0x8168	STALL_BACKEND_ST	Backend stall cycles, store.
0x816A	STALL_BACKEND_CPUBOUND	Backend stall cycles, processor bound.
0x816B	STALL_BACKEND_BUSY	Backend stall cycles, backend busy.
0x816C	STALL_BACKEND_ILOCK	Backend stall cycles, input dependency.
0x816D	STALL_BACKEND_RENAME	Backend stall cycles, rename full.
0x816E	STALL_BACKEND_ATOMIC	Backend stall cycles, atomic operation.
0x8170	CAS_NEAR_FAIL	Atomic memory Operation speculatively executed, Compare and Swap fail.
0x8171	CAS_NEAR_PASS	Atomic memory Operation speculatively executed, Compare and Swap pass.
0x8172	CAS_NEAR_SPEC	Atomic memory Operation speculatively executed, Compare and Swap near.
0x8173	CAS_FAR_SPEC	Atomic memory Operation speculatively executed, Compare and Swap far.
0x8174	CAS_SPEC	Atomic memory Operation speculatively executed, Compare and Swap.
0x8175	LSE_LD_SPEC	Atomic memory Operation speculatively executed, load.
0x8176	LSE_ST_SPEC	Atomic memory Operation speculatively executed, store.
0x8177	LSE_LDST_SPEC	Atomic memory Operation speculatively executed, load or store.
0x8178	REMOTE_ACCESS_WR	Access to a remote device, write.
0x8179	BRNL_INDNR_TAKEN_RETIRED	Branch instruction architecturally executed, indirect branch without link excluding procedure return, taken.
0x817A	BL_TAKEN_RETIRED	Branch instruction architecturally executed, branch with link, taken.
0x817B	BRNL_TAKEN_RETIRED	Branch instruction architecturally executed, branch without link, taken.
0x817C	BL_IND_TAKEN_RETIRED	Branch instruction architecturally executed, indirect branch with link, taken.
0x817D	BRNL_IND_TAKEN_RETIRED	Branch instruction architecturally executed, indirect branch without link, taken.

Number	Mnemonic	Description
0x817E	BL_IMMED_TAKEN_RETIRED	Branch instruction architecturally executed, direct branch with link, taken.
0x817F	BRNL_IMMED_TAKEN_RETIRED	Branch instruction architecturally executed, direct branch without link, taken.
0x8180	BR_UNCOND_RETIRED	Branch instruction architecturally executed, unconditional branch.
0x8181	BR_COND_RETIRED	Branch instruction architecturally executed, conditional branch.
0x8182	BR_COND_TAKEN_RETIRED	Branch instruction architecturally executed, conditional branch, taken.
0x8186	UOP_RETIRED	Micro-operation architecturally executed.
0x8188	DTLB_WALK_BLOCK	Data TLB block translation table walk.
0x8189	ITLB_WALK_BLOCK	Instruction TLB block translation table walk.
0x818A	DTLB_WALK_PAGE	Data TLB page translation table walk.
0x818B	ITLB_WALK_PAGE	Instruction TLB page translation table walk.
0x818D	BUS_REQ_RD	Bus request, read.
0x818E	BUS_REQ_WR	Bus request, write.
0x818F	BUS_REQ	Bus request.
0x8190	ISNP_HIT_RD	Snoop hit, demand instruction fetch.
0x8191	ISNP_HIT_NEAR_RD	Snoop hit in near local cache, demand instruction fetch.
0x8192	ISNP_HIT_FAR_RD	Snoop hit in far local cache, demand instruction fetch.
0x8193	ISNP_HIT_REMOTE_RD	Snoop hit in remote cache, demand instruction fetch.
0x8194	DSNP_HIT_RD	Snoop hit, demand data read.
0x8195	DSNP_HIT_NEAR_RD	Snoop hit in near local cache, demand data read.
0x8196	DSNP_HIT_FAR_RD	Snoop hit in far local cache, demand data read.
0x8197	DSNP_HIT_REMOTE_RD	Snoop hit in remote cache, demand data read.
0x8198	DSNP_HIT_WR	Snoop hit, demand data write.
0x8199	DSNP_HIT_NEAR_WR	Snoop hit in near local cache, demand data write.
0x819A	DSNP_HIT_FAR_WR	Snoop hit in far local cache, demand data write.
0x819B	DSNP_HIT_REMOTE_WR	Snoop hit in remote cache, demand data write.
0x819C	DSNP_HIT_RW	Snoop hit, demand data access.

Number	Mnemonic	Description
0x819D	DSNP_HIT_NEAR_RW	Snoop hit in near local cache, demand data access.
0x819E	DSNP_HIT_FAR_RW	Snoop hit in far local cache, demand data access.
0x819F	DSNP_HIT_REMOTE_RW	Snoop hit in remote cache, demand data access.
0x81A0	DSNP_HIT_PRFM	Snoop hit, software data prefetch.
0x81A1	DSNP_HIT_NEAR_PRFM	Snoop hit in near local cache, software data prefetch.
0x81A2	DSNP_HIT_FAR_PRFM	Snoop hit in far local cache, software data prefetch.
0x81A3	DSNP_HIT_REMOTE_PRFM	Snoop hit in remote cache, software data prefetch.
0x81A4	DSNP_HIT_HWPRF	Snoop hit, hardware data prefetch.
0x81A5	DSNP_HIT_NEAR_HWPRF	Snoop hit in near local cache, hardware data prefetch.
0x81A6	DSNP_HIT_FAR_HWPRF	Snoop hit in far local cache, hardware data prefetch.
0x81A7	DSNP_HIT_REMOTE_HWPRF	Snoop hit in remote cache, hardware data prefetch.
0x81A8	ISNP_HIT_PRFM	Snoop hit, software instruction prefetch.
0x81A9	ISNP_HIT_NEAR_PRFM	Snoop hit in near local cache, software instruction prefetch.
0x81AA	ISNP_HIT_FAR_PRFM	Snoop hit in far local cache, software instruction prefetch.
0x81AB	ISNP_HIT_REMOTE_PRFM	Snoop hit in remote cache, software instruction prefetch.
0x81AC	ISNP_HIT_HWPRF	Snoop hit, hardware instruction prefetch.
0x81AD	ISNP_HIT_NEAR_HWPRF	Snoop hit in near local cache, hardware instruction prefetch.
0x81AE	ISNP_HIT_FAR_HWPRF	Snoop hit in far local cache, hardware instruction prefetch.
0x81AF	ISNP_HIT_REMOTE_HWPRF	Snoop hit in remote cache, hardware instruction prefetch.
0x81B0	ISNP_HIT	Snoop hit, instruction.
0x81B1	ISNP_HIT_NEAR	Snoop hit in near local cache, instruction access.
0x81B2	ISNP_HIT_FAR	Snoop hit in far local cache, instruction access.
0x81B3	ISNP_HIT_REMOTE	Snoop hit in remote cache, instruction access.
0x81B4	DSNP_HIT	Snoop hit, data.
0x81B5	DSNP_HIT_NEAR	Snoop hit in near local cache, data access.
0x81B6	DSNP_HIT_FAR	Snoop hit in far local cache, data access.

Number	Mnemonic	Description
0x81B7	DSNP_HIT_REMOTE	Snoop hit in remote cache, data access.
0x81B8	L1I_CACHE_REFILL_HWPRF	Level 1 instruction cache refill, hardware prefetch.
0x81B9	L2I_CACHE_REFILL_HWPRF	Level 2 instruction cache refill, hardware prefetch.
0x81BC	L1D_CACHE_REFILL_HWPRF	Level 1 data cache refill, hardware prefetch.
0x81BD	L2D_CACHE_REFILL_HWPRF	Level 2 data cache refill, hardware prefetch.
0x81BE	L3D_CACHE_REFILL_HWPRF	Level 3 data cache refill, hardware prefetch.
0x81BF	LL_CACHE_REFILL_HWPRF	Last level cache refill, hardware prefetch.
0x81C0	L1I_CACHE_HIT_RD	Level 1 instruction cache demand fetch hit.
0x81C1	L2I_CACHE_HIT_RD	Level 2 instruction cache demand fetch hit.
0x81C4	L1D_CACHE_HIT_RD	Level 1 data cache demand access hit, read.
0x81C5	L2D_CACHE_HIT_RD	Level 2 data cache demand access hit, read.
0x81C6	L3D_CACHE_HIT_RD	Level 3 data cache demand access hit, read.
0x81C7	LL_CACHE_HIT_RD	Last level cache demand access hit, read.
0x81C8	L1D_CACHE_HIT_WR	Level 1 data cache demand access hit, write.
0x81C9	L2D_CACHE_HIT_WR	Level 2 data cache demand access hit, write.
0x81CA	L3D_CACHE_HIT_WR	Level 3 data cache demand access hit, write.
0x81CB	LL_CACHE_HIT_WR	Last level cache demand access hit, write.
0x81CC	L1D_CACHE_HIT_RW	Level 1 data cache demand access hit.
0x81CD	L2D_CACHE_HIT_RW	Level 2 data cache demand access hit.
0x81CE	L3D_CACHE_HIT_RW	Level 3 data cache demand access hit.
0x81CF	LL_CACHE_HIT_RW	Last level cache demand access hit.
0x81D0	L1I_CACHE_HIT_RD_FPRFM	Level 1 instruction cache demand fetch first hit, fetched by software prefetch.
0x81D1	L2I_CACHE_HIT_RD_FPRFM	Level 2 instruction cache demand fetch first hit, fetched by software prefetch.
0x81D4	L1D_CACHE_HIT_RD_FPRFM	Level 1 data cache demand access first hit, read, fetched by software prefetch.

Number	Mnemonic	Description
0x81D5	L2D_CACHE_HIT_RD_FPRFM	Level 2 data cache demand access first hit, read, fetched by software prefetch.
0x81D6	L3D_CACHE_HIT_RD_FPRFM	Level 3 data cache demand access first hit, read, fetched by software prefetch.
0x81D7	LL_CACHE_HIT_RD_FPRFM	Last level cache demand access first hit, read, fetched by software prefetch.
0x81D8	L1D_CACHE_HIT_WR_FPRFM	Level 1 data cache demand access first hit, write, fetched by software prefetch.
0x81D9	L2D_CACHE_HIT_WR_FPRFM	Level 2 data cache demand access first hit, write, fetched by software prefetch.
0x81DA	L3D_CACHE_HIT_WR_FPRFM	Level 3 data cache demand access first hit, write, fetched by software prefetch.
0x81DB	LL_CACHE_HIT_WR_FPRFM	Last level cache demand access first hit, write, fetched by software prefetch.
0x81DC	L1D_CACHE_HIT_RW_FPRFM	Level 1 data cache demand access first hit, fetched by software prefetch.
0x81DD	L2D_CACHE_HIT_RW_FPRFM	Level 2 data cache demand access first hit, fetched by software prefetch.
0x81DE	L3D_CACHE_HIT_RW_FPRFM	Level 3 data cache demand access first hit, fetched by software prefetch.
0x81DF	LL_CACHE_HIT_RW_FPRFM	Last level cache demand access first hit, fetched by software prefetch.
0x81E0	L1I_CACHE_HIT_RD_FHWPRF	Level 1 instruction cache demand fetch first hit, fetched by hardware prefetcher.
0x81E1	L2I_CACHE_HIT_RD_FHWPRF	Level 2 instruction cache demand fetch first hit, fetched by hardware prefetcher.
0x81E4	L1D_CACHE_HIT_RD_FHWPRF	Level 1 data cache demand access first hit, read, fetched by hardware prefetcher.
0x81E5	L2D_CACHE_HIT_RD_FHWPRF	Level 2 data cache demand access first hit, read, fetched by hardware prefetcher.
0x81E6	L3D_CACHE_HIT_RD_FHWPRF	Level 3 data cache demand access first hit, read, fetched by hardware prefetcher.
0x81E7	LL_CACHE_HIT_RD_FHWPRF	Last level cache demand access first hit, read, fetched by hardware prefetcher.
0x81E8	L1D_CACHE_HIT_WR_FHWPRF	Level 1 data cache demand access first hit, write, fetched by hardware prefetcher.

Number	Mnemonic	Description
0x8201	L2I_CACHE_HIT	Level 2 instruction cache hit.
0x8204	L1D_CACHE_HIT	Level 1 data cache hit.
0x8205	L2D_CACHE_HIT	Level 2 data cache hit.
0x8206	L3D_CACHE_HIT	Level 3 data cache hit.
0x8207	LL_CACHE_HIT	Last level cache hit.
0x8208	L1I_CACHE_HIT_PRFM	Level 1 instruction cache software prefetch hit.
0x8209	L2I_CACHE_HIT_PRFM	Level 2 instruction cache software prefetch hit.
0x820C	L1D_CACHE_HIT_PRFM	Level 1 data cache software prefetch hit.
0x820D	L2D_CACHE_HIT_PRFM	Level 2 data cache software prefetch hit.
0x820E	L3D_CACHE_HIT_PRFM	Level 3 data cache software prefetch hit.
0x820F	LL_CACHE_HIT_PRFM	Last level cache software prefetch hit.
0x8214	L1D_CACHE_HITM_RD	Level 1 data cache demand access hit modified, read.
0x8215	L2D_CACHE_HITM_RD	Level 2 data cache demand access hit modified, read.
0x8216	L3D_CACHE_HITM_RD	Level 3 data cache demand access hit modified, read.
0x8217	LL_CACHE_HITM_RD	Last level cache demand access hit modified, read.
0x8218	L1D_CACHE_HITM_WR	Level 1 data cache demand access hit modified, write.
0x8219	L2D_CACHE_HITM_WR	Level 2 data cache demand access hit modified, write.
0x821A	L3D_CACHE_HITM_WR	Level 3 data cache demand access hit modified, write.
0x821B	LL_CACHE_HITM_WR	Last level cache demand access hit modified, write.
0x821C	L1D_CACHE_HITM_RW	Level 1 data cache demand access hit modified.
0x821D	L2D_CACHE_HITM_RW	Level 2 data cache demand access hit modified.
0x821E	L3D_CACHE_HITM_RW	Level 3 data cache demand access hit modified.
0x821F	LL_CACHE_HITM_RW	Last level cache demand access hit modified.
0x8224	DSNP_HITM_RD	Snoop hit, demand data read, modified.
0x8225	DSNP_HITM_NEAR_RD	Snoop hit in near local cache, demand data read, modified.
0x8226	DSNP_HITM_FAR_RD	Snoop hit in far local cache, demand data read, modified.

Number	Mnemonic	Description
0x8227	DSNP_HITM_REMOTE_RD	Snoop hit in remote cache, demand data read, modified.
0x8228	DSNP_HITM_WR	Snoop hit, demand data write, modified.
0x8229	DSNP_HITM_NEAR_WR	Snoop hit in near local cache, demand data write, modified.
0x822A	DSNP_HITM_FAR_WR	Snoop hit in far local cache, demand data write, modified.
0x822B	DSNP_HITM_REMOTE_WR	Snoop hit in remote cache, demand data write, modified.
0x822C	DSNP_HITM_RW	Snoop hit, demand data access, modified.
0x822D	DSNP_HITM_NEAR_RW	Snoop hit in near local cache, demand data access, modified.
0x822E	DSNP_HITM_FAR_RW	Snoop hit in far local cache, demand data access, modified.
0x822F	DSNP_HITM_REMOTE_RW	Snoop hit in remote cache, demand data access, modified.
0x8230	LOCAL_MEM	Access to memory attached to this device.
0x8231	LOCAL_MEM_RD	Access to memory attached to this device, demand access, read.
0x8232	LOCAL_MEM_WR	Access to memory attached to this device, demand access, write.
0x8233	LOCAL_MEM_RW	Access to memory attached to this device, demand access.
0x8234	LOCAL_MEM_PRFM	Access to memory attached to this device, software prefetch.
0x8235	LOCAL_MEM_LD_RETIRED	Load instruction architecturally executed, access to memory attached to this device.
0x8236	LOCAL_MEM_ST_RETIRED	Store instruction architecturally executed, access to memory attached to this device.
0x8237	LOCAL_MEM_LDST_RETIRED	Load or store instruction architecturally executed, access to memory attached to this device.
0x8238	REMOTE_MEM	Access to memory attached to a remote device.
0x8239	REMOTE_MEM_RD	Access to memory attached to a remote device, demand access, read.
0x823A	REMOTE_MEM_WR	Access to memory attached to a remote device, demand access, write.
0x823B	REMOTE_MEM_RW	Access to memory attached to a remote device, demand access.
0x823C	REMOTE_MEM_PRFM	Access to memory attached to a remote device, software prefetch.

Number	Mnemonic	Description
0x823D	REMOTE_MEM_LD_RETIRED	Load instruction architecturally executed, access to memory attached to a remote device.
0x823E	REMOTE_MEM_ST_RETIRED	Store instruction architecturally executed, access to memory attached to a remote device.
0x823F	REMOTE_MEM_LDST_RETIRED	Load or store instruction architecturally executed, access to memory attached to a remote device.
0x8240	L1I_LFB_HIT_RD	Level 1 instruction cache demand fetch line-fill buffer hit.
0x8241	L2I_LFB_HIT_RD	Level 2 instruction cache demand fetch line-fill buffer hit.
0x8244	L1D_LFB_HIT_RD	Level 1 data cache demand access line-fill buffer hit, read.
0x8245	L2D_LFB_HIT_RD	Level 2 data cache demand access line-fill buffer hit, read.
0x8246	L3D_LFB_HIT_RD	Level 3 data cache demand access line-fill buffer hit, read.
0x8247	LL_LFB_HIT_RD	Last level cache demand access line-fill buffer hit, read.
0x8248	L1D_LFB_HIT_WR	Level 1 data cache demand access line-fill buffer hit, write.
0x8249	L2D_LFB_HIT_WR	Level 2 data cache demand access line-fill buffer hit, write.
0x824A	L3D_LFB_HIT_WR	Level 3 data cache demand access line-fill buffer hit, write.
0x824B	LL_LFB_HIT_WR	Last level cache demand access line-fill buffer hit, write.
0x824C	L1D_LFB_HIT_RW	Level 1 data cache demand access line-fill buffer hit.
0x824D	L2D_LFB_HIT_RW	Level 2 data cache demand access line-fill buffer hit.
0x824E	L3D_LFB_HIT_RW	Level 3 data cache demand access line-fill buffer hit.
0x824F	LL_LFB_HIT_RW	Last level cache demand access line-fill buffer hit.
0x8250	L1I_LFB_HIT_RD_FPRFM	Level 1 instruction cache demand fetch line-fill buffer first hit, recently fetched by software prefetch.
0x8251	L2I_LFB_HIT_RD_FPRFM	Level 2 instruction cache demand fetch line-fill buffer first hit, recently fetched by software prefetch.
0x8254	L1D_LFB_HIT_RD_FPRFM	Level 1 data cache demand access line-fill buffer first hit, read, recently fetched by software prefetch.
0x8255	L2D_LFB_HIT_RD_FPRFM	Level 2 data cache demand access line-fill buffer first hit, read, recently fetched by software prefetch.

0x8270	L1I_LFB_HIT_RD_FPRF	Level 1 instruction cache demand fetch line-fill buffer first hit, recently fetched by prefetch.
0x8271	L2I_LFB_HIT_RD_FPRF	Level 2 instruction cache demand fetch line-fill buffer first hit, recently fetched by prefetch.
0x8274	L1D_LFB_HIT_RD_FPRF	Level 1 data cache demand access line-fill buffer first hit, read, recently fetched by prefetch.
0x8275	L2D_LFB_HIT_RD_FPRF	Level 2 data cache demand access line-fill buffer first hit, read, recently fetched by prefetch.
0x8276	L3D_LFB_HIT_RD_FPRF	Level 3 data cache demand access line-fill buffer first hit, read, recently fetched by prefetch.
0x8277	LL_LFB_HIT_RD_FPRF	Last level cache demand access line-fill buffer first hit, read, recently fetched by prefetch.
0x8278	L1D_LFB_HIT_WR_FPRF	Level 1 data cache demand access line-fill buffer first hit, write, recently fetched by prefetch.
0x8279	L2D_LFB_HIT_WR_FPRF	Level 2 data cache demand access line-fill buffer first hit, write, recently fetched by prefetch.
0x827A	L3D_LFB_HIT_WR_FPRF	Level 3 data cache demand access line-fill buffer first hit, write, recently fetched by prefetch.
0x827B	LL_LFB_HIT_WR_FPRF	Last level cache demand access line-fill buffer first hit, write, recently fetched by prefetch.

Number	Mnemonic	Description
0x827C	L1D_LFB_HIT_RW_FPRF	Level 1 data cache demand access line-fill buffer first hit, recently fetched by prefetch.
0x827D	L2D_LFB_HIT_RW_FPRF	Level 2 data cache demand access line-fill buffer first hit, recently fetched by prefetch.
0x827E	L3D_LFB_HIT_RW_FPRF	Level 3 data cache demand access line-fill buffer first hit, recently fetched by prefetch.
0x827F	LL_LFB_HIT_RW_FPRF	Last level cache demand access line-fill buffer first hit, recently fetched by prefetch.
0x8280	L1I_CACHE_PRF	Level 1 instruction cache, prefetch hit.
0x8281	L2I_CACHE_PRF	Level 2 instruction cache, prefetch hit.
0x8284	L1D_CACHE_PRF	Level 1 data cache, prefetch hit.
0x8285	L2D_CACHE_PRF	Level 2 data cache, prefetch hit.
0x8286	L3D_CACHE_PRF	Level 3 data cache, prefetch hit.
0x8287	LL_CACHE_PRF	Last level cache, prefetch hit.
0x8288	L1I_CACHE_REFILL_PRF	Level 1 instruction cache refill, prefetch hit.
0x8289	L2I_CACHE_REFILL_PRF	Level 2 instruction cache refill, prefetch hit.
0x828C	L1D_CACHE_REFILL_PRF	Level 1 data cache refill, prefetch hit.
0x828D	L2D_CACHE_REFILL_PRF	Level 2 data cache refill, prefetch hit.
0x828E	L3D_CACHE_REFILL_PRF	Level 3 data cache refill, prefetch hit.
0x828F	LL_CACHE_REFILL_PRF	Last level cache refill, prefetch hit.
0x8290	ISNP_HIT_PRF	Snoop hit, instruction prefetch.
0x8291	ISNP_HIT_NEAR_PRF	Snoop hit in near local cache, instruction prefetch.
0x8292	ISNP_HIT_FAR_PRF	Snoop hit in far local cache, instruction prefetch.
0x8293	ISNP_HIT_REMOTE_PRF	Snoop hit in remote cache, instruction prefetch.
0x8294	DSNP_HIT_PRF	Snoop hit, data prefetch.
0x8295	DSNP_HIT_NEAR_PRF	Snoop hit in near local cache, data prefetch.
0x8296	DSNP_HIT_FAR_PRF	Snoop hit in far local cache, data prefetch.
0x8297	DSNP_HIT_REMOTE_PRF	Snoop hit in remote cache, data prefetch.
0x8298	LL_CACHE_RW	Last level cache demand access.
0x8299	LL_CACHE_PRFM	Last level cache software prefetch.
0x829A	LL_CACHE_REFILL	Last level cache refill.
0x829B	LL_CACHE_REFILL_PRFM	Last level cache refill, software prefetch.
0x829C	LL_CACHE_WB	Last level cache write-back.

Number	Mnemonic	Description
0x829D	LL_CACHE_WR	Last level cache access, write.
0x829F	LL_CACHE_REFILL_WR	Last level cache refill, write.
0x82A0	MEM_ACCESS_RW	Data memory access, demand access.
0x82A1	INST_FETCH_RD	Instruction memory access, demand fetch.
0x82A2	MEM_ACCESS_PRFM	Data memory access, software prefetch.
0x82A3	INST_FETCH_PRFM	Instruction memory access, software prefetch.
0x82A4	ASE_SVE_RETIRED	Instruction architecturally executed, Advanced SIMD data processing or SVE data processing.
0x82A8	LD_ANY_RETIRED	Instruction architecturally executed, load.
0x82A9	ST_ANY_RETIRED	Instruction architecturally executed, store.
0x82AA	LDST_ANY_RETIRED	Instruction architecturally executed, load or store.
0x82AB	DP_RETIRED	Instruction architecturally executed, integer data processing.
0x82AC	ASE_RETIRED	Instruction architecturally executed, Advanced SIMD data processing.
0x82AD	VFP_RETIRED	Instruction architecturally executed, scalar floating-point data processing.
0x82AF	CRYPTO_RETIRED	Instruction architecturally executed, cryptographic data processing.
0x82B0	L1I_CACHE_MISS_RETIRED	Instruction architecturally executed, miss in Level 1 instruction cache.
0x82B1	L2I_CACHE_MISS_RETIRED	Instruction architecturally executed, miss in Level 2 instruction cache.
0x82B3	PRF_RETIRED	Instruction architecturally executed, prefetch.
0x82B4	L1D_CACHE_MISS_LD_RETIRED	Load instruction architecturally executed, miss in Level 1 data cache.
0x82B5	L2D_CACHE_MISS_LD_RETIRED	Load instruction architecturally executed, miss in Level 2 data cache.
0x82B6	L3D_CACHE_MISS_LD_RETIRED	Load instruction architecturally executed, miss in Level 3 data cache.
0x82B7	LL_CACHE_MISS_LD_RETIRED	Load instruction architecturally executed, miss in Last level cache.
0x82B8	L1D_CACHE_MISS_ST_RETIRED	Store instruction architecturally executed, miss in Level 1 data cache.
0x82B9	L2D_CACHE_MISS_ST_RETIRED	Store instruction architecturally executed, miss in Level 2 data cache.
0x82BA	L3D_CACHE_MISS_ST_RETIRED	Store instruction architecturally executed, miss in Level 3 data cache.
0x82BB	LL_CACHE_MISS_ST_RETIRED	Store instruction architecturally executed, miss in Last level cache.

Number	Mnemonic	Description
0x82BC	L1D_CACHE_MISS_LDST_RETIRED	Load or store instruction architecturally executed, miss in Level 1 data cache.
0x82BD	L2D_CACHE_MISS_LDST_RETIRED	Load or store instruction architecturally executed, miss in Level 2 data cache.
0x82BE	L3D_CACHE_MISS_LDST_RETIRED	Load or store instruction architecturally executed, miss in Level 3 data cache.
0x82BF	LL_CACHE_MISS_LDST_RETIRED	Load or store instruction architecturally executed, miss in Last level cache.
0x82C4	L1D_CACHE_HITM_LD_RETIRED	Load instruction architecturally executed, hit modified data in Level 1 data cache.
0x82C5	L2D_CACHE_HITM_LD_RETIRED	Load instruction architecturally executed, hit modified data in Level 2 data cache.
0x82C6	L3D_CACHE_HITM_LD_RETIRED	Load instruction architecturally executed, hit modified data in Level 3 data cache.
0x82C7	LL_CACHE_HITM_LD_RETIRED	Load instruction architecturally executed, hit modified data in Last level cache.
0x82C8	L1D_CACHE_HITM_ST_RETIRED	Store instruction architecturally executed, hit modified data in Level 1 data cache.
0x82C9	L2D_CACHE_HITM_ST_RETIRED	Store instruction architecturally executed, hit modified data in Level 2 data cache.
0x82CA	L3D_CACHE_HITM_ST_RETIRED	Store instruction architecturally executed, hit modified data in Level 3 data cache.
0x82CB	LL_CACHE_HITM_ST_RETIRED	Store instruction architecturally executed, hit modified data in Last level cache.
0x82CC	L1D_CACHE_HITM_LDST_RETIRED	Load or store instruction architecturally executed, hit modified data in Level 1 data cache.
0x82CD	L2D_CACHE_HITM_LDST_RETIRED	Load or store instruction architecturally executed, hit modified data in Level 2 data cache.
0x82CE	L3D_CACHE_HITM_LDST_RETIRED	Load or store instruction architecturally executed, hit modified data in Level 3 data cache.
0x82CF	LL_CACHE_HITM_LDST_RETIRED	Load or store instruction architecturally executed, hit modified data in Last level cache.
0x82D0	L1I_LFB_HIT_RETIRED	Instruction architecturally executed, line-fill buffer hit in Level 1 instruction cache.

Number	Mnemonic	Description
0x82D1	L2I_LFB_HIT_RETIRED	Instruction architecturally executed, line-fill buffer hit in Level 2 instruction cache.
0x82D4	L1D_LFB_HIT_LD_RETIRED	Load instruction architecturally executed, line-fill buffer hit in Level 1 data cache.
0x82D5	L2D_LFB_HIT_LD_RETIRED	Load instruction architecturally executed, line-fill buffer hit in Level 2 data cache.
0x82D6	L3D_LFB_HIT_LD_RETIRED	Load instruction architecturally executed, line-fill buffer hit in Level 3 data cache.
0x82D7	LL_LFB_HIT_LD_RETIRED	Load instruction architecturally executed, line-fill buffer hit in Last level cache.
0x82D8	L1D_LFB_HIT_ST_RETIRED	Store instruction architecturally executed, line-fill buffer hit in Level 1 data cache.
0x82D9	L2D_LFB_HIT_ST_RETIRED	Store instruction architecturally executed, line-fill buffer hit in Level 2 data cache.
0x82DA	L3D_LFB_HIT_ST_RETIRED	Store instruction architecturally executed, line-fill buffer hit in Level 3 data cache.
0x82DB	LL_LFB_HIT_ST_RETIRED	Store instruction architecturally executed, line-fill buffer hit in Last level cache.
0x82DC	L1D_LFB_HIT_LDST_RETIRED	Load or store instruction architecturally executed, line-fill buffer hit in Level 1 data cache.
0x82DD	L2D_LFB_HIT_LDST_RETIRED	Load or store instruction architecturally executed, line-fill buffer hit in Level 2 data cache.
0x82DE	L3D_LFB_HIT_LDST_RETIRED	Load or store instruction architecturally executed, line-fill buffer hit in Level 3 data cache.
0x82DF	LL_LFB_HIT_LDST_RETIRED	Load or store instruction architecturally executed, line-fill buffer hit in Last level cache.
0x82E0	L1I_CACHE_HIT_RETIRED	Instruction architecturally executed, hit in Level 1 instruction cache.
0x82E1	L2I_CACHE_HIT_RETIRED	Instruction architecturally executed, hit in Level 2 instruction cache.
0x82E4	L1D_CACHE_HIT_LD_RETIRED	Load instruction architecturally executed, hit in Level 1 data cache.
0x82E5	L2D_CACHE_HIT_LD_RETIRED	Load instruction architecturally executed, hit in Level 2 data cache.
0x82E6	L3D_CACHE_HIT_LD_RETIRED	Load instruction architecturally executed, hit in Level 3 data cache.
0x82E7	LL_CACHE_HIT_LD_RETIRED	Load instruction architecturally executed, hit in Last level cache.

Number	Mnemonic	Description
0x82E8	L1D_CACHE_HIT_ST_RETIRED	Store instruction architecturally executed, hit in Level 1 data cache.
0x82E9	L2D_CACHE_HIT_ST_RETIRED	Store instruction architecturally executed, hit in Level 2 data cache.
0x82EA	L3D_CACHE_HIT_ST_RETIRED	Store instruction architecturally executed, hit in Level 3 data cache.
0x82EB	LL_CACHE_HIT_ST_RETIRED	Store instruction architecturally executed, hit in Last level cache.
0x82EC	L1D_CACHE_HIT_LDST_RETIRED	Load or store instruction architecturally executed, hit in Level 1 data cache.
0x82ED	L2D_CACHE_HIT_LDST_RETIRED	Load or store instruction architecturally executed, hit in Level 2 data cache.
0x82EE	L3D_CACHE_HIT_LDST_RETIRED	Load or store instruction architecturally executed, hit in Level 3 data cache.
0x82EF	LL_CACHE_HIT_LDST_RETIRED	Load or store instruction architecturally executed, hit in Last level cache.
0x82F0	ITLB_HIT_RETIRED	Instruction architecturally executed, no translation table walk.
0x82F1	DTLB_HIT_LD_RETIRED	Load instruction architecturally executed, no translation table walk.
0x82F2	DTLB_HIT_ST_RETIRED	Store instruction architecturally executed, no translation table walk.
0x82F3	DTLB_HIT_LDST_RETIRED	Load or store instruction architecturally executed, no translation table walk.
0x82F4	ITLB_WALK_RETIRED	Instruction architecturally executed, at least one translation table walk.
0x82F5	DTLB_WALK_LD_RETIRED	Load instruction architecturally executed, at least one translation table walk.
0x82F6	DTLB_WALK_ST_RETIRED	Store instruction architecturally executed, at least one translation table walk.
0x82F7	DTLB_WALK_LDST_RETIRED	Load or store instruction architecturally executed, at least one translation table walk.
0x82F8	DTLB_WALK_PRF	Data TLB prefetch, with at least one translation table walk.
0x82F9	ITLB_WALK_PRF	Instruction TLB prefetch, with at least one translation table walk.
0x82FA	DTLB_WALK_HWPRF	Data TLB hardware prefetch, with at least one translation table walk.
0x82FB	ITLB_WALK_HWPRF	Instruction TLB hardware prefetch, with at least one translation table walk.
0x82FC	L1D_TLB_PRF	Level 1 data TLB access, prefetch.

Number	Mnemonic	Description
0x82FD	L1I_TLB_PRF	Level 1 instruction TLB access, prefetch.
0x82FE	L1D_TLB_HWPRF	Level 1 data TLB access, hardware prefetch.
0x82FF	L1I_TLB_HWPRF	Level 1 instruction TLB access, hardware prefetch.
0x8304	DSNP_HITM_LD_RETIRED	Load instruction architecturally executed, snoop hit.
0x8305	DSNP_HITM_NEAR_LD_RETIRED	Load instruction architecturally executed, snoop hit in near cache.
0x8306	DSNP_HITM_FAR_LD_RETIRED	Load instruction architecturally executed, snoop hit in far cache.
0x8307	DSNP_HITM_REMOTE_LD_RETIRED	Load instruction architecturally executed, snoop hit in remote cache.
0x8308	DSNP_HITM_ST_RETIRED	Store instruction architecturally executed, snoop hit.
0x8309	DSNP_HITM_NEAR_ST_RETIRED	Store instruction architecturally executed, snoop hit in near cache.
0x830A	DSNP_HITM_FAR_ST_RETIRED	Store instruction architecturally executed, snoop hit in far cache.
0x830B	DSNP_HITM_REMOTE_ST_RETIRED	Store instruction architecturally executed, snoop hit in remote cache.
0x830C	DSNP_HITM_LDST_RETIRED	Load or store instruction architecturally executed, snoop hit.
0x830D	DSNP_HITM_NEAR_LDST_RETIRED	Load or store instruction architecturally executed, snoop hit in near cache.
0x830E	DSNP_HITM_FAR_LDST_RETIRED	Load or store instruction architecturally executed, snoop hit in far cache.
0x830F	DSNP_HITM_REMOTE_LDST_RETIRED	Load or store instruction architecturally executed, snoop hit in remote cache.
0x8310	ISNP_HIT_RETIRED	Instruction architecturally executed, instruction fetch snoop hit.
0x8311	ISNP_HIT_NEAR_RETIRED	Instruction architecturally executed, instruction fetch snoop hit in near cache.
0x8312	ISNP_HIT_FAR_RETIRED	Instruction architecturally executed, instruction fetch snoop hit in far cache.
0x8313	ISNP_HIT_REMOTE_RETIRED	Instruction architecturally executed, instruction fetch snoop hit in remote cache.
0x8314	DSNP_HIT_LD_RETIRED	Load instruction architecturally executed, snoop hit.
0x8315	DSNP_HIT_NEAR_LD_RETIRED	Load instruction architecturally executed, snoop hit in near cache.
0x8316	DSNP_HIT_FAR_LD_RETIRED	Load instruction architecturally executed, snoop hit in far cache.

Number	Mnemonic	Description
0x8317	DSNP_HIT_REMOTE_LD_RETIRED	Load instruction architecturally executed, snoop hit in remote cache.
0x8318	DSNP_HIT_ST_RETIRED	Store instruction architecturally executed, snoop hit.
0x8319	DSNP_HIT_NEAR_ST_RETIRED	Store instruction architecturally executed, snoop hit in near cache.
0x831A	DSNP_HIT_FAR_ST_RETIRED	Store instruction architecturally executed, snoop hit in far cache.
0x831B	DSNP_HIT_REMOTE_ST_RETIRED	Store instruction architecturally executed, snoop hit in remote cache.
0x831C	DSNP_HIT_LDST_RETIRED	Load or store instruction architecturally executed, snoop hit.
0x831D	DSNP_HIT_NEAR_LDST_RETIRED	Load or store instruction architecturally executed, snoop hit in near cache.
0x831E	DSNP_HIT_FAR_LDST_RETIRED	Load or store instruction architecturally executed, snoop hit in far cache.
0x831F	DSNP_HIT_REMOTE_LDST_RETIRED	Load or store instruction architecturally executed, snoop hit in remote cache.
0x8320	L1D_CACHE_REFILL_PERCYC	Level 1 data or unified cache refills in progress.
0x8321	L2D_CACHE_REFILL_PERCYC	Level 2 data or unified cache refills in progress.
0x8322	L3D_CACHE_REFILL_PERCYC	Level 3 data or unified cache refills in progress.
0x8324	L1I_CACHE_REFILL_PERCYC	Level 1 instruction or unified cache refills in progress.
0x8325	L2I_CACHE_REFILL_PERCYC	Level 2 instruction or unified cache refills in progress.
0x8328	REMOTE_CACHE_HIT_RD	Remote cache demand access hit, read.
0x8329	REMOTE_CACHE_HITM_RD	Remote cache demand access hit modified, read.
0x832A	REMOTE_LFB_HIT_RD	Remote cache demand access line-fill buffer hit, read.
0x832B	REMOTE_CACHE_HIT_PRFM	Remote cache software prefetch hit.
0x8330	L1GCS_CACHE	Level 1 GCS cache access.
0x8331	L1GCS_CACHE_RW	Level 1 GCS cache demand access.
0x8332	L1GCS_CACHE_HWPRF	Level 1 GCS cache hardware prefetch.
0x8334	L1GCS_CACHE_MISS	Level 1 GCS cache demand access miss.
0x8335	L1GCS_CACHE_MISS_RD	Level 1 GCS cache demand access read miss.
0x8336	L1GCS_CACHE_HIT_RW	Level 1 GCS cache demand access hit.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Number	Mnemonic	Description
0x8337	L1GCS_CACHE_HIT_RW_FHWPRF	Level 1 GCS cache demand access first hit, fetched by GCS hardware prefetcher.
0x8338	L1GCS_CACHE_REFILL	Level 1 GCS cache refill.
0x8339	L1GCS_CACHE_REFILL_HWPRF	Level 1 GCS cache refill, hardware prefetch.
0x833A	L1GCS_CACHE_REFILL_PERCYC	Level 1 GCS cache refills in progress.
0x833C	L1GCS_LFB_HIT_RW	Level 1 GCS cache demand access line-fill buffer hit.
0x833D	L1GCS_LFB_HIT_RW_FHWPRF	Level 1 GCS cache demand access line-fill buffer first hit, recently fetched by GCS hardware prefetcher.
0x833E	L1GCS_CACHE_INVAL	Level 1 GCS cache invalidate.
0x8340	L1GCS_TLB	Level 1 GCS TLB access.
0x8341	L1GCS_TLB_RW	Level 1 GCS demand TLB access.
0x8342	L1GCS_TLB_HWPRF	Level 1 GCS demand TLB access, GCS hardware prefetch.
0x8344	GCSTLB_WALK	GCS TLB access with at least one translation table walk.
0x8345	GCSTLB_WALK_RW	GCS TLB demand access with at least one translation table walk.
0x8346	GCSTLB_WALK_PERCYC	Translation table walks in progress.
0x8347	GCSTLB_WALK_STEP	GCS TLB translation table walk, step.
0x8350	STALL_BACKEND_L1GCS	Backend stall cycles, Level 1 GCS cache.
0x8351	STALL_BACKEND_GCSTLB	Backend stall cycles, GCS TLB.
0x8353	SE_FP_SPEC	Operation speculatively executed, Advanced SIMD, SVE, or SME SIMD floating-point, data-processing.
0x8359	SE_RETIRED	Instruction architecturally executed, Advanced SIMD, SVE, or SME data processing.
0x835B	SE_INST_RETIRED	Instruction architecturally executed, Advanced SIMD, SVE, or SME.
0x835D	SE_SPEC	Operation speculatively executed, Advanced SIMD, SVE, or SME data processing.
0x835F	SE_INST_SPEC	Operation speculatively executed, Advanced SIMD, SVE, or SME.
0x8361	SE_INT8_SPEC	Operation speculatively executed, Advanced SIMD, SVE, or SME SIMD 8-bit integer, data-processing.
0x8363	SE_FP_BF16_SPEC	Operation speculatively executed, Advanced SIMD, SVE, or SME SIMD BFloat16 floating-point, data-processing.
0x8365	SE_INT16_SPEC	Operation speculatively executed, Advanced SIMD, SVE, or SME SIMD 16-bit integer, data-processing.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Number	Mnemonic	Description
0x8367	SE_FP_HP_SPEC	Operation speculatively executed, Advanced SIMD, SVE, or SME SIMD half-precision floating-point, data-processing.
0x8369	SE_INT32_SPEC	Operation speculatively executed, Advanced SIMD, SVE, or SME SIMD 32-bit integer, data-processing.
0x836B	SE_FP_SP_SPEC	Operation speculatively executed, Advanced SIMD, SVE, or SME SIMD single-precision floating-point, data-processing.
0x836D	SE_INT64_SPEC	Operation speculatively executed, Advanced SIMD, SVE, or SME SIMD 64-bit integer, data-processing.
0x836F	SE_FP_DP_SPEC	Operation speculatively executed, Advanced SIMD, SVE, or SME SIMD double-precision floating-point, data-processing.
0x8371	SE_FP_ADDSUB_SPEC	Operation speculatively executed, Advanced SIMD, SVE, or SME SIMD floating-point addition or subtraction.
0x8373	SE_FP_FMA_SPEC	Operation speculatively executed, Advanced SIMD, SVE, or SME SIMD floating-point multiply-add or multiply-subtract.
0x8375	SE_FP_DOT_SPEC	Operation speculatively executed, Advanced SIMD, SVE, or SME SIMD floating-point dot product.
0x8379	SE_INT_SPEC	Operation speculatively executed, Advanced SIMD, SVE, or SME SIMD integer, data-processing.
0x837B	SE_INT_MUL_SPEC	Operation speculatively executed, Advanced SIMD, SVE, or SME SIMD integer multiply or multiply-accumulate.
0x837D	SE_INT_DOT_SPEC	Operation speculatively executed, Advanced SIMD, SVE, or SME SIMD integer dot product.
0x8380	ZA_ACTIVE	CPU cycles, ZA enabled.
0x8398	ASE_LUT_SPEC	Lookup table operation speculatively executed, Advanced SIMD data processing.
0x8399	SVE_LUT_SPEC	Lookup table operation speculatively executed, SVE data processing.
0x839B	SE_LUT_SPEC	Lookup table operation speculatively executed, Advanced SIMD, SVE, or SME data processing.
0x83A0	N1_CACHE_HIT_RD	Cache at distance 1, demand access hit, read.
0x83A1	N2_CACHE_HIT_RD	Cache at distance 2, demand access hit, read.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Number	Mnemonic	Description
0x83A2	N3_CACHE_HIT_RD	Cache at distance 3, demand access hit, read.
0x83A3	N4_CACHE_HIT_RD	Cache at distance 4, demand access hit, read.
0x83A4	N1_CACHE_HIT_PRFM	Cache at distance 1, software prefetch hit.
0x83A5	N2_CACHE_HIT_PRFM	Cache at distance 2, software prefetch hit.
0x83A6	N3_CACHE_HIT_PRFM	Cache at distance 3, software prefetch hit.
0x83A7	N4_CACHE_HIT_PRFM	Cache at distance 4, software prefetch hit.
0x83A8	N1_CACHE1_HIT_RD	Cache type 1 at distance 1 demand access hit, read.
0x83A9	N2_CACHE1_HIT_RD	Cache type 1 at distance 2 demand access hit, read.
0x83AA	N3_CACHE1_HIT_RD	Cache type 1 at distance 3 demand access hit, read.
0x83AB	N4_CACHE1_HIT_RD	Cache type 1 at distance 4 demand access hit, read.
0x83AC	N1_CACHE1_HIT_PRFM	Cache type 1 at distance 1 software prefetch hit.
0x83AD	N2_CACHE1_HIT_PRFM	Cache type 1 at distance 2 software prefetch hit.
0x83AE	N3_CACHE1_HIT_PRFM	Cache type 1 at distance 3 software prefetch hit.
0x83AF	N4_CACHE1_HIT_PRFM	Cache type 1 at distance 4 software prefetch hit.
0x83B0	N1_CACHE2_HIT_RD	Cache type 2 at distance 1 demand access hit, read.
0x83B1	N2_CACHE2_HIT_RD	Cache type 2 at distance 2 demand access hit, read.
0x83B2	N3_CACHE2_HIT_RD	Cache type 2 at distance 3 demand access hit, read.
0x83B3	N4_CACHE2_HIT_RD	Cache type 2 at distance 4 demand access hit, read.
0x83B4	N1_CACHE2_HIT_PRFM	Cache type 2 at distance 1 software prefetch hit.
0x83B5	N2_CACHE2_HIT_PRFM	Cache type 2 at distance 2 software prefetch hit.
0x83B6	N3_CACHE2_HIT_PRFM	Cache type 2 at distance 3 software prefetch hit.
0x83B7	N4_CACHE2_HIT_PRFM	Cache type 2 at distance 4 software prefetch hit.
0x83B8	N1_CACHE3_HIT_RD	Cache type 3 at distance 1 demand access hit, read.
0x83B9	N2_CACHE3_HIT_RD	Cache type 3 at distance 2 demand access hit, read.

D9.3 Common event numbers

The event numbers of the common architectural and microarchitectural events are reserved for the specified events. Each of these event numbers must either:

- Be used for its assigned event.
- Not be used.

However, see Required events.

When an implementation supports monitoring of an event that is assigned a common architectural or microarchitectural event number, Arm strongly recommends that it uses that number for the event. However, software might encounter implementations where an event assigned a number in this range is monitored using an event number from an IMPLEMENTATION DEFINED range.

Note

Arm might define other common architectural and microarchitectural event numbers. This is one reason why software must not assume that an event with an assigned common architectural or microarchitectural event number is never monitored using an event number from the IMPLEMENTATION DEFINED range.

It is IMPLEMENTATION DEFINED which events, including Common events, are generated by IMPLEMENTATION DEFINED extensions to the architecture, including accesses to IMPLEMENTATION DEFINED System registers and IMPLEMENTATION DEFINED System instructions. However, the functionality of the IMPLEMENTATION DEFINED extension must be appropriate for the generated events.

The common events are described in the following sections:

- Common architectural events.
- Common microarchitectural events.

The supported common architectural and microarchitectural events in the ranges `0x0000-0x003F` and `0x4000-0x403F` are discoverable to software through:

- PMCEID0_EL0.
- PMCEID1_EL0.

Arm recommends that the value of 0 is used for the PMCEID0_EL0 or PMCEID1_EL0 bit corresponding to any event that an implementation never generates, even if the implementation is considered to support but never count the event.

Note

For example, if an implementation never generates the L1D_CACHE_ALLOCATE event, event 31, Arm recommends that PMCEID0_EL0[31] is RAZ.

However, for some implementations, an event in the common events range might be generated by the system, meaning behavior can vary between systems. In such a case, the corresponding PMCEID*n*_EL0 bit might be RAO.

Event numbers that Table D9-2 shows as allocated for common architectural and microarchitectural events that are not described in Common architectural events and Common microarchitectural events are reserved. Future revisions of this Manual, or of the architecture, might assign these reserved values to additional common events. Events that do not require additional features in the PMU can be implemented retrospectively, meaning an implementation of a particular version of the PMU specification might support common events that are first defined in a later version of the PMU specification.

Note

The requirement that an event that is implemented retrospectively *does not require additional features in the PMU* means that it must be possible to represent the event *n* the PMEVTYPER<n>_EL0.evtCount field. This means, for example, that an implementation with a 10-bit PMEVTYPER<n>_EL0.evtCount field can only implement events with event numbers `0x0000-0x03FF`.

D9.3.1 Common architectural events

The Common architectural events are:

`0x0000`, **SW_INCR, Instruction architecturally executed, Condition code check pass, software increment**

The counter counts each write to the PMSWINC_EL0 register for each implemented event counter <n> if PMEVTYPER<n>_EL0.evtCount is `0x0000` then the counter counts each `MSR` write to PMSWINC_EL0 with bit [n] set to 1.

If the PE performs two architecturally executed writes to the PMSWINC_EL0 register without an intervening Context synchronization event, then the counter is incremented twice.

Note

In a multithreaded implementation, if the Effective value of PMEVTYPER<n>_EL0.MT is 1, then the counter counts writes by all PEs that have the same affinity at level 1 and above.

PMCEID0_EL0[0] reads as 1 if this event is implemented and 0 otherwise.

`0x0006`, **LD_RETIRED, Instruction architecturally executed, Condition code check pass, load**

The counter counts each architecturally-executed memory-reading instruction counted by INST_RETIRED.

It is IMPLEMENTATION DEFINED whether the prefetch instructions counted by PRF_RETIRED are counted as Memory-reading instructions:

- If the prefetch instructions are counted as Memory-reading instructions, then they are counted by LD_RETIRED and LD_ANY_RETIRED.
- Otherwise, if the prefetch instructions are not counted as Memory-reading instructions by LD_RETIRED, then it is further IMPLEMENTATION DEFINED which one of the following applies:
  - They are counted as data-processing instructions.
  - They are counted by LDST_ANY_RETIRED.

Arm recommends that if a prefetch instruction is not implemented as a NOP and the PRF_RETIRED event is not implemented, then the instruction is counted as a Memory-reading instruction.

PMCEID0_EL0[6] reads as 1 if this event is implemented and 0 otherwise.

`0x0007`, **ST_RETIRED, Instruction architecturally executed, Condition code check pass, store**

The counter counts each architecturally-executed memory-writing instruction counted by INST_RETIRED.

The counter does not count a Store-Exclusive instruction that fails.

PMCEID0_EL0[7] reads as 1 if this event is implemented and 0 otherwise.

`0x0008`, **INST_RETIRED, Instruction architecturally executed**

The counter counts each architecturally-executed instruction.

PMCEID0_EL0[8] reads as 1 if this event is implemented and 0 otherwise.

`0x0009`, **EXC_TAKEN, Exception taken**

The counter counts each exception taken.

The counter counts each exception taken.

Note

The counter counts the PE exceptions described in Exception entry.

PMCEID0_EL0[9] reads as 1 if this event is implemented and 0 otherwise.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

`0x000A`, **EXC_RETURN, Instruction architecturally executed, Condition code check pass, exception return**

The counter counts each architecturally-executed exception return instruction.

Instructions defined in the following sections are counted as exception return instructions:

- For an exception return from an Exception level using AArch64, Exception return.
- For an exception return from an Exception level using AArch32, Exception return instructions.

It is CONSTRAINED UNPREDICTABLE whether the execution of an exception return instruction is counted if the instruction sets PSTATE.IL and does not generate an exception return.

PMCEID0_EL0[10] reads as 1 if this event is implemented and 0 otherwise.

`0x000B`, **CID_WRITE_RETIRED, Instruction architecturally executed, Condition code check pass, write to CONTEXTIDR**

The counter counts each `MSR` write to CONTEXTIDR_EL1.

If the PE performs two architecturally-executed writes to CONTEXTIDR without an intervening Context synchronization event, it is CONSTRAINED UNPREDICTABLE whether the first write is counted.

The counter counts only writes to these named registers. For example:

- When FEAT_Debugv8p2 is implemented, the counter does not count writes using the register name CONTEXTIDR_EL2.

PMCEID0_EL0[11] reads as 1 if this event is implemented and 0 otherwise.

`0x000C`, **PC_WRITE_RETIRED, Instruction architecturally executed, Condition code check pass, Software change of the PC**

The counter counts each architecturally-executed Software change of the PC that is taken.

This includes all:

- Branch instructions.
- Memory-reading instructions that explicitly write to the PC.
- Data-processing instructions that explicitly write to the PC.
- Exception return instructions.

Note

Conditional branches are only counted if the branch is taken.

It is IMPLEMENTATION DEFINED whether the following instructions are included as a Software change of the PC:

- A `BRK` instruction.
- An UNDEFINED instruction that generates an exception.
- An exception-generating instruction, `SVC`, `HVC`, and `SMC`, that generates an exception.
- A Context synchronization barrier instruction, `ISB`.

The counter does not increment for exceptions other than those explicitly identified in these lists.

PMCEID0_EL0[12] reads as 1 if this event is implemented and 0 otherwise.

`0x000D`, **BR_IMMED_RETIRED, Branch instruction architecturally executed, immediate**

The counter counts each architecturally-executed immediate branch instruction.

The following instructions are counted as immediate branch instructions:

- For AArch64 state, the following instructions:
  - `B <label>`.
  - `B.cond <label>`.
  - `BL <label>`.
  - `CBZ <Rn>, <label>`.
  - `CBNZ <Rn>, <label>`.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- `TBZ <Rn>, <label>`.
- `TBNZ <Rn>, <label>`.

Note

Conditional branches are always counted, regardless of whether the branch is taken or not taken.

If the Context synchronization barrier instruction ISB is counted as a Software change of the PC instruction by PC_WRITE_RETIRED, then it is IMPLEMENTATION DEFINED whether ISB is counted as an immediate branch instruction.

PMCEID0_EL0[13] reads as 1 if this event is implemented and 0 otherwise.

`0x000E`, **BR_RETURN_RETIRED, Branch instruction architecturally executed, procedure return, taken**

The counter counts each architecturally executed procedure return instruction.

The following instructions are counted as procedure return instructions:

- For AArch64 state, the following instructions:
  - `RET`.
  - If FEAT_PAuth is implemented, `RETAA` and `RETAB`.

PMCEID0_EL0[14] reads as 1 if this event is implemented and 0 otherwise.

`0x000F`, **UNALIGNED_LDST_RETIRED, Instruction architecturally executed, Condition code check pass, unaligned load or store**

The counter counts each memory-reading instruction or memory-writing instruction access that would generate an Alignment fault when Alignment fault checking is enabled.

The counter does not count accesses that would generate an SP alignment fault exception if the applicable stack pointer alignment check is enabled, unless that access would also generate an Alignment fault Data Abort exception if Alignment fault checking is enabled.

It is IMPLEMENTATION DEFINED and might be UNPREDICTABLE whether this event counts accesses that generate an exception, including accesses that do generate Alignment fault Data Abort exceptions.

PMCEID0_EL0[15] reads as 1 if this event is implemented and 0 otherwise.

`0x001C`, **TTBR_WRITE_RETIRED, Instruction architecturally executed, Condition code check pass, write to TTBR**

The counter counts each `MSR` write to TTBR0_EL1 and TTBR1_EL1 in AArch64 state.

The counter counts `MSR` writes to TTBR0_EL1 and TTBR1_EL1.

If the PE executes two writes to the same TTBR, without an intervening Context synchronization event, it is CONSTRAINED UNPREDICTABLE whether the first write to the TTBR, is counted.

The counter counts only writes to these registers by name. For example:

- The counter does not count writes using the register names TTBR0_EL2 and VTTBR_EL2.

PMCEID0_EL0[28] reads as 1 if this event is implemented and 0 otherwise.

`0x001E`, **CHAIN, Chain a pair of event counters**

Even-numbered counters never increment as a result of this event.

For an odd-numbered counter <n+1>, the counter increments when an event increments the preceding even-numbered counter <n> on the same PE causing unsigned overflow of bits [31:0] of the event counter <n>.

This means the CHAIN event can be used to link the odd-numbered counter with the preceding even-numbered counter to provide a 64-bit counter.

If EL2 is implemented and <n+1> is equal to the Effective value of HDCR.HPMN, then it is UNPREDICTABLE whether the counter counts.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

- The CHAIN event allows software to use the N event counters as N 32-bit counters, N÷2 64-bit counters, or a mixture of 32-bit counters and 64-bit counters.
- The CHAIN event only counts overflows from the preceding even-numbered counter on the same PE. This means it ignores the Effective value of PMEVTYPER<n>_EL0.MT.
- The architecture does not provide atomic access to a pair of counters.

To filter the Exception levels and Security states in which the event is counted, software:

- Programs PMEVTYPER<n>_EL0 to count the event in the required conditions.
- Programs PMEVTYPER<n+1>_EL0 to count the CHAIN event in all Exception levels and states.

The PE might ignore the filter settings for the CHAIN event and behave as if they are set to count in all Exception levels and states. If software does not program the event in this way, the count becomes UNPREDICTABLE.

The architecture does not define the latency between the low counter overflowing and the high counter incrementing the CHAIN event. There is no requirement for updates to occur synchronously, but software reading or enabling the counter pair by reading the low counter first and the high counter second, with an intervening Context synchronization event, will not observe the low counter incrementing and overflowing for the event and the high counter not incrementing for the resulting CHAIN event. This means that the ISB executed after reading the low counter ensures the completion of the update of the high counter by the CHAIN event.

PMCEID0_EL0[30] reads as 1 if this event is implemented and 0 otherwise.

`0x0021`**, BR_RETIRED, Instruction architecturally executed, branch**

The counter counts each branch instruction on the architecturally executed path that would incur cost if mispredicted.

It is IMPLEMENTATION DEFINED whether the counter increments for any or all of:

- Unconditional direct branch instructions.
- Exception-generating instructions.
- Exception return instructions.
- Context synchronization instructions.

The counter counts all other branch instructions, memory-reading instructions and data-processing instructions that explicitly write to the PC, at retirement.

Note

Conditional branches are always counted, regardless of whether the branch is taken.

Arm recommends that BR_RETIRED counts Unconditional direct branch instructions and Exception return instructions.

PMCEID1_EL0[1] reads as 1 if this event is implemented and 0 otherwise.

`0x0081`**, EXC_UNDEF, Exception taken, other synchronous**

The counter counts each exception counted by EXC_TAKEN that is Taken locally and is not counted as any of the following:

- Exception taken, Supervisor Call (EXC_SVC).
- Exception taken, Secure Monitor Call (EXC_SMC).
- Exception taken, Hypervisor Call (EXC_HVC).
- Exception taken, Instruction Abort (EXC_PABORT).
- Exception taken, Data Abort or SError (EXC_DABORT).
- Exception taken, IRQ (EXC_IRQ).
- Exception taken, FIQ (EXC_FIQ).

`0x0082`**, EXC_SVC, Exception taken, Supervisor Call**

The counter counts each Supervisor Call exception counted by EXC_TAKEN that is Taken locally.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

`0x0083`, **EXC_PABORT, Exception taken, Instruction Abort**

The counter counts each Instruction Abort exception counted by EXC_TAKEN that is Taken locally.

`0x0084`, **EXC_DABORT, Exception taken, Data Abort or SError**

The counter counts each Data Abort, SError interrupt, or virtual SError interrupt exception counted by EXC_TAKEN that is Taken locally.

`0x0086`, **EXC_IRQ, Exception taken, IRQ**

The counter counts each IRQ or virtual IRQ exception counted by EXC_TAKEN that is Taken locally.

`0x0087`, **EXC_FIQ, Exception taken, FIQ**

The counter counts each FIQ or virtual FIQ exception counted by EXC_TAKEN that is Taken locally.

`0x0088`, **EXC_SMC, Exception taken, Secure Monitor Call**

The counter counts each Secure Monitor Call exception counted by EXC_TAKEN.

The counter does not count SMC instructions that generate other exceptions, including Trap exceptions and Undefined Instruction exceptions.

`0x008A`, **EXC_HVC, Exception taken, Hypervisor Call**

The counter counts each Hypervisor Call exception counted by EXC_TAKEN.

The counter does not count HVC instructions that are UNDEFINED.

`0x008B`, **EXC_TRAP_PABORT, Exception taken, Instruction Abort not Taken locally**

The counter counts each Instruction Abort exception counted by EXC_TAKEN that is not Taken locally.

`0x008C`, **EXC_TRAP_DABORT, Exception taken, Data Abort or SError not Taken locally**

The counter counts each Data Abort, SError interrupt, or virtual SError interrupt exception counted by EXC_TAKEN, that is not Taken locally.

`0x008D`, **EXC_TRAP_OTHER, Exception taken, other traps not Taken locally**

The counter counts each exception counted by EXC_TAKEN that is not Taken locally and not counted as any of the following:

- Exception taken, Secure Monitor Call (EXC_SMC).
- Exception taken, Hypervisor Call (EXC_HVC).
- Exception taken, Instruction Abort not Taken locally (EXC_TRAP_PABORT).
- Exception taken, Data Abort or SError not Taken locally (EXC_TRAP_DABORT).
- Exception taken, IRQ not Taken locally (EXC_TRAP_IRQ).
- Exception taken, FIQ not Taken locally (EXC_TRAP_FIQ).

`0x008E`, **EXC_TRAP_IRQ, Exception taken, IRQ not Taken locally**

The counter counts each IRQ or virtual IRQ exception counted by EXC_TAKEN that is not Taken locally.

`0x008F`, **EXC_TRAP_FIQ, Exception taken, FIQ not Taken locally**

The counter counts each FIQ or virtual FIQ exception counted by EXC_TAKEN that is not Taken locally.

`0x400C`, **TRB_WRAP, Trace buffer current write pointer wrapped**

The counter counts each write made by the Trace Buffer Unit to the trace buffer that causes the trace buffer current write pointer to wrap to the trace buffer base pointer.

PMCEID0_EL0[44] reads as 1 if this event is implemented and 0 otherwise.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

`0x4030`, **TSTART_RETIRED, Instruction architecturally executed, outer transaction TSTART**

The counter counts each TSTART instruction counted by INST_RETIRED that starts an outer transaction.

If PMEVTYPER<n>_EL0.T is 1, it is IMPLEMENTATION DEFINED whether or not the TSTART instruction is counted by the counter.

PMCEID1_EL0[48] reads as 1 if this event is implemented and 0 otherwise.

`0x4031`, **TCOMMIT_RETIRED, Instruction architecturally executed, outer transaction TCOMMIT**

The counter counts each TCOMMIT instruction counted by INST_RETIRED that commits an outer transaction.

If PMEVTYPER<n>_EL0.T is 1, it is IMPLEMENTATION DEFINED whether or not the TCOMMIT instruction is counted by the counter.

PMCEID1_EL0[49] reads as 1 if this event is implemented and 0 otherwise.

`0x8000`, **SIMD_INST_RETIRED, Instruction architecturally executed, SIMD**

The counter counts each architecturally executed SIMD instruction.

It is IMPLEMENTATION DEFINED whether scalar loads and stores to SIMD&FP registers other that those listed above are counted.

`0x8001`, **ASE_INST_RETIRED, Instruction architecturally executed, Advanced SIMD**

The counter counts each architecturally executed instruction counted by ASE_SVE_INST_RETIRED that is classified as an Advanced SIMD instruction.

The following instructions are counted as Advanced SIMD instructions:

- For AArch64 state:
  - The SIMD operations listed in Data processing - SIMD and floating-point.
  - If FEAT_Crypto is implemented, the Advanced SIMD Cryptographic instructions. See The Cryptographic Extension in AArch64 state.
  - Advanced SIMD loads and stores.

This includes all instructions that operate on the SIMD&FP registers, except those that are counted as one of the following:

- Integer data-processing instructions.
- Scalar floating-point data-processing instructions.

It is IMPLEMENTATION DEFINED whether Advanced SIMD scalar instructions are counted as Advanced SIMD instructions. This includes Advanced SIMD scalar instructions which operate on floating-point values.

`0x8003`, **ASE_SVE_INST_RETIRED, Instruction architecturally executed, Advanced SIMD or SVE**

The counter counts each architecturally executed instruction counted by SE_INST_RETIRED that is classified as an Advanced SIMD instruction or an SVE instruction.

See ASE_INST_RETIRED and SVE_INST_RETIRED for these classifications.

`0x8107`, **BR_SKIP_RETIRED, Branch instruction architecturally executed, not taken**

The counter counts each conditional Software change of the PC instruction that is not taken.

This includes all:

- Conditional branch instructions.
- Conditional memory-reading instructions that explicitly write to the PC.
- Conditional data-processing instructions that explicitly write to the PC.
- Conditional exception return instructions.

These are the same instructions which, if unconditional, or conditional and taken, are counted by the PC_WRITE_RETIRED event.

It is IMPLEMENTATION DEFINED whether the following instructions are included as a Software change of the PC, which the counter increments for:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- A conditional UNDEFINED instruction that does not generate an exception.
- A conditional exception-generating instruction, SVC, HVC, or SMC, that does not generate an exception.
- A conditional Context synchronization barrier instruction, ISB, that fails its condition code check.

Note

Many of these instructions can only be conditional in the AArch32 instruction sets.

The counter does not increment for exceptions other than those explicitly identified in these lists.

`0x8108`, **BR_IMMED_TAKEN_RETIRED, Branch instruction architecturally executed, immediate, taken**

The counter counts each instruction counted by both BR_IMMED_RETIRED and PC_WRITE_RETIRED.

These are all direct branch instructions on the architecturally executed path, where the branch is taken.

`0x810C`, **BR_INDNR_TAKEN_RETIRED, Branch instruction architecturally executed, indirect excluding procedure return, taken**

The counter counts each instruction counted by both BR_IND_RETIRED and PC_WRITE_RETIRED, that is not counted by BR_RETURN_RETIRED.

These are all indirect branch instructions, excluding return instructions, on the architecturally executed path, where the branch is taken.

`0x811D`, **BR_IND_RETIRED, Instruction architecturally executed, indirect branch**

The counter counts each architecturally executed indirect branch instruction.

Indirect branch instructions are Software change of the PC instructions other than exception-generating instructions and immediate branch instructions. Software change of the PC has the same definition as for the PC_WRITE_RETIRED and BR_SKIP_RETIRED events. Immediate branch instructions are defined by the BR_IMMED_RETIRED event.

Note

Conditional branches are always counted, regardless of whether the branch is taken.

`0x811F`, **BRB_FILTRATE, Branch Record captured**

The counter counts each valid Branch record captured in the branch record buffer.

Branch records that are not captured because they are removed by filtering are not counted.

When BRB_FILTRATE is generated for an exception or an exception return, it is an Exception-related event.

It is CONSTRAINED UNPREDICTABLE whether the counter counts Branch records injected by a BRB INJ instruction.

If counting this event causes unsigned overflow of the event counter counting the event and this in turn causes a BRBE freeze event then:

- The Branch record for the operation that generated the event will be generated and captured in the Branch record buffer.
- It is CONSTRAINED UNPREDICTABLE whether the Branch Record Buffer Extension generates Branch records for other operations in program order after the operation that generated the event that would otherwise be generated when generation of Branch records is not Paused.

Arm recommends that implementations minimize capture of additional branches.

`0x8179`, **BRNL_INDNR_TAKEN_RETIRED, Branch instruction architecturally executed, indirect branch without link excluding procedure return, taken**

The counter counts each branch counted by BRNL_IND_TAKEN_RETIRED that is not counted by BR_RETURN_RETIRED.

These are all indirect branch without link excluding procedure return instructions on the architecturally executed path, where the branch is taken.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

`0x817A`, **BL_TAKEN_RETIRED, Branch instruction architecturally executed, branch with link, taken**

The counter counts each Software change of the PC counted by PC_WRITE_RETIRED that calls a subroutine and sets LR to return address.

These are all branch with link instructions on the architecturally executed path, where the branch is taken.

`0x817B`, **BRNL_TAKEN_RETIRED, Branch instruction architecturally executed, branch without link, taken**

The counter counts each Software change of the PC counted by PC_WRITE_RETIRED that is not counted by BL_TAKEN_RETIRED.

These are all branch without link instructions on the architecturally executed path, where the branch is taken.

`0x817C`, **BL_IND_TAKEN_RETIRED, Branch instruction architecturally executed, indirect branch with link, taken**

The counter counts each branch counted by both BL_TAKEN_RETIRED and BR_IND_TAKEN_RETIRED.

These are all indirect branch with link instructions on the architecturally executed path, where the branch is taken.

`0x817D`, **BRNL_IND_TAKEN_RETIRED, Branch instruction architecturally executed, indirect branch without link, taken**

The counter counts each branch counted by both BRNL_TAKEN_RETIRED and BR_IND_TAKEN_RETIRED.

These are all indirect branch without link instructions on the architecturally executed path, where the branch is taken.

`0x817E`, **BL_IMMED_TAKEN_RETIRED, Branch instruction architecturally executed, direct branch with link, taken**

The counter counts each branch counted by both BL_TAKEN_RETIRED and BR_IMMED_TAKEN_RETIRED.

These are all direct branch with link instructions on the architecturally executed path, where the branch is taken.

`0x817F`, **BRNL_IMMED_TAKEN_RETIRED, Branch instruction architecturally executed, direct branch without link, taken**

The counter counts each branch counted by both BRNL_TAKEN_RETIRED and BR_IMMED_TAKEN_RETIRED.

These are all direct branch without link instructions on the architecturally executed path, where the branch is taken.

`0x8180`, **BR_UNCOND_RETIRED, Branch instruction architecturally executed, unconditional branch**

The counter counts each Software change of the PC counted by BR_RETIRED that is not counted by BR_COND_RETIRED.

These are all unconditional branch instructions on the architecturally executed path.

`0x8181`, **BR_COND_RETIRED, Branch instruction architecturally executed, conditional branch**

The counter counts each Software change of the PC counted by BR_RETIRED that is a conditional branch.

These are all conditional branch instructions on the architecturally executed path.

In the A64 instruction set, conditional branches are:

- `B.cond`, `CBNZ`, `CBZ`, `TBNZ`, and `TBZ`.

This includes conditional branch instructions with the `AL` or `NV` condition code.

`0x8182`, **BR_COND_TAKEN_RETIRED, Branch instruction architecturally executed, conditional branch, taken**

The counter counts each Software change of the PC counted by both BR_COND_RETIRED and PC_WRITE_RETIRED.

These are all conditional branch instructions on the architecturally executed path, where the branch is taken.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

`0x82A4`, **ASE_SVE_RETIRED, Instruction architecturally executed, Advanced SIMD data processing or SVE data processing**

The counter counts each architecturally executed instruction counted by INST_RETIRED that is classified as an Advanced SIMD data-processing instruction or an SVE data-processing instruction.

See ASE_RETIRED and SVE_RETIRED for these classifications.

`0x82A8`, **LD_ANY_RETIRED, Instruction architecturally executed, load**

The counter counts each architecturally executed instruction counted by LDST_ANY_RETIRED that is classified as a Memory-reading instruction.

It is IMPLEMENTATION DEFINED whether the prefetch instructions counted by PRF_RETIRED are counted as Memory-reading instructions:

- If the prefetch instructions are counted as Memory-reading instructions, then they are counted by LD_RETIRED and LD_ANY_RETIRED.
- Otherwise, if the prefetch instructions are not counted as Memory-reading instructions by LD_ANY_RETIRED, then it is further IMPLEMENTATION DEFINED which one of the following applies:
  - They are counted as data-processing instructions.
  - They are counted by LDST_ANY_RETIRED.

Arm recommends that if a prefetch instruction is not implemented as a NOP and the PRF_RETIRED event is not implemented, then the instruction is counted as a Memory-reading instruction.

`0x82A9`, **ST_ANY_RETIRED, Instruction architecturally executed, store**

The counter counts each architecturally executed instruction counted by LDST_ANY_RETIRED that is classified as a Memory-writing instruction.

`0x82AA`, **LDST_ANY_RETIRED, Instruction architecturally executed, load or store**

The counter counts each architecturally executed instruction counted by INST_RETIRED that is classified as a Memory-reading instruction or a Memory-writing instruction.

See LD_ANY_RETIRED and ST_ANY_RETIRED for these classifications.

If the PRF_RETIRED event is implemented and the prefetch instructions counted by PRF_RETIRED are not counted as Memory-reading instructions by LD_RETIRED and LD_ANY_RETIRED, then it is IMPLEMENTATION DEFINED whether these instructions are counted by LDST_ANY_RETIRED. Arm recommends that these instructions are counted by LDST_ANY_RETIRED.

`0x82AB`, **DP_RETIRED, Instruction architecturally executed, integer data processing**

The counter counts each architecturally executed instruction counted by INST_RETIRED that is classified as an integer data-processing instruction.

An integer data-processing instruction is any instruction that is not counted as any of the following:

- A load or store instruction, counted by LD_RETIRED or ST_RETIRED.
- A Software change of PC instruction, counted by PC_WRITE_RETIRED.
- A scalar floating-point data processing instruction, counted by VFP_RETIRED.
- An Advanced SIMD or SVE data processing instruction, counted by ASE_SVE_RETIRED.
- A cryptographic instruction, counted by CRYPTO_RETIRED.

That is, the following instructions are counted as integer data-processing instructions:

- In AArch64 state:
  - Instructions from Data processing - immediate.
  - Instructions from Data processing - register.
  - Instructions from System register instructions.
  - Instructions from ‘Instructions with register argument’.
  - Instructions from System instructions other than Memory-writing instructions.
  - Instructions from Hint instructions.
  - Instructions from Floating-point move (register) that transfer data between a general-purpose register and a SIMD&FP register without conversion: `FMOV` (general).

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- Instructions from SIMD move that transfer data between a general-purpose register and an element or elements in a SIMD&FP register: `DUP` (general), `SMOV`, `UMOV`, and `INS` (general). This includes the aliases `MOV` (from general) and `MOV` (to general).
- `VDUP` (general-purpose register).
- All `VMOV` instructions that transfer data between a general-purpose register and a SIMD&FP register.
- `VMRS` and `VMSR`.

`0x82AC`, **ASE_RETIRED, Instruction architecturally executed, Advanced SIMD data processing**

The counter counts each architecturally executed instruction counted by ASE_SVE_RETIRED that is classified as an Advanced SIMD data-processing instruction.

The following instructions are counted as Advanced SIMD data-processing instructions:

- For AArch64 state:
  - The SIMD operations listed in Data processing - SIMD and floating-point.
  - Advanced SIMD scalar instructions, including those which operate on floating-point values.
  - If FEAT_Crypto is implemented, the Advanced SIMD `PMULL` and `PMULL2` (1Q variants) instructions. See The Cryptographic Extension in AArch64 state.

This includes all instructions that operate on the SIMD&FP registers, except those that are counted as one of the following:

- Integer data-processing instructions.
- Scalar floating-point data-processing instructions.
- Load or store instructions.
- Cryptographic data-processing instructions counted by CRYPTO_RETIRED. CRYPTO_RETIRED does not count the Cryptographic data-processing instructions included above.

`0x82AD`, **VFP_RETIRED, Instruction architecturally executed, scalar floating-point data processing**

The counter counts each architecturally executed instruction counted by INST_RETIRED that is classified as a scalar floating-point instruction.

The following instructions are counted as scalar floating-point data-processing instructions:

- In AArch64 state:
  - The scalar floating-point instructions from Data processing - SIMD and floating-point. Only the scalar instructions are counted. SIMD floating-point instructions are not counted.
  - Instructions that take both an integer register and a floating-point register argument and perform a type conversion (to/from integer or to/from fixed-point): `FCVT{<mode>}`, `UCVTF`, and `SCVTF`.

This includes all scalar instructions that operate on the SIMD&FP registers as floating-point values, except those that are counted as one of the following:

- SIMD scalar instructions.
- Integer data-processing instructions.
- Load or store instructions.

`0x82AF`, **CRYPTO_RETIRED, Instruction architecturally executed, cryptographic data processing**

The counter counts each architecturally executed instruction counted by INST_RETIRED that is classified as a cryptographic instruction.

The following instructions are counted as cryptographic data-processing instructions:

- In AArch64 state, instructions from The Cryptographic Extension in AArch64 state other than the include Advanced SIMD `PMULL` and `PMULL2` (1Q variants) instructions.

`0x82B3`, **PRF_RETIRED, Instruction architecturally executed, prefetch**

The counter counts each architecturally executed prefetch instruction counted by INST_RETIRED.

`0x8359`, **SE_RETIRED, Instruction architecturally executed, Advanced SIMD, SVE, or SME data processing**

The counter counts each architecturally executed instruction counted by INST_RETIRED that is classified as an Advanced SIMD, SVE, or SME data-processing instruction.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

See ASE_SVE_RETIRED and SME_RETIRED for these classifications.

`0x835B`**, SE_INST_RETIRED, Instruction architecturally executed, Advanced SIMD, SVE, or SME**

The counter counts each architecturally executed instruction counted by INST_RETIRED that is classified as an Advanced SIMD, SVE, or SME instruction.

See ASE_SVE_INST_RETIRED and SME_INST_RETIRED for these classifications.

TRB_TRIG, Trace buffer Trigger Event

The counter counts each trace buffer Trigger Event.

It is IMPLEMENTATION DEFINED whether this event can be counted by the PMU.

PMCEID0_EL0[46] reads as 1 if this event is implemented and can be counted by the PMU, and 0 otherwise.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D9.3.2 Common microarchitectural events

The Common microarchitectural events are:

`0x0001`, **L1I_CACHE_REFILL, Level 1 instruction cache refill**

The counter counts each access counted by L1I_CACHE that causes a refill of the Level 1 instruction or unified cache from outside of the Level 1 instruction or unified cache.

A refill includes any access that causes data to be fetched from outside of the Level 1 caches, even if the data is ultimately not allocated into the Level 1 instruction cache. For example, data might be fetched into a buffer but then discarded, rather than being allocated into a cache. These buffers are treated as part of the cache.

For example, the counter counts accesses to the Level 1 instruction cache that cause a refill that is satisfied by fetching data from memory, a Level 2 cache, or a Level 1 cache of another PE.

The counter does not count accesses that miss in the cache but are satisfied by the refill of a previous miss and do not cause a new refill, even if that previous refill is not complete at the time of the miss.

It is IMPLEMENTATION DEFINED whether accesses that result from cache maintenance instructions are counted.

If the cache is shared and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the cache is shared by PEs other than the PEs in the multithreaded processor and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of PMEVTYPER<n>_EL0.MT.

PMCEID0_EL0[1] reads as 1 if this event is implemented and 0 otherwise.

`0x0002`, **L1I_TLB_REFILL, Level 1 instruction TLB refill**

The counter counts each Instruction memory access counted by L1I_TLB that causes a TLB refill of the Level 1 instruction TLB.

This includes each Instruction memory access that causes a memory access due to a translation table walk or an access to another level of TLB caching.

The counter does not count the access if any of the following are true:

- The access is due to a TLB maintenance instruction.
- The access generates a Translation fault because the applicable TCR_ELx.EPDy bit is 1.
- FEAT_E0PD is implemented and the access is an unprivileged access that generates a Translation fault because the applicable TCR_ELx.E0PDy bit is 1.

It is IMPLEMENTATION DEFINED whether the counter counts the access if any of the following are true:

- The access misses in the TLB and generates a translation table walk, but the result is not allocated into the TLB for any reason other than a Translation fault.
- The access generates a Translation fault for any other reason.

If the TLB is shared and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of PMEVTYPER<n>_EL0.MT.

PMCEID0_EL0[2] reads as 1 if this event is implemented and 0 otherwise.

`0x0003`, **L1D_CACHE_REFILL, Level 1 data cache refill**

The counter counts each access counted by L1D_CACHE that causes a refill of the Level 1 data or unified cache from outside of the Level 1 data or unified cache.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

A refill includes any access that causes data to be fetched from outside of the Level 1 caches, even if the data is ultimately not allocated into the Level 1 data cache. For example, data might be fetched into a buffer but then discarded, rather than being allocated into a cache. These buffers are treated as part of the cache.

For example, the counter counts accesses to the Level 1 data cache that cause a refill that is satisfier by fetching data from memory, a Level 2 cache, or a Level 1 cache of another PE.

The counter does not count accesses that:

- Miss in the cache but are satisfied by the refill of a previous miss and do not cause a new refill, even if that previous refill is not complete at the time of the miss.
- Miss in the cache but do not generate a refill, such as a write through the cache.

It is IMPLEMENTATION DEFINED whether accesses that result from cache maintenance instructions are counted.

If the cache is shared and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the cache is shared by PEs other than the PEs in the multithreaded processor and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of PMEVTYPER<n>_EL0.MT.

PMCEID0_EL0[3] reads as 1 if this event is implemented and 0 otherwise.

`0x0004`**, L1D_CACHE, Level 1 data cache access**

The counter counts each Memory-read operation or Memory-write operation that causes a cache access to at least the Level 1 data or unified cache.

Each access to a cache line is counted including the multiple accesses caused by single instructions such as `LDM` or `STM`. Each access to other Level 1 data or unified memory structures, for example refill buffers, write buffers, and write-back buffers, is also counted.

It is IMPLEMENTATION DEFINED whether accesses that result from cache maintenance instructions are counted.

If FEAT_PMUv3p4 is implemented, accesses that only update the cache status information for a cache entry without accessing the content of the cache entry are not counted.

If FEAT_PMUv3p4 is not implemented, it is IMPLEMENTATION DEFINED whether accesses that only update the cache status information for a cache entry without accessing the content of the cache entry are counted.

An example of cache status information is whether the cached data is held in an exclusive or shared state.

When the L1D_CACHE_RW event is implemented:

- If the L1D_CACHE_PRFM event is implemented, accesses to the Level 1 data cache due to a prefetch instruction are counted. Otherwise, these accesses are not counted.
- If the L1D_CACHE_HWPRF event is implemented, accesses to the Level 1 data cache due to a hardware prefetcher are counted. Otherwise these accesses are not counted.

When the L1D_CACHE_RW event is not implemented, it IMPLEMENTATION DEFINED whether accesses to the Level 1 data cache due to prefetch instructions or due to a hardware prefetcher are counted.

If the cache is shared and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the cache is shared by PEs other than the PEs in the multithreaded processor and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of PMEVTYPER<n>_EL0.MT.

PMCEID0_EL0[4] reads as 1 if this event is implemented and 0 otherwise.

`0x0005`**, L1D_TLB_REFILL, Level 1 data TLB refill**

The counter counts each access counted by L1D_TLB that causes a TLB refill of the Level 1 data or unified TLB.

This includes each access that causes a memory access due to a translation table walk or an access to another level of TLB caching.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The counter does not count the access if any of the following are true:

- The access is due to a TLB maintenance instruction.
- The access generates a Translation fault because the applicable TCR_ELx.EPDy bit is 1.
- FEAT_E0PD is implemented and the access is an unprivileged access that generates a Translation fault because the applicable TCR_ELx.E0PDy bit is 1.

It is IMPLEMENTATION DEFINED whether the counter counts the access if any of the following are true:

- The access misses in the TLB and generates a translation table walk, but the result is not allocated into the TLB for any reason other than a Translation fault.
- The access generates a Translation fault for any other reason.

If the TLB is shared and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of PMEVTYPER<n>_EL0.MT.

PMCEID0_EL0[5] reads as 1 if this event is implemented and 0 otherwise.

`0x0010`**, BR_MIS_PRED, Branch instruction speculatively executed, mispredicted or not predicted**

The counter counts each correction to the predicted program flow that occurs because of a misprediction from, or no prediction from, the branch prediction resources and that relates to instructions that the branch prediction resources are capable of predicting.

If no program-flow prediction resources are implemented, Arm recommends that the counter counts all branches that are not taken.

PMCEID0_EL0[16] reads as 1 if this event is implemented and 0 otherwise.

`0x0011`**, CPU_CYCLES, Cycle**

The counter increments on every cycle.

All counters are subject to changes in clock frequency, including when a `WFI` or `WFE` instruction stops the clock. This means that it is CONSTRAINED UNPREDICTABLE whether or not CPU_CYCLES continues to increment when the clocks are stopped by `WFI` and `WFE` instructions.

Note

Unlike PMCCNTR_EL0, this count is not affected by the cycle counter controls:

- The counter is not incremented in prohibited regions, so is not affected by PMCR_EL0.DP.
- The counter increments on every cycle, regardless of the value of PMCR_EL0.D.
- The counter is reset when event counters are reset by PMCR_EL0.P, never by PMCR_EL0.C.

In a multithreaded implementation:

- If the Effective value of PMEVTYPER<n>_EL0.MT for the event counter is 0, then the counter counts each Processor cycle when the counting PE is active.
- If the Effective value of PMEVTYPER<n>_EL0.MT for the event counter is 1, then the counter counts each Processor cycle.

PMCEID0_EL0[17] reads as 1 if this event is implemented and 0 otherwise.

`0x0012`**, BR_PRED, Predictable branch instruction speculatively executed**

The counter counts each branch or other change in the program flow that the branch prediction resources are capable of predicting.

If all branches are subject to prediction, for example a BTB or BTAC, then all branches are predictable branches.

If branches are decoded before the predictor, so that the branch prediction logic dynamically predicts only some branches, for example conditional and indirect branches, then it is IMPLEMENTATION DEFINED whether other branches are counted as predictable branches. Arm recommends that all branches are counted.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

An implementation might include other structures that predict branches, such as a loop buffer that predicts short backwards direct branches as taken. Each execution of such a branch is a predictable branch. Terminating the loop might generate a misprediction event that is counted by BR_MIS_PRED.

If no program-flow prediction resources are implemented, this event is optional, but Arm recommends that BR_PRED counts all branches.

It is IMPLEMENTATION DEFINED when the branch is counted. Arm recommends that it is counted when the branch is resolved, that is, at the same point in the instruction pipeline as when the BR_MIS_PRED event would be counted if the branch resolves as mispredicted. This means that (BR_PRED - BR_MIS_PRED) is the number of correctly predicted branches and the ratio (BR_MIS_PRED ÷ BR_PRED) can be calculated in a meaningful way.

PMCEID0_EL0[18] reads as 1 if this event is implemented and 0 otherwise.

`0x0013`**, MEM_ACCESS, Data memory access**

The counter counts each Memory-read operation or Memory-write operation that the PE makes.

The counter increments whether the access results in an access to a Level 1 data or unified cache, a Level 2 data or unified cache, or neither of these.

The number of accesses generated by each instruction is IMPLEMENTATION DEFINED.

The counter does not count:

- Instruction memory accesses.
- Translation table walks.
- Write-back from any cache.
- Refilling of any cache.

It is IMPLEMENTATION DEFINED whether accesses that result from cache maintenance instructions are counted.

PMCEID0_EL0[19] reads as 1 if this event is implemented and 0 otherwise.

`0x0014`**, L1I_CACHE, Level 1 instruction cache access**

The counter counts each Instruction memory access to at least the Level 1 instruction or unified cache.

Each Instruction memory access to other Level 1 instruction or unified memory structures, such as refill buffers, is also counted.

It is IMPLEMENTATION DEFINED whether accesses that result from cache maintenance instructions are counted.

If FEAT_PMUv3p4 is implemented, accesses that only update the cache status information for a cache entry without accessing the content of the cache entry are not counted.

If FEAT_PMUv3p4 is not implemented, it is IMPLEMENTATION DEFINED whether accesses that only update the cache status information for a cache entry without accessing the content of the cache entry are counted.

An example of cache status information is whether the cached data is held in an exclusive or shared state.

When the L1I_CACHE_RD event is implemented:

- If the L1I_CACHE_PRFM event is implemented, accesses to the Level 1 instruction cache due to a prefetch instruction are counted. Otherwise, these are not counted.
- If the L1I_CACHE_HWPRF event is implemented, accesses to the Level 1 instruction cache due to a hardware prefetcher are counted. Otherwise these events are not counted.

When the L1I_CACHE_RD event is not implemented, it IMPLEMENTATION DEFINED whether accesses to the Level 1 instruction cache due to prefetch instructions or due to a hardware prefetcher are counted.

If the cache is shared and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the cache is shared by PEs other than the PEs in the multithreaded processor and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of PMEVTYPER<n>_EL0.MT.

PMCEID0_EL0[20] reads as 1 if this event is implemented and 0 otherwise.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

`0x0015`**, L1D_CACHE_WB, Level 1 data cache write-back**

The counter counts each write-back of data from the Level 1 data or unified cache to outside of the Level 1 caches.

For example:

- A write-back of a dirty cache line to a Level 2 cache or memory.
- A write-back of a recently fetched cache line that has not been allocated to the Level 1 data cache.

Each write-back is counted once, even if multiple accesses are required to complete the write-back.

It is IMPLEMENTATION DEFINED whether the counter counts:

- A transfer of a dirty cache line from the Level 1 data cache to outside of Level 1 caches made as a result of a coherency request.
- Write-backs made as a result of cache maintenance instructions.

The counter does not count:

- The invalidation of a cache line without any write-back to outside of the Level 1 caches or memory.
- Writes that write through the Level 1 data cache to outside of the Level 1 caches.

A write-back is attributable to the agent that generated the request that caused the write-back. This might not be the same agent that caused the data being written back to be allocated into the cache.

An Unattributable write-back event occurs when a requestor outside of the PE makes a coherency request that results in write-back. If the cache is shared, then an Unattributable write-back event is not counted. If the cache is not shared, then the event is counted.

It is IMPLEMENTATION DEFINED whether a write of a whole cache line that is not the result of the eviction of a line from the cache, is counted. For example, this applies when the PE determines software is streaming writes to memory and does not allocate lines to the cache, or by a `DC ZVA` operation.

PMCEID0_EL0[21] reads as 1 if this event is implemented and 0 otherwise.

`0x0016`**, L2D_CACHE, Level 2 data cache access**

The counter counts each Memory-read operation or Memory-write operation that causes a cache access to at least the Level 2 data or unified cache.

Each access to a cache line is counted including refills of and write-backs from other caches. Each access to other Level 2 data or unified memory structures, for example refill buffers, write buffers, and write-back buffers, is also counted.

It is IMPLEMENTATION DEFINED whether accesses that result from cache maintenance instructions are counted.

If FEAT_PMUv3p4 is implemented, accesses that only update the cache status information for a cache entry without accessing the content of the cache entry are not counted.

If FEAT_PMUv3p4 is not implemented, it is IMPLEMENTATION DEFINED whether accesses that only update the cache status information for a cache entry without accessing the content of the cache entry are counted.

An example of cache status information is whether the cached data is held in an exclusive or shared state.

When the L2D_CACHE_RW event is implemented:

- If the L2D_CACHE_PRFM event is implemented, accesses to the Level 2 data cache due to a prefetch instruction are counted. Otherwise, these accesses are not counted.
- If the L2D_CACHE_HWPRF event is implemented, accesses to the Level 2 data cache due to a hardware prefetcher are counted. Otherwise these accesses are not counted.

When the L2D_CACHE_RW event is not implemented, it IMPLEMENTATION DEFINED whether accesses to the Level 2 data cache due to prefetch instructions or due to a hardware prefetcher are counted.

If the cache is shared and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the cache is shared by PEs other than the PEs in the multithreaded processor and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

PE counting the event or all events are counted, and might depend on the Effective value of PMEVTYPER<n>_EL0.MT.

PMCEID0_EL0[22] reads as 1 if this event is implemented and 0 otherwise.

0x0017, L2D_CACHE_REFILL, Level 2 data cache refill

The counter counts each access counted by L2D_CACHE that causes a refill of the Level 2 data or unified cache, or any Level 1 data, instruction, or unified cache of this PE, from outside of those caches.

A refill includes any access that causes data to be fetched from outside of the Level 1 and Level 2 caches, even if the data is ultimately not allocated into the Level 2 data cache. For example, data might be fetched into a buffer but then discarded, rather than being allocated into a cache. These buffers are treated as part of the cache.

For example, the counter counts:

- Accesses to the Level 2 data cache that cause a refill that is satisfier by fetching data from memory, a Level 3 cache, or a Level 2 cache of another PE.
- Refills of and write-backs from any Level 1 data, instruction, or unified cache of this PE that cause a refill from outside of the Level 1 and Level 2 caches of this PE.
- Accesses to the Level 2 data cache that cause a refill of a Level 1 cache of this PE from outside of the Level 1 and Level 2 caches of this PE, even if there is no refill of the Level 2 data cache.

The counter does not count accesses that:

- Miss in the cache but are satisfied by the refill of a previous miss and do not cause a new refill, even if that previous refill is not complete at the time of the miss.
- Miss in the cache but do not generate a refill, such as a write through the cache.

It is IMPLEMENTATION DEFINED whether accesses that result from cache maintenance instructions are counted.

If the cache is shared and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the cache is shared by PEs other than the PEs in the multithreaded processor and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of PMEVTYPER<n>_EL0.MT.

PMCEID0_EL0[23] reads as 1 if this event is implemented and 0 otherwise.

0x0018, L2D_CACHE_WB, Level 2 data cache write-back

The counter counts each write-back of data from the Level 2 data or unified cache to outside of the Level 1 and Level 2 caches.

For example:

- A write-back of a dirty cache line to a Level 3 cache or memory.
- A write-back of a recently fetched cache line that has not been allocated to the Level 2 data cache.

Each write-back is counted once, even if multiple accesses are required to complete the write-back.

It is IMPLEMENTATION DEFINED whether the counter counts:

- A transfer of a dirty cache line from the Level 2 data cache to outside of Level 1 and Level 2 caches made as a result of a coherency request.
- Write-backs made as a result of cache maintenance instructions.

The counter does not count:

- The invalidation of a cache line without any write-back to outside of the Level 1 and Level 2 caches or memory.
- Writes that write through the Level 2 data cache to outside of the Level 1 and Level 2 caches.
- Transfers of data from the Level 2 data cache to a Level 1 cache to satisfy a refill of the other cache.

A write-back is attributable to the agent that generated the request that caused the write-back. This might not be the same agent that caused the data being written back to be allocated into the cache.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

An Unattributable write-back event occurs when a requestor outside of the PE makes a coherency request that results in write-back. If the cache is shared, then an Unattributable write-back event is not counted. If the cache is not shared, then the event is counted.

It is IMPLEMENTATION DEFINED whether a write of a whole cache line that is not the result of the eviction of a line from the cache, is counted. For example, this applies when the PE determines software is streaming writes to memory and does not allocate lines to the cache, or by a `DC ZVA` operation.

PMCEID0_EL0[24] reads as 1 if this event is implemented and 0 otherwise.

`0x0019`**, BUS_ACCESS, Bus access**

The counter counts each Memory-read operation or Memory-write operation that accesses outside of the boundary of the PE and its closely-coupled caches.

Where this boundary lies with respect to any implemented caches is IMPLEMENTATION DEFINED. Where an implementation has multiple buses at this boundary, this event counts the sum of accesses across all buses.

A bus access is part of a bus transaction. The exact nature of a bus transaction is IMPLEMENTATION DEFINED, but for the purposes of event monitoring consists of a single access comprising one or more cycles, or beats, when the transaction occupies the bus. The BUS_ACCESS event counts each beat of each transaction. That is, each bus cycle counted by BUS_CYCLES for which the bus is active.

Bus transactions include refills of and write-backs from data, instruction, and unified caches. Whether bus transactions include operations that use the bus but do not explicitly transfer data is IMPLEMENTATION DEFINED.

An Unattributable bus transaction occurs when a requestor outside the PE makes a request that results in a bus access, for example, a coherency request.

If a bus supports multiple accesses per cycle, for example through multiple channels, the counter increments once for each channel that is active on a cycle, and so it might increment by more than one in any given cycle.

The maximum increment in any given cycle is IMPLEMENTATION DEFINED.

PMCEID0_EL0[25] reads as 1 if this event is implemented and 0 otherwise.

`0x001A`**, MEMORY_ERROR, Local memory error**

The counter counts each occurrence of a memory error signaled by a memory closely coupled to this PE.

The definition of local memories is IMPLEMENTATION DEFINED but includes caches, tightly-coupled memories, and TLB arrays.

Memory error refers to a physical error detected by the hardware, such as a parity or ECC error. It includes errors that are correctable and those that are not. It does not include errors as defined in the architecture, such as MMU faults.

PMCEID0_EL0[26] reads as 1 if this event is implemented and 0 otherwise.

`0x001B`**, INST_SPEC, Operation speculatively executed**

The counter counts each speculatively executed instruction.

This includes instructions that are subsequently not architecturally executed.

PMCEID0_EL0[27] reads as 1 if this event is implemented and 0 otherwise.

`0x001D`**, BUS_CYCLES, Bus cycle**

The counter increments on every cycle of the interface at the boundary of the PE and its closely-coupled caches. Where this boundary lies with respect to any implemented caches is IMPLEMENTATION DEFINED.

Note

If the implementation clocks the external memory interface at the same rate as the processor hardware, then the counter counts every cycle.

PMCEID0_EL0[29] reads as 1 if this event is implemented and 0 otherwise.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

`0x001F`, **L1D_CACHE_ALLOCATE, Level 1 data cache allocation without refill**

The counter counts each Memory-write operation that writes an entire line into the Level 1 data or unified cache without fetching data from outside the Level 1 data or unified cache.

These are allocations of cache lines in the Level 1 data or unified cache that are not refills counted by L1D_CACHE_REFILL. For example:

- A write of an entire cache line from a coalescing write buffer.
- An operation such as `DC ZVA`.

The counter counts only Memory-write operations Attributable to the PE counting the event, and, if the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 1, other PEs in the multithreaded implementation.

PMCEID0_EL0[31] reads as 1 if this event is implemented and 0 otherwise.

`0x0020`, **L2D_CACHE_ALLOCATE, Level 2 data cache allocation without refill**

The counter counts each Memory-write operation that writes an entire line into the Level 2 data or unified cache without fetching data from outside the Level 2 data or unified cache.

These are allocations of cache lines in the Level 2 data or unified cache that are not refills counted by L2D_CACHE_REFILL. For example:

- A write-back of an entire cache line from a Level 1 cache to the Level 2 data cache.
- A write of an entire cache line from a coalescing write buffer.
- An operation such as `DC ZVA`.

The counter counts only Memory-write operations Attributable to the PE counting the event, and, if the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 1, other PEs in the multithreaded implementation.

PMCEID1_EL0[0] reads as 1 if this event is implemented and 0 otherwise.

`0x0022`, **BR_MIS_PRED_RETIRED, Branch instruction architecturally executed, mispredicted**

The counter counts each branch instruction counted by BR_RETIRED that was not correctly predicted.

If no program-flow prediction resources are implemented, this event counts all retired not-taken branches.

PMCEID1_EL0[2] reads as 1 if this event is implemented and 0 otherwise.

`0x0023`, **STALL_FRONTEND, No operation sent for execution due to the frontend**

The counter counts each cycle counted by CPU_CYCLES where no Attributable instruction or operation was sent for execution and there was no Attributable instruction or operation available to dispatch for the PE from the frontend.

The division between frontend and backend is IMPLEMENTATION DEFINED. All STALL events are counted at the same point in the pipeline.

Note

- For a simplified pipeline model of Fetch-Decode-Issue-Execute-Retire, Arm recommends that the events are counted when instructions are dispatched from Decode to Issue.
- In a single cycle, both the STALL_BACKEND and STALL_FRONTEND events might be counted, if both the backend is unable to accept any operations and there are no operations available to issue from the frontend.

PMCEID1_EL0[3] reads as 1 if this event is implemented and 0 otherwise.

`0x0024`, **STALL_BACKEND, No operation sent for execution due to the backend**

The counter counts each cycle counted by CPU_CYCLES where Attributable instructions or operations for the PE are available to dispatch from the frontend to the backend, but no Attributable instruction or operation is sent for execution because the backend is unable to accept any of the instructions or operations available for the PE.

For example, the backend might be unable to accept operations because of a resource conflict or non-availability.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

It is IMPLEMENTATION DEFINED whether the counter also counts each cycle counted by CPU_CYCLES where no Attributable instructions or operations for the PE are available to dispatch from the frontend and the backend is unable to accept any instructions or operations for the PE.

The division between frontend and backend is IMPLEMENTATION DEFINED. For more information, see STALL_FRONTEND. All STALL events are counted at the same point in the pipeline.

Note

In a single cycle, both the STALL_BACKEND and STALL_FRONTEND events might be counted, if both the backend is unable to accept any operations and there are no operations available to issue from the frontend.

PMCEID1_EL0[4] reads as 1 if this event is implemented and 0 otherwise.

`0x0025`**, L1D_TLB, Level 1 data TLB access**

The counter counts each Memory-read operation or Memory-write operation that causes a TLB access to at least the Level 1 data or unified TLB.

Each access to a TLB entry is counted including multiple accesses caused by single instructions such as LDM or STM.

The counter does not count the access if the access is due to a TLB maintenance instruction.

If the TLB is shared and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of PMEVTYPER<n>_EL0.MT.

PMCEID1_EL0[5] reads as 1 if this event is implemented and 0 otherwise.

`0x0026`**, L1I_TLB, Level 1 instruction TLB access**

The counter counts each Instruction memory access that causes a TLB access to at least the Level 1 instruction TLB.

The counter does not count the access if the access is due to a TLB maintenance instruction.

If the TLB is shared and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of PMEVTYPER<n>_EL0.MT.

PMCEID1_EL0[6] reads as 1 if this event is implemented and 0 otherwise.

`0x0027`**, L2I_CACHE, Level 2 instruction cache access**

The counter counts each Instruction memory access to at least the Level 2 instruction or unified cache.

Each Instruction memory access to other Level 2 instruction or unified memory structures, such as refill buffers, is also counted.

It is IMPLEMENTATION DEFINED whether accesses that result from cache maintenance instructions are counted.

If FEAT_PMUv3p4 is implemented, accesses that only update the cache status information for a cache entry without accessing the content of the cache entry are not counted.

If FEAT_PMUv3p4 is not implemented, it is IMPLEMENTATION DEFINED whether accesses that only update the cache status information for a cache entry without accessing the content of the cache entry are counted.

An example of cache status information is whether the cached data is held in an exclusive or shared state.

When the L2I_CACHE_RD event is implemented:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- If the L2I_CACHE_PRFM event is implemented, accesses to the Level 2 instruction cache due to a prefetch instruction are counted. Otherwise, these are not counted.
- If the L2I_CACHE_HWPRF event is implemented, accesses to the Level 2 instruction cache due to a hardware prefetcher are counted. Otherwise these events are not counted.

When the L2I_CACHE_RD event is not implemented, it IMPLEMENTATION DEFINED whether accesses to the Level 2 instruction cache due to prefetch instructions or due to a hardware prefetcher are counted.

If the cache is shared and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the cache is shared by PEs other than the PEs in the multithreaded processor and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of PMEVTYPER<n>_EL0.MT.

PMCEID1_EL0[7] reads as 1 if this event is implemented and 0 otherwise.

`0x0028`**, L2I_CACHE_REFILL, Level 2 instruction cache refill**

The counter counts each access counted by L2I_CACHE that causes a refill of the Level 2 instruction or unified cache, or any Level 1 data, instruction, or unified cache of this PE, from outside of those caches.

A refill includes any access that causes data to be fetched from outside of the Level 1 and Level 2 caches, even if the data is ultimately not allocated into the Level 2 instruction cache. For example, data might be fetched into a buffer but then discarded, rather than being allocated into a cache. These buffers are treated as part of the cache.

For example, the counter counts:

- Accesses to the Level 2 instruction cache that cause a refill that is satisfied by fetching data from memory, a Level 3 cache, or a Level 2 cache of another PE.
- Refills of any Level 1 instruction or unified cache of this PE that cause a refill from outside of the Level 1 and Level 2 caches of this PE.
- Accesses to the Level 2 instruction cache that cause a refill of a Level 1 cache of this PE from outside of the Level 1 and Level 2 caches of this PE, even if there is no refill of the Level 2 instruction cache.

The counter does not count accesses that miss in the cache but are satisfied by the refill of a previous miss and do not cause a new refill, even if that previous refill is not complete at the time of the miss.

It is IMPLEMENTATION DEFINED whether accesses that result from cache maintenance instructions are counted.

If the cache is shared and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the cache is shared by PEs other than the PEs in the multithreaded processor and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of PMEVTYPER<n>_EL0.MT.

PMCEID1_EL0[8] reads as 1 if this event is implemented and 0 otherwise.

`0x0029`**, L3D_CACHE_ALLOCATE, Level 3 data cache allocation without refill**

The counter counts each Memory-write operation that writes an entire line into the Level 3 data or unified cache without fetching data from outside the Level 3 data or unified cache.

These are allocations of cache lines in the Level 3 data or unified cache that are not refills counted by L3D_CACHE_REFILL. For example:

- A write-back of an entire cache line from a Level 2 cache to the Level 3 data cache.
- A write of an entire cache line from a coalescing write buffer.
- An operation such as `DC ZVA`.

The counter counts only Memory-write operations Attributable to the PE counting the event, and, if the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 1, other PEs in the multithreaded implementation.

PMCEID1_EL0[9] reads as 1 if this event is implemented and 0 otherwise.

`0x002A`**, L3D_CACHE_REFILL, Level 3 data cache refill**

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The counter counts each access counted by L3D_CACHE that causes a refill of the Level 3 data or unified cache, or any Level 1 or Level 2 data, instruction, or unified cache of this PE, from outside of those caches.

A refill includes any access that causes data to be fetched from outside of the Level 1 to Level 3 caches, even if the data is ultimately not allocated into the Level 3 data cache. For example, data might be fetched into a buffer but then discarded, rather than being allocated into a cache. These buffers are treated as part of the cache.

For example, the counter counts:

- Accesses to the Level 3 data cache that cause a refill that is satisfier by fetching data from memory, a lower level cache, or a Level 3 cache of another PE.
- Refills of and write-backs from any Level 1 or Level 2 data, instruction, or unified caches of this PE that cause a refill from outside of the Level 1 to Level 3 caches of this PE.
- Accesses to the Level 3 data cache that cause a refill of a Level 2 cache of this PE from outside of the Level 1 to Level 3 caches of this PE, even if there is no refill of the Level 3 data cache.

The counter does not count accesses that:

- Miss in the cache but are satisfied by the refill of a previous miss and do not cause a new refill, even if that previous refill is not complete at the time of the miss.
- Miss in the cache but do not generate a refill, such as a write through the cache.

It is IMPLEMENTATION DEFINED whether accesses that result from cache maintenance instructions are counted.

If the cache is shared and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the cache is shared by PEs other than the PEs in the multithreaded processor and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of PMEVTYPER<n>_EL0.MT.

PMCEID1_EL0[10] reads as 1 if this event is implemented and 0 otherwise.

`0x002B`**, L3D_CACHE, Level 3 data cache access**

The counter counts each Memory-read operation or Memory-write operation that causes a cache access to at least the Level 3 data or unified cache.

Each access to a cache line is counted including refills of and write-backs from other caches. Each access to other Level 3 data or unified memory structures, for example refill buffers, write buffers, and write-back buffers, is also counted.

It is IMPLEMENTATION DEFINED whether accesses that result from cache maintenance instructions are counted.

If FEAT_PMUv3p4 is implemented, accesses that only update the cache status information for a cache entry without accessing the content of the cache entry are not counted.

If FEAT_PMUv3p4 is not implemented, it is IMPLEMENTATION DEFINED whether accesses that only update the cache status information for a cache entry without accessing the content of the cache entry are counted.

An example of cache status information is whether the cached data is held in an exclusive or shared state.

When the L3D_CACHE_RW event is implemented:

- If the L3D_CACHE_PRFM event is implemented, accesses to the Level 3 data cache due to a prefetch instruction are counted. Otherwise, these accesses are not counted.
- If the L3D_CACHE_HWPRF event is implemented, accesses to the Level 3 data cache due to a hardware prefetcher are counted. Otherwise these accesses are not counted.

When the L3D_CACHE_RW event is not implemented, it IMPLEMENTATION DEFINED whether accesses to the Level 3 data cache due to prefetch instructions or due to a hardware prefetcher are counted.

If the cache is shared and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the cache is shared by PEs other than the PEs in the multithreaded processor and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of PMEVTYPER<n>_EL0.MT.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

PMCEID1_EL0[11] reads as 1 if this event is implemented and 0 otherwise.

`0x002C`, **L3D_CACHE_WB, Level 3 data cache write-back**

The counter counts each write-back of data from the Level 3 data or unified cache to outside of the Level 1 to Level 3 caches.

For example:

- A write-back of a dirty cache line to a lower level cache or memory.
- A write-back of a recently fetched cache line that has not been allocated to the Level 3 data cache.

Each write-back is counted once, even if multiple accesses are required to complete the write-back.

It is IMPLEMENTATION DEFINED whether the counter counts:

- A transfer of a dirty cache line from the Level 3 data cache to outside of Level 1 to Level 3 caches made as a result of a coherency request.
- Write-backs made as a result of cache maintenance instructions.

The counter does not count:

- The invalidation of a cache line without any write-back to outside of the Level 1 to Level 3 caches or memory.
- Writes that write through the Level 3 data cache to outside of the Level 1 to Level 3 caches.
- Transfers of data from the Level 3 data cache to a Level 1 or Level 2 cache to satisfy a refill of the other cache.

A write-back is attributable to the agent that generated the request that caused the write-back. This might not be the same agent that caused the data being written back to be allocated into the cache.

An Unattributable write-back event occurs when a requestor outside of the PE makes a coherency request that results in write-back. If the cache is shared, then an Unattributable write-back event is not counted. If the cache is not shared, then the event is counted.

It is IMPLEMENTATION DEFINED whether a write of a whole cache line that is not the result of the eviction of a line from the cache, is counted. For example, this applies when the PE determines software is streaming writes to memory and does not allocate lines to the cache, or by a `DC ZVA` operation.

PMCEID1_EL0[12] reads as 1 if this event is implemented and 0 otherwise.

`0x002D`, **L2D_TLB_REFILL, Level 2 data TLB refill**

The counter counts each access counted by L2D_TLB that causes a TLB refill of the Level 2 data or unified TLB, or any Level 1 data, instruction, or unified TLBs of this PE.

This includes each access that causes a memory access due to a translation table walk or an access to another level of TLB caching.

The counter does not count the access if any of the following are true:

- The access is due to a TLB maintenance instruction.
- The access generates a Translation fault because the applicable TCR_ELx.EPDy bit is 1.
- FEAT_E0PD is implemented and the access is an unprivileged access that generates a Translation fault because the applicable TCR_ELx.E0PDy bit is 1.

It is IMPLEMENTATION DEFINED whether the counter counts the access if any of the following are true:

- The access misses in the TLB and generates a translation table walk, but the result is not allocated into the TLB for any reason other than a Translation fault.
- The access generates a Translation fault for any other reason.

If the TLB is shared and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of PMEVTYPER<n>_EL0.MT.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

PMCEID1_EL0[13] reads as 1 if this event is implemented and 0 otherwise.

`0x002E`, **L2I_TLB_REFILL, Level 2 instruction TLB refill**

The counter counts each Instruction memory access counted by L2I_TLB that causes a TLB refill of the Level 2 instruction TLB, or any Level 1 data, instruction, or unified TLBs of this PE.

This includes each Instruction memory access that causes a memory access due to a translation table walk or an access to another level of TLB caching.

The counter does not count the access if any of the following are true:

- The access is due to a TLB maintenance instruction.
- The access generates a Translation fault because the applicable TCR_ELx.EPDy bit is 1.
- FEAT_E0PD is implemented and the access is an unprivileged access that generates a Translation fault because the applicable TCR_ELx.E0PDy bit is 1.

It is IMPLEMENTATION DEFINED whether the counter counts the access if any of the following are true:

- The access misses in the TLB and generates a translation table walk, but the result is not allocated into the TLB for any reason other than a Translation fault.
- The access generates a Translation fault for any other reason.

If the TLB is shared and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of PMEVTYPER<n>_EL0.MT.

PMCEID1_EL0[14] reads as 1 if this event is implemented and 0 otherwise.

`0x002F`, **L2D_TLB, Level 2 data TLB access**

The counter counts each Memory-read operation or Memory-write operation that causes a TLB access to at least the Level 2 data or unified TLB.

Each access to a TLB entry is counted including refills of Level 1 TLBs.

The counter does not count the access if the access is due to a TLB maintenance instruction.

If the TLB is shared and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of PMEVTYPER<n>_EL0.MT.

PMCEID1_EL0[15] reads as 1 if this event is implemented and 0 otherwise.

`0x0030`, **L2I_TLB, Level 2 instruction TLB access**

The counter counts each Instruction memory access that causes a TLB access to at least the Level 2 instruction TLB.

The counter does not count the access if the access is due to a TLB maintenance instruction.

If the TLB is shared and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of PMEVTYPER<n>_EL0.MT.

PMCEID1_EL0[16] reads as 1 if this event is implemented and 0 otherwise.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

`0x0031`, **REMOTE_ACCESS, Access to a remote device**

The counter counts each Memory-read operation or Memory-write operation that causes an access to a remote device.

That is, a socket that does not contain the PE.

System topology is IMPLEMENTATION DEFINED. This means that it is IMPLEMENTATION DEFINED which systems are defined as multi-socket systems, and, in systems defined as multi-socket systems, which components are defined as being in the same or different sockets. Arm recommends that devices where an access through that device incurs a significant latency penalty compared to other accesses are treated as being in a different socket.

For example, in a system comprising multiple integrated circuits in a multi-chip module, an access to a different integrated circuit in the same module might be treated as an access to another socket, even though the multi-chip module is physically connected to a single socket at the motherboard. However, in another system with many such multi-chip modules, an access to a different integrated system in the same module might be treated as an access to the same socket because an access to an integrated circuit on a different module has much higher latency.

It is IMPLEMENTATION DEFINED whether an access that causes a snoop into a different socket but does not return data from or pass data to the remote socket is counted.

PMCEID1_EL0[17] reads as 1 if this event is implemented and 0 otherwise.

`0x0032`, **LL_CACHE, Last level cache access**

The counter counts each Memory-read operation or Memory-write operation that causes a cache access to at least the Last level cache.

Each access to a cache line is counted including refills of and write-backs from other caches. Each access to other Last level data or unified memory structures, for example refill buffers, write buffers, and write-back buffers, is also counted.

It is IMPLEMENTATION DEFINED whether accesses that result from cache maintenance instructions are counted.

If FEAT_PMUv3p4 is implemented, accesses that only update the cache status information for a cache entry without accessing the content of the cache entry are not counted.

If FEAT_PMUv3p4 is not implemented, it is IMPLEMENTATION DEFINED whether accesses that only update the cache status information for a cache entry without accessing the content of the cache entry are counted.

An example of cache status information is whether the cached data is held in an exclusive or shared state.

When the LL_CACHE_RW event is implemented:

- If the LL_CACHE_PRFM event is implemented, accesses to the Last level cache due to a prefetch instruction are counted. Otherwise, these accesses are not counted.
- If the LL_CACHE_HWPRF event is implemented, accesses to the Last level cache due to a hardware prefetcher are counted. Otherwise these accesses are not counted.

When the LL_CACHE_RW event is not implemented, it IMPLEMENTATION DEFINED whether accesses to the Last level cache due to prefetch instructions or due to a hardware prefetcher are counted.

If the cache is shared and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the cache is shared by PEs other than the PEs in the multithreaded processor and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of PMEVTYPER<n>_EL0.MT.

PMCEID1_EL0[18] reads as 1 if this event is implemented and 0 otherwise.

`0x0033`, **LL_CACHE_MISS, Last level cache miss**

If the LL_CACHE_RW event is implemented, the counter counts each access counted by LL_CACHE_RW that is not completed by the Last level cache.

If the LL_CACHE_RW event is not implemented, the counter counts each access counted by LL_CACHE that is not completed by the Last level cache.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

That is, the access is one of the following:

- A Memory-read operation that does not return data from the Last level cache.
- A Memory-write operation that does not update the Last level cache.

The counter does not count operations that are completed by a cache above the Last level cache.

It is IMPLEMENTATION DEFINED whether accesses that result from cache maintenance instructions are counted.

If the cache is shared and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the cache is shared by PEs other than the PEs in the multithreaded processor and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of PMEVTYPER<n>_EL0.MT.

PMCEID1_EL0[19] reads as 1 if this event is implemented and 0 otherwise.

`0x0034`**, DTLB_WALK, Data TLB access with at least one translation table walk**

The counter counts each access counted by L1D_TLB that causes a refill of a data or unified TLB involving at least one translation table walk access.

This includes each complete or partial translation table walk that causes an access to memory, including to data or translation table walk caches.

It is IMPLEMENTATION DEFINED whether accesses that cause an update of an existing TLB entry involving at least one translation table walk access are counted.

The counter does not count the access if any of the following are true:

- The access is due to a TLB maintenance instruction.
- The access generates a Translation fault because the applicable TCR_ELx.EPDy bit is 1.
- FEAT_E0PD is implemented and the access is an unprivileged access that generates a Translation fault because the applicable TCR_ELx.E0PDy bit is 1.

It is IMPLEMENTATION DEFINED whether the counter counts the access if the access generates a Translation fault for any other reason.

If the TLB is shared and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of PMEVTYPER<n>_EL0.MT.

PMCEID1_EL0[20] reads as 1 if this event is implemented and 0 otherwise.

`0x0035`**, ITLB_WALK, Instruction TLB access with at least one translation table walk**

The counter counts each access counted by L1I_TLB that causes a refill of an instruction TLB involving at least one translation table walk access.

This includes each complete or partial translation table walk that causes an access to memory, including to data or translation table walk caches.

It is IMPLEMENTATION DEFINED whether accesses that cause an update of an existing TLB entry involving at least one translation table walk access are counted.

The counter does not count the access if any of the following are true:

- The access is due to a TLB maintenance instruction.
- The access generates a Translation fault because the applicable TCR_ELx.EPDy bit is 1.
- FEAT_E0PD is implemented and the access is an unprivileged access that generates a Translation fault because the applicable TCR_ELx.E0PDy bit is 1.

It is IMPLEMENTATION DEFINED whether the counter counts the access if the access generates a Translation fault for any other reason.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

If the TLB is shared and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of PMEVTYPER<n>_EL0.MT.

PMCEID1_EL0[21] reads as 1 if this event is implemented and 0 otherwise.

`0x0036`**, LL_CACHE_RD, Last level cache access, read**

If the LL_CACHE_RW event is implemented, the counter counts each access counted by LL_CACHE_RW that is a Memory-read operation.

If the LL_CACHE_RW event is not implemented, the counter counts each access counted by LL_CACHE that is a Memory-read operation.

If the cache is shared and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the cache is shared by PEs other than the PEs in the multithreaded processor and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of PMEVTYPER<n>_EL0.MT.

PMCEID1_EL0[22] reads as 1 if this event is implemented and 0 otherwise.

`0x0037`**, LL_CACHE_MISS_RD, Last level cache miss, read**

The counter counts each access counted by both LL_CACHE_MISS and LL_CACHE_RD.

That is, every miss of the Last level cache counted by LL_CACHE_MISS that is caused by a Memory-read operation.

If the cache is shared and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the cache is shared by PEs other than the PEs in the multithreaded processor and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of PMEVTYPER<n>_EL0.MT.

PMCEID1_EL0[23] reads as 1 if this event is implemented and 0 otherwise.

`0x0038`**, REMOTE_ACCESS_RD, Access to a remote device, read**

The counter counts each access counted by REMOTE_ACCESS that is a Memory-read operation.

PMCEID1_EL0[24] reads as 1 if this event is implemented and 0 otherwise.

`0x0039`**, L1D_CACHE_LMISS_RD, Level 1 data cache long-latency read miss**

The counter counts each Memory-read operation to the Level 1 data or unified cache counted by L1D_CACHE that incurs additional latency because it returns data from outside of the Level 1 data or unified cache of this PE.

The event indicates to software that the access missed in the Level 1 data or unified cache and might have a significant performance impact due to the additional latency compared to the latency of an access that hits in the Level 1 data or unified cache.

The counter does not count:

- Accesses where the additional latency is unlikely to be significantly performance-impacting. For example, if the access hits in another cache in the same local cluster, and the additional latency is small when compared to a miss in all Level 1 caches that the access looks up in and results in an access being made to a Level 2 cache or elsewhere beyond the Level 1 data or unified cache.
- A miss that does not cause a new cache refill but is satisfied from a previous miss.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

An implementation is not required to measure the latency, nor to track the access to determine whether the additional latency caused a performance impact. An implementation can extend the definition of this event with additional scenarios where an access might have a significant performance impact due to additional latency for the access.

It is IMPLEMENTATION DEFINED whether accesses that result from cache maintenance operations are counted.

If the cache is shared and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the cache is shared by PEs other than the PEs in the multithreaded processor and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of PMEVTYPER<n>_EL0.MT.

PMCEID1_EL0[25] reads as 1 if this event is implemented and 0 otherwise.

`0x003A`, **OP_RETIRED, Micro-operation architecturally executed**

The counter counts each operation counted by OP_SPEC that would be executed in a Simple sequential execution of the program.

PMCEID1_EL0[26] reads as 1 if this event is implemented and 0 otherwise.

`0x003B`, **OP_SPEC, Micro-operation speculatively executed**

The counter counts each operation speculatively executed executed by the PE.

This includes operations that would not be executed in a Simple sequential execution of the program.

PMCEID1_EL0[27] reads as 1 if this event is implemented and 0 otherwise.

`0x003C`, **STALL, No operation sent for execution**

The counter counts each cycle counted by CPU_CYCLES where no operation was sent for execution.

On a multithreaded implementation:

- If the Effective value of PMEVTYPER<n>_EL0.MT is 0, then the counter counts cycles when the PE is active and no operation for the PE is sent for execution, even if operations Attributable to other PEs in the multithreaded implementation are sent for execution in that cycle. The counter does not count cycles when the PE is not active.
- If the Effective value of PMEVTYPER<n>_EL0.MT is 1, then the counter counts all cycles when no instructions or operations for any PE in the multithreaded implementation were sent for execution.

All STALL events are counted at the same point in the pipeline.

PMCEID1_EL0[28] reads as 1 if this event is implemented and 0 otherwise.

`0x003D`, **STALL_SLOT_BACKEND, No operation sent for execution on a Slot due to the backend**

The counter counts each Slot counted by STALL_SLOT where an Attributable instruction or operation for the PE is available on the Slot to dispatch from the frontend to the backend, but is not sent for execution because the backend is unable to accept the available instruction or operation for the PE.

It is IMPLEMENTATION DEFINED whether the counter also counts each Slot counted by STALL_SLOT where no Attributable instruction or operation for the PE is available on the Slot to dispatch from the frontend and the backend is unable to accept any instruction or operation for the PE.

The division between frontend and backend is IMPLEMENTATION DEFINED. For more information, see STALL_FRONTEND. All STALL events are counted at the same point in the pipeline. The maximum value by which STALL_SLOT_BACKEND can count in a single cycle is an IMPLEMENTATION DEFINED fixed value, `slots`.For more information, see STALL_SLOT.

Note

In a single cycle, the sum of values counted by STALL_SLOT_BACKEND and STALL_SLOT_FRONTEND might be greater-than `slots`, if both the backend is unable to accept some operations and there are fewer-than `slots` operations available to dispatch from the frontend.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

PMCEID1_EL0[29] reads as 1 if this event is implemented and 0 otherwise.

`0x003E`, **STALL_SLOT_FRONTEND, No operation sent for execution on a Slot due to the frontend**

The counter counts each Slot counted by STALL_SLOT where no Attributable instruction or operation was sent for execution and there was no Attributable instruction or operation available to dispatch for the PE from the frontend for the Slot.

The division between frontend and backend is IMPLEMENTATION DEFINED. For more information, see STALL_FRONTEND. All STALL events are counted at the same point in the pipeline. The maximum value by which STALL_SLOT_FRONTEND can count in a single cycle is an IMPLEMENTATION DEFINED fixed value, `slots`.For more information, see STALL_SLOT.

Note

In a single cycle, the sum of values counted by STALL_SLOT_BACKEND and STALL_SLOT_FRONTEND might be greater-than `slots`, if both the backend is unable to accept some operations and there are fewer-than `slots` operations available to dispatch from the frontend.

PMCEID1_EL0[30] reads as 1 if this event is implemented and 0 otherwise.

`0x003F`, **STALL_SLOT, No operation sent for execution on a Slot**

The counter increments by the number of instruction or operation Slots that were not occupied by an instruction or operation Attributable to the PE on each cycle.

All STALL events are counted at the same point in the pipeline. The maximum value by which STALL_SLOT can count in a single cycle is an IMPLEMENTATION DEFINED fixed value, `slots`. The definition of a Slot is IMPLEMENTATION DEFINED. The formula STALL_SLOT÷(CPU_CYCLES×`slots`) gives the utilization of the Slots of the processor by Attributable instruction or operations of this PE. Each Slot holds at most one instruction or operation each cycle.

On a multithreaded implementation:

- If the Effective value of PMEVTYPER<n>_EL0.MT is 0, then the counter counts Slots occupied by an instruction or operation Attributable to other PEs of the multithreaded implementation only when the PE was active in that cycle. The counter does not count Slots on cycles when the PE was not active.
- If the Effective value of PMEVTYPER<n>_EL0.MT is 1, then, for every cycle, the counter counts all Slots not occupied by any instruction or operation for any PE of the multithreaded implementation.

PMCEID1_EL0[31] reads as 1 if this event is implemented and 0 otherwise.

`0x0040`, **L1D_CACHE_RD, Level 1 data cache access, read**

If the L1D_CACHE_RW event is implemented, the counter counts each access counted by L1D_CACHE_RW that is a Memory-read operation.

If the L1D_CACHE_RW event is not implemented, the counter counts each access counted by L1D_CACHE that is a Memory-read operation.

If the cache is shared and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the cache is shared by PEs other than the PEs in the multithreaded processor and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of PMEVTYPER<n>_EL0.MT.

`0x0041`, **L1D_CACHE_WR, Level 1 data cache access, write**

If the L1D_CACHE_RW event is implemented, the counter counts each access counted by L1D_CACHE_RW that is a Memory-write operation.

If the L1D_CACHE_RW event is not implemented, the counter counts each access counted by L1D_CACHE that is a Memory-write operation.

If the cache is shared and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the

cache is shared by PEs other than the PEs in the multithreaded processor and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of PMEVTYPER<n>_EL0.MT.

`0x0042`**, L1D_CACHE_REFILL_RD, Level 1 data cache refill, read**

The counter counts each access counted by both L1D_CACHE_RD and L1D_CACHE_REFILL.

That is, every refill of the Level 1 data or unified cache counted by L1D_CACHE_REFILL that is caused by a Memory-read operation.

If the cache is shared and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the cache is shared by PEs other than the PEs in the multithreaded processor and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of PMEVTYPER<n>_EL0.MT.

`0x0043`**, L1D_CACHE_REFILL_WR, Level 1 data cache refill, write**

The counter counts each access counted by both L1D_CACHE_REFILL and L1D_CACHE_WR.

That is, every refill of the Level 1 data or unified cache counted by L1D_CACHE_REFILL that is caused by a Memory-write operation.

If the cache is shared and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the cache is shared by PEs other than the PEs in the multithreaded processor and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of PMEVTYPER<n>_EL0.MT.

`0x0044`**, L1D_CACHE_REFILL_INNER, Level 1 data cache refill, inner**

The counter counts each access counted by L1D_CACHE_REFILL that generates a refill satisfied by transfer from another cache inside of the immediate cluster.

Note

The boundary between inner and outer is IMPLEMENTATION DEFINED, and it is not necessarily linked to other similar boundaries, such as the boundary between Inner Cacheable and Outer Cacheable or the boundary between Inner Shareable and Outer Shareable.

If the cache is shared and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the cache is shared by PEs other than the PEs in the multithreaded processor and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of PMEVTYPER<n>_EL0.MT.

`0x0045`**, L1D_CACHE_REFILL_OUTER, Level 1 data cache refill, outer**

The counter counts each access counted by L1D_CACHE_REFILL that generates a refill satisfied by transfer from outside of the immediate cluster.

Note

The boundary between inner and outer is IMPLEMENTATION DEFINED, and it is not necessarily linked to other similar boundaries, such as the boundary between Inner Cacheable and Outer Cacheable or the boundary between Inner Shareable and Outer Shareable.

If the cache is shared and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0, then the counter

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the cache is shared by PEs other than the PEs in the multithreaded processor and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of PMEVTYPER<n>_EL0.MT.

`0x0046`**, L1D_CACHE_WB_VICTIM, Level 1 data cache write-back, victim**

The counter counts each write-back counted by L1D_CACHE_WB that occurs because the line is allocated for an access made by the PE.

`0x0047`**, L1D_CACHE_WB_CLEAN, Level 1 data cache write-back, cleaning and coherency**

The counter counts each write-back counted by L1D_CACHE_WB that occurs because of a coherency operation made by another PE or, optionally, the execution of a cache maintenance instruction.

Whether write-backs that are caused by the execution of a cache maintenance instruction are counted is IMPLEMENTATION DEFINED.

Note

The transfer of a dirty cache line from the Level 1 data cache of this PE to the data cache of another PE due to a hardware coherency operation is not counted unless the dirty cache line is also written back to a Level 2 cache or memory.

If a coherency request from a requestor outside of the PE results in a write-back, it is an Unattributable event.

`0x0048`**, L1D_CACHE_INVAL, Level 1 data cache invalidate**

The counter counts each invalidation of a cache line in the Level 1 data or unified cache. For example:

- Invalidation of a cache line because of a cache maintenance operation.
- Transfer of ownership of a cache line to another cache because of a coherency or refill request.

The counter does not count events if a cache refill of the Level 1 data or unified cache invalidates a line in the Level 1 data or unified cache.

If FEAT_PMUv3p4 is not implemented, the counter does not count locally-executed cache maintenance instructions that operate by set/way.

If FEAT_PMUv3p4 is implemented, it is IMPLEMENTATION DEFINED whether the counter counts locally-executed cache maintenance instructions that operate by set/way.

Note

Software that uses this event must know whether the Level 1 data cache is shared with other PEs. This event does not follow the general rule of Level 1 data cache events of only counting Attributable events.

`0x004C`**, L1D_TLB_REFILL_RD, Level 1 data TLB refill, read**

The counter counts each access counted by both L1D_TLB_RD and L1D_TLB_REFILL.

The counter does not count the access if any of the following are true:

- The access generates a Translation fault because the applicable TCR_ELx.EPDy bit is 1.
- FEAT_E0PD is implemented and the access is an unprivileged access that generates a Translation fault because the applicable TCR_ELx.E0PDy bit is 1.

It is IMPLEMENTATION DEFINED whether the counter counts the access if the access generates a Translation fault for any other reason.

If the TLB is shared and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the

PE counting the event or all events are counted, and might depend on the Effective value of PMEVTYPER<n>_EL0.MT.

`0x004D`, **L1D_TLB_REFILL_WR, Level 1 data TLB refill, write**

The counter counts each access counted by both L1D_TLB_REFILL and L1D_TLB_WR.

The counter does not count the access if any of the following are true:

- The access generates a Translation fault because the applicable TCR_ELx.EPDy bit is 1.
- FEAT_E0PD is implemented and the access is an unprivileged access that generates a Translation fault because the applicable TCR_ELx.E0PDy bit is 1.

It is IMPLEMENTATION DEFINED whether the counter counts the access if the access generates a Translation fault for any other reason.

If the TLB is shared and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of PMEVTYPER<n>_EL0.MT.

`0x004E`, **L1D_TLB_RD, Level 1 data TLB access, read**

If the L1D_TLB_RW event is implemented, the counter counts each access counted by L1D_TLB_RW that is a Memory-read operation.

If the L1D_TLB_RW event is not implemented, the counter counts each access counted by L1D_TLB that is a Memory-read operation.

If the TLB is shared and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of PMEVTYPER<n>_EL0.MT.

`0x004F`, **L1D_TLB_WR, Level 1 data TLB access, write**

If the L1D_TLB_RW event is implemented, the counter counts each access counted by L1D_TLB_RW that is a Memory-write operation.

If the L1D_TLB_RW event is not implemented, the counter counts each access counted by L1D_TLB that is a Memory-write operation.

If the TLB is shared and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of PMEVTYPER<n>_EL0.MT.

`0x0050`, **L2D_CACHE_RD, Level 2 data cache access, read**

If the L2D_CACHE_RW event is implemented, the counter counts each access counted by L2D_CACHE_RW that is a Memory-read operation.

If the L2D_CACHE_RW event is not implemented, the counter counts each access counted by L2D_CACHE that is a Memory-read operation.

If the cache is shared and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the cache is shared by PEs other than the PEs in the multithreaded processor and the Effective value of

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.

PMEVTYPER<n>_EL0.MT for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of PMEVTYPER<n>_EL0.MT.

`0x0051`**, L2D_CACHE_WR, Level 2 data cache access, write**

If the L2D_CACHE_RW event is implemented, the counter counts each access counted by L2D_CACHE_RW that is a Memory-write operation.

If the L2D_CACHE_RW event is not implemented, the counter counts each access counted by L2D_CACHE that is a Memory-write operation.

If the cache is shared and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the cache is shared by PEs other than the PEs in the multithreaded processor and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of PMEVTYPER<n>_EL0.MT.

`0x0052`**, L2D_CACHE_REFILL_RD, Level 2 data cache refill, read**

The counter counts each access counted by both L2D_CACHE_RD and L2D_CACHE_REFILL.

That is, every refill of the Level 2 data or unified cache counted by L2D_CACHE_REFILL that is caused by a Memory-read operation.

If the cache is shared and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the cache is shared by PEs other than the PEs in the multithreaded processor and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of PMEVTYPER<n>_EL0.MT.

`0x0053`**, L2D_CACHE_REFILL_WR, Level 2 data cache refill, write**

The counter counts each access counted by both L2D_CACHE_REFILL and L2D_CACHE_WR.

That is, every refill of the Level 2 data or unified cache counted by L2D_CACHE_REFILL that is caused by a Memory-write operation.

If the cache is shared and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the cache is shared by PEs other than the PEs in the multithreaded processor and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of PMEVTYPER<n>_EL0.MT.

`0x0056`**, L2D_CACHE_WB_VICTIM, Level 2 data cache write-back, victim**

The counter counts each write-back counted by L2D_CACHE_WB that occurs because the line is allocated for an access made by the PE.

`0x0057`**, L2D_CACHE_WB_CLEAN, Level 2 data cache write-back, cleaning and coherency**

The counter counts each write-back counted by L2D_CACHE_WB that occurs because of a coherency operation made by another PE or, optionally, the execution of a cache maintenance instruction.

Whether write-backs that are caused by the execution of a cache maintenance instruction are counted is IMPLEMENTATION DEFINED.

Non-Confidential

Note

The transfer of a dirty cache line from the Level 2 data cache of this PE to the data cache of another PE due to a hardware coherency operation is not counted unless the dirty cache line is also written back to a Level 3 cache or memory.

If a coherency request from a requestor outside of the PE results in a write-back, it is an Unattributable event.

`0x0058`**, L2D_CACHE_INVAL, Level 2 data cache invalidate**

The counter counts each invalidation of a cache line in the Level 2 data or unified cache. For example:

- Invalidation of a cache line because of a cache maintenance operation.
- Transfer of ownership of a cache line to another cache because of a coherency or refill request.

The counter does not count events if a cache refill of the Level 2 data or unified cache invalidates a line in the Level 2 data or unified cache.

If FEAT_PMUv3p4 is not implemented, the counter does not count locally-executed cache maintenance instructions that operate by set/way.

If FEAT_PMUv3p4 is implemented, it is IMPLEMENTATION DEFINED whether the counter counts locally-executed cache maintenance instructions that operate by set/way.

Note

Software that uses this event must know whether the Level 2 data cache is shared with other PEs. This event does not follow the general rule of Level 2 data cache events of only counting Attributable events.

`0x005C`**, L2D_TLB_REFILL_RD, Level 2 data TLB refill, read**

The counter counts each access counted by both L2D_TLB_RD and L2D_TLB_REFILL.

The counter does not count the access if any of the following are true:

- The access generates a Translation fault because the applicable TCR_ELx.EPDy bit is 1.
- FEAT_E0PD is implemented and the access is an unprivileged access that generates a Translation fault because the applicable TCR_ELx.E0PDy bit is 1.

It is IMPLEMENTATION DEFINED whether the counter counts the access if the access generates a Translation fault for any other reason.

If the TLB is shared and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of PMEVTYPER<n>_EL0.MT.

`0x005D`**, L2D_TLB_REFILL_WR, Level 2 data TLB refill, write**

The counter counts each access counted by both L2D_TLB_REFILL and L2D_TLB_WR.

The counter does not count the access if any of the following are true:

- The access generates a Translation fault because the applicable TCR_ELx.EPDy bit is 1.
- FEAT_E0PD is implemented and the access is an unprivileged access that generates a Translation fault because the applicable TCR_ELx.E0PDy bit is 1.

It is IMPLEMENTATION DEFINED whether the counter counts the access if the access generates a Translation fault for any other reason.

If the TLB is shared and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0, then the counter counts only events Attributable to the PE counting the event. Non-Confidential

multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of PMEVTYPER<n>_EL0.MT.

`0x005E`, **L2D_TLB_RD, Level 2 data TLB access, read**

The counter counts each access counted by L2D_TLB that is a Memory-read operation.

If the TLB is shared and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of PMEVTYPER<n>_EL0.MT.

`0x005F`, **L2D_TLB_WR, Level 2 data TLB access, write**

The counter counts each access counted by L2D_TLB that is a Memory-write operation.

If the TLB is shared and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of PMEVTYPER<n>_EL0.MT.

`0x0060`, **BUS_ACCESS_RD, Bus access, read**

The counter counts each access counted by BUS_ACCESS that is a Memory-read operation.

`0x0061`, **BUS_ACCESS_WR, Bus access, write**

The counter counts each access counted by BUS_ACCESS that is a Memory-write operation.

`0x0062`, **BUS_ACCESS_SHARED, Bus access, Normal, Cacheable, Shareable**

The counter counts each access counted by BUS_ACCESS that is Normal, Cacheable, Shareable.

Note

It is IMPLEMENTATION DEFINED how the PE translates the attributes from the translation table entry for a region to the attributes on the bus.
In particular, a region of memory designated as Normal, Cacheable, Inner Shareable, Not Outer Shareable by a translation table entry, might be marked as either shareable or Non-shareable at the boundary of the PE and its closely-coupled caches. This depends on where the IMPLEMENTATION DEFINED boundary lies, between Inner and Outer Shareable.
If the Inner Shareable extends beyond the PE boundary, and the bus indicates the distinction between Inner and Outer Shareable, then either is counted as shareable for the purposes of defining this event.

`0x0063`, **BUS_ACCESS_NOT_SHARED, Bus access, not Normal, Cacheable, Shareable**

The counter counts each access counted by BUS_ACCESS that is not counted by BUS_ACCESS_SHARED.

For example, the counter counts accesses marked as:

- Normal, Cacheable, Non-shareable.
- Normal, Non-cacheable.
- Device.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

It is IMPLEMENTATION DEFINED, how the PE translates the attributes from the translation table entries for a region to the attributes on the bus.
In particular, a region of memory designated as Normal, Cacheable, Inner Shareable, Not Outer Shareable by a translation table entry, might be marked as either shareable or Non-shareable at the boundary of the PE and its closely-coupled caches. This depends on where the IMPLEMENTATION DEFINED boundary lies, between Inner and Outer Shareable.
If the Inner Shareable extends beyond the PE boundary, and the bus indicates the distinction between Inner and Outer Shareable, then either is counted as shareable for the purposes of defining this event.

`0x0064`**, BUS_ACCESS_NORMAL, Bus access, normal**

The counter counts each access counted by BUS_ACCESS that is to Normal or bulk memory.

For example, the counter counts Normal, Cacheable and Normal, Non-cacheable accesses but does not count Device accesses.

`0x0065`**, BUS_ACCESS_PERIPH, Bus access, peripheral**

The counter counts each access counted by BUS_ACCESS that is not counted by BUS_ACCESS_NORMAL.

For example, the counter counts accesses to Device memory.

`0x0066`**, MEM_ACCESS_RD, Data memory access, read**

If the MEM_ACCESS_RW event is implemented, the counter counts each access counted by MEM_ACCESS_RW that is a Memory-read operation.

If the MEM_ACCESS_RW event is not implemented, the counter counts each access counted by MEM_ACCESS that is a Memory-read operation.

`0x0067`**, MEM_ACCESS_WR, Data memory access, write**

If the MEM_ACCESS_RW event is implemented, the counter counts each access counted by MEM_ACCESS_RW that is a Memory-write operation.

If the MEM_ACCESS_RW event is not implemented, the counter counts each access counted by MEM_ACCESS that is a Memory-write operation.

`0x0068`**, UNALIGNED_LD_SPEC, Unaligned access, read**

The counter counts each unaligned access counted by UNALIGNED_LDST_SPEC that is a Memory-read operation.

The unaligned access is counted even if it is subsequently transformed into multiple aligned accesses.

`0x0069`**, UNALIGNED_ST_SPEC, Unaligned access, write**

The counter counts each unaligned access counted by UNALIGNED_LDST_SPEC that is a Memory-write operation.

The unaligned access is counted even if it is subsequently transformed into multiple aligned accesses.

`0x006A`**, UNALIGNED_LDST_SPEC, Unaligned access**

The counter counts each access counted by MEM_ACCESS that is an unaligned Memory-read operation or unaligned Memory-write operation.

The unaligned access is counted even if it is subsequently transformed into multiple aligned accesses.

`0x006C`**, LDREX_SPEC, Exclusive operation speculatively executed, Load-Exclusive**

The counter counts each speculatively executed Load-Exclusive instruction.

The definition of speculatively executed is IMPLEMENTATION DEFINED but must be the same as for the STREX_SPEC event.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

`0x006D`, **STREX_PASS_SPEC, Exclusive operation speculatively executed, Store-Exclusive pass**

The counter counts each speculatively executed Store-Exclusive instruction counted by STREX_SPEC that completed a write.

`0x006E`, **STREX_FAIL_SPEC, Exclusive operation speculatively executed, Store-Exclusive fail**

The counter counts each speculatively executed Store-Exclusive instruction counted by STREX_SPEC that fails to complete a write.

It is within the IMPLEMENTATION DEFINED definition of speculatively executed whether this includes conditional instructions that fail the condition code check.

`0x006F`, **STREX_SPEC, Exclusive operation speculatively executed, Store-Exclusive**

The counter counts each speculatively executed Store-Exclusive instruction.

The definition of speculatively executed is IMPLEMENTATION DEFINED but it must be the same as for the LDREX_SPEC event.

Arm recommends that this event is implemented if it is not possible to implement the exclusive operation speculatively executed, Store-Exclusive pass, and exclusive operation speculatively executed, Store-Exclusive fail, events with the same degree of speculation as the LDREX_SPEC event.

`0x0070`, **LD_SPEC, Operation speculatively executed, load**

The counter counts each operation counted by LDST_SPEC that is a load operation.

Operations due to Memory-reading instructions are counted as load operations.

It is IMPLEMENTATION DEFINED whether operations due to the prefetch instructions counted by PRF_SPEC are counted as load operations:

- If operations due to the prefetch instructions are counted as load operations, then they are counted by LD_SPEC.
- Otherwise, if operations due to the prefetch instructions are not counted as load operations by LD_SPEC, then it is further IMPLEMENTATION DEFINED which one of the following applies:
  - They are counted as data-processing operations.
  - They are counted by LDST_SPEC.

Arm recommends that if a prefetch operation is not implemented as a NOP and the PRF_SPEC event is not implemented, then the operation is counted as a load operation.

`0x0071`, **ST_SPEC, Operation speculatively executed, store**

The counter counts each operation counted by LDST_SPEC that is a store operation.

Operations due to Memory-writing instructions are counted as store operations.

`0x0072`, **LDST_SPEC, Operation speculatively executed, load or store**

The counter counts each operation counted by INST_SPEC that is a load operation or a store operation.

See LD_SPEC and ST_SPEC for these classifications.

If the PRF_SPEC event is implemented and operations due to the prefetch instructions counted by PRF_SPEC are not counted as load operations by LD_SPEC, then it is IMPLEMENTATION DEFINED whether these operations are counted by LDST_SPEC. Arm recommends that these operations are counted by LDST_SPEC.

`0x0073`, **DP_SPEC, Operation speculatively executed, integer data processing**

The counter counts each operation counted by INST_SPEC that is an integer data-processing operation.

An integer data-processing operation is any operation that is not counted as any of the following:

- A load or store operation, counted by LDST_SPEC.
- A Software change of PC operation, counted by PC_WRITE_SPEC.
- A scalar floating-point data processing operation, counted by VFP_SPEC.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- An Advanced SIMD or SVE data processing operation, counted by ASE_SVE_SPEC.
- A cryptographic operation, counted by CRYPTO_SPEC.

That is, operations due to the following instructions are counted as integer data-processing operations:

- In AArch64 state instructions from the following sections:
  - Data processing - immediate.
  - Data processing - register.
  - System register instructions.
  - 'Instructions with register argument'.
  - System instructions other than Memory-writing instructions.
  - Hint instructions.

`0x0074`**, ASE_SPEC, Operation speculatively executed, Advanced SIMD data processing**

The counter counts each operation counted by INST_SPEC that is an Advanced SIMD data-processing operation.

Operations due to the following instructions are counted as Advanced SIMD data-processing operations:

- For AArch64 state:
  - The SIMD operations listed in Data processing - SIMD and floating-point.
  - Advanced SIMD scalar instructions, including those which operate on floating-point values.
  - If FEAT_Crypto is implemented, the Advanced SIMD `PMULL` and `PMULL2` (1Q variants) instructions. See The Cryptographic Extension in AArch64 state.

This includes all operations that operate on the SIMD&FP registers, except those that are counted as one of the following:

- Integer data-processing operations.
- Scalar floating-point data-processing operations.
- Load or store operations.
- Cryptographic data-processing operations counted by CRYPTO_SPEC. CRYPTO_SPEC does not count the Cryptographic data-processing operations included above.

`0x0075`**, VFP_SPEC, Operation speculatively executed, scalar floating-point data processing**

The counter counts each operation counted by INST_SPEC that is a scalar floating-point operation.

Operations due to the following instructions are counted as scalar floating-point data-processing operations:

- In AArch64 state:
  - The scalar floating-point operations from Data processing - SIMD and floating-point. Only the scalar operations are counted. SIMD floating-point operations are not counted.
  - Operations that take both an integer register and a floating-point register argument and perform a type conversion (to/from integer or to/from fixed-point): `FCVT{<mode>}`, `UCVTF`, and `SCVTF`.

This includes all scalar operations that operate on the SIMD&FP registers as floating-point values, except those that are counted as one of the following:

- SIMD scalar operations.
- Integer data-processing operations.
- Load or store operations.

`0x0076`**, PC_WRITE_SPEC, Operation speculatively executed, Software change of the PC**

The counter counts each operation counted by INST_SPEC that is a Software change of the PC.

Software change of the PC operations are defined by the PC_WRITE_RETIRED event.

It is IMPLEMENTATION DEFINED whether the counter counts the operation when the branch is not taken.

`0x0077`**, CRYPTO_SPEC, Operation speculatively executed, cryptographic data processing**

The counter counts each operation counted by INST_SPEC that is a cryptographic operation.

Operations due to the following instructions are counted as cryptographic data-processing operations:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- In AArch64 state, instructions from The Cryptographic Extension in AArch64 state other than the include Advanced SIMD `PMULL` and `PMULL2` (1Q variants) instructions.

`0x0078`, **BR_IMMED_SPEC, Branch speculatively executed, immediate branch**

The counter counts each speculatively executed immediate branch instruction.

Operations due to the following instructions are counted as speculatively executed immediate branch instructions:

- For AArch64 state, the following instructions:
  - `B <label>`.
  - `B.cond <label>`.
  - `BL <label>`.
  - `CBZ <Rn>, <label>`.
  - `CBNZ <Rn>, <label>`.
  - `TBZ <Rn>, <label>`.
  - `TBNZ <Rn>, <label>`.

Note

Conditional branches are always counted, regardless of whether the branch is taken or not taken.

If the Context synchronization barrier instruction ISB is counted as a Software change of the PC instruction by PC_WRITE_SPEC, then it is IMPLEMENTATION DEFINED whether ISB is counted as a speculatively executed immediate branch instruction.

`0x0079`, **BR_RETURN_SPEC, Branch speculatively executed, procedure return**

The counter counts each speculatively executed procedure return instruction.

Operations due to the following instructions are counted as speculatively executed procedure return instructions:

- For AArch64 state, the following instructions:
  - `RET`.
  - If FEAT_PAuth is implemented, `RETAA` and `RETAB`.

`0x007A`, **BR_INDIRECT_SPEC, Branch speculatively executed, indirect branch**

The counter counts each speculatively executed indirect branch instruction.

Indirect branch instructions are Software change of the PC instructions other than exception-generating instructions and immediate branch instructions. Software change of the PC has the same definition as for the PC_WRITE_SPEC event. Immediate branch instructions are defined by the BR_IMMED_SPEC event.

`0x007C`, **ISB_SPEC, Barrier speculatively executed, ISB**

The counter counts each speculatively executed Instruction Synchronization Barrier instruction.

`0x007D`, **DSB_SPEC, Barrier speculatively executed, DSB**

The counter counts each speculatively executed data synchronization and speculative load barrier instruction.

`0x007E`, **DMB_SPEC, Barrier speculatively executed, DMB**

The counter counts each speculatively executed data memory barrier instruction.

This does not include the implied barrier operations of load/store operations with release consistency semantics.

`0x007F`, **CSDB_SPEC, Barrier speculatively executed, CSDB**

The counter counts each speculatively executed control speculation barrier instruction.

`0x0090`, **RC_LD_SPEC, Release consistency operation speculatively executed, Load-Acquire**

The counter counts each speculatively executed Memory-read operation with acquire or acquirepc semantics.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

`0x0091`, **RC_ST_SPEC, Release consistency operation speculatively executed, Store-Release**

The counter counts each speculatively executed Memory-write operation with release semantics.

`0x00A0`, **L3D_CACHE_RD, Level 3 data cache access, read**

If the L3D_CACHE_RW event is implemented, the counter counts each access counted by L3D_CACHE_RW that is a Memory-read operation.

If the L3D_CACHE_RW event is not implemented, the counter counts each access counted by L3D_CACHE that is a Memory-read operation.

If the cache is shared and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the cache is shared by PEs other than the PEs in the multithreaded processor and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of PMEVTYPER<n>_EL0.MT.

`0x00A1`, **L3D_CACHE_WR, Level 3 data cache access, write**

If the L3D_CACHE_RW event is implemented, the counter counts each access counted by L3D_CACHE_RW that is a Memory-write operation.

If the L3D_CACHE_RW event is not implemented, the counter counts each access counted by L3D_CACHE that is a Memory-write operation.

If the cache is shared and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the cache is shared by PEs other than the PEs in the multithreaded processor and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of PMEVTYPER<n>_EL0.MT.

`0x00A2`, **L3D_CACHE_REFILL_RD, Level 3 data cache refill, read**

The counter counts each access counted by both L3D_CACHE_RD and L3D_CACHE_REFILL.

That is, every refill of the Level 3 data or unified cache counted by L3D_CACHE_REFILL that is caused by a Memory-read operation.

If the cache is shared and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the cache is shared by PEs other than the PEs in the multithreaded processor and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of PMEVTYPER<n>_EL0.MT.

`0x00A3`, **L3D_CACHE_REFILL_WR, Level 3 data cache refill, write**

The counter counts each access counted by both L3D_CACHE_REFILL and L3D_CACHE_WR.

That is, every refill of the Level 3 data or unified cache counted by L3D_CACHE_REFILL that is caused by a Memory-write operation.

If the cache is shared and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the cache is shared by PEs other than the PEs in the multithreaded processor and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of PMEVTYPER<n>_EL0.MT.

`0x00A6`, **L3D_CACHE_WB_VICTIM, Level 3 data cache write-back, victim**

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The counter counts each write-back counted by L3D_CACHE_WB that occurs because the line is allocated for an access made by the PE.

`0x00A7`, **L3D_CACHE_WB_CLEAN, Level 3 data cache write-back, cleaning and coherency**

The counter counts each write-back counted by L3D_CACHE_WB that occurs because of a coherency operation made by another PE or, optionally, the execution of a cache maintenance instruction.

Whether write-backs that are caused by the execution of a cache maintenance instruction are counted is IMPLEMENTATION DEFINED.

Note

The transfer of a dirty cache line from the Level 3 data cache of this PE to the data cache of another PE due to a hardware coherency operation is not counted unless the dirty cache line is also written back to a lower level cache or memory.

If a coherency request from a requestor outside of the PE results in a write-back, it is an Unattributable event.

`0x00A8`, **L3D_CACHE_INVAL, Level 3 data cache invalidate**

The counter counts each invalidation of a cache line in the Level 3 data or unified cache. For example:

- Invalidation of a cache line because of a cache maintenance operation.
- Transfer of ownership of a cache line to another cache because of a coherency or refill request.

The counter does not count events if a cache refill of the Level 3 data or unified cache invalidates a line in the Level 3 data or unified cache.

If FEAT_PMUv3p4 is not implemented, the counter does not count locally-executed cache maintenance instructions that operate by set/way.

If FEAT_PMUv3p4 is implemented, it is IMPLEMENTATION DEFINED whether the counter counts locally-executed cache maintenance instructions that operate by set/way.

Note

Software that uses this event must know whether the Level 3 data cache is shared with other PEs. This event does not follow the general rule of Level 3 data cache events of only counting Attributable events.

`0x4000`, **SAMPLE_POP, Statistical Profiling sample population**

The counter counts each operation that might be sampled, whether or not the operation was sampled.

The counter does not count when profiling is disabled.

PMCEID0_EL0[32] reads as 1 if this event is implemented and 0 otherwise.

`0x4001`, **SAMPLE_FEED, Statistical Profiling sample taken**

The counter counts each time the sample interval counter reaches zero and is reloaded, and the sample does not collide with the previous sample.

Samples that are removed by filtering, or discarded, and not written to the Profiling Buffer are counted.

PMCEID0_EL0[33] reads as 1 if this event is implemented and 0 otherwise.

`0x4002`, **SAMPLE_FILTRATE, Statistical Profiling sample taken and not removed by filtering**

The counter counts each sample counted by SAMPLE_FEED that is not removed by filtering.

Sample records that are not removed by filtering, but are discarded before being written to the Profiling Buffer because of a Profiling Buffer management event, are counted.

PMCEID0_EL0[34] reads as 1 if this event is implemented and 0 otherwise.

`0x4003`, **SAMPLE_COLLISION, Statistical Profiling sample collided with previous sample**

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The counter counts each time the sample interval counter reaches zero and is reloaded, and the sample collides with a previous sample.

For more information, see ‘Sample collisions’.

PMCEID0_EL0[35] reads as 1 if this event is implemented and 0 otherwise.

`0x4004`**, CNT_CYCLES, Constant frequency cycles**

The counter increments at a constant frequency equal to the rate of increment of the System Counter, CNTPCT_EL0.

PMCEID0_EL0[36] reads as 1 if this event is implemented and 0 otherwise.

`0x4005`**, STALL_BACKEND_MEM, Memory stall cycles**

The counter counts each cycle counted by STALL_BACKEND_MEMBOUND where there is a demand data miss in the last level of data or unified cache within the PE clock domain.

It is IMPLEMENTATION DEFINED whether the counter counts backend stall cycles when a non-cacheable data access is in progress.

PMCEID0_EL0[37] reads as 1 if this event is implemented and 0 otherwise.

`0x4006`**, L1I_CACHE_LMISS, Level 1 instruction cache long-latency miss**

If the L1I_CACHE_RD event is implemented, the counter counts each access to the Level 1 instruction or unified cache counted by L1I_CACHE_RD that incurs additional latency because it returns instructions from outside of the Level 1 instruction or unified cache of this PE.

If the L1I_CACHE_RD event is not implemented, the counter counts each access to the Level 1 instruction or unified cache counted by L1I_CACHE that incurs additional latency because it returns instructions from outside of the Level 1 instruction or unified cache of this PE.

The event indicates to software that the access missed in the Level 1 instruction or unified cache and might have a significant performance impact due to the additional latency compared to the latency of an access that hits in the Level 1 instruction or unified cache.

The counter does not count:

- Accesses where the additional latency is unlikely to be significantly performance-impacting. For example, if the access hits in another cache in the same local cluster, and the additional latency is small when compared to a miss in all Level 1 caches that the access looks up in and results in instructions being returned from a Level 2 cache or elsewhere beyond the Level 1 instruction or unified cache.
- A miss that does not cause a new cache refill but is satisfied from a previous miss.

An implementation is not required to measure the latency, nor to track the access to determine whether the additional latency caused a performance impact. An implementation can extend the definition of this event with additional scenarios where an access might have a significant performance impact due to additional latency for the access.

It is IMPLEMENTATION DEFINED whether accesses that result from cache maintenance operations are counted.

If the cache is shared and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the cache is shared by PEs other than the PEs in the multithreaded processor and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of PMEVTYPER<n>_EL0.MT.

PMCEID0_EL0[38] reads as 1 if this event is implemented and 0 otherwise.

`0x4009`**, L2D_CACHE_LMISS_RD, Level 2 data cache long-latency read miss**

The counter counts each Memory-read operation to the Level 2 data or unified cache counted by L2D_CACHE that incurs additional latency because it returns data from outside of the Level 1 and Level 2 data or unified caches of this PE.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The event indicates to software that the access missed in the Level 2 data or unified cache and might have a significant performance impact due to the additional latency compared to the latency of an access that hits in the Level 2 data or unified cache.

The counter does not count:

- Accesses where the additional latency is unlikely to be significantly performance-impacting. For example, if the access hits in another cache in the same local cluster, and the additional latency is small when compared to a miss in all Level 2 caches that the access looks up in and results in an access being made to a Level 3 cache or elsewhere beyond the Level 2 data or unified cache. This might be counted as a Level 1 cache miss.
- A miss that does not cause a new cache refill but is satisfied from a previous miss.

An implementation is not required to measure the latency, nor to track the access to determine whether the additional latency caused a performance impact. An implementation can extend the definition of this event with additional scenarios where an access might have a significant performance impact due to additional latency for the access.

It is IMPLEMENTATION DEFINED whether accesses that result from cache maintenance operations are counted.

If the cache is shared and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the cache is shared by PEs other than the PEs in the multithreaded processor and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of PMEVTYPER<n>_EL0.MT.

PMCEID0_EL0[41] reads as 1 if this event is implemented and 0 otherwise.

`0x400A`**, L2I_CACHE_LMISS, Level 2 instruction cache long-latency miss**

If the L2I_CACHE_RD event is implemented, the counter counts each access to the Level 2 instruction or unified cache counted by L2I_CACHE_RD that incurs additional latency because it returns instructions from outside of the Level 1 and Level 2 instruction or unified caches of this PE.

If the L2I_CACHE_RD event is not implemented, the counter counts each access to the Level 2 instruction or unified cache counted by L2I_CACHE that incurs additional latency because it returns instructions from outside of the Level 1 and Level 2 instruction or unified caches of this PE.

The event indicates to software that the access missed in the Level 2 instruction or unified cache and might have a significant performance impact due to the additional latency compared to the latency of an access that hits in the Level 2 instruction or unified cache.

The counter does not count:

- Accesses where the additional latency is unlikely to be significantly performance-impacting. For example, if the access hits in another cache in the same local cluster, and the additional latency is small when compared to a miss in all Level 2 caches that the access looks up in and results in instructions being returned from a Level 3 cache or elsewhere beyond the Level 2 instruction or unified cache. This might be counted as a Level 1 cache miss.
- A miss that does not cause a new cache refill but is satisfied from a previous miss.

An implementation is not required to measure the latency, nor to track the access to determine whether the additional latency caused a performance impact. An implementation can extend the definition of this event with additional scenarios where an access might have a significant performance impact due to additional latency for the access.

It is IMPLEMENTATION DEFINED whether accesses that result from cache maintenance operations are counted.

If the cache is shared and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the cache is shared by PEs other than the PEs in the multithreaded processor and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of PMEVTYPER<n>_EL0.MT.

PMCEID0_EL0[42] reads as 1 if this event is implemented and 0 otherwise.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

`0x400B`**, L3D_CACHE_LMISS_RD, Level 3 data cache long-latency read miss**

The counter counts each Memory-read operation to the Level 3 data or unified cache counted by L3D_CACHE that incurs additional latency because it returns data from outside of the Level 1 to Level 3 data or unified caches of this PE.

The event indicates to software that the access missed in the Level 3 data or unified cache and might have a significant performance impact due to the additional latency compared to the latency of an access that hits in the Level 3 data or unified cache.

The counter does not count:

- Accesses where the additional latency is unlikely to be significantly performance-impacting. For example, if the access hits in another cache in the same local cluster, and the additional latency is small when compared to a miss in all Level 3 caches that the access looks up in and results in an access being made to a lower level cache or elsewhere beyond the Level 3 data or unified cache. This might be counted as a Level 2 cache miss.
- A miss that does not cause a new cache refill but is satisfied from a previous miss.

An implementation is not required to measure the latency, nor to track the access to determine whether the additional latency caused a performance impact. An implementation can extend the definition of this event with additional scenarios where an access might have a significant performance impact due to additional latency for the access.

It is IMPLEMENTATION DEFINED whether accesses that result from cache maintenance operations are counted.

If the cache is shared and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the cache is shared by PEs other than the PEs in the multithreaded processor and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of PMEVTYPER<n>_EL0.MT.

PMCEID0_EL0[43] reads as 1 if this event is implemented and 0 otherwise.

`0x4010`**, TRCEXTOUT0, Trace unit external output 0**

The counter counts each event signaled by the trace unit on external event 0.

It is IMPLEMENTATION DEFINED whether this event is available as an external input to the ETE.

PMCEID0_EL0[48] reads as 1 if this event is implemented and 0 otherwise.

`0x4011`**, TRCEXTOUT1, Trace unit external output 1**

The counter counts each event signaled by the trace unit on external event 1.

It is IMPLEMENTATION DEFINED whether this event is available as an external input to the ETE.

PMCEID0_EL0[49] reads as 1 if this event is implemented and 0 otherwise.

`0x4012`**, TRCEXTOUT2, Trace unit external output 2**

The counter counts each event signaled by the trace unit on external event 2.

It is IMPLEMENTATION DEFINED whether this event is available as an external input to the ETE.

PMCEID0_EL0[50] reads as 1 if this event is implemented and 0 otherwise.

`0x4013`**, TRCEXTOUT3, Trace unit external output 3**

The counter counts each event signaled by the trace unit on external event 3.

It is IMPLEMENTATION DEFINED whether this event is available as an external input to the ETE.

PMCEID0_EL0[51] reads as 1 if this event is implemented and 0 otherwise.

`0x4018`**, CTI_TRIGOUT4, Cross-trigger Interface output trigger 4**

The counter counts each event signaled on CTI output trigger 4.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

CTI output triggers are input events to the PMU and trace unit.

PMCEID0_EL0[56] reads as 1 if this event is implemented and 0 otherwise.

`0x4019`, **CTI_TRIGOUT5, Cross-trigger Interface output trigger 5**

The counter counts each event signaled on CTI output trigger 5.

Note

CTI output triggers are input events to the PMU and trace unit.

PMCEID0_EL0[57] reads as 1 if this event is implemented and 0 otherwise.

`0x401A`, **CTI_TRIGOUT6, Cross-trigger Interface output trigger 6**

The counter counts each event signaled on CTI output trigger 6.

Note

CTI output triggers are input events to the PMU and trace unit.

PMCEID0_EL0[58] reads as 1 if this event is implemented and 0 otherwise.

`0x401B`, **CTI_TRIGOUT7, Cross-trigger Interface output trigger 7**

The counter counts each event signaled on CTI output trigger 7.

Note

CTI output triggers are input events to the PMU and trace unit.

PMCEID0_EL0[59] reads as 1 if this event is implemented and 0 otherwise.

`0x4020`, **LDST_ALIGN_LAT, Access with additional latency from alignment**

The counter counts each access counted by MEM_ACCESS that incurred additional latency due to the alignment of the address and size of data being accessed.

PMCEID1_EL0[32] reads as 1 if this event is implemented and 0 otherwise.

`0x4021`, **LD_ALIGN_LAT, Load with additional latency from alignment**

The counter counts each Memory-read operation counted by LDST_ALIGN_LAT.

PMCEID1_EL0[33] reads as 1 if this event is implemented and 0 otherwise.

`0x4022`, **ST_ALIGN_LAT, Store with additional latency from alignment**

The counter counts each Memory-write operation counted by LDST_ALIGN_LAT.

PMCEID1_EL0[34] reads as 1 if this event is implemented and 0 otherwise.

`0x4032`, **TME_TRANSACTION_FAILED, Transaction failed or was canceled**

The counter counts each transaction that fails or is canceled.

If PMEVTYPER<n>_EL0.T is 1, it is IMPLEMENTATION DEFINED whether or not the transaction is counted by the counter.

PMCEID1_EL0[50] reads as 1 if this event is implemented and 0 otherwise.

`0x4034`, **TME_INST_RETIRED_COMMITTED, Instruction architecturally executed, in a committed transaction**

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The counter counts each Instruction architecturally executed counted by INST_RETIRED when the PE is in Transactional state and the currently executing outer transaction commits.

It is IMPLEMENTATION DEFINED whether the counter counts more than 2^{32}-1 instructions in a single outer transaction.

Note

Two example implementations of this event are as follows:

- The implementation accumulates events to the counter directly. If the transaction fails, the counter is restored to the value it had when the transaction started.
- The implementation accumulates events without updating the counter. If the transaction commits, the counter is updated with the accumulated value.

The counter does not count the instruction if the transaction fails or is canceled.

PMCEID1_EL0[52] reads as 1 if this event is implemented and 0 otherwise.

`0x4035`**, TME_CPU_CYCLES_COMMITTED, PE cycle, in a committed transaction**

The counter counts each PE cycle counted by CPU_CYCLES when the PE is in Transactional state and the currently executing outer transaction commits.

It is IMPLEMENTATION DEFINED whether the counter counts more than 2^{32}-1 cycles in a single outer transaction.

Note

Two example implementations of this event are as follows:

- The implementation accumulates events to the counter directly. If the transaction fails, the counter is restored to the value it had when the transaction started.
- The implementation accumulates events without updating the counter. If the transaction commits, the counter is updated with the accumulated value.

The counter does not count the cycle if the transaction fails or is canceled.

PMCEID1_EL0[53] reads as 1 if this event is implemented and 0 otherwise.

`0x4038`**, TME_FAILURE_CNCL, Transaction failed with CNCL cause**

The counter counts each transaction counted by TME_TRANSACTION_FAILED that fails with CNCL cause.

If PMEVTYPER<n>_EL0.T is 1, it is IMPLEMENTATION DEFINED whether or not the transaction is counted by the counter.

PMCEID1_EL0[56] reads as 1 if this event is implemented and 0 otherwise.

`0x4039`**, TME_FAILURE_NEST, Transaction failed with NEST cause**

The counter counts each transaction counted by TME_TRANSACTION_FAILED that fails with NEST cause.

If PMEVTYPER<n>_EL0.T is 1, it is IMPLEMENTATION DEFINED whether or not the transaction is counted by the counter.

PMCEID1_EL0[57] reads as 1 if this event is implemented and 0 otherwise.

`0x403A`**, TME_FAILURE_ERR, Transaction failed with ERR cause**

The counter counts each transaction counted by TME_TRANSACTION_FAILED that fails with ERR cause.

If PMEVTYPER<n>_EL0.T is 1, it is IMPLEMENTATION DEFINED whether or not the transaction is counted by the counter.

PMCEID1_EL0[58] reads as 1 if this event is implemented and 0 otherwise.

`0x403B`**, TME_FAILURE_IMP, Transaction failed with IMP cause**

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The counter counts each transaction counted by TME_TRANSACTION_FAILED that fails with IMP cause.

If PMEVTYPER<n>_EL0.T is 1, it is IMPLEMENTATION DEFINED whether or not the transaction is counted by the counter.

PMCEID1_EL0[59] reads as 1 if this event is implemented and 0 otherwise.

`0x403C`, **TME_FAILURE_MEM, Transaction failed with MEM cause**

The counter counts each transaction counted by TME_TRANSACTION_FAILED that fails with MEM cause.

If PMEVTYPER<n>_EL0.T is 1, it is IMPLEMENTATION DEFINED whether or not the transaction is counted by the counter.

PMCEID1_EL0[60] reads as 1 if this event is implemented and 0 otherwise.

`0x403D`, **TME_FAILURE_SIZE, Transaction failed with SIZE cause**

The counter counts each transaction counted by TME_TRANSACTION_FAILED that fails with SIZE cause.

If PMEVTYPER<n>_EL0.T is 1, it is IMPLEMENTATION DEFINED whether or not the transaction is counted by the counter.

PMCEID1_EL0[61] reads as 1 if this event is implemented and 0 otherwise.

`0x403E`, **TME_FAILURE_TLBI, Transaction failed due to execution of TLBI by another PE**

The counter counts each transaction counted by TME_TRANSACTION_FAILED that fails with IMP cause due to the execution of a `TLBI` instruction by another PE.

If PMEVTYPER<n>_EL0.T is 1, it is IMPLEMENTATION DEFINED whether or not the transaction is counted by the counter.

PMCEID1_EL0[62] reads as 1 if this event is implemented and 0 otherwise.

`0x403F`, **TME_FAILURE_WSET, Transaction failed due to transactional write set limit overflow**

The counter counts each transaction counted by TME_TRANSACTION_FAILED that fails with SIZE cause due to a memory access that causes an eviction of an entry from the transactional write set.

If PMEVTYPER<n>_EL0.T is 1, it is IMPLEMENTATION DEFINED whether or not the transaction is counted by the counter.

PMCEID1_EL0[63] reads as 1 if this event is implemented and 0 otherwise.

`0x8004`, **SIMD_INST_SPEC, Operation speculatively executed, SIMD**

The counter counts each speculatively executed operation due to any of:

- An Advanced SIMD operation. Non-SIMD data-processing operations are not counted.
- A structure load/store of one or more SIMD&FP registers.
- A load and replicate to one or more SIMD&FP registers.
- A scalar load/store of a SIMD&FP Q register or pair of Q registers.
- An SVE load/store.

It is IMPLEMENTATION DEFINED whether scalar loads and stores to SIMD&FP registers other that those listed above are counted.

`0x8005`, **ASE_INST_SPEC, Operation speculatively executed, Advanced SIMD**

The counter counts each speculatively executed operation counted by ASE_SVE_INST_SPEC that is classified as an Advanced SIMD operation.

Operations due to the following instructions are counted as Advanced SIMD operations:

- For AArch64 state:
  - The SIMD operations listed in Data processing - SIMD and floating-point.
  - If FEAT_Crypto is implemented, the Advanced SIMD Cryptographic instructions. See The Cryptographic Extension in AArch64 state.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- Advanced SIMD loads and stores.

This includes all operations that operate on the SIMD&FP registers, except those that are counted as one of the following:

- Integer data-processing operations.
- Scalar floating-point data-processing operations.

It is IMPLEMENTATION DEFINED whether Advanced SIMD scalar operations are counted as Advanced SIMD operations. This includes Advanced SIMD scalar instructions which operate on floating-point values.

`0x8007`, **ASE_SVE_INST_SPEC, Operation speculatively executed, Advanced SIMD or SVE**

The counter counts each speculatively executed operation counted by SE_INST_SPEC that is classified as an Advanced SIMD operation or an SVE operation.

See ASE_INST_SPEC and SVE_INST_SPEC for these classifications.

`0x8008`, **UOP_SPEC, Microarchitectural operation speculatively executed**

The counter counts each speculatively executed microarchitectural operation.

`0x8009`, **ASE_UOP_SPEC, Microarchitectural operation speculatively executed, Advanced SIMD**

The counter counts each speculatively executed microarchitectural operation counted by ASE_SVE_UOP_SPEC due to an A64 Advanced SIMD instruction.

It is IMPLEMENTATION DEFINED whether the counter counts microarchitectural operations due to Advanced SIMD scalar instructions.

`0x800B`, **ASE_SVE_UOP_SPEC, Microarchitectural operation speculatively executed, Advanced SIMD or SVE**

The counter counts each speculatively executed microarchitectural operation counted by UOP_SPEC due to an A64 Advanced SIMD instruction.

It is IMPLEMENTATION DEFINED whether the counter counts microarchitecural operations due to Advanced SIMD scalar instructions.

`0x800C`, **SIMD_UOP_SPEC, Microarchitectural operation speculatively executed, SIMD**

The counter counts each speculatively executed microarchitectural operation counted by UOP_SPEC due to any of:

- An SVE instruction other than non-SIMD SVE instructions.
- An A64 Advanced SIMD instruction other than an Advanced SIMD scalar instruction.

`0x8010`, **FP_SPEC, Floating-point operation speculatively executed, including SIMD**

The counter counts each speculatively executed floating-point data-processing operation due to any of:

- An A64 scalar instruction.
- An A64 Advanced SIMD instruction.

It is IMPLEMENTATION DEFINED whether the counter counts any operation due to the following instructions:

- Scalar: `FABS`, or `FNEG (scalar)`.
- Advanced SIMD: `FABS`, `FNEG (vector)`, `FRECPE`, or `FRSQRTE`.
- Data movement instructions which move data without carrying out any operations on the data. This includes identity data-processing operations.
- Conditional select instructions.
- Floating-point conversion instructions.

Any operation counted by INT_SPEC is not counted.

Arm recommends that if FP_CVT_SPEC is implemented, FP_SPEC counts operations due to convert instructions.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

This event differs from the VFP_SPEC event which does not count SIMD operations.

`0x8011`, **ASE_FP_SPEC, Floating-point operation speculatively executed, Advanced SIMD**

The counter counts each speculatively executed floating-point operation counted by ASE_SVE_FP_SPEC due to an A64 Advanced SIMD instruction.

`0x8013`, **ASE_SVE_FP_SPEC, Floating-point operation speculatively executed, Advanced SIMD or SVE**

The counter counts each speculatively executed floating-point operation counted by SE_FP_SPEC due to an A64 Advanced SIMD instruction.

`0x8014`, **FP_HP_SPEC, Floating-point operation speculatively executed, half-precision**

The counter counts each speculatively executed floating-point operation counted by FP_SPEC where the largest type is half-precision.

`0x8015`, **ASE_FP_HP_SPEC, Floating-point operation speculatively executed, Advanced SIMD half-precision, data-processing**

The counter counts each speculatively executed half-precision floating-point data-processing operation counted by ASE_SVE_FP_HP_SPEC due to an Advanced SIMD instruction.

`0x8017`, **ASE_SVE_FP_HP_SPEC, Floating-point operation speculatively executed, Advanced SIMD or SVE half-precision**

The counter counts each speculatively executed half-precision floating-point operation counted by FP_HP_SPEC due to an Advanced SIMD.

`0x8018`, **FP_SP_SPEC, Floating-point operation speculatively executed, single-precision**

The counter counts each speculatively executed floating-point operation counted by FP_SPEC where the largest type is single-precision.

`0x8019`, **ASE_FP_SP_SPEC, Floating-point operation speculatively executed, Advanced SIMD single-precision, data-processing**

The counter counts each speculatively executed single-precision floating-point data-processing operation counted by ASE_SVE_FP_SP_SPEC due to an Advanced SIMD instruction.

`0x801B`, **ASE_SVE_FP_SP_SPEC, Floating-point operation speculatively executed, Advanced SIMD or SVE single-precision, data-processing**

The counter counts each speculatively executed single-precision floating-point data-processing operation counted by FP_SP_SPEC due to an Advanced SIMD.

`0x801C`, **FP_DP_SPEC, Floating-point operation speculatively executed, double-precision, data-processing**

The counter counts each speculatively executed floating-point data-processing operation counted by FP_SPEC where the largest type is double-precision.

`0x801D`, **ASE_FP_DP_SPEC, Floating-point operation speculatively executed, Advanced SIMD double-precision, data-processing**

The counter counts each speculatively executed double-precision floating-point data-processing operation counted by ASE_SVE_FP_DP_SPEC due to an Advanced SIMD instruction.

`0x801F`, **ASE_SVE_FP_DP_SPEC, Floating-point operation speculatively executed, Advanced SIMD or SVE double-precision, data-processing**

The counter counts each speculatively executed double-precision floating-point data-processing operation due to an Advanced SIMD.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

`0x8020`, **FP_DIV_SPEC, Floating-point operation speculatively executed, divide**

The counter counts each speculatively executed floating-point divide operation counted by FP_SPEC due to any of the following A64 instructions:

- Scalar: FDIV.
- Advanced SIMD: FDIV.

`0x8021`, **ASE_FP_DIV_SPEC, Floating-point operation speculatively executed, Advanced SIMD divide**

The counter counts each speculatively executed floating-point divide operation counted by ASE_SVE_FP_DIV_SPEC due to any of the following A64 instructions:

- Advanced SIMD: FDIV.

`0x8023`, **ASE_SVE_FP_DIV_SPEC, Floating-point operation speculatively executed, Advanced SIMD or SVE divide**

The counter counts each speculatively executed floating-point divide operation counted by FP_DIV_SPEC due to any of the following A64 instructions:

- Advanced SIMD: FDIV.

`0x8024`, **FP_SQRT_SPEC, Floating-point operation speculatively executed, square root**

The counter counts each speculatively executed floating-point square-root operation counted by FP_SPEC due to any of the following A64 instructions:

- Scalar: FSQRT.
- Advanced SIMD: FSQRT.

`0x8025`, **ASE_FP_SQRT_SPEC, Floating-point operation speculatively executed, Advanced SIMD square root**

The counter counts each speculatively executed floating-point square-root operation counted by ASE_SVE_FP_SQRT_SPEC due to any of the following A64 instructions:

- Advanced SIMD: FSQRT.

`0x8027`, **ASE_SVE_FP_SQRT_SPEC, Floating-point operation speculatively executed, Advanced SIMD or SVE square-root**

The counter counts each speculatively executed floating-point square-root operation counted by FP_SQRT_SPEC due to any of the following A64 instructions:

- Advanced SIMD: FSQRT.

`0x8028`, **FP_FMA_SPEC, Floating-point operation speculatively executed, FMA**

The counter counts each speculatively executed floating-point fused multiply-add or multiply-subtract operation counted by FP_SPEC due to any of the following A64 instructions:

- Scalar: FMADD, FMSUB, FNMADD, or FNMSUB.
- Advanced SIMD: FMLA or FMLS.
- When FEAT_FCMA is implemented, Advanced SIMD: FCMLA.
- When FEAT_FHM is implemented, Advanced SIMD: FMLAL, FMLAL2, FMLSL, or FMLSL2.

`0x8029`, **ASE_FP_FMA_SPEC, Floating-point operation speculatively executed, Advanced SIMD FMA**

The counter counts each speculatively executed floating-point fused multiply-add or multiply-subtract operation counted by ASE_SVE_FP_FMA_SPEC due to any of the following A64 instructions:

- Advanced SIMD: FMLA or FMLS.
- When FEAT_FCMA is implemented, Advanced SIMD: FCMLA.
- When FEAT_FHM is implemented, Advanced SIMD: FMLAL, FMLAL2, FMLSL, or FMLSL2.

`0x802B`, **ASE_SVE_FP_FMA_SPEC, Floating-point operation speculatively executed, Advanced SIMD or SVE FMA**

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The counter counts each speculatively executed floating-point fused multiply-add or multiply-subtract operation counted by FP_FMA_SPEC due to any of the following A64 instructions:

- Advanced SIMD: FMLA or FMLS.
- When FEAT_FCMA is implemented, Advanced SIMD: FCMLA.
- When FEAT_FHM is implemented, Advanced SIMD: FMLAL, FMLAL2, FMLSL, or FMLSL2.

`0x802C`, **FP_MUL_SPEC, Floating-point operation speculatively executed, multiply**

The counter counts each speculatively executed floating-point multiply operation counted by FP_SPEC due to any of the following A64 instructions:

- Scalar: FMUL or FMULX.
- Advanced SIMD: FMUL or FMULX.

`0x802D`, **ASE_FP_MUL_SPEC, Floating-point operation speculatively executed, Advanced SIMD multiply**

The counter counts each speculatively executed floating-point multiply operation counted by ASE_SVE_FP_MUL_SPEC due to any of the following A64 instructions:

- Advanced SIMD: FMUL or FMULX.

`0x802F`, **ASE_SVE_FP_MUL_SPEC, Floating-point operation speculatively executed, Advanced SIMD or SVE multiply**

The counter counts each speculatively executed floating-point fused multiply-add or multiply-subtract operation counted by FP_MUL_SPEC due to any of the following A64 instructions:

- Advanced SIMD: FMUL or FMULX.

`0x8030`, **FP_ADDSUB_SPEC, Floating-point operation speculatively executed, add or subtract**

The counter counts each speculatively executed floating-point add or subtract operation counted by FP_SPEC due to any of the following A64 instructions:

- Scalar: FADD or FSUB.
- Advanced SIMD: FABD, FADD, or FSUB.

`0x8031`, **ASE_FP_ADDSUB_SPEC, Floating-point operation speculatively executed, Advanced SIMD add or subtract**

The counter counts each speculatively executed floating-point add or subtract operation counted by ASE_SVE_FP_ADDSUB_SPEC due to any of the following A64 instructions:

- Advanced SIMD: FABD, FADD, or FSUB.

`0x8033`, **ASE_SVE_FP_ADDSUB_SPEC, Floating-point operation speculatively executed, Advanced SIMD or SVE add or subtract**

The counter counts each speculatively executed floating-point add or subtract operation counted by FP_ADDSUB_SPEC due to any of the following A64 instructions:

- Advanced SIMD: FABD, FADD, or FSUB.

`0x8034`, **FP_RECPE_SPEC, Floating-point operation speculatively executed, reciprocal estimate**

The counter counts each speculatively executed floating-point reciprocal estimate operation counted by FP_SPEC due to any of the following A64 instructions:

- Advanced SIMD: FRECPE or FRSQRTE.

`0x8035`, **ASE_FP_RECPE_SPEC, Floating-point operation speculatively executed, Advanced SIMD reciprocal estimate**

The counter counts each speculatively executed floating-point reciprocal estimate operation counted by ASE_SVE_FP_RECPE_SPEC due to any of the following A64 instructions:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- Advanced SIMD: FRECPE or FRSQRTE.

`0x8037`, **ASE_SVE_FP_RECPE_SPEC, Floating-point operation speculatively executed, Advanced SIMD or SVE reciprocal estimate**

The counter counts each speculatively executed floating-point reciprocal estimate operation counted by FP_RECPE_SPEC due to any of the following A64 instructions:

- Advanced SIMD: FRECPE or FRSQRTE.

`0x8038`, **FP_CVT_SPEC, Floating-point operation speculatively executed, convert**

The counter counts each speculatively executed floating-point convert operation due to any of:

- An A64 scalar floating-point conversion instruction.
- An Advanced SIMD floating-point conversion instruction.
- An SVE floating-point conversion instruction.

This includes both conversions between floating-point types, and conversions between integer and floating-point types.

`0x8039`, **ASE_FP_CVT_SPEC, Floating-point operation speculatively executed, Advanced SIMD convert**

The counter counts each speculatively executed floating-point convert operation counted by ASE_SVE_FP_CVT_SPEC due to an A64 Advanced SIMD instruction.

`0x803B`, **ASE_SVE_FP_CVT_SPEC, Floating-point operation speculatively executed, Advanced SIMD or SVE convert**

The counter counts each speculatively executed floating-point convert operation counted by FP_CVT_SPEC due to an A64 Advanced SIMD instruction.

`0x803D`, **ASE_FP_PREDUCE_SPEC, Floating-point operation speculatively executed, Advanced SIMD pairwise add step or pairwise reduce step**

The counter counts each speculatively executed floating-point pairwise add step or pairwise reduce step operation counted by ASE_FP_VREDUCE_SPEC due to any of the following A64 instructions:

- Advanced SIMD: FADDP, FMAXNMP, FMAXP, FMINNMP, or FMINP.

`0x803F`, **ASE_SVE_FP_VREDUCE_SPEC, Floating-point operation speculatively executed, Advanced SIMD or SVE vector reduction**

The counter counts each speculatively executed floating-point reduction operation counted by ASE_SVE_FP_SPEC due to any of the following A64 instructions:

- Advanced SIMD: FADDP, FMAXNMP, FMAXNMV, FMAXP, FMAXV, FMINNMP, FMINNMV, FMINP, or FMINV.

`0x8040`, **INT_SPEC, Integer operation speculatively executed**

The counter counts each speculatively executed integer arithmetic operation due to any of:

- An A64 scalar data-processing instruction.
- An Advanced SIMD instruction.
- An SVE data-processing instruction.

It is IMPLEMENTATION DEFINED whether the counter counts any operation due to the following instructions:

- Scalar: `FABS`, `FNEG (scalar)`.
- Advanced SIMD: `FABS`, `FNEG (vector)`, `FRECPE`, `FRSQRTE`.
- Data movement instructions which move data without carrying out any operations on the data. This includes identity data-processing operations.
- Conditional select instructions.
- Floating-point conversion instructions.

Any operation counted by FP_SPEC is not counted.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

`0x8041`, **ASE_INT_SPEC, Integer operation speculatively executed, Advanced SIMD**

The counter counts each speculatively executed integer operation counted by ASE_SVE_INT_SPEC due to an A64 Advanced SIMD instruction.

`0x8043`, **ASE_SVE_INT_SPEC, Integer operation speculatively executed, Advanced SIMD or SVE**

The counter counts each speculatively executed integer arithmetic operation counted by SE_INT_SPEC due to an A64 Advanced SIMD.

`0x8044`, **INT_DIV_SPEC, Integer operation speculatively executed, divide**

The counter counts each speculatively executed integer divide operation counted by INT_SPEC due to any of the following A64 instructions:

- Scalar: SDIV or UDIV.

`0x8045`, **INT_DIV64_SPEC, Integer operation speculatively executed, 64-bit divide**

The counter counts each speculatively executed integer divide operation counted by INT_SPEC due to any of the following A64 instructions:

- Scalar: SDIV or UDIV.

