bitmask immediate, encoded in “N:imms:immr”.

<**Xn**> Is the 64-bit name of the general-purpose source register, encoded in the “Rn” field.

Operation

The description of ANDS (immediate) gives the operational pseudocode for this instruction.

Operational Information

The description of ANDS (immediate) gives the operational information for this instruction.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

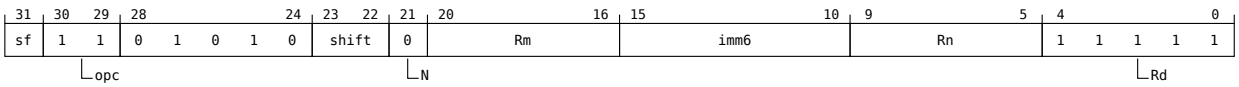
C6.2.304 TST (shifted register)

Test (shifted register)

This instruction performs a bitwise AND operation on a register value and an optionally-shifted register value. It updates the condition flags based on the result, and discards the result.

This is an alias of ANDS (shifted register). This means:

- The encodings in this description are named to match the encodings of ANDS (shifted register).
- The description of ANDS (shifted register) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.



Encoding for the 32-bit variant Applies when `(sf == 0)`

```
TST <Wn>, <Wm>{, <shift> #<amount>}
```

is equivalent to

```
ANDS WZR, <Wn>, <Wm>{, <shift> #<amount>}
```

and is always the preferred disassembly.

Encoding for the 64-bit variant Applies when `(sf == 1)`

```
TST <Xn>, <Xm>{, <shift> #<amount>}
```

is equivalent to

```
ANDS XZR, <Xn>, <Xm>{, <shift> #<amount>}
```

and is always the preferred disassembly.

Assembler Symbols

<**Wn**> Is the 32-bit name of the first general-purpose source register, encoded in the “Rn” field.

<**Wm**> Is the 32-bit name of the second general-purpose source register, encoded in the “Rm” field.

<**shift**> Is the optional shift to be applied to the final source, defaulting to LSL and encoded in “shift”:

shift	<**shift**>
00	LSL
01	LSR
10	ASR
11	ROR

<**amount**> For the “32-bit” variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the “imm6” field.

For the “64-bit” variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the “imm6” field.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

<Xn> Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.

<Xm> Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.

Operation

The description of ANDS (shifted register) gives the operational pseudocode for this instruction.

Operational Information

The description of ANDS (shifted register) gives the operational information for this instruction.

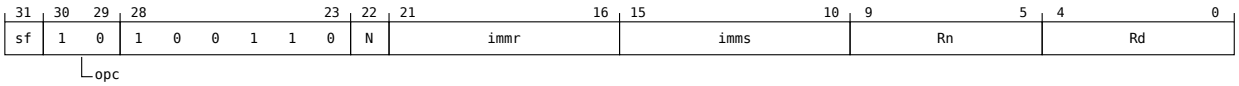
C6.2.305 UBFIZ

Unsigned bitfield insert in zeros

This instruction copies a bitfield of <width> bits from the least significant bits of the source register to bit position <lsb> of the destination register, setting the destination bits above and below the bitfield to zero.

This is an alias of UBFM. This means:

- The encodings in this description are named to match the encodings of UBFM.
- The description of UBFM gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.



Encoding for the 32-bit variant Applies when `(sf == 0 && N == 0)`

```
UBFIZ <Wd>, <Wn>, #<lsb>, #<width>
```

is equivalent to

```
UBFM <Wd>, <Wn>, #(-<lsb> MOD 32), #(<width>-1)
```

and is the preferred disassembly when `UInt(imms) < UInt(immr)`.

Encoding for the 64-bit variant Applies when `(sf == 1 && N == 1)`

```
UBFIZ <Xd>, <Xn>, #<lsb>, #<width>
```

is equivalent to

```
UBFM <Xd>, <Xn>, #(-<lsb> MOD 64), #(<width>-1)
```

and is the preferred disassembly when `UInt(imms) < UInt(immr)`.

Assembler Symbols

<**Wd**> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

<**Wn**> Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.

<**lsb**> For the "32-bit" variant: is the bit number of the lsb of the destination bitfield, in the range 0 to 31.

For the "64-bit" variant: is the bit number of the lsb of the destination bitfield, in the range 0 to 63.

<**width**> For the "32-bit" variant: is the width of the bitfield, in the range 1 to 32-<lsb>.

For the "64-bit" variant: is the width of the bitfield, in the range 1 to 64-<lsb>.

<**Xd**> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<**Xn**> Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.

Operation

The description of UBFM gives the operational pseudocode for this instruction.

Operational Information

The description of UBFM gives the operational information for this instruction.

Non-Confidential

C6.2.306 UBFM

Unsigned bitfield move

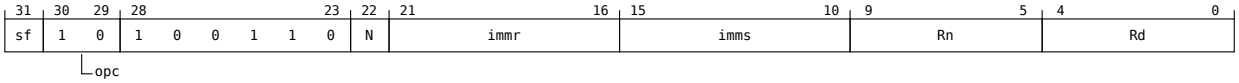
This instruction is usually accessed via one of its aliases, which are always preferred for disassembly.

If <imms> is greater than or equal to <immr>, this copies a bitfield of (<imms>-<immr>+1) bits starting from bit position <immr> in the source register to the least significant bits of the destination register.

If <imms> is less than <immr>, this copies a bitfield of (<imms>+1) bits from the least significant bits of the source register to bit position (regsize-<immr>) of the destination register, where regsize is the destination register size of 32 or 64 bits.

In both cases, the destination bits below and above the bitfield are set to zero.

This instruction is used by the aliases LSL (immediate), LSR (immediate), UBFIZ, UBFX, UXTB, and UXTH.



Encoding for the 32-bit variant Applies when `(sf == 0 && N == 0)`

```
UBFM <Wd>, <Wn>, #<immr>, #<imms>
```

Encoding for the 64-bit variant Applies when `(sf == 1 && N == 1)`

```
UBFM <Xd>, <Xn>, #<immr>, #<imms>
```

Decode for all variants of this encoding

```
if sf == '1' && N != '1' then EndOfDecode(Decode_UNDEF);
if sf == '0' && (N != '0' || immr<5> != '0' || imms<5> != '0') then EndOfDecode(Decode_UNDEF);

constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer datasize = 32 << UInt(sf);
constant integer s = UInt(imms);
constant integer r = UInt(immr);

bits(datasize) wmask;
bits(datasize) tmask;
(wmask, tmask) = DecodeBitMasks(N, imms, immr, FALSE, datasize);
```

Assembler Symbols

<**Wd**> Is the 32-bit name of the general-purpose destination register, encoded in the “Rd” field.

<**Wn**> Is the 32-bit name of the general-purpose source register, encoded in the “Rn” field.