The counter only counts operations with 64-bit operands or vector elements.

`0x8048`, **INT_MUL_SPEC, Integer operation speculatively executed, multiply**

The counter counts each speculatively executed integer multiply or multiply-accumulate operation counted by INT_SPEC due to any of the following A64 instructions:

- Scalar: MADD, MSUB, MUL, SMADDL, SMULH, UMADDL, or UMULH.
- Advanced SIMD: MLA, MLS, MUL, PMUL, PMULL, PMULL2, SMLAL, SMLAL2, SMLSL, SMLSL2, SMULL, SMULL2, SQDMLAL, SQDMLAL2, SQDMLSL, SQDMLSL2, SQDMULH, SQDMULL, SQDMULL2, SQRDMULH, UMLAL, UMLAL2, UMLSL, UMLSL2, UMULL, or UMULL2.
- When FEAT_RDM is implemented, Advanced SIMD: SQRDMLAH or SQRDMLSH.

`0x8049`, **ASE_INT_MUL_SPEC, Integer operation speculatively executed, Advanced SIMD multiply**

The counter counts each speculatively executed integer multiply or multiply-accumulate operation counted by ASE_SVE_INT_MUL_SPEC due to any of the following A64 instructions:

- Advanced SIMD: MLA, MLS, MUL, PMUL, PMULL, PMULL2, SMLAL, SMLAL2, SMLSL, SMLSL2, SMULL, SMULL2, SQDMLAL, SQDMLAL2, SQDMLSL, SQDMLSL2, SQDMULH, SQDMULL, SQDMULL2, SQRDMULH, UMLAL, UMLAL2, UMLSL, UMLSL2, UMULL, or UMULL2.
- When FEAT_RDM is implemented, Advanced SIMD: SQRDMLAH or SQRDMLSH.

`0x804B`, **ASE_SVE_INT_MUL_SPEC, Integer operation speculatively executed, Advanced SIMD or SVE multiply**

The counter counts each speculatively executed integer multiply or multiply-accumulate operation counted by INT_MUL_SPEC due to any of the following A64 instructions:

- Advanced SIMD: MLA, MLS, MUL, PMUL, PMULL, PMULL2, SMLAL, SMLAL2, SMLSL, SMLSL2, SMULL, SMULL2, SQDMLAL, SQDMLAL2, SQDMLSL, SQDMLSL2, SQDMULH, SQDMULL, SQDMULL2, SQRDMULH, UMLAL, UMLAL2, UMLSL, UMLSL2, UMULL, or UMULL2.
- When FEAT_RDM is implemented, Advanced SIMD: SQRDMLAH or SQRDMLSH.

`0x804C`, **INT_MUL64_SPEC, Integer operation speculatively executed, 64×64 multiply**

The counter counts each speculatively executed 64×64 integer multiply operation counted by INT_SPEC due to any of the following A64 instructions:

- Scalar: MADD, MSUB, MUL, SMULH, or UMULH.

The counter only counts operations that perform a 64-bit × 64-bit integer multiply operations.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

`0x804E`, **INT_MULH64_SPEC, Integer operation speculatively executed, 64×64 multiply returning high part**

The counter counts each speculatively executed widening 64×64 integer multiply operation counted by INT_SPEC due to any of the following A64 instructions:

- Scalar: SMULH or UMULH.

These instructions perform 64-bit × 64-bit integer multiply operations.

`0x8053`, **ASE_SVE_FP_BF16_SPEC, Floating-point operation speculatively executed, SVE or Advanced SIMD BFloat16, data-processing**

The counter counts each speculatively executed BFloat16 floating-point data-processing operation counted by FP_BF16_SPEC due to an Advanced SIMD.

`0x8056`, **SVE_SPEC, Operation speculatively executed, SVE data processing**

The counter counts each operation counted by ASE_SVE_SPEC that is an SVE data-processing operation.

An SVE data-processing operation is any operation due to an instruction that operates on the SVE scalable vector and predicate registers that is not any of the following:

- A load or store operation. These are counted by SVE_INST_SPEC.
- If the Cryptographic Extension is implemented, an operation counted by CRYPTO_SPEC as a Cryptographic data-processing operation.

If the Cryptographic Extension and FEAT_SVE2 are implemented, operations due to the SVE `PMULLB` and `PMULLT` (Q variants) instructions are not counted by CRYPTO_SPEC and are counted as SVE data-processing operations.

`0x8057`, **ASE_SVE_SPEC, Operation speculatively executed, Advanced SIMD data processing or SVE data processing**

The counter counts each operation counted by INST_SPEC that is an Advanced SIMD data-processing operation or an SVE data-processing operation.

See ASE_SPEC and SVE_SPEC for these classifications.

`0x8058`, **NONFP_SPEC, Non-floating-point operation speculatively executed**

The counter counts each speculatively executed data-processing operation due to any of:

- A scalar instruction that would be counted by the DP_SPEC event.
- An A64 Advanced SIMD data processing instruction defined in the section Data processing - SIMD and floating-point that would not be counted by FP_SPEC.
- An SVE instruction with vector source or destination registers that would not be counted by FP_SPEC.

`0x8059`, **ASE_NONFP_SPEC, Non-floating-point operation speculatively executed, Advanced SIMD**

The counter counts each speculatively executed non-floating-point operation counted by ASE_SVE_NONFP_SPEC due to an A64 Advanced SIMD instruction.

`0x805B`, **ASE_SVE_NONFP_SPEC, Non-floating-point operation speculatively executed, Advanced SIMD or SVE**

The counter counts each speculatively executed non-floating-point operation counted by NONFP_SPEC due to an A64 Advanced SIMD instruction.

`0x805D`, **ASE_INT_VREDUCE_SPEC, Integer operation speculatively executed, Advanced SIMD reduction**

The counter counts each speculatively executed across-vector and pairwise integer reduction operation counted by ASE_SVE_INT_VREDUCE_SPEC due to any of the following A64 instructions:

- Advanced SIMD: ADDP, ADDV, SADALP, SADDLP, SADDLV, SMAXP, SMAXV, SMINP, SMINV, UADALP, UADDLP, UADDLV, UMAXP, UMAXV, UMINP, or UMINV.

`0x805F`, **ASE_SVE_INT_VREDUCE_SPEC, Integer operation speculatively executed, Advanced SIMD or SVE reduction**

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The counter counts each speculatively executed across-vector and pairwise integer reduction operation counted by INT_SPEC due to any of the following A64 instructions:

- Advanced SIMD: ADDP, ADDV, SADALP, SADDLP, SADDLV, SMAXP, SMAXV, SMINP, SMINV, UADALP, UADDLP, UADDLV, UMAXP, UMAXV, UMINP, or UMINV.

`0x8084`, **ASE_SVE_LDST_SPEC, Operation speculatively executed, Advanced SIMD or SVE load or store**

The counter counts each speculatively executed operation that reads from or writes to memory due to an A64 Advanced SIMD load, store, or prefetch instruction.

`0x8085`, **ASE_SVE_LD_SPEC, Operation speculatively executed, Advanced SIMD or SVE load**

The counter counts each speculatively executed operation that reads from memory counted by ASE_SVE_LDST_SPEC due to an A64 Advanced SIMD load instruction.

`0x8086`, **ASE_SVE_ST_SPEC, Operation speculatively executed, Advanced SIMD or SVE store**

The counter counts each speculatively executed operation that writes to memory counted by ASE_SVE_LDST_SPEC due to an A64 Advanced SIMD store instruction.

`0x8087`, **PRF_SPEC, Operation speculatively executed, prefetch**

The counter counts each speculatively executed prefetch operation due to any of the following A64 instructions:

- Scalar: PRFM, PRFUM, or RPRFM.

`0x8088`, **BASE_LDST_REG_SPEC, Operation speculatively executed, general-purpose register load, store, or prefetch**

The counter counts each speculatively executed operation that reads from or writes to memory due to a general-purpose register load, store, or prefetch instruction.

`0x8089`, **BASE_LD_REG_SPEC, Operation speculatively executed, general-purpose register load**

The counter counts each speculatively executed operation that reads from memory counted by BASE_LDST_REG_SPEC due to a general-purpose register load instruction.

`0x808A`, **BASE_ST_REG_SPEC, Operation speculatively executed, general-purpose register store**

The counter counts each speculatively executed operation that writes to memory counted by BASE_LDST_REG_SPEC due to a general-purpose register store instruction.

It is IMPLEMENTATION DEFINED whether the counter counts operations due to `DC ZVA` instructions.

`0x808B`, **BASE_PRF_SPEC, Operation speculatively executed, general-purpose register prefetch**

The counter counts each speculatively executed prefetch operation counted by BASE_LDST_REG_SPEC due to any of the following A64 instructions:

- Scalar: PRFM, PRFUM, or RPRFM.

`0x808C`, **FPASE_LDST_REG_SPEC, Operation speculatively executed, SIMD&FP register load or store**

The counter counts each speculatively executed operation that reads from or writes to memory due to any of the following A64 instructions:

- Scalar: LDP (SIMD&FP), LDR (SIMD&FP), STP (SIMD&FP), or STR (SIMD&FP).
- Advanced SIMD: LD1, LD1R, LDNP, LDP, LDR, LDUR, ST1, STNP, STP, STR, or STUR.

`0x808D`, **FPASE_LD_REG_SPEC, Operation speculatively executed, SIMD&FP register load**

The counter counts each speculatively executed operation that reads from memory counted by FPASE_LDST_REG_SPEC due to any of the following A64 instructions:

- Scalar: LDP (SIMD&FP) or LDR (SIMD&FP).

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- Advanced SIMD: LD1, LD1R, LDNP, LDP, LDR, or LDUR.

`0x808E`, **FPASE_ST_REG_SPEC, Operation speculatively executed, SIMD&FP register store**

The counter counts each speculatively executed operation that writes to memory counted by FPASE_LDST_REG_SPEC due to any of the following A64 instructions:

- Scalar: STP (SIMD&FP) or STR (SIMD&FP).
- Advanced SIMD: ST1, STNP, STP, STR, or STUR.

`0x80A4`, **ASE_SVE_LDST_MULTI_SPEC, Operation speculatively executed, Advanced SIMD or SVE contiguous load or store multiple vector**

The counter counts each speculatively executed operation due to an A64 Advanced SIMD multiple vector contiguous structure load or store instruction.

`0x80A5`, **ASE_SVE_LD_MULTI_SPEC, Operation speculatively executed, Advanced SIMD or SVE contiguous load multiple vector**

The counter counts each speculatively executed operation that reads from memory counted by ASE_SVE_LDST_MULTI_SPEC due to an A64 Advanced SIMD multiple vector contiguous structure load instruction.

`0x80A6`, **ASE_SVE_ST_MULTI_SPEC, Operation speculatively executed, Advanced SIMD or SVE contiguous store multiple vector**

The counter counts each speculatively executed operation that writes to memory counted by ASE_SVE_LDST_MULTI_SPEC due to an A64 Advanced SIMD multiple vector contiguous structure store instruction.

`0x80B4`, **ASE_SVE_UNALIGNED_LDST_SPEC, Advanced SIMD or SVE unaligned access**

The counter counts each speculatively executed A64 Advanced SIMD load or store instruction where either:

- A contiguous vector address is not aligned to the minimum of the in-memory size of the vector and the cache line size, in bytes.
- A gather, scatter, or single element address is not aligned to the memory element access size, in bytes.

The unaligned access is counted even if it is subsequently converted into multiple aligned accesses.

`0x80B5`, **ASE_SVE_UNALIGNED_LD_SPEC, Advanced SIMD or SVE unaligned read**

The counter counts each unaligned memory access counted by ASE_SVE_UNALIGNED_LDST_SPEC due to an A64 Advanced SIMD load instruction.

The unaligned access is counted even if it is subsequently converted into multiple aligned accesses.

`0x80B6`, **ASE_SVE_UNALIGNED_ST_SPEC, Advanced SIMD or SVE unaligned write**

The counter counts each unaligned memory access counted by ASE_SVE_UNALIGNED_LDST_SPEC due to an A64 Advanced SIMD store instruction.

The unaligned access is counted even if it is subsequently converted into multiple aligned accesses.

`0x80B8`, **ASE_SVE_UNALIGNED_CONTIG_LDST_SPEC, Advanced SIMD or SVE unaligned contiguous access**

The counter counts each speculatively executed Advanced SIMD contiguous load or store operation where the address is not aligned to the minimum of the in-memory size of the vector and the cache line size, in bytes.

The unaligned access is counted even if it is subsequently converted into multiple aligned accesses.

`0x80B9`, **ASE_SVE_UNALIGNED_CONTIG_LD_SPEC, Advanced SIMD or SVE unaligned contiguous read**

The counter counts each unaligned memory access counted by ASE_SVE_UNALIGNED_CONTIG_LDST_SPEC due to an A64 Advanced SIMD load instruction.

The unaligned access is counted even if it is subsequently converted into multiple aligned accesses.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

`0x80BA`, **ASE_SVE_UNALIGNED_CONTIG_ST_SPEC, Advanced SIMD or SVE unaligned contiguous write**

The counter counts each unaligned memory access counted by ASE_SVE_UNALIGNED_CONTIG_LDST_SPEC due to a A64 Advanced SIMD store instruction.

The unaligned access is counted even if it is subsequently converted into multiple aligned accesses.

`0x80C1`, **FP_FIXED_OPS_SPEC, Non-scalable element arithmetic operations speculatively executed, floating-point**

The counter increments by v for each speculatively executed non-scalable element arithmetic operation, due to an instruction where the type was floating-point.

Where v is the number of arithmetic operations carried out by the operation or instruction which causes the counter to increment.

The counter does not count operations that are counted by FP_SCALE_OPS_SPEC.

`0x80C3`, **FP_HP_FIXED_OPS_SPEC, Non-scalable element arithmetic operations speculatively executed, largest type is half-precision floating-point**

The counter increments by v for each speculatively executed non-scalable element arithmetic operation, due to an instruction where the largest type was half-precision floating-point.

Where v is the number of arithmetic operations carried out by the operation or instruction which causes the counter to increment.

The counter does not count operations that are counted by FP_SCALE_OPS_SPEC.

`0x80C5`, **FP_SP_FIXED_OPS_SPEC, Non-scalable element arithmetic operations speculatively executed, largest type is single-precision floating-point**

The counter increments by v for each speculatively executed non-scalable element arithmetic operation, due to an instruction where the largest type was single-precision floating-point.

Where v is the number of arithmetic operations carried out by the operation or instruction which causes the counter to increment.

The counter does not count operations that are counted by FP_SCALE_OPS_SPEC.

`0x80C7`, **FP_DP_FIXED_OPS_SPEC, Non-scalable element arithmetic operations speculatively executed, largest type is double-precision floating-point**

The counter increments by v for each speculatively executed non-scalable element arithmetic operation, due to an instruction where the largest type was double-precision floating-point.

Where v is the number of arithmetic operations carried out by the operation or instruction which causes the counter to increment.

The counter does not count operations that are counted by FP_SCALE_OPS_SPEC.

`0x80C9`, **INT_FIXED_OPS_SPEC, Non-scalable element arithmetic operations speculatively executed, integer**

The counter increments by v for each speculatively executed non-scalable element arithmetic operation, due to an instruction where the type was integer.

Where v is the number of arithmetic operations carried out by the operation or instruction which causes the counter to increment.

The counter does not count operations that are counted by FP_SCALE_OPS_SPEC.

`0x80CB`, **LDST_FIXED_OPS_SPEC, Non-scalable load or store element operations speculatively executed**

The counter counts each speculatively executed Memory-read operation or Memory-write operation due to any of:

- Any load, store, or atomic operation, other than loads and stores of the SVE P and Z registers.
- Any SVE non-vector load or store operation.
- An SVE load and replicate instruction, including: `LD1R`, `LD1RB`, `LD1RD`, `LD1RH`, `LD1RQ`, `LD1RQB`, `LD1RQD`, `LD1RQH`, `LD1RQW`, `LD1RSB`, `LD1RSH`, or `LD1RSW`.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

For each instruction, the counter is incremented by the number of operations specified by the instruction. For example, the counter counts operations as follows:

- Non-SVE load and store of a single register instructions increment the counter by 1. This includes loads and stores of Sx, Dx, and Qx SIMD&FP registers.
- Non-SVE load and store of a pair of registers instructions increment the counter by 2. This includes loads and stores of Sx, Dx, and Qx SIMD&FP registers.
- Atomic store instructions increment the counter by 1. These are instructions that atomically update a value in memory without returning a value to a register.
- Atomic load, compare and swap of a single register, and swap instructions increment the counter by 2. Atomic load instructions are instructions that atomically update a value in memory, returning a value to a register.
- Compare and swap of a pair of registers increment the counter by 4.
- Advanced SIMD `LD1R` instructions increment the counter by 1.
- Advanced SIMD `LD[1-4]` and `ST[1-4]` instructions increment the counter by the number of elements transferred per vector multiplied by the number of transferred registers.
- `DC ZVA` and `DC GZVA` instructions increment by an IMPLEMENTATION DEFINED amount.

Note

When a replicating load instruction loads data of the same size as the vector length, which causes no replication to occur, the instruction is counted.

`0x80CD`**, LD_FIXED_OPS_SPEC, Non-scalable load element operations speculatively executed**

The counter counts each speculatively executed Memory-read operation counted by LDST_FIXED_OPS_SPEC.

For each instruction, the counter is incremented by the number of operations specified by the instruction. That is, the counter is incremented by:

- Half the value that the LDST_FIXED_OPS_SPEC event counts if the operation is a load atomic, compare and swap, or swap operation.
- The same as for LDST_FIXED_OPS_SPEC if the operation is any other load operation.

`0x80CF`**, ST_FIXED_OPS_SPEC, Non-scalable store element operations speculatively executed**

The counter counts each Memory-write operation counted by LDST_FIXED_OPS_SPEC.

For each instruction, the counter is incremented by the number of operations specified by the instruction. That is, the counter is incremented by:

- Half the value that the LDST_FIXED_OPS_SPEC event counts if the operation is a store atomic, compare and swap, or swap operation.
- The same as for LDST_FIXED_OPS_SPEC if the operation is any other store operation.

`0x80DB`**, LDST_FIXED_BYTES_SPEC, Non-scalable load and store bytes speculatively executed**

The counter counts each byte speculatively read or written due to any of:

- Any load, store, or atomic operation, other than loads and stores of the SVE P and Z registers.
- Any SVE non-vector load or store operation.
- An SVE load and replicate instruction, including: `LD1R`, `LD1RB`, `LD1RD`, `LD1RH`, `LD1RQ`, `LD1RQB`, `LD1RQD`, `LD1RQH`, `LD1RQW`, `LD1RSB`, `LD1RSH`, or `LD1RSW`.

For each instruction, the counter is incremented by the number of bytes transferred per register multiplied by the number of registers transferred multiplied by the number of transfers made per register. For example, the counter counts bytes as follows:

- Non-SVE load and store of a single register instructions increment the counter by (MSIZE ÷ 8). This includes loads and stores of Sx, Dx, and Qx SIMD&FP registers.
- Non-SVE load and store of a pair of registers instructions increment the counter by 2 × (MSIZE ÷ 8). This includes loads and stores of Sx, Dx, and Qx SIMD&FP registers.
- Atomic store instructions increment the counter by (MSIZE ÷ 8). These are instructions that atomically update a value in memory without returning a value to a register.
- Atomic load, compare and swap of a single register, and swap instructions increment the counter by 2 × (MSIZE ÷ 8). Atomic load instructions are instructions that atomically update a value in memory, returning a value to a register.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- Compare and swap of a pair of registers increment the counter by 4 × (MSIZE ÷ 8).
- Advanced SIMD `LD1R` instructions increment the counter by (MSIZE ÷ 8).
- Advanced SIMD `LD[1-4]` and `ST[1-4]` instructions increment the counter by the number of registers transferred multiplied by the number of bytes being transferred per register.
- `DC ZVA` instructions increment by the counter by $2^{(DCZID_EL0.BS)}$.

`0x80DD`, **LD_FIXED_BYTES_SPEC, Non-scalable load bytes speculatively executed**

The counter counts each speculatively read byte counted by LDST_FIXED_BYTES_SPEC.

For each instruction, the counter is incremented by the number of bytes transferred per register multiplied by the number of registers transferred. That is, the counter is incremented by:

- Half the value that the LDST_FIXED_BYTES_SPEC event counts if the operation is a load atomic, compare and swap, or swap operation.
- The same as for LDST_FIXED_BYTES_SPEC if the operation is any other load operation.

`0x80DF`, **ST_FIXED_BYTES_SPEC, Non-scalable store bytes speculatively executed**

The counter counts each speculatively written byte counted by LDST_FIXED_BYTES_SPEC.

For each instruction, the counter is incremented by the number of bytes transferred per register multiplied by the number of registers transferred. That is, the counter is incremented by:

- Half the value that the LDST_FIXED_BYTES_SPEC event counts if the operation is a swap, or compare and swap operation.
- The same as for LDST_FIXED_BYTES_SPEC if the operation is any other store operation, including an atomic store operation.

`0x80E1`, **ASE_INT8_SPEC, Integer operation speculatively executed, Advanced SIMD 8-bit**

The counter counts each operation counted by ASE_SVE_INT8_SPEC that is an Advanced SIMD operation.

`0x80E3`, **ASE_SVE_INT8_SPEC, Integer operation speculatively executed, Advanced SIMD or SVE 8-bit**

The counter counts each operation counted by ASE_SVE_INT_SPEC where the largest type is 8-bit integer.

`0x80E5`, **ASE_INT16_SPEC, Integer operation speculatively executed, Advanced SIMD 16-bit**

The counter counts each operation counted by ASE_SVE_INT16_SPEC that is an Advanced SIMD operation.

`0x80E7`, **ASE_SVE_INT16_SPEC, Integer operation speculatively executed, Advanced SIMD or SVE 16-bit**

The counter counts each operation counted by ASE_SVE_INT_SPEC where the largest type is 16-bit integer.

`0x80E9`, **ASE_INT32_SPEC, Integer operation speculatively executed, Advanced SIMD 32-bit**

The counter counts each operation counted by ASE_SVE_INT32_SPEC that is an Advanced SIMD operation.

`0x80EB`, **ASE_SVE_INT32_SPEC, Integer operation speculatively executed, Advanced SIMD or SVE 32-bit**

The counter counts each operation counted by ASE_SVE_INT_SPEC where the largest type is 32-bit integer.

`0x80ED`, **ASE_INT64_SPEC, Integer operation speculatively executed, Advanced SIMD 64-bit**

The counter counts each operation counted by ASE_SVE_INT64_SPEC that is an Advanced SIMD operation.

`0x80EF`, **ASE_SVE_INT64_SPEC, Integer operation speculatively executed, Advanced SIMD or SVE 64-bit**

The counter counts each operation counted by ASE_SVE_INT_SPEC where the largest type is 64-bit integer.

`0x80F1`, **ASE_FP_DOT_SPEC, Floating-point operation speculatively executed, Advanced SIMD dot-product**

The counter counts each dot-product operation counted by ASE_SVE_FP_DOT_SPEC due to any of the following A64 instructions:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

`0x80F3`, **ASE_SVE_FP_DOT_SPEC, Floating-point operation speculatively executed, Advanced SIMD or SVE dot-product**

The counter counts each dot-product operation counted by FP_SPEC due to any of the following A64 instructions:

`0x80F5`, **ASE_FP_MMLA_SPEC, Floating-point operation speculatively executed, Advanced SIMD matrix multiply**

The counter counts each floating-point matrix multiply operation counted by ASE_SVE_FP_MMLA_SPEC due to any of the following A64 instructions:

`0x80F7`, **ASE_SVE_FP_MMLA_SPEC, Floating-point operation speculatively executed, Advanced SIMD or SVE matrix multiply**

The counter counts each floating-point matrix multiply operation counted by FP_SPEC due to any of the following A64 instructions:

`0x80F9`, **ASE_INT_DOT_SPEC, Operation speculatively executed, Advanced SIMD integer dot-product**

The counter counts each integer dot product operation counted by ASE_SVE_INT_DOT_SPEC due to any of the following A64 instructions:

- When FEAT_DotProd is implemented, Advanced SIMD: SDOT or UDOT.

`0x80FB`, **ASE_SVE_INT_DOT_SPEC, Integer operation speculatively executed, Advanced SIMD or SVE dot-product**

The counter counts each integer dot product operation counted by INT_SPEC due to any of the following A64 instructions:

- When FEAT_DotProd is implemented, Advanced SIMD: SDOT or UDOT.

`0x80FD`, **ASE_INT_MMLA_SPEC, Integer operation speculatively executed, Advanced SIMD matrix multiply**

The counter counts each integer matrix multiply operation counted by ASE_SVE_INT_MMLA_SPEC due to any of the following A64 instructions:

`0x80FF`, **ASE_SVE_INT_MMLA_SPEC, Integer operation speculatively executed, Advanced SIMD or SVE matrix multiply**

The counter counts each integer matrix multiply operation counted by INT_SPEC due to any of the following A64 instructions:

`0x8110`, **BR_IMMED_PRED_RETIRED, Branch instruction architecturally executed, predicted immediate**

The counter counts each instruction counted by both BR_IMMED_RETIRED and BR_PRED_RETIRED.

These are all direct branch instructions on the architecturally executed path, where the branch is correctly predicted.

`0x8111`, **BR_IMMED_MIS_PRED_RETIRED, Branch instruction architecturally executed, mispredicted immediate**

The counter counts each instruction counted by both BR_IMMED_RETIRED and BR_MIS_PRED_RETIRED.

These are all direct branch instructions on the architecturally executed path, where the branch is mispredicted.

`0x8112`, **BR_IND_PRED_RETIRED, Branch instruction architecturally executed, predicted indirect**

The counter counts each instruction counted by both BR_IND_RETIRED and BR_PRED_RETIRED.

These are all indirect branch instructions, including return instructions, on the architecturally executed path, where the branch is correctly predicted.

`0x8113`, **BR_IND_MIS_PRED_RETIRED, Branch instruction architecturally executed, mispredicted indirect**

The counter counts each instruction counted by both BR_IND_RETIRED and BR_MIS_PRED_RETIRED.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

These are all indirect branch instructions, including return instructions, on the architecturally executed path, where the branch is mispredicted.

`0x8114`, **BR_RETURN_PRED_RETIRED, Branch instruction architecturally executed, predicted procedure return**

The counter counts each instruction counted by BR_IND_PRED_RETIRED where if taken, the branch would be counted by BR_RETURN_RETIRED.

These are all return instructions on the architecturally executed path, where the branch is correctly predicted.

`0x8115`, **BR_RETURN_MIS_PRED_RETIRED, Branch instruction architecturally executed, mispredicted procedure return**

The counter counts each instruction counted by BR_IND_MIS_PRED_RETIRED where if taken, the branch would also be counted by BR_RETURN_RETIRED.

These are all return instructions on the architecturally executed path, where the branch is mispredicted.

`0x8116`, **BR_INDNR_PRED_RETIRED, Branch instruction architecturally executed, predicted indirect excluding procedure return**

The counter counts each instruction counted by BR_IND_PRED_RETIRED where if taken, the branch would not be counted by BR_RETURN_RETIRED.

These are all indirect branch instructions, excluding return instructions, on the architecturally executed path, where the branch is correctly predicted.

`0x8117`, **BR_INDNR_MIS_PRED_RETIRED, Branch instruction architecturally executed, mispredicted indirect excluding procedure return**

The counter counts each instruction counted by BR_IND_MIS_PRED_RETIRED where if taken, the branch would not be counted by BR_RETURN_RETIRED.

These are all indirect branch instructions, excluding return instructions, on the architecturally executed path, where the branch is mispredicted.

`0x8118`, **BR_TAKEN_PRED_RETIRED, Branch instruction architecturally executed, predicted branch, taken**

The counter counts each instruction counted by both BR_PRED_RETIRED and PC_WRITE_RETIRED.

These are all branch instructions on the architecturally executed path, where the branch is correctly predicted and taken.

`0x8119`, **BR_TAKEN_MIS_PRED_RETIRED, Branch instruction architecturally executed, mispredicted branch, taken**

The counter counts each instruction counted by both BR_MIS_PRED_RETIRED and PC_WRITE_RETIRED.

These are all branch instructions on the architecturally executed path, where the branch is mispredicted and taken.

`0x811A`, **BR_SKIP_PRED_RETIRED, Branch instruction architecturally executed, predicted branch, not taken**

The counter counts each instruction counted by both BR_PRED_RETIRED and BR_SKIP_RETIRED.

These are all branch instructions on the architecturally executed path, where the branch is correctly predicted and not taken.

`0x811B`, **BR_SKIP_MIS_PRED_RETIRED, Branch instruction architecturally executed, mispredicted branch, not taken**

The counter counts each instruction counted by both BR_MIS_PRED_RETIRED and BR_SKIP_RETIRED.

These are all branch instructions on the architecturally executed path, where the branch is mispredicted and not taken.

`0x811C`, **BR_PRED_RETIRED, Branch instruction architecturally executed, predicted branch**

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The counter counts each instruction counted by BR_RETIRED that is not counted by BR_MIS_PRED_RETIRED.

These are all branch instructions on the architecturally executed path, where the branch is correctly predicted.

`0x8120`, **INST_FETCH_PERCYC, Instruction fetches in progress**

The counter increments by the number of instruction fetches counted by INST_FETCH in progress on each Processor cycle.

The ratio INST_FETCH_PERCYC ÷ INST_FETCH is the mean duration of instruction fetches in Processor cycles.

`0x8121`, **MEM_ACCESS_RD_PERCYC, Data memory reads in progress**

The counter increments by the number of data memory reads counted by MEM_ACCESS_RD in progress on each Processor cycle.

The ratio MEM_ACCESS_RD_PERCYC ÷ MEM_ACCESS_RD is the mean duration of data memory reads in Processor cycles.

`0x8122`, **SAMPLE_FEED_DS, Statistical Profiling sample taken, selected Data Source**

The counter counts each SPE sample that is a load operations where PMSDSFR_EL1[s] is 1 and s is bits [5:0] of the sampled Data Source.

The values of PMSFCR_EL1.FDS are ignored when generating this event.

Samples that are removed by filtering, or discarded, and not written to the Profiling Buffer are counted.

`0x8123`, **SAMPLE_BUFFER_FULL, Profiling Buffer full**

The counter counts each Profiling Buffer full management event.

`0x8124`, **INST_FETCH, Instruction memory access**

The counter counts each Instruction memory access.

The counter increments whether the access results in an access to a Level 1 instruction cache, a Level 2 instruction, data or unified cache, or none of these.

The counter does not increment as a result of:

- Data memory accesses.
- Translation table walks.
- Refilling of any cache.
- Accesses that result from cache maintenance instructions.

`0x8125`, **BUS_REQ_RD_PERCYC, Bus read transactions in progress**

The counter increments by the number of bus read transactions counted by BUS_REQ_RD in progress on each Processor cycle.

The ratio BUS_REQ_RD_PERCYC ÷ BUS_REQ_RD is the mean duration of bus read transactions in Processor cycles.

A bus read transaction is in progress between the transaction starting and it completing. This includes cycles when the transaction is not occupying the bus.

If the bus is shared and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the bus is shared by PEs other than the PEs in the multithreaded processor and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of PMEVTYPER<n>_EL0.MT.

`0x8126`, **BUS_REQ_WR_PERCYC, Bus write transactions in progress**

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The counter increments by the number of bus write transactions counted by BUS_REQ_WR in progress on each Processor cycle.

The ratio BUS_REQ_WR_PERCYC ÷ BUS_REQ_WR is the mean duration of bus write transactions in Processor cycles.

A bus write transaction is in progress between the transaction starting and it completing. This includes cycles when the transaction is not occupying the bus.

A mean duration value calculated using this event only measures the latency from the perspective of the bus. This is not necessarily the same as the latency for the write to be Complete, as the write might be completed on the bus before reaching its endpoint.

For some bus implementations, writes are posted, meaning that, from the perspective of the bus, the write completes immediately. There is no response when the write reaches its Completion endpoint. This event is not included for such implementations.

If the bus is shared and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the bus is shared by PEs other than the PEs in the multithreaded processor and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of PMEVTYPER<n>_EL0.MT.

`0x8127`**, PMU_SNAPSHOT, Successful PMU capture event**

The counter counts each PMU snapshot Capture event that was successful, that is, PMSSCR_EL1.NC is set to 0.

It is CONSTRAINED UNPREDICTABLE whether the counter counts successful Capture events when the PE is in Debug state.

`0x8128`**, DTLB_WALK_PERCYC, Data translation table walks in progress**

The counter increments by the number of data translation table walks counted by DTLB_WALK in progress on each Processor cycle.

The ratio DTLB_WALK_PERCYC ÷ DTLB_WALK is the mean duration of data translation table walks in Processor cycles.

If the TLB is shared and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of PMEVTYPER<n>_EL0.MT.

`0x8129`**, ITLB_WALK_PERCYC, Instruction translation table walks in progress**

The counter increments by the number of instruction translation table walks counted by ITLB_WALK in progress on each Processor cycle.

The ratio ITLB_WALK_PERCYC ÷ ITLB_WALK is the mean duration of instruction translation table walks in Processor cycles.

If the TLB is shared and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of PMEVTYPER<n>_EL0.MT.

`0x8130`**, L1D_TLB_RW, Level 1 data TLB access, demand access**

The counter counts each access counted by L1D_TLB that is due to a demand Memory-read operation or demand Memory-write operation.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

If the TLB is shared and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of PMEVTYPER<n>_EL0.MT.

Arm recommends that this event is implemented if event L1D_TLB_PRFM is implemented.

`0x8131`**, L1I_TLB_RD, Level 1 instruction TLB access, demand access**

The counter counts each access counted by L1I_TLB that is due to a demand Instruction memory access.

If the TLB is shared and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of PMEVTYPER<n>_EL0.MT.

Arm recommends that this event is implemented if event L1I_TLB_PRFM is implemented.

`0x8132`**, L1D_TLB_PRFM, Level 1 data TLB access, software prefetch**

The counter counts each access counted by L1D_TLB_PRF that is due to a prefetch instruction.

If the TLB is shared and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of PMEVTYPER<n>_EL0.MT.

Arm recommends that this event is implemented if event L1D_TLB_RW is implemented.

`0x8133`**, L1I_TLB_PRFM, Level 1 instruction TLB access, software prefetch**

The counter counts each access counted by L1I_TLB_PRF that is due to a prefetch instruction.

If the TLB is shared and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of PMEVTYPER<n>_EL0.MT.

Arm recommends that this event is implemented if event L1I_TLB_RD is implemented.

`0x8134`**, DTLB_HWUPD, Data TLB hardware update of translation table**

The counter counts each access counted by L1D_TLB that causes a hardware update of a translation table entry.

Each attempted hardware update of a translation table entry is counted once. If the PE requires multiple translation table walk accesses to perform an update, this counts as a single update. If the update fails because it would not be atomic and has to be retried, each retry is counted.

The counter does not count the access if any of the following are true:

- The access generates a Translation fault because the applicable TCR_ELx.EPDy bit is 1.
- The access is an unprivileged access that generates a Translation fault because the applicable TCR_ELx.E0PDy bit is 1.

It is IMPLEMENTATION DEFINED whether the counter counts the access if the access generates a Translation fault for any other reason.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

If the TLB is shared and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of PMEVTYPER<n>_EL0.MT.

`0x8135`**, ITLB_HWUPD, Instruction TLB hardware update of translation table**

The counter counts each access counted by L1I_TLB that causes a hardware update of a translation table entry.

Each attempted hardware update of a translation table entry is counted once. If the PE requires multiple translation table walk accesses to perform an update, this counts as a single update. If the update fails because it would not be atomic and has to be retried, each retry is counted.

The counter does not count the access if any of the following are true:

- The access generates a Translation fault because the applicable TCR_ELx.EPDy bit is 1.
- The access is an unprivileged access that generates a Translation fault because the applicable TCR_ELx.E0PDy bit is 1.

It is IMPLEMENTATION DEFINED whether the counter counts the access if the access generates a Translation fault for any other reason.

If the TLB is shared and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of PMEVTYPER<n>_EL0.MT.

`0x8136`**, DTLB_STEP, Data TLB translation table walk, step**

The counter counts each translation table walk access due to a refill of the data or unified TLB.

The event is Attributable to the access that missed in the TLB and caused the walk, not to the owner of the translation tables being accessed. For example, this means that if an EL0 access causes a translation table walk consisting of accesses to both stage 1 and stage 2 translation tables, all accesses are counted if event counting is allowed at EL0, regardless of whether event counting is allowed at EL1 and/or EL2.

The counter does not count the translation table walk access if any of the following are true:

- The access causing the refill generates a Translation fault because the applicable TCR_ELx.EPDy bit is 1.
- The access causing the refill is an unprivileged access that generates a Translation fault because the applicable TCR_ELx.E0PDy bit is 1.

It is IMPLEMENTATION DEFINED whether the counter counts the translation table walk access if the access causing the refill generates a Translation fault for any other reason.

If the TLB is shared and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of PMEVTYPER<n>_EL0.MT.

`0x8137`**, ITLB_STEP, Instruction TLB translation table walk, step**

The counter counts each translation table walk access due to a refill of the instruction TLB.

The event is Attributable to the access that missed in the TLB and caused the walk, not to the owner of the translation tables being accessed. For example, this means that if an EL0 access causes a translation table walk consisting of accesses to both stage 1 and stage 2 translation tables, all accesses are counted if event counting is allowed at EL0, regardless of whether event counting is allowed at EL1 and/or EL2.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The counter does not count the translation table walk access if any of the following are true:

- The access causing the refill generates a Translation fault because the applicable TCR_ELx.EPDy bit is 1.
- The access causing the refill is an unprivileged access that generates a Translation fault because the applicable TCR_ELx.E0PDy bit is 1.

It is IMPLEMENTATION DEFINED whether the counter counts the translation table walk access if the access causing the refill generates a Translation fault for any other reason.

If the TLB is shared and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of PMEVTYPER<n>_EL0.MT.

`0x8138`, DTLB_WALK_LARGE, Data TLB large page translation table walk

The counter counts each translation table walk counted by DTLB_WALK where the result of the walk yields a large page size.

The set of large page sizes is the complement of the set of small page sizes defined by the DTLB_WALK_SMALL event. For example, these translations might cached by dedicated TLB resources. This set is IMPLEMENTATION DEFINED and might differ between instruction and data TLBs.

The counter does not count the walk if the access generates a Translation fault.

If the TLB is shared and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of PMEVTYPER<n>_EL0.MT.

`0x8139`, ITLB_WALK_LARGE, Instruction TLB large page translation table walk

The counter counts each translation table walk counted by ITLB_WALK where the result of the walk yields a large page size.

The set of large page sizes is the complement of the set of small page sizes defined by the ITLB_WALK_SMALL event. For example, these translations might cached by dedicated TLB resources. This set is IMPLEMENTATION DEFINED and might differ between instruction and data TLBs.

The counter does not count the walk if the access generates a Translation fault.

If the TLB is shared and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of PMEVTYPER<n>_EL0.MT.

`0x813A`, DTLB_WALK_SMALL, Data TLB small page translation table walk

The counter counts each translation table walk counted by DTLB_WALK where the result of the walk yields a small page size.

The set of small page sizes is the complement of the set of large page sizes defined by the DTLB_WALK_LARGE event. For example, these translations might cached by dedicated TLB resources. This set is IMPLEMENTATION DEFINED and might differ between instruction and data TLBs.

The counter does not count the walk if the access generates a Translation fault.

If the TLB is shared and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the

TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of PMEVTYPER<n>_EL0.MT.

`0x813B`**, ITLB_WALK_SMALL, Instruction TLB small page translation table walk**

The counter counts each translation table walk counted by ITLB_WALK where the result of the walk yields a small page size.

The set of small page sizes is the complement of the set of large page sizes defined by the ITLB_WALK_LARGE event. For example, these translations might cached by dedicated TLB resources. This set is IMPLEMENTATION DEFINED and might differ between instruction and data TLBs.

The counter does not count the walk if the access generates a Translation fault.

If the TLB is shared and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of PMEVTYPER<n>_EL0.MT.

`0x813C`**, DTLB_WALK_RW, Data TLB demand access, with at least one translation table walk**

The counter counts each demand access counted by L1D_TLB_RW that causes a refill or update of a data or unified TLB involving at least one translation table walk access.

The counter does not count the demand access if any of the following are true:

- The access is due to a TLB maintenance instruction.
- The access generates a Translation fault because the applicable TCR_ELx.EPDy bit is 1.
- FEAT_E0PD is implemented and the access is an unprivileged access that generates a Translation fault because the applicable TCR_ELx.E0PDy bit is 1.

It is IMPLEMENTATION DEFINED whether the counter counts the demand access if the access generates a Translation fault for any other reason.

If the TLB is shared and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of PMEVTYPER<n>_EL0.MT.

`0x813D`**, ITLB_WALK_RD, Instruction TLB demand access, with at least one translation table walk**

The counter counts each demand access counted by L1I_TLB_RD that causes a refill or update of an instruction TLB involving at least one translation table walk access.

The counter does not count the demand access if any of the following are true:

- The access is due to a TLB maintenance instruction.
- The access generates a Translation fault because the applicable TCR_ELx.EPDy bit is 1.
- FEAT_E0PD is implemented and the access is an unprivileged access that generates a Translation fault because the applicable TCR_ELx.E0PDy bit is 1.

It is IMPLEMENTATION DEFINED whether the counter counts the demand access if the access generates a Translation fault for any other reason.

If the TLB is shared and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 1, then the counter counts only events Attributable to PEs in the

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of PMEVTYPER<n>_EL0.MT.

`0x813E`, **DTLB_WALK_PRFM, Data TLB software prefetch, with at least one translation table walk**

The counter counts each software prefetch access counted by L1D_TLB_PRFM that causes a refill or update of a data or unified TLB involving at least one translation table walk access.

The counter does not count the software prefetch access if any of the following are true:

- The access is due to a TLB maintenance instruction.
- The access generates a Translation fault because the applicable TCR_ELx.EPDy bit is 1.
- FEAT_E0PD is implemented and the access is an unprivileged access that generates a Translation fault because the applicable TCR_ELx.E0PDy bit is 1.

It is IMPLEMENTATION DEFINED whether the counter counts the software prefetch access if the access generates a Translation fault for any other reason.

If the TLB is shared and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of PMEVTYPER<n>_EL0.MT.

`0x813F`, **ITLB_WALK_PRFM, Instruction TLB software prefetch, with at least one translation table walk**

The counter counts each software prefetch access counted by L1I_TLB_PRFM that causes a refill or update of an instruction TLB involving at least one translation table walk access.

The counter does not count the software prefetch access if any of the following are true:

- The access is due to a TLB maintenance instruction.
- The access generates a Translation fault because the applicable TCR_ELx.EPDy bit is 1.
- FEAT_E0PD is implemented and the access is an unprivileged access that generates a Translation fault because the applicable TCR_ELx.E0PDy bit is 1.

It is IMPLEMENTATION DEFINED whether the counter counts the software prefetch access if the access generates a Translation fault for any other reason.

If the TLB is shared and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of PMEVTYPER<n>_EL0.MT.

`0x8140`, **L1D_CACHE_RW, Level 1 data cache demand access**

The counter counts each access counted by L1D_CACHE that is due to a demand Memory-read operation or demand Memory-write operation.

This includes accesses made by speculatively executed instructions.

Arm recommends that this event is implemented if any of the following are true:

- Event L1D_CACHE_PRFM is implemented.
- Event L1D_CACHE_HWPRF is implemented.

`0x8141`, **L1I_CACHE_RD, Level 1 instruction cache demand fetch**

The counter counts each access counted by L1I_CACHE that is due to a demand Instruction memory access.

This includes instruction prefetches made by the PE for speculatively executed instructions.

Arm recommends that this event is implemented if any of the following are true:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- Event L1I_CACHE_PRFM is implemented.
- Event L1I_CACHE_HWPRF is implemented.

`0x8142`, **L1D_CACHE_PRFM, Level 1 data cache software prefetch**

The counter counts each access counted by L1D_CACHE_PRF that is due to a prefetch instruction.

Arm recommends that this event is implemented if event L1D_CACHE_RW is implemented.

`0x8143`, **L1I_CACHE_PRFM, Level 1 instruction cache software prefetch**

The counter counts each access counted by L1I_CACHE_PRF that is due to a prefetch instruction.

Arm recommends that this event is implemented if event L1I_CACHE_RD is implemented.

`0x8144`, **L1D_CACHE_MISS, Level 1 data cache demand access miss**

The counter counts each demand access counted by L1D_CACHE_RW that misses in the Level 1 data or unified cache, causing an access to outside of the Level 1 caches of this PE.

`0x8145`, **L1I_CACHE_HWPRF, Level 1 instruction cache hardware prefetch**

The counter counts each access counted by L1I_CACHE_PRF that is due to a hardware prefetch.

The hardware prefetch is generated by a hardware prefetcher at the Level 1 instruction or unified cache.

The PE might prefetch instructions as part of instruction pipelining, and might do so for speculatively executed instruction paths. PE instruction prefetching is not counted as hardware prefetching. Unlike PE instruction prefetching, a hardware prefetch only allocates instructions into the cache.

`0x8146`, **L1D_CACHE_REFILL_PRFM, Level 1 data cache refill, software prefetch**

The counter counts each access counted by L1D_CACHE_PRFM that causes a refill of the Level 1 data or unified cache from outside of the Level 1 data or unified cache.

`0x8147`, **L1I_CACHE_REFILL_PRFM, Level 1 instruction cache refill, software prefetch**

The counter counts each access counted by L1I_CACHE_PRFM that causes a refill of the Level 1 instruction or unified cache from outside of the Level 1 instruction or unified cache.

`0x8148`, **L2D_CACHE_RW, Level 2 data cache demand access**

The counter counts each access counted by L2D_CACHE that is due to a demand Memory-read operation or demand Memory-write operation.

This includes:

- Accesses made by speculatively executed instructions.
- Accesses to the Level 2 data or unified cache due to a refill of another cache caused by a demand Memory-read operation or demand Memory-write operation.

Arm recommends that this event is implemented if any of the following are true:

- Event L2D_CACHE_PRFM is implemented.
- Event L2D_CACHE_HWPRF is implemented.

`0x8149`, **L2I_CACHE_RD, Level 2 instruction cache demand fetch**

The counter counts each access counted by L2I_CACHE that is due to a demand Instruction memory access.

This includes:

- Instruction prefetches made by the PE for speculatively executed instructions.
- Accesses to the Level 2 instruction or unified cache due to a refill of another cache caused by a demand Instruction memory access.

Arm recommends that this event is implemented if any of the following are true:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- Event L2I_CACHE_PRFM is implemented.
- Event L2I_CACHE_HWPRF is implemented.

`0x814A`, **L2D_CACHE_PRFM, Level 2 data cache software prefetch**

The counter counts each access counted by L2D_CACHE_PRF that is due to a prefetch instruction.

This includes accesses to the Level 2 data or unified cache due to a refill of another cache caused by a prefetch instruction.

Arm recommends that this event is implemented if event L2D_CACHE_RW is implemented.

`0x814B`, **L2I_CACHE_PRFM, Level 2 instruction cache software prefetch**

The counter counts each access counted by L2I_CACHE_PRF that is due to a prefetch instruction.

This includes accesses to the Level 2 instruction or unified cache due to a refill of another cache caused by a prefetch instruction.

Arm recommends that this event is implemented if event L2I_CACHE_RD is implemented.

`0x814C`, **L2D_CACHE_MISS, Level 2 data cache demand access miss**

The counter counts each demand access counted by L2D_CACHE_RW that misses in the Level 1 and Level 2 data or unified caches, causing an access to outside of the Level 1 and Level 2 caches of this PE.

`0x814D`, **L2I_CACHE_HWPRF, Level 2 instruction cache hardware prefetch**

The counter counts each access counted by L2I_CACHE_PRF that is due to a hardware prefetch.

The hardware prefetch is generated by a hardware prefetcher at the Level 2 instruction or unified cache.

`0x814E`, **L2D_CACHE_REFILL_PRFM, Level 2 data cache refill, software prefetch**

The counter counts each access counted by L2D_CACHE_PRFM that causes a refill of the Level 2 data or unified cache, or any Level 1 data, instruction, or unified cache of this PE, from outside of those caches.

`0x814F`, **L2I_CACHE_REFILL_PRFM, Level 2 instruction cache refill, software prefetch**

The counter counts each access counted by L2I_CACHE_PRFM that causes a refill of the Level 2 instruction or unified cache, or any Level 1 data, instruction, or unified cache of this PE, from outside of those caches.

`0x8150`, **L3D_CACHE_RW, Level 3 data cache demand access**

The counter counts each access counted by L3D_CACHE that is due to a demand Memory-read operation or demand Memory-write operation.

This includes:

- Accesses made by speculatively executed instructions.
- Accesses to the Level 3 data or unified cache due to a refill of another cache caused by a demand Memory-read operation or demand Memory-write operation.

Arm recommends that this event is implemented if any of the following are true:

- Event L3D_CACHE_PRFM is implemented.
- Event L3D_CACHE_HWPRF is implemented.

`0x8151`, **L3D_CACHE_PRFM, Level 3 data cache software prefetch**

The counter counts each access counted by L3D_CACHE_PRF that is due to a prefetch instruction.

This includes accesses to the Level 3 data or unified cache due to a refill of another cache caused by a prefetch instruction.

Arm recommends that this event is implemented if event L3D_CACHE_RW is implemented.

`0x8152`, **L3D_CACHE_MISS, Level 3 data cache demand access miss**

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The counter counts each demand access counted by L3D_CACHE_RW that misses in the Level 1 to Level 3 data or unified caches, causing an access to outside of the Level 1 to Level 3 caches of this PE.

`0x8153`, **L3D_CACHE_REFILL_PRFM, Level 3 data cache refill, software prefetch**

The counter counts each access counted by L3D_CACHE_PRFM that causes a refill of the Level 3 data or unified cache, or any Level 1 or Level 2 data, instruction, or unified cache of this PE, from outside of those caches.

`0x8154`, **L1D_CACHE_HWPRF, Level 1 data cache hardware prefetch**

The counter counts each access counted by L1D_CACHE_PRF that is due to a hardware prefetch.

The hardware prefetch is generated by a hardware prefetcher at the Level 1 data or unified cache.

`0x8155`, **L2D_CACHE_HWPRF, Level 2 data cache hardware prefetch**

The counter counts each access counted by L2D_CACHE_PRF that is due to a hardware prefetch.

The hardware prefetch is generated by a hardware prefetcher at the Level 2 data or unified cache.

`0x8156`, **L3D_CACHE_HWPRF, Level 3 data cache hardware prefetch**

The counter counts each access counted by L3D_CACHE_PRF that is due to a hardware prefetch.

The hardware prefetch is generated by a hardware prefetcher at the Level 3 data or unified cache.

`0x8157`, **LL_CACHE_HWPRF, Last level cache hardware prefetch**

The counter counts each access counted by LL_CACHE_PRF that is due to a hardware prefetch.

The hardware prefetch is generated by a hardware prefetcher at the Last level cache.

`0x8158`, **STALL_FRONTEND_MEMBOUND, Frontend stall cycles, memory bound**

The counter counts each cycle counted by STALL_FRONTEND when no instructions are delivered from the memory system.

The counter counts each stall that occurs when the frontend interface to memory is busy or stalled.

This includes the stalls counted by STALL_FRONTEND_L1I, STALL_FRONTEND_L2I, STALL_FRONTEND_MEM, and STALL_FRONTEND_TLB, and any other IMPLEMENTATION DEFINED memory stalls.

It does not include stalls that are counted by STALL_FRONTEND_CPUBOUND. However both events will count the same cycle counted by STALL_FRONTEND if there are both memory and processor-resource stall conditions active.

`0x8159`, **STALL_FRONTEND_L1I, Frontend stall cycles, level 1 instruction cache**

The counter counts each cycle counted by STALL_FRONTEND_MEMBOUND when there is a demand instruction miss in the first level of instruction cache.

The counter does not count the cycle if any of the following are true:

- The STALL_FRONTEND_L2I event is implemented and there is a demand instruction miss in the second level of instruction cache, meaning the STALL_FRONTEND_L2I event counts the cycle.
- There is a demand instruction miss in the last level of instruction cache within the PE clock domain, meaning the STALL_FRONTEND_MEM event counts the cycle.

`0x815A`, **STALL_FRONTEND_L2I, Frontend stall cycles, level 2 instruction cache**

The counter counts each cycle counted by STALL_FRONTEND_MEMBOUND when there is a demand instruction miss in the second level of instruction or unified cache.

The counter does not count the cycle if there is a demand instruction miss in the last level of instruction cache within the PE clock domain, meaning the STALL_FRONTEND_MEM event counts the cycle.

`0x815B`, **STALL_FRONTEND_MEM, Frontend stall cycles, last level PE cache or memory**

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The counter counts each cycle counted by STALL_FRONTEND_MEMBOUND when there is a demand instruction miss in the last level of instruction or unified cache within the PE clock domain or a non-cacheable instruction fetch in progress.

`0x815C`, **STALL_FRONTEND_TLB, Frontend stall cycles, TLB**

The counter counts each cycle counted by STALL_FRONTEND_MEMBOUND when there is a demand instruction miss in the instruction or unified TLB.

`0x8160`, **STALL_FRONTEND_CPUBOUND, Frontend stall cycles, processor bound**

The counter counts each cycle counted by STALL_FRONTEND when the frontend is stalled on a frontend processor resource, not including memory.

The counter counts each stall that occurs when a frontend processor resource is busy.

This includes the stalls counted by STALL_FRONTEND_FLOW, STALL_FRONTEND_FLUSH, and STALL_FRONTEND_RENAME, and any other IMPLEMENTATION DEFINED processor resource stalls.

It does not include stalls that are counted by STALL_FRONTEND_MEMBOUND. However both events will count the same cycle counted by STALL_FRONTEND if there are both memory and processor-resource stall conditions active.

`0x8161`, **STALL_FRONTEND_FLOW, Frontend stall cycles, flow control**

The counter counts each cycle counted by STALL_FRONTEND_CPUBOUND when the frontend is stalled on unavailability of prediction flow resources.

Note

This event is not counting stalls due to mispredictions, but rather stalls when the frontend is unable to make a prediction.

`0x8162`, **STALL_FRONTEND_FLUSH, Frontend stall cycles, flush recovery**

The counter counts each cycle counted by STALL_FRONTEND_CPUBOUND when the frontend is recovering from a pipeline flush.

The situations where the frontend is flushed are IMPLEMENTATION DEFINED. For example, the frontend might be flushed on a branch misprediction or on a Context synchronization event.

`0x8163`, **STALL_FRONTEND_RENAME, Frontend stall cycles, rename full**

The counter counts each cycle counted by STALL_FRONTEND_CPUBOUND when operations are available from the frontend but at least one is not ready to be sent to the backend because no rename register is available.

If this event is implemented and counts such stalls then the STALL_BACKEND_RENAME event counts as zero.

`0x8164`, **STALL_BACKEND_MEMBOUND, Backend stall cycles, memory bound**

The counter counts each cycle counted by STALL_BACKEND when the backend is waiting for a memory access to complete.

The counter counts each stall that occurs when the backend interface to memory is busy or stalled.

This includes the stalls counted by: STALL_BACKEND_ATOMIC, STALL_BACKEND_L1D, STALL_BACKEND_L2D, STALL_BACKEND_MEM, STALL_BACKEND_ST, STALL_BACKEND_TLB, and any other IMPLEMENTATION DEFINED memory stall events.

It does not include stalls that are counted by STALL_BACKEND_CPUBOUND, although both events might count on the same cycle counted by STALL_BACKEND if there are both memory and processor-resource stall conditions active.

`0x8165`, **STALL_BACKEND_L1D, Backend stall cycles, level 1 data cache**

The counter counts each cycle counted by STALL_BACKEND_MEMBOUND when there is a demand data miss in the first level of data or unified cache.

The counter does not count the cycle if any of the following are true:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- The STALL_BACKEND_L2D event is implemented and there is a demand data miss in the second level of data or unified cache, meaning the STALL_BACKEND_L2D event counts the cycle.
- There is a demand data miss in the last level of data or unified cache within the PE clock domain, meaning the STALL_BACKEND_MEM event counts the cycle.

`0x8166`, **STALL_BACKEND_L2D, Backend stall cycles, level 2 data cache**

The counter counts each cycle counted by STALL_BACKEND_MEMBOUND when there is a demand data miss in the second level of data or unified cache.

The counter does not count the cycle if there is a demand data miss in the last level of data or unified cache within the PE clock domain, meaning the STALL_BACKEND_MEM event counts the cycle.

`0x8167`, **STALL_BACKEND_TLB, Backend stall cycles, TLB**

The counter counts each cycle counted by STALL_BACKEND_MEMBOUND when there is a demand data miss in the data or unified TLB.

`0x8168`, **STALL_BACKEND_ST, Backend stall cycles, store**

The counter counts each cycle counted by STALL_BACKEND_MEMBOUND when the backend is stalled waiting for a store.

`0x816A`, **STALL_BACKEND_CPUBOUND, Backend stall cycles, processor bound**

The counter counts each cycle counted by STALL_BACKEND when the backend is stalled on a processor resource, not including memory.

The counter counts each stall that occurs when a backend processor resource is busy. This includes the stalls counted by STALL_BACKEND_RENAME, and any other IMPLEMENTATION DEFINED processor resource stalls.

It does not include stalls that are counted by STALL_BACKEND_MEMBOUND, although both events might count on the same cycle counted by STALL_BACKEND if there are both memory and processor-resource stall conditions active.

`0x816B`, **STALL_BACKEND_BUSY, Backend stall cycles, backend busy**

The counter counts each cycle counted by STALL_BACKEND when operations are available from the frontend but the backend is not able to accept an operation because an execution unit is busy.

For example a complex operation unit such as a divider is executing a previous operation and cannot accept a new operation.

`0x816C`, **STALL_BACKEND_ILOCK, Backend stall cycles, input dependency**

The counter counts each cycle counted by STALL_BACKEND when operations are available from the frontend but at least one is not ready to be sent to the backend because of an input dependency.

`0x816D`, **STALL_BACKEND_RENAME, Backend stall cycles, rename full**

The counter counts each cycle counted by STALL_BACKEND_CPUBOUND when operations are available from the frontend but at least one is not ready to be sent to the backend because no rename register is available.

If this event is implemented and counts such stalls then the STALL_FRONTEND_RENAME event counts as zero.

`0x816E`, **STALL_BACKEND_ATOMIC, Backend stall cycles, atomic operation**

The counter counts each cycle counted by STALL_BACKEND_MEMBOUND when the backend is processing an Atomic operation.

`0x8170`, **CAS_NEAR_FAIL, Atomic memory Operation speculatively executed, Compare and Swap fail**

The counter counts each Compare and Swap operation counted by CAS_NEAR_SPEC that does not update the location accessed.

`0x8171`, **CAS_NEAR_PASS, Atomic memory Operation speculatively executed, Compare and Swap pass**

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The counter counts each Compare and Swap operation counted by CAS_NEAR_SPEC that updates the location accessed.

`0x8172`, **CAS_NEAR_SPEC, Atomic memory Operation speculatively executed, Compare and Swap near**

The counter counts each Compare and Swap operation counted by CAS_SPEC that executes locally to the PE.

The definition of locally is IMPLEMENTATION DEFINED. Operations counted by CAS_NEAR_SPEC also generate one of the CAS_NEAR_PASS or CAS_NEAR_FAIL events.

`0x8173`, **CAS_FAR_SPEC, Atomic memory Operation speculatively executed, Compare and Swap far**

The counter counts each Compare and Swap operation counted by CAS_SPEC that does not execute locally to the PE.

The definition of locally is IMPLEMENTATION DEFINED. Operations counted by CAS_FAR_SPEC do not generate CAS_NEAR_PASS or CAS_NEAR_FAIL events.

`0x8174`, **CAS_SPEC, Atomic memory Operation speculatively executed, Compare and Swap**

The counter counts each Compare and Swap operation.

`0x8175`, **LSE_LD_SPEC, Atomic memory Operation speculatively executed, load**

The counter counts each Atomic memory operation counted by LSE_LDST_SPEC that returns a value to the PE, including Swap and Compare-and-Swap operations.

`0x8176`, **LSE_ST_SPEC, Atomic memory Operation speculatively executed, store**

The counter counts each Atomic memory operation counted by LSE_LDST_SPEC that does not return a value to the PE.

`0x8177`, **LSE_LDST_SPEC, Atomic memory Operation speculatively executed, load or store**

The counter counts each operation counted by LDST_SPEC that is an Atomic memory operation.

`0x8178`, **REMOTE_ACCESS_WR, Access to a remote device, write**

The counter counts each access counted by REMOTE_ACCESS that is a Memory-write operation.

`0x8186`, **UOP_RETIRED, Micro-operation architecturally executed**

The counter counts each micro-operation that would be executed in a Simple sequential execution of the program.

Unlike OP_RETIRED, this event is not linked to the definition of OP_SPEC, meaning it counts micro-operations that are created from other operations after those operations are counted by OP_SPEC.

`0x8188`, **DTLB_WALK_BLOCK, Data TLB block translation table walk**

The counter counts each translation table walk counted by DTLB_WALK where the result of the walk yields a Block.

That is, the translation table walk ends at a Block descriptor, at other than the last level of translation table.

If two stages of translation are used and Stage 1 and Stage 2 yield different granule sizes, the counter counts the translation table walk only if both are a Block.

The counter does not count the walk if the access generates a Translation fault.

If the TLB is shared and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of PMEVTYPER<n>_EL0.MT.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

`0x8189`, **ITLB_WALK_BLOCK, Instruction TLB block translation table walk**

The counter counts each translation table walk counted by ITLB_WALK where the result of the walk yields a Block.

That is, the translation table walk ends at a Page descriptor, at other than the last level of translation table.

If two stages of translation are used and Stage 1 and Stage 2 yield different granule sizes, the counter counts the translation table walk only if both are a Block.

The counter does not count the walk if the access generates a Translation fault.

If the TLB is shared and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of PMEVTYPER<n>_EL0.MT.

`0x818A`, **DTLB_WALK_PAGE, Data TLB page translation table walk**

The counter counts each translation table walk counted by DTLB_WALK where the result of the walk yields a Page.

That is, the translation table walk ends at a Block descriptor, at the last level of translation table.

If two stages of translation are used and Stage 1 and Stage 2 yield different granule sizes, the counter counts the translation table walk only if either is a Page.

The counter does not count the walk if the access generates a Translation fault.

If the TLB is shared and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of PMEVTYPER<n>_EL0.MT.

`0x818B`, **ITLB_WALK_PAGE, Instruction TLB page translation table walk**

The counter counts each translation table walk counted by ITLB_WALK where the result of the walk yields a Page.

That is, the translation table walk ends at a Page descriptor, at the last level of translation table.

If two stages of translation are used and Stage 1 and Stage 2 yield different granule sizes, the counter counts the translation table walk only if either is a Page.

The counter does not count the walk if the access generates a Translation fault.

If the TLB is shared and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of PMEVTYPER<n>_EL0.MT.

`0x818D`, **BUS_REQ_RD, Bus request, read**

The counter counts each transaction counted by BUS_REQ that is a Memory-read operation.

`0x818E`, **BUS_REQ_WR, Bus request, write**

The counter counts each transaction counted by BUS_REQ that is a Memory-write operation.

`0x818F`, **BUS_REQ, Bus request**

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The counter counts each request generated by a Memory-read operation or Memory-write operation that accesses outside of the boundary of the PE and its closely-coupled caches.

Where this boundary lies with respect to any implemented caches is IMPLEMENTATION DEFINED. Where an implementation has multiple buses at this boundary, this event counts the sum of requests across all buses.

A bus request is the start of a bus transaction. The exact nature of a bus transaction is IMPLEMENTATION DEFINED, but for the purposes of event monitoring consists of a single access comprising one or more cycles, or beats, when the transaction occupies the bus. The BUS_REQ event therefore counts the number of transactions. The BUS_ACCESS event counts the occupancy of the transaction on the bus.

Bus transactions include refills of and write-backs from data, instruction, and unified caches. Whether bus transactions include operations that use the bus but do not explicitly transfer data is IMPLEMENTATION DEFINED. This must be the same for the BUS_REQ and BUS_ACCESS events.

An Unattributable bus transaction occurs when a requestor outside the PE makes a request that results in a bus transaction, for example, a coherency request.

The maximum increment in any given cycle is IMPLEMENTATION DEFINED.

If the bus is shared and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the bus is shared by PEs other than the PEs in the multithreaded processor and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of PMEVTYPER<n>_EL0.MT.

`0x8190`**, ISNP_HIT_RD, Snoop hit, demand instruction fetch**

The counter counts each snoop generated by the PE in response to a demand Instruction memory access that hits in a cache outside of the cache hierarchy of this PE.

The event is counted by the PE generating the snoop, not the PE being snooped.

`0x8191`**, ISNP_HIT_NEAR_RD, Snoop hit in near local cache, demand instruction fetch**

The counter counts each snoop generated by the PE in response to a demand Instruction memory access counted by ISNP_HIT_RD that hits in a cache outside of the cache hierarchy of this PE in the local PE cluster.

The event is counted by the PE generating the snoop, not the PE being snooped.

`0x8192`**, ISNP_HIT_FAR_RD, Snoop hit in far local cache, demand instruction fetch**

The counter counts each snoop generated by the PE in response to a demand Instruction memory access counted by ISNP_HIT_RD that hits in a cache outside the local PE cluster on the same device.

The event is counted by the PE generating the snoop, not the PE being snooped.

`0x8193`**, ISNP_HIT_REMOTE_RD, Snoop hit in remote cache, demand instruction fetch**

The counter counts each snoop generated by the PE in response to a demand Instruction memory access counted by ISNP_HIT_RD that hits in a cache on a remote device.

The event is counted by the PE generating the snoop, not the PE being snooped.

`0x8194`**, DSNP_HIT_RD, Snoop hit, demand data read**

The counter counts each snoop generated by the PE in response to a demand Memory-read operation counted by DSNP_HIT_RW that hits in a cache outside of the cache hierarchy of this PE.

The event is counted by the PE generating the snoop, not the PE being snooped.

`0x8195`**, DSNP_HIT_NEAR_RD, Snoop hit in near local cache, demand data read**

The counter counts each snoop generated by the PE in response to a demand Memory-read operation counted by DSNP_HIT_RD that hits in a cache outside of the cache hierarchy of this PE in the local PE cluster.

The event is counted by the PE generating the snoop, not the PE being snooped.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

`0x8196`, **DSNP_HIT_FAR_RD, Snoop hit in far local cache, demand data read**

The counter counts each snoop generated by the PE in response to a demand Memory-read operation counted by DSNP_HIT_RD that hits in a cache outside the local PE cluster on the same device.

The event is counted by the PE generating the snoop, not the PE being snooped.

`0x8197`, **DSNP_HIT_REMOTE_RD, Snoop hit in remote cache, demand data read**

The counter counts each snoop generated by the PE in response to a demand Memory-read operation counted by DSNP_HIT_RD that hits in a cache on a remote device.

The event is counted by the PE generating the snoop, not the PE being snooped.

`0x8198`, **DSNP_HIT_WR, Snoop hit, demand data write**

The counter counts each snoop generated by the PE in response to a demand Memory-write operation counted by DSNP_HIT_RW that hits in a cache outside of the cache hierarchy of this PE.

The event is counted by the PE generating the snoop, not the PE being snooped.

`0x8199`, **DSNP_HIT_NEAR_WR, Snoop hit in near local cache, demand data write**

The counter counts each snoop generated by the PE in response to a demand Memory-write operation counted by DSNP_HIT_WR that hits in a cache outside of the cache hierarchy of this PE in the local PE cluster.

The event is counted by the PE generating the snoop, not the PE being snooped.

`0x819A`, **DSNP_HIT_FAR_WR, Snoop hit in far local cache, demand data write**

The counter counts each snoop generated by the PE in response to a demand Memory-write operation counted by DSNP_HIT_WR that hits in a cache outside the local PE cluster on the same device.

The event is counted by the PE generating the snoop, not the PE being snooped.

`0x819B`, **DSNP_HIT_REMOTE_WR, Snoop hit in remote cache, demand data write**

The counter counts each snoop generated by the PE in response to a demand Memory-write operation counted by DSNP_HIT_WR that hits in a cache on a remote device.

The event is counted by the PE generating the snoop, not the PE being snooped.

`0x819C`, **DSNP_HIT_RW, Snoop hit, demand data access**

The counter counts each snoop generated by the PE in response to a demand Memory-read operation or demand Memory-write operation that hits in a cache outside of the cache hierarchy of this PE.

The event is counted by the PE generating the snoop, not the PE being snooped.

`0x819D`, **DSNP_HIT_NEAR_RW, Snoop hit in near local cache, demand data access**

The counter counts each snoop generated by the PE in response to a demand Memory-read operation or demand Memory-write operation counted by DSNP_HIT_RW that hits in a cache outside of the cache hierarchy of this PE in the local PE cluster.

The event is counted by the PE generating the snoop, not the PE being snooped.

`0x819E`, **DSNP_HIT_FAR_RW, Snoop hit in far local cache, demand data access**

The counter counts each snoop generated by the PE in response to a demand Memory-read operation or demand Memory-write operation counted by DSNP_HIT_RW that hits in a cache outside the local PE cluster on the same device.

The event is counted by the PE generating the snoop, not the PE being snooped.

`0x819F`, **DSNP_HIT_REMOTE_RW, Snoop hit in remote cache, demand data access**

The counter counts each snoop generated by the PE in response to a demand Memory-read operation or demand Memory-write operation counted by DSNP_HIT_RW that hits in a cache on a remote device.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The event is counted by the PE generating the snoop, not the PE being snooped.

`0x81A0`, **DSNP_HIT_PRFM, Snoop hit, software data prefetch**

The counter counts each snoop generated by the PE in response to a data prefetch instruction counted by DSNP_HIT_PRF that hits in a cache outside of the cache hierarchy of this PE.

The event is counted by the PE generating the snoop, not the PE being snooped.

`0x81A1`, **DSNP_HIT_NEAR_PRFM, Snoop hit in near local cache, software data prefetch**

The counter counts each snoop generated by the PE in response to a data prefetch instruction counted by DSNP_HIT_PRFM that hits in a cache outside of the cache hierarchy of this PE in the local PE cluster.

The event is counted by the PE generating the snoop, not the PE being snooped.

`0x81A2`, **DSNP_HIT_FAR_PRFM, Snoop hit in far local cache, software data prefetch**

The counter counts each snoop generated by the PE in response to a data prefetch instruction counted by DSNP_HIT_PRFM that hits in a cache outside the local PE cluster on the same device.

The event is counted by the PE generating the snoop, not the PE being snooped.

`0x81A3`, **DSNP_HIT_REMOTE_PRFM, Snoop hit in remote cache, software data prefetch**

The counter counts each snoop generated by the PE in response to a data prefetch instruction counted by DSNP_HIT_PRFM that hits in a cache on a remote device.

The event is counted by the PE generating the snoop, not the PE being snooped.

`0x81A4`, **DSNP_HIT_HWPRF, Snoop hit, hardware data prefetch**

The counter counts each snoop generated by a data hardware prefetch counted by DSNP_HIT_PRF that hits in a cache outside of the cache hierarchy of this PE.

The event is counted by the PE generating the snoop, not the PE being snooped.

`0x81A5`, **DSNP_HIT_NEAR_HWPRF, Snoop hit in near local cache, hardware data prefetch**

The counter counts each snoop generated by a data hardware prefetch counted by DSNP_HIT_HWPRF that hits in a cache outside of the cache hierarchy of this PE in the local PE cluster.

The event is counted by the PE generating the snoop, not the PE being snooped.

`0x81A6`, **DSNP_HIT_FAR_HWPRF, Snoop hit in far local cache, hardware data prefetch**

The counter counts each snoop generated by a data hardware prefetch counted by DSNP_HIT_HWPRF that hits in a cache outside the local PE cluster on the same device.

The event is counted by the PE generating the snoop, not the PE being snooped.

`0x81A7`, **DSNP_HIT_REMOTE_HWPRF, Snoop hit in remote cache, hardware data prefetch**

The counter counts each snoop generated by a data hardware prefetch counted by DSNP_HIT_HWPRF that hits in a cache on a remote device.

The event is counted by the PE generating the snoop, not the PE being snooped.

`0x81A8`, **ISNP_HIT_PRFM, Snoop hit, software instruction prefetch**

The counter counts each snoop generated by the PE in response to an instruction prefetch instruction counted by ISNP_HIT_PRF that hits in a cache outside of the cache hierarchy of this PE.

The event is counted by the PE generating the snoop, not the PE being snooped.

`0x81A9`, **ISNP_HIT_NEAR_PRFM, Snoop hit in near local cache, software instruction prefetch**

The counter counts each snoop generated by the PE in response to an instruction prefetch instruction counted by ISNP_HIT_PRFM that hits in a cache outside of the cache hierarchy of this PE in the local PE cluster.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The event is counted by the PE generating the snoop, not the PE being snooped.

`0x81AA`, **ISNP_HIT_FAR_PRFM, Snoop hit in far local cache, software instruction prefetch**

The counter counts each snoop generated by the PE in response to an instruction prefetch instruction counted by ISNP_HIT_PRFM that hits in a cache outside the local PE cluster on the same device.

The event is counted by the PE generating the snoop, not the PE being snooped.

`0x81AB`, **ISNP_HIT_REMOTE_PRFM, Snoop hit in remote cache, software instruction prefetch**

The counter counts each snoop generated by the PE in response to an instruction prefetch instruction counted by ISNP_HIT_PRFM that hits in a cache on a remote device.

The event is counted by the PE generating the snoop, not the PE being snooped.

`0x81AC`, **ISNP_HIT_HWPRF, Snoop hit, hardware instruction prefetch**

The counter counts each snoop generated by an instruction hardware prefetch counted by ISNP_HIT_PRF that hits in a cache outside of the cache hierarchy of this PE.

The event is counted by the PE generating the snoop, not the PE being snooped.

`0x81AD`, **ISNP_HIT_NEAR_HWPRF, Snoop hit in near local cache, hardware instruction prefetch**

The counter counts each snoop generated by an instruction hardware prefetch counted by ISNP_HIT_HWPRF that hits in a cache outside of the cache hierarchy of this PE in the local PE cluster.

The event is counted by the PE generating the snoop, not the PE being snooped.

`0x81AE`, **ISNP_HIT_FAR_HWPRF, Snoop hit in far local cache, hardware instruction prefetch**

The counter counts each snoop generated by an instruction hardware prefetch counted by ISNP_HIT_HWPRF that hits in a cache outside the local PE cluster on the same device.

The event is counted by the PE generating the snoop, not the PE being snooped.

`0x81AF`, **ISNP_HIT_REMOTE_HWPRF, Snoop hit in remote cache, hardware instruction prefetch**

The counter counts each snoop generated by an instruction hardware prefetch counted by ISNP_HIT_HWPRF that hits in a cache on a remote device.

The event is counted by the PE generating the snoop, not the PE being snooped.

`0x81B0`, **ISNP_HIT, Snoop hit, instruction**

The counter counts each snoop that hits in a cache outside of the cache hierarchy of this PE.

The event is counted by the PE generating the snoop, not the PE being snooped.

`0x81B1`, **ISNP_HIT_NEAR, Snoop hit in near local cache, instruction access**

The counter counts each snoop counted by ISNP_HIT that hits in a cache outside of the cache hierarchy of this PE in the local PE cluster.

The event is counted by the PE generating the snoop, not the PE being snooped.

`0x81B2`, **ISNP_HIT_FAR, Snoop hit in far local cache, instruction access**

The counter counts each snoop counted by ISNP_HIT that hits in a cache outside the local PE cluster on the same device.

The event is counted by the PE generating the snoop, not the PE being snooped.

`0x81B3`, **ISNP_HIT_REMOTE, Snoop hit in remote cache, instruction access**

The counter counts each snoop counted by ISNP_HIT that hits in a cache on a remote device.

The event is counted by the PE generating the snoop, not the PE being snooped.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

`0x81B4`, **DSNP_HIT, Snoop hit, data**

The counter counts each snoop that hits in a cache outside of the cache hierarchy of this PE.

The event is counted by the PE generating the snoop, not the PE being snooped.

`0x81B5`, **DSNP_HIT_NEAR, Snoop hit in near local cache, data access**

The counter counts each snoop counted by DSNP_HIT that hits in a cache outside of the cache hierarchy of this PE in the local PE cluster.

The event is counted by the PE generating the snoop, not the PE being snooped.

`0x81B6`, **DSNP_HIT_FAR, Snoop hit in far local cache, data access**

The counter counts each snoop counted by DSNP_HIT that hits in a cache outside the local PE cluster on the same device.

The event is counted by the PE generating the snoop, not the PE being snooped.

`0x81B7`, **DSNP_HIT_REMOTE, Snoop hit in remote cache, data access**

The counter counts each snoop counted by DSNP_HIT that hits in a cache on a remote device.

The event is counted by the PE generating the snoop, not the PE being snooped.

`0x81B8`, **L1I_CACHE_REFILL_HWPRF, Level 1 instruction cache refill, hardware prefetch**

The counter counts each hardware prefetch counted by L1I_CACHE_HWPRF that causes a refill of the Level 1 instruction or unified cache from outside of the Level 1 instruction or unified cache.

`0x81B9`, **L2I_CACHE_REFILL_HWPRF, Level 2 instruction cache refill, hardware prefetch**

The counter counts each hardware prefetch counted by L2I_CACHE_HWPRF that causes a refill of the Level 2 instruction or unified cache, or any Level 1 data, instruction, or unified cache of this PE, from outside of those caches.

`0x81BC`, **L1D_CACHE_REFILL_HWPRF, Level 1 data cache refill, hardware prefetch**

The counter counts each hardware prefetch counted by L1D_CACHE_HWPRF that causes a refill of the Level 1 data or unified cache from outside of the Level 1 data or unified cache.

`0x81BD`, **L2D_CACHE_REFILL_HWPRF, Level 2 data cache refill, hardware prefetch**

The counter counts each hardware prefetch counted by L2D_CACHE_HWPRF that causes a refill of the Level 2 data or unified cache, or any Level 1 data, instruction, or unified cache of this PE, from outside of those caches.

`0x81BE`, **L3D_CACHE_REFILL_HWPRF, Level 3 data cache refill, hardware prefetch**

The counter counts each hardware prefetch counted by L3D_CACHE_HWPRF that causes a refill of the Level 3 data or unified cache, or any Level 1 or Level 2 data, instruction, or unified cache of this PE, from outside of those caches.

`0x81BF`, **LL_CACHE_REFILL_HWPRF, Last level cache refill, hardware prefetch**

The counter counts each hardware prefetch counted by LL_CACHE_HWPRF that causes a refill of the Last level cache, or any other data, instruction, or unified cache of this PE, from outside of those caches.

`0x81C0`, **L1I_CACHE_HIT_RD, Level 1 instruction cache demand fetch hit**

The counter counts each demand fetch counted by L1I_CACHE_RD that hits in the Level 1 instruction or unified cache.

`0x81C1`, **L2I_CACHE_HIT_RD, Level 2 instruction cache demand fetch hit**

The counter counts each demand fetch counted by L2I_CACHE_RD that hits in the Level 2 instruction or unified cache.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

`0x81C4`, **L1D_CACHE_HIT_RD, Level 1 data cache demand access hit, read**

The counter counts each demand read counted by L1D_CACHE_RD that hits in the Level 1 data or unified cache.

`0x81C5`, **L2D_CACHE_HIT_RD, Level 2 data cache demand access hit, read**

The counter counts each demand read counted by L2D_CACHE_RD that hits in the Level 2 data or unified cache.

`0x81C6`, **L3D_CACHE_HIT_RD, Level 3 data cache demand access hit, read**

The counter counts each demand read counted by L3D_CACHE_RD that hits in the Level 3 data or unified cache.

`0x81C7`, **LL_CACHE_HIT_RD, Last level cache demand access hit, read**

The counter counts each demand read counted by LL_CACHE_RD that hits in the Last level cache.

`0x81C8`, **L1D_CACHE_HIT_WR, Level 1 data cache demand access hit, write**

The counter counts each demand write counted by L1D_CACHE_WR that hits in the Level 1 data or unified cache.

`0x81C9`, **L2D_CACHE_HIT_WR, Level 2 data cache demand access hit, write**

The counter counts each demand write counted by L2D_CACHE_WR that hits in the Level 2 data or unified cache.

`0x81CA`, **L3D_CACHE_HIT_WR, Level 3 data cache demand access hit, write**

The counter counts each demand write counted by L3D_CACHE_WR that hits in the Level 3 data or unified cache.

`0x81CB`, **LL_CACHE_HIT_WR, Last level cache demand access hit, write**

The counter counts each demand write counted by LL_CACHE_WR that hits in the Last level cache.

`0x81CC`, **L1D_CACHE_HIT_RW, Level 1 data cache demand access hit**

The counter counts each demand access counted by L1D_CACHE_RW that hits in the Level 1 data or unified cache.

`0x81CD`, **L2D_CACHE_HIT_RW, Level 2 data cache demand access hit**

The counter counts each demand access counted by L2D_CACHE_RW that hits in the Level 2 data or unified cache.

`0x81CE`, **L3D_CACHE_HIT_RW, Level 3 data cache demand access hit**

The counter counts each demand access counted by L3D_CACHE_RW that hits in the Level 3 data or unified cache.

`0x81CF`, **LL_CACHE_HIT_RW, Last level cache demand access hit**

The counter counts each demand access counted by LL_CACHE_RW that hits in the Last level cache.

`0x81D0`, **L1I_CACHE_HIT_RD_FPRFM, Level 1 instruction cache demand fetch first hit, fetched by software prefetch**

The counter counts each demand fetch first hit counted by L1I_CACHE_HIT_RD_FPRF where the cache line was fetched in response to a prefetch instruction.

That is, the L1I_CACHE_REFILL_PRFM event was generated when the cache line was fetched into the cache.

Only the first hit by a demand access is counted. After this event is generated for a cache line, the event is not generated again for the same cache line while it remains in the cache.

`0x81D1`, **L2I_CACHE_HIT_RD_FPRFM, Level 2 instruction cache demand fetch first hit, fetched by software prefetch**

The counter counts each demand fetch first hit counted by L2I_CACHE_HIT_RD_FPRF where the cache line was fetched in response to a prefetch instruction.

That is, the L2I_CACHE_REFILL_PRFM event was generated when the cache line was fetched into the cache.

Only the first hit by a demand access is counted. After this event is generated for a cache line, the event is not generated again for the same cache line while it remains in the cache.

`0x81D4`, **L1D_CACHE_HIT_RD_FPRFM, Level 1 data cache demand access first hit, read, fetched by software prefetch**

The counter counts each first hit counted by L1D_CACHE_HIT_RW_FPRFM that is due to a demand Memory-read operation.

`0x81D5`, **L2D_CACHE_HIT_RD_FPRFM, Level 2 data cache demand access first hit, read, fetched by software prefetch**

The counter counts each first hit counted by L2D_CACHE_HIT_RW_FPRFM that is due to a demand Memory-read operation.

`0x81D6`, **L3D_CACHE_HIT_RD_FPRFM, Level 3 data cache demand access first hit, read, fetched by software prefetch**

The counter counts each first hit counted by L3D_CACHE_HIT_RW_FPRFM that is due to a demand Memory-read operation.

`0x81D7`, **LL_CACHE_HIT_RD_FPRFM, Last level cache demand access first hit, read, fetched by software prefetch**

The counter counts each first hit counted by LL_CACHE_HIT_RW_FPRFM that is due to a demand Memory-read operation.

`0x81D8`, **L1D_CACHE_HIT_WR_FPRFM, Level 1 data cache demand access first hit, write, fetched by software prefetch**

The counter counts each first hit counted by L1D_CACHE_HIT_RW_FPRFM that is due to a demand Memory-write operation.

`0x81D9`, **L2D_CACHE_HIT_WR_FPRFM, Level 2 data cache demand access first hit, write, fetched by software prefetch**

The counter counts each first hit counted by L2D_CACHE_HIT_RW_FPRFM that is due to a demand Memory-write operation.

`0x81DA`, **L3D_CACHE_HIT_WR_FPRFM, Level 3 data cache demand access first hit, write, fetched by software prefetch**

The counter counts each first hit counted by L3D_CACHE_HIT_RW_FPRFM that is due to a demand Memory-write operation.

`0x81DB`, **LL_CACHE_HIT_WR_FPRFM, Last level cache demand access first hit, write, fetched by software prefetch**

The counter counts each first hit counted by LL_CACHE_HIT_RW_FPRFM that is due to a demand Memory-write operation.

`0x81DC`, **L1D_CACHE_HIT_RW_FPRFM, Level 1 data cache demand access first hit, fetched by software prefetch**

The counter counts each demand access first hit counted by L1D_CACHE_HIT_RW_FPRF where the cache line was fetched in response to a prefetch instruction.

That is, the L1D_CACHE_REFILL_PRFM event was generated when the cache line was fetched into the cache.

Only the first hit by a demand access is counted. After this event is generated for a cache line, the event is not generated again for the same cache line while it remains in the cache.

`0x81DD`, **L2D_CACHE_HIT_RW_FPRFM, Level 2 data cache demand access first hit, fetched by software prefetch**

The counter counts each demand access first hit counted by L2D_CACHE_HIT_RW_FPRF where the cache line was fetched in response to a prefetch instruction.

That is, the L2D_CACHE_REFILL_PRFM event was generated when the cache line was fetched into the cache.

Only the first hit by a demand access is counted. After this event is generated for a cache line, the event is not generated again for the same cache line while it remains in the cache.

`0x81DE`, **L3D_CACHE_HIT_RW_FPRFM, Level 3 data cache demand access first hit, fetched by software prefetch**

The counter counts each demand access first hit counted by L3D_CACHE_HIT_RW_FPRF where the cache line was fetched in response to a prefetch instruction.

That is, the L3D_CACHE_REFILL_PRFM event was generated when the cache line was fetched into the cache.

Only the first hit by a demand access is counted. After this event is generated for a cache line, the event is not generated again for the same cache line while it remains in the cache.

`0x81DF`, **LL_CACHE_HIT_RW_FPRFM, Last level cache demand access first hit, fetched by software prefetch**

The counter counts each demand access first hit counted by LL_CACHE_HIT_RW_FPRF where the cache line was fetched in response to a prefetch instruction.

That is, the LL_CACHE_REFILL_PRFM event was generated when the cache line was fetched into the cache.

Only the first hit by a demand access is counted. After this event is generated for a cache line, the event is not generated again for the same cache line while it remains in the cache.

`0x81E0`, **L1I_CACHE_HIT_RD_FHWPRF, Level 1 instruction cache demand fetch first hit, fetched by hardware prefetcher**

The counter counts each demand fetch first hit counted by L1I_CACHE_HIT_RD_FPRF where the cache line was fetched by a hardware prefetcher.

That is, the L1I_CACHE_REFILL_HWPRF event was generated when the cache line was fetched into the cache.

Only the first hit by a demand access is counted. After this event is generated for a cache line, the event is not generated again for the same cache line while it remains in the cache.

`0x81E1`, **L2I_CACHE_HIT_RD_FHWPRF, Level 2 instruction cache demand fetch first hit, fetched by hardware prefetcher**

The counter counts each demand fetch first hit counted by L2I_CACHE_HIT_RD_FPRF where the cache line was fetched by a hardware prefetcher.

That is, the L2I_CACHE_REFILL_HWPRF event was generated when the cache line was fetched into the cache.

Only the first hit by a demand access is counted. After this event is generated for a cache line, the event is not generated again for the same cache line while it remains in the cache.

`0x81E4`, **L1D_CACHE_HIT_RD_FHWPRF, Level 1 data cache demand access first hit, read, fetched by hardware prefetcher**

The counter counts each first hit counted by L1D_CACHE_HIT_RW_FHWPRF that is due to a demand Memory-read operation.

`0x81E5`, **L2D_CACHE_HIT_RD_FHWPRF, Level 2 data cache demand access first hit, read, fetched by hardware prefetcher**

The counter counts each first hit counted by L2D_CACHE_HIT_RW_FHWPRF that is due to a demand Memory-read operation.

Non-Confidential

`0x81E6`, **L3D_CACHE_HIT_RD_FHWPRF, Level 3 data cache demand access first hit, read, fetched by hardware prefetcher**

The counter counts each first hit counted by L3D_CACHE_HIT_RW_FHWPRF that is due to a demand Memory-read operation.

`0x81E7`, **LL_CACHE_HIT_RD_FHWPRF, Last level cache demand access first hit, read, fetched by hardware prefetcher**

The counter counts each first hit counted by LL_CACHE_HIT_RW_FHWPRF that is due to a demand Memory-read operation.

`0x81E8`, **L1D_CACHE_HIT_WR_FHWPRF, Level 1 data cache demand access first hit, write, fetched by hardware prefetcher**

The counter counts each first hit counted by L1D_CACHE_HIT_RW_FHWPRF that is due to a demand Memory-write operation.

`0x81E9`, **L2D_CACHE_HIT_WR_FHWPRF, Level 2 data cache demand access first hit, write, fetched by hardware prefetcher**

The counter counts each first hit counted by L2D_CACHE_HIT_RW_FHWPRF that is due to a demand Memory-write operation.

`0x81EA`, **L3D_CACHE_HIT_WR_FHWPRF, Level 3 data cache demand access first hit, write, fetched by hardware prefetcher**

The counter counts each first hit counted by L3D_CACHE_HIT_RW_FHWPRF that is due to a demand Memory-write operation.

`0x81EB`, **LL_CACHE_HIT_WR_FHWPRF, Last level cache demand access first hit, write, fetched by hardware prefetcher**

The counter counts each first hit counted by LL_CACHE_HIT_RW_FHWPRF that is due to a demand Memory-write operation.

`0x81EC`, **L1D_CACHE_HIT_RW_FHWPRF, Level 1 data cache demand access first hit, fetched by hardware prefetcher**

The counter counts each demand access first hit counted by L1D_CACHE_HIT_RW_FPRF where the cache line was fetched by a hardware prefetcher.

That is, the L1D_CACHE_REFILL_HWPRF event was generated when the cache line was fetched into the cache.

Only the first hit by a demand access is counted. After this event is generated for a cache line, the event is not generated again for the same cache line while it remains in the cache.

`0x81ED`, **L2D_CACHE_HIT_RW_FHWPRF, Level 2 data cache demand access first hit, fetched by hardware prefetcher**

The counter counts each demand access first hit counted by L2D_CACHE_HIT_RW_FPRF where the cache line was fetched by a hardware prefetcher.

That is, the L2D_CACHE_REFILL_HWPRF event was generated when the cache line was fetched into the cache.

Only the first hit by a demand access is counted. After this event is generated for a cache line, the event is not generated again for the same cache line while it remains in the cache.

`0x81EE`, **L3D_CACHE_HIT_RW_FHWPRF, Level 3 data cache demand access first hit, fetched by hardware prefetcher**

The counter counts each demand access first hit counted by L3D_CACHE_HIT_RW_FPRF where the cache line was fetched by a hardware prefetcher.

That is, the L3D_CACHE_REFILL_HWPRF event was generated when the cache line was fetched into the cache.

Only the first hit by a demand access is counted. After this event is generated for a cache line, the event is not generated again for the same cache line while it remains in the cache.

`0x81EF`, **LL_CACHE_HIT_RW_FHWPRF, Last level cache demand access first hit, fetched by hardware prefetcher**

The counter counts each demand access first hit counted by LL_CACHE_HIT_RW_FPRF where the cache line was fetched by a hardware prefetcher.

That is, the LL_CACHE_REFILL_HWPRF event was generated when the cache line was fetched into the cache.

Only the first hit by a demand access is counted. After this event is generated for a cache line, the event is not generated again for the same cache line while it remains in the cache.

`0x81F0`, **L1I_CACHE_HIT_RD_FPRF, Level 1 instruction cache demand fetch first hit, fetched by prefetch**

The counter counts each demand fetch first hit counted by L1I_CACHE_HIT_RD where the cache line was fetched in response to a prefetch instruction or by a hardware prefetcher.

That is, the L1I_CACHE_REFILL_PRF event was generated when the cache line was fetched into the cache.

Only the first hit by a demand access is counted. After this event is generated for a cache line, the event is not generated again for the same cache line while it remains in the cache.

`0x81F1`, **L2I_CACHE_HIT_RD_FPRF, Level 2 instruction cache demand fetch first hit, fetched by prefetch**

The counter counts each demand fetch first hit counted by L2I_CACHE_HIT_RD where the cache line was fetched in response to a prefetch instruction or by a hardware prefetcher.

That is, the L2I_CACHE_REFILL_PRF event was generated when the cache line was fetched into the cache.

Only the first hit by a demand access is counted. After this event is generated for a cache line, the event is not generated again for the same cache line while it remains in the cache.

`0x81F4`, **L1D_CACHE_HIT_RD_FPRF, Level 1 data cache demand access first hit, read, fetched by prefetch**

The counter counts each first hit counted by L1D_CACHE_HIT_RW_FPRF that is due to a demand Memory-read operation.

`0x81F5`, **L2D_CACHE_HIT_RD_FPRF, Level 2 data cache demand access first hit, read, fetched by prefetch**

The counter counts each first hit counted by L2D_CACHE_HIT_RW_FPRF that is due to a demand Memory-read operation.

`0x81F6`, **L3D_CACHE_HIT_RD_FPRF, Level 3 data cache demand access first hit, read, fetched by prefetch**

The counter counts each first hit counted by L3D_CACHE_HIT_RW_FPRF that is due to a demand Memory-read operation.

`0x81F7`, **LL_CACHE_HIT_RD_FPRF, Last level cache demand access first hit, read, fetched by prefetch**

The counter counts each first hit counted by LL_CACHE_HIT_RW_FPRF that is due to a demand Memory-read operation.

`0x81F8`, **L1D_CACHE_HIT_WR_FPRF, Level 1 data cache demand access first hit, write, fetched by prefetch**

The counter counts each first hit counted by L1D_CACHE_HIT_RW_FPRF that is due to a demand Memory-write operation.

`0x81F9`, **L2D_CACHE_HIT_WR_FPRF, Level 2 data cache demand access first hit, write, fetched by prefetch**

The counter counts each first hit counted by L2D_CACHE_HIT_RW_FPRF that is due to a demand Memory-write operation.

`0x81FA`, **L3D_CACHE_HIT_WR_FPRF, Level 3 data cache demand access first hit, write, fetched by prefetch**

The counter counts each first hit counted by L3D_CACHE_HIT_RW_FPRF that is due to a demand Memory-write operation.

The counter counts each first hit counted by LL_CACHE_HIT_RW_FPRF that is due to a demand Memory-write operation.

`0x81FC`, **L1D_CACHE_HIT_RW_FPRF, Level 1 data cache demand access first hit, fetched by prefetch**

The counter counts each demand access first hit counted by L1D_CACHE_HIT_RW where the cache line was fetched in response to a prefetch instruction or by a hardware prefetcher.

That is, the L1D_CACHE_REFILL_PRF event was generated when the cache line was fetched into the cache.

Only the first hit by a demand access is counted. After this event is generated for a cache line, the event is not generated again for the same cache line while it remains in the cache.

`0x81FD`, **L2D_CACHE_HIT_RW_FPRF, Level 2 data cache demand access first hit, fetched by prefetch**

The counter counts each demand access first hit counted by L2D_CACHE_HIT_RW where the cache line was fetched in response to a prefetch instruction or by a hardware prefetcher.

That is, the L2D_CACHE_REFILL_PRF event was generated when the cache line was fetched into the cache.

Only the first hit by a demand access is counted. After this event is generated for a cache line, the event is not generated again for the same cache line while it remains in the cache.

`0x81FE`, **L3D_CACHE_HIT_RW_FPRF, Level 3 data cache demand access first hit, fetched by prefetch**

The counter counts each demand access first hit counted by L3D_CACHE_HIT_RW where the cache line was fetched in response to a prefetch instruction or by a hardware prefetcher.

That is, the L3D_CACHE_REFILL_PRF event was generated when the cache line was fetched into the cache.

Only the first hit by a demand access is counted. After this event is generated for a cache line, the event is not generated again for the same cache line while it remains in the cache.

`0x81FF`, **LL_CACHE_HIT_RW_FPRF, Last level cache demand access first hit, fetched by prefetch**

The counter counts each demand access first hit counted by LL_CACHE_HIT_RW where the cache line was fetched in response to a prefetch instruction or by a hardware prefetcher.

That is, the LL_CACHE_REFILL_PRF event was generated when the cache line was fetched into the cache.

Only the first hit by a demand access is counted. After this event is generated for a cache line, the event is not generated again for the same cache line while it remains in the cache.

`0x8200`, **L1I_CACHE_HIT, Level 1 instruction cache hit**

The counter counts each access counted by L1I_CACHE that hits in the Level 1 instruction or unified cache.

`0x8201`, **L2I_CACHE_HIT, Level 2 instruction cache hit**

The counter counts each access counted by L2I_CACHE that hits in the Level 2 instruction or unified cache.

`0x8204`, **L1D_CACHE_HIT, Level 1 data cache hit**

The counter counts each access counted by L1D_CACHE that hits in the Level 1 data or unified cache.

`0x8205`, **L2D_CACHE_HIT, Level 2 data cache hit**

The counter counts each access counted by L2D_CACHE that hits in the Level 2 data or unified cache.

`0x8206`, **L3D_CACHE_HIT, Level 3 data cache hit**

The counter counts each access counted by L3D_CACHE that hits in the Level 3 data or unified cache.

`0x8207`, **LL_CACHE_HIT, Last level cache hit**

The counter counts each access counted by LL_CACHE that hits in the Last level cache.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

`0x8208`, **L1I_CACHE_HIT_PRFM, Level 1 instruction cache software prefetch hit**

The counter counts each software prefetch counted by L1I_CACHE_PRFM that hits in the Level 1 instruction or unified cache.

`0x8209`, **L2I_CACHE_HIT_PRFM, Level 2 instruction cache software prefetch hit**

The counter counts each software prefetch counted by L2I_CACHE_PRFM that hits in the Level 2 instruction or unified cache.

`0x820C`, **L1D_CACHE_HIT_PRFM, Level 1 data cache software prefetch hit**

The counter counts each software prefetch counted by L1D_CACHE_PRFM that hits in the Level 1 data or unified cache.

`0x820D`, **L2D_CACHE_HIT_PRFM, Level 2 data cache software prefetch hit**

The counter counts each software prefetch counted by L2D_CACHE_PRFM that hits in the Level 2 data or unified cache.

`0x820E`, **L3D_CACHE_HIT_PRFM, Level 3 data cache software prefetch hit**

The counter counts each software prefetch counted by L3D_CACHE_PRFM that hits in the Level 3 data or unified cache.

`0x820F`, **LL_CACHE_HIT_PRFM, Last level cache software prefetch hit**

The counter counts each software prefetch counted by LL_CACHE_PRFM that hits in the Last level cache.

`0x8214`, **L1D_CACHE_HITM_RD, Level 1 data cache demand access hit modified, read**

The counter counts each cache access counted by L1D_CACHE_HIT_RD that accesses a previously modified cache location.

`0x8215`, **L2D_CACHE_HITM_RD, Level 2 data cache demand access hit modified, read**

The counter counts each cache access counted by L2D_CACHE_HIT_RD that accesses a previously modified cache location.

`0x8216`, **L3D_CACHE_HITM_RD, Level 3 data cache demand access hit modified, read**

The counter counts each cache access counted by L3D_CACHE_HIT_RD that accesses a previously modified cache location.

`0x8217`, **LL_CACHE_HITM_RD, Last level cache demand access hit modified, read**

The counter counts each cache access counted by LL_CACHE_HIT_RD that accesses a previously modified cache location.

`0x8218`, **L1D_CACHE_HITM_WR, Level 1 data cache demand access hit modified, write**

The counter counts each cache access counted by L1D_CACHE_HIT_WR that accesses a previously modified cache location.

`0x8219`, **L2D_CACHE_HITM_WR, Level 2 data cache demand access hit modified, write**

The counter counts each cache access counted by L2D_CACHE_HIT_WR that accesses a previously modified cache location.

`0x821A`, **L3D_CACHE_HITM_WR, Level 3 data cache demand access hit modified, write**

The counter counts each cache access counted by L3D_CACHE_HIT_WR that accesses a previously modified cache location.

`0x821B`, **LL_CACHE_HITM_WR, Last level cache demand access hit modified, write**

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The counter counts each cache access counted by LL_CACHE_HIT_WR that accesses a previously modified cache location.

`0x821C`, **L1D_CACHE_HITM_RW, Level 1 data cache demand access hit modified**

The counter counts each cache access counted by L1D_CACHE_HIT_RW that accesses a previously modified cache location.

`0x821D`, **L2D_CACHE_HITM_RW, Level 2 data cache demand access hit modified**

The counter counts each cache access counted by L2D_CACHE_HIT_RW that accesses a previously modified cache location.

`0x821E`, **L3D_CACHE_HITM_RW, Level 3 data cache demand access hit modified**

The counter counts each cache access counted by L3D_CACHE_HIT_RW that accesses a previously modified cache location.

`0x821F`, **LL_CACHE_HITM_RW, Last level cache demand access hit modified**

The counter counts each cache access counted by LL_CACHE_HIT_RW that accesses a previously modified cache location.

`0x8224`, **DSNP_HITM_RD, Snoop hit, demand data read, modified**

The counter counts each snoop generated by the PE in response to a demand Memory-read operation counted by DSNP_HIT_RD that accesses a previously modified cache location.

`0x8225`, **DSNP_HITM_NEAR_RD, Snoop hit in near local cache, demand data read, modified**

The counter counts each snoop generated by the PE in response to a demand Memory-read operation counted by DSNP_HIT_NEAR_RD that accesses a previously modified cache location.

`0x8226`, **DSNP_HITM_FAR_RD, Snoop hit in far local cache, demand data read, modified**

The counter counts each snoop generated by the PE in response to a demand Memory-read operation counted by DSNP_HIT_FAR_RD that accesses a previously modified cache location.

`0x8227`, **DSNP_HITM_REMOTE_RD, Snoop hit in remote cache, demand data read, modified**

The counter counts each snoop generated by the PE in response to a demand Memory-read operation counted by DSNP_HIT_REMOTE_RD that accesses a previously modified cache location.

`0x8228`, **DSNP_HITM_WR, Snoop hit, demand data write, modified**

The counter counts each snoop generated by the PE in response to a demand Memory-write operation counted by DSNP_HIT_WR that accesses a previously modified cache location.

`0x8229`, **DSNP_HITM_NEAR_WR, Snoop hit in near local cache, demand data write, modified**

The counter counts each snoop generated by the PE in response to a demand Memory-write operation counted by DSNP_HIT_NEAR_WR that accesses a previously modified cache location.

`0x822A`, **DSNP_HITM_FAR_WR, Snoop hit in far local cache, demand data write, modified**

The counter counts each snoop generated by the PE in response to a demand Memory-write operation counted by DSNP_HIT_FAR_WR that accesses a previously modified cache location.

`0x822B`, **DSNP_HITM_REMOTE_WR, Snoop hit in remote cache, demand data write, modified**

The counter counts each snoop generated by the PE in response to a demand Memory-write operation counted by DSNP_HIT_REMOTE_WR that accesses a previously modified cache location.

`0x822C`, **DSNP_HITM_RW, Snoop hit, demand data access, modified**

The counter counts each snoop generated by the PE in response to a demand Memory-read operation or demand Memory-write operation counted by DSNP_HIT_RW that accesses a previously modified cache location.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

`0x822D`, **DSNP_HITM_NEAR_RW, Snoop hit in near local cache, demand data access, modified**

The counter counts each snoop generated by the PE in response to a demand Memory-read operation or demand Memory-write operation counted by DSNP_HIT_NEAR_RW that accesses a previously modified cache location.

`0x822E`, **DSNP_HITM_FAR_RW, Snoop hit in far local cache, demand data access, modified**

The counter counts each snoop generated by the PE in response to a demand Memory-read operation or demand Memory-write operation counted by DSNP_HIT_FAR_RW that accesses a previously modified cache location.

`0x822F`, **DSNP_HITM_REMOTE_RW, Snoop hit in remote cache, demand data access, modified**

The counter counts each snoop generated by the PE in response to a demand Memory-read operation or demand Memory-write operation counted by DSNP_HIT_REMOTE_RW that accesses a previously modified cache location.

`0x8230`, **LOCAL_MEM, Access to memory attached to this device**

The counter counts each Memory-read operation or Memory-write operation access to external memory attached to this device.

In a multi-socket system this means attached to the socket that contains the PE. For more information, see REMOTE_ACCESS.

In systems where there multiple types of memory attached to this device with different performance characteristics, it is IMPLEMENTATION DEFINED whether accesses to all external memory types are counted by this event, or are classified as remote accesses and counted by REMOTE_MEM.

For example, in a system with an expansion memory connected to the device that has significantly higher latency than the main system memory, accesses to the main system memory might be counted by this event and accesses to the expansion memory by REMOTE_MEM.

`0x8231`, **LOCAL_MEM_RD, Access to memory attached to this device, demand access, read**

The counter counts each access counted by LOCAL_MEM_RW that is a demand Memory-read operation.

`0x8232`, **LOCAL_MEM_WR, Access to memory attached to this device, demand access, write**

The counter counts each access counted by LOCAL_MEM_RW that is a demand Memory-write operation.

`0x8233`, **LOCAL_MEM_RW, Access to memory attached to this device, demand access**

The counter counts each access counted by LOCAL_MEM that is a demand Memory-read operation or demand Memory-write operation.

It is IMPLEMENTATION DEFINED whether an access to external memory due to a prefetch to a cache is counted by LOCAL_MEM_RW or LOCAL_MEM_PRFM.

`0x8234`, **LOCAL_MEM_PRFM, Access to memory attached to this device, software prefetch**

The counter counts each access counted by LOCAL_MEM that is due to a prefetch instruction.

It is IMPLEMENTATION DEFINED whether an access to external memory due to a prefetch to a cache is counted by LOCAL_MEM_RW or LOCAL_MEM_PRFM.

`0x8235`, **LOCAL_MEM_LD_RETIRED, Load instruction architecturally executed, access to memory attached to this device**

The counter counts each architecturally executed instruction counted by LOCAL_MEM_LDST_RETIRED that is a Memory-reading instruction.

`0x8236`, **LOCAL_MEM_ST_RETIRED, Store instruction architecturally executed, access to memory attached to this device**

The counter counts each architecturally executed instruction counted by LOCAL_MEM_LDST_RETIRED that is a Memory-writing instruction.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

`0x8237`, **LOCAL_MEM_LDST_RETIRED, Load or store instruction architecturally executed, access to memory attached to this device**

The counter counts each Memory-reading instruction or Memory-writing instruction architecturally executed counted by LDST_ANY_RETIRED that accessed external memory attached to this device.

`0x8238`, **REMOTE_MEM, Access to memory attached to a remote device**

The counter counts each Memory-read operation or Memory-write operation access counted by REMOTE_ACCESS to external memory attached to a remote device.

The counter also counts any accesses to external memory that are not counted by LOCAL_MEM because the implementation classifies them as remote accesses. For example, accesses to expansion memory connected to the device that has significantly higher latency than the main system memory might be classified as remote accesses. For more information, see LOCAL_MEM.

`0x8239`, **REMOTE_MEM_RD, Access to memory attached to a remote device, demand access, read**

The counter counts each access counted by REMOTE_MEM_RW that is a demand Memory-read operation.

`0x823A`, **REMOTE_MEM_WR, Access to memory attached to a remote device, demand access, write**

The counter counts each access counted by REMOTE_MEM_RW that is a demand Memory-write operation.

`0x823B`, **REMOTE_MEM_RW, Access to memory attached to a remote device, demand access**

The counter counts each access counted by REMOTE_MEM that is a demand Memory-read operation or demand Memory-write operation.

`0x823C`, **REMOTE_MEM_PRFM, Access to memory attached to a remote device, software prefetch**

The counter counts each access counted by REMOTE_MEM that is due to a prefetch instruction.

`0x823D`, **REMOTE_MEM_LD_RETIRED, Load instruction architecturally executed, access to memory attached to a remote device**

The counter counts each architecturally executed instruction counted by REMOTE_MEM_LDST_RETIRED that is a Memory-reading instruction.

`0x823E`, **REMOTE_MEM_ST_RETIRED, Store instruction architecturally executed, access to memory attached to a remote device**

The counter counts each architecturally executed instruction counted by REMOTE_MEM_LDST_RETIRED that is a Memory-writing instruction.

`0x823F`, **REMOTE_MEM_LDST_RETIRED, Load or store instruction architecturally executed, access to memory attached to a remote device**

The counter counts each Memory-reading instruction or Memory-writing instruction architecturally executed counted by LDST_ANY_RETIRED that accessed external memory attached to a remote device.

`0x8240`, **L1I_LFB_HIT_RD, Level 1 instruction cache demand fetch line-fill buffer hit**

The counter counts each demand access counted by L1I_CACHE_HIT_RD that hits a recently fetched line in the Level 1 instruction or unified cache.

That is, the access hits a cache line that is in the process of being loaded into the Level 1 instruction or unified cache, and so does not generate a new refill, but has to wait for the previous refill to complete.

`0x8241`, **L2I_LFB_HIT_RD, Level 2 instruction cache demand fetch line-fill buffer hit**

The counter counts each demand access counted by L2I_CACHE_HIT_RD that hits a recently fetched line in the Level 2 instruction or unified cache.

That is, the access hits a cache line that is in the process of being loaded into the Level 2 instruction or unified cache, and so does not generate a new refill, but has to wait for the previous refill to complete.

`0x8244`**, L1D_LFB_HIT_RD, Level 1 data cache demand access line-fill buffer hit, read**

The counter counts each demand access counted by L1D_CACHE_HIT_RD that hits a recently fetched line in the Level 1 data or unified cache.

That is, the access hits a cache line that is in the process of being loaded into the Level 1 data or unified cache, and so does not generate a new refill, but has to wait for the previous refill to complete.

`0x8245`**, L2D_LFB_HIT_RD, Level 2 data cache demand access line-fill buffer hit, read**

The counter counts each demand access counted by L2D_CACHE_HIT_RD that hits a recently fetched line in the Level 2 data or unified cache.

That is, the access hits a cache line that is in the process of being loaded into the Level 2 data or unified cache, and so does not generate a new refill, but has to wait for the previous refill to complete.

`0x8246`**, L3D_LFB_HIT_RD, Level 3 data cache demand access line-fill buffer hit, read**

The counter counts each demand access counted by L3D_CACHE_HIT_RD that hits a recently fetched line in the Level 3 data or unified cache.

That is, the access hits a cache line that is in the process of being loaded into the Level 3 data or unified cache, and so does not generate a new refill, but has to wait for the previous refill to complete.

`0x8247`**, LL_LFB_HIT_RD, Last level cache demand access line-fill buffer hit, read**

The counter counts each demand access counted by LL_CACHE_HIT_RD that hits a recently fetched line in the Last level cache.

That is, the access hits a cache line that is in the process of being loaded into the Last level cache, and so does not generate a new refill, but has to wait for the previous refill to complete.

`0x8248`**, L1D_LFB_HIT_WR, Level 1 data cache demand access line-fill buffer hit, write**

The counter counts each demand access counted by L1D_CACHE_HIT_WR that hits a recently fetched line in the Level 1 data or unified cache.

That is, the access hits a cache line that is in the process of being loaded into the Level 1 data or unified cache, and so does not generate a new refill, but has to wait for the previous refill to complete.

`0x8249`**, L2D_LFB_HIT_WR, Level 2 data cache demand access line-fill buffer hit, write**

The counter counts each demand access counted by L2D_CACHE_HIT_WR that hits a recently fetched line in the Level 2 data or unified cache.

That is, the access hits a cache line that is in the process of being loaded into the Level 2 data or unified cache, and so does not generate a new refill, but has to wait for the previous refill to complete.

`0x824A`**, L3D_LFB_HIT_WR, Level 3 data cache demand access line-fill buffer hit, write**

The counter counts each demand access counted by L3D_CACHE_HIT_WR that hits a recently fetched line in the Level 3 data or unified cache.

That is, the access hits a cache line that is in the process of being loaded into the Level 3 data or unified cache, and so does not generate a new refill, but has to wait for the previous refill to complete.

`0x824B`**, LL_LFB_HIT_WR, Last level cache demand access line-fill buffer hit, write**

The counter counts each demand access counted by LL_CACHE_HIT_WR that hits a recently fetched line in the Last level cache.

That is, the access hits a cache line that is in the process of being loaded into the Last level cache, and so does not generate a new refill, but has to wait for the previous refill to complete.

`0x824C`**, L1D_LFB_HIT_RW, Level 1 data cache demand access line-fill buffer hit**

The counter counts each demand access counted by L1D_CACHE_HIT_RW that hits a recently fetched line in the Level 1 data or unified cache.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

That is, the access hits a cache line that is in the process of being loaded into the Level 1 data or unified cache, and so does not generate a new refill, but has to wait for the previous refill to complete.

`0x824D`, **L2D_LFB_HIT_RW, Level 2 data cache demand access line-fill buffer hit**

The counter counts each demand access counted by L2D_CACHE_HIT_RW that hits a recently fetched line in the Level 2 data or unified cache.

That is, the access hits a cache line that is in the process of being loaded into the Level 2 data or unified cache, and so does not generate a new refill, but has to wait for the previous refill to complete.

`0x824E`, **L3D_LFB_HIT_RW, Level 3 data cache demand access line-fill buffer hit**

The counter counts each demand access counted by L3D_CACHE_HIT_RW that hits a recently fetched line in the Level 3 data or unified cache.

That is, the access hits a cache line that is in the process of being loaded into the Level 3 data or unified cache, and so does not generate a new refill, but has to wait for the previous refill to complete.

`0x824F`, **LL_LFB_HIT_RW, Last level cache demand access line-fill buffer hit**

The counter counts each demand access counted by LL_CACHE_HIT_RW that hits a recently fetched line in the Last level cache.

That is, the access hits a cache line that is in the process of being loaded into the Last level cache, and so does not generate a new refill, but has to wait for the previous refill to complete.

`0x8250`, **L1I_LFB_HIT_RD_FPRFM, Level 1 instruction cache demand fetch line-fill buffer first hit, recently fetched by software prefetch**

The counter counts each demand fetch line-fill buffer first hit counted by L1I_LFB_HIT_RD_FPRF where the cache line was fetched in response to a prefetch instruction.

That is, the fetch hits a cache line that is in the process of being loaded into the Level 1 instruction or unified cache, and so does not generate a new refill, but has to wait for the previous refill to complete, and the L1I_CACHE_REFILL_PRFM event was generated when the cache line was fetched into the cache.

Only the first hit by a demand access is counted. After this event is generated for a cache line, the event is not generated again for the same cache line while it remains in the cache.

`0x8251`, **L2I_LFB_HIT_RD_FPRFM, Level 2 instruction cache demand fetch line-fill buffer first hit, recently fetched by software prefetch**

The counter counts each demand fetch line-fill buffer first hit counted by L2I_LFB_HIT_RD_FPRF where the cache line was fetched in response to a prefetch instruction.

That is, the fetch hits a cache line that is in the process of being loaded into the Level 2 instruction or unified cache, and so does not generate a new refill, but has to wait for the previous refill to complete, and the L2I_CACHE_REFILL_PRFM event was generated when the cache line was fetched into the cache.

Only the first hit by a demand access is counted. After this event is generated for a cache line, the event is not generated again for the same cache line while it remains in the cache.

`0x8254`, **L1D_LFB_HIT_RD_FPRFM, Level 1 data cache demand access line-fill buffer first hit, read, recently fetched by software prefetch**

The counter counts each line-fill buffer first hit counted by L1D_LFB_HIT_RW_FPRFM that is due to a demand Memory-read operation.

`0x8255`, **L2D_LFB_HIT_RD_FPRFM, Level 2 data cache demand access line-fill buffer first hit, read, recently fetched by software prefetch**

The counter counts each line-fill buffer first hit counted by L2D_LFB_HIT_RW_FPRFM that is due to a demand Memory-read operation.

`0x8256`, **L3D_LFB_HIT_RD_FPRFM, Level 3 data cache demand access line-fill buffer first hit, read, recently fetched by software prefetch**

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.

`0x8280`**, L1I_CACHE_PRF, Level 1 instruction cache, prefetch hit**

The counter counts each access counted by L1I_CACHE that is due to a prefetch instruction, or hardware prefetch.

`0x8281`**, L2I_CACHE_PRF, Level 2 instruction cache, prefetch hit**

The counter counts each access counted by L2I_CACHE that is due to a prefetch instruction, or hardware prefetch.

This includes accesses to the Level 2 instruction or unified cache due to a refill of another cache caused by a prefetch instruction, or hardware prefetch.

`0x8284`**, L1D_CACHE_PRF, Level 1 data cache, prefetch hit**

The counter counts each access counted by L1D_CACHE that is due to a prefetch instruction, or hardware prefetch.

`0x8285`**, L2D_CACHE_PRF, Level 2 data cache, prefetch hit**

The counter counts each access counted by L2D_CACHE that is due to a prefetch instruction, or hardware prefetch.

This includes accesses to the Level 2 data or unified cache due to a refill of another cache caused by a prefetch instruction, or hardware prefetch.

`0x8286`**, L3D_CACHE_PRF, Level 3 data cache, prefetch hit**

The counter counts each access counted by L3D_CACHE that is due to a prefetch instruction, or hardware prefetch.

This includes accesses to the Level 3 data or unified cache due to a refill of another cache caused by a prefetch instruction, or hardware prefetch.

`0x8287`**, LL_CACHE_PRF, Last level cache, prefetch hit**

The counter counts each access counted by LL_CACHE that is due to a prefetch instruction, or hardware prefetch.

This includes accesses to the Last level cache due to a refill of another cache caused by a prefetch instruction, or hardware prefetch.

`0x8288`**, L1I_CACHE_REFILL_PRF, Level 1 instruction cache refill, prefetch hit**

The counter counts each access counted by L1I_CACHE_PRF that causes a refill of the Level 1 instruction or unified cache from outside of the Level 1 instruction or unified cache.

`0x8289`**, L2I_CACHE_REFILL_PRF, Level 2 instruction cache refill, prefetch hit**

The counter counts each access counted by L2I_CACHE_PRF that causes a refill of the Level 2 instruction or unified cache, or any Level 1 data, instruction, or unified cache of this PE, from outside of those caches.

`0x828C`**, L1D_CACHE_REFILL_PRF, Level 1 data cache refill, prefetch hit**

The counter counts each access counted by L1D_CACHE_PRF that causes a refill of the Level 1 data or unified cache from outside of the Level 1 data or unified cache.

`0x828D`**, L2D_CACHE_REFILL_PRF, Level 2 data cache refill, prefetch hit**

The counter counts each access counted by L2D_CACHE_PRF that causes a refill of the Level 2 data or unified cache, or any Level 1 data, instruction, or unified cache of this PE, from outside of those caches.

`0x828E`**, L3D_CACHE_REFILL_PRF, Level 3 data cache refill, prefetch hit**

The counter counts each access counted by L3D_CACHE_PRF that causes a refill of the Level 3 data or unified cache, or any Level 1 or Level 2 data, instruction, or unified cache of this PE, from outside of those caches.

`0x828F`**, LL_CACHE_REFILL_PRF, Last level cache refill, prefetch hit**

The counter counts each access counted by LL_CACHE_PRF that causes a refill of the Last level cache, or any other data, instruction, or unified cache of this PE, from outside of those caches.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

`0x8290`**, ISNP_HIT_PRF, Snoop hit, instruction prefetch**

The counter counts each snoop generated by the PE in response to an instruction prefetch instruction, or by an instruction hardware prefetch that hits in a cache outside of the cache hierarchy of this PE.

The event is counted by the PE generating the snoop, not the PE being snooped.

`0x8291`**, ISNP_HIT_NEAR_PRF, Snoop hit in near local cache, instruction prefetch**

The counter counts each snoop generated by the PE in response to an instruction prefetch instruction, or by an instruction hardware prefetch counted by ISNP_HIT_PRF that hits in a cache outside of the cache hierarchy of this PE in the local PE cluster.

The event is counted by the PE generating the snoop, not the PE being snooped.

`0x8292`**, ISNP_HIT_FAR_PRF, Snoop hit in far local cache, instruction prefetch**

The counter counts each snoop generated by the PE in response to an instruction prefetch instruction, or by an instruction hardware prefetch counted by ISNP_HIT_PRF that hits in a cache outside the local PE cluster on the same device.

The event is counted by the PE generating the snoop, not the PE being snooped.

`0x8293`**, ISNP_HIT_REMOTE_PRF, Snoop hit in remote cache, instruction prefetch**

The counter counts each snoop generated by the PE in response to an instruction prefetch instruction, or by an instruction hardware prefetch counted by ISNP_HIT_PRF that hits in a cache on a remote device.

The event is counted by the PE generating the snoop, not the PE being snooped.

`0x8294`**, DSNP_HIT_PRF, Snoop hit, data prefetch**

The counter counts each snoop generated by the PE in response to a data prefetch instruction, or by a data hardware prefetch that hits in a cache outside of the cache hierarchy of this PE.

The event is counted by the PE generating the snoop, not the PE being snooped.

`0x8295`**, DSNP_HIT_NEAR_PRF, Snoop hit in near local cache, data prefetch**

The counter counts each snoop generated by the PE in response to a data prefetch instruction, or by a data hardware prefetch counted by DSNP_HIT_PRF that hits in a cache outside of the cache hierarchy of this PE in the local PE cluster.

The event is counted by the PE generating the snoop, not the PE being snooped.

`0x8296`**, DSNP_HIT_FAR_PRF, Snoop hit in far local cache, data prefetch**

The counter counts each snoop generated by the PE in response to a data prefetch instruction, or by a data hardware prefetch counted by DSNP_HIT_PRF that hits in a cache outside the local PE cluster on the same device.

The event is counted by the PE generating the snoop, not the PE being snooped.

`0x8297`**, DSNP_HIT_REMOTE_PRF, Snoop hit in remote cache, data prefetch**

The counter counts each snoop generated by the PE in response to a data prefetch instruction, or by a data hardware prefetch counted by DSNP_HIT_PRF that hits in a cache on a remote device.

The event is counted by the PE generating the snoop, not the PE being snooped.

`0x8298`**, LL_CACHE_RW, Last level cache demand access**

The counter counts each access counted by LL_CACHE that is due to a demand Memory-read operation or demand Memory-write operation.

This includes:

- Accesses made by speculatively executed instructions.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- Accesses to the Last level cache due to a refill of another cache caused by a demand Memory-read operation or demand Memory-write operation.

Arm recommends that this event is implemented if any of the following are true:

- Event LL_CACHE_PRFM is implemented.
- Event LL_CACHE_HWPRF is implemented.

`0x8299`, **LL_CACHE_PRFM, Last level cache software prefetch**

The counter counts each access counted by LL_CACHE_PRF that is due to a prefetch instruction.

This includes accesses to the Last level cache due to a refill of another cache caused by a prefetch instruction.

Arm recommends that this event is implemented if event LL_CACHE_RW is implemented.

`0x829A`, **LL_CACHE_REFILL, Last level cache refill**

The counter counts each access counted by LL_CACHE that causes a refill of the Last level cache, or any other data, instruction, or unified cache of this PE, from outside of those caches.

A refill includes any access that causes data to be fetched from outside of the Level 1 to Last level caches, even if the data is ultimately not allocated into the Last level cache. For example, data might be fetched into a buffer but then discarded, rather than being allocated into a cache. These buffers are treated as part of the cache.

For example, the counter counts:

- Accesses to the Last level cache that cause a refill that is satisfier by fetching data from memory, or a Last level cache of another PE.
- Refills of and write-backs from any other data, instruction, or unified caches of this PE that cause a refill from outside of the Level 1 to Last level caches of this PE.
- Accesses to the Last level cache that cause a refill of a higher level cache of this PE from outside of the Level 1 to Last level caches of this PE, even if there is no refill of the Last level cache.

The counter does not count accesses that:

- Miss in the cache but are satisfied by the refill of a previous miss and do not cause a new refill, even if that previous refill is not complete at the time of the miss.
- Miss in the cache but do not generate a refill, such as a write through the cache.

It is IMPLEMENTATION DEFINED whether accesses that result from cache maintenance instructions are counted.

If the cache is shared and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the cache is shared by PEs other than the PEs in the multithreaded processor and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of PMEVTYPER<n>_EL0.MT.

`0x829B`, **LL_CACHE_REFILL_PRFM, Last level cache refill, software prefetch**

The counter counts each access counted by LL_CACHE_PRFM that causes a refill of the Last level cache, or any other data, instruction, or unified cache of this PE, from outside of those caches.

`0x829C`, **LL_CACHE_WB, Last level cache write-back**

The counter counts each write-back of data from the Last level cache to outside of the Level 1 to Last level caches.

For example:

- A write-back of a dirty cache line to memory.
- A write-back of a recently fetched cache line that has not been allocated to the Last level cache.

Each write-back is counted once, even if multiple accesses are required to complete the write-back.

It is IMPLEMENTATION DEFINED whether the counter counts:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- A transfer of a dirty cache line from the Last level cache to outside of Level 1 to Last level caches made as a result of a coherency request.
- Write-backs made as a result of cache maintenance instructions.

The counter does not count:

- The invalidation of a cache line without any write-back to outside of the Level 1 to Last level caches or memory.
- Writes that write through the Last level cache to outside of the Level 1 to Last level caches.
- Transfers of data from the Last level cache to another cache to satisfy a refill of the other cache.

A write-back is attributable to the agent that generated the request that caused the write-back. This might not be the same agent that caused the data being written back to be allocated into the cache.

An Unattributable write-back event occurs when a requestor outside of the PE makes a coherency request that results in write-back. If the cache is shared, then an Unattributable write-back event is not counted. If the cache is not shared, then the event is counted.

It is IMPLEMENTATION DEFINED whether a write of a whole cache line that is not the result of the eviction of a line from the cache, is counted. For example, this applies when the PE determines software is streaming writes to memory and does not allocate lines to the cache, or by a `DC ZVA` operation.

`0x829D`, **LL_CACHE_WR, Last level cache access, write**

If the LL_CACHE_RW event is implemented, the counter counts each access counted by LL_CACHE_RW that is a Memory-write operation.

If the LL_CACHE_RW event is not implemented, the counter counts each access counted by LL_CACHE that is a Memory-write operation.

If the cache is shared and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the cache is shared by PEs other than the PEs in the multithreaded processor and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of PMEVTYPER<n>_EL0.MT.

`0x829F`, **LL_CACHE_REFILL_WR, Last level cache refill, write**

The counter counts each access counted by both LL_CACHE_REFILL and LL_CACHE_WR.

That is, every refill of the Last level cache counted by LL_CACHE_REFILL that is caused by a Memory-write operation.

If the cache is shared and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the cache is shared by PEs other than the PEs in the multithreaded processor and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of PMEVTYPER<n>_EL0.MT.

`0x82A0`, **MEM_ACCESS_RW, Data memory access, demand access**

The counter counts each access counted by MEM_ACCESS that is a demand Memory-read operation or demand Memory-write operation.

This includes accesses made by speculative instructions.

`0x82A1`, **INST_FETCH_RD, Instruction memory access, demand fetch**

The counter counts each fetch counted by INST_FETCH that is a demand Instruction memory access.

This includes any fetch made for a speculative instruction.

`0x82A2`, **MEM_ACCESS_PRFM, Data memory access, software prefetch**

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The counter counts each access counted by MEM_ACCESS that is due to a prefetch instruction.

`0x82A3`, **INST_FETCH_PRFM, Instruction memory access, software prefetch**

The counter counts each fetch counted by INST_FETCH that is due to a prefetch instruction.

`0x82B0`, **L1I_CACHE_MISS_RETIRED, Instruction architecturally executed, miss in Level 1 instruction cache**

The counter counts each instruction architecturally executed counted by INST_RETIRED that missed in Level 1 instruction or unified cache when fetched.

`0x82B1`, **L2I_CACHE_MISS_RETIRED, Instruction architecturally executed, miss in Level 2 instruction cache**

The counter counts each instruction architecturally executed counted by INST_RETIRED that missed in Level 2 instruction or unified cache when fetched.

`0x82B4`, **L1D_CACHE_MISS_LD_RETIRED, Load instruction architecturally executed, miss in Level 1 data cache**

The counter counts each architecturally executed instruction counted by L1D_CACHE_MISS_LDST_RETIRED that is a Memory-reading instruction.

`0x82B5`, **L2D_CACHE_MISS_LD_RETIRED, Load instruction architecturally executed, miss in Level 2 data cache**

The counter counts each architecturally executed instruction counted by L2D_CACHE_MISS_LDST_RETIRED that is a Memory-reading instruction.

`0x82B6`, **L3D_CACHE_MISS_LD_RETIRED, Load instruction architecturally executed, miss in Level 3 data cache**

The counter counts each architecturally executed instruction counted by L3D_CACHE_MISS_LDST_RETIRED that is a Memory-reading instruction.

`0x82B7`, **LL_CACHE_MISS_LD_RETIRED, Load instruction architecturally executed, miss in Last level cache**

The counter counts each architecturally executed instruction counted by LL_CACHE_MISS_LDST_RETIRED that is a Memory-reading instruction.

`0x82B8`, **L1D_CACHE_MISS_ST_RETIRED, Store instruction architecturally executed, miss in Level 1 data cache**

The counter counts each architecturally executed instruction counted by L1D_CACHE_MISS_LDST_RETIRED that is a Memory-writing instruction.

`0x82B9`, **L2D_CACHE_MISS_ST_RETIRED, Store instruction architecturally executed, miss in Level 2 data cache**

The counter counts each architecturally executed instruction counted by L2D_CACHE_MISS_LDST_RETIRED that is a Memory-writing instruction.

`0x82BA`, **L3D_CACHE_MISS_ST_RETIRED, Store instruction architecturally executed, miss in Level 3 data cache**

The counter counts each architecturally executed instruction counted by L3D_CACHE_MISS_LDST_RETIRED that is a Memory-writing instruction.

`0x82BB`, **LL_CACHE_MISS_ST_RETIRED, Store instruction architecturally executed, miss in Last level cache**

The counter counts each architecturally executed instruction counted by LL_CACHE_MISS_LDST_RETIRED that is a Memory-writing instruction.

`0x82BC`, **L1D_CACHE_MISS_LDST_RETIRED, Load or store instruction architecturally executed, miss in Level 1 data cache**

The counter counts each architecturally executed Memory-reading instruction or Memory-writing instruction counted by LDST_ANY_RETIRED that missed in Level 1 data or unified cache.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

`0x82BD`, **L2D_CACHE_MISS_LDST_RETIRED, Load or store instruction architecturally executed, miss in Level 2 data cache**

The counter counts each architecturally executed Memory-reading instruction or Memory-writing instruction counted by LDST_ANY_RETIRED that missed in Level 2 data or unified cache.

`0x82BE`, **L3D_CACHE_MISS_LDST_RETIRED, Load or store instruction architecturally executed, miss in Level 3 data cache**

The counter counts each architecturally executed Memory-reading instruction or Memory-writing instruction counted by LDST_ANY_RETIRED that missed in Level 3 data or unified cache.

`0x82BF`, **LL_CACHE_MISS_LDST_RETIRED, Load or store instruction architecturally executed, miss in Last level cache**

The counter counts each architecturally executed Memory-reading instruction or Memory-writing instruction counted by LDST_ANY_RETIRED that missed in Last level cache.

`0x82C4`, **L1D_CACHE_HITM_LD_RETIRED, Load instruction architecturally executed, hit modified data in Level 1 data cache**

The counter counts each architecturally executed instruction counted by L1D_CACHE_HITM_LDST_RETIRED that is a Memory-reading instruction.

`0x82C5`, **L2D_CACHE_HITM_LD_RETIRED, Load instruction architecturally executed, hit modified data in Level 2 data cache**

The counter counts each architecturally executed instruction counted by L2D_CACHE_HITM_LDST_RETIRED that is a Memory-reading instruction.

`0x82C6`, **L3D_CACHE_HITM_LD_RETIRED, Load instruction architecturally executed, hit modified data in Level 3 data cache**

The counter counts each architecturally executed instruction counted by L3D_CACHE_HITM_LDST_RETIRED that is a Memory-reading instruction.

`0x82C7`, **LL_CACHE_HITM_LD_RETIRED, Load instruction architecturally executed, hit modified data in Last level cache**

The counter counts each architecturally executed instruction counted by LL_CACHE_HITM_LDST_RETIRED that is a Memory-reading instruction.

`0x82C8`, **L1D_CACHE_HITM_ST_RETIRED, Store instruction architecturally executed, hit modified data in Level 1 data cache**

The counter counts each architecturally executed instruction counted by L1D_CACHE_HITM_LDST_RETIRED that is a Memory-writing instruction.

`0x82C9`, **L2D_CACHE_HITM_ST_RETIRED, Store instruction architecturally executed, hit modified data in Level 2 data cache**

The counter counts each architecturally executed instruction counted by L2D_CACHE_HITM_LDST_RETIRED that is a Memory-writing instruction.

`0x82CA`, **L3D_CACHE_HITM_ST_RETIRED, Store instruction architecturally executed, hit modified data in Level 3 data cache**

The counter counts each architecturally executed instruction counted by L3D_CACHE_HITM_LDST_RETIRED that is a Memory-writing instruction.

`0x82CB`, **LL_CACHE_HITM_ST_RETIRED, Store instruction architecturally executed, hit modified data in Last level cache**

The counter counts each architecturally executed instruction counted by LL_CACHE_HITM_LDST_RETIRED that is a Memory-writing instruction.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

`0x82CC`, **L1D_CACHE_HITM_LDST_RETIRED, Load or store instruction architecturally executed, hit modified data in Level 1 data cache**

The counter counts each architecturally executed Memory-reading instruction or Memory-writing instruction counted by L1D_CACHE_HIT_LDST_RETIRED that hit modified data in Level 1 data or unified cache.

`0x82CD`, **L2D_CACHE_HITM_LDST_RETIRED, Load or store instruction architecturally executed, hit modified data in Level 2 data cache**

The counter counts each architecturally executed Memory-reading instruction or Memory-writing instruction counted by L2D_CACHE_HIT_LDST_RETIRED that hit modified data in Level 2 data or unified cache.

`0x82CE`, **L3D_CACHE_HITM_LDST_RETIRED, Load or store instruction architecturally executed, hit modified data in Level 3 data cache**

The counter counts each architecturally executed Memory-reading instruction or Memory-writing instruction counted by L3D_CACHE_HIT_LDST_RETIRED that hit modified data in Level 3 data or unified cache.

`0x82CF`, **LL_CACHE_HITM_LDST_RETIRED, Load or store instruction architecturally executed, hit modified data in Last level cache**

The counter counts each architecturally executed Memory-reading instruction or Memory-writing instruction counted by LL_CACHE_HIT_LDST_RETIRED that hit modified data in Last level cache.

`0x82D0`, **L1I_LFB_HIT_RETIRED, Instruction architecturally executed, line-fill buffer hit in Level 1 instruction cache**

The counter counts each instruction architecturally executed counted by L1I_CACHE_HIT_RETIRED that hit a recently fetched line in Level 1 instruction or unified cache when fetched.

`0x82D1`, **L2I_LFB_HIT_RETIRED, Instruction architecturally executed, line-fill buffer hit in Level 2 instruction cache**

The counter counts each instruction architecturally executed counted by L2I_CACHE_HIT_RETIRED that hit a recently fetched line in Level 2 instruction or unified cache when fetched.

`0x82D4`, **L1D_LFB_HIT_LD_RETIRED, Load instruction architecturally executed, line-fill buffer hit in Level 1 data cache**

The counter counts each architecturally executed instruction counted by L1D_LFB_HIT_LDST_RETIRED that is a Memory-reading instruction.

`0x82D5`, **L2D_LFB_HIT_LD_RETIRED, Load instruction architecturally executed, line-fill buffer hit in Level 2 data cache**

The counter counts each architecturally executed instruction counted by L2D_LFB_HIT_LDST_RETIRED that is a Memory-reading instruction.

`0x82D6`, **L3D_LFB_HIT_LD_RETIRED, Load instruction architecturally executed, line-fill buffer hit in Level 3 data cache**

The counter counts each architecturally executed instruction counted by L3D_LFB_HIT_LDST_RETIRED that is a Memory-reading instruction.

`0x82D7`, **LL_LFB_HIT_LD_RETIRED, Load instruction architecturally executed, line-fill buffer hit in Last level cache**

The counter counts each architecturally executed instruction counted by LL_LFB_HIT_LDST_RETIRED that is a Memory-reading instruction.

`0x82D8`, **L1D_LFB_HIT_ST_RETIRED, Store instruction architecturally executed, line-fill buffer hit in Level 1 data cache**

The counter counts each architecturally executed instruction counted by L1D_LFB_HIT_LDST_RETIRED that is a Memory-writing instruction.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

`0x82D9`, **L2D_LFB_HIT_ST_RETIRED, Store instruction architecturally executed, line-fill buffer hit in Level 2 data cache**

The counter counts each architecturally executed instruction counted by L2D_LFB_HIT_LDST_RETIRED that is a Memory-writing instruction.

`0x82DA`, **L3D_LFB_HIT_ST_RETIRED, Store instruction architecturally executed, line-fill buffer hit in Level 3 data cache**

The counter counts each architecturally executed instruction counted by L3D_LFB_HIT_LDST_RETIRED that is a Memory-writing instruction.

`0x82DB`, **LL_LFB_HIT_ST_RETIRED, Store instruction architecturally executed, line-fill buffer hit in Last level cache**

The counter counts each architecturally executed instruction counted by LL_LFB_HIT_LDST_RETIRED that is a Memory-writing instruction.

`0x82DC`, **L1D_LFB_HIT_LDST_RETIRED, Load or store instruction architecturally executed, line-fill buffer hit in Level 1 data cache**

The counter counts each architecturally executed Memory-reading instruction or Memory-writing instruction counted by L1D_CACHE_HIT_LDST_RETIRED that hit a recently fetched line in Level 1 data or unified cache.

`0x82DD`, **L2D_LFB_HIT_LDST_RETIRED, Load or store instruction architecturally executed, line-fill buffer hit in Level 2 data cache**

The counter counts each architecturally executed Memory-reading instruction or Memory-writing instruction counted by L2D_CACHE_HIT_LDST_RETIRED that hit a recently fetched line in Level 2 data or unified cache.

`0x82DE`, **L3D_LFB_HIT_LDST_RETIRED, Load or store instruction architecturally executed, line-fill buffer hit in Level 3 data cache**

The counter counts each architecturally executed Memory-reading instruction or Memory-writing instruction counted by L3D_CACHE_HIT_LDST_RETIRED that hit a recently fetched line in Level 3 data or unified cache.

`0x82DF`, **LL_LFB_HIT_LDST_RETIRED, Load or store instruction architecturally executed, line-fill buffer hit in Last level cache**

The counter counts each architecturally executed Memory-reading instruction or Memory-writing instruction counted by LL_CACHE_HIT_LDST_RETIRED that hit a recently fetched line in Last level cache.

`0x82E0`, **L1I_CACHE_HIT_RETIRED, Instruction architecturally executed, hit in Level 1 instruction cache**

The counter counts each instruction architecturally executed counted by INST_RETIRED that hit in Level 1 instruction or unified cache when fetched.

`0x82E1`, **L2I_CACHE_HIT_RETIRED, Instruction architecturally executed, hit in Level 2 instruction cache**

The counter counts each instruction architecturally executed counted by INST_RETIRED that hit in Level 2 instruction or unified cache when fetched.

`0x82E4`, **L1D_CACHE_HIT_LD_RETIRED, Load instruction architecturally executed, hit in Level 1 data cache**

The counter counts each architecturally executed instruction counted by L1D_CACHE_HIT_LDST_RETIRED that is a Memory-reading instruction.

`0x82E5`, **L2D_CACHE_HIT_LD_RETIRED, Load instruction architecturally executed, hit in Level 2 data cache**

The counter counts each architecturally executed instruction counted by L2D_CACHE_HIT_LDST_RETIRED that is a Memory-reading instruction.

`0x82E6`, **L3D_CACHE_HIT_LD_RETIRED, Load instruction architecturally executed, hit in Level 3 data cache**

The counter counts each architecturally executed instruction counted by L3D_CACHE_HIT_LDST_RETIRED that is a Memory-reading instruction.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

`0x82E7`, **LL_CACHE_HIT_LD_RETIRED, Load instruction architecturally executed, hit in Last level cache**

The counter counts each architecturally executed instruction counted by LL_CACHE_HIT_LDST_RETIRED that is a Memory-reading instruction.

`0x82E8`, **L1D_CACHE_HIT_ST_RETIRED, Store instruction architecturally executed, hit in Level 1 data cache**

The counter counts each architecturally executed instruction counted by L1D_CACHE_HIT_LDST_RETIRED that is a Memory-writing instruction.

`0x82E9`, **L2D_CACHE_HIT_ST_RETIRED, Store instruction architecturally executed, hit in Level 2 data cache**

The counter counts each architecturally executed instruction counted by L2D_CACHE_HIT_LDST_RETIRED that is a Memory-writing instruction.

`0x82EA`, **L3D_CACHE_HIT_ST_RETIRED, Store instruction architecturally executed, hit in Level 3 data cache**

The counter counts each architecturally executed instruction counted by L3D_CACHE_HIT_LDST_RETIRED that is a Memory-writing instruction.

`0x82EB`, **LL_CACHE_HIT_ST_RETIRED, Store instruction architecturally executed, hit in Last level cache**

The counter counts each architecturally executed instruction counted by LL_CACHE_HIT_LDST_RETIRED that is a Memory-writing instruction.

`0x82EC`, **L1D_CACHE_HIT_LDST_RETIRED, Load or store instruction architecturally executed, hit in Level 1 data cache**

The counter counts each architecturally executed Memory-reading instruction or Memory-writing instruction counted by LDST_ANY_RETIRED that hit in Level 1 data or unified cache.

`0x82ED`, **L2D_CACHE_HIT_LDST_RETIRED, Load or store instruction architecturally executed, hit in Level 2 data cache**

The counter counts each architecturally executed Memory-reading instruction or Memory-writing instruction counted by LDST_ANY_RETIRED that hit in Level 2 data or unified cache.

`0x82EE`, **L3D_CACHE_HIT_LDST_RETIRED, Load or store instruction architecturally executed, hit in Level 3 data cache**

The counter counts each architecturally executed Memory-reading instruction or Memory-writing instruction counted by LDST_ANY_RETIRED that hit in Level 3 data or unified cache.

`0x82EF`, **LL_CACHE_HIT_LDST_RETIRED, Load or store instruction architecturally executed, hit in Last level cache**

The counter counts each architecturally executed Memory-reading instruction or Memory-writing instruction counted by LDST_ANY_RETIRED that hit in Last level cache.

`0x82F0`, **ITLB_HIT_RETIRED, Instruction architecturally executed, no translation table walk**

The counter counts each instruction which was architecturally executed counted by INST_RETIRED that did not cause a refill of an instruction TLB involving at least one translation table walk access.

The counter does not count the instruction which was architecturally executed if any of the following are true:

- The access generates a Translation fault because the applicable TCR_ELx.EPDy bit is 1.
- FEAT_E0PD is implemented and the access is an unprivileged access that generates a Translation fault because the applicable TCR_ELx.E0PDy bit is 1.

It is IMPLEMENTATION DEFINED whether the counter counts the instruction which was architecturally executed if the access generates a Translation fault for any other reason.

`0x82F1`, **DTLB_HIT_LD_RETIRED, Load instruction architecturally executed, no translation table walk**

The counter counts each Memory-reading instruction architecturally executed counted by DTLB_HIT_LDST_RETIRED that did not cause a refill of a data TLB involving at least one translation table walk access.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

`0x82F2`, **DTLB_HIT_ST_RETIRED, Store instruction architecturally executed, no translation table walk**

The counter counts each Memory-writing instruction architecturally executed counted by DTLB_HIT_LDST_RETIRED that did not cause a refill of a data TLB involving at least one translation table walk access.

`0x82F3`, **DTLB_HIT_LDST_RETIRED, Load or store instruction architecturally executed, no translation table walk**

The counter counts each Memory-reading instruction or Memory-writing instruction architecturally executed counted by LDST_ANY_RETIRED that did not cause a refill of a data TLB involving at least one translation table walk access.

`0x82F4`, **ITLB_WALK_RETIRED, Instruction architecturally executed, at least one translation table walk**

The counter counts each instruction which was architecturally executed counted by INST_RETIRED that caused a refill of an instruction TLB involving at least one translation table walk access.

The counter does not count the instruction which was architecturally executed if any of the following are true:

- The access generates a Translation fault because the applicable TCR_ELx.EPDy bit is 1.
- FEAT_E0PD is implemented and the access is an unprivileged access that generates a Translation fault because the applicable TCR_ELx.E0PDy bit is 1.

It is IMPLEMENTATION DEFINED whether the counter counts the instruction which was architecturally executed if the access generates a Translation fault for any other reason.

`0x82F5`, **DTLB_WALK_LD_RETIRED, Load instruction architecturally executed, at least one translation table walk**

The counter counts each Memory-reading instruction architecturally executed counted by DTLB_WALK_LDST_RETIRED that caused a refill of a data TLB involving at least one translation table walk access.

The counter does not count the Memory-reading instruction architecturally executed if any of the following are true:

- The access generates a Translation fault because the applicable TCR_ELx.EPDy bit is 1.
- FEAT_E0PD is implemented and the access is an unprivileged access that generates a Translation fault because the applicable TCR_ELx.E0PDy bit is 1.

It is IMPLEMENTATION DEFINED whether the counter counts the Memory-reading instruction architecturally executed if the access generates a Translation fault for any other reason.

`0x82F6`, **DTLB_WALK_ST_RETIRED, Store instruction architecturally executed, at least one translation table walk**

The counter counts each Memory-writing instruction architecturally executed counted by DTLB_WALK_LDST_RETIRED that caused a refill of a data TLB involving at least one translation table walk access.

The counter does not count the Memory-writing instruction architecturally executed if any of the following are true:

- The access generates a Translation fault because the applicable TCR_ELx.EPDy bit is 1.
- FEAT_E0PD is implemented and the access is an unprivileged access that generates a Translation fault because the applicable TCR_ELx.E0PDy bit is 1.

It is IMPLEMENTATION DEFINED whether the counter counts the Memory-writing instruction architecturally executed if the access generates a Translation fault for any other reason.

`0x82F7`, **DTLB_WALK_LDST_RETIRED, Load or store instruction architecturally executed, at least one translation table walk**

The counter counts each Memory-reading instruction or Memory-writing instruction architecturally executed counted by LDST_ANY_RETIRED that caused a refill of a data TLB involving at least one translation table walk access.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The counter does not count the Memory-reading instruction or Memory-writing instruction architecturally executed if any of the following are true:

- The access generates a Translation fault because the applicable TCR_ELx.EPDy bit is 1.
- FEAT_E0PD is implemented and the access is an unprivileged access that generates a Translation fault because the applicable TCR_ELx.E0PDy bit is 1.

It is IMPLEMENTATION DEFINED whether the counter counts the Memory-reading instruction or Memory-writing instruction architecturally executed if the access generates a Translation fault for any other reason.

`0x82F8`**, DTLB_WALK_PRF, Data TLB prefetch, with at least one translation table walk**

The counter counts each software prefetch or hardware prefetch access counted by L1D_TLB_PRF that causes a refill or update of a data or unified TLB involving at least one translation table walk access.

The counter does not count the software prefetch or hardware prefetch access if any of the following are true:

- The access is due to a TLB maintenance instruction.
- The access generates a Translation fault because the applicable TCR_ELx.EPDy bit is 1.
- FEAT_E0PD is implemented and the access is an unprivileged access that generates a Translation fault because the applicable TCR_ELx.E0PDy bit is 1.

It is IMPLEMENTATION DEFINED whether the counter counts the software prefetch or hardware prefetch access if the access generates a Translation fault for any other reason.

If the TLB is shared and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of PMEVTYPER<n>_EL0.MT.

`0x82F9`**, ITLB_WALK_PRF, Instruction TLB prefetch, with at least one translation table walk**

The counter counts each software prefetch or hardware prefetch access counted by L1I_TLB_PRF that causes a refill or update of an instruction TLB involving at least one translation table walk access.

The counter does not count the software prefetch or hardware prefetch access if any of the following are true:

- The access is due to a TLB maintenance instruction.
- The access generates a Translation fault because the applicable TCR_ELx.EPDy bit is 1.
- FEAT_E0PD is implemented and the access is an unprivileged access that generates a Translation fault because the applicable TCR_ELx.E0PDy bit is 1.

It is IMPLEMENTATION DEFINED whether the counter counts the software prefetch or hardware prefetch access if the access generates a Translation fault for any other reason.

If the TLB is shared and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of PMEVTYPER<n>_EL0.MT.

`0x82FA`**, DTLB_WALK_HWPRF, Data TLB hardware prefetch, with at least one translation table walk**

The counter counts each hardware prefetch access counted by L1D_TLB_HWPRF that causes a refill or update of a data or unified TLB involving at least one translation table walk access.

The counter does not count the hardware prefetch access if any of the following are true:

- The access is due to a TLB maintenance instruction.
- The access generates a Translation fault because the applicable TCR_ELx.EPDy bit is 1.
- FEAT_E0PD is implemented and the access is an unprivileged access that generates a Translation fault because the applicable TCR_ELx.E0PDy bit is 1.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

It is IMPLEMENTATION DEFINED whether the counter counts the hardware prefetch access if the access generates a Translation fault for any other reason.

If the TLB is shared and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of PMEVTYPER<n>_EL0.MT.

`0x82FB`**, ITLB_WALK_HWPRF, Instruction TLB hardware prefetch, with at least one translation table walk**

The counter counts each hardware prefetch access counted by L1I_TLB_HWPRF that causes a refill or update of an instruction TLB involving at least one translation table walk access.

The counter does not count the hardware prefetch access if any of the following are true:

- The access is due to a TLB maintenance instruction.
- The access generates a Translation fault because the applicable TCR_ELx.EPDy bit is 1.
- FEAT_E0PD is implemented and the access is an unprivileged access that generates a Translation fault because the applicable TCR_ELx.E0PDy bit is 1.

It is IMPLEMENTATION DEFINED whether the counter counts the hardware prefetch access if the access generates a Translation fault for any other reason.

If the TLB is shared and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of PMEVTYPER<n>_EL0.MT.

`0x82FC`**, L1D_TLB_PRF, Level 1 data TLB access, prefetch**

The counter counts each access counted by L1D_TLB that is due to a prefetch instruction, or hardware prefetch.

The counter does not count the access if any of the following are true:

- The access generates a Translation fault because the applicable TCR_ELx.EPDy bit is 1.
- FEAT_E0PD is implemented and the access is an unprivileged access that generates a Translation fault because the applicable TCR_ELx.E0PDy bit is 1.

It is IMPLEMENTATION DEFINED whether the counter counts the access if the access generates a Translation fault for any other reason.

If the TLB is shared and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of PMEVTYPER<n>_EL0.MT.

`0x82FD`**, L1I_TLB_PRF, Level 1 instruction TLB access, prefetch**

The counter counts each access counted by L1I_TLB that is due to a prefetch instruction, or hardware prefetch.

The counter does not count the access if any of the following are true:

- The access generates a Translation fault because the applicable TCR_ELx.EPDy bit is 1.
- FEAT_E0PD is implemented and the access is an unprivileged access that generates a Translation fault because the applicable TCR_ELx.E0PDy bit is 1.

It is IMPLEMENTATION DEFINED whether the counter counts the access if the access generates a Translation fault for any other reason.

Non-Confidential

If the TLB is shared and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of PMEVTYPER<n>_EL0.MT.

`0x82FE`, **L1D_TLB_HWPRF, Level 1 data TLB access, hardware prefetch**

The counter counts each access counted by L1D_TLB_PRF that is due to a hardware prefetch.

The counter does not count the access if any of the following are true:

- The access generates a Translation fault because the applicable TCR_ELx.EPDy bit is 1.
- FEAT_E0PD is implemented and the access is an unprivileged access that generates a Translation fault because the applicable TCR_ELx.E0PDy bit is 1.

It is IMPLEMENTATION DEFINED whether the counter counts the access if the access generates a Translation fault for any other reason.

If the TLB is shared and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of PMEVTYPER<n>_EL0.MT.

`0x82FF`, **L1I_TLB_HWPRF, Level 1 instruction TLB access, hardware prefetch**

The counter counts each access counted by L1I_TLB_PRF that is due to a hardware prefetch.

The counter does not count the access if any of the following are true:

- The access generates a Translation fault because the applicable TCR_ELx.EPDy bit is 1.
- FEAT_E0PD is implemented and the access is an unprivileged access that generates a Translation fault because the applicable TCR_ELx.E0PDy bit is 1.

It is IMPLEMENTATION DEFINED whether the counter counts the access if the access generates a Translation fault for any other reason.

If the TLB is shared and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of PMEVTYPER<n>_EL0.MT.

`0x8304`, **DSNP_HITM_LD_RETIRED, Load instruction architecturally executed, snoop hit**

The counter counts each architecturally executed instruction counted by DSNP_HITM_LDST_RETIRED that is a Memory-reading instruction.

`0x8305`, **DSNP_HITM_NEAR_LD_RETIRED, Load instruction architecturally executed, snoop hit in near cache**

The counter counts each architecturally executed instruction counted by DSNP_HITM_NEAR_LDST_RETIRED that is a Memory-reading instruction.

`0x8306`, **DSNP_HITM_FAR_LD_RETIRED, Load instruction architecturally executed, snoop hit in far cache**

The counter counts each architecturally executed instruction counted by DSNP_HITM_FAR_LDST_RETIRED that is a Memory-reading instruction.

`0x8307`, **DSNP_HITM_REMOTE_LD_RETIRED, Load instruction architecturally executed, snoop hit in remote cache**

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The counter counts each architecturally executed instruction counted by DSNP_HITM_REMOTE_LDST_RETIRED that is a Memory-reading instruction.

`0x8308`, **DSNP_HITM_ST_RETIRED, Store instruction architecturally executed, snoop hit**

The counter counts each architecturally executed instruction counted by DSNP_HITM_LDST_RETIRED that is a Memory-writing instruction.

`0x8309`, **DSNP_HITM_NEAR_ST_RETIRED, Store instruction architecturally executed, snoop hit in near cache**

The counter counts each architecturally executed instruction counted by DSNP_HITM_NEAR_LDST_RETIRED that is a Memory-writing instruction.

`0x830A`, **DSNP_HITM_FAR_ST_RETIRED, Store instruction architecturally executed, snoop hit in far cache**

The counter counts each architecturally executed instruction counted by DSNP_HITM_FAR_LDST_RETIRED that is a Memory-writing instruction.

`0x830B`, **DSNP_HITM_REMOTE_ST_RETIRED, Store instruction architecturally executed, snoop hit in remote cache**

The counter counts each architecturally executed instruction counted by DSNP_HITM_REMOTE_LDST_RETIRED that is a Memory-writing instruction.

`0x830C`, **DSNP_HITM_LDST_RETIRED, Load or store instruction architecturally executed, snoop hit**

The counter counts each architecturally executed Memory-reading instruction or Memory-writing instruction counted by LDST_ANY_RETIRED that hit modified data in a data cache outside the cache hierarchy of this PE.

`0x830D`, **DSNP_HITM_NEAR_LDST_RETIRED, Load or store instruction architecturally executed, snoop hit in near cache**

The counter counts each architecturally executed Memory-reading instruction or Memory-writing instruction counted by DSNP_HITM_LDST_RETIRED that hit modified data outside of the cache hierarchy of this PE in the local PE cluster.

`0x830E`, **DSNP_HITM_FAR_LDST_RETIRED, Load or store instruction architecturally executed, snoop hit in far cache**

The counter counts each architecturally executed Memory-reading instruction or Memory-writing instruction counted by DSNP_HITM_LDST_RETIRED that hit modified data outside the local PE cluster on the same device.

`0x830F`, **DSNP_HITM_REMOTE_LDST_RETIRED, Load or store instruction architecturally executed, snoop hit in remote cache**

The counter counts each architecturally executed Memory-reading instruction or Memory-writing instruction counted by DSNP_HITM_LDST_RETIRED that hit modified data on a remote device.

`0x8310`, **ISNP_HIT_RETIRED, Instruction architecturally executed, instruction fetch snoop hit**

The counter counts each instruction architecturally executed counted by INST_RETIRED that hit in an instruction cache outside the cache hierarchy of this PE when fetched.

`0x8311`, **ISNP_HIT_NEAR_RETIRED, Instruction architecturally executed, instruction fetch snoop hit in near cache**

The counter counts each instruction architecturally executed counted by ISNP_HIT_RETIRED that hit outside of the cache hierarchy of this PE in the local PE cluster when fetched.

`0x8312`, **ISNP_HIT_FAR_RETIRED, Instruction architecturally executed, instruction fetch snoop hit in far cache**

The counter counts each instruction architecturally executed counted by ISNP_HIT_RETIRED that hit outside the local PE cluster on the same device when fetched.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

`0x8313`, **ISNP_HIT_REMOTE_RETIRED, Instruction architecturally executed, instruction fetch snoop hit in remote cache**

The counter counts each instruction architecturally executed counted by ISNP_HIT_RETIRED that hit on a remote device when fetched.

`0x8314`, **DSNP_HIT_LD_RETIRED, Load instruction architecturally executed, snoop hit**

The counter counts each architecturally executed instruction counted by DSNP_HIT_LDST_RETIRED that is a Memory-reading instruction.

`0x8315`, **DSNP_HIT_NEAR_LD_RETIRED, Load instruction architecturally executed, snoop hit in near cache**

The counter counts each architecturally executed instruction counted by DSNP_HIT_NEAR_LDST_RETIRED that is a Memory-reading instruction.

`0x8316`, **DSNP_HIT_FAR_LD_RETIRED, Load instruction architecturally executed, snoop hit in far cache**

The counter counts each architecturally executed instruction counted by DSNP_HIT_FAR_LDST_RETIRED that is a Memory-reading instruction.

`0x8317`, **DSNP_HIT_REMOTE_LD_RETIRED, Load instruction architecturally executed, snoop hit in remote cache**

The counter counts each architecturally executed instruction counted by DSNP_HIT_REMOTE_LDST_RETIRED that is a Memory-reading instruction.

`0x8318`, **DSNP_HIT_ST_RETIRED, Store instruction architecturally executed, snoop hit**

The counter counts each architecturally executed instruction counted by DSNP_HIT_LDST_RETIRED that is a Memory-writing instruction.

`0x8319`, **DSNP_HIT_NEAR_ST_RETIRED, Store instruction architecturally executed, snoop hit in near cache**

The counter counts each architecturally executed instruction counted by DSNP_HIT_NEAR_LDST_RETIRED that is a Memory-writing instruction.

`0x831A`, **DSNP_HIT_FAR_ST_RETIRED, Store instruction architecturally executed, snoop hit in far cache**

The counter counts each architecturally executed instruction counted by DSNP_HIT_FAR_LDST_RETIRED that is a Memory-writing instruction.

`0x831B`, **DSNP_HIT_REMOTE_ST_RETIRED, Store instruction architecturally executed, snoop hit in remote cache**

The counter counts each architecturally executed instruction counted by DSNP_HIT_REMOTE_LDST_RETIRED that is a Memory-writing instruction.

`0x831C`, **DSNP_HIT_LDST_RETIRED, Load or store instruction architecturally executed, snoop hit**

The counter counts each architecturally executed Memory-reading instruction or Memory-writing instruction counted by LDST_ANY_RETIRED that hit in a data cache outside the cache hierarchy of this PE.

`0x831D`, **DSNP_HIT_NEAR_LDST_RETIRED, Load or store instruction architecturally executed, snoop hit in near cache**

The counter counts each architecturally executed Memory-reading instruction or Memory-writing instruction counted by DSNP_HIT_LDST_RETIRED that hit outside of the cache hierarchy of this PE in the local PE cluster.

`0x831E`, **DSNP_HIT_FAR_LDST_RETIRED, Load or store instruction architecturally executed, snoop hit in far cache**

The counter counts each architecturally executed Memory-reading instruction or Memory-writing instruction counted by DSNP_HIT_LDST_RETIRED that hit outside the local PE cluster on the same device.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

`0x831F`, **DSNP_HIT_REMOTE_LDST_RETIRED, Load or store instruction architecturally executed, snoop hit in remote cache**

The counter counts each architecturally executed Memory-reading instruction or Memory-writing instruction counted by DSNP_HIT_LDST_RETIRED that hit on a remote device.

`0x8320`, **L1D_CACHE_REFILL_PERCYC, Level 1 data or unified cache refills in progress**

The counter increments by the number of Level 1 data or unified cache refills counted by L1D_CACHE_REFILL in progress on each Processor cycle.

The ratio L1D_CACHE_REFILL_PERCYC ÷ L1D_CACHE_REFILL is the mean duration of Level 1 data or unified cache refills in Processor cycles.

`0x8321`, **L2D_CACHE_REFILL_PERCYC, Level 2 data or unified cache refills in progress**

The counter increments by the number of Level 2 data or unified cache refills counted by L2D_CACHE_REFILL in progress on each Processor cycle.

The ratio L2D_CACHE_REFILL_PERCYC ÷ L2D_CACHE_REFILL is the mean duration of Level 2 data or unified cache refills in Processor cycles.

`0x8322`, **L3D_CACHE_REFILL_PERCYC, Level 3 data or unified cache refills in progress**

The counter increments by the number of Level 3 data or unified cache refills counted by L3D_CACHE_REFILL in progress on each Processor cycle.

The ratio L3D_CACHE_REFILL_PERCYC ÷ L3D_CACHE_REFILL is the mean duration of Level 3 data or unified cache refills in Processor cycles.

`0x8324`, **L1I_CACHE_REFILL_PERCYC, Level 1 instruction or unified cache refills in progress**

The counter increments by the number of Level 1 instruction or unified cache refills counted by L1I_CACHE_REFILL in progress on each Processor cycle.

The ratio L1I_CACHE_REFILL_PERCYC ÷ L1I_CACHE_REFILL is the mean duration of Level 1 instruction or unified cache refills in Processor cycles.

`0x8325`, **L2I_CACHE_REFILL_PERCYC, Level 2 instruction or unified cache refills in progress**

The counter increments by the number of Level 2 instruction or unified cache refills counted by L2I_CACHE_REFILL in progress on each Processor cycle.

The ratio L2I_CACHE_REFILL_PERCYC ÷ L2I_CACHE_REFILL is the mean duration of Level 2 instruction or unified cache refills in Processor cycles.

`0x8328`, **REMOTE_CACHE_HIT_RD, Remote cache demand access hit, read**

The counter counts each cache hit on a remote device due to a demand read.

`0x8329`, **REMOTE_CACHE_HITM_RD, Remote cache demand access hit modified, read**

The counter counts each cache hit on a remote device counted by REMOTE_CACHE_HIT_RD that accesses a previously modified location.

`0x832A`, **REMOTE_LFB_HIT_RD, Remote cache demand access line-fill buffer hit, read**

The counter counts each cache hit on a remote device counted by REMOTE_CACHE_HIT_RD that hits a recently fetched line.

That is, the read hits a cache line that is in the process of being loaded into the cache attached to a remote device, and so does not generate a new refill, but has to wait for the previous refill to complete.

`0x832B`, **REMOTE_CACHE_HIT_PRFM, Remote cache software prefetch hit**

The counter counts each cache hit on a remote device due to a software prefetch.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

`0x8330`, **L1GCS_CACHE, Level 1 GCS cache access**

The counter counts each GCS data read operation or GCS data write operation that causes a cache access to at least a Level 1 cache.

Each access to a cache line is counted including the multiple accesses caused by single instructions such as `GCSPUSHX` or `GCSPOPX`. Each access to other Level 1 memory structures, for example refill buffers, write buffers, and write-back buffers, is also counted.

Accesses to a Level 1 cache due to a GCS hardware prefetcher as well are counted.

When there are separate GCS caching structures implemented:

- It is IMPLEMENTATION DEFINED whether accesses that result from cache maintenance instructions are counted.
- Accesses that only update the cache status information for a cache entry without accessing the content of the cache entry are not counted.

`0x8331`, **L1GCS_CACHE_RW, Level 1 GCS cache demand access**

The counter counts each access counted by L1GCS_CACHE that is due to a demand Memory-read operation or demand Memory-write operation.

This includes accesses made by Speculatively executed instructions.

Arm recommends that this event is implemented if event L1GCS_CACHE_HWPRF is implemented.

`0x8332`, **L1GCS_CACHE_HWPRF, Level 1 GCS cache hardware prefetch**

The counter counts each access counted by L1GCS_CACHE that is due to a GCS hardware prefetcher.

`0x8334`, **L1GCS_CACHE_MISS, Level 1 GCS cache demand access miss**

The counter counts each access counted by L1GCS_CACHE_RW that misses in the Level 1 caches causing an access to outside of the Level 1 caches of this PE.

`0x8335`, **L1GCS_CACHE_MISS_RD, Level 1 GCS cache demand access read miss**

The counter counts each access counted by L1GCS_CACHE_MISS that is also a Memory-read operation.

It is IMPLEMENTATION DEFINED whether accesses that result from cache maintenance instructions are counted.

If the cache is shared and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the cache is shared by PEs other than the PEs in the multithreaded processor and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of PMEVTYPER<n>_EL0.MT.

Arm recommends that this event is implemented if event L1GCS_CACHE is implemented.

`0x8336`, **L1GCS_CACHE_HIT_RW, Level 1 GCS cache demand access hit**

The counter counts each access counted by L1GCS_CACHE_RW that hits in a Level 1 cache.

`0x8337`, **L1GCS_CACHE_HIT_RW_FHWPRF, Level 1 GCS cache demand access first hit, fetched by GCS hardware prefetcher**

The counter counts each demand access first hit counted by L1GCS_CACHE_HIT_RW where the cache line was fetched by a GCS hardware prefetcher.

That is, the L1GCS_CACHE_REFILL_HWPRF event was generated when the cache line was fetched into the cache.

Only the first hit by a demand access is counted. After this event is generated for a cache line, the event is not generated again for the same cache line while it remains in the cache.

`0x8338`, **L1GCS_CACHE_REFILL, Level 1 GCS cache refill**

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The counter counts each access counted by L1GCS_CACHE that causes a refill of a Level 1 cache from outside of the Level 1 cache.

A refill includes any access that causes data to be fetched from outside of the Level 1 caches, even if the data is ultimately not allocated into the Level 1 cache. For example, data might be fetched into a buffer but then discarded, rather than being allocated into a cache. These buffers are treated as part of the cache.

For example, the counter counts accesses to the Level 1 cache that cause a refill that is satisfied by fetching data from memory, a Level 2 cache, or a Level 1 cache of another PE.

The counter does not count accesses that:

- Miss in the cache but are satisfied by the refill of a previous miss and do not cause a new refill, even if that previous refill is not complete at the time of the miss.
- Miss in the cache but do not generate a refill, such as a write through the cache.

If the cache is shared and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the cache is shared by PEs other than the PEs in the multithreaded processor and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of PMEVTYPER<n>_EL0.MT.

`0x8339`, **L1GCS_CACHE_REFILL_HWPRF, Level 1 GCS cache refill, hardware prefetch**

The counter counts each hardware prefetch counted by L1GCS_CACHE_HWPRF that causes a refill of a Level 1 cache from outside of the Level 1 cache.

`0x833A`, **L1GCS_CACHE_REFILL_PERCYC, Level 1 GCS cache refills in progress**

The counter increments by the number of Level 1 GCS cache refills counted by L1GCS_CACHE_REFILL in progress on each Processor cycle.

The ratio L1GCS_CACHE_REFILL_PERCYC ÷ L1GCS_CACHE_REFILL is the mean duration of Level 1 GCS cache refills in Processor cycles.

`0x833C`, **L1GCS_LFB_HIT_RW, Level 1 GCS cache demand access line-fill buffer hit**

The counter counts each demand access counted by L1GCS_CACHE_HIT_RW that hits a recently fetched line in a Level 1 cache.

That is, the access hits a cache line that is in the process of being loaded into the Level 1 cache, and so does not generate a new refill, but has to wait for the previous refill to complete.

`0x833D`, **L1GCS_LFB_HIT_RW_FHWPRF, Level 1 GCS cache demand access line-fill buffer first hit, recently fetched by GCS hardware prefetcher**

The counter counts each demand access line-fill buffer first hit counted by L1GCS_LFB_HIT_RW where the cache line was fetched by a GCS hardware prefetcher.

That is, the access hits a cache line that is in the process of being loaded into the Level 1 cache, and so does not generate a new refill, but has to wait for the previous refill to complete, and the L1GCS_CACHE_REFILL_HWPRF event was generated when the cache line was fetched into the cache.

`0x833E`, **L1GCS_CACHE_INVAL, Level 1 GCS cache invalidate**

The counter counts each invalidation of a cache line in a Level 1 GCS cache.

For example:

- Invalidation of a cache line because of a `GCSB` effect.
- Transfer of ownership of a cache line to another cache because of a coherency or refill request.

The counter does not count events if a cache refill of the Level 1 cache invalidates a line in the Level 1 cache.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

Software that uses this event must know whether the Level 1 cache is shared with other PEs. This event does not follow the general rule of Level 1 cache events of only counting Attributable events.

`0x8340`**, L1GCS_TLB, Level 1 GCS TLB access**

The counter counts each GCS data read operation or GCS data write operation that causes a TLB access to at least a Level 1 TLB.

Each access to a TLB entry is counted including multiple accesses caused by single instructions such as `GCSPUSHX` or `GCSPOPX`.

The counter does not count the access if the access is due to a TLB maintenance instruction.

If the TLB is shared and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of PMEVTYPER<n>_EL0.MT.

`0x8341`**, L1GCS_TLB_RW, Level 1 GCS demand TLB access**

The counter counts each access counted by L1GCS_TLB that is due to a demand Memory-read operation or demand Memory-write operation.

If the TLB is shared and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of PMEVTYPER<n>_EL0.MT.

`0x8342`**, L1GCS_TLB_HWPRF, Level 1 GCS demand TLB access, GCS hardware prefetch**

The counter counts each access counted by L1GCS_TLB that is due to a GCS hardware prefetch.

If the TLB is shared and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of PMEVTYPER<n>_EL0.MT.

`0x8344`**, GCSTLB_WALK, GCS TLB access with at least one translation table walk**

The counter counts each access counted by L1GCS_TLB that causes a refill of a TLB involving at least one translation table walk access.

This includes each complete or partial translation table walk that causes an access to memory, including to data or translation table walk caches.

Accesses that cause an update of an existing TLB entry involving at least one translation table walk access are counted.

The counter does not count the access if any of the following are true:

- FEAT_E0PD is implemented and the access is an unprivileged access that generates a Translation fault because the applicable TCR_ELx.E0PDy bit is 1.
- The access generates a Translation fault because the applicable TCR_ELx.EPDy bit is 1.
- The access is due to a TLB maintenance instruction.

It is IMPLEMENTATION DEFINED whether the counter counts the access if the access generates a Translation fault for any other reason.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The counter does not count the access if any of the following are true:

- The access generates a Translation fault because the applicable TCR_ELx.EPDy bit is 1.
- FEAT_E0PD is implemented and the access is an unprivileged access that generates a Translation fault because the applicable TCR_ELx.E0PDy bit is 1.

It is IMPLEMENTATION DEFINED whether the counter counts the access if the access generates a Translation fault for any other reason.

If the TLB is shared and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of PMEVTYPER<n>_EL0.MT.

`0x8345`**, GCSTLB_WALK_RW, GCS TLB demand access with at least one translation table walk**

The counter counts each demand access counted by both GCSTLB_WALK and L1GCS_TLB_RW.

If the TLB is shared and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of PMEVTYPER<n>_EL0.MT.

`0x8346`**, GCSTLB_WALK_PERCYC, Translation table walks in progress**

The counter increments by the number of translation table walks counted by GCSTLB_WALK in progress on each Processor cycle.

The ratio GCSTLB_WALK_PERCYC ÷ GCSTLB_WALK is the mean duration of translation table walks in Processor cycles.

If the TLB is shared and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of PMEVTYPER<n>_EL0.MT.

`0x8347`**, GCSTLB_WALK_STEP, GCS TLB translation table walk, step**

The counter counts each translation table walk access due to a refill of a TLB.

The translation table walk must be due to either GCS data read operation or GCS data write operation.

The event is Attributable to the access that missed in the TLB and caused the walk, not to the owner of the translation tables being accessed. For example, this means that if an EL0 access causes a translation table walk consisting of accesses to both stage 1 and stage 2 translation tables, all accesses are counted if event counting is allowed at EL0, regardless of whether event counting is allowed at EL1 and/or EL2.

The counter does not count the event if any of the following are true:

- The access causing the refill generates a Translation fault because the applicable TCR_ELx.EPDy bit is 1.
- The access causing the refill is an unprivileged access that generates a Translation fault because the applicable TCR_ELx.E0PDy bit is 1.

It is IMPLEMENTATION DEFINED whether the counter counts the event if the access causing the refill generates a Translation fault for any other reason.

Implementation of this optional event requires that FEAT_E0PD is implemented.

If the TLB is shared and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of PMEVTYPER<n>_EL0.MT for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of PMEVTYPER<n>_EL0.MT.

`0x8350`, **STALL_BACKEND_L1GCS, Backend stall cycles, Level 1 GCS cache**

The counter counts each cycle counted by STALL_BACKEND_MEMBOUND when there is a demand data miss in a first level cache.

The demand data miss must be due to either GCS data read operation or GCS data write operation.

The counter does not count the cycle if any of the following are true:

- The STALL_BACKEND_L2D event is implemented and there is a demand data miss in the second level of data or unified cache, meaning the STALL_BACKEND_L2D event counts the cycle.
- There is a demand data miss in the last level of data or unified cache within the PE clock domain, meaning the STALL_BACKEND_MEM event counts the cycle.

Implementation of this optional event requires that the first level cache is implemented within the PE clock domain and is not the last level cache within the PE clock domain.

Implementation of this optional event requires implementing L1GCS_CACHE event.

Note

It is possible that both the events STALL_BACKEND_L1GCS and STALL_BACKEND_L1D events may be counted on a same cycle.

`0x8351`, **STALL_BACKEND_GCSTLB, Backend stall cycles, GCS TLB**

The counter counts each cycle counted by STALL_BACKEND_MEMBOUND when there is a demand data miss in a TLB.

The demand data miss must be due to translation of a GCS data read operation or GCS data write operation.

Implementation of this optional event requires implementing L1GCS_TLB event.

`0x8353`, **SE_FP_SPEC, Operation speculatively executed, Advanced SIMD, SVE, or SME SIMD floating-point, data-processing**

The counter counts each speculatively executed floating-point data-processing operation counted by FP_SPEC due to an A64 Advanced SIMD, SVE, or SME operation.

That is, each operation counted by ASE_FP_SPEC, SVE_FP_SPEC, or SME_FP_SPEC.

`0x835D`, **SE_SPEC, Operation speculatively executed, Advanced SIMD, SVE, or SME data processing**

The counter counts each operation counted by INST_SPEC that is an Advanced SIMD, SVE, or SME data-processing operation.

See ASE_SVE_SPEC and SME_SPEC for these classifications.

`0x835F`, **SE_INST_SPEC, Operation speculatively executed, Advanced SIMD, SVE, or SME**

The counter counts each speculatively executed operation counted by INST_SPEC that is classified as an Advanced SIMD, SVE, or SME operation.

See ASE_SVE_INST_SPEC and SME_INST_SPEC for these classifications.

`0x8361`, **SE_INT8_SPEC, Operation speculatively executed, Advanced SIMD, SVE, or SME SIMD 8-bit integer, data-processing**

The counter counts each speculatively executed 8-bit integer data-processing operation counted by SE_INT_SPEC due to an A64 Advanced SIMD, SVE, or SME operation.

That is, each operation counted by ASE_INT8_SPEC, SVE_INT8_SPEC, or SME_INT8_SPEC.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

`0x8363`, **SE_FP_BF16_SPEC, Operation speculatively executed, Advanced SIMD, SVE, or SME SIMD BFloat16 floating-point, data-processing**

The counter counts each speculatively executed BFloat16 floating-point data-processing operation counted by SE_FP_SPEC due to an A64 Advanced SIMD, SVE, or SME operation.

That is, each operation counted by SVE_FP_BF16_SPEC, or SME_FP_BF16_SPEC.

`0x8365`, **SE_INT16_SPEC, Operation speculatively executed, Advanced SIMD, SVE, or SME SIMD 16-bit integer, data-processing**

The counter counts each speculatively executed 16-bit integer data-processing operation counted by SE_INT_SPEC due to an A64 Advanced SIMD, SVE, or SME operation.

That is, each operation counted by ASE_INT16_SPEC, SVE_INT16_SPEC, or SME_INT16_SPEC.

`0x8367`, **SE_FP_HP_SPEC, Operation speculatively executed, Advanced SIMD, SVE, or SME SIMD half-precision floating-point, data-processing**

The counter counts each speculatively executed half-precision floating-point data-processing operation counted by SE_FP_SPEC due to an A64 Advanced SIMD, SVE, or SME operation.

That is, each operation counted by ASE_FP_HP_SPEC, SVE_FP_HP_SPEC, or SME_FP_HP_SPEC.

`0x8369`, **SE_INT32_SPEC, Operation speculatively executed, Advanced SIMD, SVE, or SME SIMD 32-bit integer, data-processing**

The counter counts each speculatively executed 32-bit integer data-processing operation counted by SE_INT_SPEC due to an A64 Advanced SIMD, SVE, or SME operation.

That is, each operation counted by ASE_INT32_SPEC, SVE_INT32_SPEC, or SME_INT32_SPEC.

`0x836B`, **SE_FP_SP_SPEC, Operation speculatively executed, Advanced SIMD, SVE, or SME SIMD single-precision floating-point, data-processing**

The counter counts each speculatively executed single-precision floating-point data-processing operation counted by SE_FP_SPEC due to an A64 Advanced SIMD, SVE, or SME operation.

That is, each operation counted by ASE_FP_SP_SPEC, SVE_FP_SP_SPEC, or SME_FP_SP_SPEC.

`0x836D`, **SE_INT64_SPEC, Operation speculatively executed, Advanced SIMD, SVE, or SME SIMD 64-bit integer, data-processing**

The counter counts each speculatively executed 64-bit integer data-processing operation counted by SE_INT_SPEC due to an A64 Advanced SIMD, SVE, or SME operation.

That is, each operation counted by ASE_INT64_SPEC, SVE_INT64_SPEC, or SME_INT64_SPEC.

`0x836F`, **SE_FP_DP_SPEC, Operation speculatively executed, Advanced SIMD, SVE, or SME SIMD double-precision floating-point, data-processing**

The counter counts each speculatively executed double-precision floating-point data-processing operation counted by SE_FP_SPEC due to an A64 Advanced SIMD, SVE, or SME operation.

That is, each operation counted by ASE_FP_DP_SPEC, SVE_FP_DP_SPEC, or SME_FP_DP_SPEC.

`0x8371`, **SE_FP_ADDSUB_SPEC, Operation speculatively executed, Advanced SIMD, SVE, or SME SIMD floating-point addition or subtraction**

The counter counts each speculatively executed floating-point addition or subtraction operation counted by SE_FP_SPEC due to an A64 Advanced SIMD, SVE, or SME operation.

That is, each operation counted by ASE_FP_ADDSUB_SPEC, SVE_FP_ADDSUB_SPEC, or SME_FP_ADDSUB_SPEC.

`0x8373`, **SE_FP_FMA_SPEC, Operation speculatively executed, Advanced SIMD, SVE, or SME SIMD floating-point multiply-add or multiply-subtract**

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The counter counts each speculatively executed floating-point multiply-add, multiply-add long, multiply-subtract, or multiply-subtract long operation counted by SE_FP_SPEC due to an A64 Advanced SIMD, SVE, or SME operation.

That is, each operation counted by ASE_FP_FMA_SPEC, SVE_FP_FMA_SPEC, or SME_FP_FMA_SPEC.

`0x8375`, **SE_FP_DOT_SPEC, Operation speculatively executed, Advanced SIMD, SVE, or SME SIMD floating-point dot product**

The counter counts each speculatively executed floating-point dot product operation counted by SE_FP_SPEC due to any of the following A64 instructions:

That is, each operation counted by ASE_FP_DOT_SPEC, SVE_FP_DOT_SPEC, or SME_FP_DOT_SPEC.

`0x8379`, **SE_INT_SPEC, Operation speculatively executed, Advanced SIMD, SVE, or SME SIMD integer, data-processing**

The counter counts each speculatively executed integer data-processing operation counted by INT_SPEC due to an A64 Advanced SIMD, SVE, or SME operation.

That is, each operation counted by ASE_INT_SPEC, SVE_INT_SPEC, or SME_INT_SPEC.

`0x837B`, **SE_INT_MUL_SPEC, Operation speculatively executed, Advanced SIMD, SVE, or SME SIMD integer multiply or multiply-accumulate**

The counter counts each speculatively executed integer multiply, multiply-add, or multiply-subtract operation counted by SE_INT_SPEC due to an A64 Advanced SIMD, SVE, or SME operation.

That is, each operation counted by ASE_INT_MUL_SPEC, SVE_INT_MUL_SPEC, or SME_INT_MUL_SPEC.

`0x837D`, **SE_INT_DOT_SPEC, Operation speculatively executed, Advanced SIMD, SVE, or SME SIMD integer dot product**

The counter counts each speculatively executed integer dot product operation counted by SE_INT_SPEC due to any of the following A64 instructions:

- When FEAT_DotProd is implemented, Advanced SIMD: SDOT or UDOT.

That is, each operation counted by ASE_INT_DOT_SPEC, SVE_INT_DOT_SPEC, or SME_INT_DOT_SPEC.

`0x8380`, **ZA_ACTIVE, CPU cycles, ZA enabled**

The counter counts each cycle counted by CPU_CYCLES when PSTATE.ZA is 1.

`0x8398`, **ASE_LUT_SPEC, Lookup table operation speculatively executed, Advanced SIMD data processing**

The counter counts each speculatively executed LUT operation counted by SE_LUT_SPEC that returns a value from a lookup table made up of a V register which is indexed by values from a V register.

`0x8399`, **SVE_LUT_SPEC, Lookup table operation speculatively executed, SVE data processing**

The counter counts each speculatively executed LUT operation counted by SE_LUT_SPEC that returns a value from a lookup table made up of a Z register which is indexed by values from a Z register.

That is, due to any of the following instructions:

`0x839B`, **SE_LUT_SPEC, Lookup table operation speculatively executed, Advanced SIMD, SVE, or SME data processing**

The counter counts each speculatively executed LUT operation counted by SE_INST_SPEC that returns a value from a lookup table made up of a ZT register, Z or V register which is indexed by values from a Z or V register.

`0x83A0`, **N1_CACHE_HIT_RD, Cache at distance 1, demand access hit, read**

The counter counts each cache hit at distance 1 due to a demand read.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

`0x83A1`**, N2_CACHE_HIT_RD, Cache at distance 2, demand access hit, read**

The counter counts each cache hit at distance 2 due to a demand read.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

Cache distance 2 represents a further distance of travel than cache distance 1.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

`0x83A2`**, N3_CACHE_HIT_RD, Cache at distance 3, demand access hit, read**

The counter counts each cache hit at distance 3 due to a demand read.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

Cache distance 3 represents a further distance of travel than cache distance 2.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

`0x83A3`**, N4_CACHE_HIT_RD, Cache at distance 4, demand access hit, read**

The counter counts each cache hit at distance 4 due to a demand read.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

Cache distance 4 represents a further distance of travel than cache distance 3.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

`0x83A4`**, N1_CACHE_HIT_PRFM, Cache at distance 1, software prefetch hit**

The counter counts each cache hit at distance 1 due to a software prefetch.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

`0x83A5`**, N2_CACHE_HIT_PRFM, Cache at distance 2, software prefetch hit**

The counter counts each cache hit at distance 2 due to a software prefetch.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

Cache distance 2 represents a further distance of travel than cache distance 1.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

`0x83A6`, **N3_CACHE_HIT_PRFM, Cache at distance 3, software prefetch hit**

The counter counts each cache hit at distance 3 due to a software prefetch.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

Cache distance 3 represents a further distance of travel than cache distance 2.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

`0x83A7`, **N4_CACHE_HIT_PRFM, Cache at distance 4, software prefetch hit**

The counter counts each cache hit at distance 4 due to a software prefetch.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

Cache distance 4 represents a further distance of travel than cache distance 3.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

`0x83A8`, **N1_CACHE1_HIT_RD, Cache type 1 at distance 1 demand access hit, read**

The counter counts each demand read counted by N1_CACHE_HIT_RD due to a demand read accessing a first cache type at distance 1.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

`0x83A9`, **N2_CACHE1_HIT_RD, Cache type 1 at distance 2 demand access hit, read**

The counter counts each demand read counted by N2_CACHE_HIT_RD due to a demand read accessing a first cache type at distance 2.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

`0x83AA`, **N3_CACHE1_HIT_RD, Cache type 1 at distance 3 demand access hit, read**

The counter counts each demand read counted by N3_CACHE_HIT_RD due to a demand read accessing a first cache type at distance 3.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

`0x83AB`, **N4_CACHE1_HIT_RD, Cache type 1 at distance 4 demand access hit, read**

The counter counts each demand read counted by N4_CACHE_HIT_RD due to a demand read accessing a first cache type at distance 4.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

`0x83AC`, **N1_CACHE1_HIT_PRFM, Cache type 1 at distance 1 software prefetch hit**

The counter counts each software prefetch counted by N1_CACHE_HIT_PRFM due to a software prefetch accessing a first cache type at distance 1.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

`0x83AD`, **N2_CACHE1_HIT_PRFM, Cache type 1 at distance 2 software prefetch hit**

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.

The counter counts each software prefetch counted by N2_CACHE_HIT_PRFM due to a software prefetch accessing a first cache type at distance 2.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

`0x83AE`, **N3_CACHE1_HIT_PRFM, Cache type 1 at distance 3 software prefetch hit**

The counter counts each software prefetch counted by N3_CACHE_HIT_PRFM due to a software prefetch accessing a first cache type at distance 3.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

`0x83AF`, **N4_CACHE1_HIT_PRFM, Cache type 1 at distance 4 software prefetch hit**

The counter counts each software prefetch counted by N4_CACHE_HIT_PRFM due to a software prefetch accessing a first cache type at distance 4.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

`0x83B0`, **N1_CACHE2_HIT_RD, Cache type 2 at distance 1 demand access hit, read**

The counter counts each demand read counted by N1_CACHE_HIT_RD due to a demand read accessing a second cache type at distance 1.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

`0x83B1`, **N2_CACHE2_HIT_RD, Cache type 2 at distance 2 demand access hit, read**

The counter counts each demand read counted by N2_CACHE_HIT_RD due to a demand read accessing a second cache type at distance 2.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

`0x83B2`, **N3_CACHE2_HIT_RD, Cache type 2 at distance 3 demand access hit, read**

The counter counts each demand read counted by N3_CACHE_HIT_RD due to a demand read accessing a second cache type at distance 3.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

`0x83B3`, **N4_CACHE2_HIT_RD, Cache type 2 at distance 4 demand access hit, read**

The counter counts each demand read counted by N4_CACHE_HIT_RD due to a demand read accessing a second cache type at distance 4.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

`0x83B4`, **N1_CACHE2_HIT_PRFM, Cache type 2 at distance 1 software prefetch hit**

The counter counts each software prefetch counted by N1_CACHE_HIT_PRFM due to a software prefetch accessing a second cache type at distance 1.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

`0x83B5`, **N2_CACHE2_HIT_PRFM, Cache type 2 at distance 2 software prefetch hit**

The counter counts each software prefetch counted by N2_CACHE_HIT_PRFM due to a software prefetch accessing a second cache type at distance 2.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

`0x83B6`, **N3_CACHE2_HIT_PRFM, Cache type 2 at distance 3 software prefetch hit**

The counter counts each software prefetch counted by N3_CACHE_HIT_PRFM due to a software prefetch accessing a second cache type at distance 3.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

`0x83B7`, **N4_CACHE2_HIT_PRFM, Cache type 2 at distance 4 software prefetch hit**

The counter counts each software prefetch counted by N4_CACHE_HIT_PRFM due to a software prefetch accessing a second cache type at distance 4.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

`0x83B8`, **N1_CACHE3_HIT_RD, Cache type 3 at distance 1 demand access hit, read**

The counter counts each demand read counted by N1_CACHE_HIT_RD due to a demand read accessing a third cache type at distance 1.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

`0x83B9`, **N2_CACHE3_HIT_RD, Cache type 3 at distance 2 demand access hit, read**

The counter counts each demand read counted by N2_CACHE_HIT_RD due to a demand read accessing a third cache type at distance 2.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

`0x83BA`, **N3_CACHE3_HIT_RD, Cache type 3 at distance 3 demand access hit, read**

The counter counts each demand read counted by N3_CACHE_HIT_RD due to a demand read accessing a third cache type at distance 3.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

`0x83BB`, **N4_CACHE3_HIT_RD, Cache type 3 at distance 4 demand access hit, read**

The counter counts each demand read counted by N4_CACHE_HIT_RD due to a demand read accessing a third cache type at distance 4.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

`0x83BC`, **N1_CACHE3_HIT_PRFM, Cache type 3 at distance 1 software prefetch hit**

The counter counts each software prefetch counted by N1_CACHE_HIT_PRFM due to a software prefetch accessing a third cache type at distance 1.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

`0x83BD`, **N2_CACHE3_HIT_PRFM, Cache type 3 at distance 2 software prefetch hit**

The counter counts each software prefetch counted by N2_CACHE_HIT_PRFM due to a software prefetch accessing a third cache type at distance 2.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

`0x83BE`, **N3_CACHE3_HIT_PRFM, Cache type 3 at distance 3 software prefetch hit**

The counter counts each software prefetch counted by N3_CACHE_HIT_PRFM due to a software prefetch accessing a third cache type at distance 3.

Non-Confidential

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

`0x83BF`, **N4_CACHE3_HIT_PRFM, Cache type 3 at distance 4 software prefetch hit**

The counter counts each software prefetch counted by N4_CACHE_HIT_PRFM due to a software prefetch accessing a third cache type at distance 4.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

`0x83C0`, **N1_CACHE_HITM_RD, Cache at distance 1, demand access hit modified, read**

The counter counts each demand read counted by N1_CACHE_HIT_RD that accesses a previously modified location in a cache at distance 1.

`0x83C1`, **N2_CACHE_HITM_RD, Cache at distance 2, demand access hit modified, read**

The counter counts each demand read counted by N2_CACHE_HIT_RD that accesses a previously modified location in a cache at distance 2.

`0x83C2`, **N3_CACHE_HITM_RD, Cache at distance 3, demand access hit modified, read**

The counter counts each demand read counted by N3_CACHE_HIT_RD that accesses a previously modified location in a cache at distance 3.

`0x83C3`, **N4_CACHE_HITM_RD, Cache at distance 4, demand access hit modified, read**

The counter counts each demand read counted by N4_CACHE_HIT_RD that accesses a previously modified location in a cache at distance 4.

`0x83C4`, **N1_LFB_HIT_RD, Cache at distance 1 demand access line-fill buffer hit, read**

The counter counts each demand read counted by N1_CACHE_HIT_RD that hits a recently fetched line in a cache at distance 1.

That is, the read hits a cache line that is in the process of being loaded into the cache at distance 1, and so does not generate a new refill, but has to wait for the previous refill to complete.

`0x83C5`, **N2_LFB_HIT_RD, Cache at distance 2 demand access line-fill buffer hit, read**

The counter counts each demand read counted by N2_CACHE_HIT_RD that hits a recently fetched line in a cache at distance 2.

That is, the read hits a cache line that is in the process of being loaded into the cache at distance 2, and so does not generate a new refill, but has to wait for the previous refill to complete.

`0x83C6`, **N3_LFB_HIT_RD, Cache at distance 3 demand access line-fill buffer hit, read**

The counter counts each demand read counted by N3_CACHE_HIT_RD that hits a recently fetched line in a cache at distance 3.

That is, the read hits a cache line that is in the process of being loaded into the cache at distance 3, and so does not generate a new refill, but has to wait for the previous refill to complete.

`0x83C7`, **N4_LFB_HIT_RD, Cache at distance 4 demand access line-fill buffer hit, read**

The counter counts each demand read counted by N4_CACHE_HIT_RD that hits a recently fetched line in a cache at distance 4.

That is, the read hits a cache line that is in the process of being loaded into the cache at distance 4, and so does not generate a new refill, but has to wait for the previous refill to complete.

`0x83C8`, **N1_CACHE1_HITM_RD, Cache type 1 at distance 1 demand access hit modified, read**

The counter counts each demand read counted by N1_CACHE_HITM_RD that accesses a previously modified location in a first cache type at distance 1.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

`0x83C9`, **N2_CACHE1_HITM_RD, Cache type 1 at distance 2 demand access hit modified, read**

The counter counts each demand read counted by N2_CACHE_HITM_RD that accesses a previously modified location in a first cache type at distance 2.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

`0x83CA`, **N3_CACHE1_HITM_RD, Cache type 1 at distance 3 demand access hit modified, read**

The counter counts each demand read counted by N3_CACHE_HITM_RD that accesses a previously modified location in a first cache type at distance 3.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

`0x83CB`, **N4_CACHE1_HITM_RD, Cache type 1 at distance 4 demand access hit modified, read**

The counter counts each demand read counted by N4_CACHE_HITM_RD that accesses a previously modified location in a first cache type at distance 4.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

`0x83CC`, **N1_LFB1_HIT_RD, Cache type 1 at distance 1 demand access line-fill buffer hit, read**

The counter counts each demand read counted by N1_LFB_HIT_RD that hits a recently fetched line in a first cache type at distance 1.

That is, the read hits a cache line that is in the process of being loaded into the cache at distance 1, and so does not generate a new refill, but has to wait for the previous refill to complete.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

`0x83CD`, **N2_LFB1_HIT_RD, Cache type 1 at distance 2 demand access line-fill buffer hit, read**

The counter counts each demand read counted by N2_LFB_HIT_RD that hits a recently fetched line in a first cache type at distance 2.

That is, the read hits a cache line that is in the process of being loaded into the cache at distance 2, and so does not generate a new refill, but has to wait for the previous refill to complete.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

`0x83CE`, **N3_LFB1_HIT_RD, Cache type 1 at distance 3 demand access line-fill buffer hit, read**

The counter counts each demand read counted by N3_LFB_HIT_RD that hits a recently fetched line in a first cache type at distance 3.

That is, the read hits a cache line that is in the process of being loaded into the cache at distance 3, and so does not generate a new refill, but has to wait for the previous refill to complete.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

`0x83CF`, **N4_LFB1_HIT_RD, Cache type 1 at distance 4 demand access line-fill buffer hit, read**

The counter counts each demand read counted by N4_LFB_HIT_RD that hits a recently fetched line in a first cache type at distance 4.

That is, the read hits a cache line that is in the process of being loaded into the cache at distance 4, and so does not generate a new refill, but has to wait for the previous refill to complete.

That is, the read hits a cache line that is in the process of being loaded into the cache at distance 3, and so does not generate a new refill, but has to wait for the previous refill to complete.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

`0x83DF`, **N4_LFB3_HIT_RD, Cache type 3 at distance 4 demand access line-fill buffer hit, read**

The counter counts each demand read counted by N4_LFB_HIT_RD that hits a recently fetched line in a third cache type at distance 4.

That is, the read hits a cache line that is in the process of being loaded into the cache at distance 4, and so does not generate a new refill, but has to wait for the previous refill to complete.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

`0x83E0`, **N1_MEM_RD, Access to memory at distance 1, demand access, read**

The counter counts each demand read to memory at distance 1.

The memory distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

`0x83E1`, **N2_MEM_RD, Access to memory at distance 2, demand access, read**

The counter counts each demand read to memory at distance 2.

The memory distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

Distance 2 represents a further distance of travel than distance 1.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

`0x83E2`, **N3_MEM_RD, Access to memory at distance 3, demand access, read**

The counter counts each demand read to memory at distance 3.

The memory distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

Distance 3 represents a further distance of travel than distance 2.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

`0x83E3`, **N4_MEM_RD, Access to memory at distance 4, demand access, read**

The counter counts each demand read to memory at distance 4.

The memory distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

Distance 4 represents a further distance of travel than distance 3.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

`0x83E4`, **N1_MEM_PRFM, Access to memory at distance 1, software prefetch**

The counter counts each software prefetch to memory at distance 1.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The memory distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

`0x83E5`**, N2_MEM_PRFM, Access to memory at distance 2, software prefetch**

The counter counts each software prefetch to memory at distance 2.

The memory distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

Distance 2 represents a further distance of travel than distance 1.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

`0x83E6`**, N3_MEM_PRFM, Access to memory at distance 3, software prefetch**

The counter counts each software prefetch to memory at distance 3.

The memory distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

Distance 3 represents a further distance of travel than distance 2.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

`0x83E7`**, N4_MEM_PRFM, Access to memory at distance 4, software prefetch**

The counter counts each software prefetch to memory at distance 4.

The memory distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

Distance 4 represents a further distance of travel than distance 3.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

`0x83E8`**, N1_MEM1_RD, Access to type 1 memory at distance 1, demand access, read**

The counter counts each demand read counted by N1_MEM_RD to a first memory type at distance 1.

The definition of memory types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system. See also N1_MEM1_RD.

For example, the first memory type might be commodity DRAM connected to a device. However, this must be the same for all devices in the system, such that, for example, N1_MEM1_RD refers to commodity DRAM for a PE at distance 1 from the memory, regardless of which device the PE is located on, and N4_MEM1_RD refers to the same memory for any PE located at distance 4. This means that when a process counting the N1_MEM1_RD event migrates between PEs on different devices, its relative view of the first memory type remains unchanged, even if the distance changes.

`0x83E9`**, N2_MEM1_RD, Access to type 1 memory at distance 2, demand access, read**

The counter counts each demand read counted by N2_MEM_RD to a first memory type at distance 2.

The definition of memory types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system. See also N1_MEM1_RD.

`0x83EA`**, N3_MEM1_RD, Access to type 1 memory at distance 3, demand access, read**

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The counter counts each demand read counted by N3_MEM_RD to a first memory type at distance 3.

The definition of memory types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system. See also N1_MEM1_RD.

`0x83EB`, **N4_MEM1_RD, Access to type 1 memory at distance 4, demand access, read**

The counter counts each demand read counted by N4_MEM_RD to a first memory type at distance 4.

The definition of memory types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system. See also N1_MEM1_RD.

`0x83EC`, **N1_MEM1_PRFM, Access to type 1 memory at distance 1, software prefetch**

The counter counts each software prefetch counted by N1_MEM_PRFM to a first memory type at distance 1.

The definition of memory types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

`0x83ED`, **N2_MEM1_PRFM, Access to type 1 memory at distance 2, software prefetch**

The counter counts each software prefetch counted by N2_MEM_PRFM to a first memory type at distance 2.

The definition of memory types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

`0x83EE`, **N3_MEM1_PRFM, Access to type 1 memory at distance 3, software prefetch**

The counter counts each software prefetch counted by N3_MEM_PRFM to a first memory type at distance 3.

The definition of memory types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

`0x83EF`, **N4_MEM1_PRFM, Access to type 1 memory at distance 4, software prefetch**

The counter counts each software prefetch counted by N4_MEM_PRFM to a first memory type at distance 4.

The definition of memory types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

`0x83F0`, **N1_MEM2_RD, Access to type 2 memory at distance 1, demand access, read**

The counter counts each demand read counted by N1_MEM_RD to a second memory type at distance 1.

The definition of memory types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system. See also N1_MEM2_RD.

For example, the second memory type might be bulk expansion memory connected to a device. However, this must be the same for all devices in the system, such that, for example, N1_MEM2_RD refers to bulk expansion memory for a PE at distance 1 from the memory, regardless of which device the PE is located on, and N4_MEM2_RD refers to the same memory for any PE located at distance 4. This means that when a process counting the N1_MEM2_RD event migrates between PEs on different devices, its relative view of the second memory type remains unchanged, even if the distance changes.

`0x83F1`, **N2_MEM2_RD, Access to type 2 memory at distance 2, demand access, read**

The counter counts each demand read counted by N2_MEM_RD to a second memory type at distance 2.

The definition of memory types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system. See also N1_MEM2_RD.

`0x83F2`, **N3_MEM2_RD, Access to type 2 memory at distance 3, demand access, read**

The counter counts each demand read counted by N3_MEM_RD to a second memory type at distance 3.

The definition of memory types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system. See also N1_MEM2_RD.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

`0x83F3`, **N4_MEM2_RD, Access to type 2 memory at distance 4, demand access, read**

The counter counts each demand read counted by N4_MEM_RD to a second memory type at distance 4.

The definition of memory types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system. See also N1_MEM2_RD.

`0x83F4`, **N1_MEM2_PRFM, Access to type 2 memory at distance 1, software prefetch**

The counter counts each software prefetch counted by N1_MEM_PRFM to a second memory type at distance 1.

The definition of memory types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

`0x83F5`, **N2_MEM2_PRFM, Access to type 2 memory at distance 2, software prefetch**

The counter counts each software prefetch counted by N2_MEM_PRFM to a second memory type at distance 2.

The definition of memory types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

`0x83F6`, **N3_MEM2_PRFM, Access to type 2 memory at distance 3, software prefetch**

The counter counts each software prefetch counted by N3_MEM_PRFM to a second memory type at distance 3.

The definition of memory types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

`0x83F7`, **N4_MEM2_PRFM, Access to type 2 memory at distance 4, software prefetch**

The counter counts each software prefetch counted by N4_MEM_PRFM to a second memory type at distance 4.

The definition of memory types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

`0x83F8`, **N1_MEM3_RD, Access to type 3 memory at distance 1, demand access, read**

The counter counts each demand read counted by N1_MEM_RD to a third memory type at distance 1.

The definition of memory types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system. See also N1_MEM3_RD.

For example, the third memory type might be high-bandwidth memory connected to a device. However, this must be the same for all devices in the system, such that, for example, N1_MEM3_RD refers to high-bandwidth memory for a PE at distance 1 from the memory, regardless of which device the PE is located on, and N4_MEM3_RD refers to the same memory for any PE located at distance 4. This means that when a process counting the N1_MEM3_RD event migrates between PEs on different devices, its relative view of the third memory type remains unchanged, even if the distance changes.

`0x83F9`, **N2_MEM3_RD, Access to type 3 memory at distance 2, demand access, read**

The counter counts each demand read counted by N2_MEM_RD to a third memory type at distance 2.

The definition of memory types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system. See also N1_MEM3_RD.

`0x83FA`, **N3_MEM3_RD, Access to type 3 memory at distance 3, demand access, read**

The counter counts each demand read counted by N3_MEM_RD to a third memory type at distance 3.

The definition of memory types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system. See also N1_MEM3_RD.

`0x83FB`, **N4_MEM3_RD, Access to type 3 memory at distance 4, demand access, read**

The counter counts each demand read counted by N4_MEM_RD to a third memory type at distance 4.

The definition of memory types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system. See also N1_MEM3_RD.

`0x83FC`, **N1_MEM3_PRFM, Access to type 3 memory at distance 1, software prefetch**

The counter counts each software prefetch counted by N1_MEM_PRFM to a third memory type at distance 1.

The definition of memory types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

`0x83FD`, **N2_MEM3_PRFM, Access to type 3 memory at distance 2, software prefetch**

The counter counts each software prefetch counted by N2_MEM_PRFM to a third memory type at distance 2.

The definition of memory types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

`0x83FE`, **N3_MEM3_PRFM, Access to type 3 memory at distance 3, software prefetch**

The counter counts each software prefetch counted by N3_MEM_PRFM to a third memory type at distance 3.

The definition of memory types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

`0x83FF`, **N4_MEM3_PRFM, Access to type 3 memory at distance 4, software prefetch**

The counter counts each software prefetch counted by N4_MEM_PRFM to a third memory type at distance 4.

The definition of memory types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

`0x8400`, **ISNP_HIT_N1_RD, Snoop hit in cache at distance 1, demand instruction fetch**

The counter counts each snoop generated by the PE in response to a demand Instruction memory access counted by ISNP_HIT_RD that hits in a cache at distance 1.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

`0x8401`, **ISNP_HIT_N2_RD, Snoop hit in cache at distance 2, demand instruction fetch**

The counter counts each snoop generated by the PE in response to a demand Instruction memory access counted by ISNP_HIT_RD that hits in a cache at distance 2.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

`0x8402`, **ISNP_HIT_N3_RD, Snoop hit in cache at distance 3, demand instruction fetch**

The counter counts each snoop generated by the PE in response to a demand Instruction memory access counted by ISNP_HIT_RD that hits in a cache at distance 3.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

`0x8403`, **ISNP_HIT_N4_RD, Snoop hit in cache at distance 4, demand instruction fetch**

The counter counts each snoop generated by the PE in response to a demand Instruction memory access counted by ISNP_HIT_RD that hits in a cache at distance 4.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

`0x8404`, **DSNP_HIT_N1_RD, Snoop hit in cache at distance 1, demand data read**

The counter counts each snoop generated by the PE in response to a demand Memory-read operation counted by DSNP_HIT_RD that hits in a cache at distance 1.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

`0x8405`, **DSNP_HIT_N2_RD, Snoop hit in cache at distance 2, demand data read**

The counter counts each snoop generated by the PE in response to a demand Memory-read operation counted by DSNP_HIT_RD that hits in a cache at distance 2.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

`0x8406`, **DSNP_HIT_N3_RD, Snoop hit in cache at distance 3, demand data read**

The counter counts each snoop generated by the PE in response to a demand Memory-read operation counted by DSNP_HIT_RD that hits in a cache at distance 3.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

`0x8407`, **DSNP_HIT_N4_RD, Snoop hit in cache at distance 4, demand data read**

The counter counts each snoop generated by the PE in response to a demand Memory-read operation counted by DSNP_HIT_RD that hits in a cache at distance 4.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

`0x8408`, **DSNP_HIT_N1_WR, Snoop hit in cache at distance 1, demand data write**

The counter counts each snoop generated by the PE in response to a demand Memory-write operation counted by DSNP_HIT_WR that hits in a cache at distance 1.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

`0x8409`, **DSNP_HIT_N2_WR, Snoop hit in cache at distance 2, demand data write**

The counter counts each snoop generated by the PE in response to a demand Memory-write operation counted by DSNP_HIT_WR that hits in a cache at distance 2.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

`0x840A`, **DSNP_HIT_N3_WR, Snoop hit in cache at distance 3, demand data write**

The counter counts each snoop generated by the PE in response to a demand Memory-write operation counted by DSNP_HIT_WR that hits in a cache at distance 3.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

`0x840B`, **DSNP_HIT_N4_WR, Snoop hit in cache at distance 4, demand data write**

The counter counts each snoop generated by the PE in response to a demand Memory-write operation counted by DSNP_HIT_WR that hits in a cache at distance 4.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

`0x840C`, **DSNP_HIT_N1_RW, Snoop hit in cache at distance 1, demand data access**

The counter counts each snoop generated by the PE in response to a demand Memory-read operation or demand Memory-write operation counted by DSNP_HIT_RW that hits in a cache at distance 1.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

`0x840D`, **DSNP_HIT_N2_RW, Snoop hit in cache at distance 2, demand data access**

The counter counts each snoop generated by the PE in response to a demand Memory-read operation or demand Memory-write operation counted by DSNP_HIT_RW that hits in a cache at distance 2.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

`0x840E`, **DSNP_HIT_N3_RW, Snoop hit in cache at distance 3, demand data access**

The counter counts each snoop generated by the PE in response to a demand Memory-read operation or demand Memory-write operation counted by DSNP_HIT_RW that hits in a cache at distance 3.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

`0x840F`, **DSNP_HIT_N4_RW, Snoop hit in cache at distance 4, demand data access**

The counter counts each snoop generated by the PE in response to a demand Memory-read operation or demand Memory-write operation counted by DSNP_HIT_RW that hits in a cache at distance 4.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

`0x8410`, **DSNP_HIT_N1_PRFM, Snoop hit in cache at distance 1, software data prefetch**

The counter counts each snoop generated by the PE in response to a data prefetch instruction counted by DSNP_HIT_PRFM that hits in a cache at distance 1.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

`0x8411`, **DSNP_HIT_N2_PRFM, Snoop hit in cache at distance 2, software data prefetch**

The counter counts each snoop generated by the PE in response to a data prefetch instruction counted by DSNP_HIT_PRFM that hits in a cache at distance 2.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

`0x8412`, **DSNP_HIT_N3_PRFM, Snoop hit in cache at distance 3, software data prefetch**

The counter counts each snoop generated by the PE in response to a data prefetch instruction counted by DSNP_HIT_PRFM that hits in a cache at distance 3.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

`0x8413`, **DSNP_HIT_N4_PRFM, Snoop hit in cache at distance 4, software data prefetch**

The counter counts each snoop generated by the PE in response to a data prefetch instruction counted by DSNP_HIT_PRFM that hits in a cache at distance 4.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

`0x8414`, **DSNP_HIT_N1_HWPRF, Snoop hit in cache at distance 1, hardware data prefetch**

The counter counts each snoop generated by a data hardware prefetch counted by DSNP_HIT_HWPRF that hits in a cache at distance 1.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

`0x8415`, **DSNP_HIT_N2_HWPRF, Snoop hit in cache at distance 2, hardware data prefetch**

The counter counts each snoop generated by a data hardware prefetch counted by DSNP_HIT_HWPRF that hits in a cache at distance 2.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

`0x8416`, **DSNP_HIT_N3_HWPRF, Snoop hit in cache at distance 3, hardware data prefetch**

The counter counts each snoop generated by a data hardware prefetch counted by DSNP_HIT_HWPRF that hits in a cache at distance 3.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

`0x8426`**, ISNP_HIT_N3_PRF, Snoop hit in cache at distance 3, instruction prefetch**

The counter counts each snoop generated by the PE in response to an instruction prefetch instruction, or by an instruction hardware prefetch counted by ISNP_HIT_PRF that hits in a cache at distance 3.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

`0x8427`**, ISNP_HIT_N4_PRF, Snoop hit in cache at distance 4, instruction prefetch**

The counter counts each snoop generated by the PE in response to an instruction prefetch instruction, or by an instruction hardware prefetch counted by ISNP_HIT_PRF that hits in a cache at distance 4.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

`0x8428`**, ISNP_HIT_N1, Snoop hit in cache at distance 1, instruction access**

The counter counts each snoop counted by ISNP_HIT that hits in a cache at distance 1.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

`0x8429`**, ISNP_HIT_N2, Snoop hit in cache at distance 2, instruction access**

The counter counts each snoop counted by ISNP_HIT that hits in a cache at distance 2.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

`0x842A`**, ISNP_HIT_N3, Snoop hit in cache at distance 3, instruction access**

The counter counts each snoop counted by ISNP_HIT that hits in a cache at distance 3.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

`0x842B`**, ISNP_HIT_N4, Snoop hit in cache at distance 4, instruction access**

The counter counts each snoop counted by ISNP_HIT that hits in a cache at distance 4.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

`0x842C`, **DSNP_HIT_N1, Snoop hit in cache at distance 1, data access**

The counter counts each snoop counted by DSNP_HIT that hits in a cache at distance 1.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

`0x842D`, **DSNP_HIT_N2, Snoop hit in cache at distance 2, data access**

The counter counts each snoop counted by DSNP_HIT that hits in a cache at distance 2.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

`0x842E`, **DSNP_HIT_N3, Snoop hit in cache at distance 3, data access**

The counter counts each snoop counted by DSNP_HIT that hits in a cache at distance 3.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

`0x842F`, **DSNP_HIT_N4, Snoop hit in cache at distance 4, data access**

The counter counts each snoop counted by DSNP_HIT that hits in a cache at distance 4.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

`0x8431`, **ASE_FP_VREDUCE_SPEC, Floating-point operation speculatively executed, Advanced SIMD pairwise or reduction**

The counter counts each speculatively executed floating-point treewise reduction or pairwise operation counted by ASE_SVE_FP_VREDUCE_SPEC due to any of the following A64 instructions:

- Advanced SIMD: FADDP, FMAXNMP, FMAXNMV, FMAXP, FMAXV, FMINNMP, FMINNMV, FMINP, or FMINV.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

Treewise reduction instructions might be executed and counted as multiple pairwise operations.

`0x8432`, **SVE_FP_PREDUCE_SPEC, Floating-point operation speculatively executed, SVE pairwise add step or pairwise reduce step**

The counter counts each speculatively executed floating-point pairwise add step or pairwise reduce step operation counted by SVE_FP_VREDUCE_SPEC due to any of the following instructions:

`0x8434`, **DSNP_HITM_N1_RD, Snoop hit in cache at distance 1, demand data read, modified**

The counter counts each snoop generated by the PE in response to a demand Memory-read operation counted by DSNP_HIT_N1_RD that accesses a previously modified cache location.

`0x8435`, **DSNP_HITM_N2_RD, Snoop hit in cache at distance 2, demand data read, modified**

The counter counts each snoop generated by the PE in response to a demand Memory-read operation counted by DSNP_HIT_N2_RD that accesses a previously modified cache location.

`0x8436`, **DSNP_HITM_N3_RD, Snoop hit in cache at distance 3, demand data read, modified**

The counter counts each snoop generated by the PE in response to a demand Memory-read operation counted by DSNP_HIT_N3_RD that accesses a previously modified cache location.

`0x8437`, **DSNP_HITM_N4_RD, Snoop hit in cache at distance 4, demand data read, modified**

The counter counts each snoop generated by the PE in response to a demand Memory-read operation counted by DSNP_HIT_N4_RD that accesses a previously modified cache location.

`0x8438`, **DSNP_HITM_N1_WR, Snoop hit in cache at distance 1, demand data write, modified**

The counter counts each snoop generated by the PE in response to a demand Memory-write operation counted by DSNP_HIT_N1_WR that accesses a previously modified cache location.

`0x8439`, **DSNP_HITM_N2_WR, Snoop hit in cache at distance 2, demand data write, modified**

The counter counts each snoop generated by the PE in response to a demand Memory-write operation counted by DSNP_HIT_N2_WR that accesses a previously modified cache location.

`0x843A`, **DSNP_HITM_N3_WR, Snoop hit in cache at distance 3, demand data write, modified**

The counter counts each snoop generated by the PE in response to a demand Memory-write operation counted by DSNP_HIT_N3_WR that accesses a previously modified cache location.

`0x843B`, **DSNP_HITM_N4_WR, Snoop hit in cache at distance 4, demand data write, modified**

The counter counts each snoop generated by the PE in response to a demand Memory-write operation counted by DSNP_HIT_N4_WR that accesses a previously modified cache location.

`0x843C`, **DSNP_HITM_N1_RW, Snoop hit in cache at distance 1, demand data access, modified**

The counter counts each snoop generated by the PE in response to a demand Memory-read operation or demand Memory-write operation counted by DSNP_HIT_N1_RW that accesses a previously modified cache location.

`0x843D`, **DSNP_HITM_N2_RW, Snoop hit in cache at distance 2, demand data access, modified**

The counter counts each snoop generated by the PE in response to a demand Memory-read operation or demand Memory-write operation counted by DSNP_HIT_N2_RW that accesses a previously modified cache location.

`0x843E`, **DSNP_HITM_N3_RW, Snoop hit in cache at distance 3, demand data access, modified**

The counter counts each snoop generated by the PE in response to a demand Memory-read operation or demand Memory-write operation counted by DSNP_HIT_N3_RW that accesses a previously modified cache location.

`0x843F`, **DSNP_HITM_N4_RW, Snoop hit in cache at distance 4, demand data access, modified**

The counter counts each snoop generated by the PE in response to a demand Memory-read operation or demand Memory-write operation counted by DSNP_HIT_N4_RW that accesses a previously modified cache location.

`0x8440`, **ASE_FP_SP_MIN_SPEC, Advanced SIMD data processing operation speculatively executed, smallest type is single-precision floating-point**

The counter counts each Advanced SIMD data-processing operation counted by ASE_SVE_FP_SP_MIN_SPEC due to an instruction where the smallest type was single-precision floating-point.

`0x8442`, **ASE_FP_HP_MIN_SPEC, Advanced SIMD data processing operation speculatively executed, smallest type is half-precision floating-point**

The counter counts each Advanced SIMD data-processing operation counted by ASE_SVE_FP_HP_MIN_SPEC due to an instruction where the smallest type was half-precision floating-point.

`0x8443`, **ASE_FP_BF16_MIN_SPEC, Advanced SIMD data processing operation speculatively executed, smallest type is BFloat16 floating-point**

The counter counts each Advanced SIMD data-processing operation counted by ASE_SVE_FP_BF16_MIN_SPEC due to an instruction where the smallest type was BFloat16 floating-point.

`0x8444`, **ASE_FP_FP8_MIN_SPEC, Advanced SIMD data processing operation speculatively executed, smallest type is 8-bit floating-point**

The counter counts each Advanced SIMD data-processing operation counted by ASE_SVE_FP_FP8_MIN_SPEC due to an instruction where the smallest type was 8-bit floating-point.

`0x8448`, **ASE_SVE_FP_SP_MIN_SPEC, Advanced SIMD data processing or SVE data processing operation speculatively executed, smallest type is single-precision floating-point**

The counter counts each Advanced SIMD or SVE data-processing operation counted by SE_FP_SP_MIN_SPEC due to an instruction where the smallest type was single-precision floating-point.

`0x844A`, **ASE_SVE_FP_HP_MIN_SPEC, Advanced SIMD data processing or SVE data processing operation speculatively executed, smallest type is half-precision floating-point**

The counter counts each Advanced SIMD or SVE data-processing operation counted by SE_FP_HP_MIN_SPEC due to an instruction where the smallest type was half-precision floating-point.

`0x844B`, **ASE_SVE_FP_BF16_MIN_SPEC, Advanced SIMD data processing or SVE data processing operation speculatively executed, smallest type is BFloat16 floating-point**

The counter counts each Advanced SIMD or SVE data-processing operation counted by SE_FP_BF16_MIN_SPEC due to an instruction where the smallest type was BFloat16 floating-point.

`0x844C`, **ASE_SVE_FP_FP8_MIN_SPEC, Advanced SIMD data processing or SVE data processing operation speculatively executed, smallest type is 8-bit floating-point**

The counter counts each Advanced SIMD or SVE data-processing operation counted by SE_FP_FP8_MIN_SPEC due to an instruction where the smallest type was 8-bit floating-point.

`0x8450`, **SE_FP_SP_MIN_SPEC, Advanced SIMD, SVE, or SME data processing operation speculatively executed, smallest type is single-precision floating-point**

The counter counts each Advanced SIMD, SVE, or SME data processing operation counted by FP_SP_MIN_SPEC due to an instruction where the smallest type was single-precision floating-point.

`0x8452`, **SE_FP_HP_MIN_SPEC, Advanced SIMD, SVE, or SME data processing operation speculatively executed, smallest type is half-precision floating-point**

The counter counts each Advanced SIMD, SVE, or SME data processing operation counted by FP_HP_MIN_SPEC due to an instruction where the smallest type was half-precision floating-point.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

`0x8453`, **SE_FP_BF16_MIN_SPEC, Advanced SIMD, SVE, or SME data processing operation speculatively executed, smallest type is BFloat16 floating-point**

The counter counts each Advanced SIMD, SVE, or SME data processing operation counted by FP_BF16_MIN_SPEC due to an instruction where the smallest type was BFloat16 floating-point.

`0x8454`, **SE_FP_FP8_MIN_SPEC, Advanced SIMD, SVE, or SME data processing operation speculatively executed, smallest type is 8-bit floating-point**

The counter counts each Advanced SIMD, SVE, or SME data processing operation counted by FP_FP8_MIN_SPEC due to an instruction where the smallest type was 8-bit floating-point.

`0x8458`, **SME_FP_SP_MIN_SPEC, SME data processing operation speculatively executed, smallest type is single-precision floating-point**

The counter counts each SME data-processing operation counted by SE_FP_SP_MIN_SPEC due to an instruction where the smallest type was single-precision floating-point.

`0x845A`, **SME_FP_HP_MIN_SPEC, SME data processing operation speculatively executed, smallest type is half-precision floating-point**

The counter counts each SME data-processing operation counted by SE_FP_HP_MIN_SPEC due to an instruction where the smallest type was half-precision floating-point.

`0x845B`, **SME_FP_BF16_MIN_SPEC, SME data processing operation speculatively executed, smallest type is BFloat16 floating-point**

The counter counts each SME data-processing operation counted by SE_FP_BF16_MIN_SPEC due to an instruction where the smallest type was BFloat16 floating-point.

`0x845C`, **SME_FP_FP8_MIN_SPEC, SME data processing operation speculatively executed, smallest type is 8-bit floating-point**

The counter counts each SME data-processing operation counted by SE_FP_FP8_MIN_SPEC due to an instruction where the smallest type was 8-bit floating-point.

`0x8460`, **SVE_FP_SP_MIN_SPEC, SVE data processing operation speculatively executed, smallest type is single-precision floating-point**

The counter counts each SVE data-processing operation counted by ASE_SVE_FP_SP_MIN_SPEC due to an instruction where the smallest type was single-precision floating-point.

`0x8462`, **SVE_FP_HP_MIN_SPEC, SVE data processing operation speculatively executed, smallest type is half-precision floating-point**

The counter counts each SVE data-processing operation counted by ASE_SVE_FP_HP_MIN_SPEC due to an instruction where the smallest type was half-precision floating-point.

`0x8463`, **SVE_FP_BF16_MIN_SPEC, SVE data processing operation speculatively executed, smallest type is BFloat16 floating-point**

The counter counts each SVE data-processing operation counted by ASE_SVE_FP_BF16_MIN_SPEC due to an instruction where the smallest type was BFloat16 floating-point.

`0x8464`, **SVE_FP_FP8_MIN_SPEC, SVE data processing operation speculatively executed, smallest type is 8-bit floating-point**

The counter counts each SVE data-processing operation counted by ASE_SVE_FP_FP8_MIN_SPEC due to an instruction where the smallest type was 8-bit floating-point.

`0x846B`, **FP_BF16_FIXED_OPS_SPEC, Non-scalable element arithmetic operations speculatively executed, largest type is BFloat16 floating-point**

The counter increments by v for each speculatively executed non-scalable element arithmetic operation, due to an instruction where the largest type was BFloat16 floating-point.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Where v is the number of arithmetic operations carried out by the operation or instruction which causes the counter to increment.

The counter does not count operations that are counted by FP_SCALE_OPS_SPEC.

`0x8470`, **FP_SP_MIN_SPEC, Floating-point operation speculatively executed, smallest type is single-precision floating-point**

The counter counts each floating-point operation counted by FP_SPEC due to an instruction where the smallest type was single-precision floating-point.

`0x8472`, **FP_HP_MIN_SPEC, Floating-point operation speculatively executed, smallest type is half-precision floating-point**

The counter counts each floating-point operation counted by FP_SPEC due to an instruction where the smallest type was half-precision floating-point.

`0x8473`, **FP_BF16_MIN_SPEC, Floating-point operation speculatively executed, smallest type is BFloat16 floating-point**

The counter counts each floating-point operation counted by FP_SPEC due to an instruction where the smallest type was BFloat16 floating-point.

`0x8474`, **FP_FP8_MIN_SPEC, Floating-point operation speculatively executed, smallest type is 8-bit floating-point**

The counter counts each floating-point operation counted by FP_SPEC due to an instruction where the smallest type was 8-bit floating-point.

`0x8480`, **FP_SP_FIXED_MIN_OPS_SPEC, Non-scalable element arithmetic operations speculatively executed, smallest type is single-precision floating-point**

The counter increments by v for each speculatively executed non-scalable element arithmetic operation, due to an instruction where the smallest type was single-precision floating-point.

Where v is the number of arithmetic operations carried out by the operation or instruction which causes the counter to increment.

The counter does not count operations that are counted by FP_SCALE_OPS_SPEC.

`0x8482`, **FP_HP_FIXED_MIN_OPS_SPEC, Non-scalable element arithmetic operations speculatively executed, smallest type is half-precision floating-point**

The counter increments by v for each speculatively executed non-scalable element arithmetic operation, due to an instruction where the smallest type was half-precision floating-point.

Where v is the number of arithmetic operations carried out by the operation or instruction which causes the counter to increment.

The counter does not count operations that are counted by FP_SCALE_OPS_SPEC.

`0x8483`, **FP_BF16_FIXED_MIN_OPS_SPEC, Non-scalable element arithmetic operations speculatively executed, smallest type is BFloat16 floating-point**

The counter increments by v for each speculatively executed non-scalable element arithmetic operation, due to an instruction where the smallest type was BFloat16 floating-point.

Where v is the number of arithmetic operations carried out by the operation or instruction which causes the counter to increment.

The counter does not count operations that are counted by FP_SCALE_OPS_SPEC.

`0x8484`, **FP_FP8_FIXED_MIN_OPS_SPEC, Non-scalable element arithmetic operations speculatively executed, smallest type is 8-bit floating-point**

The counter increments by v for each speculatively executed non-scalable element arithmetic operation, due to an instruction where the smallest type was 8-bit floating-point.

D9.4 Cycle event counting

The CPU_CYCLES event and the cycle counter, PMCCNTR_EL0, Performance Monitors Cycle Count Register, count cycles. The duration of a cycle is subject to any changes in clock frequency, including clock stopping caused by the WFI and WFE instructions.

It is IMPLEMENTATION SPECIFIC whether CPU_CYCLES and PMCCNTR_EL0, Performance Monitors Cycle Count Register count when the PE is in WFI or WFE state, even if the clocks are not stopped.

In addition, events such as STALL, STALL_FRONTEND and STALL_BACKEND that are defined to only count cycles that are counted by the CPU_CYCLES event have the same limitation.

D9.4.1 Cycle event counting in multithreaded implementations

Multithreaded implementations can have various forms, some examples of these are:

- *Simultaneous Multithreading* (SMT), where every PE thread is active on every Processor cycle.
- *Fine-grained Multithreading* (FGMT), also known as a Barrel processor, where one PE thread is active on each Processor cycle, and this changes regularly.
- *Switch on Event Multithreading* (SoEMT), also known as *Coarse-grained Multithreading* (CGMT), where high latency events cause the processor to switch the active PE thread.

In the above examples, active means that the PE might execute the instructions. A PE can be active but not executing instructions when no instruction is available or because of limited execution resources.

It is IMPLEMENTATION SPECIFIC whether a thread is active when the thread is in WFE or WFI state. This applies for all forms of multithreaded implementation.

When the PMU implementation supports multithreading, the Effective value of PMEVTYPER<n>_EL0.MT bit is 0, and the thread is not in WFE or WFI state, the CPU_CYCLES event only counts Processor cycles when the thread is active. For the example multithreaded implementations, this means that, if the event counter is enabled, event counting is not prohibited, and the thread is not in WFE or WFI state:

- For an SMT implementation, the CPU_CYCLES event counts every Processor cycle.
- For a particular FGMT implementation, that alternates between two threads on each Processor cycle, the CPU_CYCLES event counts every other Processor cycle.
- For a particular SoEMT implementation, that is waiting for a long latency operation, the CPU_CYCLES event does not count Processor cycles, as the PE thread is not active.

It is IMPLEMENTATION SPECIFIC whether CPU_CYCLES event counts Processor cycles when the Effective value of PMEVTYPER<n>_EL0.MT bit is 0, the thread is active, and the thread is in WFE or WFI state.

If the Effective value of PMEVTYPER<n>_EL0.MT bit is 1 and at least one thread is not in WFE or WFI state, then the CPU_CYCLES event counts each Processor cycle, and can only count a maximum of one for each Processor cycle.

If the Effective value of PMEVTYPER<n>_EL0.MT bit is 1, then all of the following apply for events that count PE cycles when a condition applies:

- The event does not count Processor cycles when all threads are in WFE or WFI state.
- If the event counts PE cycles when a stall condition is true and a second condition is true, then the counter counts Processor cycles when the stall condition is true for all of these PEs, and the second condition is true for any of these PEs.
- If the event counts PE cycles when any other condition is true, then the counter counts Processor cycle when the condition is true for any of these PEs.
- Otherwise, the event counts by the sum of the count across all of these PEs.

For the stall events, the stall condition means the applicable condition described by the STALL, STALL_FRONTEND, or STALL_BACKEND event. The second condition is any condition in addition to this. For example, for the STALL_FRONTEND_L1I event, the stall condition is STALL_FRONTEND, and the second condition is when there is a demand instruction miss in the first level of instruction cache. For the STALL, STALL_FRONTEND, and STALL_BACKEND events themselves, the second condition is the null TRUE condition.

Non-Confidential

Note

The cycle counter, PMCCNTR_EL0, Performance Monitors Cycle Count Register, is not affected by whether the thread is active or inactive. When enabled, PMCCNTR_EL0, Performance Monitors Cycle Count Register counts every processor cycle.

See Multithreaded implementationsMDCR_EL3.MTPME for more information about when the Effective value of PMEVTYPER<n>_EL0.MT is 0.

D9.4.2 Time as measured by the Performance Monitors cycle counter

The Performance Monitors cycle counter, accessed through PMCCNTR_EL0 increments from the hardware processor clock, not PE clock cycles.

The relationship between the count recorded by the Performance Monitors cycle counter and the passage of real time is IMPLEMENTATION DEFINED.

See Controlling the PMU counters for information about when the cycle counter does not increment.

Note

- This means that, in an implementation where PEs are multithreaded, when enabled, the cycle counter continues to increment across all PEs, rather than only counting cycles for which the current PE is active.
- Although the architecture requires that direct reads of PMCCNTR_EL0 occur in program order, there is no requirement that the count increments between two such reads. Even when the counter is incrementing on every clock cycle, software might need check that the difference between two reads of the counter is nonzero.

  The architecture requires that an indirect write to the PMCCNTR_EL0 is observable to direct reads of the register in finite time. The counter increments from the hardware processor clock are indirect writes to these registers.

D9.5 Meaningful combinations of common events

The architecture highlights some meaningful combinations of common events. The following tables list the highlighted combinations:

- Table D9-4, REFILL events and associated access events.
- Table D9-5, Meaningful combinations of latency events.
- Table D9-6, Cache hit events and associated data source events.
- Table D9-7, Meaningful combinations of cache line state tracking events.
- Table D9-8, Meaningful combinations of TLB events.
- Table D9-9, Meaningful combinations of at-retirement events.
- Bytes loaded and stored events.

D9.5.1 Refill events and associated access events

I_{GSMLS} The following are meaningful combinations of refill events and associated access events:

Table D9-4 Meaningful combinations of refill events and associated access events

Numerator	Denominator	Ratio
0x0001 L1I_CACHE_REFILL	0x0014 L1I_CACHE	Attributable Level 1 instruction cache refill rate
0x0002 L1I_TLB_REFILL	0x0026 L1I_TLB	Attributable Level 1 instruction TLB refill rate
0x0003 L1D_CACHE_REFILL	0x0004 L1D_CACHE	Attributable Level 1 data or unified cache refill rate
0x0005 L1D_TLB_REFILL	0x0025 L1D_TLB	Attributable Level 1 data or unified TLB refill rate
0x0017 L2D_CACHE_REFILL	0x0016 L2D_CACHE	Attributable Level 2 data or unified cache refill rate
0x0028 L2I_CACHE_REFILL	0x0027 L2I_CACHE	Attributable Level 2 instruction cache refill rate
0x002A L3D_CACHE_REFILL	0x002B L3D_CACHE	Attributable Level 3 data or unified cache refill rate
0x002D L2D_TLB_REFILL	0x002F L2D_TLB	Attributable Level 2 data or unified TLB refill rate

0x00A3 L3D_CACHE_REFILL_WR	0x00A1 L3D_CACHE_WR	Attributable Level 3 data cache refill rate, write

D9.5.2 Latency events

I_{ZHFDC} The following are meaningful combination of latency events:

Table D9-5 Meaningful combinations of latency events

Numerator	Denominator	Ratio
0x8120 INST_FETCH_PERCYC	0x8124 INST_FETCH	Mean duration of instruction fetch events in processor cycles
0x8121 MEM_ACCESS_RD_PERCYC	0x0066 MEM_ACCESS_RD	Mean duration of memory read access events in processor cycles
0x8125, BUS_REQ_RD_PERCYC	0x818D, BUS_REQ_RD	Bus read transaction average latency
0x8128 DTLB_WALK_PERCYC	0x0034 DTLB_WALK	Mean duration of data or unified TLB walk events in processor cycles
0x8129 ITLB_WALK_PERCYC	0x0035 ITLB_WALK	Mean duration of instruction TLB walk events in processor cycles
0x8320, L1D_CACHE_REFILL_PERCYC	0x0003, L1D_CACHE_REFILL	Level 1 data cache refill average duration

D9.5.3 Cache hit events and associated data source events

I_{HMZQY} The following are meaningful combination of cache hit events:

Table D9-6 Meaningful combinations of cache hit events and associated data source events

Numerator	Denominator	Ratio
0x820C, L1D_CACHE_HIT_PRFM [a]	0x8142, L1D_CACHE_PRFM [a]	Level 1 data or unified cache software prefetch hit ratio[a]
0x81CC, L1D_CACHE_HIT_RW [a]	0x82A0, MEM_ACCESS_RW	Level 1 data or unified cache demand cache hit rate[a]
0x81CF, LL_CACHE_HIT_RW	0x82A0, MEM_ACCESS_RW	Last level cache demand cache hit rate
0x8232, LOCAL_MEM_RW	0x82A0, MEM_ACCESS_RW	Local memory demand access rate
0x823B, REMOTE_MEM_RW	0x82A0, MEM_ACCESS_RW	Remote memory demand access rate
0x821D, L2D_CACHE_HITM_RW [a]	0x81CD, L2D_CACHE_HIT_RW [a]	Level 2 data or unified cache demand cache hit rate[a]

a. Similar ratios can be defined for other caches.

D9.5.4 Cache line state tracking events

I_{LGBBR} The following are meaningful combination of cache line stake tracking events:

Table D9-7 Meaningful combinations of cache line state tracking events

Ratio	Meaning
1 - (0x81EC, L1D_CACHE_HIT_RW_FHWPRF ÷ 0x8154, L1D_CACHE_HWPRF)[a]	Level 1 data or unified cache data fetched by hardware prefetcher not used[a]
1 - (0x81DC, L1D_CACHE_HIT_RW_FPRFM ÷ 0x8142, L1D_CACHE_PRFM)[a]	Level 1 data or unified cache data fetched by software prefetch not used[a]
0x825C, L1D_LFB_HIT_RW_FPRFM ÷ 0x8142, L1D_CACHE_PRFM [a]	Level 1 data or unified cache data fetched late by software prefetch[a]

a. Similar ratios can be defined for other caches.

D9.5.5 TLB events

I_{PHZQV} The following are meaningful combination of TLB events:

Table D9-8 Meaningful combinations of TLB events

Numerator	Denominator	Ratio
0x8188, DTLB_WALK_BLOCK [a]	0x0034, DTLB_WALK [a]	Data TLB block translation table walk fraction[a]
0x818A, DTLB_WALK_PAGE [a]	0x0034, DTLB_WALK [a]	Data TLB page translation table walk fraction[a]

a. Similar ratios can be defined for instruction TLB accesses.

D9.5.6 At-retirement events

I_{CYQZJ} The following are meaningful combinations of at-retirement events:

Table D9-9 Meaningful combinations of at-retirement events

Numerator	Denominator	Ratio
0x82B0, L1I_CACHE_HIT_RETIRED	0x0008, INST_RETIRED	Architecturally executed instruction hit Level 1 instruction cache
0x82E0, L2I_CACHE_MISS_RETIRED	0x0008, INST_RETIRED	Architecturally executed instruction missed Level 2 instruction cache
0x82EC, L1D_CACHE_HIT_LDST_RETIRED	0x0008, INST_RETIRED	Architecturally executed load or store instruction hit in Level 1 data cache
0x82C9, L2D_CACHE_HITM_ST_RETIRED	0x0008, INST_RETIRED	Architecturally executed store instruction hit modified data in Level 2 data cache
0x82B7, LL_CACHE_MISS_LD_RETIRED	0x0008, INST_RETIRED	Architecturally executed load instruction missed in Last level cache

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.

Numerator	Denominator	Ratio
0x82F0, ITLB_HIT_RETIRED	0x0008, INST_RETIRED	Architecturally executed instruction which hit in the ITLB
0x82F7, DTLB_WALK_LDST_RETIRED	0x82AA, LDST_ANY_RETIRED	Architecturally executed LDST instructions DTLB miss fraction
0x82AF, CRYPTO_RETIRED	0x0008, INST_RETIRED	Architecturally executed cryptographic data processing fraction

D9.5.7 Speculatively executed operation events

I_{RDHPB} The number of speculatively executed operations performed on individual scalar values can be determined from a pair of event counters. Combined multiply-add and multiply-subtract instructions are counted as two operations per element.

Table D9-10 Meaningful combinations of speculatively executed operation events

Ratio	Meaning
0x80C0, FP_SCALE_OPS_SPEC × VL ÷ 128 + 0x80C1, FP_FIXED_OPS_SPEC	Total number of individual floating-point operations (any precision) performed
0x80C2, FP_HP_SCALE_OPS_SPEC × VL ÷ 128 + 0x80C3, FP_HP_FIXED_OPS_SPEC	Total number of individual half-precision floating-point operations performed
0x80C4, FP_SP_SCALE_OPS_SPEC × VL ÷ 128 + 0x80C5, FP_SP_FIXED_OPS_SPEC	Total number of individual single-precision floating-point operations performed
0x80C6, FP_DP_SCALE_OPS_SPEC × VL ÷ 128 + 0x80C7, FP_DP_FIXED_OPS_SPEC	Total number of individual double-precision floating-point operations performed
0x80C8, INT_SCALE_OPS_SPEC × VL ÷ 128 + 0x80C9 INT_FIXED_OPS_SPEC	Total number of individual integer operations performed
0x80CA, LDST_SCALE_OPS_SPEC × VL ÷ 128 + 0x80CB, LDST_FIXED_OPS_SPEC	Total number of individual load/store accesses performed
0x80CC, LD_SCALE_OPS_SPEC × VL ÷ 128 + 0x80CD, LD_FIXED_OPS_SPEC	Total number of individual load accesses performed
0x80CE, ST_SCALE_OPS_SPEC × VL ÷ 128 + 0x80CF, ST_FIXED_OPS_SPEC	Total number of individual store accesses performed

D9.5.8 Bytes loaded and stored events

I_{NYJRH} The number of bytes speculatively loaded from memory or stored to memory can be determined from a pair of event counters.

Table D9-11 Meaningful combinations of speculative load or store events

Ratio	Meaning
0x80DA, LDST_SCALE_BYTES_SPEC × VL ÷ 128 + 0x80DB, LDST_FIXED_BYTES_SPEC	Total number of bytes loaded from memory and stored to memory

D9.6 Required events

When at least one event counter is implemented, the following common events are implemented:

- 0x0000, SW_INCR, Instruction architecturally executed, Condition code check pass, software increment.
- 0x0003, L1D_CACHE_REFILL, Level 1 data cache refill.

  Note

  Event 0x0003 is only required if the implementation includes a Level 1 data or unified cache.

- 0x0004, L1D_CACHE, Level 1 data cache access.

  Note

  Event 0x0004 is only required if the implementation includes a Level 1 data or unified cache.

- 0x0010, BR_MIS_PRED, Mispredicted or not predicted branch Speculatively executed.

  Note

  Event 0x0010 is only required if the implementation includes program-flow prediction. However, Arm strongly recommends that the event is implemented as described in Common microarchitectural events.

- 0x0011, CPU_CYCLES, Cycle.
- 0x0012, BR_PRED, Predictable branch Speculatively executed.

  Note

  Event 0x0012 is only required if the implementation includes program-flow prediction. However, Arm recommends that the event is implemented as described in Common microarchitectural events.

- When FEAT_PMUv3_ICNTR is implemented:
  - 0x0008, INST_RETIRED, Instruction architecturally executed.
- When FEAT_PMUv3_ICNTR is not implemented, at least one of:
  - 0x0008, INST_RETIRED, Instruction architecturally executed.
  - 0x001B, INST_SPEC, Operation Speculatively executed.

  Note

  Arm strongly recommends that event 0x0008 is implemented.

- When FEAT_PMUv3p1 is implemented:
  - 0x0023, STALL_FRONTEND, No operation issued due to the frontend.
  - 0x0024, STALL_BACKEND, No operation issued due to the backend.

- When FEAT_PMUv3p4 is implemented:
  - 0x003C, STALL, No operation sent for execution.
  - 0x0039, L1D_CACHE_LMISS_RD, Level 1 data cache long-latency read miss.
  - 0x4006, L1I_CACHE_LMISS, Level 1 instruction cache long-latency miss.
  - 0x0040, L1D_CACHE_RD, Level 1 data cache read.

When any of the following common events are implemented, all three of them are implemented:

- 0x003D, STALL_SLOT_BACKEND, No operation sent for execution on a Slot due to the backend.
- 0x003E, STALL_SLOT_FRONTEND, No operation sent for execution on a Slot due to the frontend.
- 0x003F, STALL_SLOT, No operation sent for execution on a Slot.

Arm strongly recommends that the following events are implemented:

- 0x0021, BR_RETIRED.

D9.7 Synchronous events

Only events that count instructions at retirement can be synchronous events, but not all such events are required to be synchronous events.

An at-retirement event is an event generated by an architecturally-executed instruction that does not generate an exception.

Arm expects the set of synchronous events to include, but not be limited to:

- Existing events that count instructions at retirement:
  - INST_RETIRED.
  - Events that count instructions based on a taxonomy of instruction types.
  - Other existing branch events that count branches at retirement based on their behavior during execution.
- Events that count retired instructions that missed or hit in the instruction TLB or cache.
- Events that count retired load instructions that missed or hit in the data TLB or cache.

Events that are not attributable to an instruction, or are attributable to an instruction that generates an exception, such as EXC_TAKEN, are never synchronous events.

Note

Software requires *a priori* knowledge of which events are synchronous events. There is no hardware identification mechanism. A systematic software ID mechanism, such as a table in firmware, should be implemented.

D9.8 IMPLEMENTATION DEFINED event numbers

Arm recommends that implementers establish a standardized numbering scheme for their IMPLEMENTATION DEFINED events, with common definitions, and common event numbers, applied to all of their implementations. In general, the recommended approach is for standardization across implementations with common features. However, Arm recognizes that attempting to standardize the encoding of microarchitectural features across too wide a range of implementations is not productive.

The Arm architecture guarantees not to define any event prefixed with *IMP_* as part of the standard Arm architecture.

Arm strongly recommends that at least the following classes of event are identified in the IMPLEMENTATION DEFINED events:

- Separating each of the STALL_FRONTEND and STALL_SLOT_FRONTEND events to count holes in instruction availability.
- Separating each of the STALL_BACKEND and STALL_SLOT_BACKEND events, to count, for example, cumulative duration of stalls, unavailability of execution resources, or missed superscalar issue opportunities.
- Miss rates for additional levels of caches and TLBs.
- Any external events passed to the PE through an IMPLEMENTATION DEFINED mechanism.
- Cumulative duration of a PSTATE.{A, I, F} interrupt mask set to 1.
- Cumulative occupancy for resource queues, such as data access queues, and entry/exit counts, so that average latencies can be determined, separating out counts for key resources that might exist. An implementation might also provide registers in the IMPLEMENTATION DEFINED space to further extend such counts, for example by specifying a minimum latency for an event to be counted.
- Any other microarchitectural features that the implementer considers are valuable to count.

The range of possible IMPLEMENTATION DEFINED event numbers is described in The PMU event number space and common events.

It is not required that implementations document the behavior of all IMPLEMENTATION DEFINED PMU events, including which PMU event numbers are used for these IMPLEMENTATION DEFINED events. However, Arm strongly recommends that implementations do include and document IMPLEMENTATION DEFINED PMU events. In particular events related to microarchitectural characteristics of the implementation not covered by Common events.

Chapter D10
RAS PE Architecture

This chapter describes the RAS Extension PE Architecture. It contains the following sections:

- About the RAS Extension.
- PE error handling.
- Generating error exceptions.
- Taking error exceptions.
- Error synchronization event.
- Virtual SError exceptions and delegated SError exceptions.
- Error records in the PE.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D10.1 About the RAS Extension

I_{LBKPL} The RAS Extension extends the exception syndrome registers to include fields that allow the PE to report a PE error state when an Error exception is taken.

I_{THGHB} The RAS Extension defines System registers that are specific to RAS, including to access optional Error records defined by the RAS System Architecture. The format of the error record registers is defined in Error record System register view.

R_{YWXWL} The RAS Extension does not prescribe the level of reliability, availability, and serviceability in the PE. The RAS features that the system and PE include, for example to detect, correct, contain, or defer errors, are IMPLEMENTATION DEFINED. The RAS Extension defines a framework for building RAS features in a PE.

Example D10-1 Common error handling for RAS features

For a system with a requirement for high reliability and error containment:

- When errors are detected, they are recorded in error records. This includes both correctable and uncorrectable errors. Error correction and detection logic exists on all significant memory structures, and might include other non-memory structures.
- Most uncorrectable errors generate poison values to defer the error.
- On consuming poison from the memory system, a load instruction that would corrupt PE state generates a synchronous External Abort exception, regardless of the memory type.
- On taking error exceptions, the PE error state is Recoverable state (UER).

I_{QGLBZ} See also *Arm® Reliability Availability and Serviceability (RAS) System Architecture, for A-profile architecture* (ARM IHI 0100) for more information about the framework for building RAS features in a system.

D10.2 PE error handling

D10.2.1 PE error detection

I_{KRYQW} When a PE accesses memory or other state, an error might be detected in that memory or state, and corrected, deferred, or signaled to the PE as a Detected error with an in-band error response.
Note:
- An error that is deferred might be signaled to the PE with an in-band error response.
- An error might also be signaled to a PE by means other than an in-band error response.

I_{SLYLK} The response from memory or other state is defined by Detecting and consuming errors. For more information, see *Arm® Reliability, Availability, and Serviceability (RAS) System Architecture, for A-profile architecture* (ARM IHI 0100).

I_{DWWQJ} When an error is detected by a component on a read or a cache maintenance operation from the PE:
- If the error can be corrected, it is corrected and corrected data is returned.
- If the error cannot be corrected and can be deferred, it is deferred. For example, on a load by poisoning the PE state, if this is supported by the PE implementation.
- If the error cannot be corrected and if implemented and enabled at the component, the Detected error is signaled to the PE as an in-band error response.

I_{BKVQP} When an error is detected by a component consuming a write from the PE:
- If the error can be corrected, it is corrected.
- If the error cannot be corrected and can be deferred, it is deferred to the consumer. For example, by poisoning the location being written.
- If the error cannot be corrected and if implemented and enabled at the component, the Detected error is signaled to the PE as an in-band error response.

I_{PDDNB} The component might record the Detected error and generate a Fault handling interrupt and/or Error recovery interrupt.

I_{VRYFF} If the component implements the RAS System Architecture, its behavior is defined by the RAS System Architecture, and depends on the nature of the error and IMPLEMENTATION DEFINED properties of the component. In each of these cases, the component might be a part of the processor, such as a cache, or might be outside of the processor.
The component might also report the error to a RAS System Architecture node, which records the error and might generate one or more of a Fault handling interrupt, Error recovery interrupt, or Critical Error interrupt depending on the features and configuration of the node.
See also Other errors.

I_{FLXTY} An in-band error response is sometimes referred to as an *External abort*. To avoid confusion with the External abort *exception*, the RAS sections in this Manual use in-band error response to describe the response to the PE for a memory access.
For more information, see *Arm® Reliability, Availability, and Serviceability (RAS) System Architecture, for A-profile architecture* (ARM IHI 0100).

R_{WLTPV} The size of the protection granule for any implemented error detection mechanism in memory is IMPLEMENTATION DEFINED and might vary from moment to moment and instruction to instruction.
For example, the size of the protection granule might depend on one or more of the following:
- The physical address of the Location being accessed.
- Whether a copy of the Location held in a cache is being accessed, and the cache it is held in.
- The type of access being made.
- If FEAT_SME is implemented, whether the PE is in Streaming SVE mode or is not in Streaming SVE mode.

I_{JJJGW} A system might implement multiple error detection mechanisms with differing protection granule sizes.

I_{YBRSM} For a Deferred error, Clearing Deferred errors from poisoned Locations describes mechanisms to remove poison and clear the error. The architecture also permits IMPLEMENTATION DEFINED mechanisms for clearing an error or poison from memory.

Non-Confidential

D10.2.2 PE error propagation

I_{RPLQT} The program-visible architectural state of the PE, referred to as the PE state, includes:

- General-purpose and SIMD&FP registers.
- System registers.
- Special-purpose registers.
- PSTATE.

R_{XMBNW} An error is consumed by the PE by any of the following:

- An instruction commits the corruption into the PE state.
- The error is on an instruction fetch and the corrupt instruction is committed for execution.
- The error is on a translation table walk for a committed load, store, or instruction fetch.

I_{HVFKW} For a PE, Error propagation applies to the propagation of Detected error by the PE between the PE state, and any other PE state or memory.

Note: *Memory* includes structures that cache the contents of memory, such as an instruction cache, data cache, or TLB.

R_{VGXBJ} An error is propagated by the PE by one or more of the following occurring that would not have been permitted to occur had the fault not been activated:

- Consumption of the corrupt value by any instruction, propagating the error to the target(s) of the instruction. This includes:
  - A store of a corrupt value.
  - A write of a corrupt value to a System register, Special-purpose register, or PSTATE. Infecting a System register state might mean that the PE generates transactions that would not otherwise be permitted.
- Any operation occurring that should not have occurred, including:
  - A load, translation table walk, or instruction fetch that would not have been permitted, including those from hardware speculation or prefetching.
  - A store to an incorrect address, or a store that would not have been made or not permitted.
  - A direct or indirect write to a Special-purpose or System register that would not have been made or not permitted.
  - Assertion of any signal, such as an interrupt, that would not have been asserted.
- Any operation not occurring that should have occurred.
- Causing the PE to take an imprecise exception, other than an Error exception in response to the error itself. For more information, see Definition of a precise exception and imprecise exception.
- The PE discarding data that it holds in a modified state.
- Any other loss of required uniprocessor semantics, ordering, or coherency.

I_{RMZNK} In R_{VGXBJ}, *not have been permitted to occur* means that the observable behavior of the PE is a deviation from the correct service of the PE, as defined by the architecture. Deviations from the normal behavior of the PE implementation that would otherwise be permitted by the architecture are not deviations from correct service.

Example D10-2

A PE takes an Error exception asynchronously as follows, in program order:

1. A load returns a corrupt value from a first location to a general-purpose register.
2. The PE suppresses a store of the register to a second memory location. In particular, the location is not updated and so retains its previous value.
3. The Error exception is taken.
4. At the point when the Error exception is taken, the ordering constraints imposed by the architecture have not been violated, in particular those relating to the observability of the store at step 2.

Although the error has not been propagated, the PE state is not consistent with the PE having executed all of the instructions up to the point when the Error exception is taken, and so it would be unlikely that software would be able to recover execution.

R_{NQDWB} An error propagated by the PE is silently propagated by the PE only if all of the following are true:

1. The propagation is not part of the required operation of the PE in taking an Error exception generated by the error.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

2. The propagation is not part of the required operation of the PE executing an ESB instruction that synchronizes the error.
3. The error is not signaled to the consumer as a Detected error or Deferred error.
4. Any of the following are true:
   - The corrupt value is held in other than the general-purpose and SIMD&FP registers.
   - The error is propagated by an instruction in program order before either taking an Error exception generated by the error or executing an ESB instruction that synchronizes the error, and is propagated to outside of the general-purpose and SIMD&FP registers.
   - The error is propagated other than by an instruction that consumes the corrupt value as an input operand but otherwise behaves correctly.

I_{BRBFF} In R_{NQDWB}, item 4 means that after taking the Error exception generated by the error, or an ESB, propagating an error by, for example, storing the corrupt value to memory, is not considered as silent propagation of the error by the PE.

Example D10-3

A PE takes an Error exception in response to a load that returns a corrupt value to a general-purpose register. The error is not silently propagated to outside of the general-purpose registers before the Error exception is taken. Neither of the following are considered silent propagation of the error by the PE:

- Taking the Error exception causes the ESR_ELx, ELR_ELx, and SPSR_ELx registers to be updated. This is part of the required operation of the PE.
- After taking the Error exception, software stores the contents of the general-purpose register to memory, and this is not signaled to memory as a Deferred error. This happens in program order after the exception is taken.

The error is not silently propagated by the PE.

Example D10-4

Further to Example D10-2, if either of the following example additional operations occur between 2 and 3, then the PE has silently propagated the error:

- A second store to a third location is performed by the PE, and the architecture requires that the first store is ordered-before the second store. For example, the second store is a store-release operation. In this case, the PE violates the external ordering constraints for the two stores, and the error is silently propagated to any observer of the second store.
- A second load from the second location returns the previous value, and a second store writes that value to a third location. In this case, the PE violates the requirements of the Coherence-before relation because the second load cannot be Coherence-before the first store. The error silently propagates to any observer of the second store.

If instead of the PE suppressing the store at 2, the PE poisons the second memory location, and in the second example propagates that poison through the second load and second store, then the error is not silently propagated.

R_{DTRFQ} The features that a PE includes to prevent silent propagation of an error are IMPLEMENTATION DEFINED.

Example D10-5

An implementation ensures that a corrupt value in a general-purpose or SIMD&FP register is not silently propagated, by signalling a Deferred error on any write of data to any memory location, such that the memory location is poisoned.

D10.2.3 Clearing Deferred errors from poisoned Locations

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D10.2.3.1 Poison-atomicity of Memory Write Effects

D_{YQQLJ} A Memory Write Effect is *poison-atomic* if the Memory Write Effect removes a Deferred error (poison) at all Locations written to by the Memory Write Effect.

R_{XVFDG} For each store instruction with Explicit Memory Write Effects, it is IMPLEMENTATION DEFINED whether the Memory Write Effects are poison-atomic for a region of physical memory. This includes the `DC ZVA` and/or `DC GZVA` instructions.

R_{QSBKL} If a Location in a region of physical memory supports the poison-atomic property for a store instruction, then all Locations in the same naturally-aligned region support this for the same store instruction, where the size of the region is the largest translation granule that the PE supports.

I_{CSJLP} Support for the poison-atomic property for a store instruction is a property of both the PE as well as the system. That is, if the system includes a PE that supports the poison-atomic property for the instruction, then both the PE and the system support this instruction such that it is guaranteed to be poison-atomic.

For example, the system should not split cache line writes of data to be smaller than the poison granule of the downstream component in order to preserve poison-atomicity of a `DC {G}ZVA` instruction.

I_{ZRSSM} There is no architected means to discover the poison-atomic property for `DC ZVA` or `DC GZVA` for any region of physical memory.

I_{NXNTY} When a Memory Write Effect to a Location is not poison-atomic, the Memory Write Effect propagates a Deferred error previously at the Location to the new value being written.

Example D10-6

A region of physical memory uses Error Correction Codes (ECC) to provide error detection and correction. The protection granule for this region of memory is the size of a range covered by a single ECC. The ECC is also used to encode a poison value. This means the poison granule is the same size as the protection granule, for this region of physical memory.

A write that is smaller than the protection granule to this region of physical memory must read the protection granule containing the Location being written in order to compute a new ECC for the protection granule. If the protection granule contains poison, then a poisoned value is written back, meaning the write is not poison-atomic.

If a write overwrites the entire protection granule, then the system can compute a new ECC for the protection granule without reading the previous contents, meaning the write can be poison-atomic.

I_{GLFCV} A system might require software to stop using the protection granule until the Deferred error can be removed.

For example, by not using the physical page containing the granule until the system is reset. The architecture does not set any limit on the size of a protection granule, and it might be larger than a translation granule.

I_{HPJFJ} The size of the poison granule is IMPLEMENTATION DEFINED and might vary from moment to moment, instruction to instruction, and by Location. The size of the poison granule might be the same as the size of the protection granule, but this is not guaranteed. See also R_{WLTPV}.

I_{CBCMK} The regions of physical memory that support the poison-atomic property are IMPLEMENTATION DEFINED. Systems might have multiple physical memory types, including multiple physical memory regions used for bulk memory.

D10.2.3.2 Removing poison

I_{VZRKL} For guidance on mechanisms that software can use to remove poison from a Location, see Use of the RAS Extension.

I_{PSLGW} In order to test that poison has been removed from a Location, after the Location has been overwritten by a known-good value, software must be able to read back the Location from physical memory to check that the poison has been removed and the error is not persistent.

To do this, software must ensure that the Location has been cleaned and invalidated from all caches, so that the read returns a value from the Point of Physical Storage for the Location, and not any intermediate cache.

The Point of Coherency might be before a transparent unified cache, meaning that it might be before the Point of Physical Storage for a Location.

For more information on the Point of Physical Storage, see A64 Cache maintenance instructions.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D10.2.4 Other errors

I_{KRQMR} The RAS Extension deals mostly with errors detected by components outside of the PE, such as memory, and consumed by the PE.

Other errors might be detected from within the processor that implements the PE. If the error is not an error in the PE state then the error might be treated as an error detected by another component.

In the following examples, the *component* reports these errors to a RAS System Architecture node that implements Error records and records the errors, and might generate one or more of a Fault handling interrupt, Error recovery interrupt, or Critical Error interrupt depending on the features and configuration of the node.

Example D10-7

A processor cache can be treated as a component outside the PE.
The cache detects an error in the cache state that cannot be corrected:

- If the error is detected in dirty cache data being evicted from the cache when the PE makes an access, then the error might be deferred by the cache writing poison in the evicted cache data.
- If the PE is performing a partial write that does not completely overwrite the protection granule, then the error might be deferred by the cache writing poisoned to the cache location, and/or evicting the cache line with poison. Deferring the error means the error is not consumed by the PE.

Otherwise, the cache component generates the in-band error response to the PE.

Example D10-8

A processor memory interface can be treated as a component outside the PE.
A processor detects a corrupt or poisoned value being returned on the interface that is not being signaled as an in-band error response and cannot be corrected or deferred. For example, in response to a non-cacheable read or a cache refill.
The memory interface component generates the in-band error response to the PE.

I_{VNTWD} An implementation might include error detection logic within the PE state itself. When the PE detects an error in the PE state, the instruction that uses that state consumes the error, and the PE generates an IMPLEMENTATION DEFINED Error exception, taken as an SError exception. See R_{FNVVJ}.

In this case, the processor that implements the PE includes a RAS System Architecture node that implements Error records that record these errors.

I_{JRQDM} An implementation might support poisoning within the PE state. When the PE consumes a Deferred error, for example a poisoned value, from memory into the PE state, the PE state becomes poisoned. Subsequent operations that read the poisoned value can continue to defer the error by poisoning the result of the operation.

However, if the PE attempts to execute an operation that reads the poisoned value and cannot defer the error further, the PE generates an IMPLEMENTATION DEFINED Error exception, taken as an SError exception. See R_{FNVVJ}.

In this case, the processor that implements the PE includes a RAS System Architecture node that implements Error records that record these errors.

I_{JHQVK} Components outside of the PE might detect errors that are not consumed by the PE. These components might report such errors to a PE using Error recovery interrupts.

I_{MJQQZ} Errors from software faults are outside the scope of the RAS Extension. For more information, see *Arm® Reliability, Availability, and Serviceability (RAS) System Architecture, for A-profile architecture* (ARM IHI 0100).

D10.3 Generating error exceptions

R_{VJRKF} An Error exception is generated when a detected error is signaled to the PE as an in-band error response to an architecturally-executed memory access or cache maintenance operation. This includes any explicit data access, instruction fetch, translation table walk, or hardware update to the translation tables made by an architecturally-executed instruction.

I_{PJHZS} An Error exception is taken as an asynchronous SError exception, a synchronous External Data Abort exception, or a synchronous External Instruction Abort exception.

R_{MBNBH} It is IMPLEMENTATION DEFINED whether an Error exception can be generated for an error that is consumed by hardware speculation or prefetching by a PE, but that is not committed to the architecturally visible state of the PE.

R_{SHKJB} It is IMPLEMENTATION DEFINED whether an Error exception can be generated for a detected error that is deferred.

R_{GVWJD} It is IMPLEMENTATION DEFINED whether an Error exception can be generated for a detected error that is corrected.

R_{FNVVJ} An Error exception can also be generated for IMPLEMENTATION DEFINED causes. An Error exception generated for an IMPLEMENTATION DEFINED cause is taken as an SError exception.

Example D10-9

An error is detected and neither corrected nor deferred to the PE, and signaled to the PE by means other than an in-band error response, such as a wired SError exception pin. Asserting the SError exception pin causes the PE to generate an SError exception.

Example D10-10

An error is detected by the PE in the PE state, or in the result of a calculation performed by the PE. The detected error generates an SError exception.

Non-Confidential

D10.4 Taking error exceptions

R_{PKGLV} For an error signaled on a non-speculative instruction fetch or a translation table walk or hardware update of translation tables, it is IMPLEMENTATION DEFINED whether an Error exception on these accesses is taken as a synchronous External Abort exception or as an asynchronous SError exception.

R_{VLFTP} Unless otherwise stated, it is IMPLEMENTATION DEFINED whether an Error exception is handled precisely and synchronously, or handled asynchronously for each non-speculative:

- Explicit memory access made by an instruction.
- Cache maintenance operation.
- Translation table walk or hardware update of translation tables.

D_{SRYHT} In this section, *Handled precisely and synchronously* means the error generates a precise synchronous Data Abort exception.

D_{THFRY} In this section, *Handled asynchronously* means the error generates an asynchronous SError exception.

R_{CLFJM} All Error exceptions generated by speculative memory accesses are taken as an asynchronous SError exception.

R_{WFNJG} When an Error exception is taken as an asynchronous SError exception, the exception is taken in finite time.

R_{BCXKN} When any of the following exceptions are taken, the PE records the PE error state in the exception syndrome register:

- A synchronous External abort.
- An SError exception.

I_{GGCQQ} The exception type and target Execution state determine the set of PE error state values the PE can record.

I_{WSYXB} The recorded PE error state informs software whether software can recover execution and, if so, whether any action by the recovery software to locate and repair the error is necessary first.

I_{TRWXF} Other than as described by I_{WBVYC}, the PE error state recorded in the exception syndrome register describes the recovery of the PE state only. For example, the PE state might be recoverable when the state of system is such that system-level recovery is not possible. See also I_{ZQRGL}.

I_{NFDSM} Software is only able to successfully recover execution and make progress from a restart address for the exception by executing an Exception Return instruction to branch to the instruction at this restart address if all of the following are true:

- The error has not been silently propagated by the PE.
- At the point when the Exception Return instruction is executed, the PE state and memory system state are consistent with the PE having executed all of the instructions up to but not including the instruction at the restart address, and none afterwards. That is, at least one of the following restart conditions is true:
  - The error has been not architecturally consumed by the PE and infected the PE state.
  - Executing the instruction at the restart address will not consume the error and will correct any corrupt state by overwriting it with the correct value or values.

R_{DCKHJ} On taking an Error exception, the PE determines that software is able to recover execution at the point where the exception is taken, with no additional action from software, if and only if all of the following are true:

- The error has not been silently propagated by the PE.
- The restart conditions are met because all of the following are true:
  - Either the error does not remain latent or executing the instruction at the restart address will not consume the error and will correct any corrupt PE state.
  - The restart address is the preferred return address for the exception.
- The PE has not elected to determine that software is not able to recover execution, and has not elected to determine that software is able to recover execution if software takes action to locate and repair the error.

R_{JBHWY} On taking an Error exception, the PE determines that software is able to recover execution if software takes action to locate and repair the error, to get the PE state and memory system state into this consistent state before attempting recovery, if and only if all the following are true:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- The error has not been silently propagated by the PE.
- The restart conditions can be met because the restart address is the preferred return address for the exception and at least one of the following is true:
  - The error remains latent and executing the instruction at the restart address will access the corrupt state. If the error is removed then executing the instruction at the restart address will correct any corrupt PE state and/or corrupt memory state. For example, the instruction at the restart address is a load that will consume the error and corrupts PE state.
  - The error does not remain latent and the PE has elected to determine that software is able to recover execution if software takes action to locate and repair the error.
  - Executing the instruction at the restart address will not consume the error and the PE has elected to determine that software is able to recover execution if software takes action to locate and repair the error.
- The PE has not elected to determine that software is not able to recover execution.

R_{GJQWN} On taking an Error exception, the PE determines that software is not able to recover execution if and only if one or more of the following are true:

- The error has been silently propagated by the PE.
- The restart conditions cannot be met even if software takes action to locate and repair the error. This is because at least one of the following is true:
  - The error remains latent and executing the instruction at the restart address will consume the error and corrupt PE state. Either the error cannot be removed or executing the instruction at the restart address will not correct any corrupt PE state.
  - The restart address is not the preferred return address for the exception.
- The PE has elected to determine that software is not able to recover execution.

I_{XMCCR} That the PE determines that software is able to recover execution if software takes action to locate and repair the error does not mean that software can locate and repair the error. For example, the error in memory might be one which cannot be located or cannot be repaired. See I_{ZQRGL}.
Error recovery software might instead make the PE state and memory system state consistent with an *alternative execution* of the program.

Example D10-11

An Error exception is generated by a load from a location in a clean page of memory that is infected by an error. Software might be able to repair the error by:

- Reloading the page from a backing store. This makes the memory system state consistent with the uncorrupted view. Executing the instruction at the restart address will load the uncorrupted value into the PE state.
- Invalidating the clean page and marking it page as inaccessible. Executing the instruction at the restart address will result in a Translation fault being generated when the program tries to access the page. The target of the load will contain an UNKNOWN value, which is permitted by the architecture. The MMU fault handler can then reload the page from the backing store, as it would for a page that has not been previously accessed or has been paged out.

Either approach might result in the virtual address to physical address mapping for the page being changed by software, meaning the memory system state is not consistent with the previously executed instructions. However, the memory system state is consistent with a valid alternative view of the execution of the program that allows software to recover execution.
This recovery is only possible if the error can be isolated to a location.

I_{RHPPV} A PE might include additional IMPLEMENTATION DEFINED mechanisms to aid software locate and repair the error.
If software has to use IMPLEMENTATION DEFINED mechanisms to locate and repair the error, then the PE reports that it has determined that software is not able to recover execution. The PE might use IMPLEMENTATION DEFINED additional syndrome registers to report that software is able to recover execution if software takes action to locate and repair the error using the IMPLEMENTATION DEFINED mechanisms.

D10.4.1 PE error state recording in the exception syndrome

R_{WPKYM} When an asynchronous SError exception is taken to AArch64 state, the PE records the PE error state in the ESR_ELx exception syndrome register as the applicable one of:

- Uncontainable (UC).
- Unrecoverable state (UEU).
- Recoverable state (UER).
- Restartable state (UEO).
- Corrected (CE).
- Uncategorized error.
- IMPLEMENTATION DEFINED syndrome.

I_{SDDLL} When an asynchronous SError exception is taken to AArch64 state:

- Uncategorized error is recorded by setting ESR_ELx.ISS to zero. This includes setting ESR_ELx.IDS and ESR_ELx.DFSC to zero.
- IMPLEMENTATION DEFINED syndrome is recorded by setting ESR_ELx.IDS to `0b1`. The remainder of the ESR_ELx.ISS syndrome is IMPLEMENTATION DEFINED.

Other values for the PE error state are recorded in ESR_ELx.AET, by setting ESR_ELx.IDS to `0b0` and ESR_ELx.DFSC to the applicable nonzero fault status code, indicating ESR_ELx.AET is valid.

R_{FKHHF} When a synchronous External abort exception is taken, the PE records the PE error state in ESR_ELx.SET as the applicable one of the following:

- Uncontainable (UC).
- Recoverable state (UER).
- Restartable state (UEO).

Other values for the PE error state are not supported by synchronous External abort exceptions.

I_{QVVSM} Table D10-1 summarizes the supported PE error state syndrome values for each type of Error exception.

Table D10-1 Summary of Error exception types and supported PE error state syndrome values

PE error state	External abort	SError exception
Recorded in:	ESR_ELx.SET	ESR_ELx.AET
Uncategorized error	No	Yes (ISS==0)
IMPLEMENTATION DEFINED syndrome	No	Yes (IDS==1)
Uncontainable (UC),	Yes (`0b10`)	Yes (`0b000`)
Unrecoverable state (UEU)	No	Yes (`0b001`)
Recoverable state (UER)	Yes (`0b00`)	Yes (`0b011`)
Restartable state (UEO)	Yes (`0b11`)	Yes (`0b010`)
Deferred (DE)	No	No
Corrected (CE)	No	Yes (`0b110`)

D10.4.2 PE error state classification

I_{CCKWK} The PE determines which PE error state to record based on the following criteria:

- The PE error state syndrome values supported by the type of Error exception being taken. See PE error state recording in the exception syndrome.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- The following IMPLEMENTATION SPECIFIC properties and behaviors of the PE on taking the exception:
  - Whether the error has been silently propagated by the PE.
  - Whether the PE determines that software is able to recover execution at the point where the exception is taken.
  - If the PE determines that software can recover execution, whether software needs locate and repair the error before attempting to recover. If software does not locate and repair the error, then attempting to recover execution might cause the Error exception to be generated again.
  - If the PE determines that software cannot recover execution, whether the error is a synchronizable error.
- Whether the implementation elects to record the PE error state as another state. The PE only does this when the criteria for the other, recorded state are met. The conditions under which the PE elects to record the PE error state as another state are IMPLEMENTATION DEFINED.

The recorded PE error state is defined by the rules in this section.

R_{QKZLB} If and only if all of the following are true, then on taking an Error exception the PE error state is recorded as Uncontainable (UC):

- One or more of the following are true:
  - The error has been silently propagated by the PE.
  - The PE determines that software is not able to recover execution from the preferred return address of the exception and the error is not a synchronizable error.
  - The PE determines that software is not able to recover execution from the preferred return address of the exception and the Error exception is taken as a synchronous External abort to AArch64 state. (That is, the type of Error exception does not support reporting the PE error state as Unrecoverable state (UEU).)
  - The implementation has elected to record the PE error state as Uncontainable (UC).
- The implementation has not elected to record the PE error state as IMPLEMENTATION DEFINED syndrome or Uncategorized error, or the type of Error exception does not support reporting the PE error state as IMPLEMENTATION DEFINED syndrome or Uncategorized error.

R_{QGNYD} If and only if all of the following are true, then on taking an Error exception the PE error state is recorded as Unrecoverable state (UEU):

- The error has not been silently propagated by the PE.
- The Error exception is taken as an SError exception.
- One or more of the following are true:
  - The PE determines that software is not able to recover execution from the preferred return address of the exception and the error is a synchronizable error.
  - The implementation has elected to record the PE error state as Unrecoverable state (UEU).
- The implementation has not elected to record the PE error state as Uncontainable (UC), IMPLEMENTATION DEFINED syndrome, or Uncategorized error.

I_{FJCZP} Error synchronization event defines synchronizable error.

R_{JHNVT} If and only if all of the following are true, then on taking an Error exception the PE error state is recorded as Recoverable state (UER):

- The error has not been silently propagated by the PE.
- The PE determines that software is able to recover execution from the preferred return address of the exception.
- One or more of the following are true:
  - The PE determines that software must take action to locate and repair the error to successfully recover execution. This might be because the exception was taken before the error was architecturally consumed by the PE, at the point when the PE was not be able to make correct progress without either consuming the error or otherwise making the state of the PE unrecoverable.
  - The implementation has elected to record the PE error state as Recoverable state (UER).
- The implementation has not elected to record the PE error state as Unrecoverable state (UEU), Uncontainable (UC), IMPLEMENTATION DEFINED syndrome, or Uncategorized error.

R_{MBVCF} If and only if all of the following are true, then on taking an Error exception the PE error state is recorded as Restartable state (UEO):

- The error has not been silently propagated by the PE.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- The PE determines that software can recover execution from the preferred return address of the exception without the need for software to take action to locate and repair the error first.
- One or more of the following are true:
  - The error is an uncorrected error. This includes a deferred error.
  - The error is a corrected error and the Error exception is not taken as an SError exception taken to AArch64 state.
  - The implementation has elected to record the PE error state as Restartable state (UEO).
- The implementation has not elected to record the PE error state as any of Recoverable state (UER), Unrecoverable state (UEU), Uncontainable (UC), IMPLEMENTATION DEFINED syndrome, or Uncategorized error.

R_{LFXRD} If and only if all of the following are true, then on taking an Error exception the PE error state is recorded as Corrected (CE):

- The error has been corrected and not silently propagated by the PE.
- The Error exception is taken as an SError exception taken to AArch64 state.
- Software can recover execution from the preferred return address of the exception. Because the error has been corrected, software does not need to take action to locate and repair the error.
- The implementation has not elected to record the PE error state as any other type.

R_{NZYRP} If and only if all the following are true, then on taking an Error exception the PE error state is recorded as an Uncategorized error:

- The Error exception is taken as an asynchronous SError exception taken to AArch64 state.
- The implementation has elected to record the PE error state as an Uncategorized error.

R_{VHWHD} If and only if all the following are true, then on taking an Error exception the PE error state is recorded as an IMPLEMENTATION DEFINED syndrome:

- The Error exception is taken as an asynchronous SError exception taken to AArch64 state.
- The implementation has elected to record the PE error state as an IMPLEMENTATION DEFINED syndrome.

I_{SRPJD} The IMPLEMENTATION DEFINED syndrome type might provide additional IMPLEMENTATION DEFINED syndrome recorded in the exception syndrome register. Software might be able to determine the state of the PE from this syndrome, or other IMPLEMENTATION DEFINED syndrome registers.

I_{WLZRP} Uncategorized error and IMPLEMENTATION DEFINED syndrome are defined for backward compatibility with previous versions of the architecture. Arm does not recommend use of these PE error state values in new implementations that include other RAS features.

I_{VKMZB} The PE error states are summarized by Figure D10-1. Figure D10-1 assumes the type of Error exception supports the resulting PE error state, never elects to record an error as a different PE error state when permitted, and does not show Uncategorized error or IMPLEMENTATION DEFINED syndrome.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

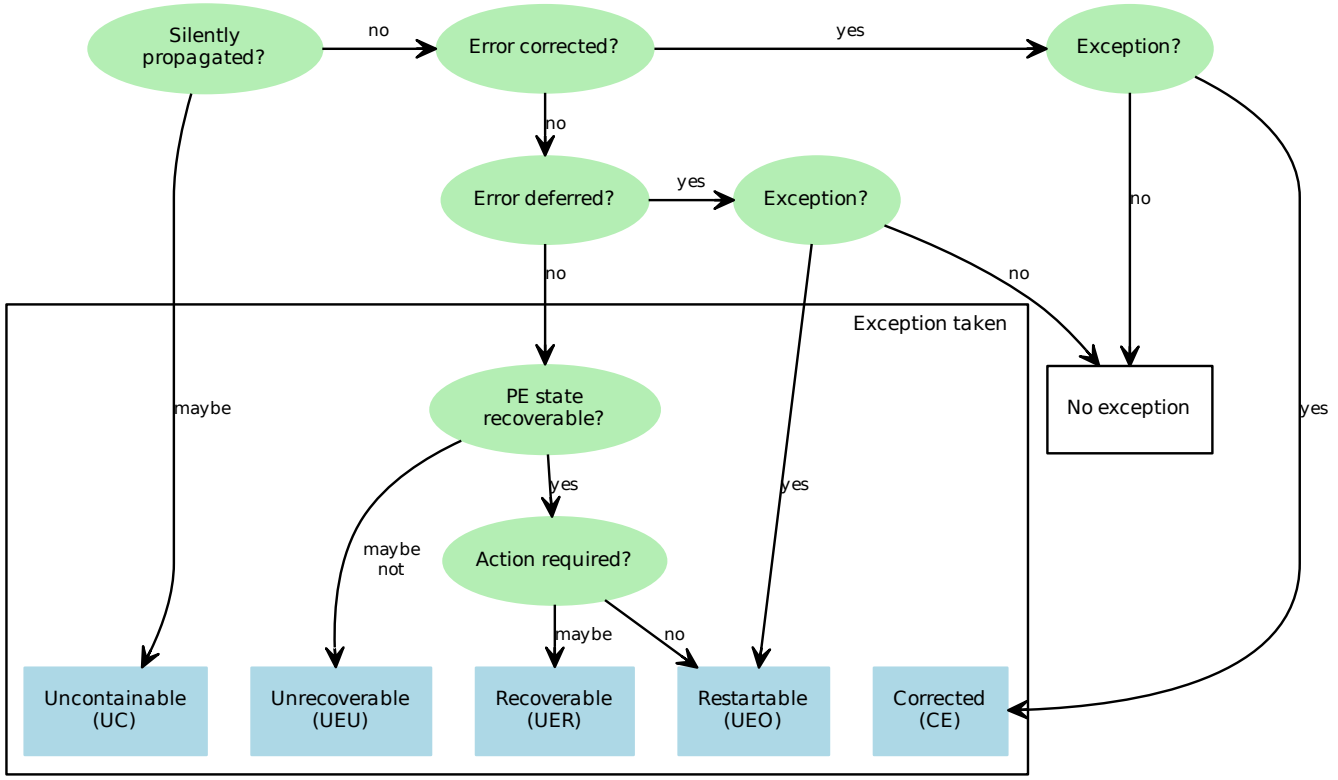

Figure D10-1 PE error states

I_{ZQRGL} If the PE error state reports that software can recover execution, or that software isolation might be possible because the error is a synchronizable error, then this does not necessarily mean that the error can be recovered from because the error in the system might be one which does not allow software to recover the operation. Rather, software *might* be able to recover if it can repair the error and continue.

Example D10-12

A component detects an error when accessed by a PE, and records in a RAS System Architecture node that the error is uncontainable at the component, meaning the system has to be shut down to avoid catastrophic failure. The component signals the error with an in-band error response to a PE, which does not report the severity of the error. The recorded PE error state refers only to the PE, not the system error state.

I_{WBVYC} If the in-band error response can signal the severity of the error to the PE, then the PE might use this information to elect to report the PE error state as the severity of error reported to it, if permitted by the preceding rules.
However, this is not required, and software must not rely on this behavior and should determine from the system whether the error is recoverable at the system level.

Example D10-13

A processor cache detects an uncontainable tag RAM error, and the PE reports the PE error state as Uncontainable (UC), even though the state of the PE itself is Recoverable state (UER). R_{QKZLB} allows this.

I_{TXFMY} An SError exception that is masked when it is generated remains pending until taken later when no longer masked.
In these cases, the PE error state is also unlikely to be *Restartable* or *Recoverable*.

I_{TGPQZ} See also:

- PE error propagation.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- Error synchronization event.

D10.4.2.1 Using the PE error state classification

S_{XSKNS} When the PE error state is recorded as Uncontainable (UC):

- The error handling software must assume that either:
  - The error has been silently propagated by the PE.
  - Software is not able to recover execution from the preferred return address of the exception and the error was not a synchronizable error.
- If the error handling software cannot isolate the error to an application or VM, or both, by other means, then the system must be shut down by software to avoid catastrophic failure.

S_{HYWFL} When the PE error state is recorded as Unrecoverable state (UEU):

- The error handling software can assume the error has not been silently propagated by the PE.
- The error handler cannot safely recover execution from the preferred return address of the exception, even if it takes action to locate and repair the error. The state of the affected software, or both, is unrecoverable. However, if the software includes Error synchronization events, the error handler can use the properties of the Error synchronization event to determine which software is affected by the error.
- The affected software cannot continue and must be isolated by the error handling software.

S_{LSFYM} When the PE error state is recorded as Recoverable state (UER):

- The uncorrected error might remain latent in the system.
- If the error handling software takes action to locate and repair the uncorrected error, then the error handler can safely recover execution from the preferred return address of the exception. Otherwise on restart of the affected software the PE might attempt to consume the error again, causing a further Error exception. If the error handler cannot locate and repair the error, then the affected software must be isolated by the error handling software.

S_{GLPZY} When the PE error state is recorded as Restartable state (UEO):

- The error might remain latent in the system.
- The error handling software might take action to locate and repair the error before it is consumed. However, the affected software can be safely restarted by the error handler without software taking any action to locate and repair the error.

For example, the error was signaled when the PE speculatively accessed corrupt data.

S_{GRZQS} When the PE error state is recorded as IMPLEMENTATION DEFINED syndrome or Uncategorized error, if the error handling software is not able to determine the actual state of the PE and memory, it should treat IMPLEMENTATION DEFINED syndrome and Uncategorized error as Uncontainable (UC).

D10.4.3 Multiple SError exceptions

I_{CPJLW} Multiple physical and/or virtual SError exception conditions might be pending together. The architecture does not define relative priorities for asynchronous exceptions.

R_{DHKQZ} If multiple physical and/or virtual SError exception conditions are pending, then it is IMPLEMENTATION DEFINED whether the multiple pending SError exception conditions are taken as a single SError exception.

R_{JBQSC} On taking an SError exception for more than one SError condition:

- If the exception is taken and one or more pending SError conditions would be reported as IMPLEMENTATION DEFINED syndrome or Uncategorized error, then the syndrome recorded in ESR_ELx.ISS is IMPLEMENTATION DEFINED.
- Otherwise, the recorded PE error state applies recorded by combined effect of the errors.

I_{GNHXJ} Any pending SError conditions that are not taken with other SError exceptions as a single SError exception remains pending after the SError exception is taken.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D10.4.4 Target Exception level for External abort and SError exceptions taken to AArch64 state

D_{FWSVH} This section is included for completeness. It repeats the definitions from this Manual and so is *non-normative*.

I_{NRZXZ} The default target Exception level for synchronous External abort exceptions is:

- EL1, if taken from EL0 or EL1.
- EL2, if taken from EL2.

The default target Exception level for SError exceptions is EL1.

However:

- If HCR_EL2.AMO is `0b1` or HCR_EL2.TGE is `0b1`, then the target Exception level for SError exceptions is EL2.
- If HCR_EL2.TEA is `0b1` or HCR_EL2.TGE is `0b1`, then the target Exception level for synchronous External abort exceptions taken from EL0 and EL1 is EL2.

When executing at a higher Exception level than the target Exception level for SError exceptions, SError exceptions are implicitly masked and not taken.

I_{BPGXV} See also The AArch64 System Level Programmers' Model.

D10.5 Error synchronization event

R_{GRJVN} An Error synchronization event is generated by any of the following:

- Executing an ESB instruction.
- When FEAT_IESB is implemented, and one of the following is true, taking an exception to an Exception level, ELx, the appropriate SCTLR_ELx.IESB bit is 0b1.
  In Debug state this also applies to executing a DCPSx instruction to ELx.
- When FEAT_IESB is implemented, and one of the following is true, executing an exception return instruction at an Exception level, ELx, the appropriate SCTLR_ELx.IESB bit is 0b1.
  In Debug state this also applies to executing a DRET instruction at ELx.

I_{PMGVM} In addition to generating an Error synchronization event, the ESB instruction might additionally record and then clear a masked pending asynchronous SError exception. This is also referred to as deferring the pending asynchronous SError exception.

R_{WPPWC} A synchronizable error is one of a subset of errors specific to the implementation that are synchronized by Error synchronization events, generated by an instruction executed on the same PE as the Error synchronization events.

Note: Synchronizable error must not be confused with a synchronous error exception. An Error exception for a synchronizable error might be taken asynchronously.

R_{BZPTV} If the Error exception for a synchronizable error is taken in program order after the Error synchronization event completes, and either physical SError exceptions are unmasked when the Error synchronization event occurs or the Error exception is taken synchronously, then all of the following are true:

- The instruction that generated the synchronizable error is in program order after the Error synchronization event.
- On completion of the Error synchronization event, the PE state and memory system state are consistent with the PE having executed all instructions in program order before the Error synchronization event.

R_{ZRHDD} If the Error exception for a synchronizable error is taken asynchronously as an SError exception, physical SError exceptions are masked when the Error synchronization event occurs, and the SError exception is not pending when the Error synchronization event completes, then all of the following are true:

- The instruction that generated the synchronizable error is in program order after the Error synchronization event.
- On completion of the Error synchronization event, the PE state and memory system state are consistent with the PE having executed all instructions in program order before the Error synchronization event.

The SError exception is not pending when the Error synchronization event completes if a subsequent read of ISR_EL1.A returns 0b0.

R_{YCJTN} If the Error exception for a synchronizable error is taken asynchronously as an SError exception, the Error synchronization event is generated by an ESB instruction executed when physical SError exceptions are masked, and the ESB instruction does not set DISR_EL1.A to 0b1, then all of the following are true:

- The instruction that generated the synchronizable error is in program order after the ESB.
- On completion of the ESB, the PE state and memory system state are consistent with the PE having executed all instructions in program order before the ESB.

R_{NFKMQ} Taken in program order after the Error synchronization event completes means:

- For an Error synchronization event generated by an ESB instruction, the exception is taken in program order after the instruction.
- For an Error synchronization event generated by an exception return instruction when FEAT_IESB implemented, the exception is taken in program order after the instruction.
- For an Error synchronization event generated by an exception entry when FEAT_IESB is implemented, one of the following is true:
  - The exception is taken in program order strictly after the first instruction of the exception handler at the exception vector address.
  - The exception is taken from the first instruction of the exception handler at the exception vector address and the ESR_ELx.IESB syndrome bit is recorded as 0b0.

I_{QZSHG} The definition of synchronizable error means that if the error that is a synchronizable error is generated by an instruction in program order before the Error synchronization event, then either the Error exception is taken before the Error synchronization event, or on executing the Error synchronization event the following apply:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- If physical SError exceptions are unmasked or the Error exception is taken synchronously, then the Error synchronization event ensures that the Error exception is not taken in program order after the Error synchronization event. This allows isolation of the software affected by the error.
- If physical SError exceptions are masked and the Error exception is taken asynchronously, then:
  - If the Error synchronization event was generated by an ESB, then the error is recorded in DISR_EL1. Software can use the PE error state recorded in DISR_EL1 to determine what recovery is possible.
  - Otherwise, the Error exception is pending when the Error synchronization event completes.

The SError exception might have been pending before or made pending by the Error synchronization event.

The definition does not mean that if the error is generated by a instruction in program order after the Error synchronization event, then the Error exception will only be taken after the Error synchronization event. The Error exception might be taken before the Error synchronization event, if the PE speculated past the Error synchronization event and speculatively executed the instruction that generated the error. This might cause software to generate a false failure. Error synchronization events are not speculation barriers.

I_{SQCFG} The criteria for the PE error state mean that if the PE reports the PE error state as one of the following, then the error must be either explicitly or implicitly a synchronizable error:

- Unrecoverable state (UEU).
- Recoverable state (UER).
- Restartable state (UEO).

This is because whether the error is a synchronizable error is a criterion for Unrecoverable state (UEU), and the criteria for Recoverable state (UER) and Restartable state (UEO) satisfy the definition of synchronizable error.

For other physical errors:

- An error that has been silently propagated by the PE and is not reported as either IMPLEMENTATION DEFINED syndrome or Uncategorized error must be reported as Uncontainable (UC) and is not containable even if the error is a synchronizable error. Software must assume the error has been silently propagated even if the error is a synchronizable error.
- It is IMPLEMENTATION SPECIFIC whether an error reported with an ESR_ELx.ISS syndrome that is IMPLEMENTATION DEFINED syndrome or Uncategorized error is a synchronizable error.
- The following errors have not been consumed by the PE:
  - A *Deferred error*.
  - A *Corrected error*.
  - An Error exception from a read by hardware speculation that does not corrupt the state of the PE.

  Software can recover execution from these errors regardless of whether the error is a synchronizable error.
- An implementation might have other IMPLEMENTATION DEFINED Error exception and other sources of SError exception, see R_{FNVVJ}. If an IMPLEMENTATION DEFINED SError exception is generated by a level-sensitive interrupt signal, then the SError exception cannot be a synchronizable error.

I_{VFFYW} An Error synchronization event might operate as follows:

1. The PE ensures that any synchronizable error generated by an instruction in program order before the Error synchronization event has caused a physical SError exception to become pending.
2. If a physical SError exception is pending for a synchronizable error and generated by an instruction in program order before the Error synchronization event, and physical SError exceptions are not masked at the current Exception level, then the physical SError exception is taken before completion of the Error synchronization event. The SError exception might have been made pending by the Error synchronization event, or might have been pending before the Error synchronization event.

R_{NPPGJ} If an SError exception for a synchronizable error is pending after completing the Error synchronization event generated by an ESB instruction, and physical SError exceptions are masked at the current Exception level, then the ESB instruction performs the following steps:

1. The pending physical SError exception is recorded in DISR_EL1. This includes the PE error state that the pending Error exception would record if taken.
2. The DISR_EL1.A bit bit is set to `0b1`.
3. The pending state of the physical SError exception is cleared.

The SError exception might have been made pending by the Error synchronization event, or might have been pending before the Error synchronization event.

R_{BLRTM} The criteria for ESB recording the PE error state in DISR_EL1 are the same as for that for recording the PE error state in ESR_ELx when an SError exception taken to the current execution state.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

R_{KNWBN} If an SError exception is taken as part of an Error synchronization event generated by an ESB instruction, then the ESB instruction address is the *preferred return address* of the exception.

For the definition of the *preferred return address* for an exception, see Preferred return address.

R_{SFHDS} On executing an ESB instruction when SError exceptions are masked, any pending SError exception generated by an error that is not a synchronizable error:

- Remains pending after completion of the Error synchronization event.
- Does not update DISR_EL1.

I_{CQKXL} The Error recovery interrupt, Fault handling interrupt, and Critical Error interrupt interrupts described by RAS System Architecture are asynchronous interrupts, and so are not synchronizable errors.

I_{BBGXN} If multiple SError exception conditions are pending, then an Error synchronization event synchronizes all errors that are synchronizable errors.

S_{VFHGT} Software must be aware that an SError exception taken at an Error synchronization event or recorded in the DISR_EL1 register by an ESB instruction might have been generated by hardware speculation of an instruction in program order after the Error synchronization event.

D10.5.1 ESB and virtual SError exceptions

R_{TFVYW} If VSESR_EL2 is writable, then an ESB instruction executed at EL0 or EL1 synchronizes a pending virtual SError exception.

In these cases, a virtual SError exception is pending, and the following occur when an ESB instruction is executed at EL0 or EL1:

- If the virtual SError exception is unmasked at the current Exception level, then the exception is taken before the completion of the ESB instruction.
- If the virtual SError exception is masked at the current Exception level, then all the following occur:
  - HCR_EL2.VSE cleared to 0b0.
  - The virtual SError exception syndrome from VSESR_EL2 is recorded in VDISR_EL2. See R_{HDCTW} and R_{FLYGZ}.
  - VDISR_EL2.A is set to 0b1 to indicate the SError exception was pending prior to the execution of the ESB instruction.

R_{GXHYX} If all of the following are true, then it is IMPLEMENTATION DEFINED whether or not an ESB instruction executed at EL0 or EL1 synchronizes a pending virtual SError exception:

- EL2 is implemented and enabled in the current Security state.
- EL2 is using AArch64, HCR_EL2.TGE is 0b0, HCR_EL2.VSE is 0b1 and either:
  - HCR_EL2.AMO is 0b1.
- VSESR_EL2 is implemented as RAZ/WI.

In these cases, a virtual SError exception is pending. If the IMPLEMENTATION DEFINED choice is that the ESB instruction synchronizes a pending virtual SError exception, then the following occur when an ESB instruction is executed at EL0 or EL1:

- If the virtual SError exception is unmasked at the current Exception level, then the exception is taken before the completion of the ESB instruction.
- If the virtual SError exception is masked at the current Exception level, then all the following occur:
  - HCR_EL2.VSE cleared to 0b0.
  - The virtual SError exception syndrome in VDISR_EL2 is set to zero.
  - VDISR_EL2.A is set to 0b1 to indicate the virtual SError exception was pending prior to the execution of the ESB instruction.

If the IMPLEMENTATION DEFINED choice is that the ESB instruction does not synchronize a pending virtual SError exception, then an ESB instruction executed at EL0 or EL1 ignores the pending virtual SError exception and the virtual SError exception stays pending.

See also Syndrome registers.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I_{VKQGL} If both a virtual SError exception and a physical SError exception are pending as described in R_{LLLVR} and Error synchronization event, then the physical SError exception is not masked at the current Exception level, because this is not possible when a virtual SError exception is pending. This means that:

- If the virtual SError exception is masked at the current Exception level, then the physical SError exception will be taken before the `ESB` instruction completes and HCR_EL2.VSE and VDISR_EL2 are unchanged.
- If the virtual SError exception is not masked at the current Exception level, then it is IMPLEMENTATION DEFINED which of the virtual SError or physical SError exceptions is taken before the `ESB` instruction completes. If the virtual SError exception is taken and, after taking the exception to EL1, the physical SError exception is still pending, then the physical SError exception is still not masked and will be taken.

D10.5.2 Extension for synchronization at exception entry and return

D_{DPSJR} The rules in this section apply when FEAT_IESB is implemented.

I_{WDSBL} An implicit Error synchronization event has no effect on DISR_EL1 or VDISR_EL2.

D10.5.2.1 Synchronization on exception entry

R_{RNZWY} For each value of ELx in EL1 or EL2, if all of the following are true, then each exception that is taken to ELx generates an Error synchronization event:

- The Effective value of SCTLR_ELx.IESB is `0b1`.

R_{RPBWR} For each value of ELx in EL1 or EL2 if all of the following are true, then executing a `DCPSx` instruction generates an Error synchronization event:

- The PE is in Debug state.
- The Effective value of SCTLR_ELx.IESB is `0b1`.

R_{JQSKQ} If an SError exception is taken to the Exception level ELy as a result of the Error synchronization event generated on exception entry by the FEAT_IESB mechanism, then all the following occur:

- The PE sets the ESR_ELy.IESB bit in the SError exception syndrome to `0b1`.
- The preferred return address for the SError exception is the exception vector address for the original exception.

Note: ELy might be the same Exception level as ELx.

I_{FWZHV} If SError exceptions are masked at ELx, then any SError exception made pending by the Error synchronization event stays pending.

I_{MMVJW} The prioritization of asynchronous exceptions is IMPLEMENTATION DEFINED. This means that an implementation might choose to behave as if the SError exception made pending by the Error synchronization event was taken before the implicit Error synchronization event, if the SError exception was not masked, taking the SError exception in place of the original exception, unless the original exception is also an SError exception.

In this case, ESR_ELy.IESB is set to `0b0` and the reported PE error state correctly indicates, for instance, whether software can recover execution from the preferred return address for the SError exception in ELR_ELy.

D10.5.2.2 Synchronization on exception return

R_{SKRCR} For each value of ELx in EL1 or EL2 if all of the following are true, then executing an exception return instruction at ELx generates an Error synchronization event:

- The instruction does not generate any exception.
- The Effective value of SCTLR_ELx.IESB is `0b1`.

I_{GPPXQ} On an illegal return event, the exception return instruction sets PSTATE.IL to `0b1`, which causes the next instruction to generate an Illegal State exception. The exception return instruction does not generate the exception.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

R_{CVPDN} For each value of ELx in EL1 or EL2 if all of the following are true, then executing an `DRPS` instruction at ELx generates an Error synchronization event:

- The PE is in Debug state and the instruction does not generate any exception.
- The Effective value of SCTLR_ELx.IESB is `0b1`.

R_{GXQYD} Any SError exception taken as part of the Error synchronization event terminates execution of the instruction.

R_{LPKVM} If an SError exception is taken to an Exception level, ELy, as a result of the Error synchronization event generated on exception return by the FEAT_IESB mechanism, then all the following occur:

- The PE sets the ESR_ELy.IESB bit in the SError exception syndrome to an IMPLEMENTATION DEFINED choice of `0b0` or `0b1`.
- The preferred return address for the SError exception is the address of the `ERET` instruction.

I_{JZHDB} If SError exceptions are masked at ELx, then any SError exception made pending by the Error synchronization event stays pending.

D10.5.3 Error synchronization barriers in a minimal implementation

I_{HQRLS} Error synchronization events and the `ESB` instruction can be implemented as no-ops if either there are no sources of SError exceptions, or all SError exceptions are reported as Uncategorized error and are not synchronizable errors.
This allows for a very low cost implementation of the RAS Extension.
Such an implementation might include FEAT_IESB, meaning the SCTLR_ELx.IESB controls have no effect.

I_{HSHJG} See also Syndrome registers.

D10.6 Virtual SError exceptions and delegated SError exceptions

I_{LSSCN} EL2 provides a virtual SError exception.

For more information, see:

- Virtual interrupts
- Virtual exceptions when an implementation includes EL2.

I_{ZXMPL} FEAT_RAS provides:

- Mechanisms to allow a hypervisor to specify the syndrome value reported to a guest Operating System on taking a virtual SError exception.
- Mechanisms to allow firmware to specify the syndrome value reported to a hypervisor or guest Operating System on taking a delegated SError exception.
- Support for EL0 or EL1 to isolate a virtual SError exception and for EL0, EL1, or EL2 to isolate a delegated SError exception as if it was a physical SError exception. See ESB and virtual SError exceptions.

D10.7 Error records in the PE

I_{KMMPK} A component that records detected errors is called a node by the RAS System Architecture. Each node implements one or more Error records.

R_{VNLPC} It is IMPLEMENTATION DEFINED whether the processor that implements a PE implements any nodes.

R_{XKDRX} A PE implementing the RAS Extension might implement the System register interface to nodes.

I_{SCVSB} The System register interface to nodes is not restricted to accessing only PE nodes.

I_{ZRKKQ} When an error is recorded by a PE node, one or more of the following might be generated, according to the configuration of the node:

- A Fault handling interrupt.
- An Error recovery interrupt.
- A Critical Error interrupt.
- An in-band error response.

D10.7.1 Error record System register view

I_{SLVDW} If the System register interface to a node is implemented, then software can access the Error records of the node using Error record System registers.

R_{BYLZQ} The number of Error records that can be accessed using the System registers is IMPLEMENTATION DEFINED, and might be zero. The ERRIDR_EL1 registers indicate the highest numbered index of the Error records that can be accessed using System registers, plus one.

I_{NWBNQ} The AArch64 Error record System registers are those registers with an ERX*_EL1 mnemonic.

I_{BJNDF} The following table describes the AArch64 Error record System registers.
The descriptions in this section apply whether the Error record is accessed through the indirection mechanism, as described in Table D10-2, or as memory-mapped registers, as described in RAS registers summary.

Table D10-2 Using AArch64 System registers, System register map

Use	To Access	Access	Description
ERXADDR_EL1	ERR<n>ADDR	RW	Error Record <*n*> Address Register
ERXCTLR_EL1	ERR<n>CTLR	RW	Error Record <*n*> Control Register
ERXFR_EL1	ERR<n>FR	RO	Error Record <*n*> Feature Register
ERXMISC0_EL1	ERR<n>MISC0	RW	Error Record <*n*> Miscellaneous Register 0
ERXMISC1_EL1	ERR<n>MISC1	RW	Error Record <*n*> Miscellaneous Register 1
ERXMISC2_EL1[a]	ERR<n>MISC2	RW	Error Record <*n*> Miscellaneous Register 2
ERXMISC3_EL1[a]	ERR<n>MISC3	RW	Error Record <*n*> Miscellaneous Register 3
ERXPFGCDN_EL1	ERR<n>PFGCDN	RW	Error Record <*n*> Pseudo-fault Generation Countdown Register
ERXPFGCTL_EL1	ERR<n>PFGCTL	RW	Error Record <*n*> Pseudo-fault Generation Control Register
ERXPFGF_EL1	ERR<n>PFGF	RO	Error Record <*n*> Pseudo-fault Generation Feature Register
ERXSTATUS_EL1	ERR<n>STATUS	RW	Error Record <*n*> Primary Status Register

a. If FEAT_RASv1p1 is implemented.

R_{ZBCFZ} If FEAT_RASv1p1 is implemented, then all Error records accessible through System registers implement RAS System Architecture version 1.1.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

S_{VBBNY} To access an Error record, software:

1. Sets the error selection register, ERRSELR_EL1.SEL or ERRSELR.SEL, to the index of the record being accessed.
2. Accesses the Error record using the ERX*_EL1 or ERX* System registers, as described in I_{BJNDF}.

I_{WKXSB} The Error records accessed through the System registers might be accessible only to the PE associated with those System registers, or they might be shared and therefore accessible to other PEs through either System registers or as a memory-mapped component.

I_{JMVVD} Direct reads of the System registers, including Error record System registers, can occur speculatively and out-of-order relative to other instructions executed on the same PE.

R_{WFPWF} Direct reads and writes of the Error records through the ERX*_EL1 AArch64 System registers, as described in I_{BJNDF}, are indirect reads of ERRSELR_EL1.

D10.7.1.1 Syndrome registers

I_{RGMHN} ESR_ELx is the exception syndrome registers. The PE records syndrome information in an exception syndrome register on taking a physical SError exception or synchronous External abort exception. ESR_ELx is also used by other exceptions.
DISR_EL1 is the deferred error syndrome registers. The PE records syndrome information in a deferred error syndrome register on deferring a physical SError exception.
The PE also records a virtual syndrome value in ESR_EL1 or DISR_EL1 on taking or deferring a virtual SError exception. The virtual syndrome value is provided by software in a corresponding virtual error syndrome register, VSESR_EL2 or VDISR_EL2 respectively.
The PE also records a delegated syndrome value in ESR_EL2, ESR_EL1, VDISR_EL2, or DISR_EL1 on taking or deferring a delegated SError exception.

R_{SLNMV} For a given implementation:

- If ESB never synchronizes any errors, then DISR_EL1.A might be RES0.
- The deferred and virtual syndrome registers are capable of storing any syndrome value that might be recorded by the PE in an exception syndrome register on taking a physical SError exception or synchronous External abort exception.
- If any of ESR_ELx[24:0] is not used and always set to zero by the PE on taking a physical SError exception or synchronous External abort exception, then that bit can be RES0 in that exception syndrome register.
- A bit that is not used and always set to zero or always set to one by the PE on taking a physical SError exception is permitted to be RES0 or RES1 respectively in the corresponding deferred and virtual error syndrome registers. See Table D10-3.

In Table D10-3, the deferred or virtual error syndrome register bit described in the left-hand column is permitted to be RES0 or RES1 only if the corresponding bit is always set to zero or always set to one (respectively) on taking a physical SError exception in all of the implemented exception syndrome registers listed in the other columns marked *Yes* on that row. Otherwise, the bit is read/write.

Table D10-3 Permitted relaxations for bits in deferred and virtual error syndrome registers

Bit is permitted to be res0 or res1	ESR_ELx[*n*] *n* ∈ [24:0]
VSESR_EL2[*n*]	Yes
VDISR_EL2[*n*]	Yes
DISR_EL1[*n*]	Yes

I_{NQNWV} R_{SLNMV} means that VSESR_EL2 can be implemented as RAZ/WI when ESR_ELx[24:0] are always set to zero by the PE on taking a physical SError exception or synchronous External abort exception. When this is the case, the PE error state is always reported as Uncategorized error when a physical SError exception is taken.
I_{GQQCK}, in Error synchronization barriers in a minimal implementation then further allows ESB to be executed as a NOP, meaning DISR_EL1 and VDISR_EL2 can also be implemented as RAZ/WI.
This allows for a very low-cost implementation of the RAS Extension.

Chapter D11
AArch64 System Register Encoding

This chapter describes the AArch64 System register encoding space. It contains the following sections:

- The System register encoding space.
- Moves to and from debug and trace System registers.
- Moves to and from non-debug System registers, Special-purpose registers.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D11.1 The System register encoding space

The A64 instruction set includes instructions that access the System register encoding space. These instructions provide:

- Access to *System registers*, including the debug registers, that provide system control, and system status information.
- Access to Special-purpose registers such as SPSR_ELx, ELR_ELx, and the equivalent fields of the Process State.
- The cache and TLB maintenance instructions and address translation instructions.
- Barriers and the `CLREX` instruction.
- Architectural hint instructions.

This section describes the parts of the System register encoding space that provides access to the System registers described in AArch64 System Register Descriptions.

Note

- See Fixed values in AArch64 instruction and System register descriptions for information about abbreviations used in the System instruction descriptions.

Principles of the System instruction class encoding describes some general properties of these encodings. System instruction class encoding overview then describes the top-level encoding of these instructions, identifying that:

- Entries in the encoding space are characterized by the parameter set {`op0`, `op1`, `CRn`, `CRm`, `op2`}.
- `op0` is the most significant parameter for determining allocations in this space.

Much of this encoding space is used for System instructions, as described in The A64 System Instruction Class. This chapter describes only the part of the encoding space that is used for System registers, in the following sections:

- Moves to and from debug and trace System registers.
- Moves to and from non-debug System registers, Special-purpose registers.

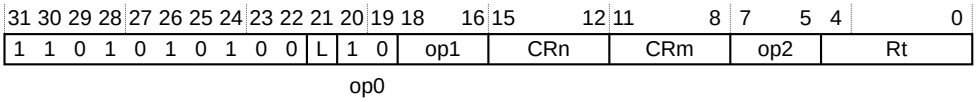
D11.2 Moves to and from debug and trace System registers

The instructions that move data to and from the debug, execution environment, and trace System registers are encoded with `op0== 0b10`. This means the encoding of these instructions is:



Note

- The section describes the use of all of the `op0==0b10` region of the System register encoding space.

The value of `op1` provides the next level of decode of these instructions, as follows:

`op1` == {`0b000`, `0b011`, `0b100`, `0b101`, `0b110`, `0b111`}

Debug, PMU, and System PMU registers.

Note

The standard encoding of debug registers is `op0` == `0b10`, `op1` == {0, 3, 4}. The registers in the `op0` == `0b11` encoding space that are classified as debug registers are DLR_EL0, DSPSR_EL0, MDCR_EL2,. See Instructions for accessing non-debug System registers for the encodings of these registers.

`op1` == {`0b001`} Trace and BRBE registers.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D11.2.1 Instructions for accessing debug System registers

The instructions for accessing debug System registers are:

```
MSR <System_register>, Xt    ; Write to System register
MRS Xt, <System_register>    ; Read from System register
```

Where `<System_register>` is the register name, for example MDCCSR_EL0.

This section includes only the System register access encodings for which both:

- `op0` is `0b10`.
- The value of `op1` is one of {`0b000`, `0b001`, `0b011`, `0b100`, `0b101`, `0b110`, `0b111`}.

Table D11-1 shows the mapping of the System register encodings for debug System register access.

Table D11-1 Instruction encodings for debug System register access in the (`op0==0b10`) encoding space

op1	CRn	CRm	op2	Access	Mnemonic	Accesses

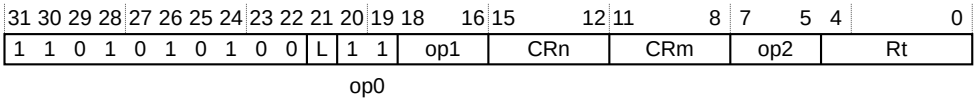
D11.3 Moves to and from non-debug System registers, Special-purpose registers

The instructions that move data to and from non-debug System registers are encoded with `op0== 0b11`, except that some of this encoding space is reserved for IMPLEMENTATION DEFINED functionality. The encoding of these instructions is:



The value of `CRn` provides the next level of decode of these instructions, as follows:

`CRn` == {`0b0000`, `0b0001`, `0b0010`, `0b0011`, `0b0101`, `0b0110`, `0b0111`, `0b1001`, `0b1010`, `0b1100`, `0b1101`, `0b1110`}

See Instructions for accessing non-debug System registers.

`CRn` == {`0b0100`}

See Instructions for accessing Special-purpose registers.

`CRn`=={`0b1011`, `0b1111`}

See Reserved encodings for IMPLEMENTATION DEFINED registers.

D11.3.1 Instructions for accessing non-debug System registers

The A64 instructions for accessing System registers are:

```
MSR <System_register>, Xt     ; Write to 64-bit System register
MSRR <System_register>, Xt    ; Write to 128-bit System register
MRS Xt, <System_register>     ; Read from 64-bit System register
MRRS Xt, <System_register>    ; Read from 128-bit System register
```

Where `<System_register>` is the register name, for example MIDR_EL1.

This section includes only the System register access encodings for which both:

- `op0` is `0b11`.
- The value of `CRn` is one of {`0b0000`, `0b0001`, `0b0010`, `0b0011`, `0b0100`, `0b0101`, `0b0110`, `0b0111`, `0b1001`, `0b1010`, `0b1100`, `0b1101`, `0b1110`}.

Direct accesses to some regions of the system register encoding space have a defined behavior even if no register is currently allocated or implemented for the encodings in those regions. The Feature ID space is the System register space in AArch64 with `op0==3, op1=={0, 1, 3}, CRn==0, CRm=={0-7}, op2=={0-7}`. The properties for this space are that:

- For unused encodings in the part of the space that has `op1` == `0` and `CRm` == `{2-7}`, the following apply:
  - It is IMPLEMENTATION DEFINED whether direct reads can be trapped by HCR_EL2.TID3.
  - Direct reads that are not trapped behave as Reserved, RES0 to ensure correct behavior if the encodings are used for ID registers in the future.
- For unused encodings in the part of the space that has either `op1` == `0` and `CRm` == `0`, or `op1` == `{1, 3}`, the following apply:
  - Direct reads are UNDEFINED and therefore generate exceptions reported with EC syndrome value `0x00`.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

- While this group is described as accessing the non-debug System registers, its correct characterization is by the {op0, CRn} values given in this subsection, and the group includes the debug registers DLR_EL0, DSPSR_EL0, MDCR_EL2, MDCR_EL3, and SDER32_EL3 and MDCR_EL3, which are described in Debug registers. These registers are exceptions to the standard encoding of debug registers, which has op0 == 0b10, see Instructions for accessing debug System registers.
- All unused encodings in the range Op0 == 3, op1 == 0, CRn == 0, CRm == {2-7}, op2 == {0-7} are defined to be accessible as Reserved, RAZ to ensure correct behavior if the encodings are used for ID registers in the future.

The instruction encoding for these accesses is:

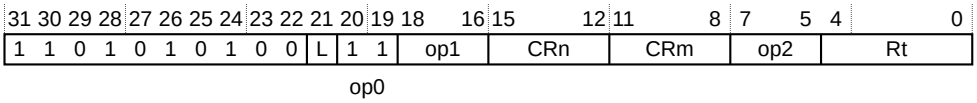


Table D11-2 shows the encodings of the register access instructions.

See the register descriptions for information about the control that determines whether these accesses are permitted.

Table D11-2 Instruction encodings for non-debug System register access in the (op0==0b11) encoding space

D11.3.1.1 About the GIC System registers

From version 3.0 of the GIC architecture, the specification defines three groups of System registers, identified by the prefix of the register name:

ICC_ GIC physical CPU interface System registers.

ICH_ GIC virtual interface control System registers.

ICV_ GIC Virtual CPU interface System registers.

Note

These registers are in addition to the GIC memory-mapped register groups GICC_, GICD_, GICH_, GICR_, GICV_, and GITS_.

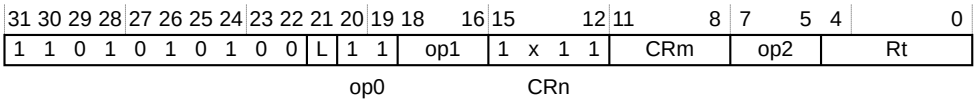
When implemented, the GIC System registers form part of an Arm processor implementation, and therefore these registers are included in the register summaries. However, the registers are defined only in the GIC Architecture Specification.

As Table D11-2 shows, the ICV_* registers have the same {op0, op1, CRn, CRm, op2} encodings as the corresponding ICC_* registers. For these encodings, GIC register configuration fields determine which register is accessed.

For more information, see the *Arm® Generic Interrupt Controller Architecture Specification, GIC architecture version 3.0 and version 4.0* (ARM IHI 0069).

D11.3.2 Reserved encodings for IMPLEMENTATION DEFINED registers

The System register encoding space with op0 == 0b11 reserves the following encodings for IMPLEMENTATION DEFINED registers:



Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The value of `L` defines the access type and the use of `Rt` as follows:

0 Write the value in `Rt` to the IMPLEMENTATION DEFINED register.

1 Read the value of the IMPLEMENTATION DEFINED register to `Rt`.

For more information about these encodings, see S3_<op1>_<Cn>_<Cm>_<op2>, IMPLEMENTATION DEFINED Registers.

As that section describes, any IMPLEMENTATION DEFINED registers are accessed in a similar way to architecturally-defined System registers, using `MRS`, and `MSR`instructions, see:

- MRS.
- MSR (immediate).
- MSR (register).

The Arm architecture guarantees not to define any register name prefixed with *IMP_* as part of the standard Arm architecture.

Note

Arm strongly recommends that any register names created in the IMPLEMENTATION DEFINED register spaces be prefixed with *IMP_* and postfixed with *_ELx*, where appropriate.

Chapter D12
AArch64 System Register Descriptions

This chapter defines the AArch64 System registers. It contains the following sections:

- About the AArch64 System registers.
- General system control registers.
- Debug registers.
- Trace registers.
- Performance Monitors registers.
- PMSA registers
- RAS registers.
- Generic Timer registers.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D12.1 About the AArch64 System registers

The following sections describe common features of the AArch64 registers:

- Fixed values and reserved values in the System register descriptions.
- General behavior of accesses to the AArch64 System registers.
- Principles of the ID scheme for fields in ID registers.

D12.1.1 Fixed values and reserved values in the System register descriptions

See Fixed values in AArch64 instruction and System register descriptions. This section defines how the glossary terms RAZ, RES0, RAO, and RES1 can be represented in the System register descriptions.

See Reserved values in System and memory-mapped registers and translation table entries. This section describes the behavior of reserved values in the System register descriptions.

D12.1.2 General behavior of accesses to the AArch64 System registers

The following subsections give general information about the behavior of accesses to the System registers:

- Reset behavior of AArch64 System registers.
- Synchronization requirements for AArch64 System registers.

D12.1.2.1 Reset behavior of AArch64 System registers

Reset values apply only to RW registers and fields, however:

- Some RO registers or fields, including feature ID registers and some status registers or register fields, always return a known value.
- Some RW and RO registers or register fields return status information about the PE. Unless the register description indicates that the value is UNKNOWN on reset, a read of the register immediately after a reset returns valid information.
- Some RW and RO registers and fields are aliases of other registers or fields. In these cases, the reset behavior of the aliased register or field determines the value returned by a read of the register immediately after a reset.
- WO registers that only have an effect on writes do not have meaningful reset values. However, an access to a WO register might affect underlying state, and that state might have a defined reset value.
- IMPLEMENTATION DEFINED registers have IMPLEMENTATION DEFINED reset behavior.

After a reset, only a limited subset of the PE state is guaranteed to be set to defined values. Also, for debug and trace System registers, reset requirements must take account of different levels of reset. For more information about the reset behavior of System registers when the PE resets into an Exception level that is using AArch64, see:

- Reset behavior.
- The appropriate Trace architecture specification, for the Trace System registers.

For a PE reset into an Exception level that is using AArch64, the architecture defines which AArch64 System registers have a defined reset value, and when that defined reset value applies. The register descriptions include this information, and Reset behavior summarizes these architectural requirements. Otherwise, RW registers that have a meaningful reset value reset to an architecturally UNKNOWN value.

D12.1.2.1.1 Pseudocode description of resetting System registers

The `AArch64.ResetSystemRegisters()` pseudocode function resets all System registers, and register fields, that have defined reset values, as described in this section and Reset behavior.

Note

For debug and trace System registers, this function resets registers as defined for the appropriate level of reset.

D12.1.2.2 Synchronization requirements for AArch64 System registers

Reads of the System registers can occur out of order with respect to earlier instructions executed on the same PE, provided that both:

- Any data dependencies between the instructions, including read-after-read dependencies, are respected.
- The reads to the register do not occur earlier than the most recent Context Synchronization event to its architectural position in the instruction stream.

Note

In particular, the values read from System registers that hold self-incrementing counts, such as the Performance Monitors counters or the Generic Timer counter or timers, could be accessed from any time after the previous Context Synchronization event. For example, where a memory access is used to communicate a read of such a counter, an `ISB` must be inserted between the read of the memory location that is known to have returned its data, either as a result of a condition on that data or of the read having completed, and the read of the counter, if it is necessary that the counter returns a count value after the memory communication.

Unless otherwise stated in its System register definition, a direct write to a System register requires synchronization before software can rely on the effects of that write to affect instructions appearing in program order after the write. This does not apply to Special-purpose registers; for more information, see Instructions for accessing Special-purpose registers. Direct writes to System registers are not allowed to affect any instructions appearing in program order before the direct write. The only exceptions are:

- All direct writes to the same register, that use the same encoding for that register, are guaranteed to occur in program order relative to each other.
- All direct writes to a register occur in program order with respect to all direct reads to the same register using the same encoding.
- Any System register access that an Arm *Architecture Specification* or equivalent specification defines as not requiring synchronization.
- When FEAT_BRBE is implemented, execution of `BRB INJ` does not require explicit synchronization to use the result of direct writes to the Branch record injection data registers in program order before `BRB INJ`.

Explicit synchronization occurs as a result of a Context Synchronization event, which is one of the following events:

- Execution of an `ISB` instruction.
- Exception entry, if FEAT_ExS is not implemented, or if FEAT_ExS is implemented and defines that exception entries to this Exception level are Context Synchronization events.
- Exception return, if FEAT_ExS is not implemented, or if FEAT_ExS is implemented and defines that exception returns from this Exception level are Context Synchronization events.
- Execution of a `DCPS` instruction in Debug state.
- Execution of a `DRPS` instruction in Debug state.
- Exit from Debug state.

Note

The `ISB` and exception entry events are applicable both in Debug state and in Non-debug state.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The pseudocode for each of these events defines the point at which the explicit synchronization takes effect, as a result of a call to the `SynchronizeContext()` function or `InstructionSynchronizationBarrier()` function. The principle behind the position of the call to `SynchronizeContext()` or `InstructionSynchronizationBarrier()` is that it occurs before indirect reads of System registers that are used in the construction of the target context, but is permitted to occur after indirect reads of System registers that apply to the context in which the instruction is executed or from which the event is taken.

Note

For some instructions, this means that some System registers are indirectly read before the explicit synchronization, and therefore changes to those System registers might need an explicit Context synchronization event before the instruction. For example, changes to some fields of HCR_EL2 at EL2 need an explicit ISB in program order before an ERET instruction.

In addition, any system instructions that cause a write to a System register must be synchronized before the result is guaranteed to be visible to subsequent direct reads of that System register.

Direct and indirect reads and writes to RGSR_EL1, Random Allocation Tag Seed Register, appear to occur in program order relative to other instructions, without the need for any explicit synchronization.

Direct reads to any one of the following registers, using the same encoding, occur in program order relative to each other:

- ISR_EL1.
- The Generic Timer registers, that is, CNTPCT_EL0 and CNTVCT_EL0, and the Counter registers CNTP_TVAL_EL0, CNTV_TVAL_EL0, CNTHP_TVAL_EL2, and CNTPS_TVAL_EL1.
- DBGCLAIMCLR_EL1.
- The PMU Counters, that is, PMCCNTR_EL0, PMEVCNTR<n>_EL0, PMXEVCNTR_EL0, PMOVSCLR_EL0, and PMOVSSET_EL0.
- The System PMU Counters, that is, SPMEVCNTR<n>_EL0, SPMOVSCLR_EL0, and SPMOVSSET_EL0.
- The Debug Communications Channel registers, that is, DBGDTRRX_EL0, DBGDTR_EL0, and MDCCSR_EL0.

All other direct reads of System registers can occur in any order if synchronization has not been performed.

Table D12-1 describes the synchronization requirements between two successive read or write accesses to the same register, where the ordering of the read or write accesses is:

1. Program order, in the event that both the reads or writes are caused by an instruction executed on this PE, other than one caused by a memory access by this PE.
2. The order of arrival of asynchronous reads and writes at the PE relative to the execution of instructions that cause reads or writes.
3. The order of arrival of asynchronous reads and writes at the PE relative to each other.

Table D12-1 Synchronization requirements

First read/write	Second read/write	Synchronization requirement

	Indirect read	None
	Indirect write	None
Indirect write	Direct read	Required, see Notes
	Direct write	None, see Notes
	Indirect read	Required, see Notes
	Indirect write	None, see Notes

D12.1.2.2.1 Notes

The terms Direct read, Direct write, Indirect read, and Indirect write, as used in Table D12-1, are defined as follows:

Direct read Where software uses an MRS or MRRS system register access instruction to read that register into a general purpose register.

Where a direct read of a register has a side-effect that changes the contents of a register, the effect of a direct read on that register is defined to be an indirect write. In this case, the indirect write is only guaranteed to have occurred, and be visible to subsequent direct or indirect reads or writes, if synchronization is performed after the direct read.

Direct write Where software uses an MSR (register) or MSRR access instruction to write to that register from a general purpose register.

Where a direct write to a register has an effect on the register that means that the value in the register is not always the last value that is written (as is the case with set and clear registers), the effect of a direct write on that register is defined to be an indirect write. In this case, the indirect write is only guaranteed to be visible to subsequent direct or indirect reads or writes if synchronization is performed after the direct write and before the subsequent direct or indirect reads or writes.

Indirect read Where an instruction uses a System register to establish operating conditions for the instruction, for example, the TTBR_ELx address or whether memory accesses are forced to be Non-cacheable. This includes situations where the contents of one System register selects what value is read or written using a different register. Indirect reads also include reads of the System register by external agents such as debuggers. Instruction execution from MDSTEPOP_EL1 is an indirect read of MDSTEPOP_EL1. Where an indirect read of a register has a side-effect that changes the contents of that register, that is defined to be an indirect write.

Indirect write Where a System register is written as the consequence of some other instruction, exception, operation, or by the asynchronous operation of an external agent, including the passage of time as seen in counters, timers, or performance counters, the assertion of interrupts, or writes from an external debugger.

Note

Registers such as the Exception Syndrome registers that are indirectly written as part of exception entry do not require additional synchronization. This behavior is independent of the value of SCTLR_ELx.EIS, and the list of affected registers is described in the definition of that field.

The value of a system register does not change unless one of the following occurs:

- As the result of a direct write to the register, that is not specified as being trapped, UNDEFINED or IGNORED.
- As the result of one of the specified indirect writes to the register.
- A reset, if the register has a specified reset behavior for that reset.
- The register is set to an UNKNOWN value as the result of one of the above.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Where a direct read or write to a register is followed by an indirect write caused by an external agent, autonomous asynchronous event, or as a result of memory mapped write, synchronization is required to guarantee the order of those two accesses.

Where an indirect write caused by a direct write is followed by an indirect write caused by an external agent, autonomous asynchronous event, or as a result of memory mapped write, synchronization is required to guarantee the order of those two indirect accesses.

Where a direct read to one register causes a bit or field in a different register (or the same register using a different encoding) to be updated, the change to the different register (or same register using a different encoding) is defined to be an indirect write. In this case, the indirect write is only guaranteed to be visible to subsequent direct or indirect reads or writes if synchronization is performed after the direct read and before the subsequent direct or indirect reads or writes.

Where a direct write to one register causes a bit or field in a different register (or the same register using a different encoding) to be updated as a side-effect of that direct write (as opposed to simply being a direct write to the different encoding), the change to the different register (or same register using a different encoding) is defined to be an indirect write. In this case, the indirect write is only guaranteed to be visible to subsequent direct or indirect reads or writes if synchronization is performed after the direct write and before the subsequent direct or indirect reads or writes.

Where indirect writes are caused by the actions of external agents such as debuggers, or by memory-mapped reads or writes by the PE, then an indirect write by that agent and mechanism to a register, followed by an indirect read by that agent and mechanism to the same register using the same address, does not require synchronization.

Where an indirect write occurs as a side-effect of an access, this happens atomically with the access, meaning no other accesses are allowed between the register access and its side-effect.

Note

Even though the 64-bit and 128-bit form of a system register share the same values of `{op0, op1, CRn, CRm, op2}`, they are considered to be distinct encodings. Therefore, explicit synchronization is required to guarantee ordering in all of the following cases:

- MSRR followed by an MRS from the same register.
- MSR (register) followed by an MRRS from the same register.

Where indirect writes to GCSPR_ELx are made by the following instructions, explicit synchronization is not required to be visible to direct reads, indirect reads, and indirect writes in program order after the initial indirect write:

- All Branch with Link instructions.
- All procedure return instructions.
- `GCSPOPM` and `GCSPUSHM`.
- `GCSPOPX`, `GCSPOPCX`, and `GCSPUSHX`.
- `GCSSS1` and `GCSSS2`.

Indirect writes caused by external agents, autonomous asynchronous events, or as a result of memory-mapped writes, to the registers shown in Table D12-2, are required to be observable to:

- Direct reads in finite time without explicit synchronization.
- Subsequent indirect reads without explicit synchronization.

Without explicit synchronization to guarantee the order of the accesses, where the same register is accessed by two or more of a System register access instruction, and external agent, and autonomous asynchronous event, or as a result of a memory-mapped access, the behavior must be as if the accesses occurred atomically and in any order. This applies even if the accesses occur simultaneously.

EDSCR.PipeAdv	External Debug Status and Control Register

In addition to the requirements shown in Table D12-2:

- Indirect writes to the following registers as a result of memory-mapped writes, including accesses by external agents, are required to be observable to the indirect read made in determining the response to a subsequent memory-mapped access without explicit synchronization:
  - OSLAR_EL1. OSLAR_EL1 is indirectly read to determine whether the subsequent access is permitted.
  - EDLAR, if implemented. EDLAR is indirectly read to determine whether a subsequent write or side-effect of an access is ignored.

  Note

  This requirement is stricter than the general requirement for the observability of indirect writes.

- The requirement that an indirect write to the registers in Table D12-2 is observable to direct reads in finite time does not imply that all observers will observe the indirect write at the same time.

  For example, an increment of the system counter is an autonomous asynchronous event that performs an indirect write to the counter. This asynchronous event might generate a timer interrupt request, resulting in a Context Synchronization event. When a GIC is used, the timer interrupt might arrive at the GIC after the PE has taken an interrupt request from another source, but before software reads the current interrupt ID from the GIC. This means that the GIC might identify the timer interrupt as the current interrupt. Software must not assume that a subsequent direct read of the counter register is guaranteed to observe the updated value of that register.

  Although this example uses the counter-timer registers, it applies equally to other registers that might be linked to interrupt requests, including the PMU and Statistical Profiling status registers.
- When the PE is in Debug state, there are synchronization requirements for the Debug Communication Channel and Instruction Transfer registers. See DCC and ITR access in Debug state.

Note

- The provision of explicit synchronization requirements to System registers is provided to allow the direct access to these registers to be implemented in a small number of cycles, and that updates to multiple registers can be performed quickly with the synchronization penalty being paid only when the updates have occurred.
- Since toolkits might use registers such as the thread-local storage registers within compiled code, it is recommended that access to these registers is implemented to take a small number of cycles.
- While no synchronization is required between a direct write and a direct read, or between a direct read and an indirect write, this does not imply that a direct read causes synchronization of a previous direct write. That is, the sequence direct write → direct read → indirect read, with no intervening context synchronization, does not guarantee that the indirect read observes the result of the direct write.

D12.1.3 Principles of the ID scheme for fields in ID registers

The Arm architecture specifies a number of *ID registers* that are characterized as comprising a set of 4-bit *ID fields,* Each ID field identifies the presence, and possibly the level of support for, a particular feature in an implementation of the architecture. These fields follow an architectural model that aids their use by software and provides future compatibility. This section describes that model. ID registers to which this scheme applies identifies the set of ID registers.

A small number of ID fields do not follow the scheme described in this section. In these cases, the field description states that it does not follow this scheme.

Note

- The ID fields described here are unlike the ones that enumerate the number of resources, such as the number of breakpoints, watchpoints, or performance monitors.
- ID fields that do not follow this scheme include the ID_AA64DFR0_EL1.PMUVer, ID_DFR0_EL1.PerfMon, ID_DFR0.PerfMon and EDDFR.PMUVer fields, see Alternative ID scheme used for the Performance Monitors Extension version.
- The presence of an ID field for a feature does not imply that the feature is optional.

To provide forward compatibility, software can rely on the features of these fields that are described in this section.

The ID fields, which are either signed or unsigned, use increasing numerical values to indicate increases in functionality. Therefore, for an unsigned ID field, if the value `0x1` indicates the presence of some instructions, then the value `0x2` will indicate the presence of those instructions plus some additional instructions or functionality. This means software can be written in the form:

```
if (value >= number) {
    // do something that relies on the value of the feature
}
```

For ID fields where the value `0x0` defines that a feature is not present, the field holds an unsigned value. This covers the vast majority of such fields.

In a few cases, the architecture has been changed to permit implementations to exclude a feature that has previously been required and for which no ID field has been defined. In these cases, a new ID field is defined and:

- The field holds a signed value.
- The field value `0x0` indicates that the feature is implemented.
- The field value `0xF` indicates that the feature is not implemented.
- Increasingly negative values indicate additional aspects of the architecture that are not implemented as a result of the feature not being implemented.
- Software that depends on the feature can use the test:

```
if value >= 0 {
    // Software features that depend on the presence of the hardware feature
}
```

In some cases, it has been decided retrospectively that the increase in functionality between two consecutive numerical values is too great, and it is desirable to permit an intermediate degree of functionality, and the means to discover this. This is done by the introduction of a *fractional* field that both:

- Is referred to in the definition of the original field.
- Applies only when the original field is at the lower value of the step.

In principle, a fractional field can be used for two different fractional steps, with different meanings associated with each of these steps. For this reason, a fractional field must be interpreted in the context of the field to which it relates and the value of that field. Example D12-1 shows the use of such a field.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Example D12-1 Example of the use of a fractional field

For a field describing some class of functionality:

- The value `0x1` was defined as indicating that item A is present.
- The value `0x2` was defined as indicating that items B and C are present, in addition to item A.

Subsequently, it might be necessary to introduce a second ID field to indicate that A and B only are present. This new field is a fractional field, and might be defined as having the value `0x1` when A and B only are present. This fractional field is valid only when the original ID field has the value `0x1`.
This approach means that:

- Software that depends on the test if `(value >= 0x2)` can rely on features A, B, and C being present,
- Software that depends on the test `if (value >= 0x1)` can rely on feature A being present.
- If new software needs to check only that features A and B are present, then it can test:

```
if (value >= 0x2 || (value == 0x1 && fractional_value >= 0x1)) {
    // Software features that depend on A and B only
}
```

A fractional field uses the same approach of increasing numerical values indicating increasing functionality, and the fractional approach can also be applied recursively to fractional fields.

Unused ID fields, and fractional fields that are not applicable, are RES0 to allow their future use when features, or fractional implementation options, are added.

D12.1.3.1 ID registers to which this scheme applies

This scheme applies to the following registers:

AArch64 System registers

- The Auxiliary Feature register ID_AFR0_EL1.
- The Processor Feature registers ID_PFR0_EL1, ID_PFR1_EL1, and ID_PFR2_EL1.
- The Debug Feature register ID_DFR0_EL1 and ID_DFR1_EL1.
- The Memory Model Feature registers ID_MMFR0_EL1, ID_MMFR1_EL1, ID_MMFR2_EL1, ID_MMFR3_EL1, ID_MMFR4_EL1, and ID_MMFR5_EL1.
- The Instruction Set Attribute registers ID_ISAR0_EL1, ID_ISAR1_EL1, ID_ISAR2_EL1, ID_ISAR3_EL1, ID_ISAR4_EL1, ID_ISAR5_EL1, and ID_ISAR6_EL1.
- The Media and VFP Feature registers MVFR0_EL1, MVFR1_EL1, and MVFR2_EL1.
- The AArch64 Auxiliary Feature registers ID_AA64AFR0_EL1 and ID_AA64AFR1_EL1.
- The AArch64 Processor Feature registers ID_AA64PFR0_EL1, ID_AA64PFR1_EL1, and ID_AA64PFR2_EL1.
- The AArch64 Debug Feature registers ID_AA64DFR0_EL1, ID_AA64DFR1_EL1, and ID_AA64DFR2_EL1.
- The AArch64 Memory Model Feature registers ID_AA64MMFR0_EL1, ID_AA64MMFR1_EL1, ID_AA64MMFR2_EL1, ID_AA64MMFR3_EL1, and ID_AA64MMFR4_EL1.
- The AArch64 Instruction Set Attribute registers ID_AA64ISAR0_EL1, ID_AA64ISAR1_EL1, ID_AA64ISAR2_EL1, and ID_AA64ISAR3_EL1.
- The AArch64 SVE Feature ID register ID_AA64ZFR0_EL1.

AArch64 System registers

- The Auxiliary Feature register ID_AFR0_EL1.
- The Processor Feature registers ID_PFR0_EL1, ID_PFR1_EL1, and ID_PFR2_EL1.
- The Debug Feature register ID_DFR0_EL1 and ID_DFR1_EL1.
- The Memory Model Feature registers ID_MMFR0_EL1, ID_MMFR1_EL1, ID_MMFR2_EL1, ID_MMFR3_EL1, ID_MMFR4_EL1, and ID_MMFR5_EL1.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- The Instruction Set Attribute registers ID_ISAR0_EL1, ID_ISAR1_EL1, ID_ISAR2_EL1, ID_ISAR3_EL1, ID_ISAR4_EL1, ID_ISAR5_EL1, and ID_ISAR6_EL1.
- The Media and VFP Feature registers MVFR0_EL1, MVFR1_EL1, and MVFR2_EL1.
- The AArch64 Auxiliary Feature registers ID_AA64AFR0_EL1 and ID_AA64AFR1_EL1.
- The AArch64 Processor Feature registers ID_AA64PFR0_EL1, ID_AA64PFR1_EL1, and ID_AA64PFR2_EL1.
- The AArch64 Debug Feature registers ID_AA64DFR0_EL1, ID_AA64DFR1_EL1, and ID_AA64DFR2_EL1.
- The AArch64 Memory Model Feature registers ID_AA64MMFR0_EL1, ID_AA64MMFR1_EL1, ID_AA64MMFR2_EL1, ID_AA64MMFR3_EL1, and ID_AA64MMFR4_EL1.
- The AArch64 Instruction Set Attribute registers ID_AA64ISAR0_EL1, ID_AA64ISAR1_EL1, ID_AA64ISAR2_EL1.

Memory-mapped registers

- The External Debug Processor Feature register EDPFR.
- The External Debug Feature register EDDFR.
- The External Debug Auxiliary Processor Feature register EDAA32PFR.

D12.1.3.2 Alternative ID scheme used for the Performance Monitors Extension version

The ID_AA64DFR0_EL1.PMUVer, ID_DFR0_EL1.PerfMon, ID_DFR0.PerfMon and EDDFR.PMUVer fields, that identify the version of the Performance Monitors Extension, do not follow the standard ID scheme. Software must treat these fields as follows:

- The value `0xF` indicates that the Arm-architected Performance Monitors Extension is not implemented.
- If the field value is not `0xF`, the field is treated as an unsigned value, as described for the standard ID scheme.

This means that software that depends on the implementation of a particular version of the Arm Performance Monitors Extension must be written in the form:

```
if (value != 0xF and value >= number) {
    // do something that relies on version 'number' of the feature
}
```

For these fields, Arm deprecates use of the value `0xF` in new implementations.

D12.1.3.3 Alternative ID scheme used for ID_AA64MMFR0_EL1 stage 2 granule sizes

The ID_AA64MMFR0_EL1.{TGran4_2, TGran64_2, TGran16_2} fields that identify the memory translation stage 2 granule size, do not follow the standard ID scheme. Software must treat these fields as follows:

- The value `0x0` indicates that support is identified by another field.
- If the field value is not `0x0`, the value indicates the level of support provided.

This means that software should use a test of the form:

```
if (field !=0 and field > value) {
    // do something that relies on the value of the feature
}
```

D12.1.3.4 Alternative ID scheme used for ID_AA64SMFR0_EL1 and ID_AA64FPFR0_EL1

Apart from the ID_AA64SMFR0_EL1.SMEver field, which is a 4-bit unsigned integer conforming to the standard scheme, software must treat the other fields in these registers as follows:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- A 1-bit field value where the bit is `0b0` indicates that the specified feature or instructions described by this field are not implemented.
- A 1-bit field value where the bit is `0b1` indicates that the specified feature or instructions described by this field are implemented.
- In ID_AA64SMFR0_EL1, a 4-bit field indicates whether a group of related SME instructions is implemented, with permitted values defined in the field description. Bits within such a field which only permit the value `0b0000` might be used to identify new instructions in a future version of SME, without changing the meaning of those bits that permit the value `0b0001`.

D12.2 General system control registers

This section lists the System registers in AArch64 that are not part of one of the other listed groups.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D12.2.1 ACTLR_EL1, Auxiliary Control Register (EL1)

The ACTLR_EL1 characteristics are:

Purpose

Provides IMPLEMENTATION DEFINED configuration and control options for execution at EL1 and EL0.

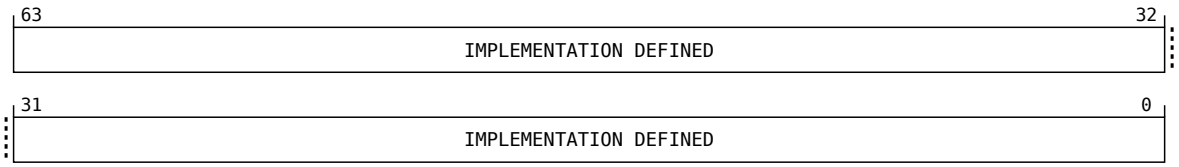
Configuration

There are no configuration notes.

Attributes

ACTLR_EL1 is a 64-bit register.

Field descriptions



IMPLEMENTATION DEFINED, bits [63:0]

IMPLEMENTATION DEFINED.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing ACTLR_EL1

Accesses to this register use the following encodings in the System register encoding space:

`MRS <Xt>, ACTLR_EL1`

op0	op1	CRn	CRm	op2
0b11	0b000	0b0001	0b0000	0b001

```
if PSTATE.EL == EL0 then
    UNDEFINED;
elsif PSTATE.EL == EL1 then
    if HCR_EL2.TACR == '1' then
        AArch64.SystemAccessTrap(EL2, 0x18);
    else
        X[t, 64] = ACTLR_EL1;
elsif PSTATE.EL == EL2 then
    X[t, 64] = ACTLR_EL1;
```

`MSR ACTLR_EL1, <Xt>`

op0	op1	CRn	CRm	op2
0b11	0b000	0b0001	0b0000	0b001

Non-Confidential

D12.2.2 ACTLR_EL2, Auxiliary Control Register (EL2)

The ACTLR_EL2 characteristics are:

Purpose

Provides IMPLEMENTATION DEFINED configuration and control options for EL2.

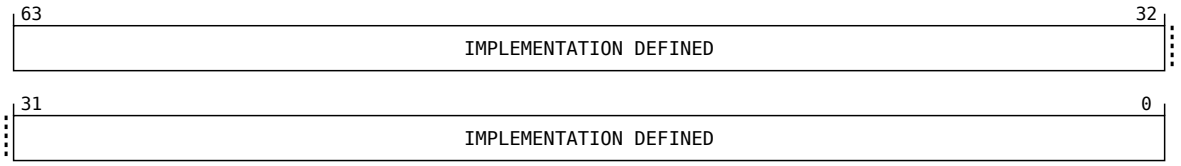
Configuration

There are no configuration notes.

Attributes

ACTLR_EL2 is a 64-bit register.

Field descriptions



IMPLEMENTATION DEFINED, bits [63:0]

IMPLEMENTATION DEFINED.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing ACTLR_EL2

Accesses to this register use the following encodings in the System register encoding space:

`MRS <Xt>, ACTLR_EL2`

op0	op1	CRn	CRm	op2
0b11	0b100	0b0001	0b0000	0b001

```
if PSTATE.EL == EL0 then
    UNDEFINED;
elsif PSTATE.EL == EL1 then
    UNDEFINED;
elsif PSTATE.EL == EL2 then
    X[t, 64] = ACTLR_EL2;
```

`MSR ACTLR_EL2, <Xt>`

op0	op1	CRn	CRm	op2
0b11	0b100	0b0001	0b0000	0b001

```
if PSTATE.EL == EL0 then
    UNDEFINED;
elsif PSTATE.EL == EL1 then
    UNDEFINED;
elsif PSTATE.EL == EL2 then
    ACTLR_EL2 = X[t, 64];
```

D12.2.3 AFSR0_EL1, Auxiliary Fault Status Register 0 (EL1)

The AFSR0_EL1 characteristics are:

Purpose

Provides additional IMPLEMENTATION DEFINED fault status information for exceptions taken to EL1.

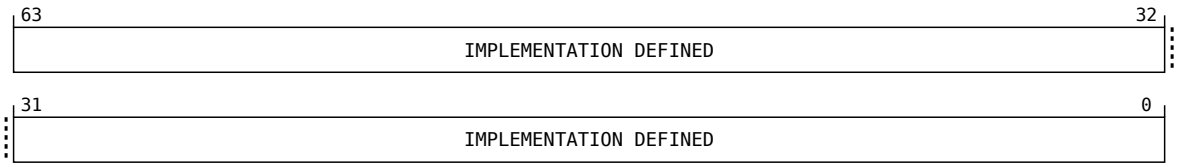
Configuration

There are no configuration notes.

Attributes

AFSR0_EL1 is a 64-bit register.

Field descriptions



IMPLEMENTATION DEFINED, bits [63:0]

IMPLEMENTATION DEFINED.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing AFSR0_EL1

Accesses to this register use the following encodings in the System register encoding space:

`MRS <Xt>, AFSR0_EL1`

op0	op1	CRn	CRm	op2
0b11	0b000	0b0101	0b0001	0b000

D12.2.5 AFSR1_EL1, Auxiliary Fault Status Register 1 (EL1)

The AFSR1_EL1 characteristics are:

Purpose

Provides additional IMPLEMENTATION DEFINED fault status information for exceptions taken to EL1.

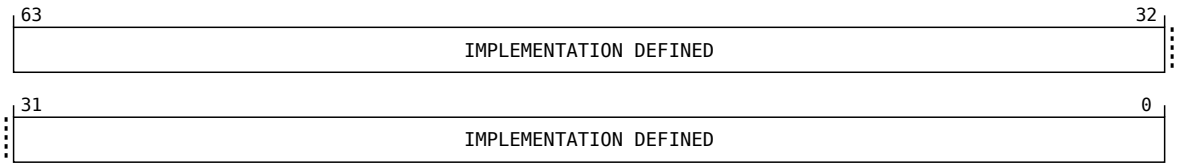
Configuration

There are no configuration notes.

Attributes

AFSR1_EL1 is a 64-bit register.

Field descriptions



IMPLEMENTATION DEFINED, bits [63:0]

IMPLEMENTATION DEFINED.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing AFSR1_EL1

Accesses to this register use the following encodings in the System register encoding space:

`MRS <Xt>, AFSR1_EL1`

op0	op1	CRn	CRm	op2
0b11	0b000	0b0101	0b0001	0b001

```
if PSTATE.EL == EL0 then

D12.2.7 AIDR_EL1, Auxiliary ID Register

The AIDR_EL1 characteristics are:

Purpose

Provides IMPLEMENTATION DEFINED identification information.

The value of this register must be interpreted in conjunction with the value of MIDR_EL1.

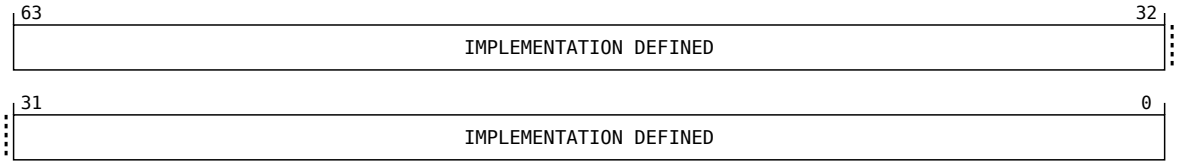
Configuration

There are no configuration notes.

Attributes

AIDR_EL1 is a 64-bit register.

Field descriptions



IMPLEMENTATION DEFINED, bits [63:0]

IMPLEMENTATION DEFINED.

Accessing AIDR_EL1

Accesses to this register use the following encodings in the System register encoding space:

`MRS <Xt>, AIDR_EL1`

op0	op1	CRn	CRm	op2
0b11	0b001	0b0000	0b0000	0b111

```

D12.2.8 AMAIR_EL1, Auxiliary Memory Attribute Indirection Register (EL1)

The AMAIR_EL1 characteristics are:

Purpose

Provides IMPLEMENTATION DEFINED memory attributes for the memory regions specified by MAIR_EL1.

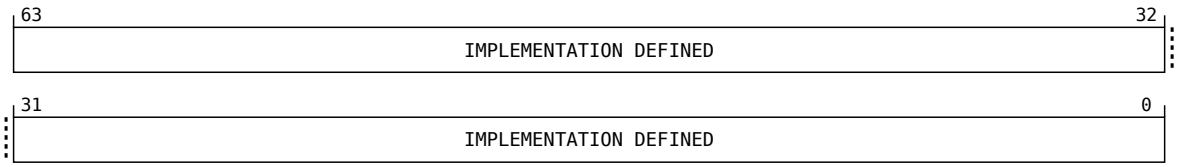
Configuration

There are no configuration notes.

Attributes

AMAIR_EL1 is a 64-bit register.

Field descriptions



AMAIR_EL1 is permitted to be cached in a TLB.

IMPLEMENTATION DEFINED, bits [63:0]

IMPLEMENTATION DEFINED.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing AMAIR_EL1

Accesses to this register use the following encodings in the System register encoding space:

D12.2.10 APDAKeyHi_EL1, Pointer Authentication Key A for Data (bits[127:64])

The APDAKeyHi_EL1 characteristics are:

Purpose

Holds bits[127:64] of key A used for authentication of data pointer values.

Note

The term APDAKey_EL1 is used to describe the concatenation of APDAKeyHi_EL1: APDAKeyLo_EL1.

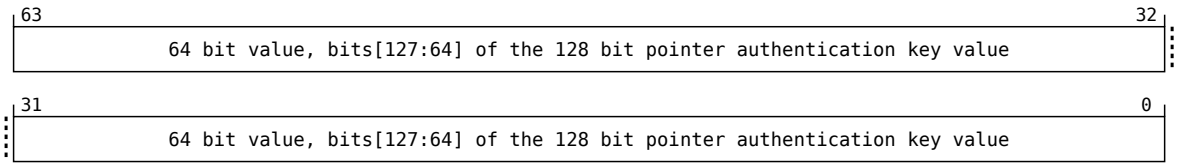
Configuration

This register is present only when FEAT_PAuth is implemented. Otherwise, direct accesses to APDAKeyHi_EL1 are UNDEFINED.

Attributes

APDAKeyHi_EL1 is a 64-bit register.

Field descriptions



APDAKeyHi, bits [63:0]

64 bit value, bits[127:64] of the 128 bit pointer authentication key value.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing APDAKeyHi_EL1

Accesses to this register use the following encodings in the System register encoding space:

`MRS <Xt>, APDAKeyHi_EL1`

op0	op1	CRn	CRm	op2
0b11	0b000	0b0010	0b0010	0b001

D12.2.11 APDAKeyLo_EL1, Pointer Authentication Key A for Data (bits[63:0])

The APDAKeyLo_EL1 characteristics are:

Purpose

Holds bits[63:0] of key A used for authentication of data pointer values.

Note

The term APDAKey_EL1 is used to describe the concatenation of APDAKeyHi_EL1: APDAKeyLo_EL1.

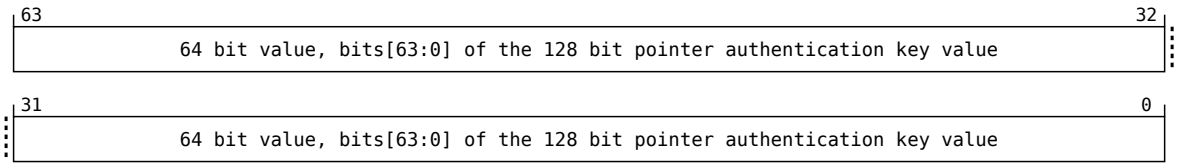
Configuration

This register is present only when FEAT_PAuth is implemented. Otherwise, direct accesses to APDAKeyLo_EL1 are UNDEFINED.

Attributes

APDAKeyLo_EL1 is a 64-bit register.

Field descriptions



APDAKeyLo, bits [63:0]

64 bit value, bits[63:0] of the 128 bit pointer authentication key value.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing APDAKeyLo_EL1

Accesses to this register use the following encodings in the System register encoding space:

`MRS <Xt>, APDAKeyLo_EL1`

op0	op1	CRn	CRm	op2
0b11	0b000	0b0010	0b0010	0b000

D12.2.20 CCSIDR2_EL1, Current Cache Size ID Register 2

The CCSIDR2_EL1 characteristics are:

Purpose

Provides the information about the architecture of the currently selected cache from bits[63:32] of CCSIDR_EL1.

Configuration

In an implementation which does not support AArch32 at EL1, it is IMPLEMENTATION DEFINED whether reading this register gives an UNKNOWN value or is UNDEFINED.

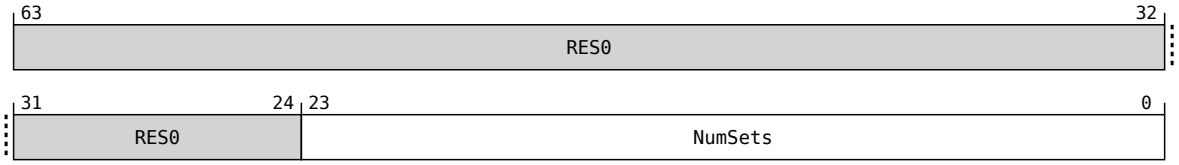
The implementation includes one CCSIDR2_EL1 for each cache that it can access. CSSELR_EL1 selects which Cache Size ID Register is accessible.

This register is present only when FEAT_CCIDX is implemented. Otherwise, direct accesses to CCSIDR2_EL1 are UNDEFINED.

Attributes

CCSIDR2_EL1 is a 64-bit register.

Field descriptions



Bits [63:24]

Reserved, RES0.

NumSets, bits [23:0]

(Number of sets in cache) - 1, therefore a value of 0 indicates 1 set in the cache. The number of sets does not have to be a power of 2.

Accessing CCSIDR2_EL1

If CSSELR_EL1.{TnD, Level, InD} is programmed to a cache level that is not implemented, then on a read of the CCSIDR2_EL1 the behavior is CONSTRAINED UNPREDICTABLE, and can be one of the following:

- The CCSIDR2_EL1 read is treated as NOP.
- The CCSIDR2_EL1 read is UNDEFINED. If FEAT_IDST is implemented, this is permitted to be reported with EC syndrome value 0x18.
- The CCSIDR2_EL1 read returns an UNKNOWN value.