<**immr**> For the “32-bit” variant: is the right rotate amount, in the range 0 to 31, encoded in the “immr” field.

For the “64-bit” variant: is the right rotate amount, in the range 0 to 63, encoded in the “immr” field.

<**imms**> For the “32-bit” variant: is the leftmost bit number to be moved from the source, in the range 0 to 31, encoded in the “imms” field.

For the “64-bit” variant: is the leftmost bit number to be moved from the source, in the range 0 to 63, encoded in the “imms” field.

<**Xd**> Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

<Xn> Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.

Alias Conditions

Alias	Of variant	Is preferred when
LSL (immediate)	32-bit	`imms != '011111' &&UInt(imms) + 1 == UInt(immr)`
LSL (immediate)	64-bit	`imms != '111111' &&UInt(imms) + 1 == UInt(immr)`
LSR (immediate)	32-bit	`imms == '011111'`
LSR (immediate)	64-bit	`imms == '111111'`
UBFIZ		`UInt(imms) < UInt(immr)`
UBFX		`BFXPreferred(sf, opc<1>, imms, immr)`
UXTB		`immr == '000000' && imms == '000111'`
UXTH		`immr == '000000' && imms == '001111'`

Operation

```
constant bits(datasize) src = X[n, datasize];

// Perform bitfield move on low bits
constant bits(datasize) bot = ROR(src, r) AND wmask;

// Combine extension bits and result bits
X[d, datasize] = bot AND tmask;
```

Operational information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

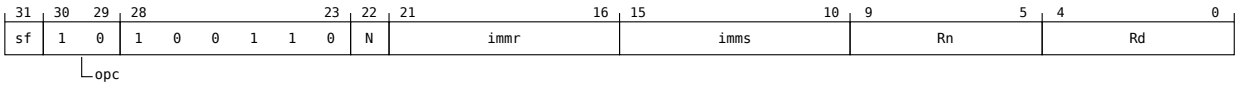
C6.2.307 UBFX

Unsigned bitfield extract

This instruction copies a bitfield of <width> bits starting from bit position <lsb> in the source register to the least significant bits of the destination register, and sets destination bits above the bitfield to zero.

This is an alias of UBFM. This means:

- The encodings in this description are named to match the encodings of UBFM.
- The description of UBFM gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.



Encoding for the 32-bit variant Applies when `(sf == 0 && N == 0)`

```
UBFX <Wd>, <Wn>, #<lsb>, #<width>
```

is equivalent to

```
UBFM <Wd>, <Wn>, #<lsb>, #(<lsb>+<width>-1)
```

and is the preferred disassembly when `BFXPreferred(sf, opc<1>, imms, immr)`.

Encoding for the 64-bit variant Applies when `(sf == 1 && N == 1)`

```
UBFX <Xd>, <Xn>, #<lsb>, #<width>
```

is equivalent to

```
UBFM <Xd>, <Xn>, #<lsb>, #(<lsb>+<width>-1)
```

and is the preferred disassembly when `BFXPreferred(sf, opc<1>, imms, immr)`.

Assembler Symbols

<**Wd**> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

<**Wn**> Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.

<**lsb**> For the "32-bit" variant: is the bit number of the lsb of the source bitfield, in the range 0 to 31.

For the "64-bit" variant: is the bit number of the lsb of the source bitfield, in the range 0 to 63.

<**width**> For the "32-bit" variant: is the width of the bitfield, in the range 1 to 32-<lsb>.

For the "64-bit" variant: is the width of the bitfield, in the range 1 to 64-<lsb>.

<**Xd**> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<**Xn**> Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.

Operation

The description of UBFM gives the operational pseudocode for this instruction.

Operational Information

The description of UBFM gives the operational information for this instruction.

C6.2.308 UDF

Permanently undefined

This instruction generates an Undefined Instruction exception (ESR_ELx.EC = 0b000000). The encodings for `UDF` used in this section are defined as permanently UNDEFINED.

Encoding

```
UDF #<imm>
```

Decode for this encoding

```
// The imm16 field is ignored by hardware.
EndOfDecode(Decode_UNDEF);
```

Assembler Symbols

<imm> is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm16" field. The PE ignores the value of this constant.

Operation

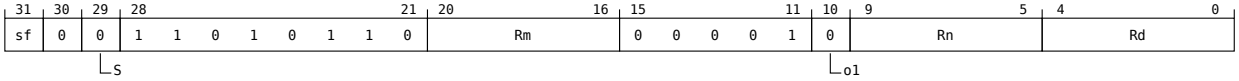
```
// No operation.
```

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.309 UDIV

Unsigned divide

This instruction divides the first unsigned source register value by the second unsigned source register value, and writes the result to the destination register. Dividing by zero writes the value zero to the destination register. The condition flags are not affected.



Encoding for the 32-bit variant Applies when `(sf == 0)`

```
UDIV <Wd>, <Wn>, <Wm>
```

Encoding for the 64-bit variant Applies when `(sf == 1)`

```
UDIV <Xd>, <Xn>, <Xm>
```

Decode for all variants of this encoding

```
constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer m = UInt(Rm);
constant integer datasize = 32 << UInt(sf);
```

Assembler Symbols

<**Wd**> Is the 32-bit name of the general-purpose destination register, encoded in the “Rd” field.

<**Wn**> Is the 32-bit name of the first general-purpose source register, encoded in the “Rn” field.

<**Wm**> Is the 32-bit name of the second general-purpose source register, encoded in the “Rm” field.

<**Xd**> Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

<**Xn**> Is the 64-bit name of the first general-purpose source register, encoded in the “Rn” field.

<**Xm**> Is the 64-bit name of the second general-purpose source register, encoded in the “Rm” field.

Operation

```
constant bits(datasize) operand1 = X[n, datasize];
constant bits(datasize) operand2 = X[m, datasize];
constant integer dividend = UInt(operand1);
constant integer divisor  = UInt(operand2);
integer result;
if divisor == 0 then
    result = 0;
else
    result = dividend DIV divisor;
X[d, datasize] = result<datasize-1:0>;
```

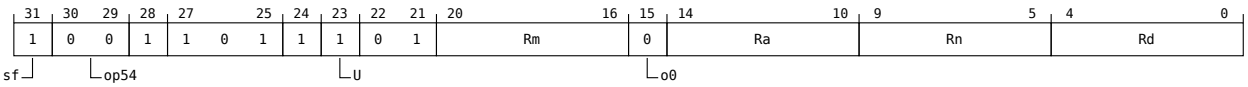
C6.2.310 UMADDL

Unsigned multiply-add long

This instruction multiplies two 32-bit register values, adds a 64-bit register value, and writes the result to the 64-bit destination register.

This instruction is used by the alias UMULL.



Encoding

UMADDL <Xd>, <Wn>, <Wm>, <Xa>

Decode for this encoding

```
constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer m = UInt(Rm);
constant integer a = UInt(Ra);
```

Assembler Symbols

<**Xd**> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<**Wn**> Is the 32-bit name of the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.