Accesses to this register use the following encodings in the System register encoding space:

```
MRS <Xt>, CCSIDR2_EL1
```

op0	op1	CRn	CRm	op2
0b11	0b001	0b0000	0b0000	0b010

```
if !IsFeatureImplemented(FEAT_CCIDX) then
    UnimplementedIDRegister();

D12.2.21 CCSIDR_EL1, Current Cache Size ID Register

The CCSIDR_EL1 characteristics are:

Purpose

Provides information about the architecture of the currently selected cache.

Configuration

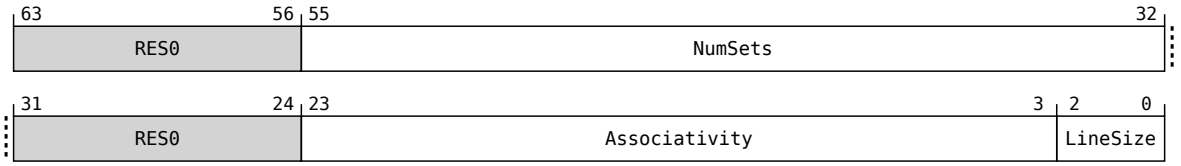
The implementation includes one CCSIDR_EL1 for each cache that it can access. CSSELR_EL1 selects which Cache Size ID Register is accessible.

Attributes

CCSIDR_EL1 is a 64-bit register.

Field descriptions

When FEAT_CCIDX is implemented:



Note

The parameters NumSets, Associativity, and LineSize in these registers define the architecturally visible parameters that are required for the cache maintenance by Set/Way instructions. They are not guaranteed to represent the actual microarchitectural features of a design. You cannot make any inference about the actual sizes of caches based on these parameters.

Bits [63:56]

Reserved, RES0.

NumSets, bits [55:32]

(Number of sets in cache) - 1, therefore a value of 0 indicates 1 set in the cache. The number of sets does not have to be a power of 2.

Bits [31:24]

Reserved, RES0.

Associativity, bits [23:3]

(Associativity of cache) - 1, therefore a value of 0 indicates an associativity of 1. The associativity does not have to be a power of 2.

LineSize, bits [2:0]

(Log_2(Number of bytes in cache line)) - 4. For example:

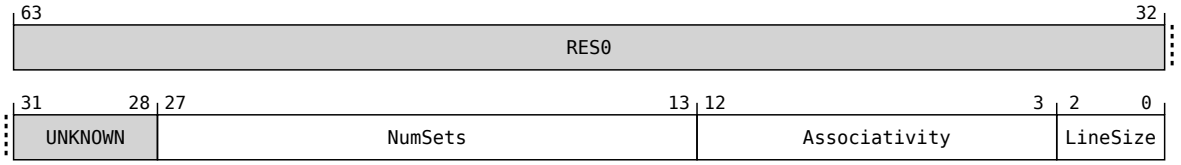
- For a line length of 16 bytes: $Log_2(16) = 4$, LineSize entry = 0. This is the minimum line length.
- For a line length of 32 bytes: $Log_2(32) = 5$, LineSize entry = 1.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

The C++ 17 specification has two defined parameters relating to the granularity of memory that does not interfere. For generic software and tools, Arm will set the hardware_destructive_interference_size parameter to 256 bytes and the hardware_constructive_interference_size parameter to 64 bytes.

Otherwise:



Note

The parameters NumSets, Associativity, and LineSize in these registers define the architecturally visible parameters that are required for the cache maintenance by Set/Way instructions. They are not guaranteed to represent the actual microarchitectural features of a design. You cannot make any inference about the actual sizes of caches based on these parameters.

Bits [63:32]

Reserved, RES0.

Bits [31:28]

Reserved, UNKNOWN.

NumSets, bits [27:13]

(Number of sets in cache) - 1, therefore a value of 0 indicates 1 set in the cache. The number of sets does not have to be a power of 2.

Associativity, bits [12:3]

(Associativity of cache) - 1, therefore a value of 0 indicates an associativity of 1. The associativity does not have to be a power of 2.

LineSize, bits [2:0]

(Log_2(Number of bytes in cache line)) - 4. For example:

- For a line length of 16 bytes: $Log_2(16) = 4$, LineSize entry = 0. This is the minimum line length.
- For a line length of 32 bytes: $Log_2(32) = 5$, LineSize entry = 1.

Note

The C++ 17 specification has two defined parameters relating to the granularity of memory that does not interfere. For generic software and tools, Arm will set the hardware_destructive_interference_size parameter to 256 bytes and the hardware_constructive_interference_size parameter to 64 bytes.

Accessing CCSIDR_EL1

If CSSELR_EL1.{TnD, Level, InD} is programmed to a cache level that is not implemented, then on a read of the CCSIDR_EL1 the behavior is CONSTRAINED UNPREDICTABLE, and can be one of the following:

- The CCSIDR_EL1 read is treated as NOP.
- The CCSIDR_EL1 read is UNDEFINED. If FEAT_IDST is implemented, this is permitted to be reported with EC syndrome value `0x18`.
- The CCSIDR_EL1 read returns an UNKNOWN value.

Accesses to this register use the following encodings in the System register encoding space:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

```
MRS <Xt>, CCSIDR_EL1
```

op0	op1	CRn	CRm	op2
0b11	0b001	0b0000	0b0000	0b000

```
if PSTATE.EL == EL0 then
    if IsFeatureImplemented(FEAT_IDST) then
        if HCR_EL2.TGE == '1' then
            AArch64.SystemAccessTrap(EL2, 0x18);
        else
            AArch64.SystemAccessTrap(EL1, 0x18);
    else
        UNDEFINED;
elsif PSTATE.EL == EL1 then
    if HCR_EL2.TID2 == '1' then
        AArch64.SystemAccessTrap(EL2, 0x18);
    else
        X[t, 64] = CCSIDR_EL1;
elsif PSTATE.EL == EL2 then
    X[t, 64] = CCSIDR_EL1;
```

D12.2.22 CLIDR_EL1, Cache Level ID Register

The CLIDR_EL1 characteristics are:

Purpose

Identifies the type of cache, or caches, that are implemented at each level and can be managed using the architected cache maintenance instructions that operate by set/way, up to a maximum of seven levels. Also identifies the Level of Coherence (LoC) and Level of Unification (LoU) for the cache hierarchy.

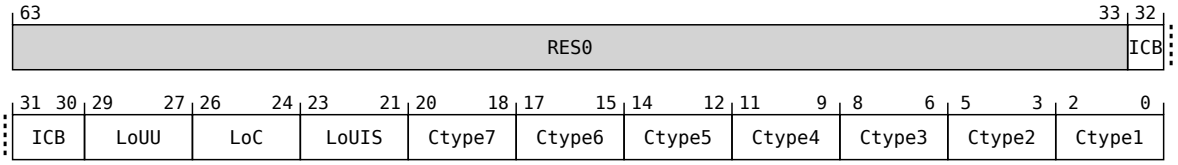
Configuration

There are no configuration notes.

Attributes

CLIDR_EL1 is a 64-bit register.

Field descriptions



Bits [63:33]

Reserved, RES0.

ICB, bits [32:30]

Inner cache boundary. This field indicates the boundary for caching Inner Cacheable memory regions.

The value of this field is an IMPLEMENTATION DEFINED choice of:

ICB	Meaning
0b000	Not disclosed by this mechanism.
0b001	L1 cache is the highest Inner Cacheable level.
0b010	L2 cache is the highest Inner Cacheable level.
0b011	L3 cache is the highest Inner Cacheable level.
0b100	L4 cache is the highest Inner Cacheable level.
0b101	L5 cache is the highest Inner Cacheable level.
0b110	L6 cache is the highest Inner Cacheable level.
0b111	L7 cache is the highest Inner Cacheable level.

Access to this field is RO.

LoUU, bits [29:27]

Level of Unification Uniprocessor for the cache hierarchy.

For a description of the values of this field, see Terminology for Clean, Invalidate, and Clean and Invalidate instructions.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

This field does not describe the requirements for instruction cache invalidation. See CTR_EL0.DIC.

Note

When FEAT_S2FWB is implemented, the architecture requires that this field is zero so that no levels of data cache need to be cleaned in order to manage coherency with instruction fetches.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

LoC, bits [26:24]

Level of Coherence for the cache hierarchy.

For a description of the values of this field, see Terminology for Clean, Invalidate, and Clean and Invalidate instructions.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

LoUIS, bits [23:21]

Level of Unification Inner Shareable for the cache hierarchy.

For a description of the values of this field, see Terminology for Clean, Invalidate, and Clean and Invalidate instructions.

Note

This field does not describe the requirements for instruction cache invalidation. See CTR_EL0.DIC.

Note

When FEAT_S2FWB is implemented, the architecture requires that this field is zero so that no levels of data cache need to be cleaned in order to manage coherency with instruction fetches.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

Ctype<n> , bits [3(n-1)+2:3(n-1)], for n = 7 to 1

Cache Type fields. Indicate the type of cache that is implemented and can be managed using the architected cache maintenance instructions that operate by set/way at each level, from Level 1 up to a maximum of seven levels of cache hierarchy. Possible values of each field are:

Ctype<n>	Meaning
0b000	No cache.
0b001	Instruction cache only.
0b010	Data cache only.
0b011	Separate instruction and data caches.
0b100	Unified cache.

All other values are reserved.

If software reads the Cache Type fields from Ctype1 upwards, once it has seen a value of 0b000, no caches that can be managed using the architected cache maintenance instructions that operate by set/way exist at further-out levels of the hierarchy. So, for example, if Ctype3 is the first Cache Type field with a value of 0b000, the values of Ctype4 to Ctype7 must be ignored.

D12.2.23 CONTEXTIDR_EL1, Context ID Register (EL1)

The CONTEXTIDR_EL1 characteristics are:

Purpose

Identifies the current Process Identifier.

The value of the whole of this register is called the Context ID and is used by:

- The debug logic, for Linked and Unlinked Context ID matching.
- The trace logic, to identify the current process.

The significance of this register is for debug and trace use only.

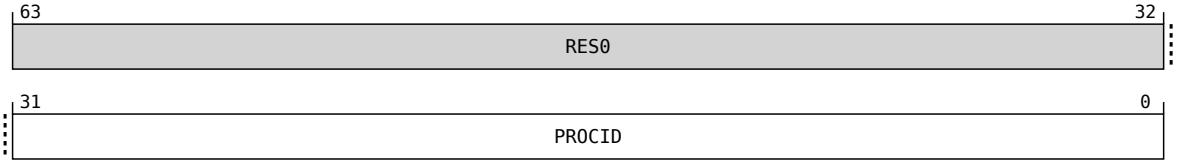
Configuration

There are no configuration notes.

Attributes

CONTEXTIDR_EL1 is a 64-bit register.

Field descriptions



Bits [63:32]

Reserved, RES0.

PROCID, bits [31:0]

Process Identifier. This field must be programmed with a unique value that identifies the current process.

Note

In AArch64 state, CONTEXTIDR_EL1 is independent of the ASID, and for the EL1&0 translation regime either TTBR0_EL1 or TTBR1_EL1 holds the ASID.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing CONTEXTIDR_EL1

Accesses to this register use the following encodings in the System register encoding space:

```
MRS <Xt>, CONTEXTIDR_EL1
```

op0	op1	CRn	CRm	op2

D12.2.24 CONTEXTIDR_EL2, Context ID Register (EL2)

The CONTEXTIDR_EL2 characteristics are:

Purpose

Identifies the current Process Identifier for EL2.

The value of the whole of this register is called the Context ID and is used by:

- The debug logic, for Linked and Unlinked Context ID matching.
- The trace logic, to identify the current process.

The significance of this register is for debug and trace use only.

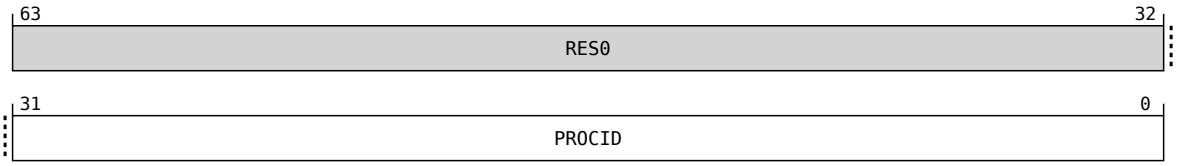
Configuration

This register is present only when FEAT_Debugv8p1 is implemented. Otherwise, direct accesses to CONTEXTIDR_EL2 are UNDEFINED.

Attributes

CONTEXTIDR_EL2 is a 64-bit register.

Field descriptions



Bits [63:32]

Reserved, RES0.

PROCID, bits [31:0]

Process Identifier. This field must be programmed with a unique value that identifies the current process.

D12.2.25 CPACR_EL1, Architectural Feature Access Control Register

The CPACR_EL1 characteristics are:

Purpose

Controls access to trace, and Advanced SIMD and floating-point functionality.

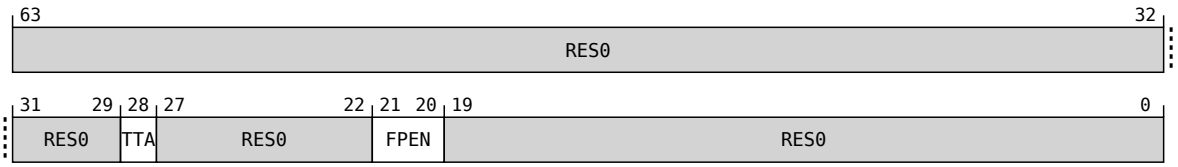
Configuration

There are no configuration notes.

Attributes

CPACR_EL1 is a 64-bit register.

Field descriptions



Bits [63:29]

Reserved, RES0.

TTA, bit [28]

When System register access to the trace unit registers is implemented:

Traps EL0 and EL1 System register accesses to all implemented trace registers from both Execution states to EL1, or to EL2 when it is implemented and enabled in the current Security state and HCR_EL2.TGE is 1, as follows:

- In AArch64 state, accesses to trace registers are trapped, reported using EC syndrome value `0x18`.

TTA	Meaning
`0b0`	This control does not cause any instructions to be trapped.
`0b1`	This control causes EL0 and EL1 System register accesses to all implemented trace registers to be trapped.

Note

- The ETMv4 architecture does not permit EL0 to access the trace registers. If the trace unit implements FEAT_ETMv4, EL0 accesses to the trace registers are UNDEFINED, and any resulting exception is higher priority than an exception that would be generated because the value of CPACR_EL1.TTA is 1.
- The Armv8-A architecture does not provide traps on trace register accesses through the optional memory-mapped interface.

System register accesses to the trace registers can have side-effects. When a System register access is trapped, any side-effects that are normally associated with the access do not occur before the exception is taken.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Otherwise:

Reserved, RES0.

Bits [27:22]

Reserved, RES0.

FPEN, bits [21:20]

Traps execution at EL1 and EL0 of instructions that access the Advanced SIMD and floating-point registers from both Execution states to EL1, reported using EC syndrome value 0x07, or to EL2 reported using EC syndrome value 0x00 when EL2 is implemented and enabled in the current Security state and HCR_EL2.TGE is 1, as follows:

- In AArch64 state, accesses to FPCR, FPSR, and any of the SIMD and floating-point registers V0-V31, including their views as D0-D31 registers or S0-31 registers.

FPEN	Meaning
0b00	This control causes execution of these instructions at EL1 and EL0 to be trapped.
0b01	This control causes execution of these instructions at EL0 to be trapped, but does not cause execution of any instructions at EL1 to be trapped.
0b10	This control causes execution of these instructions at EL1 and EL0 to be trapped.
0b11	This control does not cause execution of any instructions to be trapped.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [19:0]

Reserved, RES0.

Accessing CPACR_EL1

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, CPACR_EL1

op0	op1	CRn	CRm	op2
0b11	0b000	0b0001	0b0000	0b010

```
if PSTATE.EL == EL0 then
    UNDEFINED;
elsif PSTATE.EL == EL1 then
    if CPTR_EL2.TCPAC == '1' then
        AArch64.SystemAccessTrap(EL2, 0x18);
    else
        X[t, 64] = CPACR_EL1;
elsif PSTATE.EL == EL2 then
    X[t, 64] = CPACR_EL1;
```

D12.2.26 CPTR_EL2, Architectural Feature Trap Register (EL2)

The CPTR_EL2 characteristics are:

Purpose

Controls trapping to EL2 of accesses to CPACR, CPACR_EL1, trace, Activity Monitor, and Advanced SIMD and floating-point functionality.

Configuration

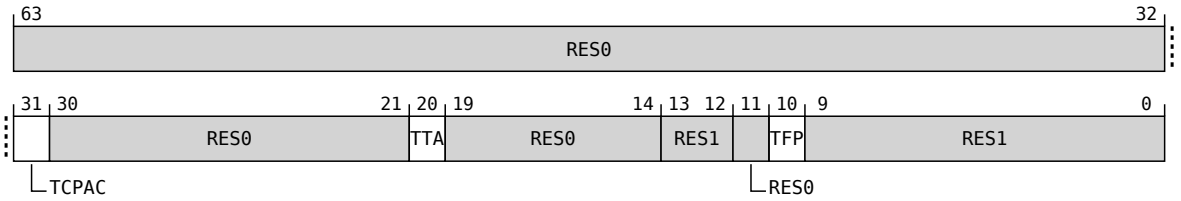
There are no configuration notes.

Attributes

CPTR_EL2 is a 64-bit register.

Field descriptions

!ELIsInHost(EL2)



This format applies in all Armv8.0 implementations.

Bits [63:32]

Reserved, RES0.

TCPAC, bit [31]

In AArch64 state, traps accesses to CPACR_EL1 from EL1 to EL2, when EL2 is enabled in the current Security state. The exception is reported using EC syndrome value `0x18`.

TCPAC	Meaning
`0b0`	This control does not cause any instructions to be trapped.
`0b1`	EL1 accesses to the following registers are trapped to EL2, when EL2 is enabled in the current Security state: • CPACR_EL1.

When HCR_EL2.TGE is 1, this control does not cause any instructions to be trapped.

Note

CPACR_EL1 and CPACR are not accessible at EL0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [30:21]

Reserved, RES0.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

TTA, bit [20]

When System register access to the trace unit registers is implemented:

Traps System register accesses to all implemented trace registers from both Execution states to EL2, when EL2 is enabled in the current Security state, as follows:

- In AArch64 state, accesses to trace registers with op0=2, op1=1, and CRn<0b1000 are trapped to EL2, reported using EC syndrome value 0x18.

TTA	Meaning
0b0	This control does not cause any instructions to be trapped.
0b1	Any attempt at EL0, EL1, or EL2, to execute a System register access to an implemented trace register is trapped to EL2, when EL2 is enabled in the current Security state, unless it is trapped by one of the following controls: • CPACR_EL1.TTA.

Note

- FEAT_ETMv4 and FEAT_ETE do not permit EL0 to access the trace registers. EL0 accesses to the trace System registers are UNDEFINED, and any resulting exception is higher priority than an exception that would be generated because the value of CPTR_EL2.TTA is 1.
- EL2 does not provide traps on trace register accesses through the optional memory-mapped interface.

System register accesses to the trace registers can have side-effects. When a System register access is trapped, any side-effects that are normally associated with the access do not occur before the exception is taken.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bits [19:14]

Reserved, RES0.

Bits [13:12]

Reserved, RES1.

Bit [11]

Reserved, RES0.

TFP, bit [10]

Traps execution of instructions which access the Advanced SIMD and floating-point functionality, from both Execution states to EL2, when EL2 is enabled in the current Security state, as follows:

- In AArch64 state, accesses to the following registers are trapped to EL2, reported using EC syndrome value 0x07:
  - FPCR, FPSR, and any of the SIMD and floating-point registers V0-V31, including their views as D0-D31 registers or S0-31 registers.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

TFP	Meaning
0b0	This control does not cause execution of any instructions to be trapped.
0b1	This control causes execution of these instructions at EL2, EL1, and EL0 to be trapped.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [9:0]

Reserved, RES1.

Accessing CPTR_EL2

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, CPTR_EL2

op0	op1	CRn	CRm	op2

D12.2.27 CSSELR_EL1, Cache Size Selection Register

The CSSELR_EL1 characteristics are:

Purpose

Selects the current Cache Size ID Register, CCSIDR_EL1, by specifying the required cache level and the cache type (either instruction or data cache).

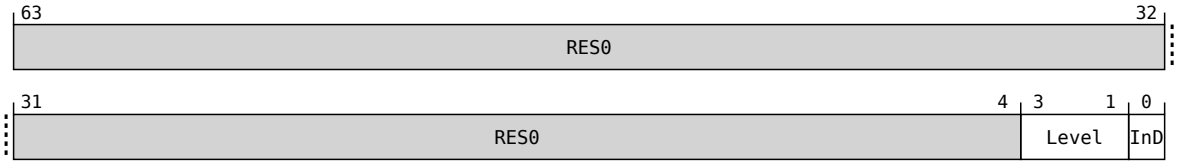
Configuration

There are no configuration notes.

Attributes

CSSELR_EL1 is a 64-bit register.

Field descriptions



Bits [63:4]

Reserved, RES0.

Level, bits [3:1]

Cache level of required cache.

Level	Meaning
0b000	Level 1 cache.
0b001	Level 2 cache.
0b010	Level 3 cache.
0b011	Level 4 cache.
0b100	Level 5 cache.
0b101	Level 6 cache.
0b110	Level 7 cache.

All other values are reserved.

If CSSELR_EL1.{Level, InD} is programmed to a cache level that is not implemented, then the value for this field on a read of CSSELR_EL1 is UNKNOWN.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

InD, bit [0]

Instruction not Data bit.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

InD	Meaning
0b0	Data or unified cache.
0b1	Instruction cache.

If CSSELR_EL1.{Level, InD} is programmed to a cache level that is not implemented, then a read of CSSELR_EL1 is CONSTRAINED UNPREDICTABLE, and returns UNKNOWN values for CSSELR_EL1.{Level, InD}.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing CSSELR_EL1

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, CSSELR_EL1

op0	op1	CRn	CRm	op2

D12.2.28 CTR_EL0, Cache Type Register

The CTR_EL0 characteristics are:

Purpose

Provides information about the architecture of the caches.

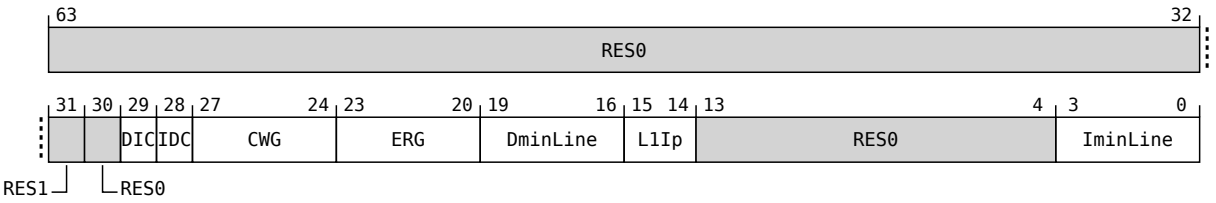
Configuration

There are no configuration notes.

Attributes

CTR_EL0 is a 64-bit register.

Field descriptions



Bits [63:32]

Reserved, RES0.

Bit [31]

Reserved, RES1.

Bit [30]

Reserved, RES0.

DIC, bit [29]

Instruction cache invalidation requirements for data to instruction coherence.

The value of this field is an IMPLEMENTATION DEFINED choice of:

DIC	Meaning
0b0	Instruction cache invalidation to the Point of Unification is required for data to instruction coherence.
0b1	Instruction cache invalidation to the Point of Unification is not required for data to instruction coherence.

All PEs in the same Inner Shareable shareability domain must have a common value of this field.

Note

If CTR_EL0.DIC is 1, instruction cache maintenance is not required after overwriting instructions, including for different VA aliases of the affected Locations, regardless of the value of CTR_EL0.L1Ip.

Access to this field is RO.

IDC, bit [28]

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Data cache clean requirements for instruction to data coherence. The meaning of this bit is:

The value of this field is an IMPLEMENTATION DEFINED choice of:

IDC	Meaning
0b0	Data cache clean to the Point of Unification is required for instruction to data coherence, unless CLIDR_EL1.LoC == 0b000 or (CLIDR_EL1.LoUIS == 0b000 and CLIDR_EL1.LoUU == 0b000).
0b1	Data cache clean to the Point of Unification is not required for instruction to data coherence.

If CTR_EL0.DIC is 1 then the value reported in this field must also be 1.

The Effective value of IDC is 1 if any of the following are true:

- CTR_EL0.IDC == 1.
- CLIDR_EL1.LoC == 0b000.
- CLIDR_EL1.LoUIS == 0b000 and CLIDR_EL1.LoUU == 0b000.

All PEs in the same Inner Shareable shareability domain must have a common Effective value of IDC.

Access to this field is RO.

CWG, bits [27:24]

Cache writeback granule. Log_2 of the number of words of the maximum size of memory that can be overwritten as a result of the eviction of a cache entry that has had a memory location in it modified.

A value of 0b0000 indicates that this register does not provide Cache writeback granule information and either:

- The architectural maximum of 512 words (2KB) must be assumed.
- The Cache writeback granule can be determined from maximum cache line size encoded in the Cache Size ID Registers.

Values greater than 0b1001 are reserved.

Arm recommends that an implementation that does not support cache write-back implements this field as 0b0001. This applies, for example, to an implementation that supports only write-through caches.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

ERG, bits [23:20]

Exclusives reservation granule. Log_2 of the number of words of the maximum size of the reservation granule that has been implemented for the Load-Exclusive and Store-Exclusive instructions.

The use of the value 0b0000 is deprecated.

The value 0b0001 and values greater than 0b1001 are reserved.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

DminLine, bits [19:16]

Log_2 of the number of words in the smallest cache line of all the data caches and unified caches that are controlled by the PE.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

L1Ip, bits [15:14]

Level 1 instruction cache policy. Indicates the indexing and tagging policy for the L1 instruction cache.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The value of this field is an IMPLEMENTATION DEFINED choice of:

L1Ip	Meaning
0b00	Reserved.
0b01	ASID-tagged Virtual Index, Virtual Tag (AIVIVT).
0b10	Virtual Index, Physical Tag (VIPT).
0b11	Physical Index, Physical Tag (PIPT).

From Armv8.0, the value 0b01 is reserved.

Access to this field is RO.

Bits [13:4]

Reserved, RES0.

IminLine, bits [3:0]

Log_2 of the number of words in the smallest cache line of all the instruction caches that are controlled by the PE.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

Accessing CTR_EL0

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, CTR_EL0

op0	op1	CRn	CRm	op2
0b11	0b011	0b0000	0b0000	0b001

```
if PSTATE.EL == EL0 then
    if !ELIsInHost(EL0) && SCTLR_EL1.UCT == '0' then
        if HCR_EL2.TGE == '1' then
            AArch64.SystemAccessTrap(EL2, 0x18);
        else
            AArch64.SystemAccessTrap(EL1, 0x18);
    elsif !ELIsInHost(EL0) && HCR_EL2.TID2 == '1' then
        AArch64.SystemAccessTrap(EL2, 0x18);
    else
        X[t, 64] = CTR_EL0;
elsif PSTATE.EL == EL1 then
    if HCR_EL2.TID2 == '1' then
        AArch64.SystemAccessTrap(EL2, 0x18);
    else
        X[t, 64] = CTR_EL0;
elsif PSTATE.EL == EL2 then
    X[t, 64] = CTR_EL0;
```

D12.2.29 DCZID_EL0, Data Cache Zero ID Register

The DCZID_EL0 characteristics are:

Purpose

Indicates the block size that is written with byte values of 0 by the DC ZVA (Data Cache Zero by Address) System instruction.

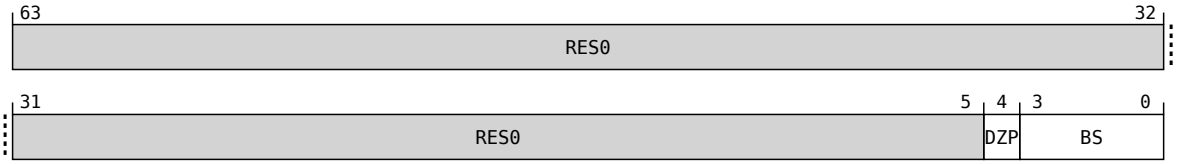
Configuration

There are no configuration notes.

Attributes

DCZID_EL0 is a 64-bit register.

Field descriptions



Bits [63:5]

Reserved, RES0.

DZP, bit [4]

Data Zero Prohibited. This field indicates whether use of DC ZVA instructions is permitted or prohibited.

DZP	Meaning
0b0	Instructions are permitted.
0b1	Instructions are prohibited.

The value read from this field is governed by the current Exception level and the values of the following fields:

- The Effective value of HCR_EL2.TDZ.
- When the Effective value of HCR_EL2.{E2H, TGE} != '11', SCTLR_EL1.DZE.

BS, bits [3:0]

Log_2 of the block size in words written by a DC ZVA instruction. The maximum size supported is 2KB, indicated by value 0b1001.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

Accessing DCZID_EL0

Accesses to this register use the following encodings in the System register encoding space:

```
MRS <Xt>, DCZID_EL0
```

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

op0	op1	CRn	CRm	op2
0b11	0b011	0b0000	0b0000	0b111

```
if PSTATE.EL == EL0 then
    X[t, 64] = DCZID_EL0;
elsif PSTATE.EL == EL1 then
    X[t, 64] = DCZID_EL0;
elsif PSTATE.EL == EL2 then
    X[t, 64] = DCZID_EL0;
```

Non-Confidential

D12.2.30 ESR_EL1, Exception Syndrome Register (EL1)

The ESR_EL1 characteristics are:

Purpose

Holds syndrome information for an exception taken to EL1.

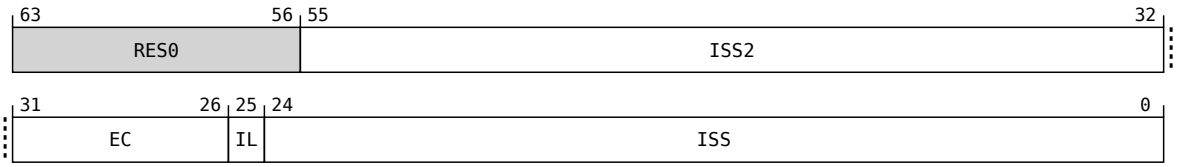
Configuration

There are no configuration notes.

Attributes

ESR_EL1 is a 64-bit register.

Field descriptions



ESR_EL1 is made UNKNOWN as a result of an exception return from EL1.

When an UNPREDICTABLE instruction is treated as UNDEFINED, and the exception is taken to EL1, the value of ESR_EL1 is UNKNOWN. The value written to ESR_EL1 must be consistent with a value that could be created as a result of an exception from the same Exception level that generated the exception as a result of a situation that is not UNPREDICTABLE at that Exception level, in order to avoid the possibility of a privilege violation.

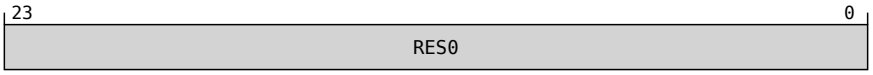
Bits [63:56]

Reserved, RES0.

ISS2, bits [55:32]

ISS2 encoding for an exception, the bit assignments are:

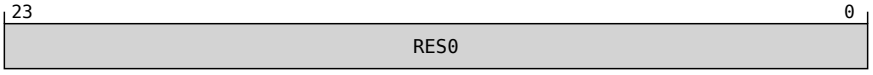
ISS2 encoding for an exception from a Data Abort



Bits [23:0]

Reserved, RES0.

ISS2 encoding for an exception from an Instruction Abort

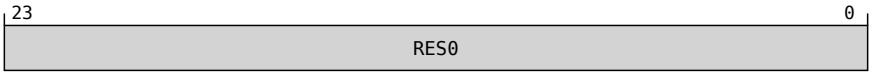


Bits [23:0]

Reserved, RES0.

ISS2 encoding for an exception from a Watchpoint exception

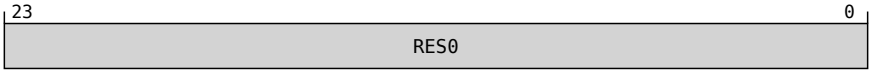
Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential



Bits [23:0]

Reserved, RES0.

ISS2 encoding for all other exceptions



Bits [23:0]

Reserved, RES0.

EC, bits [31:26]

Exception Class. Indicates the reason for the exception that this register holds information about.

For each EC value, the table references a subsection that gives information about:

- The cause of the exception, for example the configuration required to enable the trap.
- The encoding of the associated ISS.

Possible values of the EC field are:

EC	Meaning	ISS	ISS2	Applies when
0b000000	Unknown reason.	ISS encoding for exceptions with an unknown reason	ISS2 encoding for all other exceptions	
0b000001	Trapped WF* instruction execution. Conditional WF* instructions that fail their condition code check do not cause an exception.	ISS encoding for an exception from a WF* instruction	ISS2 encoding for all other exceptions	
0b000111	Access to Advanced SIMD or floating-point functionality trapped by CPACR_EL1.FPEN, CPTR_EL2.FPEN, CPTR_EL2.TFP, or CPTR_EL3.TFP control. Excludes exceptions resulting from CPACR_EL1 when the value of HCR_EL2.TGE is 1, or because Advanced SIMD and floating-point are not implemented. These are reported with EC value 0b000000.	ISS encoding for an exception from an access to a register or instruction resulting from the FPEN and TFP traps	ISS2 encoding for all other exceptions	
0b001001	Trapped use of a Pointer authentication instruction.	ISS encoding for an exception from a trapped Pointer Authentication instruction	ISS2 encoding for all other exceptions	FEAT_PAuth is implemented
0b001110	Illegal Execution state.	ISS encoding for an exception from an Illegal Execution state, or a PC or SP alignment fault	ISS2 encoding for all other exceptions	

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

EC	Meaning	ISS	ISS2	Applies when
0b010101	SVC instruction execution in AArch64 state.	ISS encoding for an exception from HVC or SVC instruction execution	ISS2 encoding for all other exceptions	
0b011000	Trapped MSR, MRS or System instruction execution in AArch64 state, that is not reported using EC values 0b000000, 0b000001, or 0b000111. This includes all instructions that cause exceptions that are part of the encoding space defined in 'System instruction class encoding overview', except for those exceptions reported using EC values 0b000000, 0b000001, or 0b000111.	ISS encoding for an exception from MSR, MRS, or System instruction execution in AArch64 state	ISS2 encoding for all other exceptions	
0b011100	Exception from a PAC Fail	ISS encoding for a PAC Fail exception	ISS2 encoding for all other exceptions	FEAT_FPAC is implemented
0b100000	Instruction Abort from a lower Exception level. Used for MMU and MPU faults generated by instruction accesses and synchronous External aborts, including synchronous parity or ECC errors. Not used for debug-related exceptions.	ISS encoding for an exception from an Instruction Abort	ISS2 encoding for an exception from an Instruction Abort	
0b100001	Instruction Abort taken without a change in Exception level. Used for MMU and MPU faults generated by instruction accesses and synchronous External aborts, including synchronous parity or ECC errors. Not used for debug-related exceptions.	ISS encoding for an exception from an Instruction Abort	ISS2 encoding for an exception from an Instruction Abort	
0b100010	PC alignment fault exception.	ISS encoding for an exception from an Illegal Execution state, or a PC or SP alignment fault	ISS2 encoding for all other exceptions	
0b100100	Data Abort exception from a lower Exception level. Used for MMU and MPU faults generated by data accesses, alignment faults other than those caused by Stack Pointer misalignment, and synchronous External aborts, including synchronous parity or ECC errors. Not used for debug-related exceptions.	ISS encoding for an exception from a Data Abort	ISS2 encoding for an exception from a Data Abort	

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

EC	Meaning	ISS	ISS2	Applies when
0b100101	Data Abort exception taken without a change in Exception level. Used for MMU and MPU faults generated by instruction accesses and synchronous External aborts, including synchronous parity or ECC errors. Not used for debug-related exceptions.	ISS encoding for an exception from a Data Abort	ISS2 encoding for an exception from a Data Abort	
0b100110	SP alignment fault exception.	ISS encoding for an exception from an Illegal Execution state, or a PC or SP alignment fault	ISS2 encoding for all other exceptions	
0b101100	Trapped floating-point exception taken from AArch64 state. This EC value is valid if the implementation supports trapping of floating-point exceptions, otherwise it is reserved. Whether a floating-point implementation supports trapping of floating-point exceptions is IMPLEMENTATION DEFINED.	ISS encoding for an exception from a trapped floating-point exception	ISS2 encoding for all other exceptions	
0b101111	SError exception.	ISS encoding for an SError exception	ISS2 encoding for all other exceptions	
0b110000	Breakpoint exception from a lower Exception level.	ISS encoding for an exception from a Breakpoint or Vector Catch debug exception	ISS2 encoding for all other exceptions	
0b110001	Breakpoint exception taken without a change in Exception level.	ISS encoding for an exception from a Breakpoint or Vector Catch debug exception	ISS2 encoding for all other exceptions	
0b110010	Software Step exception from a lower Exception level.	ISS encoding for an exception from a Software Step exception	ISS2 encoding for all other exceptions	
0b110011	Software Step exception taken without a change in Exception level.	ISS encoding for an exception from a Software Step exception	ISS2 encoding for all other exceptions	
0b110100	Watchpoint exception from a lower Exception level.	ISS encoding for an exception from a Watchpoint exception	ISS2 encoding for an exception from a Watchpoint exception	
0b110101	Watchpoint exception taken without a change in Exception level.	ISS encoding for an exception from a Watchpoint exception	ISS2 encoding for an exception from a Watchpoint exception	

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

0b111100	BRK instruction execution in AArch64 state.	ISS encoding for an exception from execution of a Breakpoint instruction	ISS2 encoding for all other exceptions

All other EC values are reserved by Arm, and:

- Unused values in the range 0b000000 - 0b101100 (0x00 - 0x2C) are reserved for future use for synchronous exceptions.
- Unused values in the range 0b101101 - 0b111111 (0x2D - 0x3F) are reserved for future use, and might be used for synchronous or asynchronous exceptions.

The effect of programming this field to a reserved value is that behavior is CONSTRAINED UNPREDICTABLE.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

IL, bit [25]

Instruction Length for synchronous exceptions. Possible values of this bit are:

IL	Meaning
0b0	16-bit instruction trapped.

0b1	32-bit instruction trapped. This value is also used when the exception is one of the following:
	• An SError exception.
	• An Instruction Abort exception.
	• A PC alignment fault exception.
	• An SP alignment fault exception.
	• A Data Abort exception for which the value of the ISV bit is 0.
	• An Illegal Execution state exception.
	• Any debug exception except for Breakpoint instruction exceptions. For Breakpoint instruction exceptions, this bit has its standard meaning:
	  • 0b0: 16-bit T32 BKPT instruction.
	  • 0b1: 32-bit A32 BKPT instruction or A64 BRK instruction.
	• An exception reported using EC value 0b000000.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

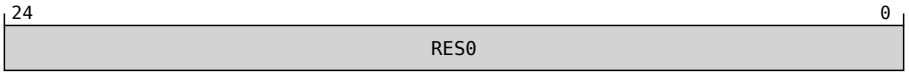
ISS, bits [24:0]

Instruction Specific Syndrome. Architecturally, this field can be defined independently for each defined Exception class. However, in practice, some ISS encodings are used for more than one Exception class.

Typically, an ISS encoding has a number of subfields. When an ISS subfield holds a register number, the value returned in that field is the AArch64 view of the register number.

ISS encoding for exceptions with an unknown reason

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential



Bits [24:0]

Reserved, RES0.

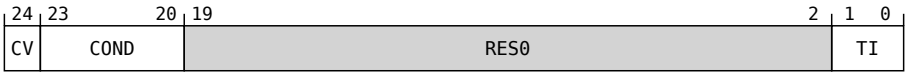
Additional Information for ISS encoding for exceptions with an unknown reason

When an exception is reported using this EC value, the IL field is set to 1.

This EC value is used for all exceptions that are not covered by any other EC value. This includes exceptions that are generated in the following situations:

- The attempted execution of an instruction bit pattern that has no allocated instruction or that is not accessible at the current Exception level and Security state, including:
  - A read access using a System register pattern that is not allocated for reads or that does not permit reads at the current Exception level and Security state.
  - A write access using a System register pattern that is not allocated for writes or that does not permit writes at the current Exception level and Security state.
  - Instruction encodings that are unallocated.
  - Instruction encodings for instructions or System registers that are not implemented in the implementation.
- In Debug state, the attempted execution of an instruction bit pattern that is not accessible in Debug state.
- In Non-debug state, the attempted execution of an instruction bit pattern that is not accessible in Non-debug state.
- In an implementation that does not include Advanced SIMD and floating-point functionality, an attempted access to Advanced SIMD or floating-point functionality under conditions where that access would be permitted if that functionality was present. This includes the attempted execution of an Advanced SIMD or floating-point instruction, and attempted accesses to Advanced SIMD and floating-point System registers.
- An exception generated because of the value of one of the SCTLR_EL1.{ITD, SED, CP15BEN} control bits.
- Attempted execution of:
  - An HVC instruction when disabled by HCR_EL2.HCD.
  - An SMC instruction when disabled by HCR_EL2.TSC.
  - An HLT instruction when disabled by EDSCR.HDE.
- Attempted execution of an MSR or MRS instruction to access SP_EL0 when the value of SPSel.SP is 0.
- Attempted execution of an MSR or MRS instruction using a _EL12 register name.
- Attempted execution, in Debug state, of:
  - A DCPS1 instruction when the value of HCR_EL2.TGE is 1.
  - A DCPS2 instruction from EL1 or EL0 when EL2 is disabled or not implemented in the current Security state.
  - A DCPS3 instruction when the value of EDSCR.SDD is 1.
- In Debug state when the value of EDSCR.SDD is 1, the attempted execution at EL1 or EL0 of an instruction that is configured to trap to EL2.
- An exception that is taken to EL2 because the value of HCR_EL2.TGE is 1. If the value of HCR_EL2.TGE is 0, this exception is reported using an ESR_EL1.EC value of `0b000111`.

ISS encoding for an exception from a WF* instruction



CV, bit [24]

Condition code valid.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

CV	Meaning
0b0	The COND field is not valid.
0b1	The COND field is valid.

For exceptions taken from AArch64, CV is set to 1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

COND, bits [23:20]

For exceptions taken from AArch64, this field is set to 0b1110.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [19:2]

Reserved, RES0.

TI, bits [1:0]

Trapped instruction. Possible values of this bit are:

TI	Meaning
0b00	WFI trapped.
0b01	WFE trapped.

The reset behavior of this field is:

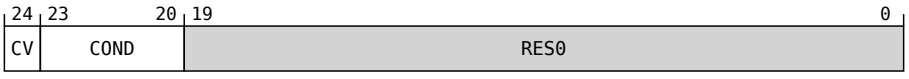
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Additional Information for ISS encoding for an exception from a WF* instruction

The following fields describe configuration settings for generating this exception:

- SCTLR_EL1.{nTWE, nTWI}.
- SCTLR_EL2.{nTWE, nTWI}.
- HCR_EL2.{TWE, TWI}.

ISS encoding for an exception from an access to a register or instruction resulting from the FPEN and TFP traps



The accesses covered by this trap include:

- Execution of Advanced SIMD and floating-point instructions.
- Accesses to the Advanced SIMD and floating-point System registers.

For an implementation that does not include support for Advanced SIMD and floating-point, the exception is reported using the EC value 0b000000.

CV, bit [24]

Condition code valid.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

CV	Meaning
0b0	The COND field is not valid.
0b1	The COND field is valid.

For exceptions taken from AArch64, CV is set to 1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

COND, bits [23:20]

For exceptions taken from AArch64, this field is set to 0b1110.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [19:0]

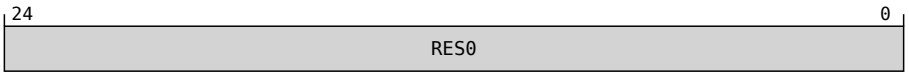
Reserved, RES0.

Additional Information for ISS encoding for an exception from an access to a register or instruction resulting from the FPEN and TFP traps

The following fields describe the configuration settings for the traps that are reported using EC value 0b000111:

- CPACR_EL1.FPEN, for accesses to SIMD and floating-point registers trapped to EL1.
- CPTR_EL2.FPEN and CPTR_EL2.TFP, for accesses to SIMD and floating-point registers trapped to EL2.

ISS encoding for an exception from an Illegal Execution state, or a PC or SP alignment fault



Bits [24:0]

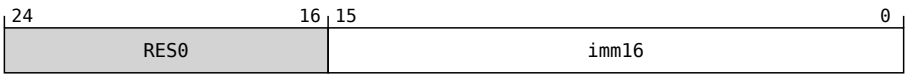
Reserved, RES0.

Additional Information for ISS encoding for an exception from an Illegal Execution state, or a PC or SP alignment fault

There are no configuration settings for generating Illegal Execution state exceptions and PC alignment fault exceptions. For more information about PC alignment fault exceptions, see 'PC alignment checking'.

'SP alignment checking' describes the configuration settings for generating SP alignment fault exceptions.

ISS encoding for an exception from HVC or SVC instruction execution



Bits [24:16]

Reserved, RES0.

imm16, bits [15:0]

The value of the immediate field from the HVC or SVC instruction.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

For an HVC instruction, and for an A64 SVC instruction, this is the value of the imm16 field of the issued instruction.

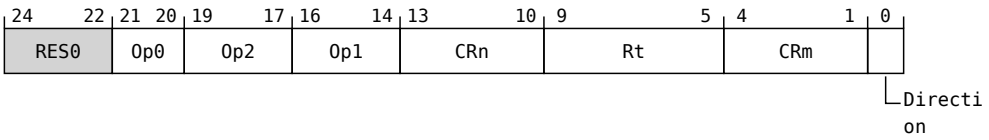
The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Additional Information for ISS encoding for an exception from HVC or SVC instruction execution

For A64 instructions, see 'SVC' and 'HVC'.

ISS encoding for an exception from MSR, MRS, or System instruction execution in AArch64 state



Bits [24:22]

Reserved, RES0.

Op0, bits [21:20]

The Op0 value from the issued instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Op2, bits [19:17]

The Op2 value from the issued instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Op1, bits [16:14]

The Op1 value from the issued instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

CRn, bits [13:10]

The CRn value from the issued instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Rt, bits [9:5]

The Rt value from the issued instruction, the general-purpose register used for the transfer.

For system instructions which require that the opcode Rt field is set to `0b11111`, but where the trapped instruction has a different value of Rt, an implementation is permitted to return the value `0b11111`, instead of the value of Rt from the trapped instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

CRm, bits [4:1]

The CRm value from the issued instruction.

The reset behavior of this field is:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Direction, bit [0]

Indicates the direction of the trapped instruction.

Direction	Meaning
0b0	Write access, including MSR instructions.
0b1	Read access, including MRS instructions.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Additional Information for ISS encoding for an exception from MSR, MRS, or System instruction execution in AArch64 state

For exceptions caused by System instructions, see 'System instructions' subsection of 'Branches, exception generating and System instructions' for the encoding values returned by an instruction.

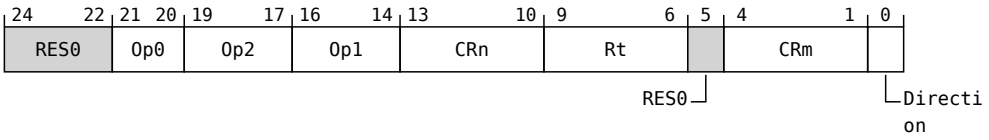
The following fields describe configuration settings for generating the exception that is reported using EC value 0b011000:

- SCTLR_EL1.UCI, for execution of cache maintenance instructions using AArch64 state, execution is trapped to EL1 or EL2.
- SCTLR_EL1.UCT, for accesses to CTR_EL0 using AArch64 state, MSR or MRS access trapped to EL1 or EL2.
- SCTLR_EL1.DZE, for execution of DC ZVA instructions using AArch64 state, execution is trapped to EL1 or EL2.
- SCTLR_EL1.UMA, for accesses to the PSTATE interrupt masks using AArch64 state, MSR or MRS access trapped to EL1 or EL2.
- CPACR_EL1.TTA, for accesses to the trace registers using AArch64 state, MSR or MRS access trapped to EL1 or EL2.
- MDSCR_EL1.TDCC, for accesses to the Debug Communications Channel (DCC) registers using AArch64 state, MSR or MRS access trapped to EL1 or EL2.
- CNTKCTL_EL1.{EL0PTEN, EL0VTEN, EL0PCTEN, EL0VCTEN} accesses to the Generic Timer registers using AArch64 state, MSR or MRS access trapped to EL1 or EL2.
- PMUSERENR_EL0, for accesses to the Performance Monitor registers using AArch64 state, MSR or MRS access trapped to EL1 or EL2.
- AMUSERENR_EL0.EN, for accesses to Activity Monitors registers using AArch64 state, MSR or MRS access trapped to EL1 or EL2.
- HCR_EL2.{TRVM, TVM}, for accesses to virtual memory control registers using AArch64 state, MSR or MRS access trapped to EL2.
- HCR_EL2.TDZ, for execution of DC ZVA instructions using AArch64 state, execution is trapped to EL2.
- HCR_EL2.TTLB, for execution of TLB maintenance instructions using AArch64 state, execution is trapped to EL2.
- HCR_EL2.{TSW, TPC, TPU}, for execution of cache maintenance instructions using AArch64 state, execution is trapped to EL2.
- HCR_EL2.TACR, for accesses to the Auxiliary Control Register, ACTLR_EL1, using AArch64 state, MSR or MRS access trapped to EL2.
- HCR_EL2.TIDCP, for accesses to lockdown, DMA, and TCM operations using AArch64 state, MSR or MRS access trapped to EL2.
- HCR_EL2.{TID1, TID2, TID3}, for accesses to ID group 1, ID group 2 or ID group 3 registers, using AArch64 state, MSR or MRS access trapped to EL2.
- CPTR_EL2.TCPAC, for accesses to CPACR_EL1, using AArch64 state, MSR or MRS access trapped to EL2.
- CPTR_EL2.TTA, for accesses to the trace registers, using AArch64 state, MSR or MRS access trapped to EL2.
- MDCR_EL2.TTRF, for accesses to the trace filter control register, TRFCR_EL1, using AArch64 state, MSR or MRS access trapped to EL2.
- MDCR_EL2.TDRA, for accesses to Debug ROM registers, using AArch64 state, MSR or MRS access trapped to EL2.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- MDCR_EL2.TDOSA, for accesses to powerdown debug registers using AArch64 state, MSR or MRS access trapped to EL2.
- CNTHCTL_EL2.{EL1PCEN, EL1PCTEN}, for accesses to the Generic Timer registers using AArch64 state, MSR or MRS access trapped to EL2.
- MDCR_EL2.TDA, for accesses to debug registers using AArch64 state, MSR or MRS access trapped to EL2.
- MDCR_EL2.{TPM, TPMCR}, for accesses to Performance Monitor registers, using AArch64 state, MSR or MRS access trapped to EL2.
- CPTR_EL2.TAM, for accesses to Activity Monitors registers, using AArch64 state, MSR or MRS access trapped to EL2.
- HCR_EL2.APK, for accesses to Pointer authentication key registers, using AArch64 state, MSR or MRS access trapped to EL2.
- HCR_EL2.{NV, NV1}, for Nested virtualization register access, using AArch64 state, MSR or MRS access, trapped to EL2.
- HCR_EL2.AT, for execution of AT S1E* instructions, using AArch64 state, execution is trapped to EL2.
- HCR_EL2.{TERR, FIEN}, for accesses to RAS registers, using AArch64 state, MSR or MRS access, trapped to EL2.
- CPTR_EL3.TAM, for accesses to Activity Monitors registers, using AArch64 state, MSR or MRS access, trapped to EL3.

ISS encoding for an exception from MSRR, MRRS, or 128-bit System instruction execution in AArch64 state



Bits [24:22]

Reserved, RES0.

Op0, bits [21:20]

The Op0 value from the issued instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Op2, bits [19:17]

The Op2 value from the issued instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Op1, bits [16:14]

The Op1 value from the issued instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

CRn, bits [13:10]

The CRn value from the issued instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Rt, bits [9:6]

The Rt value from the issued instruction, the general-purpose register used for the transfer.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

This value represents register pair of X[Rt:0], X[Rt:1].

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [5]

Reserved, RES0.

CRm, bits [4:1]

The CRm value from the issued instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Direction, bit [0]

Indicates the direction of the trapped instruction.

Direction	Meaning
0b0	Write access, MSRR instructions.
0b1	Read access, MRRS instructions.

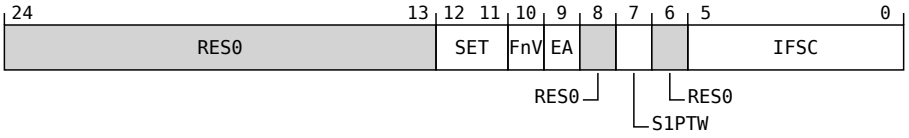
The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Additional Information for ISS encoding for an exception from MSRR, MRRS, or 128-bit System instruction execution in AArch64 state

The following fields describe configuration settings for generating exceptions from an MSRR or MRRS access that are reported using EC value 0b010100:

ISS encoding for an exception from an Instruction Abort



Bits [24:13]

Reserved, RES0.

SET, bits [12:11]

When IsFeatureImplemented(FEAT_RAS) && ((IFSC == 0b010000 || IFSC IN {0b01001x}) || IFSC IN {0b0101xx}):

Synchronous Error Type. Describes the PE error state after taking the Instruction Abort exception.

SET	Meaning
0b00	Recoverable state (UER).
0b10	Uncontainable (UC).
0b11	Restartable state (UEO).

All other values are reserved.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

Software can use this information to determine what recovery might be possible. Taking a synchronous External abort exception might result in a PE state that is not recoverable.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

FnV, bit [10]

FAR not Valid, for a synchronous External abort other than a synchronous External abort on a translation table walk.

FnV	Meaning
0b0	FAR is valid.
0b1	FAR is not valid, and holds an UNKNOWN value.

This field is valid only if the IFSC code is 0b010000. It is RES0 for all other aborts.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

EA, bit [9]

External abort type. This bit can provide an IMPLEMENTATION DEFINED classification of External aborts.

For any abort other than an External abort this bit returns a value of 0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [8]

Reserved, RES0.

S1PTW, bit [7]

For a stage 2 fault, indicates whether the fault was a stage 2 fault on an access made for a stage 1 translation table walk:

S1PTW	Meaning
0b0	Fault not on a stage 2 translation for a stage 1 translation table walk.
0b1	Fault on the stage 2 translation of an access for a stage 1 translation table walk.

For any abort other than a stage 2 fault this bit is RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [6]

Reserved, RES0.

IFSC, bits [5:0]

Instruction Fault Status Code.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

IFSC	Meaning	Applies when
0b000000	Address size fault, level 0 of translation or translation table base register.	
0b000001	Address size fault, level 1.	
0b000010	Address size fault, level 2.	
0b000011	Address size fault, level 3.	
0b000100	Translation fault, level 0.	
0b000101	Translation fault, level 1.	
0b000110	Translation fault, level 2.	
0b000111	Translation fault, level 3.	
0b001001	Access flag fault, level 1.	
0b001010	Access flag fault, level 2.	
0b001011	Access flag fault, level 3.	
0b001100	Permission fault, level 0.	
0b001101	Permission fault, level 1.	
0b001110	Permission fault, level 2.	
0b001111	Permission fault, level 3.	
0b010000	Synchronous External abort, not on translation table walk or hardware update of translation table.	
0b010100	Synchronous External abort on translation table walk or hardware update of translation table, level 0.	
0b010101	Synchronous External abort on translation table walk or hardware update of translation table, level 1.	
0b010110	Synchronous External abort on translation table walk or hardware update of translation table, level 2.	
0b010111	Synchronous External abort on translation table walk or hardware update of translation table, level 3.	
0b011000	Synchronous parity or ECC error on memory access, not on translation table walk.	FEAT_RAS is not implemented
0b011100	Synchronous parity or ECC error on memory access on translation table walk or hardware update of translation table, level 0.	FEAT_RAS is not implemented
0b011101	Synchronous parity or ECC error on memory access on translation table walk or hardware update of translation table, level 1.	FEAT_RAS is not implemented
0b011110	Synchronous parity or ECC error on memory access on translation table walk or hardware update of translation table, level 2.	FEAT_RAS is not implemented
0b011111	Synchronous parity or ECC error on memory access on translation table walk or hardware update of translation table, level 3.	FEAT_RAS is not implemented
0b110000	TLB conflict abort.	
0b110001	Unsupported atomic hardware update fault.	FEAT_HAFDBS is implemented

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

All other values are reserved.

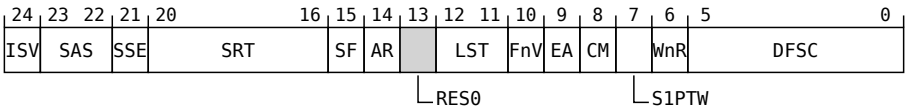
For more information about the lookup level associated with a fault, see 'The lookup level associated with MMU faults'.

If the S1PTW bit is set, then the level refers the level of the stage2 translation that is translating a stage 1 translation walk.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

ISS encoding for an exception from a Data Abort



ISV, bit [24]

Instruction Syndrome Valid. Indicates whether the syndrome information in ISS[23:14] is valid.

ISV	Meaning
0b0	No valid instruction syndrome. ISS[23:14] are RES0.
0b1	ISS[23:14] hold a valid instruction syndrome.

This bit is 0 for all faults reported in ESR_EL2 except the following stage 2 aborts:

- AArch64 loads and stores of a single general-purpose register (including the register specified with 0b11111, including those with Acquire/Release semantics, but excluding Load Exclusive or Store Exclusive and excluding those with writeback).

For these stage 2 aborts, ISV is UNKNOWN if the exception was generated in Debug state in Memory access mode, and otherwise indicates whether ISS[23:14] hold a valid syndrome.

ISV is 0 for all faults reported in ESR_EL1 or ESR_EL3.

When FEAT_RAS is implemented, ISV is 0 for any synchronous External abort.

When FEAT_RAS is not implemented, it is IMPLEMENTATION DEFINED whether ISV is set to 1 or 0 on a synchronous External abort on a stage 2 translation table walk.

For ISS reporting, a stage 2 abort on a stage 1 translation table walk does not return a valid instruction syndrome, and therefore ISV is 0 for these aborts.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

SAS, bits [23:22]

When ISV == '1':

Syndrome Access Size. Indicates the size of the access attempted by the faulting operation.

SAS	Meaning
0b00	Byte
0b01	Halfword
0b10	Word
0b11	Doubleword

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

This field is UNKNOWN when the value of ISV is UNKNOWN.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

SSE, bit [21]

When ISV == '1':

Syndrome Sign Extend. For a byte, halfword, or word load operation, indicates whether the data item must be sign extended.

SSE	Meaning
0b0	Sign-extension not required.
0b1	Data item must be sign-extended.

For all other operations, this field is 0.

This field is UNKNOWN when the value of ISV is UNKNOWN.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

SRT, bits [20:16]

When ISV == '1':

Syndrome Register Transfer. The register number of the Wt/Xt/Rt operand of the faulting instruction.

This field is UNKNOWN when the value of ISV is UNKNOWN.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bit [15]

When ISV == '1':

SF, bit [15]

Sixty Four bit general-purpose register transfer. Width of the register accessed by the instruction is 64-bit.

SF	Meaning
0b0	Instruction loads/stores a 32-bit general-purpose register.
0b1	Instruction loads/stores a 64-bit general-purpose register.

Note

This field specifies the register width identified by the instruction, not the Execution state.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

This field is UNKNOWN when the value of ISV is UNKNOWN.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

FnP, bit [15]

FAR not Precise.

FnP	Meaning
0b0	The FAR holds the faulting virtual address that generated the Data Abort.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

AR, bit [14]

When ISV == '1':

Acquire/Release.

AR	Meaning
0b0	Instruction did not have acquire/release semantics.
0b1	Instruction did have acquire/release semantics.

This field is UNKNOWN when the value of ISV is UNKNOWN.

For a load-acquire instruction that does not have acquire semantics as the result of the destination register being ZR, it is IMPLEMENTATION SPECIFIC whether this field is reported as 0 or 1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bit [13]

Reserved, RES0.

Bits [12:11]

When (DFSC IN {0b00xxxx} || DFSC IN {0b10101x}) && !(DFSC IN {0b0000xx}):

LST, bits [12:11]

Load/Store Type. Used when a Translation fault, Access flag fault, or Permission fault generates a Data Abort.

LST	Meaning
0b00	The instruction that generated the Data Abort is not specified by this field.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

When IsFeatureImplemented(FEAT_RAS) && ((DFSC == 0b010000 || DFSC IN {0b01001x}) || DFSC IN {0b0101xx}):

SET, bits [12:11]

Synchronous Error Type. Used when a synchronous External abort, not on a Translation table walk or hardware update of the Translation table, generated the Data Abort. Describes the PE error state after taking the Data Abort exception.

SET	Meaning
0b00	Recoverable state (UER).
0b10	Uncontainable (UC).
0b11	Restartable state (UEO).

Note

Software can use this information to determine what recovery might be possible. Taking a synchronous External abort exception might result in a PE state that is not recoverable.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

FnV, bit [10]

FAR not Valid, for a synchronous External abort other than a synchronous External abort on a translation table walk.

FnV	Meaning
0b0	FAR is valid.
0b1	FAR is not valid, and holds an UNKNOWN value.

This field is valid only if the DFSC code is 0b010000. It is RES0 for all other aborts.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

EA, bit [9]

External abort type. This bit can provide an IMPLEMENTATION DEFINED classification of External aborts.

For any abort other than an External abort this bit returns a value of 0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

CM, bit [8]

Cache maintenance. Indicates whether the Data Abort came from a cache maintenance or address translation instruction:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

CM	Meaning
0b0	The Data Abort was not generated by the execution of one of the System instructions identified in the description of value 1.
0b1	The Data Abort was generated by either the execution of a cache maintenance instruction or by a synchronous fault on the execution of an address translation instruction. The DC ZVA, DC GVA, and DC GZVA instructions are not classified as cache maintenance instructions, and therefore their execution cannot cause this field to be set to 1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

S1PTW, bit [7]

For a stage 2 fault, indicates whether the fault was a stage 2 fault on an access made for a stage 1 translation table walk:

S1PTW	Meaning
0b0	Fault not on a stage 2 translation for a stage 1 translation table walk.
0b1	Fault on the stage 2 translation of an access for a stage 1 translation table walk.

For any abort other than a stage 2 fault this bit is RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

WnR, bit [6]

Write not Read. Indicates whether a synchronous abort was caused by an instruction writing to a memory location, or by an instruction reading from a memory location.

WnR	Meaning
0b0	Abort caused by an instruction reading from a memory location.
0b1	Abort caused by an instruction writing to a memory location.

For faults on cache maintenance and address translation instructions, this bit always returns a value of 1.

For faults from an atomic instruction that both reads and writes from a memory location, this bit is set to 0 if a read of the address specified by the instruction would have generated the fault which is being reported, otherwise it is set to 1. The architecture permits, but does not require, a relaxation of this requirement such that for all stage 2 aborts on stage 1 translation table walks for atomic instructions, the WnR bit is always 0.

This field is UNKNOWN for:

- An External abort on an Atomic access.
- A fault reported using a DFSC value of 0b110101 or 0b110001, indicating an unsupported Exclusive or atomic access.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

DFSC, bits [5:0]

Data Fault Status Code.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

DFSC	Meaning	Applies when
0b000000	Address size fault, level 0 of translation or translation table base register.	
0b000001	Address size fault, level 1.	
0b000010	Address size fault, level 2.	
0b000011	Address size fault, level 3.	
0b000100	Translation fault, level 0.	
0b000101	Translation fault, level 1.	
0b000110	Translation fault, level 2.	
0b000111	Translation fault, level 3.	
0b001001	Access flag fault, level 1.	
0b001010	Access flag fault, level 2.	
0b001011	Access flag fault, level 3.	
0b001100	Permission fault, level 0.	
0b001101	Permission fault, level 1.	
0b001110	Permission fault, level 2.	
0b001111	Permission fault, level 3.	
0b010000	Synchronous External abort, not on translation table walk or hardware update of translation table.	
0b010100	Synchronous External abort on translation table walk or hardware update of translation table, level 0.	
0b010101	Synchronous External abort on translation table walk or hardware update of translation table, level 1.	
0b010110	Synchronous External abort on translation table walk or hardware update of translation table, level 2.	
0b010111	Synchronous External abort on translation table walk or hardware update of translation table, level 3.	
0b011000	Synchronous parity or ECC error on memory access, not on translation table walk.	FEAT_RAS is not implemented
0b011100	Synchronous parity or ECC error on memory access on translation table walk or hardware update of translation table, level 0.	FEAT_RAS is not implemented
0b011101	Synchronous parity or ECC error on memory access on translation table walk or hardware update of translation table, level 1.	FEAT_RAS is not implemented
0b011110	Synchronous parity or ECC error on memory access on translation table walk or hardware update of translation table, level 2.	FEAT_RAS is not implemented
0b011111	Synchronous parity or ECC error on memory access on translation table walk or hardware update of translation table, level 3.	FEAT_RAS is not implemented
0b100001	Alignment fault.	
0b110000	TLB conflict abort.	
0b110001	Unsupported atomic hardware update fault.	FEAT_HAFDBS is implemented
0b110100	IMPLEMENTATION DEFINED fault (Lockdown).	

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

0b110101	IMPLEMENTATION DEFINED fault (Unsupported Exclusive or Atomic access).

All other values are reserved.

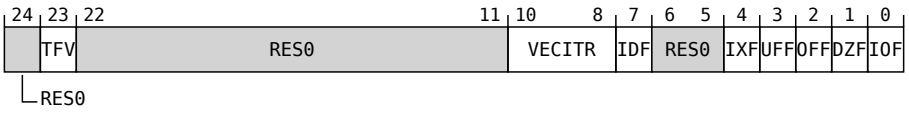
For more information about the lookup level associated with a fault, see 'The lookup level associated with MMU faults'.

If the S1PTW bit is set, then the level refers the level of the stage2 translation that is translating a stage 1 translation walk.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

ISS encoding for an exception from a trapped floating-point exception



Bit [24]

Reserved, RES0.

TFV, bit [23]

Trapped Fault Valid bit. Indicates whether the IDF, IXF, UFF, OFF, DZF, and IOF bits hold valid information about trapped floating-point exceptions.

TFV	Meaning
0b0	The IDF, IXF, UFF, OFF, DZF, and IOF bits do not hold valid information about trapped floating-point exceptions and are UNKNOWN.
0b1	One or more floating-point exceptions occurred during an operation performed while executing the reported instruction. The IDF, IXF, UFF, OFF, DZF, and IOF bits indicate trapped floating-point exceptions that occurred. For more information, see 'Floating-point exceptions and exception traps'.

It is IMPLEMENTATION DEFINED whether this field is set to 0 on an exception generated by a trapped floating-point exception from an instruction that is performing floating-point operations on more than one lane of a vector.

Note

This is not a requirement. Implementations can set this field to 1 on a trapped floating-point exception from an instruction and return valid information in the {IDF, IXF, UFF, OFF, DZF, IOF} fields.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [22:11]

Reserved, RES0.

VECITR, bits [10:8]

For a trapped floating-point exception from an instruction executed in AArch64 state this field is UNKNOWN.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

IDF, bit [7]

Input Denormal floating-point exception trapped bit. If the TFV field is 0, this bit is UNKNOWN. Otherwise, the possible values of this bit are:

IDF	Meaning
0b0	Input denormal floating-point exception has not occurred.
0b1	Input denormal floating-point exception occurred during execution of the reported instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [6:5]

Reserved, RES0.

IXF, bit [4]

Inexact floating-point exception trapped bit. If the TFV field is 0, this bit is UNKNOWN. Otherwise, the possible values of this bit are:

IXF	Meaning
0b0	Inexact floating-point exception has not occurred.
0b1	Inexact floating-point exception occurred during execution of the reported instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

UFF, bit [3]

Underflow floating-point exception trapped bit. If the TFV field is 0, this bit is UNKNOWN. Otherwise, the possible values of this bit are:

UFF	Meaning
0b0	Underflow floating-point exception has not occurred.
0b1	Underflow floating-point exception occurred during execution of the reported instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

OFF, bit [2]

Overflow floating-point exception trapped bit. If the TFV field is 0, this bit is UNKNOWN. Otherwise, the possible values of this bit are:

OFF	Meaning
0b0	Overflow floating-point exception has not occurred.
0b1	Overflow floating-point exception occurred during execution of the reported instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

DZF, bit [1]

Divide by Zero floating-point exception trapped bit. If the TFV field is 0, this bit is UNKNOWN. Otherwise, the possible values of this bit are:

DZF	Meaning
0b0	Divide by Zero floating-point exception has not occurred.
0b1	Divide by Zero floating-point exception occurred during execution of the reported instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

IOF, bit [0]

Invalid Operation floating-point exception trapped bit. If the TFV field is 0, this bit is UNKNOWN. Otherwise, the possible values of this bit are:

IOF	Meaning
0b0	Invalid Operation floating-point exception has not occurred.
0b1	Invalid Operation floating-point exception occurred during execution of the reported instruction.

The reset behavior of this field is:

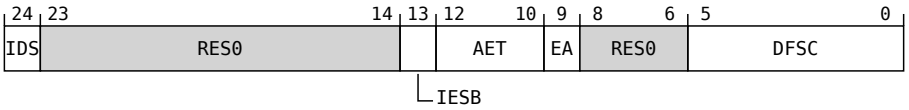
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Additional Information for ISS encoding for an exception from a trapped floating-point exception

In an implementation that supports the trapping of floating-point exceptions:

- From an Exception level using AArch64, the FPCR.{IDE, IXE, UFE, OFE, DZE, IOE} bits enable each of the floating-point exception traps.

ISS encoding for an SError exception



Note

In earlier versions of the architecture, an SError exception is referred to as an SError interrupt or an asynchronous External abort exception.

IDS, bit [24]

IMPLEMENTATION DEFINED syndrome.

IDS	Meaning
0b0	Bits [23:0] of the ISS field holds the fields described in this encoding. **Note** If FEAT_RAS is not implemented, bits [23:0] of the ISS field are RES0.
0b1	Bits [23:0] of the ISS field holds IMPLEMENTATION DEFINED syndrome information that can be used to provide additional information about the SError exception.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

This field was previously called ISV.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [23:14]

Reserved, RES0.

IESB, bit [13]

When FEAT_IESB is implemented and DFSC == 0b010001:

Implicit error synchronization event.

IESB	Meaning
0b0	The SError exception was either not synchronized by the implicit error synchronization event or not taken immediately.
0b1	The SError exception was synchronized by the implicit error synchronization event and taken immediately.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

AET, bits [12:10]

When FEAT_RAS is implemented and DFSC == 0b010001:

Asynchronous Error Type.

Describes the PE error state after taking the SError exception.

AET	Meaning
0b000	Uncontainable (UC).
0b001	Unrecoverable state (UEU).
0b010	Restartable state (UEO).
0b011	Recoverable state (UER).
0b110	Corrected (CE).

All other values are reserved.

If multiple errors are taken as a single SError exception, the overall PE error state is reported.

Note

Software can use this information to determine what recovery might be possible. The recovery software must also examine any implemented fault records to determine the location and extent of the error.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Otherwise:

Reserved, RES0.

EA, bit [9]

When FEAT_RAS is implemented and DFSC == 0b010001:

External abort type. Provides an IMPLEMENTATION DEFINED classification of External aborts.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bits [8:6]

Reserved, RES0.

DFSC, bits [5:0]

When FEAT_RAS is implemented:

Data Fault Status Code.

DFSC	Meaning
0b000000	Uncategorized error.
0b010001	Asynchronous SError exception.

All other values are reserved.

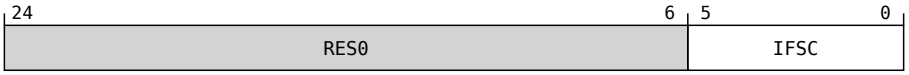
The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

ISS encoding for an exception from a Breakpoint or Vector Catch debug exception



Bits [24:6]

Reserved, RES0.

IFSC, bits [5:0]

Instruction Fault Status Code.

IFSC	Meaning
0b100010	Debug exception.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

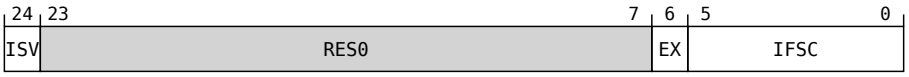
Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Additional Information for ISS encoding for an exception from a Breakpoint or Vector Catch debug exception

For more information about generating these exceptions:

- For exceptions from AArch64, see 'Breakpoint exceptions'.

ISS encoding for an exception from a Software Step exception



ISV, bit [24]

Instruction syndrome valid. Indicates whether the EX bit, ISS[6], is valid, as follows:

ISV	Meaning
0b0	EX bit is RES0.
0b1	EX bit is valid.

See the EX bit description for more information.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [23:7]

Reserved, RES0.

EX, bit [6]

Exclusive operation. If the ISV bit is set to 1, this bit indicates whether a Load-Exclusive instruction was stepped.

EX	Meaning
0b0	An instruction other than a Load-Exclusive instruction was stepped.
0b1	A Load-Exclusive instruction was stepped.

If the ISV bit is set to 0, this bit is RES0, indicating no syndrome data is available.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

IFSC, bits [5:0]

Instruction Fault Status Code.

IFSC	Meaning
0b100010	Debug exception.

The reset behavior of this field is:

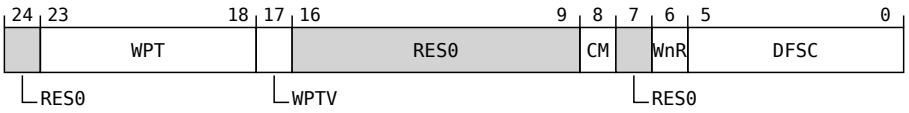
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Additional Information for ISS encoding for an exception from a Software Step exception

For more information about generating these exceptions, see 'Software Step exceptions'.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

ISS encoding for an exception from a Watchpoint exception



Bit [24]

Reserved, RES0.

WPT, bits [23:18]

When FEAT_Debugv8p2 is implemented:

Watchpoint number.

All other values are reserved.

Otherwise:

Reserved, RES0.

WPTV, bit [17]

When FEAT_Debugv8p2 is implemented:

Watchpoint number Valid.

WPTV	Meaning
0b0	The WPT field is invalid, and holds an UNKNOWN value.
0b1	The WPT field is valid, and holds the number of a watchpoint that triggered a Watchpoint exception.

When a Watchpoint exception is triggered by a watchpoint match:

- If the PE sets any of FnV, FnP, or WPF to 1, then the PE sets WPTV to 1.
- Otherwise, the PE sets WPTV to an IMPLEMENTATION DEFINED value, 0 or 1.

Otherwise:

Reserved, RES0.

Bits [16:9]

Reserved, RES0.

CM, bit [8]

Cache maintenance. Indicates whether the Watchpoint exception came from a cache maintenance instruction:

CM	Meaning
0b0	The Watchpoint exception was not generated by the execution of one of the System instructions identified in the description of value 1.
0b1	The Watchpoint exception was generated by the execution of a cache maintenance instruction. The DC ZVA instruction is not classifed as a cache maintenance instruction, and therefore their execution does not cause this field to be set to 1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Bit [7]

Reserved, RES0.

WnR, bit [6]

Write not Read. Indicates whether the Watchpoint exception was caused by an instruction writing to a memory location, or by an instruction reading from a memory location.

WnR	Meaning
0b0	Watchpoint exception caused by an instruction reading from a memory location.
0b1	Watchpoint exception caused by an instruction writing to a memory location.

For Watchpoint exceptions on cache maintenance instructions, this bit always returns a value of 1.

For Watchpoint exceptions from an atomic instruction, this field is set to 0 if a read of the location would have generated the Watchpoint exception, otherwise it is set to 1.

If multiple watchpoints match on the same access, it is UNPREDICTABLE which watchpoint generates the Watchpoint exception.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

DFSC, bits [5:0]

Data Fault Status Code.

DFSC	Meaning
0b100010	Debug exception.

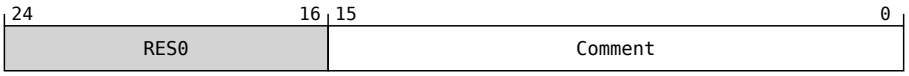
The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Additional Information for ISS encoding for an exception from a Watchpoint exception

For more information about generating these exceptions, see 'Watchpoint exceptions'.

ISS encoding for an exception from execution of a Breakpoint instruction



Bits [24:16]

Reserved, RES0.

Comment, bits [15:0]

Set to the instruction comment field value, zero extended as necessary.

The reset behavior of this field is:

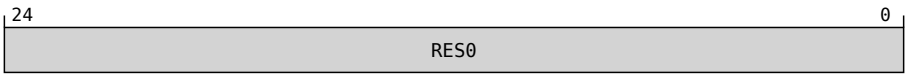
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Additional Information for ISS encoding for an exception from execution of a Breakpoint instruction

For more information about generating these exceptions, see 'Breakpoint instruction exceptions'.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

ISS encoding for an exception from a trapped Pointer Authentication instruction



Bits [24:0]

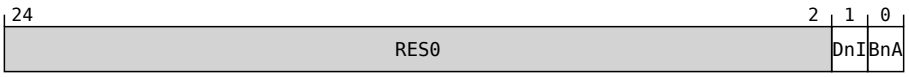
Reserved, RES0.

Additional Information for ISS encoding for an exception from a trapped Pointer Authentication instruction

For more information about generating these exceptions, see:

- HCR_EL2.API, for exceptions from Pointer authentication instructions, using AArch64 state, trapped to EL2.

ISS encoding for a PAC Fail exception



Bits [24:2]

Reserved, RES0.

DnI, bit [1]

This field indicates whether the exception is as a result of an Instruction key or a Data key.

DnI	Meaning
0b0	Instruction Key.
0b1	Data Key.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

BnA, bit [0]

This field indicates whether the exception is as a result of an A key or a B key.

BnA	Meaning
0b0	A key.
0b1	B key.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Additional Information for ISS encoding for a PAC Fail exception

The following instructions generate a PAC Fail exception when the Pointer Authentication Code (PAC) is incorrect:

- AUTDA, AUTDZA.
- AUTDB, AUTDZB.
- AUTIA, AUTIA1716, AUTIASP, AUTIAZ, AUTIZA.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- AUTIB, AUTIB1716, AUTIBSP, AUTIBZ, AUTIZB.
- AUTIASPPC, AUTIASPPCR, AUTIA171615.
- AUTIBSPPC, AUTIBSPPCR, AUTIB171615.

If FEAT_FPACCOMBINE is implemented, the following instructions generate a PAC Fail exception when the Pointer Authentication Code (PAC) is incorrect:

- RETAA, RETAB.
- RETAASPPC, RETABSPPC.
- RETAASPPCR, RETABSPPCR.
- BLRAA, BLRAAZ, BLRAB, BLRABZ.
- BRAA, BRAB, BRAAZ, BRABZ.
- ERETAA, ERETAB.
- LDRAA, LDRAB, whether the authenticated address is written back to the base register or not.

Accessing ESR_EL1

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, ESR_EL1

op0	op1	CRn	CRm	op2
0b11	0b000	0b0101	0b0010	0b000

```
if PSTATE.EL == EL0 then
    UNDEFINED;
elsif PSTATE.EL == EL1 then
    if HCR_EL2.TRVM == '1' then
        AArch64.SystemAccessTrap(EL2, 0x18);
    else
        X[t, 64] = ESR_EL1;
elsif PSTATE.EL == EL2 then
    X[t, 64] = ESR_EL1;
```

MSR ESR_EL1, <Xt>

op0	op1	CRn	CRm	op2
0b11	0b000	0b0101	0b0010	0b000

```
if PSTATE.EL == EL0 then
    UNDEFINED;
elsif PSTATE.EL == EL1 then
    if HCR_EL2.TVM == '1' then
        AArch64.SystemAccessTrap(EL2, 0x18);
    else
        ESR_EL1 = X[t, 64];
elsif PSTATE.EL == EL2 then
    ESR_EL1 = X[t, 64];
```

MRS <Xt>, ESR_EL2

op0	op1	CRn	CRm	op2
0b11	0b100	0b0101	0b0010	0b000

```
if PSTATE.EL == EL0 then
    UNDEFINED;
elsif PSTATE.EL == EL1 then
    UNDEFINED;
elsif PSTATE.EL == EL2 then
    X[t, 64] = ESR_EL2;
```

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

```
MSR ESR_EL2, <Xt>
```

op0	op1	CRn	CRm	op2
0b11	0b100	0b0101	0b0010	0b000

```
if PSTATE.EL == EL0 then
    UNDEFINED;
elsif PSTATE.EL == EL1 then
    UNDEFINED;
elsif PSTATE.EL == EL2 then
    ESR_EL2 = X[t, 64];
```

D12.2.31 ESR_EL2, Exception Syndrome Register (EL2)

The ESR_EL2 characteristics are:

Purpose

Holds syndrome information for an exception taken to EL2.

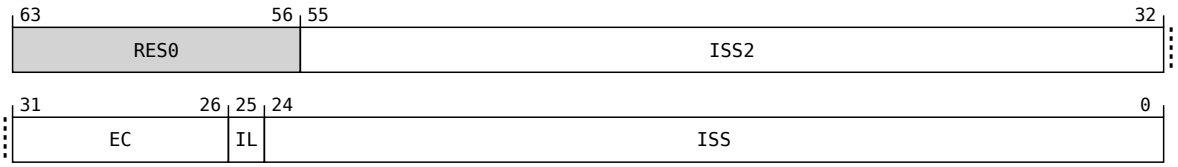
Configuration

There are no configuration notes.

Attributes

ESR_EL2 is a 64-bit register.

Field descriptions



ESR_EL2 is made UNKNOWN as a result of an exception return from EL2.

When an UNPREDICTABLE instruction is treated as UNDEFINED, and the exception is taken to EL2, the value of ESR_EL2 is UNKNOWN. The value written to ESR_EL2 must be consistent with a value that could be created as a result of an exception from the same Exception level that generated the exception as a result of a situation that is not UNPREDICTABLE at that Exception level, in order to avoid the possibility of a privilege violation.

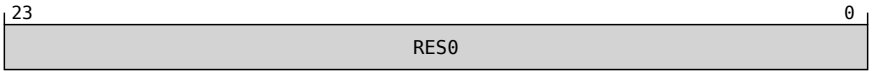
Bits [63:56]

Reserved, RES0.

ISS2, bits [55:32]

ISS2 encoding for an exception, the bit assignments are:

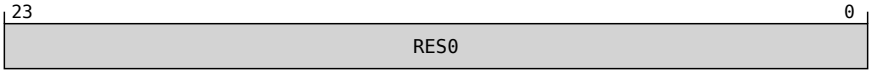
ISS2 encoding for an exception from a Data Abort



Bits [23:0]

Reserved, RES0.

ISS2 encoding for an exception from an Instruction Abort

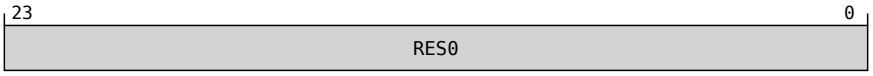


Bits [23:0]

Reserved, RES0.

ISS2 encoding for an exception from a Watchpoint exception

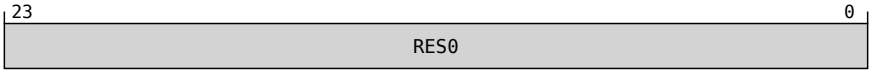
Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential



Bits [23:0]

Reserved, RES0.

ISS2 encoding for all other exceptions



Bits [23:0]

Reserved, RES0.

EC, bits [31:26]

Exception Class. Indicates the reason for the exception that this register holds information about.

For each EC value, the table references a subsection that gives information about:

- The cause of the exception, for example the configuration required to enable the trap.
- The encoding of the associated ISS.

Possible values of the EC field are:

EC	Meaning	ISS	ISS2	Applies when
0b000000	Unknown reason.	ISS encoding for exceptions with an unknown reason	ISS2 encoding for all other exceptions	
0b000001	Trapped WF* instruction execution. Conditional WF* instructions that fail their condition code check do not cause an exception.	ISS encoding for an exception from a WF* instruction	ISS2 encoding for all other exceptions	
0b000111	Access to Advanced SIMD or floating-point functionality trapped by CPACR_EL1.FPEN, CPTR_EL2.FPEN, CPTR_EL2.TFP, or CPTR_EL3.TFP control. Excludes exceptions resulting from CPACR_EL1 when the value of HCR_EL2.TGE is 1, or because Advanced SIMD and floating-point are not implemented. These are reported with EC value 0b000000.	ISS encoding for an exception from an access to a register or instruction resulting from the FPEN and TFP traps	ISS2 encoding for all other exceptions	
0b001001	Trapped use of a Pointer authentication instruction.	ISS encoding for an exception from a trapped Pointer Authentication instruction	ISS2 encoding for all other exceptions	FEAT_PAuth is implemented
0b001110	Illegal Execution state.	ISS encoding for an exception from an Illegal Execution state, or a PC or SP alignment fault	ISS2 encoding for all other exceptions	

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

EC	Meaning	ISS	ISS2	Applies when
0b010101	SVC instruction execution in AArch64 state.	ISS encoding for an exception from HVC or SVC instruction execution	ISS2 encoding for all other exceptions	
0b010110	HVC instruction execution in AArch64 state, when HVC is not disabled.	ISS encoding for an exception from HVC or SVC instruction execution	ISS2 encoding for all other exceptions	
0b010111	SMC instruction execution in AArch64 state, when SMC is not disabled. This is reported in ESR_EL2 only when the exception is generated because the value of HCR_EL2.TSC is 1.	ISS encoding for an exception from SMC instruction execution in AArch64 state	ISS2 encoding for all other exceptions	
0b011000	Trapped MSR, MRS or System instruction execution in AArch64 state, that is not reported using EC values 0b000000, 0b000001 or 0b000111. This includes all instructions that cause exceptions that are part of the encoding space defined in 'System instruction class encoding overview', except for those exceptions reported using EC values 0b000000, 0b000001, or 0b000111.	ISS encoding for an exception from MSR, MRS, or System instruction execution in AArch64 state	ISS2 encoding for all other exceptions	
0b011100	Exception from a PAC Fail	ISS encoding for a PAC Fail exception	ISS2 encoding for all other exceptions	FEAT_FPAC is implemented
0b100000	Instruction Abort from a lower Exception level. Used for MMU and MPU faults generated by instruction accesses and synchronous External aborts, including synchronous parity or ECC errors. Not used for debug-related exceptions.	ISS encoding for an exception from an Instruction Abort	ISS2 encoding for an exception from an Instruction Abort	
0b100001	Used for MMU and MPU faults generated by instruction accesses and synchronous External aborts, including synchronous parity or ECC errors. Not used for debug-related exceptions.	ISS encoding for an exception from an Instruction Abort	ISS2 encoding for an exception from an Instruction Abort	
0b100010	PC alignment fault exception.	ISS encoding for an exception from an Illegal Execution state, or a PC or SP alignment fault	ISS2 encoding for all other exceptions	

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

EC	Meaning	ISS	ISS2	Applies when
0b100100	Data Abort exception from a lower Exception level, excluding Data Abort exceptions taken to EL2 as a result of accesses generated associated with VNCR_EL2 as part of nested virtualization support. These Data Abort exceptions might be generated from Exception levels in any Execution state. Used for MMU and MPU faults generated by data accesses, alignment faults other than those caused by Stack Pointer misalignment, and synchronous External aborts, including synchronous parity or ECC errors. Not used for debug-related exceptions.	ISS encoding for an exception from a Data Abort	ISS2 encoding for an exception from a Data Abort	
0b100101	Data Abort exception without a change in Exception level, or Data Abort exceptions taken to EL2 as a result of accesses generated associated with VNCR_EL2 as part of nested virtualization support. Used for MMU and MPU faults generated by data accesses, alignment faults other than those caused by Stack Pointer misalignment, and synchronous External aborts, including synchronous parity or ECC errors. Not used for debug-related exceptions.	ISS encoding for an exception from a Data Abort	ISS2 encoding for an exception from a Data Abort	
0b100110	SP alignment fault exception.	ISS encoding for an exception from an Illegal Execution state, or a PC or SP alignment fault	ISS2 encoding for all other exceptions	
0b101100	Trapped floating-point exception taken from AArch64 state. This EC value is valid if the implementation supports trapping of floating-point exceptions, otherwise it is reserved. Whether a floating-point implementation supports trapping of floating-point exceptions is IMPLEMENTATION DEFINED.	ISS encoding for an exception from a trapped floating-point exception	ISS2 encoding for all other exceptions	
0b101111	SError exception.	ISS encoding for an SError exception	ISS2 encoding for all other exceptions	
0b110000	Breakpoint exception from a lower Exception level.	ISS encoding for an exception from a Breakpoint or Vector Catch debug exception	ISS2 encoding for all other exceptions	

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

EC	Meaning	ISS	ISS2	Applies when
0b110001	Breakpoint exception taken without a change in Exception level.	ISS encoding for an exception from a Breakpoint or Vector Catch debug exception	ISS2 encoding for all other exceptions	
0b110010	Software Step exception from a lower Exception level.	ISS encoding for an exception from a Software Step exception	ISS2 encoding for all other exceptions	
0b110011	Software Step exception taken without a change in Exception level.	ISS encoding for an exception from a Software Step exception	ISS2 encoding for all other exceptions	
0b110100	Watchpoint from a lower Exception level, excluding Watchpoint Exceptions taken to EL2 as a result of accesses generated associated with VNCR_EL2 as part of nested virtualization support. These Watchpoint Exceptions might be generated from Exception levels using any Execution state.	ISS encoding for an exception from a Watchpoint exception	ISS2 encoding for an exception from a Watchpoint exception	
0b110101	Watchpoint exceptions without a change in Exception level, or Watchpoint exceptions taken to EL2 as a result of accesses generated associated with VNCR_EL2 as part of nested virtualization support.	ISS encoding for an exception from a Watchpoint exception	ISS2 encoding for an exception from a Watchpoint exception	
0b111100	BRK instruction execution in AArch64 state.	ISS encoding for an exception from execution of a Breakpoint instruction	ISS2 encoding for all other exceptions	

All other EC values are reserved by Arm, and:

- Unused values in the range 0b000000 - 0b101100 (0x00 - 0x2C) are reserved for future use for synchronous exceptions.
- Unused values in the range 0b101101 - 0b111111 (0x2D - 0x3F) are reserved for future use, and might be used for synchronous or asynchronous exceptions.

The effect of programming this field to a reserved value is that behavior is CONSTRAINED UNPREDICTABLE.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

IL, bit [25]

Instruction Length for synchronous exceptions. Possible values of this bit are:

IL	Meaning
0b0	16-bit instruction trapped.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

IL	Meaning

0b1	32-bit instruction trapped. This value is also used when the exception is one of the following:
	• An SError exception.
	• An Instruction Abort exception.
	• A PC alignment fault exception.
	• An SP alignment fault exception.
	• A Data Abort exception for which the value of the ISV bit is 0.
	• An Illegal Execution state exception.
	• Any debug exception except for Breakpoint instruction exceptions. For Breakpoint instruction exceptions, this bit has its standard meaning:
	  • 0b0: 16-bit T32 BKPT instruction.
	  • 0b1: 32-bit A32 BKPT instruction or A64 BRK instruction.
	• An exception reported using EC value 0b000000.

The reset behavior of this field is:

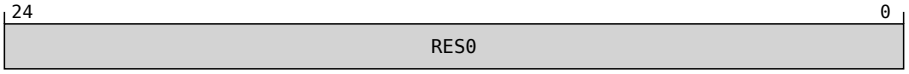
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

ISS, bits [24:0]

Instruction Specific Syndrome. Architecturally, this field can be defined independently for each defined Exception class. However, in practice, some ISS encodings are used for more than one Exception class.

Typically, an ISS encoding has a number of subfields. When an ISS subfield holds a register number, the value returned in that field is the AArch64 view of the register number.

ISS encoding for exceptions with an unknown reason



Bits [24:0]

Reserved, RES0.

Additional Information for ISS encoding for exceptions with an unknown reason

When an exception is reported using this EC value, the IL field is set to 1.

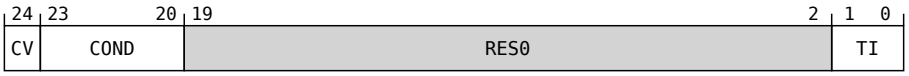
This EC value is used for all exceptions that are not covered by any other EC value. This includes exceptions that are generated in the following situations:

- The attempted execution of an instruction bit pattern that has no allocated instruction or that is not accessible at the current Exception level and Security state, including:
  - A read access using a System register pattern that is not allocated for reads or that does not permit reads at the current Exception level and Security state.
  - A write access using a System register pattern that is not allocated for writes or that does not permit writes at the current Exception level and Security state.
  - Instruction encodings that are unallocated.
  - Instruction encodings for instructions or System registers that are not implemented in the implementation.
- In Debug state, the attempted execution of an instruction bit pattern that is not accessible in Debug state.
- In Non-debug state, the attempted execution of an instruction bit pattern that is not accessible in Non-debug state.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- In an implementation that does not include Advanced SIMD and floating-point functionality, an attempted access to Advanced SIMD or floating-point functionality under conditions where that access would be permitted if that functionality was present. This includes the attempted execution of an Advanced SIMD or floating-point instruction, and attempted accesses to Advanced SIMD and floating-point System registers.
- An exception generated because of the value of one of the SCTLR_EL1.{ITD, SED, CP15BEN} control bits.
- Attempted execution of:
  - An HVC instruction when disabled by HCR_EL2.HCD.
  - An SMC instruction when disabled by HCR_EL2.TSC.
  - An HLT instruction when disabled by EDSCR.HDE.
- Attempted execution of an MSR or MRS instruction to access SP_EL0 when the value of SPSel.SP is 0.
- Attempted execution of an MSR or MRS instruction using a _EL12 register name.
- Attempted execution, in Debug state, of:
  - A DCPS1 instruction when the value of HCR_EL2.TGE is 1.
  - A DCPS2 instruction from EL1 or EL0 when EL2 is disabled or not implemented in the current Security state.
  - A DCPS3 instruction when the value of EDSCR.SDD is 1.
- In Debug state when the value of EDSCR.SDD is 1, the attempted execution at EL1 or EL0 of an instruction that is configured to trap to EL2.
- An exception that is taken to EL2 because the value of HCR_EL2.TGE is 1. If the value of HCR_EL2.TGE is 0, this exception is reported using an ESR_EL2.EC value of `0b000111`.

ISS encoding for an exception from a WF* instruction



CV, bit [24]

Condition code valid.

CV	Meaning
`0b0`	The COND field is not valid.
`0b1`	The COND field is valid.

For exceptions taken from AArch64, CV is set to 1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

COND, bits [23:20]

For exceptions taken from AArch64, this field is set to `0b1110`.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [19:2]

Reserved, RES0.

TI, bits [1:0]

Trapped instruction. Possible values of this bit are:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

TI	Meaning
0b00	WFI trapped.
0b01	WFE trapped.

The reset behavior of this field is:

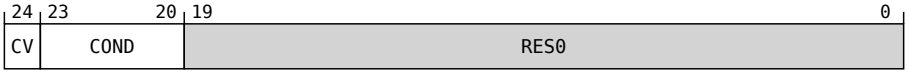
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Additional Information for ISS encoding for an exception from a WF* instruction

The following fields describe configuration settings for generating this exception:

- SCTLR_EL1.{nTWE, nTWI}.
- SCTLR_EL2.{nTWE, nTWI}.
- HCR_EL2.{TWE, TWI}.

ISS encoding for an exception from an access to a register or instruction resulting from the FPEN and TFP traps



The accesses covered by this trap include:

- Execution of Advanced SIMD and floating-point instructions.
- Accesses to the Advanced SIMD and floating-point System registers.

For an implementation that does not include support for Advanced SIMD and floating-point, the exception is reported using the EC value 0b000000.

CV, bit [24]

Condition code valid.

CV	Meaning
0b0	The COND field is not valid.
0b1	The COND field is valid.

For exceptions taken from AArch64, CV is set to 1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

COND, bits [23:20]

For exceptions taken from AArch64, this field is set to 0b1110.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [19:0]

Reserved, RES0.

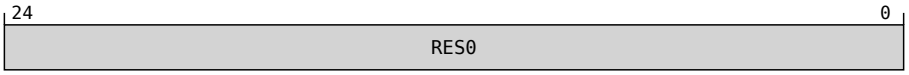
Additional Information for ISS encoding for an exception from an access to a register or instruction resulting from the FPEN and TFP traps

The following fields describe the configuration settings for the traps that are reported using EC value 0b000111:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- CPACR_EL1.FPEN, for accesses to SIMD and floating-point registers trapped to EL1.
- CPTR_EL2.FPEN and CPTR_EL2.TFP, for accesses to SIMD and floating-point registers trapped to EL2.

ISS encoding for an exception from an Illegal Execution state, or a PC or SP alignment fault



Bits [24:0]

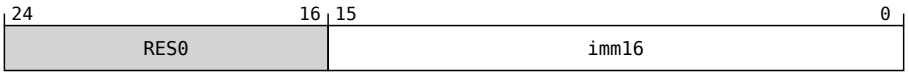
Reserved, RES0.

Additional Information for ISS encoding for an exception from an Illegal Execution state, or a PC or SP alignment fault

There are no configuration settings for generating Illegal Execution state exceptions and PC alignment fault exceptions. For more information about PC alignment fault exceptions, see 'PC alignment checking'.

'SP alignment checking' describes the configuration settings for generating SP alignment fault exceptions.

ISS encoding for an exception from HVC or SVC instruction execution



Bits [24:16]

Reserved, RES0.

imm16, bits [15:0]

The value of the immediate field from the HVC or SVC instruction.

For an HVC instruction, and for an A64 SVC instruction, this is the value of the imm16 field of the issued instruction.

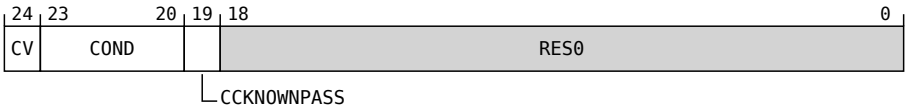
The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Additional Information for ISS encoding for an exception from HVC or SVC instruction execution

For A64 instructions, see 'SVC' and 'HVC'.

ISS encoding for an exception from SMC instruction execution in AArch32 state



For an SMC instruction that completes normally and generates an exception that is taken to EL3, the ISS encoding is RES0.

For an SMC instruction that is trapped to EL2 from EL1 because HCR_EL2.TSC is 1, the ISS encoding is as shown in the diagram.

CV, bit [24]

Condition code valid.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

CV	Meaning
0b0	The COND field is not valid.
0b1	The COND field is valid.

For exceptions taken from AArch64, CV is set to 1.

This field is valid only if CCKNOWNPASS is 1, otherwise it is RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

COND, bits [23:20]

For exceptions taken from AArch64, this field is set to 0b1110.

This field is valid only if CCKNOWNPASS is 1, otherwise it is RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

CCKNOWNPASS, bit [19]

Indicates whether the instruction might have failed its condition code check.

CCKNOWNPASS	Meaning
0b0	The instruction was unconditional, or was conditional and passed its condition code check.
0b1	The instruction was conditional, and might have failed its condition code check.

Note

In an implementation in which an SMC instruction that fails it code check is not trapped, this field can always return the value 0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

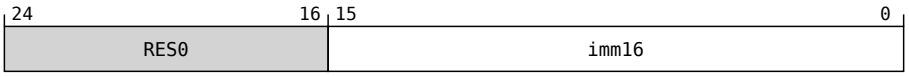
Bits [18:0]

Reserved, RES0.

Additional Information for ISS encoding for an exception from SMC instruction execution in AArch32 state

HCR_EL2.TSC describes the configuration settings for trapping SMC instructions to EL2.

ISS encoding for an exception from SMC instruction execution in AArch64 state



Bits [24:16]

Reserved, RES0.

imm16, bits [15:0]

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The value of the immediate field from the issued SMC instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

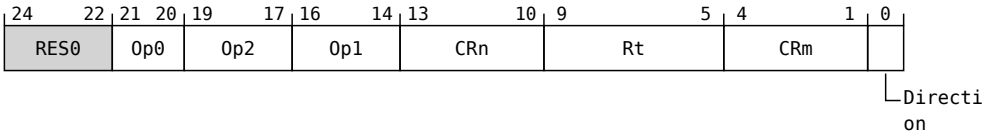
Additional Information for ISS encoding for an exception from SMC instruction execution in AArch64 state

The value of ISS[24:0] described here is used both:

- When an SMC instruction is trapped from EL1 modes.
- When an SMC instruction is not trapped, so completes normally and generates an exception that is taken to EL3.

HCR_EL2.TSC describes the configuration settings for trapping SMC from EL1 modes.

ISS encoding for an exception from MSR, MRS, or System instruction execution in AArch64 state



Bits [24:22]

Reserved, RES0.

Op0, bits [21:20]

The Op0 value from the issued instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Op2, bits [19:17]

The Op2 value from the issued instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Op1, bits [16:14]

The Op1 value from the issued instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

CRn, bits [13:10]

The CRn value from the issued instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Rt, bits [9:5]

The Rt value from the issued instruction, the general-purpose register used for the transfer.

For system instructions which require that the opcode Rt field is set to `0b11111`, but where the trapped instruction has a different value of Rt, an implementation is permitted to return the value `0b11111`, instead of the value of Rt from the trapped instruction.

The reset behavior of this field is:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

CRm, bits [4:1]

The CRm value from the issued instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Direction, bit [0]

Indicates the direction of the trapped instruction.

Direction	Meaning
0b0	Write access, including MSR instructions.
0b1	Read access, including MRS instructions.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Additional Information for ISS encoding for an exception from MSR, MRS, or System instruction execution in AArch64 state

For exceptions caused by System instructions, see 'System instructions' subsection of 'Branches, exception generating and System instructions' for the encoding values returned by an instruction.

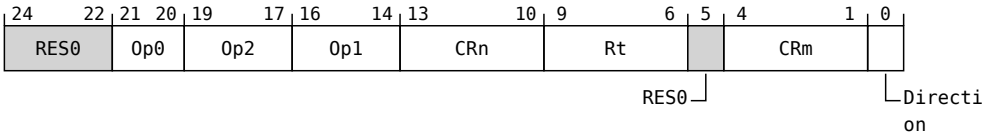
The following fields describe configuration settings for generating the exception that is reported using EC value 0b011000:

- SCTLR_EL1.UCI, for execution of cache maintenance instructions using AArch64 state, execution is trapped to EL1 or EL2.
- SCTLR_EL1.UCT, for accesses to CTR_EL0 using AArch64 state, MSR or MRS access trapped to EL1 or EL2.
- SCTLR_EL1.DZE, for execution of DC ZVA instructions using AArch64 state, execution is trapped to EL1 or EL2.
- SCTLR_EL1.UMA, for accesses to the PSTATE interrupt masks using AArch64 state, MSR or MRS access trapped to EL1 or EL2.
- CPACR_EL1.TTA, for accesses to the trace registers using AArch64 state, MSR or MRS access trapped to EL1 or EL2.
- MDSCR_EL1.TDCC, for accesses to the Debug Communications Channel (DCC) registers using AArch64 state, MSR or MRS access trapped to EL1 or EL2.
- CNTKCTL_EL1.{EL0PTEN, EL0VTEN, EL0PCTEN, EL0VCTEN} accesses to the Generic Timer registers using AArch64 state, MSR or MRS access trapped to EL1 or EL2.
- PMUSERENR_EL0, for accesses to the Performance Monitor registers using AArch64 state, MSR or MRS access trapped to EL1 or EL2.
- AMUSERENR_EL0.EN, for accesses to Activity Monitors registers using AArch64 state, MSR or MRS access trapped to EL1 or EL2.
- HCR_EL2.{TRVM, TVM}, for accesses to virtual memory control registers using AArch64 state, MSR or MRS access trapped to EL2.
- HCR_EL2.TDZ, for execution of DC ZVA instructions using AArch64 state, execution is trapped to EL2.
- HCR_EL2.TTLB, for execution of TLB maintenance instructions using AArch64 state, execution is trapped to EL2.
- HCR_EL2.{TSW, TPC, TPU}, for execution of cache maintenance instructions using AArch64 state, execution is trapped to EL2.
- HCR_EL2.TACR, for accesses to the Auxiliary Control Register, ACTLR_EL1, using AArch64 state, MSR or MRS access trapped to EL2.
- HCR_EL2.TIDCP, for accesses to lockdown, DMA, and TCM operations using AArch64 state, MSR or MRS access trapped to EL2.
- HCR_EL2.{TID1, TID2, TID3}, for accesses to ID group 1, ID group 2 or ID group 3 registers, using AArch64 state, MSR or MRS access trapped to EL2.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- CPTR_EL2.TCPAC, for accesses to CPACR_EL1, using AArch64 state, MSR or MRS access trapped to EL2.
- CPTR_EL2.TTA, for accesses to the trace registers, using AArch64 state, MSR or MRS access trapped to EL2.
- MDCR_EL2.TTRF, for accesses to the trace filter control register, TRFCR_EL1, using AArch64 state, MSR or MRS access trapped to EL2.
- MDCR_EL2.TDRA, for accesses to Debug ROM registers, using AArch64 state, MSR or MRS access trapped to EL2.
- MDCR_EL2.TDOSA, for accesses to powerdown debug registers using AArch64 state, MSR or MRS access trapped to EL2.
- CNTHCTL_EL2.{EL1PCEN, EL1PCTEN}, for accesses to the Generic Timer registers using AArch64 state, MSR or MRS access trapped to EL2.
- MDCR_EL2.TDA, for accesses to debug registers using AArch64 state, MSR or MRS access trapped to EL2.
- MDCR_EL2.{TPM, TPMCR}, for accesses to Performance Monitor registers, using AArch64 state, MSR or MRS access trapped to EL2.
- CPTR_EL2.TAM, for accesses to Activity Monitors registers, using AArch64 state, MSR or MRS access trapped to EL2.
- HCR_EL2.APK, for accesses to Pointer authentication key registers, using AArch64 state, MSR or MRS access trapped to EL2.
- HCR_EL2.{NV, NV1}, for Nested virtualization register access, using AArch64 state, MSR or MRS access, trapped to EL2.
- HCR_EL2.AT, for execution of AT S1E* instructions, using AArch64 state, execution is trapped to EL2.
- HCR_EL2.{TERR, FIEN}, for accesses to RAS registers, using AArch64 state, MSR or MRS access, trapped to EL2.
- CPTR_EL3.TAM, for accesses to Activity Monitors registers, using AArch64 state, MSR or MRS access, trapped to EL3.

ISS encoding for an exception from MSRR, MRRS, or 128-bit System instruction execution in AArch64 state



Bits [24:22]

Reserved, RES0.

Op0, bits [21:20]

The Op0 value from the issued instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Op2, bits [19:17]

The Op2 value from the issued instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Op1, bits [16:14]

The Op1 value from the issued instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

CRn, bits [13:10]

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The CRn value from the issued instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Rt, bits [9:6]

The Rt value from the issued instruction, the general-purpose register used for the transfer.

Note

This value represents register pair of X[Rt:0], X[Rt:1].

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [5]

Reserved, RES0.

CRm, bits [4:1]

The CRm value from the issued instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Direction, bit [0]

Indicates the direction of the trapped instruction.

Direction	Meaning
0b0	Write access, MSRR instructions.
0b1	Read access, MRRS instructions.

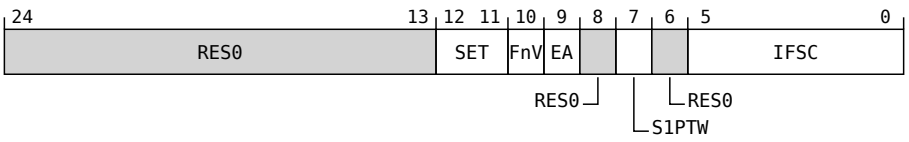
The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Additional Information for ISS encoding for an exception from MSRR, MRRS, or 128-bit System instruction execution in AArch64 state

The following fields describe configuration settings for generating exceptions from an MSRR or MRRS access that are reported using EC value 0b010100:

ISS encoding for an exception from an Instruction Abort



Bits [24:13]

Reserved, RES0.

SET, bits [12:11]

When FEAT_RAS is implemented and IFSC == 0b010000:

Synchronous Error Type. When IFSC is 0b010000, describes the PE error state after taking the Instruction Abort exception.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

SET	Meaning
0b00	Recoverable state (UER).
0b10	Uncontainable (UC).
0b11	Restartable state (UEO).

All other values are reserved.

Note

Software can use this information to determine what recovery might be possible. Taking a synchronous External abort exception might result in a PE state that is not recoverable.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

FnV, bit [10]

When IFSC == 0b010000:

FAR not Valid, for a synchronous External abort other than a synchronous External abort on a translation table walk.

FnV	Meaning
0b0	FAR is valid.
0b1	FAR is not valid, and holds an UNKNOWN value.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

EA, bit [9]

External abort type. This bit can provide an IMPLEMENTATION DEFINED classification of External aborts.

For any abort other than an External abort this bit returns a value of 0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [8]

Reserved, RES0.

S1PTW, bit [7]

For a stage 2 fault, indicates whether the fault was a stage 2 fault on an access made for a stage 1 translation table walk:

S1PTW	Meaning
0b0	Fault not on a stage 2 translation for a stage 1 translation table walk.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

S1PTW	Meaning
0b1	Fault on the stage 2 translation of an access for a stage 1 translation table walk.

For any abort other than a stage 2 fault this bit is RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [6]

Reserved, RES0.

IFSC, bits [5:0]

Instruction Fault Status Code.

IFSC	Meaning	Applies when
0b000000	Address size fault, level 0 of translation or translation table base register.	
0b000001	Address size fault, level 1.	
0b000010	Address size fault, level 2.	
0b000011	Address size fault, level 3.	
0b000100	Translation fault, level 0.	
0b000101	Translation fault, level 1.	
0b000110	Translation fault, level 2.	
0b000111	Translation fault, level 3.	
0b001001	Access flag fault, level 1.	
0b001010	Access flag fault, level 2.	
0b001011	Access flag fault, level 3.	
0b001100	Permission fault, level 0.	
0b001101	Permission fault, level 1.	
0b001110	Permission fault, level 2.	
0b001111	Permission fault, level 3.	
0b010000	Synchronous External abort, not on translation table walk or hardware update of translation table.	
0b010100	Synchronous External abort on translation table walk or hardware update of translation table, level 0.	
0b010101	Synchronous External abort on translation table walk or hardware update of translation table, level 1.	
0b010110	Synchronous External abort on translation table walk or hardware update of translation table, level 2.	
0b010111	Synchronous External abort on translation table walk or hardware update of translation table, level 3.	

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

IFSC	Meaning	Applies when
0b011000	Synchronous parity or ECC error on memory access, not on translation table walk.	FEAT_RAS is not implemented
0b011100	Synchronous parity or ECC error on memory access on translation table walk or hardware update of translation table, level 0.	FEAT_RAS is not implemented
0b011101	Synchronous parity or ECC error on memory access on translation table walk or hardware update of translation table, level 1.	FEAT_RAS is not implemented
0b011110	Synchronous parity or ECC error on memory access on translation table walk or hardware update of translation table, level 2.	FEAT_RAS is not implemented
0b011111	Synchronous parity or ECC error on memory access on translation table walk or hardware update of translation table, level 3.	FEAT_RAS is not implemented
0b110000	TLB conflict abort.	
0b110001	Unsupported atomic hardware update fault.	FEAT_HAFDBS is implemented

All other values are reserved.

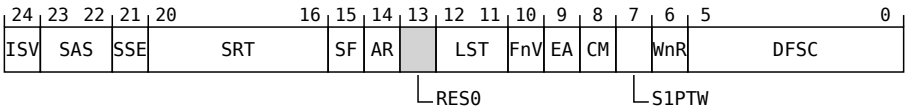
For more information about the lookup level associated with a fault, see 'The lookup level associated with MMU faults'.

If the S1PTW bit is set, then the level refers the level of the stage2 translation that is translating a stage 1 translation walk.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

ISS encoding for an exception from a Data Abort



ISV, bit [24]

Instruction Syndrome Valid. Indicates whether the syndrome information in ISS[23:14] is valid.

ISV	Meaning
0b0	No valid instruction syndrome. ISS[23:14] are RES0.
0b1	ISS[23:14] hold a valid instruction syndrome.

This bit is 0 for all faults reported in ESR_EL2 except the following stage 2 aborts:

- AArch64 loads and stores of a single general-purpose register (including the register specified with 0b11111, including those with Acquire/Release semantics, but excluding Load Exclusive or Store Exclusive and excluding those with writeback).

For these stage 2 aborts, ISV is UNKNOWN if the exception was generated in Debug state in Memory access mode, and otherwise indicates whether ISS[23:14] hold a valid syndrome.

ISV is 0 for all faults reported in ESR_EL1 or ESR_EL3.

When FEAT_RAS is implemented, ISV is 0 for any synchronous External abort.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

When FEAT_RAS is not implemented, it is IMPLEMENTATION DEFINED whether ISV is set to 1 or 0 on a synchronous External abort on a stage 2 translation table walk.

For ISS reporting, a stage 2 abort on a stage 1 translation table walk does not return a valid instruction syndrome, and therefore ISV is 0 for these aborts.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

SAS, bits [23:22]

When ISV == '1':

Syndrome Access Size. Indicates the size of the access attempted by the faulting operation.

SAS	Meaning
0b00	Byte
0b01	Halfword
0b10	Word
0b11	Doubleword

This field is UNKNOWN when the value of ISV is UNKNOWN.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

SSE, bit [21]

When ISV == '1':

Syndrome Sign Extend. For a byte, halfword, or word load operation, indicates whether the data item must be sign extended.

SSE	Meaning
0b0	Sign-extension not required.
0b1	Data item must be sign-extended.

For all other operations, this field is 0.

This field is UNKNOWN when the value of ISV is UNKNOWN.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

SRT, bits [20:16]

When ISV == '1':

Syndrome Register Transfer. The register number of the Wt/Xt/Rt operand of the faulting instruction.

This field is UNKNOWN when the value of ISV is UNKNOWN.

The reset behavior of this field is:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bit [15]

When ISV == '1':

SF, bit [15]

Sixty Four bit general-purpose register transfer. Width of the register accessed by the instruction is 64-bit.

SF	Meaning
0b0	Instruction loads/stores a 32-bit general-purpose register.
0b1	Instruction loads/stores a 64-bit general-purpose register.

Note

This field specifies the register width identified by the instruction, not the Execution state.

This field is UNKNOWN when the value of ISV is UNKNOWN.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

FnP, bit [15]

FAR not Precise.

FnP	Meaning
0b0	The FAR holds the faulting virtual address that generated the Data Abort.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

AR, bit [14]

When ISV == '1':

Acquire/Release.

AR	Meaning
0b0	Instruction did not have acquire/release semantics.
0b1	Instruction did have acquire/release semantics.

This field is UNKNOWN when the value of ISV is UNKNOWN.

For a load-acquire instruction that does not have acquire semantics as the result of the destination register being ZR, it is IMPLEMENTATION SPECIFIC whether this field is reported as 0 or 1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Otherwise:

Reserved, RES0.

Bit [13]

Reserved, RES0.

Bits [12:11]

When (DFSC IN {0b00xxxx} || DFSC IN {0b10101x}) && !(DFSC IN {0b0000xx}):

LST, bits [12:11]

Load/Store Type. Used when a Translation fault, Access flag fault, or Permission fault generates a Data Abort.

LST	Meaning
0b00	The instruction that generated the Data Abort is not specified by this field.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

When IsFeatureImplemented(FEAT_RAS) && ((DFSC == 0b010000 || DFSC IN {0b01001x}) || DFSC IN {0b0101xx}):

SET, bits [12:11]

Synchronous Error Type. Used when a synchronous External abort, not on a Translation table walk or hardware update of the Translation table, generated the Data Abort. Describes the PE error state after taking the Data Abort exception.

SET	Meaning
0b00	Recoverable state (UER).
0b11	Restartable state (UEO).

Note

Software can use this information to determine what recovery might be possible. Taking a synchronous External abort exception might result in a PE state that is not recoverable.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

FnV, bit [10]

FAR not Valid, for a synchronous External abort other than a synchronous External abort on a translation table walk.

FnV	Meaning
0b0	FAR is valid.
0b1	FAR is not valid, and holds an UNKNOWN value.

This field is valid only if the DFSC code is 0b010000. It is RES0 for all other aborts.

The reset behavior of this field is:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

EA, bit [9]

External abort type. This bit can provide an IMPLEMENTATION DEFINED classification of External aborts.

For any abort other than an External abort this bit returns a value of 0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

CM, bit [8]

Cache maintenance. Indicates whether the Data Abort came from a cache maintenance or address translation instruction:

CM	Meaning
0b0	The Data Abort was not generated by the execution of one of the System instructions identified in the description of value 1.
0b1	The Data Abort was generated by either the execution of a cache maintenance instruction or by a synchronous fault on the execution of an address translation instruction. The DC ZVA, DC GVA, and DC GZVA instructions are not classified as cache maintenance instructions, and therefore their execution cannot cause this field to be set to 1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

S1PTW, bit [7]

For a stage 2 fault, indicates whether the fault was a stage 2 fault on an access made for a stage 1 translation table walk:

S1PTW	Meaning
0b0	Fault not on a stage 2 translation for a stage 1 translation table walk.
0b1	Fault on the stage 2 translation of an access for a stage 1 translation table walk.

For any abort other than a stage 2 fault this bit is RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

WnR, bit [6]

Write not Read. Indicates whether a synchronous abort was caused by an instruction writing to a memory location, or by an instruction reading from a memory location.

WnR	Meaning
0b0	Abort caused by an instruction reading from a memory location.
0b1	Abort caused by an instruction writing to a memory location.

For faults on cache maintenance and address translation instructions, this bit always returns a value of 1.

For faults from an atomic instruction that both reads and writes from a memory location, this bit is set to 0 if a read of the address specified by the instruction would have generated the fault which is being reported, otherwise it is set to 1. The architecture permits, but does not require, a relaxation of this requirement such that for all stage 2 aborts on stage 1 translation table walks for atomic instructions, the WnR bit is always 0.

This field is UNKNOWN for:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- An External abort on an Atomic access.
- A fault reported using a DFSC value of `0b110101` or `0b110001`, indicating an unsupported Exclusive or atomic access.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

DFSC, bits [5:0]

Data Fault Status Code.

DFSC	Meaning	Applies when
`0b000000`	Address size fault, level 0 of translation or translation table base register.	
`0b000001`	Address size fault, level 1.	
`0b000010`	Address size fault, level 2.	
`0b000011`	Address size fault, level 3.	
`0b000100`	Translation fault, level 0.	
`0b000101`	Translation fault, level 1.	
`0b000110`	Translation fault, level 2.	
`0b000111`	Translation fault, level 3.	
`0b001001`	Access flag fault, level 1.	
`0b001010`	Access flag fault, level 2.	
`0b001011`	Access flag fault, level 3.	
`0b001100`	Permission fault, level 0.	
`0b001101`	Permission fault, level 1.	
`0b001110`	Permission fault, level 2.	
`0b001111`	Permission fault, level 3.	
`0b010000`	Synchronous External abort, not on translation table walk or hardware update of translation table.	
`0b010100`	Synchronous External abort on translation table walk or hardware update of translation table, level 0.	
`0b010101`	Synchronous External abort on translation table walk or hardware update of translation table, level 1.	
`0b010110`	Synchronous External abort on translation table walk or hardware update of translation table, level 2.	
`0b010111`	Synchronous External abort on translation table walk or hardware update of translation table, level 3.	
`0b011000`	Synchronous parity or ECC error on memory access, not on translation table walk.	FEAT_RAS is not implemented
`0b011100`	Synchronous parity or ECC error on memory access on translation table walk or hardware update of translation table, level 0.	FEAT_RAS is not implemented
`0b011101`	Synchronous parity or ECC error on memory access on translation table walk or hardware update of translation table, level 1.	FEAT_RAS is not implemented
`0b011110`	Synchronous parity or ECC error on memory access on translation table walk or hardware update of translation table, level 2.	FEAT_RAS is not implemented

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

DFSC	Meaning	Applies when
0b011111	Synchronous parity or ECC error on memory access on translation table walk or hardware update of translation table, level 3.	FEAT_RAS is not implemented
0b100001	Alignment fault.	
0b110000	TLB conflict abort.	
0b110001	Unsupported atomic hardware update fault.	FEAT_HAFDBS is implemented
0b110100	IMPLEMENTATION DEFINED fault (Lockdown).	
0b110101	IMPLEMENTATION DEFINED fault (Unsupported Exclusive or Atomic access).	

All other values are reserved.

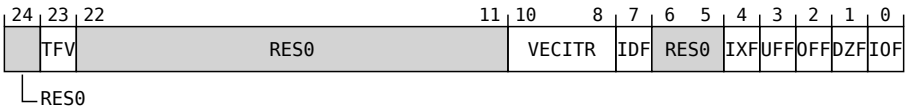
For more information about the lookup level associated with a fault, see 'The lookup level associated with MMU faults'.

If the S1PTW bit is set, then the level refers the level of the stage2 translation that is translating a stage 1 translation walk.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

ISS encoding for an exception from a trapped floating-point exception



Bit [24]

Reserved, RES0.

TFV, bit [23]

Trapped Fault Valid bit. Indicates whether the IDF, IXF, UFF, OFF, DZF, and IOF bits hold valid information about trapped floating-point exceptions.

TFV	Meaning
0b0	The IDF, IXF, UFF, OFF, DZF, and IOF bits do not hold valid information about trapped floating-point exceptions and are UNKNOWN.
0b1	One or more floating-point exceptions occurred during an operation performed while executing the reported instruction. The IDF, IXF, UFF, OFF, DZF, and IOF bits indicate trapped floating-point exceptions that occurred. For more information, see 'Floating-point exceptions and exception traps'.

It is IMPLEMENTATION DEFINED whether this field is set to 0 on an exception generated by a trapped floating-point exception from an instruction that is performing floating-point operations on more than one lane of a vector.

Note

This is not a requirement. Implementations can set this field to 1 on a trapped floating-point exception from an instruction and return valid information in the {IDF, IXF, UFF, OFF, DZF, IOF} fields.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Bits [22:11]

Reserved, RES0.

VECITR, bits [10:8]

For a trapped floating-point exception from an instruction executed in AArch64 state this field is UNKNOWN.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

IDF, bit [7]

Input Denormal floating-point exception trapped bit. If the TFV field is 0, this bit is UNKNOWN. Otherwise, the possible values of this bit are:

IDF	Meaning
0b0	Input denormal floating-point exception has not occurred.
0b1	Input denormal floating-point exception occurred during execution of the reported instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [6:5]

Reserved, RES0.

IXF, bit [4]

Inexact floating-point exception trapped bit. If the TFV field is 0, this bit is UNKNOWN. Otherwise, the possible values of this bit are:

IXF	Meaning
0b0	Inexact floating-point exception has not occurred.
0b1	Inexact floating-point exception occurred during execution of the reported instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

UFF, bit [3]

Underflow floating-point exception trapped bit. If the TFV field is 0, this bit is UNKNOWN. Otherwise, the possible values of this bit are:

UFF	Meaning
0b0	Underflow floating-point exception has not occurred.
0b1	Underflow floating-point exception occurred during execution of the reported instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

OFF, bit [2]

Overflow floating-point exception trapped bit. If the TFV field is 0, this bit is UNKNOWN. Otherwise, the possible values of this bit are:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

OFF	Meaning
0b0	Overflow floating-point exception has not occurred.
0b1	Overflow floating-point exception occurred during execution of the reported instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

DZF, bit [1]

Divide by Zero floating-point exception trapped bit. If the TFV field is 0, this bit is UNKNOWN. Otherwise, the possible values of this bit are:

DZF	Meaning
0b0	Divide by Zero floating-point exception has not occurred.
0b1	Divide by Zero floating-point exception occurred during execution of the reported instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

IOF, bit [0]

Invalid Operation floating-point exception trapped bit. If the TFV field is 0, this bit is UNKNOWN. Otherwise, the possible values of this bit are:

IOF	Meaning
0b0	Invalid Operation floating-point exception has not occurred.
0b1	Invalid Operation floating-point exception occurred during execution of the reported instruction.

The reset behavior of this field is:

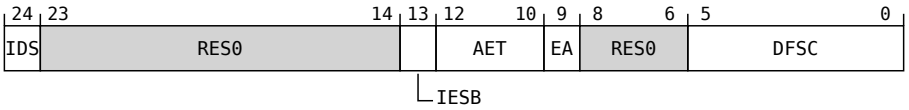
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Additional Information for ISS encoding for an exception from a trapped floating-point exception

In an implementation that supports the trapping of floating-point exceptions:

- From an Exception level using AArch64, the FPCR.{IDE, IXE, UFE, OFE, DZE, IOE} bits enable each of the floating-point exception traps.

ISS encoding for an SError exception



Note

In earlier versions of the architecture, an SError exception is referred to as an SError interrupt or an asynchronous External abort exception.

IDS, bit [24]

IMPLEMENTATION DEFINED syndrome.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

IDS	Meaning
0b0	Bits [23:0] of the ISS field holds the fields described in this encoding. **Note** If FEAT_RAS is not implemented, bits [23:0] of the ISS field are RES0.
0b1	Bits [23:0] of the ISS field holds IMPLEMENTATION DEFINED syndrome information that can be used to provide additional information about the SError exception.

Note

This field was previously called ISV.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [23:14]

Reserved, RES0.

IESB, bit [13]

When FEAT_IESB is implemented and DFSC == 0b010001:

Implicit error synchronization event.

IESB	Meaning
0b0	The SError exception was either not synchronized by the implicit error synchronization event or not taken immediately.
0b1	The SError exception was synchronized by the implicit error synchronization event and taken immediately.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

AET, bits [12:10]

When FEAT_RAS is implemented and DFSC == 0b010001:

Asynchronous Error Type.

Describes the PE error state after taking the SError exception.

AET	Meaning
0b000	Uncontainable (UC).
0b001	Unrecoverable state (UEU).
0b010	Restartable state (UEO).
0b011	Recoverable state (UER).
0b110	Corrected (CE).

All other values are reserved.

If multiple errors are taken as a single SError exception, the overall PE error state is reported.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

Software can use this information to determine what recovery might be possible. The recovery software must also examine any implemented fault records to determine the location and extent of the error.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

EA, bit [9]

When FEAT_RAS is implemented and DFSC == 0b010001:

External abort type. Provides an IMPLEMENTATION DEFINED classification of External aborts.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bits [8:6]

Reserved, RES0.

DFSC, bits [5:0]

When FEAT_RAS is implemented:

Data Fault Status Code.

DFSC	Meaning
0b000000	Uncategorized error.
0b010001	Asynchronous SError exception.

All other values are reserved.

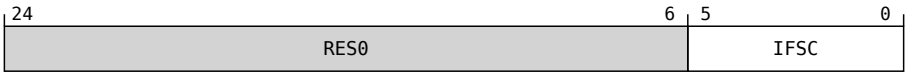
The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

ISS encoding for an exception from a Breakpoint or Vector Catch debug exception



Bits [24:6]

Reserved, RES0.

IFSC, bits [5:0]

Instruction Fault Status Code.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

IFSC	Meaning
0b100010	Debug exception.

The reset behavior of this field is:

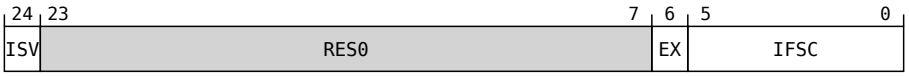
- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Additional Information for ISS encoding for an exception from a Breakpoint or Vector Catch debug exception

For more information about generating these exceptions:

- For exceptions from AArch64, see 'Breakpoint exceptions'.

ISS encoding for an exception from a Software Step exception



ISV, bit [24]

Instruction syndrome valid. Indicates whether the EX bit, ISS[6], is valid, as follows:

ISV	Meaning
0b0	EX bit is RES0.
0b1	EX bit is valid.

See the EX bit description for more information.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [23:7]

Reserved, RES0.

EX, bit [6]

Exclusive operation. If the ISV bit is set to 1, this bit indicates whether a Load-Exclusive instruction was stepped.

EX	Meaning
0b0	An instruction other than a Load-Exclusive instruction was stepped.
0b1	A Load-Exclusive instruction was stepped.

If the ISV bit is set to 0, this bit is RES0, indicating no syndrome data is available.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

IFSC, bits [5:0]

Instruction Fault Status Code.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

IFSC	Meaning
0b100010	Debug exception.

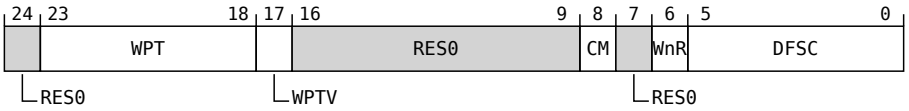
The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Additional Information for ISS encoding for an exception from a Software Step exception

For more information about generating these exceptions, see 'Software Step exceptions'.

ISS encoding for an exception from a Watchpoint exception



Bit [24]

Reserved, RES0.

WPT, bits [23:18]

When FEAT_Debugv8p2 is implemented:

Watchpoint number.

All other values are reserved.

Otherwise:

Reserved, RES0.

WPTV, bit [17]

When FEAT_Debugv8p2 is implemented:

Watchpoint number Valid.

WPTV	Meaning
0b0	The WPT field is invalid, and holds an UNKNOWN value.
0b1	The WPT field is valid, and holds the number of a watchpoint that triggered a Watchpoint exception.

When a Watchpoint exception is triggered by a watchpoint match:

- If the PE sets any of FnV, FnP, or WPF to 1, then the PE sets WPTV to 1.
- Otherwise, the PE sets WPTV to an IMPLEMENTATION DEFINED value, 0 or 1.

Otherwise:

Reserved, RES0.

Bits [16:9]

Reserved, RES0.

CM, bit [8]

Cache maintenance. Indicates whether the Watchpoint exception came from a cache maintenance instruction:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

CM	Meaning
0b0	The Watchpoint exception was not generated by the execution of one of the System instructions identified in the description of value 1.
0b1	The Watchpoint exception was generated by the execution of a cache maintenance instruction. The DC ZVA instruction is not classifed as a cache maintenance instruction, and therefore their execution does not cause this field to be set to 1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [7]

Reserved, RES0.

WnR, bit [6]

Write not Read. Indicates whether the Watchpoint exception was caused by an instruction writing to a memory location, or by an instruction reading from a memory location.

WnR	Meaning
0b0	Watchpoint exception caused by an instruction reading from a memory location.
0b1	Watchpoint exception caused by an instruction writing to a memory location.

For Watchpoint exceptions on cache maintenance instructions, this bit always returns a value of 1.

For Watchpoint exceptions from an atomic instruction, this field is set to 0 if a read of the location would have generated the Watchpoint exception, otherwise it is set to 1.

If multiple watchpoints match on the same access, it is UNPREDICTABLE which watchpoint generates the Watchpoint exception.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

DFSC, bits [5:0]

Data Fault Status Code.

DFSC	Meaning
0b100010	Debug exception.

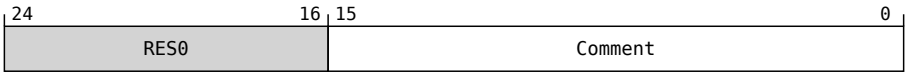
The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Additional Information for ISS encoding for an exception from a Watchpoint exception

For more information about generating these exceptions, see 'Watchpoint exceptions'.

ISS encoding for an exception from execution of a Breakpoint instruction



Bits [24:16]

Reserved, RES0.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Comment, bits [15:0]

Set to the instruction comment field value, zero extended as necessary.

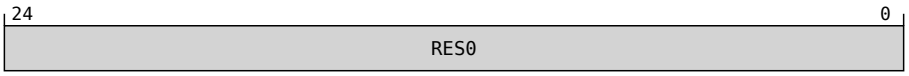
The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Additional Information for ISS encoding for an exception from execution of a Breakpoint instruction

For more information about generating these exceptions, see 'Breakpoint instruction exceptions'.

ISS encoding for an exception from a trapped Pointer Authentication instruction



Bits [24:0]

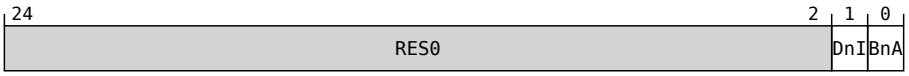
Reserved, RES0.

Additional Information for ISS encoding for an exception from a trapped Pointer Authentication instruction

For more information about generating these exceptions, see:

- HCR_EL2.API, for exceptions from Pointer authentication instructions, using AArch64 state, trapped to EL2.

ISS encoding for a PAC Fail exception



Bits [24:2]

Reserved, RES0.

DnI, bit [1]

This field indicates whether the exception is as a result of an Instruction key or a Data key.

DnI	Meaning
0b0	Instruction Key.
0b1	Data Key.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

BnA, bit [0]

This field indicates whether the exception is as a result of an A key or a B key.

BnA	Meaning
0b0	A key.
0b1	B key.

The reset behavior of this field is:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Additional Information for ISS encoding for a PAC Fail exception

The following instructions generate a PAC Fail exception when the Pointer Authentication Code (PAC) is incorrect:

- AUTDA, AUTDZA.
- AUTDB, AUTDZB.
- AUTIA, AUTIA1716, AUTIASP, AUTIAZ, AUTIZA.
- AUTIB, AUTIB1716, AUTIBSP, AUTIBZ, AUTIZB.
- AUTIASPPC, AUTIASPPCR, AUTIA171615.
- AUTIBSPPC, AUTIBSPPCR, AUTIB171615.

If FEAT_FPACCOMBINE is implemented, the following instructions generate a PAC Fail exception when the Pointer Authentication Code (PAC) is incorrect:

- RETAA, RETAB.
- RETAASPPC, RETABSPPC.
- RETAASPPCR, RETABSPPCR.
- BLRAA, BLRAAZ, BLRAB, BLRABZ.
- BRAA, BRAB, BRAAZ, BRABZ.
- ERETAA, ERETAB.
- LDRAA, LDRAB, whether the authenticated address is written back to the base register or not.

Accessing ESR_EL2

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, ESR_EL2

op0	op1	CRn	CRm	op2
0b11	0b100	0b0101	0b0010	0b000

```
if PSTATE.EL == EL0 then
    UNDEFINED;
elsif PSTATE.EL == EL1 then
    UNDEFINED;
elsif PSTATE.EL == EL2 then
    X[t, 64] = ESR_EL2;
```

MSR ESR_EL2, <Xt>

D12.2.32 FAR_EL1, Fault Address Register (EL1)

The FAR_EL1 characteristics are:

Purpose

Holds the faulting Virtual Address for all synchronous Instruction Abort exceptions, Data Abort exceptions, PC alignment fault exceptions and Watchpoint exceptions that are taken to EL1.

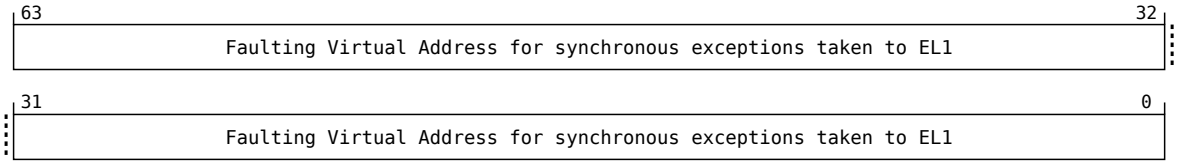
Configuration

There are no configuration notes.

Attributes

FAR_EL1 is a 64-bit register.

Field descriptions



VA, bits [63:0]

Faulting Virtual Address for synchronous exceptions taken to EL1. Exceptions that set the FAR_EL1 are Instruction Aborts (EC `0x20` or `0x21`), Data Aborts (EC `0x24` or `0x25`), PC alignment faults (EC `0x22`), and Watchpoints (EC `0x34` or `0x35`). ESR_EL1.EC holds the EC syndrome value for the exception.

For a synchronous External abort:

- If the VA that generated the abort was from an address range for which Address tagging is enabled for the translation regime in use when the abort was generated, then bits[63:56] of FAR_EL1 are UNKNOWN.
- If the VA that generated the abort was from an address range for which Address tagging is disabled and Logical Address Tagging is enabled for the translation regime in use when the abort was generated, then bits[59:56] of FAR_EL1 are UNKNOWN.

For a synchronous External abort other than a synchronous External abort on a translation table walk, this field is valid only if ESR_EL1.FnV is 0, and FAR_EL1 is UNKNOWN if ESR_EL1.FnV is 1.

If a memory fault that sets FAR_EL1 is generated from a data cache maintenance or other DC instruction, this field holds the address specified in the register argument of the instruction.

When the PE sets ESR_EL1.{FnV,FnP} to {0,1} on taking a Watchpoint exception, the PE sets FAR_EL1 to any address within the naturally-aligned fault granule that contains the virtual address of the memory access that generated the Watchpoint exception.

For a Data Abort exception or Watchpoint exception, if address tagging is enabled for the address accessed by the data access that caused the exception, then this field includes the tag. For more information about address tagging, see ‘Address tagging’.

Execution at EL0 makes FAR_EL1 become UNKNOWN.

Note

The address held in this field is an address accessed by the instruction fetch or data access that caused the exception that actually gave rise to the instruction or Data Abort. It is the lower address that gave rise to the fault that is reported. Where different faults from different addresses arise from the same instruction, such as for an instruction that loads or stores an unaligned address that crosses a page boundary, the architecture does not prioritize which fault is reported.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

For all other exceptions taken to EL1, FAR_EL1 is UNKNOWN.

FAR_EL1 is made UNKNOWN on an exception return from EL1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing FAR_EL1

Accesses to this register use the following encodings in the System register encoding space:

`MRS <Xt>, FAR_EL1`

op0	op1	CRn	CRm	op2
0b11	0b000	0b0110	0b0000	0b000

```
if PSTATE.EL == EL0 then
    UNDEFINED;
elsif PSTATE.EL == EL1 then
    if HCR_EL2.TRVM == '1' then
        AArch64.SystemAccessTrap(EL2, 0x18);
    else
        X[t, 64] = FAR_EL1;
elsif PSTATE.EL == EL2 then
    X[t, 64] = FAR_EL1;
```

`MSR FAR_EL1, <Xt>`

op0	op1	CRn	CRm	op2
0b11	0b000	0b0110	0b0000	0b000

```
if PSTATE.EL == EL0 then
    UNDEFINED;
elsif PSTATE.EL == EL1 then
    if HCR_EL2.TVM == '1' then
        AArch64.SystemAccessTrap(EL2, 0x18);
    else
        FAR_EL1 = X[t, 64];
elsif PSTATE.EL == EL2 then
    FAR_EL1 = X[t, 64];
```

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D12.2.33 FAR_EL2, Fault Address Register (EL2)

The FAR_EL2 characteristics are:

Purpose

Holds the faulting Virtual Address for all synchronous Instruction Abort exceptions, Data Abort exceptions, PC alignment fault exceptions and Watchpoint exceptions that are taken to EL2.

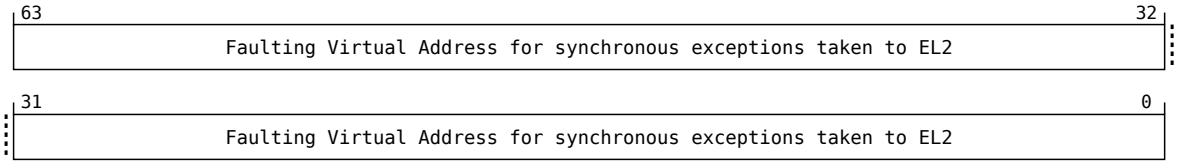
Configuration

There are no configuration notes.

Attributes

FAR_EL2 is a 64-bit register.

Field descriptions



VA, bits [63:0]

Faulting Virtual Address for synchronous exceptions taken to EL2. Exceptions that set the FAR_EL2 are Instruction Aborts (EC `0x20` or `0x21`), Data Aborts (EC `0x24` or `0x25`), PC alignment faults (EC `0x22`), and Watchpoints (EC `0x34` or `0x35`). ESR_EL2.EC holds the EC syndrome value for the exception.

For a synchronous External abort:

- If the VA that generated the abort was from an address range for which Address tagging is enabled for the translation regime in use when the abort was generated, then bits[63:56] of FAR_EL2 are UNKNOWN.
- If the VA that generated the abort was from an address range for which Address tagging is disabled and Logical Address Tagging is enabled for the translation regime in use when the abort was generated, then bits[59:56] of FAR_EL2 are UNKNOWN.

For a synchronous External abort other than a synchronous External abort on a translation table walk, this field is valid only if ESR_EL2.FnV is 0, and FAR_EL2 is UNKNOWN if ESR_EL2.FnV is 1.

If a memory fault that sets FAR_EL2 is generated from a data cache maintenance or other DC instruction, this field holds the address specified in the register argument of the instruction.

When the PE sets ESR_EL2.{FnV,FnP} to {0,1} on taking a Watchpoint exception, the PE sets FAR_EL2 to any address within the naturally-aligned fault granule that contains the virtual address of the memory access that generated the Watchpoint exception.

For a Data Abort exception or Watchpoint exception, if address tagging is enabled for the address accessed by the data access that caused the exception, then this field includes the tag. For more information about address tagging, see 'Address tagging'.

Execution at EL1 or EL0 makes FAR_EL2 become UNKNOWN.

Note

The address held in this field is an address accessed by the instruction fetch or data access that caused the exception that actually gave rise to the instruction or Data Abort. It is the lower address that gave rise to the fault that is reported. Where different faults from different addresses arise from the same instruction, such as for an instruction that loads or stores an unaligned address that crosses a page boundary, the architecture does not prioritize which fault is reported.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

For all other exceptions taken to EL2, FAR_EL2 is UNKNOWN.

FAR_EL2 is made UNKNOWN on an exception return from EL2.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing FAR_EL2

Accesses to this register use the following encodings in the System register encoding space:

`MRS <Xt>, FAR_EL2`

op0	op1	CRn	CRm	op2
0b11	0b100	0b0110	0b0000	0b000

```
if PSTATE.EL == EL0 then
    UNDEFINED;
elsif PSTATE.EL == EL1 then
    UNDEFINED;
elsif PSTATE.EL == EL2 then
    X[t, 64] = FAR_EL2;
```

`MSR FAR_EL2, <Xt>`

op0	op1	CRn	CRm	op2
0b11	0b100	0b0110	0b0000	0b000

```
if PSTATE.EL == EL0 then
    UNDEFINED;
elsif PSTATE.EL == EL1 then
    UNDEFINED;
elsif PSTATE.EL == EL2 then
    FAR_EL2 = X[t, 64];
```

D12.2.34 HACR_EL2, Hypervisor Auxiliary Control Register

The HACR_EL2 characteristics are:

Purpose

Controls trapping to EL2 of IMPLEMENTATION DEFINED aspects of EL1 or EL0 operation.

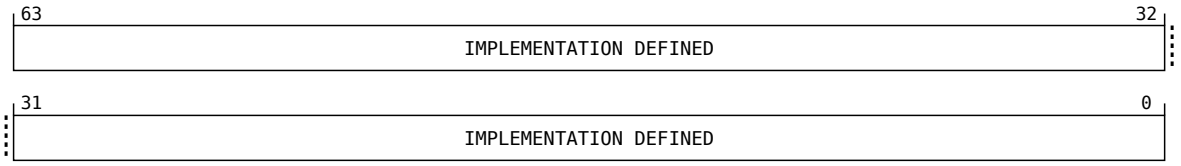
Configuration

There are no configuration notes.

Attributes

HACR_EL2 is a 64-bit register.

Field descriptions



IMPLEMENTATION DEFINED, bits [63:0]

IMPLEMENTATION DEFINED.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing HACR_EL2

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, HACR_EL2

op0	op1	CRn	CRm	op2
0b11	0b100	0b0001	0b0001	0b111

```
if PSTATE.EL == EL0 then
    UNDEFINED;
elsif PSTATE.EL == EL1 then
    UNDEFINED;
elsif PSTATE.EL == EL2 then
    X[t, 64] = HACR_EL2;
```

MSR HACR_EL2, <Xt>

op0	op1	CRn	CRm	op2
0b11	0b100	0b0001	0b0001	0b111

```
if PSTATE.EL == EL0 then
    UNDEFINED;
elsif PSTATE.EL == EL1 then
    UNDEFINED;
elsif PSTATE.EL == EL2 then
    HACR_EL2 = X[t, 64];
```

Non-Confidential

D12.2.35 HCR_EL2, Hypervisor Configuration Register

The HCR_EL2 characteristics are:

Purpose

Provides configuration controls for virtualization, including defining whether various operations are trapped to EL2.

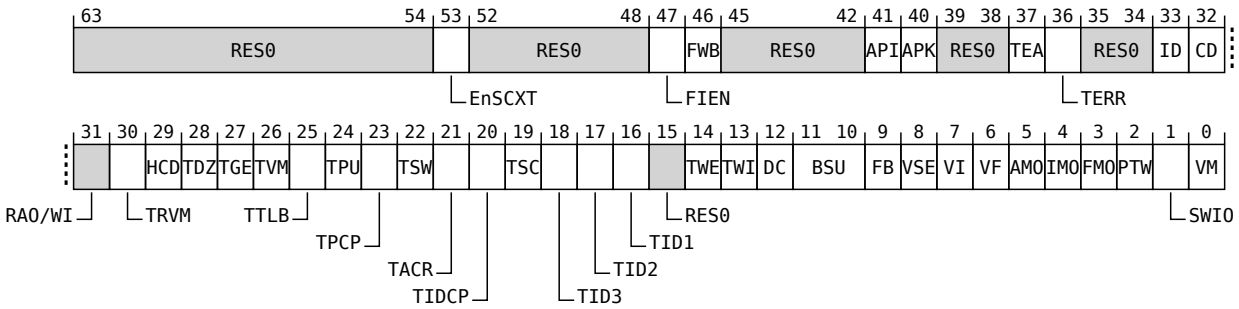
Configuration

There are no configuration notes.

Attributes

HCR_EL2 is a 64-bit register.

Field descriptions



Bits [63:54]

Reserved, RES0.

EnSCXT, bit [53]

When FEAT_CSV2_2 is implemented or FEAT_CSV2_1p2 is implemented:

Enable Access to the SCXTNUM_EL1 and SCXTNUM_EL0 registers. The defined values are:

EnSCXT	Meaning
0b0	When EL2 is enabled in the current Security state, EL1 accesses to SCXTNUM_EL0 and SCXTNUM_EL1 are disabled, causing an exception to EL2, and the value of the registers to be treated as 0. When EL2 is enabled in the current Security state, EL0 access to SCXTNUM_EL0 is disabled, causing an exception to EL2, and the value of the register to be treated as 0.
0b1	This control does not cause accesses to SCXTNUM_EL0 or SCXTNUM_EL1 to be trapped.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bits [52:48]

Reserved, RES0.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

FIEN, bit [47]

When FEAT_RASv1p1 is implemented:

Fault Injection Enable. Unless this bit is set to 1, accesses to the ERXPFGCDN_EL1, ERXPFGCTL_EL1, and ERXPFGF_EL1 registers from EL1 generate a Trap exception to EL2, reported using EC syndrome value 0x18.

FIEN	Meaning
0b0	Accesses to the specified registers from EL1 are trapped to EL2.
0b1	This control does not cause any instructions to be trapped.

If ERRIDR_EL1.NUM is zero, meaning no error records are implemented, or no error record accessible using System registers is owned by a node that implements the RAS Common Fault Injection Model Extension, then this bit might be RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

FWB, bit [46]

When FEAT_S2FWB is implemented:

Forced Write-Back. Defines the combined cacheability attributes in a 2 stage translation regime.

FWB	Meaning
0b0	When this bit is 0, then the combination of stage 1 and stage 2 translations on memory type and cacheability attributes are as described in the Armv8.0 architecture. For more information, see 'Combining stage 1 and stage 2 memory type attributes'. For an R profile implementation: The encoding of the stage 2 memory type and cacheability attributes is derived from MAIR_EL2 register, as described in the Armv8-R AArch64 architecture.
0b1	When this bit is 1, then the encoding of the stage 2 memory type and cacheability attributes in bits[5:2] of the stage 2 Page or Block descriptors are as described in 'Stage 2 memory type and Cacheability attributes when FEAT_S2FWB is enabled'. For an R profile implementation: • If the inner and outer memory attributes for stage 2 EL1&0 translation regime must be the same with the same encoding, otherwise, the combined attribute is UNKNOWN. • If the stage 2 EL1&0 translation regime memory attribute is Write-Back with MAIR_EL2.Attr[7:6] = 0b11, then the combined attribute is Normal Write-Back. For all other encodings, the combination of stage 1 and stage 2 translations on memory type and cacheability attributes are as described in the Armv8.0 architecture.

This bit is permitted to be cached in a TLB.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bits [45:42]

Reserved, RES0.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

API, bit [41]

When FEAT_PAuth is implemented:

Controls the use of instructions related to Pointer Authentication:

- PACGA.
- AUTDA, AUTDB, AUTDZA, AUTDZB, AUTIA, AUTIA1716, AUTIASP, AUTIAZ, AUTIB, AUTIB1716, AUTIBSP, AUTIBZ, AUTIZA, AUTIZB.
- PACDA, PACDB, PACDZA, PACDZB, PACIA, PACIA1716, PACIASP, PACIAZ, PACIB, PACIB1716, PACIBSP, PACIBZ, PACIZA, PACIZB.
- RETAA, RETAB, BRAA, BRAB, BLRAA, BLRAB, BRAAZ, BRABZ, BLRAAZ, BLRABZ.
- ERETAA, ERETAB, LDRAA, and LDRAB.

This field is ignored if the instruction is disabled as a result of the SCTLR_ELx.{EnIB, EnIA, EnDA, EnDB} fields.

API	Meaning
0b0	The instructions related to Pointer Authentication are trapped to EL2 and reported using EC syndrome value 0x09, when the instructions are enabled for the EL1&0 translation regime, from: • EL0. • EL1.
0b1	This control does not cause any instructions to be trapped.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

APK, bit [40]

When FEAT_PAuth is implemented:

Trap registers holding "key" values for Pointer Authentication. Traps accesses to the following registers from EL1 to EL2, reported using EC syndrome value 0x18:

- APIAKeyLo_EL1, APIAKeyHi_EL1, APIBKeyLo_EL1, APIBKeyHi_EL1, APDAKeyLo_EL1, APDAKeyHi_EL1, APDBKeyLo_EL1, APDBKeyHi_EL1, APGAKeyLo_EL1, and APGAKeyHi_EL1.

APK	Meaning
0b0	Access to the registers holding "key" values for pointer authentication from EL1 are trapped to EL2.
0b1	This control does not cause any instructions to be trapped.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bits [39:38]

Reserved, RES0.

TEA, bit [37]

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

When FEAT_RAS is implemented:

Route synchronous External abort exceptions to EL2.

TEA	Meaning
0b0	Synchronous External abort exceptions are unaffected by this mechanism. That is, synchronous External abort exceptions are not taken to EL2 unless routed to EL2 by another control.
0b1	When executing at Exception levels below EL2, synchronous External abort exceptions are taken to EL2.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

TERR, bit [36]

When FEAT_RAS is implemented:

Trap accesses of Error Record registers. Enables a trap to EL2 on accesses of Error Record registers.

TERR	Meaning
0b0	Accesses of the specified Error Record registers are not trapped by this mechanism.
0b1	Accesses of the specified Error Record registers at EL1 are trapped to EL2, unless the instruction generates a higher priority exception.

In AArch64 state, the instructions affected by this control are:

- MRS and MSR accesses to ERRSELR_EL1, ERXADDR_EL1, ERXCTLR_EL1, ERXMISC0_EL1, ERXMISC1_EL1, and ERXSTATUS_EL1.
- MRS accesses to ERRIDR_EL1 and ERXFR_EL1.
- If FEAT_RASv1p1 is implemented, MRS and MSR accesses to ERXMISC2_EL1 and ERXMISC3_EL1.

Unless the instruction generates a higher priority exception, trapped instructions generate an exception to EL2.

Trapped AArch64 instructions are reported using EC syndrome value 0x18.

Accessing this field has the following behavior:

- This field is permitted to be RES0 if all of the following are true:
  - ERRSELR_EL1 and all ERX* registers are implemented as UNDEFINED or RAZ/WI.
  - ERRIDR_EL1.NUM is zero.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bits [35:34]

Reserved, RES0.

ID, bit [33]

Stage 2 Instruction access cacheability disable. For the EL1&0 translation regime, when HCR_EL2.VM==1, this control forces all stage 2 translations for instruction accesses to Normal memory to be Non-cacheable.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

The behavior is the same irrespective of whether the instruction accesses are to an MPU region or Background region.

ID	Meaning
0b0	This control has no effect on stage 2 of the EL1&0 translation regime.
0b1	Forces all stage 2 translations for instruction accesses to Normal memory to be Non-cacheable.

This bit has no effect on the EL2 translation regime.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

CD, bit [32]

Stage 2 Data access cacheability disable. For the EL1&0 translation regime, when HCR_EL2.VM==1, this control forces all stage 2 translations for data accesses and translation table walks to Normal memory to be Non-cacheable.

Note

The behavior is same irrespective of whether the data accesses is to MPU region or Background region.

CD	Meaning
0b0	This control has no effect on stage 2 of the EL1&0 translation regime for data accesses and translation table walks.
0b1	Forces all stage 2 translations for data accesses and translation table walks to Normal memory to be Non-cacheable.

This bit has no effect on the EL2 translation regime.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [31]

Reserved, RAO/WI.

TRVM, bit [30]

Trap Reads of Virtual Memory controls. Traps reads of the virtual memory control registers to EL2 as follows:

- If EL1 is using AArch64, EL1 accesses to the following registers are trapped to EL2 and reported using EC syndrome value 0x18 for MRS:
  - SCTLR_EL1, TTBR0_EL1, TTBR1_EL1, TCR_EL1, ESR_EL1, FAR_EL1, AFSR0_EL1, AFSR1_EL1, MAIR_EL1, AMAIR_EL1, and CONTEXTIDR_EL1.
  - If EL1 is in PMSAv8-64 context, EL1 accesses to the following registers are also trapped to EL2 and reported using EC syndrome value 0x18 - PRENR_EL1, PRSELR_EL1, PRBAR_EL1, PRBARn_EL1, PRLAR_EL1, and PRLARn_EL1.

TRVM	Meaning
0b0	This control does not cause any instructions to be trapped.
0b1	Read accesses to the specified Virtual Memory control registers are trapped to EL2.

When HCR_EL2.TGE is 1, the PE ignores the value of this field for all purposes other than a direct read of this field.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

EL2 provides a second stage of address translation, that a hypervisor can use to remap the address map defined by a Guest OS. In addition, a hypervisor can trap attempts by a Guest OS to write to the registers that control the memory system. A hypervisor might use this trap as part of its virtualization of memory management.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

HCD, bit [29]

HVC instruction disable. Disables EL1 and EL2 execution of HVC instructions, from both Execution states, reported using EC syndrome value `0x00`.

HCD	Meaning
`0b0`	HVC instruction execution is enabled at EL2 and EL1.
`0b1`	HVC instructions are UNDEFINED at EL2 and EL1. Any resulting exception is taken to the Exception level at which the HVC instruction is executed.

Note

HVC instructions are always UNDEFINED at EL0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

TDZ, bit [28]

Traps EL0 and EL1 execution of the following instructions to EL2 from AArch64 state only, reported using EC syndrome value `0x18`:

- DC ZVA.

TDZ	Meaning
`0b0`	This control does not cause any instructions to be trapped.
`0b1`	In AArch64 state, any attempt to execute an instruction this trap applies to at EL1, or at EL0 when the instruction is not UNDEFINED at EL0, is trapped to EL2. Reading the DCZID_EL0 returns a value that indicates that the instructions this trap applies to are not supported.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

TGE, bit [27]

Trap General Exceptions, from EL0.

TGE	Meaning
`0b0`	This control has no effect on execution at EL0.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

TGE	Meaning
0b1	When EL2 is not enabled in the current Security state, this control has no effect on execution at EL0. When EL2 is enabled in the current Security state, in all cases: • All exceptions that would be routed to EL1 are routed to EL2. • If EL1 is using AArch64, the SCTLR_EL1.M field is treated as being 0 for all purposes other than returning the result of a direct read of SCTLR_EL1. • If stage 1 EL1&0 translation regime is in PMSAv8-64 context, the SCTLR_EL1.BR field is treated as being 0 for all purposes other than returning the result of a direct read of SCTLR_EL1. • All virtual interrupts and virtual exceptions are disabled. • Any IMPLEMENTATION DEFINED mechanisms for signaling virtual interrupts are disabled. • An exception return to EL1 is treated as an illegal exception return. • The MDCR_EL2.{TDRA, TDOSA, TDA, TDE} fields are treated as being 1 for all purposes other than returning the result of a direct read of MDCR_EL2. In addition, when EL2 is enabled in the current Security state, the Effective values of the HCR_EL2.{FMO, IMO, AMO} fields are 1.

HCR_EL2.TGE must not be cached in a TLB.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

TVM, bit [26]

Trap Virtual Memory controls. Traps writes to the virtual memory control registers to EL2 as follows:

- If EL1 is using AArch64, the following registers are trapped to EL2 and reported using EC syndrome value 0x18 for MSR:
  - SCTLR_EL1, TTBR0_EL1, TTBR1_EL1, TCR_EL1, ESR_EL1, FAR_EL1, AFSR0_EL1, AFSR1_EL1, MAIR_EL1, AMAIR_EL1, and CONTEXTIDR_EL1.
  - If EL1 is in PMSAv8-64 context, EL1 accesses to the following registers are also trapped to EL2 and reported using EC syndrome value 0x18 - PRENR_EL1, PRSELR_EL1, PRBAR_EL1, PRBARn_EL1, and PRLAR_EL1, and PRLARn_EL1.

TVM	Meaning
0b0	This control does not cause any instructions to be trapped.
0b1	Write accesses to the specified Virtual Memory control registers are trapped to EL2.

When HCR_EL2.TGE is 1, the PE ignores the value of this field for all purposes other than a direct read of this field.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

TTLB, bit [25]

Trap TLB maintenance instructions. Traps execution of TLB maintenance instructions at EL1 to EL2 as follows:

- If EL1 is using AArch64, then the following instructions are trapped to EL2 and reported using EC syndrome value 0x18:
  - TLBI VMALLE1, TLBI VAE1, TLBI ASIDE1, TLBI VAAE1, TLBI VALE1, and TLBI VAALE1.
  - TLBI VMALLE1IS, TLBI VAE1IS, TLBI ASIDE1IS, TLBI VAAE1IS, TLBI VALE1IS, and TLBI VAALE1IS.
  - If FEAT_TLBIOS is implemented, TLBI VMALLE1OS, TLBI VAE1OS, TLBI ASIDE1OS, TLBI VAAE1OS, TLBI VALE1OS, and TLBI VAALE1OS.
  - If FEAT_TLBIRANGE is implemented, TLBI RVAE1, TLBI RVAAE1, TLBI RVALE1, TLBI RVAALE1, TLBI RVAE1IS, TLBI RVAAE1IS, TLBI RVALE1IS, and TLBI RVAALE1IS.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- If FEAT_TLBIOS and FEAT_TLBIRANGE are implemented, TLBI RVAE1OS, TLBI RVAAE1OS, TLBI RVALE1OS, and TLBI RVAALE1OS.

TTLB	Meaning
0b0	This control does not cause any instructions to be trapped.
0b1	EL1 execution of the specified TLB maintenance instructions are trapped to EL2.

When HCR_EL2.TGE is 1, the PE ignores the value of this field for all purposes other than a direct read of this field.

Note

The TLB maintenance instructions are UNDEFINED at EL0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

TPU, bit [24]

Trap cache maintenance instructions that operate to the Point of Unification. Traps execution of those cache maintenance instructions at EL0 and EL1 to EL2 as follows:

- If EL0 is using AArch64 and the value of SCTLR_EL1.UCI is 1, then the following instructions at EL0 are trapped to EL2 and reported with EC syndrome value 0x18:
  - IC IVAU and DC CVAU.
- If EL1 is using AArch64, then the following instructions at EL1 are trapped to EL2 and reported with EC syndrome value 0x18:
  - IC IVAU, IC IALLU, IC IALLUIS, and DC CVAU.

Note

When SCTLR_EL1.UCI is 0, the trap on execution of instructions at EL0 is higher priority than this control. An exception generated because an instruction is UNDEFINED at EL0 is higher priority than this trap to EL2. In addition:

- IC IALLUIS and IC IALLU are always UNDEFINED at EL0 using AArch64.

TPU	Meaning
0b0	This control does not cause any instructions to be trapped.
0b1	For each of the specified instructions, if the execution of the instruction can be trapped, access is trapped to EL2.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

TPCP, bit [23]

Trap data or unified cache maintenance instructions that operate to the Point of Coherency or Persistence. When EL2 is enabled in the current Security state, traps execution of cache maintenance instructions at EL0 and EL1 to EL2 as follows:

- If EL0 is using AArch64 and the value of SCTLR_EL1.UCI is 1, then the following instructions at EL0 are trapped to EL2 and reported using EC syndrome value 0x18:
  - DC CIVAC and DC CVAC.
  - If FEAT_DPB is implemented, DC CVAP.
  - If FEAT_DPB2 is implemented, DC CVADP.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- If EL1 is using AArch64, then the following instructions at EL1 are trapped to EL2 and reported using EC syndrome value `0x18`:
  - DC IVAC, DC CIVAC and DC CVAC.
  - If FEAT_DPB is implemented, DC CVAP.
  - If FEAT_DPB2 is implemented, DC CVADP.

Note

This field was previously named TPC.
When SCTLR_EL1.UCI is 0, the trap on execution of instructions at EL0 is higher priority than this control.
An exception generated because an instruction is UNDEFINED at EL0 is higher priority than this trap to EL2. In addition:

- AArch64 instructions which invalidate by VA to the Point of Coherency are always UNDEFINED at EL0 using AArch64.

TPCP	Meaning
`0b0`	This control does not cause any instructions to be trapped.
`0b1`	For each of the specified instructions, if the execution of the instruction can be trapped, it is trapped to EL2.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

TSW, bit [22]

Trap data or unified cache maintenance instructions that operate by Set/Way. Traps execution of those cache maintenance instructions at EL1 to EL2 as follows:

- If EL1 is using AArch64, then the following instructions are trapped to EL2 and reported with EC syndrome value `0x18`:
  - DC ISW, DC CSW, and DC CISW.

Note

An exception generated because an instruction is UNDEFINED at EL0 is higher priority than this trap to EL2, and these instructions are always UNDEFINED at EL0.

TSW	Meaning
`0b0`	This control does not cause any instructions to be trapped.
`0b1`	Execution of the specified instructions is trapped to EL2.

When HCR_EL2.TGE is 1, the PE ignores the value of this field for all purposes other than a direct read of this field.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

TACR, bit [21]

Trap Auxiliary Control Registers. Traps EL1 accesses to the Auxiliary Control Registers to EL2 as follows:

- If EL1 is using AArch64, accesses to ACTLR_EL1 to EL2, are trapped to EL2 and reported using EC syndrome value `0x18`.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

TACR	Meaning
0b0	This control does not cause any instructions to be trapped.
0b1	EL1 accesses to the specified registers are trapped to EL2.

When HCR_EL2.TGE is 1, the PE ignores the value of this field for all purposes other than a direct read of this field.

Note

ACTLR_EL1 is not accessible at EL0.
The Auxiliary Control Registers are IMPLEMENTATION DEFINED registers that might implement global control bits for the PE.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

TIDCP, bit [20]

Trap IMPLEMENTATION DEFINED functionality. Traps EL1 accesses to the encodings reserved for IMPLEMENTATION DEFINED functionality to EL2 as follows:

- In AArch64 state, EL0 access to the encodings in the following reserved encoding spaces are trapped:
  - IMPLEMENTATION DEFINED System instructions, which are accessed using SYS and SYSL, with CRn == {11, 15}, and are reported using EC syndrome value 0x18.
  - IMPLEMENTATION DEFINED System instructions, which are accessed using SYSP, with CRn == {11, 15}, and are reported using EC syndrome value 0x14.
  - IMPLEMENTATION DEFINED System registers, which are accessed using MRS and MSR with the S3_<op1>_<Cn>_<Cm>_<op2> register name, and are reported using EC syndrome 0x18.
  - IMPLEMENTATION DEFINED System registers, which are accessed using MRRS and MSRR with the S3_<op1>_<Cn>_<Cm>_<op2> register name, and are reported using EC syndrome 0x14.

When this functionality is accessed from EL0:

- If HCR_EL2.TIDCP is 1, it is IMPLEMENTATION DEFINED whether any accesses from EL0 are trapped to EL2.
- If HCR_EL2.TIDCP is 0, any accesses from EL0 are UNDEFINED and generate an exception that is taken to EL1 or EL2.

TIDCP	Meaning
0b0	This control does not cause any instructions to be trapped.
0b1	EL1 accesses to or execution of the specified encodings reserved for IMPLEMENTATION DEFINED functionality are trapped to EL2.

An implementation can also include IMPLEMENTATION DEFINED registers that provide additional controls, to give finer-grained control of the trapping of IMPLEMENTATION DEFINED features.

Note

The trapping of accesses to these registers from EL1 is higher priority than an exception resulting from the register access being UNDEFINED.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

TSC, bit [19]

Trap SMC instructions. Traps EL1 execution of SMC instructions to EL2.

If execution is in AArch64 state, the trap is reported using EC syndrome value 0x17.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

HCR_EL2.TSC traps execution of the SMC instruction. It is not a routing control for the SMC exception. Trap exceptions and SMC exceptions have different preferred return addresses.

TSC	Meaning
0b0	This control does not cause any instructions to be trapped.
0b1	If EL3 is not implemented and the Effective value of HCR_EL2.NV is 1, then any attempt to execute an SMC instruction at EL1 using AArch64 is trapped to EL2. If EL3 is not implemented and the Effective value of HCR_EL2.NV is 0, then it is IMPLEMENTATION DEFINED whether: • Any attempt to execute an SMC instruction at EL1 is trapped to EL2. • Any attempt to execute an SMC instruction is UNDEFINED.

SMC instructions are UNDEFINED at EL0.

If EL3 is not implemented, and the Effective value of HCR_EL2.NV is 0, then it is IMPLEMENTATION DEFINED whether this bit is:

- RES0.
- Implemented with the functionality as described in HCR_EL2.TSC.

When HCR_EL2.TGE is 1, the PE ignores the value of this field for all purposes other than a direct read of this field.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

TID3, bit [18]

Trap ID group 3. Traps EL1 reads of group 3 ID registers to EL2, when EL2 is enabled in the current Security state, as follows:

In AArch64 state:

- Reads of the following registers are trapped to EL2, reported using EC syndrome value 0x18:
  - ID_PFR0_EL1, ID_PFR1_EL1, ID_DFR0_EL1, ID_AFR0_EL1, ID_MMFR0_EL1, ID_MMFR1_EL1, ID_MMFR2_EL1, ID_MMFR3_EL1, ID_ISAR0_EL1, ID_ISAR1_EL1, ID_ISAR2_EL1, ID_ISAR3_EL1, ID_ISAR4_EL1, ID_ISAR5_EL1, MVFR0_EL1, MVFR1_EL1, and MVFR2_EL1.
  - ID_AA64PFR0_EL1, ID_AA64PFR1_EL1, ID_AA64DFR0_EL1, ID_AA64DFR1_EL1, ID_AA64ISAR0_EL1, ID_AA64ISAR1_EL1, ID_AA64MMFR0_EL1, ID_AA64MMFR1_EL1, ID_AA64AFR0_EL1, and ID_AA64AFR1_EL1.
  - Reads of the following registers are trapped to EL2, unless the register is implemented as RAZ when it it IMPLEMENTATION DEFINED whether accesses are trapped to EL2.
  - — ID_PFR2_EL1, ID_MMFR4_EL1 and ID_MMFR5_EL1.
  - — ID_AA64MMFR4_EL1.
  - — ID_AA64MMFR2_EL1 and ID_ISAR6_EL1.
  - It is IMPLEMENTATION DEFINED whether this field traps MRS accesses to registers in the following range that are not already mentioned in this field description: op0 == 3, op1 == 0, CRn == 0, CRm == {2-7}, op2 == {0-7}.

TID3	Meaning
0b0	This control does not cause any instructions to be trapped.
0b1	The specified EL1 read accesses to ID group 3 registers are trapped to EL2.

When HCR_EL2.TGE is 1, the PE ignores the value of this field for all purposes other than a direct read of this field.

The reset behavior of this field is:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

TID2, bit [17]

Trap ID group 2. Traps the following register accesses to EL2 as follows:

- If EL1 is using AArch64, reads of CTR_EL0, CCSIDR_EL1, CCSIDR2_EL1, CLIDR_EL1, and CSSELR_EL1 are trapped to EL2, reported using EC syndrome value `0x18`.
- If EL0 is using AArch64 and the value of SCTLR_EL1.UCT is not 0, reads of CTR_EL0 are trapped to EL2, reported using EC syndrome value `0x18`. If the value of SCTLR_EL1.UCT is 0, then EL0 reads of CTR_EL0 are trapped to EL1 and the resulting exception takes precedence over this trap.
- If EL1 is using AArch64, writes to CSSELR_EL1 are trapped to EL2, reported using EC syndrome value `0x18`.

TID2	Meaning
`0b0`	This control does not cause any instructions to be trapped.
`0b1`	The specified EL1 and EL0 accesses to ID group 2 registers are trapped to EL2.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

TID1, bit [16]

Trap ID group 1. Traps EL1 reads of the following registers to EL2 as follows:

- Accesses of MPUIR_EL1, REVIDR_EL1, and AIDR_EL1, reported using EC syndrome value `0x18`.

TID1	Meaning
`0b0`	This control does not cause any instructions to be trapped.
`0b1`	The specified EL1 read accesses to ID group 1 registers are trapped to EL2.

When HCR_EL2.TGE is 1, the PE ignores the value of this field for all purposes other than a direct read of this field.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [15]

Reserved, RES0.

TWE, bit [14]

Traps EL0 and EL1 execution of WFE instructions to EL2 from both Execution states, reported using EC syndrome value `0x01`.

TWE	Meaning
`0b0`	This control does not cause any instructions to be trapped.
`0b1`	Any attempt to execute a WFE instruction at EL0 or EL1 is trapped to EL2, if the instruction would otherwise have caused the PE to enter a low-power state and it is not trapped by SCTLR.nTWE or SCTLR_EL1.nTWE.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

Since a WFE can complete at any time, even without a Wakeup event, the traps on WFE are not guaranteed to be taken, even if the WFE is executed when there is no Wakeup event. The only guarantee is that if the instruction does not complete in finite time in the absence of a Wakeup event, the trap will be taken.

For more information about when WFE instructions can cause the PE to enter a low-power state, see 'Wait for Event mechanism and Send event'.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

TWI, bit [13]

Traps EL0 and EL1 execution of WFI instructions to EL2 from both Execution states, reported using EC syndrome value `0x01`.

TWI	Meaning
`0b0`	This control does not cause any instructions to be trapped.
`0b1`	Any attempt to execute a WFI instruction at EL0 or EL1 is trapped to EL2, if the instruction would otherwise have caused the PE to enter a low-power state and it is not trapped by SCTLR.nTWI or SCTLR_EL1.nTWI.

Note

Since a WFI can complete at any time, even without a Wakeup event, the traps on WFI are not guaranteed to be taken, even if the WFI is executed when there is no Wakeup event. The only guarantee is that if the instruction does not complete in finite time in the absence of a Wakeup event, the trap will be taken.

For more information about when WFI instructions can cause the PE to enter a low-power state, see 'Wait for Interrupt'.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

DC, bit [12]

Default Cacheability.

DC	Meaning
`0b0`	This control has no effect on the EL1&0 translation regime.
`0b1`	In both Security states: • When EL1 is using AArch64, the PE behaves as if the value of the SCTLR_EL1.M field is 0 for all purposes other than returning the value of a direct read of SCTLR_EL1. • If stage 1 EL1&0 translation regime is in PMSAv8-64 context, the PE behaves as if the value of the SCTLR_EL1.BR field is 0 for all purposes other than returning the value of a direct read of SCTLR_EL1. • The PE behaves as if the value of the HCR_EL2.VM field is 1 for all purposes other than returning the value of a direct read of HCR_EL2. • The memory type produced by stage 1 of the EL10 translation regime is Normal Non-Shareable, Inner Write-Back Read-Allocate Write-Allocate, Outer Write-Back Read-Allocate Write-Allocate.

This field has no effect on the EL2 translation regime.

This bit is permitted to be cached in a TLB.

The reset behavior of this field is:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

BSU, bits [11:10]

Barrier Shareability upgrade. This field determines the minimum shareability domain that is applied to any barrier instruction executed from EL1 or EL0:

BSU	Meaning
0b00	No effect.
0b01	Inner Shareable.
0b10	Outer Shareable.
0b11	Full system.

This value is combined with the specified level of the barrier held in its instruction, using the same principles as combining the shareability attributes from two stages of address translation.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

FB, bit [9]

Force broadcast. Causes the following Non-shareable invalidate instructions to be broadcast within the Inner Shareable domain when executed from EL1:

- In AArch64 state:
  - All TLBI instructions that are executable at EL1 and do not specify IS or OS.
  - IC IALLU.

For more information, see 'A64 System instructions for TLB maintenance'.

FB	Meaning
0b0	The specified instructions are not affected by this control.
0b1	When one of the specified Non-shareable instructions is executed at EL1, the operation is broadcast within the Inner Shareable shareability domain.

When HCR_EL2.TGE is 1, the PE ignores the value of this field for all purposes other than a direct read of this field.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

VSE, bit [8]

Virtual SError exception.

VSE	Meaning
0b0	This mechanism is not making a virtual SError exception pending.
0b1	A virtual SError exception is pending because of this mechanism.

The virtual SError exception is enabled only when HCR_EL2.{TGE, AMO} is {0, 1}.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

VI, bit [7]

Virtual IRQ Interrupt.

VI	Meaning
0b0	This mechanism is not making a virtual IRQ pending.
0b1	A virtual IRQ is pending because of this mechanism.

The virtual IRQ is enabled only when the value of HCR_EL2.{TGE, IMO} is {0, 1}.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

VF, bit [6]

Virtual FIQ Interrupt.

VF	Meaning
0b0	This mechanism is not making a virtual FIQ pending.
0b1	A virtual FIQ is pending because of this mechanism.

The virtual FIQ is enabled only when the value of HCR_EL2.{TGE, FMO} is {0, 1}.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

AMO, bit [5]

Physical SError exception routing.

AMO	Meaning
0b0	When executing at Exception levels below EL2, and EL2 is enabled in the current Security state, all of the following apply: • If HCR_EL2.TGE is 0, then the routing of physical SError exceptions is unaffected by this mechanism • If HCR_EL2.TGE is 1, then physical SError exceptions are taken to EL2. • Virtual SError exceptions are disabled.
0b1	When the Effective value of HCR_EL2.TGE is 0: • Physical SError exceptions are taken to EL2. • Virtual SError exceptions are enabled.

When the Effective value of HCR_EL2.TGE is 1, regardless of the value of the AMO bit, all of the following are true:

- Physical SError exceptions target EL2.
- Virtual SError exceptions are disabled.

When the Effective value of HCR_EL2.TGE is 0, it is IMPLEMENTATION DEFINED whether the Effective value of HCR_EL2.AMO is 1 or the value programmed.

For more information, see 'Asynchronous exception routing'.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

IMO, bit [4]

Physical IRQ Routing.

IMO	Meaning
0b0	When the Effective value of HCR_EL2.TGE is 0: • Physical IRQ interrupts are not taken to EL2. • Virtual IRQ interrupts are disabled.
0b1	When the Effective value of HCR_EL2.TGE is 0: • Physical IRQ exceptions are taken to EL2. • Virtual IRQ interrupts are enabled.

When the Effective value of HCR_EL2.TGE is 1, regardless of the value of the IMO bit, all of the following are true:

- Physical IRQ Interrupts target EL2 unless they are routed to EL3.
- Virtual IRQ interrupts are disabled.

When the Effective value of HCR_EL2.TGE is 0, it is IMPLEMENTATION DEFINED whether the Effective value of HCR_EL2.IMO is 1 or the value programmed.

For more information, see 'Asynchronous exception routing'.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

FMO, bit [3]

Physical FIQ Routing.

FMO	Meaning
0b0	When the Effective value of HCR_EL2.TGE is 0: • Physical FIQ interrupts are not taken to EL2. • Virtual FIQ interrupts are disabled.
0b1	When the Effective value of HCR_EL2.TGE is 0: • Physical FIQ exceptions are taken to EL2. • Virtual FIQ interrupts are enabled.

When the Effective value of HCR_EL2.TGE is 1, regardless of the value of the FMO bit, all of the following are true:

- Physical FIQ Interrupts target EL2 unless they are routed to EL3.
- Virtual FIQ interrupts are disabled.

When the Effective value of HCR_EL2.TGE is 0, it is IMPLEMENTATION DEFINED whether the Effective value of HCR_EL2.FMO is 1 or the value programmed.

For more information, see 'Asynchronous exception routing'.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

PTW, bit [2]

Protected Table Walk. In the EL1&0 translation regime, a translation table access made as part of a stage 1 translation table walk is subject to a stage 2 translation. The combining of the memory type attributes from the two

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

stages of translation means the access might be made to a type of Device memory. If this occurs, then the value of this bit determines the behavior:

PTW	Meaning
0b0	The translation table walk occurs as if it is to Normal Non-cacheable memory. This means it can be made speculatively.
0b1	The memory access generates a stage 2 Permission fault.

This bit is permitted to be cached in a TLB.

When HCR_EL2.TGE is 1, the PE ignores the value of this field for all purposes other than a direct read of this field.

In a PMSA-only implementation, this bit is permitted to be RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

SWIO, bit [1]

Set/Way Invalidation Override. Causes EL1 execution of the data cache invalidate by set/way instructions to perform a data cache clean and invalidate by set/way:

SWIO	Meaning
0b0	This control has no effect on the operation of data cache invalidate by set/way instructions.
0b1	Data cache invalidate by set/way instructions perform a data cache clean and invalidate by set/way.

When the value of this bit is 1:

AArch64: DC ISW performs the same invalidation as a DC CISW instruction.

This bit can be implemented as RES1.

When HCR_EL2.TGE is 1, the PE ignores the value of this field for all purposes other than a direct read of this field.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

VM, bit [0]

Virtualization enable. Enables stage 2 address translation for the EL1&0 translation regime.

VM	Meaning
0b0	EL1&0 stage 2 address translation disabled.
0b1	EL1&0 stage 2 address translation enabled.

If HCR_EL2.VM is 1 and SCTLR_EL2.{M, BR} is {0, 0}, then the behavior is a CONSTRAINED UNPREDICTABLE choice of:

- The memory attribute becomes UNKNOWN.
- Raise stage 2 level 0 Translation fault.

When the value of this bit is 1, data cache invalidate instructions executed at EL1 perform a data cache clean and invalidate. For the invalidate by set/way instruction this behavior applies regardless of the value of the HCR_EL2.SWIO bit.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

This bit is permitted to be cached in a TLB.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing HCR_EL2

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, HCR_EL2

op0	op1	CRn	CRm	op2
0b11	0b100	0b0001	0b0001	0b000

```
if PSTATE.EL == EL0 then
    UNDEFINED;
elsif PSTATE.EL == EL1 then
    UNDEFINED;
elsif PSTATE.EL == EL2 then
    X[t, 64] = HCR_EL2;
```

MSR HCR_EL2, <Xt>

op0	op1	CRn	CRm	op2
0b11	0b100	0b0001	0b0001	0b000

```
if PSTATE.EL == EL0 then
    UNDEFINED;
elsif PSTATE.EL == EL1 then
    UNDEFINED;
elsif PSTATE.EL == EL2 then
    HCR_EL2 = X[t, 64];
```

D12.2.36 HPFAR_EL2, Hypervisor IPA Fault Address Register

The HPFAR_EL2 characteristics are:

Purpose

Holds the faulting IPA for some aborts on a stage 2 translation taken to EL2 due to a fault on an access for a stage 2 translation.

Configuration

The HPFAR_EL2 is written for:

- A Translation fault, Access Flag fault, or Address Size fault on a stage 2 translation not on a stage 1 translation table walk.
- A Translation fault, Access Flag fault, Address Size fault, or Permission fault on stage 2 translation of an address accessed in a stage 1 translation table walk.

For all other exceptions taken to EL2, this register is UNKNOWN.

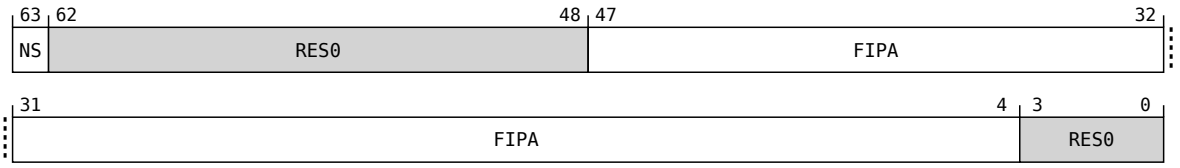
Note

The address held in this register is an address accessed by the instruction fetch or data access that caused the exception that gave rise to the Instruction Abort exception or Data Abort exception. It is the lower address that gave rise to the fault that is reported. Where different faults from different addresses arise from the same instruction, such as for an instruction that loads or stores an unaligned address that crosses a page boundary, the architecture does not prioritize which fault is reported.

Attributes

HPFAR_EL2 is a 64-bit register.

Field descriptions



Execution at EL1 or EL0 makes HPFAR_EL2 become UNKNOWN.

NS, bit [63]

When FEAT_SEL2 is implemented:

Faulting IPA address space.

NS	Meaning
0b0	Faulting IPA is from the Secure IPA space.
0b1	Faulting IPA is from the Non-secure IPA space.

For Data Abort exceptions or Instruction Abort exceptions taken to Non-secure EL2:

- This field is RES0.
- The address is from the Non-secure IPA space.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Otherwise:

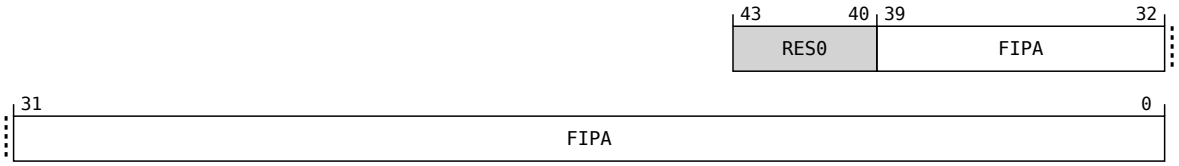
Reserved, RES0.

Bits [62:48]

Reserved, RES0.

FIPA, bits [47:4]

When FEAT_LPA is implemented:



Bits [43:40]

Reserved, RES0.

FIPA, bits [39:0]

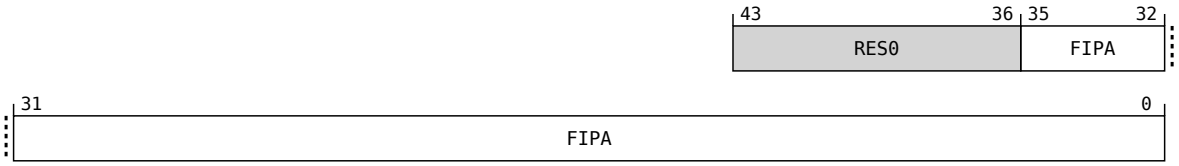
Bits [51:12] of the Faulting Intermediate Physical Address.

For implementations with fewer than 52 physical address bits, the corresponding upper bits in this field are RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

When FEAT_LPA is not implemented:



Bits [43:36]

Reserved, RES0.

FIPA, bits [35:0]

Bits[47:12] Faulting Intermediate Physical Address.

For implementations with fewer than 48 physical address bits, the corresponding upper bits in this field are RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [3:0]

Reserved, RES0.

Accessing HPFAR_EL2

D12.2.37 HSTR_EL2, Hypervisor System Trap Register

The HSTR_EL2 characteristics are:

Purpose

Controls trapping to EL2 of EL1 or lower AArch32 accesses to the System register in the coproc == 0b1111 encoding space, by the CRn value used to access the register using MCR or MRC instruction. When the register is accessible using an MCRR or MRRC instruction, this is the CRm value used to access the register.

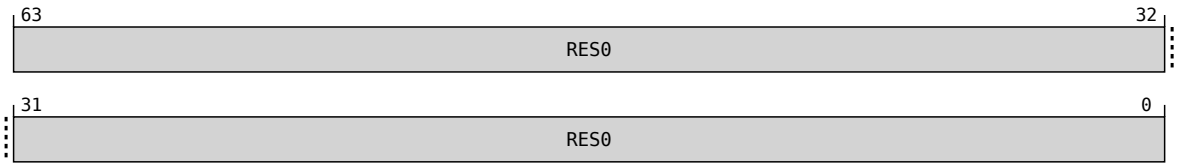
Configuration

There are no configuration notes.

Attributes

HSTR_EL2 is a 64-bit register.

Field descriptions



Bits [63:0]

Reserved, RES0.

Accessing HSTR_EL2

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, HSTR_EL2

op0	op1	CRn	CRm	op2
0b11	0b100	0b0001	0b0001	0b011

D12.2.40 ID_AA64DFR0_EL1, AArch64 Debug Feature Register 0

The ID_AA64DFR0_EL1 characteristics are:

Purpose

Provides top-level information about the debug system in AArch64 state.

For general information about the interpretation of the ID registers, see 'Principles of the ID scheme for fields in ID registers'.

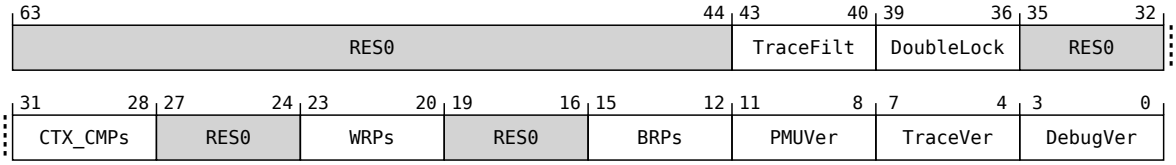
Configuration

The external register EDDFR gives information from this register.

Attributes

ID_AA64DFR0_EL1 is a 64-bit register.

Field descriptions



Bits [63:44]

Reserved, RES0.

TraceFilt, bits [43:40]

Armv8.4 Self-hosted Trace Extension version.

The value of this field is an IMPLEMENTATION DEFINED choice of:

TraceFilt	Meaning
0b0000	Armv8.4 Self-hosted Trace Extension not implemented.
0b0001	Armv8.4 Self-hosted Trace Extension implemented.

All other values are reserved.

FEAT_TRF implements the functionality identified by the value 0b0001.

From Armv8.4, if FEAT_ETMv4 is implemented, the value 0b0000 is not permitted.

Access to this field is RO.

DoubleLock, bits [39:36]

OS Double Lock implemented.

The value of this field is an IMPLEMENTATION DEFINED choice of:

DoubleLock	Meaning
0b0000	OS Double Lock implemented. OSDLR_EL1 is RW.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

0b1111	OS Double Lock not implemented. OSDLR_EL1 is RAZ/WI.

All other values are reserved.

FEAT_DoubleLock implements the functionality identified by the value 0b0000.

In Armv8.0, the only permitted value is 0b0000.

If FEAT_Debugv8p2 is implemented and FEAT_DoPD is not implemented, the permitted values are 0b0000 and 0b1111.

If FEAT_DoPD is implemented, the only permitted value is 0b1111.

Access to this field is RO.

Bits [35:32]

Reserved, RES0.

CTX_CMPs, bits [31:28]

Number of context-aware breakpoints, minus 1.

The value of this field is an IMPLEMENTATION DEFINED choice of:

CTX_CMPs	Meaning
0b0000..0b1110	The number of context-aware breakpoints, minus 1.
0b1111	If ID_AA64DFR1_EL1.CTX_CMPs is zero, then 16 context-aware breakpoints are implemented. Otherwise, 16 or more context-aware breakpoints are implemented and ID_AA64DFR1_EL1.CTX_CMPs indicates how many.

Values greater than ID_AA64DFR0_EL1.BRPs are not permitted.

Access to this field is RO.

Bits [27:24]

Reserved, RES0.

WRPs, bits [23:20]

Number of watchpoints, minus 1.

The value of this field is an IMPLEMENTATION DEFINED choice of:

WRPs	Meaning
0b0001..0b1111	The number of watchpoints, minus 1.

The value 0b0000 is reserved.

Access to this field is RO.

Bits [19:16]

Reserved, RES0.

BRPs, bits [15:12]

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Index of the highest numbered context-aware breakpoint. Identifies which of the implemented breakpoints are context-aware breakpoints.

The value of this field is an IMPLEMENTATION DEFINED choice of:

BRPs	Meaning
0b0001..0b1110	Index of the highest numbered context-aware breakpoint.
0b1111	If ID_AA64DFR0_EL1.CTX_CMPs and ID_AA64DFR1_EL1.CTX_CMPs indicate that 16 or fewer breakpoints are context-aware, then the index of the highest context-aware breakpoint is 15. Otherwise, the context-aware breakpoints are the lowest numbered breakpoints.

The value 0b0000 is reserved.

Access to this field is RO.

PMUVer, bits [11:8]

Performance Monitors Extension version.

This field does not follow the standard ID scheme, but uses the alternative ID scheme described in 'Alternative ID scheme used for the Performance Monitors Extension version'.

The value of this field is an IMPLEMENTATION DEFINED choice of:

All other values are reserved.

FEAT_PMUv3 implements the functionality identified by the value 0b0001.

FEAT_PMUv3p1 implements the functionality identified by the value 0b0100.

FEAT_PMUv3p4 implements the functionality identified by the value 0b0101.

From Armv8.1, if FEAT_PMUv3 is implemented, the value 0b0001 is not permitted.

From Armv8.4, if FEAT_PMUv3 is implemented, the value 0b0100 is not permitted.

Access to this field is RO.

TraceVer, bits [7:4]

Trace support. Indicates whether System register interface to a trace unit is implemented.

The value of this field is an IMPLEMENTATION DEFINED choice of:

TraceVer	Meaning
0b0000	Trace unit System registers not implemented.
0b0001	Trace unit System registers implemented.

All other values are reserved.

See the ETM Architecture Specification for more information.

A value of 0b0000 only indicates that no System register interface to a trace unit is implemented. A trace unit might nevertheless be implemented without a System register interface.

Access to this field is RO.

DebugVer, bits [3:0]

Debug architecture version. Indicates presence of Armv8 debug architecture.

The value of this field is an IMPLEMENTATION DEFINED choice of:

All other values are reserved.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

FEAT_Debugv8p1 implements the functionality identified by the value 0b0111.

FEAT_Debugv8p2 implements the functionality identified by the value 0b1000.

FEAT_Debugv8p4 implements the functionality identified by the value 0b1001.

From Armv8.1, when FEAT_Debugv8p1 is implemented the value 0b0110 is not permitted.

From Armv8.2, the values 0b0110 and 0b0111 are not permitted.

From Armv8.4, the value 0b1000 is not permitted.

Access to this field is RO.

Accessing ID_AA64DFR0_EL1

Accesses to this register use the following encodings in the System register encoding space:

D12.2.43 ID_AA64ISAR0_EL1, AArch64 Instruction Set Attribute Register 0

The ID_AA64ISAR0_EL1 characteristics are:

Purpose

Provides information about the instructions implemented in AArch64 state.

For general information about the interpretation of the ID registers, see 'Principles of the ID scheme for fields in ID registers'.

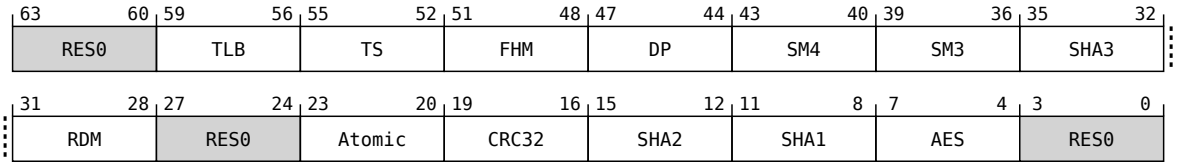
Configuration

There are no configuration notes.

Attributes

ID_AA64ISAR0_EL1 is a 64-bit register.

Field descriptions



Bits [63:60]

Reserved, RES0.

TLB, bits [59:56]

Indicates support for Outer Shareable and TLB range maintenance instructions.

The value of this field is an IMPLEMENTATION DEFINED choice of:

TLB	Meaning
0b0000	Outer Shareable and TLB range maintenance instructions are not implemented.
0b0001	Outer Shareable TLB maintenance instructions are implemented.
0b0010	Outer Shareable and TLB range maintenance instructions are implemented.

All other values are reserved.

FEAT_TLBIOS implements the functionality identified by the values 0b0001 and 0b0010.

FEAT_TLBIRANGE implements the functionality identified by the value 0b0010.

From Armv8.4, the values 0b0000 and 0b0001 are not permitted.

Access to this field is RO.

TS, bits [55:52]

Indicates support for flag manipulation instructions.

The value of this field is an IMPLEMENTATION DEFINED choice of:

All other values are reserved.

FEAT_FlagM implements the functionality identified by the value 0b0001.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

In Armv8.4, the value 0b0000 is not permitted.

Access to this field is RO.

FHM, bits [51:48]

Indicates support for the Advanced SIMD half-precision to single-precision multiply instructions.

The value of this field is an IMPLEMENTATION DEFINED choice of:

FHM	Meaning
0b0000	The Advanced SIMD half-precision to single-precision multiply instructions are not implemented.
0b0001	FMLAL and FMLSL instructions are implemented.

All other values are reserved.

FEAT_FHM implements the functionality identified by the value 0b0001.

From Armv8.4, if FEAT_FP16 is implemented, the value 0b0000 is not permitted.

Access to this field is RO.

DP, bits [47:44]

Indicates support for Dot Product instructions in AArch64 state.

The value of this field is an IMPLEMENTATION DEFINED choice of:

DP	Meaning
0b0000	No Dot Product instructions implemented.
0b0001	UDOT and SDOT instructions implemented.

All other values are reserved.

FEAT_DotProd implements the functionality identified by the value 0b0001.

From Armv8.4, if FEAT_AdvSIMD is implemented, the value 0b0000 is not permitted.

Access to this field is RO.

SM4, bits [43:40]

Indicates support for SM4 instructions in AArch64 state.

The value of this field is an IMPLEMENTATION DEFINED choice of:

SM4	Meaning
0b0000	No SM4 instructions implemented.
0b0001	SM4E and SM4EKEY instructions implemented.

All other values are reserved.

If FEAT_SM4 is not implemented, the value 0b0001 is reserved.

FEAT_SM4 implements the functionality identified by the value 0b0001.

This field must have the same value as ID_AA64ISAR0_EL1.SM3.

Access to this field is RO.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

SM3, bits [39:36]

Indicates support for the following SM3 instructions SM3SS1, SM3TT1A, SM3TT1B, SM3TT2A, SM3TT2B, SM3PARTW1, and SM3PARTW2 in AArch64 state.

The value of this field is an IMPLEMENTATION DEFINED choice of:

SM3	Meaning
0b0000	The specified instructions are not implemented.
0b0001	The specified instructions are implemented.

All other values are reserved.

If FEAT_SM3 is not implemented, the value 0b0001 is reserved.

FEAT_SM3 implements the functionality identified by the value 0b0001.

This field must have the same value as ID_AA64ISAR0_EL1.SM4.

Access to this field is RO.

SHA3, bits [35:32]

Indicates support for the following SHA3 instructions EOR3, RAX1, XAR, and BCAX in AArch64 state.

The value of this field is an IMPLEMENTATION DEFINED choice of:

SHA3	Meaning
0b0000	The specified instructions are not implemented.
0b0001	The specified instructions are implemented.

All other values are reserved.

If FEAT_SHA3 is not implemented, the value 0b0001 is reserved.

FEAT_SHA3 implements the functionality identified by the value 0b0001.

If the value of ID_AA64ISAR0_EL1.SHA1 is 0b0000, this field must have the value 0b0000.

If the value of this field is 0b0001, ID_AA64ISAR0_EL1.SHA2 must have the value 0b0010.

Access to this field is RO.

RDM, bits [31:28]

Indicates support for SQRDMLAH and SQRDMLSH instructions in AArch64 state.

The value of this field is an IMPLEMENTATION DEFINED choice of:

RDM	Meaning
0b0000	No RDMA instructions implemented.
0b0001	SQRDMLAH and SQRDMLSH instructions implemented.

All other values are reserved.

FEAT_RDM implements the functionality identified by the value 0b0001.

From Armv8.1, the value 0b0000 is not permitted.

Access to this field is RO.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Bits [27:24]

Reserved, RES0.

Atomic, bits [23:20]

Indicates support for Atomic instructions in AArch64 state.

The value of this field is an IMPLEMENTATION DEFINED choice of:

All other values are reserved.

FEAT_LSE implements the functionality identified by the value 0b0010.

From Armv8.1, the value 0b0000 is not permitted.

Access to this field is RO.

CRC32, bits [19:16]

Indicates support for the following CRC32 instructions CRC32B, CRC32H, CRC32W, CRC32X, CRC32CB, CRC32CH, CRC32CW, and CRC32CX in AArch64 state.

The value of this field is an IMPLEMENTATION DEFINED choice of:

CRC32	Meaning
0b0000	The specified instructions are not implemented.
0b0001	The specified instructions are implemented.

All other values are reserved.

FEAT_CRC32 implements the functionality identified by the value 0b0001.

From Armv8.1, the value 0b0000 is not permitted.

Access to this field is RO.

SHA2, bits [15:12]

Indicates support for SHA2 instructions in AArch64 state.

The value of this field is an IMPLEMENTATION DEFINED choice of:

SHA2	Meaning
0b0000	No SHA2 instructions implemented.
0b0001	Implements instructions: SHA256H, SHA256H2, SHA256SU0, and SHA256SU1.
0b0010	Implements instructions: • SHA256H, SHA256H2, SHA256SU0, and SHA256SU1. • SHA512H, SHA512H2, SHA512SU0, and SHA512SU1.

All other values are reserved.

FEAT_SHA256 implements the functionality identified by the value 0b0001.

FEAT_SHA512 implements the functionality identified by the value 0b0010.

If the value of ID_AA64ISAR0_EL1.SHA1 is 0b0000, this field must have the value 0b0000.

If the value of this field is 0b0010, ID_AA64ISAR0_EL1.SHA3 must have the value 0b0001.

Access to this field is RO.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

SHA1, bits [11:8]

Indicates support for the following SHA1 instructions SHA1C, SHA1P, SHA1M, SHA1H, SHA1SU0, and SHA1SU1 in AArch64 state.

The value of this field is an IMPLEMENTATION DEFINED choice of:

SHA1	Meaning
0b0000	The specified instructions are not implemented.
0b0001	The specified instructions are implemented.

All other values are reserved.

FEAT_SHA1 implements the functionality identified by the value 0b0001.

If the value of ID_AA64ISAR0_EL1.SHA2 is 0b0000, this field must have the value 0b0000.

Access to this field is RO.

AES, bits [7:4]

Indicates support for AES instructions in AArch64 state.

The value of this field is an IMPLEMENTATION DEFINED choice of:

AES	Meaning
0b0000	No AES instructions implemented.
0b0001	AESE, AESD, AESMC, and AESIMC instructions implemented.
0b0010	As for 0b0001, plus PMULL and PMULL2 instructions operating on 64-bit source elements.

FEAT_AES implements the functionality identified by the value 0b0001.

FEAT_PMULL implements the functionality identified by the value 0b0010.

All other values are reserved.

Access to this field is RO.

Bits [3:0]

Reserved, RES0.

Accessing ID_AA64ISAR0_EL1

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, ID_AA64ISAR0_EL1

op0	op1	CRn	CRm	op2
0b11	0b000	0b0000	0b0110	0b000

```
if PSTATE.EL == EL0 then
    if IsFeatureImplemented(FEAT_IDST) then
        if HCR_EL2.TGE == '1' then

D12.2.44 ID_AA64ISAR1_EL1, AArch64 Instruction Set Attribute Register 1

The ID_AA64ISAR1_EL1 characteristics are:

Purpose

Provides information about the features and instructions implemented in AArch64 state.

For general information about the interpretation of the ID registers, see 'Principles of the ID scheme for fields in ID registers'.

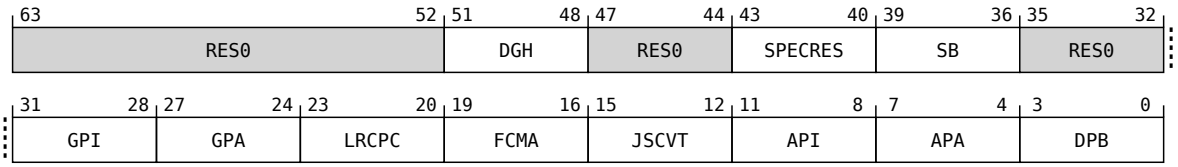
Configuration

There are no configuration notes.

Attributes

ID_AA64ISAR1_EL1 is a 64-bit register.

Field descriptions



Bits [63:52]

Reserved, RES0.

DGH, bits [51:48]

Indicates support for the Data Gathering Hint instruction.

The value of this field is an IMPLEMENTATION DEFINED choice of:

DGH	Meaning
0b0000	Data Gathering Hint is not implemented.
0b0001	Data Gathering Hint is implemented.

All other values are reserved.

FEAT_DGH implements the functionality identified by 0b0001.

From Armv8.0, the permitted values are 0b0000 and 0b0001.

If the DGH instruction has no effect in preventing the merging of memory accesses, the value of this field is 0b0000.

Access to this field is RO.

Bits [47:44]

Reserved, RES0.

SPECRES, bits [43:40]

Indicates support for prediction invalidation instructions in AArch64 state.

The value of this field is an IMPLEMENTATION DEFINED choice of:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

All other values are reserved.

FEAT_SPECRES implements the functionality identified by 0b0001.

In Armv8-R, the permitted values are 0b0000 and 0b0001.

Access to this field is RO.

SB, bits [39:36]

Indicates support for SB instruction in AArch64 state.

The value of this field is an IMPLEMENTATION DEFINED choice of:

SB	Meaning
0b0000	SB instruction is not implemented.
0b0001	SB instruction is implemented.

All other values are reserved.

FEAT_SB implements the functionality identified by 0b0001.

In Armv8-R, the permitted values are 0b0000 and 0b0001.

Access to this field is RO.

Bits [35:32]

Reserved, RES0.

GPI, bits [31:28]

Indicates support for an IMPLEMENTATION DEFINED algorithm is implemented in the PE for generic code authentication in AArch64 state.

The value of this field is an IMPLEMENTATION DEFINED choice of:

GPI	Meaning
0b0000	Generic Authentication using an IMPLEMENTATION DEFINED algorithm is not implemented.
0b0001	Generic Authentication using an IMPLEMENTATION DEFINED algorithm is implemented. This includes the PACGA instruction.

All other values are reserved.

When this field is nonzero, FEAT_PACIMP is implemented.

From Armv8.3, the permitted values are 0b0000 and 0b0001.

If the value of ID_AA64ISAR1_EL1.GPA is nonzero, this field must have the value 0b0000.

Access to this field is RO.

GPA, bits [27:24]

Indicates whether the QARMA5 algorithm is implemented in the PE for generic code authentication in AArch64 state.

The value of this field is an IMPLEMENTATION DEFINED choice of:

GPA	Meaning
0b0000	Generic Authentication using the QARMA5 algorithm is not implemented.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

GPA	Meaning
0b0001	Generic Authentication using the QARMA5 algorithm is implemented. This includes the PACGA instruction.

All other values are reserved.

FEAT_PACQARMA5 implements the functionality identified by 0b0001.

When this field is nonzero, FEAT_PACQARMA5 is implemented.

From Armv8.3, the permitted values are 0b0000 and 0b0001.

If the value of ID_AA64ISAR1_EL1.GPI is nonzero, this field must have the value 0b0000.

Access to this field is RO.

LRCPC, bits [23:20]

Indicates support for weaker release consistency, RCpc, based model.

The value of this field is an IMPLEMENTATION DEFINED choice of:

All other values are reserved.

FEAT_LRCPC implements the functionality identified by the value 0b0001.

FEAT_LRCPC2 implements the functionality identified by the value 0b0010.

From Armv8.3, the value 0b0000 is not permitted.

From Armv8.4, the value 0b0001 is not permitted.

Access to this field is RO.

FCMA, bits [19:16]

Indicates support for complex number addition and multiplication, where numbers are stored in vectors.

The value of this field is an IMPLEMENTATION DEFINED choice of:

FCMA	Meaning
0b0000	The FCMLA and FCADD instructions are not implemented.
0b0001	The FCMLA and FCADD instructions are implemented.

All other values are reserved.

FEAT_FCMA implements the functionality identified by the value 0b0001.

From Armv8.3, if Advanced SIMD or floating-point is implemented, the value 0b0000 is not permitted.