<**Wm**> Is the 32-bit name of the second general-purpose source register holding the multiplier, encoded in the "Rm" field.

<**Xa**> Is the 64-bit name of the third general-purpose source register holding the addend, encoded in the "Ra" field.

Alias Conditions

Alias	Is preferred when
UMULL	Ra == '11111'

Operation

```
constant bits(32) operand1 = X[n, 32];
constant bits(32) operand2 = X[m, 32];
constant bits(64) operand3 = X[a, 64];

constant integer result = UInt(operand3) + (UInt(operand1) * UInt(operand2));

X[d, 64] = result<63:0>;
```

Operational information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

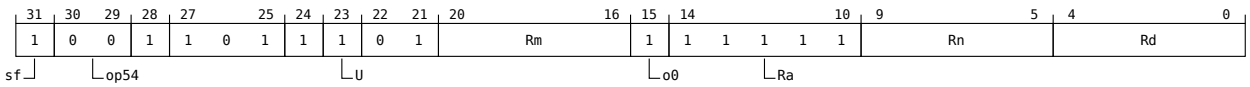
C6.2.311 UMNEGL

Unsigned multiply-negate long

This instruction multiplies two 32-bit register values, negates the product, and writes the result to the 64-bit destination register.

This is an alias of UMSUBL. This means:

- The encodings in this description are named to match the encodings of UMSUBL.
- The description of UMSUBL gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.



Encoding

```
UMNEGL <Xd>, <Wn>, <Wm>
```

is equivalent to

```
UMSUBL <Xd>, <Wn>, <Wm>, XZR
```

and is always the preferred disassembly.

Assembler Symbols

<**Xd**> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<**Wn**> Is the 32-bit name of the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.

<**Wm**> Is the 32-bit name of the second general-purpose source register holding the multiplier, encoded in the "Rm" field.

Operation

The description of UMSUBL gives the operational pseudocode for this instruction.

Operational Information

The description of UMSUBL gives the operational information for this instruction.

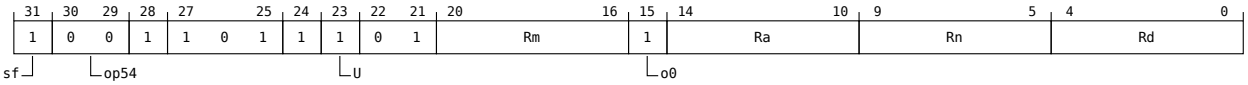
Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.312 UMSUBL

Unsigned multiply-subtract long

This instruction multiplies two 32-bit register values, subtracts the product from a 64-bit register value, and writes the result to the 64-bit destination register.

This instruction is used by the alias UMNEGL.



Encoding

UMSUBL <Xd>, <Wn>, <Wm>, <Xa>

Decode for this encoding

```
constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer m = UInt(Rm);
constant integer a = UInt(Ra);
```

Assembler Symbols

<**Xd**> Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

<**Wn**> Is the 32-bit name of the first general-purpose source register holding the multiplicand, encoded in the “Rn” field.

<**Wm**> Is the 32-bit name of the second general-purpose source register holding the multiplier, encoded in the “Rm” field.

<**Xa**> Is the 64-bit name of the third general-purpose source register holding the minuend, encoded in the “Ra” field.

Alias Conditions

Alias	Is preferred when
UMNEGL	Ra == '11111'

Operation

```
constant bits(32) operand1 = X[n, 32];
constant bits(32) operand2 = X[m, 32];
constant bits(64) operand3 = X[a, 64];

constant integer result = UInt(operand3) - (UInt(operand1) * UInt(operand2));

X[d, 64] = result<63:0>;
```

Operational information

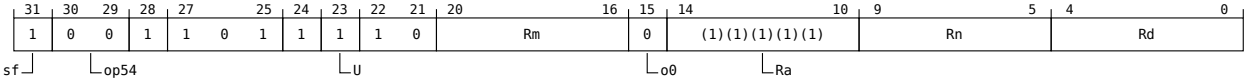
This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.313 UMULH

Unsigned multiply high

This instruction multiplies two 64-bit register values, and writes bits[127:64] of the 128-bit result to the 64-bit destination register.



Encoding

```
UMULH <Xd>, <Xn>, <Xm>
```

Decode for this encoding

```
constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer m = UInt(Rm);
```

Assembler Symbols

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Xn> Is the 64-bit name of the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.

<Xm> Is the 64-bit name of the second general-purpose source register holding the multiplier, encoded in the "Rm" field.

Operation

```
constant bits(64) operand1 = X[n, 64];
constant bits(64) operand2 = X[m, 64];

constant integer result = UInt(operand1) * UInt(operand2);

X[d, 64] = result<127:64>;
```

Operational information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

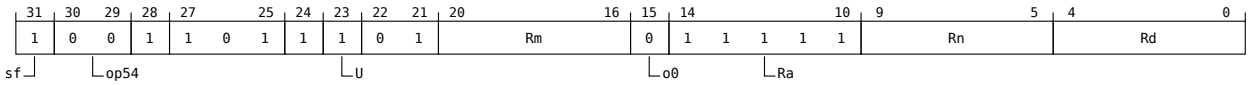
C6.2.314 UMULL

Unsigned multiply long

This instruction multiplies two 32-bit register values, and writes the result to the 64-bit destination register.

This is an alias of UMADDL. This means:

- The encodings in this description are named to match the encodings of UMADDL.
- The description of UMADDL gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.



Encoding

```
UMULL <Xd>, <Wn>, <Wm>
```

is equivalent to

```
UMADDL <Xd>, <Wn>, <Wm>, XZR
```

and is always the preferred disassembly.

Assembler Symbols

<**Xd**> Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

<**Wn**> Is the 32-bit name of the first general-purpose source register holding the multiplicand, encoded in the “Rn” field.

<**Wm**> Is the 32-bit name of the second general-purpose source register holding the multiplier, encoded in the “Rm” field.

Operation

The description of UMADDL gives the operational pseudocode for this instruction.

Operational Information

The description of UMADDL gives the operational information for this instruction.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.

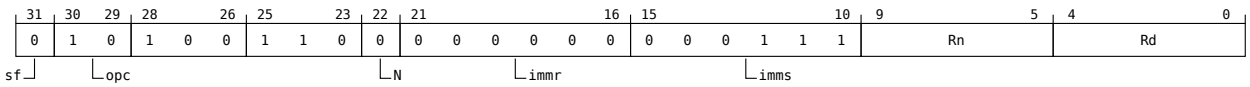
C6.2.315 UXTB

Unsigned extend byte

This instruction extracts an 8-bit value from a register, zero-extends it to the size of the register, and writes the result to the destination register.

This is an alias of UBFM. This means:

- The encodings in this description are named to match the encodings of UBFM.
- The description of UBFM gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.



Encoding

UXTB <Wd>, <Wn>

is equivalent to

UBFM <Wd>, <Wn>, #0, #7

and is always the preferred disassembly.

Assembler Symbols

<**Wd**> Is the 32-bit name of the general-purpose destination register, encoded in the “Rd” field.

<**Wn**> Is the 32-bit name of the general-purpose source register, encoded in the “Rn” field.

Operation

The description of UBFM gives the operational pseudocode for this instruction.

Operational Information

The description of UBFM gives the operational information for this instruction.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

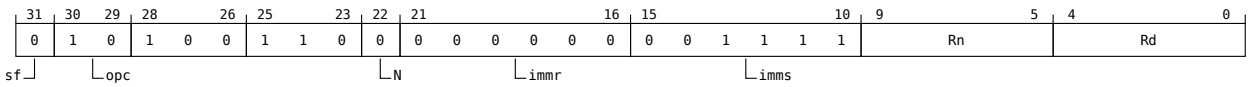
C6.2.316 UXTH

Unsigned extend halfword

This instruction extracts a 16-bit value from a register, zero-extends it to the size of the register, and writes the result to the destination register.

This is an alias of UBFM. This means:

- The encodings in this description are named to match the encodings of UBFM.
- The description of UBFM gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.



Encoding

UXTH <Wd>, <Wn>

is equivalent to

UBFM <Wd>, <Wn>, #0, #15

and is always the preferred disassembly.

Assembler Symbols

<**Wd**> Is the 32-bit name of the general-purpose destination register, encoded in the “Rd” field.

<**Wn**> Is the 32-bit name of the general-purpose source register, encoded in the “Rn” field.

Operation

The description of UBFM gives the operational pseudocode for this instruction.

Operational Information

The description of UBFM gives the operational information for this instruction.

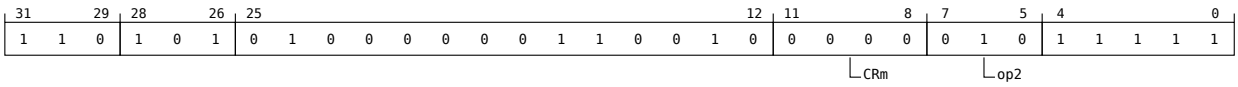
C6.2.317 WFE

Wait for event

This instruction is a hint instruction that indicates that the PE can enter a low-power state and remain there until a wakeup event occurs. Wakeup events include the event signaled as a result of executing the `SEV` instruction on any PE in the multiprocessor system. For more information, see Wait For Event mechanism and Send event.

As described in Wait For Event mechanism and Send event, the execution of a `WFE` instruction that would otherwise cause entry to a low-power state can be trapped to a higher Exception level.



Encoding

`WFE`

Decode for this encoding

```
// Empty.
```

Operation

```
Hint_WFE();
```

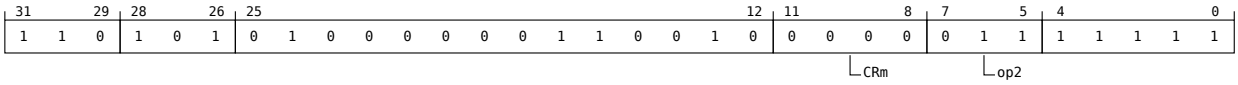
Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.318 WFI

Wait for interrupt

This instruction is a hint instruction that indicates that the PE can enter a low-power state and remain there until a wakeup event occurs. For more information, see Wait For Interrupt.

As described in Wait For Interrupt, the execution of a `WFI` instruction that would otherwise cause entry to a low-power state can be trapped to a higher Exception level.



Encoding

```
WFI
```

Decode for this encoding

```
// Empty.
```

Operation

```
Hint_WFI();
```

C6.2.319 XPACD, XPACI, XPACLRI

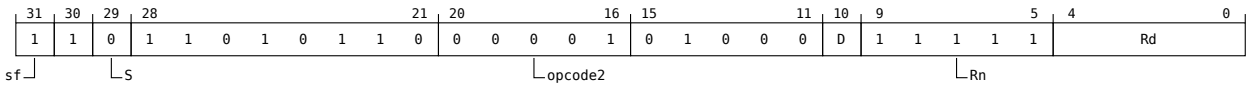
Strip Pointer Authentication Code

This instruction removes the Pointer Authentication Code from an address. The address is in the specified general-purpose register for `XPACI` and `XPACD`, and is in LR for `XPACLRI`.

The `XPACD` instruction is used for data addresses, and `XPACI` and `XPACLRI` are used for instruction addresses.

It has encodings from 2 classes: Integer and System

Integer
(FEAT_PAuth)



Encoding for the XPACD variant Applies when `(D == 1)`

```
XPACD <Xd>
```

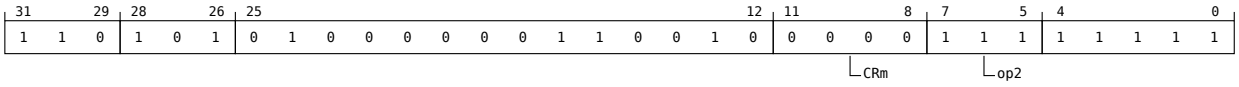
Encoding for the XPACI variant Applies when `(D == 0)`

```
XPACI <Xd>
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_PAuth) then EndOfDecode(Decode_UNDEF);
constant integer d = UInt(Rd);
constant boolean data = (D == '1');
```

System
(FEAT_PAuth)



Encoding

```
XPACLRI
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_PAuth) then EndOfDecode(Decode_NOP);
constant integer d = 30;
constant boolean data = FALSE;
```

Assembler Symbols

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

Operation

```
X[d, 64] = Strip(X[d, 64], data);
```

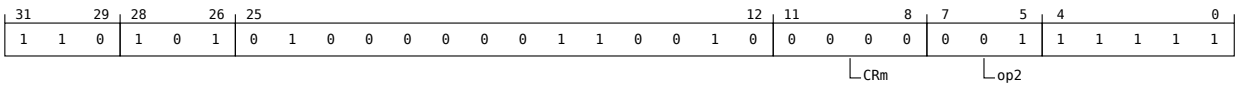
C6.2.320 YIELD

Yield

This instruction is a hint instruction. Software with a multithreading capability can use a `YIELD` instruction to indicate to the PE that it is performing a task, for example a spin-lock, that could be swapped out to improve overall system performance. The PE can use this hint to suspend and resume multiple software threads if it supports the capability.

For more information about the recommended use of this instruction, see The YIELD instruction.



Encoding

`YIELD`

Decode for this encoding

```
// Empty.
```

Operation

```
Hint_Yield();
```

Chapter C7
A64 Advanced SIMD and Floating-point Instruction Descriptions

This chapter describes the A64 Advanced SIMD and floating-point instructions.