From Armv8.3, if Advanced SIMD or floating-point is not implemented, the only permitted value is 0b0000.

Access to this field is RO.

JSCVT, bits [15:12]

Indicates support for JavaScript conversion from double-precision floating-point values to integers in AArch64 state.

The value of this field is an IMPLEMENTATION DEFINED choice of:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

JSCVT	Meaning
0b0000	The FJCVTZS instruction is not implemented.
0b0001	The FJCVTZS instruction is implemented.

All other values are reserved.

FEAT_JSCVT implements the functionality identified by 0b0001.

From Armv8.3, if Advanced SIMD or floating-point is implemented, the value 0b0000 is not permitted.

From Armv8.3, if Advanced SIMD or floating-point is not implemented, the only permitted value is 0b0000.

Access to this field is RO.

API, bits [11:8]

Indicates whether an IMPLEMENTATION DEFINED algorithm is implemented in the PE for address authentication, in AArch64 state. This applies to all Pointer Authentication instructions other than the PACGA instruction.

The value of this field is an IMPLEMENTATION DEFINED choice of:

All other values are reserved.

FEAT_PAuth implements the functionality identified by 0b0001.

FEAT_EPAC implements the functionality identified by 0b0010.

FEAT_PAuth2 implements the functionality identified by 0b0011.

FEAT_FPAC implements the functionality identified by 0b0100.

FEAT_FPACCOMBINE implements the functionality identified by 0b0101.

When this field is nonzero, FEAT_PACIMP is implemented.

In Armv8-R, the permitted values are 0b0000, 0b0001, 0b0010, 0b0011, 0b0100, and 0b0101.

If the value of ID_AA64ISAR1_EL1.APA is nonzero, this field must have the value 0b0000.

Access to this field is RO.

APA, bits [7:4]

Indicates whether the QARMA5 algorithm is implemented in the PE for address authentication, in AArch64 state. This applies to all Pointer Authentication instructions other than the PACGA instruction.

The value of this field is an IMPLEMENTATION DEFINED choice of:

All other values are reserved.

FEAT_PAuth implements the functionality identified by 0b0001.

FEAT_EPAC implements the functionality identified by 0b0010.

FEAT_PAuth2 implements the functionality identified by 0b0011.

FEAT_FPAC implements the functionality identified by 0b0100.

FEAT_FPACCOMBINE implements the functionality identified by 0b0101.

When this field is nonzero, FEAT_PACQARMA5 is implemented.

In Armv8-R, the permitted values are 0b0000, 0b0001, 0b0010, 0b0011, 0b0100, and 0b0101.

If the value of ID_AA64ISAR1_EL1.API is nonzero, this field must have the value 0b0000.

Access to this field is RO.

DPB, bits [3:0]

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Data Persistence writeback. Indicates support for the DC CVAP and DC CVADP instructions in AArch64 state.

The value of this field is an IMPLEMENTATION DEFINED choice of:

DPB	Meaning
0b0000	DC CVAP not supported.
0b0001	DC CVAP supported.
0b0010	DC CVAP and DC CVADP supported.

All other values are reserved.

FEAT_DPB implements the functionality identified by the value 0b0001.

FEAT_DPB2 implements the functionality identified by the value 0b0010.

In Armv8-R, the value 0b0000 is not permitted.

Access to this field is RO.

Accessing ID_AA64ISAR1_EL1

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, ID_AA64ISAR1_EL1

op0	op1	CRn	CRm	op2
0b11	0b000	0b0000	0b0110	0b001

```

D12.2.45 ID_AA64ISAR2_EL1, AArch64 Instruction Set Attribute Register 2

The ID_AA64ISAR2_EL1 characteristics are:

Purpose

Provides information about the features and instructions implemented in AArch64 state.

For general information about the interpretation of the ID registers, see 'Principles of the ID scheme for fields in ID registers'.

Configuration

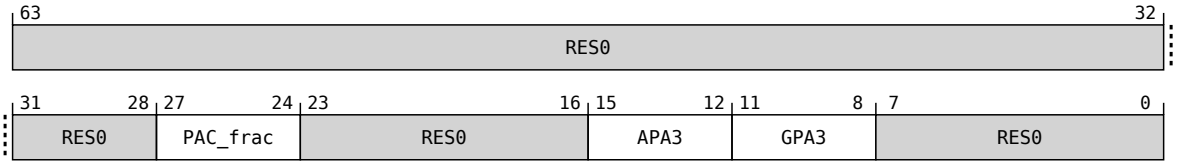
Note

Prior to the introduction of the features described by this register, this register was unnamed and reserved, RES0 from EL1 and EL2.

Attributes

ID_AA64ISAR2_EL1 is a 64-bit register.

Field descriptions



Bits [63:28]

Reserved, RES0.

PAC_frac, bits [27:24]

Indicates which address bit is used to determine the size of the PAC field.

The value of this field is an IMPLEMENTATION DEFINED choice of:

PAC_frac	Meaning
0b0000	The address bit which is used to define the size of the PAC field is dependent on whether address tagging is used.
0b0001	The address bit which is used to define the size of the PAC field is fixed.

All other values are reserved.

FEAT_CONSTPACFIELD implements the functionality identified by the value 0b0001.

From Armv8.3, the permitted values are 0b0000 and 0b0001.

Access to this field is RO.

Bits [23:16]

Reserved, RES0.

APA3, bits [15:12]

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Indicates whether the QARMA3 algorithm is implemented in the PE for address authentication in AArch64 state. This applies to all Pointer Authentication instructions other than the PACGA instruction.

The value of this field is an IMPLEMENTATION DEFINED choice of:

All other values are reserved.

FEAT_PAuth implements the functionality identified by the value 0b0001.

FEAT_EPAC implements the functionality identified by the value 0b0010.

FEAT_PAuth2 implements the functionality identified by the value 0b0011.

FEAT_FPAC implements the functionality identified by the value 0b0100.

FEAT_FPACCOMBINE implements the functionality identified by the value 0b0101.

When this field is nonzero, FEAT_PACQARMA3 is implemented.

In Armv8.3, the permitted values are 0b0000, 0b0001, 0b0010, 0b0011, 0b0100, and 0b0101.

From Armv8.6, the permitted values are 0b0000, 0b0011, 0b0100, and 0b0101.

If the value of ID_AA64ISAR1_EL1.API is nonzero, or the value of ID_AA64ISAR1_EL1.APA is nonzero, this field must have the value 0b0000.

Access to this field is RO.

GPA3, bits [11:8]

Indicates whether the QARMA3 algorithm is implemented in the PE for generic code authentication in AArch64 state.

The value of this field is an IMPLEMENTATION DEFINED choice of:

GPA3	Meaning
0b0000	Generic Authentication using the QARMA3 algorithm is not implemented.
0b0001	Generic Authentication using the QARMA3 algorithm is implemented. This includes the PACGA instruction.

All other values are reserved.

FEAT_PACQARMA3 implements the functionality identified by the value 0b0001.

When this field is nonzero, FEAT_PACQARMA3 is implemented.

From Armv8.3, the permitted values are 0b0000 and 0b0001.

If the value of ID_AA64ISAR1_EL1.GPI is nonzero, or the value of ID_AA64ISAR1_EL1.GPA is nonzero, this field must have the value 0b0000.

Access to this field is RO.

Bits [7:0]

Reserved, RES0.

Accessing ID_AA64ISAR2_EL1

Accesses to this register use the following encodings in the System register encoding space:

D12.2.46 ID_AA64MMFR0_EL1, AArch64 Memory Model Feature Register 0

The ID_AA64MMFR0_EL1 characteristics are:

Purpose

Provides information about the implemented memory model and memory management support in AArch64 state.

For general information about the interpretation of the ID registers, see 'Principles of the ID scheme for fields in ID registers'.

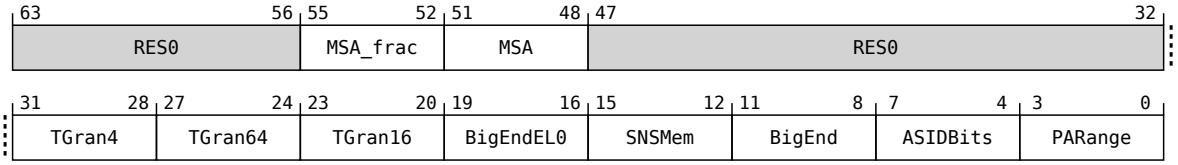
Configuration

There are no configuration notes.

Attributes

ID_AA64MMFR0_EL1 is a 64-bit register.

Field descriptions



Bits [63:56]

Reserved, RES0.

MSA_frac, bits [55:52]

Memory System Architecture fractional field. This holds the information on additional Memory System Architectures supported.

The value of this field is an IMPLEMENTATION DEFINED choice of:

MSA_frac	Meaning
0b0000	PMSAv8-64 not supported in any translation regime.
0b0001	PMSAv8-64 supported in all translation regimes. No support for VMSAv8-64.
0b0010	PMSAv8-64 supported in all translation regimes. In addition to PMSAv8-64, stage 1 EL1&0 translation regime also supports VMSAv8-64.

All other values are reserved.

The permitted values are 0b0001 and 0b0010.

This field is valid only when ID_AA64MMFR0_EL1.MSA is 0b1111.

Access to this field is RO.

MSA, bits [51:48]

Memory System Architecture ID field. This holds the information on Memory System Architectures supported.

The value of this field is an IMPLEMENTATION DEFINED choice of:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

MSA	Meaning
0b0000	VMSAv8-64 supported in all translation regimes. No support for PMSAv8-64.
0b1111	See ID_AA64MMFR0_EL1.MSA_frac for the Memory System Architectures supported.

All other values are reserved.

In Armv8-R, the only permitted value is 0b1111.

Access to this field is RO.

Bits [47:32]

Reserved, RES0.

TGran4, bits [31:28]

Indicates support for 4KB memory translation granule size.

The value of this field is an IMPLEMENTATION DEFINED choice of:

All other values are reserved.

Access to this field is RO.

TGran64, bits [27:24]

Indicates support for 64KB memory translation granule size.

The value of this field is an IMPLEMENTATION DEFINED choice of:

TGran64	Meaning
0b0000	64KB granule supported.
0b1111	64KB granule not supported.

All other values are reserved.

Access to this field is RO.

TGran16, bits [23:20]

Indicates support for 16KB memory translation granule size.

The value of this field is an IMPLEMENTATION DEFINED choice of:

All other values are reserved.

Access to this field is RO.

BigEndEL0, bits [19:16]

Indicates support for mixed-endian at EL0 only.

The value of this field is an IMPLEMENTATION DEFINED choice of:

BigEndEL0	Meaning
0b0000	No mixed-endian support at EL0. The SCTLR_EL1.E0E bit has a fixed value.
0b0001	Mixed-endian support at EL0. The SCTLR_EL1.E0E bit can be configured.

FEAT_MixedEndEL0 implements the functionality identified by the value 0b0001.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

All other values are reserved.

This field is invalid and is RES0 if ID_AA64MMFR0_EL1.BigEnd is not 0b0000.

Access to this field is RO.

SNSMem, bits [15:12]

Indicates support for a distinction between Secure and Non-secure Memory.

The value of this field is an IMPLEMENTATION DEFINED choice of:

SNSMem	Meaning
0b0000	Does not support a distinction between Secure and Non-secure Memory.
0b0001	Does support a distinction between Secure and Non-secure Memory.

Note

If EL3 is implemented, the value 0b0000 is not permitted.

All other values are reserved.

Access to this field is RO.

BigEnd, bits [11:8]

Indicates support for mixed-endian configuration.

The value of this field is an IMPLEMENTATION DEFINED choice of:

BigEnd	Meaning
0b0000	No mixed-endian support. The SCTLR_ELx.EE bits have a fixed value. See the BigEndEL0 field, bits[19:16], for whether EL0 supports mixed-endian.
0b0001	Mixed-endian support. The SCTLR_ELx.EE and SCTLR_EL1.E0E bits can be configured.

FEAT_MixedEnd implements the functionality identified by the value 0b0001.

If this field is 0b0001, FEAT_MixedEndEL0 is also implemented.

All other values are reserved.

Access to this field is RO.

ASIDBits, bits [7:4]

Number of ASID bits.

The value of this field is an IMPLEMENTATION DEFINED choice of:

ASIDBits	Meaning
0b0000	8 bits.
0b0010	16 bits.

All other values are reserved.

Access to this field is RO.

PARange, bits [3:0]

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Physical Address range supported.

The value of this field is an IMPLEMENTATION DEFINED choice of:

PARange	Meaning	Applies when
0b0000	32 bits, 4GB.	
0b0001	36 bits, 64GB.	
0b0010	40 bits, 1TB.	
0b0011	42 bits, 4TB.	
0b0100	44 bits, 16TB.	
0b0101	48 bits, 256TB.	
0b0110	52 bits, 4PB.	FEAT_LPA is implemented

All other values are reserved.

Access to this field is RO.

Accessing ID_AA64MMFR0_EL1

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, ID_AA64MMFR0_EL1

op0	op1	CRn	CRm	op2
0b11	0b000	0b0000	0b0111	0b000

```
if PSTATE.EL == EL0 then
    if IsFeatureImplemented(FEAT_IDST) then
        if HCR_EL2.TGE == '1' then

D12.2.47 ID_AA64MMFR1_EL1, AArch64 Memory Model Feature Register 1

The ID_AA64MMFR1_EL1 characteristics are:

Purpose

Provides information about the implemented memory model and memory management support in AArch64 state.

For general information about the interpretation of the ID registers, see 'Principles of the ID scheme for fields in ID registers'.

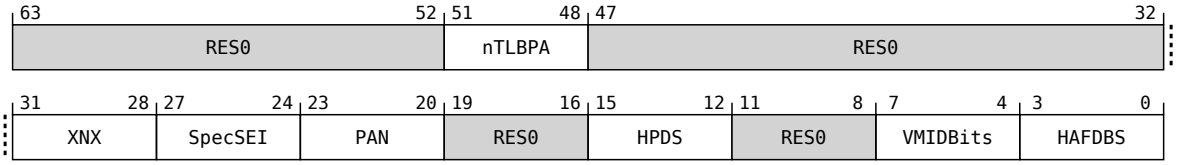
Configuration

There are no configuration notes.

Attributes

ID_AA64MMFR1_EL1 is a 64-bit register.

Field descriptions



Bits [63:52]

Reserved, RES0.

nTLBPA, bits [51:48]

When architecture implements VMSA extension:

Indicates support for intermediate caching of translation table walks.

The value of this field is an IMPLEMENTATION DEFINED choice of:

nTLBPA	Meaning
0b0000	The intermediate caching of translation table walks might include non-coherent physical translation caches.
0b0001	The intermediate caching of translation table walks does not include non-coherent physical translation caches.

Non-coherent physical translation caches are non-coherent caches of previous valid translation table entries since the last completed relevant TLBI applicable to the PE, where either:

- The caching is indexed by the physical address of the location holding the translation table entry.
- The caching is used for stage 1 translations and is indexed by the intermediate physical address of the location holding the translation table entry.

All other values are reserved.

FEAT_nTLBPA implements the functionality identified by the value 0b0001.

Access to this field is RO.

Otherwise:

Reserved, RES0.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Bits [47:32]

Reserved, RES0.

XNX, bits [31:28]

Indicates support for execute-never control distinction by Exception level at stage 2.

The value of this field is an IMPLEMENTATION DEFINED choice of:

XNX	Meaning
0b0000	Distinction between EL0 and EL1 execute-never control at stage 2 not supported.
0b0001	Distinction between EL0 and EL1 execute-never control at stage 2 supported.

All other values are reserved.

FEAT_XNX implements the functionality identified by the value 0b0001.

From Armv8.2, the value 0b0000 is not permitted.

Access to this field is RO.

SpecSEI, bits [27:24]

When FEAT_RAS is implemented:

Describes whether the PE can generate SError exceptions from speculative reads of memory, including speculative instruction fetches.

The value of this field is an IMPLEMENTATION DEFINED choice of:

SpecSEI	Meaning
0b0000	The PE never generates an SError exception due to an External abort on a speculative read.
0b0001	The PE might generate an SError exception due to an External abort on a speculative read.

All other values are reserved.

FEAT_SpecSEI implements the functionality identified by the value 0b0001.

Access to this field is RO.

Otherwise:

Reserved, RES0.

PAN, bits [23:20]

Privileged Access Never. Indicates support for the PAN bit in PSTATE, SPSR_EL1, SPSR_EL2, SPSR_EL3, and DSPSR_EL0.

The value of this field is an IMPLEMENTATION DEFINED choice of:

All other values are reserved.

FEAT_PAN implements the functionality identified by the value 0b0001.

FEAT_PAN2 implements the functionality added by the value 0b0010.

From Armv8.1, the value 0b0000 is not permitted.

From Armv8.2, the value 0b0001 is not permitted.

Access to this field is RO.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Bits [19:16]

Reserved, RES0.

HPDS, bits [15:12]

When architecture implements VMSA extension:

Hierarchical Permission Disables. Indicates support for disabling hierarchical controls in translation tables.

The value of this field is an IMPLEMENTATION DEFINED choice of:

HPDS	Meaning
0b0000	Disabling of hierarchical controls not supported.
0b0001	Disabling of hierarchical controls supported with the TCR_EL1.{HPD1, HPD0}, TCR_EL2.HPD or TCR_EL2.{HPD1, HPD0}, and TCR_EL3.HPD bits.
0b0010	As for value 0b0001, and adds possible hardware allocation of bits[62:59] of the Translation table descriptors from the final lookup level for IMPLEMENTATION DEFINED use.

All other values are reserved.

FEAT_HPDS implements the functionality identified by the value 0b0001.

FEAT_HPDS2 implements the functionality identified by the value 0b0010.

From Armv8.1, the value 0b0000 is not permitted.

Access to this field is RO.

Otherwise:

Reserved, RES0.

Bits [11:8]

Reserved, RES0.

VMIDBits, bits [7:4]

Number of VMID bits.

The value of this field is an IMPLEMENTATION DEFINED choice of:

VMIDBits	Meaning
0b0000	8 bits
0b0010	16 bits

All other values are reserved.

FEAT_VMID16 implements the functionality identified by the value 0b0010.

Access to this field is RO.

HAFDBS, bits [3:0]

When architecture implements VMSA extension:

Hardware updates to Access flag and Dirty state in translation tables.

The value of this field is an IMPLEMENTATION DEFINED choice of:

All other values are reserved.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

FEAT_HAFDBS implements the functionality identified by the values 0b0001 and 0b0010.

Access to this field is RO.

Otherwise:

Reserved, RES0.

Accessing ID_AA64MMFR1_EL1

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, ID_AA64MMFR1_EL1

op0	op1	CRn	CRm	op2
0b11	0b000	0b0000	0b0111	0b001

```
if PSTATE.EL == EL0 then
    if IsFeatureImplemented(FEAT_IDST) then
        if HCR_EL2.TGE == '1' then
            AArch64.SystemAccessTrap(EL2, 0x18);
        else
            AArch64.SystemAccessTrap(EL1, 0x18);
    else
        UNDEFINED;
elsif PSTATE.EL == EL1 then
    if HCR_EL2.TID3 == '1' then
        AArch64.SystemAccessTrap(EL2, 0x18);
    else
        X[t, 64] = ID_AA64MMFR1_EL1;
elsif PSTATE.EL == EL2 then
    X[t, 64] = ID_AA64MMFR1_EL1;
```

D12.2.48 ID_AA64MMFR2_EL1, AArch64 Memory Model Feature Register 2

The ID_AA64MMFR2_EL1 characteristics are:

Purpose

Provides information about the implemented memory model and memory management support in AArch64 state.

For general information about the interpretation of the ID registers, see 'Principles of the ID scheme for fields in ID registers'.

Configuration

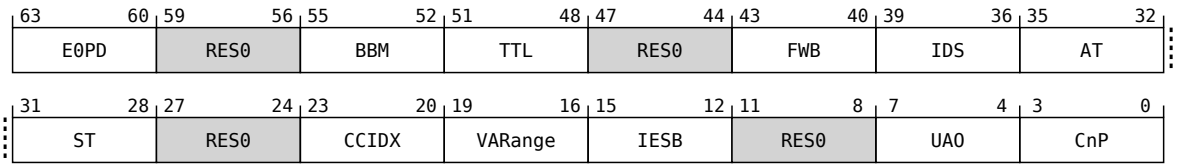
Note

Prior to the introduction of the features described by this register, this register was unnamed and reserved, RES0 from EL1 and EL2.

Attributes

ID_AA64MMFR2_EL1 is a 64-bit register.

Field descriptions



E0PD, bits [63:60]

When architecture implements VMSA extension:

Indicates support for the E0PD mechanism.

The value of this field is an IMPLEMENTATION DEFINED choice of:

E0PD	Meaning
0b0000	E0PDx mechanism is not implemented.
0b0001	E0PDx mechanism is implemented.

All other values are reserved.

FEAT_E0PD implements the functionality identified by the value 0b0001.

In Armv8.4, the permitted values are 0b0000 and 0b0001.

If FEAT_E0PD is implemented, FEAT_CSV3 must be implemented.

Access to this field is RO.

Otherwise:

Reserved, RES0.

Bits [59:56]

Reserved, RES0.

BBM, bits [55:52]

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

When architecture implements VMSA extension:

Allows identification of the requirements of the hardware to have break-before-make sequences when changing block or table size for a translation.

The value of this field is an IMPLEMENTATION DEFINED choice of:

All other values are reserved.

FEAT_BBML1 implements the functionality identified by the value 0b0001.

FEAT_BBML2 implements the functionality identified by the value 0b0010.

Access to this field is RO.

Otherwise:

Reserved, RES0.

TTL, bits [51:48]

When architecture implements VMSA extension:

Indicates support for TTL field in address operations.

The value of this field is an IMPLEMENTATION DEFINED choice of:

TTL	Meaning
0b0000	TLB maintenance instructions by address have bits[47:44] as RES0.
0b0001	TLB maintenance instructions by address have bits[47:44] holding the TTL field.

All other values are reserved.

FEAT_TTL implements the functionality identified by the value 0b0001.

This field affects TLBI IPAS2E1, TLBI IPAS2E1IS, TLBI IPAS2E1OS, TLBI IPAS2LE1, TLBI IPAS2LE1IS, TLBI IPAS2LE1OS, TLBI VAAE1, TLBI VAAE1IS, TLBI VAAE1OS, TLBI VAALE1, TLBI VAALE1IS, TLBI VAALE1OS, TLBI VAE1, TLBI VAE1IS, TLBI VAE1OS, TLBI VAE2, TLBI VAE2IS, TLBI VAE2OS, TLBI VAE3, TLBI VAE3IS, TLBI VAE3OS,TLBI VALE1, TLBI VALE1IS, TLBI VALE1OS, TLBI VALE2, TLBI VALE2IS, TLBI VALE2OS, TLBI VALE3, TLBI VALE3IS, TLBI VALE3OS.

From Armv8.4, the value 0b0000 is not permitted.

Access to this field is RO.

Otherwise:

Reserved, RES0.

Bits [47:44]

Reserved, RES0.

FWB, bits [43:40]

Indicates support for HCR_EL2.FWB.

The value of this field is an IMPLEMENTATION DEFINED choice of:

FWB	Meaning
0b0000	HCR_EL2.FWB bit is not supported.
0b0001	HCR_EL2.FWB is supported.

All other values reserved.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

FEAT_S2FWB implements the functionality identified by the value 0b0001.

From Armv8.4, the value 0b0000 is not permitted.

Access to this field is RO.

IDS, bits [39:36]

Indicates the EC syndrome value in ESR_ELx.EC that is reported if an exception is generated by a read access to the feature ID space.

The value of this field is an IMPLEMENTATION DEFINED choice of:

All other values are reserved.

The Feature ID space is defined as the System register space in AArch64 with op0==3, op1=={0, 1, 3}, CRn==0, CRm=={0-7}, op2=={0-7}.

FEAT_IDST implements the functionality identified by the value 0b0001.

From Armv8.4, the value 0b0000 is not permitted.

Access to this field is RO.

AT, bits [35:32]

Identifies support for unaligned single-copy atomicity and atomic functions.

The value of this field is an IMPLEMENTATION DEFINED choice of:

AT	Meaning
0b0000	Unaligned single-copy atomicity and atomic functions are not supported.
0b0001	Unaligned single-copy atomicity and atomic functions with a 16-byte address range aligned to 16-bytes are supported.

All other values are reserved.

FEAT_LSE2 implements the functionality identified by the value 0b0001.

From Armv8.4, the value 0b0000 is not permitted.

Access to this field is RO.

ST, bits [31:28]

When architecture implements VMSA extension:

Identifies support for small translation tables.

The value of this field is an IMPLEMENTATION DEFINED choice of:

ST	Meaning
0b0000	The maximum value of the TCR_ELx.{T0SZ,T1SZ} and VTCR_EL2.T0SZ fields is 39.
0b0001	The maximum value of the TCR_ELx.{T0SZ,T1SZ} and VTCR_EL2.T0SZ fields is 48 for 4KB and 16KB granules, and 47 for 64KB granules.

All other values are reserved.

FEAT_TTST implements the functionality identified by the value 0b0001.

When FEAT_SEL2 is implemented, the value 0b0000 is not permitted.

Access to this field is RO.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Otherwise:

Reserved, RES0.

Bits [27:24]

Reserved, RES0.

CCIDX, bits [23:20]

Support for the use of revised CCSIDR_EL1 register format.

The value of this field is an IMPLEMENTATION DEFINED choice of:

CCIDX	Meaning
0b0000	32-bit format implemented for all levels of the CCSIDR_EL1.
0b0001	64-bit format implemented for all levels of the CCSIDR_EL1.

All other values are reserved.

FEAT_CCIDX implements the functionality identified by the value 0b0001.

From Armv8.3, the permitted values are 0b0000 and 0b0001.

Access to this field is RO.

VARange, bits [19:16]

Indicates support for a larger virtual address.

The value of this field is an IMPLEMENTATION DEFINED choice of:

All other values are reserved.

FEAT_LVA implements the functionality identified by the value 0b0001.

Access to this field is RO.

IESB, bits [15:12]

Indicates support for the IESB bit in the SCTLR_ELx registers.

The value of this field is an IMPLEMENTATION DEFINED choice of:

IESB	Meaning
0b0000	IESB bit in the SCTLR_ELx registers is not supported.
0b0001	IESB bit in the SCTLR_ELx registers is supported.

All other values are reserved.

FEAT_IESB implements the functionality identified by the value 0b0001.

Access to this field is RO.

Bits [11:8]

Reserved, RES0.

UAO, bits [7:4]

User Access Override.

The value of this field is an IMPLEMENTATION DEFINED choice of:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

UAO	Meaning
0b0000	UAO not supported.
0b0001	UAO supported.

All other values are reserved.

FEAT_UAO implements the functionality identified by the value 0b0001.

From Armv8.2, the value 0b0000 is not permitted.

Access to this field is RO.

CnP, bits [3:0]

When architecture implements VMSA extension:

Indicates support for Common not Private translations.

The value of this field is an IMPLEMENTATION DEFINED choice of:

CnP	Meaning
0b0000	Common not Private translations not supported.
0b0001	Common not Private translations supported.

All other values are reserved.

FEAT_TTCNP implements the functionality identified by the value 0b0001.

From Armv8.2, the value 0b0000 is not permitted.

Access to this field is RO.

Otherwise:

Reserved, RES0.

D12.2.49 ID_AA64MMFR3_EL1, AArch64 Memory Model Feature Register 3

The ID_AA64MMFR3_EL1 characteristics are:

Purpose

Provides information about the implemented memory model and memory management support in AArch64 state.

Configuration

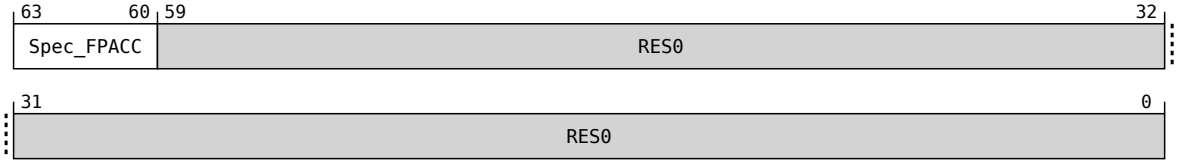
Note

Prior to the introduction of the features described by this register, this register was unnamed and reserved, RES0 from EL1 and EL2.

Attributes

ID_AA64MMFR3_EL1 is a 64-bit register.

Field descriptions



Spec_FPACC, bits [63:60]

When FEAT_FPACCOMBINE is implemented:

Speculative behavior in the event of a PAC authentication failure in an implementation that includes FEAT_FPACCOMBINE.

The value of this field is an IMPLEMENTATION DEFINED choice of:

Spec_FPACC	Meaning
0b0000	The implementation does not disclose whether the speculative use of pointers processed by a PAC Authentication is materially different in terms of the impact on cached microarchitectural state between passing and failing of the PAC Authentication.
0b0001	The speculative use of pointers processed by a PAC Authentication is not materially different in terms of the impact on cached microarchitectural state between passing and failing of the PAC Authentication.

All other values are reserved.

For the purpose of this definition, cached microarchitecture state is the state of caching agents such as instruction caches, data caches and TLBs which can be altered as a result of speculation caused by a mispredicted execution, but is not restored to the state prior to the speculation when the misprediction is corrected.

Access to this field is RO.

D12.2.50 ID_AA64MMFR4_EL1, AArch64 Memory Model Feature Register 4

The ID_AA64MMFR4_EL1 characteristics are:

Purpose

Provides additional information about implemented memory model and memory management support in AArch64.

Configuration

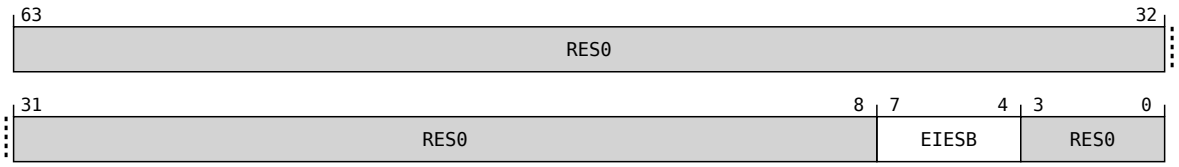
Note

Prior to the introduction of the features described by this register, this register was unnamed and reserved, RES0 from EL1 and EL2.

Attributes

ID_AA64MMFR4_EL1 is a 64-bit register.

Field descriptions



Bits [63:8]

Reserved, RES0.

EIESB, bits [7:4]

When FEAT_IESB is implemented:

Early Implicit Error Synchronization event. Indicates whether the implicit Error synchronization event inserted on taking an exception to ELx when SCTLR_ELx.IESB is 1 is inserted before or after the exception is taken.

The value of this field is an IMPLEMENTATION DEFINED choice of:

EIESB	Meaning
0b1111	FEAT_IESB is implemented. When SError exceptions are routed to EL3, and either FEAT_DoubleFault is not implemented or the Effective value of SCR_EL3.NMEA is 1, an implicit Error synchronization event might be inserted after an exception is taken to EL3.
0b0000	FEAT_IESB is not implemented, or behavior is not described.
0b0001	FEAT_IESB is implemented. When SError exceptions are routed to EL3, and either FEAT_DoubleFault is not implemented or the Effective value of SCR_EL3.NMEA is 1, an implicit Error synchronization event is inserted before an exception taken to EL3.
0b0010	As 0b0001, and also: • When SError exceptions are routed to EL1, and either FEAT_DoubleFault2 is not implemented or the Effective value of SCTLR2_EL1.NMEA is 1, an implicit Error synchronization event is inserted before an exception taken to EL1. • When SError exceptions are routed to EL2, and either FEAT_DoubleFault2 is not implemented or the Effective value of SCTLR2_EL2.NMEA is 1, an implicit Error synchronization event is inserted before an exception taken to EL2.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

All other values are reserved.

This field describes the PE behavior on taking an exception to ELx when SCTLR_ELx.IESB is 1. This field does not describe the behavior when SCTLR_ELx.IESB is 0.

The behavior described by this field only applies for the conditions described above. For example, if ID_AA64MMFR4_EL1.EIESB reads as `0b0001`, then it does not describe the behavior when SError exceptions are not routed to EL3, or when FEAT_DoubleFault is implemented and the Effective value of SCR_EL3.NMEA is 0.

Inserting the event before the exception is taken means that if the Error synchronization event causes an SError exception to become pending, and SError exceptions are not masked and not disabled, then the SError exception is taken in place of the original exception.

When FEAT_IESB is not implemented, the only permitted value of this field is `0b0000`.

Access to this field is RO.

D12.2.51 ID_AA64PFR0_EL1, AArch64 Processor Feature Register 0

The ID_AA64PFR0_EL1 characteristics are:

Purpose

Provides additional information about implemented PE features in AArch64 state.

For general information about the interpretation of the ID registers, see 'Principles of the ID scheme for fields in ID registers'.

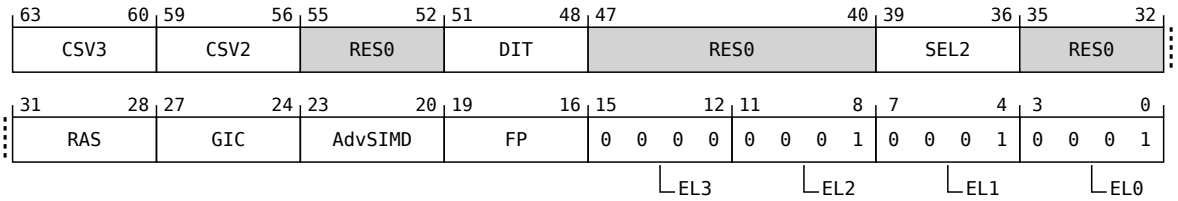
Configuration

The external register EDPFR gives information from this register.

Attributes

ID_AA64PFR0_EL1 is a 64-bit register.

Field descriptions



CSV3, bits [63:60]

Speculative use of faulting data.

The value of this field is an IMPLEMENTATION DEFINED choice of:

CSV3	Meaning
0b0000	This PE does not disclose whether data loaded or read from a register under speculation where the data load or register read would not be permitted architecturally, can be used by instructions newer than the load or register read in a manner that allows the value of the inaccessible data to be recovered by code architecturally executed.
0b0001	Data loaded or read from a register under speculation where the data load or register read would not be permitted architecturally, cannot be used by instructions newer than the load or register read in a manner that allows the value of the inaccessible data to be recovered by code architecturally executed.

All other values are reserved.

FEAT_CSV3 implements the functionality identified by the value 0b0001.

If FEAT_E0PD is implemented, FEAT_CSV3 must be implemented.

From Armv8.5, the value 0b0000 is not permitted.

Access to this field is RO.

CSV2, bits [59:56]

Speculative use of out of context prediction resources.

The value of this field is an IMPLEMENTATION DEFINED choice of:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

CSV2	Meaning
0b0000	The implementation does not disclose whether FEAT_CSV2 is implemented.
0b0001	FEAT_CSV2 is implemented, but FEAT_CSV2_2 and FEAT_CSV2_3 are not implemented. ID_AA64PFR1_EL1.CSV2_frac determines whether either or both of FEAT_CSV2_1p1 or FEAT_CSV2_1p2 are implemented.
0b0010	FEAT_CSV2_2 is implemented, but FEAT_CSV2_3 is not implemented.
0b0011	FEAT_CSV2_3 is implemented.

All other values are reserved.

FEAT_CSV2 implements the functionality identified by the value 0b0001.

FEAT_CSV2_2 implements the functionality identified by the value 0b0010.

FEAT_CSV2_3 implements the functionality identified by the feature 0b0011.

Access to this field is RO.

Bits [55:52]

Reserved, RES0.

DIT, bits [51:48]

Data Independent Timing.

The value of this field is an IMPLEMENTATION DEFINED choice of:

All other values are reserved.

FEAT_DIT implements the functionality identified by the value 0b0001.

From Armv8.4, the value 0b0000 is not permitted.

Access to this field is RO.

Bits [47:40]

Reserved, RES0.

SEL2, bits [39:36]

Secure EL2.

The value of this field is an IMPLEMENTATION DEFINED choice of:

SEL2	Meaning
0b0000	Secure EL2 is not implemented.
0b0001	Secure EL2 is implemented.

All other values are reserved.

FEAT_SEL2 implements the functionality identified by the value 0b0001.

From Armv8.4, if Secure state and EL2 are implemented, the value 0b0000 is not permitted.

From Armv8.4, if Secure state is not implemented, or if EL2 is not implemented, the only permitted value is 0b0000.

Access to this field is RO.

Bits [35:32]

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Reserved, RES0.

RAS, bits [31:28]

RAS Extension version.

The value of this field is an IMPLEMENTATION DEFINED choice of:

All other values are reserved.

FEAT_RAS implements the functionality identified by the value 0b0001.

FEAT_RASv1p1 and FEAT_DoubleFault implement the functionality identified by the value 0b0010.

In Armv8.0 and Armv8.1, the permitted values are 0b0000 and 0b0001.

From Armv8.2, the value 0b0000 is not permitted.

From Armv8.4, if FEAT_DoubleFault is implemented or ERRIDR_EL1.NUM is nonzero, the value 0b0001 is not permitted.

Note

When the value of this field is 0b0001, ID_AA64PFR1_EL1.RAS_frac indicates whether FEAT_RASv1p1 is implemented.

Access to this field is RO.

GIC, bits [27:24]

System register GIC CPU interface.

The value of this field is an IMPLEMENTATION DEFINED choice of:

GIC	Meaning
0b0000	GIC CPU interface system registers not implemented.
0b0001	System register interface to versions 3.0 and 4.0 of the GIC CPU interface is supported.
0b0011	System register interface to version 4.1 of the GIC CPU interface is supported.

All other values are reserved.

Access to this field is RO.

AdvSIMD, bits [23:20]

Advanced SIMD.

The value of this field is an IMPLEMENTATION DEFINED choice of:

AdvSIMD	Meaning
0b0000	Advanced SIMD is implemented, including support for the following SISD and SIMD operations: • Integer byte, halfword, word and doubleword element operations. • Single-precision and double-precision floating-point arithmetic. • Conversions between single-precision and half-precision data types, and double-precision and half-precision data types.
0b0001	As for 0b0000, and also includes support for half-precision floating-point arithmetic.
0b1111	Advanced SIMD is not implemented.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

All other values are reserved.

This field must have the same value as the FP field.

The permitted values are:

- 0b0000 in an implementation with Advanced SIMD support that does not include the FEAT_FP16 extension.
- 0b0001 in an implementation with Advanced SIMD support that includes the FEAT_FP16 extension.
- 0b1111 in an implementation without Advanced SIMD support.

Access to this field is RO.

FP, bits [19:16]

Floating-point.

The value of this field is an IMPLEMENTATION DEFINED choice of:

FP	Meaning
0b0000	Floating-point is implemented, and includes support for: • Single-precision and double-precision floating-point types. • Conversions between single-precision and half-precision data types, and double-precision and half-precision data types.
0b0001	As for 0b0000, and also includes support for half-precision floating-point arithmetic.
0b1111	Floating-point is not implemented.

All other values are reserved.

This field must have the same value as the AdvSIMD field.

The permitted values are:

- 0b0000 in an implementation with floating-point support that does not include the FEAT_FP16 extension.
- 0b0001 in an implementation with floating-point support that includes the FEAT_FP16 extension.
- 0b1111 in an implementation without floating-point support.

Access to this field is RO.

EL3, bits [15:12]

EL3 Exception level handling. In Armv8-R, the only permitted value is 0b0000. All other values are reserved.

EL3	Meaning
0b0000	EL3 is not implemented.

Access to this field is RO.

EL2, bits [11:8]

EL2 Exception level handling. In Armv8-R, the only permitted value is 0b0001. All other values are reserved.

EL2	Meaning
0b0001	EL2 can be executed in AArch64 state only.

Access to this field is RO.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

EL1, bits [7:4]

EL1 Exception level handling. In Armv8-R, the only permitted value is `0b0001`. All other values are reserved.

EL1	Meaning
0b0001	EL1 can be executed in AArch64 state only.

Access to this field is RO.

EL0, bits [3:0]

EL0 Exception level handling. In Armv8-R, the only permitted value is `0b0001`. All other values are reserved.

EL0	Meaning
0b0001	EL0 can be executed in AArch64 state only.

Access to this field is RO.

Accessing ID_AA64PFR0_EL1

Accesses to this register use the following encodings in the System register encoding space:

`MRS <Xt>, ID_AA64PFR0_EL1`

op0	op1	CRn	CRm	op2
0b11	0b000	0b0000	0b0100	0b000

```
if PSTATE.EL == EL0 then
    if IsFeatureImplemented(FEAT_IDST) then
        if HCR_EL2.TGE == '1' then
            AArch64.SystemAccessTrap(EL2, 0x18);
        else
            AArch64.SystemAccessTrap(EL1, 0x18);
    else
        UNDEFINED;
elsif PSTATE.EL == EL1 then
    if HCR_EL2.TID3 == '1' then
        AArch64.SystemAccessTrap(EL2, 0x18);
    else
        X[t, 64] = ID_AA64PFR0_EL1;
elsif PSTATE.EL == EL2 then
    X[t, 64] = ID_AA64PFR0_EL1;
```

D12.2.52 ID_AA64PFR1_EL1, AArch64 Processor Feature Register 1

The ID_AA64PFR1_EL1 characteristics are:

Purpose

Provides additional information about implemented PE features in AArch64 state.

For general information about the interpretation of the ID registers, see 'Principles of the ID scheme for fields in ID registers'.

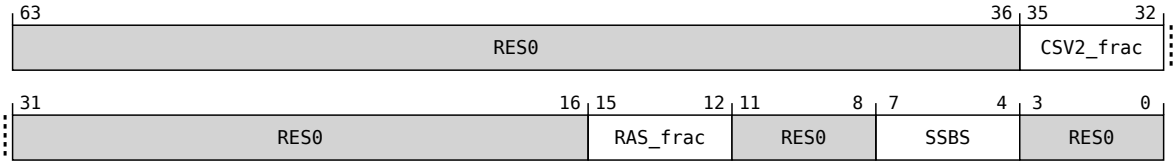
Configuration

There are no configuration notes.

Attributes

ID_AA64PFR1_EL1 is a 64-bit register.

Field descriptions



Bits [63:36]

Reserved, RES0.

CSV2_frac, bits [35:32]

CSV2 fractional field.

The value of this field is an IMPLEMENTATION DEFINED choice of:

CSV2_frac	Meaning
0b0000	Either ID_AA64PFR0_EL1.CSV2 is not 0b0001, or the implementation does not disclose whether FEAT_CSV2_1p1 is implemented. FEAT_CSV2_1p2 is not implemented.
0b0001	FEAT_CSV2_1p1 is implemented, but FEAT_CSV2_1p2 is not implemented.
0b0010	FEAT_CSV2_1p2 is implemented.

All other values are reserved.

FEAT_CSV2_1p1 implements the functionality identified by the value 0b0001.

FEAT_CSV2_1p2 implements the functionality identified by the value 0b0010.

In Armv8-R, the permitted values are 0b0000, 0b0001, and 0b0010.

The values 0b0001 and 0b0010 are permitted only when ID_AA64PFR0_EL1.CSV2 is 0b0001.

Access to this field is RO.

Bits [31:16]

Reserved, RES0.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

RAS_frac, bits [15:12]

RAS Extension fractional field.

The value of this field is an IMPLEMENTATION DEFINED choice of:

RAS_frac	Meaning
0b0000	If ID_AA64PFR0_EL1.RAS == 0b0001, support for the Reliability, Availability, and Serviceability Extension is implemented.
0b0001	If ID_AA64PFR0_EL1.RAS == 0b0001, as 0b0000 and adds support for: • Additional ERXMISC<m>_EL1 System registers. • Additional System registers ERXPFGCDN_EL1, ERXPFGCTL_EL1, and ERXPFGF_EL1, and the SCR_EL3.FIEN and HCR_EL2.FIEN trap controls, to support the optional RAS Common Fault Injection Model Extension. Error records accessed through System registers conform to RAS System Architecture v1.1, which includes simplifications to ERR<n>STATUS, and support for the optional RAS Timestamp and RAS Common Fault Injection Model Extensions.

All other values are reserved.

FEAT_RAS implements the functionality identified by the value 0b0000.

FEAT_RASv1p1 implements the functionality identified by the value 0b0001.

This field is valid only if ID_AA64PFR0_EL1.RAS == 0b0001.

Access to this field is RO.

Bits [11:8]

Reserved, RES0.

SSBS, bits [7:4]

Speculative Store Bypassing controls in AArch64 state.

The value of this field is an IMPLEMENTATION DEFINED choice of:

SSBS	Meaning
0b0000	AArch64 provides no mechanism to control the use of Speculative Store Bypassing.
0b0001	AArch64 provides the PSTATE.SSBS mechanism to mark regions that are Speculative Store Bypass Safe.
0b0010	As 0b0001, and adds the MSR and MRS instructions to directly read and write the PSTATE.SSBS field.

All other values are reserved.

FEAT_SSBS implements the functionality identified by the value 0b0001.

FEAT_SSBS2 implements the functionality identified by the value 0b0010.

Access to this field is RO.

Bits [3:0]

Reserved, RES0.

Accessing ID_AA64PFR1_EL1

Accesses to this register use the following encodings in the System register encoding space:

D12.2.53 ID_AA64PFR2_EL1, AArch64 Processor Feature Register 2

The ID_AA64PFR2_EL1 characteristics are:

Purpose

Provides additional information about implemented PE features in AArch64 state.

For general information about the interpretation of the ID registers, see 'Principles of the ID scheme for fields in ID registers'.

Configuration

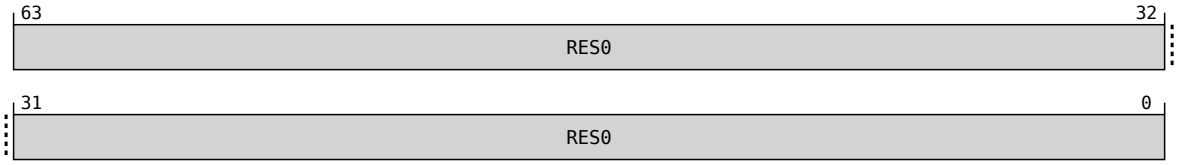
Note

Prior to the introduction of the features described by this register, this register was unnamed and reserved, RES0 from EL1 and EL2.

Attributes

ID_AA64PFR2_EL1 is a 64-bit register.

Field descriptions



Bits [63:0]

Reserved, RES0.

Accessing ID_AA64PFR2_EL1

Accesses to this register use the following encodings in the System register encoding space:

D12.2.54 ID_AFR0_EL1, AArch32 Auxiliary Feature Register 0

The ID_AFR0_EL1 characteristics are:

Purpose

Provides information about the IMPLEMENTATION DEFINED features of the PE in AArch32 state.

Must be interpreted with the Main ID Register, MIDR_EL1.

For general information about the interpretation of the ID registers see 'Principles of the ID scheme for fields in ID registers'.

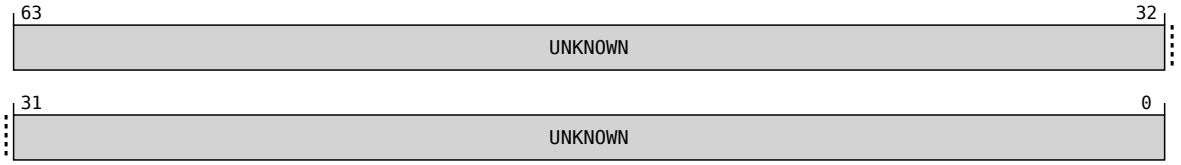
Configuration

There are no configuration notes.

Attributes

ID_AFR0_EL1 is a 64-bit register.

Field descriptions



Bits [63:0]

Reserved, UNKNOWN.

Accessing ID_AFR0_EL1

Accesses to this register use the following encodings in the System register encoding space:

D12.2.60 ID_ISAR3_EL1, AArch32 Instruction Set Attribute Register 3

The ID_ISAR3_EL1 characteristics are:

Purpose

Provides information about the instruction sets implemented by the PE in AArch32 state.

Must be interpreted with ID_ISAR0_EL1, ID_ISAR1_EL1, ID_ISAR2_EL1, ID_ISAR4_EL1, and ID_ISAR5_EL1.

For general information about the interpretation of the ID registers see 'Principles of the ID scheme for fields in ID registers'.

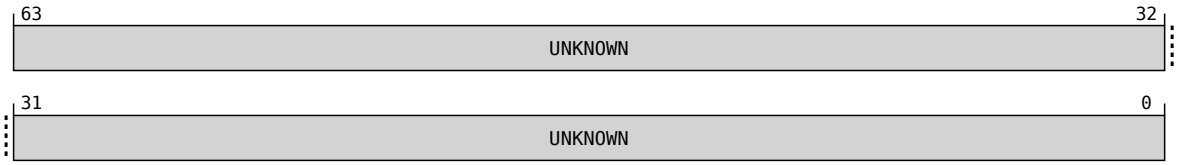
Configuration

There are no configuration notes.

Attributes

ID_ISAR3_EL1 is a 64-bit register.

Field descriptions



Bits [63:0]

Reserved, UNKNOWN.

Accessing ID_ISAR3_EL1

Accesses to this register use the following encodings in the System register encoding space:

`MRS <Xt>, ID_ISAR3_EL1`

op0	op1	CRn	CRm	op2
0b11	0b000	0b0000	0b0010	0b011

```

D12.2.61 ID_ISAR4_EL1, AArch32 Instruction Set Attribute Register 4

The ID_ISAR4_EL1 characteristics are:

Purpose

Provides information about the instruction sets implemented by the PE in AArch32 state.

Must be interpreted with ID_ISAR0_EL1, ID_ISAR1_EL1, ID_ISAR2_EL1, ID_ISAR3_EL1, and ID_ISAR5_EL1.

For general information about the interpretation of the ID registers, see 'Principles of the ID scheme for fields in ID registers'.

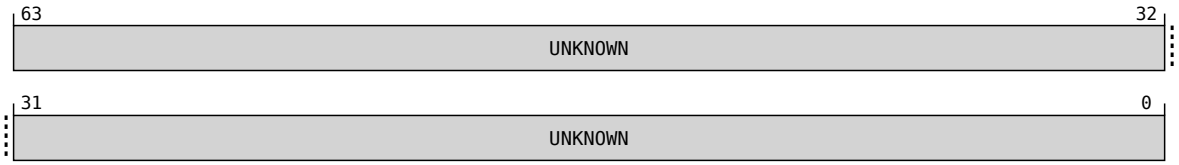
Configuration

There are no configuration notes.

Attributes

ID_ISAR4_EL1 is a 64-bit register.

Field descriptions



Bits [63:0]

Reserved, UNKNOWN.

Accessing ID_ISAR4_EL1

Accesses to this register use the following encodings in the System register encoding space:

`MRS <Xt>, ID_ISAR4_EL1`

D12.2.73 ISR_EL1, Interrupt Status Register

The ISR_EL1 characteristics are:

Purpose

Shows the pending status of IRQ and FIQ interrupts and SError exceptions.

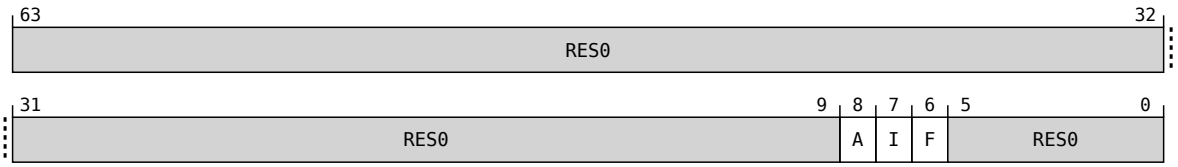
Configuration

There are no configuration notes.

Attributes

ISR_EL1 is a 64-bit register.

Field descriptions



Bits [63:9]

Reserved, RES0.

A, bit [8]

SError exception pending bit. Indicates whether an SError exception is pending.

A	Meaning
0b0	No pending SError.
0b1	An SError exception is pending.

If all of the following apply, then this field shows the pending status of virtual SError exceptions:

- HCR_EL2.AMO is 1.
- The PE is executing at EL1.

Otherwise, this field shows the pending status of physical SError exceptions.

If the physical SError exception is edge-triggered, this field is cleared to zero when the physical SError exception is taken.

I, bit [7]

IRQ pending bit. Indicates whether an IRQ interrupt is pending.

I	Meaning
0b0	No pending IRQ.
0b1	An IRQ interrupt is pending.

If all of the following apply, then this field shows the pending status of virtual IRQ interrupts:

- HCR_EL2.IMO is 1.
- The PE is executing at EL1.

Otherwise, this field shows the pending status of physical IRQ interrupts.

F, bit [6]

FIQ pending bit. Indicates whether an FIQ interrupt is pending.

F	Meaning
0b0	No pending FIQ.
0b1	An FIQ interrupt is pending.

If all of the following apply, then this field shows the pending status of virtual FIQ interrupts:

- HCR_EL2.FMO is 1.
- The PE is executing at EL1.

Otherwise, this field shows the pending status of physical FIQ interrupts.

Bits [5:0]

Reserved, RES0.

Accessing ISR_EL1

Accesses to this register use the following encodings in the System register encoding space:

```
MRS <Xt>, ISR_EL1
```

op0	op1	CRn	CRm	op2
0b11	0b000	0b1100	0b0001	0b000

```
if PSTATE.EL == EL0 then
    UNDEFINED;
elsif PSTATE.EL == EL1 then
    X[t, 64] = ISR_EL1;
elsif PSTATE.EL == EL2 then
    X[t, 64] = ISR_EL1;
```

D12.2.74 MAIR_EL1, Memory Attribute Indirection Register (EL1)

The MAIR_EL1 characteristics are:

Purpose

If VMSAv8-64 is enabled at stage 1 of EL1&0 translation regime, this register provides the memory attribute encodings corresponding to the possible AttrIndx values in a Long-descriptor format translation table entry for stage 1 translations at EL1.

If PMSAv8-64 is enabled at stage 1 of EL1&0 translation regime, this register provides the memory attribute encodings corresponding to the possible AttrIndx values in PRLAR_EL1 register for stage 1 translations.

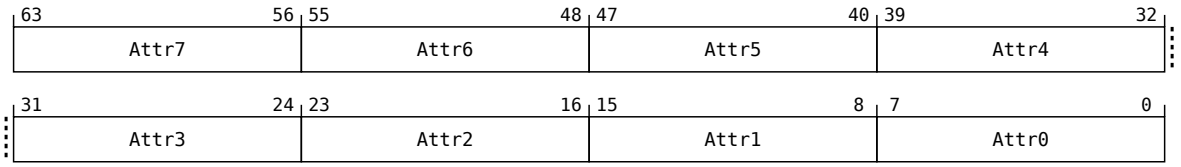
Configuration

There are no configuration notes.

Attributes

MAIR_EL1 is a 64-bit register.

Field descriptions



MAIR_EL1 is permitted to be cached in a TLB.

Attr<n> , bits [8n+7:8n], for n = 7 to 0

The memory attribute encoding for an AttrIndx[2:0] gives the value of <n> in Attr<n>.

Attr is encoded as follows:

Attr		Meaning
0b0000dd00		Device memory. See encoding of 'dd' for the type of Device memory.
0b0000ddxx	where xx != 00	UNPREDICTABLE.
0boooooiii	where oooo != 0000 and iiii != 0000	Normal memory. See encoding of 'oooo' and 'iiii' for the type of Normal memory.
0bxxxx0000	where xxxx != 0000	UNPREDICTABLE.

dd is encoded as follows:

'dd'	Meaning
0b00	Device-nGnRnE memory.
0b01	Device-nGnRE memory.
0b10	Device-nGRE memory.
0b11	Device-GRE memory.

oooo is encoded as follows:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

'oooo'		Meaning
0b0000		See encoding of Attr.
0b00RW	where RW != 00	Normal memory, Outer Write-Through Transient.
0b0100		Normal memory, Outer Non-cacheable.
0b01RW	where RW != 00	Normal memory, Outer Write-Back Transient.
0b10RW		Normal memory, Outer Write-Through Non-transient.
0b11RW		Normal memory, Outer Write-Back Non-transient.

R encodes the Outer Read-Allocate policy and W encodes the Outer Write-Allocate policy.

iiii is encoded as follows:

'iiii'		Meaning
0b0000		See encoding of Attr.
0b00RW	where RW != 00	Normal memory, Inner Write-Through Transient.
0b0100		Normal memory, Inner Non-cacheable.
0b01RW	where RW != 00	Normal memory, Inner Write-Back Transient.
0b10RW		Normal memory, Inner Write-Through Non-transient.
0b11RW		Normal memory, Inner Write-Back Non-transient.

R encodes the Inner Read-Allocate policy and W encodes the Inner Write-Allocate policy.

In oooo and iiii, R and W are encoded as follows:

'R' or 'W'	Meaning
0b0	No Allocate.
0b1	Allocate.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing MAIR_EL1

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, MAIR_EL1

op0	op1	CRn	CRm	op2
0b11	0b000	0b1010	0b0010	0b000

```
if PSTATE.EL == EL0 then
    UNDEFINED;
elsif PSTATE.EL == EL1 then
    if HCR_EL2.TRVM == '1' then
        AArch64.SystemAccessTrap(EL2, 0x18);
    else
        X[t, 64] = MAIR_EL1;
elsif PSTATE.EL == EL2 then

D12.2.75 MAIR_EL2, Memory Attribute Indirection Register (EL2)

The MAIR_EL2 characteristics are:

Purpose

Provides the memory attribute encodings corresponding to the possible AttrIndx values in PRLAR_EL2 for stage 1 EL2 translation regime and for stage 2 EL1&0 translation regime.

For stage 2 EL1&0 translations, the memory attributes are derived from MAIR_EL2 register as described in the Armv8-R AArch64 architecture.

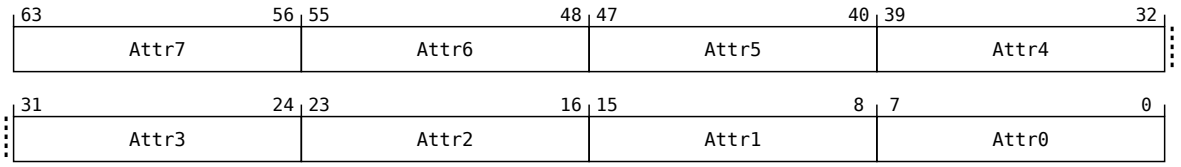
Configuration

There are no configuration notes.

Attributes

MAIR_EL2 is a 64-bit register.

Field descriptions



MAIR_EL2 is permitted to be cached in a TLB.

Attr<n> , bits [8n+7:8n], for n = 7 to 0

The memory attribute encoding for an AttrIndx[2:0] gives the value of <n> in Attr<n>.

Attr is encoded as follows:

Attr		Meaning
0b0000dd00		Device memory. See encoding of 'dd' for the type of Device memory.
0b0000ddxx	where xx != 00	UNPREDICTABLE.
0boooiiii	where oooo != 0000 and iiii != 0000	Normal memory. See encoding of 'oooo' and 'iiii' for the type of Normal memory.
0bxxxx0000	where xxxx != 0000	UNPREDICTABLE.

dd is encoded as follows:

'dd'	Meaning
0b00	Device-nGnRnE memory.
0b01	Device-nGnRE memory.
0b10	Device-nGRE memory.
0b11	Device-GRE memory.

oooo is encoded as follows:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

'oooo'		Meaning
0b0000		See encoding of Attr.
0b00RW	where RW != 00	Normal memory, Outer Write-Through Transient.
0b0100		Normal memory, Outer Non-cacheable.
0b01RW	where RW != 00	Normal memory, Outer Write-Back Transient.
0b10RW		Normal memory, Outer Write-Through Non-transient.
0b11RW		Normal memory, Outer Write-Back Non-transient.

R encodes the Outer Read-Allocate policy and W encodes the Outer Write-Allocate policy.

iiii is encoded as follows:

'iiii'		Meaning
0b0000		See encoding of Attr.
0b00RW	where RW != 00	Normal memory, Inner Write-Through Transient.
0b0100		Normal memory, Inner Non-cacheable.
0b01RW	where RW != 00	Normal memory, Inner Write-Back Transient.
0b10RW		Normal memory, Inner Write-Through Non-transient.
0b11RW		Normal memory, Inner Write-Back Non-transient.

R encodes the Inner Read-Allocate policy and W encodes the Inner Write-Allocate policy.

In oooo and iiii, R and W are encoded as follows:

'R' or 'W'	Meaning
0b0	No Allocate.
0b1	Allocate.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing MAIR_EL2

D12.2.76 MIDR_EL1, Main ID Register

The MIDR_EL1 characteristics are:

Purpose

Provides identification information for the PE, including an implementer code for the device and a device ID number.

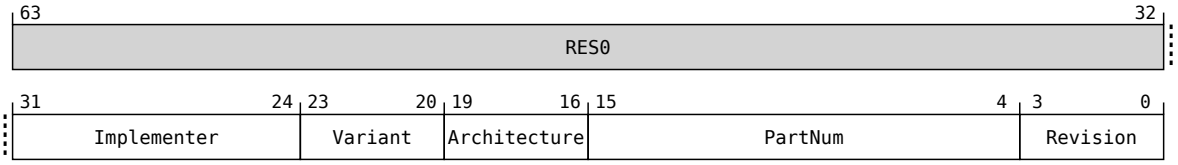
Configuration

AArch64 System register MIDR_EL1 bits [31:0] are architecturally mapped to External register MIDR_EL1[31:0].

Attributes

MIDR_EL1 is a 64-bit register.

Field descriptions



Bits [63:32]

Reserved, RES0.

Implementer, bits [31:24]

The Implementer code. This field must hold an implementer code that has been assigned by Arm.

The value of this field is an IMPLEMENTATION DEFINED choice of:

Implementer	Meaning
0x00	Reserved for software use.
0x41	Arm Limited.
0x42	Broadcom Corporation.
0x43	Cavium Inc.
0x44	Digital Equipment Corporation.
0x46	Fujitsu Ltd.
0x49	Infineon Technologies AG.
0x4D	Motorola or Freescale Semiconductor Inc.
0x4E	NVIDIA Corporation.
0x50	Applied Micro Circuits Corporation.
0x51	Qualcomm Inc.
0x56	Marvell International Ltd.
0x69	Intel Corporation.
0xC0	Ampere Computing.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Arm can assign codes that are not published in this manual. All values not assigned by Arm are reserved and must not be used.

Access to this field is RO.

Variant, bits [23:20]

Variant number. Typically, this field is used to distinguish between different product variants, or major revisions of a product.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

Architecture, bits [19:16]

Architecture version.

The value of this field is an IMPLEMENTATION DEFINED choice of:

Architecture	Meaning
0b0001	Armv4.
0b0010	Armv4T.
0b0011	Armv5 (obsolete).
0b0100	Armv5T.
0b0101	Armv5TE.
0b0110	Armv5TEJ.
0b0111	Armv6.
0b1111	Architectural features are individually identified in the ID_* registers.

All other values are reserved.

Access to this field is RO.

PartNum, bits [15:4]

Primary Part Number for the device.

On processors implemented by Arm, if the top four bits of the primary part number are 0x0 or 0x7, the variant and architecture are encoded differently.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

Revision, bits [3:0]

Revision number for the device.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

Accessing MIDR_EL1

Accesses to this register use the following encodings in the System register encoding space:

```
MRS <Xt>, MIDR_EL1
```

D12.2.77 MPIDR_EL1, Multiprocessor Affinity Register

The MPIDR_EL1 characteristics are:

Purpose

In a multiprocessor system, provides an additional PE identification mechanism.

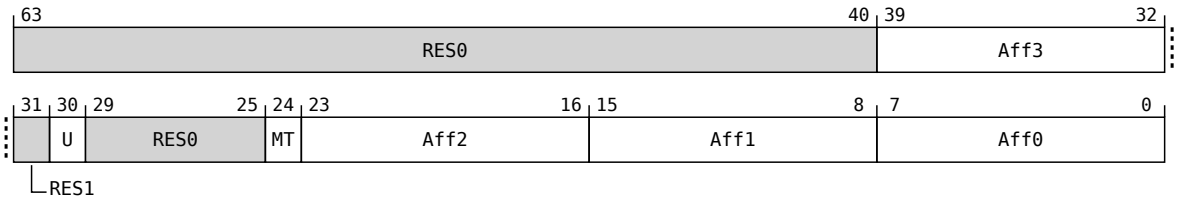
Configuration

In a uniprocessor system, Arm recommends that each Aff<n> field of this register returns a value of 0.

Attributes

MPIDR_EL1 is a 64-bit register.

Field descriptions



Bits [63:40]

Reserved, RES0.

Aff3, bits [39:32]

Affinity level 3. See the description of Aff0 for more information.

Aff3 is not supported in AArch32 state.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

Bit [31]

Reserved, RES1.

U, bit [30]

Indicates a Uniprocessor system, as distinct from PE 0 in a multiprocessor system.

The value of this field is an IMPLEMENTATION DEFINED choice of:

U	Meaning
0b0	Processor is part of a multiprocessor system.
0b1	Processor is part of a uniprocessor system.

Access to this field is RO.

Bits [29:25]

Reserved, RES0.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

MT, bit [24]

Indicates whether the lowest level of affinity consists of logical PEs that are implemented using an interdependent approach, such as multithreading. See the description of Aff0 for more information about affinity levels.

The value of this field is an IMPLEMENTATION DEFINED choice of:

MT	Meaning
0b0	Performance of PEs with different affinity level 0 values, and the same values for affinity level 1 and higher, is largely independent.
0b1	Performance of PEs with different affinity level 0 values, and the same values for affinity level 1 and higher, is very interdependent.

Note

This field does not indicate that multithreading is implemented and does not indicate that PEs with different affinity level 0 values, and the same values for affinity level 1 and higher are implemented.

Access to this field is RO.

Aff2, bits [23:16]

Affinity level 2. See the description of Aff0 for more information.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

Aff1, bits [15:8]

Affinity level 1. See the description of Aff0 for more information.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

Aff0, bits [7:0]

Affinity level 0. The value of the MPIDR.{Aff2, Aff1, Aff0} or MPIDR_EL1.{Aff3, Aff2, Aff1, Aff0} set of fields of each PE must be unique within the system as a whole.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

Accessing MPIDR_EL1

Accesses to this register use the following encodings in the System register encoding space:

```
MRS <Xt>, MPIDR_EL1
```

op0	op1	CRn	CRm	op2
0b11	0b000	0b0000	0b0000	0b101

```
if PSTATE.EL == EL0 then
    if IsFeatureImplemented(FEAT_IDST) then
        if HCR_EL2.TGE == '1' then
            AArch64.SystemAccessTrap(EL2, 0x18);
        else
            AArch64.SystemAccessTrap(EL1, 0x18);
    else
        UNDEFINED;
elsif PSTATE.EL == EL1 then

D12.2.78 MVFR0_EL1, AArch32 Media and VFP Feature Register 0

The MVFR0_EL1 characteristics are:

Purpose

Describes the features provided by the AArch32 Advanced SIMD and floating-point implementation.

Must be interpreted with MVFR1_EL1 and MVFR2_EL1.

For general information about the interpretation of the ID registers see 'Principles of the ID scheme for fields in ID registers'.

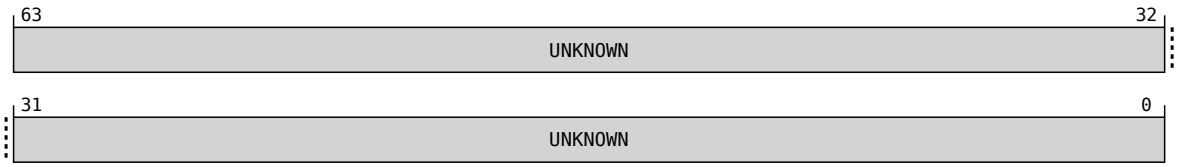
Configuration

In an implementation where at least one Exception level supports execution in AArch32 state, but there is no support for Advanced SIMD and floating-point operation, this register is RAZ.

Attributes

MVFR0_EL1 is a 64-bit register.

Field descriptions



Bits [63:0]

Reserved, UNKNOWN.

Accessing MVFR0_EL1

Accesses to this register use the following encodings in the System register encoding space:

`MRS <Xt>, MVFR0_EL1`

op0	op1	CRn	CRm	op2
0b11	0b000	0b0000	0b0011	0b000

D12.2.80 MVFR2_EL1, AArch32 Media and VFP Feature Register 2

The MVFR2_EL1 characteristics are:

Purpose

Describes the features provided by the AArch32 Advanced SIMD and floating-point implementation.

Must be interpreted with MVFR0_EL1 and MVFR1_EL1.

For general information about the interpretation of the ID registers, see 'Principles of the ID scheme for fields in ID registers'.

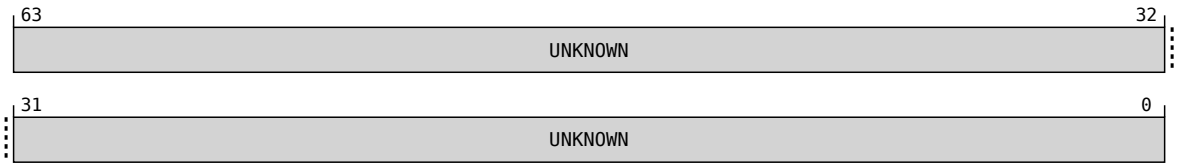
Configuration

In an implementation where at least one Exception level supports execution in AArch32 state, but there is no support for Advanced SIMD and floating-point operation, this register is RAZ.

Attributes

MVFR2_EL1 is a 64-bit register.

Field descriptions



Bits [63:0]

Reserved, UNKNOWN.

Accessing MVFR2_EL1

Accesses to this register use the following encodings in the System register encoding space:

`MRS <Xt>, MVFR2_EL1`

op0	op1	CRn	CRm	op2
0b11	0b000	0b0000	0b0011	0b010

D12.2.81 PAR_EL1, Physical Address Register

The PAR_EL1 characteristics are:

Purpose

Returns the output address (OA) from an Address translation instruction that executed successfully, or fault information if the instruction did not execute successfully.

Configuration

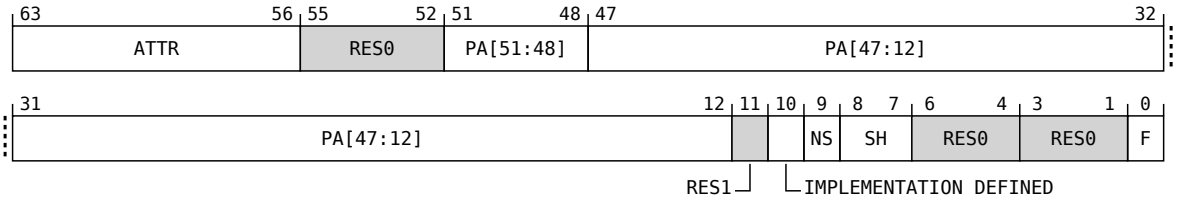
There are no configuration notes.

Attributes

PAR_EL1 is a 64-bit register.

Field descriptions

When GetPAR_EL1_F() == '0':



This section describes the register value returned by the successful execution of an Address translation instruction. Software might subsequently write a different value to the register, and that write does not affect the operation of the PE.

On a successful conversion, the PAR_EL1 can return a value that indicates the resulting attributes, rather than the values that appear in the Translation table descriptors. More precisely:

- The PAR_EL1.{ATTR, SH} fields are permitted to report the resulting attributes, as determined by any permitted implementation choices and any applicable configuration bits, instead of reporting the values that appear in the Translation table descriptors.
- See the PAR_EL1.NS bit description for constraints on the value it returns.

ATTR, bits [63:56]

Memory attributes for the returned output address. This field uses the same encoding as the Attr<n> fields in MAIR_EL1, and MAIR_EL2.

The value returned in this field can be the resulting attribute that is actually implemented by the implementation, as determined by any permitted implementation choices and any applicable configuration bits, instead of the value that appears in the Translation table descriptor.

Note

The attributes presented are consistent with the stages of translation applied in the address translation instruction. If the instruction performed a stage 1 translation only, the attributes are from the stage 1 translation. If the instruction performed a stage 1 and stage 2 translation, the attributes are from the combined stage 1 and stage 2 translation.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [55:52, 6:4]

Reserved, RES0.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

PA[51:48], bits [51:48]

When FEAT_LPA is implemented:

Extension to PA[47:12]. For more information, see PA[47:12].

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

PA[47:12], bits [47:12]

Output address. The output address (OA) corresponding to the supplied input address. This field returns address bits[47:12].

When FEAT_LPA is implemented and 52-bit addresses are in use, PA[51:48] forms the upper part of the address value. Otherwise, when 52-bit addresses are not in use, PA[51:48] is RES0.

For implementations with fewer than 48 physical address bits, the corresponding upper bits in this field are RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [11]

Reserved, RES1.

IMPLEMENTATION DEFINED, bit [10]

IMPLEMENTATION DEFINED.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

NS, bit [9]

Non-secure. The NS attribute for a translation table entry from a Secure translation regime.

For a result from a Secure translation regime, when SCR_EL3.EEL2 is 1, this bit distinguishes between the Secure and Non-secure intermediate physical address space of the translation for the instructions:

- In AArch64 state: AT S1E1R, AT S1E1W, AT S1E1RP, AT S1E1WP, AT S1E0R, and AT S1E0W.

Otherwise, this bit reflects the Security state of the physical address space of the translation. This means it reflects the effect of the NSTable bits of earlier levels of the translation table walk if those NSTable bits have an effect on the translation.

For a result from a Non-secure translation regime, this bit is UNKNOWN.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

SH, bits [8:7]

Shareability attribute, for the returned output address.

SH	Meaning
0b00	Non-shareable.
0b10	Outer Shareable.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

SH	Meaning
0b11	Inner Shareable.

The value 0b01 is reserved.

Note

This field returns the value 0b10 for:

- Any type of Device memory.
- Normal memory with both Inner Non-cacheable and Outer Non-cacheable attributes.

The value returned in this field can be the resulting attribute, as determined by any permitted implementation choices and any applicable configuration bits, instead of the value that appears in the Translation table descriptor.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [3:1]

Reserved, RES0.

F, bit [0]

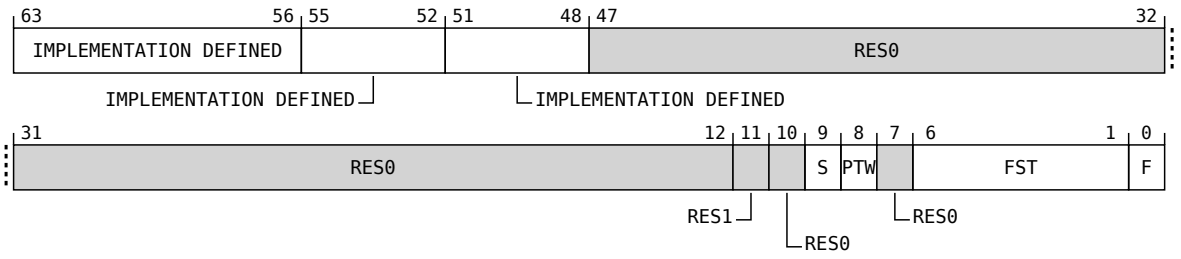
Indicates whether the instruction performed a successful address translation.

F	Meaning
0b0	Address translation completed successfully.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

When GetPAR_EL1_F() == '1':



This section describes the register value returned by a fault on the execution of an Address translation instruction. Software might subsequently write a different value to the register, and that write does not affect the operation of the PE.

IMPLEMENTATION DEFINED, bits [63:56]

IMPLEMENTATION DEFINED.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

IMPLEMENTATION DEFINED, bits [55:52]

IMPLEMENTATION DEFINED.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

IMPLEMENTATION DEFINED, bits [51:48]

IMPLEMENTATION DEFINED.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [47:12]

Reserved, RES0.

Bit [11]

Reserved, RES1.

Bit [10]

Reserved, RES0.

S, bit [9]

Indicates the translation stage at which the translation aborted:

S	Meaning
0b0	Translation aborted because of a fault in the stage 1 translation.
0b1	Translation aborted because of a fault in the stage 2 translation.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

PTW, bit [8]

If this bit is set to 1, it indicates the translation aborted because of a stage 2 fault during a stage 1 translation table walk.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [7]

Reserved, RES0.

FST, bits [6:1]

Fault status code, as shown in the Data Abort exception ESR encoding.

FST	Meaning	Applies when
0b000000	Address size fault, level 0 of translation or translation table base register.	
0b000001	Address size fault, level 1.	
0b000010	Address size fault, level 2.	
0b000011	Address size fault, level 3.	

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

FST	Meaning	Applies when
0b000100	Translation fault, level 0.	
0b000101	Translation fault, level 1.	
0b000110	Translation fault, level 2.	
0b000111	Translation fault, level 3.	
0b001001	Access flag fault, level 1.	
0b001010	Access flag fault, level 2.	
0b001011	Access flag fault, level 3.	
0b001100	Permission fault, level 0.	
0b001101	Permission fault, level 1.	
0b001110	Permission fault, level 2.	
0b001111	Permission fault, level 3.	
0b011100	Synchronous parity or ECC error on memory access on translation table walk or hardware update of translation table, level 0.	FEAT_RAS is not implemented
0b011101	Synchronous parity or ECC error on memory access on translation table walk or hardware update of translation table, level 1.	FEAT_RAS is not implemented
0b011110	Synchronous parity or ECC error on memory access on translation table walk or hardware update of translation table, level 2.	FEAT_RAS is not implemented
0b011111	Synchronous parity or ECC error on memory access on translation table walk or hardware update of translation table, level 3.	FEAT_RAS is not implemented
0b110000	TLB conflict abort.	
0b110001	Unsupported atomic hardware update fault.	FEAT_HAFDBS is implemented

Note

The encodings for FST do not include Synchronous External abort on translation table walk or hardware update of translation table, because these MMU faults are reported as a Data Abort exception instead of being recorded in PAR_EL1. See Exceptions to reporting the fault in PAR_EL1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

F, bit [0]

Indicates whether the instruction performed a successful address translation.

F	Meaning
0b1	Address translation aborted.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing PAR_EL1

Accesses to this register use the following encodings in the System register encoding space:

```
MRS <Xt>, PAR_EL1
```

D12.2.82 REVIDR_EL1, Revision ID Register

The REVIDR_EL1 characteristics are:

Purpose

Provides implementation-specific minor revision information.

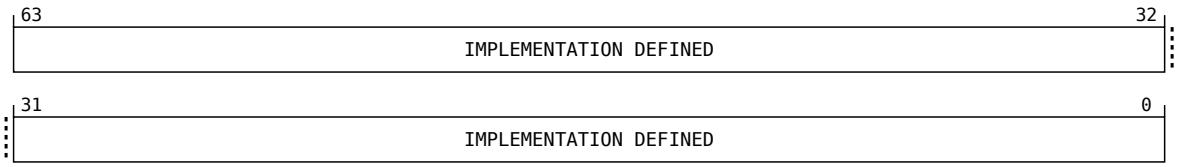
Configuration

If REVIDR_EL1 has the same value as MIDR_EL1, then its contents have no significance.

Attributes

REVIDR_EL1 is a 64-bit register.

Field descriptions



IMPLEMENTATION DEFINED, bits [63:0]

IMPLEMENTATION DEFINED.

Accessing REVIDR_EL1

Accesses to this register use the following encodings in the System register encoding space:

`MRS <Xt>, REVIDR_EL1`

op0	op1	CRn	CRm	op2
0b11	0b000	0b0000	0b0000	0b110

```
if PSTATE.EL == EL0 then
    if IsFeatureImplemented(FEAT_IDST) then
        if HCR_EL2.TGE == '1' then

D12.2.83 RMR_EL2, Reset Management Register (EL2)

The RMR_EL2 characteristics are:

Purpose

When this register is implemented:

- A write to the register at EL2 can request a Warm reset.
- If EL2 can use all Execution states, this register specifies the Execution state that the PE boots into on a Warm reset.

Configuration

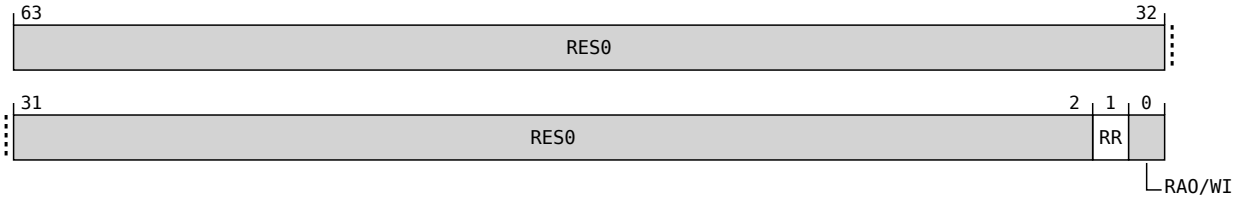
When EL2 is the highest implemented Exception level:

- If EL2 can use all Execution states then this register must be implemented.
- In an AArch64 only implementation it is IMPLEMENTATION DEFINED whether the register is implemented.

Attributes

RMR_EL2 is a 64-bit register.

Field descriptions



Bits [63:2]

Reserved, RES0.

RR, bit [1]

Reset Request. Setting this bit to 1 requests a Warm reset.

The reset behavior of this field is:

- On a Warm reset, this field resets to '0'.

Bit [0]

Reserved, RAO/WI.

Accessing RMR_EL2

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, RMR_EL2

op0	op1	CRn	CRm	op2
0b11	0b100	0b1100	0b0000	0b010

D12.2.84 RVBAR_EL2, Reset Vector Base Address Register (if EL3 not implemented)

The RVBAR_EL2 characteristics are:

Purpose

If EL2 is the highest Exception level implemented, contains the IMPLEMENTATION DEFINED address that execution starts from after reset when executing in AArch64 state.

Configuration

There are no configuration notes.

Attributes

RVBAR_EL2 is a 64-bit register.

Field descriptions

ResetAddress, bits [63:0]

The IMPLEMENTATION DEFINED address that execution starts from after reset when executing in 64-bit state. Bits[1:0] of this register are 00, as this address must be aligned, and the address must be within the physical address size supported by the PE.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

Accessing RVBAR_EL2

Accesses to this register use the following encodings in the System register encoding space:

```
MRS <Xt>, RVBAR_EL2
```

op0	op1	CRn	CRm	op2
0b11	0b100	0b1100	0b0000	0b001

```
if PSTATE.EL == EL2 then
    X[t, 64] = RVBAR_EL2;
else
    UNDEFINED;
```

D12.2.85 S3_<op1>_<Cn>_<Cm>_<op2>, IMPLEMENTATION DEFINED Registers

The S3_<op1><*Cn*><Cm>_<op2> characteristics are:

Purpose

This area of the instruction set space is reserved for IMPLEMENTATION DEFINED registers.

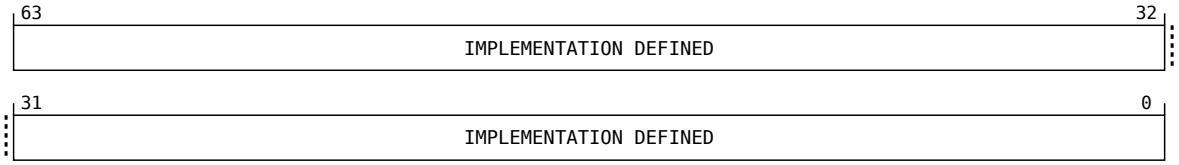
Configuration

There are no configuration notes.

Attributes

S3_<op1><*Cn*><Cm>_<op2> is a 64-bit register.

Field descriptions



IMPLEMENTATION DEFINED, bits [63:0]

IMPLEMENTATION DEFINED.

Accessing S3_<op1>_<Cn>_<Cm>_<op2>

D12.2.86 SCTLR_EL1, System Control Register (EL1)

The SCTLR_EL1 characteristics are:

Purpose

Provides top-level control of the system, including its memory system, at EL1 and EL0.

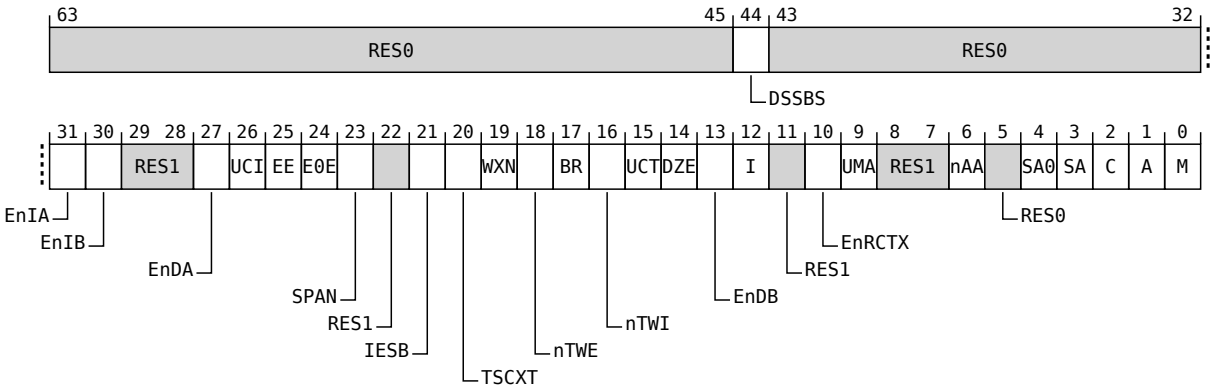
Configuration

There are no configuration notes.

Attributes

SCTLR_EL1 is a 64-bit register.

Field descriptions



Bits [63:45]

Reserved, RES0.

DSSBS, bit [44]

When FEAT_SSBS is implemented:

Default PSTATE.SSBS value on Exception Entry.

DSSBS	Meaning
0b0	PSTATE.SSBS is set to 0 on an exception to EL1.
0b1	PSTATE.SSBS is set to 1 on an exception to EL1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an IMPLEMENTATION DEFINED value.

Otherwise:

Reserved, RES0.

Bits [43:32]

Reserved, RES0.

EnIA, bit [31]

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

When FEAT_PAuth is implemented:

Controls enabling of pointer authentication of instruction addresses, using the APIAKey_EL1 key, at EL1 and at EL0 in the EL1&0 translation regime.

EnIA	Meaning
0b0	Pointer authentication of instruction addresses at EL1 and at EL0 in the EL1&0 translation regime, using the APIAKey_EL1 key, is not enabled.
0b1	Pointer authentication of instruction addresses at EL1 and at EL0 in the EL1&0 translation regime, using the APIAKey_EL1 key, is enabled.

Note

This field controls the behavior of the AddPACIA and AuthIA pseudocode functions. When pointer authentication is enabled, AddPACIA returns a copy of a pointer to which a pointer authentication code has been added, and AuthIA returns an authenticated copy of a pointer. When pointer authentication is disabled, both of these functions are NOP.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

EnIB, bit [30]

When FEAT_PAuth is implemented:

Controls enabling of pointer authentication of instruction addresses, using the APIBKey_EL1 key, at EL1 and at EL0 in the EL1&0 translation regime.

EnIB	Meaning
0b0	Pointer authentication of instruction addresses at EL1 and at EL0 in the EL1&0 translation regime, using the APIBKey_EL1 key, is not enabled.
0b1	Pointer authentication of instruction addresses at EL1 and at EL0 in the EL1&0 translation regime, using the APIBKey_EL1 key, is enabled.

Note

This field controls the behavior of the AddPACIB and AuthIB pseudocode functions. When pointer authentication is enabled, AddPACIB returns a copy of a pointer to which a pointer authentication code has been added, and AuthIB returns an authenticated copy of a pointer. When pointer authentication is disabled, both of these functions are NOP.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bits [29:28]

Reserved, RES1.

EnDA, bit [27]

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

When FEAT_PAuth is implemented:

Controls enabling of pointer authentication of data addresses, using the APDAKey_EL1 key, at EL1 and at EL0 in the EL1&0 translation regime.

EnDA	Meaning
0b0	Pointer authentication of data addresses at EL1 and at EL0 in the EL1&0 translation regime, using the APDAKey_EL1 key, is not enabled.
0b1	Pointer authentication of data addresses at EL1 and at EL0 in the EL1&0 translation regime, using the APDAKey_EL1 key, is enabled.

Note

This field controls the behavior of the AddPACDA and AuthDA pseudocode functions. When pointer authentication is enabled, AddPACDA returns a copy of a pointer to which a pointer authentication code has been added, and AuthDA returns an authenticated copy of a pointer. When pointer authentication is disabled, both of these functions are NOP.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

UCI, bit [26]

Traps EL0 execution of cache maintenance instructions, to EL1, or to EL2 when HCR_EL2.TGE is 1, from AArch64 state only, reported using EC syndrome value 0x18, as follows:

- DC CVAU, DC CIVAC, DC CVAC, and IC IVAU.
- If FEAT_DPB is implemented, DC CVAP.
- If FEAT_DPB2 is implemented, DC CVADP.

UCI	Meaning
0b0	For each of the specified instructions, if the execution of the instruction can be trapped, access at EL0 using AArch64 is trapped.
0b1	This control does not cause any instructions to be trapped.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

EE, bit [25]

When FEAT_MixedEnd is implemented:

Endianness of data accesses at EL1, and stage 1 translation table walks in the EL1&0 translation regime.

EE	Meaning
0b0	Explicit data accesses at EL1, and stage 1 translation table walks in the EL1&0 translation regime are little-endian.
0b1	Explicit data accesses at EL1, and stage 1 translation table walks in the EL1&0 translation regime are big-endian.

The EE bit is permitted to be cached in a TLB.

The reset behavior of this field is:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- On a Warm reset, this field resets to an IMPLEMENTATION DEFINED value.

When FEAT_BigEnd is implemented:

Explicit data accesses at EL1, and stage 1 translation table walks in the EL1&0 translation regime are big-endian.

Reserved, RES1.

Otherwise:

Explicit data accesses at EL1, and stage 1 translation table walks in the EL1&0 translation regime are little-endian.

Reserved, RES0.

E0E, bit [24]

When FEAT_MixedEndEL0 is implemented:

Endianness of data accesses at EL0.

E0E	Meaning
0b0	Explicit data accesses at EL0 are little-endian.
0b1	Explicit data accesses at EL0 are big-endian.

This bit has no effect on the endianness of Explicit Memory Effects generated by unprivileged memory access instructions executed at EL1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

When FEAT_BigEndEL0 is implemented:

Explicit data accesses at EL0 are big-endian.

Reserved, RES1.

Otherwise:

Explicit data accesses at EL0 are little-endian.

Reserved, RES0.

SPAN, bit [23]

When FEAT_PAN is implemented:

Set Privileged Access Never, on taking an exception to EL1.

SPAN	Meaning
0b0	PSTATE.PAN is set to 1 on taking an exception to EL1.
0b1	The value of PSTATE.PAN is left unchanged on taking an exception to EL1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES1.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Bit [22]

Reserved, RES1.

IESB, bit [21]

When FEAT_IESB is implemented:

Implicit Error Synchronization event enable. Possible values are:

IESB	Meaning
0b0	Disabled.
0b1	An implicit error synchronization event is added: • At each exception taken to EL1. • Before the operational pseudocode of each Exception Return instruction executed at EL1.

When the PE is in Debug state, the effect of this field is CONSTRAINED UNPREDICTABLE, and its Effective value might be 0 or 1 regardless of the value of the field. If the Effective value of the field is 1, then an implicit error synchronization event is added after each DCPSx instruction taken to EL1 and before each DRPS instruction executed at EL1, in addition to the other cases where it is added.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

TSCXT, bit [20]

When FEAT_CSV2_2 is implemented or FEAT_CSV2_1p2 is implemented:

Trap EL0 Access to the SCXTNUM_EL0 register, when EL0 is using AArch64.

TSCXT	Meaning
0b0	EL0 access to SCXTNUM_EL0 is not disabled by this mechanism.
0b1	EL0 access to SCXTNUM_EL0 is disabled, causing an exception to EL1, or to EL2 whenHCR_EL2.TGE is 1. The value of SCXTNUM_EL0 is treated as 0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES1.

WXN, bit [19]

Write permission implies XN (Execute-never). For the EL1&0 translation regime, this bit can restrict execute permissions on writeable pages.

WXN	Meaning
0b0	This control has no effect on memory access permissions.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

0b1	In the EL1&0 translation regime, any region of memory that is writeable at EL1 is XN at EL1, and any region of memory that is writeable at EL0 is XN at EL0.

This bit applies only when SCTLR_EL1.M bit is set.

The WXN bit is permitted to be cached in a TLB.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

nTWE, bit [18]

Traps EL0 execution of WFE instructions to EL1, or to EL2 when HCR_EL2.TGE is 1, from both Execution states, reported using EC syndrome value 0x01.

nTWE	Meaning
0b0	Any attempt to execute a WFE instruction at EL0 is trapped, if the instruction would otherwise have caused the PE to enter a low-power state.
0b1	This control does not cause any instructions to be trapped.

Note

Since a WFE or WFI can complete at any time, even without a Wakeup event, the traps on WFE of WFI are not guaranteed to be taken, even if the WFE or WFI is executed when there is no Wakeup event. The only guarantee is that if the instruction does not complete in finite time in the absence of a Wakeup event, the trap will be taken.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

BR, bit [17]

When VTCR_EL2.MSA == '0':

Background region enable for EL1 MPU memory regions.

BR	Meaning
0b0	Background region disabled for stage 1 EL1&0 translation regime.
0b1	Background region enabled for stage 1 EL1&0 translation regime.

If the value of HCR_EL2.{DC, TGE} is not {0, 0}, then PE behaves as if the value of the SCTLR_EL1.BR field is 0 for all purposes other than returning the value of a direct read of the field.

If EL1 MPU is enabled, then EL0 access that does not match an EL1 MPU region always results in a Translation fault.

The reset behavior of this field is:

- On a Warm reset, this field resets to '0'.

Otherwise:

Reserved, RES0.

nTWI, bit [16]

Traps EL0 execution of WFI instructions to EL1, or to EL2 when HCR_EL2.TGE is 1, from both Execution states, reported using EC syndrome value 0x01.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

nTWI	Meaning
0b0	Any attempt to execute a WFI instruction at EL0 is trapped, if the instruction would otherwise have caused the PE to enter a low-power state.
0b1	This control does not cause any instructions to be trapped.

Note

Since a WFE or WFI can complete at any time, even without a Wakeup event, the traps on WFE of WFI are not guaranteed to be taken, even if the WFE or WFI is executed when there is no Wakeup event. The only guarantee is that if the instruction does not complete in finite time in the absence of a Wakeup event, the trap will be taken.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

UCT, bit [15]

Traps EL0 accesses to the CTR_EL0 to EL1, or to EL2 when HCR_EL2.TGE is 1, from AArch64 state only, reported using EC syndrome value 0x18.

UCT	Meaning
0b0	Accesses to the CTR_EL0 from EL0 using AArch64 are trapped.
0b1	This control does not cause any instructions to be trapped.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

DZE, bit [14]

Traps EL0 execution of DC ZVA instructions to EL1, or to EL2 when HCR_EL2.TGE is 1, from AArch64 state only, reported using EC syndrome value 0x18.

DZE	Meaning
0b0	Any attempt to execute an instruction that this trap applies to at EL0 using AArch64 is trapped. Reading DCZID_EL0.DZP from EL0 returns 1, indicating that the instructions this trap applies to are not supported.
0b1	This control does not cause any instructions to be trapped.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

EnDB, bit [13]

When FEAT_PAuth is implemented:

Controls enabling of pointer authentication of data addresses, using the APDBKey_EL1 key, at EL1 and at EL0 in the EL1&0 translation regime.

EnDB	Meaning
0b0	Pointer authentication of data addresses at EL1 and at EL0 in the EL1&0 translation regime, using the APDBKey_EL1 key, is not enabled.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

EnDB	Meaning
0b1	Pointer authentication of data addresses at EL1 and at EL0 in the EL1&0 translation regime, using the APDBKey_EL1 key, is enabled.

Note

This field controls the behavior of the AddPACDB and AuthDB pseudocode functions. When pointer authentication is enabled, AddPACDB returns a copy of a pointer to which a pointer authentication code has been added, and AuthDB returns an authenticated copy of a pointer. When pointer authentication is disabled, both of these functions are NOP.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

I, bit [12]

Stage 1 instruction access Cacheability control, for accesses at EL0 and EL1:

I	Meaning
0b0	All instruction access to Stage 1 Normal memory from EL0 and EL1 are Stage 1 Non-cacheable. If stage 1 EL1&0 translation is in VMSAv8-64 context and the value of SCTLR_EL1.M is 0, then instruction accesses from stage 1 are to Normal, Outer Shareable, Inner Non-cacheable, Outer Non-cacheable memory. If stage 1 EL1&0 translation is in PMSAv8-64 context and the value of SCTLR_EL1.{BR, M} = {0, 0}, then instruction accesses from stage 1 are to Normal, Outer Shareable, Inner Non-cacheable, Outer Non-cacheable memory.
0b1	This control has no effect on the Stage 1 Cacheability of instruction access to Stage 1 Normal memory from EL0 and EL1. If stage 1 EL1&0 translation is in VMSAv8-64 context and the value of SCTLR_EL1.M is 0, then instruction accesses from stage 1 are to Normal, Outer Shareable, Inner Write-Through, Outer Write-Through memory. If stage 1 EL1&0 translation is in PMSAv8-64 context, and the value of SCTLR_EL1.{BR, M} = {0, 0}, then instruction accesses from stage 1 are to Normal, Outer Shareable, Inner Write-Through, Outer Write-Through memory.

When the value of the HCR_EL2.DC bit is 1, then instruction access to Normal memory from EL0 and EL1 are Cacheable regardless of the value of the SCTLR_EL1.I bit.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [11]

Reserved, RES1.

EnRCTX, bit [10]

When FEAT_SPECRES is implemented:

Enable EL0 access to the following System instructions:

- CFP RCTX, DVP RCTX and CPP RCTX instructions.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

EnRCTX	Meaning
0b0	EL0 access to these instructions is disabled, and these instructions are trapped to EL1, or to EL2 when it is implemented and enabled for the current Security state and HCR_EL2.TGE is 1.
0b1	EL0 access to these instructions is enabled.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

UMA, bit [9]

User Mask Access. Traps EL0 execution of MSR and MRS instructions that access the PSTATE.{D, A, I, F} masks to EL1, or to EL2 when HCR_EL2.TGE is 1, from AArch64 state only, reported using EC syndrome value 0x18.

UMA	Meaning
0b0	Any attempt at EL0 using AArch64 to execute an MRS, MSR(register), or MSR(immediate) instruction that accesses the DAIF is trapped.
0b1	This control does not cause any instructions to be trapped.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [8:7]

Reserved, RES1.

nAA, bit [6]

When FEAT_LSE2 is implemented:

Non-aligned access. This bit controls generation of Alignment faults at EL1 and EL0 under certain conditions.

The following instructions generate an Alignment fault if all bytes being accessed are not within a single naturally aligned 16-byte quantity, for access:

- LDAPR, LDAPRH, LDAPUR, LDAPURH, LDAPURSH, LDAPURSW, LDAR, LDARH, LDLAR, LDLARH.
- STLLR, STLLRH, STLR, STLRH, STLUR, and STLURH.

nAA	Meaning
0b0	Unaligned accesses by the specified instructions generate an Alignment fault.
0b1	This control does not generate Alignment faults.

For a load-acquire instruction that does not have acquire semantics as the result of the destination register, or registers, being ZR, it is IMPLEMENTATION SPECIFIC whether this field behaves as 1 or the programmed value.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Otherwise:

Reserved, RES0.

Bit [5]

Reserved, RES0.

SA0, bit [4]

SP Alignment check enable for EL0. When set to 1, if a load or store instruction executed at EL0 uses the SP as the base address and the SP is not aligned to a 16-byte boundary, then an SP alignment fault exception is generated. For more information, see 'SP alignment checking'.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

SA, bit [3]

SP Alignment check enable. When set to 1, if a load or store instruction executed at EL1 uses the SP as the base address and the SP is not aligned to a 16-byte boundary, then an SP alignment fault exception is generated. For more information, see 'SP alignment checking'.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

C, bit [2]

Stage 1 Cacheability control, for data accesses.

C	Meaning
0b0	All data access to Stage 1 Normal memory from EL0 and EL1, and all Normal memory accesses from unified cache to the EL1&0 Stage 1 translation tables, are treated as Stage 1 Non-cacheable.
0b1	This control has no effect on the Stage 1 Cacheability of: • Data access to Normal memory from EL0 and EL1. • Normal memory accesses to the EL1&0 Stage 1 translation tables.

When the Effective value of the HCR_EL2.DC bit in the current Security state is 1, the PE ignores SCTLR_EL1.C. This means that EL0 and EL1 data accesses to Normal memory are Cacheable.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

A, bit [1]

Alignment check enable. This is the enable bit for Alignment fault checking at EL1 and EL0.

A	Meaning
0b0	Alignment fault checking is disabled when executing at EL1 or EL0. Alignment checks on some instructions are not disabled by this control. For more information, see 'Alignment of data accesses'.
0b1	Alignment fault checking is enabled when executing at EL1 or EL0. All instructions that load or store one or more registers have an alignment check that the address being accessed is aligned to the size of the data element(s) being accessed. If this check fails it causes an Alignment fault, which is taken as a Data Abort exception.

The reset behavior of this field is:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

M, bit [0]

MMU or MPU enable for EL1&0 stage 1 address translation.

This is the enable bit for:

- MPU, if stage 1 EL1&0 translation is in PMSAv8-64 context.
- MMU, if stage 1 EL1&0 translation is in VMSAv8-64 context.

M	Meaning
0b0	EL1 MPU(PMSAv8-64) or MMU(VMSAv8-64) disabled See the SCTLR_EL1.I field for the behavior of instruction accesses to Normal memory.
0b1	EL1 MPU(PMSAv8-64) or MMU(VMSAv8-64) enabled

If the Effective value of HCR_EL2.{DC, TGE} in the current Security state is not {0, 0}, then the PE behaves as if the value of the SCTLR_EL1.M field is 0 for all purposes other than returning the value of a direct read of the field.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing SCTLR_EL1

Accesses to this register use the following encodings in the System register encoding space:

`MRS <Xt>, SCTLR_EL1`

op0	op1	CRn	CRm	op2
0b11	0b000	0b0001	0b0000	0b000

```
if PSTATE.EL == EL0 then
    UNDEFINED;
elsif PSTATE.EL == EL1 then
    if HCR_EL2.TRVM == '1' then
        AArch64.SystemAccessTrap(EL2, 0x18);
    else
        X[t, 64] = SCTLR_EL1;
elsif PSTATE.EL == EL2 then
    X[t, 64] = SCTLR_EL1;
```

`MSR SCTLR_EL1, <Xt>`

op0	op1	CRn	CRm	op2
0b11	0b000	0b0001	0b0000	0b000

```
if PSTATE.EL == EL0 then
    UNDEFINED;
elsif PSTATE.EL == EL1 then
    if HCR_EL2.TVM == '1' then
        AArch64.SystemAccessTrap(EL2, 0x18);
    else
        SCTLR_EL1 = X[t, 64];
elsif PSTATE.EL == EL2 then
    SCTLR_EL1 = X[t, 64];
```

D12.2.87 SCTLR_EL2, System Control Register (EL2)

The SCTLR_EL2 characteristics are:

Purpose

Provides top-level control of the system, including its memory system, at EL2.

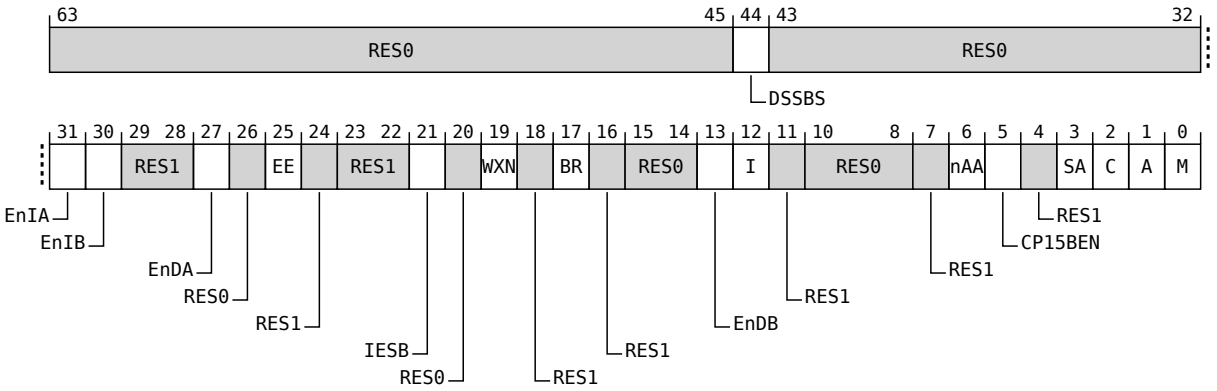
Configuration

There are no configuration notes.

Attributes

SCTLR_EL2 is a 64-bit register.

Field descriptions



Bits [63:45]

Reserved, RES0.

DSSBS, bit [44]

When FEAT_SSBS is implemented:

Default PSTATE.SSBS value on exception entry.

DSSBS	Meaning
0b0	PSTATE.SSBS is set to 0 on an exception to EL2.
0b1	PSTATE.SSBS is set to 1 on an exception to EL2.

The reset behavior of this field is:

- On a Warm reset, this field resets to an IMPLEMENTATION DEFINED value.

Otherwise:

Reserved, RES0.

Bits [43:32]

Reserved, RES0.

EnIA, bit [31]

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

When FEAT_PAuth is implemented:

Controls enabling of pointer authentication of instruction addresses, using the APIAKey_EL1 key, at EL2 and at EL0 in the EL2&0 translation regime.

EnIA	Meaning
0b0	Pointer authentication of instruction addresses at EL2 and at EL0 in the EL2&0 translation regime, using the APIAKey_EL1 key, is not enabled.
0b1	Pointer authentication of instruction addresses at EL2 and at EL0 in the EL2&0 translation regime, using the APIAKey_EL1 key, is enabled.

Note

This field controls the behavior of the AddPACIA and AuthIA pseudocode functions. When pointer authentication is enabled, AddPACIA returns a copy of a pointer to which a pointer authentication code has been added, and AuthIA returns an authenticated copy of a pointer. When pointer authentication is disabled, both of these functions are NOP.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

EnIB, bit [30]

When FEAT_PAuth is implemented:

Controls enabling of pointer authentication of instruction addresses, using the APIBKey_EL1 key, at EL2 and at EL0 in the EL2&0 translation regime.

EnIB	Meaning
0b0	Pointer authentication of instruction addresses at EL2 and at EL0 in the EL2&0 translation regime, using the APIBKey_EL1 key, is not enabled.
0b1	Pointer authentication of instruction addresses at EL2 and at EL0 in the EL2&0 translation regime, using the APIBKey_EL1 key, is enabled.

Note

This field controls the behavior of the AddPACIB and AuthIB pseudocode functions. When pointer authentication is enabled, AddPACIB returns a copy of a pointer to which a pointer authentication code has been added, and AuthIB returns an authenticated copy of a pointer. When pointer authentication is disabled, both of these functions are NOP.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bits [29:28]

Reserved, RES1.

EnDA, bit [27]

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

When FEAT_PAuth is implemented:

Controls enabling of pointer authentication of data addresses, using the APDAKey_EL1 key, at EL2 and at EL0 in the EL2&0 translation regime.

EnDA	Meaning
0b0	Pointer authentication of data addresses at EL2 and at EL0 in the EL2&0 translation regime, using the APDAKey_EL1 key, is not enabled.
0b1	Pointer authentication of data addresses at EL2 and at EL0 in the EL2&0 translation regime, using the APDAKey_EL1 key, is enabled.

Note

This field controls the behavior of the AddPACDA and AuthDA pseudocode functions. When pointer authentication is enabled, AddPACDA returns a copy of a pointer to which a pointer authentication code has been added, and AuthDA returns an authenticated copy of a pointer. When pointer authentication is disabled, both of these functions are NOP.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bit [26]

Reserved, RES0.

EE, bit [25]

When FEAT_MixedEnd is implemented:

Endianness of data accesses at EL2.

EE	Meaning
0b0	Explicit data accesses at EL2 are little-endian.
0b1	Explicit data accesses at EL2 are big-endian.

The EE bit is permitted to be cached in a TLB.

The reset behavior of this field is:

- On a Warm reset, this field resets to an IMPLEMENTATION DEFINED value.

When FEAT_BigEnd is implemented:

Explicit data accesses at EL1, and stage 1 translation table walks in the EL1&0 translation regime are big-endian.

Reserved, RES1.

Otherwise:

Explicit data accesses at EL1, and stage 1 translation table walks in the EL1&0 translation regime are little-endian.

Reserved, RES0.

Bit [24]

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

When FEAT_BigEndEL0 is implemented:

Bit [24]

Explicit data accesses at EL0 are big-endian.

Reserved, RES1.

Otherwise:

Bit [24]

Explicit data accesses at EL0 are little-endian.

Reserved, RES0.

Bits [23:22]

Reserved, RES1.

IESB, bit [21]

When FEAT_IESB is implemented:

Implicit Error Synchronization event enable.

IESB	Meaning
0b0	Disabled.
0b1	An implicit error synchronization event is added: • At each exception taken to EL2. • Before the operational pseudocode of each Exception Return instruction executed at EL2.

When the PE is in Debug state, the effect of this field is CONSTRAINED UNPREDICTABLE, and its Effective value might be 0 or 1 regardless of the value of the field. If the Effective value of the field is 1, then an implicit error synchronization event is added after each DCPSx instruction taken to EL2 and before each DRPS instruction executed at EL2, in addition to the other cases where it is added.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bit [20]

Reserved, RES0.

WXN, bit [19]

Write permission implies XN (Execute-never). For the EL2 or EL2&0 translation regime, this bit can restrict execute permissions on writeable pages.

WXN	Meaning
0b0	This control has no effect on memory access permissions.
0b1	In the EL2 or EL2&0 translation regime, any region of memory that is writeable at EL2 is XN at EL2. In the EL2&0 translation regime, any region of memory that is writeable at EL0 is XN at EL0.

This bit applies only when SCTLR_EL2.M bit is set.

The WXN bit is permitted to be cached in a TLB.

The reset behavior of this field is:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [18]

Reserved, RES1.

BR, bit [17]

Background region enable for EL2 MPU memory regions.

BR	Meaning
0b0	Background region disabled for stage 1 EL2 translation regime and stage 2 EL1&0 translation regime.
0b1	Background region enabled for stage 1 EL2 translation regime and stage 2 EL1&0 translation regime.

If EL2 MPU is enabled, then EL0 and EL1 access that does not match an EL2 MPU region always results in a Translation fault.

The reset behavior of this field is:

- On a Warm reset, this field resets to '0'.

Bit [16]

Reserved, RES1.

Bits [15:14]

Reserved, RES0.

EnDB, bit [13]

When FEAT_PAuth is implemented:

Controls enabling of pointer authentication of data addresses, using the APDBKey_EL1 key, at EL2 and at EL0 in the EL2&0 translation regime.

EnDB	Meaning
0b0	Pointer authentication of data addresses at EL2 and at EL0 in the EL2&0 translation regime, using the APDBKey_EL1 key, is not enabled.
0b1	Pointer authentication of data addresses at EL2 and at EL0 in the EL2&0 translation regime, using the APDBKey_EL1 key, is enabled.

Note

This field controls the behavior of the AddPACDB and AuthDB pseudocode functions. When pointer authentication is enabled, AddPACDB returns a copy of a pointer to which a pointer authentication code has been added, and AuthDB returns an authenticated copy of a pointer. When pointer authentication is disabled, both of these functions are NOP.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

I, bit [12]

Instruction access Cacheability control, for accesses at EL2.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I	Meaning
0b0	All instruction accesses to Normal memory from EL2 are Non-cacheable for all levels of instruction and unified cache. If SCTLR_EL2.{BR, M} == {0, 0}, then instruction accesses from stage 1 of the EL2 translation regime are to Normal, Outer Shareable, Inner Non-cacheable, Outer Non-cacheable memory.
0b1	This control has no effect on the Cacheability of instruction access to Normal memory from EL2. If SCTLR_EL2.{BR, M} = {0, 0}, then instruction accesses from stage 1 of the EL2 translation regime are to Normal, Outer Shareable, Inner Write-Through, Outer Write-Through memory.

This bit has no effect on the EL1&0 translation regime.

The reset behavior of this field is:

- On a Warm reset, this field resets to '0'.

Bit [11]

Reserved, RES1.

Bits [10:8]

Reserved, RES0.

Bit [7]

Reserved, RES1.

nAA, bit [6]

When FEAT_LSE2 is implemented:

Non-aligned access. This bit controls generation of Alignment faults under certain conditions at EL2.

The following instructions generate an Alignment fault if all bytes being accessed are not within a single naturally aligned 16-byte quantity, for access:

- LDAPR, LDAPRH, LDAPUR, LDAPURH, LDAPURSH, LDAPURSW, LDAR, LDARH, LDLAR, LDLARH.
- STLLR, STLLRH, STLR, STLRH, STLUR, and STLURH.

nAA	Meaning
0b0	Unaligned accesses by the specified instructions generate an Alignment fault.
0b1	Unaligned accesses by the specified instructions do not generate an Alignment fault.

For a load-acquire instruction that does not have acquire semantics as the result of the destination register, or registers, being ZR, it is IMPLEMENTATION SPECIFIC whether this field behaves as 1 or the programmed value.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

CP15BEN, bit [5]

Access to this field is RES0.

Bit [4]

Reserved, RES1.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

SA, bit [3]

SP Alignment check enable. When set to 1, if a load or store instruction executed at EL2 uses the SP as the base address and the SP is not aligned to a 16-byte boundary, then an SP alignment fault exception is generated. For more information, see 'SP alignment checking'.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

C, bit [2]

Data access Cacheability control, for accesses at EL2.

C	Meaning
0b0	All data accesses to Normal memory from EL2 are Non-cacheable for all levels of data and unified cache.
0b1	This control has no effect on the Cacheability of data accesses to Normal memory from EL2.

This bit has no effect on the EL1&0 translation regime.

The reset behavior of this field is:

- On a Warm reset, this field resets to '0'.

A, bit [1]

Alignment check enable. This is the enable bit for Alignment fault checking at EL2.

A	Meaning
0b0	Alignment fault checking is disabled when executing at EL2. Alignment checks on some instructions are not disabled by this control. For more information, see 'Alignment of data accesses'.
0b1	Alignment fault checking is enabled when executing at EL2. All instructions that load or store one or more registers have an alignment check that the address being accessed is aligned to the size of the data element(s) being accessed. If this check fails it causes an Alignment fault, which is taken as a Data Abort exception.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

M, bit [0]

MPU enable for EL2 stage 1 and EL1&0 stage 2 address translation.

M	Meaning
0b0	MPU disabled for EL2 and EL1&0 stage 2 address translation. See the SCTLR_EL2.I field for the behavior of instruction accesses to Normal memory.
0b1	MPU enabled for EL2 and EL1&0 stage 2 address translation.

The reset behavior of this field is:

- On a Warm reset, this field resets to '0'.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Accessing SCTLR_EL2

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, SCTLR_EL2

op0	op1	CRn	CRm	op2
0b11	0b100	0b0001	0b0000	0b000

D12.2.88 SCXTNUM_EL0, EL0 Read/Write Software Context Number

The SCXTNUM_EL0 characteristics are:

Purpose

Provides a number that can be used to separate out different context numbers with the EL0 exception level, for the purpose of protecting against side-channels using branch prediction and similar resources.

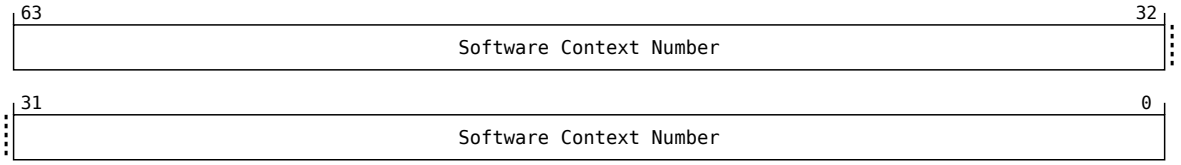
Configuration

This register is present only when FEAT_CSV2_2 is implemented or FEAT_CSV2_1p2 is implemented. Otherwise, direct accesses to SCXTNUM_EL0 are UNDEFINED.

Attributes

SCXTNUM_EL0 is a 64-bit register.

Field descriptions



SCXTNUM, bits [63:0]

Software Context Number. A number to identify the context within the EL0 exception level.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing SCXTNUM_EL0

Accesses to this register use the following encodings in the System register encoding space:

`MRS <Xt>, SCXTNUM_EL0`

op0	op1	CRn	CRm	op2
0b11	0b011	0b1101	0b0000	0b111

D12.2.89 SCXTNUM_EL1, EL1 Read/Write Software Context Number

The SCXTNUM_EL1 characteristics are:

Purpose

Provides a number that can be used to separate out different context numbers with the EL1 exception level, for the purpose of protecting against side-channels using branch prediction and similar resources.

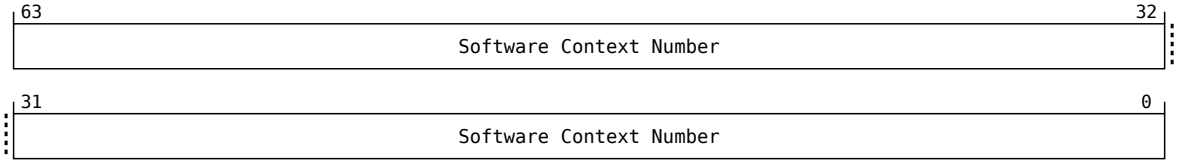
Configuration

This register is present only when FEAT_CSV2_2 is implemented or FEAT_CSV2_1p2 is implemented. Otherwise, direct accesses to SCXTNUM_EL1 are UNDEFINED.

Attributes

SCXTNUM_EL1 is a 64-bit register.

Field descriptions



SCXTNUM, bits [63:0]

Software Context Number. A number to identify the context within the EL1 exception level.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing SCXTNUM_EL1

Accesses to this register use the following encodings in the System register encoding space:

`MRS <Xt>, SCXTNUM_EL1`

D12.2.90 SCXTNUM_EL2, EL2 Read/Write Software Context Number

The SCXTNUM_EL2 characteristics are:

Purpose

Provides a number that can be used to separate out different context numbers with the EL2 exception level, for the purpose of protecting against side-channels using branch prediction and similar resources.

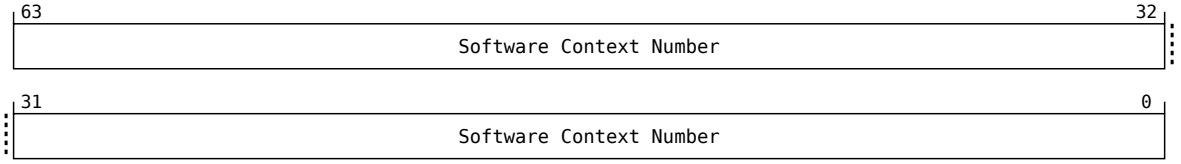
Configuration

This register is present only when FEAT_CSV2_2 is implemented or FEAT_CSV2_1p2 is implemented. Otherwise, direct accesses to SCXTNUM_EL2 are UNDEFINED.

Attributes

SCXTNUM_EL2 is a 64-bit register.

Field descriptions



SCXTNUM, bits [63:0]

Software Context Number. A number to identify the context within the EL2 exception level.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing SCXTNUM_EL2

Accesses to this register use the following encodings in the System register encoding space:

`MRS <Xt>, SCXTNUM_EL2`

op0	op1	CRn	CRm	op2
0b11	0b100	0b1101	0b0000	0b111

```
if !(IsFeatureImplemented(FEAT_CSV2_2) || IsFeatureImplemented(FEAT_CSV2_1p2)) then
    UNDEFINED;
elsif PSTATE.EL == EL0 then
    UNDEFINED;
elsif PSTATE.EL == EL1 then
    UNDEFINED;
elsif PSTATE.EL == EL2 then
    X[t, 64] = SCXTNUM_EL2;
```

`MSR SCXTNUM_EL2, <Xt>`

op0	op1	CRn	CRm	op2
0b11	0b100	0b1101	0b0000	0b111

D12.2.91 TCR_EL1, Translation Control Register (EL1)

The TCR_EL1 characteristics are:

Purpose

The control register for stage 1 of the EL1&0 translation regime.

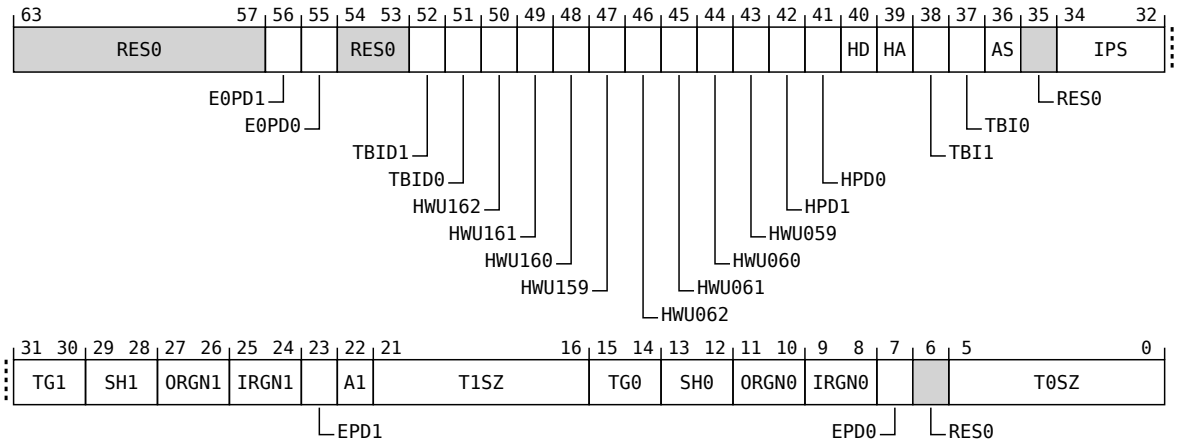
Configuration

There are no configuration notes.

Attributes

TCR_EL1 is a 64-bit register.

Field descriptions



Any of the bits in TCR_EL1, other than the EPDx bits when they have the value 1, and the A1 bit are permitted to be cached in a TLB.

Bits [63:57]

Reserved, RES0.

E0PD1, bit [56]

When VTCR_EL2.MSA == '1' and FEAT_E0PD is implemented:

Faulting control for unprivileged access to any address translated by TTBR1_EL1.

E0PD1	Meaning
0b0	Unprivileged access to any address translated by TTBR1_EL1 will not generate a fault by this mechanism.
0b1	Unprivileged access to any address translated by TTBR1_EL1 will generate a level 0 Translation fault.

Level 0 Translation faults generated as a result of this field are not counted as TLB misses for performance monitoring. The fault should take the same time to generate, whether the address is present in the TLB or not, to mitigate attacks that use fault timing.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Otherwise:

Reserved, RES0.

E0PD0, bit [55]

When VTCR_EL2.MSA == '1' and FEAT_E0PD is implemented:

Faulting control for unprivileged access to any address translated by TTBR0_EL1.

E0PD0	Meaning
0b0	Unprivileged access to any address translated by TTBR0_EL1 will not generate a fault by this mechanism.
0b1	Unprivileged access to any address translated by TTBR0_EL1 will generate a level 0 Translation fault.

Level 0 Translation faults generated as a result of this field are not counted as TLB misses for performance monitoring. The fault should take the same time to generate, whether the address is present in the TLB or not, to mitigate attacks that use fault timing.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bits [54:53]

Reserved, RES0.

TBID1, bit [52]

When VTCR_EL2.MSA == '1' and FEAT_PAuth is implemented:

Controls the use of the top byte of instruction addresses for address matching.

For the purpose of this field, all cache maintenance and address translation instructions that perform address translation are treated as data accesses.

For more information, see 'Address tagging'.

TBID1	Meaning
0b0	TCR_EL1.TBI1 applies to Instruction and Data accesses.
0b1	TCR_EL1.TBI1 applies to Data accesses only.

This affects addresses where the address would be translated by tables pointed to by TTBR1_EL1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

TBID0, bit [51]

When VTCR_EL2.MSA == '1' and FEAT_PAuth is implemented:

Controls the use of the top byte of instruction addresses for address matching.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

For the purpose of this field, all cache maintenance and address translation instructions that perform address translation are treated as data accesses.

For more information, see 'Address tagging'.

TBID0	Meaning
0b0	TCR_EL1.TBI0 applies to Instruction and Data accesses.
0b1	TCR_EL1.TBI0 applies to Data accesses only.

This affects addresses where the address would be translated by tables pointed to by TTBR0_EL1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

When FEAT_PAuth is implemented and VTCR_EL2.MSA == '0':

Controls the use of the top byte of instruction addresses for address matching.

For the purpose of this field, all cache maintenance and address translation instructions that perform address translation are treated as data accesses.

For more information, see 'Address tagging'.

TBID0	Meaning
0b0	TCR_EL1.TBI0 applies to Instruction and Data accesses.
0b1	TCR_EL1.TBI0 applies to Data accesses only.

This affects addresses where the address would be translated by EL1 MPU.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

HWU162, bit [50]

When VTCR_EL2.MSA == '1' and FEAT_HPDS2 is implemented:

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[62] of the stage 1 translation table Block or Page entry for translations using TTBR1_EL1.

HWU162	Meaning
0b0	For translations using TTBR1_EL1, bit[62] of each stage 1 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.
0b1	For translations using TTBR1_EL1, bit[62] of each stage 1 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose if the value of TCR_EL1.HPD1 is 1.

The Effective value of this field is 0 if the value of TCR_EL1.HPD1 is 0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

HWU161, bit [49]

When VTCR_EL2.MSA == '1' and FEAT_HPDS2 is implemented:

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[61] of the stage 1 translation table Block or Page entry for translations using TTBR1_EL1.

HWU161	Meaning
0b0	For translations using TTBR1_EL1, bit[61] of each stage 1 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.
0b1	For translations using TTBR1_EL1, bit[61] of each stage 1 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose if the value of TCR_EL1.HPD1 is 1.

The Effective value of this field is 0 if the value of TCR_EL1.HPD1 is 0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

HWU160, bit [48]

When VTCR_EL2.MSA == '1' and FEAT_HPDS2 is implemented:

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[60] of the stage 1 translation table Block or Page entry for translations using TTBR1_EL1.

HWU160	Meaning
0b0	For translations using TTBR1_EL1, bit[60] of each stage 1 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.
0b1	For translations using TTBR1_EL1, bit[60] of each stage 1 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose if the value of TCR_EL1.HPD1 is 1.

The Effective value of this field is 0 if the value of TCR_EL1.HPD1 is 0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

HWU159, bit [47]

When VTCR_EL2.MSA == '1' and FEAT_HPDS2 is implemented:

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[59] of the stage 1 translation table Block or Page entry for translations using TTBR1_EL1.

HWU159	Meaning
0b0	For translations using TTBR1_EL1, bit[59] of each stage 1 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

HWU159	Meaning
0b1	For translations using TTBR1_EL1, bit[59] of each stage 1 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose if the value of TCR_EL1.HPD1 is 1.

The Effective value of this field is 0 if the value of TCR_EL1.HPD1 is 0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

HWU062, bit [46]

When VTCR_EL2.MSA == '1' and FEAT_HPDS2 is implemented:

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[62] of the stage 1 translation table Block or Page entry for translations using TTBR0_EL1.

HWU062	Meaning
0b0	For translations using TTBR0_EL1, bit[62] of each stage 1 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.
0b1	For translations using TTBR0_EL1, bit[62] of each stage 1 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose if the value of TCR_EL1.HPD0 is 1.

The Effective value of this field is 0 if the value of TCR_EL1.HPD0 is 0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

HWU061, bit [45]

When VTCR_EL2.MSA == '1' and FEAT_HPDS2 is implemented:

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[61] of the stage 1 translation table Block or Page entry for translations using TTBR0_EL1.

HWU061	Meaning
0b0	For translations using TTBR0_EL1, bit[61] of each stage 1 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.
0b1	For translations using TTBR0_EL1, bit[61] of each stage 1 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose if the value of TCR_EL1.HPD0 is 1.

The Effective value of this field is 0 if the value of TCR_EL1.HPD0 is 0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Otherwise:

Reserved, RES0.

HWU060, bit [44]

When VTCR_EL2.MSA == '1' and FEAT_HPDS2 is implemented:

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[60] of the stage 1 translation table Block or Page entry for translations using TTBR0_EL1.

HWU060	Meaning
0b0	For translations using TTBR0_EL1, bit[60] of each stage 1 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.
0b1	For translations using TTBR0_EL1, bit[60] of each stage 1 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose if the value of TCR_EL1.HPD0 is 1.

The Effective value of this field is 0 if the value of TCR_EL1.HPD0 is 0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

HWU059, bit [43]

When VTCR_EL2.MSA == '1' and FEAT_HPDS2 is implemented:

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[59] of the stage 1 translation table Block or Page entry for translations using TTBR0_EL1.

HWU059	Meaning
0b0	For translations using TTBR0_EL1, bit[59] of each stage 1 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.
0b1	For translations using TTBR0_EL1, bit[59] of each stage 1 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose if the value of TCR_EL1.HPD0 is 1.

The Effective value of this field is 0 if the value of TCR_EL1.HPD0 is 0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

HPD1, bit [42]

When VTCR_EL2.MSA == '1' and FEAT_HPDS is implemented:

Hierarchical Permission Disables. This affects the hierarchical control bits, APTable, PXNTable, and UXNTable, except NSTable, in the translation tables pointed to by TTBR1_EL1.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

HPD1	Meaning
0b0	Hierarchical permissions are enabled.
0b1	Hierarchical permissions are disabled.

When disabled, the permissions are treated as if the bits are zero.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

HPD0, bit [41]

When VTCR_EL2.MSA == '1' and FEAT_HPDS is implemented:

Hierarchical Permission Disables. This affects the hierarchical control bits, APTable, PXNTable, and UXNTable, except NSTable, in the translation tables pointed to by TTBR0_EL1.

HPD0	Meaning
0b0	Hierarchical permissions are enabled.
0b1	Hierarchical permissions are disabled.

When disabled, the permissions are treated as if the bits are zero.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

HD, bit [40]

When VTCR_EL2.MSA == '1' and FEAT_HAFDBS is implemented:

Hardware management of dirty state in stage 1 translations from EL0 and EL1.

HD	Meaning
0b0	Stage 1 hardware management of dirty state disabled.
0b1	Stage 1 hardware management of dirty state enabled.

When the Effective value of TCR_EL1.HA is 0, this field behaves as 0 for all purposes other than a direct read of the value of this field.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

HA, bit [39]

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

When VTCR_EL2.MSA == '1' and FEAT_HAFDBS is implemented:

Hardware Access flag update in stage 1 translations from EL0 and EL1.

HA	Meaning
0b0	Stage 1 Access flag update disabled.
0b1	Stage 1 Access flag update enabled.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

When VTCR_EL2.MSA == '0':

Reserved, RES0.

Otherwise:

Reserved, RES0.

TBI1, bit [38]

When VTCR_EL2.MSA == '1':

Top Byte ignored. Indicates whether the top byte of an address is used for address match for the TTBR1_EL1 region, or ignored and used for tagged addresses.

TBI1	Meaning
0b0	Top Byte used in the address calculation.
0b1	Top Byte ignored in the address calculation.

This affects addresses generated in EL0 and EL1 using AArch64 where the address would be translated by tables pointed to by TTBR1_EL1. It has an effect whether the EL1&0 translation regime is enabled or not.

If FEAT_PAuth is implemented and TCR_EL1.TBID1 is 1, then this field only applies to Data accesses.

Otherwise, if the value of TBI1 is 1 and bit [55] of the target address to be stored to the PC is 1, then bits[63:56] of that target address are also set to 1 before the address is stored in the PC, in the following cases:

- A branch or procedure return within EL0 or EL1.
- An exception taken to EL1.
- An exception return to EL0 or EL1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

When VTCR_EL2.MSA == '0':

Reserved, RES0.

Otherwise:

Reserved, RES0.

TBI0, bit [37]

When VTCR_EL2.MSA == '1':

Top Byte ignored. Indicates whether the top byte of an address is used for address match for the TTBR0_EL1 region, or ignored and used for tagged addresses.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

TBI0	Meaning
0b0	Top Byte used in the address calculation.
0b1	Top Byte ignored in the address calculation.

This affects addresses generated in EL0 and EL1 using AArch64 where the address would be translated by tables pointed to by TTBR0_EL1. It has an effect whether the EL1&0 translation regime is enabled or not.

If FEAT_PAuth is implemented and TCR_EL1.TBID0 is 1, then this field only applies to Data accesses.

Otherwise, if the value of TBI0 is 1 and bit [55] of the target address to be stored to the PC is 0, then bits[63:56] of that target address are also set to 0 before the address is stored in the PC, in the following cases:

- A branch or procedure return within EL0 or EL1.
- An exception taken to EL1.
- An exception return to EL0 or EL1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

When VTCR_EL2.MSA == '0':

Top Byte ignored. Indicates whether the top byte of an address is used for an address match for the EL1 MPU regions, or ignored and used for tagged addresses.

TBI0	Meaning
0b0	Top Byte used in the address calculation.
0b1	Top Byte ignored in the address calculation.

This affects addresses generated in EL0 and EL1, where the address would be translated by the EL1 MPU.

If FEAT_PAuth is implemented and TCR_EL1.TBID0 is 1, then this field only applies to Data accesses.

Otherwise, if the value of TBI0 is 1 and bit [55] of the target address to be stored to the PC is 0, then bits[63:56] of that target address are also set to 0 before the address is stored in the PC, in the following cases:

- A branch or procedure return within EL0 or EL1.
- An exception taken to EL1.
- An exception return to EL0 or EL1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

AS, bit [36]

When VTCR_EL2.MSA == '1':

ASID Size.

AS	Meaning
0b0	8 bit - the upper 8 bits of TTBR0_EL1 and TTBR1_EL1 are ignored by hardware for every purpose except reading back the register, and are treated as if they are all zeros for when used for allocation and matching entries in the TLB.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

AS	Meaning
0b1	16 bit - the upper 16 bits of TTBR0_EL1 and TTBR1_EL1 are used for allocation and matching in the TLB.

If the implementation has only 8 bits of ASID, this field is RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

When VTCR_EL2.MSA == '0':

ASID Size.

AS	Meaning
0b0	8 bit - the upper 8 bits of TTBR0_EL1 are ignored by hardware for every purpose except reading back the register, and are treated as if they are all zeros when used for address matching.
0b1	16 bit - the upper 16 bits of TTBR0_EL1 are used for address matching.

If the implementation has only 8 bits of ASID, this field is RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bit [35]

Reserved, RES0.

IPS, bits [34:32]

When VTCR_EL2.MSA == '1':

Intermediate Physical Address Size.

IPS	Meaning
0b000	32 bits, 4GB.
0b001	36 bits, 64GB.
0b010	40 bits, 1TB.
0b011	42 bits, 4TB.
0b100	44 bits, 16TB.
0b101	48 bits, 256TB.
0b110	52 bits, 4PB.
0b111	56 bits, 64PB.

All other values are reserved.

The reserved values behave in the same way as the 0b101 or 0b110 encoding, but software must not rely on this property as the behavior of the reserved values might change in a future revision of the architecture.

The values 0b110 and 0b111 represent different output address sizes depending on implementation choices and translation configuration.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The following table captures the output address size represented by the value 0b110:

Descriptor Format	ID_AA64MMFR0_EL1.PARange	Translation Granule	DS[1] | Represented OA size |
Any	0b0101	Any	Any	48 bits, 256TB
VMSAv8-64	0b011x	4KB or 16KB	0	48 bits, 256TB
VMSAv8-64	0b011x	4KB or 16KB	1	52 bits, 4PB
VMSAv8-64	0b011x	64KB	N/A	52 bits, 4PB
VMSAv9-128	0b011x	Any	N/A	52 bits, 4PB

[1] This column represents the value of TCR_EL1.DS.

The following table captures the output address size represented by the value 0b111:

Descriptor Format	ID_AA64MMFR0_EL1.PARange	Translation Granule	Represented OA size
Any	0b0110	Any	OA size represented by 0b110
VMSAv8-64	0b0111	Any	OA size represented by 0b110
VMSAv9-128	0b0111	Any	56 bits, 64PB

If 52-bit PA is supported, and the translation table descriptors cannot express an OA larger than 48-bits, then bits[51:48] of every translation table base address are treated as 0b0000 for the stage of translation controlled by TCR_EL1.

If 56-bit PA is supported, and the translation table descriptors cannot express an OA larger than 52-bits, then bits[55:52] of every translation table base address are treated as 0b0000 for the stage of translation controlled by TCR_EL1.

If the output address size represented by this field is larger than the supported PA size expressed in ID_AA64MMFR0_EL1.PARange, then the output address size is treated as being the same as the supported PA size. Arm strongly recommends that software avoids configuring this field to a value representing an output address size larger than the supported PA size.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

TG1, bits [31:30]

When VTCR_EL2.MSA == '1':

Granule size for the TTBR1_EL1.

TG1	Meaning
0b01	16KB.
0b10	4KB.
0b11	64KB.

Other values are reserved.

If the value is programmed to either a reserved value or a size that has not been implemented, then the hardware will treat the field as if it has been programmed to an IMPLEMENTATION DEFINED choice of the sizes that has been implemented for all purposes other than the value read back from this register.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

It is IMPLEMENTATION DEFINED whether the value read back is the value programmed or the value that corresponds to the size chosen.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

SH1, bits [29:28]

When VTCR_EL2.MSA == '1':

Shareability attribute for memory associated with translation table walks using TTBR1_EL1.

SH1	Meaning
0b00	Non-shareable.
0b10	Outer Shareable.
0b11	Inner Shareable.

Other values are reserved. The effect of programming this field to a Reserved value is that behavior is CONSTRAINED UNPREDICTABLE.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

ORGN1, bits [27:26]

When VTCR_EL2.MSA == '1':

Outer cacheability attribute for memory associated with translation table walks using TTBR1_EL1.

ORGN1	Meaning
0b00	Normal memory, Outer Non-cacheable.
0b01	Normal memory, Outer Write-Back Read-Allocate Write-Allocate Cacheable.
0b10	Normal memory, Outer Write-Through Read-Allocate No Write-Allocate Cacheable.
0b11	Normal memory, Outer Write-Back Read-Allocate No Write-Allocate Cacheable.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

IRGN1, bits [25:24]

When VTCR_EL2.MSA == '1':

Inner cacheability attribute for memory associated with translation table walks using TTBR1_EL1.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

IRGN1	Meaning
0b00	Normal memory, Inner Non-cacheable.
0b01	Normal memory, Inner Write-Back Read-Allocate Write-Allocate Cacheable.
0b10	Normal memory, Inner Write-Through Read-Allocate No Write-Allocate Cacheable.
0b11	Normal memory, Inner Write-Back Read-Allocate No Write-Allocate Cacheable.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

EPD1, bit [23]

When VTCR_EL2.MSA == '1':

Translation table walk disable for translations using TTBR1_EL1. This bit controls whether a translation table walk is performed on a TLB miss, for an address that is translated using TTBR1_EL1. The encoding of this bit is:

EPD1	Meaning
0b0	Perform translation table walks using TTBR1_EL1.
0b1	A TLB miss on an address that is translated using TTBR1_EL1 generates a Translation fault. No translation table walk is performed.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

A1, bit [22]

When VTCR_EL2.MSA == '1':

Selects whether TTBR0_EL1 or TTBR1_EL1 defines the ASID. The encoding of this bit is:

A1	Meaning
0b0	TTBR0_EL1.ASID defines the ASID.
0b1	TTBR1_EL1.ASID defines the ASID.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

T1SZ, bits [21:16]

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

When VTCR_EL2.MSA == '1':

The size offset of the memory region addressed by TTBR1_EL1. The region size is $2^{(64-T1SZ)}$ bytes.

The maximum and minimum possible values for T1SZ depend on the level of translation table and the memory translation granule size, as described in the AArch64 Virtual Memory System Architecture chapter.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

TG0, bits [15:14]

When VTCR_EL2.MSA == '1':

Granule size for the TTBR0_EL1.

TG0	Meaning
0b00	4KB
0b01	64KB
0b10	16KB

Other values are reserved.

If the value is programmed to either a reserved value or a size that has not been implemented, then the hardware will treat the field as if it has been programmed to an IMPLEMENTATION DEFINED choice of the sizes that has been implemented for all purposes other than the value read back from this register.

It is IMPLEMENTATION DEFINED whether the value read back is the value programmed or the value that corresponds to the size chosen.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

SH0, bits [13:12]

When VTCR_EL2.MSA == '1':

Shareability attribute for memory associated with translation table walks using TTBR0_EL1.

SH0	Meaning
0b00	Non-shareable
0b10	Outer Shareable
0b11	Inner Shareable

Other values are reserved. The effect of programming this field to a Reserved value is that behavior is CONSTRAINED UNPREDICTABLE.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Otherwise:

Reserved, RES0.

ORGN0, bits [11:10]

When VTCR_EL2.MSA == '1':

Outer cacheability attribute for memory associated with translation table walks using TTBR0_EL1.

ORGN0	Meaning
0b00	Normal memory, Outer Non-cacheable.
0b01	Normal memory, Outer Write-Back Read-Allocate Write-Allocate Cacheable.
0b10	Normal memory, Outer Write-Through Read-Allocate No Write-Allocate Cacheable.
0b11	Normal memory, Outer Write-Back Read-Allocate No Write-Allocate Cacheable.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

IRGN0, bits [9:8]

When VTCR_EL2.MSA == '1':

Inner cacheability attribute for memory associated with translation table walks using TTBR0_EL1.

IRGN0	Meaning
0b00	Normal memory, Inner Non-cacheable.
0b01	Normal memory, Inner Write-Back Read-Allocate Write-Allocate Cacheable.
0b10	Normal memory, Inner Write-Through Read-Allocate No Write-Allocate Cacheable.
0b11	Normal memory, Inner Write-Back Read-Allocate No Write-Allocate Cacheable.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

EPD0, bit [7]

When VTCR_EL2.MSA == '1':

Translation table walk disable for translations using TTBR0_EL1. This bit controls whether a translation table walk is performed on a TLB miss, for an address that is translated using TTBR0_EL1. The encoding of this bit is:

EPD0	Meaning
0b0	Perform translation table walks using TTBR0_EL1.
0b1	A TLB miss on an address that is translated using TTBR0_EL1 generates a Translation fault. No translation table walk is performed.

The reset behavior of this field is:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bit [6]

Reserved, RES0.

T0SZ, bits [5:0]

When VTCR_EL2.MSA == '1':

The size offset of the memory region addressed by TTBR0_EL1. The region size is $2^{(64-T0SZ)}$ bytes.

The maximum and minimum possible values for T0SZ depend on the level of translation table and the memory translation granule size, as described in the AArch64 Virtual Memory System Architecture chapter.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Accessing TCR_EL1

Accesses to this register use the following encodings in the System register encoding space:

```
MRS <Xt>, TCR_EL1
```

op0	op1	CRn	CRm	op2
0b11	0b000	0b0010	0b0000	0b010

```
if PSTATE.EL == EL0 then
    UNDEFINED;
elsif PSTATE.EL == EL1 then
    if HCR_EL2.TRVM == '1' then
        AArch64.SystemAccessTrap(EL2, 0x18);
    else
        X[t, 64] = TCR_EL1;
elsif PSTATE.EL == EL2 then
    X[t, 64] = TCR_EL1;
```

```
MSR TCR_EL1, <Xt>
```

op0	op1	CRn	CRm	op2
0b11	0b000	0b0010	0b0000	0b010

```
if PSTATE.EL == EL0 then
    UNDEFINED;
elsif PSTATE.EL == EL1 then
    if HCR_EL2.TVM == '1' then
        AArch64.SystemAccessTrap(EL2, 0x18);
    else
        TCR_EL1 = X[t, 64];
elsif PSTATE.EL == EL2 then
    TCR_EL1 = X[t, 64];
```

D12.2.92 TCR_EL2, Translation Control Register (EL2)

The TCR_EL2 characteristics are:

Purpose

This register controls stage 1 of the EL2 translation regime, translated by the EL2-MPU.

Configuration

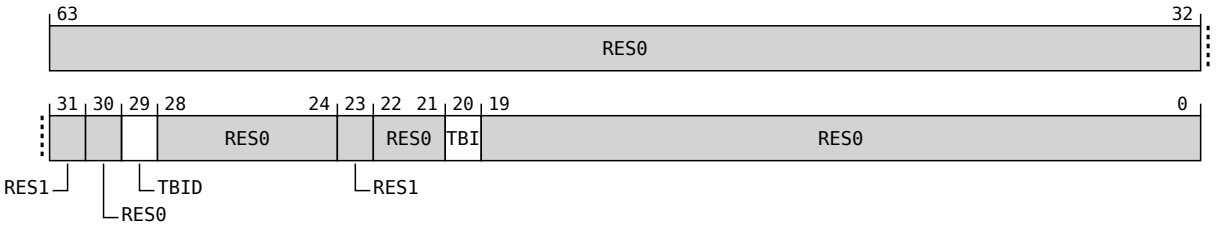
There are no configuration notes.

Attributes

TCR_EL2 is a 64-bit register.

Field descriptions

IsProfile(PROFILE_R)



Any of the bits in TCR_EL2 are permitted to be cached in a TLB.

Bits [63:32]

Reserved, RES0.

Bit [31]

Reserved, RES1.

Bit [30]

Reserved, RES0.

TBID, bit [29]

When FEAT_PAuth is implemented:

Controls the use of the top byte of instruction addresses for address matching.

For the purpose of this field, all cache maintenance and address translation instructions that perform address translation are treated as data accesses.

For more information, see 'Address tagging'.

TBID	Meaning
0b0	TCR_EL2.TBI applies to Instruction and Data accesses.
0b1	TCR_EL2.TBI applies to Data accesses only.

This affects addresses where the address would be translated by EL2 MPU.

The reset behavior of this field is:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bits [28:24]

Reserved, RES0.

Bit [23]

Reserved, RES1.

Bits [22:21]

Reserved, RES0.

TBI, bit [20]

Top Byte ignored. Indicates whether the top byte of an address is used for address match for the EL2 MPU regions, or ignored and used for tagged addresses.

For more information, see 'Address tagging'.

TBI	Meaning
0b0	Top Byte used in the address calculation.
0b1	Top Byte ignored in the address calculation.

This affects addresses generated in EL2 using AArch64 where the address would be translated by the EL2 MPU. It has an effect whether the EL2 translation regime is enabled or not.

If FEAT_PAuth is implemented and TCR_EL2.TBID is 1, then this field only applies to Data accesses.

If the value of TBI is 1, then bits[63:56] of that target address are also set to 0 before the address is stored in the PC, in the following cases:

- A branch or procedure return within EL2.
- An exception taken to EL2.
- An exception return to EL2.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [19:0]

Reserved, RES0.

Accessing TCR_EL2

Accesses to this register use the following encodings in the System register encoding space:

`MRS <Xt>, TCR_EL2`

op0	op1	CRn	CRm	op2
0b11	0b100	0b0010	0b0000	0b010

```
if PSTATE.EL == EL0 then
    UNDEFINED;
elsif PSTATE.EL == EL1 then
    UNDEFINED;
elsif PSTATE.EL == EL2 then
    X[t, 64] = TCR_EL2;
```

D12.2.93 TPIDR_EL0, EL0 Read/Write Software Thread ID Register

The TPIDR_EL0 characteristics are:

Purpose

Provides a location where software executing at EL0 can store thread identifying information, for OS management purposes.

The PE makes no use of this register.

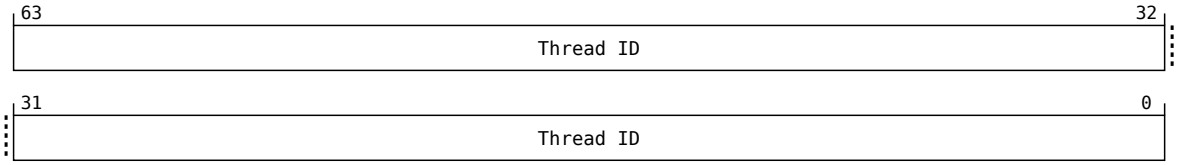
Configuration

There are no configuration notes.

Attributes

TPIDR_EL0 is a 64-bit register.

Field descriptions



ThreadID, bits [63:0]

Thread ID. Thread identifying information stored by software running at this Exception level.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing TPIDR_EL0

Accesses to this register use the following encodings in the System register encoding space:

`MRS <Xt>, TPIDR_EL0`

op0	op1	CRn	CRm	op2
0b11	0b011	0b1101	0b0000	0b010

```
if PSTATE.EL == EL0 then
    X[t, 64] = TPIDR_EL0;
elsif PSTATE.EL == EL1 then
    X[t, 64] = TPIDR_EL0;
elsif PSTATE.EL == EL2 then
    X[t, 64] = TPIDR_EL0;
```

D12.2.94 TPIDR_EL1, EL1 Software Thread ID Register

The TPIDR_EL1 characteristics are:

Purpose

Provides a location where software executing at EL1 can store thread identifying information, for OS management purposes.

The PE makes no use of this register.

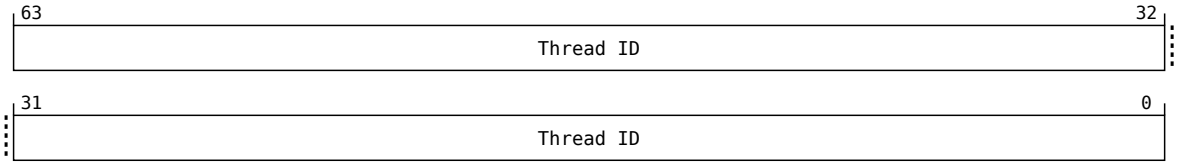
Configuration

There are no configuration notes.

Attributes

TPIDR_EL1 is a 64-bit register.

Field descriptions



ThreadID, bits [63:0]

Thread ID. Thread identifying information stored by software running at this Exception level.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing TPIDR_EL1

Accesses to this register use the following encodings in the System register encoding space:

`MRS <Xt>, TPIDR_EL1`

op0	op1	CRn	CRm	op2
0b11	0b000	0b1101	0b0000	0b100

```
if PSTATE.EL == EL0 then

D12.2.96 TPIDRRO_EL0, EL0 Read-Only Software Thread ID Register

The TPIDRRO_EL0 characteristics are:

Purpose

Provides a location where software executing at EL1 or higher can store thread identifying information that is visible to software executing at EL0, for OS management purposes.

The PE makes no use of this register.

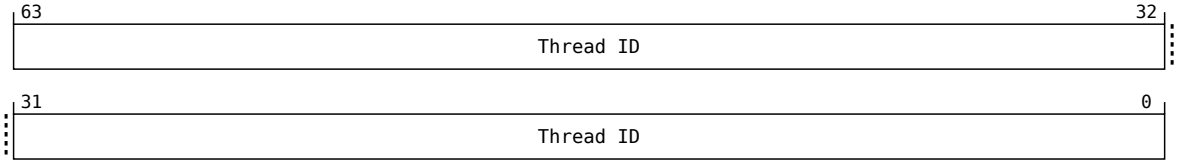
Configuration

There are no configuration notes.

Attributes

TPIDRRO_EL0 is a 64-bit register.

Field descriptions



ThreadID, bits [63:0]

Thread ID. Thread identifying information stored by software running at this Exception level.

Accessing TPIDRRO_EL0

Accesses to this register use the following encodings in the System register encoding space:

`MRS <Xt>, TPIDRRO_EL0`

op0	op1	CRn	CRm	op2
0b11	0b011	0b1101	0b0000	0b011

Non-Confidential

D12.2.97 TTBR0_EL1, Translation Table Base Register 0 (EL1)

The TTBR0_EL1 characteristics are:

Purpose

Holds the base address of the translation table for the initial lookup for stage 1 of the translation of an address from the lower VA range in the EL1&0 translation regime, and other information for this translation regime.

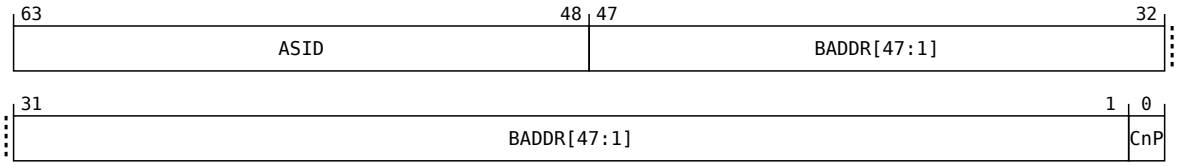
Configuration

There are no configuration notes.

Attributes

TTBR0_EL1 is a 64-bit register.

Field descriptions



ASID, bits [63:48]

When VTCR_EL2.MSA == '1':

An ASID for the translation table base address. The TCR_EL1.A1 field selects either TTBR0_EL1.ASID or TTBR1_EL1.ASID.

If the implementation has only 8 bits of ASID, then the upper 8 bits of this field are RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

When VTCR_EL2.MSA == '0':

An ASID for addresses defined by the current EL1 MPU configuration.

If the implementation has only 8 bits of ASID, then the upper 8 bits of this field are RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

BADDR[47:1], bits [47:1]

When VTCR_EL2.MSA == '1':

Translation table base address:

- Bits A[47:x] of the stage 1 translation table base address bits are in register bits[47:x].
- Bits A[(x-1):0] of the stage 1 translation table base address are zero.

Address bit x is the minimum address bit required to align the translation table to the size of the table. The AArch64 Virtual Memory System Architecture chapter describes how x is calculated based on the value of TCR_EL1.T0SZ, the translation stage, and the translation granule size.

The BADDR field represents a 52-bit address if any of the following apply:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- The value of TCR_EL1.IPS represents an OA size of 52 bits.
- The Effective value of TCR_EL1.DS is 1.

When TTBR0_EL1.BADDR represents a 52-bit addresses, all of the following apply:

- Bits A[51:48] of the stage 1 translation table base address bits are in register bits[5:2].
- Register bit[1] is RES0.
- The smallest permitted value of x is 6.
- When x>6, register bits[(x-1):6] are RES0.

Otherwise, all of the following apply:

- Register bits[(x-1):1] are RES0.
- If 52-bit PA is supported, then bits A[51:48] of the stage 1 translation table base address are treated as `0b0000`.

Note

If BADDR represents a 52-bit address, and the translation table has fewer than eight entries, the table must be aligned to 64 bytes. Otherwise the translation table must be aligned to the size of the table.
For the 64KB granule, if 52-bit PA is not supported, and the value of TCR_EL1.IPS is `0b110` or `0b111`, one of the following IMPLEMENTATION DEFINED behaviors occur:

- BADDR uses the extended format to represent a 52-bit base address.
- BADDR does not use the extended format.

If any register bit[47:1] that is defined as RES0 has the value 1 when a translation table walk is done using TTBR0_EL1, then the translation table base address might be misaligned, with effects that are CONSTRAINED UNPREDICTABLE, and must be one of the following:

- Bits A[(x-1):0] of the stage 1 translation table base address are treated as if all the bits are zero. The value read back from the corresponding register bits is either the value written to the register or zero.
- The result of the calculation of an address for a translation table walk using this register can be corrupted in those bits that are nonzero.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

CnP, bit [0]

When VTCR_EL2.MSA == '1' and FEAT_TTCNP is implemented:

Common not Private. This bit indicates whether each entry that is pointed to by TTBR0_EL1 is a member of a common set that can be used by every PE in the Inner Shareable domain for which the value of TTBR0_EL1.CnP is 1.

CnP	Meaning
`0b0`	The translation table entries pointed to by TTBR0_EL1, for the current translation regime and ASID, are permitted to differ from corresponding entries for TTBR0_EL1 for other PEs in the Inner Shareable domain. This is not affected by: • The value of TTBR0_EL1.CnP on those other PEs. • The value of the current ASID. • If EL2 is implemented and enabled in the current Security state, the value of the current VMID.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

CnP	Meaning
0b1	The translation table entries pointed to by TTBR0_EL1 are the same as the translation table entries for every other PE in the Inner Shareable domain for which the value of TTBR0_EL1.CnP is 1 and all of the following apply: • The translation table entries are pointed to by TTBR0_EL1. • The translation tables relate to the same translation regime. • The ASID is the same as the current ASID. • If EL2 is implemented and enabled in the current Security state, the value of the current VMID.

This bit is permitted to be cached in a TLB.

When a TLB combines entries from stage 1 translation and stage 2 translation into a single entry, that entry can only be shared between different PEs if the value of the CnP bit is 1 for both stage 1 and stage 2.

Note

If the value of the TTBR0_EL1.CnP bit is 1 on multiple PEs in the same Inner Shareable domain and those TTBR0_EL1s do not point to the same translation table entries when the other conditions specified for the case when the value of CnP is 1 apply, then the results of translations are CONSTRAINED UNPREDICTABLE, see 'CONSTRAINED UNPREDICTABLE behaviors due to caching of control or data values'.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

When VTCR_EL2.MSA == '0':

Reserved, RES0.

Otherwise:

Reserved, RES0.

Accessing TTBR0_EL1

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, TTBR0_EL1

op0	op1	CRn	CRm	op2
0b11	0b000	0b0010	0b0000	0b000

D12.2.98 TTBR1_EL1, Translation Table Base Register 1 (EL1)

The TTBR1_EL1 characteristics are:

Purpose

Holds the base address of the translation table for the initial lookup for stage 1 of the translation of an address from the higher VA range in the EL1&0 stage 1 translation regime, and other information for this translation regime.

Configuration

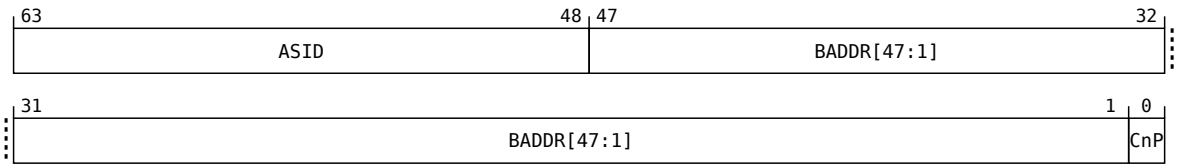
In a PMSAv8-64 only implementation, this register is UNDEFINED.

This register is present only when architecture implements VMSA extension. Otherwise, direct accesses to TTBR1_EL1 are UNDEFINED.

Attributes

TTBR1_EL1 is a 64-bit register.

Field descriptions



ASID, bits [63:48]

When VTCR_EL2.MSA == '1':

An ASID for the translation table base address. The TCR_EL1.A1 field selects either TTBR0_EL1.ASID or TTBR1_EL1.ASID.

If the implementation has only 8 bits of ASID, then the upper 8 bits of this field are RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

BADDR[47:1], bits [47:1]

When VTCR_EL2.MSA == '1':

Translation table base address:

- Bits A[47:x] of the stage 1 translation table base address bits are in register bits[47:x].
- Bits A[(x-1):0] of the stage 1 translation table base address are zero.

Address bit x is the minimum address bit required to align the translation table to the size of the table. The AArch64 Virtual Memory System Architecture chapter describes how x is calculated based on the value of TCR_EL1.T1SZ, the translation stage, and the translation granule size.

The BADDR field represents a 52-bit address if any of the following apply:

- The value of TCR_EL1.IPS represents an OA size of 52 bits.
- The Effective value of TCR_EL1.DS is 1.

When TTBR1_EL1.BADDR represents a 52-bit addresses, all of the following apply:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- Bits A[51:48] of the stage 1 translation table base address bits are in register bits[5:2].
- Register bit[1] is RES0.
- The smallest permitted value of x is 6.
- When x>6, register bits[(x-1):6] are RES0.

Otherwise, all of the following apply:

- Register bits[(x-1):1] are RES0.
- If 52-bit PA is supported, then bits A[51:48] of the stage 1 translation table base address are treated as `0b0000`.

Note

If BADDR represents a 52-bit address, and the translation table has fewer than eight entries, the table must be aligned to 64 bytes. Otherwise the translation table must be aligned to the size of the table.
For the 64KB granule, if 52-bit PA is not supported, and the value of TCR_EL1.IPS is `0b110` or `0b111`, one of the following IMPLEMENTATION DEFINED behaviors occur:

- BADDR uses the extended format to represent a 52-bit base address.
- BADDR does not use the extended format.

If any register bit[47:1] that is defined as RES0 has the value 1 when a translation table walk is done using TTBR1_EL1, then the translation table base address might be misaligned, with effects that are CONSTRAINED UNPREDICTABLE, and must be one of the following:

- Bits A[(x-1):0] of the stage 1 translation table base address are treated as if all the bits are zero. The value read back from the corresponding register bits is either the value written to the register or zero.
- The result of the calculation of an address for a translation table walk using this register can be corrupted in those bits that are nonzero.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

CnP, bit [0]

When VTCR_EL2.MSA == '1' and FEAT_TTCNP is implemented:

Common not Private. This bit indicates whether each entry that is pointed to by TBR1_EL1 is a member of a common set that can be used by every PE in the Inner Shareable domain for which the value of TTBR1_EL1.CnP is 1.

CnP	Meaning
`0b0`	The translation table entries pointed to by TTBR1_EL1, for the current translation regime and ASID, are permitted to differ from corresponding entries for TTBR1_EL1 for other PEs in the Inner Shareable domain. This is not affected by: • The value of TTBR1_EL1.CnP on those other PEs. • The value of the current ASID. • The value of the current VMID.
`0b1`	The translation table entries pointed to by TTBR1_EL1 are the same as the translation table entries for every other PE in the Inner Shareable domain for which the value of TTBR1_EL1.CnP is 1 and all of the following apply: • The translation table entries are pointed to by TTBR1_EL1. • The translation tables relate to the same translation regime. • The ASID is the same as the current ASID. • The value of the current VMID.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

This bit is permitted to be cached in a TLB.

When a TLB combines entries from stage 1 translation and stage 2 translation into a single entry, that entry can only be shared between different PEs if the value of the CnP bit is 1 for both stage 1 and stage 2.

Note

If the value of the TTBR1_EL1.CnP bit is 1 on multiple PEs in the same Inner Shareable domain and those TTBR1_EL1s do not point to the same translation table entries when the other conditions specified for the case when the value of CnP is 1 apply, then the results of translations are CONSTRAINED UNPREDICTABLE, see 'CONSTRAINED UNPREDICTABLE behaviors due to caching of control or data values'.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

D12.2.99 VBAR_EL1, Vector Base Address Register (EL1)

The VBAR_EL1 characteristics are:

Purpose

Holds the vector base address for any exception that is taken to EL1.

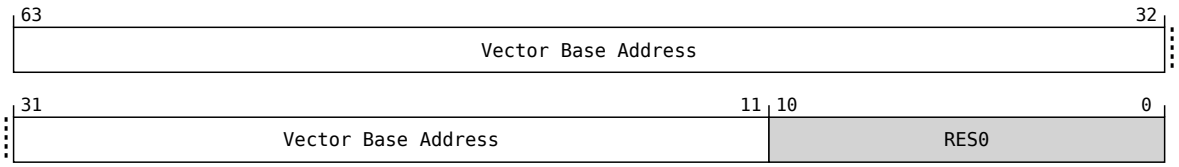
Configuration

There are no configuration notes.

Attributes

VBAR_EL1 is a 64-bit register.

Field descriptions



VBA, bits [63:11]

Vector Base Address. Base address of the exception vectors for exceptions taken to EL1.

Note

If the implementation supports FEAT_LVA, then:

- If tagged addresses are being used, bits [55:52] of VBAR_EL1 must be the same or else the use of the vector address will result in a recursive exception.
- If tagged addresses are not being used, bits [63:52] of VBAR_EL1 must be the same or else the use of the vector address will result in a recursive exception.

If the implementation does not support FEAT_LVA, then:

- If tagged addresses are being used, bits [55:48] of VBAR_EL1 must be the same or else the use of the vector address will result in a recursive exception.
- If tagged addresses are not being used, bits [63:48] of VBAR_EL1 must be the same or else the use of the vector address will result in a recursive exception.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [10:0]

Reserved, RES0.

Accessing VBAR_EL1

Accesses to this register use the following encodings in the System register encoding space:

D12.2.100 VBAR_EL2, Vector Base Address Register (EL2)

The VBAR_EL2 characteristics are:

Purpose

Holds the vector base address for any exception that is taken to EL2.

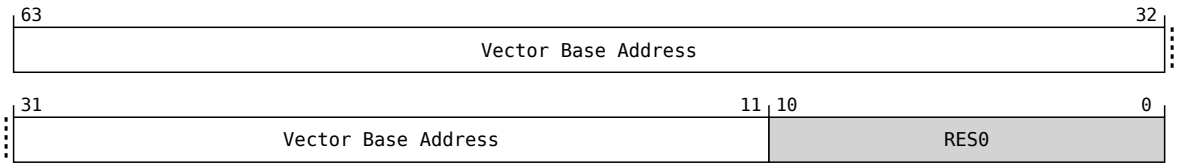
Configuration

There are no configuration notes.

Attributes

VBAR_EL2 is a 64-bit register.

Field descriptions



VBA, bits [63:11]

Vector Base Address. Base address of the exception vectors for exceptions taken to EL2.

Note

If FEAT_LVA is implemented:

```
- If tagged addresses are being used, bits [55:52] of VBAR_EL2 must be 0 or else the use of the
    ↪vector address will result in a recursive exception.
- If tagged addresses are not being used, bits [63:52] of VBAR_EL2 must be 0 or else the use of the
    ↪vector address will result in a recursive exception.
```

If FEAT_LVA is not implemented:

```
- If tagged addresses are being used, bits [55:48] of VBAR_EL2 must be 0 or else the use of the
    ↪vector address will result in a recursive exception.
- If tagged addresses are not being used, bits [63:48] of VBAR_EL2 must be 0 or else the use of
    ↪the vector address will result in a recursive exception.
```

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [10:0]

Reserved, RES0.

Accessing VBAR_EL2

Accesses to this register use the following encodings in the System register encoding space:

```

D12.2.101 VMPIDR_EL2, Virtualization Multiprocessor ID Register

The VMPIDR_EL2 characteristics are:

Purpose

Holds the value of the Virtualization Multiprocessor ID. This is the value returned by EL1 reads of MPIDR_EL1, which in a multiprocessor system, provides an additional PE identification system.

Configuration

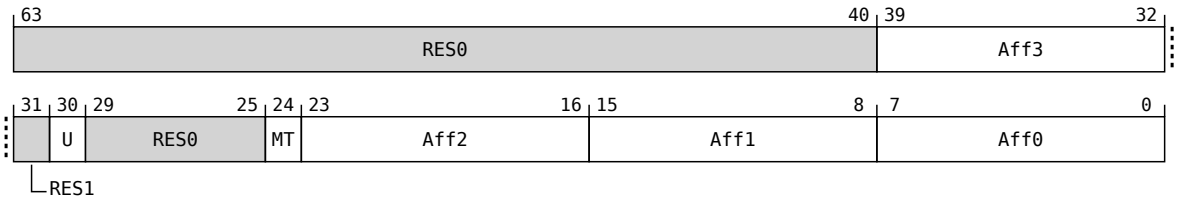
If EL2 is not implemented, reads of this register return the value of the MPIDR_EL1 and writes to the register are ignored.

This register has no effect if EL2 is not enabled in the current Security state.

Attributes

VMPIDR_EL2 is a 64-bit register.

Field descriptions



Bits [63:40]

Reserved, RES0.

Aff3, bits [39:32]

Affinity level 3. See the description of VMPIDR_EL2.Aff0 for more information.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [31]

Reserved, RES1.

U, bit [30]

Indicates a Uniprocessor system, as distinct from PE 0 in a multiprocessor system.

U	Meaning
0b0	Processor is part of a multiprocessor system.
0b1	Processor is part of a uniprocessor system.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [29:25]

Reserved, RES0.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

MT, bit [24]

Indicates whether the lowest level of affinity consists of logical PEs that are implemented using a multithreading type approach. See the description of VMPIDR_EL2.Aff0 for more information about affinity levels.

MT	Meaning
0b0	Performance of PEs at the lowest affinity level is largely independent.
0b1	Performance of PEs at the lowest affinity level is very interdependent.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Aff2, bits [23:16]

Affinity level 2. See the description of VMPIDR_EL2.Aff0 for more information.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Aff1, bits [15:8]

Affinity level 1. See the description of VMPIDR_EL2.Aff0 for more information.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Aff0, bits [7:0]

Affinity level 0.

The assigned value of the MPIDR_EL1.{Aff3, Aff2, Aff1, Aff0} set of fields of each PE must be unique within the system as a whole.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing VMPIDR_EL2

Accesses to this register use the following encodings in the System register encoding space:

`MRS <Xt>, VMPIDR_EL2`

op0	op1	CRn	CRm	op2
0b11	0b100	0b0000	0b0000	0b101

```

D12.2.102 VPIDR_EL2, Virtualization Processor ID Register

The VPIDR_EL2 characteristics are:

Purpose

Holds the value of the Virtualization Processor ID. This is the value returned by EL1 reads of MIDR_EL1.

Configuration

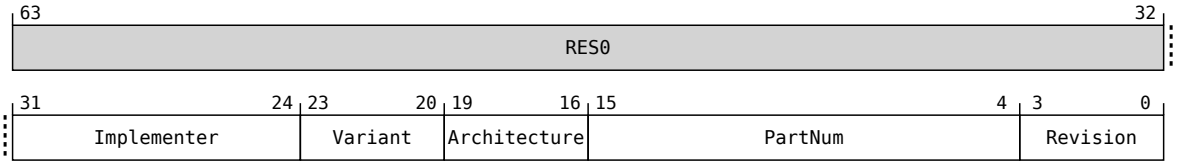
If EL2 is not implemented, reads of this register return the value of the MIDR_EL1 and writes to the register are ignored.

This register has no effect if EL2 is not enabled in the current Security state.

Attributes

VPIDR_EL2 is a 64-bit register.

Field descriptions



Bits [63:32]

Reserved, RES0.

Implementer, bits [31:24]

The Implementer code. This field must hold an implementer code that has been assigned by Arm.

Implementer	Meaning
0x00	Reserved for software use.
0x41	Arm Limited.
0x42	Broadcom Corporation.
0x43	Cavium Inc.
0x44	Digital Equipment Corporation.
0x46	Fujitsu Ltd.
0x49	Infineon Technologies AG.
0x4D	Motorola or Freescale Semiconductor Inc.
0x4E	NVIDIA Corporation.
0x50	Applied Micro Circuits Corporation.
0x51	Qualcomm Inc.
0x56	Marvell International Ltd.
0x69	Intel Corporation.
0xC0	Ampere Computing.

Arm can assign codes that are not published in this manual. All values not assigned by Arm are reserved and must not be used.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Variant, bits [23:20]

An IMPLEMENTATION DEFINED variant number. Typically, this field is used to distinguish between different product variants, or major revisions of a product.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Architecture, bits [19:16]

Architecture version.

Architecture	Meaning
0b0001	Armv4.
0b0010	Armv4T.
0b0011	Armv5 (obsolete).
0b0100	Armv5T.
0b0101	Armv5TE.
0b0110	Armv5TEJ.
0b0111	Armv6.
0b1111	Architectural features are individually identified in the ID_* registers.

All other values are reserved.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

PartNum, bits [15:4]

An IMPLEMENTATION DEFINED primary part number for the device.

On processors implemented by Arm, if the top four bits of the primary part number are 0x0 or 0x7, the variant and architecture are encoded differently.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Revision, bits [3:0]

An IMPLEMENTATION DEFINED revision number for the device.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing VPIDR_EL2

Accesses to this register use the following encodings in the System register encoding space:

```

D12.2.103 VSTCR_EL2, Virtualization Secure Translation Control Register

The VSTCR_EL2 characteristics are:

Purpose

The control register for stage 2 of the Secure EL1&0 translation regime.

Configuration

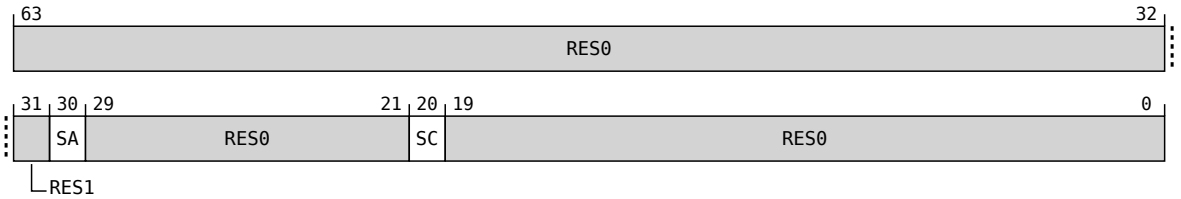
This register is present only when FEAT_SEL2 is implemented. Otherwise, direct accesses to VSTCR_EL2 are UNDEFINED.

Attributes

VSTCR_EL2 is a 64-bit register.

Field descriptions

IsProfile(PROFILE_R)



Any of the bits in VSTCR_EL2 are permitted to be cached in a TLB.

Bits [63:32]

Reserved, RES0.

Bit [31]

Reserved, RES1.

SA, bit [30]

Secure stage 2 translation output address space.

SA	Meaning
0b0	All stage 2 translations for the Secure PA space access the Secure PA space.
0b1	All stage 2 translations for the Secure PA space access the Non-secure PA space.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [29:21]

Reserved, RES0.

SC, bit [20]

NS check enable bit.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

SC	Meaning
0b0	Least secure NS configuration is selected from the stage 1 and stage 2 EL1&0 translation regime for the given address.
0b1	Stage 2 NS configuration is checked against stage 1 NS configuration in EL1&0 translation regime for the given address, and generate a fault if they are different.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [19:0]

Reserved, RES0.

Accessing VSTCR_EL2

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, VSTCR_EL2

op0	op1	CRn	CRm	op2
0b11	0b100	0b0010	0b0110	0b010

```
if !IsFeatureImplemented(FEAT_SEL2) then

D12.2.104 VTCR_EL2, Virtualization Translation Control Register

The VTCR_EL2 characteristics are:

Purpose

The control register for stage 2 of the EL1&0 translation regime.

Configuration

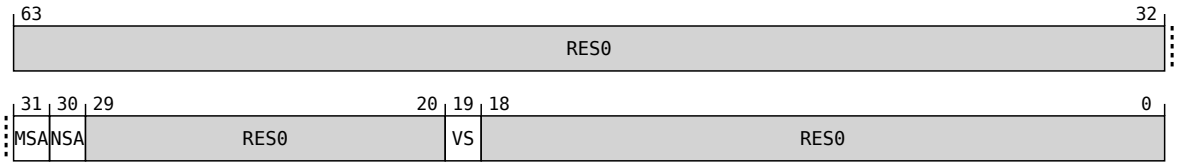
There are no configuration notes.

Attributes

VTCR_EL2 is a 64-bit register.

Field descriptions

IsProfile(PROFILE_R)



Any of the bits in VTCR_EL2 are permitted to be cached in a TLB.

Bits [63:32]

Reserved, RES0.

MSA, bit [31]

When ID_AA64MMFR0_EL1.MSA_frac == '0010':

Stage 1 EL1&0 translation regime memory system architecture.

MSA	Meaning
0b0	Stage 1 EL1&0 translation regime uses PMSAv8-64 memory architecture.
0b1	Stage 1 EL1&0 translation regime uses VMSAv8-64 memory architecture.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

When ID_AA64MMFR0_EL1.MSA_frac == '0001':

Reserved, RES0.

Otherwise:

Reserved, RES1.

NSA, bit [30]

When FEAT_SEL2 is implemented:

Non-secure stage 2 translation output address space.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

NSA	Meaning
0b0	All stage 2 translations for the Non-secure PA space of the Secure EL1&0 translation regime access the Secure PA space.
0b1	All stage 2 translations for the Non-secure PA space of the Secure EL1&0 translation regime access the Non-secure PA space.

This bit behaves as 1 for all purposes other than reading back the value of the bit when the value of VSTCR_EL2.SA is 1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bits [29:20]

Reserved, RES0.

VS, bit [19]

When FEAT_VMID16 is implemented:

VMID Size.

VS	Meaning
0b0	8-bit VMID. The upper 8 bits of VSCTLR_EL2 are ignored by the hardware, and treated as if they are all zeros, for every purpose except when reading back the register.
0b1	16-bit VMID. The upper 8 bits of VSCTLR_EL2 are used for allocation and matching in the TLB.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bits [18:0]

Reserved, RES0.

Accessing VTCR_EL2

Unless stated otherwise, any of the bits in VTCR_EL2 are permitted to be cached in a TLB.

Accesses to this register use the following encodings in the System register encoding space:

`MRS <Xt>, VTCR_EL2`

op0	op1	CRn	CRm	op2
0b11	0b100	0b0010	0b0001	0b010

```
if PSTATE.EL == EL0 then

D12.3 Debug registers

This section lists the Debug System registers in AArch64 state, in alphabetic order:

- The principal encoding space for debug registers is `op0` == `0b10`, `op1` == {0, 3, 4}. Instructions for accessing debug System registers summarizes the registers in this encoding space and lists them in order of their encodings.
- In addition, the following registers in the `op0` == `0b11` encoding space are classified as Debug registers:
  - DLR_EL0.
  - DSPSR_EL0.
  - MDCR_EL2.
  - MDCR_EL3.
  - SDER32_EL3.

D12.3.1 DBGAUTHSTATUS_EL1, Debug Authentication Status Register

The DBGAUTHSTATUS_EL1 characteristics are:

Purpose

Provides information about the state of the IMPLEMENTATION DEFINED authentication interface for debug.

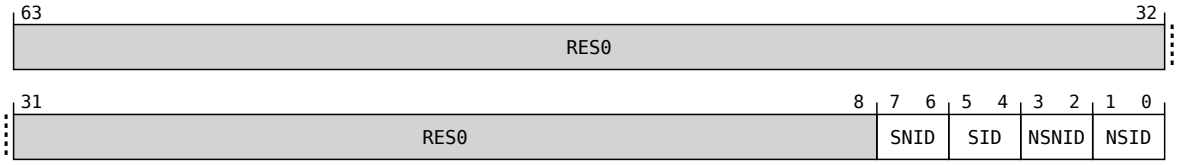
Configuration

AArch64 System register DBGAUTHSTATUS_EL1 bits [31:0] are architecturally mapped to External register DBGAUTHSTATUS_EL1[31:0].

Attributes

DBGAUTHSTATUS_EL1 is a 64-bit register.

Field descriptions



Bits [63:8]

Reserved, RES0.

SNID, bits [7:6]

When FEAT_Debugv8p4 is implemented:

Secure non-invasive debug.

This field has the same value as DBGAUTHSTATUS_EL1.SID.

Otherwise:

Secure non-invasive debug.

SNID	Meaning
0b00	Secure state is not implemented.
0b10	Implemented and disabled. ExternalSecureNoninvasiveDebugEnabled() == FALSE.
0b11	Implemented and enabled. ExternalSecureNoninvasiveDebugEnabled() == TRUE.

All other values are reserved.

SID, bits [5:4]

Secure invasive debug.

SID	Meaning
0b00	Secure state is not implemented.
0b10	Implemented and disabled. ExternalSecureInvasiveDebugEnabled() == FALSE.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

0b11	Implemented and enabled. ExternalSecureInvasiveDebugEnabled() == TRUE.

All other values are reserved.

NSNID, bits [3:2]

When FEAT_Debugv8p4 is implemented:

Non-secure non-invasive debug.

NSNID	Meaning
0b00	Non-secure state is not implemented.
0b11	Implemented and enabled. EL3 is implemented or the Effective value of SCR_EL3.NS is 1.

All other values are reserved.

Otherwise:

Non-secure non-invasive debug.

NSNID	Meaning
0b00	Non-secure state is not implemented.
0b10	Implemented and disabled. ExternalNoninvasiveDebugEnabled() == FALSE.
0b11	Implemented and enabled. ExternalNoninvasiveDebugEnabled() == TRUE.

All other values are reserved.

NSID, bits [1:0]

Non-secure invasive debug.

NSID	Meaning
0b00	Non-secure state is not implemented.
0b10	Implemented and disabled. ExternalInvasiveDebugEnabled() == FALSE.
0b11	Implemented and enabled. ExternalInvasiveDebugEnabled() == TRUE.

All other values are reserved.

Accessing DBGAUTHSTATUS_EL1

Accesses to this register use the following encodings in the System register encoding space:

`MRS <Xt>, DBGAUTHSTATUS_EL1`

op0	op1	CRn	CRm	op2
0b10	0b000	0b0111	0b1110	0b110

```
if PSTATE.EL == EL0 then
    UNDEFINED;
elsif PSTATE.EL == EL1 then
    if MDCR_EL2.<TDE,TDA> != '00' then
        AArch64.SystemAccessTrap(EL2, 0x18);
```

D12.3.2 DBGBCR<n>_EL1, Debug Breakpoint Control Registers, n = 0 - 63

The DBGBCR<n>_EL1 characteristics are:

Purpose

Holds control information for a breakpoint. Forms breakpoint n together with value register DBGBVR<n>_EL1.

Configuration

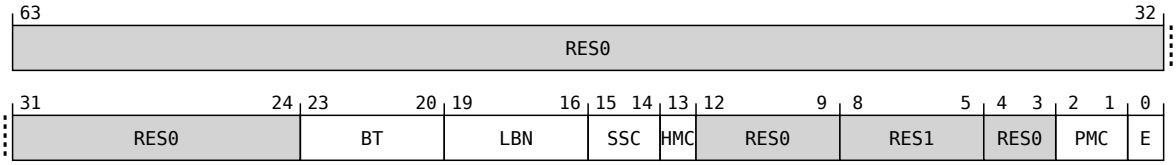
If breakpoint n is not implemented, accesses to this register are UNDEFINED.

AArch64 System register DBGBCR<n>_EL1 bits [31:0] are architecturally mapped to External register DBGBCR<n>_EL1[31:0].

Attributes

DBGBCR<n>_EL1 is a 64-bit register.

Field descriptions



Bits [63:24]

Reserved, RES0.

BT, bits [23:20]

Breakpoint Type.

Specifies breakpoint type.

BT	Meaning	Applies when
0b0000	Unlinked instruction address match. DBGBVR<n>_EL1 is the address of an instruction.	
0b0001	Linked instruction address match. As 0b0000, but linked to a breakpoint that has linking enabled.	
0b0010	Unlinked Context ID match. If the Effective value of HCR_EL2.E2H is 1, and either the PE is executing at EL0 with HCR_EL2.TGE set to 1 or the PE is executing at EL2, then DBGBVR<n>_EL1.ContextID is compared against CONTEXTIDR_EL2. Otherwise, DBGBVR<n>_EL1.ContextID is compared against CONTEXTIDR_EL1.	breakpoint n is context-aware
0b0011	As 0b0010, with linking enabled.	breakpoint n is context-aware
0b0110	Unlinked CONTEXTIDR_EL1 match. DBGBVR<n>_EL1.ContextID is a Context ID compared against CONTEXTIDR_EL1.	FEAT_Debugv8p1 is implemented and breakpoint n is context-aware
0b0111	As 0b0110, with linking enabled.	FEAT_Debugv8p1 is implemented and breakpoint n is context-aware

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

BT	Meaning	Applies when
0b1000	Unlinked VMID match. DBGBVR<n>_EL1.VMID is a VMID compared against VTTBR_EL2.VMID.	breakpoint n is context-aware
0b1001	As 0b1000, with linking enabled.	breakpoint n is context-aware
0b1010	Unlinked VMID and Context ID match. DBGBVR<n>_EL1.ContextID is a Context ID compared against CONTEXTIDR_EL1, and DBGBVR<n>_EL1.VMID is a VMID compared against VSCTLR_EL2.VMID.	breakpoint n is context-aware
0b1011	As 0b1010, with linking enabled.	breakpoint n is context-aware
0b1100	Unlinked CONTEXTIDR_EL2 match. DBGBVR<n>_EL1.ContextID2 is a Context ID compared against CONTEXTIDR_EL2.	FEAT_Debugv8p1 is implemented and breakpoint n is context-aware
0b1101	As 0b1100, with linking enabled.	FEAT_Debugv8p1 is implemented and breakpoint n is context-aware
0b1110	Unlinked Full Context ID match. DBGBVR<n>_EL1.ContextID is compared against CONTEXTIDR_EL1, and DBGBVR<n>_EL1.ContextID2 is compared against CONTEXTIDR_EL2.	FEAT_Debugv8p1 is implemented and breakpoint n is context-aware
0b1111	As 0b1110, with linking enabled.	FEAT_Debugv8p1 is implemented and breakpoint n is context-aware

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

LBN, bits [19:16]

Linked Breakpoint Number.

For Linked address matching breakpoints, specifies the index of the breakpoint linked to.

For all other breakpoint types, this field is ignored and reads of the register return an UNKNOWN value.

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

SSC, bits [15:14]

Security state control. Determines the Security states under which a Breakpoint debug event for breakpoint n is generated.

The fields that indicate when the breakpoint can be generated are: HMC, PMC, and SSC. These fields must be considered in combination, and the values that are permitted for these fields are constrained.

For more information on the operation of these fields, see 'Execution conditions for which a breakpoint generates Breakpoint exceptions'.

For more information on the effect of programming the fields to a reserved set of values, see 'Reserved DBGBCR<n>_EL1.{SSC, HMC, PMC} values'.

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

HMC, bit [13]

Higher mode control. Determines the debug perspective for deciding when a Breakpoint debug event for breakpoint n is generated.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The fields that indicate when the breakpoint can be generated are: HMC, PMC, and SSC. These fields must be considered in combination, and the values that are permitted for these fields are constrained.

For more information on the operation of these fields, see 'Execution conditions for which a breakpoint generates Breakpoint exceptions'.

For more information, see DBGBCR<n>_EL1.SSC.

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

Bits [12:9]

Reserved, RES0.

Bits [8:5]

Reserved, RES1.

Bits [4:3]

Reserved, RES0.

PMC, bits [2:1]

Privilege mode control. Determines the Exception level or levels at which a Breakpoint debug event for breakpoint n is generated.

The fields that indicate when the breakpoint can be generated are: HMC, PMC, and SSC. These fields must be considered in combination, and the values that are permitted for these fields are constrained.

For more information on the operation of these fields, see 'Execution conditions for which a breakpoint generates Breakpoint exceptions'.

For more information, see DBGBCR<n>_EL1.SSC.

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

E, bit [0]

Enable breakpoint n.

E	Meaning
0b0	Breakpoint n disabled.
0b1	Breakpoint n enabled.

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

Accessing DBGBCR<n>_EL1

Accesses to this register use the following encodings in the System register encoding space:

```
MRS <Xt>, DBGBCR<m>_EL1 ; Where m = 0-15
```

op0	op1	CRn	CRm	op2

D12.3.3 DBGBVR<n>_EL1, Debug Breakpoint Value Registers, n = 0 - 63

The DBGBVR<n>_EL1 characteristics are:

Purpose

Holds a virtual address, or a VMID and/or a context ID, for use in breakpoint matching. Forms breakpoint n together with control register DBGBCR<n>_EL1.

Configuration

How this register is interpreted depends on the value of DBGBCR<n>_EL1.BT.

- When DBGBCR<n>_EL1.BT is `0b000x`, this register holds a virtual address.
- When DBGBCR<n>_EL1.BT is `0b001x`, `0b011x`, or `0b110x`, this register holds a Context ID.
- When DBGBCR<n>_EL1.BT is `0b100x`, this register holds a VMID.
- When DBGBCR<n>_EL1.BT is `0b101x`, this register holds a VMID and a Context ID.
- When DBGBCR<n>_EL1.BT is `0b111x`, this register holds two Context ID values.

For other values of DBGBCR<n>_EL1.BT, this register is RES0.

If breakpoint n is not implemented then accesses to this register are UNDEFINED.

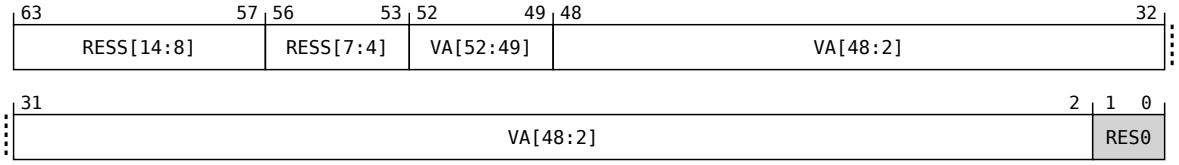
AArch64 System register DBGBVR<n>_EL1 bits [63:0] are architecturally mapped to External register DBGBVR<n>_EL1[63:0].

Attributes

DBGBVR<n>_EL1 is a 64-bit register.

Field descriptions

When DBGBCR<n>_EL1.BT IN {'000x'}:



RESS[14:8], bits [63:57]

Reserved, Sign extended. Software must set all bits in this field to the same value as the most significant bit of the VA field. If all bits in this field are not the same value as the most significant bit of the VA field, then all of the following apply:

- It is CONSTRAINED UNPREDICTABLE whether the PE ignores this field when comparing an address.
- If the breakpoint is not context-aware, it is IMPLEMENTATION DEFINED whether the value read back in each bit of this field is a copy of the most significant bit of the VA field or the value written.

RESS[7:4], bits [56:53]

Extension to RESS[14:8]. For more information, see RESS[14:8].

Bits [52:49]

When FEAT_LVA is implemented:

VA[52:49], bits [52:49]

Extension to VA[48:2]. For more information, see VA[48:2].

The reset behavior of this field is:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

RESS[3:0], bits [52:49]

Extension to RESS[14:8]. For more information, see RESS[14:8].

VA[48:2], bits [48:2]

Bits[48:2] of the address value for comparison.

When FEAT_LVA is implemented, VA[52:49] forms the upper part of the address value. If FEAT_LVA is not implemented, bits [52:49] are part of the RESS field.

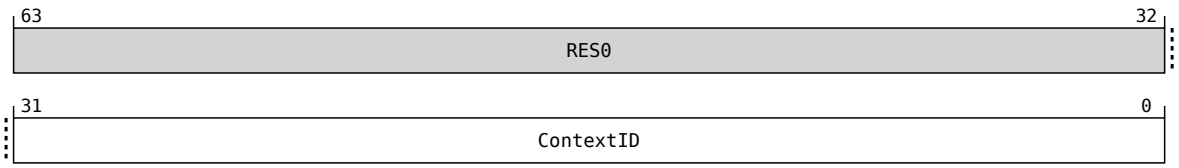
The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

Bits [1:0]

Reserved, RES0.

When DBGBCR<n>_EL1.BT IN {'001x'}:



Bits [63:32]

Reserved, RES0.

ContextID, bits [31:0]

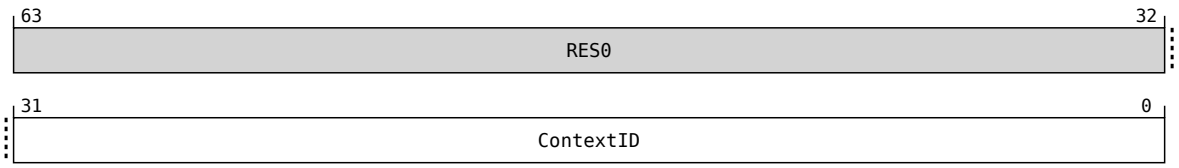
Context ID value for comparison.

The value is compared against CONTEXTIDR_EL1.

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

When DBGBCR<n>_EL1.BT IN {'011x'} and FEAT_Debugv8p1 is implemented:



Bits [63:32]

Reserved, RES0.

ContextID, bits [31:0]

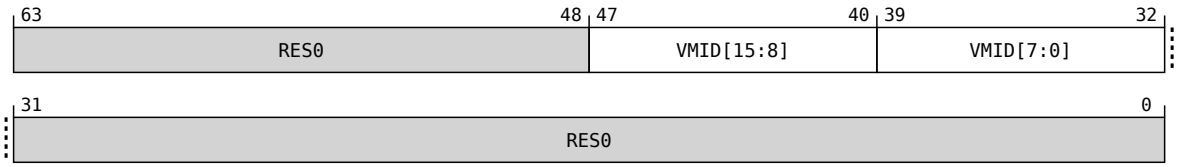
Context ID value for comparison against CONTEXTIDR_EL1.

The reset behavior of this field is:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

When DBGBCR<n>_EL1.BT IN {'100x'}:



Bits [63:48]

Reserved, RES0.

VMID[15:8], bits [47:40]

When FEAT_VMID16 is implemented and VTCR_EL2.VS == '1':

Extension to VMID[7:0]. For more information, see DBGBVR<n>_EL1.VMID[7:0].

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

VMID[7:0], bits [39:32]

VMID value for comparison.

The VMID is 8 bits when any of the following are true:

- VTCR_EL2.VS is 0.
- FEAT_VMID16 is not implemented.

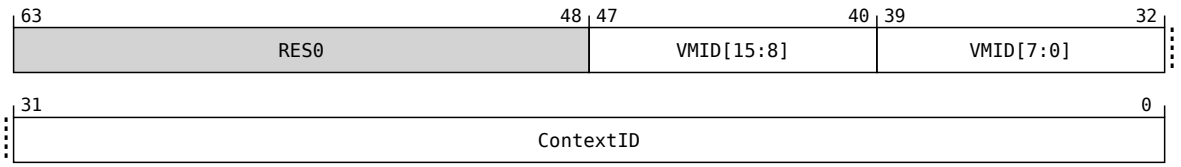
The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

Bits [31:0]

Reserved, RES0.

When DBGBCR<n>_EL1.BT IN {'101x'}:



Bits [63:48]

Reserved, RES0.

VMID[15:8], bits [47:40]

When FEAT_VMID16 is implemented and VTCR_EL2.VS == '1':

Extension to VMID[7:0]. For more information, see DBGBVR<n>_EL1.VMID[7:0].

The reset behavior of this field is:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

VMID[7:0], bits [39:32]

VMID value for comparison.

The VMID is 8 bits when any of the following are true:

- VTCR_EL2.VS is 0.
- FEAT_VMID16 is not implemented.

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

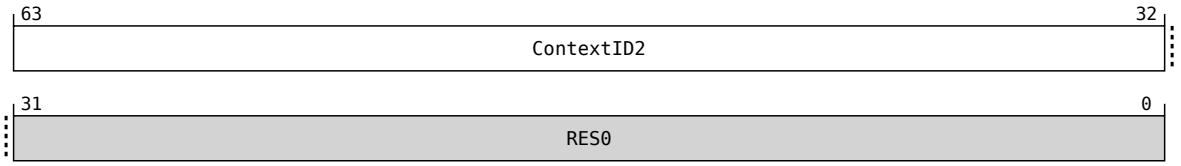
ContextID, bits [31:0]

Context ID value for comparison against CONTEXTIDR_EL1.

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

When DBGBCR<n>_EL1.BT IN {'110x'} and FEAT_Debugv8p1 is implemented:



ContextID2, bits [63:32]

Context ID value for comparison against CONTEXTIDR_EL2.

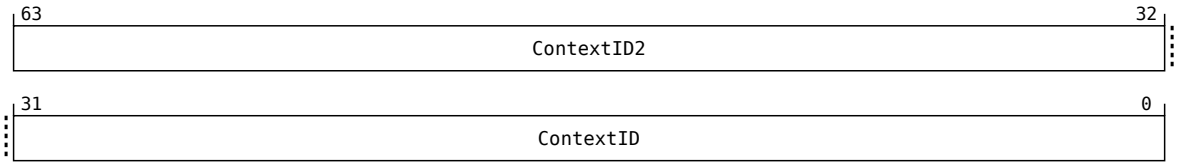
The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

Bits [31:0]

Reserved, RES0.

When DBGBCR<n>_EL1.BT IN {'111x'} and FEAT_Debugv8p1 is implemented:



ContextID2, bits [63:32]

Context ID value for comparison against CONTEXTIDR_EL2.

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

ContextID, bits [31:0]

Context ID value for comparison against CONTEXTIDR_EL1.

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

Accessing DBGBVR<n>_EL1

Accesses to this register use the following encodings in the System register encoding space:

```
MRS <Xt>, DBGBVR<m>_EL1 ; Where m = 0-15

D12.3.4 DBGCLAIMCLR_EL1, Debug CLAIM Tag Clear Register

The DBGCLAIMCLR_EL1 characteristics are:

Purpose

Used by software to read the values of the CLAIM tag bits, and to clear CLAIM tag bits to 0.

The architecture does not define any functionality for the CLAIM tag bits.

Note

CLAIM tags are typically used for communication between the debugger and target software.

Used in conjunction with the DBGCLAIMSET_EL1 register.

Configuration

An implementation must include eight CLAIM tag bits.

AArch64 System register DBGCLAIMCLR_EL1 bits [63:0] are architecturally mapped to AArch64 System register DBGCLAIMSET_EL1[63:0].

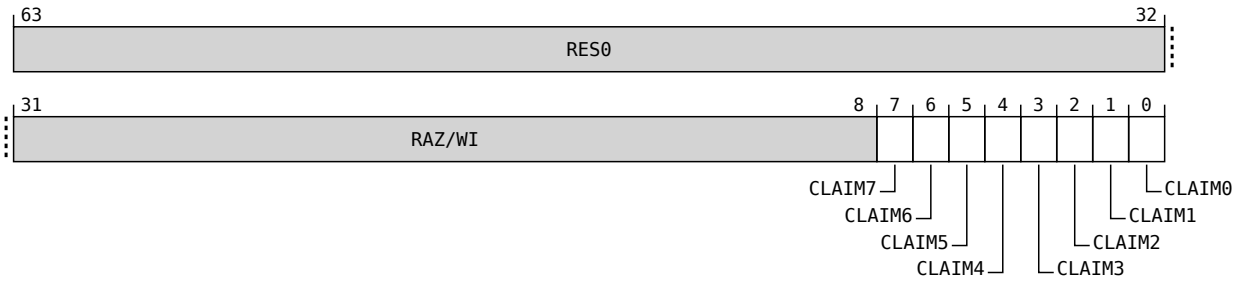
AArch64 System register DBGCLAIMCLR_EL1 bits [31:0] are architecturally mapped to External register DBGCLAIMCLR_EL1[31:0].

AArch64 System register DBGCLAIMCLR_EL1 bits [31:0] are architecturally mapped to External register DBGCLAIMSET_EL1[31:0].

Attributes

DBGCLAIMCLR_EL1 is a 64-bit register.

Field descriptions



Bits [63:32]

Reserved, RES0.

Bits [31:8]

D12.3.6 DBGDTR_EL0, Debug Data Transfer Register, half-duplex

The DBGDTR_EL0 characteristics are:

Purpose

Transfers 64 bits of data between the PE and an external debugger. Can transfer both ways using only a single register.

Configuration

When written, AArch64 System register DBGDTR_EL0 bits [63:32] are architecturally mapped to External register DBGDTRRX_EL0[31:0].

When written, AArch64 System register DBGDTR_EL0 bits [63:32] are architecturally mapped to AArch64 System register DBGDTRRX_EL0[31:0].

When written, AArch64 System register DBGDTR_EL0 bits [31:0] are architecturally mapped to External register DBGDTRTX_EL0[31:0].

When written, AArch64 System register DBGDTR_EL0 bits [31:0] are architecturally mapped to AArch64 System register DBGDTRTX_EL0[31:0].

When read, AArch64 System register DBGDTR_EL0 bits [63:32] are architecturally mapped to External register DBGDTRTX_EL0[31:0].

When read, AArch64 System register DBGDTR_EL0 bits [63:32] are architecturally mapped to AArch64 System register DBGDTRTX_EL0[31:0].

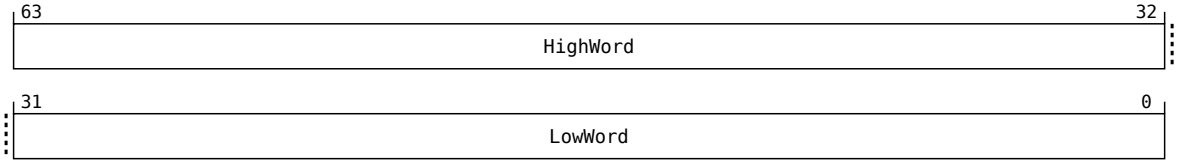
When read, AArch64 System register DBGDTR_EL0 bits [31:0] are architecturally mapped to External register DBGDTRRX_EL0[31:0].

When read, AArch64 System register DBGDTR_EL0 bits [31:0] are architecturally mapped to AArch64 System register DBGDTRRX_EL0[31:0].

Attributes

DBGDTR_EL0 is a 64-bit register.

Field descriptions



HighWord, bits [63:32]

Writes to this register set DTRRX to the value in this field and do not change RXfull.

Reads of this register:

- If RXfull is 1, return the last value written to DTRTX.
- If RXfull is 0, return an UNKNOWN value.

After the read, RXfull is cleared to 0.

LowWord, bits [31:0]

Writes to this register set DTRTX to the value in this field and set TXfull to 1.

Reads of this register:

- If RXfull is 1, return the last value written to DTRRX.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- If RXfull is 0, return an UNKNOWN value.

After the read, RXfull is cleared to 0.

Accessing DBGDTR_EL0

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, DBGDTR_EL0

op0	op1	CRn	CRm	op2
0b10	0b011	0b0000	0b0100	0b000

```
if Halted() then
    X[t, 64] = Read_DBGDTR_EL0(64);
elsif PSTATE.EL == EL0 then
    if MDSCR_EL1.TDCC == '1' then

D12.3.7 DBGDTRRX_EL0, Debug Data Transfer Register, Receive

The DBGDTRRX_EL0 characteristics are:

Purpose

Transfers data from an external debugger to the PE. For example, it is used by a debugger transferring commands and data to a debug target. See DBGDTR_EL0 for additional architectural mappings. It is a component of the Debug Communications Channel.

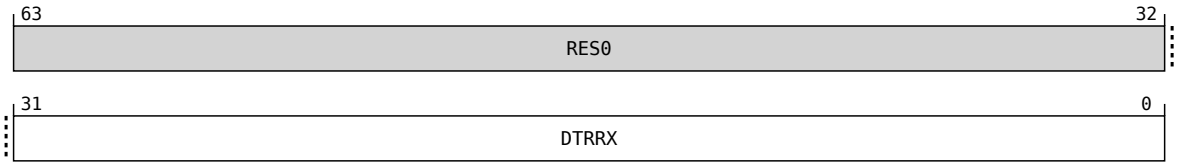
Configuration

AArch64 System register DBGDTRRX_EL0 bits [31:0] are architecturally mapped to External register DBGDTRRX_EL0[31:0].

Attributes

DBGDTRRX_EL0 is a 64-bit register.

Field descriptions



Bits [63:32]

Reserved, RES0.

DTRRX, bits [31:0]

DTRRX. Reads of this register:

- If RXfull is 1, return the last value written to DTRRX.
- If RXfull is 0, return an UNKNOWN value.

After the read, RXfull is cleared to 0.

For the full behavior of the Debug Communications Channel, see 'The Debug Communication Channel and Instruction Transfer Register'.

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

Accessing DBGDTRRX_EL0

Accesses to this register use the following encodings in the System register encoding space:

```
MRS <Xt>, DBGDTRRX_EL0
```

op0	op1	CRn	CRm	op2
0b10	0b011	0b0000	0b0101	0b000

```
if Halted() then
    X[t, 32] = Read_DBGDTR_EL0(32);

D12.3.8 DBGDTRTX_EL0, Debug Data Transfer Register, Transmit

The DBGDTRTX_EL0 characteristics are:

Purpose

Transfers data from the PE to an external debugger. For example, it is used by a debug target to transfer data to the debugger. See DBGDTR_EL0 for additional architectural mappings. It is a component of the Debug Communication Channel.

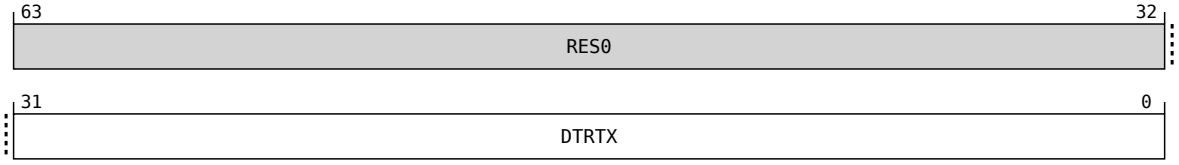
Configuration

AArch64 System register DBGDTRTX_EL0 bits [31:0] are architecturally mapped to External register DBGDTRTX_EL0[31:0].

Attributes

DBGDTRTX_EL0 is a 64-bit register.

Field descriptions



Bits [63:32]

Reserved, RES0.

DTRTX, bits [31:0]

DTRTX. Writes to this register:

- If TXfull is 1, DTRTX is set to an UNKNOWN value.
- If TXfull is 0, update the value in DTRTX.

After the write, TXfull is set to 1.

For the full behavior of the Debug Communications Channel, see 'The Debug Communication Channel and Instruction Transfer Register'.

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

Accessing DBGDTRTX_EL0

Accesses to this register use the following encodings in the System register encoding space:

```
MSR DBGDTRTX_EL0, <Xt>

D12.3.9 DBGPRCR_EL1, Debug Power Control Register

The DBGPRCR_EL1 characteristics are:

Purpose

Controls behavior of the PE on powerdown request.

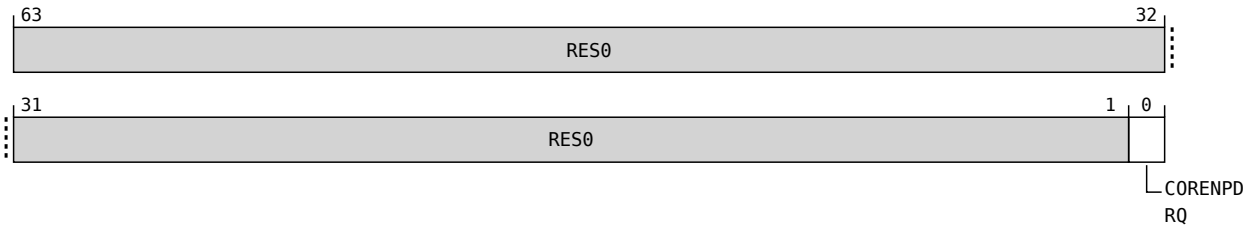
Configuration

AArch64 System register DBGPRCR_EL1 bit [0] is architecturally mapped to External register EDPRCR[0].

Attributes

DBGPRCR_EL1 is a 64-bit register.

Field descriptions



Bits [63:1]

Reserved, RES0.

CORENPDRQ, bit [0]

When FEAT_DoPD is implemented:

Core no powerdown request. Requests emulation of powerdown.

This request is typically passed to an external power controller. This means that whether a request causes power up is dependent on the IMPLEMENTATION DEFINED nature of the system. The power controller must not allow the Core power domain to switch off while this bit is 1.

CORENPDRQ	Meaning
0b0	If the system responds to a powerdown request, it powers down Core power domain.
0b1	If the system responds to a powerdown request, it does not powerdown the Core power domain, but instead emulates a powerdown of that domain.

In an implementation that includes the recommended external debug interface, this bit drives the **DBGNOPWRDWN** signal.

It is IMPLEMENTATION DEFINED whether this bit is reset to its Cold reset value on exit from an IMPLEMENTATION DEFINED software-visible retention state. For more information about retention states see 'Core power domain power states'.

Note

Writes to this bit are not prohibited by the IMPLEMENTATION DEFINED authentication interface. This means that a debugger can request emulation of powerdown regardless of whether invasive debug is permitted.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

On a Cold reset, if the powerup request is implemented and the powerup request has been asserted, this field is set to an IMPLEMENTATION DEFINED choice of 0 or 1. If the powerup request is not asserted, this field is set to 0.

Otherwise:

Core no powerdown request. Requests emulation of powerdown.

This request is typically passed to an external power controller. This means that whether a request causes power up is dependent on the IMPLEMENTATION DEFINED nature of the system. The power controller must not allow the Core power domain to switch off while this bit is 1.

CORENPDRQ	Meaning
0b0	If the system responds to a powerdown request, it powers down Core power domain.
0b1	If the system responds to a powerdown request, it does not powerdown the Core power domain, but instead emulates a powerdown of that domain.

In an implementation that includes the recommended external debug interface, this bit drives the **DBGNOPWRDWN** signal.

It is IMPLEMENTATION DEFINED whether this bit is reset to the value of EDPRCR.COREPURQ on exit from an IMPLEMENTATION DEFINED software-visible retention state. For more information about retention states see 'Core power domain power states'.

Note

Writes to this bit are not prohibited by the IMPLEMENTATION DEFINED authentication interface. This means that a debugger can request emulation of powerdown regardless of whether invasive debug is permitted.

The reset behavior of this field is:

- On a Cold reset, this field resets to the value in EDPRCR.COREPURQ.

Accessing DBGPRCR_EL1

Accesses to this register use the following encodings in the System register encoding space:

`MRS <Xt>, DBGPRCR_EL1`

op0	op1	CRn	CRm	op2
0b10	0b000	0b0001	0b0100	0b100

```
if PSTATE.EL == EL0 then
    UNDEFINED;
elsif PSTATE.EL == EL1 then
    if MDCR_EL2.<TDE,TDOSA> != '00' then
        AArch64.SystemAccessTrap(EL2, 0x18);
    else
        X[t, 64] = DBGPRCR_EL1;
elsif PSTATE.EL == EL2 then
    X[t, 64] = DBGPRCR_EL1;
```

`MSR DBGPRCR_EL1, <Xt>`

D12.3.10 DBGWCR<n>_EL1, Debug Watchpoint Control Registers, n = 0 - 63

The DBGWCR<n>_EL1 characteristics are:

Purpose

Holds control information for a watchpoint. Forms watchpoint n together with value register DBGWVR<n>_EL1.

Configuration

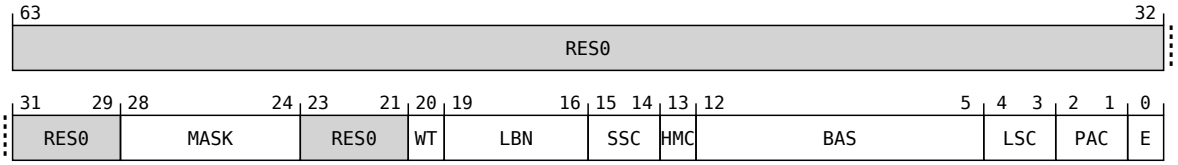
If watchpoint n is not implemented then accesses to this register are UNDEFINED.

AArch64 System register DBGWCR<n>_EL1 bits [31:0] are architecturally mapped to External register DBGWCR<n>_EL1[31:0].

Attributes

DBGWCR<n>_EL1 is a 64-bit register.

Field descriptions



Bits [63:29]

Reserved, RES0.

MASK, bits [28:24]

Address Mask. Only address ranges up to 2GB can be watched using a single mask.

MASK	Meaning
0b00000	No mask.
0b00011..0b11111	Number of address bits masked.

All other values are reserved.

Indicates the number of masked address bits, from 0b00011 masking 3 address bits (0x00000007 mask for address) to 0b11111 masking 31 address bits (0x7FFFFFFF mask for address).

If programmed with a reserved value, the watchpoint behaves as if one of the following:

- DBGWCR<n>_EL1.MASK has been programmed with a defined value, which might be 0b00000 (no mask), other than for a direct read of DBGWCR<n>_EL1.
- The watchpoint is disabled.

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

Bits [23:21]

Reserved, RES0.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

WT, bit [20]

Watchpoint type. Possible values are:

WT	Meaning
0b0	Unlinked watchpoint.
0b1	Linked watchpoint.

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

LBN, bits [19:16]

Linked Breakpoint Number.

For Linked data address watchpoints, specifies the index of the breakpoint linked to.

For all other watchpoint types, this field is ignored and reads of the register return an UNKNOWN value.

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

SSC, bits [15:14]

Security state control. Determines the Security states under which a Watchpoint debug event for watchpoint n is generated.

The fields that indicate when the watchpoint can be generated are: HMC, PAC, and SSC. These fields must be considered in combination, and the values that are permitted for these fields are constrained.

For more information on the operation of these fields, see 'Execution conditions for which a watchpoint generates Watchpoint exceptions'.

For more information on the effect of programming the fields to a reserved value, see 'Reserved DBGWCR<n>_EL1.{SSC, HMC, PAC} values'.

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

HMC, bit [13]

Higher mode control. Determines the debug perspective for deciding when a Watchpoint debug event for watchpoint n is generated.

The fields that indicate when the watchpoint can be generated are: HMC, PAC, and SSC. These fields must be considered in combination, and the values that are permitted for these fields are constrained.

For more information on the operation of these fields, see 'Execution conditions for which a watchpoint generates Watchpoint exceptions'.

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

BAS, bits [12:5]

Byte address select. Each bit of this field selects whether a byte from within the word or double-word addressed by DBGWVR<n>_EL1 is being watched.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

BAS	Description
xxxxxxx1	Match byte at DBGWVR<n>_EL1
xxxxxx1x	Match byte at DBGWVR<n>_EL1 + 1
xxxxx1xx	Match byte at DBGWVR<n>_EL1 + 2
xxxx1xxx	Match byte at DBGWVR<n>_EL1 + 3

In cases where DBGWVR<n>_EL1 addresses a double-word:

BAS	Description, if DBGWVR<n>_EL1[2] == 0
xxx1xxxx	Match byte at DBGWVR<n>_EL1 + 4
xx1xxxxx	Match byte at DBGWVR<n>_EL1 + 5
x1xxxxxx	Match byte at DBGWVR<n>_EL1 + 6
1xxxxxxx	Match byte at DBGWVR<n>_EL1 + 7

If DBGWVR<n>_EL1[2] == 1, only BAS[3:0] are used and BAS[7:4] are ignored. Arm deprecates setting DBGWVR<n>_EL1[2] == 1.

The valid values for BAS are nonzero binary numbers all of whose set bits are contiguous. All other values are reserved and must not be used by software. See 'Reserved DBGWCR<n>_EL1.BAS values'.

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

LSC, bits [4:3]

Load/store control. This field enables watchpoint matching on the type of access being made. Possible values of this field are:

LSC	Meaning
0b01	Match instructions that load from a watchpointed address.
0b10	Match instructions that store to a watchpointed address.
0b11	Match instructions that load from or store to a watchpointed address.

All other values are reserved, but must behave as if the watchpoint is disabled. Software must not rely on this property as the behavior of reserved values might change in a future revision of the architecture.

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

PAC, bits [2:1]

Privilege of access control. Determines the Exception level or levels at which a Watchpoint debug event for watchpoint n is generated.

The fields that indicate when the watchpoint can be generated are: HMC, PAC, and SSC. These fields must be considered in combination, and the values that are permitted for these fields are constrained.

For more information on the operation of these fields, see 'Execution conditions for which a watchpoint generates Watchpoint exceptions'.

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

E, bit [0]

Enable watchpoint n.

E	Meaning
0b0	Watchpoint n disabled.
0b1	Watchpoint n enabled.

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

Accessing DBGWCR<n>_EL1

Accesses to this register use the following encodings in the System register encoding space:

```
MRS <Xt>, DBGWCR<m>_EL1 ; Where m = 0-15
```

op0	op1	CRn	CRm	op2
0b10	0b000	0b0000	m[3:0]	0b111

```

D12.3.11 DBGWVR<n>_EL1, Debug Watchpoint Value Registers, n = 0 - 63

The DBGWVR<n>_EL1 characteristics are:

Purpose

Holds a data address value for use in watchpoint matching. Forms watchpoint n together with control register DBGWCR<n>_EL1.

Configuration

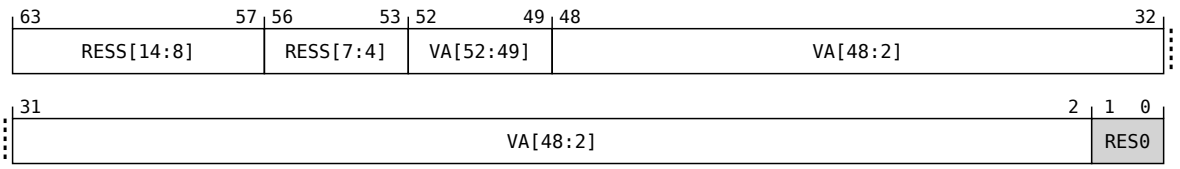
If watchpoint n is not implemented then accesses to this register are UNDEFINED.

AArch64 System register DBGWVR<n>_EL1 bits [63:0] are architecturally mapped to External register DBGWVR<n>_EL1[63:0].

Attributes

DBGWVR<n>_EL1 is a 64-bit register.

Field descriptions



RESS[14:8], bits [63:57]

Reserved, Sign extended. Software must set all bits in this field to the same value as the most significant bit of the VA field. If all bits in this field are not the same value as the most significant bit of the VA field, then all of the following apply:

- It is CONSTRAINED UNPREDICTABLE whether the PE ignores this field when comparing an address.
- It is IMPLEMENTATION DEFINED whether the value read back in each bit of this field is a copy of the most significant bit of the VA field or the value written.

RESS[7:4], bits [56:53]

Extension to RESS[14:8]. For more information, see RESS[14:8].

Bits [52:49]

When FEAT_LVA is implemented:

VA[52:49], bits [52:49]

Extension to VA[48:2]. For more information, see VA[48:2].

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

RESS[3:0], bits [52:49]

Extension to RESS[14:8]. For more information, see RESS[14:8].

VA[48:2], bits [48:2]

Bits[48:2] of the address value for comparison.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

When FEAT_LVA is implemented, VA[52:49] forms the upper part of the address value. If FEAT_LVA is not implemented, bits [52:49] are part of the RESS field.

Arm deprecates setting DBGWVR<n>_EL1[2] == 1.

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

Bits [1:0]

Reserved, RES0.

Accessing DBGWVR<n>_EL1

Accesses to this register use the following encodings in the System register encoding space:

```
MRS <Xt>, DBGWVR<m>_EL1 ; Where m = 0-15
```

op0	op1	CRn	CRm	op2
0b10	0b000	0b0000	m[3:0]	0b110

```
integer m = UInt(CRm<3:0>);

D12.3.12 DLR_EL0, Debug Link Register

The DLR_EL0 characteristics are:

Purpose

In Debug state, holds the address to restart from.

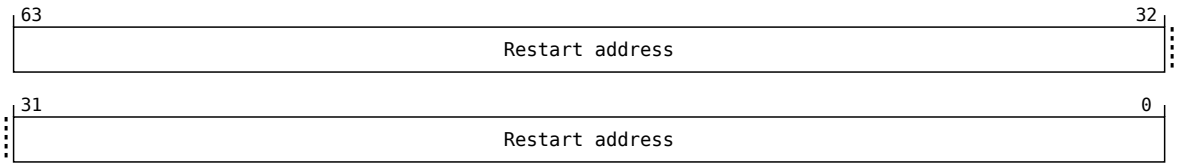
Configuration

There are no configuration notes.

Attributes

DLR_EL0 is a 64-bit register.

Field descriptions



ADDR, bits [63:0]

Restart address.

Accessing DLR_EL0

Accesses to this register use the following encodings in the System register encoding space:

`MRS <Xt>, DLR_EL0`

op0	op1	CRn	CRm	op2
0b11	0b011	0b0100	0b0101	0b001

```
if !Halted() then
    UNDEFINED;
else
    X[t, 64] = DLR_EL0;
```

`MSR DLR_EL0, <Xt>`

op0	op1	CRn	CRm	op2
0b11	0b011	0b0100	0b0101	0b001

```
if !Halted() then
    UNDEFINED;
else
    DLR_EL0 = X[t, 64];
```

D12.3.13 DSPSR_EL0, Debug Saved Program Status Register

The DSPSR_EL0 characteristics are:

Purpose

Holds the saved process state for Debug state. On entering Debug state, PSTATE information is written to this register. On exiting Debug state, values are copied from this register to PSTATE.

Configuration

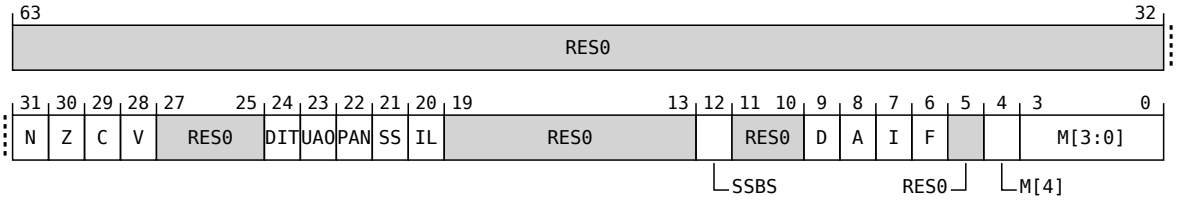
There are no configuration notes.

Attributes

DSPSR_EL0 is a 64-bit register.

Field descriptions

When entering or exiting Debug state from or to AArch64 state:



Bits [63:32]

Reserved, RES0.

N, bit [31]

Negative Condition flag. Set to the value of PSTATE.N on entering Debug state, and copied to PSTATE.N on exiting Debug state.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Z, bit [30]

Zero Condition flag. Set to the value of PSTATE.Z on entering Debug state, and copied to PSTATE.Z on exiting Debug state.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

C, bit [29]

Carry Condition flag. Set to the value of PSTATE.C on entering Debug state, and copied to PSTATE.C on exiting Debug state.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

V, bit [28]

Overflow Condition flag. Set to the value of PSTATE.V on entering Debug state, and copied to PSTATE.V on exiting Debug state.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [27:25]

Reserved, RES0.

DIT, bit [24]

When FEAT_DIT is implemented:

Data Independent Timing. Set to the value of PSTATE.DIT on entering Debug state, and copied to PSTATE.DIT on exiting Debug state.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

UAO, bit [23]

When FEAT_UAO is implemented:

User Access Override. Set to the value of PSTATE.UAO on entering Debug state, and copied to PSTATE.UAO on exiting Debug state.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

PAN, bit [22]

When FEAT_PAN is implemented:

Privileged Access Never. Set to the value of PSTATE.PAN on entering Debug state, and copied to PSTATE.PAN on exiting Debug state.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

SS, bit [21]

Software Step. Set to the value of PSTATE.SS on entering Debug state, and conditionally copied to PSTATE.SS on exiting Debug state.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

IL, bit [20]

Illegal Execution state. Set to the value of PSTATE.IL on entering Debug state, and copied to PSTATE.IL on exiting Debug state.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Bits [19:13]

Reserved, RES0.

SSBS, bit [12]

When FEAT_SSBS is implemented:

Speculative Store Bypass. Set to the value of PSTATE.SSBS on entering Debug state, and copied to PSTATE.SSBS on exiting Debug state.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bits [11:10]

Reserved, RES0.

D, bit [9]

Debug exception mask. Set to the value of PSTATE.D on entering Debug state, and copied to PSTATE.D on exiting Debug state.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

A, bit [8]

SError exception mask. Set to the value of PSTATE.A on entering Debug state, and copied to PSTATE.A on exiting Debug state.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

I, bit [7]

IRQ interrupt mask. Set to the value of PSTATE.I on entering Debug state, and copied to PSTATE.I on exiting Debug state.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

F, bit [6]

FIQ interrupt mask. Set to the value of PSTATE.F on entering Debug state, and copied to PSTATE.F on exiting Debug state.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [5]

Reserved, RES0.

M[4], bit [4]

Execution state. Set to `0b0`, the value of PSTATE.nRW, on entering Debug state from AArch64 state, and copied to PSTATE.nRW on exiting Debug state.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

M[4]	Meaning
0b0	AArch64 execution state.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

M[3:0], bits [3:0]

AArch64 Exception level and selected Stack Pointer.

M[3:0]	Meaning
0b0000	EL0.
0b0100	EL1 with SP_EL0 (EL1t).
0b0101	EL1 with SP_EL1 (EL1h).
0b1000	EL2 with SP_EL0 (EL2t).
0b1001	EL2 with SP_EL2 (EL2h).

Other values are reserved. If DSPSR_EL0.M[3:0] has a Reserved value, or a value for an unimplemented Exception level, exiting Debug state is an illegal return event, as described in 'Illegal return events from AArch64 state'.

The bits in this field are interpreted as follows:

- M[3:2] is set to the value of PSTATE.EL on entering Debug state and copied to PSTATE.EL on exiting Debug state.
- M[1] is unused and is 0 for all non-reserved values.
- M[0] is set to the value of PSTATE.SP on entering Debug state and copied to PSTATE.SP on exiting Debug state.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing DSPSR_EL0

Accesses to this register use the following encodings in the System register encoding space:

`MRS <Xt>, DSPSR_EL0`

op0	op1	CRn	CRm	op2
0b11	0b011	0b0100	0b0101	0b000

```
if !Halted() then
    UNDEFINED;
else
    X[t, 64] = DSPSR_EL0;
```

`MSR DSPSR_EL0, <Xt>`

op0	op1	CRn	CRm	op2
0b11	0b011	0b0100	0b0101	0b000

```
if !Halted() then
    UNDEFINED;
else
    DSPSR_EL0 = X[t, 64];
```

D12.3.14 MDCCINT_EL1, Monitor DCC Interrupt Enable Register

The MDCCINT_EL1 characteristics are:

Purpose

Enables interrupt requests to be signaled based on the DCC status flags.

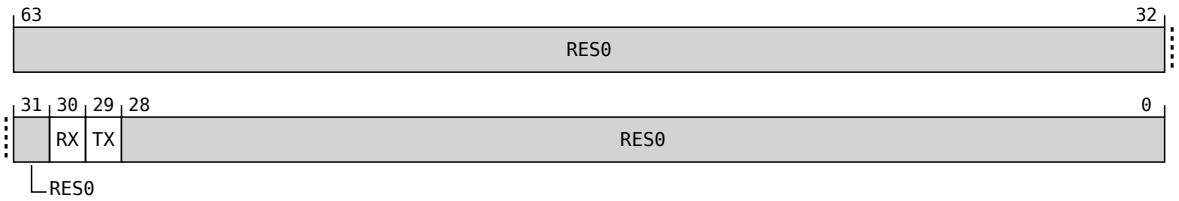
Configuration

There are no configuration notes.

Attributes

MDCCINT_EL1 is a 64-bit register.

Field descriptions



Bits [63:31]

Reserved, RES0.

RX, bit [30]

DCC interrupt request enable control for DTRRX. Enables a common **COMMIRQ** interrupt request to be signaled based on the DCC status flags.

RX	Meaning
0b0	No interrupt request generated by DTRRX.
0b1	Interrupt request will be generated on RXfull == 1.

If legacy **COMMRX** and **COMMTX** signals are implemented, then these are not affected by the value of this bit.

The reset behavior of this field is:

- On a Warm reset, this field resets to '0'.

TX, bit [29]

DCC interrupt request enable control for DTRTX. Enables a common **COMMIRQ** interrupt request to be signaled based on the DCC status flags.

TX	Meaning
0b0	No interrupt request generated by DTRTX.
0b1	Interrupt request will be generated on TXfull == 0.

If legacy **COMMRX** and **COMMTX** signals are implemented, then these are not affected by the value of this bit.

The reset behavior of this field is:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- On a Warm reset, this field resets to '0'.

Bits [28:0]

Reserved, RES0.

Accessing MDCCINT_EL1

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, MDCCINT_EL1

op0	op1	CRn	CRm	op2
0b10	0b000	0b0000	0b0010	0b000

```
if PSTATE.EL == EL0 then
    UNDEFINED;
elsif Halted() && ConstrainUnpredictableBool(Unpredictable_IGNORETRAPINDEBUG) then
    X[t, 64] = MDCCINT_EL1;
elsif PSTATE.EL == EL1 then
    if MDCR_EL2.<TDE,TDA> != '00' then

D12.3.15 MDCCSR_EL0, Monitor DCC Status Register

The MDCCSR_EL0 characteristics are:

Purpose

Read-only register containing control status flags for the DCC.

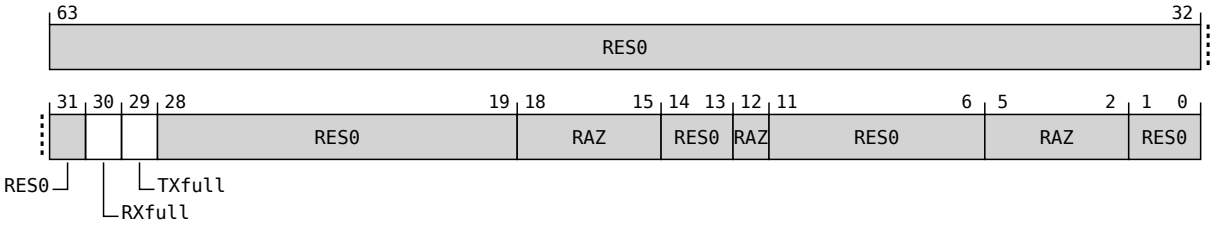
Configuration

AArch64 System register MDCCSR_EL0 bits [30:29] are architecturally mapped to External register EDSCR[30:29].

Attributes

MDCCSR_EL0 is a 64-bit register.

Field descriptions



Bits [63:31]

Reserved, RES0.

RXfull, bit [30]

DTRRX full. Read-only view of the equivalent bit in the EDSCR.

The reset behavior of this field is:

- On a Cold reset, this field resets to '0'.

TXfull, bit [29]

DTRTX full. Read-only view of the equivalent bit in the EDSCR.

The reset behavior of this field is:

- On a Cold reset, this field resets to '0'.

Bits [28:19]

Reserved, RES0.

Bits [18:15]

Reserved, RAZ.

Bits [14:13]

Reserved, RES0.

Bit [12]

Reserved, RAZ.

Non-Confidential

Bits [11:6]

Reserved, RES0.

Bits [5:2]

Reserved, RAZ.

Bits [1:0]

Reserved, RES0.

Accessing MDCCSR_EL0

Accesses to this register use the following encodings in the System register encoding space:

`MRS <Xt>, MDCCSR_EL0`

op0	op1	CRn	CRm	op2
0b10	0b011	0b0000	0b0001	0b000

```
if Halted() && ConstrainUnpredictableBool(Unpredictable_IGNORETRAPINDEBUG) then
    X[t, 64] = MDCCSR_EL0;
elsif PSTATE.EL == EL0 then
    if MDSCR_EL1.TDCC == '1' then
        if HCR_EL2.TGE == '1' then
            AArch64.SystemAccessTrap(EL2, 0x18);
        else
            AArch64.SystemAccessTrap(EL1, 0x18);
    elsif HCR_EL2.TGE == '1' || MDCR_EL2.<TDE,TDA> != '00' then
        AArch64.SystemAccessTrap(EL2, 0x18);
    else
        X[t, 64] = MDCCSR_EL0;
elsif PSTATE.EL == EL1 then
    if MDCR_EL2.<TDE,TDA> != '00' then
        AArch64.SystemAccessTrap(EL2, 0x18);
    else
        X[t, 64] = MDCCSR_EL0;
elsif PSTATE.EL == EL2 then
    X[t, 64] = MDCCSR_EL0;
```

D12.3.16 MDCR_EL2, Monitor Debug Configuration Register (EL2)

The MDCR_EL2 characteristics are:

Purpose

Provides EL2 configuration options for self-hosted debug and the Performance Monitors Extension.

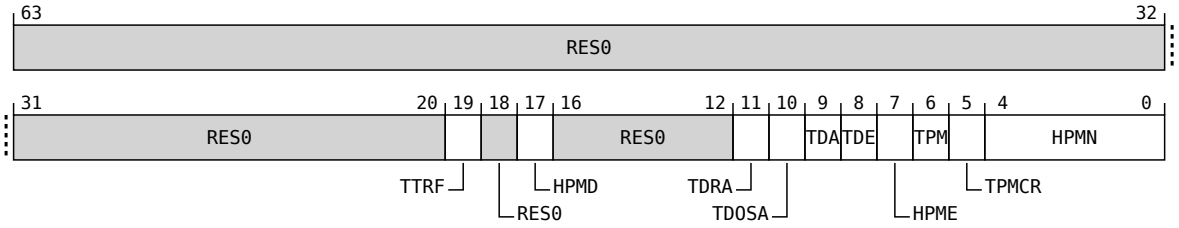
Configuration

There are no configuration notes.

Attributes

MDCR_EL2 is a 64-bit register.

Field descriptions



Bits [63:20]

Reserved, RES0.

TTRF, bit [19]

When FEAT_TRF is implemented:

Traps use of the Trace Filter Control registers at EL1 to EL2, as follows:

- Access to TRFCR_EL1 is trapped to EL2, reported using EC syndrome value `0x18`.

TTRF	Meaning
`0b0`	Accesses to the specified registers at EL1 are not affected by this control.
`0b1`	Accesses to the specified registers at EL1 generate a trap exception to EL2 when EL2 is enabled in the current Security state.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bit [18]

Reserved, RES0.

HPMD, bit [17]

When FEAT_PMUv3p1 is implemented and FEAT_Debugv8p2 is implemented:

Guest Performance Monitors Disable. Controls PMU operation at EL2.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

HPMD	Meaning
0b0	Counters are not affected by this mechanism.
0b1	Affected counters are prohibited from counting at EL2. If PMCR_EL0.DP is 1, then PMCCNTR_EL0 is disabled at EL2. Otherwise, PMCCNTR_EL0 is not affected by this mechanism.

The counters affected by this field are:

- Event counters in the first range.
- If PMCR_EL0.DP is 1, the cycle counter PMCCNTR_EL0.

Other event counters are not affected by this field.

When PMCR_EL0.DP is 0, PMCCNTR_EL0 is not affected by this field.

The reset behavior of this field is:

- On a Warm reset, this field resets to '0'.

When FEAT_PMUv3p1 is implemented:

Guest Performance Monitors Disable. Controls PMU operation at EL2 when ExternalSecureNoninvasiveDebugEnabled() is FALSE.

HPMD	Meaning
0b0	Counters are not affected by this mechanism.
0b1	If ExternalSecureNoninvasiveDebugEnabled() is FALSE, then all the following apply: • Affected event counters are prohibited from counting at EL2. • If PMCR_EL0.DP is 1, then PMCCNTR_EL0 is disabled at EL2. Otherwise, PMCCNTR_EL0 is not affected by this mechanism.

If ExternalSecureNoninvasiveDebugEnabled() is TRUE, then the event counters and PMCCNTR_EL0 are not affected by this field.

Otherwise, the counters affected by this field are:

- Event counters in the first range.
- If PMCR_EL0.DP is 1, the cycle counter, PMCCNTR_EL0.

Other event counters are not affected by this field. When PMCR_EL0.DP is 0, PMCCNTR_EL0 is not affected by this field.

The reset behavior of this field is:

- On a Warm reset, this field resets to '0'.

Otherwise:

Reserved, RES0.

Bits [16:12]

Reserved, RES0.

TDRA, bit [11]

Trap Debug ROM Address register access. Traps System register accesses to the Debug ROM registers to EL2 when EL2 is enabled in the current Security state as follows:

- If EL1 is using AArch64, accesses to MDRAR_EL1 are trapped to EL2, reported using EC syndrome value 0x18.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

TDRA	Meaning
0b0	This control does not cause any instructions to be trapped.
0b1	EL0 and EL1 System register accesses to the Debug ROM registers are trapped to EL2 when EL2 is enabled in the current Security state, unless it is trapped by the following: • MDSCR_EL1.TDCC.

This field is treated as being 1 for all purposes other than a direct read when one or more of the following are true:

- MDCR_EL2.TDE == 1.
- HCR_EL2.TGE == 1.

Note

EL2 does not provide traps on debug register accesses through the optional memory-mapped external debug interfaces.

System register accesses to the debug registers might have side-effects. When a System register access is trapped to EL2, no side-effects occur before the exception is taken to EL2.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

TDOSA, bit [10]

When FEAT_DoubleLock is implemented:

Trap debug OS-related register access. Traps EL1 System register accesses to the powerdown debug registers to EL2, from both Execution states as follows:

- In AArch64 state, accesses to the following registers are trapped to EL2, reported using EC syndrome value 0x18:
  - OSLAR_EL1, OSLSR_EL1, OSDLR_EL1, and DBGPRCR_EL1.
  - Any IMPLEMENTATION DEFINED register with similar functionality that the implementation specifies as trapped by this bit.

TDOSA	Meaning
0b0	This control does not cause any instructions to be trapped.
0b1	EL1 System register accesses to the powerdown debug registers are trapped to EL2 when EL2 is enabled in the current Security state.

Note

These registers are not accessible at EL0.

This field is treated as being 1 for all purposes other than a direct read when one or more of the following are true:

- MDCR_EL2.TDE == 1.
- HCR_EL2.TGE == 1.

System register accesses to the debug registers might have side-effects. When a System register access is trapped to EL2, no side-effects occur before the exception is taken to EL2.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Otherwise:

Trap debug OS-related register access. Traps EL1 System register accesses to the powerdown debug registers to EL2, from both Execution states as follows:

- In AArch64 state, accesses to the following registers are trapped to EL2, reported using EC syndrome value `0x18`:
  - OSLAR_EL1, OSLSR_EL1, and DBGPRCR_EL1.
  - Any IMPLEMENTATION DEFINED register with similar functionality that the implementation specifies as trapped by this bit.

It is IMPLEMENTATION DEFINED whether accesses to OSDLR_EL1 are trapped.

TDOSA	Meaning
`0b0`	This control does not cause any instructions to be trapped.
`0b1`	EL1 System register accesses to the powerdown debug registers are trapped to EL2 when EL2 is enabled in the current Security state.

Note

These registers are not accessible at EL0.

This field is treated as being 1 for all purposes other than a direct read when one or more of the following are true:

- MDCR_EL2.TDE == 1.
- HCR_EL2.TGE == 1.

Note

EL2 does not provide traps on debug register accesses through the optional memory-mapped external debug interfaces.

System register accesses to the debug registers might have side-effects. When a System register access is trapped to EL2, no side-effects occur before the exception is taken to EL2.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

TDA, bit [9]

Trap accesses of debug System registers. Enables a trap to EL2 on accesses of debug System registers.

TDA	Meaning
`0b0`	Accesses of the specified debug System registers are not trapped by this mechanism.
`0b1`	Accesses of the specified debug System registers at EL1 and EL0 are trapped to EL2, unless the instruction generates a higher priority exception.

In AArch64 state, the instructions affected by this control are:

- `MRS` and `MSR` accesses to DBGAUTHSTATUS_EL1, DBGBCR<n>_EL1, DBGBVR<n>_EL1, DBGCLAIMCLR_EL1, DBGCLAIMSET_EL1, DBGWCR<n>_EL1, DBGWVR<n>_EL1, MDCCINT_EL1, MDCCSR_EL0, MDSCR_EL1, OSDTRRX_EL1, OSDTRTX_EL1, and OSECCR_EL1.
- In Non-debug state, `MRS` accesses to DBGDTRRX_EL0 and DBGDTR_EL0 and `MSR` accesses to DBGDTRTX_EL0 and DBGDTR_EL0.

Trapped AArch64 instructions are reported using EC syndrome value `0x18`.

The following instructions are not trapped in Debug state:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- AArch64 MRS accesses to DBGDTRRX_EL0 and DBGDTR_EL0 and MSR accesses to DBGDTRTX_EL0 and DBGDTR_EL0.
- AArch32 MRC accesses to DBGDTRRXint and MCR accesses to DBGDTRTXint.

This field is ignored by the PE and treated as one when any of the following are true:

- MDCR_EL2.TDE == 1.
- HCR_EL2.TGE == 1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

TDE, bit [8]

Trap Debug Exceptions. Controls routing of Debug exceptions, and defines the debug target Exception level, EL_D.

TDE	Meaning
0b0	The debug target Exception level is EL1.
0b1	If EL2 is enabled for the current Effective value of SCR_EL3.NS, the debug target Exception level is EL2, otherwise the debug target Exception level is EL1. The MDCR_EL2.{TDRA, TDOSA, TDA} fields are treated as being 1 for all purposes other than returning the result of a direct read of the register.

For more information, see 'Routing debug exceptions'.

This field is treated as being 1 for all purposes other than a direct read when HCR_EL2.TGE == 1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

HPME, bit [7]

When FEAT_PMUv3 is implemented:

Hyp Enable.

HPME	Meaning
0b0	Affected counters are disabled and do not count.
0b1	Affected counters are enabled by PMCNTENSET_EL0.

The counters affected by this field are the event counters in the second range.

The following counters are not affected by this field:

- Other event counters.
- PMCCNTR_EL0.

If MDCR_EL2.HPMN is equal to `GetNumEventCountersSelfHosted()`, then this field has no effect.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

TPM, bit [6]

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

When FEAT_PMUv3 is implemented:

Trap accesses of PMU registers. Enables a trap to EL2 on accesses of PMU registers.

TPM	Meaning
0b0	Accesses of the specified PMU registers are not trapped by this mechanism.
0b1	Accesses of the specified PMU registers at EL1 and EL0 are trapped to EL2, unless the instruction generates a higher priority exception.

In AArch64 state, the instructions affected by this control are:

- MRS and MSR accesses to PMCCFILTR_EL0, PMCCNTR_EL0, PMCNTENCLR_EL0, PMCNTENSET_EL0, PMCR_EL0, PMEVCNTR<n>_EL0, PMEVTYPER<n>_EL0, PMINTENCLR_EL1, PMINTENSET_EL1, PMOVSCLR_EL0, PMOVSSET_EL0, PMSELR_EL0, PMSWINC_EL0, PMUSERENR_EL0, PMXEVCNTR_EL0, and PMXEVTYPER_EL0.
- MRS accesses to PMCEID0_EL0 and PMCEID1_EL0.
- If FEAT_PMUv3p4 is implemented, MRS accesses to PMMIR_EL1.

Trapped AArch64 instructions are reported using EC syndrome value 0x18.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

TPMCR, bit [5]

When FEAT_PMUv3 is implemented:

Trap PMCR_EL0 or PMCR accesses. Traps EL0 and EL1 accesses to EL2, when EL2 is enabled in the current Security state, as follows:

- In AArch64 state, accesses to PMCR_EL0 are trapped to EL2, reported using EC syndrome value 0x18.

TPMCR	Meaning
0b0	This control does not cause any instructions to be trapped.
0b1	EL0 and EL1 accesses to the specified registers are trapped to EL2 when EL2 is enabled in the current Security state, unless they are trapped by the following: • PMUSERENR_EL0.EN.

Note

EL2 does not provide traps on Performance Monitor register accesses through the optional memory-mapped external debug interface.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

HPMN, bits [4:0]

When FEAT_PMUv3 is implemented:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Defines the number of event counters PMEVCNTR<n>_EL0 that are accessible from EL1 and, if permitted, from EL0.

MDCR_EL2.HPMN divides the event counters into a first range and a second range.

If MDCR_EL2.HPMN is not 0 and is less than the number of PMU event counters implemented by the PE, NUM_PMU_COUNTERS, then event counters [0..(MDCR_EL2.HPMN-1)] are in the first range, and the remaining event counters [MDCR_EL2.HPMN..(NUM_PMU_COUNTERS-1)] are in the second range.

The pseudocode function GetNumEventCountersSelfHosted() returns the value NUM_PMU_COUNTERS.

If MDCR_EL2.HPMN is equal to GetNumEventCountersSelfHosted(), or EL2 is not implemented, then all of the following apply:

- All event counters are in the first range.
- No event counters are in the second range.

All of the following apply for an event counter PMEVCNTR<n>_EL0 in the first range:

- The counter is accessible from EL1 and EL2.
- The counter is accessible from EL0 if permitted by PMUSERENR_EL0 or PMUSERENR.
- PMCR_EL0.E and PMCNTENSET_EL0[n] enable the operation of the event counter.

All of the following apply for an event counter PMEVCNTR<n>_EL0 in the second range:

- The counter is only accessible from EL2.
- MDCR_EL2.HPME and PMCNTENSET_EL0[n] enable the operation of the event counter.

Values greater than GetNumEventCountersSelfHosted() and 0 are reserved.

If this field is set to a reserved value, then the following CONSTRAINED UNPREDICTABLE behaviors apply:

- The value returned by a direct read of MDCR_EL2.HPMN is UNKNOWN.
- The number of event counters in each of the first and second ranges is UNKNOWN. That is, either:
  - The PE behaves as if MDCR_EL2.HPMN is set to an UNKNOWN nonzero value less than or equal to NUM_PMU_COUNTERS.
  - All counters are in the second range and none are in the first range.

The reset behavior of this field is:

- On a Warm reset, this field resets to the expression NUM_PMU_COUNTERS.

Otherwise:

Reserved, RES0.

Accessing MDCR_EL2

Accesses to this register use the following encodings in the System register encoding space:

```
MRS <Xt>, MDCR_EL2
```

op0	op1	CRn	CRm	op2
0b11	0b100	0b0001	0b0001	0b001

```
if PSTATE.EL == EL0 then
    UNDEFINED;
elsif PSTATE.EL == EL1 then
    UNDEFINED;
elsif PSTATE.EL == EL2 then
    X[t, 64] = MDCR_EL2;
```

```
MSR MDCR_EL2, <Xt>
```

D12.3.17 MDRAR_EL1, Monitor Debug ROM Address Register

The MDRAR_EL1 characteristics are:

Purpose

Defines the base physical address of a 4KB-aligned memory-mapped debug component, usually a ROM table that locates and describes the memory-mapped debug components in the system. Use of this register is deprecated.

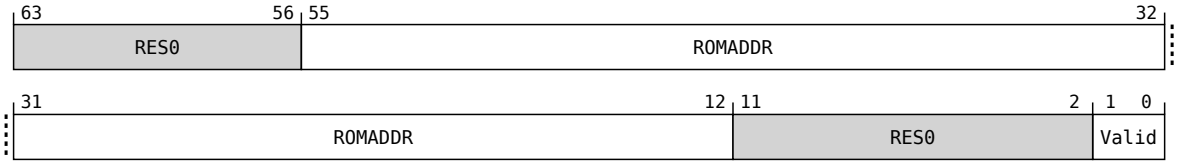
Configuration

There are no configuration notes.

Attributes

MDRAR_EL1 is a 64-bit register.

Field descriptions

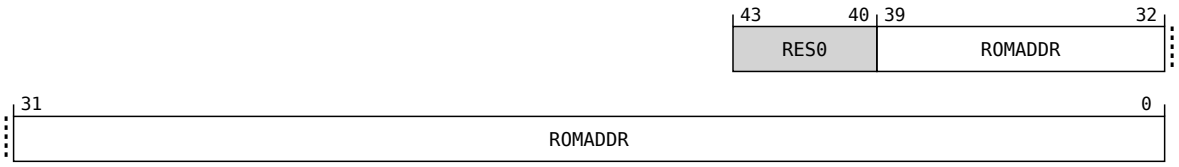


Bits [63:56]

Reserved, RES0.

ROMADDR, bits [55:12]

When FEAT_LPA is implemented and MDRAR_EL1.Valid != '00':



Bits [43:40]

Reserved, RES0.

ROMADDR, bits [39:0]

Bits [51:12] of the ROM table physical address.

Bits [11:0] of the ROM table physical address are zero.

This field has an IMPLEMENTATION DEFINED value.

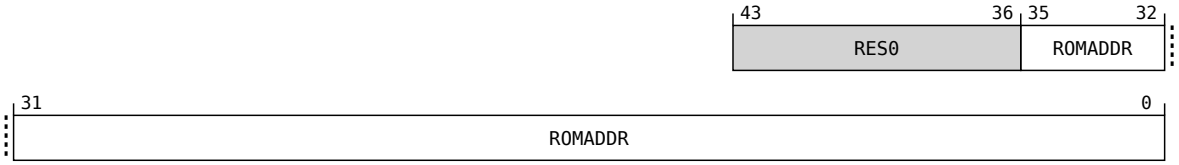
For implementations with fewer than 52 physical address bits, the corresponding upper bits of this field are RES0

In an implementation that includes EL3, ROMADDR is an address in Non-secure memory. It is IMPLEMENTATION DEFINED whether the ROM table is also accessible in Secure memory.

Access to this field is RO.

When FEAT_LPA is not implemented and MDRAR_EL1.Valid != '00':

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential



Bits [43:36]

Reserved, RES0.

ROMADDR, bits [35:0]

Bits [39:12] of the ROM table physical address.

Bits [11:0] of the ROM table physical address are zero.

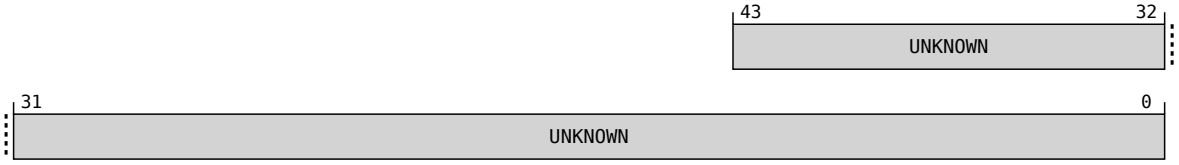
This field has an IMPLEMENTATION DEFINED value.

For implementations with fewer than 48 physical address bits, the corresponding upper bits of this field are RES0

In an implementation that includes EL3, ROMADDR is an address in Non-secure memory. It is IMPLEMENTATION DEFINED whether the ROM table is also accessible in Secure memory.

Access to this field is RO.

When MDRAR_EL1.Valid == '00':



Bits [43:0]

Reserved, UNKNOWN.

Bits [11:2]

Reserved, RES0.

Valid, bits [1:0]

This field indicates whether the ROM Table address is valid.

The value of this field is an IMPLEMENTATION DEFINED choice of:

Valid	Meaning
0b00	ROM Table address is not valid. Software must ignore ROMADDR.
0b11	ROM Table address is valid.

Other values are reserved.

Arm recommends implementations set this field to zero.

Access to this field is RO.

Accessing MDRAR_EL1

Accesses to this register use the following encodings in the System register encoding space:

`MRS <Xt>, MDRAR_EL1`

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

op0	op1	CRn	CRm	op2
0b10	0b000	0b0001	0b0000	0b000

```
if PSTATE.EL == EL0 then
    UNDEFINED;
elsif PSTATE.EL == EL1 then
    if MDCR_EL2.<TDE,TDRA> != '00' then
        AArch64.SystemAccessTrap(EL2, 0x18);
    else
        X[t, 64] = MDRAR_EL1;
elsif PSTATE.EL == EL2 then
    X[t, 64] = MDRAR_EL1;
```

D12.3.18 MDSCR_EL1, Monitor Debug System Control Register

The MDSCR_EL1 characteristics are:

Purpose

Main control register for the debug implementation.

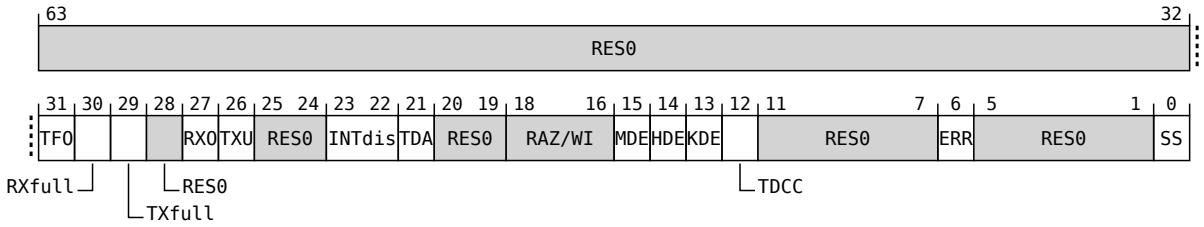
Configuration

AArch64 System register MDSCR_EL1 bits [31:29, 27:26, 23:21, 19, 14, 6] are architecturally mapped to External register EDSCR[31:29, 27:26, 23:21, 19, 14, 6].

Attributes

MDSCR_EL1 is a 64-bit register.

Field descriptions



Bits [63:32]

Reserved, RES0.

TFO, bit [31]

When FEAT_TRF is implemented:

Trace Filter override. Used for save/restore of EDSCR.TFO.

When OSLSR_EL1.OSLK == 0, software must treat this bit as UNK/SBZP.

When OSLSR_EL1.OSLK == 1, this bit holds the value of EDSCR.TFO. Reads and writes of this bit are indirect accesses to EDSCR.TFO.

The reset behavior of this field is:

- On a Cold reset, this field resets to `'0'`.

Accessing this field has the following behavior:

- When OSLSR_EL1.OSLK == '1', access to this field is RW.
- When OSLSR_EL1.OSLK == '0', access to this field is RO.

Otherwise:

Reserved, RES0.

RXfull, bit [30]

Used for save/restore of EDSCR.RXfull.

When OSLSR_EL1.OSLK == 0, software must treat this bit as UNK/SBZP.

When OSLSR_EL1.OSLK == 1, this bit holds the value of EDSCR.RXfull. Reads and writes of this bit are indirect accesses to EDSCR.RXfull.

The reset behavior of this field is:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- On a Cold reset, this field resets to '0'.

Accessing this field has the following behavior:

- When OSLSR_EL1.OSLK == '1', access to this field is RW.
- When OSLSR_EL1.OSLK == '0', access to this field is RO.

TXfull, bit [29]

Used for save/restore of EDSCR.TXfull.

When OSLSR_EL1.OSLK == 0, software must treat this bit as UNK/SBZP.

When OSLSR_EL1.OSLK == 1, this bit holds the value of EDSCR.TXfull. Reads and writes of this bit are indirect accesses to EDSCR.TXfull.

The reset behavior of this field is:

- On a Cold reset, this field resets to '0'.

Accessing this field has the following behavior:

- When OSLSR_EL1.OSLK == '1', access to this field is RW.
- When OSLSR_EL1.OSLK == '0', access to this field is RO.

Bit [28]

Reserved, RES0.

RXO, bit [27]

Used for save/restore of EDSCR.RXO.

When OSLSR_EL1.OSLK == 0, software must treat this bit as UNK/SBZP.

When OSLSR_EL1.OSLK == 1, this bit holds the value of EDSCR.RXO. Reads and writes of this bit are indirect accesses to EDSCR.RXO.

When OSLSR_EL1.OSLK == 1, if bits [27,6] of the value written to MDSCR_EL1 are {1,0}, that is, the RXO bit is 1 and the ERR bit is 0, the PE sets EDSCR.{RXO,ERR} to UNKNOWN values.

The reset behavior of this field is:

- On a Cold reset, this field resets to '0'.

Accessing this field has the following behavior:

- When OSLSR_EL1.OSLK == '1', access to this field is RW.
- When OSLSR_EL1.OSLK == '0', access to this field is RO.

TXU, bit [26]

Used for save/restore of EDSCR.TXU.

When OSLSR_EL1.OSLK == 0, software must treat this bit as UNK/SBZP.

When OSLSR_EL1.OSLK == 1, this bit holds the value of EDSCR.TXU. Reads and writes of this bit are indirect accesses to EDSCR.TXU.

When OSLSR_EL1.OSLK == 1, if bits [26,6] of the value written to MDSCR_EL1 are {1,0}, that is, the TXU bit is 1 and the ERR bit is 0, the PE sets EDSCR.{TXU,ERR} to UNKNOWN values.

The reset behavior of this field is:

- On a Cold reset, this field resets to '0'.

Accessing this field has the following behavior:

- When OSLSR_EL1.OSLK == '1', access to this field is RW.
- When OSLSR_EL1.OSLK == '0', access to this field is RO.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Bits [25:24]

Reserved, RES0.

INTdis, bits [23:22]

Used for save/restore of EDSCR.INTdis.

When OSLSR_EL1.OSLK == 0, software must treat this bit as UNK/SBZP.

When OSLSR_EL1.OSLK == 1, this field holds the value of EDSCR.INTdis. Reads and writes of this field are indirect accesses to EDSCR.INTdis.

The reset behavior of this field is:

- On a Cold reset, this field resets to `'00'`.

Accessing this field has the following behavior:

- When OSLSR_EL1.OSLK == '1', access to this field is RW.
- When OSLSR_EL1.OSLK == '0', access to this field is RO.

TDA, bit [21]

Used for save/restore of EDSCR.TDA.

When OSLSR_EL1.OSLK == 0, software must treat this bit as UNK/SBZP.

When OSLSR_EL1.OSLK == 1, this bit holds the value of EDSCR.TDA. Reads and writes of this bit are indirect accesses to EDSCR.TDA.

The reset behavior of this field is:

- On a Cold reset, this field resets to `'0'`.

Accessing this field has the following behavior:

- When OSLSR_EL1.OSLK == '1', access to this field is RW.
- When OSLSR_EL1.OSLK == '0', access to this field is RO.

Bits [20:19]

Reserved, RES0.

Bits [18:16]

Reserved, RAZ/WI.

Hardware must implement this field as RAZ/WI. Software must not rely on the register reading as zero, and must use a read-modify-write sequence to write to the register.

MDE, bit [15]

Monitor debug events. Enable Breakpoint, Watchpoint, and Vector Catch exceptions.

MDE	Meaning
`0b0`	Breakpoint, Watchpoint, and Vector Catch exceptions disabled.
`0b1`	Breakpoint, Watchpoint, and Vector Catch exceptions enabled.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

HDE, bit [14]

Used for save/restore of EDSCR.HDE.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

When OSLSR_EL1.OSLK == 0, software must treat this bit as UNK/SBZP.

When OSLSR_EL1.OSLK == 1, this bit holds the value of EDSCR.HDE. Reads and writes of this bit are indirect accesses to EDSCR.HDE.

The reset behavior of this field is:

- On a Cold reset, this field resets to `'0'`.

Accessing this field has the following behavior:

- When OSLSR_EL1.OSLK == '1', access to this field is RW.
- When OSLSR_EL1.OSLK == '0', access to this field is RO.

KDE, bit [13]

Local (kernel) debug enable. If EL_D is using AArch64, enable debug exceptions within EL_D. Permitted values are:

KDE	Meaning
`0b0`	Debug exceptions, other than Breakpoint Instruction exceptions, disabled within EL_D.
`0b1`	All debug exceptions enabled within EL_D.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

TDCC, bit [12]

Traps EL0 accesses to the Debug Communication Channel (DCC) registers to EL1, or to EL2 when it is implemented and enabled for the current Security state and HCR_EL2.TGE is 1, from both Execution states, as follows:

- In AArch64 state, MRS or MSR accesses to the following DCC registers are trapped, reported using EC syndrome value `0x18`:
  - MDCCSR_EL0.
  - If not in Debug state, DBGDTR_EL0, DBGDTRTX_EL0, and DBGDTRRX_EL0.

TDCC	Meaning
`0b0`	This control does not cause any instructions to be trapped.
`0b1`	EL0 using AArch64: EL0 accesses to the AArch64 DCC registers are trapped.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [11:7]

Reserved, RES0.

ERR, bit [6]

Used for save/restore of EDSCR.ERR.

When OSLSR_EL1.OSLK == 0, software must treat this bit as UNK/SBZP.

When OSLSR_EL1.OSLK == 1, this bit holds the value of EDSCR.ERR. Reads and writes of this bit are indirect accesses to EDSCR.ERR.

The reset behavior of this field is:

- On a Cold reset, this field resets to `'0'`.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Accessing this field has the following behavior:

- When OSLSR_EL1.OSLK == ‘1’, access to this field is RW.
- When OSLSR_EL1.OSLK == ‘0’, access to this field is RO.

Bits [5:1]

Reserved, RES0.

SS, bit [0]

Software step control bit. If EL_D is using AArch64, enable Software step. Permitted values are:

SS	Meaning
0b0	Software step disabled
0b1	Software step enabled.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing MDSCR_EL1

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, MDSCR_EL1

op0	op1	CRn	CRm	op2
0b10	0b000	0b0000	0b0010	0b010

```
if PSTATE.EL == EL0 then
    UNDEFINED;
elsif PSTATE.EL == EL1 then
    if MDCR_EL2.<TDE,TDA> != '00' then
        AArch64.SystemAccessTrap(EL2, 0x18);
    else
        X[t, 64] = MDSCR_EL1;
elsif PSTATE.EL == EL2 then
    X[t, 64] = MDSCR_EL1;
```

MSR MDSCR_EL1, <Xt>

op0	op1	CRn	CRm	op2
0b10	0b000	0b0000	0b0010	0b010

```
if PSTATE.EL == EL0 then
    UNDEFINED;
elsif PSTATE.EL == EL1 then
    if MDCR_EL2.<TDE,TDA> != '00' then
        AArch64.SystemAccessTrap(EL2, 0x18);
    else
        MDSCR_EL1 = X[t, 64];
elsif PSTATE.EL == EL2 then
    MDSCR_EL1 = X[t, 64];
```

D12.3.19 OSDLR_EL1, OS Double Lock Register

The OSDLR_EL1 characteristics are:

Purpose

Used to control the OS Double Lock.

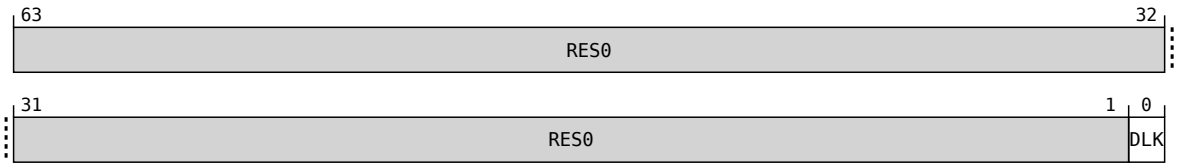
Configuration

There are no configuration notes.

Attributes

OSDLR_EL1 is a 64-bit register.

Field descriptions



Bits [63:1]

Reserved, RES0.

DLK, bit [0]

When FEAT_DoubleLock is implemented:

OS Double Lock control bit.

DLK	Meaning
0b0	OS Double Lock unlocked.
0b1	OS Double Lock locked, if DBGPRCR_EL1.CORENPDRQ (Core no powerdown request) bit is set to 0 and the PE is in Non-debug state.

The reset behavior of this field is:

- On a Warm reset, this field resets to '0'.

Otherwise:

Reserved, RAZ/WI.

Accessing OSDLR_EL1

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, OSDLR_EL1

D12.3.20 OSDTRRX_EL1, OS Lock Data Transfer Register, Receive

The OSDTRRX_EL1 characteristics are:

Purpose

Used for save and restore of DBGDTRRX_EL0. It is a component of the Debug Communications Channel.

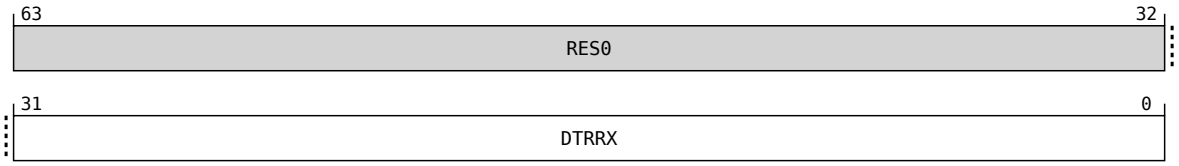
Configuration

There are no configuration notes.

Attributes

OSDTRRX_EL1 is a 64-bit register.

Field descriptions



Bits [63:32]

Reserved, RES0.

DTRRX, bits [31:0]

Update DTRRX without side-effect.

Writes to this register update the value in DTRRX and do not change RXfull.

Reads of this register return the last value written to DTRRX and do not change RXfull.

For the full behavior of the Debug Communications Channel, see 'The Debug Communication Channel and Instruction Transfer Register'.

Accessing OSDTRRX_EL1

Arm deprecates reads and writes of OSDTRRX_EL1 when the OS Lock is unlocked.

Accesses to this register use the following encodings in the System register encoding space:

`MRS <Xt>, OSDTRRX_EL1`

op0	op1	CRn	CRm	op2
0b10	0b000	0b0000	0b0000	0b010

D12.3.21 OSDTRTX_EL1, OS Lock Data Transfer Register, Transmit

The OSDTRTX_EL1 characteristics are:

Purpose

Used for save/restore of DBGDTRTX_EL0. It is a component of the Debug Communications Channel.

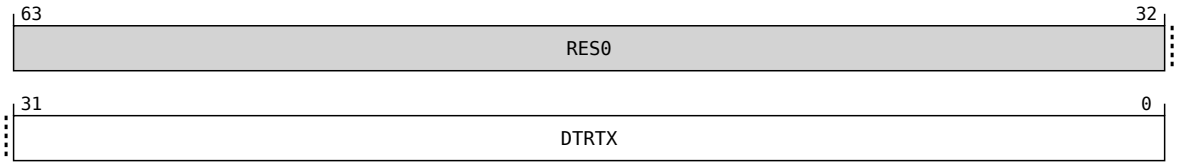
Configuration

There are no configuration notes.

Attributes

OSDTRTX_EL1 is a 64-bit register.

Field descriptions



Bits [63:32]

Reserved, RES0.

DTRTX, bits [31:0]

Return DTRTX without side-effect.

Reads of this register return the value in DTRTX and do not change TXfull.

Writes of this register update the value in DTRTX and do not change TXfull.

For the full behavior of the Debug Communications Channel, see 'The Debug Communication Channel and Instruction Transfer Register'.

Accessing OSDTRTX_EL1

Arm deprecates reads and writes of OSDTRTX_EL1 when the OS Lock is unlocked.

Accesses to this register use the following encodings in the System register encoding space:

```
MRS <Xt>, OSDTRTX_EL1
```

op0	op1	CRn	CRm	op2

D12.3.22 OSECCR_EL1, OS Lock Exception Catch Control Register

The OSECCR_EL1 characteristics are:

Purpose

Provides a mechanism for an operating system to access the contents of EDECCR that are otherwise invisible to software, so it can save/restore the contents of EDECCR over powerdown on behalf of the external debugger.

Configuration

If OSLSR_EL1.OSLK == 0, then OSECCR_EL1 returns an UNKNOWN value on reads and ignores writes.

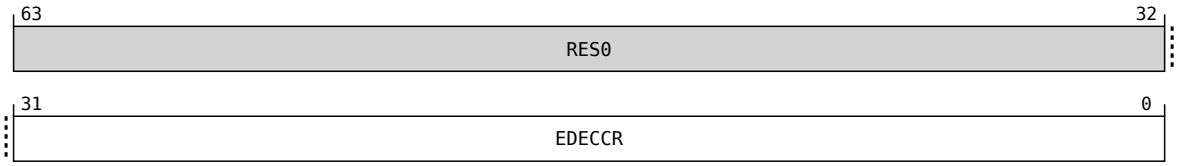
AArch64 System register OSECCR_EL1 bits [31:0] are architecturally mapped to External register EDECCR[31:0].

Attributes

OSECCR_EL1 is a 64-bit register.

Field descriptions

When OSLSR_EL1.OSLK == '1':



Bits [63:32]

Reserved, RES0.

EDECCR, bits [31:0]

Used for save/restore to EDECCR over powerdown.

Reads or writes to this field are indirect accesses to EDECCR.

The reset behavior of this field is:

- On a Cold reset, this field resets to 0x00000000.

Accessing OSECCR_EL1

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, OSECCR_EL1

op0	op1	CRn	CRm	op2
0b10	0b000	0b0000	0b0110	0b010

```
if PSTATE.EL == EL0 then
    UNDEFINED;
elsif PSTATE.EL == EL1 then
    if MDCR_EL2.<TDE,TDA> != '00' then
        AArch64.SystemAccessTrap(EL2, 0x18);
    elsif OSLSR_EL1.OSLK == '0' then
        X[t, 64] = bits(64) UNKNOWN;
    else
```

D12.3.23 OSLAR_EL1, OS Lock Access Register

The OSLAR_EL1 characteristics are:

Purpose

Used to lock or unlock the OS Lock.

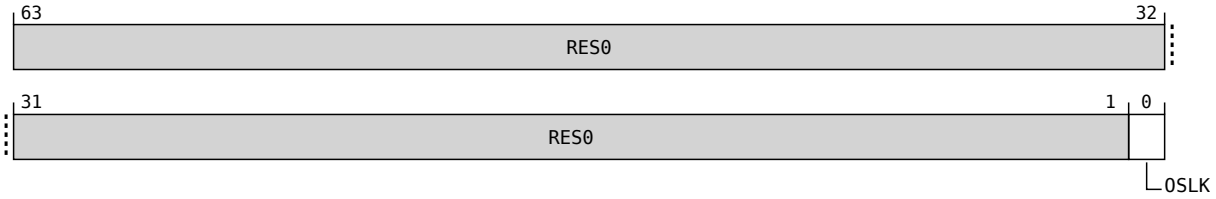
Configuration

AArch64 System register OSLAR_EL1 bits [31:0] are architecturally mapped to External register OSLAR_EL1[31:0].

Attributes

OSLAR_EL1 is a 64-bit register.

Field descriptions



Bits [63:1]

Reserved, RES0.

OSLK, bit [0]

On writes to OSLAR_EL1, bit[0] is copied to the OS Lock.

Use OSLSR_EL1.OSLK to check the current status of the lock.

Accessing OSLAR_EL1

Accesses to this register use the following encodings in the System register encoding space:

`MSR OSLAR_EL1, <Xt>`

op0	op1	CRn	CRm	op2
0b10	0b000	0b0001	0b0000	0b100

```
if PSTATE.EL == EL0 then
    UNDEFINED;
elsif PSTATE.EL == EL1 then
    if MDCR_EL2.<TDE,TDOSA> != '00' then
        AArch64.SystemAccessTrap(EL2, 0x18);
    else
        OSLAR_EL1 = X[t, 64];
elsif PSTATE.EL == EL2 then
    OSLAR_EL1 = X[t, 64];
```

D12.3.24 OSLSR_EL1, OS Lock Status Register

The OSLSR_EL1 characteristics are:

Purpose

Provides the status of the OS Lock.

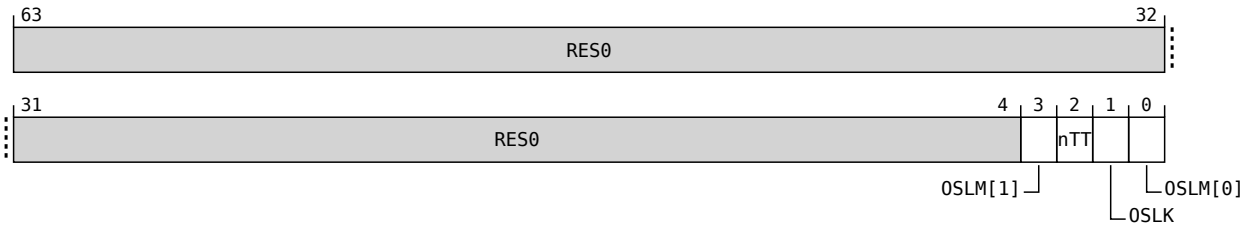
Configuration

There are no configuration notes.

Attributes

OSLSR_EL1 is a 64-bit register.

Field descriptions



Bits [63:4]

Reserved, RES0.

OSLM, bits [3, 0]

OS Lock model implemented. Identifies the form of OS save and restore mechanism implemented.

The value of this field is an IMPLEMENTATION DEFINED choice of:

OSLM	Meaning
0b00	OS Lock not implemented.
0b10	OS Lock implemented.

All other values are reserved. In an Armv8 implementation the value 0b00 is not permitted.

Access to this field is RO.

nTT, bit [2]

Not 32-bit access. This bit is always RAZ. It indicates that a 32-bit access is needed to write the key to the OS Lock Access Register.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

OSLK, bit [1]

OS Lock Status.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

OSLK	Meaning
0b0	OS Lock unlocked.
0b1	OS Lock locked.

The OS Lock is locked and unlocked by writing to the OS Lock Access Register.

The reset behavior of this field is:

- On a Cold reset, this field resets to '1'.

Accessing OSLSR_EL1

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, OSLSR_EL1

op0	op1	CRn	CRm	op2
0b10	0b000	0b0001	0b0001	0b100

```
if PSTATE.EL == EL0 then
    UNDEFINED;
elsif PSTATE.EL == EL1 then
    if MDCR_EL2.<TDE,TDOSA> != '00' then
        AArch64.SystemAccessTrap(EL2, 0x18);
    else
        X[t, 64] = OSLSR_EL1;
elsif PSTATE.EL == EL2 then
    X[t, 64] = OSLSR_EL1;
```

D12.4 Trace registers

This section lists the Trace registers in AArch64.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D12.4.1 TRFCR_EL1, Trace Filter Control Register (EL1)

The TRFCR_EL1 characteristics are:

Purpose

Provides EL1 controls for Trace.

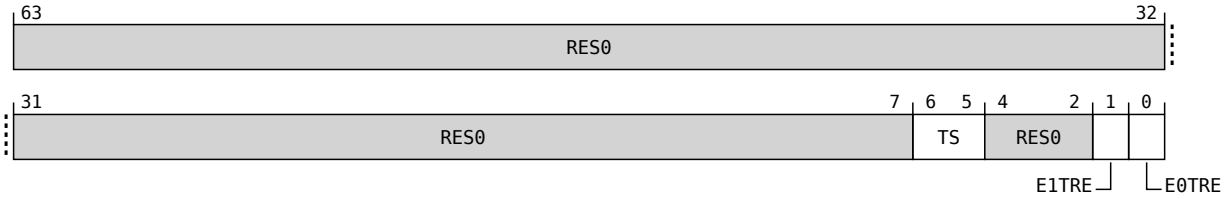
Configuration

This register is present only when FEAT_TRF is implemented. Otherwise, direct accesses to TRFCR_EL1 are UNDEFINED.

Attributes

TRFCR_EL1 is a 64-bit register.

Field descriptions



Bits [63:7]

Reserved, RES0.

TS, bits [6:5]

Timestamp Control. Controls which timebase is used for trace timestamps.

TS	Meaning
0b01	Virtual timestamp. The traced timestamp is the physical counter value minus the value of CNTVOFF_EL2.
0b11	Physical timestamp. The traced timestamp is the physical counter value.

All other values are reserved.

If any of the following are true, then this field is ignored by the PE:

- EL2 is implemented and TRFCR_EL2.TS is not 0b00.
- SelfHostedTraceEnabled() == FALSE.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [4:2]

Reserved, RES0.

E1TRE, bit [1]

EL1 Trace Enable.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

E1TRE	Meaning
0b0	Trace is prohibited at EL1.
0b1	Trace is allowed at EL1.

If any of the following are true, then this field is ignored by the PE:

- SelfHostedTraceEnabled() == FALSE.
- The Effective value of HCR_EL2.TGE is 1.

The reset behavior of this field is:

- On a Warm reset, this field resets to '0'.

E0TRE, bit [0]

EL0 Trace Enable.

E0TRE	Meaning
0b0	Trace is prohibited at EL0.
0b1	Trace is allowed at EL0.

If any of the following are true, then this field is ignored by the PE:

- SelfHostedTraceEnabled() == FALSE.
- The Effective value of HCR_EL2.TGE is 1.

The reset behavior of this field is:

- On a Warm reset, this field resets to '0'.

Accessing TRFCR_EL1

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, TRFCR_EL1

op0	op1	CRn	CRm	op2
0b11	0b000	0b0001	0b0010	0b001

D12.4.2 TRFCR_EL2, Trace Filter Control Register (EL2)

The TRFCR_EL2 characteristics are:

Purpose

Provides EL2 controls for Trace.

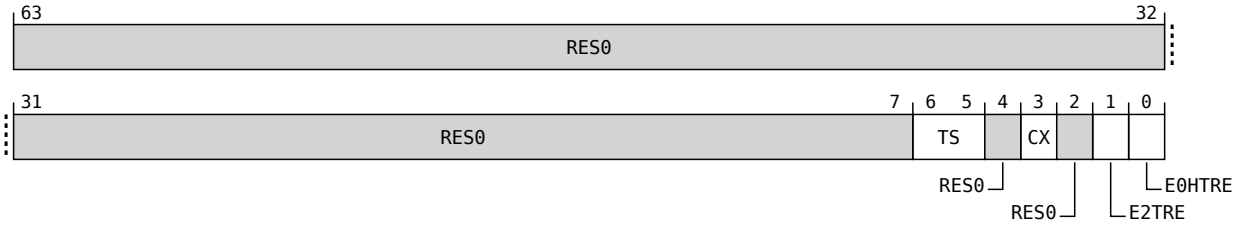
Configuration

This register is present only when FEAT_TRF is implemented. Otherwise, direct accesses to TRFCR_EL2 are UNDEFINED.

Attributes

TRFCR_EL2 is a 64-bit register.

Field descriptions



Bits [63:7]

Reserved, RES0.

TS, bits [6:5]

Timestamp Control. Controls which timebase is used for trace timestamps.

TS	Meaning
0b00	Timestamp controlled by TRFCR_EL1.TS.
0b01	Virtual timestamp. The traced timestamp is the physical counter value minus the value of CNTVOFF_EL2.
0b11	Physical timestamp. The traced timestamp is the physical counter value.

If SelfHostedTraceEnabled() == FALSE, then this field is ignored by the PE.

The reset behavior of this field is:

- On a Warm reset, this field resets to '00'.

Bit [4]

Reserved, RES0.

CX, bit [3]

CONTEXTIDR_EL2 and VMID trace enable.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

CX	Meaning
0b0	CONTEXTIDR_EL2 and VMID trace prohibited.
0b1	CONTEXTIDR_EL2 and VMID trace allowed.

If SelfHostedTraceEnabled() == FALSE, then this field is ignored by the PE.

The reset behavior of this field is:

- On a Warm reset, this field resets to '0'.

Bit [2]

Reserved, RES0.

E2TRE, bit [1]

EL2 Trace Enable.

E2TRE	Meaning
0b0	Trace is prohibited at EL2.
0b1	Trace is allowed at EL2.

If SelfHostedTraceEnabled() == FALSE, then this field is ignored by the PE.

The reset behavior of this field is:

- On a Warm reset, this field resets to '0'.

E0HTRE, bit [0]

EL0 Trace Enable.

E0HTRE	Meaning
0b0	Trace is prohibited at EL0.
0b1	Trace is allowed at EL0.

If any of the following are true, then this field is ignored by the PE:

- SelfHostedTraceEnabled() == FALSE.
- The Effective value of HCR_EL2.TGE is 0.

The reset behavior of this field is:

- On a Warm reset, this field resets to '0'.

Accessing TRFCR_EL2

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, TRFCR_EL2

D12.5.1 PMCCFILTR_EL0, Performance Monitors Cycle Count Filter Register

The PMCCFILTR_EL0 characteristics are:

Purpose

Determines the modes in which the Cycle Counter, PMCCNTR_EL0, increments.

Configuration

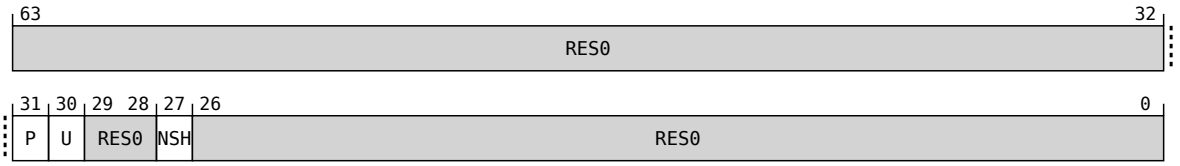
AArch64 System register PMCCFILTR_EL0 bits [31:0] are architecturally mapped to External register PMCCFILTR_EL0[31:0].

This register is present only when FEAT_PMUv3 is implemented. Otherwise, direct accesses to PMCCFILTR_EL0 are UNDEFINED.

Attributes

PMCCFILTR_EL0 is a 64-bit register.

Field descriptions



Bits [63:32]

Reserved, RES0.

P, bit [31]

EL1 filtering. Controls counting cycles in EL1.

P	Meaning
0b0	This mechanism has no effect on filtering of cycles.
0b1	The PE does not count cycles in EL1.

If Secure and Non-secure states are implemented, then counting cycles in Non-secure EL1 is further controlled by PMCCFILTR_EL0.NSK.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

U, bit [30]

EL0 filtering. Controls counting cycles in EL0.

U	Meaning
0b0	This mechanism has no effect on filtering of cycles.
0b1	The PE does not count cycles in EL0.

If Secure and Non-secure states are implemented, then counting cycles in Non-secure EL0 is further controlled by PMCCFILTR_EL0.NSU.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [29:28]

Reserved, RES0.

NSH, bit [27]

EL2 filtering. Controls counting cycles in EL2.

NSH	Meaning
0b0	The PE does not count cycles in EL2.
0b1	This mechanism has no effect on filtering of cycles.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [26:0]

Reserved, RES0.

Accessing PMCCFILTR_EL0

PMCCFILTR_EL0 can also be accessed by using PMXEVTYPER_EL0 with PMSELR_EL0.SEL set to 0b11111.

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, PMCCFILTR_EL0

D12.5.2 PMCCNTR_EL0, Performance Monitors Cycle Count Register

The PMCCNTR_EL0 characteristics are:

Purpose

Holds the value of the processor Cycle Counter, CCNT, that counts processor clock cycles. See 'Time as measured by the Performance Monitors cycle counter' for more information.

PMCCFILTR_EL0 determines the modes and states in which the PMCCNTR_EL0 can increment.

Configuration

All counters are subject to any changes in clock frequency, including clock stopping caused by the WFI and WFE instructions. This means that it is CONSTRAINED UNPREDICTABLE whether or not PMCCNTR_EL0 continues to increment when clocks are stopped by WFI and WFE instructions.

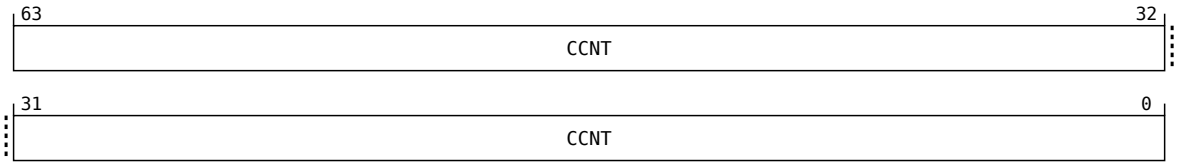
AArch64 System register PMCCNTR_EL0 bits [63:0] are architecturally mapped to External register PMCCNTR_EL0[63:0].

This register is present only when FEAT_PMUv3 is implemented. Otherwise, direct accesses to PMCCNTR_EL0 are UNDEFINED.

Attributes

PMCCNTR_EL0 is a 64-bit register.

Field descriptions



CCNT, bits [63:0]

Cycle count. Depending on the values of PMCR_EL0.{LC,D}, this field increments in one of the following ways:

- Every processor clock cycle.
- Every 64th processor clock cycle.

Writing 1 to PMCR_EL0.C sets this field to 0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing PMCCNTR_EL0

Accesses to this register use the following encodings in the System register encoding space:

`MRS <Xt>, PMCCNTR_EL0`

op0	op1	CRn	CRm	op2
0b11	0b011	0b1001	0b1101	0b000

D12.5.3 PMCEID0_EL0, Performance Monitors Common Event Identification Register 0

The PMCEID0_EL0 characteristics are:

Purpose

Defines which Common architectural events and Common microarchitectural events are implemented, or counted, using PMU events in the ranges `0x0000` to `0x001F` and `0x4000` to `0x401F`.

For more information about the Common events and the use of the PMCEID<n>_EL0 registers see 'The PMU event number space and common events'.

Configuration

AArch64 System register PMCEID0_EL0 bits [31:0] are architecturally mapped to External register PMCEID0[31:0].

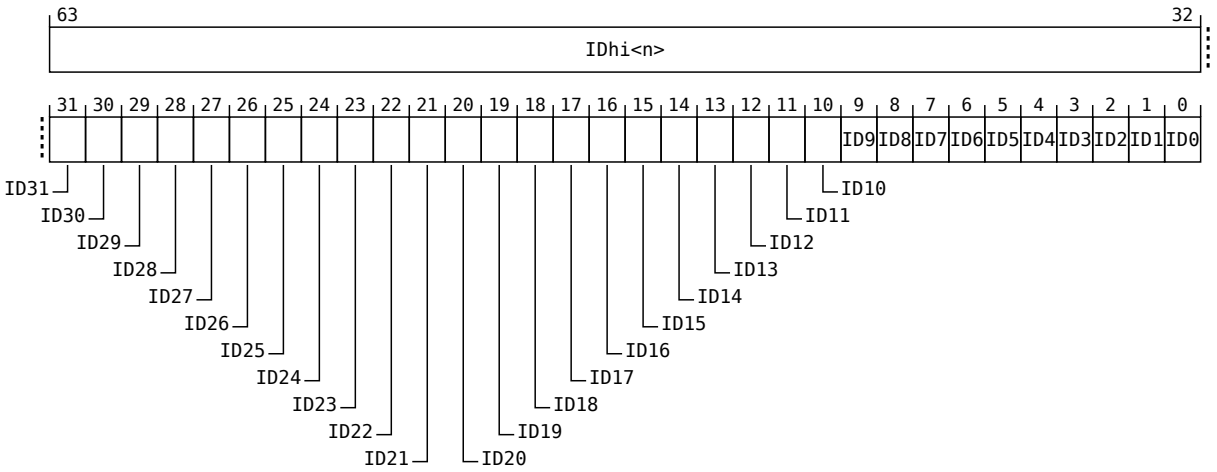
AArch64 System register PMCEID0_EL0 bits [63:32] are architecturally mapped to External register PMCEID2[31:0].

This register is present only when FEAT_PMUv3 is implemented. Otherwise, direct accesses to PMCEID0_EL0 are UNDEFINED.

Attributes

PMCEID0_EL0 is a 64-bit register.

Field descriptions



IDhi<n> , bits [n+32], for n = 31 to 0

When FEAT_PMUv3p1 is implemented:

IDhi[n] corresponds to Common event (`0x4000` + n).

For each bit:

IDhi<n>	Meaning
`0b0`	The Common event is not implemented, or not counted.
`0b1`	The Common event is implemented.

When the value of a bit in the field is 1, the corresponding Common event is implemented and counted.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

Arm recommends that if a Common event is never counted, the value of the corresponding bit is 0.

A bit that corresponds to a reserved event number is reserved. The value might be used in a future revision of the architecture to identify an additional Common event.

Note

Such an event might be added retrospectively to an earlier version of the PMU architecture, provided the event does not require any additional PMU features and has an event number that can be represented in the PMCEID<n>_EL0 registers of that earlier version of the PMU architecture.

Otherwise:

Reserved, RES0.

ID<n> , bits [n], for n = 31 to 0

ID[n] corresponds to Common event n.

For each bit:

ID<n>	Meaning
0b0	The Common event is not implemented, or not counted.
0b1	The Common event is implemented.

When the value of a bit in the field is 1, the corresponding Common event is implemented and counted.

Note

Arm recommends that if a Common event is never counted, the value of the corresponding bit is 0.

A bit that corresponds to a reserved event number is reserved. The value might be used in a future revision of the architecture to identify an additional Common event.

Note

Such an event might be added retrospectively to an earlier version of the PMU architecture, provided the event does not require any additional PMU features and has an event number that can be represented in the PMCEID<n>_EL0 registers of that earlier version of the PMU architecture.

Accessing PMCEID0_EL0

Accesses to this register use the following encodings in the System register encoding space:

`MRS <Xt>, PMCEID0_EL0`

D12.5.4 PMCEID1_EL0, Performance Monitors Common Event Identification Register 1

The PMCEID1_EL0 characteristics are:

Purpose

Defines which Common architectural events and Common microarchitectural events are implemented, or counted, using PMU events in the ranges `0x0020` to `0x003F` and `0x4020` to `0x403F`.

For more information about the Common events and the use of the PMCEID<n>_EL0 registers see 'The PMU event number space and common events'.

Configuration

AArch64 System register PMCEID1_EL0 bits [31:0] are architecturally mapped to External register PMCEID1[31:0].

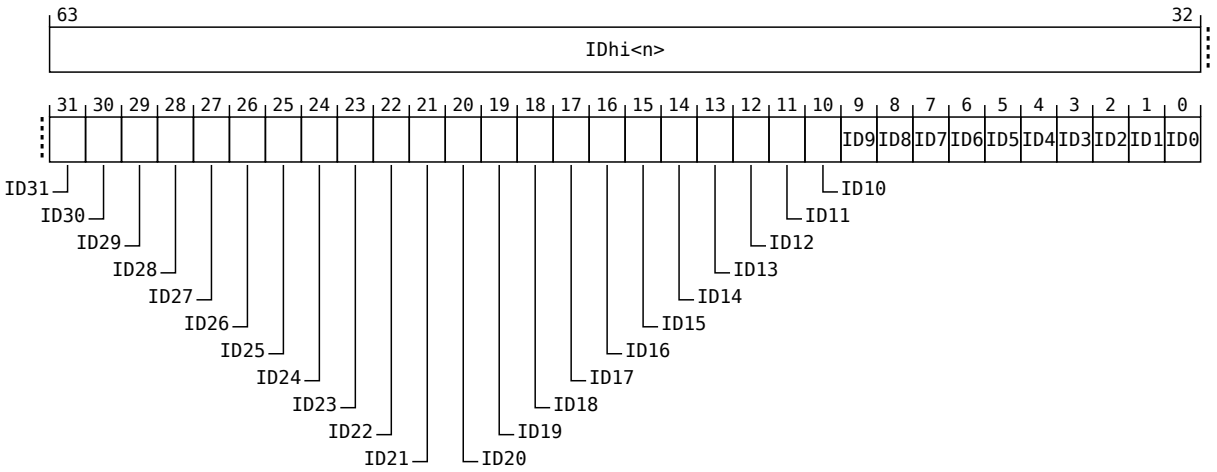
AArch64 System register PMCEID1_EL0 bits [63:32] are architecturally mapped to External register PMCEID3[31:0].

This register is present only when FEAT_PMUv3 is implemented. Otherwise, direct accesses to PMCEID1_EL0 are UNDEFINED.

Attributes

PMCEID1_EL0 is a 64-bit register.

Field descriptions



IDhi<n> , bits [n+32], for n = 31 to 0

When FEAT_PMUv3p1 is implemented:

IDhi[n] corresponds to Common event (`0x4020` + n).

For each bit:

IDhi<n>	Meaning
`0b0`	The Common event is not implemented, or not counted.
`0b1`	The Common event is implemented.

When the value of a bit in the field is 1, the corresponding Common event is implemented and counted.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

Arm recommends that if a Common event is never counted, the value of the corresponding bit is 0.

A bit that corresponds to a reserved event number is reserved. The value might be used in a future revision of the architecture to identify an additional Common event.

Note

Such an event might be added retrospectively to an earlier version of the PMU architecture, provided the event does not require any additional PMU features and has an event number that can be represented in the PMCEID<n>_EL0 registers of that earlier version of the PMU architecture.

Otherwise:

Reserved, RES0.

ID<n> , bits [n], for n = 31 to 0

ID[n] corresponds to Common event (0x0020 + n).

For each bit:

ID<n>	Meaning
0b0	The Common event is not implemented, or not counted.
0b1	The Common event is implemented.

When the value of a bit in the field is 1, the corresponding Common event is implemented and counted.

Note

Arm recommends that if a Common event is never counted, the value of the corresponding bit is 0.

A bit that corresponds to a reserved event number is reserved. The value might be used in a future revision of the architecture to identify an additional Common event.

Note

Such an event might be added retrospectively to an earlier version of the PMU architecture, provided the event does not require any additional PMU features and has an event number that can be represented in the PMCEID<n>_EL0 registers of that earlier version of the PMU architecture.

Accessing PMCEID1_EL0

Accesses to this register use the following encodings in the System register encoding space:

```
MRS <Xt>, PMCEID1_EL0
```

op0	op1	CRn	CRm	op2
0b11	0b011	0b1001	0b1100	0b111

D12.5.5 PMCNTENCLR_EL0, Performance Monitors Count Enable Clear Register

The PMCNTENCLR_EL0 characteristics are:

Purpose

Allows software to disable the following counters:

- The cycle counter PMCCNTR_EL0.
- The event counters PMEVCNTR<n>_EL0.

Reading from this register shows which counters are enabled.

Configuration

AArch64 System register PMCNTENCLR_EL0 bits [63:0] are architecturally mapped to AArch64 System register PMCNTENSET_EL0[63:0].

AArch64 System register PMCNTENCLR_EL0 bits [31:0] are architecturally mapped to External register PMCNTENCLR_EL0[31:0].

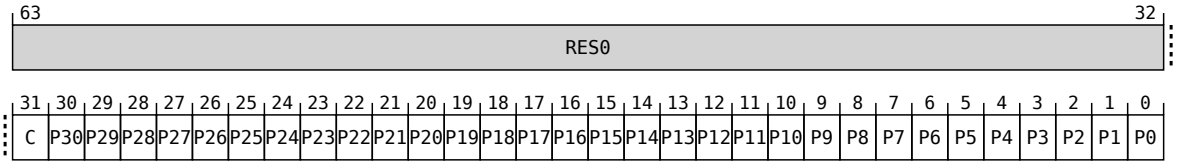
AArch64 System register PMCNTENCLR_EL0 bits [31:0] are architecturally mapped to External register PMCNTENSET_EL0[31:0].

This register is present only when FEAT_PMUv3 is implemented. Otherwise, direct accesses to PMCNTENCLR_EL0 are UNDEFINED.

Attributes

PMCNTENCLR_EL0 is a 64-bit register.

Field descriptions



Bits [63:32]

Reserved, RES0.

C, bit [31]

PMCCNTR_EL0 disable. On writes, allows software to disable PMCCNTR_EL0. On reads, returns the PMCCNTR_EL0 enable status.

C	Meaning
0b0	PMCCNTR_EL0 disabled.
0b1	PMCCNTR_EL0 enabled.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Access to this field is W1C.

P<m> , bits [m], for m = 30 to 0

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

PMEVCNTR<m>_EL0 disable. On writes, allows software to disable PMEVCNTR<m>_EL0. On reads, returns the PMEVCNTR<m>_EL0 enable status.

P<m>	Meaning
0b0	PMEVCNTR<m>_EL0 disabled.
0b1	PMEVCNTR<m>_EL0 enabled.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing this field has the following behavior:

- When m >= GetNumEventCountersAccessible(), access to this field is RAZ/WI.
- Otherwise, access to this field is W1C.

Accessing PMCNTENCLR_EL0

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, PMCNTENCLR_EL0

op0	op1	CRn	CRm	op2
0b11	0b011	0b1001	0b1100	0b010

D12.5.6 PMCNTENSET_EL0, Performance Monitors Count Enable Set Register

The PMCNTENSET_EL0 characteristics are:

Purpose

Allows software to enable the following counters:

- The cycle counter PMCCNTR_EL0.
- The event counters PMEVCNTR<n>_EL0.

Reading from this register shows which counters are enabled.

Configuration

AArch64 System register PMCNTENSET_EL0 bits [63:0] are architecturally mapped to AArch64 System register PMCNTENCLR_EL0[63:0].

AArch64 System register PMCNTENSET_EL0 bits [31:0] are architecturally mapped to External register PMCNTENSET_EL0[31:0].

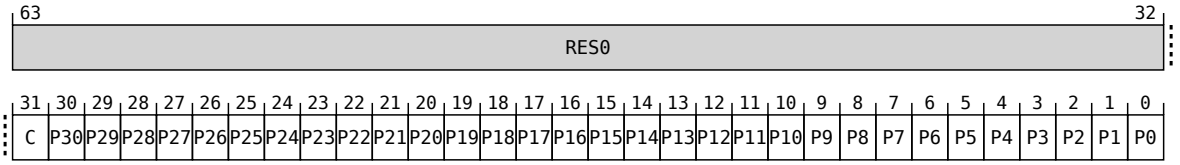
AArch64 System register PMCNTENSET_EL0 bits [31:0] are architecturally mapped to External register PMCNTENCLR_EL0[31:0].

This register is present only when FEAT_PMUv3 is implemented. Otherwise, direct accesses to PMCNTENSET_EL0 are UNDEFINED.

Attributes

PMCNTENSET_EL0 is a 64-bit register.

Field descriptions



Bits [63:32]

Reserved, RES0.

C, bit [31]

PMCCNTR_EL0 enable. On writes, allows software to enable PMCCNTR_EL0. On reads, returns the PMCCNTR_EL0 enable status.

D12.5.7 PMCR_EL0, Performance Monitors Control Register

The PMCR_EL0 characteristics are:

Purpose

Provides details of the Performance Monitors implementation, including the number of counters implemented, and configures and controls the counters.

Configuration

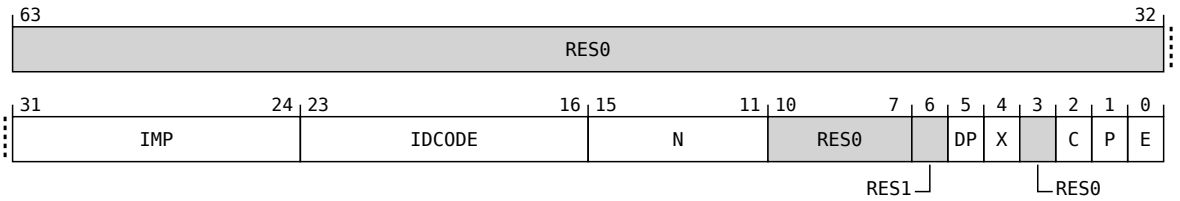
AArch64 System register PMCR_EL0 bits [31:0] are architecturally mapped to External register PMCR_EL0[31:0].

This register is present only when FEAT_PMUv3 is implemented. Otherwise, direct accesses to PMCR_EL0 are UNDEFINED.

Attributes

PMCR_EL0 is a 64-bit register.

Field descriptions



Bits [63:32]

Reserved, RES0.

IMP, bits [31:24]

Implementer code.

If this field is zero, then PMCR_EL0.IDCODE is RES0 and software must use MIDR_EL1 to identify the PE.

Otherwise, this field and PMCR_EL0.IDCODE identify the PMU implementation to software. The implementer codes are allocated by Arm. A nonzero value has the same interpretation as MIDR_EL1.Implementer.

This field has an IMPLEMENTATION DEFINED value.

Arm deprecates use of this field.

Access to this field is RO.

IDCODE, bits [23:16]

When PMCR_EL0.IMP != '00000000':

Identification code. Arm deprecates use of this field.

Each implementer must maintain a list of identification codes that are specific to the implementer. A specific implementation is identified by the combination of the implementer code and the identification code.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

Otherwise:

Reserved, RES0.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

N, bits [15:11]

Indicates the number of event counters implemented. This value is in the range of `0b00000`-`0b11111`. If the value is `0b00000`, then only PMCCNTR_EL0 is implemented. If the value is `0b11111`, then PMCCNTR_EL0 and 31 event counters are implemented.

When EL2 is implemented and enabled for the current Security state, reads of this field from EL1 and EL0 return the Effective value of MDCR_EL2.HPMN.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

Bits [10:7]

Reserved, RES0.

Bit [6]

Reserved, RES1.

DP, bit [5]

When FEAT_PMUv3p1 is implemented:

Disable cycle counter when event counting is prohibited.

DP	Meaning
`0b0`	Cycle counting by PMCCNTR_EL0 is not affected by this mechanism.
`0b1`	Cycle counting by PMCCNTR_EL0 is disabled in prohibited regions: • If FEAT_PMUv3p1 is implemented, EL2 is implemented, and MDCR_EL2.HPMD is 1, then cycle counting by PMCCNTR_EL0 is disabled at EL2.

The conditions when this field disables the cycle counter are the same as when event counting by an event counter in the first range is prohibited. For more information about event counter ranges, see MDCR_EL2.HPMN.

For more information, see 'Prohibiting event and cycle counting'.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

X, bit [4]

When the implementation includes a PMU event export bus:

Enable export of events in an IMPLEMENTATION DEFINED PMU event export bus.

X	Meaning
`0b0`	Do not export events.
`0b1`	Export events where not prohibited.

This field enables the exporting of events over an IMPLEMENTATION DEFINED PMU event export bus to another device.

No events are exported when counting is prohibited.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

This field does not affect the generation of Performance Monitors overflow interrupt requests or signaling to a cross-trigger interface (CTI) that can be implemented as signals exported from the PE.

If FEAT_ETMv4 is implemented, this field does affect the use of PMU events as an External Input by the trace unit.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RAZ/WI.

Bit [3]

Reserved, RES0.

C, bit [2]

Cycle counter reset. The effects of writing to this field are:

C	Meaning
0b0	No action.
0b1	Reset PMCCNTR_EL0 to zero.

Note

Resetting PMCCNTR_EL0 does not change the cycle counter overflow field. The value of PMCR_EL0.LC is ignored, and bits [63:0] of the cycle counter are reset.

Access to this field is WO/RAZ.

P, bit [1]

Event counter reset.

P	Meaning
0b0	No action.
0b1	Reset all affected event counters PMEVCNTR<n>_EL0 to zero.

The event counters affected by this field are:

- All event counters in the first range.
- If any of the following are true, all event counters in the second range:
  - EL2 is not implemented.
  - The PE is executing at EL2.

Writes to this field do not affect other event counters or the cycle counter PMCCNTR_EL0.

For more information about event counter ranges, see MDCR_EL2.HPMN.

Note

Resetting the event counters does not change the event counter overflow fields.

Access to this field is WO/RAZ.

E, bit [0]

Enable.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

E	Meaning
0b0	Affected counters are disabled and do not count.
0b1	Affected counters are enabled by PMCNTENSET_EL0.

The counters affected by this field are:

- The event counters in the first range. For more information about event counter ranges, see MDCR_EL2.HPMN.
- The cycle counter PMCCNTR_EL0.

Other event counters are not affected by this field.

The reset behavior of this field is:

- On a Warm reset, this field resets to '0'.

D12.5.8 PMEVCNTR<n>_EL0, Performance Monitors Event Count Registers, n = 0 - 30

The PMEVCNTR<n>_EL0 characteristics are:

Purpose

Holds event counter n, which counts events, where n is 0 to 30.

Configuration

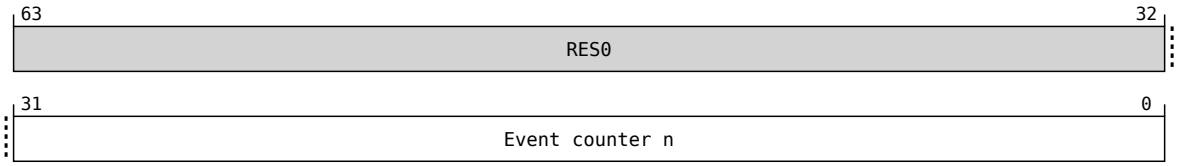
AArch64 System register PMEVCNTR<n>_EL0 bits [31:0] are architecturally mapped to External register PMEVCNTR_EL0[31:0].

This register is present only when FEAT_PMUv3 is implemented. Otherwise, direct accesses to PMEVCNTR<n>_EL0 are UNDEFINED.

Attributes

PMEVCNTR<n>_EL0 is a 64-bit register.

Field descriptions



Bits [63:32]

Reserved, RES0.

EVCNT, bits [31:0]

Event counter n. Value of event counter n, where n is the number of this register and is a number from 0 to 30.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing PMEVCNTR<n>_EL0

PMEVCNTR<n>_EL0 can also be accessed by using PMXEVCNTR_EL0 with PMSELR_EL0.SEL set to the value of <n>.

If <n> is greater than or equal to the number of accessible event counters, then reads and writes of PMEVCNTR<n>_EL0 are CONSTRAINED UNPREDICTABLE, and the following behaviors are permitted:

- Accesses to the register are UNDEFINED.
- Accesses to the register behave as RAZ/WI.
- Accesses to the register execute as a NOP.
- Accesses to the register behave as if <n> is an UNKNOWN value less-than-or-equal-to the index of the highest accessible event counter.
- If EL2 is implemented and enabled in the current Security state, and <n> is less than the number of implemented event counters, accesses from EL1 or permitted accesses from EL0 are trapped to EL2.

Note

In EL0, an access is permitted if it is enabled by PMUSERENR_EL0.{ER,EN}.
In EL1 and EL0, MDCR_EL2.HPMN identifies the number of accessible event counters. Otherwise, the number of accessible event counters is the number of implemented event counters. For more information, see MDCR_EL2.HPMN.

Accesses to this register use the following encodings in the System register encoding space:

D12.5.9 PMEVTYPER<n>_EL0, Performance Monitors Event Type Registers, n = 0 - 30

The PMEVTYPER<n>_EL0 characteristics are:

Purpose

Configures event counter n, where n is 0 to 30.

Configuration

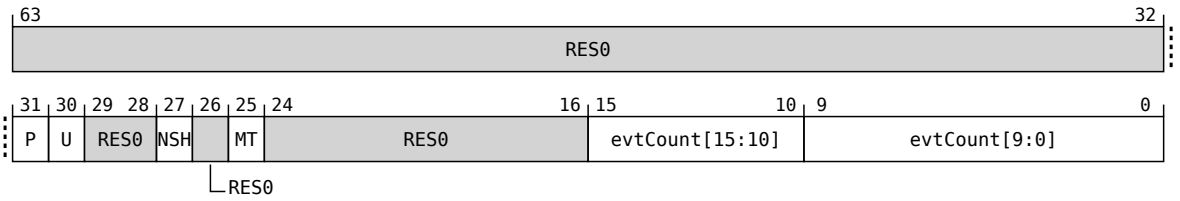
AArch64 System register PMEVTYPER<n>_EL0 bits [31:0] are architecturally mapped to External register PMEVTYPER_EL0[31:0].

This register is present only when FEAT_PMUv3 is implemented. Otherwise, direct accesses to PMEVTYPER<n>_EL0 are UNDEFINED.

Attributes

PMEVTYPER<n>_EL0 is a 64-bit register.

Field descriptions



Bits [63:32]

Reserved, RES0.

P, bit [31]

EL1 filtering. Controls counting events in EL1.

P	Meaning
0b0	This mechanism has no effect on filtering of events.
0b1	The PE does not count events in EL1.

If Secure and Non-secure states are implemented, then counting events in Non-secure EL1 is further controlled by PMEVTYPER<n>_EL0.NSK.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

U, bit [30]

EL0 filtering. Controls counting events in EL0.

U	Meaning
0b0	This mechanism has no effect on filtering of events.
0b1	The PE does not count events in EL0.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

If Secure and Non-secure states are implemented, then counting events in Non-secure EL0 is further controlled by PMEVTYPER<n>_EL0.NSU.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [29:28]

Reserved, RES0.

NSH, bit [27]

EL2 filtering. Controls counting events in EL2.

NSH	Meaning
0b0	The PE does not count events in EL2.
0b1	This mechanism has no effect on filtering of events.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [26]

Reserved, RES0.

MT, bit [25]

When an IMPLEMENTATION DEFINED multi-threaded PMU extension is implemented:

Multithreading.

MT	Meaning
0b0	Count events only on controlling PE.
0b1	Count events from any PE with the same affinity at level 1 and above as this PE.

Unless otherwise stated:

- If the event counts PE cycles when a stall condition is true and a second condition is true, then the counter counts Processor cycles when the stall condition is true for all of these PEs, and the second condition is true for any of these PEs.
- If the event counts PE cycles when any other condition is true, then the counter counts Processor cycles when the condition is true for any of these PEs.
- Otherwise, the event counts by the sum of the count across all of these PEs.

For the stall events, the stall condition means the applicable condition described by the STALL, STALL_FRONTEND, or STALL_BACKEND event.

The second condition is any condition in addition to this.

For example, for the STALL_FRONTEND_L1I event, the stall condition is STALL_FRONTEND, and the second condition is when there is a demand instruction miss in the first level of instruction cache.

For the STALL, STALL_FRONTEND, and STALL_BACKEND events themselves, the second condition is the null TRUE condition.

See ‘Multithreaded implementations’ and ‘Cycle event counting in multithreaded implementations’.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Otherwise:

Reserved, RES0.

Bits [24:16]

Reserved, RES0.

evtCount[15:10], bits [15:10]

When FEAT_PMUv3p1 is implemented:

Extension to evtCount[9:0]. For more information, see evtCount[9:0].

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

evtCount[9:0], bits [9:0]

Event to count.

The event number of the event that is counted by event counter PMEVCNTR<n>_EL0.

The ranges of event numbers allocated to each type of event are shown in 'Allocation of the PMU event number space'.

If PMEVTYPER<n>_EL0.evtCount is programmed to an event that is reserved or not supported by the PE, the behavior depends on the value written:

- For the range 0x0000 to 0x003F, no events are counted and the value returned by a direct or external read of the PMEVTYPER<n>_EL0.evtCount field is the value written to the field.
- If FEAT_PMUv3p1 is implemented, for the range 0x4000 to 0x403F, no events are counted and the value returned by a direct or external read of the PMEVTYPER<n>_EL0.evtCount field is the value written to the field.
- For other values, it is UNPREDICTABLE what event, if any, is counted and the value returned by a direct or external read of the PMEVTYPER<n>_EL0.evtCount field is UNKNOWN.

Note

UNPREDICTABLE means the event must not expose privileged information.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing PMEVTYPER<n>_EL0

PMEVTYPER<n>_EL0 can also be accessed by using PMXEVTYPER_EL0 with PMSELR_EL0.SEL set to n.

If <n> is greater than or equal to the number of accessible event counters, then reads and writes of PMEVTYPER<n>_EL0 are CONSTRAINED UNPREDICTABLE, and the following behaviors are permitted:

- Accesses to the register are UNDEFINED.
- Accesses to the register behave as RAZ/WI.
- Accesses to the register execute as a NOP.
- Accesses to the register behave as if <n> is an UNKNOWN value less-than-or-equal-to the index of the highest accessible event counter.
- If EL2 is implemented and enabled in the current Security state, and <n> is less than the number of implemented event counters, accesses from EL1 or permitted accesses from EL0 are trapped to EL2.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

In EL0, an access is permitted if it is enabled by PMUSERENR_EL0.EN.
If EL2 is implemented and enabled in the current Security state, in EL1 and EL0, MDCR_EL2.HPMN identifies the number of accessible event counters. Otherwise, the number of accessible event counters is the number of implemented event counters. For more information, see MDCR_EL2.HPMN.

Accesses to this register use the following encodings in the System register encoding space:

D12.5.10 PMINTENCLR_EL1, Performance Monitors Interrupt Enable Clear Register

The PMINTENCLR_EL1 characteristics are:

Purpose

Allows software to disable the generation of interrupt requests on overflows from the following counters:

- The cycle counter PMCCNTR_EL0.
- The event counters PMEVCNTR<n>_EL0.

Reading from this register shows which overflow interrupt requests are enabled.

Configuration

AArch64 System register PMINTENCLR_EL1 bits [63:0] are architecturally mapped to AArch64 System register PMINTENSET_EL1[63:0].

AArch64 System register PMINTENCLR_EL1 bits [31:0] are architecturally mapped to External register PMINTENCLR_EL1[31:0].

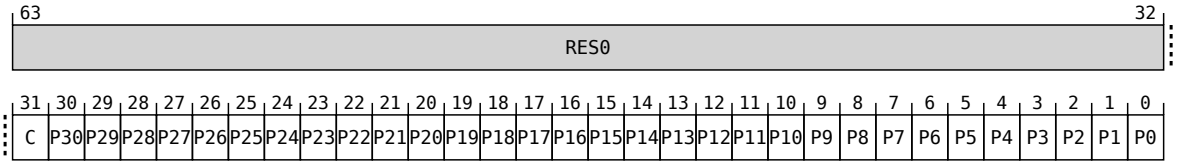
AArch64 System register PMINTENCLR_EL1 bits [31:0] are architecturally mapped to External register PMINTENSET_EL1[31:0].

This register is present only when FEAT_PMUv3 is implemented. Otherwise, direct accesses to PMINTENCLR_EL1 are UNDEFINED.

Attributes

PMINTENCLR_EL1 is a 64-bit register.

Field descriptions



Bits [63:32]

Reserved, RES0.

C, bit [31]

Interrupt request on unsigned overflow of PMCCNTR_EL0 disable. On writes, allows software to disable the interrupt request on unsigned overflow of PMCCNTR_EL0. On reads, returns the interrupt request on unsigned overflow of PMCCNTR_EL0 enable status.

C	Meaning
0b0	Interrupt request on unsigned overflow of PMCCNTR_EL0 disabled.
0b1	Interrupt request on unsigned overflow of PMCCNTR_EL0 enabled.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Access to this field is W1C.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

P<m> , bits [m], for m = 30 to 0

Interrupt request on unsigned overflow of PMEVCNTR<m>_EL0 disable. On writes, allows software to disable the interrupt request on unsigned overflow of PMEVCNTR<m>_EL0. On reads, returns the interrupt request on unsigned overflow of PMEVCNTR<m>_EL0 enable status.

P<m>	Meaning
0b0	Interrupt request on unsigned overflow of PMEVCNTR<m>_EL0 disabled.
0b1	Interrupt request on unsigned overflow of PMEVCNTR<m>_EL0 enabled.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing this field has the following behavior:

- When m >= GetNumEventCountersAccessible(), access to this field is RAZ/WI.
- Otherwise, access to this field is W1C.

Accessing PMINTENCLR_EL1

Accesses to this register use the following encodings in the System register encoding space:

D12.5.12 PMMIR_EL1, Performance Monitors Machine Identification Register

The PMMIR_EL1 characteristics are:

Purpose

Describes Performance Monitors parameters specific to the implementation to software.

Configuration

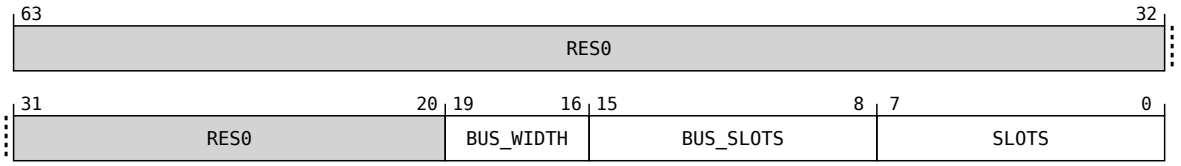
When FEAT_PMUv3_EXT is implemented and FEAT_PMUv3p4 is implemented, AArch64 System register PMMIR_EL1 bits [31:0] are architecturally mapped to External register PMMIR[31:0].

This register is present only when FEAT_PMUv3p4 is implemented. Otherwise, direct accesses to PMMIR_EL1 are UNDEFINED.

Attributes

PMMIR_EL1 is a 64-bit register.

Field descriptions



Bits [63:20]

Reserved, RES0.

BUS_WIDTH, bits [19:16]

Bus width. Indicates the number of bytes each BUS_ACCESS event relates to. Encoded as Log_2(number of bytes), plus one.

The value of this field is an IMPLEMENTATION DEFINED choice of:

BUS_WIDTH	Meaning
0b0000	The information is not available.
0b0011	Four bytes.
0b0100	8 bytes.
0b0101	16 bytes.
0b0110	32 bytes.
0b0111	64 bytes.
0b1000	128 bytes.
0b1001	256 bytes.
0b1010	512 bytes.
0b1011	1024 bytes.
0b1100	2048 bytes.

All other values are reserved.

Each transfer is up to this number of bytes. An access might be smaller than the bus width.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

When this field is nonzero, each access counted by BUS_ACCESS is at most BUS_WIDTH bytes. An implementation might treat a wide bus as multiple narrower buses, such that a wide access on the bus increments the BUS_ACCESS counter by more than one.

Access to this field is RO.

BUS_SLOTS, bits [15:8]

Bus count. The largest value by which the BUS_ACCESS event might increment in a single BUS_CYCLES cycle.

This field has an IMPLEMENTATION DEFINED value.

When this field is nonzero, the largest value by which the BUS_ACCESS event might increment in a single BUS_CYCLES cycle is BUS_SLOTS.

If the bus count information is not available, this field will read as zero.

Access to this field is RO.

SLOTS, bits [7:0]

Operation width. The largest value by which the STALL_SLOT event might increment in a single cycle. If the STALL_SLOT event is not implemented, this field might read as zero.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

Accessing PMMIR_EL1

Accesses to this register use the following encodings in the System register encoding space:

```
MRS <Xt>, PMMIR_EL1
```

op0	op1	CRn	CRm	op2
0b11	0b000	0b1001	0b1110	0b110

```
if !IsFeatureImplemented(FEAT_PMUv3p4) then
    UNDEFINED;
elsif PSTATE.EL == EL0 then
    UNDEFINED;
elsif PSTATE.EL == EL1 then

D12.5.13 PMOVSCLR_EL0, Performance Monitors Overflow Flag Status Clear Register

The PMOVSCLR_EL0 characteristics are:

Purpose

Allows software to clear the unsigned overflow flags for the following counters to 0:

- The cycle counter PMCCNTR_EL0.
- The event counters PMEVCNTR<n>_EL0.

Reading from this register shows the current unsigned overflow flag values.

Configuration

AArch64 System register PMOVSCLR_EL0 bits [63:0] are architecturally mapped to AArch64 System register PMOVSSET_EL0[63:0].

AArch64 System register PMOVSCLR_EL0 bits [31:0] are architecturally mapped to External register PMOVSCLR_EL0[31:0].

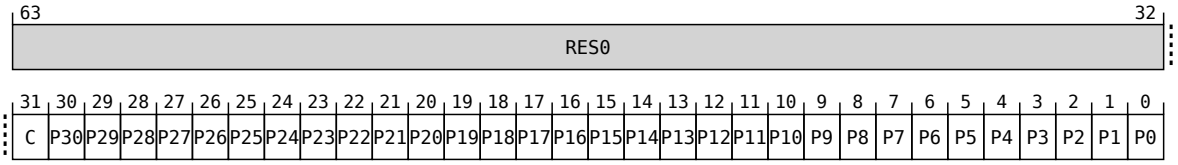
AArch64 System register PMOVSCLR_EL0 bits [31:0] are architecturally mapped to External register PMOVSSET_EL0[31:0].

This register is present only when FEAT_PMUv3 is implemented. Otherwise, direct accesses to PMOVSCLR_EL0 are UNDEFINED.

Attributes

PMOVSCLR_EL0 is a 64-bit register.

Field descriptions



Bits [63:32]

Reserved, RES0.

C, bit [31]

Unsigned overflow flag for PMCCNTR_EL0 clear. On writes, allows software to clear the unsigned overflow flag for PMCCNTR_EL0 to 0. On reads, returns the unsigned overflow flag for PMCCNTR_EL0 overflow status.

C	Meaning
0b0	PMCCNTR_EL0 has not overflowed.
0b1	PMCCNTR_EL0 has overflowed.

PMCR_EL0.LC controls whether an overflow is detected from unsigned overflow of PMCCNTR_EL0[31:0] or unsigned overflow of PMCCNTR_EL0[63:0].

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Access to this field is W1C.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

P<m> , bits [m], for m = 30 to 0

Unsigned overflow flag for PMEVCNTR<m>_EL0 clear. On writes, allows software to clear the unsigned overflow flag for PMEVCNTR<m>_EL0 to 0. On reads, returns the unsigned overflow flag for PMEVCNTR<m>_EL0 overflow status.

P<m>	Meaning
0b0	PMEVCNTR<m>_EL0 has not overflowed.
0b1	PMEVCNTR<m>_EL0 has overflowed.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing this field has the following behavior:

- When m >= GetNumEventCountersAccessible(), access to this field is RAZ/WI.
- Otherwise, access to this field is W1C.

D12.5.14 PMOVSSET_EL0, Performance Monitors Overflow Flag Status Set Register

The PMOVSSET_EL0 characteristics are:

Purpose

Allows software to set the unsigned overflow flags for the following counters to 1:

- The cycle counter PMCCNTR_EL0.
- The event counters PMEVCNTR<n>_EL0.

Reading from this register shows the current unsigned overflow flag values.

Configuration

AArch64 System register PMOVSSET_EL0 bits [63:0] are architecturally mapped to AArch64 System register PMOVSCLR_EL0[63:0].

AArch64 System register PMOVSSET_EL0 bits [31:0] are architecturally mapped to External register PMOVSCLR_EL0[31:0].

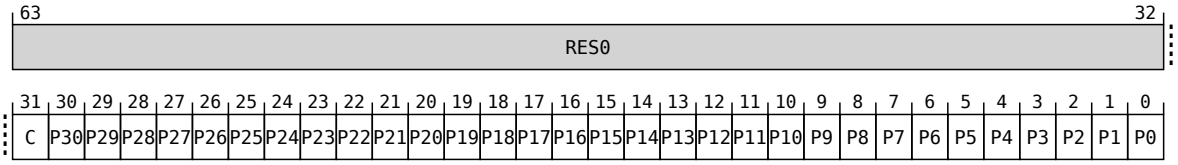
AArch64 System register PMOVSSET_EL0 bits [31:0] are architecturally mapped to External register PMOVSSET_EL0[31:0].

This register is present only when FEAT_PMUv3 is implemented. Otherwise, direct accesses to PMOVSSET_EL0 are UNDEFINED.

Attributes

PMOVSSET_EL0 is a 64-bit register.

Field descriptions



Bits [63:32]

Reserved, RES0.

C, bit [31]

Unsigned overflow flag for PMCCNTR_EL0 set. On writes, allows software to set the unsigned overflow flag for PMCCNTR_EL0 to 1. On reads, returns the unsigned overflow flag for PMCCNTR_EL0 overflow status.

C	Meaning
0b0	PMCCNTR_EL0 has not overflowed.
0b1	PMCCNTR_EL0 has overflowed.

PMCR_EL0.LC controls whether an overflow is detected from unsigned overflow of PMCCNTR_EL0[31:0] or unsigned overflow of PMCCNTR_EL0[63:0].

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Access to this field is W1S.

D12.5.15 PMSELR_EL0, Performance Monitors Event Counter Selection Register

The PMSELR_EL0 characteristics are:

Purpose

Selects the current event counter PMEVCNTR<n>_EL0 or the cycle counter PMCCNTR_EL0.

Used in conjunction with PMXEVTYPER_EL0 to determine the event that increments a selected counter, and the modes and states in which the selected counter increments.

Used in conjunction with PMXEVCNTR_EL0 to determine the value of a selected counter.

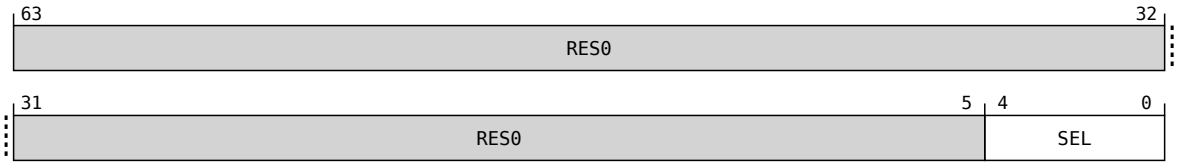
Configuration

This register is present only when FEAT_PMUv3 is implemented. Otherwise, direct accesses to PMSELR_EL0 are UNDEFINED.

Attributes

PMSELR_EL0 is a 64-bit register.

Field descriptions



Bits [63:5]

Reserved, RES0.

SEL, bits [4:0]

Event counter select. Selects the counter accessed by subsequent accesses to PMXEVTYPER_EL0 and PMXEVCNTR_EL0.

SEL	Meaning
0b00000..0b11110	Select event counter PMEVCNTR<n>_EL0, where n is the value of this field: • MRS and MSR of PMXEVTYPER_EL0 access PMEVTYPER<n>_EL0. • MRS and MSR of PMXEVCNTR_EL0 access PMEVCNTR<n>_EL0.
0b11111	Select the cycle counter, PMCCNTR_EL0: • MRS and MSR of PMXEVTYPER_EL0 access PMCCFILTR_EL0. • MRS and MSR of PMXEVCNTR_EL0 are CONSTRAINED UNPREDICTABLE. For more information, see PMXEVCNTR_EL0.

If this field is set to a value greater than or equal to the number of implemented counters, but not equal to 31, then direct reads of this field return an UNKNOWN value.

For more information about the results of accesses to the event counters, including when PMSELR_EL0.SEL is set to the index of an unimplemented or inaccessible event counter, see PMXEVTYPER_EL0 and PMXEVCNTR_EL0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

D12.5.16 PMSWINC_EL0, Performance Monitors Software Increment Register

The PMSWINC_EL0 characteristics are:

Purpose

Increments a counter that is configured to count the Software increment event, event `0x00`. For more information, see 'SW_INCR'.

Configuration

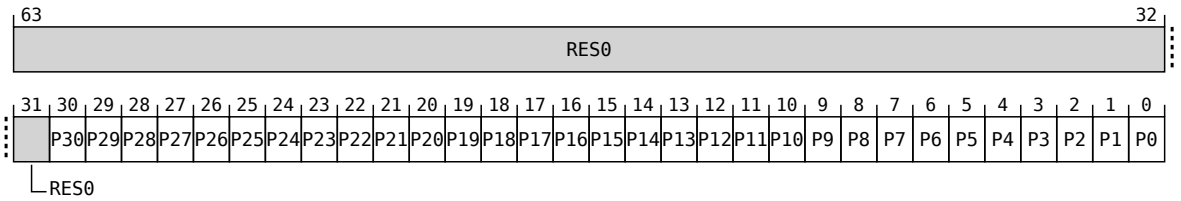
When FEAT_PMUv3_EXT32 is implemented, AArch64 System register PMSWINC_EL0 bits [31:0] are architecturally mapped to External register PMSWINC_EL0[31:0].

This register is present only when FEAT_PMUv3 is implemented. Otherwise, direct accesses to PMSWINC_EL0 are UNDEFINED.

Attributes

PMSWINC_EL0 is a 64-bit register.

Field descriptions



Bits [63:31]

Reserved, RES0.

P<m> , bits [m], for m = 30 to 0

Software increment.

P<m>	Meaning
`0b0`	Write is ignored.
`0b1`	Increment PMEVCNTR<m>_EL0, if PMEVCNTR<m>_EL0 is configured to count software increment events.

Accessing this field has the following behavior:

- When m >= GetNumEventCountersAccessible(), access to this field is RAZ/WI.
- Otherwise, access to this field is WO/RAZ.

Accessing PMSWINC_EL0

Accesses to this register use the following encodings in the System register encoding space:

`MSR PMSWINC_EL0, <Xt>`

op0	op1	CRn	CRm	op2

D12.5.17 PMUSERENR_EL0, Performance Monitors User Enable Register

The PMUSERENR_EL0 characteristics are:

Purpose

Enables or disables EL0 access to the Performance Monitors.

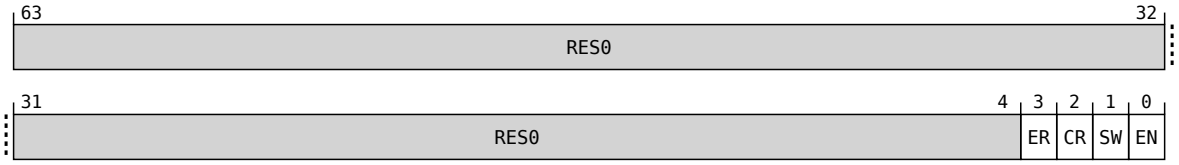
Configuration

This register is present only when FEAT_PMUv3 is implemented. Otherwise, direct accesses to PMUSERENR_EL0 are UNDEFINED.

Attributes

PMUSERENR_EL0 is a 64-bit register.

Field descriptions



Bits [63:4]

Reserved, RES0.

ER, bit [3]

Event counters Read enable.

When PMUSERENR_EL0.EN is 0, PMUSERENR_EL0.ER enables EL0 reads of the event counters and EL0 reads and writes of the select register.

ER	Meaning
0b0	EL0 reads of the event counters and EL0 reads and writes of the select register are disabled, unless enabled by PMUSERENR_EL0.EN.
0b1	EL0 reads of the event counters and EL0 reads and writes of the select register are enabled, unless trapped by another control.

In AArch64 state, the register accesses affected by this control are:

- MRS reads of PMEVCNTR<n>_EL0 and PMXEVCNTR_EL0.
- MRS and MSR accesses to PMSELR_EL0.

When disabled, reads and writes generate an exception to EL1, or to EL2 when EL2 is implemented and enabled for the current Security state and HCR_EL2.TGE is 1, and:

- AArch64 MRS and MSR accesses are reported using EC syndrome value 0x18.

This field is ignored by the PE when PMUSERENR_EL0.EN == 1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

CR, bit [2]

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Cycle counter Read enable.

When PMUSERENR_EL0.EN is 0, PMUSERENR_EL0.CR enables EL0 reads of the cycle counter.

CR	Meaning
0b0	EL0 reads of the cycle counter are disabled, unless enabled by PMUSERENR_EL0.EN.
0b1	EL0 reads of the cycle counter are enabled, unless trapped by another control.

In AArch64 state, the register accesses affected by this control are:

- MRS reads of PMCCNTR_EL0.

When disabled, reads generate an exception to EL1, or to EL2 when EL2 is implemented and enabled for the current Security state and HCR_EL2.TGE is 1, and:

- AArch64 MRS reads are reported using EC syndrome value 0x18.

This field is ignored by the PE when PMUSERENR_EL0.EN == 1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

SW, bit [1]

Software increment register Write enable.

When PMUSERENR_EL0.EN is 0, PMUSERENR_EL0.SW enables EL0 writes to the Software increment register.

SW	Meaning
0b0	EL0 writes to the Software increment register are disabled, unless enabled by PMUSERENR_EL0.EN.
0b1	EL0 writes to the Software increment register are enabled, unless trapped by another control.

In AArch64 state, the register accesses affected by this control are:

- MSR writes to PMSWINC_EL0.

When disabled, writes generate an exception to EL1, or to EL2 when EL2 is implemented and enabled for the current Security state and HCR_EL2.TGE is 1, and:

- AArch64 MSR writes are reported using EC syndrome value 0x18.

This field is ignored by the PE when PMUSERENR_EL0.EN == 1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

EN, bit [0]

Enable.

Enables EL0 read/write access to PMU registers.

EN	Meaning
0b0	EL0 accesses to the specified PMU System registers are trapped, unless enabled by PMUSERENR_EL0.{ER,CR,SW}.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

0b1	EL0 accesses to the specified PMU System registers are enabled, unless trapped by another control.

In AArch64 state, the register accesses affected by this control are:

- MRS or MSR accesses to PMCCFILTR_EL0, PMCCNTR_EL0, PMCNTENCLR_EL0, PMCNTENSET_EL0, PMCR_EL0, PMEVCNTR<n>_EL0, PMEVTYPER<n>_EL0, PMOVSCLR_EL0, PMOVSSET_EL0, PMSELR_EL0, PMXEVCNTR_EL0, and PMXEVTYPER_EL0.
- MRS reads of PMCEID0_EL0 and PMCEID1_EL0.
- MSR writes to PMSWINC_EL0.

When trapped, reads and writes generate an exception to EL1, or to EL2 when EL2 is implemented and enabled for the current Security state and HCR_EL2.TGE is 1, and:

- AArch64 MRS and MSR accesses are reported using EC syndrome value 0x18.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing PMUSERENR_EL0

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, PMUSERENR_EL0

op0	op1	CRn	CRm	op2

D12.5.18 PMXEVCNTR_EL0, Performance Monitors Selected Event Count Register

The PMXEVCNTR_EL0 characteristics are:

Purpose

Reads or writes the value of the selected event counter, PMEVCNTR<n>_EL0. PMSELR_EL0.SEL determines which event counter is selected.

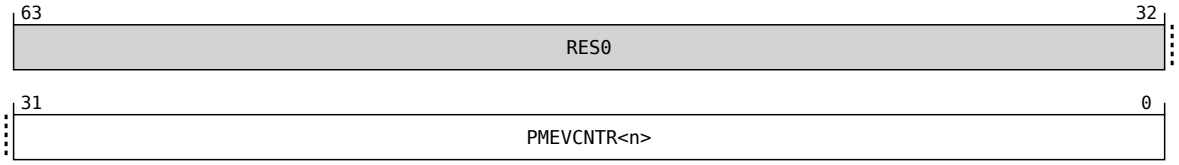
Configuration

This register is present only when FEAT_PMUv3 is implemented. Otherwise, direct accesses to PMXEVCNTR_EL0 are UNDEFINED.

Attributes

PMXEVCNTR_EL0 is a 64-bit register.

Field descriptions



Bits [63:32]

Reserved, RES0.

PMEVCNTR<n>, bits [31:0]

Value of the selected event counter, PMEVCNTR<n>_EL0, where n is the value stored in PMSELR_EL0.SEL.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing PMXEVCNTR_EL0

If PMSELR_EL0.SEL is greater than or equal to the number of accessible event counters, then reads and writes of PMXEVCNTR_EL0 are CONSTRAINED UNPREDICTABLE, and the following behaviors are permitted:

- Accesses to the register are UNDEFINED.
- Accesses to the register behave as RAZ/WI.
- Accesses to the register execute as a NOP
- Accesses to the register behave as if PMSELR_EL0.SEL has an UNKNOWN value less than the number of counters accessible at the current Exception level and Security state.
- If EL2 is implemented and enabled in the current Security state, and PMSELR_EL0.SEL is less than the number of implemented event counters, accesses from EL1 or permitted accesses from EL0 are trapped to EL2.

Note

In EL0, an access is permitted if it is enabled by PMUSERENR_EL0.{ER,EN}.
If EL2 is implemented and enabled in the current Security state, in EL1 and EL0, MDCR_EL2.HPMN identifies the number of accessible event counters.
Otherwise, the number of accessible event counters is the number of implemented event counters. For more information, see MDCR_EL2.HPMN.

Accesses to this register use the following encodings in the System register encoding space:

D12.5.19 PMXEVTYPER_EL0, Performance Monitors Selected Event Type Register

The PMXEVTYPER_EL0 characteristics are:

Purpose

When PMSELR_EL0.SEL selects an event counter, this accesses a PMEVTYPER<n>_EL0 register. When PMSELR_EL0.SEL selects the cycle counter, this accesses PMCCFILTR_EL0.

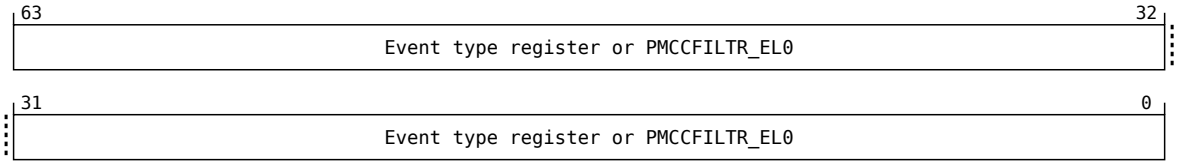
Configuration

This register is present only when FEAT_PMUv3 is implemented. Otherwise, direct accesses to PMXEVTYPER_EL0 are UNDEFINED.

Attributes

PMXEVTYPER_EL0 is a 64-bit register.

Field descriptions



EVTYPERn, bits [63:0]

When PMSELR_EL0.SEL == 31, this register accesses PMCCFILTR_EL0.

Otherwise, this register accesses PMEVTYPER<n>_EL0 where n is the value in PMSELR_EL0.SEL.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing PMXEVTYPER_EL0

If PMSELR_EL0.SEL is not 31, and is greater than or equal to the number of accessible event counters, then reads and writes of PMXEVTYPER_EL0 are CONSTRAINED UNPREDICTABLE, and the following behaviors are permitted:

- Accesses to the register are UNDEFINED.
- Accesses to the register behave as RAZ/WI.
- Accesses to the register execute as a NOP.
- Accesses to the register behave as if PMSELR_EL0.SEL has an UNKNOWN value less than the number of event counters accessible at the current Exception level and Security state.
- Accesses to the register behave as if PMSELR_EL0.SEL is 31.
- If PMSELR_EL0 is less than the number of implemented event counters, accesses from EL1 or permitted accesses from EL0 are trapped to EL2.

Note

In EL0, an access is permitted if it is enabled by PMUSERENR_EL0.EN.
In in EL1 and EL0, MDCR_EL2.HPMN identifies the number of accessible event counters.
Otherwise, the number of accessible event counters is the number of implemented event counters. For more information, see MDCR_EL2.HPMN.

Accesses to this register use the following encodings in the System register encoding space:

```
MRS <Xt>, PMXEVTYPER_EL0
```

D12.6.1 MPUIR_EL1, MPU Type Register (EL1)

The MPUIR_EL1 characteristics are:

Purpose

Identifies the number of regions supported by the EL1 MPU.

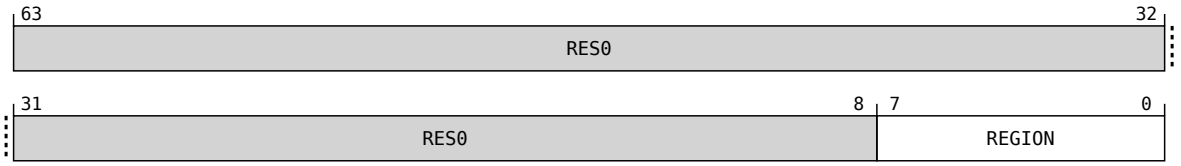
Configuration

There are no configuration notes.

Attributes

MPUIR_EL1 is a 64-bit register.

Field descriptions



Bits [63:8]

Reserved, RES0.

REGION, bits [7:0]

The number of EL1 MPU regions supported.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

Accessing MPUIR_EL1

Accesses to this register use the following encodings in the System register encoding space:

```
MRS <Xt>, MPUIR_EL1
```

op0	op1	CRn	CRm	op2
0b11	0b000	0b0000	0b0000	0b100

```

D12.6.3 PRBAR_EL1, Protection Region Base Address Register (EL1)

The PRBAR_EL1 characteristics are:

Purpose

Provides access to the base addresses for the EL1 MPU region. PRSELR_EL1.REGION determines which MPU region is selected.

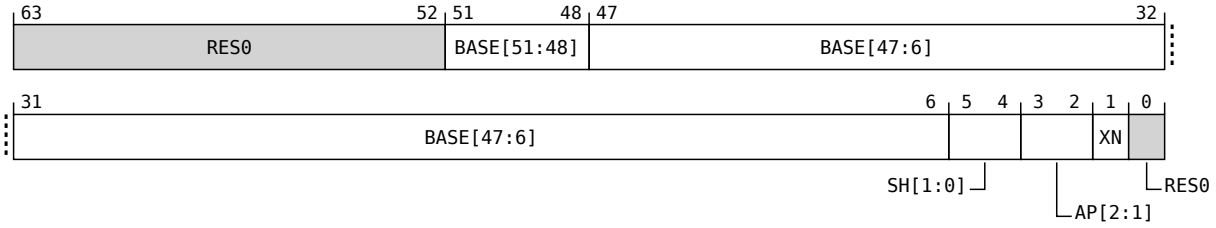
Configuration

All bits above implemented physical address range in this register should be treated as RES0.

Attributes

PRBAR_EL1 is a 64-bit register.

Field descriptions



Bits [63:52]

Reserved, RES0.

BASE[51:48], bits [51:48]

When FEAT_LPA is implemented:

Extension to BASE[47:6]. When FEAT_LPA is implemented, BASE[51:48] form the upper part of the address value. Otherwise, for implementations with fewer than 52 physical address bits, the upper bits of this field, corresponding to address bits that are not implemented, are RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

BASE[47:6], bits [47:6]

Bits[47:6] of the lower inclusive limit of the selected EL1 MPU memory region. This value is zero extended to provide the base address to be checked against.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

SH[1:0], bits [5:4]

Shareability attribute.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

SH[1:0]	Meaning
0b00	Non-shareable
0b01	Reserved, CONSTRAINED UNPREDICTABLE
0b10	Outer Shareable
0b11	Inner Shareable

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

AP[2:1], bits [3:2]

Access Permission attributes.

AP[2:1]	Meaning
0b00	Read/write at EL1, no access at EL0
0b01	Read/write at EL1 and EL0
0b10	Read-only at EL1, no access at EL0
0b11	Read-only at EL1 and EL0

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

XN, bit [1]

Execute Never

XN	Meaning
0b0	Execution of instructions fetched from the region is permitted.
0b1	Execution of instructions fetched from the region is not permitted.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [0]

Reserved, RES0.

Accessing PRBAR_EL1

Any access to MPU region register PRBAR_EL1 above the number of implemented regions specified by MPUIR_EL1.REGION is CONSTRAINED UNPREDICTABLE.

CONSTRAINED UNPREDICTABLE behavior is defined as:

- Reads of unimplemented PRBAR_EL1 register return an UNKNOWN value.
- Writes to unimplemented PRBAR_EL1 register make all PRBAR_EL1 registers value UNKNOWN.

Accesses to this register use the following encodings in the System register encoding space:

```
MRS <Xt>, PRBAR_EL1
```

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.

D12.6.4 PRBAR_EL2, Protection Region Base Address Register (EL2)

The PRBAR_EL2 characteristics are:

Purpose

Provides access to the base addresses for the EL2 MPU region. PRSELR_EL2.REGION determines which MPU region is selected.

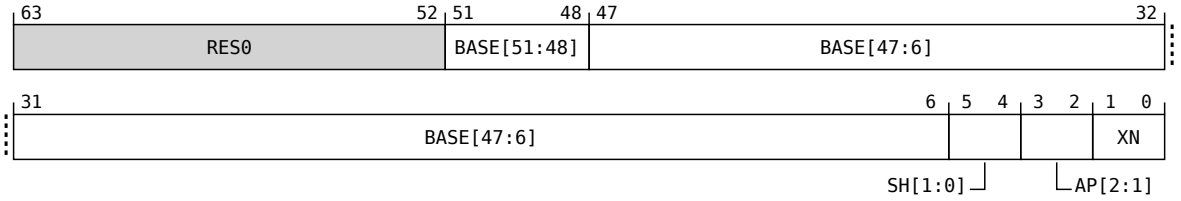
Configuration

All bits above implemented physical address range in this register should be treated as RES0.

Attributes

PRBAR_EL2 is a 64-bit register.

Field descriptions



Bits [63:52]

Reserved, RES0.

BASE[51:48], bits [51:48]

When FEAT_LPA is implemented:

Extension to BASE[47:6]. When FEAT_LPA is implemented, BASE[51:48] form the upper part of the address value. Otherwise, for implementations with fewer than 52 physical address bits, the upper bits of this field, corresponding to address bits that are not implemented, are RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

BASE[47:6], bits [47:6]

Bits[47:6] of the lower inclusive limit of the selected EL2 MPU memory region. This value is zero extended to provide the base address to be checked against.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

SH[1:0], bits [5:4]

Shareability attribute.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

SH[1:0]	Meaning
0b00	Non-shareable
0b01	Reserved, CONSTRAINED UNPREDICTABLE
0b10	Outer Shareable
0b11	Inner Shareable

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

AP[2:1], bits [3:2]

Access Permission attributes.

AP[2:1]	Meaning
0b00	Read/write at EL2, no access at EL1 or EL0
0b01	Read/write at EL2, EL1 and EL0
0b10	Read-only at EL2, no access at EL1 or EL0
0b11	Read-only at EL2, EL1 and EL0

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

XN, bits [1:0]

Execute Never. For

- Stage 1 EL2 translation regime and
- Stage 2 EL1&0 translation regime when FEAT_XNX is not implemented

XN[1] determines whether execution of the instructions fetched from the MPU memory region is permitted. In this case, XN[0] is RES0

For stage 2 EL1&0 translation regime when FEAT_XNX is implemented, the behavior of XN[1:0] is same as that defined by VMSAv8-64 for EL1&0 stage 2 translation table XN[1:0],bits[54:53] field in Armv8-A architecture.

XN	Meaning
0b00	Execution of instructions fetched from the region is permitted.
0b01	Execution of instructions fetched from the region is not permitted.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing PRBAR_EL2

Any access to MPU region register PRBAR_EL2 above the number of implemented regions specified by MPUIR_EL2.REGION is CONSTRAINED UNPREDICTABLE.

CONSTRAINED UNPREDICTABLE behavior is defined as:

- Reads of unimplemented PRBAR_EL2 register return an UNKNOWN value.
- Writes to unimplemented PRBAR_EL2 register make all PRBAR_EL2 registers value UNKNOWN.

Accesses to this register use the following encodings in the System register encoding space:

D12.6.7 PRLAR_EL1, Protection Region Limit Address Register (EL1)

The PRLAR_EL1 characteristics are:

Purpose

Provides access to the limit addresses for the EL1 MPU region. PRSELR_EL1.REGION determines which MPU region is selected.

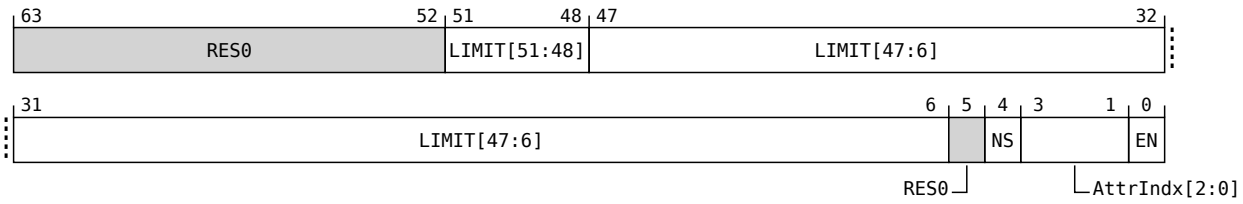
Configuration

All bits above implemented physical address range in this register should be treated as RES0.

Attributes

PRLAR_EL1 is a 64-bit register.

Field descriptions



Bits [63:52]

Reserved, RES0.

LIMIT[51:48], bits [51:48]

When FEAT_LPA is implemented:

Extension to LIMIT[47:6]. When FEAT_LPA is implemented, LIMIT[51:48] form the upper part of the address value. Otherwise, for implementations with fewer than 52 physical address bits, the upper bits of this field, corresponding to address bits that are not implemented, are RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

LIMIT[47:6], bits [47:6]

Bits[47:6] of the upper inclusive limit of the selected EL1 MPU memory region. This value is concatenated with the value `0x3F` to provide the limit address to be checked against.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [5]

Reserved, RES0.

NS, bit [4]

Non-secure bit. Specifies whether the output address is in the Secure or Non-secure memory.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

NS	Meaning
0b0	Output address is in Secure address space.
0b1	Output address is in Non-secure address space.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

AttrIndx[2:0], bits [3:1]

Selects attributes from within the associated Memory Attribute Indirection Register.

AttrIndx[2:0]	Meaning
0b000	Select the Attr0 field from MAIR_EL1.
0b001	Select the Attr1 field from MAIR_EL1.
0b010	Select the Attr2 field from MAIR_EL1.
0b011	Select the Attr3 field from MAIR_EL1.
0b100	Select the Attr4 field from MAIR_EL1.
0b101	Select the Attr5 field from MAIR_EL1.
0b110	Select the Attr6 field from MAIR_EL1.
0b111	Select the Attr7 field from MAIR_EL1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

EN, bit [0]

Region enable bit.

EN	Meaning
0b0	Region disabled.
0b1	Region enabled.

The reset behavior of this field is:

- On a Warm reset, this field resets to '0'.

Accessing PRLAR_EL1

Any access to MPU region register PRLAR_EL1 above the number of implemented regions specified by MPUIR_EL1.REGION is CONSTRAINED UNPREDICTABLE.

CONSTRAINED UNPREDICTABLE behavior is defined as:

- Reads of unimplemented PRLAR_EL1 register return an UNKNOWN value.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- Writes to unimplemented PRLAR_EL1 register make all PRLAR_EL1 registers value UNKNOWN.

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, PRLAR_EL1

op0	op1	CRn	CRm	op2
0b11	0b000	0b0110	0b1000	0b001

```
if UInt(PRSELR_EL1.REGION) >= UInt(MPUIR_EL1.REGION) then

D12.6.8 PRLAR_EL2, Protection Region Limit Address Register (EL2)

The PRLAR_EL2 characteristics are:

Purpose

Provides access to the limit addresses for the EL2 MPU region. PRSELR_EL2.REGION determines which MPU region is selected.

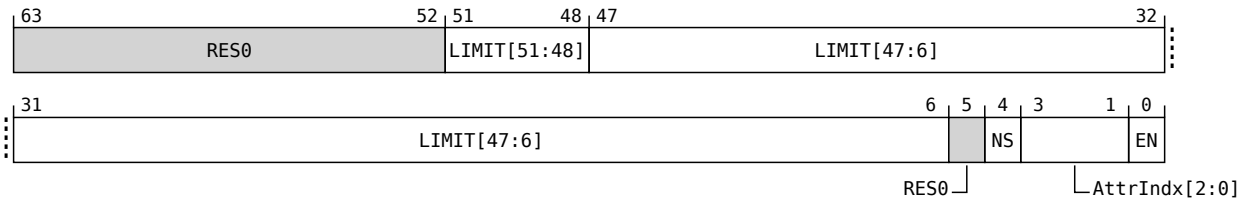
Configuration

All bits above implemented physical address range in this register should be treated as RES0.

Attributes

PRLAR_EL2 is a 64-bit register.

Field descriptions



Bits [63:52]

Reserved, RES0.

LIMIT[51:48], bits [51:48]

When FEAT_LPA is implemented:

Extension to LIMIT[47:6]. When FEAT_LPA is implemented, LIMIT[51:48] form the upper part of the address value. Otherwise, for implementations with fewer than 52 physical address bits, the upper bits of this field, corresponding to address bits that are not implemented, are RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

LIMIT[47:6], bits [47:6]

Bits[47:6] of the upper inclusive limit of the selected EL2 MPU memory region. This value is concatenated with the value `0x3F` to provide the limit address to be checked against.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [5]

Reserved, RES0.

NS, bit [4]

Non-secure bit. Specifies whether the output address is in the Secure or Non-secure memory.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

NS	Meaning
0b0	Output address is in Secure address space.
0b1	Output address is in Non-secure address space.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

AttrIndx[2:0], bits [3:1]

Selects attributes from within the associated Memory Attribute Indirection Register.

AttrIndx[2:0]	Meaning
0b000	Select the Attr0 field from MAIR_EL2.
0b001	Select the Attr1 field from MAIR_EL2.
0b010	Select the Attr2 field from MAIR_EL2.
0b011	Select the Attr3 field from MAIR_EL2.
0b100	Select the Attr4 field from MAIR_EL2.
0b101	Select the Attr5 field from MAIR_EL2.
0b110	Select the Attr6 field from MAIR_EL2.
0b111	Select the Attr7 field from MAIR_EL2.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

EN, bit [0]

Region enable bit.

EN	Meaning
0b0	Region disabled.
0b1	Region enabled.

The reset behavior of this field is:

- On a Warm reset, this field resets to '0'.

Accessing PRLAR_EL2

Any access to MPU region register PRLAR_EL2 above the number of implemented regions specified by MPUIR_EL2.REGION is CONSTRAINED UNPREDICTABLE.

CONSTRAINED UNPREDICTABLE behavior is defined as:

- Reads of unimplemented PRLAR_EL2 register return an UNKNOWN value.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- Writes to unimplemented PRLAR_EL2 register make all PRLAR_EL2 registers value UNKNOWN.

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, PRLAR_EL2

op0	op1	CRn	CRm	op2
0b11	0b100	0b0110	0b1000	0b001

```

D12.6.9 PRSELR_EL1, Protection Region Selection Register (EL1)

The PRSELR_EL1 characteristics are:

Purpose

Selects the region number for the EL1 MPU region associated with the PRBAR_EL1 and PRLAR_EL1 registers.

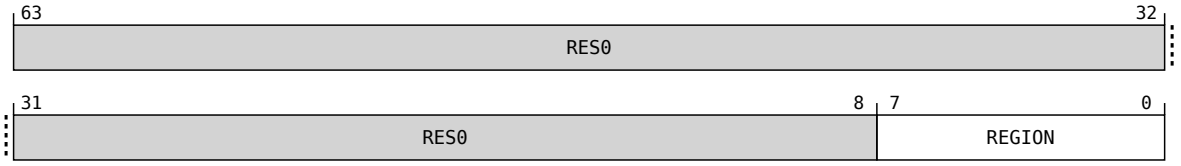
Configuration

There are no configuration notes.

Attributes

PRSELR_EL1 is a 64-bit register.

Field descriptions



Bits [63:8]

Reserved, RES0.

REGION, bits [7:0]

The number of the current EL1 MPU region visible in PRBAR_EL1 and PRLAR_EL1. For N implemented MPU regions, memory region numbering starts at 0 and increments by 1 to the value N-1.

Writing a value greater than or equal to the number of implemented MPU regions specified by MPUIR_EL1.REGION, results in CONSTRAINED UNPREDICTABLE behavior.

CONSTRAINED UNPREDICTABLE behavior is that PRSELR_EL1 register becomes UNKNOWN.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing PRSELR_EL1

Accesses to this register use the following encodings in the System register encoding space:

```
MRS <Xt>, PRSELR_EL1
```

op0	op1	CRn	CRm	op2
0b11	0b000	0b0110	0b0010	0b001

D12.6.10 PRSELR_EL2, Protection Region Selection Register (EL2)

The PRSELR_EL2 characteristics are:

Purpose

Selects the region number for the EL2 MPU region associated with the PRBAR_EL2 and PRLAR_EL2 registers.

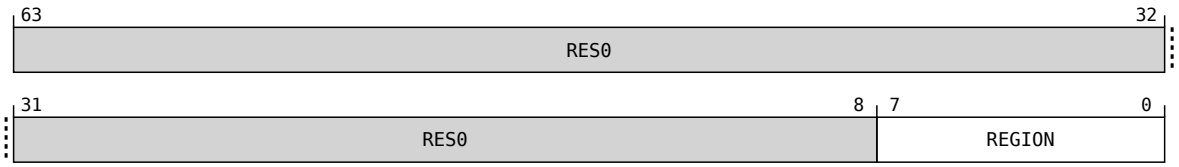
Configuration

There are no configuration notes.

Attributes

PRSELR_EL2 is a 64-bit register.

Field descriptions



Bits [63:8]

Reserved, RES0.

REGION, bits [7:0]

The number of the current EL2 MPU region visible in PRBAR_EL2 and PRLAR_EL2. For N implemented MPU regions, memory region numbering starts at 0 and increments by 1 to the value N-1.

Writing a value greater than or equal to the number of implemented MPU regions specified by MPUIR_EL2.REGION, results in CONSTRAINED UNPREDICTABLE behavior.

CONSTRAINED UNPREDICTABLE behavior is that PRSELR_EL2 register becomes UNKNOWN.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing PRSELR_EL2

Accesses to this register use the following encodings in the System register encoding space:

```
MRS <Xt>, PRSELR_EL2
```

op0	op1	CRn	CRm	op2
0b11	0b100	0b0110	0b0010	0b001

D12.7.1 DISR_EL1, Deferred Interrupt Status Register

The DISR_EL1 characteristics are:

Purpose

Records that an SError exception has been consumed by an ESB instruction.

Configuration

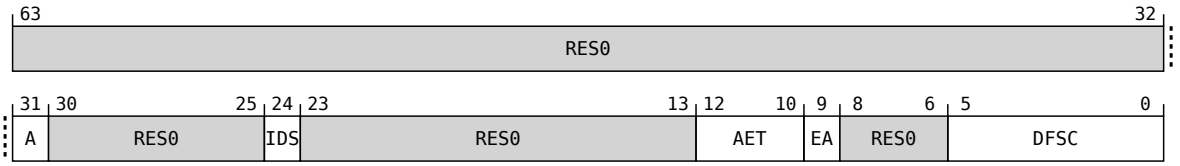
This register is present only when FEAT_RAS is implemented. Otherwise, direct accesses to DISR_EL1 are UNDEFINED.

Attributes

DISR_EL1 is a 64-bit register.

Field descriptions

When DISR_EL1.IDS == '0':



Bits [63:32]

Reserved, RES0.

A, bit [31]

Set to 1 when an ESB instruction defers an asynchronous SError exception. If the implementation does not include any sources of SError exception that can be synchronized by an Error Synchronization Barrier, then this bit is RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [30:25]

Reserved, RES0.

IDS, bit [24]

Indicates the deferred SError exception type.

IDS	Meaning
0b0	Deferred error uses architecturally-defined format.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [23:13]

Reserved, RES0.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

AET, bits [12:10]

Asynchronous Error Type. See the description of ESR_ELx.AET for an SError exception.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

EA, bit [9]

External abort Type. See the description of ESR_ELx.EA for an SError exception.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [8:6]

Reserved, RES0.

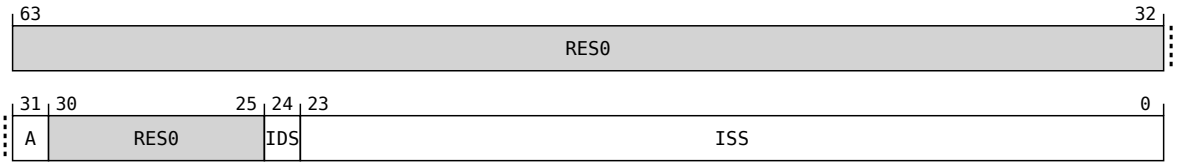
DFSC, bits [5:0]

Fault Status Code. See the description of ESR_ELx.DFSC for an SError exception.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

When DISR_EL1.IDS == '1':



Bits [63:32]

Reserved, RES0.

A, bit [31]

Set to 1 when an ESB instruction defers an asynchronous SError exception. If the implementation does not include any sources of SError exception that can be synchronized by an Error Synchronization Barrier, then this bit is RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [30:25]

Reserved, RES0.

IDS, bit [24]

Indicates the deferred SError exception type.

IDS	Meaning
0b1	Deferred error uses IMPLEMENTATION DEFINED format.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

IMPLEMENTATION DEFINED, bits [23:0]

IMPLEMENTATION DEFINED syndrome. See the description of ESR_ELx[23:0] for an SError exception.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing DISR_EL1

An indirect write to DISR_EL1 made by an ESB instruction does not require an explicit synchronization operation for the value that is written to be observed by a direct read of DISR_EL1 occurring in program order after the ESB instruction.

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, DISR_EL1

op0	op1	CRn	CRm	op2
0b11	0b000	0b1100	0b0001	0b001

```
if !IsFeatureImplemented(FEAT_RAS) then

D12.7.2 ERRIDR_EL1, Error Record ID Register

The ERRIDR_EL1 characteristics are:

Purpose

Defines the highest numbered index of the error records that can be accessed through the Error Record System registers.

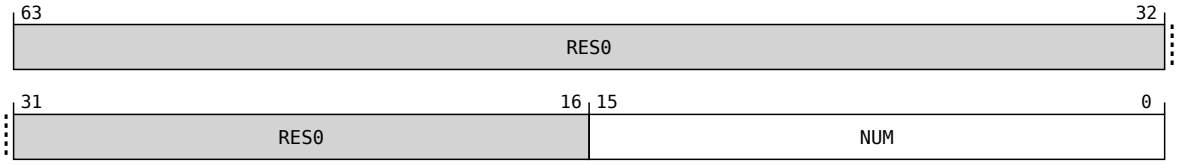
Configuration

This register is present only when FEAT_RAS is implemented. Otherwise, direct accesses to ERRIDR_EL1 are UNDEFINED.

Attributes

ERRIDR_EL1 is a 64-bit register.

Field descriptions



Bits [63:16]

Reserved, RES0.

NUM, bits [15:0]

Highest numbered index of the records that can be accessed through the Error Record System registers plus one. Zero indicates no records can be accessed through the Error Record System registers.

Each implemented record is owned by a node. A node might own multiple records.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

Accessing ERRIDR_EL1

Accesses to this register use the following encodings in the System register encoding space:

`MRS <Xt>, ERRIDR_EL1`

op0	op1	CRn	CRm	op2
0b11	0b000	0b0101	0b0011	0b000

```

D12.7.3 ERRSELR_EL1, Error Record Select Register

The ERRSELR_EL1 characteristics are:

Purpose

Selects an error record to be accessed through the Error Record System registers.

Configuration

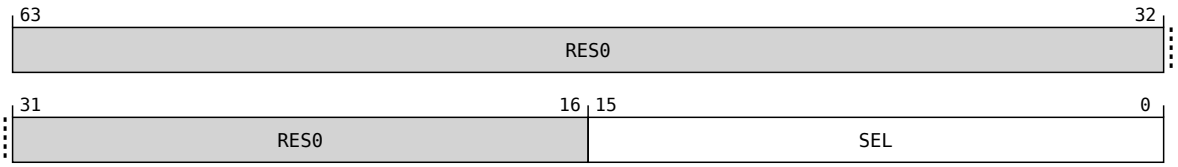
If ERRIDR_EL1 indicates that zero error records are implemented, then it is IMPLEMENTATION DEFINED whether ERRSELR_EL1 is UNDEFINED or RES0.

This register is present only when FEAT_RAS is implemented. Otherwise, direct accesses to ERRSELR_EL1 are UNDEFINED.

Attributes

ERRSELR_EL1 is a 64-bit register.

Field descriptions



Bits [63:16]

Reserved, RES0.

SEL, bits [15:0]

Selects the error record accessed through the ERX registers.

For example, if ERRSELR_EL1.SEL is 0x0004, then direct reads and writes of ERXSTATUS_EL1 access ERR4STATUS.

If ERRSELR_EL1.SEL is greater than or equal to ERRIDR_EL1.NUM, then all of the following apply:

- The value read back from ERRSELR_EL1.SEL is UNKNOWN.
- Unless the access to an ERX*_EL1 register generates a higher priority exception, one of the following occurs:
  - An UNKNOWN error record is selected.
  - The ERX*_EL1 registers are RAZ/WI.
  - ERX*_EL1 register reads and writes are NOPs.
  - ERX*_EL1 register reads and writes are UNDEFINED.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing ERRSELR_EL1

Accesses to this register use the following encodings in the System register encoding space:

```
MRS <Xt>, ERRSELR_EL1
```

op0	op1	CRn	CRm	op2

D12.7.4 ERXADDR_EL1, Selected Error Record Address Register

The ERXADDR_EL1 characteristics are:

Purpose

Accesses ERR<n>ADDR for the error record <n> selected by ERRSELR_EL1.SEL.

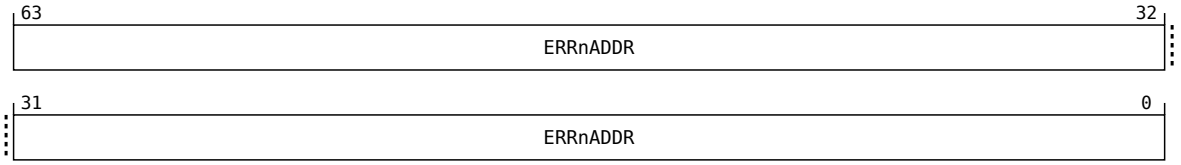
Configuration

This register is present only when FEAT_RAS is implemented. Otherwise, direct accesses to ERXADDR_EL1 are UNDEFINED.

Attributes

ERXADDR_EL1 is a 64-bit register.

Field descriptions



ERRnADDR, bits [63:0]

ERXADDR_EL1 accesses ERR<n>ADDR, where <n> is the value in ERRSELR_EL1.SEL.

Accessing ERXADDR_EL1

If ERRIDR_EL1.NUM is 0x0000 or ERRSELR_EL1.SEL is greater than or equal to ERRIDR_EL1.NUM, then one of the following occurs:

- An UNKNOWN error record is selected.
- ERXADDR_EL1 is RAZ/WI.
- Direct reads and writes of ERXADDR_EL1 are NOPs.
- Direct reads and writes of ERXADDR_EL1 are UNDEFINED.

ERR<n>ADDR describes additional constraints that also apply when ERR<n>ADDR is accessed through ERXADDR_EL1.

Accesses to this register use the following encodings in the System register encoding space:

```
MRS <Xt>, ERXADDR_EL1
```

op0	op1	CRn	CRm	op2
0b11	0b000	0b0101	0b0100	0b011

```
if !IsFeatureImplemented(FEAT_RAS) then
    UNDEFINED;
elsif PSTATE.EL == EL0 then
    UNDEFINED;

D12.7.5 ERXCTLR_EL1, Selected Error Record Control Register

The ERXCTLR_EL1 characteristics are:

Purpose

Accesses ERR<n>CTLR for the error record <n> selected by ERRSELR_EL1.SEL.

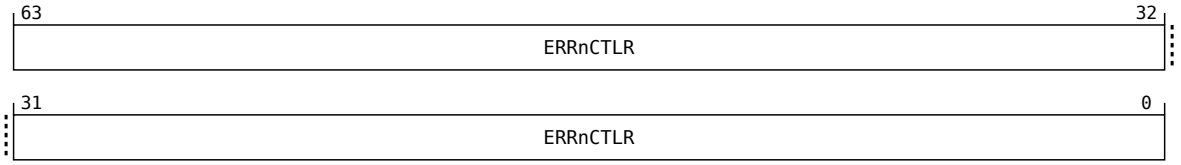
Configuration

This register is present only when FEAT_RAS is implemented. Otherwise, direct accesses to ERXCTLR_EL1 are UNDEFINED.

Attributes

ERXCTLR_EL1 is a 64-bit register.

Field descriptions



ERRnCTLR, bits [63:0]

ERXCTLR_EL1 accesses ERR<n>CTLR, where <n> is the value in ERRSELR_EL1.SEL.

Accessing ERXCTLR_EL1

If ERRIDR_EL1.NUM is 0x0000 or ERRSELR_EL1.SEL is greater than or equal to ERRIDR_EL1.NUM, then one of the following occurs:

- An UNKNOWN error record is selected.
- ERXCTLR_EL1 is RAZ/WI.
- Direct reads and writes of ERXCTLR_EL1 are NOPs.
- Direct reads and writes of ERXCTLR_EL1 are UNDEFINED.

If ERRSELR_EL1.SEL is not the index of the first error record owned by a node, then ERR<n>CTLR is not present, meaning reads and writes of ERXCTLR_EL1 are RES0.

Accesses to this register use the following encodings in the System register encoding space:

```
MRS <Xt>, ERXCTLR_EL1
```

op0	op1	CRn	CRm	op2
0b11	0b000	0b0101	0b0100	0b001

D12.7.6 ERXFR_EL1, Selected Error Record Feature Register

The ERXFR_EL1 characteristics are:

Purpose

Accesses ERR<n>FR for the error record <n> selected by ERRSELR_EL1.SEL.

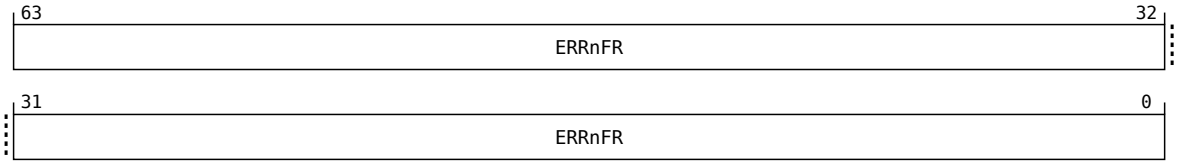
Configuration

This register is present only when FEAT_RAS is implemented. Otherwise, direct accesses to ERXFR_EL1 are UNDEFINED.

Attributes

ERXFR_EL1 is a 64-bit register.

Field descriptions



ERRnFR, bits [63:0]

ERXFR_EL1 accesses ERR<n>FR, where <n> is the value in ERRSELR_EL1.SEL.

Accessing ERXFR_EL1

If ERRIDR_EL1.NUM is `0x0000` or ERRSELR_EL1.SEL is greater than or equal to ERRIDR_EL1.NUM, then one of the following occurs:

- An UNKNOWN error record is selected.
- ERXFR_EL1 is RAZ.
- Direct reads of ERXFR_EL1 are NOPs.
- Direct reads of ERXFR_EL1 are UNDEFINED.

Accesses to this register use the following encodings in the System register encoding space:

`MRS <Xt>, ERXFR_EL1`

op0	op1	CRn	CRm	op2

D12.7.7 ERXMISC0_EL1, Selected Error Record Miscellaneous Register 0

The ERXMISC0_EL1 characteristics are:

Purpose

Accesses ERR<n>MISC0 for the error record <n> selected by ERRSELR_EL1.SEL.

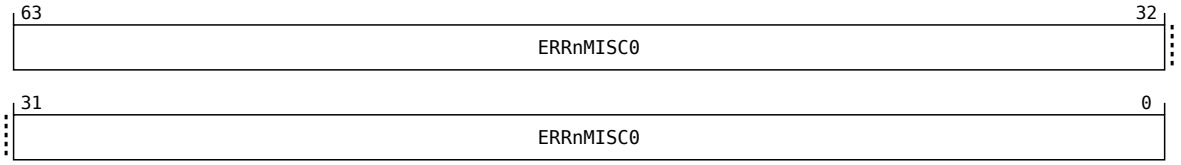
Configuration

This register is present only when FEAT_RAS is implemented. Otherwise, direct accesses to ERXMISC0_EL1 are UNDEFINED.

Attributes

ERXMISC0_EL1 is a 64-bit register.

Field descriptions



ERRnMISC0, bits [63:0]

ERXMISC0_EL1 accesses ERR<n>MISC0, where <n> is the value in ERRSELR_EL1.SEL.

Accessing ERXMISC0_EL1

If ERRIDR_EL1.NUM is `0x0000` or ERRSELR_EL1.SEL is greater than or equal to ERRIDR_EL1.NUM, then one of the following occurs:

- An UNKNOWN error record is selected.
- ERXMISC0_EL1 is RAZ/WI.
- Direct reads and writes of ERXMISC0_EL1 are NOPs.
- Direct reads and writes of ERXMISC0_EL1 are UNDEFINED.

ERR<n>MISC0 describes additional constraints that also apply when ERR<n>MISC0 is accessed through ERXMISC0_EL1.

D12.7.8 ERXMISC1_EL1, Selected Error Record Miscellaneous Register 1

The ERXMISC1_EL1 characteristics are:

Purpose

Accesses ERR<n>MISC1 for the error record <n> selected by ERRSELR_EL1.SEL.

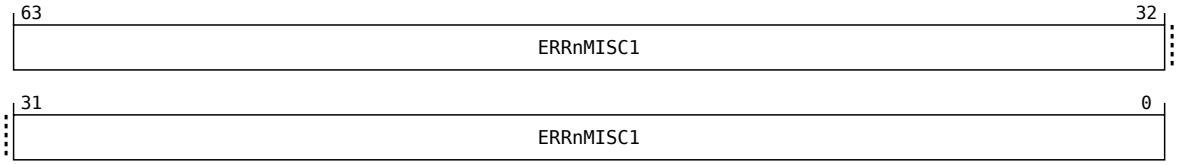
Configuration

This register is present only when FEAT_RAS is implemented. Otherwise, direct accesses to ERXMISC1_EL1 are UNDEFINED.

Attributes

ERXMISC1_EL1 is a 64-bit register.

Field descriptions



ERRnMISC1, bits [63:0]

ERXMISC1_EL1 accesses ERR<n>MISC1, where <n> is the value in ERRSELR_EL1.SEL.

Accessing ERXMISC1_EL1

If ERRIDR_EL1.NUM is `0x0000` or ERRSELR_EL1.SEL is greater than or equal to ERRIDR_EL1.NUM, then one of the following occurs:

- An UNKNOWN error record is selected.
- ERXMISC1_EL1 is RAZ/WI.
- Direct reads and writes of ERXMISC1_EL1 are NOPs.

D12.7.9 ERXMISC2_EL1, Selected Error Record Miscellaneous Register 2

The ERXMISC2_EL1 characteristics are:

Purpose

Accesses ERR<n>MISC2 for the error record <n> selected by ERRSELR_EL1.SEL.

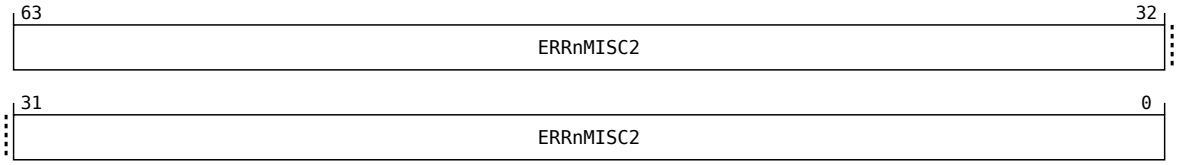
Configuration

This register is present only when FEAT_RASv1p1 is implemented. Otherwise, direct accesses to ERXMISC2_EL1 are UNDEFINED.