It contains the following sections:

- About the A64 Advanced SIMD and floating-point instructions.
- Alphabetical list of A64 Advanced SIMD and floating-point instructions.

C7.1 About the A64 Advanced SIMD and floating-point instructions

Alphabetical list of A64 Advanced SIMD and floating-point instructions gives full descriptions of the A64 instructions that are in the following instruction groups:

- Loads and store instructions associated with the SIMD and floating-point registers.
- Data processing instructions with SIMD and floating-point registers.

A64 instruction set encoding in the A64 Instruction Encodings chapter provides an overview of the instruction encodings as part of an instruction class within a functional group.

The rest of this section is a general description of the SIMD and floating-point instructions. It contains the following subsections:

- Register size.
- Output element control.
- Data types.
- Condition flags and related instructions.

C7.1.1 Register size

A64 provides a comprehensive set of packed Single Instruction Multiple Data (SIMD) and scalar operations using data held in the 32 entry 128-bit wide SIMD and floating-point register file.

Each SIMD and floating-point register can be used to hold:

- A single scalar value of the floating-point or integer type.
- A 64-bit wide vector containing one or more elements.
- A 128-bit wide vector containing two or more elements.

Where the entire 128-bit wide register is not fully utilized, the vector or scalar quantity is held in the least significant bits of the register, with the most significant bits being cleared to zero on a write, see Advanced SIMD vector formats.

The following instructions can insert data into individual elements within a SIMD and floating-pointer register without clearing the remaining bits to zero:

- Insert vector element from another vector element or general-purpose register, `INS`.
- Load structure into a single lane, for example `LD3`.
- All second-part narrowing operations, for example `SHRN2`.

C7.1.2 Output element control

When FEAT_AFP is implemented, the FPCR.NEP bit controls how output elements are determined for the scalar Advanced SIMD instructions for elements other than the lowest element of the vector.

If FPCR.NEP == 1, the following instructions determine output elements as follows:

- The 3-input floating-point scalar versions of FMLA (by element) and FMLS (by element) take output elements other than the lowest element from the <Hd>, <Sd>, or <Dd> register.
- The 3-input floating-point FMADD, FMSUB, FNMADD, and FNMSUB instructions take output elements other than the lowest element from the <Ha>, <Sa>, or <Da> register.
- The 2-input floating-point scalar versions of FCMGE (register), FCMGT (register), FCMEQ (register), FACGE, FACGT, take output elements other than the lowest element from the <Hm>, <Sm>, or <Dm> register.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- The 2-input floating-point scalar versions of FMULX, FRECPS, FRSQRTS, FABD, FMUL (by element), FMUL (scalar), FDIV (scalar), FADD (scalar), FSUB (scalar), FMAX (scalar), FMIN (scalar), FMAXNM (scalar), FMINNM (scalar), FNMUL (scalar), take output elements other than the lowest element from the <Hn>, <Sn>, or <Dn> register.
- For 1-input floating-point scalar versions of the instructions FCVTNS (vector), FCVTMS (vector), FCVTAS (vector), FCVTPS (vector), SCVTF (vector, integer), UCVTF (vector, integer) FCVTZS (vector, integer), FCVTZU (vector, integer), FCVTNU (vector), FCVTMU (vector), FCVTAU (vector), FCVTPU (vector), SCVTF (vector, fixed-point), UCVTF (vector, fixed-point), FCVTZS (vector, fixed-point), FCVTZU (vector, fixed-point), SCVTF (scalar, integer), UCVTF (scalar, integer), SCVTF (scalar, fixed-point), UCVTF (scalar, fixed-point), FCVT, FCVTXN, FRECPE, FRECPX, FRSQRTE, FABS (scalar), FNEG (scalar), FSQRT (scalar), FRINTN (scalar), FRINTP (scalar), FRINTM (scalar), FRINTZ (scalar), FRINTA (scalar), FRINTI (scalar), FRINTX (scalar), take output elements other than the lowest element from the <Hd>, <Sd>, or <Dd> register.

C7.1.3 Data types

The A64 instruction set provides support for arithmetic, conversion, and bitwise operations on:

- Half-precision, single-precision, and double-precision floating-points.
- Signed and unsigned integers.
- Polynomials over {0, 1}.
- When FEAT_FCMA is implemented, complex numbers.

For all AArch64 floating-point operations, including SIMD operations, the rounding mode and exception trap handling are controlled by the FPCR.

Note

In AArch64 state, floating-point multiply-add operations are always performed as fused operations.

In addition to operations that consume and produce values of the same width and type, the A64 instruction set supports SIMD and scalar operations that produce a wider or narrower vector result:

- Where a SIMD operation narrows a 128-bit vector to a 64-bit vector, the A64 instruction set provides a second-part operation, for example SHRN2, that can pack the result of a second operation into the upper part of the same destination register.
- Where a SIMD operation widens a 64-bit vector to a 128-bit vector, the A64 instruction set provides a second-part operation, for example SMLAL2, that can extract the source from the upper 64 bits of the source registers.

All SIMD operations that could produce side-effects that are not limited to the destination SIMD and floating-point register, for example a potential update of FPSR.Q or FPSR.IDC, have a dedicated scalar variant to support the use of SIMD with loops requiring specialized head or tail handling, or both.

C7.1.4 Condition flags and related instructions

The A64 instruction set provides support for flag setting and conditional operations on the SIMD and floating-point register file:

- Floating-point FCSEL and FCCMP instructions are equivalent to the integer CSEL and CCMP instructions.
- Floating-point FCMP, FCMPE, FCCMP, and FCCMP instructions set the PSTATE.{N, Z, C, V} flags based on the result of the floating-point comparison.
- Floating-point FJCVTZS instruction sets the PSTATE.Z flag if the result of the conversion, when converted back to a double-precision floating-point number, gives precisely the same value as the original. Other PSTATE flags are cleared by this instruction.
- Floating-point and integer instructions provide a means of producing either a scalar or a vector mask based on a comparison in a SIMD and floating-point register, for example FCMEQ.

C7.2.1 ABS

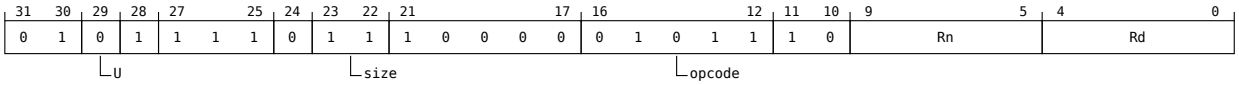
Absolute value (vector)

This instruction calculates the absolute value of each vector element in the source SIMD&FP register, puts the result into a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Scalar and Vector

Scalar
(FEAT_AdvSIMD)



Encoding

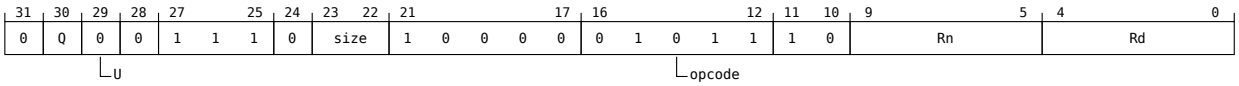
```
ABS D<d>, D<n>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_AdvSIMD) then EndOfDecode(Decode_UNDEF);
constant integer d = UInt(Rd);
constant integer n = UInt(Rn);

constant integer esize = 8 << UInt(size);
constant integer datasize = esize;
constant integer elements = 1;
```

Vector
(FEAT_AdvSIMD)



Encoding

```
ABS <Vd>.<T>, <Vn>.<T>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_AdvSIMD) then EndOfDecode(Decode_UNDEF);
if size:Q == '110' then EndOfDecode(Decode_UNDEF);
constant integer d = UInt(Rd);
constant integer n = UInt(Rn);

constant integer esize = 8 << UInt(size);
constant integer datasize = 64 << UInt(Q);
constant integer elements = datasize DIV esize;
```

Assembler Symbols

<d> Is the number of the SIMD&FP destination register, encoded in the “Rd” field.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

<**n**> Is the number of the SIMD&FP source register, encoded in the “Rn” field.

<**Vd**> Is the name of the SIMD&FP destination register, encoded in the “Rd” field.

<**T**> Is an arrangement specifier, encoded in “size:Q”:

size	Q	<T>
00	0	8B
00	1	16B
01	0	4H
01	1	8H
10	0	2S
10	1	4S
11	0	RESERVED
11	1	2D

<**Vn**> Is the name of the SIMD&FP source register, encoded in the “Rn” field.

Operation

```
AArch64.CheckFPAdvSIMDEnabled();
constant bits(datasize) operand = V[n, datasize];
bits(datasize) result;
integer element;

for e = 0 to elements-1
    element = SInt(Elem[operand, e, esize]);
    element = Abs(element);
    Elem[result, e, esize] = element<esize-1:0>;

V[d, datasize] = result;
```

Operational information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C7.2.2 ADD (vector)

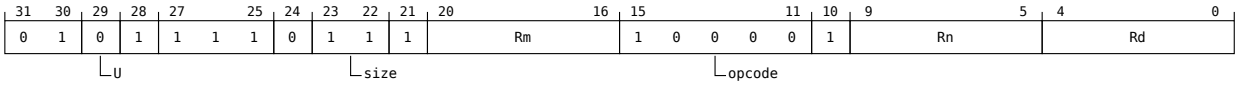
Add (vector)

This instruction adds corresponding elements in the two source SIMD&FP registers, places the results into a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Scalar and Vector

Scalar
(FEAT_AdvSIMD)



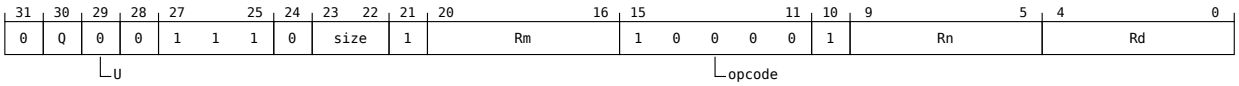
Encoding

```
ADD D<d>, D<n>, D<m>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_AdvSIMD) then EndOfDecode(Decode_UNDEF);
constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer m = UInt(Rm);
constant integer esize = 8 << UInt(size);
constant integer datasize = esize;
constant integer elements = 1;
```

Vector
(FEAT_AdvSIMD)



Encoding

```
ADD <Vd>.<T>, <Vn>.<T>, <Vm>.<T>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_AdvSIMD) then EndOfDecode(Decode_UNDEF);
if size:Q == '110' then EndOfDecode(Decode_UNDEF);
constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer m = UInt(Rm);
constant integer esize = 8 << UInt(size);
constant integer datasize = 64 << UInt(Q);
constant integer elements = datasize DIV esize;
```

Assembler Symbols

<**d**> Is the number of the SIMD&FP destination register, encoded in the “Rd” field.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

<**n**> Is the number of the first SIMD&FP source register, encoded in the “Rn” field.

<**m**> Is the number of the second SIMD&FP source register, encoded in the “Rm” field.

<**Vd**> Is the name of the SIMD&FP destination register, encoded in the “Rd” field.

<**T**> Is an arrangement specifier, encoded in “size:Q”:

size	Q	<T>
00	0	8B
00	1	16B
01	0	4H
01	1	8H
10	0	2S
10	1	4S
11	0	RESERVED
11	1	2D

<**Vn**> Is the name of the first SIMD&FP source register, encoded in the “Rn” field.

<**Vm**> Is the name of the second SIMD&FP source register, encoded in the “Rm” field.

Operation

```
AArch64.CheckFPAdvSIMDEnabled();
constant bits(datasize) operand1 = V[n, datasize];
constant bits(datasize) operand2 = V[m, datasize];
bits(datasize) result;
bits(esize) element1;
bits(esize) element2;

for e = 0 to elements-1
    element1 = Elem[operand1, e, esize];
    element2 = Elem[operand2, e, esize];
    Elem[result, e, esize] = element1 + element2;
V[d, datasize] = result;
```

Operational information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C7.2.3 ADDHN, ADDHN2

Add returning high narrow

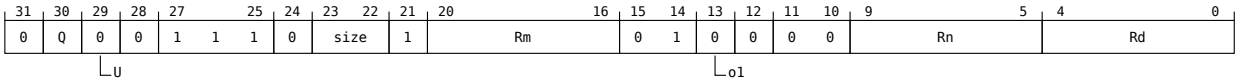
This instruction adds each vector element in the first source SIMD&FP register to the corresponding vector element in the second source SIMD&FP register, places the most significant half of the result into a vector, and writes the vector to the lower or upper half of the destination SIMD&FP register.

The results are truncated. For rounded results, see RADDHN.

The ADDHN instruction writes the vector to the lower half of the destination register and clears the upper half. The ADDHN2 instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Three registers, not all the same type
(FEAT_AdvSIMD)



Encoding

```
ADDHN{2} <Vd>.<Tb>, <Vn>.<Ta>, <Vm>.<Ta>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_AdvSIMD) then EndOfDecode(Decode_UNDEF);
if size == '11' then EndOfDecode(Decode_UNDEF);
constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer m = UInt(Rm);

constant integer esize = 8 << UInt(size);
constant integer datasize = 64;
constant integer part = UInt(Q);
constant integer elements = datasize DIV esize;
constant boolean round = FALSE;
```

Assembler Symbols

2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in “Q”:

Q	2
0	[absent]
1	[present]

<**Vd**> Is the name of the SIMD&FP destination register, encoded in the “Rd” field.