Attributes

ERXMISC2_EL1 is a 64-bit register.

Field descriptions



ERRnMISC2, bits [63:0]

ERXMISC2_EL1 accesses ERR<n>MISC2, where <n> is the value in ERRSELR_EL1.SEL.

Accessing ERXMISC2_EL1

If ERRIDR_EL1.NUM is 0x0000 or ERRSELR_EL1.SEL is greater than or equal to ERRIDR_EL1.NUM, then one of the following occurs:

- An UNKNOWN error record is selected.
- ERXMISC2_EL1 is RAZ/WI.
- Direct reads and writes of ERXMISC2_EL1 are NOPs.
- Direct reads and writes of ERXMISC2_EL1 are UNDEFINED.

D12.7.11 ERXPFGCDN_EL1, Selected Pseudo-fault Generation Countdown Register

The ERXPFGCDN_EL1 characteristics are:

Purpose

Accesses ERR<n>PFGCDN for the error record <n> selected by ERRSELR_EL1.SEL.

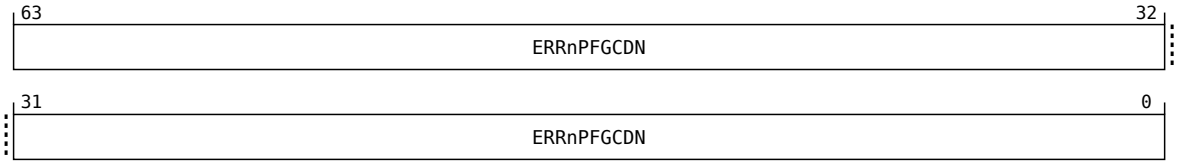
Configuration

This register is present only when FEAT_RASv1p1 is implemented. Otherwise, direct accesses to ERXPFGCDN_EL1 are UNDEFINED.

Attributes

ERXPFGCDN_EL1 is a 64-bit register.

Field descriptions



ERRnPFGCDN, bits [63:0]

ERXPFGCDN_EL1 accesses ERR<n>PFGCDN, where <n> is the value in ERRSELR_EL1.SEL.

Accessing ERXPFGCDN_EL1

If ERRIDR_EL1.NUM is `0x0000` or ERRSELR_EL1.SEL is greater than or equal to ERRIDR_EL1.NUM, then one of the following occurs:

- An UNKNOWN error record is selected.
- ERXPFGCDN_EL1 is RAZ/WI.
- Direct reads and writes of ERXPFGCDN_EL1 are NOPs.
- Direct reads and writes of ERXPFGCDN_EL1 are UNDEFINED.

If ERRSELR_EL1.SEL selects an error record owned by a node that does not implement the Common Fault Injection Model Extension, then one of the following occurs:

- ERXPFGCDN_EL1 is RAZ/WI.
- Direct reads and writes of ERXPFGCDN_EL1 are NOPs.
- Direct reads and writes of ERXPFGCDN_EL1 are UNDEFINED.

Note

A node does not implement the Common Fault Injection Model Extension if ERR<q>FR.INJ reads as `0b00`. <q> is the index of the first error record owned by the same node as error record <n>, where <n> is the value in ERRSELR_EL1.SEL. If the node owns a single record then q = n.

If ERRSELR_EL1.SEL is not the index of the first error record owned by a node, then ERR<n>PFGCDN is not present, meaning reads and writes of ERXPFGCDN_EL1 are RES0.

ERR<n>PFGCDN describes additional constraints that also apply when ERR<n>PFGCDN is accessed through ERXPFGCDN_EL1.

D12.7.12 ERXPFGCTL_EL1, Selected Pseudo-fault Generation Control Register

The ERXPFGCTL_EL1 characteristics are:

Purpose

Accesses ERR<n>PFGCTL for the error record <n> selected by ERRSELR_EL1.SEL.

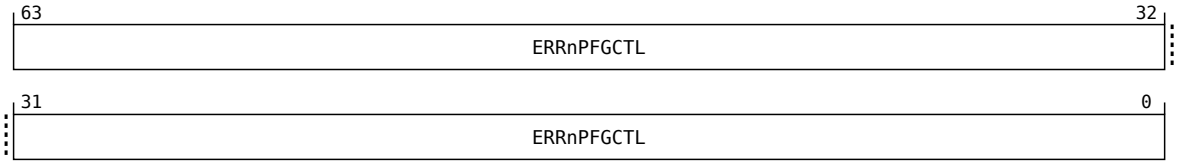
Configuration

This register is present only when FEAT_RASv1p1 is implemented. Otherwise, direct accesses to ERXPFGCTL_EL1 are UNDEFINED.

Attributes

ERXPFGCTL_EL1 is a 64-bit register.

Field descriptions



ERRnPFGCTL, bits [63:0]

ERXPFGCTL_EL1 accesses ERR<n>PFGCTL, where <n> is the value in ERRSELR_EL1.SEL.

Accessing ERXPFGCTL_EL1

If ERRIDR_EL1.NUM is `0x0000` or ERRSELR_EL1.SEL is greater than or equal to ERRIDR_EL1.NUM, then one of the following occurs:

- An UNKNOWN error record is selected.
- ERXPFGCTL_EL1 is RAZ/WI.
- Direct reads and writes of ERXPFGCTL_EL1 are NOPs.
- Direct reads and writes of ERXPFGCTL_EL1 are UNDEFINED.

If ERRSELR_EL1.SEL selects an error record owned by a node that does not implement the Common Fault Injection Model Extension, then one of the following occurs:

- ERXPFGCTL_EL1 is RAZ/WI.
- Direct reads and writes of ERXPFGCTL_EL1 are NOPs.
- Direct reads and writes of ERXPFGCTL_EL1 are UNDEFINED.

Note

A node does not implement the Common Fault Injection Model Extension if ERR<q>FR.INJ reads as `0b00`. <q> is the index of the first error record owned by the same node as error record <n>, where <n> is the value in ERRSELR_EL1.SEL. If the node owns a single record then q = n.

If ERRSELR_EL1.SEL is not the index of the first error record owned by a node, then ERR<n>PFGCTL is not present, meaning reads and writes of ERXPFGCTL_EL1 are RES0.

ERR<n>PFGCTL describes additional constraints that also apply when ERR<n>PFGCTL is accessed through ERXPFGCTL_EL1.

D12.7.13 ERXPFGF_EL1, Selected Pseudo-fault Generation Feature Register

The ERXPFGF_EL1 characteristics are:

Purpose

Accesses ERR<n>PFGF for the error record <n> selected by ERRSELR_EL1.SEL.

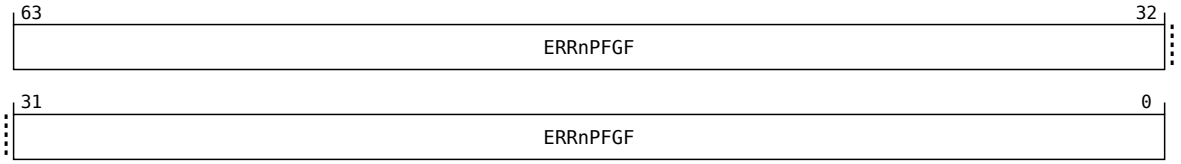
Configuration

This register is present only when FEAT_RASv1p1 is implemented. Otherwise, direct accesses to ERXPFGF_EL1 are UNDEFINED.

Attributes

ERXPFGF_EL1 is a 64-bit register.

Field descriptions



ERRnPFGF, bits [63:0]

ERXPFGF_EL1 accesses ERR<n>PFGF, where <n> is the value in ERRSELR_EL1.SEL.

Accessing ERXPFGF_EL1

If ERRIDR_EL1.NUM is `0x0000` or ERRSELR_EL1.SEL is greater than or equal to ERRIDR_EL1.NUM, then one of the following occurs:

- An UNKNOWN error record is selected.
- ERXPFGF_EL1 is RAZ.
- Direct reads of ERXPFGF_EL1 are NOPs.
- Direct reads of ERXPFGF_EL1 are UNDEFINED.

If ERRSELR_EL1.SEL selects an error record owned by a node that does not implement the Common Fault Injection Model Extension, then one of the following occurs:

- ERXPFGF_EL1 is RAZ.
- Direct reads of ERXPFGF_EL1 are NOPs.
- Direct reads of ERXPFGF_EL1 are UNDEFINED.

Note

A node does not implement the Common Fault Injection Model Extension if ERR<q>FR.INJ reads as `0b00`. <q> is the index of the first error record owned by the same node as error record <n>, where <n> is the value in ERRSELR_EL1.SEL. If the node owns a single record then q = n.

If ERRSELR_EL1.SEL is not the index of the first error record owned by a node, then ERR<n>PFGF is not present, meaning reads of ERXPFGF_EL1 are RES0.

ERR<n>PFGF describes additional constraints that also apply when ERR<n>PFGF is accessed through ERXPFGF_EL1.

Accesses to this register use the following encodings in the System register encoding space:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.

D12.7.14 ERXSTATUS_EL1, Selected Error Record Primary Status Register

The ERXSTATUS_EL1 characteristics are:

Purpose

Accesses ERR<n>STATUS for the error record <n> selected by ERRSELR_EL1.SEL.

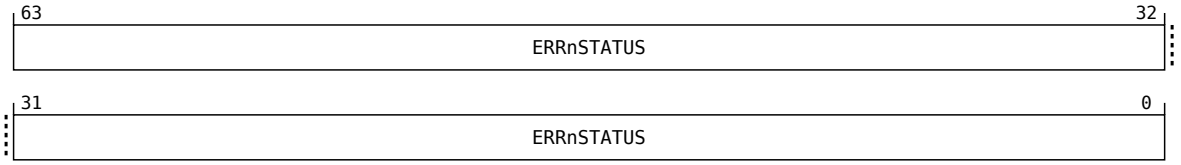
Configuration

This register is present only when FEAT_RAS is implemented. Otherwise, direct accesses to ERXSTATUS_EL1 are UNDEFINED.

Attributes

ERXSTATUS_EL1 is a 64-bit register.

Field descriptions



ERRnSTATUS, bits [63:0]

ERXSTATUS_EL1 accesses ERR<n>STATUS, where <n> is the value in ERRSELR_EL1.SEL.

Accessing ERXSTATUS_EL1

If ERRIDR_EL1.NUM is `0x0000` or ERRSELR_EL1.SEL is greater than or equal to ERRIDR_EL1.NUM, then one of the following occurs:

- An UNKNOWN error record is selected.
- ERXSTATUS_EL1 is RAZ/WI.
- Direct reads and writes of ERXSTATUS_EL1 are NOPs.
- Direct reads and writes of ERXSTATUS_EL1 are UNDEFINED.

ERR<n>STATUS describes additional constraints that also apply when ERR<n>STATUS is accessed through ERXSTATUS_EL1.

Accesses to this register use the following encodings in the System register encoding space:

`MRS <Xt>, ERXSTATUS_EL1`

D12.7.15 VDISR_EL2, Virtual Deferred Interrupt Status Register (EL2)

The VDISR_EL2 characteristics are:

Purpose

Records that a virtual SError exception has been consumed by an ESB instruction executed at EL1 or EL0.

An indirect write to VDISR_EL2 made by an ESB instruction does not require an explicit synchronization operation for the value written to be observed by a direct read of one of the following registers occurring in program order after the ESB instruction:

- DISR_EL1.

Configuration

If EL2 is not implemented, this register is RES0 from EL3.

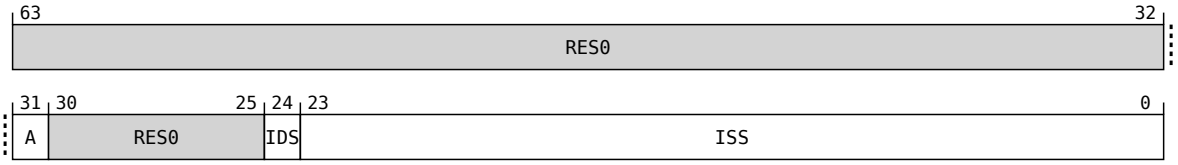
This register has no effect if EL2 is not enabled in the current Security state.

This register is present only when FEAT_RAS is implemented. Otherwise, direct accesses to VDISR_EL2 are UNDEFINED.

Attributes

VDISR_EL2 is a 64-bit register.

Field descriptions



Bits [63:32]

Reserved, RES0.

A, bit [31]

Set to 1 when an ESB instruction defers a virtual SError exception.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [30:25]

Reserved, RES0.

IDS, bit [24]

The value copied from VSESR_EL2.IDS.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

ISS, bits [23:0]

The value copied from VSESR_EL2.ISS.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

D12.7.16 VSESR_EL2, Virtual SError Exception Syndrome Register (EL2)

The VSESR_EL2 characteristics are:

Purpose

Provides the syndrome value reported to software on taking a virtual SError exception to EL1, or on executing an ESB instruction at EL1.

When the virtual SError exception injected using HCR_EL2.VSE is taken to EL1 using AArch64, then the syndrome value is reported in ESR_EL1.

When the virtual SError exception injected using HCR_EL2.VSE is deferred by an ESB instruction, then the syndrome value is written to VDISR_EL2.

Configuration

If EL2 is not implemented, this register is RES0 from EL3.

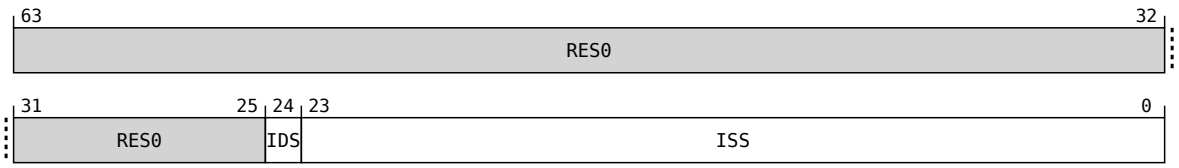
This register has no effect if EL2 is not enabled in the current Security state.

This register is present only when FEAT_RAS is implemented. Otherwise, direct accesses to VSESR_EL2 are UNDEFINED.

Attributes

VSESR_EL2 is a 64-bit register.

Field descriptions



Bits [63:25]

Reserved, RES0.

IDS, bit [24]

When a virtual SError exception is taken to EL1 using AArch64, ESR_EL1[24] is set to VSESR_EL2.IDS.

When a virtual SError exception is deferred by an ESB instruction, VDISR_EL2[24] is set to VSESR_EL2.IDS.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

ISS, bits [23:0]

When a virtual SError exception is taken to EL1 using AArch64, ESR_EL1[23:0] is set to VSESR_EL2.ISS.

When a virtual SError exception is deferred by an ESB instruction, VDISR_EL2[23:0] is set to VSESR_EL2.ISS.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing VSESR_EL2

Accesses to this register use the following encodings in the System register encoding space:

```

D12.8 Generic Timer registers

This section lists the Generic Timer registers in AArch64.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D12.8.1 CNTFRQ_EL0, Counter-timer Frequency Register

The CNTFRQ_EL0 characteristics are:

Purpose

This register is provided so that software can discover the effective frequency of the system counter. It must be programmed with this value as part of system initialization. The value of the register is not interpreted by hardware.

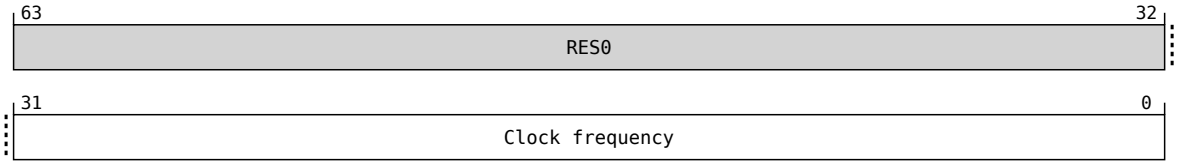
Configuration

There are no configuration notes.

Attributes

CNTFRQ_EL0 is a 64-bit register.

Field descriptions



Bits [63:32]

Reserved, RES0.

ClockFreq, bits [31:0]

Clock frequency. Indicates the effective frequency of the system counter, in Hz.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing CNTFRQ_EL0

Accesses to this register use the following encodings in the System register encoding space:

`MRS <Xt>, CNTFRQ_EL0`

D12.8.2 CNTHCTL_EL2, Counter-timer Hypervisor Control Register

The CNTHCTL_EL2 characteristics are:

Purpose

Controls the generation of an event stream from the physical counter, and access from EL1 to the physical counter and the EL1 physical timer.

Configuration

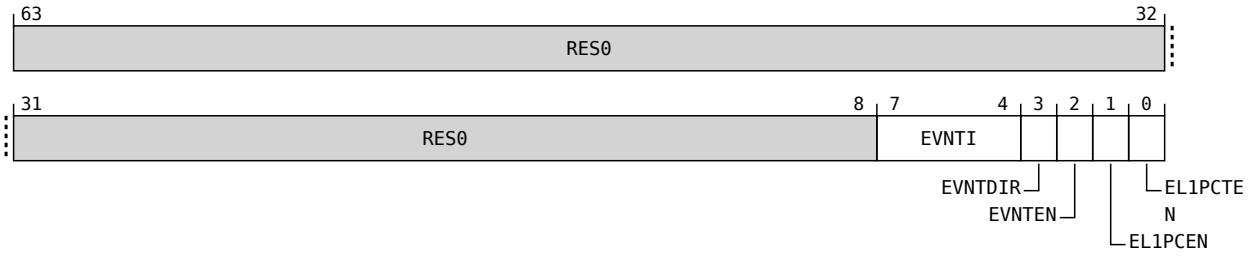
There are no configuration notes.

Attributes

CNTHCTL_EL2 is a 64-bit register.

Field descriptions

!ELIsInHost(EL2)



The following field descriptions apply in all Armv8.0 implementations.

Bits [63:8]

Reserved, RES0.

EVNTI, bits [7:4]

Selects which bit of CNTPCT_EL0, as seen from EL2,is the trigger for the event stream generated from that counter when that stream is enabled.

This field selects a trigger bit in the range 0 to 15 of CNTPCT_EL0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

EVNTDIR, bit [3]

Controls which transition of the CNTPCT_EL0 trigger bit, as seen from EL2 and defined by EVNTI, generates an event when the event stream is enabled.

EVNTDIR	Meaning
0b0	A 0 to 1 transition of the trigger bit triggers an event.
0b1	A 1 to 0 transition of the trigger bit triggers an event.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

EVNTEN, bit [2]

Enables the generation of an event stream from CNTPCT_EL0 as seen from EL2.

EVNTEN	Meaning
0b0	Disables the event stream.
0b1	Enables the event stream.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

EL1PCEN, bit [1]

Traps EL0 and EL1 accesses to the EL1 physical timer registers to EL2 when EL2 is enabled in the current Security state, as follows:

- In AArch64 state, accesses to CNTP_CTL_EL0, CNTP_CVAL_EL0, CNTP_TVAL_EL0 are trapped to EL2, reported using EC syndrome value 0x18, unless they are trapped by CNTKCTL_EL1.EL0PTEN.

EL1PCEN	Meaning
0b0	EL0 and EL1 accesses to the specified registers are trapped to EL2.
0b1	This control does not cause any instructions to be trapped.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

EL1PCTEN, bit [0]

Traps EL0 and EL1 accesses to the EL1 physical counter registers to EL2 when EL2 is enabled in the current Security state, as follows:

- In AArch64 state, accesses to CNTPCT_EL0 and CNTPCTSS_EL0 are trapped to EL2 and reported using EC syndrome value 0x18, unless they are trapped by CNTKCTL_EL1.EL0PCTEN.

EL1PCTEN	Meaning
0b0	EL0 and EL1 accesses to the specified registers are trapped to EL2.
0b1	This control does not cause any instructions to be trapped.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing CNTHCTL_EL2

Accesses to this register use the following encodings in the System register encoding space:

```
MRS <Xt>, CNTHCTL_EL2
```

op0	op1	CRn	CRm	op2
0b11	0b100	0b1110	0b0001	0b000

```
if PSTATE.EL == EL0 then
    UNDEFINED;

D12.8.3 CNTHPS_CTL_EL2, Counter-timer Secure Physical Timer Control Register (EL2)

The CNTHPS_CTL_EL2 characteristics are:

Purpose

Control register for the Secure EL2 physical timer.

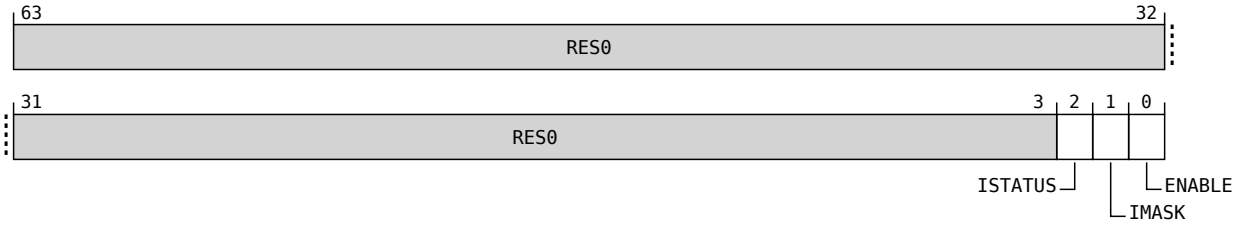
Configuration

This register is present only when FEAT_SEL2 is implemented. Otherwise, direct accesses to CNTHPS_CTL_EL2 are UNDEFINED.

Attributes

CNTHPS_CTL_EL2 is a 64-bit register.

Field descriptions



Bits [63:3]

Reserved, RES0.

ISTATUS, bit [2]

The status of the timer. This bit indicates whether the timer condition is met:

ISTATUS	Meaning
0b0	Timer condition is not met.
0b1	Timer condition is met.

When the value of the CNTHPS_CTL_EL2.ENABLE bit is 1, ISTATUS indicates whether the timer condition is met. ISTATUS takes no account of the value of the IMASK bit. If the value of ISTATUS is 1 and the value of IMASK is 0 then the timer interrupt is asserted.

When the value of the CNTHPS_CTL_EL2.ENABLE bit is 0, the ISTATUS field is UNKNOWN.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Access to this field is RO.

IMASK, bit [1]

Timer interrupt mask bit. Permitted values are:

IMASK	Meaning
0b0	Timer interrupt is not masked by the IMASK bit.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

IMASK	Meaning
0b1	Timer interrupt is masked by the IMASK bit.

For more information, see the description of the ISTATUS bit.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

ENABLE, bit [0]

Enables the timer. Permitted values are:

ENABLE	Meaning
0b0	Timer disabled.
0b1	Timer enabled.

Setting this bit to 0 disables the timer output signal, but the timer value accessible from CNTHPS_TVAL_EL2 continues to count down.

Note

Disabling the output signal might be a power-saving option.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing CNTHPS_CTL_EL2

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, CNTHPS_CTL_EL2

op0	op1	CRn	CRm	op2
0b11	0b100	0b1110	0b0101	0b001

```

Non-Confidential

D12.8.4 CNTHPS_CVAL_EL2, Counter-timer Secure Physical Timer CompareValue Register (EL2)

The CNTHPS_CVAL_EL2 characteristics are:

Purpose

Holds the compare value for the Secure EL2 physical timer.

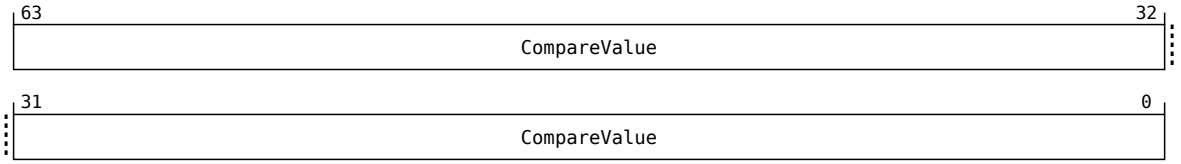
Configuration

This register is present only when FEAT_SEL2 is implemented. Otherwise, direct accesses to CNTHPS_CVAL_EL2 are UNDEFINED.

Attributes

CNTHPS_CVAL_EL2 is a 64-bit register.

Field descriptions



CompareValue, bits [63:0]

Holds the EL2 physical timer CompareValue.

When CNTHPS_CTL_EL2.ENABLE is 1, and TimerConditionMet is TRUE for the Secure EL2 physical timer, the timer condition is met and all of the following are true:

- CNTHPS_CTL_EL2.ISTATUS is set to 1.
- If CNTHPS_CTL_EL2.IMASK is 0, an interrupt is generated.

TimerConditionMet is defined by 'Operation of the CompareValue views of the timers'.

The CompareValue view of the timer acts like a 64-bit upcounter timer.

When CNTHPS_CTL_EL2.ENABLE is 0, the timer condition is not met, but CNTPCT_EL0 continues to count.

If the Generic counter is implemented at a size less than 64 bits, then this field is permitted to be implemented at the same width as the counter, and the upper bits are RES0.

The value of this field is treated as zero-extended in all counter calculations.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing CNTHPS_CVAL_EL2

Accesses to this register use the following encodings in the System register encoding space:

```
MRS <Xt>, CNTHPS_CVAL_EL2
```

op0	op1	CRn	CRm	op2
0b11	0b100	0b1110	0b0101	0b010

D12.8.5 CNTHPS_TVAL_EL2, Counter-timer Secure Physical Timer TimerValue Register (EL2)

The CNTHPS_TVAL_EL2 characteristics are:

Purpose

Holds the timer value for the Secure EL2 physical timer.

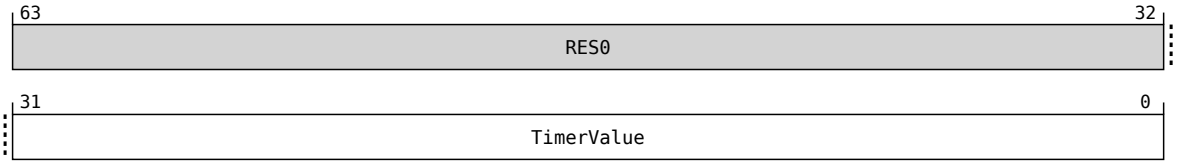
Configuration

This register is present only when FEAT_SEL2 is implemented. Otherwise, direct accesses to CNTHPS_TVAL_EL2 are UNDEFINED.

Attributes

CNTHPS_TVAL_EL2 is a 64-bit register.

Field descriptions



Bits [63:32]

Reserved, RES0.

TimerValue, bits [31:0]

The TimerValue view of the EL2 physical timer.

On a read of this register:

- If CNTHPS_CTL_EL2.ENABLE is 0, the value returned is UNKNOWN.
- If CNTHPS_CTL_EL2.ENABLE is 1, the value returned is (CNTHPS_CVAL_EL2 - CNTPCT_EL0).

On a write of this register, CNTHPS_CVAL_EL2 is set to (CNTPCT_EL0 + TimerValue), where TimerValue is treated as a signed 32-bit integer.

When CNTHPS_CTL_EL2.ENABLE is 1, the timer condition is met when (CNTPCT_EL0 - CNTHPS_CVAL_EL2) is greater than or equal to zero. This means that TimerValue acts like a 32-bit downcounter timer. When the timer condition is met:

- CNTHPS_CTL_EL2.ISTATUS is set to 1.
- If CNTHPS_CTL_EL2.IMASK is 0, an interrupt is generated.

When CNTHPS_CTL_EL2.ENABLE is 0, the TimerValue cannot be read but continues to decrement. When the timer is enabled, the TimerValue represents the elapsed time whether that time was spent enabled or disabled.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing CNTHPS_TVAL_EL2

Accesses to this register use the following encodings in the System register encoding space:

```
MRS <Xt>, CNTHPS_TVAL_EL2
```

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D12.8.6 CNTKCTL_EL1, Counter-timer Kernel Control Register

The CNTKCTL_EL1 characteristics are:

Purpose

This register controls the generation of an event stream from the virtual counter, and access from EL0 to the physical counter, virtual counter, EL1 physical timers, and the virtual timer.

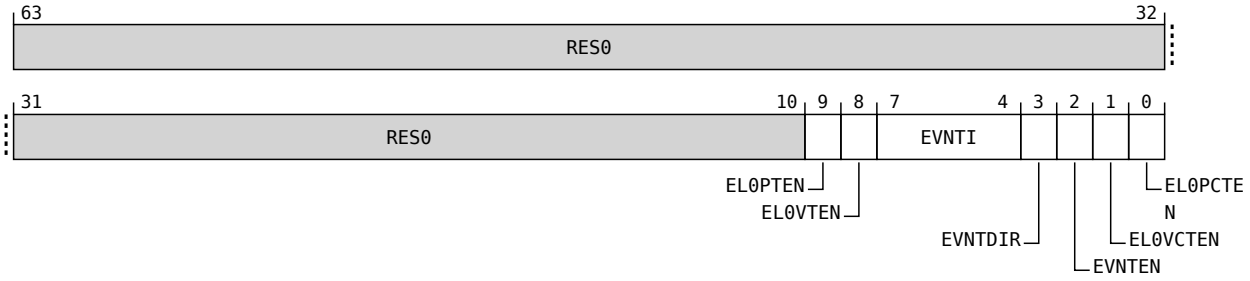
Configuration

There are no configuration notes.

Attributes

CNTKCTL_EL1 is a 64-bit register.

Field descriptions



Bits [63:10]

Reserved, RES0.

EL0PTEN, bit [9]

Traps EL0 accesses to the physical timer registers to EL1, or to EL2 when it is implemented and enabled for the current Security state and HCR_EL2.TGE is 1, as follows:

- In AArch64 state, the following registers are trapped and reported using EC syndrome value `0x18`:
  - CNTP_CTL_EL0, CNTP_CVAL_EL0, and CNTP_TVAL_EL0.

EL0PTEN	Meaning
`0b0`	EL0 accesses to the physical timer registers are trapped to EL1.
`0b1`	This control does not cause any instructions to be trapped.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

EL0VTEN, bit [8]

Traps EL0 accesses to the virtual timer registers to EL1, or to EL2 when it is implemented and enabled for the current Security state and HCR_EL2.TGE is 1, as follows:

- In AArch64 state, accesses to the following registers are trapped and reported using EC syndrome value `0x18`:
  - CNTV_CTL_EL0, CNTV_CVAL_EL0, and CNTV_TVAL_EL0.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

EL0VTEN	Meaning
0b0	EL0 accesses to the virtual timer registers are trapped.
0b1	This control does not cause any instructions to be trapped.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

EVNTI, bits [7:4]

Selects which bit of CNTVCT_EL0, as seen from EL1, is the trigger for the event stream generated from that counter when that stream is enabled.

This field selects a trigger bit in the range 0 to 15 of CNTVCT_EL0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

EVNTDIR, bit [3]

Controls which transition of the CNTVCT_EL0 trigger bit, as seen from EL1 and defined by EVNTI, generates an event when the event stream is enabled.

EVNTDIR	Meaning
0b0	A 0 to 1 transition of the trigger bit triggers an event.
0b1	A 1 to 0 transition of the trigger bit triggers an event.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

EVNTEN, bit [2]

Enables the generation of an event stream from CNTVCT_EL0 as seen from EL1.

EVNTEN	Meaning
0b0	Disables the event stream.
0b1	Enables the event stream.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

EL0VCTEN, bit [1]

Traps EL0 accesses to the frequency register and virtual counter registers to EL1, or to EL2 when it is implemented and enabled for the current Security state and HCR_EL2.TGE is 1, as follows:

- In AArch64 state, accesses to the following registers are trapped and reported using EC syndrome value 0x18:
  - CNTVCT_EL0.
  - CNTVCTSS_EL0.
  - If CNTKCTL_EL1.EL0PCTEN is 0, CNTFRQ_EL0.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

EL0VCTEN	Meaning
0b0	EL0 accesses to the frequency register and virtual counter registers are trapped.
0b1	This control does not cause any instructions to be trapped.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

EL0PCTEN, bit [0]

Traps EL0 accesses to the frequency register and physical counter register to EL1, or to EL2 when it is implemented and enabled for the current Security state and HCR_EL2.TGE is 1, as follows:

- In AArch64 state, the following registers are trapped and reported using EC syndrome value 0x18:
  - CNTPCT_EL0
  - CNTPCTSS_EL0
  - If CNTKCTL_EL1.EL0VCTEN is 0, CNTFRQ_EL0.

EL0PCTEN	Meaning
0b0	EL0 accesses to the frequency register and physical counter register are trapped.
0b1	This control does not cause any instructions to be trapped.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing CNTKCTL_EL1

Accesses to this register use the following encodings in the System register encoding space:

```
MRS <Xt>, CNTKCTL_EL1
```

op0	op1	CRn	CRm	op2
0b11	0b000	0b1110	0b0001	0b000

```
if PSTATE.EL == EL0 then
    UNDEFINED;
elsif PSTATE.EL == EL1 then
    X[t, 64] = CNTKCTL_EL1;
elsif PSTATE.EL == EL2 then
    X[t, 64] = CNTKCTL_EL1;
```

```
MSR CNTKCTL_EL1, <Xt>
```

op0	op1	CRn	CRm	op2
0b11	0b000	0b1110	0b0001	0b000

D12.8.7 CNTP_CTL_EL0, Counter-timer Physical Timer Control Register

The CNTP_CTL_EL0 characteristics are:

Purpose

Control register for the EL1 physical timer.

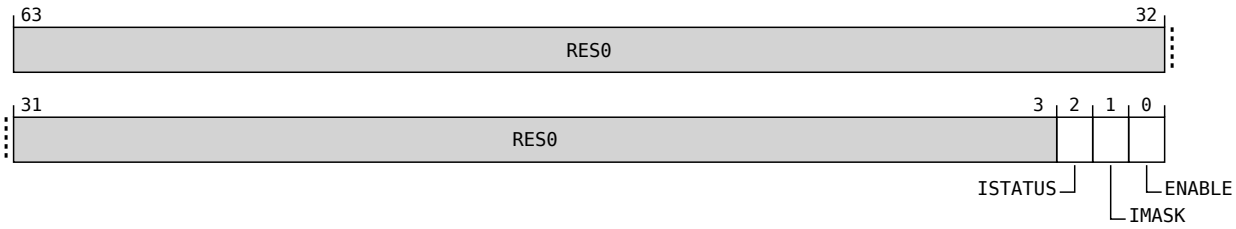
Configuration

There are no configuration notes.

Attributes

CNTP_CTL_EL0 is a 64-bit register.

Field descriptions



Bits [63:3]

Reserved, RES0.

ISTATUS, bit [2]

The status of the timer. This bit indicates whether the timer condition is met:

ISTATUS	Meaning
0b0	Timer condition is not met.
0b1	Timer condition is met.

When the value of the ENABLE bit is 1, ISTATUS indicates whether the timer condition is met. ISTATUS takes no account of the value of the IMASK bit. If the value of ISTATUS is 1 and the value of IMASK is 0 then the timer interrupt is asserted.

When the value of the ENABLE bit is 0, the ISTATUS field is UNKNOWN.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Access to this field is RO.

IMASK, bit [1]

Timer interrupt mask bit. Permitted values are:

IMASK	Meaning
0b0	Timer interrupt is not masked by the IMASK bit.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

0b1	Timer interrupt is masked by the IMASK bit.

For more information, see the description of the ISTATUS bit.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

ENABLE, bit [0]

Enables the timer. Permitted values are:

ENABLE	Meaning
0b0	Timer disabled.
0b1	Timer enabled.

Setting this bit to 0 disables the timer output signal, but the timer value accessible from CNTP_TVAL_EL0 continues to count down.

Note

Disabling the output signal might be a power-saving option.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing CNTP_CTL_EL0

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, CNTP_CTL_EL0

op0	op1	CRn	CRm	op2
0b11	0b011	0b1110	0b0010	0b001

D12.8.8 CNTP_CVAL_EL0, Counter-timer Physical Timer CompareValue Register

The CNTP_CVAL_EL0 characteristics are:

Purpose

Holds the compare value for the EL1 physical timer.

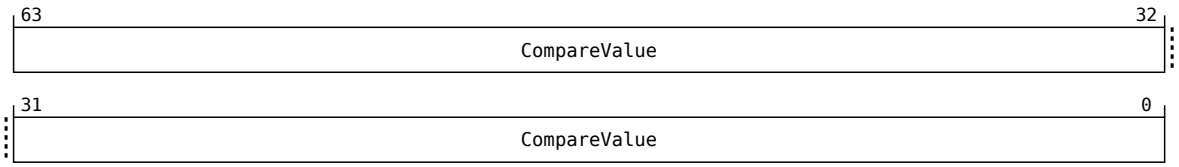
Configuration

There are no configuration notes.

Attributes

CNTP_CVAL_EL0 is a 64-bit register.

Field descriptions



CompareValue, bits [63:0]

Holds the EL1 physical timer CompareValue.

When CNTP_CTL_EL0.ENABLE is 1, and TimerConditionMet is TRUE for the EL1 physical timer, the timer condition is met and all of the following are true:

- CNTP_CTL_EL0.ISTATUS is set to 1.
- If CNTP_CTL_EL0.IMASK is 0, an interrupt is generated.

TimerConditionMet is defined by 'Operation of the CompareValue views of the timers'.

The CompareValue view of the timer acts like a 64-bit upcounter timer.

When CNTP_CTL_EL0.ENABLE is 0, the timer condition is not met, but CNTPCT_EL0 continues to count.

If the Generic counter is implemented at a size less than 64 bits, then this field is permitted to be implemented at the same width as the counter, and the upper bits are RES0.

The value of this field is treated as zero-extended in all counter calculations.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing CNTP_CVAL_EL0

Accesses to this register use the following encodings in the System register encoding space:

```
MRS <Xt>, CNTP_CVAL_EL0
```

op0	op1	CRn	CRm	op2
0b11	0b011	0b1110	0b0010	0b010

D12.8.9 CNTP_TVAL_EL0, Counter-timer Physical Timer TimerValue Register

The CNTP_TVAL_EL0 characteristics are:

Purpose

Holds the timer value for the EL1 physical timer.

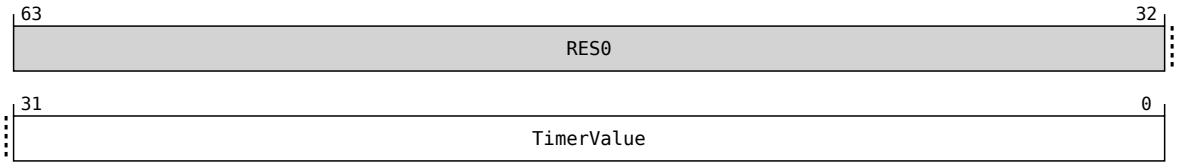
Configuration

There are no configuration notes.

Attributes

CNTP_TVAL_EL0 is a 64-bit register.

Field descriptions



Bits [63:32]

Reserved, RES0.

TimerValue, bits [31:0]

The TimerValue view of the EL1 physical timer.

On a read of this register:

- If CNTP_CTL_EL0.ENABLE is 0, the value returned is UNKNOWN.
- If CNTP_CTL_EL0.ENABLE is 1, the value returned is (CNTP_CVAL_EL0 - CNTPCT_EL0).

On a write of this register, CNTP_CVAL_EL0 is set to (CNTPCT_EL0 + TimerValue), where TimerValue is treated as a signed 32-bit integer.

When CNTP_CTL_EL0.ENABLE is 1, the timer condition is met when (CNTPCT_EL0 - CNTP_CVAL_EL0) is greater than or equal to zero. This means that TimerValue acts like a 32-bit downcounter timer. When the timer condition is met:

- CNTP_CTL_EL0.ISTATUS is set to 1.
- If CNTP_CTL_EL0.IMASK is 0, an interrupt is generated.

When CNTP_CTL_EL0.ENABLE is 0, the TimerValue cannot be read but continues to decrement. When the timer is enabled, the TimerValue represents the elapsed time whether that time was spent enabled or disabled.

Note

The value of CNTPCT_EL0 used in these calculations is the value seen at the Exception level that the CNTPCT_EL0 register is being read or written from.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing CNTP_TVAL_EL0

Accesses to this register use the following encodings in the System register encoding space:

```
MRS <Xt>, CNTP_TVAL_EL0
```

D12.8.10 CNTPCT_EL0, Counter-timer Physical Count Register

The CNTPCT_EL0 characteristics are:

Purpose

Reads of CNTPCT_EL0 return the 64-bit physical count value minus a physical offset.

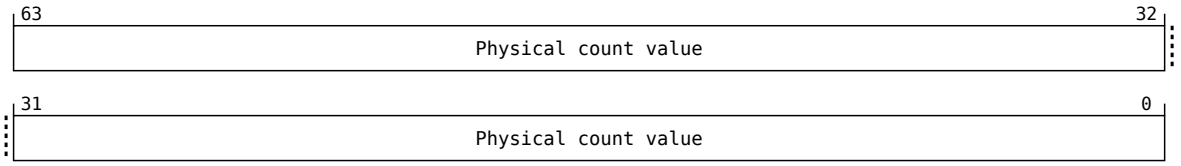
Configuration

There are no configuration notes.

Attributes

CNTPCT_EL0 is a 64-bit register.

Field descriptions



PhysicalCount, bits [63:0]

Physical count value.

Reads of CNTPCT_EL0 return PhysicalCountInt<63:0>.

PhysicalCountInt is defined by 'The Physical Counter'.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing CNTPCT_EL0

Accesses to this register use the following encodings in the System register encoding space:

`MRS <Xt>, CNTPCT_EL0`

op0	op1	CRn	CRm	op2
0b11	0b011	0b1110	0b0000	0b001

```

D12.8.11 CNTV_CTL_EL0, Counter-timer Virtual Timer Control Register

The CNTV_CTL_EL0 characteristics are:

Purpose

Control register for the virtual timer.

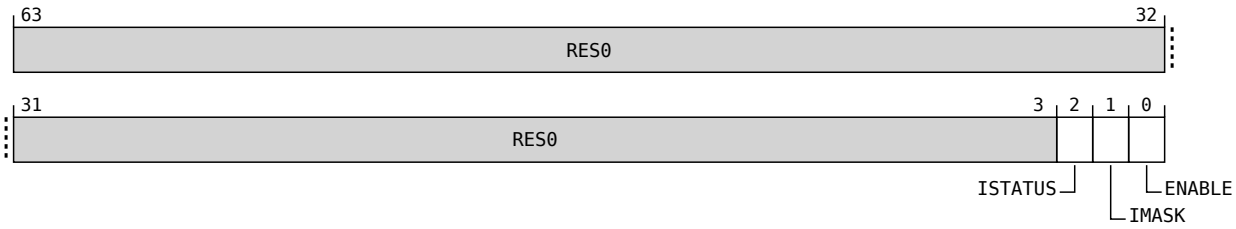
Configuration

There are no configuration notes.

Attributes

CNTV_CTL_EL0 is a 64-bit register.

Field descriptions



Bits [63:3]

Reserved, RES0.

ISTATUS, bit [2]

The status of the timer. This bit indicates whether the timer condition is met:

ISTATUS	Meaning
0b0	Timer condition is not met.
0b1	Timer condition is met.

When the value of the ENABLE bit is 1, ISTATUS indicates whether the timer condition is met. ISTATUS takes no account of the value of the IMASK bit. If the value of ISTATUS is 1 and the value of IMASK is 0 then the timer interrupt is asserted.

When the value of the ENABLE bit is 0, the ISTATUS field is UNKNOWN.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Access to this field is RO.

IMASK, bit [1]

Timer interrupt mask bit. Permitted values are:

IMASK	Meaning
0b0	Timer interrupt is not masked by the IMASK bit.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

0b1	Timer interrupt is masked by the IMASK bit.

For more information, see the description of the ISTATUS bit.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

ENABLE, bit [0]

Enables the timer. Permitted values are:

ENABLE	Meaning
0b0	Timer disabled.
0b1	Timer enabled.

Setting this bit to 0 disables the timer output signal, but the timer value accessible from CNTV_TVAL_EL0 continues to count down.

Note

Disabling the output signal might be a power-saving option.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing CNTV_CTL_EL0

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, CNTV_CTL_EL0

op0	op1	CRn	CRm	op2
0b11	0b011	0b1110	0b0011	0b001

```

D12.8.12 CNTV_CVAL_EL0, Counter-timer Virtual Timer CompareValue Register

The CNTV_CVAL_EL0 characteristics are:

Purpose

Holds the compare value for the virtual timer.

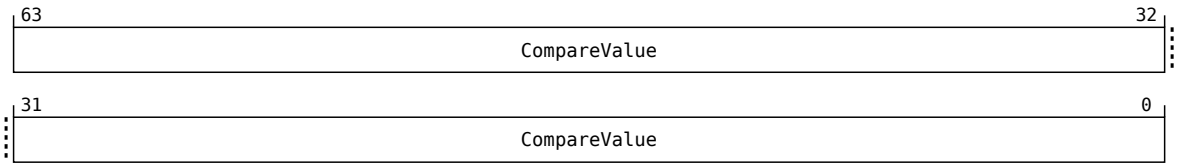
Configuration

There are no configuration notes.

Attributes

CNTV_CVAL_EL0 is a 64-bit register.

Field descriptions



CompareValue, bits [63:0]

Holds the EL1 virtual timer CompareValue.

When CNTV_CTL_EL0.ENABLE is 1, and TimerConditionMet is TRUE for the EL1 virtual timer, the timer condition is met and all of the following are true:

- CNTV_CTL_EL0.ISTATUS is set to 1.
- If CNTV_CTL_EL0.IMASK is 0, an interrupt is generated.

TimerConditionMet is defined by 'Operation of the CompareValue views of the timers'.

The CompareValue view of the timer acts like a 64-bit upcounter timer.

When CNTV_CTL_EL0.ENABLE is 0, the timer condition is not met, but CNTVCT_EL0 continues to count.

If the Generic counter is implemented at a size less than 64 bits, then this field is permitted to be implemented at the same width as the counter, and the upper bits are RES0.

The value of this field is treated as zero-extended in all counter calculations.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing CNTV_CVAL_EL0

Accesses to this register use the following encodings in the System register encoding space:

```
MRS <Xt>, CNTV_CVAL_EL0
```

op0	op1	CRn	CRm	op2

D12.8.13 CNTV_TVAL_EL0, Counter-timer Virtual Timer TimerValue Register

The CNTV_TVAL_EL0 characteristics are:

Purpose

Holds the timer value for the EL1 virtual timer.

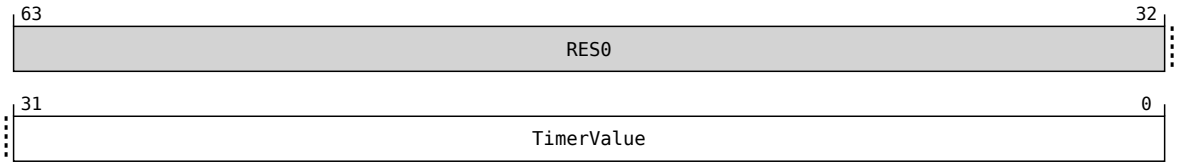
Configuration

There are no configuration notes.

Attributes

CNTV_TVAL_EL0 is a 64-bit register.

Field descriptions



Bits [63:32]

Reserved, RES0.

TimerValue, bits [31:0]

The TimerValue view of the EL1 virtual timer.

On a read of this register:

- If CNTV_CTL_EL0.ENABLE is 0, the value returned is UNKNOWN.
- If CNTV_CTL_EL0.ENABLE is 1, the value returned is (CNTV_CVAL_EL0 - CNTVCT_EL0).

On a write of this register, CNTV_CVAL_EL0 is set to (CNTVCT_EL0 + TimerValue), where TimerValue is treated as a signed 32-bit integer.

When CNTV_CTL_EL0.ENABLE is 1, the timer condition is met when (CNTVCT_EL0 - CNTV_CVAL_EL0) is greater than or equal to zero. This means that TimerValue acts like a 32-bit downcounter timer. When the timer condition is met:

- CNTV_CTL_EL0.ISTATUS is set to 1.
- If CNTV_CTL_EL0.IMASK is 0, an interrupt is generated.

When CNTV_CTL_EL0.ENABLE is 0, the TimerValue cannot be read but continues to decrement. When the timer is enabled, the TimerValue represents the elapsed time whether that time was spent enabled or disabled.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing CNTV_TVAL_EL0

Accesses to this register use the following encodings in the System register encoding space:

```
MRS <Xt>, CNTV_TVAL_EL0
```

D12.8.14 CNTVCT_EL0, Counter-timer Virtual Count Register

The CNTVCT_EL0 characteristics are:

Purpose

Reads of CNTVCT_EL0 return the 64-bit physical count value minus a virtual offset.

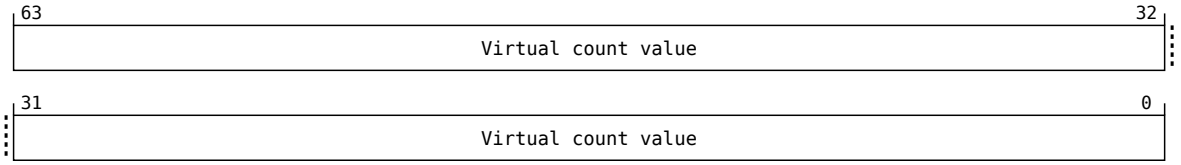
Configuration

There are no configuration notes.

Attributes

CNTVCT_EL0 is a 64-bit register.

Field descriptions



VirtualCount, bits [63:0]

Virtual count value.

Reads of CNTVCT_EL0 return PhysicalCountInt<63:0>.

PhysicalCountInt is defined by 'The Physical Counter'.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing CNTVCT_EL0

Accesses to this register use the following encodings in the System register encoding space:

`MRS <Xt>, CNTVCT_EL0`

D12.8.15 CNTVOFF_EL2, Counter-timer Virtual Offset Register

The CNTVOFF_EL2 characteristics are:

Purpose

Holds the 64-bit virtual offset. This is the offset for the AArch64 virtual timers and counters.

Configuration

The virtual offset applies to:

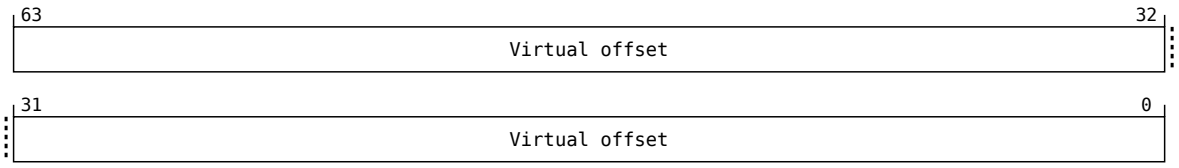
- Direct reads of CNTVCT_EL0.
- Indirect reads of the virtual counter by the EL1 virtual timer. See 'The Generic Timer in AArch64 state'.
- Indirect reads of the virtual counter for timestamps generated by profiling logic. See 'AArch64 Self-hosted Trace'.

The virtual offset only applies under conditions described by the relevant sections.

Attributes

CNTVOFF_EL2 is a 64-bit register.

Field descriptions



VOffset, bits [63:0]

Virtual offset.

If the Generic counter is implemented at a size less than 64 bits, then this field is permitted to be implemented at the same width as the counter, and the upper bits are RES0.

The value of this field is treated as zero-extended in all counter calculations.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing CNTVOFF_EL2

Accesses to this register use the following encodings in the System register encoding space:

```

Chapter E1
About External Debug

This chapter gives an overview of A-profile external debug and specifies the required debug authentication. It contains the following sections:

- Introduction to external debug.
- External debug.
- Required debug authentication.

Note

For information about self-hosted debug, see AArch64 Self-hosted Debug.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

E1.1 Introduction to external debug

The R-profile supports both:

Self-hosted debug

The PE itself hosts a debugger. That is, developers developing software to run on the PE use debugger software running on the same PE.

External debug

The debugger is external to the PE. The debugging might be either on-chip, for example in a second PE, or off-chip, for example a JTAG debugger that accesses the chip through a Debug Access Port.

External debug is particularly useful for:

- Hardware bring-up. That is, debugging during development when a system is first powered up and not all of the software functionality is available.
- PEs that are deeply embedded inside systems.

To support external debug, the Arm architecture defines required features that are called *external debug features*.

Note

An external debugger has a potentially high level of control over and visibility into the PE. The system sets this level using debug authentication. See Required debug authentication.
If the debug authentication level is set too low, agents may be able to bypass elements of the security and privilege models. This includes both off-chip agents and on-chip agents such as unprivileged or Non-secure software.

E1.1.1 Definition and constraints of a debugger in the context of external debug

When the description of external debug in this Part of the manual describes a *debugger* as controlling external debug this debugger might be a second on-chip PE or an off-chip device such as a JTAG debugger using a Debug Access Port (DAP).

If a Debug Access Port is implemented:

- When debug is prohibited at the Debug Access Port, the port must not generate accesses to the external debug interface of the PE.
- When debug is prohibited for a Security state at the Debug Access Port, it must not be possible to generate accesses to PA spaces that are not accessible for that Security state.
- When accesses for a Security state are allowed at the Debug Access Port, the port must be able to generate accesses to PA spaces that are accessible for that Security state.

If FEAT_Debugv8p4 is not implemented, accesses to the PE are controlled by the external authentication interface functions, `ExternalInvasiveDebugEnabled()`, `ExternalNoninvasiveDebugEnabled()`, `ExternalSecureNoninvasiveDebugEnabled()`, and `ExternalSecureInvasiveDebugEnabled()`.

The Debug Access Port is not required to use the same authentication interface as the PE.

Arm recommends that when `ExternalSecureInvasiveDebugEnabled()` == FALSE at the PE, access through the DAP is disabled.

See also Required debug authentication.

E1.2 External debug

Debug events allow an external debugger to halt the PE. The R-profile provides the following debug events:

- Halting Step debug events:
  - The debugger can use this resource to make the PE step through code one line at a time.
- Halt Instruction debug event:
  - This might occur when software executes the Halting breakpoint instruction, `HLT`.
- Exception Catch debug event:
  - This can be programmed to occur on all entries to a given Exception level.
- External Debug Request debug event:
  - An embedded cross-trigger can signal this debug event.
- OS Unlock Catch debug event:
  - This might occur when the state of the OS Lock changes from locked to unlocked.
- Reset Catch debug events:
  - This might occur when the PE exits reset state.
- Software Access debug event:
  - This can be programmed to occur when software tries to access the Breakpoint Value registers, the Breakpoint Control registers, the Watchpoint value registers, or the Watchpoint Control registers. It caused a trap to Debug state.

Breakpoints and watchpoints can also halt the PE.

When the PE is in Debug state:

- It stops executing instructions from the location indicated by the program counter, and is instead controlled through the external debug interface.
- The *Instruction Transfer Register,* ITR, passes instructions to the PE to execute in Debug state:
  - The ITR contains a single register, EDITR, and associated flow-control flags.
- The *Debug Communications Channel*, DCC, passes data between the PE and the debugger:
  - The DCC includes the data transfer registers, DTRRX and DTRTX, and associated flow-control flags.
  - Although the DCC is an essential part of Debug state operation, it can also be used in Non-debug state.
- The PE cannot service any interrupts in Debug state.

Debug State describes Debug state in more detail.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

E1.3 Required debug authentication

Any implementation must provide the debug authentication defined in this section, which controls:

- Whether the PE can halt.
- Whether some aspects of non-invasive debug are permitted.

The pseudocode functions shown in , and the conditions that follow that table, define the architectural requirements for debug authentication.

Table E1-1 Debug authentication functions

Pseudocode function	Description
`ExternalNoninvasiveDebugEnabled()`	Returns TRUE if Non-secure non-invasive debug is enabled.
`ExternalInvasiveDebugEnabled()`	Returns TRUE if Non-secure invasive debug is enabled.
`ExternalSecureNoninvasiveDebugEnabled()`	Returns TRUE if Secure non-invasive debug is enabled.
`ExternalSecureInvasiveDebugEnabled()`	Returns TRUE if Secure invasive debug is enabled.

The following conditions always apply:

- If `ExternalInvasiveDebugEnabled()` is FALSE then `ExternalSecureInvasiveDebugEnabled()` is FALSE.
- If `ExternalNoninvasiveDebugEnabled()` is FALSE then `ExternalSecureNoninvasiveDebugEnabled()` is FALSE.
- If `ExternalInvasiveDebugEnabled()` is TRUE then `ExternalNoninvasiveDebugEnabled()` is TRUE.
- If `ExternalSecureInvasiveDebugEnabled()` is TRUE then `ExternalSecureNoninvasiveDebugEnabled()` is TRUE.

If FEAT_Debugv8p4 is implemented:

- `ExternalNoninvasiveDebugEnabled()` always returns TRUE.
- `ExternalSecureNoninvasiveDebugEnabled()` returns the same as `ExternalSecureInvasiveDebugEnabled()`.

Arm recommends the use of the interface described in Recommended authentication interface to provide this debug authentication. The pseudocode functions in A-profile Architecture Pseudocode, which are linked to by the entries in the Pseudocode function column of , assume that this interface is implemented.

Chapter E2
Debug State

This chapter describes Debug state. It contains the following sections:

- About Debug state.
- Halting the PE on debug events.
- Entering Debug state.
- Behavior in Debug state.
- Exiting Debug state.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

E2.1 About Debug state

In external debug, debug events allow an external debugger to halt the PE. The PE then enters Debug state. When the PE is in Debug state:

- It stops executing instructions from the location indicated by the Program Counter, and is instead controlled through the external debug interface.
- The *Instruction Transfer Register,* ITR, passes instructions to the PE to execute in Debug state.
- The *Debug Communications Channel*, DCC, passes data between the PE and the debugger.

The PE cannot service any interrupts in Debug state.

Non-Confidential

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

E2.2 Halting the PE on debug events

For details of debug events, see Introduction to Halting debug events and Breakpoint and Watchpoint debug events.

On a debug event, the PE must do one of the following:

- Enter Debug state.
- Pend the debug event.
- Generate a debug exception.
- Ignore the debug event.

This behavior depends on both:

- Whether halting is allowed by the current state of the debug authentication interface. See Halting allowed and halting prohibited.
- The type of debug event and the programming of the debug control registers.
  - See Halting debug events for all Halting debug events.
  - See Breakpoint and Watchpoint debug events for Breakpoint and Watchpoint debug events.

See also Other debug exceptions.

This means that behavior can be CONSTRAINED UNPREDICTABLE if the conditions change. See Synchronization and Halting debug events.

Table E3-1 summarizes the possible outcomes of each type of debug event.

E2.2.1 Halting allowed and halting prohibited

Halting can be either allowed or prohibited:

- Halting is always prohibited in Debug state.
- Halting is always prohibited when `DoubleLockStatus()` == TRUE.
  - This means that FEAT_DoubleLock is implemented and OS Double lock is locked.
- Halting is also controlled by the IMPLEMENTATION DEFINED authentication interface, and is prohibited when `ExternalSecureInvasiveDebugEnabled()` == FALSE.
- Otherwise, halting is allowed.

For more information, see:

- Pseudocode description of Halting on debug events.
- Required debug authentication.
- Recommended External Debug Interface.

E2.2.2 Halting debug events

The Halting debug events are described in Halting Debug Events.

When a Halting debug event is generated, it causes entry to Debug state if all of the following are true:

- Halting is allowed. See Halting allowed and halting prohibited.
- The Halting debug event is one of:
  - A Halt Instruction debug event and EDSCR.HDE == 1.
  - A Software Access debug event and OSLSR_EL1.OSLK == 0, meaning that the OS Lock is unlocked.
  - Neither a Halt Instruction debug event nor a Software Access debug event.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

— A Halt Instruction debug event is the only Halting debug event that relies on EDSCR.HDE == 1.

— Halting on Breakpoint and Watchpoint debug events is also controlled by EDSCR.HDE. See Breakpoint and Watchpoint debug events.

— EDSCR.HDE can be written by software when the OS Lock is locked. Privileged code can use MDCR_EL2, Monitor Debug Configuration Register (EL2).TDOSA to trap writes to OS Lock registers.

If a Halting debug event does not generate entry to Debug state because the conditions listed in this section do not hold, then:

- If the Halting debug event is a Halt Instruction debug event, the instruction that generated the Halting debug event is treated as UNDEFINED.
- If the Halting debug event is a Software Access debug event, it is ignored.
- If the Halting debug event is an Exception Catch debug event, it is ignored except when FEAT_Debugv8p8 is implemented, in which case the event might be pended.

In all other cases the Halting debug event is pended, see Pending Halting debug events.

Summary of actions from debug events summarizes the possible outcome for each type of Debug event.

Note

Halting debug events never generate debug exceptions.

E2.2.3 Breakpoint and Watchpoint debug events

A breakpoint or watchpoint generates an entry to Debug state if all of the following conditions hold:

- Halting debug is enabled, that is EDSCR.HDE == 1.
- Halting is allowed. See Halting allowed and halting prohibited.
- The OS Lock is unlocked, that is OSLSR_EL1, OS Lock Status Register.OSLK == 0.

The Address Mismatch breakpoint type is reserved when all of these conditions are met.

MDSCR_EL1.MDE is ignored when determining whether to enter Debug state. A breakpoint or watchpoint that generates entry to Debug state is a Breakpoint or Watchpoint debug event and does not generate a debug exception.

A breakpoint or watchpoint that does not generate an entry to Debug state either:

- Generates a Breakpoint or Watchpoint exception.
- Is ignored.

Note

EDSCR.HDE is ignored when determining whether to generate a debug exception. The debug exception is suppressed only if the PE enters Debug state. This means that the use of Halting debug mode in one Security state does not affect the Exception model in another Security state.

See AArch64 Self-hosted Debug, and the Note in Other debug exceptions.

E2.2.4 Other debug exceptions

The following events never generate entry to Debug state:

- Breakpoint Instruction exceptions.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- Software Step exceptions.

The behavior of these events is unchanged when Halting debug mode is enabled, that is when EDSCR.HDE == 1. This means that these events can do one of the following:

- They can generate a debug exception.
- They can be ignored.

For additional information, see AArch64 Self-hosted Debug.

E2.2.5 Debug state entry and debug event prioritization

The following are synchronous debug events:

- Breakpoint debug event.
- Watchpoint debug event.
- Halting Step debug event.
- Halt Instruction debug event.
- Exception Catch debug event.
- Software Access debug event.
- Reset Catch debug event.

Each of these synchronous debug events are treated as a synchronous exception generated by an instruction, or by the taking of an exception or reset. That is, if halting is allowed, the synchronous debug event must be taken before any subsequent instructions are executed. Reset Catch debug events must be taken before the PE executes the instruction at the reset vector.

Note

- Reset Catch and Exception Catch debug events might be generated asynchronously, because they can result from an asynchronous exception. However, if halting is allowed after the reset or asynchronous exception has been processed, the Reset Catch or Exception Catch debug event is taken synchronously.
- The Halting Step debug event is generated by the instruction after the stepped instruction. Therefore, if the stepped instruction generates any other synchronous exceptions or debug events these are taken first.

If halting is prohibited then Halting Step debug events and Reset Catch debug events might be pended and taken asynchronously. OS Unlock Catch debug events are always pended and taken asynchronously. See Pending Halting debug events.

The architecture does not define when asynchronous debug events are taken, and therefore the prioritization of asynchronous debug events is IMPLEMENTATION DEFINED. See Synchronization and Halting debug events.

The following list shows how the synchronous debug events are prioritized, with 1 being the highest priority.

Note

The priority numbering is the same as the numbering for AArch64 synchronous exception priorities listed in Synchronous exception types, and in particular Prioritization of interrupts.

The priority for synchronous debug events is as follows:

1 Reset Catch debug event. See Reset Catch debug events.

This debug event has a higher priority than the synchronous exceptions listed in Synchronous exception types.

2 Exception Catch debug event if it has a priority of 2. See Exception Catch debug event.

This debug event can be assigned one of two priorities, 2 or 6. When it has a priority of 2, it has a higher priority than the synchronous exceptions listed in the Exception model.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

3	Halting Step debug event. See Halting Step debug events. This debug event has a higher priority than the synchronous exceptions listed in the Exception model.
4-5	These events are not debug events.
6	Exception Catch debug event if it has a priority of 6. See Exception Catch debug event. This debug event can be assigned one of two priorities, 2 or 6.
7-9	These events are not debug events.
10	Breakpoint debug events. See Breakpoint and Watchpoint debug events.
11-12	These events are not debug events.
13	Halt Instruction debug event. See Halt Instruction debug event.
14-39	These events are not debug events.
40	Software Access debug event. See Software Access debug event.
41-45	These events are not debug events.
46	Watchpoint debug events. See Breakpoint and Watchpoint debug events.
47-48	These events are not debug events.

For Reset Catch debug events and Halting Step debug events, the priorities listed in this section apply only when halting is allowed at the time the event is generated. This means that the event is taken synchronously and not pended.

For more information on the prioritization of exceptions, see:

- Synchronous exception types.
- Prioritization of interrupts.

E2.2.6 Imprecise entry to Debug state

Debug state entry is normally *precise*. This means that the PE cannot enter Debug state if it can neither complete nor abandon all currently executing instructions and leave the PE in a precise state. See Definition of a precise exception and imprecise exception.

A debugger can write a value of 1 to EDRCR.CBRRQ to allow imprecise entry to Debug state. An External Debug Request debug event must be pending before writing 1 to this bit. Support for this feature is OPTIONAL and it is IMPLEMENTATION DEFINED when it is effective at forcing entry to Debug state.

The PE ignores writes to this bit when `ExternalInvasiveDebugEnabled()` == FALSE.

Example E2-1 shows how entry to Debug state can be forced.

Example E2-1 Forcing entry to Debug state

The debugger pends an External Debug Request debug event through the CTI to halt a program that has stopped responding. However, the memory system is not responding and a memory access instruction cannot complete. This means that Debug state cannot be entered precisely. The debugger writes a value of 1 to EDRCR.CBRRQ. The PE cancels all outstanding memory accesses and enters Debug state. As some instructions might not have completed correctly, entry to Debug state is imprecise.

When Debug state is entered imprecisely, all memory access instructions executed through the ITR have CONSTRAINED UNPREDICTABLE behavior. The value of all registers is UNKNOWN, but might be useful for diagnostic purposes.

E2.2.7 Summary of actions from debug events

Table E2-1 shows the Software and Halting debug events. In Table E2-1, the columns have the following meaning:

Debug event type

This means the type of debug event where:

Other software Means one of:

- Software Step exceptions.
- Breakpoint Instruction exceptions.

Other Halting Means one of the following:

- Halting Step debug events.
- External Debug Request debug event.
- Reset Catch debug events.
- OS Unlock Catch debug event.

Other debug events are referred to explicitly.

Authentication

This means halting is allowed by the IMPLEMENTATION DEFINED external authentication interface. It is the result of `ExternalSecureInvasiveDebugEnabled()`.

DLK This indicates whether FEAT_DoubleLock is implemented and locked, `DoubleLockStatus()` == TRUE.

OSLK This is the value of OSLSR_EL1, OS Lock Status Register.OSLK. It indicates whether the OS Lock is locked.

HDE This is the value of EDSCR.HDE. It indicates whether Halting debug is enabled.

The letter X in Table E2-1 indicates that the value can be either 0 or 1.

Table E2-1 Debug authentication for external debug

Debug event type	Authentication	DLK	OSLK	HDE	Behavior
Other software	X	X	X	X	Handled by the Exception model
Breakpoint or Watchpoint debug event	X	TRUE	X	X	Handled by the Exception model (ignored)
	X	FALSE	1	X	Handled by the Exception model (ignored)
	FALSE	FALSE	0	X	Handled by the Exception model
	TRUE	FALSE	0	0	Handled by the Exception model
	TRUE	FALSE	0	1	Entry to Debug state
Halt Instruction debug event	FALSE	X	X	X	UNDEFINED
	TRUE	TRUE	X	X	UNDEFINED
	TRUE	FALSE	X	0	UNDEFINED
	TRUE	FALSE	X	1	Entry to Debug state
Exception Catch debug event	FALSE	X	X	X	Might be pended[a]

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Debug event type	Authentication	DLK	OSLK	HDE	Behavior
	TRUE	TRUE	X	X	Ignored
	TRUE	FALSE	X	X	Entry to Debug state
Software Access debug event	FALSE	X	X	X	Ignored
	TRUE	TRUE	X	X	Ignored
	TRUE	FALSE	1	X	Ignored
	TRUE	FALSE	0	X	Entry to Debug state
Other Halting	FALSE	X	X	X	Debug event is pended
	TRUE	TRUE	X	X	Debug event is pended
	TRUE	FALSE	X	X	Entry to Debug state

a. See Exception Catch debug event.

E2.2.8 Pseudocode description of Halting on debug events

The `Halted()`, `Restarting()`, `HaltingAllowed()`, and `HaltOnBreakpointOrWatchpoint()` functions are described in the pseudocode.

E2.3 Entering Debug state

On entry to Debug state, the preferred restart address and PSTATE are saved in DLR_EL0, Debug Link Register and DSPSR_EL0, Debug Saved Program Status Register. The PE remains in the mode and Security state from which it entered Debug state.

If EDRCR.CBRRQ has a value of 0, entry to Debug state is precise. If EDRCR.CBRRQ has a value of 1, then imprecise entry to Debug state is permitted.

If a Watchpoint debug event causes an entry to Debug state, the PE records all of the following:

- When FEAT_EDHSR is not implemented or the PE sets EDHSR.FnV to 0, the address of the access that generated the Watchpoint debug event is recorded in EDWAR.
- When FEAT_EDHSR is implemented, information about the access that generated the Watchpoint debug event is recorded in EDHSR.

For more information, see:

- Exception syndrome information, fault address information, and preferred return address for a debug event taken from AArch64 state.

Other than the effect on PSTATE and EDSCR, entry to Debug state is not a Context Synchronization event. The effects of entry to Debug state on PSTATE and EDSCR are synchronized.

E2.3.1 Effect of Debug state entry on DLR and DSPSR

DLR_EL0, Debug Link Register is set to the preferred restart address for the debug event, which depends on the event type. The value of PSTATE is saved in DSPSR_EL0, Debug Saved Program Status Register.

For synchronous Halting debug events, the preferred restart address is the address of the instruction that generated the debug event.

For asynchronous Halting debug events, including pending Halting debug events taken asynchronously, the preferred restart address is the address of the first instruction that must be executed on exit from Debug state.

This means that:

- For Breakpoint and Watchpoint debug events, the preferred restart address is the same as the preferred return address for a debug exception, as described in AArch64 Self-hosted Debug.
- For Halt Instruction debug events, DLR_EL0, Debug Link Register is set to the address of the `HLT` instruction and DSPSR_EL0, Debug Saved Program Status Register.IT is correct for the `HLT` instruction.
- For Software Access debug events, DLR_EL0, Debug Link Register is set to the address of the accessing instruction and DSPSR_EL0, Debug Saved Program Status Register.IT is correct for this instruction.
- For Halting Step debug events taken synchronously, DLR_EL0, Debug Link Register and DSPSR_EL0, Debug Saved Program Status Register are set as the ELR and SPSR would be set for a Software Step exception. This is usually the address of, and PSTATE for, the instruction after the one that was stepped.
- For Exception Catch debug events, DLR_EL0, Debug Link Register is set to the address of the first instruction that must be executed on exit from Debug state, and DSPSR_EL0, Debug Saved Program Status Register is correct for this instruction. This is the exception vector or reset vector address.
  - If the debug event is generated on taking an exception to a trapped Exception level, the DLR_EL0, Debug Link Register is set to the address of the exception vector the PE would have started fetching from. This is UNKNOWN if the VBAR for the Exception level has never been initialized. The DSPSR_EL0, Debug Saved Program Status Register records the value of PSTATE after taking the exception. The Exception Catch occurs after the SPSR and the Link register are set, and the debugger can use these registers to determine where in the application program the exception occurred.

    Note

    Depending on the target Exception level and Execution state for the exception, the Link register is one of ELR_EL1, ELR_EL2 or LR (R14).

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

— If the debug event is generated on an exception return to a trapped Exception level, the DLR_EL0, Debug Link Register is set to the target address of the exception return and the DSPSR_EL0, Debug Saved Program Status Register records the value of PSTATE after the exception return.

- Reset Catch debug events taken synchronously behave like Exception Catch debug events.
- For Reset Catch debug events and Exception Catch debug events generated on reset to a trapped Exception level, the DLR_EL0, Debug Link Register is set to is set to the reset address and the DSPSR_EL0, Debug Saved Program Status Register records the reset value of PSTATE.
- For pending Halting debug events and External Debug Request debug events, DLR_EL0, Debug Link Register is set to the address of the first instruction that must be executed on exit from Debug state. See Pending Halting debug events.

Normally DLR_EL0, Debug Link Register is aligned according to the instruction set state indicated in DSPSR_EL0, Debug Saved Program Status Register. However, a debug event might be taken at a point where the PC is not aligned.

E2.3.2 Effect of Debug state entry on System registers, the Event register, and Exclusives monitors

Entering Debug state has no effect on System registers other than DLR_EL0, Debug Link Register and DSPSR_EL0, Debug Saved Program Status Register. In particular, ESRs, FARs, and FSRs are not updated on entering Debug state.

Entering Debug state has no architecturally-defined effect on the Event Register and Exclusives monitors.

Note

Entry to Debug state might set the Event Register or clear the Exclusives monitors, or both. However, this is not a requirement, and debuggers must not rely on any IMPLEMENTATION SPECIFIC behavior.

Unless otherwise described in this reference manual, instructions executed in Debug state have their architecturally-defined effects on the System registers, the Event register, and Exclusives monitors.

E2.3.3 Effect of entering Debug state on PSTATE

The effect of an entry to Debug state on PSTATE is described in Entering Debug state.

On entry to Debug state after PSTATE is saved in DSPSR_EL0, Debug Saved Program Status Register:

- PSTATE.IL is cleared to 0.
- PSTATE.{SS, D, A, I, F, SSBS} are set to UNKNOWN values.

PSTATE.{N, Z, C, V, Q, M, nRW, EL, SP, PAN, DIT} are unchanged.

For more information, see PSTATE in Debug state.

E2.3.4 Entering Debug state during loads and stores

The PE can enter Debug state during instructions that perform a sequence of memory accesses, as opposed to a single single-copy atomic access, because of a Watchpoint debug event. The effect of entering Debug state on such an instruction is the same as taking a Data Abort exception during such an instruction.

In addition, the PE can enter Debug state because of an External Debug Request debug event during instructions that perform a sequence of memory accesses. The effect of entering Debug state on such an instruction is the same as taking an interrupt exception during such an instruction.

This applies to all memory types.

E2.3.5 Entering Debug state and Software Step

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

When Software Step is active, a debug event that causes entry to Debug state behaves like an exception taken to an Exception level above the debug target Exception level. That is:

- If the instruction that is stepped generates a synchronous debug event that causes entry to Debug state, or an asynchronous debug event is taken before the step completes, the PE enters Debug state with DSPSR_EL0, Debug Saved Program Status Register.SS set to 1.
- A pending Halting debug event or an asynchronous debug event can be taken after the step has completed. In this case the PE enters Debug state with DSPSR_EL0, Debug Saved Program Status Register.SS set to 0.

In addition:

- If the instruction that is stepped generates an exception trapped by an Exception Catch debug event, the PE enters Debug state at the exception vector with DSPSR_EL0, Debug Saved Program Status Register.SS set to 0. This is because PSTATE.SS is set to 0 by taking the exception.
- If the PE is reset, PSTATE.SS is reset to 0. If the following debug events are enabled, and halting is allowed, the PE enters Debug state with DSPSR_EL0, Debug Saved Program Status Register.SS set to 0:
  - Reset Catch debug event at the reset Exception level.
  - Exception Catch debug event at the reset Exception level.
  - Halting Step debug event.
- If Halting Step is also active, then Halting Step and Software Step operate in parallel and can both become active-pending. In this case Halting step has a higher priority than Software step. This means that the PE enters Debug state and DSPSR_EL0, Debug Saved Program Status Register.SS is set to 0.

E2.3.6 Pseudocode description of entering Debug state

The `DebugHalt` constants are described in shared/debug/halting/DebugHalt in the pseudocode. The `UpdateEDSCRFields()` and `Halt()` functions are described in A-profile Architecture Pseudocode.

E2.4 Behavior in Debug state

Instructions are executed in Debug state from the Instruction Transfer Register, ITR. The debugger controls which instructions are executed in Debug state by writing the instructions to the External Debug Instruction Transfer register, EDITR.

Some instructions are available only in Debug state. See Debug state operations, DCPS, DRPS, MRS, MSR. In Non-debug state these instructions are UNDEFINED.

The following sections describe behavior in Debug state:

- PSTATE in Debug state.
- Executing instructions in Debug state.
- Decode tables.
- Security in Debug state.
- Privilege in Debug state.
- Debug state operations, DCPS, DRPS, MRS, MSR.
- Exceptions in Debug state.
- Accessing registers in Debug state.
- Accessing memory in Debug state.

This section specifies the CONSTRAINED UNPREDICTABLE behaviors that apply in Debug state, but see Changing the value of EDECR.SS when not in Debug state for a change in Non-debug state that causes CONSTRAINED UNPREDICTABLE behavior.

E2.4.1 PSTATE in Debug state

PSTATE.{N, Z, C, V, SS, ALLINT, SSBS, BTYPE, D, A, I, F, PM}{N, Z, C, V, Q, SS, SSBS, D, A, I, F, PM} are all ignored in Debug state:

- There are no conditional instructions in Debug state.
- Software step is inactive.
- Asynchronous exceptions and debug events are ignored.
- If FEAT_SSBS is implemented, then hardware is permitted to load or store speculatively, regardless of the value of PSTATE.SSBS.

Instructions executed in Debug state indirectly read PSTATE.{PAN, IL, nRW, EL, SP} as they would in Non-debug state.

Note

PSTATE.DIT is not guaranteed to have any effect in Debug state.

In Debug state:

- PSTATE.PAN is set to 1 by:
  - A `DCPS<n>` instruction to EL1 using AArch64 if SCTLR_EL1.SPAN == 0.
  - A `DCPS<n>` instruction to EL2 using AArch64 if SCTLR_EL2.SPAN == 0.
- PSTATE.UAO is set to 0 by a `DCPS<n>` instruction to AArch64 state.
- If FEAT_SSBS is implemented, the `DCPS<n>` instruction leaves the PSTATE.SSBS bit UNKNOWN.

PSTATE can also be changed by taking exceptions in Debug state, and by the execution of `DCPS<n>` and `DRPS` instructions.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

E2.4.2 Executing instructions in Debug state

The instructions executed in Debug state must be either A64 instructions, depending on the current Execution state.

Each instruction falls into one of the following groups:

- Debug state instructions. These are instructions that are changed in Debug state. See A64 instructions that are changed in Debug state.
- Instructions that are unchanged in Debug state. See A64 instructions that are unchanged in Debug state. Where these sections describe the behavior of an instruction as unchanged in Debug state, or having the same behavior as in Non-debug state, and that instruction would generate an exception in Non-debug state, then the behavior of the exception is as described in Exceptions in Debug state.
- Instructions that are UNPREDICTABLE or CONSTRAINED UNPREDICTABLE in Debug state. See A64 instructions that are CONSTRAINED UNPREDICTABLE in Debug state.

If EDSCR.SDD == 1, then an exception from Non-secure state is never taken to Secure state.

See Security in Debug state.

E2.4.2.1 Executing A64 instructions in Debug state

The following sections describe the behavior of the A64 instructions in Debug state:

- A64 instructions that are changed in Debug state.
- A64 instructions that are unchanged in Debug state.
- A64 instructions that are CONSTRAINED UNPREDICTABLE in Debug state.

E2.4.2.1.1 A64 instructions that are changed in Debug state

The following instructions are defined in Debug state, but are UNDEFINED in Non-debug state:

- `DCPS`.

  Note

  `DCPS` can be UNDEFINED in certain conditions in Debug state. See DCPS<n>.

- `DRPS`.
- `MRS` (DLR_EL0), `MRS` (DSPSR_EL0), `MSR` (DLR_EL0), `MSR` (DSPSR_EL0)

For more information, see Debug state operations, DCPS, DRPS, MRS, MSR.

E2.4.2.1.2 A64 instructions that are unchanged in Debug state

The following list shows the instructions that are unchanged in Debug state:

Any instruction that is UNDEFINED in Non-debug state

This list of instructions excludes:

- Any instruction listed in A64 instructions that are changed in Debug state.
- Any instruction listed in A64 instructions that are CONSTRAINED UNPREDICTABLE in Debug state that is UNDEFINED because an enable or disable bit is not RES0 or RES1

Instructions that move System or Special-purpose registers to or from a general-purpose register

This list of instructions:

- Includes the instructions to transfer a general-purpose register to or from the DTR, which can be executed at any Exception level.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- Excludes PSTATE access instructions.

These instructions are:

- `MRS <special_reg>`, `MSR <special_reg>`.

  Note

  This does not include NZCV, DAIF, DAIFSet, DAIFClr, SPSel, CurrentEL, PAN, UAO and DIT.

- `MRS <system_reg>`, `MSR <system_reg>`.

Floating-point moves between a SIMD&FP register and a general-purpose register

These instructions are:

- `FMOV` (between a general-purpose register and a half-precision register).
- `FMOV` (between a general-purpose register and a single-precision register).
- `FMOV` (between a general-purpose register and a double-precision register).
- `FMOV` (between a general-purpose register and a SIMD element).

SIMD moves between a SIMD&FP register and a general-purpose register

These instructions are:

- `INS` (from a general-purpose register to a SIMD element).
- `UMOV` (from a SIMD element to a general-purpose register).

Barriers These instructions are:

- `DMB`.
- `DSB`.
- `ISB`.
- `CSDB`.
- `SSBB`.
- `PSSBB`.
- If FEAT_SB is implemented, then `SB`.

Memory access instructions at various access sizes

The following constraints apply:

- General purpose-registers only.
- One of the following addressing modes:
  - Unscaled (9-bit signed) immediate offset.
  - Immediate (9-bit signed) post-indexed.
  - Immediate (9-bit signed) pre-indexed.
  - Unprivileged (9-bit signed).
- Not literal.
- One of the following types:
  - (Single) register.
  - Exclusive.
  - Exclusive pair.
  - Acquire/Release.
  - Acquire/Release Exclusive.
  - Acquire/Release Exclusive pair.
- 32-bit and 64-bit target register variants.

These instructions are:

- `LDR`, `LDRB`, `LDRH`, `LDRSB`, `LDRSH`, `LDRSW` (immediate, not literal).

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- `LDUR`, `LDURB`, `LDURH`, `LDURSB`, `LDURSH`, `LDURSW` (immediate).
- `LDTR`, `LDTRB`, `LDTRH`, `LDTRSB`, `LDTRSH`, `LDTRSW` (immediate).
- `LDAR`, `LDARB`, `LDARH`, `LDXR`, `LDXRB`, `LDXRH`, `LDAXR`, `LDAXRB`, `LDAXRH`.
- `LDXP`, `LDAXP`.
- `STR`, `STRB`, `STRH` (immediate).
- `STUR`, `STURB`, `STURH` (immediate).
- `STTR`,`STTRB`, `STTRH` (immediate).
- `STLR`, `STLRB`, `STLRH`, `STXR`, `STXRB`, `STXRH`, `STLXR`, `STLXRB`, `STLXRH`.
- `STXP`, `STLXP`.
- If FEAT_LOR is implemented, then:
  - `LDLAR`, `LDLARB`, `LDLARH`.
  - `STLLR`, `STLLRBB`, `STLLRH`.
- If FEAT_LSE is implemented, then:
  - `CAS`, `CASB`, `CASH`, `CASP`.
  - `SWP`, `SWPB`, `SWPH`.
  - `LDADD`, `LDADDB`, `LDADDH`.
  - `LDCLR`, `LDCLRB`, `LDCLRH`.
  - `LDEOR`, `LDEORB`, `LDEORH`.
  - `LDSET`, `LDSETB`, `LDSETH`.
  - `LDSMAX`, `LDSMAXB`, `LDSMAXH`.
  - `LDSMIN`, `LDSMINB`, `LDSMINH`.
  - `LDUMAX`, `LDUMAXB`, `LDUMAXH`.
  - `LDUMIN`, `LDUMINB`, `LDUMINH`.
  - `STADD`, `STADDB`, `STADDH`.
  - `STCLR`, `STCLB`, `STCLRH`.
  - `STEOR`, `STEORB`, `STEORH`.
  - `STSET`, `STSETB`, `STSETH`.
  - `STSMAX`, `STSMAXB`, `STSMAXH`.
  - `STSMIN`, `STSMINB`, `STSMINH`.
  - `STUMAX`, `STUMAXB`, `STUMAXH`.
  - `STUMIN`, `STUMINB`, `STUMINH`.
- If FEAT_LRCPC is implemented, then `LDAPR, LDAPRB, LDAPRH`.
- If FEAT_LRCPC2 is implemented, then:
  - `LDAPURH, LDAPURSH, LDAPUR, LDAPURSW, LDAPURSB, LDAPURB`.
  - `STLUR, STLURH, STLURB`.

Move immediate to general-purpose register

These instructions are:

- `MOVZ`, `MOVN`, `MOVK` (immediate).
- `MOV` (between a general-purpose register and the stack pointer).

System instructions, Send Event, NOP, Clear Exclusive, and Prediction

In this context, the System instructions are the Cache maintenance instructions, TLB maintenance instructions, Address translation instructions, the prediction restriction instructions, and the check feature instruction.

These instructions are:

- `IC`.
- `DC`.
- `TLBI`.
- `AT`.
- `SEV`, `SEVL`.
- `NOP`.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- CLREX.
- CFP.
- CPP.
- DVP.

Pointer authentication instructions

These instructions are:

- If FEAT_PAuth is implemented, then:
  - AUTIA, AUTIAZ, AUTIZA.
  - AUTIB, AUTIBZ, AUTIZB.
  - AUTDA, AUTDZA.
  - AUTDB, AUTDZB.
  - PACIA, PACIAZ, PACIZA.
  - PACIB, PACIBZ, PACIZB.
  - PACDA, PACDZA.
  - PACDB, PACDZB.
  - PACGA.
  - XPACD, XPACI, XPACLRI.

E2.4.2.1.3 A64 instructions that are CONSTRAINED UNPREDICTABLE in Debug state

This subsection describes all instructions that are not listed in either:

- A64 instructions that are changed in Debug state.
- A64 instructions that are unchanged in Debug state.

These instructions are CONSTRAINED UNPREDICTABLE in Debug state. In general, the permissible behaviors are:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- If the instruction reads the PC or PSTATE, it uses an UNKNOWN value.
- If the instruction modifies the PC or PSTATE, other than by advancing the PC to the sequentially next instruction, it sets DLR_EL0 and DSPSR_EL0 to UNKNOWN values.
- If the instruction is similar to a Debug state instruction, it executes as that Debug state instruction.
- The instruction has the same behavior as in Non-debug state.

The following list shows the permissible behaviors for A64 instruction in Debug state. An instruction might appear multiple times in the list, in which case the choice of permissible behaviors is any of those listed. An example of this is CCMP.

Exception-generating instructions

These instructions are:

- SVC.
- HVC.
- SMC.
- BRK.
- HLT.

These instructions behave in one of the following ways:

- They are UNDEFINED.
- They execute as a NOP.
- SVC behaves as DCPS1.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- `HVC` behaves as `DCPS2`.
- They generate the exception that the instruction would generate in Non-debug state. The exception is taken as described in Exceptions in Debug state.

Instructions that explicitly write to the PC (branches)

These instructions are:

- `B`, `B.cond`, `BL`, `BLR`, `BR`, `CBZ`, `CBNZ`, `RET`, `TBZ`, `TBNZ`.
- If FEAT_PAuth is implemented, then `RETAA`, `RETAB`, `BRAA`, `BRAB`, `BLRAA`, `BLRAB`, `BLRAAZ`, `BLRABZ`.

These instructions behave in one of the following ways:

- They are UNDEFINED.
- They execute as a `NOP`.
- They execute as in Non-debug state without branching and set DSPSR_EL0 and DLR_EL0 to UNKNOWN values.

Exception return and related instructions

These instructions are:

- `ERET`.
- If FEAT_PAuth is implemented, then `ERETAA`, `ERETAB`.

These instructions behave in one of the following ways:

- They are UNDEFINED.
- They execute as a `NOP`.
- They execute as in Non-debug state without branching, set DSPSR_EL0 and DLR_EL0 to UNKNOWN values, and either:
  - Execute the `DRPS` operation instead of performing an exception return, using UNKNOWN SPSR values.
  - Do not change the Exception level.

Instructions that request entry to a low-power state

These instructions are `WFE`, `WFI`.

These instructions behave in one of the following ways:

- They are UNDEFINED.
- They execute as a `NOP`.
- They generate a synchronous exception if the corresponding instruction would be trapped in Non-debug state. See Configurable instruction controls.
- A `WFE` instruction clears the Event register if it is set.

Note

This means that these instructions must not suspend execution.

Instructions that read the PC

These instructions are:

- `LDR` (literal), `LDRSW` (literal).
- `ADR`, `ADRP`.
- `PRFM` (literal).

These instructions behave in one of the following ways:

- They are UNDEFINED.
- They execute as a `NOP`.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- They execute as in Non-debug state, using an UNKNOWN value for the PC operand.

Instructions that explicitly modify PSTATE, other than `DCPS` and `DRPS`

These instructions are:

- `ADDS`, `SUBS`, `ADCS`, `SBCS`, `ANDS`, `BICS`, `CCMN`, `CCMP`.
- `FCMP`, `FCMPE`, `FCCMP`, `FCCMPE`.
- `MSR DAIFSet` (immediate), `MSR DAIFClr` (immediate), `MSR SPSel` (immediate).
- `MSR NZCV` (register), `MSR DAIF` (register), `MSR SPSel` (register).
- If FEAT_PAN is implemented, then:
  - `MSR PAN` (immediate).
  - `MSR PAN` (register).
- If FEAT_UAO is implemented, then:
  - `MSR UAO` (immediate).
  - `MSR UAO` (register).
- If FEAT_FlagM is implemented, then:
  - `CFINV`.
  - `RMIF`.
  - `SETF8`.
  - `SETF16`.
- If FEAT_DIT is implemented, then `MSR DIT`.

These instructions behave in one of the following ways:

- They are UNDEFINED.
- They execute as a `NOP`.
- They execute as in Non-debug state, setting DSPSR_EL0 and DLR_EL0 to UNKNOWN values.
- For the `PACM` instruction, PSTATE.PACM is set to an UNKNOWN value.

Instructions that read PSTATE.{N, Z, C, V} or other PSTATE fields

These instructions are:

- `CSEL`, `CSINC`, `CSINV`, `CSNEG`, `CCMN`, `CCMP`, `FCSEL`, `FCCMP`, `FCCMPE`.
- `ADC`, `ADCS`, `SBC`, `SBCS`.
- `MRS NZCV`, `MRS DAIF`, `MRS SPSel`, `MRS CurrentEL`.
- If FEAT_PAN is implemented, then `MRS PAN`.
- If FEAT_UAO is implemented, then `MRS UAO`.
- If FEAT_FlagM is implemented, then `CFINV`.
- If FEAT_DIT is implemented, then `MRS DIT`.

These instructions behave in one of the following ways:

- They are UNDEFINED.
- They execute as a `NOP`.
- They execute as in Non-debug state:
  - For the conditional operations and those that use Condition flags as an input, these instructions use UNKNOWN values for the Condition flag.
  - For the `MRS` instruction, they return an UNKNOWN value.
  - For the `RCW` and `RCWS` instructions, they return an UNKNOWN value.
  - For the `PACIASP` and `PACIBSP` instructions when PSTATE.PACM is 1, they use an UNKNOWN value for the PC operand.

Hint instructions

If FEAT_DGH is implemented, then this instruction is:

- `DGH`.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

This instruction behaves in one of the following ways:

- It executes as a NOP.
- It executes as in Non-debug state.

All other instructions

These instructions behave in one of the following ways:

- They are UNDEFINED.
- They execute as a NOP.
- They execute as in Non-debug state.

Note

This includes instructions defined as UNPREDICTABLE or CONSTRAINED UNPREDICTABLE in Non-debug state. These instructions are UNPREDICTABLE or CONSTRAINED UNPREDICTABLE in Debug state.

E2.4.3 Decode tables

The syntax in the decode tables is defined as follows:

1	The bit has a fixed value of 1.
0	The bit has a fixed value of 0.
!=	The field has any value other than the value or values specified. The field might be an encoding field in the instruction whose value is supplied by the debugger.

Note

The instruction encodings in A64 Base Instruction Descriptions might show these bits as (0) or (1). A debugger must set these bits to 0 or 1, as appropriate.

Any other value indicates an encoding field in the instruction whose value is supplied by the debugger. Some values might be reserved or UNDEFINED, in which case the instruction is UNDEFINED or CONSTRAINED UNPREDICTABLE in Debug state, as it is in Non-debug state.

For more information about the instruction encodings, see A64 Base Instruction Descriptions.

For information about the syntax used in Figure E2-1, and see:

- Common syntax terms.
- Assembler symbols.

E2.4.4 Security in Debug state

On entry to Debug state EDSCR.SDD is the Secure debug disabled flag. If entering Debug state from Secure state, EDSCR.SDD is set to 0.

Note

If halting is prohibited in a Security state, it is not possible to enter Debug state from that Security state. However, because changes to the authentication signals require a Context Synchronization event to guarantee their effect, there is a period during which the PE might halt even though the authentication signals prohibit halting.

In Debug state The value of EDSCR.SDD does not change, even if `ExternalSecureInvasiveDebugEnabled()` changes.

Note

- DBGAUTHSTATUS_EL1 is not frozen in Debug state. However, a Context Synchronization event is required to guarantee that changes are visible in DBGAUTHSTATUS_EL1.
- If EDSCR.SDD is 1 in Debug state, there is no means to enter a Security state where halting was prohibited on entry to Debug state. This means that it is not possible for the PE to be in such a Security state when EDSCR.SDD is 1. This is a general principle of behavior in Debug state.

In Non-debug state EDSCR.SDD returns the inverse of `ExternalSecureInvasiveDebugEnabled()`. If the authentication signals that control `ExternalSecureInvasiveDebugEnabled()` change, a Context Synchronization event is required to guarantee their effect.

Note

- A Context Synchronization event is also required to guarantee that changes in the authentication signals are visible in DBGAUTHSTATUS_EL1.

Non-Confidential

E2.4.5 Privilege in Debug state

The only additional privileges offered to Debug state are:

- The privilege to execute Debug state operations, DCPS, DRPS, MRS, MSR.
- The privilege to execute DTR access instructions regardless of the Exception level and traps.

The DTR access instructions can be executed at any Exception level, including EL0, regardless of any control register settings that might force these instructions to be UNDEFINED or trapped in Non-debug state. These instruction are:

- The MRS and MSR instructions that access DBGDTR_EL0, DBGDTRTX_EL0, and DBGDTRRX_EL0 in AArch64 state.

All other instructions operate with the privilege determined by the current Exception level and Security state. This applies to all Special-purpose and System registers accesses, memory accesses, and UNDEFINED instructions, and includes generating exceptions when the System registers trap or disable an instruction.

E2.4.6 Debug state operations, DCPS, DRPS, MRS, MSR

The architecture defines operations to change between Exception levels in Debug state. These operations can also change the mode at the current Exception level.

E2.4.6.1 DCPS<n>

Executing a DCPS<n> instruction in Debug state moves the PE to a higher Exception level.

The effect on endianness is the same as for exceptions and exception returns in Non-debug state. In AArch64 state the current endianness is determined by the value of SCTLR_ELx.EE for the target Exception level.

The DCPS<n> instructions are:

In AArch64 state

- DCPS1
- DCPS2
- DCPS3

The DCPS instructions are UNDEFINED in Non-debug state.

Table E2-2 shows the target of the instruction. In Table E2-2, the entries have the following meaning:

EL1h/Svc This means that the target is EL1h.

EL2h/Hyp This means that the target is EL2h.

Table E2-2 Target for DCPS instructions in Debug state

Instruction	Target when DCPS instruction executed at stated Exception level:		
	EL0	EL1	EL2
DCPS1	EL1h	EL1h	EL2h
DCPS2	EL2h	EL2h	EL2h
DCPS3	•	•	•

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Instruction	Target when DCPS instruction executed at stated Exception level:		
	EL0	EL1	EL2

However:

- DCPS1 is UNDEFINED at EL0 if EL2 is implemented and HCR_EL2.TGE == 1.
- DCPS3 is UNDEFINED at all Exception levels.

On executing a DCPS instruction:

- If the target Exception level is using AArch64:
  - ELR_ELx of the target Exception level becomes UNKNOWN.
  - SPSR_ELx of the target Exception level becomes UNKNOWN.
  - ESR_ELx of the target Exception level becomes UNKNOWN.
  - DLR_EL0 and DSPSR_EL0 become UNKNOWN.

The DCPSInstruction() function is described in A-profile Architecture Pseudocode.

E2.4.6.2 DRPS

Executing the DRPS operation in Debug state moves the PE to a lower Exception level, or the current Exception level, by copying the current SPSR to PSTATE.

If the target Exception level is the current Exception level, then the PE does not change Exception level.

The effect on endianness is the same as for exceptions and exception returns in Non-debug state.

Current endianness is set according to the Effective values of SCTLR_ELx.EE, or SCTLR_EL1.E0E for the target Exception level.

For more information see DRPS.

If the SPSR specifies an illegal exception return, then PSTATE.{nRW, EL, SP} are unchanged and PSTATE.IL is set to 1. For further information on illegal exception returns, see Illegal exception returns from AArch64 state.

Some PSTATE fields are ignored in Debug state. The effect of the DRPS operation on them is to set them to an UNKNOWN value that might be the value from the SPSR. For more information, see PSTATE in Debug state.

All other PSTATE fields are copied from SPSR.

DRPS is UNDEFINED at EL0 and in Non-debug state.

Note

Unlike an exception return, the DRPS operation has no architecturally-defined effect on the Event Register and Exclusives monitors. DRPS might set the Event Register or clear the Exclusives monitors, or both, but this is not a requirement and debuggers must not rely on any IMPLEMENTATION SPECIFIC behavior.

On executing a DRPS instruction, then DLR_EL0 and DSPSR_EL0 become UNKNOWN.

The DRPSInstruction() function is described in A-profile Architecture Pseudocode.

E2.4.6.3 MRS and MSR

The other Debug state instructions are used to read or write DLR_EL0 and DSPSR_EL0.

These instructions are:

In AArch64 state

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- MRS
- MSR (register)

```
MRS <Xt>, DLR_EL0          ; Copy DLR_EL0 to <Xt>
```

```
MRS <Xt>, DSPSR_EL0    ; Copy DSPSR_EL0 to <Xt>
```

```
MSR DLR_EL0, <Xt>      ; Copy <Xt> to DLR_EL0
```

```
MSR DSPSR_EL0, <Xt>    ; Copy <Xt> to DSPSR_EL0
```

These instructions can be executed at any Exception level when in Debug state, including EL0. They are UNDEFINED in Non-debug state.

E2.4.7 Exceptions in Debug state

The following sections describe how exceptions are handled in Debug state:

- Generating exceptions when in Debug state.
- Taking exceptions when in Debug state.
- Reset in Debug state.

E2.4.7.1 Generating exceptions when in Debug state

In Debug state:

- Instruction Abort exceptions cannot happen because instructions are not fetched from memory.
- Interrupts, including SError and virtual interrupts are ignored and remain pending:
  - The pending interrupt remains visible in ISR_EL1, Interrupt Status Register.
- Debug exceptions and debug events are ignored.
- Any attempt to execute an instruction bit pattern that is an allocated instruction at the current Exception level, but is listed in Executing instructions in Debug state as UNDEFINED in Debug state, generates an exception.
  The priority and syndrome for these exceptions is the same as for executing an encoding that does not have an allocated instruction.

Otherwise, synchronous exceptions are generated as they would be in Non-debug state and taken to the appropriate Exception level in Debug state.

E2.4.7.2 Taking exceptions when in Debug state

When the PE is in Debug state, all exceptions are synchronous. When an exception is generated, it is taken to Debug state. This means that:

- The target Exception level is as defined for the exception in Non-debug state.
- The exception syndrome is reported as defined for the exception in Non-debug state, except for the case described in Data Aborts in Memory access mode for which the reporting requirements are relaxed.
  The exception syndrome is reported using the syndrome register or registers for the target Exception level. In AArch64 state, these are ESR_ELx, and FAR_ELx. For example, if an instruction is trapped to an Exception level using AArch64 due to a configurable trap, disable, or enable, the exception code reported is the same as it would be in Non-debug state.

The effect on auxiliary syndrome registers, such as AFSR, is IMPLEMENTATION DEFINED.

- The PE remains in Debug state and changes to the target mode.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- The endianness switches to that indicated by the EE bit of the System register for the target Exception level.
- The SPSR for the target Exception level or mode is corrupted and becomes UNKNOWN.
- If the target Exception level is using AArch64, ELR_ELx for the target Exception level becomes UNKNOWN.
- DLR_EL0, Debug Link Register and DSPSR_EL0, Debug Saved Program Status Register become UNKNOWN.
- The cumulative error flag, EDSCR.ERR, is set to 1. See Cumulative error flag.
- PSTATE.IL is cleared to 0.
- PSTATE.{IT, T, SS, D, A, I, F} are set to UNKNOWN values, and PSTATE.{N, Z, C, V, Q, GE} are unchanged. However, these fields are ignored and are not observable in Debug state. For more information, see PSTATE in Debug state.

The debugger must save any state that can be corrupted by an exception before executing an instruction that might generate another exception.

E2.4.7.3 Pseudocode description of taking exceptions in Debug state

`AArch64.TakeException()` shows the behavior when the PE takes an exception to an Exception level using AArch64 in Non-debug state. In Debug state, this redirects to `AArch64.TakeExceptionInDebugState()`.

E2.4.7.4 Reset in Debug state

If the PE is reset when in Debug state, it exits Debug state and enters Non-debug reset state. When the PE is in reset state, EDSCR.STATUS == `0b000010` and writes to EDITR are ignored.

Note

If EDECR.RCE == 1 or CTIDEVCTL.RCE ==1, meaning that a Reset Catch debug event is programmed, and if halting is allowed on exiting reset state, then on exiting reset state the PE halts and re-enters Debug state. See Reset Catch debug events. All PE registers have taken their reset values, which might be UNKNOWN.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

E2.4.8 Accessing registers in Debug state

Register accesses are unchanged in Debug state. The view of each register is determined by either the current Exception level or the mode, or both, and accesses might be disabled or trapped by controls at a higher Exception level.

E2.4.8.1 General-purpose register access, other than AArch64 state SP access

A single general-purpose register can be read by issuing an `MSR` instruction through the ITR to write DBGDTR_EL0 in AArch64 state. The debugger can then read the DTR register or registers through the external debug interface. The reverse sequence writes to a general-purpose register.

Figure E2-2 shows the reading and writing of general-purpose registers, other than SP, in Debug state in AArch64 state.

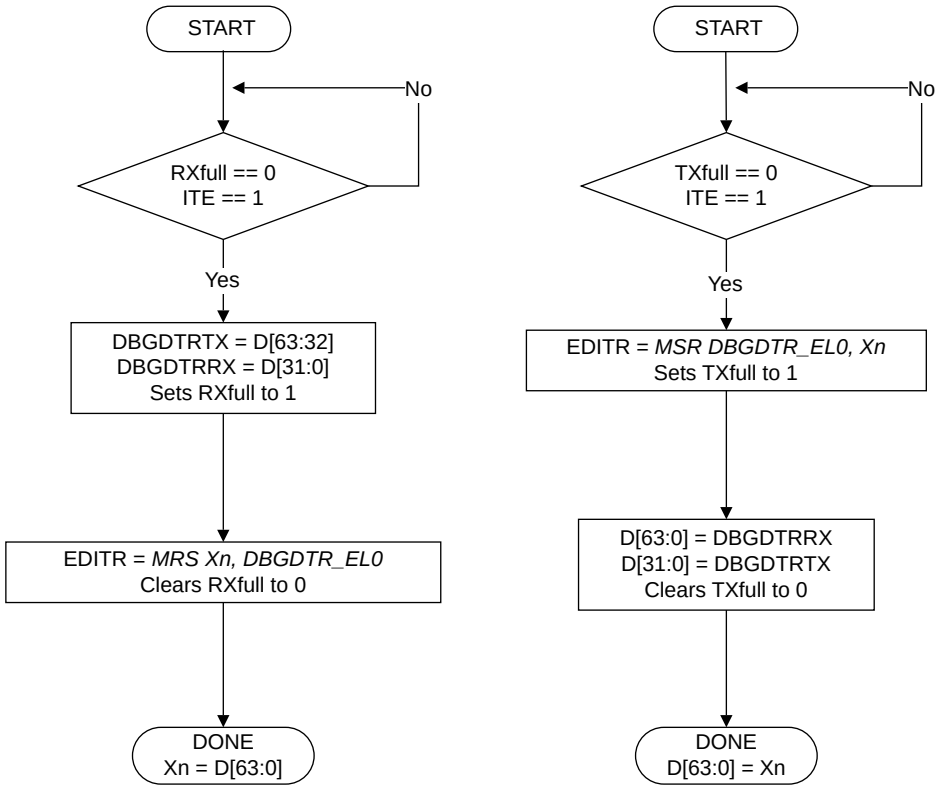

Figure E2-2 Reading and writing general-purpose registers, other than SP, in Debug state in AArch64 state

E2.4.8.2 SIMD&FP register, System register, and AArch64 state SP accesses

To read a SIMD&FP register or System register, the debugger must first copy the value into a general-purpose register using:

- An `FMOV` instruction for floating-point transfers to SIMD&FP registers.
- A `UMOV` instruction for SIMD transfers to SIMD&FP registers.
- An `MRS` instruction for System registers.
- A `MOV Xd,SP` instruction for the SP register.

The debugger can then read out the particular general-purpose register. The reverse sequence writes a register.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

E2.4.8.3 PC and PSTATE access

The debugger reads the Program Counter and PSTATE of the process being debugged through the DLR_EL0 and DSPSR_EL0 System registers. The actual values of PC and PSTATE cannot be directly observed in Debug state:

- Instructions that are used for direct reads and writes of PC and PSTATE in Non-debug state are CONSTRAINED UNPREDICTABLE in Debug state.
- On taking an exception, ELR_ELx and SPSR_ELx at the target Exception level are UNKNOWN. They do not record the PC and PSTATE.

PSTATE.{UAO, PAN, IL, nRW, EL, M} are indirectly read by instructions executed in Debug state, but all other PSTATE fields are ignored and cannot be observed. See also:

- PSTATE in Debug state.
- Executing instructions in Debug state.
- Exceptions in Debug state.

E2.4.9 Accessing memory in Debug state

How the PE accesses memory is unchanged in Debug state. This includes:

- The operation of the MMU, including address translation, access permissions, memory attribute determination, and the operation of any TLBs.
- The operation of any caches and coherency mechanisms.
- Alignment support.
- Endianness support.
- The Memory order model.
- The operation of the MPU, including accesse permissions and memory attribute determination.

E2.4.9.1 Simple memory transfers

Simple memory accesses can be performed in Debug state by issuing memory access instructions through the ITR and passing data through the DTR registers. Executing instructions in Debug state lists the memory access instructions that are supported in Debug state.

E2.4.9.2 Bulk memory transfers

Memory access mode can accelerate bulk memory transfers in Debug state. See DCC and ITR access modes.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

E2.5 Exiting Debug state

The PE exits Debug state when it receives a Restart request trigger event. If EDSCR.ITE == 0, when the PE receives a Restart Request trigger event, the behavior of any instruction issued through the ITR in Normal access mode or an operation issued by a DTR access in Memory access mode that has not completed execution is one of the following:

- The instruction completes execution in Debug state and the PE ignores the restart request and remains in Debug state.
- The instruction completes execution in Debug state before the PE executes the restart sequence.
- The instruction completes execution in Non-debug state after the PE executes the restart sequence.
- The instruction is abandoned. This means that the instruction does not execute. Any registers or memory accessed by the instruction are left in an UNKNOWN state.

Note

- Implementations can set EDSCR.ITE to 1 to indicate that further instructions can be accepted by ITR before the previous instructions have completed. If any previous instruction has not completed and EDSCR.ITE == 1, then the PE must complete these instructions in Debug state before executing the restart sequence. EDSCR.ITE == 0 indicates that the PE is not ready to restart.
- A debugger must observe that any instructions issued through EDITR that might generate a synchronous exception, as complete, before issuing a restart request. It can do this by observing the completion of a later instruction, as synchronous exceptions must occur in program order. For example, a debugger can observe that an instruction that reads or writes a DTR register is complete because of its effect on the EDSCR.{TXfull, RXfull} flags.

On exiting Debug state, the PE sets the Program Counter to the address in DLR_EL0, Debug Link Register, where:

- If exiting to AArch64 state:
  - Bits[63:56] of DLR_EL0 might be ignored as part of tagged address handling. See Address tagging.
  - Otherwise the PC is set from DLR_EL0.

Exit from Debug state can give rise to a PC alignment fault exception when the Program Counter is used. For more information, see PC alignment checking.

On exiting Debug state, PSTATE is set from DSPSR_EL0, Debug Saved Program Status Register in the same way that an exception return sets PSTATE from SPSR_ELx:

- The same illegal exception return checks that apply to an exception return also apply to exiting Debug state. If the return from Debug state is an illegal exception return then the effect on PSTATE and the PC is the same as for any other illegal exception return. See Exception return.
- PSTATE.SS is copied from DSPSR_EL0, Debug Saved Program Status Register.SS if all of the following hold:
  - MDSCR_EL1.SS == 1.
  - The debug target Exception level is using AArch64.
  - Software step exceptions from the restart Exception level are enabled.

  Otherwise PSTATE.SS is set to 0.

  Note

  Unlike a return using ERET, PSTATE.SS must be restored from DSPSR_EL0, Debug Saved Program Status Register.SS because otherwise it is UNKNOWN.

  However, if OSDLR_EL1, OS Double Lock Register.DLK == 1 and DBGPRCR_EL1, Debug Power Control Register.CORENPDRQ == 0, meaning FEAT_DoubleLock is implemented and locked in Non-debug state and therefore Software Step exceptions are disabled, but otherwise Software Step exceptions would be enabled from the restart Exception level, it is CONSTRAINED UNPREDICTABLE whether PSTATE.SS is copied from DSPSR_EL0, Debug Saved Program Status Register.SS.
- If FEAT_SSBS is implemented, DSPSR_EL0, Debug Saved Program Status Register.SSBS is copied to PSTATE.SSBS.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- If FEAT_PAN is implemented, DSPSR_EL0, Debug Saved Program Status Register.PAN is copied to PSTATE.PAN.
- If FEAT_UAO is implemented, on exit from Debug state, DSPSR_EL0.UAO is copied to PSTATE.UAO.
- If FEAT_DIT is implemented, on exit from Debug state, DSPSR_EL0, Debug Saved Program Status Register.DIT is copied to PSTATE.DIT.

Note

- One important difference between Debug state exit and an exception return is that the PE can exit Debug state at EL0. Despite this, the behavior of an exit from Debug state is similar to an exception return. For example, PSTATE.{D, A, I, F} is updated regardless of the value of SCTLR_EL1.UMA.
- Exit from Debug state has no architecturally-defined effect on the Event Register and Exclusives monitors. An exit from Debug state might set the Event Register or clear the Exclusives monitors, or both, but this is not a requirement and debuggers must not rely on any IMPLEMENTATION SPECIFIC behavior.

The `ExitDebugState()` function is described in A-profile Architecture Pseudocode.

Chapter E3
Halting Debug Events

This chapter describes a particular class of debug events. It contains the following sections:

- Introduction to Halting debug events.
- Halting Step debug events.
- Halt Instruction debug event.
- Exception Catch debug event.
- External Debug Request debug event.
- OS Unlock Catch debug event.
- Reset Catch debug events.
- Software Access debug event.
- Synchronization and Halting debug events.

Non-Confidential

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

E3.1 Introduction to Halting debug events

External debug defines Halting debug events. The following Halting debug events are available from the introduction of Armv8:

- Halting Step debug events.
- Halt Instruction debug event.
- Exception Catch debug event.
- External Debug Request debug event.
- OS Unlock Catch debug event.
- Reset Catch debug events.
- Software Access debug event.

If halting is allowed, a Halting debug event halts the PE. The PE enters Debug state.

In addition, breakpoints and watchpoints might halt the PE if halting is allowed. See Breakpoint and Watchpoint debug events. Because breakpoints and watchpoints can generate an exception or halt the PE, Breakpoint and Watchpoint debug events are not classified as Halting debug events.

For a definition of Debug state, see Debug State. For a definition of halting allowed, see Halting allowed and halting prohibited.

Debug state entry and debug event prioritization describes the behavior when multiple debug events are generated by an instruction.

See also Synchronization and Halting debug events.

Table E3-1 shows the behavior of Breakpoint, Watchpoint, and Halting debug events.

Table E3-1 Summary of debug events and possible outcomes

Debug event type	PE behavior when halting is:	
	Allowed	Prohibited
Breakpoint and Watchpoint debug events	Halt	See Table D2-1
Halt Instruction debug event	Halt	UNDEFINED
Software Access debug event	Halt	Ignored
Exception Catch debug event	Halt	Ignored or pended
Halting Step debug events	Halt	Pended
External Debug Request debug event	Halt	Pended
Reset Catch debug events	Halt	Pended
OS Unlock Catch debug event	Pended	Pended

Table E3-2 shows where the pseudocode for each Halting debug event type is located.

Table E3-2 Pseudocode description of Halting debug events

E3.2 Halting Step debug events

Halting Step is a debug resource that a debugger can use to make the PE step through code one instruction at a time. This section describes the Halting Step debug events. It is divided into the following sections:

- Overview of a Halting Step debug event.
- The Halting Step state machine.
- Using Halting Step.
- Detailed Halting Step state machine behavior.
- Synchronization and the Halting Step state machine.
- Disabling interrupts while stepping.
- Syndrome information on Halting Step.
- Pseudocode description of Halting Step debug events.

The architecture describes the behavior as a simple Halting Step state machine. See The Halting Step state machine.

E3.2.1 Overview of a Halting Step debug event

The behavior of Halting Step is defined by a state machine, shown in Figure E3-1. A Halting Step debug event executes a single instruction and then returns control to the debugger. When the debugger software wants to execute a Halting Step:

1. With the PE in Debug state, the debugger activates Halting Step.
2. The debugger signals the PE to exit Debug state and return to the instruction that is to be stepped.
3. The PE executes that single instruction.
4. The PE enters Debug state before executing the next instruction.

However, an exception might be generated while the instruction is being stepped. That is either:

- A synchronous exception generated by the instruction being stepped.
- An asynchronous exception taken before or after the instruction being stepped.

Halting Step has its own enable control bit, EDECR.SS and EDESR.SS.

Note

Because the Halting Step state machine states occur as a result of normal PE operation, the states can be described as both:

- PE states.
- Halting Step states.

E3.2.2 The Halting Step state machine

The state machine states are:

Inactive Halting Step is inactive. No Halting Step debug events can be generated, therefore execution is not affected by Halting Step. The PE is in this state whenever either of the following is true:

- Halting Step is disabled. That is, EDECR.SS is set to 0 and EDESR.SS is set to 0.
- Halting is prohibited. See Halting the PE on debug events. In this state, if EDECR.SS is set to 1, then a Halting Step debug event is pending.

In Figure E3-1, this state is shown in red.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Active-not-pending

Halting Step is enabled and active. This is the state in which the PE steps an instruction. EDECR.SS == 1 and EDESR.SS == 0. Software must not set EDECR.SS to 1 unless the PE is in Debug state, otherwise behavior is CONSTRAINED UNPREDICTABLE, as described in Changing the value of EDECR.SS when not in Debug state.

In Figure E3-1, this state is shown in green.

Active-pending

Halting Step is enabled and active. The step has completed and the PE enters Debug state. EDESR.SS == 1.

In Figure E3-1, this state is shown in green.

Whenever Halting Step is enabled and active, whether the state machine is in the active-not-pending state or in the active-pending state depends on EDESR.SS. Table E3-3 shows this.

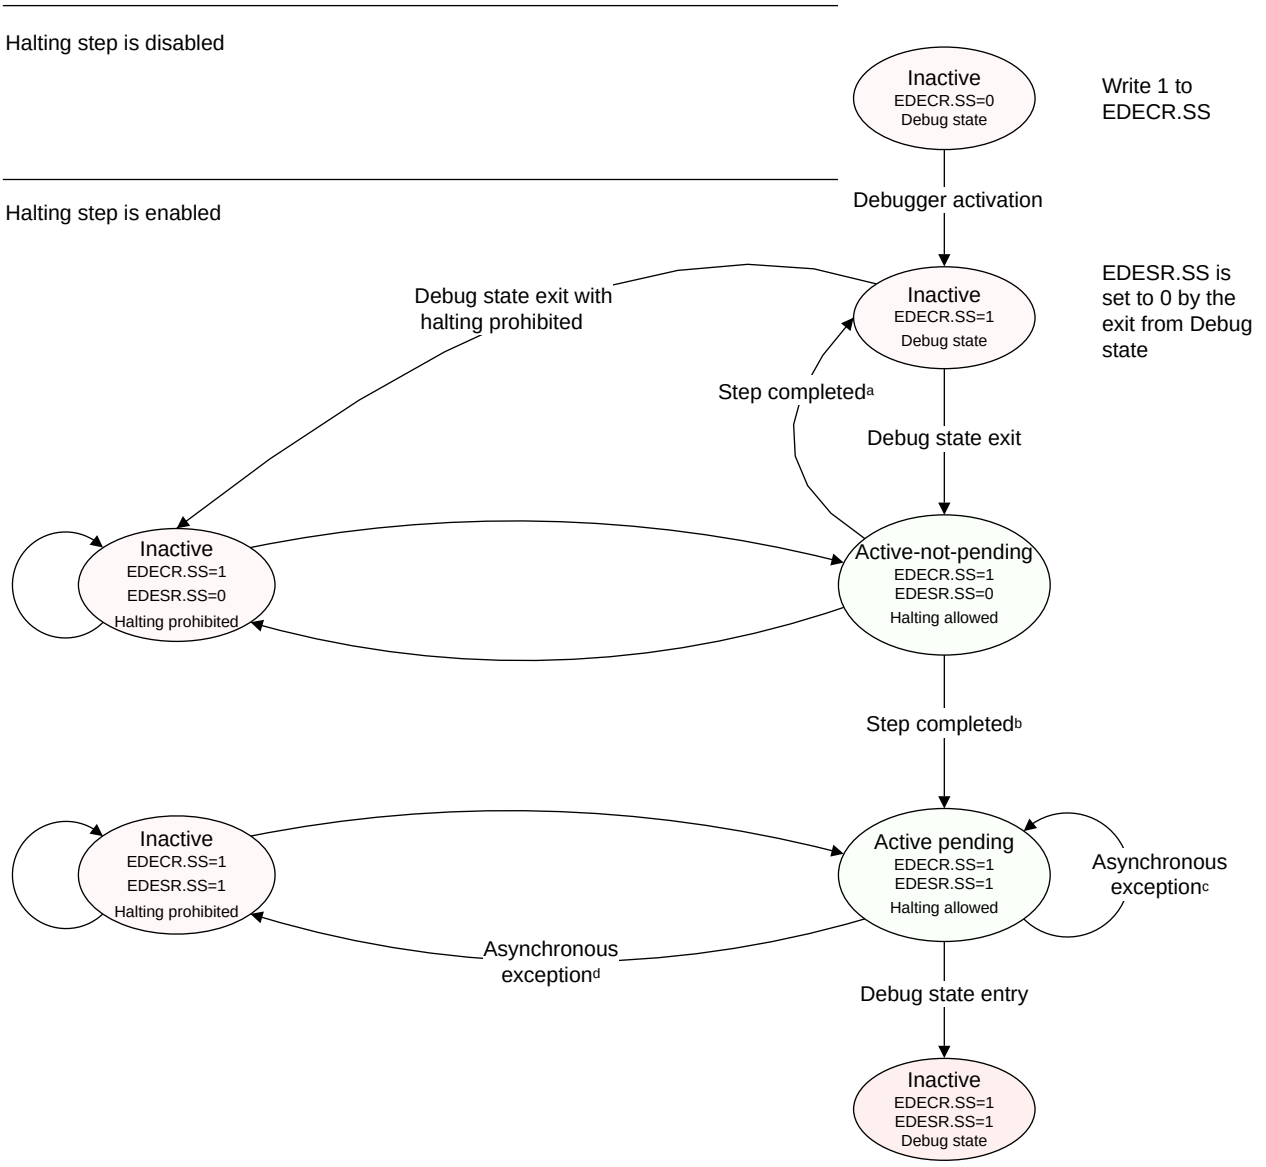
In the simple sequential execution of the program, the PE executes the Halting Step state machine as follows:

1. Initially, Halting Step is inactive.
2. After exiting Debug state, Halting Step is active-not-pending.
3. The PE executes an instruction and Halting Step is active-pending.
4. The pending Debug state entry is taken on the next instruction and the step is complete.

Exceptions and other changes to the PE context can interrupt this sequence.

Figure E3-1 shows a Halting Step state machine.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential



a. Step completed occurs when:
   - A debug event, other than a Halting Step debug event, causes entry into Debug state.

b. Step completed occurs when:
   - An instruction is executed without taking an exception.
   - An exception is taken to a state where halting is allowed.
   - A reset.

c. An asynchronous exception taken to a state where halting is allowed.

d. An asynchronous exception taken to Secure state where halting is prohibited.

Figure E3-1 Halting Step state machine

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

Figure E3-1 describes only state transitions to and from the inactive state by exit from Debug state, executing an exception return, or taking an exception. Other changes to the PE context, including writes to registers such as EDECR and OSDLR_EL1, OS Double Lock Register and changes to the authentication interface can also cause changes to the Halting Step state machine. These can lead to UNPREDICTABLE or CONSTRAINED UNPREDICTABLE behavior. See Synchronization and the Halting Step state machine.

The following bits control the state machine, as shown in Table E3-3:

- EDECR.SS. This is the Halting Step enable bit.
- EDESR.SS. This is the Halting Step debug event pending bit.

Table E3-3 shows the Halting Step state machine states. The letter X in a register column means that the relevant bit can be set to either zero or one.

Table E3-3 Halting Step state machine states

Halting	EDECR.SS	EDESR.SS	Halting Step state
Prohibited	X	X	Inactive (Halting Step debug even not pending)
Prohibited	X	1	Inactive (Halting Step debug event pending)
Allowed	0	0	Inactive
Allowed	1	0	Active-not-pending
Allowed	X	1	Active-pending

E3.2.3 Using Halting Step

To step a single instruction the PE must be in Debug state:

1. The debugger sets EDECR.SS to 1 to enable Halting step.
2. The debugger signals the PE to exit Debug state with DLR_EL0, Debug Link Register set to the address of the instruction being stepped. The PE clears EDESR.SS to 0 and the Halting Step state machine enters the active-not-pending state.
3. The PE executes the instruction being stepped.
   If an exception is taken to a state where halting is prohibited, then EDESR.SS is always correct for the preferred return address of the exception.
4. The PE enters Debug state before executing the next instruction and the step is complete.

Note

- If FEAT_DoPD is not implemented, EDECR.SS value is in the Debug power domain, meaning that the state machine is maintained over a powerdown of the Core power domain.
- If FEAT_DoPD is implemented, the values of EDECR.SS and EDESR.SS are set to 0 on a Cold reset, and, if the PE was stepping an instruction, EDESR.SS is effectively UNKNOWN after a Warm reset. A debugger must use a Reset Catch debug event to step over a powerdown state.
- A debugger must only change the value of EDECR.SS when the PE is in Debug state, otherwise behavior is CONSTRAINED UNPREDICTABLE as described in Changing the value of EDECR.SS when not in Debug state.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

E3.2.4 Detailed Halting Step state machine behavior

The behavior of the Halting Step state machine is described in the following sections:

- Entering the active-not-pending state.
- PE behavior in the active-not-pending state.
- Entering the active-pending state.
- PE behavior in the active-pending state.
- PE behavior in the inactive state when in Non-debug state.
- PE behavior in Debug state.

E3.2.4.1 Entering the active-not-pending state

The PE enters the active-not-pending state:

- By exiting Debug state to a state where halting is allowed with EDECR.SS == 1.
- By an exception return from a state where halting is prohibited to a state where halting is allowed with EDECR.SS == 1 and EDESR.SS == 0.
- As described in Synchronization and the Halting Step state machine.

E3.2.4.2 PE behavior in the active-not-pending state

When the PE is in the active-not-pending state it does one of the following:

- It executes one instruction and does one of the following:
  - Completes it without taking a synchronous exception.
  - Takes a synchronous exception generated by the instruction.
  - Generates a debug event that causes entry to Debug state.
- It takes an asynchronous exception without executing any instruction.
- It takes an asynchronous debug event into Debug state.

E3.2.4.2.1 If no exception or debug event is generated

If no exception or debug event is generated the PE sets EDESR.SS to 1. This means that the Halting Step state machine advances to the active-pending state.

E3.2.4.2.2 If an exception or debug event is generated

The PE sets EDESR.SS according to all of the following:

- The type of exception.
- The target Exception level of the exception.

If an exception or debug event is generated, the PE sets EDESR.SS to 1 if the exception is an SMC exception or is taken to a state where halting is allowed.

Otherwise, EDESR.SS is unchanged.

It is UNPREDICTABLE whether EDESR.SS is set to 1 or unchanged when an SError exception is taken to EL3 without executing the instruction, and halting is prohibited at EL3.

If halting is prohibited after taking the exception or debug event, then the Halting Step state machine advances to the inactive state. Otherwise, the Halting Step state machine advances to the active-pending state.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

The underlying criteria for the value of EDESR.SS on an exception are:

- Whether halting is allowed at the target of the exception. If halting is allowed, the PE must step into the exception. If halting is prohibited, the PE must step over the exception.
- Whether the preferred return address of the exception is the instruction itself or the next instruction, if the PE steps over the exception.

Table E3-4 shows the behavior of the active-not-pending state.

Table E3-4 Summary of active-not-pending state behavior

Event	Target Exception level	Value written to EDESR.SS
No exception or debug event	Not applicable	1
SMC exception	EL2 if trapped	1
Reset	Highest	1
Exception, other than SMC exception	EL1	1
	EL2	1
Debug event	Debug state	Unchanged

E3.2.4.3 Entering the active-pending state

The PE enters the active-pending state by one of the following:

- From the active-not-pending state by:
  - Executing an instruction without taking an exception.
  - Taking an exception so that the PE remains in a state where halting is allowed.
- An exception return from a state where halting is prohibited when EDESR.SS == 1.
- A reset when the value of EDECR.SS == 1, regardless of the state the PE was in before the reset occurred.
- From the active-pending state by taking an asynchronous exception to a state where halting is allowed.
- Following the description in Synchronization and the Halting Step state machine.

E3.2.4.4 PE behavior in the active-pending state

When the PE is in the active-pending state, it enters Debug state before executing an instruction.

The entry into Debug state has higher priority than all other types of synchronous debug event and synchronous exception. However, the architecture does not define the prioritization of this Debug state entry with respect to any unmasked pending asynchronous exception. If an asynchronous exception is prioritized over the entry to Debug state, then EDESR.SS is unchanged.

For more information on the prioritization of debug events, see Debug state entry and debug event prioritization.

E3.2.4.5 PE behavior in the inactive state when in Non-debug state

EDESR.SS is not updated by the execution of an instruction or the taking of an exception when Halting Step is inactive. This means that EDESR.SS is not changed by an exception handled in a state where halting is prohibited.

On return to a state where halting is allowed, the Halting Step state machine is restored either to the active-pending state or the active-not-pending state, depending on the value of EDESR.SS. The return to a state where halting is allowed is normally by an exception return, which in some situations is a Context Synchronization event.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

See also Synchronization and the Halting Step state machine.

E3.2.4.6 PE behavior in Debug state

Halting Step is inactive in Debug state because halting is prohibited, see Halting allowed and halting prohibited.

Entry to Debug state does not change EDESR.SS.

EDESR.SS is cleared to 0 on exiting Debug state as the result of a restart request. If EDECR.SS == 1, Halting Step enters the active-not-pending state.

Note

This means that EDESR.SS is never cleared to 0 by the execution of an instruction in Debug state, or by taking an exception when in Debug state as described in PE behavior in the active-not-pending state, because the Halting Step state machine is not in the active-not-pending state. EDESR.SS can be cleared by a write to EDESR, see the register description.

However, if the PE exits Debug state as the result of a PE reset and EDECR.SS == 1, then Halting Step immediately enters the active-pending state, as EDESR.SS is set to the value of EDECR.SS.

E3.2.5 Synchronization and the Halting Step state machine

The Halting Step state machine also changes state if:

- Halting becomes allowed or prohibited other than by exit from Debug state, an exception return, or taking an exception. This means that halting becomes allowed or prohibited because:
  - The Security state changes without an exception return. See State and mode changes without explicit Context Synchronization events.
  - The external authentication interface changes.
  - FEAT_DoubleLock is implemented and the status, `DoubleLockStatus()`, changes.
- A write to EDECR when the PE is in Non-debug state changes the value of EDECR.SS.

  Note

  Behavior is CONSTRAINED UNPREDICTABLE if the value of EDECR.SS is changed when the PE is in Non-debug state, see Changing the value of EDECR.SS when not in Debug state.

- A write to EDESR when the PE is in Non-debug state clears EDESR.SS to 0.

These operations are guaranteed to take effect only after a Context Synchronization event. If the instruction being stepped generates a Context Synchronization event, then the PE might use the old or new state.

The PE must perform the required behavior of the new state before or immediately following the next Context Synchronization event, but it is not required to do so immediately. This means that the PE can perform the required behavior of the old state before the next Context Synchronization event. This is illustrated in Example E3-1 and Example E3-2.

Example E3-1 Synchronization requirements 1

EDECR.SS is set to 1 in Debug state, requesting the active-not-pending state on exit from Debug state. On exit from Debug state the PE immediately takes an exception to EL2, where halting is prohibited. The PE does not step any instructions but executes the software at EL2 as normal. EDESR.SS remains set to 0. If halting is subsequently allowed, the PE must perform the required behavior of the active-not-pending state before or immediately following the next Context Synchronization event, but it is not required to do so immediately.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Example E3-2 Synchronization requirements 2

EDECR.SS is set to 1 in Debug state. On exit from Debug the PE executes an `MSR` instruction that sets OSDLR_EL1.DLK to 1 and `DoubleLockStatus()` becomes TRUE. This change requires a Context Synchronization event to guarantee its effect, meaning it is CONSTRAINED UNPREDICTABLE whether:

- Halting is allowed:
  - The PE enters Debug state on the next instruction.
- Halting is prohibited:
  - The PE does not enter Debug state.

The value in EDESR.SS depends on whether halting was allowed or prohibited when the write to OSDLR_EL1.DLK completed, and so it might be 0 or 1. If a second `MSR` instruction clears OSDLR_EL1.DLK to 0, the PE must perform the required behavior of the state indicated by EDESR.SS before or immediately following the next Context Synchronization event, but it is not required to do so immediately.

See also Synchronization and Halting debug events.

E3.2.5.1 Changing the value of EDECR.SS when not in Debug state

If software changes the value of EDECR.SS when the PE is not in Debug state then behavior is CONSTRAINED UNPREDICTABLE, and one or more of the following behaviors occurs:

- The value of EDECR.SS becomes UNKNOWN.
- The state of the Halting Step state machine becomes UNKNOWN.
- On a reset of the PE, the value of EDECR.SS and the state of the Halting Step state machine are UNKNOWN.

E3.2.6 Disabling interrupts while stepping

When using Halting Step, the sequence of entering Debug state, interacting with the debugger, and then exiting Debug state for each instruction reduces the rate at which the PE executes instructions. However, the rate at which certain interrupts, such as timer interrupts, are generated might be fixed by the system. This means it might be necessary to disable interrupts while using Halting Step by setting EDSCR.INTdis, to allow the code being debugged to make forward progress.

E3.2.7 Syndrome information on Halting Step

Three EDSCR.STATUS encodings record different scenarios for entering Debug state on a Halting Step debug event:

Halting Step, normal

An instruction other than a Load-Exclusive instruction was stepped.

Halting Step, exclusive

A Load-Exclusive instruction was stepped.

Halting Step, no syndrome

The syndrome data is not available.

If the PE enters Debug state due to a Halting Step debug event immediately after stepping an instruction in the active-not-pending state, EDSCR.STATUS is set to either:

- Halting Step, normal, if the stepped instruction was not a Load-Exclusive instruction.
- Halting Step, exclusive, if the stepped instruction was a Load-Exclusive instruction.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

If the stepped instruction was a conditional Load-Exclusive instruction that failed its Condition code check, EDSCR.STATUS is set to a CONSTRAINED UNPREDICTABLE choice of Halting Step, normal, or Halting Step, exclusive.

Otherwise, the PE enters Debug state without stepping an instruction. This means that the Halting Step state machine enters the active-pending state directly from the inactive state, without going through active-not-pending state. In this case, EDSCR.STATUS is set to Halting Step, no syndrome.

In addition, EDSCR.STATUS is CONSTRAINED UNPREDICTABLE when:

- A different exception is taken before the Halting Step debug event.
  In this case EDSCR.STATUS is set to a CONSTRAINED UNPREDICTABLE choice of:
  - Halting Step, no syndrome, or Halting Step, normal, if the stepped instruction was not a Load-Exclusive instruction.
  - Halting Step, no syndrome, or Halting Step, exclusive, if the stepped instruction was a Load-Exclusive instruction.
- The instruction that was stepped was an Exception Return instruction or an `ISB`. As these instructions are not in the Load-Exclusive instructions, EDSCR.STATUS is set to a CONSTRAINED UNPREDICTABLE choice of Halting Step, no syndrome or Halting Step, normal.
- The PE enters directly into the active-pending state on a Warm reset because EDECR.SS is set to 1. EDSCR.STATUS is set to a CONSTRAINED UNPREDICTABLE choice of Halting Step, no syndrome or Halting Step, normal.

In all cases, if EDSCR.STATUS is not set to Halting Step, no syndrome, then it must indicate whether the stepped instruction was a Load-Exclusive instruction by setting EDSCR.STATUS to Halting Step, normal or Halting Step, exclusive.

Note

If the PE cannot determine whether the stepped instruction was a Load-Exclusive instruction or not, then it sets EDSCR.STATUS to Halting Step, no syndrome. For example, the exception is taken before the PE decodes the stepped instruction, or the exception means the PE has no valid stepped instruction to decode.

Note

The architecture does not permit an implementation to always set EDSCR.STATUS to Halting Step, no syndrome.

E3.2.8 Pseudocode description of Halting Step debug events

There are two pseudocode functions for Halting Step debug events:

- `HSAdvance()`. This is called after an instruction has executed and any exception generated by the instruction is taken, except for the case of an SVC, HVC, or SMC exception, in which case it is called before the exception is taken. `HSAdvance()` affects the next instruction.
- `CheckHaltingStep()`. This is called before the next instruction is executed. If a step is pending, it generates the debug event.

Non-Confidential

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

E3.3 Halt Instruction debug event

A Halt Instruction debug event is generated when EDSCR.HDE == 1, halting is allowed, and the PE executes the Halt instruction, `HLT`.

The pseudocode for Halt Instruction debug events is described in HLT.

`HLT` never generates a debug exception. It is treated as UNDEFINED if EDSCR.HDE == 0, or if halting is prohibited.

Note

A debugger can replace a program instruction with a Halt instruction to generate a Halt Instruction debug event. Debuggers that use the `HLT` instruction must be aware of the rules for concurrent modification of executable code, CMODX. The rules for concurrent modification and execution of instructions do not allow one thread of execution or an external debugger to replace an instruction with an `HLT` instruction when these same instructions are being executed by a different thread of execution. See Concurrent modification and execution of instructions.

E3.4 Exception Catch debug event

Exception Catch debug events:

- Are generated when the corresponding bit in the Exception Catch Control Register, EDECCR, is set to 1 on all entries to a given Exception level. This means:
  - Exceptions taken to the Exception level.
  - Exception returns to the Exception level.
  - It is IMPLEMENTATION DEFINED whether a reset into an Exception level generates an Exception Catch debug event.
- Might be taken synchronously, after the exception or reset entry or the exception return has been processed by the PE.
- Ignore the Execution state of the target Exception level.
- Might be ignored if halting is prohibited.

The EDECCR register contains fields that control when Exception Catch debug events are generated.

See Controlling Exception Catch debug events when FEAT_Debugv8p2 is implemented and Controlling Exception Catch debug events when FEAT_Debugv8p2 is not implemented.

For exception returns, the final Exception level of the exception return determines whether an Exception Catch debug event is generated. On an illegal exception return, an Exception Catch debug event is generated only if EDECCR is programmed to generate an Exception Catch debug event for an exception return to the current Exception level.

E3.4.1 Prioritization of Exception Catch debug events

The following rules define the prioritization of Exception Catch debug events:

- It is IMPLEMENTATION DEFINED whether Exception Catch debug events are higher or lower priority than Software Step exceptions and Halting Step debug events.
- Exception Catch debug events are higher priority than all synchronous exceptions other than Software Step exceptions and debug events other than Halting Step debug events.
- Exception Catch debug events are lower priority than Reset Catch debug events.
- When FEAT_Debugv8p2 is implemented, Exception Catch debug events are higher priority than pending asynchronous exceptions. Otherwise, the prioritization between asynchronous exceptions, asynchronous debug events, and an Exception Catch debug event, is IMPLEMENTATION DEFINED.

Note

As described in Prioritization of Synchronous exceptions taken to AArch64 state, an exception trapping form of a Vector Catch debug event might generate a second debug exception as part of the exception entry, before the Exception Catch debug event is taken. See Vector Catch exceptions or Vector Catch exceptions.

E3.4.2 Generating Exception Catch debug events when FEAT_Debugv8p2 is not implemented

When an Exception Catch debug event is generated after exception entry and halting is allowed at the target of the exception, the PE halts and enters Debug state:

- The PE halts and enters Debug state before the first instruction at the handler is executed, after the exception entry has updated the program counter, PSTATE, and syndrome registers for the exception.
- The PE does not fetch instructions from the vector address before entering Debug state, if address translation is disabled in the translation regime at the target Exception level.
- A second unmasked asynchronous exception can be taken before the PE enters Debug state. If this second exception does not generate an Exception Catch debug event, the exception handler executed at the higher Exception level later returns to the trapped Exception level, causing the Exception Catch debug event to be generated again.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

When an Exception Catch debug event is generated on exception return and halting is allowed at the target of the exception return:

- There is no prioritization between asynchronous exceptions, asynchronous debug events, and an Exception Catch debug event generated on an exception return.
- The PE halts and enters Debug state after the exception return has updated the program counter and PSTATE, and before the execution of the first instruction at the return address is completed.

Otherwise, when the PE is executing code at a given Exception level, and the corresponding EDECCR bit is 1, it is CONSTRAINED UNPREDICTABLE whether an Exception Catch debug event is generated.

Examples of this are:

- If the debugger writes to EDECCR so that the current Exception level is trapped.
- If the OS restore code writes to OSECCR_EL1, OS Lock Exception Catch Control Register so that the current Exception level is trapped.

See also Debug state entry and debug event prioritization.

Note

It is possible to generate Exception Catch debug events:

- As a trap on all instruction fetches from the trapped Exception level as part of an instruction fetch.
- On entry to the Exception level, as described in Detailed Halting Step state machine behavior.

This is similar to the implementation options allowed for Vector Catch debug events. The architecture does not require that the event is generated following an `ISB` operation executed at the Exception level.

E3.4.3 Controlling Exception Catch debug events when FEAT_Debugv8p2 is implemented

When FEAT_Debugv8p2 is implemented the fields EDECCR.{NSR, SR, NSE, SE} control generation of Exception Catch debug events:

- On exception entry but not on exception return.
- On exception return but not on exception entry.
- On exception entry and exception return.

Exception entry, reset and exception return Exception Catch debug events are enabled as shown in Table E3-5.

Table E3-5 Summary of Exception Catch debug event control when FEAT_Debugv8p2 is implemented

(N)SR<n>	(N)SE<n>	Behavior on exception return to ELn	Behavior on exception taken to ELn, and if resets are Exception Catch debug events, reset into ELn
0	0	No action.	No action.
0	1	Halt if allowed.	Halt if allowed.
1	0	Halt if allowed.	No action.
1	1	No action.	Halt if allowed.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

E3.4.4 Controlling Exception Catch debug events when FEAT_Debugv8p2 is not implemented

When FEAT_Debugv8p2 is not implemented, all Exception Catch debug events are enabled by a combination of the fields NSE and SE in EDECCR, as shown in Table E3-6.

Table E3-6 Summary of Exception Catch debug event control when FEAT_Debugv8p2 is not implemented

(N)SE<n>	Behavior on exception taken to ELn, return to ELn, and if resets are Exception Catch debug events, reset into ELn
0	No action.
1	Halt if allowed.

E3.4.5 Examples of Exception Catch debug events

If EDECCR == `0x0020`, meaning that the Exception Catch debug event is enabled for EL1, then the following exceptions generate Exception Catch debug events:

- An exception taken from EL0 to EL1.
- An exception return from EL2 to EL1.

For example, on taking a Data Abort exception from EL0 to EL1, using AArch64:

- ELR_EL1 and SPSR_EL1 are written with the preferred return address and PE state for a return to EL0.
- ESR_EL1 and FAR_EL1 are written with the syndrome information for the exception.
- DLR_EL0 is set to VBAR_EL1 + `0x400`, the synchronous exception vector.
- DSPSR_EL0 is written with the PE state for an exit to EL1.

The following do not generate Exception Catch debug events:

- An exception taken from EL0 to EL2.
- An exception return from EL2 to EL0.
- An exception taken from EL0 to EL1.

E3.4.6 Pseudocode description of Exception Catch debug events

The pseudocode functions `CheckExceptionCatch()` and `CheckPendingExceptionCatch()` are described in A-profile Architecture Pseudocode.

E3.5 External Debug Request debug event

External Debug Request debug events are asynchronous debug events.

An External Debug Request debug event can be generated by any of the following:

- When signaled by the embedded cross-trigger. See The Embedded Cross-Trigger Interface.
- The Performance Monitoring Unit. See PMU Overflow external debug request.
- An implementation might also support IMPLEMENTATION DEFINED ways of generating an External Debug Request debug event.

E3.5.1 Synchronization and External Debug Request debug events

For all Context synchronization events, if an External Debug Request debug event is asserted before the Context Synchronization event, and the External Debug Request debug event remains asserted and halting is allowed after the Context synchronization event, then the debug event is taken and the PE enters Debug state before the first instruction following the Context synchronization event completes its execution.

An External Debug Request debug event that is being asserted when the PE comes out of reset is taken, and the PE enters Debug state before the first instruction after the reset completes its execution, provided that halting is allowed when the PE exits reset state.

If the first instruction after the Context Synchronization event or after coming out of reset generates a synchronous exception then the architecture does not define the order in which the debug event and the exception or exceptions are taken.

Otherwise, when all of the following are true, External Debug Request debug events must be taken in finite time, without requiring the synchronization of any necessary change to the external authentication interface:

- Halting is allowed.
- The PE is not in a low-power state that is not required to exit on an external debug request. See Core power domain power states.

External debug request is a wakeup event for `WFI`, `WFE`, or `WFET` instructions. See Mechanisms for entering a low-power state.

Note

These rules are based on the rules that apply when taking asynchronous exceptions. See Asynchronous exception types.

If an unmasked External Debug Request debug event was pending but is changed to not pending before it is taken, then the architecture permits the External Debug Request debug event to be taken, but does not require this to happen. If the External Debug Request debug event is taken then it must be taken before the first Context Synchronization event after the External Debug Request debug event was changed to not pending.

Example E3-3 shows an example of the synchronization requirements.

Example E3-3 Synchronization requirements

Secure software locks up in a tight loop, so it executes indefinitely without any synchronization operations. An External debug request must be able to break the PE out of that loop. This is a requirement even if **DBGEN** or **SPIDEN** or both are LOW on entry to the loop, meaning that halting is prohibited, and are only asserted HIGH later.

E3.5.2 PMU Overflow external debug request

When the PE halts and enters Debug state because of a PMU Overflow external debug request:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- DLR_EL0 is set to the address of the first instruction that must be executed on exit from Debug state. DSPSR_EL0 is correct for this instruction.
- EDSCR.STATUS is set to `0b010011`, external debug request.

E3.5.3 Pseudocode description of External Debug Request debug events

The `ExternalDebugRequest()` function is described in R-profile Architecture Pseudocode.

E3.6 OS Unlock Catch debug event

An OS Unlock Catch debug event is generated when enabled and the state of the OS Lock changes from locked to unlocked. When FEAT_DoPD is implemented, CTIDEVCTL.OSUCE enables an OS Unlock Catch debug event, otherwise EDECR.OSUCE enables an OS Unlock Catch debug event.

When the OS Lock is unlocked, the PE sets EDESR.OSUC to 1 if the OS Unlock Catch debug event is enabled, and the PE is in Non-debug state, meaning the OS Unlock Catch debug event becomes pending. However, this is an indirect write to EDESR.OSUC, meaning the OS Unlock Catch debug event is not guaranteed to be taken before a subsequent Context synchronization event. If the PE enters Debug state or the OS Unlock Catch debug event is disabled before EDESR.OSUC becomes set to 1, then EDESR.OSUC might not be set.

OS Unlock Catch debug events are not generated if the OS Lock is unlocked when the PE is in Debug state. See also Synchronization and Halting debug events.

EDESR.OSUC is cleared to 0 on a Warm reset and on exiting Debug state.

E3.6.1 Using the OS Unlock Catch debug event

When the Core power domain is completely off or in a low-power state, a debugger is permitted to access a debug register that is implemented in the External debug power domain. However, if a debugger attempts to access a debug register that is implemented in the Core power domain when the Core power domain registers cannot be accessed, and that access returns an error, the debugger must retry the access.

Regularly powering down the Core power domain can result in unreliable debugger behavior.

The debugger can program a Reset Catch debug event to halt the PE when it has powered up, and can program the debug registers from Debug state. However, if the PE boot software restores the debug registers, as described in Debug OS Save and Restore sequences, then newly written values are overwritten by the restore sequence.

The debugger can program an OS Unlock Catch debug event to halt the PE after the restore sequence has completed, and program the debug registers from Debug state.

E3.6.2 Pseudocode description of OS Unlock Catch debug event

The `CheckOSUnlockCatch()` function is called when the OS Lock is unlocked.

The `CheckPendingOSUnlockCatch()` function is called before an instruction is executed. If an OS Unlock Catch is pending, it generates the debug event.

Non-Confidential

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

E3.7 Reset Catch debug events

A Reset Catch debug event is generated when enabled, and the PE exits reset state. When the Reset Catch debug event is generated, it is recorded by setting EDESR.RC to 1. When FEAT_DoPD is implemented, CTIDEVCTL.RCE enables a Reset Catch debug event, otherwise EDECR.RCE enables a Reset Catch debug event.

If halting is allowed when the event is generated, the Reset Catch debug event is taken immediately and synchronously. On entering Debug state, DLR_EL0, Debug Link Register has the address of the reset vector. The PE must not fetch any instructions from memory.

Otherwise, the Reset Catch debug event is pended and taken when halting is allowed. See Synchronization and Halting debug events for more information.

This means that EDESR.RC is set to the value of EDECR.RCE or CTIDEVCTL.RCE on a Warm reset. EDESR.RC is cleared to 0 on exiting Debug state.

E3.7.1 Pseudocode description of Reset Catch debug event

The `CheckResetCatch()` function is called after reset before executing any instruction.

The `CheckPendingResetCatch()` function is called before an instruction is executed. If a Reset Catch is pending, it generates the Reset Catch debug event.

E3.8 Software Access debug event

When the value of EDSCR.TDA is 1, software access to the following AArch64 debug System registers generate a Software Access debug event:

- The Breakpoint Value Registers, DBGBVR<n>_EL1, Debug Breakpoint Value Registers, n = 0 - 63.
- The Breakpoint Control Registers, DBGBCR<n>_EL1, Debug Breakpoint Control Registers, n = 0 - 63.
- The Watchpoint Value Registers, DBGWVR<n>_EL1, Debug Watchpoint Value Registers, n = 0 - 63.
- The Watchpoint Control Registers, DBGWCR<n>_EL1, Debug Watchpoint Control Registers, n = 0 - 63.

However, EDSCR.TDA is ignored if any of the following applies:

- The value of OSLSR_EL1, OS Lock Status Register.OSLK == 1, meaning that the OS Lock is locked.
- Halting is prohibited. See Halting allowed and halting prohibited.
- The register access generates a higher priority synchronous exception or debug event.

Note

- The only accesses to the specified registers that generate a Software Access debug event are accesses to System registers in AArch64 state.
- Accesses by a PE using the external debug interface never generate a Software Access debug event.

E3.8.1 Pseudocode description of Software Access debug event

The `CheckSoftwareAccessToDebugRegisters()` function is described in R-profile Architecture Pseudocode.

E3.9 Synchronization and Halting debug events

The behavior of external debug depends on:

- Indirect reads of:
  - External debug registers.
  - System registers, including system debug registers.
  - Special-purpose registers.
- The state of the external authentication interface.

For some registers, all read and write accesses that update the register occur in program order, without any additional synchronization, but others require an explicit Context Synchronization event. For more information on the synchronization of register updates, see:

- Synchronization requirements for AArch64 System registers.
- Synchronization of changes to the external debug registers.

Changes to the external authentication interface do not require explicit synchronization to affect External Debug Request debug events. See Synchronization and External Debug Request debug events.

For changes that require explicit synchronization, it is CONSTRAINED UNPREDICTABLE whether instructions between the change and the Context Synchronization event observe the old state or the new state.

This means that any change to these registers or the external authentication interface requires explicit synchronization by a Context Synchronization event before the change takes effect. This ensures that for instructions appearing in program order after the change, the change affects the following:

- The generation and behavior of Breakpoint and Watchpoint debug events. See Synchronization and debug exceptions for exceptions taken from AArch64 state.
- The generation of all Halting debug events by instructions.
- Taking a pending Halting debug event or other asynchronous debug event. See:
  - Pending Halting debug events.
  - Synchronization and External Debug Request debug events.
- The behavior of the Halting Step state machine. See Synchronization and the Halting Step state machine.

E3.9.1 Pending Halting debug events

A Halting debug event might be pending:

- If Halting Step of an instruction sets EDESR.SS to 1, and halting is prohibited following the step, then the Halting Step state machine is inactive but a Halting Step debug event is pending.
- If a Reset Catch debug event sets EDESR.RC to 1, and halting is prohibited following reset, then a Reset Catch debug event is pending.
- If an OS Unlock Catch debug event sets EDESR.OSUC to 1, then an OS Unlock Catch debug event is pending.

Pending Halting debug events are taken asynchronously when halting is allowed.

Pending Halting debug events are discarded by a Cold reset. The debugger can also force a pending event to be dropped by writing to EDESR.

Any Halting debug event that is observed as pending in the EDESR before a Context Synchronization event is taken and the PE enters Debug state before the first instruction following the Context Synchronization event completes its execution. This is possible only if halting is allowed after completion of the Context Synchronization event.

If the first instruction after the Context Synchronization event generates a synchronous exception then the architecture does not define the order in which the debug event and the exception or exceptions are taken, unless a Halting Step debug event is pending and EDESR.SS == 1.

Chapter E4
The Debug Communication Channel and Instruction Transfer Register

This chapter describes communication between a debugger and the implemented debug logic, using the *Debug Communications Channel* (DCC) and the *Instruction Transfer Register* (ITR), and associated control flags. It contains the following sections:

- Introduction.
- DCC and ITR registers.
- DCC and ITR access modes.
- Flow control of the DCC and ITR registers.
- Synchronization of DCC and ITR accesses.
- Interrupt-driven use of the DCC.
- Pseudocode description of the operation of the DCC and ITR registers.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

E4.1 Introduction

The *Debug Communications Channel*, DCC, is a channel for passing data between the PE and an external agent, such as a debugger. The DCC provides a communications channel between:

- An external debugger, described as the *debug host*.
- The debug implementation on the PE, described as the *debug target*.

The DCC can be used:

- As a 32-bit full-duplex channel.
- As a 64-bit half-duplex channel.

The DCC is an essential part of Debug state operation and can also be used in Non-debug state.

The *Instruction Transfer Register*, ITR, passes instructions to the PE to execute in Debug state.

The PE includes flow-control mechanisms for both the DCC and ITR.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

E4.2 DCC and ITR registers

The DCC comprises *data transfer registers*, the DTRs, and associated flow-control flags. The data transfer registers are DTRRX and DTRTX.

The ITR comprises a single register, EDITR, and associated flow-control flags.

In AArch64 state, software can access the data transfer registers as:

- A receive and transmit pair for 32-bit full duplex operation:
  - The write-only DBGDTRTX_EL0 register to transmit data.
  - The read-only DBGDTRRX_EL0 register to receive data.
- A single 64-bit read/write register, DBGDTR_EL0, for 64-bit half-duplex operation.
- The read/write OSDTRTX_EL1 and OSDTRRX_EL1 registers for save and restore.

The data transfer registers are also accessible by the external debug interface as a pair of 32-bit registers, DBGDTRRX_EL0 and DBGDTRTX_EL0. Both registers are read/write, allowing both 32-bit full-duplex and 64-bit half-duplex operation.

The DCC flow-control flags are EDSCR.{RXfull, TXfull, RXO, TXU}:

- The RXfull and TXfull ready flags are used for flow-control and are visible to software in the Debug system registers in MDCCSR_EL0, Monitor DCC Status Register.
- The RX overrun flag, RXO, and the TX underrun flag, TXU, report flow-control errors.
- The flow-control flags are also accessible by software as simple read/write bits for saving and restoring over a powerdown when the OS Lock is locked in MDSCR_EL1, Monitor Debug System Control Register.
- The flow-control flags are accessible from the external debug interface in EDSCR.

Figure E4-1 shows the System register and external debug interface views of the EDSCR and DTR registers. These figures do not include the save and restore views.

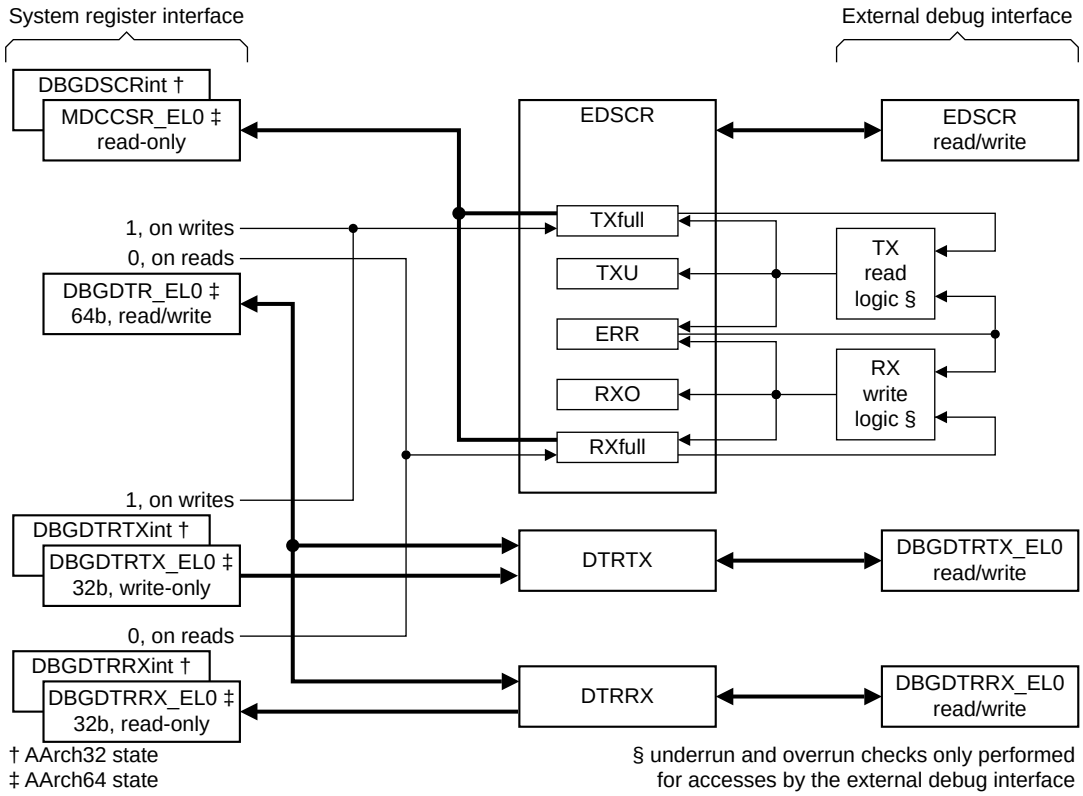

Figure E4-1 System register and external debug interface views of EDSCR and DTR registers, Normal access mode

EDITR and the ITR flow-control flags, EDSCR.{ITE, ITO} are accessible only by the external debug interface:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- The EDITR specifies an instruction to execute in Debug state.
- The ITR empty flag, ITE, is used for flow-control.
- The ITR overrun flag, ITO, reports flow-control errors.

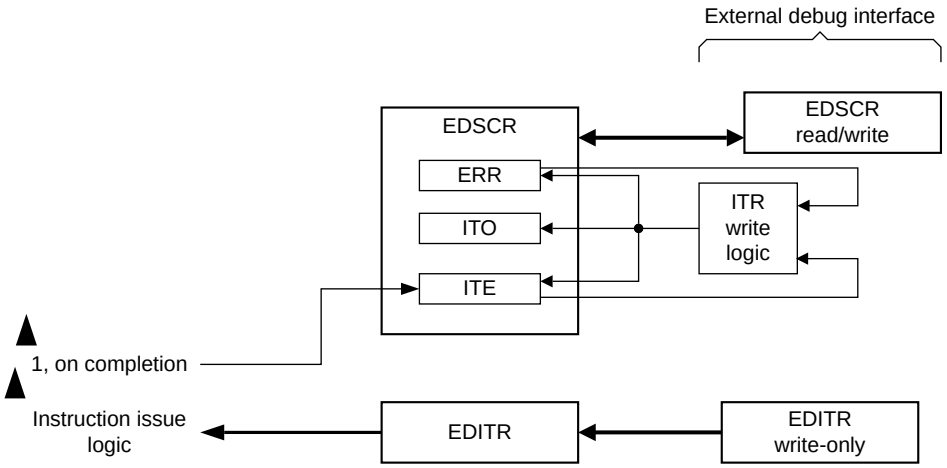

Figure E4-2 External debug interface views of EDSCR and EDITR registers, Normal access mode

The sticky overflow flag, EDSCR.ERR, is used by both the DCC and ITR to report flow-control errors.

To save and restore the DCC registers for an external debugger over powerdown, software uses:

- The MDSCR_EL1, OSDTRTX_EL1, and OSDTRRX_EL1 registers in AArch64 state.

Note

There is no save and restore mechanism for the ITR registers as the ITR is used only in Debug state.

E4.3 DCC and ITR access modes

The DCC and ITR support two access modes:

DCC and ITR access mode, links to description	Applies when:
Normal access mode	EDSCR.MA == 0 or the PE is in Non-debug state
Memory access mode	EDSCR.MA == 1 and the PE is in Debug state

E4.3.1 Normal access mode

The Normal access mode allows use of the DCC as a communications channel between target and host. It also allows the use of the ITR for issuing instructions to the PE in Debug state.

In Normal access mode, if there is no overrun or underrun, the following occurs:

For accesses by software:

- Direct writes to DBGDTRTX_EL0, Debug Data Transfer Register, Transmit update the value in DTRTX and indirectly write 1 to TXfull.
- Direct reads from DBGDTRRX_EL0, Debug Data Transfer Register, Receive return the value in DTRRX and indirectly write 0 to RXfull.
- Direct writes to DBGDTR_EL0 update both DTRTX and DTRRX, indirectly write 1 to TXfull, and do not change RXfull:
  - DTRTX is set from bits[31:0] of the transfer register.
  - DTRRX is set from bits[63:32] of the transfer register.
- In AArch64 state, direct reads from DBGDTR_EL0 return the concatenation of DTRRX and DTRTX, indirectly write 0 to RXfull, and do not change TXfull:
  - Bits[31:0] of the transfer register are set from DTRRX.
  - Bits[63:32] of the transfer register are set from DTRTX.

Note

For DBGDTR_EL0, the word order is reversed for reads with respect to writes.

Software reads TXfull and RXfull using MDCCSR_EL0, Monitor DCC Status Register.

For accesses by the external debug interface:

- Writes to EDITR trigger the instruction to be executed if the PE is in Debug state, if the PE is in AArch64 state, this is an A64 instruction.
- Reads of DBGDTRTX_EL0 return the value in DTRTX and indirectly write 0 to TXfull.
- Writes to DBGDTRTX_EL0 update the value in DTRTX and do not change TXfull.
- Reads of DBGDTRRX_EL0 return the value in DTRRX and do not change RXfull.
- Writes to DBGDTRRX_EL0 update the value in DTRRX and indirectly write 1 to RXfull.
  TXfull and RXfull are visible to the external debug interface in EDSCR.
  The PE detects overrun and underrun by the external debug interface, and records errors in EDSCR.{TXU, RXO, ITO, ERR}. See Flow control of the DCC and ITR registers.

See also Synchronization of DCC and ITR accesses.

E4.3.2 Memory access mode

When the PE is in Debug state, *Memory access mode* can be selected to accelerate word-aligned block reads or writes of memory by an external debugger. Memory access mode can be enabled only in Debug state, and no instructions can be issued directly by the debugger when in Memory access mode.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

If there is no overrun or underrun when in Memory access mode, an access by the external debug interface results in the following:

- External reads from DBGDTRTX_EL0 cause:
  1. The existing value in DTRTX to be returned. This clears EDSCR.TXfull to 0.
  2. The equivalent of `LDR W1,[X0],#4` to be executed.
  3. The equivalent of the `MSR DBGDTRTX_EL0,X1` instruction to be executed.
  4. EDSCR.{TXfull, ITE} to be set to {1,1}, and X1 or R1 to be set to an UNKNOWN value.
- External writes to DBGDTRRX_EL0 cause:
  1. The value in DTRRX to be updated. This sets EDSCR.RXfull to 1.
  2. The equivalent of the instruction `MRS X1,DBGDTRRX_EL0` to be executed.
  3. The equivalent of the instruction `STR W1,[X0],#4` to be executed.
  4. EDSCR.{RXfull, ITE} to be set to {0,1}, and X1 or R1 to be set to an UNKNOWN value.
- External reads from DBGDTRRX_EL0 return the last value written to DTRRX.
- External writes to EDITR generate an overrun error.

During these accesses, EDSCR.{TXfull, RXfull, ITE} are used for flow control.

Note

An overrun or underrun might result in EDSCR.ERR being set to 1 asynchronously to the sequence of operations that are outlined in this section. As this is timing-dependent, it is UNPREDICTABLE when the EDSCR.ERR flag affects the instructions and therefore whether neither instruction, only the first instruction, or both instructions are executed. If the second instruction is executed, then the first instruction must have been executed. However, in each case X1 or R1 is set to an UNKNOWN value. This means that:

- In both cases, if the memory access instruction is not executed, then the base register X0 or R0 is not updated, meaning the debugger can determine the last accessed location.
- In the list describing External reads from DBGDTRTX_EL0, DTRTX and EDSCR.TXfull get set to UNKNOWN values. If the load was executed, then the value that was read by the PE is lost. This means the operation might need to be repeated by the debugger, and it is not advisable to use Memory access mode to read from read-sensitive locations using the underrun and overrun detection for flow control.
- In the list describing External writes to DBGDTRRX_EL0, EDSCR.RXfull is set to an UNKNOWN value.

A Data Abort from the memory access can also set EDSCR.ERR to 1. See Data Aborts in Memory access mode.

The architecture does not require precisely when these flags are set or cleared by the sequence of operations outlined in this section. For example, in the case of an external write to DBGDTRRX_EL0, in AArch64 state, RXfull might be cleared after step 2, or it might not be cleared until after step 3, as an implementation is free to fuse these steps into a single operation. The architecture does require that the flags are set as at step 4 when the PE is ready to accept a further read or write without causing an overrun error or an underrun error.

The process outlined in this section represents a simple sequential execution model of Memory access mode. An implementation is free to pipeline, buffer, and reorder instructions and transactions, as long as the following remain true:

- Data items are transferred into and out of the DTR in order and without loss of data, other than as a result of an overrun or an underrun.
- Data Aborts occur in order.
- The constraints of the memory type are met.
- In the list describing External reads from :
  - The `MSR` equivalent operation at step 3 of the sequence reads the value loaded by step 2.
  - If the list is performed in a loop, for all but the first iteration of this list, the value read by step 1 returns the values written by the `MSR` equivalent operation at the previous iteration of step 3.
- In the list describing External writes to :
  - The `MRS` equivalent operation at step 2 of the sequence returns the value written at step 1.
  - The `STR` equivalent at step 3 of the sequence writes the value read at step 2.
- If the PE cannot accept a read or write, as applicable, during the sequence, then the flags are updated to indicate an overrun or underrun.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

See Flow control of the DCC and ITR registers for more information on overrun and underrun.

E4.3.2.1 Ordering, access sizes and effect on Exclusives monitors

For the purposes of memory ordering, access sizes, and effect on the Exclusives monitor, accesses in Memory access mode are consistent with load/store word instructions executed by the PE.

The simple sequential access model of Memory access mode, as stated in Memory access mode, must also be ordered with respect to instructions executed as a result of External writes to EDITR in Normal mode both before and after accesses to the DTR registers in Memory access mode.

E4.3.2.2 Data Aborts in Memory access mode

If a memory access generates a Data Abort, then:

- The Data Abort exception is taken. See Exceptions in Debug state:
  - This means EDSCR.ERR is set to 1, see Cumulative error flag.
  - If the Data Abort occurs on stage 2 of an address translation, then the values returned in the ISV field and in bits[23:14] of the ISS are UNKNOWN.
    If this Data Abort is taken to EL2, the ISS is returned by ESR_EL2. ISS encoding for an exception from a Data Abort describes the usual encoding of this ISS.
- Register R0 retains the address that generated the abort.
- Register R1 is set to an UNKNOWN value.
- EDSCR.TXfull, for a load, or EDSCR.RXfull, for a store, is set to an UNKNOWN value.
- DTRTX, for a load, or DTRRX, for a store, is set to an UNKNOWN value.
- EDSCR.ITE is set to 1.

E4.3.2.3 Illegal Execution state exception

If PSTATE.IL is set to 1 when EDSCR.MA == 1, then on an external write access to DBGDTRRX_EL0 or an external read from DBGDTRTX_EL0, it is CONSTRAINED UNPREDICTABLE whether the PE:

- Takes an Illegal Execution state exception without performing any operations. In this case:
  - EDSCR.ERR is set to 1, see Cumulative error flag.
  - Register R0 is unchanged.
  - Register R1 is set to an UNKNOWN value.
  - EDSCR.TXfull or EDSCR.RXfull, as applicable, is set to an UNKNOWN value.
  - DTRTX or DTRRX, as applicable, is set an UNKNOWN value.
  - EDSCR.ITE is set to 1.

  See also Exceptions in Debug state.
- Ignores PSTATE.IL.

Note

The typical usage model for Memory access mode involves executing instructions in Normal access mode to set up X0 before setting EDSCR.MA to 1. These instructions generate an Illegal state exception if PSTATE.IL is set to 1.

E4.3.2.4 Alignment constraints

If the address in R0 is not aligned to a multiple of four, the behavior is as follows:

- For each external DTR access a CONSTRAINED UNPREDICTABLE choice of:
  1. The PE makes an unaligned memory access to R0. If alignment checking is enabled for the memory access, this generates an Alignment fault.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

2. The PE makes a memory access to `Align(X[0],4)`.
3. The PE generates an Alignment fault, regardless of whether alignment checking is enabled.
4. The PE does nothing.

- Following each memory access, if there is no Data Abort, R0 is updated with an UNKNOWN value.
- For external writes to DBGDTRRX_EL0, if the PE writes to memory, an UNKNOWN value is written.
- For external reads of DBGDTRTX_EL0 an UNKNOWN value is returned.
- The RXfull and TXfull flags are left in an UNKNOWN state, meaning that a DBGDTRTX_EL0 read can trigger a TX underrun, and a DBGDTRTX_EL0 write can trigger an RX overrun.

E4.3.3 Memory-mapped accesses to the DCC and ITR

Writes to the flags in EDSCR by external debug interface accesses to the DCC and the ITR registers are indirect writes, because they are a side-effect of the access. The indirect write might not occur for a memory-mapped access to the external debug interface. For more information, see Register access permissions for memory-mapped accesses.

E4.4 Flow control of the DCC and ITR registers

- Ready flags.
- Buffering writes to EDITR.
- Overrun and underrun flags.
- Cumulative error flag.

E4.4.1 Ready flags

In Normal access mode:

- For the DTR registers there are two ready flags:
  - EDSCR.RXfull == 1 indicates that DBGDTRRX_EL0 contains a valid value that has been written by the external debugger and not yet read by software running on the target.
  - EDSCR.TXfull == 1 indicates that DBGDTRTX_EL0 contains a valid value that has been written by software running on the target and not yet read by an external debugger.
- For the ITR register there is a single ready flag:
  - EDSCR.ITE == 1 indicates that the PE is ready to accept an instruction to the ITR.

Note

The architecture permits a PE to continue to accept and buffer instructions when previous instructions have not completed their architecturally defined behavior, as long as those instructions are discarded if EDSCR.ERR is 1, either by an underrun or overrun or by any of the other error conditions described in this architecture, such as an instruction generating an abort.

In Memory access mode:

- EDSCR.{RXfull, ITE} == {0,1} indicates that DBGDTRRX_EL0 is empty and the PE is ready to accept a word external write to DBGDTRRX_EL0.
- EDSCR.{TXfull, ITE} == {1,1} indicates that DBGDTRTX_EL0 is full and the PE is ready to accept a word external read from DBGDTRTX_EL0.

All other values indicate that the PE is not ready, and result in a DTR overrun or underrun error, an ITR overrun error, or both, as defined in Overrun and underrun flags.

EDSCR.{ITE, RXfull, TXfull} shows the status of the ITR and DCC registers. It ignores the question of whether a read or write cannot be accepted because, for example, EDSCR.ERR is set or the OPTIONAL Software Lock is locked for memory-mapped accesses (EDLSR.SLK == 1).

E4.4.2 Buffering writes to EDITR

The architecture permits a processor to continue to accept and buffer instructions when previous instructions have not completed their architecturally defined behavior, provided that:

- Those instructions are discarded if EDSCR.ERR is set to 1, either by an underrun or an overrun, or by any other error conditions described in this architecture, such as an instruction generating an abort.
- The PE maintains the simple sequential execution model with the order of instructions determined by the order in which the PE accepts the EDITR writes. In particular, the buffered instructions must be executed in the Execution state consistent with a simple sequential execution of the instructions, even if one of the previous instructions is a state changing operation, such as `DCPS` or `DRPS`.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

E4.4.3 Overrun and underrun flags

Each of the ready flags has a corresponding overrun or a corresponding underrun flag. These are sticky status flags that are set if the register is accessed using the external debug interface when the corresponding ready flag is not in the ready state.

If the PE is in Debug state and Memory access mode, the corresponding error flag is also set if the PE is not ready to accept an operation because a previous load or store is still in progress. The sticky status flag remains set until cleared by writing 1 to EDRCR.CSE.

Note

The architecture permits a PE to continue to accept and buffer data to write to memory in Memory access mode.

Table E4-2 shows DCC and ITR ready flags and the overrun and underrun flags associated with them.

Table E4-2 DCC and ITR ready flags and the associated overrun/underrun flags

External debug interface access	Overrun/Underrun condition	EDSCR flag
Write DBGDTRRX_EL0	`EDSCR.RXfull == '1' || (Halted() && EDSCR.MA == '1' && EDSCR.ITE == '0')`	RXO
Read DBGDTRTX_EL0	`EDSCR.TXfull == '0' || (Halted() && EDSCR.MA == '1' && EDSCR.ITE == '0')`	TXU
Write EDITR	`Halted() && (EDSCR.ITE == '0' || EDSCR.MA == '1')`	ITO

When an overrun or underrun flag is set to 1, the cumulative error flag, EDSCR.ERR, described in Cumulative error flag, is also set to 1.

In the event of an external write to DBGDTRRX_EL0 or EDITR generating an overrun, or an external read from DBGDTRTX_EL0 generating an underrun:

- For a write, the written value is ignored.
- For a read, an UNKNOWN value is returned.
- EDSCR.TXfull, EDSCR.RXfull or EDSCR.ITE, as applicable, are not updated.

There is no overrun or underrun detection on external reads of DBGDTRRX_EL0 or external writes of DBGDTRTX_EL0.

There is no overrun or underrun detection of direct reads and direct writes of the DTR System registers by software:

- If RXfull == 0, a direct read of DBGDTRRX_EL0, Debug Data Transfer Register, Receive or DBGDTR_EL0 returns UNKNOWN.
- If TXfull == 1, a direct write of:
  - DBGDTRTX_EL0, Debug Data Transfer Register, Transmit sets DTRTX to UNKNOWN.
  - DBGDTR_EL0 sets DTRRX and DTRTX to UNKNOWN.

See DCC accesses in Non-debug state for more information.

E4.4.3.1 Accessing 64-bit data

In AArch64 state, a software access to the DBGDTR_EL0 register and an external debugger access to both DBGDTRRX_EL0 and DBGDTRTX_EL0 can perform a 64-bit half-duplex operation.

However, there is only overrun and underrun detection on one of the external debug registers. That is:

- If software directly writes a 64-bit value to DBGDTR_EL0, only TXfull is set to 1, meaning:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

  - A subsequent external write to DBGDTRRX_EL0 would not be detected as an overrun.
  - If the external debugger reads DBGDTRTX_EL0 first, software might observe MDCCSR_EL0.TXfull == 0 and send a second value before the external debugger reads DBGDTRRX_EL0, leading to an undetected overrun.
- On external writes to both DBGDTRRX_EL0 and DBGDTRTX_EL0, only RXfull is set to 1, meaning:
  - A subsequent direct write of DBGDTRTX_EL0 would not be detected as an overrun.
  - If the external debugger writes to DBGDTRRX_EL0 first, software might observe MDCCSR_EL0.RXfull == 1 and read a full 64-bit value, before the external debugger writes to DBGDTRTX_EL0, leading to an undetected underrun.

To avoid this, debuggers need to be aware of the data size used by software for transfers and ensure that 64-bit data is read or written in the correct order. If the PE is in Non-debug state, this order is as follows:

- The external debugger must check EDSCR.{RXfull, TXfull} before each transfer.
- To receive a 64-bit value from the target, the external debugger must read DBGDTRRX_EL0 before reading DBGDTRTX_EL0.
- To send a 64-bit value to the target, the external debugger must write to DBGDTRTX_EL0 before writing DBGDTRRX_EL0.

Because three accesses are required to transfer 64 bits of data, 64-bit transfers are not recommended for regular communication between host and target. The use of underrun and overrun detection means that only one access is required for 32 bits of data when using 32-bit transfers.

In Debug state, the debugger controls the instructions executed by the PE, so these limitations do not apply. 64-bit transfers provide a means to transfer a 64-bit general register between the host and the target in Debug state.

E4.4.4 Cumulative error flag

The cumulative error flag, EDSCR.ERR, is set to 1:

- On taking an exception from Debug state.
- On any signaled overrun or underrun in the DCC or ITR.

When EDSCR.ERR == 1:

- External reads of DBGDTRTX_EL0 do not have any side-effects.
- External writes to DBGDTRRX_EL0 are ignored.
- External writes to EDITR are ignored.
- No further instructions can be issued in Debug state. This includes any instructions previously accepted as external writes to EDITR that occur in program order after the instruction or access that caused the error.

This allows a debugger to stream data, or, in Debug state, instructions, to the target without having to:

- Check EDSCR.{RXfull, TXfull, ITE} before each access.
- Check EDSCR.{ITO, RXO, TXU} following each access, for overrun or underrun.
- Check PSTATE or other syndrome registers, or both, for an exception following each instruction executed in Debug state that might generate a synchronous exception.

The cumulative error flag remains set until cleared to 0 by writing 1 to EDRCR.CSE. However, the effect of writing 1 to EDRCR.CSE to clear EDSCR.ERR is CONSTRAINED UNPREDICTABLE when both of the following apply:

- The PE is in Debug state.
- The value of EDSCR.ITE is 0.

When these conditions apply and a value of 1 is written to EDRCR.CSE, either or both of the following might occur:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- EDSCR.ERR is not cleared to 0.
- Any instructions in EDITR that have not been executed might be executed subsequently, rather than being ignored.

Note

This means that a debugger must poll EDSCR.ITE until it has the value 1, indicating that EDITR is empty, before writing to EDRCR.CSE to clear the EDSCR.ERR flag to 0.

For overruns and underruns, EDSCR.{ITO, RXO, TXU} record the error type.

E4.4.4.1 Pseudocode description of clearing the error flag

The `ClearStickyErrors()` pseudocode function is described in R-profile Architecture Pseudocode.

E4.5 Synchronization of DCC and ITR accesses

In addition to the standard synchronization requirements for register accesses, the following subsections describe additional requirements that apply for the DCC and ITR registers:

- Summary of System register accesses to the DCC.
- DCC accesses in Non-debug state.
- Synchronization of DCC interrupt request signals.
- DCC and ITR access in Debug state.

In these sections, accesses by the external debug interface are referred to as external reads and external writes. Accesses to System registers are referred to as direct reads, direct writes, indirect reads, and indirect writes.

Note

In Synchronization requirements for AArch64 System registers external reads and external writes are described as forms of indirect access. This whole section uses more explicit terminology.

The DTR registers and the DCC flags, TXfull and RXfull, form a communication channel, with one end operating asynchronously to the other. Implementations must respect the ordering of accesses to these registers in order to maintain the correct behavior of the channel.

External reads of, and external writes to DBGDTRRX_EL0 and DBGDTRTX_EL0 are asynchronous to direct reads of, and direct writes to, DBGDTRRX_EL0, Debug Data Transfer Register, Receive, DBGDTRTX_EL0, Debug Data Transfer Register, Transmit, and in AArch64 state DBGDTR_EL0, made by software using System register access instructions. The direct reads and direct writes indirectly write to the DCC flags. The external reads and external writes indirectly read the DCC flags to check for underrun and overrun.

Throughout this section:

DCC flags Means any or all of the following:

- The EDSCR.{RXfull.TXfull} ready flags.
- The EDSCR.RXO overrun flag.
- The EDSCR.TXU underrun flag.
- The EDSCR.ERR cumulative error flag.

ITR flags Means any or all of the following:

- The EDSCR.ITE ready flag.
- The EDSCR.ITO overrun flag.
- The EDSCR.ERR cumulative error flag.

E4.5.1 Summary of System register accesses to the DCC

System register accesses to the DTR registers are direct reads and writes of those registers, as shown in Table E4-3. Several of these instructions access the same registers using different encodings.

DBGDTRRX_EL0 and DBGDTRTX_EL0 are encoded as MRS and MSR accesses respectively to the same System register, even though they access different underlying register values. DBGDTRRX_EL0, Debug Data Transfer Register, Receive and DBGDTRTX_EL0, Debug Data Transfer Register, Transmit are similarly encoded as MRC and MCR accesses respectively to the same System register. The encoding means that direct reads and writes using these encodings must be ordered with respect to each other. For more information, see Synchronization requirements for AArch64 System registers.

Table E4-3 shows a summary of System register accesses to the DCC.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Table E4-3 Summary of System register accesses to the DCC

Operation	OS Lock	AArch64 (MRS/MSR)	Description
Read	-	DBGDTRRX_EL0	Direct read of DTRRX. Indirect write to the DCC flags. An STC instruction that reads DBGDTRRXint makes an indirect write to DBGDSCRint.RXfull.
Write	-	DBGDTRTX_EL0	Direct read of DTRTX. Indirect write to the DCC flags. An LDC instruction that writes to DBGDTRTXint using a value read from memory is a direct write to DBGDTRTXint.
Read/write	-	DBGDTR_EL0	Direct read/write of both DTRRX and DTRTX. Indirect write to the DCC flags.
Read	-	MDCCSR_EL0	Direct read of the DCC flags.
Read/write	-	OSDTRRX_EL1	Direct read/write of DTRRX.
Read/write	-	OSDTRTX_EL1	Direct read/write of DTRTX.
Read	Unlocked	MDSCR_EL1	Direct read of DCC flags.
Read/write	Locked	MDSCR_EL1	Direct read/write of DCC flags.

E4.5.2 DCC accesses in Non-debug state

In Non-debug state DCC accesses are as described in Normal access mode:

- If a direct read of MDCCSR_EL0, Monitor DCC Status Register returns RXfull == 1, then a following direct read of DBGDTRRX_EL0, Debug Data Transfer Register, Receive, or in AArch64 state of DBGDTR_EL0, returns valid data and indirectly writes 0 to MDCCSR_EL0, Monitor DCC Status Register.RXfull as a side-effect.
- If a direct read of MDCCSR_EL0, Monitor DCC Status Register returns TXfull == 0, then a following direct write to DBGDTRTX_EL0, Debug Data Transfer Register, Transmit, or in AArch64 state to DBGDTR_EL0, writes the intended value, and indirectly writes 1 to MDCCSR_EL0, Monitor DCC Status Register.TXfull as a side-effect.

No Context Synchronization event is required between these two instructions. Overrun and underrun detection prevents intervening external reads and external writes affecting the outcome of the second instruction.

The indirect write to the DCC flags as part of the DTR access instruction is made atomically with the DTR access.

Because a direct read of DBGDTRRX_EL0, Debug Data Transfer Register, Receive is an indirect write to MDCCSR_EL0, Monitor DCC Status Register.RXfull, it must occur in program order with respect to the direct read of MDCCSR_EL0, Monitor DCC Status Register, meaning it must not return a speculative value for DTTRX that predates the RXfull flag returned by the read of MDCCSR_EL0, Monitor DCC Status Register. The direct write to DBGDTRTX_EL0, Debug Data Transfer Register, Transmit must not be executed speculatively.

Direct reads of DBGDTRRX_EL0, Debug Data Transfer Register, Receive, or in AArch64 state DBGDTR_EL0, and MDCCSR_EL0, Monitor DCC Status Register, must occur in program order with respect to other direct reads of the same register using the same encoding.

The following accesses have an implied order within the atomic access:

- In the simple sequential execution of the program the indirect write of the DCC flags occurs immediately after the direct DTR access.

  Note

  For an access to DBGDTR_EL0, this means the indirect write happens after both DBGDTRRX_EL0 and DBGDTRTX_EL0 have been accessed.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- In the simple sequential execution model, for an external read of DBGDTRTX_EL0 or an external write of DBGDTRRX_EL0:
  - The check of the DCC flags for overrun or underrun occurs immediately before the access.
  - If there is no underrun or overrun, the update of the DCC flags occurs immediately after the access.
  - If there is underrun or overrun, the update of the DCC underrun or overrun flags occurs immediately after the access.

All observers must observe the same order for accesses.

Note

These requirements do not create order where order does not otherwise exist. It applies only for ordered accesses.

Without explicit synchronization following external writes and external reads:

- The value written by the external write to DBGDTRRX_EL0 that does not overrun, must be observable to direct reads of DBGDTRRX_EL0, Debug Data Transfer Register, Receive and DBGDTR_EL0 in finite time.
- The DCC flags that are updated as a side-effect of the external write or external read must be observable:
  - To subsequent external reads of EDSCR.
  - To subsequent external reads of DBGDTRRX_EL0 when checking for underrun.
  - To subsequent external writes to DBGDTRTX_EL0 when checking for overrun.
  - To direct reads of MDCCSR_EL0, Monitor DCC Status Register in finite time.

However, explicit synchronization is required to guarantee that a direct read of MDCCSR_EL0, Monitor DCC Status Register returns up-to-date DCC flags. This means that if a signal is received from another agent that indicates that MDCCSR_EL0, Monitor DCC Status Register must be read, an `ISB` is required to ensure that the direct read of MDCCSR_EL0, Monitor DCC Status Register occurs after the signal has been received. This also synchronizes the value in DBGDTRRX_EL0, Debug Data Transfer Register, Receive, if applicable. However, if that signal is an interrupt exception triggered by **COMMIRQ**, **COMMTX**, or **COMMRX**, the exception entry is sufficient synchronization. See Synchronization of DCC interrupt request signals.

Explicit synchronization is required following a direct read or direct write:

- To ensure that a value directly written to DBGDTRTX_EL0, Debug Data Transfer Register, Transmit is observable to external reads of DBGDTRTX_EL0.
- To ensure that a value directly written to DBGDTR_EL0 is observable to external reads of DBGDTRTX_EL0 and DBGDTRRX_EL0.
- To guarantee that the indirect writes to the DCC flags that were a side-effect of the direct read or direct write have occurred, and therefore that the updated values are:
  - Observable to external reads of EDSCR.
  - Observable to external reads of DBGDTRRX_EL0 when checking for underrun.
  - Observable to external writes of DBGDTRTX_EL0 when checking for overrun.
  - Returned by a following direct read of MDCCSR_EL0, Monitor DCC Status Register.