<**Tb**> Is an arrangement specifier, encoded in “size:Q”:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

size	Q	<Tb>
00	0	8B
00	1	16B
01	0	4H
01	1	8H
10	0	2S
10	1	4S
11	x	RESERVED

<**Vn**> Is the name of the first SIMD&FP source register, encoded in the “Rn” field.

<**Ta**> Is an arrangement specifier, encoded in “size”:

size	<Ta>
00	8H
01	4S
10	2D
11	RESERVED

<**Vm**> Is the name of the second SIMD&FP source register, encoded in the “Rm” field.

Operation

```
AArch64.CheckFPAdvSIMDEnabled();
constant bits(2*datasize) operand1 = V[n, 2*datasize];
constant bits(2*datasize) operand2 = V[m, 2*datasize];
bits(datasize) result;
integer element1;
integer element2;
integer sum;

for e = 0 to elements-1
    element1 = UInt(Elem[operand1, e, 2*esize]);
    element2 = UInt(Elem[operand2, e, 2*esize]);
    sum = element1 + element2;
    sum = RShr(sum, esize, round);
    Elem[result, e, esize] = sum<esize-1:0>;

Vpart[d, part, datasize] = result;
```

Operational information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

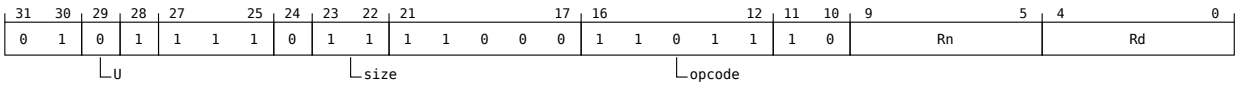
C7.2.4 ADDP (scalar)

Add pair of elements (scalar)

This instruction adds two vector elements in the source SIMD&FP register and writes the scalar result into the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Advanced SIMD
(FEAT_AdvSIMD)



Encoding

```
ADDP D<d>, <Vn>.2D
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_AdvSIMD) then EndOfDecode(Decode_UNDEF);
constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer esize = 64;
constant integer datasize = 128;
```

Assembler Symbols

<d> Is the number of the SIMD&FP destination register, encoded in the “Rd” field.

<Vn> Is the name of the SIMD&FP source register, encoded in the “Rn” field.

Operation

```
AArch64.CheckFPAdvSIMDEnabled();
constant bits(datasize) operand = V[n, datasize];
V[d, esize] = IntReduce(ReduceOp_ADD, operand, esize);
```

Operational information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

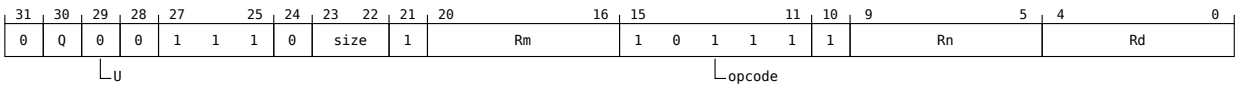
C7.2.5 ADDP (vector)

Add pairwise (vector)

This instruction creates a vector by concatenating the vector elements of the first source SIMD&FP register after the vector elements of the second source SIMD&FP register, reads each pair of adjacent vector elements from the concatenated vector, adds each pair of values together, places the result into a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Three registers of the same type
(FEAT_AdvSIMD)



Encoding

```
ADDP <Vd>.<T>, <Vn>.<T>, <Vm>.<T>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_AdvSIMD) then EndOfDecode(Decode_UNDEF);
if size:Q == '110' then EndOfDecode(Decode_UNDEF);
constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer m = UInt(Rm);

constant integer esize = 8 << UInt(size);
constant integer datasize = 64 << UInt(Q);
constant integer elements = datasize DIV esize;
```

Assembler Symbols

<**Vd**> Is the name of the SIMD&FP destination register, encoded in the “Rd” field.

<**T**> Is an arrangement specifier, encoded in “size:Q”:

size	Q	<T>
00	0	8B
00	1	16B
01	0	4H
01	1	8H
10	0	2S
10	1	4S
11	0	RESERVED
11	1	2D

<**Vn**> Is the name of the first SIMD&FP source register, encoded in the “Rn” field.

<**Vm**> Is the name of the second SIMD&FP source register, encoded in the “Rm” field.

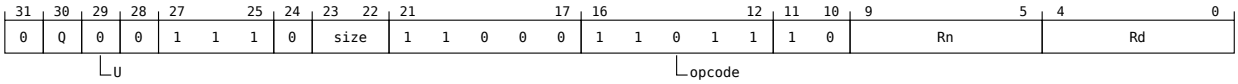
C7.2.6 ADDV

Add across vector

This instruction adds every vector element in the source SIMD&FP register together, and writes the scalar result to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Advanced SIMD
(FEAT_AdvSIMD)



Encoding

```
ADDV <V><d>, <Vn>.<T>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_AdvSIMD) then EndOfDecode(Decode_UNDEF);
if size:Q == '100' then EndOfDecode(Decode_UNDEF);
if size == '11' then EndOfDecode(Decode_UNDEF);

constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer esize = 8 << UInt(size);
constant integer datasize = 64 << UInt(Q);
```

Assembler Symbols

<**V**> Is the destination width specifier, encoded in "size":

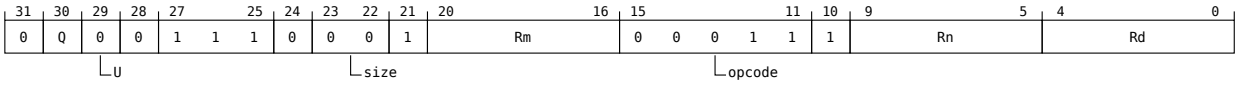
C7.2.11 AND (vector)

Bitwise AND (vector)

This instruction performs a bitwise AND between the two source SIMD&FP registers, and writes the result to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Three registers of the same type
(FEAT_AdvSIMD)



Encoding

```
AND <Vd>.<T>, <Vn>.<T>, <Vm>.<T>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_AdvSIMD) then EndOfDecode(Decode_UNDEF);
constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer m = UInt(Rm);
constant integer datasize = 64 << UInt(Q);
```

Assembler Symbols

<**Vd**> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<**T**> Is an arrangement specifier, encoded in "Q":

Q	<T>
0	8B
1	16B

<**Vn**> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

<**Vm**> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

Operation

```
AArch64.CheckFPAdvSIMDEnabled();
constant bits(datasize) operand1 = V[n, datasize];
constant bits(datasize) operand2 = V[m, datasize];
V[d, datasize] = operand1 AND operand2;

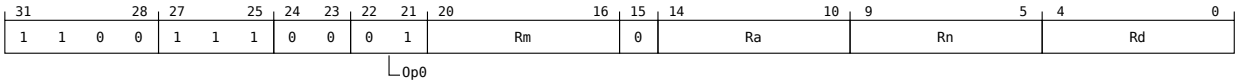
C7.2.12 BCAX

Bit clear and exclusive-OR

This instruction performs a bitwise AND of the 128-bit vector in a source SIMD&FP register and the complement of the vector in another source SIMD&FP register, then performs a bitwise exclusive-OR of the resulting vector and the vector in a third source SIMD&FP register, and writes the result to the destination SIMD&FP register.

Advanced SIMD
(FEAT_SHA3)



Encoding

```
BCAX <Vd>.16B, <Vn>.16B, <Vm>.16B, <Va>.16B
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_SHA3) then EndOfDecode(Decode_UNDEF);
constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer m = UInt(Rm);
constant integer a = UInt(Ra);
```

Assembler Symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the “Rd” field.

<Vn> Is the name of the first SIMD&FP source register, encoded in the “Rn” field.

<Vm> Is the name of the second SIMD&FP source register, encoded in the “Rm” field.

<Va> Is the name of the third SIMD&FP source register, encoded in the “Ra” field.

Operation

```
AArch64.CheckFPAdvSIMDEnabled();

constant bits(128) operand1 = V[m, 128];
constant bits(128) operand2 = V[n, 128];
constant bits(128) operand3 = V[a, 128];

V[d, 128] = operand2 EOR (operand1 AND NOT(operand3));
```

Operational information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

Non-Confidential

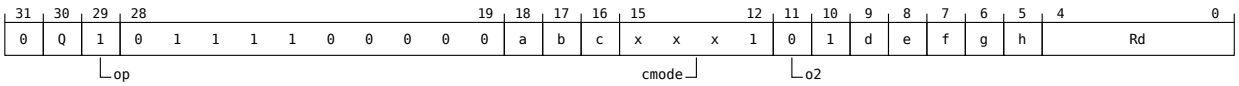
C7.2.13 BIC (vector, immediate)

Bitwise bit clear (vector, immediate)

This instruction reads each vector element from the destination SIMD&FP register, performs a bitwise AND between each result and the complement of an immediate constant, places the result into a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Shifted immediate
(FEAT_AdvSIMD)



Encoding for the 16-bit variant Applies when `(cmode == 10x1)`

```
BIC <Vd>.<T>, #<imm8>{, LSL #<amount>}
```

Encoding for the 32-bit variant Applies when `(cmode == 0xx1)`

```
BIC <Vd>.<T>, #<imm8>{, LSL #<amount>}
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_AdvSIMD) then EndOfDecode(Decode_UNDEF);
constant integer rd = UInt(Rd);
constant integer datasize = 64 << UInt(Q);
constant bits(64) imm64 = AdvSIMDExpandImm(op, cmode, a:b:c:d:e:f:g:h);
constant bits(datasize) imm = Replicate(imm64, datasize DIV 64);
```

Assembler Symbols

<**Vd**> Is the name of the SIMD&FP register, encoded in the "Rd" field.

<**T**> For the "16-bit" variant: is an arrangement specifier, encoded in "Q":

Q	<T>
0	4H
1	8H

For the "32-bit" variant: is an arrangement specifier, encoded in "Q":

Q	<T>
0	2S
1	4S

<**imm8**> Is an 8-bit immediate encoded in "a:b:c:d:e:f:g:h".

Non-Confidential

<**amount**> For the “16-bit” variant: is the shift amount encoded in “cmode<1>”:

cmode<1>	<**amount**>
0	0
1	8

defaulting to 0 if LSL is omitted.

For the “32-bit” variant: is the shift amount encoded in “cmode<2:1>”:

cmode<2:1>	<**amount**>
00	0
01	8
10	16
11	24

defaulting to 0 if LSL is omitted.

Operation

```
AArch64.CheckFPAdvSIMDEnabled();
constant bits(datasize) operand = V[rd, datasize];
V[rd, datasize] = operand AND NOT(imm);
```

Operational information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

C7.2.24 CMGT (register)

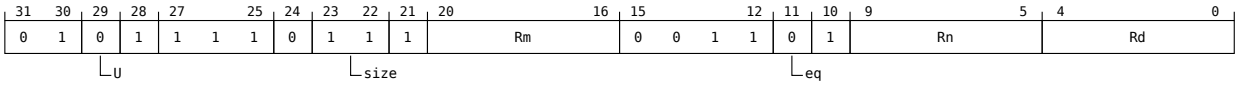
Compare signed greater than (vector)

This instruction compares each vector element in the first source SIMD&FP register with the corresponding vector element in the second source SIMD&FP register and if the first signed integer value is greater than the second signed integer value sets every bit of the corresponding vector element in the destination SIMD&FP register to one, otherwise sets every bit of the corresponding vector element in the destination SIMD&FP register to zero.

Depending on the settings in the CPACR_EL1 and CPTR_EL2 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Scalar and Vector

Scalar
(FEAT_AdvSIMD)



Encoding

```
CMGT D<d>, D<n>, D<m>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_AdvSIMD) then EndOfDecode(Decode_UNDEF);
if size != '11' then EndOfDecode(Decode_UNDEF);
constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer m = UInt(Rm);
constant integer esize = 8 << UInt(size);
constant integer datasize = esize;
constant integer elements = 1;
```

Vector

Assembler Symbols

<**V**> Is the destination width specifier, encoded in "imm5":

imm5	<V>
x0000	RESERVED
xxxx1	B
xxx10	H
xx100	S
x1000	D

<**d**> Is the number of the SIMD&FP destination register, encoded in the "Rd" field.

<**Vn**> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<**T**> For the "Scalar" variant: is the element width specifier, encoded in "imm5":

imm5	<T>
x0000	RESERVED
xxxx1	B
xxx10	H
xx100	S
x1000	D

For the "Vector" variant: is an arrangement specifier, encoded in "imm5:Q":

imm5	Q	<T>
x0000	x	RESERVED
xxxx1	0	8B
xxxx1	1	16B
xxx10	0	4H
xxx10	1	8H
xx100	0	2S
xx100	1	4S
x1000	0	RESERVED
x1000	1	2D

<**index**> Is the element index encoded in "imm5":

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

imm5	<index>
x0000	RESERVED
xxxx1	UInt(imm5<4:1>)
xxx10	UInt(imm5<4:2>)
xx100	UInt(imm5<4:3>)
x1000	UInt(imm5<4>)

<**Vd**> Is the name of the SIMD&FP destination register, encoded in the “Rd” field.

<**Ts**> Is an element size specifier, encoded in “imm5”:

imm5	<Ts>
x0000	RESERVED
xxxx1	B
xxx10	H
xx100	S
x1000	D

Operation

```
AArch64.CheckFPAdvSIMDEnabled();
constant bits(idxdsize) operand = V[n, idxdsize];
bits(datasize) result;
bits(esize) element;

element = Elem[operand, index, esize];
for e = 0 to elements-1
    Elem[result, e, esize] = element;
V[d, datasize] = result;
```

Operational information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.