See also Memory-mapped accesses to the DCC and ITR and Synchronization of changes to the external debug registers.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

These ordering rules mean that software:

- Must not read DBGDTRRX_EL0, Debug Data Transfer Register, Receive without first checking MDCCSR_EL0, Monitor DCC Status Register.RXfull or if the previously-read value of MDCCSR_EL0, Monitor DCC Status Register.RXfull is 0.

  It is not sufficient to read both registers and then later decide whether to discard the read value, as there might be an intervening write from the external debug interface.

- Must not write DBGDTRTX_EL0, Debug Data Transfer Register, Transmit without first checking MDCCSR_EL0, Monitor DCC Status Register.TXfull or if the previously-read value of MDCCSR_EL0, Monitor DCC Status Register.TXfull is 1.

  The write to DBGDTRTX_EL0, Debug Data Transfer Register, Transmit overwrites the value in DTRTX, and the external debugger might or might not have read this value.

- Must ensure there is an explicit Context Synchronization event following a DTR access, even if not immediately returning to read MDCCSR_EL0, Monitor DCC Status Register again. This synchronization operation can be an exception return.

E4.5.2.1 Derived requirements

The rules for DCC accesses in Non-debug state are as follows:

- Following a direct read of DBGDTRRX_EL0, Debug Data Transfer Register, Receive when RXfull is 1:
  - If an external write to DBGDTRRX_EL0, Debug Data Transfer Register, Receive checks the RXfull flag for overrun and observes that the value of RXfull is 0, the value returned by the previous direct read must not be affected by the external write.
  - If an external read of EDSCR returns a RXfull value of 0, then the value returned by the previous direct read must not be affected by a following external write to DBGDTRRX_EL0, Debug Data Transfer Register, Receive, and the following external write does not overrun.
- Following a direct read of DBGDTR_EL0, when RXfull is 1:
  - If an external write to DBGDTRRX_EL0, Debug Data Transfer Register, Receive checks the RXfull flag for overrun and observes that the value of RXfull is 0, the value returned by the previous direct read must not be affected by the external write nor by a following direct write to DBGDTRTX_EL0, Debug Data Transfer Register, Transmit.
  - If an external read of EDSCR returns a RXfull value of 0, then the value returned by the previous direct read must not be affected by subsequent external writes to DBGDTRRX_EL0, Debug Data Transfer Register, Receive and DBGDTRTX_EL0, Debug Data Transfer Register, Transmit in any order, and the following external write of DBGDTRRX_EL0, Debug Data Transfer Register, Receive will not overrun.
- Following a direct write to DBGDTRTX_EL0, Debug Data Transfer Register, Transmit, when TXfull is 0:
  - If an external read of DBGDTRTX_EL0, Debug Data Transfer Register, Transmit checks the TXfull flag for underrun and observes that the value of TXfull is 1, the value returned by the external read must be the value written by the previous direct write.
  - If an external read of EDSCR returns a TXfull value of 1, then the value returned by a following external read of DBGDTRRX_EL0, Debug Data Transfer Register, Receive must be the value written by the previous direct read, and the subsequent external read will not underrun.
- Following a direct write to DBGDTR_EL0, when TXfull is 0:
  - If an external read of DBGDTRTX_EL0, Debug Data Transfer Register, Transmit checks the TXfull flag for underrun and observes that the value of TXfull is 1, the values returned by the external read and by a subsequent external read of DBGDTRRX_EL0, Debug Data Transfer Register, Receive must be the value written by the previous direct write.
  - If an external read of EDSCR returns a TXfull value of 1, then the value returned by subsequent external reads of DBGDTRRX_EL0, Debug Data Transfer Register, Receive and DBGDTRTX_EL0, Debug Data Transfer Register, Transmit, in any order, must be the value written by the previous direct read, and the subsequent external read of DBGDTRTX_EL0, Debug Data Transfer Register, Transmit does not underrun.
- Following an external read of DBGDTRTX_EL0, Debug Data Transfer Register, Transmit that does not underrun, if a direct read of MDCCSR_EL0, Monitor DCC Status Register returns a TXfull value of 0, then the

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

value returned by the external read must not be affected by a following direct write to DBGDTRTX_EL0, Debug Data Transfer Register, Transmit.

- Following a first external read DBGDTRRX_EL0, Debug Data Transfer Register, Receive and a following second external read of DBGDTRTX_EL0, Debug Data Transfer Register, Transmit that does not underrun, if a direct read of MDCCSR_EL0, Monitor DCC Status Register returns a TXfull value of 0, then the values returned by the external reads must not be affected by a following direct write to DBGDTR_EL0.
- Following an external write to DBGDTRRX_EL0, Debug Data Transfer Register, Receive that does not overrun, if a direct read of MDCCSR_EL0, Monitor DCC Status Register returns an RXfull value of 1, then the value returned by a following direct read of DBGDTRRX_EL0, Debug Data Transfer Register, Receive or DBGDTR_EL0 must be the value written by the previous external write.
- Following a first external write to DBGDTRTX_EL0, Debug Data Transfer Register, Transmit and a following second external write to DBGDTRRX_EL0, Debug Data Transfer Register, Receive that does not overrun, if a direct read of MDCCSR_EL0, Monitor DCC Status Register returns an RXfull value of 1, then the value returned by a subsequent direct read of DBGDTR_EL0 must return the values written by the previous external writes.

E4.5.3 Synchronization of DCC interrupt request signals

Following an external read or external write access to the DTR registers, the interrupt request signals, **COMMIRQ**, **COMMTX**, and **COMMRX**, must be updated in finite time without explicit synchronization.

The updated values must be observable to a direct read of MDCCSR_EL0, Monitor DCC Status Register or DBGDTRRX_EL0, Debug Data Transfer Register, Receive, or a direct write of DBGDTRTX_EL0, Debug Data Transfer Register, Transmit executed after taking an interrupt exception generated by the interrupt request. The updated values must also be observable to a direct write of DBGDTRTX_EL0, Debug Data Transfer Register, Transmit executed after taking an interrupt exception generated by the interrupt request.

Note

The requirement that indirect writes to registers are observable to direct reads in finite time does not imply that all observers will observe the indirect write at the same time. For more information, see Synchronization requirements for AArch64 System registers.

Following a direct read of DBGDTRRX_EL0, Debug Data Transfer Register, Receive or a direct write to DBGDTRRX_EL0, Debug Data Transfer Register, Receive, software must execute a Context Synchronization event to guarantee the interrupt request signals have been updated in finite time. This synchronization operation can be an exception return.

E4.5.4 DCC and ITR access in Debug state

In Debug state, stricter observability rules apply for instructions issued through the ITR, to maintain communication between a debugger and the PE, without requiring excessive explicit synchronization.

In Normal access mode, without explicit synchronization:

- A direct read or direct write of the DTR registers by an instruction written to EDITR must be observable to an external write or an external read in finite time:
  - A direct read of DBGDTRRX_EL0, Debug Data Transfer Register, Receive must be observable to an external write of DBGDTRRX_EL0.
  - A direct read of DBGDTR_EL0 must be observable to an external write of DBGDTRRX_EL0 and DBGDTRTX_EL0.
  - A direct write of DBGDTRTX_EL0, Debug Data Transfer Register, Transmit must be observable to an external read of DBGDTRTX_EL0.
  - A direct write of DBGDTR_EL0 must be observable to an external read of DBGDTRRX_EL0 and DBGDTRTX_EL0.

  This includes the indirect write to the DCC flags that occurs atomically with the access as described in DCC accesses in Non-debug state.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The subsequent external write or external read must observe either the old or the new values of both the DTR contents and DCC flags. If the old values are observed, this typically results in overrun or underrun, assuming the old values of the DCC flags indicate an overrun or underrun condition, as would normally be the case.

This means the debugger can observe the direct read or direct write without explicit synchronization and without explicitly testing the DCC flags in EDSCR, because it can rely on overrun and underrun tests.

- External reads of DBGDTRTX_EL0 that do not underrun and external writes to DBGDTRRX_EL0 that do not overrun must be observable to an instruction subsequently written to EDITR on completion of the first external access. This includes the indirect write to the DCC flags.

  This means that without explicit synchronization and without the need to first check the DCC flags in MDCCSR_EL0, Monitor DCC Status Register:

  — If the instruction is a direct read of DBGDTRRX_EL0, Debug Data Transfer Register, Receive, it observes the external write.

  — If the instruction is a direct write of DBGDTRTX_EL0, Debug Data Transfer Register, Transmit, it observes the external read.

- Writes to EDITR that do not overrun commit an instruction for execution immediately. The instruction must complete execution in finite time without requiring any further operation by the debugger.
- After an external write to the EDITR, the ITR flags that are updated as a side effect of that write must be observable by:

  — An external read of the EDSCR that follows the external write to the EDITR.

  — When checking for overrun, another external write to the EDITR that follows the original external write to the EDITR.

In Memory access mode, these requirements shift to the instructions implicitly executed by external reads and external writes of the DTR registers, as described in Memory access mode.

E4.6 Interrupt-driven use of the DCC

Arm recommends implementations provide a level-sensitive DCC interrupt request through the IMPLEMENTATION DEFINED interrupt controller as a Private Peripheral Interrupt for the originating PE.

Note

- In addition to connection to the interrupt controller Arm also recommends **COMMIRQ**, **COMMTX**, and **COMMRX** signals that might be implemented for use by any legacy system peripherals.
- GICv3 reserves a Private Peripheral Interrupt number for the **COMMIRQ** interrupt.

The MDCCINT_EL1, Monitor DCC Interrupt Enable Register register provides a first level of interrupt masking within the PE, meaning only a single interrupt source, **COMMIRQ**, is needed at the interrupt controller.

See also Synchronization of DCC interrupt request signals.

E4.7 Pseudocode description of the operation of the DCC and ITR registers

The basic operation of the DCC and ITR registers is shown by the following pseudocode functions. These functions do not cover the behavior when OSLSR_EL1, OS Lock Status Register.OSLK == 1, meaning that the OS Lock is locked:

- `Write_DBGDTR_EL0[].`
- `Write_DBGDTRRX_EL0[].`
- `Write_DBGDTRTX_EL0[].`
- `Write_EDITR[].`
- `CheckForDCCInterrupts().`

For the definition of the DTR Registers, see shared/debug/dccanditr/DTR.

Chapter E5
The Embedded Cross-Trigger Interface

This chapter describes the Embedded Cross-Trigger interface. It contains the following sections:

- About the Embedded Cross-Trigger.
- Basic operation on the ECT.
- Cross-triggers on a PE in an Arm A-profile implementation.
- Description and allocation of CTI triggers.
- CTI registers programmers' model.
- Examples.

E5.1 About the Embedded Cross-Trigger

The *Embedded Cross-Trigger* (ECT) allows a debugger to:

- Send trigger events to a PE. For example, this might be done to halt the PE.
- Send a trigger event to one or more PEs, or other system components, when a trigger event occurs on another PE or system component. For example, this might be done to halt all PEs when one individual PE halts.

Figure E5-1 shows the logical structure of an ECT.

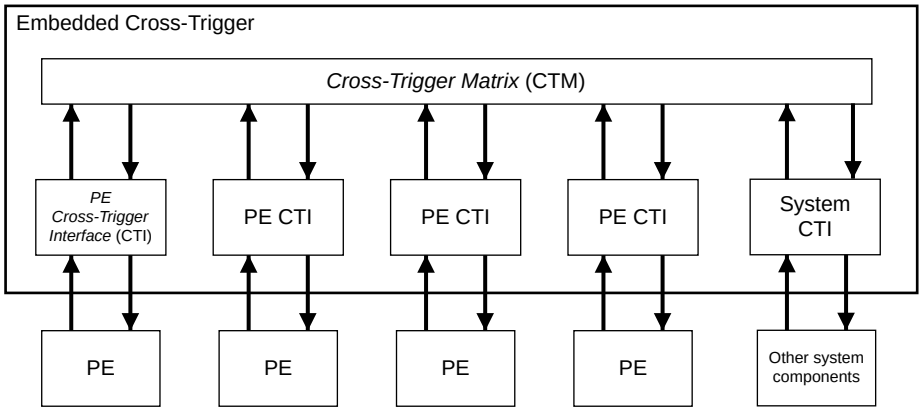

Figure E5-1 Structure of an Embedded Cross-Trigger

The ECT can deliver many types of trigger events, which are described in the following sections:

- Debug request trigger event.
- Restart request trigger event.
- Cross-halt trigger event.
- Performance Monitors overflow trigger event.
- Generic trace external input trigger events.
- Generic trace external output trigger events.
- Generic CTI interrupt trigger event.

From the introduction of Armv8, an A-profileR-profile implementation must:

- Include a Cross-Trigger interface, CTI.
- Implement at least the input and output triggers defined in this architecture.

In addition, see Cross-triggers on a PE in an Arm R-profile implementation.

Arm recommends that this Cross-Trigger interface includes:

- The ability to route trigger events between Trace Units, which typically have advanced event triggering logic.
- An output trigger to the interrupt controller.

Also, Arm recommends that the Embedded Cross-Trigger includes the capability to send and receive IMPLEMENTATION DEFINED system trigger events to and from other system components, including a system counter, using a system CTI. See Halt-on-debug.

Note

The ECT and CTI must only signal trigger events for external debugging. They must not route software events, such as interrupts. For example, the Performance Monitors overflow input trigger is provided to allow entry to Debug state on a counter overflow, and the output trigger to the interrupt controller is provided to generally allow events from the external debug subsystem to be routed to a software agent. However, the combination of the two must not be used as a mechanism to route Performance Monitors overflows to an interrupt controller.

Note

CTI version 1 (CTIv1) is defined by the *CoreSight™ SoC Technical Reference Manual*. CTIv2 extends CTIv1 with the addition of the input channel gate. See Implementation with CTIv2.

E5.1.1 Implementation with a CoreSight CTI

For details of the recommended connections for an A-profile implementation, see Recommended External Debug Interface. See also *CoreSight™ SoC Technical Reference Manual.*

E5.1.2 Implementation with CTIv2

If the CTI implemented is CTIv2 then:

- The CTIDEVARCH, CTIDEVAFF0, and CTIDEVAFF1 registers must be implemented.
- If the channel gate function is implemented, it applies to both input and output channels.
- The input channel gate function must be implemented if either of the following is true:
  - The CTM is implemented and the architecture variant is Armv8.5 or higher.
  - The CTIDEVARCH.REVISION field reads as `0b0001` or higher.

Implementation of CTIv2 features in architecture variants below Armv8.5 is OPTIONAL, but Arm recommends that CTIv2 is implemented, CTIv2 must be implemented from Armv8.5.

E5.2 Basic operation on the ECT

The ECT comprises a Cross-Trigger Matrix, CTM, and one Cross-Trigger Interface, CTI, for each PE. The ECT might also include other CTIs for other system components. The CTM passes events between the CTI blocks over channels. The CTM can have a maximum of 32 channels.

The main interfaces of the Cross-Trigger interface, CTI, are:

- The input triggers:
  - These are trigger event inputs from the PE to the CTI.
- The output triggers:
  - These are trigger event outputs from the CTI to the PE.
- The input channels:
  - These are channel event inputs from the Cross-Trigger matrix, CTM, to the CTI.
- The output channels:
  - These are channel event outputs from the CTI to the CTM.

Each CTI block has:

- Up to 32 input triggers that come from the PE:
  - The input triggers are numbered 0-31.
- Up to 32 output triggers that go to the PE:
  - The output triggers are numbered 0-31.

If the CTI is not powered up when the Core power domain is powered up, the CTI ignores all input triggers and input channel events, and does not generate any output triggers or output channel events.

Figure E5-2 shows the logical internal structure of a CTI.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

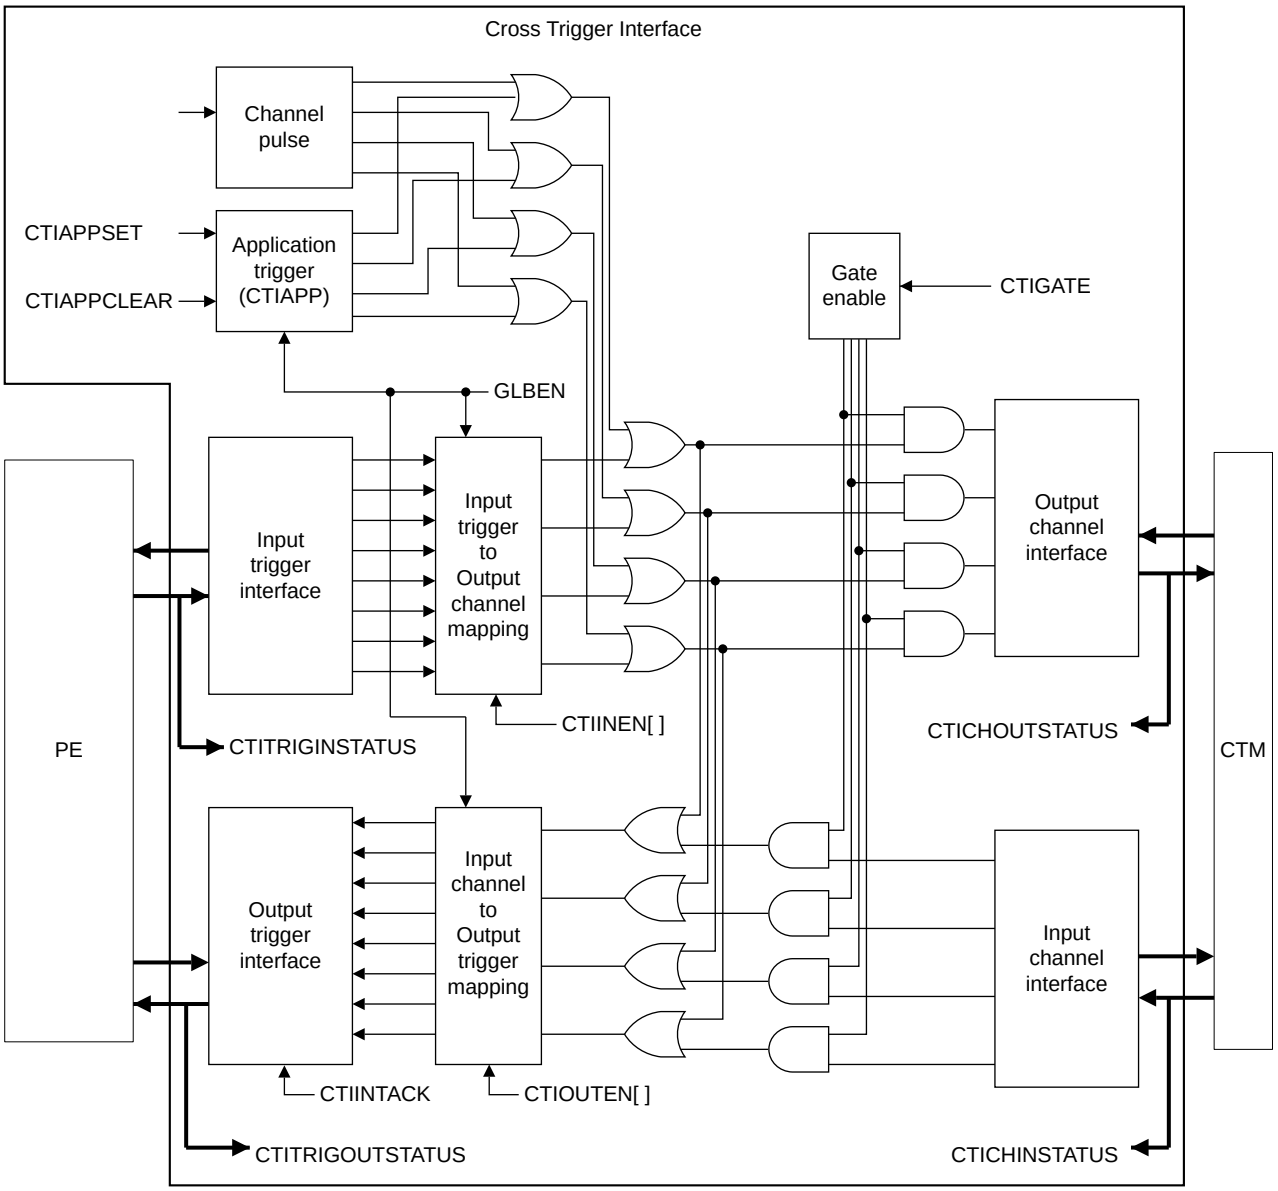

Figure E5-2 Structure of a Cross-Trigger interface

Note

- The number of triggers in IMPLEMENTATION DEFINED. Figure E5-2 shows eight input and eight output triggers.
- The number of channels is IMPLEMENTATION DEFINED. Figure E5-2 shows four channels.
- In Figure E5-2 the input channel gate function is a CTIv2 feature.

When the CTI receives an input trigger event, this generates channel events on one or more internal channels, according to the *mapping function* defined by the *Input trigger→output channel mapping registers*, CTIINEN<n>.

The CTI also contains an *application trigger* and *channel pulse* to allow a debugger to create channel events directly on internal channels by writing to the CTI control registers.

Channel events on each internal channel are passed to a corresponding output channel that is controlled by a *channel gate*. The channel gate can block propagation of channel events from an internal channel to an output channel.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

If the CTM is implemented:

- The gate function must be implemented.
- If the CTI is CTIv1, the gate function applies to output triggers only.

The output channels from a CTI are combined, using a logical OR function, with the output channels from all other CTIs to form the input channels on other CTIs. The input channels of this CTI are the logical OR of the output channels on all other CTIs. This is the *Cross-Trigger Matrix*, CTM. Therefore, the number of input channels must equal the number of output channels.

Note

The number of input triggers and output triggers is not required to be the same.

The internal channels form an internal Cross-Trigger matrix within the CTI. This delivers events directly from the input triggers to the output triggers. Therefore the number of internal channels is the same as the number of input and output channels on the external CTM, and there is a direct mapping between the two.

Channel events received on each input channel are passed to the corresponding internal channel. It is IMPLEMENTATION DEFINED whether the Cross-Trigger gate also blocks propagation of channel events from input channels to internal channels.

Note

If CTIv2 is implemented, the Cross-Trigger gate also blocks propagation of channel events from input channels to internal channels.

When the CTI receives a channel event on an internal channel this generates trigger events on one or more output triggers, according to the mapping function defined by the *Input channel → output trigger mapping registers*, CTIOUTEN<n>.

The CTI contains the input and output trigger interfaces to the PE and the interface of the Cross-Trigger matrix. The architecture does not define the signal protocol used on the trigger interfaces, and:

- It is IMPLEMENTATION DEFINED whether the CTI supports multicycle input trigger events.
- It is IMPLEMENTATION DEFINED whether the CTM supports multicycle channel events.

See Multicycle events.

However, an output trigger is asserted until acknowledged. The output trigger can be:

- Self-acknowledging. This means that no further action is required from the debugger.
- Acknowledged by the debugger writing 1 to the corresponding bit of CTIINTACK.

The time taken to propagate a trigger event from the first PE, through its CTI, across the CTM to another CTI, and thereby to a second PE is IMPLEMENTATION DEFINED.

Note

Arm recommends that this path is not longer than the shortest software communication path between those PEs. This is because if the first PE halts, the Cross-halt trigger event can propagate through the ECT and halt the second PE without causing software on the second PE to malfunction because the first PE is in Debug state and is not responding.

E5.2.1 Multicycle events

A multicycle event is one with a continuous state that might persist over many cycles, as opposed to a discrete event. A typical implementation of a multicycle event is a level-based signal interface, whereas a discrete event might be implemented as a pulse signal or message.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

CTI support for multicycle trigger events is IMPLEMENTATION DEFINED. Use of multicycle trigger events is deprecated. Of the architecturally defined input trigger events, the Performance Monitors overflow trigger event and Generic trace external output trigger events can be multicycle input triggers.

CTM support for multicycle channel events is IMPLEMENTATION DEFINED. A CTM that does not support multicycle channel events cannot propagate a multicycle trigger event between CTIs.

Note

A full ECT might comprise a mix of CTIs, some of which can support multicycle trigger events. In bridging these components, multicycle channel events become single channel events at the boundary between the CTIs.

E5.2.1.1 An ECT that supports multicycle trigger events

When an ECT supports multicycle trigger events, an input trigger event to the CTI continuously asserts channel events on all output channels mapped to it until either:

- The input trigger event is removed.
- The channel mapping function is disabled.

This means that an input trigger that is asserted for multiple cycles causes any channels that are mapped to it to become active for multiple cycles. Consequently, any output triggers mapped from that channel are asserted for multiple cycles.

Note

The output trigger remains asserted for at least as long as the channel remains active. This means that even if the output trigger is acknowledged, it remains asserted until the channel deactivates.

The CTI does not guarantee that these events have precisely the same duration, as the triggers and channels can cross between clock domains.

CTIAPPSET and CTIAPPCLEAR can set a channel active for multiple cycles. CTIAPPPULSE generates a single channel event. CTICHINSTATUS and CTICHOUTSTATUS can report whether a channel is active.

E5.2.1.2 An ECT that does not support multicycle trigger events

When an ECT does not support multicycle trigger events, an input trigger event to the CTI generates a single channel event on all output channels mapped to it, regardless of how long the input trigger event is asserted.

This means that an input trigger event that is asserted for multiple cycles generates a single channel event on any channels mapped to it. Consequently any self-acknowledging output triggers mapped from those channels are single trigger events.

Note

A single event is typically a single cycle, but there is no guarantee that this is always the case.

CTIAPPSET and CTIAPPCLEAR can only generate a single channel event. CTIAPPPULSE generates a single channel event. If the ECT does not support multicycle channel events, use of CTIAPPSET and CTIAPPCLEAR is deprecated, and the debugger must only use CTIAPPPULSE. CTICHINSTATUS and CTICHOUTSTATUS must be treated as UNKNOWN.

E5.3 Cross-triggers on a PE in an Arm R-profile implementation

An R-profile PE must include a Cross-Trigger interface, and the implementation must include at least the input and output triggers defined in this architecture. The number of channels in the Cross-Trigger matrix is IMPLEMENTATION DEFINED, but there must be a minimum of three. Software can read CTIDEVID.NUMCHAN to discover the number of implemented channels.

The CTM must connect to all PEs in the same Inner Shareability domain as the PE that includes the Cross-Trigger interface, but can also connect to additional PEs. Arm strongly recommends that the CTM connects all PEs implementing a CTI in the system. This includes other PEs that can be connected using a CoreSight CTI module.

Note

In a uniprocessor system the CTM is OPTIONAL. In a multiprocessor system the CTM is required. The CTM might be connected other CTI modules for non-PEs, such as triggers for system visibility components. Arm recommends that the CTM is implemented.

Any CTI connected to a PE that is not an Arm PE must implement at least:

- The Debug request trigger event.
- The Restart trigger event.
- The Cross-halt trigger event.

For more information about the CTI, see the *CoreSight™ SoC Technical Reference Manual*. Arm architecture refines the generic CTI by defining roles for each of the implemented input and output triggers.

E5.4 Description and allocation of CTI triggers

Table E5-1 shows the output trigger events defined by the architecture and the related trigger numbers.

Table E5-1 Allocation of CTI output trigger events

Number	Source	Destination	Event description
0	CTI	PE	Debug request trigger event
1	CTI	PE	Restart request trigger event
2	CTI	IRQ controller	Generic CTI interrupt trigger event
3	-	-	Reserved
4 - 7	CTI	Trace unit	OPTIONAL Generic trace external input trigger events
8 - 15	-	-	Reserved

Note

Output triggers from the CTI are inputs to other blocks.

Table E5-2 shows the input trigger events defined by the architecture and the related trigger numbers.

Table E5-2 Allocation of CTI input trigger events

Number	Source	Destination	Event description
0	PE	CTI	Cross-halt trigger event
1	PE	CTI	Performance Monitors overflow trigger event
2	-	-	Reserved
3	-	-	Reserved
4 - 7	Trace unit	CTI	OPTIONAL Generic trace external output trigger events
8 - 10	-	-	Reserved
11 - 15	-	-	IMPLEMENTATION DEFINED.

Note

Input triggers to the CTI are outputs from other blocks.

Table E5-1 and Table E5-2 show the minimum set of trigger events defined by the architecture. However:

- The Generic trace external input and output trigger events are required only if the OPTIONAL trace unit is implemented. If the OPTIONAL trace unit is not implemented, these trigger events are reserved.
- Support for the generic CTI interrupt trigger event is IMPLEMENTATION DEFINED because details of interrupt handling in the system, including any interrupt controllers, are IMPLEMENTATION DEFINED. Details regarding how the CTI interrupt is connected to an interrupt controller and its allocated interrupt number lie outside the scope of the architecture. Arm strongly recommends that implementations provide a means to generate interrupts based on external debug events.
- The other trigger events are required by the architecture.

An implementation can extend the CTI with additional triggers.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

E5.4.1 Debug request trigger event

This is an output trigger event from the CTI, and an input trigger event to the PE, asserted by the CTI to force the PE into Debug state. The trigger event is asserted until acknowledged by the debugger. The debugger acknowledges the trigger event by writing 1 to CTIINTACK[0].

Note

A debugger must poll CTITRIGOUTSTATUS[0] until it reads as 0, to confirm that the output trigger has been deasserted before generating any event that must be ordered after the write to CTIINTACK, such as a write to CTIAPPPULSE to activate another trigger.

If the PE is already in Debug state, the PE ignores the trigger event, but the CTI continues to assert it until it is removed by the debugger. See also External Debug Request debug event.

E5.4.2 Restart request trigger event

This is an output trigger event from the CTI, and an input trigger event to the PE, asserted by the CTI to request the PE to exit Debug state. If the PE is in Non-debug state, the request is ignored by the PE.

If a Restart request trigger event is received at or about the same time as the PE enters Debug state, it is CONSTRAINED UNPREDICTABLE whether:

- The request is ignored by the PE. In this case the PE enters Debug state and remains in Debug state.
- The PE enters Debug state and then immediately restarts.

Debuggers must program the CTI to send Restart request trigger events only to PEs that are halted. To enable the PE to disambiguate discrete Restart request trigger events, after sending a Restart request trigger event, the debugger must confirm that the PE has restarted and halted before sending another Restart request trigger event. Debuggers can use EDPRSR.{SDR, HALTED} to determine the Execution state of the PE.

Note

Before generating a Restart request trigger event for a PE, a debugger must ensure any Debug request trigger event targeting that PE is cleared. Debug request trigger event describes how to do this.

The trigger event is self-acknowledging, meaning that the debugger requires no further action to remove the trigger event. The trigger event is acknowledged even if the request is ignored by the PE. See also Exiting Debug state.

E5.4.3 Cross-halt trigger event

This is an input trigger event to the CTI, and an output trigger event from the PE, asserted by a PE when it is entering Debug state.

Note

To reduce the latency of halting, Arm recommends that an implementation issues the Cross-halt trigger event early in the committed process of entering Debug state. This means that there is no requirement to wait until all aspects of entry to Debug state have completed before issuing the trigger event. Speculative emission of Cross-halt trigger events is not allowed. The Cross-halt trigger event must not be issued early enough for a subsequent Debug request trigger event, which might be derived from the Cross-halt trigger event, to be recorded in the EDSCR.STATUS field. This applies to Debug request trigger events that are acting as inputs to the PE.

E5.4.4 Performance Monitors overflow trigger event

This is an input trigger event to the CTI, and an output trigger event from the PE, asserted each time the PE records a Performance Monitors counter overflow. See The Performance Monitors Extension.

If the CTI supports multicycle trigger events, then the trigger event remains asserted while any of the following are true, and deasserted otherwise:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- An event counter <n> is implemented, the global enable control for the event counter is 1, PMINTENSET_EL1, Performance Monitors Interrupt Enable Set Register.P[n] is 1, and PMOVSSET_EL0, Performance Monitors Overflow Flag Status Set Register.P[n] is 1. The global enable control is defined in Enabling PMU counters.
- [**multi:pmctr?**].E is 1, PMINTENSET_EL1, Performance Monitors Interrupt Enable Set Register.C is 1, and PMOVSSET_EL0, Performance Monitors Overflow Flag Status Set Register.C is 1.

Note

- This does not replace the recommended connection of Performance Monitors overflow trigger event to an interrupt controller. Software must be able to program an interrupt on Performance Monitors overflow without programming the CTI.
- Events can be counted when `ExternalNoninvasiveDebugEnabled()` == FALSE, and, in Secure state, when `ExternalSecureNoninvasiveDebugEnabled()` == FALSE. Secure software must be aware that overflow trigger events are nevertheless visible to the CTI.

If the CTI does not support multicycle trigger events, then the trigger event is asserted whenever a counter overflows, causing the PE to set PMOVSSET_EL0, Performance Monitors Overflow Flag Status Set Register.P[n] to 1, or a direct write to a System register means the above conditions become true.

For more information, see An ECT that supports multicycle trigger events.

E5.4.5 Generic trace external input trigger events

These are output trigger events from the CTI, and input trigger events to the OPTIONAL trace unit, that are used in conjunction with the Generic trace external output trigger events to pass trigger events between:

- The PE and the OPTIONAL trace unit.
- The OPTIONAL trace unit and any other component attached to the CTM, including other Trace Units.

There are four Generic trace external input trigger events.

The trigger events are self-acknowledging. This means that the debugger does not have to take any further action to remove the events.

E5.4.6 Generic trace external output trigger events

These are input trigger events to the CTI, and output trigger events from the OPTIONAL trace unit, used in conjunction with the Generic trace external input trigger events to pass trigger events between:

- The PE and the OPTIONAL trace unit.
- The OPTIONAL trace unit and any other component attached to the CTM, including other Trace Units.

There are four Generic trace external output trigger events.

E5.4.7 Generic CTI interrupt trigger event

This is an output trigger event from the CTI, and an input to an IMPLEMENTATION DEFINED interrupt controller, and can transfer trigger events from the PE, trace units, or any other component attached to the CTI and CTM to software as an interrupt. The Generic CTI interrupt trigger event must be connected to the interrupt controller as an interrupt that can target the originating PE.

Note

- Arm recommends that the Generic CTI interrupt trigger event is a private peripheral interrupt, but implementations might instead make this trigger event available as a shared peripheral interrupt or a local peripheral interrupt.
- GICv3 reserves a private peripheral interrupt number for this interrupt.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

It is IMPLEMENTATION DEFINED whether this trigger event is:

- Self-acknowledging. This means that the debugger is not required to take any further action, and that the interrupt controller must treat the trigger event as a pulse or edge-sensitive interrupt.
- Acknowledged by the debugger. The debugger acknowledges the trigger event by writing 1 to CTIINTACK[2]. This means that the interrupt controller must treat the trigger event as a level-sensitive interrupt.

Arm recommends that the Generic CTI interrupt trigger event is a self-acknowledging trigger event.

E5.5 CTI registers programmers' model

The CTI registers programmers' model is described in About the External Debug Registers. The following sections contain information specific to the CTI:

- External debug register resets.
- External debug interface register access permissions.
- Cross-trigger interface registers.
- The individual register descriptions in Cross-Trigger Interface registers.

See also Memory-mapped accesses to the external debug interface.

E5.5.1 CTI reset

An External Debug reset resets the CTI. See External debug register resets for details of CTI register resets. All CTI output triggers and output channels are deasserted on an External Debug reset.

Note

An indirect read of an output trigger might not observe the deasserted state until the processor is Cold reset. For more information, see Synchronization of changes to the external debug registers.

E5.5.2 CTI authentication

The CTI ignores the state of the IMPLEMENTATION DEFINED authentication interface. This means that:

- CTITRIGINSTATUS shows the status of the input triggers and CTICHINSTATUS shows the status of the input channels, regardless of the value of `ExternalNoninvasiveDebugEnabled()`.

  Note

  The PE does not generate the Cross-halt trigger event and the trace unit does not generate Generic trace external output trigger events when `ExternalNoninvasiveDebugEnabled()` == FALSE. However, the PE can generate Performance Monitors overflow trigger events.

- The CTI can generate external triggers regardless of the value of `ExternalInvasiveDebugEnabled()`.

  Note

  The PE ignores Debug request and Restart request trigger events when `ExternalInvasiveDebugEnabled()` is FALSE.
  The trace unit ignores Generic trace external input trigger events when `ExternalNoninvasiveDebugEnabled()` is FALSE.
  The behavior of Generic CTI interrupt requests is part of the IMPLEMENTATION DEFINED handling of these interrupts, but it is permissible for an interrupt controller to receive these requests even when `ExternalInvasiveDebugEnabled()` is FALSE.

E5.6 Examples

The CTI is fully programmable and allows for flexible cross-triggering of events within a PE and between PEs in a multiprocessor system. For example:

- The Cross-halt trigger event and the Debug request trigger event can be used for cross-triggering in a multiprocessor system.
- The Cross-halt trigger event and the Generic interrupt trigger event can be used for event-driven debugging in a multiprocessor system.
- The Performance Monitors overflow trigger event and the Debug request trigger event can force entry to Debug state on overflow of a Performance Monitors event counter, for event-driven profiling.

  Note

  This does not replace the recommended connection of Performance Monitors overflow trigger events to an interrupt controller. Software must be able to program an interrupt on Performance Monitors overflow without programming the CTI. Arm recommends that the Performance Monitors overflow signal is directly available as a local interrupt source.

- The Generic trace external input and Generic trace external output trigger events can pass trace events into and out of the event logic of the trace unit. They can do this:
  - To pass trace events between Trace Units.
  - In conjunction with the Performance Monitors overflow trigger event, to couple the Performance Monitors to the PE trace unit.
  - In conjunction with the Debug request trigger event, to trigger entry to Debug state on a trace event.
  - In conjunction with other CTIs, to signal a trace trigger event onto a CoreSight trace interconnect.

The following sections describe some examples in more detail:

- Example E5-1.
- Example E5-2.
- Example E5-3.
- Example E5-4.

Example E5-1 Halting a single PE

To halt a single PE, set:

1. CTIGATE[0] to 0, so that the CTI does not pass channel events on internal channel 0 to the CTM.
2. CTIOUTEN0[0] to 1, so that the CTI generates a Debug request trigger event in response to a channel event on channel 0.

   Note

   The Cross-halt trigger event is input trigger 0, meaning it is controlled by the instance of CTIOUTEN<n> for which <n> is 0.

3. CTIAPPPULSE[0] to 1, to generate a channel event on channel 0.

When the PE has entered Debug state, clear the Debug request trigger event by writing 1 to CTIINTACK[0], before restarting the PE.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Example E5-2 Halting all PEs in a group when any one PE halts

To program a group of PEs so that when one PE in the group halts, all of the PEs in that group halt, set the following registers for each PE in the group:

1. CTIGATE[2] to 1, so that each CTI passes channel events on internal channel 2 to the CTM.
2. CTIINEN0[2] to 1, so that each CTI generates a channel event on channel 2 in response to a Cross-halt trigger event.
3. CTIOUTEN0[2] to 1, so that each CTI generates a Debug request trigger event in response to a channel event on channel 2.

   Note

   The Cross-halt trigger event is input trigger 0, meaning it is controlled by the instances of CTIINEN<n> and CTIOUTEN<n> for which <n> is 0.

When a PE has halted, clear the Debug request trigger event by writing a value of 1to CTIINTACK[0], before restarting the PE.

Example E5-3 Synchronously restarting a group of PEs

To restart a group of PEs, for each PE in the group:

1. If the PE was halted because of a Debug request trigger event, the debugger must ensure the trigger event is deasserted. It can do this by:
   a. Writing 1 to CTIINTACK[0] to clear the Debug request trigger event.
   b. Polling CTITRIGOUTSTATUS[0], until it reads as 0, to confirm that the trigger event has been deasserted.
2. Set CTIGATE[1] to 1, so that each CTI passes channel events on internal channel 1 to the CTM.
3. Set CTIOUTEN1[1] to 1, so that each CTI generates a Restart request trigger event in response to a channel event on channel 1.

   Note

   This example must use the instance of CTIOUTEN<n> for which <n> is 1.

4. Set CTIAPPPULSE[1] to 1 on any one PE in the group, to generate a channel event on channel 1.

Example E5-4 Halting a single PE on Performance Monitors overflow

To halt a single PE on a Performance Monitors overflow set:

1. CTIGATE[3] to 0, so that the CTI does not pass channel events on internal channel 3 to the CTM.
2. CTIINEN1[3] to 1, so that the CTI generates a channel event on channel 3 in response to a Performance Monitors overflow trigger event.

   Note

   This step of this example must use the instance of CTIINEN<n> for which <n> is 1.

3. CTIOUTEN0[3] to 1, so that the CTI generates a Debug request trigger event in response to a channel event on channel 3.

   Note

   This step of this example must use the instance of CTIOUTEN<n> for which <n> is 0.

When the PE has entered Debug state, clear the Debug request trigger event by writing 1 to CTIINTACK[0], before restarting the PE. Clear the overflow status by writing to PMOVSCLR_EL0.

Chapter E6
Debug Reset and Powerdown Support

This chapter describes the reset and powerdown support in the Debug architecture. It contains the following sections:

- About Debug over powerdown.
- Power domains and debug.
- Core power domain power states.
- Emulating low-power states.
- Powerup request mechanism.
- Debug OS Save and Restore sequences.
- Reset and debug.

E6.1 About Debug over powerdown

Arm A-profile external debug defines a logical model for the hardware on which a PE executes. This hardware is logically split into the *Core power domain* and the *Debug power domain*, and the model contains descriptions of the states of those domains. See:

- Power domains and debug.
- Core power domain power states.

An implementation may allow power domains to be powered up and down independently. Debug over powerdown provides:

- A facility for software executing on the PE to save and restore the PE state on behalf of a self-hosted or external debugger or both. See Debug OS Save and Restore sequences.
- A facility for an external debugger to request power up of the Core power domain. See Powerup request mechanism.
- A facility for an external debugger, or software executing on the PE, to request emulation of powerdown of the Core power domain. See Emulating low-power states.

E6.2 Power domains and debug

Arm A-profile external debug has two logical power domains, each with its own reset:

- The Debug power domain contains the interface between the PE and the external debugger, and is powered up whenever an external debugger is connected to the SoC. It remains powered up while the external debugger is connected. When the Core power domain is completely off or in a low-power state, a debugger is permitted to access a register that is implemented in the Debug power domain. Registers in this domain are reset by an External Debug reset.
- The Core power domain contains the rest of the PE, and might be allowed to power up and power down independently of the Debug power domain.

Note

- The model of two logical power domains has an impact on the reset and access permission requirements of the debug programmers' model.
- The power domains are described as logical because the architecture defines the requirements but does not require two physical power domains. Any power domain split that meets the requirements of the programmers' model is a valid implementation.

The Core power domain contains several types of registers:

- Non-debug logic refers to all registers and logic that are not associated with debug.
- Self-hosted debug logic refers to registers and logic associated solely with the self-hosted debug aspects of the architecture.
- Shared debug logic refers to registers and logic associated with both the self-hosted and external debug aspects of the architecture.
- External debug logic refers to registers and logic associated solely with the external debug aspects of the architecture.

For information about which groups of registers and components are in each power domain, and which registers change power domain if FEAT_DoPD is implemented, see:

- Access permissions for the External debug interface registers.
- Cross-trigger interface registers.
- Management register access permissions.
- Access permissions for external views of the Performance Monitors.

E6.3 Core power domain power states

The Arm architecture does not define the power states of the PE as these are not normally visible to software. However, they are visible to the external debugger. Arm A-profile external debug uses a four logical power states model for the Core power domain. Mechanisms for entering a low-power state describes the architectural mechanisms for entering low-power states.

When the PE enters a low-power state other than Powerdown by executing a `WFI` or `WFE` instruction, it remains in that low-power state until it receives a wakeup event. See Mechanisms for entering a low-power state for the definition of wakeup events. When halting is allowed, an External Debug Request is a wakeup event. In addition, if the PE enters the Standby state for any reason, it will leave that state to service an External Debug Request debug event.

The four logical power states are as follows:

Normal The Core power domain is fully powered up and the debug registers are accessible.

Standby The Core power domain is on, but there are measures to reduce energy consumption. There can be other IMPLEMENTATION DEFINED measures the OS can take to enter standby.

The PE preserves the PE state, including the debug logic state. Changing from standby to normal operation does not involve a reset of the PE.

Standby is the least invasive OS energy saving state. Standby implies only that the PE is unavailable and does not clear any debug settings. For standby, the Debug architecture requires only the following:

- If the external debug interface is accessed, the PE must respond to that access. Arm recommends that, if the PE executed a `WFI` or `WFE` instruction to enter standby, then it does not retire that instruction.

Standby is transparent, meaning that to software and to an external debugger it is indistinguishable from normal operation.

Retention The PE state, including debug settings, is preserved in low-power structures, allowing the Core power domain to be at least partially turned off.

Changing from low-power retention to normal operation does not involve a reset of the PE. The saved PE state is restored on changing from low-power retention state to normal operation. If software has to use an IMPLEMENTATION DEFINED code sequence before entering, or after leaving, a retention state, this is referred to as a *software-visible retention state*. It is IMPLEMENTATION DEFINED whether the value of DBGPRCR.CORENPDRQ is set to its Cold reset value on leaving the software-visible retention state. See the description of DBGPRCR.CORENPDRQ for more information.

Note

- This model of retention does not include implementations where the PE exits the state in response to a debug register access. From the Debug architecture perspective, implementations like this are forms of standby.

Powerdown These measures must include the OS saving any PE state, including the debug settings, that must be preserved over powerdown.

If FEAT_DoubleLock is implemented, it is used during powerdown.

Changing from powerdown to normal operation must include:

- A Cold reset of the PE after the power level has been restored.
- The OS restoring the saved PE state.

External Debug Request debug events stay pending and debug registers in the Core power domain cannot be accessed.

An implementation might support enabling and disabling threads, either dynamically or once at reset time. Threads that are disabled in this way must appear to the external debugger as either:

- Powered off, meaning they are either:
  - In a powerdown state.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

  - In a retention state.

- Held in reset state.

Arm A-profile external debug uses a simpler two states model for the Debug power domain. The two states are:

Off The Debug power domain is turned off.

On The Debug power domain is turned on.

The available power states, including the cross-product of Core power domain and Debug power domain power states is IMPLEMENTATION DEFINED. Implementations are not required to implement all of these states and might include additional states. These additional states must appear to the debugger as one of the logical power states defined by this model. The control of power states is IMPLEMENTATION DEFINED.

Note

As a result, it is IMPLEMENTATION DEFINED whether it is possible for the Debug power domain to be on when the Core power domain is off.

If the Debug power domain is implemented but is not powered up when the Core power domain is powered up, the Reset Catch debug event and the OS Unlock Catch debug event are disabled.

E6.4 Powerup request mechanism

If a powerup request mechanism is implemented, asserting the powerup request requests the power controller to power up the Core power domain, and to emulate any subsequent powerdown requests, until the powerup request mechanism is deasserted.

E6.4.1 Powerup request mechanism if FEAT_DoPD is implemented

If FEAT_DoPD is implemented, the external debug component implements an OPTIONAL powerup request mechanism.

If the powerup request mechanism is implemented, Arm strongly recommends that the powerup request is a CoreSight Class `0x9` ROM table block that contains both:

- A parent entry for the debug registers of the PE.
- A parent entry for the PMU registers of the PE, if the OPTIONAL PMU with an external debug interface is implemented.

A parent entry of a component is an entry in a ROM table that either locates the component, or locates another ROM table that contains the parent entry for the component.

Note

The ROM table and any descendants might describe other debug components, including debug components for other PEs. The ROM table might have a parent entry in a second ROM table and that parent entry might also have a powerup request mechanism in the second ROM table. This applies recursively.

The parent entries for the debug components have the following properties:

For the debug registers and Performance Monitors registers: These components are in the Core power domain.

The POWERIDVALID bit is 1.

All parent entries must have the same IMPLEMENTATION DEFINED POWERID value.

Note

The IMPLEMENTATION DEFINED POWERID value does not need to be unique for each PE.

For the CTI registers: This component is in the Debug power domain.

The POWERIDVALID bit is IMPLEMENTATION DEFINED.

If the POWERIDVALID bit is 1, the entries must have a valid POWERID value.

Note

If the Core power domain can be powered down independently of the Debug power domain, Arm recommends the system implements an external debug component with a powerup request mechanism which can request the Core power domain to be powered up.

For more information about Coresight Class `0x9` ROM Tables, see *ARM® CoreSight™ Architecture Specification*.

On a Cold reset, if FEAT_DoPD is implemented, DBGPRCR_EL1, Debug Power Control Register.CORENPDRQ is set to an IMPLEMENTATION DEFINED choice between 0 and 1 if the powerup request is implemented and asserted, and 0 otherwise.

E6.4.2 Powerup request mechanism if FEAT_DoPD is not implemented

If FEAT_DoPD is not implemented, the bit EDPRCR.COREPURQ is the powerup request mechanism.

The control registers DBGPRCR_EL1, Debug Power Control Register.CORENPDRQ and EDPRCR.COREPURQ provide an interface between the power controller and the PE. They typically map directly to signals in the recommended external debug interface.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

On Cold reset, if FEAT_DoPD is not implemented, DBGPRCR_EL1, Debug Power Control Register.CORENPDRQ is set to the value of EDPRCR.COREPURQ.

Non-Confidential

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

E6.5 Emulating low-power states

DBGPRCR_EL1, Debug Power Control Register.CORENPDRQ and the powerup request mechanism can request the power controller to emulate states where the Core power domain is completely off or in a low-power state where the Core power domain registers cannot be accessed. This simplifies the requirements on software by sacrificing entirely realistic behavior.

If FEAT_DoPD is not implemented, EDPRSR.{SPD, PU} indicates the Core power domain power state. For more information, see:

- The DBGPRCR_EL1 and DBGPRCR System register descriptions.
- The EDPRCR and EDPRSR external debug register descriptions.
- Recommended External Debug Interface.

The measures to emulate powerdown are IMPLEMENTATION DEFINED. The ability of the debugger to access the state of the PE and the system might be limited as a result of the measures adopted.

In an emulated powerdown state, the debugger must be able to access all debug, PMU, CTI, and trace unit registers that are accessible on the external debug interface and are in one of:

- The Debug power domain.
- The Core power domain.
- When a trace unit with a separate trace unit Core power domain is implemented, and the trace unit Core power domain is powered on, the trace unit Core power domain.

That is, the debugger must be able to read and write to such registers without receiving errors. This allows an external debugger to debug the powerup sequence.

Arm recommends that any IMPLEMENTATION DEFINED registers that are on the external debug interface and in either the Core power domain or the Debug power domain are also accessible in an emulated powerdown state.

If FEAT_DoubleLock is implemented, `DoubleLockStatus() == FALSE` when DBGPRCR_EL1, Debug Power Control Register.CORENPDRQ == 1.

Otherwise, the behavior of the PE in emulated powerdown must be similar to that in a real powerdown state. In particular, the PE must not respond to other system stimuli, such as interrupts.

Example E6-1 and Example E6-2 are examples of two approaches to emulating powerdown.

Example E6-1 An example of emulating powerdown

The PE is held in Standby state, isolated from any system stimuli. It is IMPLEMENTATION DEFINED whether the PE can respond to debug stimuli such as an External Debug Request debug event.
If the PE can enter Debug state, then the external debugger is able to use the ITR to execute instructions, such as loads and stores. This causes the external debugger to interact with the system. If the external debugger restarts the PE, the PE leaves Standby state and restarts fetching instructions from memory.

Example E6-2 Another example of emulating powerdown

The PE is held in Warm reset. This limits the ability of an external debugger to access the resources of the PE. For example, the PE cannot be put into Debug state.

On exit from emulated powerdown the PE is reset. However, the debug registers that are only reset by a Cold reset must not be reset. Typically this means that a Warm reset is substituted for the Cold reset. As such, the effect of accessing any register that is reset by a Warm reset while the PE is in the emulated powerdown state will have an IMPLEMENTATION DEFINED effect on that register.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

- Warm reset and Cold reset have different effects apart from resetting the debug registers. In particular, RMR_ELx is reset by a Cold reset and controls the reset state on a Warm reset. This means that if a Cold reset is substituted by a Warm reset, the behavior of the reset code might be different.
- The timing effects of powering down are typically not factored in the powerdown emulation. Examples of these timing effects are clock and voltage stabilization.
- Emulation does not model the state lost during powerdown, meaning that it might mask errors in the state storage and recovery routines.

E6.6 Debug OS Save and Restore sequences

From the introduction of Armv8-R, the following registers provide the OS Save and Restore mechanism:

- The *OS Lock Access Register*, OSLSR_EL1, OS Lock Status Register, locks the OS Lock to restrict access to debug registers before starting an OS Save sequence, and unlocks the OS Lock after an OS Restore sequence.
- The *OS Lock Status Register*, OSLSR_EL1, OS Lock Status Register, shows the status of the OS Lock.
- The PE can be configured to generate an OS Unlock Catch debug event when the OS Lock is unlocked.
- If FEAT_DoubleLock is implemented, the OS Double Lock locks out an external debug interface entirely. This is only used immediately before a powerdown sequence.

See also:

- FEAT_DoubleLock
- Reset and debug
- Example OS Save and Restore Sequences

E6.6.1 EDPRSR.{DLK, SPD, PU} and the Core power domain

If FEAT_DoPD is not implemented, a debugger uses EDPRSR.{DLK, SPD, PU} to determine whether registers in the Core power domain can be accessed, and whether their state has been lost since the last time the register was read.

Table E6-1 Interpretation of the EDPRSR.{DLK, SPD, PU} bits

EDPRSR			Core power domain			Notes
DLK	SPD	PU	Power	Accesses	State lost	
0	0	1	On	OK	No	-
0	1	1	On	OK	Yes	SPD is cleared to 0 following the read.
1	X	1	On	Error	Not known	FEAT_DoubleLock is implemented and `DoubleLockStatus()` == TRUE. Software locks the OS Double Lock before removing power.
X	1	0	Off	Error	Yes	A Cold reset will be asserted on exiting powerdown state, but not on exiting low-power retention state.
X	0	0	Not known	Error	Not known	

If FEAT_DoPD is implemented, accesses to EDPRSR return an error when the Core power domain is off or in a retention state, meaning successful reads of EDPRSR always return 1 for EDPRSR.PU.

When FEAT_Debugv8p4 is implemented, and whenever FEAT_DoubleLock is not implemented, EDPRSR.DLK is always 0.

If FEAT_DoubleLock is not implemented, `DoubleLockStatus()` always returns FALSE.

If the Core power domain is powered up and `DoubleLockStatus()` == TRUE, then:

- When FEAT_Debugv8p2 is not implemented, EDPRSR.{DLK, SPD, PU} can read either {1, UNKNOWN, 1} or {UNKNOWN, 0, 0}.
- When FEAT_Debugv8p2 is implemented, and FEAT_Debugv8p4 is not implemented, EDPRSR.{DLK, SPD, PU} can only read {UNKNOWN, 0, 0}.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

E6.6.2 EDPRSR.SPD when the Core domain is in either retention or powerdown state

If FEAT_DoPD is not implemented, when the Core power domain is in either the retention or powerdown state, EDPRSR.SPD is not cleared following a read of EDPRSR and it is IMPLEMENTATION DEFINED whether:

- EDPRSR.SPD shows whether the state of the debug registers in the Core power domain has been lost since the last time that EDPRSR was read. This means that:
  - When the Core power domain is in the powerdown state, EDPRSR.SPD is RAO, this indicates that the state of the debug registers has been lost.
  - When the Core power domain is in the retention state, EDPRSR.SPD indicates whether the state of the debug registers was lost before the Core power domain entered retention state.
- EDPRSR.SPD is RAZ, and:
  - On leaving the powerdown state, EDPRSR.SPD is set to 1 which indicates that the state of the debug registers has been lost.
  - On leaving the retention state, EDPRSR.SPD reverts the value it had on entering the retention state.

Note

If FEAT_DoPD is implemented, accesses to EDPRSR return an error when the Core power domain is off or in a retention state.

E6.6.3 EDPRSR.{DLK, R} and reset state

If FEAT_DoPD is implemented, accesses to EDPRSR return an error when the Core power domain is off or in a retention state, meaning successful reads of EDPRSR always return 1 for EDPRSR.PU.

When FEAT_Debugv8p4 is implemented, and whenever FEAT_DoubleLock is not implemented, EDPRSR.DLK is always 0.

If FEAT_DoubleLock is not implemented, `DoubleLockStatus()` always returns FALSE.

If FEAT_DoubleLock is implemented and enabled, the behavior of all registers and fields except EDPRSR.DLK is the same as their behavior if FEAT_Debugv8p4 is not implemented.

If FEAT_Debugv8p4 is implemented EDPRSR.DLK is always 0 and does not give any information about the OS Double Lock.

EDPRSR.R is UNKNOWN when `DoubleLockStatus()` == TRUE. OSDLR_EL1.DLK is cleared to 0 by a reset. If the Core power domain is powered up and entered reset state with the OS Double Lock locked, it is CONSTRAINED UNPREDICTABLE whether a read of EDPRSR while the PE is in reset state returns:

- EDPRSR.{DLK, R, PU} == {1, UNKNOWN, 1} indicating that the OS Double Lock is locked. This is not permitted from Armv8.2.
- EDPRSR.{DLK, R, PU} == {0, 1, 1} indicating that the PE is in reset state.
- EDPRSR.{DLK, R, PU} == {UNKNOWN, UNKNOWN, 0} indicating that the registers in the Core power domain cannot be accessed because the OS Double Lock is locked.

If the PE was powered up and the OS Double Lock was unlocked when the PE was reset, then EDPRSR.{DLK, R, PU} reads as {0, 1, 1} while the PE is in reset state.

On leaving reset state, EDPRSR.{DLK, R} reads as {0, 0}.

E6.6.4 Debug registers to save over powerdown

Table E6-2 shows the different requirements for self-hosted debug over powerdown and external debug over powerdown:

- The column labeled Self-hosted lists registers that software must preserve over powerdown so that it can support self-hosted debug over powerdown. This does not require use of the OS Save and Restore mechanism.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- The column labeled External lists registers that software must preserve over powerdown so that it can support external debug over powerdown. This requires use of the OS Save and Restore mechanism:
  - Some external debug registers are not normally accessible to software executing on the PE. Additional debug registers are provided that give software the required access to save and restore these external debug registers when OSLSR_EL1, OS Lock Status Register.OSLK is locked. These registers include OSECCR_EL1, OS Lock Exception Catch Control Register, OSDTRRX_EL1, OS Lock Data Transfer Register, Receive, and OSDTRTX_EL1, OS Lock Data Transfer Register, Transmit.
- Some registers might only present in some implementations, or might not be accessible at all Exception levels or in Non-secure state. .

Table E6-2 does not include registers for the OPTIONAL Trace and Performance Monitor extensions.

Table E6-2 Debug registers to save over powerdown

Register in AArch64 state	Self-hosted	External
MDSCR_EL1	Yes	Yes
DBGBVR<n>_EL1	Yes	Yes
DBGBCR<n>_EL1	Yes	Yes
DBGWVR<n>_EL1	Yes	Yes
DBGWCR<n>_EL1	Yes	Yes
MDCR_EL2	Yes	-
DBGCLAIMSET_EL1 DBGCLAIMCLR_EL1	-	Yes
OSECCR_EL1	-	Yes
OSDTRRX_EL1 OSDTRTX_EL1	-	Yes

E6.6.5 OS Save sequence

To preserve the debug logic state over a powerdown, the state must be saved to nonvolatile storage. This means the OS Save sequence must:

1. Lock the OS Lock by writing 1 to OSLAR_EL1.OSLK.
2. Execute an `ISB` instruction.
3. Walk through the debug registers listed in Debug registers to save over powerdown and save the values to the nonvolatile storage.

If the FEAT_DoubleLock is implemented, before removing power from the Core power domain, software must:

1. Lock the OS Double Lock by writing 1 to OSDLR_EL1.DLK.
   If FEAT_DoubleLock is not implemented, OSDLR_EL1 ignores writes.
2. Execute a Context Synchronization event.

E6.6.6 OS Restore sequence

After a powerdown, the OS Restore sequence must perform the following steps to restore the debug logic state from the non-volatile storage:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

1. Lock the OS Lock, as described in OS Save sequence. The OS Lock is generally locked by the Cold reset, but this step ensures that it is locked.
2. Execute an `ISB` instruction.
3. Write 0 to MDSCR_EL1 to ensure that, if an external debugger clears the OS Lock before the end of this sequence, no debug exceptions are generated.
4. Walk through the debug registers listed in Debug registers to save over powerdown, and restore the values from the nonvolatile storage. The last register to be restored must be MDSCR_EL1.
5. Execute an `ISB` instruction.
6. Unlock the OS Lock by writing 0 to OSLAR_EL1.OSLK.
7. Execute a Context Synchronization event.

Note

The OS Restore sequence overwrites the debug registers with the values that were saved. If there are valid values in these registers immediately before the restore sequence, then those values are lost.

E6.6.7 Debug behavior when the OS Lock is locked

The main purpose of the OS Lock is to prevent updates to debug registers during an OS Save or OS Restore operation. The OS Lock is locked on a Cold reset.

When the OS Lock is locked:

- Access to debug registers through the System register interface is mainly unchanged except that:
  - Certain registers are read and written without side-effects.
  - Fields in MDSCR_EL1, Monitor Debug System Control Register and OSECCR_EL1, OS Lock Exception Catch Control Register that are normally read-only become read/write.

  This allows the state to be saved or restored. For more information, see the relevant register description in External Debug Register Descriptions.
- Access to debug registers by the external debug interface is restricted to prevent an external debugger modifying the registers that are being saved or restored. For more information, see External debug interface register access permissions summary.
- Debug exceptions, other than Breakpoint Instruction exceptions are not generated.
- Breakpoint and Watchpoint debug events are not generated. The OS Lock has no effect on Breakpoint Instruction exceptions and other debug events.

E6.6.8 Debug behavior when the OS Lock is unlocked

When the OS Lock is unlocked, the PE sets EDESR.OSUC to 1 if the OS Unlock Catch debug event is enabled and the PE is in Non-debug state, meaning the OS Unlock Catch debug event becomes pending. See OS Unlock Catch debug event.

E6.6.9 Debug behavior when the OS Double Lock is locked

If the FEAT_DoubleLock is implemented, software locks the OS Double Lock immediately before a powerdown sequence.

The OS Double Lock ensures that it is safe to remove core power by forcing the debug interfaces to be quiescent.

When `DoubleLockStatus()` == TRUE:

Non-Confidential

- The external debug interface has only restricted access to the debug registers, so that it is quiescent before removing power. See External debug interface register access permissions summary.
- Debug exceptions, other than Breakpoint Instruction exceptions, are not generated.
- Halting is prohibited. See Halting allowed and halting prohibited.

Note

Pending Halting debug events might be lost when core power is removed.

- No asynchronous debug events are `WF*` wakeup events.

If the FEAT_DoubleLock is not implemented, the PE ensures these conditions are met before allowing power to be removed.

Software must synchronize the update to OSDLR_EL1, OS Double Lock Register before it indicates to the system that core power can be removed. The interface between the PE and its power controller is IMPLEMENTATION DEFINED.

Typically software indicates that core power can be removed by entering the Wait For Interrupt state. This means that software must explicitly synchronize the OSDLR_EL1, OS Double Lock Register update before issuing the `WFI` instruction.

OSDLR_EL1, OS Double Lock Register.DLK is ignored and `DoubleLockStatus()` == FALSE if either:

- The PE is in Debug state.
- DBGPRCR_EL1, Debug Power Control Register.CORENPDRQ is set to 1.

Note

It is possible to enter Debug state with OSDLR_EL1, OS Double Lock Register.DLK set to 1. This is because a Context Synchronization event is required to ensure the OS Double Lock is locked, meaning that Debug state might be entered before the OSDLR_EL1, OS Double Lock Register update is synchronized.

Because OSDLR_EL1, OS Double Lock Register.DLK is ignored when DBGPRCR_EL1, Debug Power Control Register.CORENPDRQ is set to 1, an external debugger can write to DBGPRCR_EL1, Debug Power Control Register.CORENPDRQ, and the FEAT_DoubleLock is not always implemented, software must not rely on using the OS Double Lock to disable debug exceptions or to prohibit halting, or both. Arm deprecates use of the OS Double Lock for these purposes, and instead recommends that software:

- Uses the OS Lock to disable debug exceptions during save or restore sequences.
- Uses the debug authentication interface to prohibit halting and external debug access to debug registers at times other than immediately prior to removing power.

As the purpose of the OS Double Lock is to ensure that it is safe to remove core power, if the FEAT_DoubleLock is implemented, it is important to avoid race conditions that defeat this purpose. Arm recommends that:

- Once the write to OSDLR_EL1, OS Double Lock Register.DLK has been synchronized by a Context Synchronization event and `DoubleLockStatus()` == TRUE, a PE must:
  - Not allow a debug event generated before the Context Synchronization event to cause an entry to Debug state or act as a wakeup event for a `WFI` or `WFE` instruction after the Context Synchronization event has completed.
  - Complete any external debug access started before the Context Synchronization event by the time the Context Synchronization event completes.

    Note

    A debug register access might be in progress when software sets OSDLR_EL1, OS Double Lock Register.DLK to 1. An implementation must not permit the synchronization of locking the OS Double Lock to stall indefinitely while waiting for that access to complete. This means that any debug register access that is in progress when software sets OSDLR_EL1, OS Double Lock Register.DLK to 1 must complete or return an error in finite time.

- If a write to DBGPRCR_EL1, Debug Power Control Register or EDPRCR made when OSDLR_EL1, OS Double Lock Register.DLK == 1 changes DBGPRCR_EL1, Debug Power Control Register.CORENPDRQ or

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

EDPRCR.CORENPDRQ from 1 to 0, meaning `DoubleLockStatus()` changes from FALSE to TRUE, then before signaling to the system that the CORENPDRQ field has been cleared and emulation of powerdown is no longer requested, meaning the system can remove core power, the PE must ensure that all the requirements for `DoubleLockStatus()` == TRUE listed in this section are met.

In a standard OS Save sequence, the OS Lock is locked before the OS Double Lock is locked. This means that writes to CORENPDRQ are ignored by the time the OS Double Lock is locked. However, if `DoubleLockStatus()` == FALSE, an external debugger can clear the OS Lock at any time, and then write to EDPRCR.

E6.7 Reset and debug

All registers in the Core power domain are either:

- Reset by both a Cold and a Warm reset.
- Reset only by a Cold reset and are not changed by a Warm reset.

For more information, see Resets and power domains.

All registers in the Debug power domain are reset by an External Debug reset.

If FEAT_SPMU is implemented, the reset signals for a System PMU are IMPLEMENTATION DEFINED.

Figure E6-1 shows this reset scheme. The following three reset signals are an example implementation of the reset scheme:

- **CORERESET**, which must be asserted for a Warm reset.
- **CPUPORESET**, which must be asserted for a Cold reset.
- **PRESETDBG**, which must be asserted for an External Debug reset.

As shown in the figure, the external debug logic is split between the Debug power domain and the Core power domain.

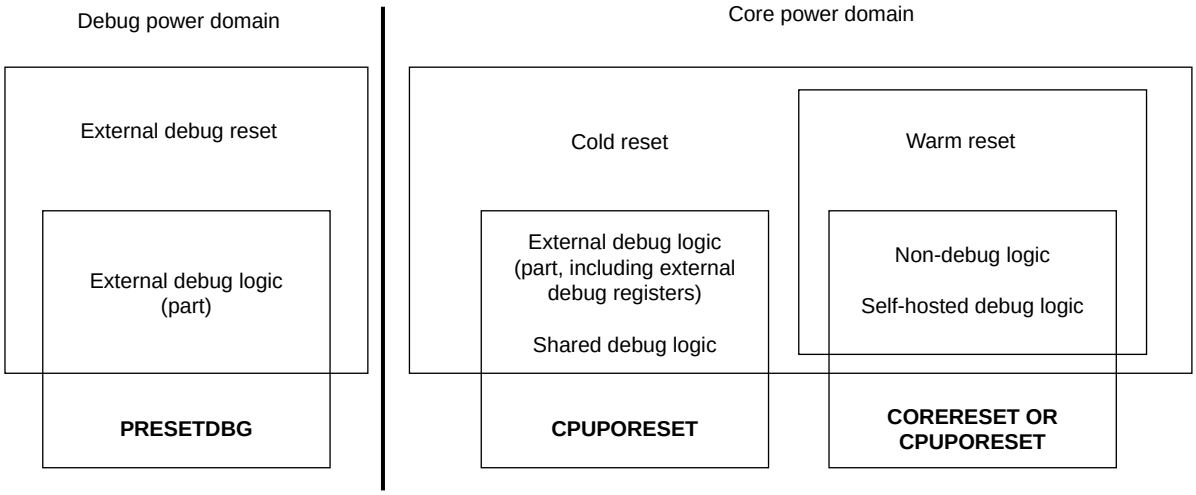

Figure E6-1 Power and reset domains

For more information about power domains and power states, see Power domains and debug.

When power is first applied to the Debug power domain, **PRESETDBG** must be asserted.

When power is first applied to the Core power domain, **CPUPORESET** must be asserted.

Note

In this scheme, logic in the Warm reset domain is reset by asserting either **CORERESET** or **CPUPORESET**. This implies a particular implementation style that permits these approaches.

CPUPORESET is not normally asserted on moving from a low-power state, where power has not been removed, to a full-power state. This can occur, for example, on exiting a low-power retention state. See also Emulating low-power states and the EDPRSR register description.

E6.7.1 External debug interface accesses to registers in reset

If a reset signal is asserted and the external debug interface:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- Writes a register, or indirectly writes a register or register field as a side-effect of an access:
  - Then, if the register or register field is reset by that reset signal, it is CONSTRAINED UNPREDICTABLE whether the register or register field takes the reset value or the value written. The reset value might be UNKNOWN.
  - Otherwise, the register or register field takes the value that is written.
- Reads a register, or indirectly reads a register or register field, as part of an access:
  - Then, if the register or register field is reset by that reset signal, the value returned in UNKNOWN.
  - Otherwise, the value of the register or register field is returned.

It is IMPLEMENTATION DEFINED whether any register can be accessed when External Debug reset is being asserted. The result of these accesses is IMPLEMENTATION DEFINED.

Chapter E7
The PC Sample-based Profiling Extension

This chapter describes the OPTIONAL PC Sample-based Profiling Extension that provides a non-invasive external debug component.

It contains the following section:

- About the PC Sample-based Profiling Extension.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

E7.1 About the PC Sample-based Profiling Extension

The PC Sample-based Profiling Extension is an OPTIONAL extension that provides coarse-grained, non-invasive profiling by an external debugger. See also Non-invasive behavior.

When the PC Sample-based Profiling Extension is implemented, the PE implements a PC sample register and one or more context sample registers as external registers. Reads of the PC sample register return a PC sample value and capture the PE context in the context sample registers. For example, tools can use these samples to populate a statistical model of the performance of software executing on the PE.

Note

Data returned by periodic sampling of PC Sample-based Profiling registers is sufficient to allow tools to estimate the distribution of time spent executing software on the PE.
The delay between an instruction being executed by the PE and its address appearing in the PC Sample Register is not defined, and the architecture does not require that the sampled instruction was recently executed. For example, if a piece of software executes a load instruction that reads the PC Sample Register of the PE it is running on, there is no guaranteed relationship between the address of the load instruction and the value read. The PC Sample Register is intended only for use by an external agent to provide statistical information for software profiling.

It must be possible to sample references to branch targets. It is IMPLEMENTATION DEFINED whether references to other instructions can be sampled. The branch target for a conditional branch instruction that fails its condition check is the instruction that follows the conditional branch instruction. The branch target for an exception is the exception vector address.

Note

In the Armv7 PC Sample-based Profiling Extension, an offset was applied to the sampled Program Counter value and this offset and the instruction set state indicated in bits [1:0] of the sampled value. From the introduction of the Armv8 PC Sample-based Profiling Extension, the sampled value is the address of an instruction that has executed, with no offset and no indication of the instruction set state.

- Controlling the PC Sample-based Profiling Extension.
- Registers implemented by the PC Sample-based Profiling Extension.
- Permitted behavior that might make the PC Sample-based profiling registers UNKNOWN.
- Pseudocode description of PC Sample-based Profiling.

E7.1.1 Controlling the PC Sample-based Profiling Extension

PC Sample-based Profiling is controlled by the IMPLEMENTATION DEFINED authentication interface `ExternalNoninvasiveDebugEnabled()`.

PC Sample-based Profiling is allowed if both of the following apply:

- `ExternalNoninvasiveDebugEnabled()` == TRUE.
- `ExternalSecureNoninvasiveDebugEnabled()` == TRUE.

The state of the IMPLEMENTATION DEFINED authentication interface is visible through DBGAUTHSTATUS_EL1. See Recommended authentication interface.

E7.1.1.1 Suspending and activating PC Sample-based Profiling

The state of PC Sample-based Profiling at Warm reset is an IMPLEMENTATION DEFINED one of suspended or active.

When all of the following apply, reading PMPCSR[31:0] or PMPCSR[63:0] makes PC Sample-based Profiling active:

- PC Sample-based Profiling is suspended.
- PC sampling is allowed.

A subsequent external read of PMPCSR will observe the updated state.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

There is no mechanism to return to suspended state, other than Warm reset.

E7.1.2 Registers implemented by the PC Sample-based Profiling Extension

If FEAT_PCSRv8p2 is implemented and the 64-bit external PMU programmers' model extension is not implemented, the following PC Sample-based Profiling Extension registers can be implemented in the Performance Monitors memory-mapped register space:

- PMCID1SR and PMCID2SR.
- PMPCSR.
- PMVIDSR.

When the 64-bit external PMU programmers' model extension is implemented, the PC Sample-based Profiling Extension registers are:

- PMCCIDSR.
- PMPCSR.
- PMVCIDSR.

See Performance Monitors external register views.

If FEAT_PCSRv8p2 is implemented but the Performance Monitors Extension is not implemented, then the PC Sample-based Profiling Extension registers are implemented in their own memory-mapped register space, within the area that is reserved for the Performance Monitors, see Table E7-1. If CoreSight compliance is required:

- The management registers are defined as in The Arm® Architecture Reference Manual, for A-profile architecture.
- The support for PC Sample-based profiling is defined in the following registers:
  - PMDEVTYPE.MAJOR has the value `0x0`.
  - PMDEVARCH.ARCHID has the value `0x0A10` or `0x0A20`.

For more information, see PMDEVARCH.

Table E7-1 PC Sample-based Profiling register map without the Performance Monitors Extension

Offset	Description
`0x200`	PMPCSR[31:0]
`0x204`	PMPCSR[63:32]
`0x208`	PMCID1SR
`0x20C`	PMVIDSR
`0x220`	PMPCSR[31:0] (alias)
`0x224`	PMPCSR[63:32] (alias)
`0x228`	PMCID1SR (alias)
`0x22C`	PMCID2SR
`0x600-0x6FC`	IMPLEMENTATION DEFINED
`0xE80-0xEFC`	IMPLEMENTATION DEFINED for CoreSight compliance
`0xFF0-0xFFc`	Management and CoreSight compliance registers

Non-Confidential

E7.1.3 Permitted behavior that might make the PC Sample-based profiling registers UNKNOWN

The architecture permits IMPLEMENTATION DEFINED extensions to external debug to define mechanisms that make the values of the PC Sample-based profiling registers UNKNOWN. However, it requires that any such mechanism is disabled by default. This means that powerup or a hard reset of the PE must leave the PE in a state where the PC Sample-based Profiling Extension, if implemented, exhibits its architecturally-defined behavior.

Note

A mechanism that, when enabled, makes the PC Sample-based profiling registers UNKNOWN might use other sample-based profiling events that are appropriate for a use that is independent of PC Sample-based Profiling.

If no branch instruction has been retired since the PE left Debug state, suspended state, or a state where PC Sample-based profiling is prohibited, then the sampled value is UNKNOWN.

If all of the following apply, then a read of PMPCSR[31:0] or PMPCSR[63:0] is permitted but not required to return `0xFFFF_FFFF` for PMPCSR[31:0].

- The PE has not retired any branch instruction since leaving a state where PC Sample-based Profiling was suspended.
- Sampling on reads is not disabled.

This includes a read of PMPCSR[31:0] or PMPCSR[63:0] that indirectly makes PC Sample-based Profiling active.

E7.1.4 Pseudocode description of PC Sample-based Profiling

When FEAT_PCSRv8p2 is implemented, the functionality is described by the pseudocode functions:

- `CreatePCSample()`, which populates a variable of type `PCSample`.
- `Read_PMPCSR[]`, which writes a PC Sample to the PMPCSR and associated registers.

E8.2 Endianness and supported access sizes

The debug registers, Performance Monitors registers, and CTI registers are implemented as memory-mapped peripherals. The Arm architecture requires memory-mapped peripherals to be little-endian.

The memory access sizes supported by any peripheral is IMPLEMENTATION DEFINED by the peripheral. For accesses to the debug registers, Performance Monitors registers, and CTI registers, implementations must:

- Comply with the requirements of Supported access sizes.
- Support word-aligned 32-bit accesses to access 32-bit registers or either half of a 64-bit register mapped to a doubleword-aligned pair of adjacent 32-bit locations, even if all components with direct memory access to the memory-mapped peripheral support making 64-bit accesses.

Note

These requirements mean that a system implementing the debug registers using a 32-bit bus, such as an AMBA APB3, with a wider system interconnect must implement a bridge between the system and the debug bus that can split 64-bit accesses.

For accesses from the external debug interface, the size of an access is determined by the interface. For an access from an ADIv5-compliant Memory Access Port, MEM-AP, this is specified by the MEM-AP CSW register.

E8.3 Synchronization of changes to the external debug registers

This section describes the synchronization requirements for the external debug interface.

For more information on how these requirements affect debug, see:

- Synchronization and debug exceptions for exceptions taken from AArch64 state.
- Synchronization and Halting debug events.
- Synchronization of DCC and ITR accesses.

This section refers to accesses from the external debug interface as external reads and external writes. It refers to accesses to System registers as direct reads, direct writes, indirect reads, and indirect writes.

Note

Synchronization requirements for AArch64 System registers define direct read, direct write, indirect read, and indirect write, and classifies external reads as indirect reads, and external writes as indirect writes.

For general information about synchronization, access completion, ordering, and observability, see Synchronization of memory-mapped registers.

Writes to the same register are serialized, meaning they are observed in the same order by all observers, although some observers might not observe all of the writes. With the exception of DBGBCR<n>_EL1, DBGBVR<n>_EL1, DBGWCR<n>_EL1, and DBGWVR<n>_EL1, external writes to different registers are not necessarily observed in the same order by all observers as the order in which they complete.

Synchronization of DCC and ITR accesses describes the synchronization requirements for the DCC and ITR.

Changes to the IMPLEMENTATION DEFINED authentication interface are external writes to the authentication status registers by the Requester of the authentication interface. See Synchronization and the authentication interface.

The external agent must be able to guarantee completion of a write. For example by:

- Marking the memory as Device-nGnRnE and executing a `DSB` barrier, if the system supports this property.
- Reading back the value written.
- Some guaranteed property of the connection between the PE and the external agent.

Note

For an external Debug Access Port, access completion is an IMPLEMENTATION DEFINED property. For a CoreSight system using APB-AP to access a debug APB, accesses complete in order.

However, the external agent cannot force synchronization of completed writes without halting the PE. Executing an `ISB` instruction, either in Debug state or in Non-debug state, and exiting from Debug state forces synchronization. If the PE is in Debug state, executing an `ISB` instruction is guaranteed to explicitly synchronize any external reads, external writes, and changes to the authentication interface that are ordered before the external write to EDITR.

For any given observer, external writes to the following register groups are guaranteed to be observable in the same order in which they complete:

- The breakpoint registers, DBGBCR<n>_EL1 and DBGBVR<n>_EL1.
- The watchpoint registers, DBGWCR<n>_EL1 and DBGWVR<n>_EL1.

This guarantee applies only to external writes to registers within one of these groups. There is no guarantee regarding the ordering of the observability of external writes within these groups with respect to external writes to registers, for example EDSCR, or between breakpoints and watchpoints, including watchpoints linked to context matching breakpoints.

Note

This means that a debugger can rely on the external writes to be observed in the same order in which they complete. It does not mean that a debugger can rely on the external writes being observed in finite time.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

In a simple sequential execution an indirect write that occurs as a side-effect of an access happens atomically with the access, meaning no other accesses are allowed between the register access and its side-effect.

If two or more interfaces simultaneously access a register, the behavior must be as if the accesses occurred atomically and in any order. This is described in Examples of the synchronization of changes to the external debug registers.

Note

Where simultaneous writes occur, once an order has been established by the implementation, some registers have behavior that is incompatible with the implementation simply dropping the older write and only performing the actions of the younger write. In these cases, the implementation must ensure that the register update is consistent with both writes having occurred. For example, writing one to write-one-to-clear or write-one-to-set fields in the older write can produce effects that persist even after writing zero to the same field in the younger write. Examples of registers with this behavior include DBGCLAIMSET_EL1, DBGCLAIMCLR_EL1, PMCR_EL0, PMOVSSET_EL0, PMOVSCLR_EL0, PMCNTENSET_EL0, PMCNTENCLR_EL0, PMINTENSET_EL1, PMINTENCLR_EL1, PMSWINC_EL0, and PMZR_EL0, all of which are simultaneously accessible via external debug and System register access.

E8.3.1 Synchronization and the authentication interface

Changes to the authentication interface are indirect writes to the state of the PE by the Requester of the authentication interface.

For an external debug interface read of any Authentication Status register, or an indirect read of the authentication interface made in determining the response to a subsequent external debug interface access, a change on the authentication interface must be observable following a subsequent explicit Context Synchronization event, and:

- It is IMPLEMENTATION DEFINED whether a change is guaranteed to be observable in finite time.
- It is IMPLEMENTATION DEFINED whether a change is guaranteed to be observable following an entry to Debug state.

For a System register read of DBGAUTHSTATUS_EL1, a change on the authentication interface is guaranteed to be observable only after a Context Synchronization event.

Note

- In some systems, the authentication interface is fixed by configuration or is changed under the control of software. These systems can require explicit synchronization for any change to the authentication interface.
- In other systems, the authentication interface is controlled dynamically by an external agent. In these systems, it is desirable that changes to the authentication interface do not require explicit synchronization by software executing on the PE to be observable by subsequent external debug interface accesses, and are either observable in finite time or are synchronized by entry to Debug state. Otherwise, there are scenarios where a debugger is not able to halt and debug the system.

E8.3.2 Examples of the synchronization of changes to the external debug registers

Example E8-1, Example E8-2, and Example E8-3 show the synchronization of changes to the external debug registers.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Example E8-1 Order of synchronization of Breakpoint and Watchpoint register writes

Initially DBGBVR<n>_EL1 is `0x8000` and DBGBCR<n>_EL1 is `0x0181`. This means that a breakpoint is enabled on the halfword T32 instruction at address `0x8000`.
A sequence of external writes occurs in the following order:

1. `0x0000` is written to DBGBCR<n>_EL1, disabling the breakpoint.
2. `0x9000` is written to DBGBVR<n>_EL1[31:0].
3. `0x0061` is written to DBGBCR<n>_EL1, enabling a breakpoint on the halfword at address `0x9002`.

The external writes must be observable to indirect reads in the same order as the external writes complete. This means that at no point is there a breakpoint enabled on either of the halfwords at address `0x8002` and `0x9000`. Similarly a breakpoint or watchpoint must be disabled:

- If both halves of a 64-bit address have to be updated.
- If any of the DBGBCR<n>_EL1 or DBGWCR<n>_EL1 fields are modified at the same time as updating the address.

Example E8-2 Simultaneous accesses to DTR registers

Initially EDSCR.{TXfull, TXU, ERR} are 0. Then:

- `0x0DCCDA7A` is directly written to DBGDTRTX_EL0 by an `MSR` instruction.
- DBGDTRTX_EL0 is indirectly read by the external debug interface.

These accesses might happen at the same time and in any order.
If the direct write of `0x0DCCDA7A` to DBGDTRTX_EL0 is handled first, then:

- The external debug interface read of DBGDTRTX_EL0 clears EDSCR.TXfull to 0.
- EDSCR.{TXU, ERR} are unchanged.
- The external debug interface read returns `0x0DCCDA7A`.

If the indirect read of DBGDTRTX_EL0 by the external debug interface is handled first, then:

- The external debug interface read of DBGDTRTX_EL0 causes an underrun and as a result EDSCR.{TXU, ERR} are both set to 1.
- The external debug interface returns an UNKNOWN value.
- Writing `0x0DCCDA7A` to DBGDTRTX_EL0 sets DTRTX to `0x0DCCDA7A` and EDSCR.TXfull to 1.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Example E8-3 Simultaneous writes to CLAIM registers

Initially all CLAIM tag bits are 0. Then:

- `0x01` is written to DBGCLAIMSET_EL1 by a direct write, followed by an explicit Context Synchronization event.
- `0x02` is written to DBGCLAIMSET_EL1 by an external write.

These events might happen at the same time and in either order.
After this:

- DBGCLAIMCLR_EL1 is read by a direct read.
- DBGCLAIMCLR_EL1 is read by an external read.

In this case, a direct read can return either `0x01` or `0x03`, and the external read can return either `0x02` or `0x03`.
The only permitted final result for the CLAIM tags is the value `0x03`, because this would be the result regardless of whether `0x01` or `0x02` is written first. This is because the external write is guaranteed to be observable to a direct read in finite time. See Synchronization requirements for AArch64 System registers.
It is not possible for a direct read to return `0x01` and the external read to return `0x02`, because the writes to DBGCLAIMCLR_EL1 are serialized.
In the following scenario, there is only one permitted result. Both observers observe the value `0x03`, and then, at the same time, two writes occur:

- `0x04` is written to DBGCLAIMSET_EL1 by a direct write, followed by an explicit Context Synchronization event.
- `0x01` is written to DBGCLAIMCLR_EL1 by an external write.

In this case, the only permitted final result for the CLAIM tags is the value `0x06`.

E8.4 Memory-mapped accesses to the external debug interface

Support for memory-mapped access to the external debug interface is OPTIONAL. When memory-mapped access to the external debug interface is supported, the external debug interface is accessed as a little-endian memory-mapped peripheral.

If the external debug interface is CoreSight compliant, then an OPTIONAL Software Lock can be implemented for memory-mapped accesses to each component.

The Software Lock is OPTIONAL and deprecated. If FEAT_Debugv8p4 is implemented, the Software Lock is not implemented. If it is not implemented, the behavior is as if it is unlocked. The Software Locks are controlled by EDLSR and EDLAR, PMLSR and PMLAR, and CTILSR and CTILAR. See Management registers and CoreSight compliance.

If FEAT_DoPD is implemented, Software Lock is not implemented by the architecturally-defined debug components in the Core power domain.

With the exception of these registers and the effect of the Software Lock, the behavior of the memory-mapped accesses is the same as for other accesses to the external debug interface.

Note

The recommended memory-mapped accesses to the external debug interface are not compatible with the memory-mapped interface defined in Armv7. In particular:

- The memory map is different.
- Memory-mapped accesses do not behave differently to Debug Access Port accesses when OSLSR_EL1, OS Lock Status Register.OSLK == 1, meaning that the OS Lock is locked.

The following sections give more information about these memory-mapped accesses:

- Register access permissions for memory-mapped accesses.
- Synchronization of memory-mapped accesses to external debug registers.

See also Supported access sizes.

E8.4.1 Register access permissions for memory-mapped accesses

It is IMPLEMENTATION DEFINED whether unprivileged memory-mapped accesses are allowed. Privileged software is responsible for controlling memory-mapped accesses using the MMU.

If FEAT_Debugv8p4 is implemented, the Security state view of a debug component is mapped into the physical memory for that Security state.

If FEAT_Debugv8p4 is implemented, the access permissions are different in each Security state, but Secure and Non-secure views of the debug components are identical. Arm recommends the views are located at the same address in the Secure and Non-secure physical address maps.

If memory-mapped accesses are made through an ADIv5 interface, the Debug Access Port can block the access using DBGSWENABLE. This is outside the scope of the Arm architecture. See *Arm® Debug Interface Architecture Specification ADIv5.0 to ADIv5.2*.

E8.4.1.1 Effect of the OPTIONAL Software Lock on memory-mapped access

For memory-mapped accesses, if other controls permit access to a register, the OPTIONAL Software Lock is implemented, and EDLSR.SLK, PMLSR.SLK, or CTILSR.SLK is set to 1, meaning the Software Lock is locked, then with the exception of the LAR itself:

- If other controls permit access to a register, then writes are ignored. That is:
  - Read/write (RW) registers become read-only, writes ignored (RO/WI).
  - Write-only (WO) registers become writes ignored (WI).

- Reads and writes have no side-effects. A side-effect is where a direct read or a direct write of a register creates an indirect write of the same or another register. When the Software Lock is locked, the indirect write does not occur.
- Writes to EDLAR, PMLAR, and CTILAR are unaffected.

This behavior must also apply to all IMPLEMENTATION DEFINED registers.

For example, if EDLSR.SLK is set to 1:

- EDSCR.{TXfull, TXU, ERR} are unchanged by a memory-mapped read from DBGDTRTX_EL0.
- EDSCR.{RXfull, RXO, ERR} are unchanged by a memory-mapped write to DBGDTRRX_EL0 that is ignored.
- EDSCR.{ITE, ITO, ERR} are unchanged by a memory-mapped write to EDITR that is ignored.
- OSLSR_EL1, OS Lock Status Register.OSLK is unchanged by a memory-mapped write to OSLAR_EL1 that is ignored.
- EDPCSR[63:32], EDCIDSR, and EDVIDSR are unchanged by a memory-mapped read from EDPCSR[31:0].

  Note

  Updating EDVIDSR, EDCIDSR, and EDPCSRhi are side-effects of reading EDPCSRlo, such that these registers contain the matching context for EDPCSRlo. The process that updates EDPCSRlo with PC samples is not a side-effect of the access. Reads of EDPCSRlo made when the Software Lock is locked can be used to profile software.

- PMPCSR[63:32], PMCID1SR/PMCID2SR, and PMVIDSR are unchanged by a memory-mapped read from PMPCSR[31:0].

  Note

  Updating PMVIDSR, PMCID1SR/PMCID2SR, and PMPCSR[31:0] are side-effects of reading PMPCSR[63:32], such that these registers contain the matching context for PMPCSR[63:32]. The process that updates PMPCSR[63:32] with PC samples is not a side-effect of the access. Reads of PMPCSR[63:32] made when the Software Lock is locked can be used to profile software.

- EDPRSR.{SDR, SPMAD, SDAD, SR, SPD} are unchanged by a memory-mapped read from EDPRSR.
- EDPRSR.SDAD is not set if an error response is returned due to a memory-mapped read or write of any debug register as the result of the value of the EDAD field.
- The CLAIM tags are unchanged by memory-mapped writes to DBGCLAIMSET_EL1 and DBGCLAIMCLR_EL1 which are ignored.

Similarly, if PMLSR.SLK is set to 1, then EDPRSR.SPMAD is not set if an error response is returned to a memory-mapped read or write of any Performance Monitors register due to the value of the EPMAD field.

E8.4.1.2 Behavior of a not permitted memory-mapped access

Where the architecture requires that an external debug interface access generates an error response, a memory-mapped access must also generate an error response. However, it is IMPLEMENTATION DEFINED how the error response is handled, as this depends on the system.

Arm recommends that the error is returned as either:

- A synchronous external Data Abort.
- An SError exception.

E8.4.2 Synchronization of memory-mapped accesses to external debug registers

The synchronization requirements for memory-mapped accesses to the external debug interface is described in Synchronization of changes to the external debug registers and Synchronization of memory-mapped registers.

The synchronization requirements between different routes to the external debug interface, that is, between Debug Access Port accesses and memory-mapped accesses are IMPLEMENTATION DEFINED.

E8.5 External debug interface register access permissions

Some external accesses to debug registers and Performance Monitor registers are not permitted and return an error response if:

- The Core power domain is powered down or is in low-power state where the registers cannot be accessed.
- OSLSR_EL1, OS Lock Status Register.OSLK == 1. The OS Lock is locked.
- FEAT_DoubleLock is implemented and `DoubleLockStatus()` == TRUE. The OS Double Lock is locked.
- The access is disabled by either the authentication interface or secure monitor.

Not all registers are affected in all of these cases. For more information, see External debug interface register access permissions summary.

E8.5.1 External debug over powerdown and locks

Accessing registers using the external debug interface is not possible when the Debug power domain is off. In this case, all accesses return an error.

External accesses to debug and Performance Monitors registers in the Core power domain are not permitted and return an error response if:

- The Core power domain is off or in low-power state where the registers cannot be accessed.
- OSLSR_EL1, OS Lock Status Register.OSLK == 1, meaning that the OS Lock is locked. This allows software to prevent external debugger modification of the registers while it saves and restores them over powerdown.
- FEAT_DoubleLock is implemented and `DoubleLockStatus()` == TRUE. This means that the OS Double Lock is locked. The OS Double Lock ensures that it is safe to remove Core power by forcing the debug interface to be quiescent.

If FEAT_DoubleLock is not implemented, the hardware must provide another method to safely remove Core power.

The OS Lock condition does not apply to the following debug registers:

- OSLAR_EL1. This means that an external debugger can override this lock.
- EDESR. This means that an external debugger can program a debug event for when software unlocks the OS Lock. See OS Unlock Catch debug event.
- The ID registers that describe the PE to the debugger.

See also Debug registers to save over powerdown.

E8.5.2 External access disabled

Accesses are further controlled by the external authentication interface. An untrusted external debugger cannot program the breakpoint and watchpoint registers to generate spurious debug exceptions. If external invasive debugging is not enabled, these external accesses to the registers are disabled.

The disable applies to:

- The DBGBVR<n>_EL1, DBGBCR<n>_EL1, DBGWVR<n>_EL1, and DBGWCR<n>_EL1 registers.
- From Armv8.2, the OSLAR_EL1 register.

If FEAT_Debugv8p4 is implemented, accesses from the external debug interface to these registers are not permitted if any of the following are true:

- The PE behaves as if the Security state is Secure, and the access is Non-secure.
- The access is not permitted by [**multi:sdcr?**].EDAD.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The `AllowExternalDebugAccess()` pseudocode function describes these accessibility rules.

PEs might also provide an OPTIONAL external debug interface to the Performance Monitor registers. The authentication interface and [**multi:sdcr?**] provide similar external access disable controls for those registers.

Note

Arm recommends that Secure software that is not making use of debug hardware does not lock out the external debug interface.

The `AllowExternalPMUAccess()` pseudocode function describes these accessibility rules.

E8.5.3 Behavior of a not permitted access

For an external debug interface access by a Debug Access Port, the Debug Access Port receives the error response and must signal this to the external debugger. For an ADIv5 implementation of a Debug Access Port, the error sets a sticky error flag in the Debug Access Port that the debugger can poll, and that suppresses further accesses until it is explicitly cleared.

When an error is returned because external access is disabled, and this is the highest priority error condition, a sticky error flag in EDPRSR is indirectly written to 1 as a side-effect of the access:

- For a debug register access when `AllowExternalDebugAccess()` == FALSE, EDPRSR.SDAD is indirectly written to 1.
- For Performance Monitor register access when `AllowExternalPMUAccess()` == FALSE, EDPRSR.SPMAD is indirectly written to 1.

The indirect write might not occur for a memory-mapped access to the external debug interface. For more information, see Register access permissions for memory-mapped accesses.

If no error is returned, or the error is returned because of a higher priority error condition, the flag in EDPRSR is unchanged.

See also Behavior of a not permitted memory-mapped access.

For more information, see *Arm® Debug Interface Architecture Specification*.

E8.5.4 External debug interface register access permissions summary

For accesses to:

- IMPLEMENTATION DEFINED registers, see IMPLEMENTATION DEFINED registers.
- OPTIONAL registers for CoreSight compliance, see Arm® Architecture Reference Manual, for A-profile architecture.
- Reserved, unallocated, or unimplemented registers, writes to read-only registers, and reads of write-only registers, see Reserved and unallocated registers.

For all other external debug interface, CTI, and Performance Monitor registers, Table E8-3, Table E8-4, Table E8-6 and Table F3-1, show the response of the PE to accesses by the external debug interface.

E8.5.5 IMPLEMENTATION DEFINED registers

Register access permissions for IMPLEMENTATION DEFINED debug, Performance Monitors, and CTI registers are IMPLEMENTATION DEFINED, other than as follows:

- If FEAT_DoPD is implemented, then all of the following apply:
  - All debug and Performance Monitors registers, including IMPLEMENTATION DEFINED registers, are implemented in the Core power domain and accesses return an error when the Core power domain is off or in a low-power state.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

  - CTI registers, including IMPLEMENTATION DEFINED registers, are implemented in the Debug power domain.
- When memory-mapped access to the external debug interface is supported, the additional constraints in Register access permissions for memory-mapped accesses apply to IMPLEMENTATION DEFINED registers.

E8.5.6 Reserved and unallocated registers

The default access requirements for reserved and unallocated registers are described in Access requirements for reserved and unallocated registers.

Note

Reads of WO and writes to RO refers to the default access permissions for a register. For example, when the SLK field is 1, meaning that the relevant registers become RO, a memory-mapped write to a RW register is ignored, and not treated as a reserved access.

The following reserved registers are RES0 in all conditions, other than when debug power is off:

- All reserved CTI registers.
- For the debug registers, and Performance Monitors registers, if the implementation is CoreSight architecture compliant, and either FEAT_DoPD is not implemented or the Core power domain is on, all reserved registers in the range `0xF00 - 0xFFC`. See Management register access permissions.

Otherwise, the architecture defines that:

1. If debug power is off, all register accesses, including reserved accesses, return an error.
2. For reserved debug registers and Performance Monitors registers, if FEAT_DoPD is implemented, and the Core power domain is off or in a low-power state, the response is an error. Otherwise, the response is a CONSTRAINED UNPREDICTABLE choice of error or RES0, when any of the following hold:

   Off The Core power domain is either completely off or in a low-power state in which the Core power domain registers cannot be accessed.

   DLK FEAT_DoubleLock is implemented and `DoubleLockStatus()` == TRUE. The OS Double Lock is locked.

   OSLK OSLSR_EL1, OS Lock Status Register.OSLK == 1. The OS Lock is locked.
3. In addition, for reserved debug registers in the address ranges `0x400 - 0x4FC` and `0x800 - 0x8FC`, the response is a CONSTRAINED UNPREDICTABLE choice of error or RES0 when conditions 1 or 2 do not apply and:

   EDAD `AllowExternalDebugAccess()` == FALSE. External debug is disabled.

   Note

   See also Behavior of a not permitted access.
4. In addition, for reserved Performance Monitors registers in the address ranges `0x000 - 0xEFC`, the response is a CONSTRAINED UNPREDICTABLE choice of error or RES0 when conditions 1 or 2 do not apply and:

   EPMAD `AllowExternalPMUAccess()` == FALSE. External Performance Monitor access is disabled.

   Note

   See also Behavior of a not permitted access.
5. For reads of WO locations, the response is a CONSTRAINED UNPREDICTABLE choice of error or RES0 when the architecture permits or requires a write to the location to return an error.
6. For writes of RO locations, the response is a CONSTRAINED UNPREDICTABLE choice of error or RES0 when the architecture permits or requires a read to the location to return an error.
7. For reads and writes of locations for features that are not implemented, the response is a CONSTRAINED UNPREDICTABLE choice of error or RES0 when the architecture permits or requires an access to the location to return an error if the feature is implemented.

0xFFC	EDCIDR3	External Debug Component Identification Register 3	RO

E8.6.1 Access permissions for the External debug interface registers

Table E8-3 and Table E8-4 show the access permissions for the external debug interface registers in an Arm A-profile Debug implementation. The terms are defined as follows:

Domain This describes the power domain in which the register is logically implemented. Registers described as implemented in the Core power domain might be implemented in the Debug power domain, as long as they exhibit the required behavior.

If FEAT_DoPD is implemented, most External debug interface registers are in the Core power domain, as shown in Table E8-3.

If FEAT_DoPD is not implemented, most of the registers are in the Debug Power Domain, as shown in Table E8-4.

Conditions This lists the conditions under which the access is attempted.

To determine the access permissions for a register, read these columns from left to right, and stop at first column that lists the condition as being true.

The conditions are:

Off The Core power domain is completely off, or in low-power state. In these cases the Core power domain registers cannot be accessed, and if FEAT_DoPD is not implemented, EDPRSR.PU will read as 0.

Note

When the Core power domain is off, or in a low-power state, a debugger is permitted to access a debug register that is implemented in the external Debug power domain. When the Debug power domain is off, all accesses to the registers in the external Debug power domain return an error.

DLK FEAT_DoubleLock is implemented and `DoubleLockStatus()` == TRUE. The OS Double Lock is locked. If FEAT_DoPD is implemented, FEAT_DoubleLock is not implemented and so Table E8-3 does not include this column.

OSLK OSLSR_EL1, OS Lock Status Register.OSLK == 1. The OS Lock is locked.

EDAD `AllowExternalDebugAccess()` == FALSE. External debug access is disabled for the access. See also Behavior of a not permitted access.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

EPMAD `AllowExternalPMUAccess()` == FALSE. Access to the external Performance Monitors is disabled for the access. See also Behavior of a not permitted access.

SLK The Software Lock is implemented and `SoftwareLockStatus()` == TRUE. This provides the modified default access permissions for OPTIONAL memory-mapped accesses to the external debug interface if the OPTIONAL Software Lock is locked for the access. See Register access permissions for memory-mapped accesses. If FEAT_DoPD is implemented, the Software Lock is not locked or not implemented, then this column is ignored.

Default This provides the default access permissions, if there are no conditions that prevent access to the register.

The access permissions are:

- This means that the default access permission applies. See the Default column, or the SLK column, if applicable.

RO This means that the register or field is read-only, and:

- Unless the register description states otherwise, a RO field in an RW register ignores writes.
- Where the `SLK` control makes a RW register RO, the register ignores writes.

RW This means that the register or field is read/write. Individual fields within the register might be RO or WO. See the relevant register description for details.

RC This means that a read of the register bit clears the field to 0.

WO This means that the register or field is write-only. Unless the register description states otherwise, a WO field in a RW register returns an UNKNOWN value on a read of the register.

WI This means that the register or field ignores writes.

IMP DEF This means that the access permissions are IMPLEMENTATION DEFINED.

DBGBVR<n>_EL1 and DBGWVR<n>_EL1, and if FEAT_Debugv8p9 is implemented, DBGBCR<n>_EL1 and DBGWCR<n>_EL1, are 64-bit registers mapped to pairs of 32-bit locations in the external debug interface. Doubleword accesses to these register are not guaranteed to be 64-bit single copy atomic. Software must take care before altering the values of DBGBVR<n>_EL1, DBGWVR<n>_EL1, DBGBCR<n>_EL1, and DBGWCR<n>_EL1 to prevent UNPREDICTABLE behavior. See Endianness and supported access sizes for more information.

If OPTIONAL memory-mapped access to the external debug interface is supported, there might be additional constraints on memory-mapped accesses. See Register access permissions for memory-mapped accesses.

For the reset values for the external debug interface registers, see Table E8-7.

Table E8-3 Access permissions for the external debug interface registers if FEAT_DoPD is implemented

E8.7 Cross-trigger interface registers

The Embedded Cross-Trigger Interface, CTI, is located within its own block of the external debug memory map. There must be one such block for each PE.

If the CTI of a PE does not implement the CTIDEVAFF0 or CTIDEVAFF1 registers it must be located 64KB above the debug registers in the external debug interface.

When FEAT_Debugv8p4 is implemented, each debug component has a Secure and Non-secure view. The Secure view of a debug component is mapped into Secure physical memory and the Non-secure view of a debug component is mapped into Non-secure memory. Apart from access conditions, the Non-secure and Secure views of the debug components are identical.

Table E8-5 shows the CTI register map.

Table E8-5 Summary of the Embedded Cross-Trigger Interface, CTI, registers

Offset	Name	Description	Access
0x000	CTICONTROL	CTI Control register	RW
0x010	CTIINTACK	CTI Output Trigger Acknowledge register	WO
0x014	CTIAPPSET	CTI Application Trigger Set register	RW

E8.8 External debug register resets

Each register or field has a defined reset domain:

- Registers and fields in the Warm reset domain are also reset by a Cold reset and unchanged by an External Debug reset that is not coincident with a Cold reset or a Warm reset.
- Registers and fields in the Cold reset domain are unchanged by a Warm reset or an External Debug reset that is not coincident with a Cold reset.
- Registers and fields in the External Debug reset domain are unchanged by a Cold reset or a Warm reset that is not coincident with an External Debug reset.

A reset might change the value of a register. Specific rules apply to the observability of registers in the External Debug reset domain by indirect reads from the Core power domain when an External Debug reset is asserted without a coincident Cold reset. For more information, see Synchronization of changes to the external debug registers.

Table E8-2 and Table E8-5 show the external debug register and CTI register resets. For other debug registers, see Management register resets.

Note

By reference to Figure E6-1 the power domain can be deduced from the reset domain.

Table E8-2 and Table E8-5 do not include:

- Read-only identification registers, such as Processor ID Registers and PMCFGR, that have a fixed value from reset.
- Read-only status registers, such as EDSCR.RW, that are evaluated each time the register is read and that have no meaningful reset value.
- Write-only registers, such as EDRCR, that only have an effect on writes, and have no meaningful reset value.
- Read/write registers, such as breakpoint and watchpoint registers, and EDPRCR.CORENPDRQ, that alias other registers. The reset values are described by the descriptions of those other registers.
- IMPLEMENTATION DEFINED registers. The reset values and reset domains of these registers are also IMPLEMENTATION DEFINED and might be UNKNOWN.

All other fields in the registers are set to an IMPLEMENTATION DEFINED value that can be UNKNOWN. The register is in the specified reset domain.

Note

An IMPLEMENTATION DEFINED reset value, which can be UNKNOWN, means that hardware is not required to reset the register on the specified reset, but software must not rely on the register being preserved over reset.

Table E8-7 Summary of external debug register resets, debug registers

Register	Reset domain	Field	Value	Description
DBGPRCR_EL1	Cold into AArch64 state	CORENPDRQ	The value of the powerup request[a]	Debug Power Control Register.
EDESR, if FEAT_DoPD is not implemented	Warm	SS	EDECR.SS	Halting Step debug event pending
		RC	EDECR.RCE	Reset Catch debug event pending
		OSUC	0	OS Unlock Catch debug event pending
EDESR, if FEAT_DoPD is implemented	Cold	SS	0	Halting Step debug event pending
	Warm	RC	CTIDEVCTL.RCE	Reset Catch debug event pending

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Register	Reset domain	Field	Value	Description
		OSUC	0	OS Unlock Catch debug event pending
EDECR, if FEAT_DoPD is implemented	Cold	SS	0	Halting Step debug event enable
EDECR, if FEAT_DoPD is not implemented	External debug	SS	0	Halting Step debug event enable
		RCE	0	Reset Catch debug event enable
		OSUCE	0	OS Unlock Catch debug event enable
EDWAR	Cold	-	-	All fields
EDSCR	Cold	RXfull	0	DTRRX register full
		TXfull	0	DTRTX register full
		RXO	0	DTRRX overrun
		TXU	0	DTRTX underrun
		INTdis	0	Interrupt disable
		TDA	0	Trap debug register accesses to Debug state
		MA	0	Memory access mode in Debug state
		HDE	0	Halting debug mode enable
		ERR	0	Cumulative error flag
EDECCR	Cold	NSE[2:1]	`0b00`	Coarse-grained Non-secure Exception Catch
		SE[3,1]	`0b00`	Coarse-grained Secure Exception Catch
EDPRCR, if FEAT_DoPD is implemented	Cold	-	-	-
EDPRCR, if FEAT_DoPD is not implemented	External debug	COREPURQ[b]	-	Core powerup request
EDPRSR	Warm	SDR	-	Sticky debug restart
	Cold	SPMAD	0	Sticky EPMAD error
		SDAD	0	Sticky EDAD error
	Warm	SR	1	Sticky reset status
	Cold	SPD	1	Sticky powerdown status

a. If FEAT_DoPD is not implemented, the powerup request is the EDPRCR.COREPURQ control bit.

b. If FEAT_DoPD is not implemented, on a Cold reset into AArch64 state, DBGPRCR_EL1.CORENPDRQ resets to the value of EDPRCR.COREPURQ. If an External Debug reset and a Cold reset coincide, both EDPRCR.COREPURQ and the CORENPDRQ field of the appropriate System register are reset to 0.

Table E8-5 shows the reset values for the CTI registers

Table E8-8 Summary of external debug register resets, CTI registers

Chapter E9
External Debug Register Descriptions

This chapter provides a description of the external debug registers. It contains the following sections:

- About the external debug registers.
- External debug registers.
- External trace registers.
- External Trace Buffer registers.
- Cross-Trigger Interface registers.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

E9.1 About the external debug registers

The following sections describe the registers that are accessible through the external debug interface:

- External debug registers.
- External trace registers.
- Cross-Trigger Interface registers.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.

E9.2 External debug registers

This section describes the debug registers that are accessible through the external debug interface and are used for external debug.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

E9.2.1 DBGAUTHSTATUS_EL1, Debug Authentication Status Register

The DBGAUTHSTATUS_EL1 characteristics are:

Purpose

Provides information about the state of the IMPLEMENTATION DEFINED authentication interface for debug.

Configuration

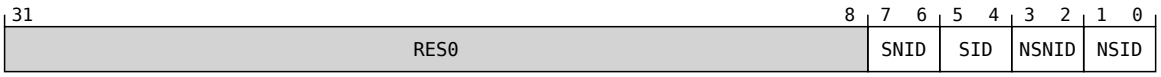
When FEAT_DoPD is implemented, DBGAUTHSTATUS_EL1 is in the Core power domain. Otherwise, DBGAUTHSTATUS_EL1 is in the Debug power domain

External register DBGAUTHSTATUS_EL1 bits [31:0] are architecturally mapped to AArch64 System register DBGAUTHSTATUS_EL1[31:0].

Attributes

DBGAUTHSTATUS_EL1 is a 32-bit register.

Field descriptions



Bits [31:8]

Reserved, RES0.

SNID, bits [7:6]

When FEAT_Debugv8p4 is implemented:

Secure non-invasive debug.

This field has the same value as DBGAUTHSTATUS_EL1.SID.

Otherwise:

Secure non-invasive debug.

SNID	Meaning
0b00	Secure state is not implemented.
0b10	Implemented and disabled. ExternalSecureNoninvasiveDebugEnabled() == FALSE.
0b11	Implemented and enabled. ExternalSecureNoninvasiveDebugEnabled() == TRUE.

All other values are reserved.

SID, bits [5:4]

Secure invasive debug.

SID	Meaning
0b00	Secure state is not implemented.
0b10	Implemented and disabled. ExternalSecureInvasiveDebugEnabled() == FALSE.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

0b11	Implemented and enabled. ExternalSecureInvasiveDebugEnabled() == TRUE.

All other values are reserved.

NSNID, bits [3:2]

When FEAT_Debugv8p4 is implemented:

Non-secure non-invasive debug.

NSNID	Meaning
0b00	Non-secure state is not implemented.
0b11	Implemented and enabled. ExternalNoninvasiveDebugEnabled() == TRUE.

All other values are reserved.

Otherwise:

Non-secure non-invasive debug.

NSNID	Meaning
0b00	Non-secure state is not implemented.
0b10	Implemented and disabled. ExternalNoninvasiveDebugEnabled() == FALSE.
0b11	Implemented and enabled. ExternalNoninvasiveDebugEnabled() == TRUE.

All other values are reserved.

NSID, bits [1:0]

Non-secure invasive debug.

NSID	Meaning
0b00	Non-secure state is not implemented.
0b10	Implemented and disabled. ExternalInvasiveDebugEnabled() == FALSE.
0b11	Implemented and enabled. ExternalInvasiveDebugEnabled() == TRUE.

All other values are reserved.

Accessing DBGAUTHSTATUS_EL1

DBGAUTHSTATUS_EL1 can be accessed through the external debug interface:

Component	Offset	Instance
Debug	0xFB8	DBGAUTHSTATUS_EL1

Accessible as follows:

- When FEAT_DoPD is implemented and !IsCorePowered(), accesses to this register return an ERROR.
- Otherwise, accesses to this register are RO.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

E9.2.2 DBGBCR<n>_EL1, Debug Breakpoint Control Registers, n = 0 - 63

The DBGBCR<n>_EL1 characteristics are:

Purpose

Holds control information for a breakpoint. Forms breakpoint n together with value register DBGBVR<n>_EL1.

Configuration

DBGBCR<n>_EL1 is in the Core power domain

If breakpoint n is not implemented, then accesses to this register are:

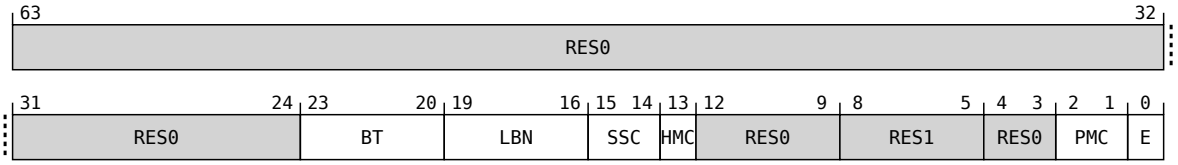
- RES0 when IsCorePowered() && !DoubleLockStatus() && !OSLockStatus() && AllowExternalDebugAccess().
- A CONSTRAINED UNPREDICTABLE choice of RES0 or ERROR otherwise.

External register DBGBCR<n>_EL1 bits [31:0] are architecturally mapped to AArch64 System register DBGBCR<n>_EL1[31:0].

Attributes

DBGBCR<n>_EL1 is a 64-bit register.

Field descriptions



When the E field is zero, all the other fields in the register are ignored.

Bits [63:24]

Reserved, RES0.

BT, bits [23:20]

Breakpoint Type.

Specifies breakpoint type.

BT	Meaning	Applies when
0b0000	Unlinked instruction address match. DBGBVR<n>_EL1 is the address of an instruction.	
0b0001	Linked instruction address match. As 0b0000, but linked to a breakpoint that has linking enabled.	
0b0010	Unlinked Context ID match. If the Effective value of HCR_EL2.E2H is 1 and either the PE is executing at EL0 with HCR_EL2.TGE set to 1 or the PE is executing at EL2, then DBGBVR<n>_EL1.ContextID is compared against CONTEXTIDR_EL2. Otherwise, DBGBVR<n>_EL1.ContextID is compared against CONTEXTIDR_EL1.	breakpoint n is context-aware
0b0011	As 0b0010, with linking enabled.	breakpoint n is context-aware

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

BT	Meaning	Applies when
0b0110	Unlinked CONTEXTIDR_EL1 match. DBGBVR<n>_EL1.ContextID is a Context ID compared against CONTEXTIDR_EL1.	FEAT_Debugv8p1 is implemented and breakpoint n is context-aware
0b0111	As 0b0110, with linking enabled.	FEAT_Debugv8p1 is implemented and breakpoint n is context-aware
0b1000	Unlinked VMID match. DBGBVR<n>_EL1.VMID is a VMID compared against VTTBR_EL2.VMID.	breakpoint n is context-aware
0b1001	As 0b1000, with linking enabled.	breakpoint n is context-aware
0b1010	Unlinked VMID and Context ID match. DBGBVR<n>_EL1.ContextID is a Context ID compared against CONTEXTIDR_EL1, and DBGBVR<n>_EL1.VMID is a VMID compared against VTTBR_EL2.VMID.	breakpoint n is context-aware
0b1011	As 0b1010, with linking enabled.	breakpoint n is context-aware
0b1100	Unlinked CONTEXTIDR_EL2 match. DBGBVR<n>_EL1.ContextID2 is a Context ID compared against CONTEXTIDR_EL2.	FEAT_Debugv8p1 is implemented and breakpoint n is context-aware
0b1101	As 0b1100, with linking enabled.	FEAT_Debugv8p1 is implemented and breakpoint n is context-aware
0b1110	Unlinked Full Context ID match. DBGBVR<n>_EL1.ContextID is compared against CONTEXTIDR_EL1, and DBGBVR<n>_EL1.ContextID2 is compared against CONTEXTIDR_EL2.	FEAT_Debugv8p1 is implemented and breakpoint n is context-aware
0b1111	As 0b1110, with linking enabled.	FEAT_Debugv8p1 is implemented and breakpoint n is context-aware

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

LBN, bits [19:16]

Linked Breakpoint Number.

For Linked address matching breakpoints, specifies the index of the breakpoint linked to.

For all other breakpoint types, this field is ignored and reads of the register return an UNKNOWN value.

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

SSC, bits [15:14]

Security state control. Determines the Security states under which a Breakpoint debug event for breakpoint n is generated. This field must be interpreted along with the HMC and PMC fields, and there are constraints on the permitted values of the {HMC, SSC, PMC} fields. For more information, including the effect of programming the fields to a reserved set of values, see 'Reserved DBGBCR<n>_EL1.{SSC, HMC, PMC} values'.

For more information on the operation of the SSC, HMC, and PMC fields, see 'Execution conditions for which a breakpoint generates Breakpoint exceptions'.

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

HMC, bit [13]

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Higher mode control. Determines the debug perspective for deciding when a Breakpoint debug event for breakpoint n is generated. This field must be interpreted along with the SSC and PMC fields, and there are constraints on the permitted values of the {HMC, SSC, PMC} fields. For more information see DBGBCR<n>_EL1.SSC description.

For more information on the operation of the SSC, HMC, and PMC fields, see 'Execution conditions for which a breakpoint generates Breakpoint exceptions'.

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

Bits [12:9]

Reserved, RES0.

Bits [8:5]

Reserved, RES1.

Bits [4:3]

Reserved, RES0.

PMC, bits [2:1]

Privilege mode control. Determines the Exception level or levels at which a Breakpoint debug event for breakpoint n is generated. This field must be interpreted along with the SSC and HMC fields, and there are constraints on the permitted values of the {HMC, SSC, PMC} fields. For more information see the DBGBCR<n>_EL1.SSC description.

For more information on the operation of the SSC, HMC, and PMC fields, see 'Execution conditions for which a breakpoint generates Breakpoint exceptions'.

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

E, bit [0]

Enable breakpoint n.

E	Meaning
0b0	Breakpoint n disabled.
0b1	Breakpoint n enabled.

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

Accessing DBGBCR<n>_EL1

Note

SoftwareLockStatus() depends on the type of access attempted and AllowExternalDebugAccess() has a new definition from Armv8.4. Refer to the Pseudocode definitions for more information.

This register is 32-bits wide and offset 0x40C + (16 * n) is reserved.

DBGBCR<n>_EL1 can be accessed through the external debug interface:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Component	Offset	Instance
Debug	`0x408 + (16 * n)`	DBGBCR<n>_EL1

Accessible as follows:

- When DoubleLockStatus(), or !IsCorePowered(), or OSLockStatus(), or !AllowExternalDebugAccess(addrdesc), accesses to this register return an ERROR.
- When SoftwareLockStatus(), accesses to this register are RO.
- Otherwise, accesses to this register are RW.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

E9.2.3 DBGBVR<n>_EL1, Debug Breakpoint Value Registers, n = 0 - 63

The DBGBVR<n>_EL1 characteristics are:

Purpose

Holds a virtual address, or a VMID and/or a context ID, for use in breakpoint matching. Forms breakpoint n together with control register DBGBCR<n>_EL1.

Configuration

DBGBVR<n>_EL1 is in the Core power domain

How this register is interpreted depends on the value of DBGBCR<n>_EL1.BT.

- When DBGBCR<n>_EL1.BT is `0b0x0x`, this register holds a virtual address.
- When DBGBCR<n>_EL1.BT is `0b001x`, `0b011x`, or `0b110x`, this register holds a Context ID.
- When DBGBCR<n>_EL1.BT is `0b100x`, this register holds a VMID.
- When DBGBCR<n>_EL1.BT is `0b101x`, this register holds a VMID and a Context ID.
- When DBGBCR<n>_EL1.BT is `0b111x`, this register holds two Context ID values.

For other values of DBGBCR<n>_EL1.BT, this register is RES0.

If breakpoint n is not implemented, then accesses to this register are:

- RES0 when IsCorePowered() && !DoubleLockStatus() && !OSLockStatus() && AllowExternalDebugAccess().
- A CONSTRAINED UNPREDICTABLE choice of RES0 or ERROR otherwise.

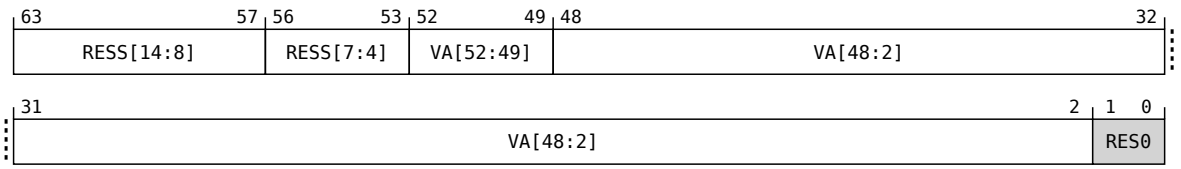
External register DBGBVR<n>_EL1 bits [63:0] are architecturally mapped to AArch64 System register DBGBVR<n>_EL1[63:0].

Attributes

DBGBVR<n>_EL1 is a 64-bit register.

Field descriptions

When DBGBCR<n>_EL1.BT IN {'`0x0`x'}:



RESS[14:8], bits [63:57]

Reserved, Sign extended. Software must treat this field as RES0 if the most significant bit of VA is 0 or RES0, and as RES1 if the most significant bit of VA is 1.

Hardware always ignores the value of these bits and it is IMPLEMENTATION DEFINED whether:

- The bits are hardwired to a copy of the most significant bit of VA, meaning writes to these bits are ignored, and reads to the bits always return the hardwired value.
- The value in those bits can be written, and reads will return the last value written. The value held in those bits is ignored by hardware.

RESS[7:4], bits [56:53]

Extension to RESS[14:8]. For more information, see RESS[14:8].

Bits [52:49]

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

When FEAT_LVA is implemented:

VA[52:49], bits [52:49]

Extension to VA[48:2]. For more information, see VA[48:2].

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

RESS[3:0], bits [52:49]

Extension to RESS[14:8]. For more information, see RESS[14:8].

VA[48:2], bits [48:2]

If the address is being matched in an AArch64 stage 1 translation regime:

- This field contains bits[48:2] of the address for comparison.
- When FEAT_LVA is implemented, VA[52:49] forms the upper part of the address value. If FEAT_LVA is not implemented, bits [52:49] are part of the RESS field.

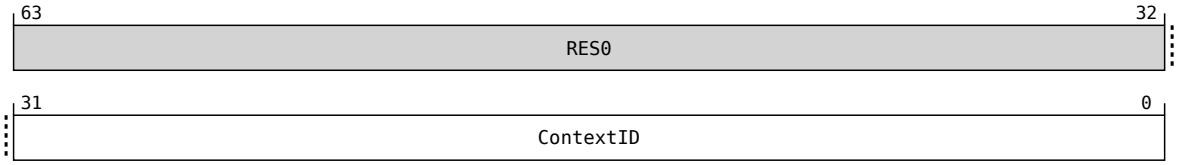
The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

Bits [1:0]

Reserved, RES0.

When DBGBCR<n>_EL1.BT IN {'001x'}:



Bits [63:32]

Reserved, RES0.

ContextID, bits [31:0]

Context ID value for comparison.

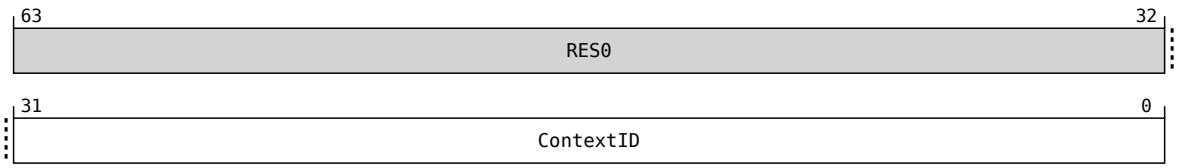
The value is compared against the following:

- CONTEXTIDR_EL1 when the PE is executing at AArch64.

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

When DBGBCR<n>_EL1.BT IN {'011x'} and FEAT_Debugv8p1 is implemented:



Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Bits [63:32]

Reserved, RES0.

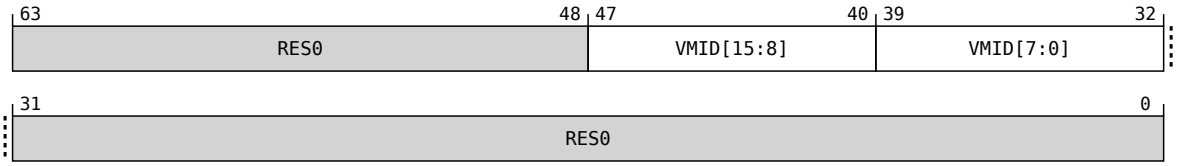
ContextID, bits [31:0]

Context ID value for comparison against CONTEXTIDR_EL1.

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

When DBGBCR<n>_EL1.BT IN {'100x'}:



Bits [63:48]

Reserved, RES0.

VMID[15:8], bits [47:40]

When FEAT_VMID16 is implemented and VTCR_EL2.VS == '1':

Extension to VMID[7:0]. For more information, see DBGBVR<n>_EL1.VMID[7:0].

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

VMID[7:0], bits [39:32]

VMID value for comparison.

The VMID is 8 bits when any of the following are true:

- VTCR_EL2.VS is 0.
- FEAT_VMID16 is not implemented.

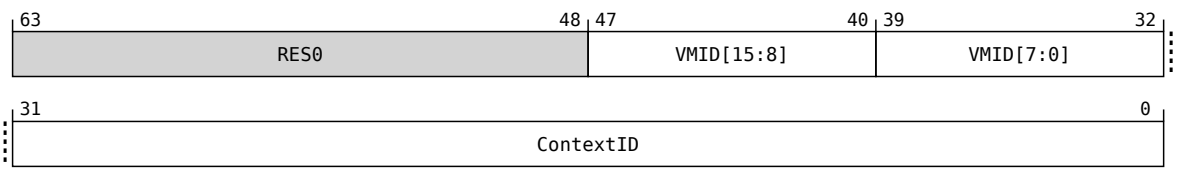
The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

Bits [31:0]

Reserved, RES0.

When DBGBCR<n>_EL1.BT IN {'101x'}:



Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Bits [63:48]

Reserved, RES0.

VMID[15:8], bits [47:40]

When FEAT_VMID16 is implemented and VTCR_EL2.VS == '1':

Extension to VMID[7:0]. For more information, see DBGBVR<n>_EL1.VMID[7:0].

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

VMID[7:0], bits [39:32]

VMID value for comparison.

The VMID is 8 bits when any of the following are true:

- VTCR_EL2.VS is 0.
- FEAT_VMID16 is not implemented.

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

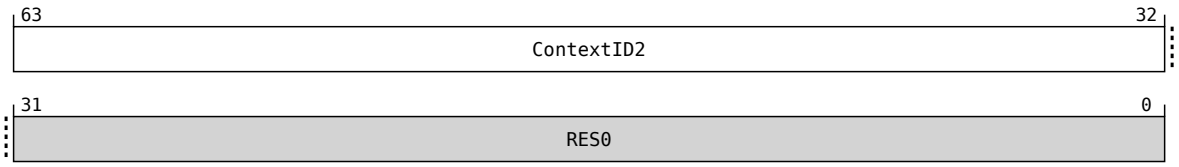
ContextID, bits [31:0]

Context ID value for comparison against CONTEXTIDR_EL1.

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

When DBGBCR<n>_EL1.BT IN {'110x'} and FEAT_Debugv8p1 is implemented:



ContextID2, bits [63:32]

Context ID value for comparison against CONTEXTIDR_EL2.

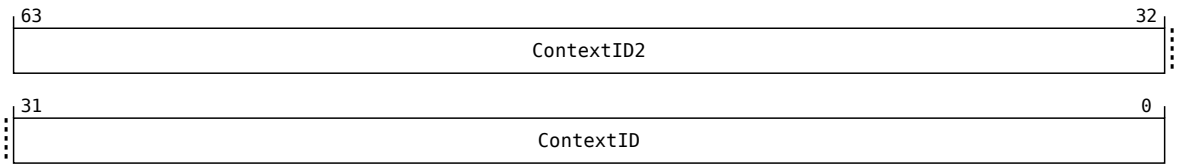
The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

Bits [31:0]

Reserved, RES0.

When DBGBCR<n>_EL1.BT IN {'111x'} and FEAT_Debugv8p1 is implemented:



Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

ContextID2, bits [63:32]

Context ID value for comparison against CONTEXTIDR_EL2.

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

ContextID, bits [31:0]

Context ID value for comparison against CONTEXTIDR_EL1.

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

Accessing DBGBVR<n>_EL1

Note

SoftwareLockStatus() depends on the type of access attempted and AllowExternalDebugAccess() has a new definition from Armv8.4. Refer to the Pseudocode definitions for more information.

DBGBVR<n>_EL1 can be accessed through the external debug interface:

Component	Offset	Instance	Range
Debug	`0x400 + (16 * n)`	DBGBVR<n>_EL1	63:0

Accessible as follows:

- When DoubleLockStatus(), or !IsCorePowered(), or OSLockStatus(), or !AllowExternalDebugAccess(addrdesc), accesses to this register return an ERROR.
- When SoftwareLockStatus(), accesses to this register are RO.
- Otherwise, accesses to this register are RW.

E9.2.4 DBGCLAIMCLR_EL1, Debug CLAIM Tag Clear Register

The DBGCLAIMCLR_EL1 characteristics are:

Purpose

Used by software to read the values of the CLAIM tag bits, and to clear CLAIM tag bits to 0.

The architecture does not define any functionality for the CLAIM tag bits.

Note

CLAIM tags are typically used for communication between the debugger and target software.

Used in conjunction with the DBGCLAIMSET_EL1 register.

Configuration

DBGCLAIMCLR_EL1 is in the Core power domain

An implementation must include eight CLAIM tag bits.

External register DBGCLAIMCLR_EL1 bits [31:0] are architecturally mapped to AArch64 System register DBGCLAIMCLR_EL1[31:0].

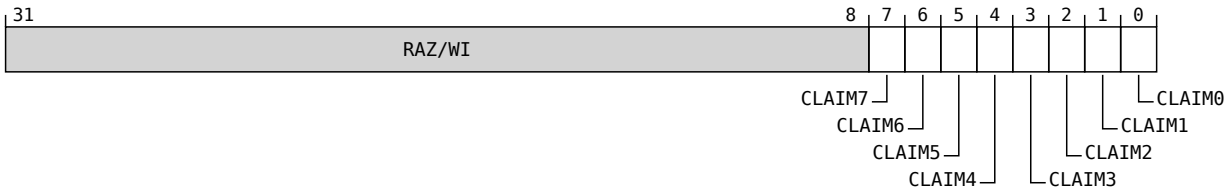
External register DBGCLAIMCLR_EL1 bits [31:0] are architecturally mapped to AArch64 System register DBGCLAIMSET_EL1[31:0].

External register DBGCLAIMCLR_EL1 bits [31:0] are architecturally mapped to External register DBGCLAIMSET_EL1[31:0].

Attributes

DBGCLAIMCLR_EL1 is a 32-bit register.

Field descriptions



Bits [31:8]

Reserved, RAZ/WI.

CLAIM<m> , bits [m], for m = 7 to 0

Claim Tag Clear. Indicates the current status of Claim Tag bit <m>, and is used to clear Claim Tag bit <m> to 0.

CLAIM<m>	Meaning
0b0	On a read: Claim Tag bit <m> is not set. On a write: Ignored.
0b1	On a read: Claim Tag bit <m> is set. On a write: Clear Claim tag bit <m> to 0.

The reset behavior of this field is:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- On a Cold reset, this field resets to `'0'`.

Access to this field is W1C.

Accessing DBGCLAIMCLR_EL1

DBGCLAIMCLR_EL1 can be accessed through the external debug interface:

Component	Offset	Instance
Debug	`0xFA4`	DBGCLAIMCLR_EL1

Accessible as follows:

- When DoubleLockStatus(), or !IsCorePowered(), or OSLockStatus(), accesses to this register return an ERROR.
- When SoftwareLockStatus(), accesses to this register are RO.
- Otherwise, accesses to this register are RW.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

E9.2.5 DBGCLAIMSET_EL1, Debug CLAIM Tag Set Register

The DBGCLAIMSET_EL1 characteristics are:

Purpose

Used by software to set the CLAIM tag bits to 1.

The architecture does not define any functionality for the CLAIM tag bits.

Note

CLAIM tags are typically used for communication between the debugger and target software.

Used in conjunction with the DBGCLAIMCLR_EL1 register.

Configuration

DBGCLAIMSET_EL1 is in the Core power domain

An implementation must include eight CLAIM tag bits.

External register DBGCLAIMSET_EL1 bits [31:0] are architecturally mapped to AArch64 System register DBGCLAIMSET_EL1[31:0].

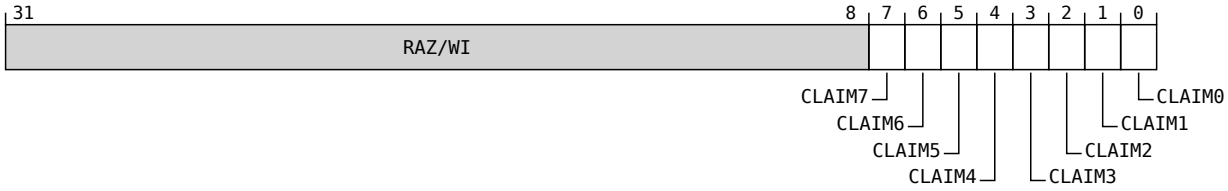
External register DBGCLAIMSET_EL1 bits [31:0] are architecturally mapped to AArch64 System register DBGCLAIMCLR_EL1[31:0].

External register DBGCLAIMSET_EL1 bits [31:0] are architecturally mapped to External register DBGCLAIMCLR_EL1[31:0].

Attributes

DBGCLAIMSET_EL1 is a 32-bit register.

Field descriptions



Bits [31:8]

Reserved, RAZ/WI.

CLAIM<m> , bits [m], for m = 7 to 0

Claim Tag Set. Used to set Claim Tag bit <m> to 1.

CLAIM<m>	Meaning
0b0	On a write: Ignored.
0b1	On a write: Set Claim Tag bit <m> to 1.

Access to this field is RAO/W1S.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Accessing DBGCLAIMSET_EL1

DBGCLAIMSET_EL1 can be accessed through the external debug interface:

Component	Offset	Instance
Debug	0xFA0	DBGCLAIMSET_EL1

Accessible as follows:

- When DoubleLockStatus(), or !IsCorePowered(), or OSLockStatus(), accesses to this register return an ERROR.
- When SoftwareLockStatus(), accesses to this register are RO.
- Otherwise, accesses to this register are RW.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

E9.2.6 DBGDTRRX_EL0, Debug Data Transfer Register, Receive

The DBGDTRRX_EL0 characteristics are:

Purpose

Transfers data from an external debugger to the PE. For example, it is used by a debugger transferring commands and data to a debug target. See DBGDTR_EL0 for additional architectural mappings. It is a component of the Debug Communications Channel.

Configuration

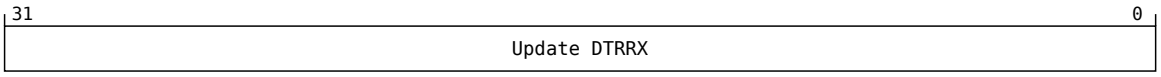
DBGDTRRX_EL0 is in the Core power domain

External register DBGDTRRX_EL0 bits [31:0] are architecturally mapped to AArch64 System register DBGDTRRX_EL0[31:0].

Attributes

DBGDTRRX_EL0 is a 32-bit register.

Field descriptions



DTRRX, bits [31:0]

Update DTRRX.

Writes to this register:

- If RXfull is 0, update the value in DTRRX and set RXfull to 1.
- If RXfull is 1, the written value is ignored and RXO is set to 1.

Reads of this register return the last value written to DTRRX and do not change RXfull.

For the full behavior of the Debug Communications Channel, see 'The Debug Communication Channel and Instruction Transfer Register'.

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

Accessing DBGDTRRX_EL0

If EDSCR.ITE == 0 when the PE exits Debug state on receiving a Restart request trigger event, the behavior of any operation issued by a DTR access in Memory access mode that has not completed execution is CONSTRAINED UNPREDICTABLE, and must do one of the following:

- It must complete execution in Debug state before the PE executes the restart sequence.
- It must complete execution in Non-debug state before the PE executes the restart sequence.
- It must be abandoned. This means that the instruction does not execute. Any registers or memory accessed by the instruction are left in an UNKNOWN state.

DBGDTRRX_EL0 can be accessed through the external debug interface:

Component	Offset	Instance
Debug	0x080	DBGDTRRX_EL0

Accessible as follows:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- When DoubleLockStatus(), or !IsCorePowered(), or OSLockStatus(), accesses to this register return an ERROR.
- When SoftwareLockStatus(), accesses to this register are RO.
- Otherwise, accesses to this register are RW.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

E9.2.7 DBGDTRTX_EL0, Debug Data Transfer Register, Transmit

The DBGDTRTX_EL0 characteristics are:

Purpose

Transfers data from the PE to an external debugger. For example, it is used by a debug target to transfer data to the debugger. See DBGDTR_EL0 for additional architectural mappings. It is a component of the Debug Communication Channel.

Configuration

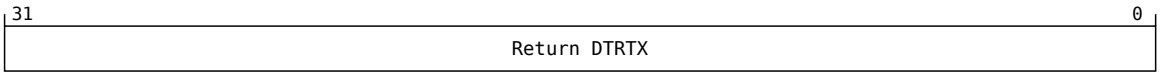
DBGDTRTX_EL0 is in the Core power domain

External register DBGDTRTX_EL0 bits [31:0] are architecturally mapped to AArch64 System register DBGDTRTX_EL0[31:0].

Attributes

DBGDTRTX_EL0 is a 32-bit register.

Field descriptions



DTRTX, bits [31:0]

Return DTRTX.

Reads of this register:

- If TXfull is 1, return the value in DTRTX and clear TXfull to 0.
- If TXfull is 0, return an UNKNOWN value and set TXU to 1.

Writes of this register update the value in DTRTX and do not change TXfull.

For the full behavior of the Debug Communications Channel, see 'The Debug Communication Channel and Instruction Transfer Register'.

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

Accessing DBGDTRTX_EL0

If EDSCR.ITE == 0 when the PE exits Debug state on receiving a Restart request trigger event, the behavior of any operation issued by a DTR access in Memory access mode that has not completed execution is CONSTRAINED UNPREDICTABLE, and must do one of the following:

- It must complete execution in Debug state before the PE executes the restart sequence.
- It must complete execution in Non-debug state before the PE executes the restart sequence.
- It must be abandoned. This means that the instruction does not execute. Any registers or memory accessed by the instruction are left in an UNKNOWN state.

DBGDTRTX_EL0 can be accessed through the external debug interface:

Component	Offset	Instance
Debug	0x08C	DBGDTRTX_EL0

Accessible as follows:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- When DoubleLockStatus(), or !IsCorePowered(), or OSLockStatus(), accesses to this register return an ERROR.
- When SoftwareLockStatus(), accesses to this register are RO.
- Otherwise, accesses to this register are RW.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

E9.2.8 DBGWCR<n>_EL1, Debug Watchpoint Control Registers, n = 0 - 63

The DBGWCR<n>_EL1 characteristics are:

Purpose

Holds control information for a watchpoint. Forms watchpoint n together with value register DBGWVR<n>_EL1.

Configuration

DBGWCR<n>_EL1 is in the Core power domain

If watchpoint n is not implemented, then accesses to this register are:

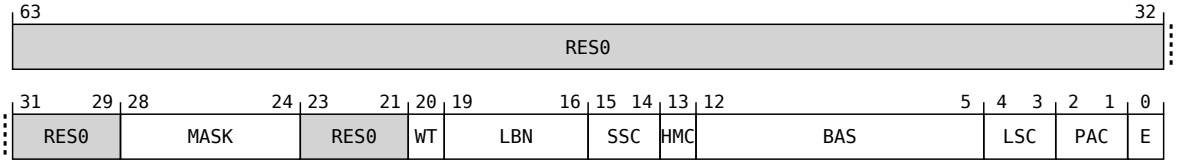
- When IsCorePowered() && !DoubleLockStatus() && !OSLockStatus() && AllowExternalDebugAccess(), RES0.
- Otherwise, a CONSTRAINED UNPREDICTABLE choice of RES0 or ERROR.

External register DBGWCR<n>_EL1 bits [31:0] are architecturally mapped to AArch64 System register DBGWCR<n>_EL1[31:0].

Attributes

DBGWCR<n>_EL1 is a 64-bit register.

Field descriptions



Bits [63:29]

Reserved, RES0.

MASK, bits [28:24]

Address Mask. Only address ranges up to 2GB can be watched using a single mask.

MASK	Meaning
0b00000	No mask.
0b00011..0b11111	Number of address bits masked.

All other values are reserved.

Indicates the number of masked address bits, from 0b00011 masking 3 address bits (0x00000007 mask for address) to 0b11111 masking 31 address bits (0x7FFFFFFF mask for address).

If programmed with a reserved value, the watchpoint behaves as if one of the following:

- DBGWCR<n>_EL1.MASK has been programmed with a defined value, which might be 0b00000 (no mask), other than for a direct read of DBGWCR<n>_EL1.
- The watchpoint is disabled.

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Bits [23:21]

Reserved, RES0.

WT, bit [20]

Watchpoint type. Possible values are:

WT	Meaning
0b0	Unlinked data address match.
0b1	Linked data address match.

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

LBN, bits [19:16]

Linked Breakpoint Number.

For Linked data address watchpoints, specifies the index of the breakpoint linked to.

For all other watchpoint types, this field is ignored and reads of the register return an UNKNOWN value.

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

SSC, bits [15:14]

Security state control. Determines the Security states under which a Watchpoint debug event for watchpoint n is generated. This field must be interpreted along with the HMC and PAC fields.

For more information on the operation of the SSC, HMC, and PAC fields, see 'Execution conditions for which a watchpoint generates Watchpoint exceptions'.

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

HMC, bit [13]

Higher mode control. Determines the debug perspective for deciding when a Watchpoint debug event for watchpoint n is generated. This field must be interpreted along with the SSC and PAC fields.

For more information on the operation of the SSC, HMC, and PAC fields, see 'Execution conditions for which a watchpoint generates Watchpoint exceptions'.

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

BAS, bits [12:5]

Byte address select. Each bit of this field selects whether a byte from within the word or double-word addressed by DBGWVR<n>_EL1 is being watched.

BAS	Description
xxxxxxx1	Match byte at DBGWVR<n>_EL1
xxxxxx1x	Match byte at DBGWVR<n>_EL1 + 1
xxxxx1xx	Match byte at DBGWVR<n>_EL1 + 2

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

BAS	Description
xxxx1xxx	Match byte at DBGWVR<n>_EL1 + 3

In cases where DBGWVR<n>_EL1 addresses a double-word:

BAS	Description, if DBGWVR<n>_EL1[2] == 0
xxx1xxxx	Match byte at DBGWVR<n>_EL1 + 4
xx1xxxxx	Match byte at DBGWVR<n>_EL1 + 5
x1xxxxxx	Match byte at DBGWVR<n>_EL1 + 6
1xxxxxxx	Match byte at DBGWVR<n>_EL1 + 7

If DBGWVR<n>_EL1[2] == 1, only BAS[3:0] is used. Arm deprecates setting DBGWVR<n>_EL1[2] == 1.

The valid values for BAS are nonzero binary number all of whose set bits are contiguous. All other values are reserved and must not be used by software. See 'Reserved DBGWCR<n>.BAS values'.

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

LSC, bits [4:3]

Load/store control. This field enables watchpoint matching on the type of access being made. Possible values of this field are:

LSC	Meaning
0b01	Match instructions that load from a watchpointed address.
0b10	Match instructions that store to a watchpointed address.
0b11	Match instructions that load from or store to a watchpointed address.

All other values are reserved, but must behave as if the watchpoint is disabled. Software must not rely on this property as the behavior of reserved values might change in a future revision of the architecture.

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

PAC, bits [2:1]

Privilege of access control. Determines the Exception level or levels at which a Watchpoint debug event for watchpoint n is generated. This field must be interpreted along with the SSC and HMC fields.

For more information on the operation of the SSC, HMC, and PAC fields, see 'Execution conditions for which a watchpoint generates Watchpoint exceptions'.

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

E, bit [0]

Enable watchpoint n.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

E	Meaning
0b0	Watchpoint n disabled.
0b1	Watchpoint n enabled.

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

Accessing DBGWCR<n>_EL1

Note

SoftwareLockStatus() depends on the type of access attempted and AllowExternalDebugAccess() has a new definition from Armv8.4. Refer to the Pseudocode definitions for more information.

This register is 32-bits wide and offset 0x80C + (16 * n) is reserved.

DBGWCR<n>_EL1 can be accessed through the external debug interface:

Component	Offset	Instance
Debug	0x808 + (16 * n)	DBGWCR<n>_EL1

Accessible as follows:

- When DoubleLockStatus(), or !IsCorePowered(), or OSLockStatus(), or !AllowExternalDebugAccess(addrdesc), accesses to this register return an ERROR.
- When SoftwareLockStatus(), accesses to this register are RO.
- Otherwise, accesses to this register are RW.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

E9.2.9 DBGWVR<n>_EL1, Debug Watchpoint Value Registers, n = 0 - 63

The DBGWVR<n>_EL1 characteristics are:

Purpose

Holds a data address value for use in watchpoint matching. Forms watchpoint n together with control register DBGWCR<n>_EL1.

Configuration

DBGWVR<n>_EL1 is in the Core power domain

If watchpoint n is not implemented, then accesses to this register are:

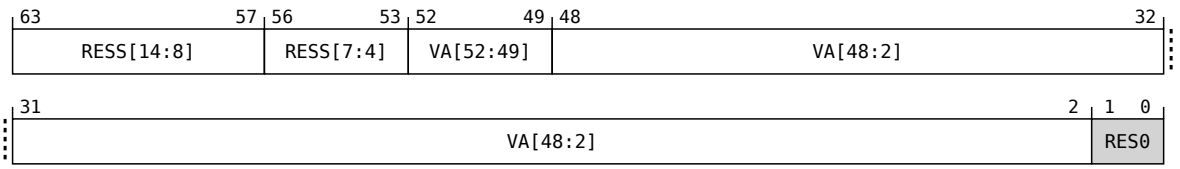
- When IsCorePowered() && !DoubleLockStatus() && !OSLockStatus() && AllowExternalDebugAccess(), RES0.
- Otherwise, a CONSTRAINED UNPREDICTABLE choice of RES0 or ERROR.

External register DBGWVR<n>_EL1 bits [63:0] are architecturally mapped to AArch64 System register DBGWVR<n>_EL1[63:0].

Attributes

DBGWVR<n>_EL1 is a 64-bit register.

Field descriptions



RESS[14:8], bits [63:57]

Reserved, Sign extended. Hardware and software must treat this field as RES0 if the most significant bit of VA is 0 or RES0, and as RES1 if the most significant bit of VA is 1.

Hardware always ignores the value of these bits and it is IMPLEMENTATION DEFINED whether:

- The bits are hardwired to a copy of the most significant bit of VA, meaning writes to these bits are ignored, and reads to the bits always return the hardwired value.
- The value in those bits can be written, and reads will return the last value written. The value held in those bits is ignored by hardware.

RESS[7:4], bits [56:53]

Extension to RESS[14:8]. For more information, see RESS[14:8].

Bits [52:49]

When FEAT_LVA is implemented:

VA[52:49], bits [52:49]

Extension to VA[48:2]. For more information, see VA[48:2].

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

RESS[3:0], bits [52:49]

Extension to RESS[14:8]. For more information, see RESS[14:8].

VA[48:2], bits [48:2]

Bits[48:2] of the address value for comparison.

When FEAT_LVA is implemented, VA[52:49] forms the upper part of the address value. If FEAT_LVA is not implemented, bits [52:49] are part of the RESS field.

Arm deprecates setting DBGWVR<n>_EL1[2] == 1.

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

Bits [1:0]

Reserved, RES0.

Accessing DBGWVR<n>_EL1

Note

SoftwareLockStatus() depends on the type of access attempted and AllowExternalDebugAccess() has a new definition from Armv8.4. Refer to the Pseudocode definitions for more information.

DBGWVR<n>_EL1 can be accessed through the external debug interface:

Component	Offset	Instance	Range
Debug	`0x800 + (16 * n)`	DBGWVR<n>_EL1	63:0

Accessible as follows:

- When DoubleLockStatus(), or !IsCorePowered(), or OSLockStatus(), or !AllowExternalDebugAccess(addrdesc), accesses to this register return an ERROR.
- When SoftwareLockStatus(), accesses to this register are RO.
- Otherwise, accesses to this register are RW.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

E9.2.10 EDAA32PFR, External Debug Auxiliary Processor Feature Register

The EDAA32PFR characteristics are:

Purpose

Provides information about implemented PE features.

Note

The register mnemonic, EDAA32PFR, is derived from previous definitions of this register that defined this register only when AArch64 was not supported.

For general information about the interpretation of the ID registers, see 'Principles of the ID scheme for fields in ID registers'.

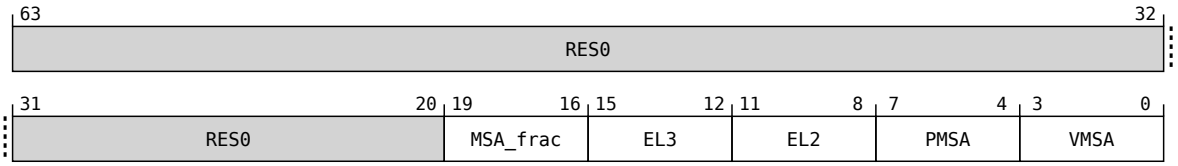
Configuration

There are no configuration notes.

Attributes

EDAA32PFR is a 64-bit register.

Field descriptions



Bits [63:20]

Reserved, RES0.

MSA_frac, bits [19:16]

When EDAA32PFR.PMSA == '0000' and EDAA32PFR.VMSA == '1111':

Memory System Architecture fractional field. This holds the information on additional Memory System Architectures supported.

The value of this field is an IMPLEMENTATION DEFINED choice of:

MSA_frac	Meaning
0b0001	PMSAv8-64 supported in all translation regimes. VMSAv8-64 not supported.
0b0010	PMSAv8-64 supported in all translation regimes. In addition to PMSAv8-64, stage 1 EL1&0 translation regime also supports VMSAv8-64.

All other values are reserved.

In Armv8-R AArch64, the only permitted values are 0b0001 and 0b0010.

Access to this field is RO.

Otherwise:

Reserved, RES0.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

EL3, bits [15:12]

When EDPFR.EL3 == '0000':

AArch32 EL3 Exception level handling.

The value of this field is an IMPLEMENTATION DEFINED choice of:

EL3	Meaning
0b0000	EL3 is not implemented or can be executed in AArch64 state.
0b0001	EL3 can be executed in AArch32 state only.

All other values are reserved.

In an Armv8-R AArch64 implementation this field returns the value of 0b0000.

Access to this field is RO.

Otherwise:

Reserved, RAZ.

EL2, bits [11:8]

When EDPFR.EL2 == '0000':

AArch32 EL2 Exception level handling.

The value of this field is an IMPLEMENTATION DEFINED choice of:

EL2	Meaning
0b0000	EL2 is not implemented or can be executed in AArch64 state.
0b0001	EL2 can be executed in AArch32 state only.

All other values are reserved.

In an Armv8-R AArch64 implementation this field returns the value of 0b0000.

Access to this field is RO.

Otherwise:

Reserved, RAZ.

PMSA, bits [7:4]

Indicates support for a 32-bit PMSA.

The value of this field is an IMPLEMENTATION DEFINED choice of:

PMSA	Meaning
0b0000	PMSA-32 not supported.
0b0100	PMSAv8-32 supported.

Access to this field is RO.

VMSA, bits [3:0]

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

When EDAA32PFR.PMSA != '0000':

Indicates support for a VMSA in addition to a 32-bit PMSA.

VMSA	Meaning
0b0000	VMSA not supported.

All other values are reserved.

Access to this field is RO.

When EDAA32PFR.PMSA == '0000':

The value of this field is an IMPLEMENTATION DEFINED choice of:

VMSA	Meaning
0b0000	VMSAv8-64 supported. PMSAv8-64 not supported.
0b1111	Memory system architecture described by EDAA32PFR.MSA_frac.

All other values are reserved.

In Armv8-R AArch64, the only permitted value is 0b1111.

Access to this field is RO.

Otherwise:

Reserved, RAZ.

Accessing EDAA32PFR

EDAA32PFR can be accessed through the external debug interface:

Component	Offset	Instance
Debug	0xD60	EDAA32PFR

Accessible as follows:

- When IsCorePowered() and !DoubleLockStatus(), accesses to this register are RO.
- When FEAT_DoPD is implemented and !IsCorePowered(), accesses to this register return an ERROR.
- Otherwise, accesses to this register are IMPLEMENTATION DEFINED.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

E9.2.11 EDACR, External Debug Auxiliary Control Register

The EDACR characteristics are:

Purpose

Allows implementations to support IMPLEMENTATION DEFINED controls.

Configuration

When FEAT_DoPD is implemented, EDACR is in the Core power domain. Otherwise, it is IMPLEMENTATION DEFINED whether EDACR is implemented in the Core power domain or in the Debug power domain

If this register is implemented, EDDEVID.AuxRegs == `0b0001`.

If FEAT_DoPD is implemented, any mechanism to preserve control bits in EDACR over power down is optional and IMPLEMENTATION DEFINED.

If FEAT_DoPD is not implemented and EDACR contains any control bits that must be preserved over power down, then these bits must be accessible by the external debug interface when the OS Lock is locked, OSLSR_EL1.OSLK == 1, and when the Core is powered off.

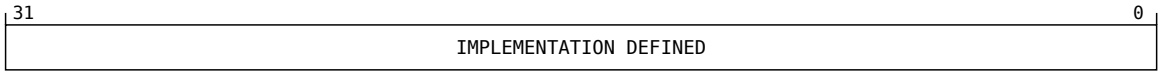
Changing this register from its reset value causes IMPLEMENTATION DEFINED behavior, including possible deviation from the architecturally-defined behavior.

Implementation of this register is OPTIONAL.

Attributes

EDACR is a 32-bit register.

Field descriptions



IMPLEMENTATION DEFINED, bits [31:0]

IMPLEMENTATION DEFINED.

The following resets apply:

- If the register is implemented in the Core power domain:
  - On a Cold reset, this field resets to an architecturally UNKNOWN value.
  - On an External debug reset, the value of this field is unchanged.
  - On a Warm reset, the value of this field is unchanged.
- If the register is implemented in the External debug power domain:
  - On a Cold reset, the value of this field is unchanged.
  - On an External debug reset, this field resets to an architecturally UNKNOWN value.
  - On a Warm reset, the value of this field is unchanged.

Accessing EDACR

EDACR can be accessed through the external debug interface:

Component	Offset	Instance
Debug	`0x094`	EDACR

Accessible as follows:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- When DoubleLockStatus(), or !IsCorePowered(), or OSLockStatus(), accesses to this register are IMPLEMENTATION DEFINED.
- When SoftwareLockStatus(), accesses to this register are RO.
- Otherwise, accesses to this register are RW.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

E9.2.12 EDCIDR0, External Debug Component Identification Register 0

The EDCIDR0 characteristics are:

Purpose

Provides information to identify an external debug component.

For more information, see ‘About the Component Identification scheme’.

Configuration

When FEAT_DoPD is implemented, EDCIDR0 is in the Core power domain. Otherwise, EDCIDR0 is in the Debug power domain

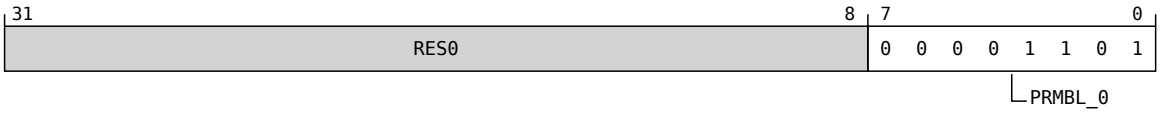
This register is required for CoreSight compliance.

Implementation of this register is OPTIONAL.

Attributes

EDCIDR0 is a 32-bit register.

Field descriptions



Bits [31:8]

Reserved, RES0.

PRMBL_0, bits [7:0]

Preamble.

Reads as `0x0D`

Access to this field is RO.

Accessing EDCIDR0

EDCIDR0 can be accessed through the external debug interface:

Component	Offset	Instance
Debug	`0xFF0`	EDCIDR0

Accessible as follows:

- When FEAT_DoPD is implemented and !IsCorePowered(), accesses to this register return an ERROR.
- Otherwise, accesses to this register are RO.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

E9.2.13 EDCIDR1, External Debug Component Identification Register 1

The EDCIDR1 characteristics are:

Purpose

Provides information to identify an external debug component.

For more information, see ‘About the Component Identification scheme’.

Configuration

When FEAT_DoPD is implemented, EDCIDR1 is in the Core power domain. Otherwise, EDCIDR1 is in the Debug power domain

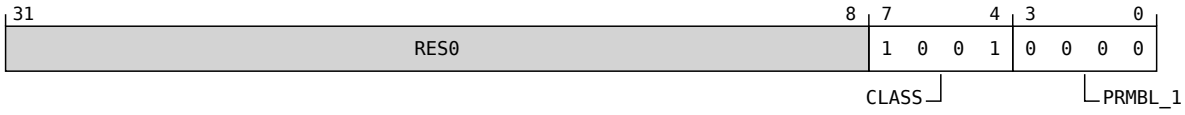
This register is required for CoreSight compliance.

Implementation of this register is OPTIONAL.

Attributes

EDCIDR1 is a 32-bit register.

Field descriptions



Bits [31:8]

Reserved, RES0.

CLASS, bits [7:4]

Component class.

CLASS	Meaning
0b1001	CoreSight component.

Other values are defined by the CoreSight Architecture.

This field reads as 0x9.

Access to this field is RO.

PRMBL_1, bits [3:0]

Preamble.

Reads as 0b0000

Access to this field is RO.

Accessing EDCIDR1

EDCIDR1 can be accessed through the external debug interface:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Component	Offset	Instance
Debug	0xFF4	EDCIDR1

Accessible as follows:

- When FEAT_DoPD is implemented and !IsCorePowered(), accesses to this register return an ERROR.
- Otherwise, accesses to this register are RO.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

E9.2.14 EDCIDR2, External Debug Component Identification Register 2

The EDCIDR2 characteristics are:

Purpose

Provides information to identify an external debug component.

For more information, see ‘About the Component Identification scheme’.

Configuration

When FEAT_DoPD is implemented, EDCIDR2 is in the Core power domain. Otherwise, EDCIDR2 is in the Debug power domain

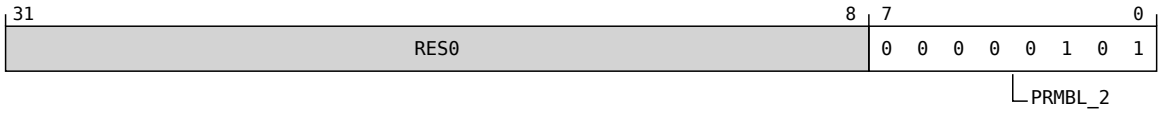
This register is required for CoreSight compliance.

Implementation of this register is OPTIONAL.

Attributes

EDCIDR2 is a 32-bit register.

Field descriptions



Bits [31:8]

Reserved, RES0.

PRMBL_2, bits [7:0]

Preamble.

Reads as `0x05`

Access to this field is RO.

Accessing EDCIDR2

EDCIDR2 can be accessed through the external debug interface:

Component	Offset	Instance
Debug	`0xFF8`	EDCIDR2

Accessible as follows:

- When FEAT_DoPD is implemented and !IsCorePowered(), accesses to this register return an ERROR.
- Otherwise, accesses to this register are RO.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

E9.2.15 EDCIDR3, External Debug Component Identification Register 3

The EDCIDR3 characteristics are:

Purpose

Provides information to identify an external debug component.

For more information, see ‘About the Component Identification scheme’.

Configuration

When FEAT_DoPD is implemented, EDCIDR3 is in the Core power domain. Otherwise, EDCIDR3 is in the Debug power domain

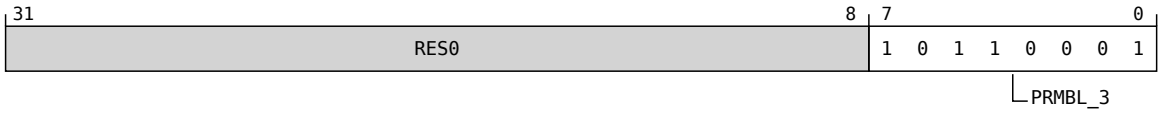
This register is required for CoreSight compliance.

Implementation of this register is OPTIONAL.

Attributes

EDCIDR3 is a 32-bit register.

Field descriptions



Bits [31:8]

Reserved, RES0.

PRMBL_3, bits [7:0]

Preamble.

Reads as `0xB1`

Access to this field is RO.

Accessing EDCIDR3

EDCIDR3 can be accessed through the external debug interface:

Component	Offset	Instance
Debug	`0xFFC`	EDCIDR3

Accessible as follows:

- When FEAT_DoPD is implemented and !IsCorePowered(), accesses to this register return an ERROR.
- Otherwise, accesses to this register are RO.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

E9.2.16 EDDEVAFF0, External Debug Device Affinity register 0

The EDDEVAFF0 characteristics are:

Purpose

Copy of the low half of the PE MPIDR_EL1 register that allows a debugger to determine which PE in a multiprocessor system the external debug component relates to.

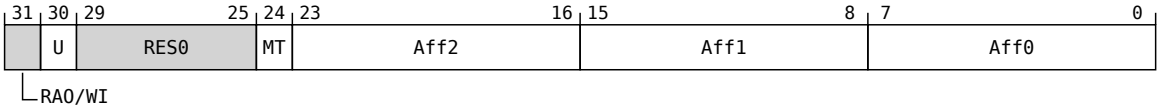
Configuration

When FEAT_DoPD is implemented, EDDEVAFF0 is in the Core power domain. Otherwise, EDDEVAFF0 is in the Debug power domain

Attributes

EDDEVAFF0 is a 32-bit register.

Field descriptions



Bit [31]

Reserved, RAO/WI.

U, bit [30]

Indicates a Uniprocessor system, as distinct from PE 0 in a multiprocessor system.

The value of this field is an IMPLEMENTATION DEFINED choice of:

U	Meaning
0b0	Processor is part of a multiprocessor system.
0b1	Processor is part of a uniprocessor system.

Access to this field is RO.

Bits [29:25]

Reserved, RES0.

MT, bit [24]

Indicates whether the lowest level of affinity consists of logical PEs that are implemented using an interdependent approach, such as multithreading. See the description of Aff0 for more information about affinity levels.

The value of this field is an IMPLEMENTATION DEFINED choice of:

MT	Meaning
0b0	Performance of PEs with different affinity level 0 values, and the same values for affinity level 1 and higher, is largely independent.
0b1	Performance of PEs with different affinity level 0 values, and the same values for affinity level 1 and higher, is very interdependent.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

This field does not indicate that multithreading is implemented and does not indicate that PEs with different affinity level 0 values, and the same values for affinity level 1 and higher are implemented.

Access to this field is RO.

Aff2, bits [23:16]

Affinity level 2. See the description of Aff0 for more information.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

Aff1, bits [15:8]

Affinity level 1. See the description of Aff0 for more information.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

Aff0, bits [7:0]

Affinity level 0. The value of the MPIDR.{Aff2, Aff1, Aff0} or MPIDR_EL1.{Aff3, Aff2, Aff1, Aff0} set of fields of each PE must be unique within the system as a whole.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

Accessing EDDEVAFF0

EDDEVAFF0 can be accessed through the external debug interface:

Component	Offset	Instance
Debug	0xFA8	EDDEVAFF0

Accessible as follows:

- When FEAT_DoPD is implemented and !IsCorePowered(), accesses to this register return an ERROR.
- Otherwise, accesses to this register are RO.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

E9.2.17 EDDEVAFF1, External Debug Device Affinity register 1

The EDDEVAFF1 characteristics are:

Purpose

Copy of the high half of the PE MPIDR_EL1 register that allows a debugger to determine which PE in a multiprocessor system the external debug component relates to.

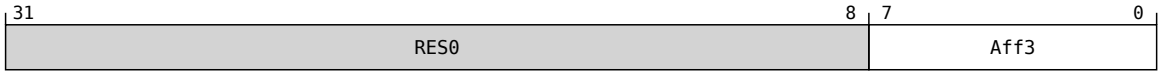
Configuration

When FEAT_DoPD is implemented, EDDEVAFF1 is in the Core power domain. Otherwise, EDDEVAFF1 is in the Debug power domain

Attributes

EDDEVAFF1 is a 32-bit register.

Field descriptions



Bits [31:8]

Reserved, RES0.

Aff3, bits [7:0]

Affinity level 3. See the description of EDDEVAFF0.Aff0 for more information.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

Accessing EDDEVAFF1

EDDEVAFF1 can be accessed through the external debug interface:

Component	Offset	Instance
Debug	0xFAC	EDDEVAFF1

Accessible as follows:

- When FEAT_DoPD is implemented and !IsCorePowered(), accesses to this register return an ERROR.
- Otherwise, accesses to this register are RO.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

E9.2.18 EDDEVARCH, External Debug Device Architecture Register

The EDDEVARCH characteristics are:

Purpose

Identifies the programmers' model architecture of the external debug component.

Configuration

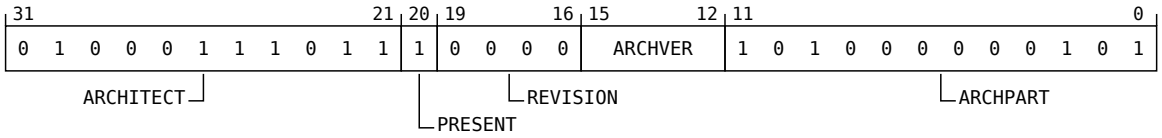
When FEAT_DoPD is implemented, EDDEVARCH is in the Core power domain. Otherwise, EDDEVARCH is in the Debug power domain

Implementation of this register is OPTIONAL.

Attributes

EDDEVARCH is a 32-bit register.

Field descriptions



ARCHITECT, bits [31:21]

Defines the architect of the component. For External Debug, this is Arm Limited.

Bits [31:28] are the JEP106 continuation code, `0b0100`.

Bits [27:21] are the JEP106 identification code, `0b0111011`.

Reads as `0b01000111011`

Access to this field is RO.

PRESENT, bit [20]

DEVARCH present. Indicates that the EDDEVARCH register is present.

Reads as `0b1`

Access to this field is RO.

REVISION, bits [19:16]

Defines the architecture revision. For architectures defined by Arm this is the minor revision.

For debug, the revision defined by Armv8 is `0x0`.

All other values are reserved.

Reads as `0b0000`

Access to this field is RO.

ARCHVER, bits [15:12]

Architecture Version. Defines the architecture version of the component.

The value of this field is an IMPLEMENTATION DEFINED choice of:

EDDEVARCH.ARCHVER and EDDEVARCH.ARCHPART are also defined as a single field, EDDEVARCH.ARCHID, so that EDDEVARCH.ARCHVER is EDDEVARCH.ARCHID[15:12].

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

FEAT_Debugv8p1 implements the functionality identified by the value 0b0111.

FEAT_Debugv8p2 implements the functionality identified by the value 0b1000.

FEAT_Debugv8p4 implements the functionality identified by the value 0b1001.

From Armv8.1, when FEAT_Debugv8p1 is implemented the value 0b0110 is not permitted.

From Armv8.2, the values 0b0110 and 0b0111 are not permitted.

From Armv8.4, the value 0b1000 is not permitted.

Access to this field is RO.

ARCHPART, bits [11:0]

Architecture Part. Defines the architecture of the component.

ARCHPART	Meaning
0xA05	Armv8-R AArch64 debug architecture.

EDDEVARCH.ARCHVER and EDDEVARCH.ARCHPART are also defined as a single field, EDDEVARCH.ARCHID, so that EDDEVARCH.ARCHPART is EDDEVARCH.ARCHID[11:0].

Armv8-R debug architecture.

Access to this field is RO.

Accessing EDDEVARCH

EDDEVARCH can be accessed through the external debug interface:

Component	Offset	Instance
Debug	0xFBC	EDDEVARCH

Accessible as follows:

- When FEAT_DoPD is implemented and !IsCorePowered(), accesses to this register return an ERROR.
- Otherwise, accesses to this register are RO.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

E9.2.19 EDDEVID, External Debug Device ID register 0

The EDDEVID characteristics are:

Purpose

Provides extra information for external debuggers about features of the debug implementation.

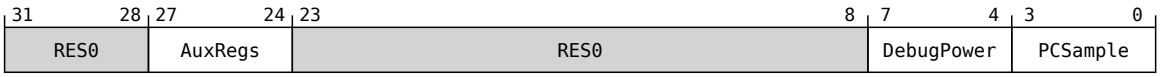
Configuration

When FEAT_DoPD is implemented, EDDEVID is in the Core power domain. Otherwise, EDDEVID is in the Debug power domain

Attributes

EDDEVID is a 32-bit register.

Field descriptions



Bits [31:28]

Reserved, RES0.

AuxRegs, bits [27:24]

Indicates support for Auxiliary registers.

The value of this field is an IMPLEMENTATION DEFINED choice of:

AuxRegs	Meaning
0b0000	None supported.
0b0001	Support for External Debug Auxiliary Control Register, EDACR.

All other values are reserved.

Access to this field is RO.

Bits [23:8]

Reserved, RES0.

DebugPower, bits [7:4]

Indicates support for the FEAT_DoPD feature.

The value of this field is an IMPLEMENTATION DEFINED choice of:

DebugPower	Meaning
0b0000	FEAT_DoPD not implemented. Registers in the external debug interface register map are implemented in a mix of the Debug and Core power domains.
0b0001	FEAT_DoPD implemented. All registers in the external debug interface register map are implemented in the Core power domain.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

FEAT_DoPD implements the functionality added by the value 0b0001.

All other values are reserved.

Access to this field is RO.

PCSample, bits [3:0]

Indicates the level of PC Sample-based Profiling support using external debug registers.

The value of this field is an IMPLEMENTATION DEFINED choice of:

PCSample	Meaning
0b0000	PC Sample-based Profiling Extension is not implemented in the external debug registers space.
0b0010	Only EDPCSR and EDCIDSR are implemented. This option is only permitted if EL3 and EL2 are not implemented.
0b0011	EDPCSR, EDCIDSR, and EDVIDSR are implemented.

All other values are reserved.

When FEAT_PCSRv8p2 is implemented, the only permitted value is 0b0000.

Note

FEAT_PCSRv8p2 implements the PC Sample-based Profiling Extension in the Performance Monitors register space, as indicated by the value of PMDEVID.PCSample.

Access to this field is RO.

Accessing EDDEVID

EDDEVID can be accessed through the external debug interface:

Component	Offset	Instance
Debug	0xFC8	EDDEVID

Accessible as follows:

- When FEAT_DoPD is implemented and !IsCorePowered(), accesses to this register return an ERROR.
- Otherwise, accesses to this register are RO.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

E9.2.20 EDDEVID1, External Debug Device ID Register 1

The EDDEVID1 characteristics are:

Purpose

Provides extra information for external debuggers about features of the debug implementation.

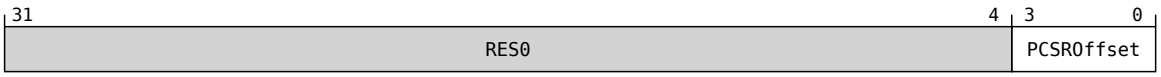
Configuration

When FEAT_DoPD is implemented, EDDEVID1 is in the Core power domain. Otherwise, EDDEVID1 is in the Debug power domain

Attributes

EDDEVID1 is a 32-bit register.

Field descriptions



Bits [31:4]

Reserved, RES0.

PCSROffset, bits [3:0]

Indicates the offset applied to PC samples returned by reads of EDPCSR.

The value of this field is an IMPLEMENTATION DEFINED choice of:

PCSROffset	Meaning
0b0000	EDPCSR not implemented.
0b0010	EDPCSR implemented, and samples have no offset applied.

When FEAT_PCSRv8p2 is implemented, the only permitted value is 0b0000.

Note

FEAT_PCSRv8p2 implements the PC Sample-based Profiling Extension in the Performance Monitors register space, as indicated by the value of PMDEVID.PCSample.

Access to this field is RO.

Accessing EDDEVID1

EDDEVID1 can be accessed through the external debug interface:

Component	Offset	Instance
Debug	0xFC4	EDDEVID1

Accessible as follows:

- When FEAT_DoPD is implemented and !IsCorePowered(), accesses to this register return an ERROR.
- Otherwise, accesses to this register are RO.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

E9.2.21 EDDEVID2, External Debug Device ID register 2

The EDDEVID2 characteristics are:

Purpose

Reserved for future descriptions of features of the debug implementation.

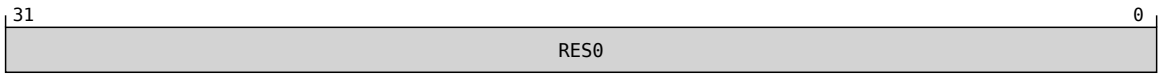
Configuration

When FEAT_DoPD is implemented, EDDEVID2 is in the Core power domain. Otherwise, EDDEVID2 is in the Debug power domain

Attributes

EDDEVID2 is a 32-bit register.

Field descriptions



Bits [31:0]

Reserved, RES0.

Accessing EDDEVID2

EDDEVID2 can be accessed through the external debug interface:

Component	Offset	Instance
Debug	0xFC0	EDDEVID2

Accessible as follows:

- When FEAT_DoPD is implemented and !IsCorePowered(), accesses to this register return an ERROR.
- Otherwise, accesses to this register are RO.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

E9.2.22 EDDEVTYPE, External Debug Device Type register

The EDDEVTYPE characteristics are:

Purpose

Indicates to a debugger that this component is part of a PE's debug logic.

Configuration

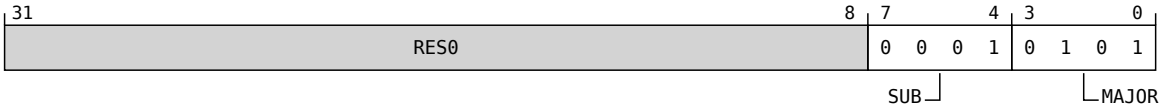
When FEAT_DoPD is implemented, EDDEVTYPE is in the Core power domain. Otherwise, EDDEVTYPE is in the Debug power domain

Implementation of this register is OPTIONAL.

Attributes

EDDEVTYPE is a 32-bit register.

Field descriptions



Bits [31:8]

Reserved, RES0.

SUB, bits [7:4]

Subtype. Indicates this is a component within a PE.

Reads as `0b0001`

Access to this field is RO.

MAJOR, bits [3:0]

Major type. Indicates this is a debug logic component.

Reads as `0b0101`

Access to this field is RO.

Accessing EDDEVTYPE

EDDEVTYPE can be accessed through the external debug interface:

Component	Offset	Instance
Debug	`0xFCC`	EDDEVTYPE

Accessible as follows:

- When FEAT_DoPD is implemented and !IsCorePowered(), accesses to this register return an ERROR.
- Otherwise, accesses to this register are RO.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

E9.2.23 EDDFR, External Debug Feature Register

The EDDFR characteristics are:

Purpose

Provides top-level information about the debug system.

Note

Debuggers must use EDDEVARCH to determine the Debug architecture version.

For general information about the interpretation of the ID registers, see 'Principles of the ID scheme for fields in ID registers'.

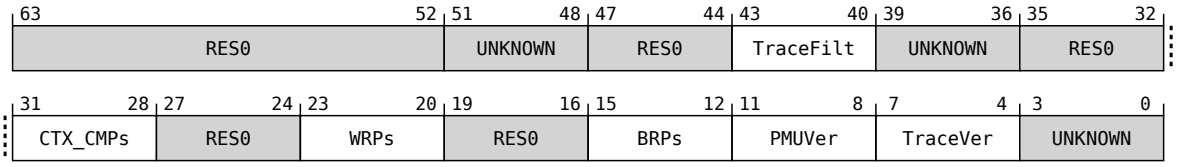
Configuration

There are no configuration notes.

Attributes

EDDFR is a 64-bit register.

Field descriptions



Bits [63:52]

Reserved, RES0.

Bits [51:48]

Reserved, UNKNOWN.

Bits [47:44]

Reserved, RES0.

TraceFilt, bits [43:40]

Armv8.4 Self-hosted Trace Extension version.

The value of this field is an IMPLEMENTATION DEFINED choice of:

TraceFilt	Meaning
0b0000	Armv8.4 Self-hosted Trace Extension not implemented.
0b0001	Armv8.4 Self-hosted Trace Extension implemented.

All other values are reserved.

FEAT_TRF implements the functionality identified by the value 0b0001.

From Armv8.4, if FEAT_ETMv4 is implemented, the value 0b0000 is not permitted.

Access to this field is RO.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Bits [39:36]

Reserved, UNKNOWN.

Bits [35:32]

Reserved, RES0.

CTX_CMPs, bits [31:28]

Number of context-aware breakpoints, minus 1.

The value of this field is an IMPLEMENTATION DEFINED choice of:

CTX_CMPs	Meaning
0b0000..0b1111	The number of context-aware breakpoints, minus 1.

The value of this field is never greater than EDDFR.BRPs.

This field has the same value as ID_AA64DFR0_EL1.CTX_CMPs.

Access to this field is RO.

Bits [27:24]

Reserved, RES0.

WRPs, bits [23:20]

Number of watchpoints, minus 1.

The value of this field is an IMPLEMENTATION DEFINED choice of:

WRPs	Meaning
0b0001..0b1111	The number of watchpoints, minus 1.

This field has the same value as ID_AA64DFR0_EL1.WRPs.

The value 0b0000 is reserved.

Access to this field is RO.

Bits [19:16]

Reserved, RES0.

BRPs, bits [15:12]

Number of breakpoints, minus 1.

The value of this field is an IMPLEMENTATION DEFINED choice of:

BRPs	Meaning
0b0001..0b1111	The number of breakpoints, minus 1.

This field has the same value as ID_AA64DFR0_EL1.BRPs.

The value 0b0000 is reserved.

Access to this field is RO.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

PMUVer, bits [11:8]

Performance Monitors Extension version.

This field does not follow the standard ID scheme, but uses the alternative ID scheme described in 'Alternative ID scheme used for the Performance Monitors Extension version'

The value of this field is an IMPLEMENTATION DEFINED choice of:

All other values are reserved.

FEAT_PMUv3 implements the functionality identified by the value `0b0001`.

FEAT_PMUv3p1 implements the functionality identified by the value `0b0100`.

FEAT_PMUv3p4 implements the functionality identified by the value `0b0101`.

From Armv8.1, if FEAT_PMUv3 is implemented, the value `0b0001` is not permitted.

From Armv8.4, if FEAT_PMUv3 is implemented, the value `0b0100` is not permitted.

This field has the same value as ID_AA64DFR0_EL1.PMUVer.

Access to this field is RO.

TraceVer, bits [7:4]

Trace support. Indicates whether System register interface to a trace unit is implemented.

The value of this field is an IMPLEMENTATION DEFINED choice of:

TraceVer	Meaning
`0b0000`	Trace unit System registers not implemented.
`0b0001`	Trace unit System registers implemented.

All other values are reserved.

A value of `0b0000` only indicates that no System register interface to a trace unit is implemented. A trace unit might nevertheless be implemented without a System register interface.

In an Armv8-A implementation that supports AArch64, this field returns the value of ID_AA64DFR0_EL1.TraceVer.

Access to this field is RO.

Bits [3:0]

Reserved, UNKNOWN.

Accessing EDDFR

EDDFR can be accessed through the external debug interface:

Component	Offset	Instance
Debug	`0xD28`	EDDFR

Accessible as follows:

- When IsCorePowered() and !DoubleLockStatus(), accesses to this register are RO.
- When FEAT_DoPD is implemented and !IsCorePowered(), accesses to this register return an ERROR.
- Otherwise, accesses to this register are IMPLEMENTATION DEFINED.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

E9.2.24 EDECCR, External Debug Exception Catch Control Register

The EDECCR characteristics are:

Purpose

Controls Exception Catch debug events. For more information, see 'Exception Catch debug event'.

Configuration

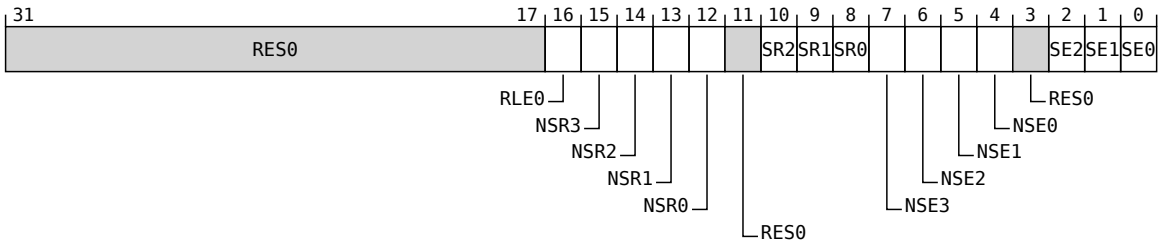
EDECCR is in the Core power domain

External register EDECCR bits [31:0] are architecturally mapped to AArch64 System register OSECCR_EL1[31:0].

Attributes

EDECCR is a 32-bit register.

Field descriptions



Bits [31:17]

Reserved, RES0.

RLE0, bit [16]

Access to this field is RES0.

NSR3, bit [15]

Access to this field is RES0.

NSR2, bit [14]

When FEAT_Debugv8p2 is implemented and Non-secure EL2 is implemented:

Controls exception catch on exception return to Non-secure EL2 in conjunction with EDECCR.NSE2.

NSR2	Meaning
0b0	If EDECCR.NSE2 is 0, then Exception Catch debug events are disabled for Non-secure EL2. If EDECCR.NSE2 is 1, then Exception Catch debug events are enabled for exception entry, reset entry, and exception return to Non-secure EL2.
0b1	If EDECCR.NSE2 is 0, then Exception Catch debug events are enabled for exception returns to Non-secure EL2. If EDECCR.NSE2 is 1, then Exception Catch debug events are enabled for exception entry and reset entry to Non-secure EL2.

The reset behavior of this field is:

- On a Cold reset, this field resets to '0'.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Otherwise:

Reserved, RES0.

NSR1, bit [13]

When FEAT_Debugv8p2 is implemented and Non-secure EL1 is implemented:

Controls exception catch on exception return to Non-secure EL1 in conjunction with EDECCR.NSE1.

NSR1	Meaning
0b0	If EDECCR.NSE1 is 0, then Exception Catch debug events are disabled for Non-secure EL1. If EDECCR.NSE1 is 1, then Exception Catch debug events are enabled for exception entry, reset entry, and exception return to Non-secure EL1.
0b1	If EDECCR.NSE1 is 0, then Exception Catch debug events are enabled for exception returns to Non-secure EL1. If EDECCR.NSE1 is 1, then Exception Catch debug events are enabled for exception entry and reset entry to Non-secure EL1.

The reset behavior of this field is:

- On a Cold reset, this field resets to '0'.

Otherwise:

Reserved, RES0.

NSR0, bit [12]

When FEAT_Debugv8p2 is implemented and Non-secure EL0 is implemented:

Controls exception catch on exception return to Non-secure EL0.

NSR0	Meaning
0b0	Exception Catch debug events are disabled for Non-secure EL0.
0b1	Exception Catch debug events are enabled for exception returns to Non-secure EL0.

The reset behavior of this field is:

- On a Cold reset, this field resets to '0'.

Otherwise:

Reserved, RES0.

Bit [11]

Reserved, RES0.

SR2, bit [10]

When FEAT_Debugv8p2 is implemented and FEAT_SEL2 is implemented:

Controls exception catch on exception return to Secure EL2 in conjunction with EDECCR.SE2.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

SR2	Meaning
0b0	If EDECCR.SE2 is 0, then Exception Catch debug events are disabled for Secure EL2. If EDECCR.SE2 is 1, then Exception Catch debug events are enabled for exception entry, reset entry, and exception return to Secure EL2.
0b1	If EDECCR.SE2 is 0, then Exception Catch debug events are enabled for exception returns to Secure EL2. If EDECCR.SE2 is 1, then Exception Catch debug events are enabled for exception entry and reset entry to Secure EL2.

The reset behavior of this field is:

- On a Cold reset, this field resets to '0'.

Otherwise:

Reserved, RES0.

SR1, bit [9]

When FEAT_Debugv8p2 is implemented and Secure EL1 is implemented:

Controls exception catch on exception return to Secure EL1 in conjunction with EDECCR.SE1.

SR1	Meaning
0b0	If EDECCR.SE1 is 0, then Exception Catch debug events are disabled for Secure EL1. If EDECCR.SE1 is 1, then Exception Catch debug events are enabled for exception entry, reset entry, and exception return to Secure EL1.
0b1	If EDECCR.SE1 is 0, then Exception Catch debug events are enabled for exception returns to Secure EL1. If EDECCR.SE1 is 1, then Exception Catch debug events are enabled for exception entry and reset entry to Secure EL1.

The reset behavior of this field is:

- On a Cold reset, this field resets to '0'.

Otherwise:

Reserved, RES0.

SR0, bit [8]

When FEAT_Debugv8p2 is implemented and Secure EL0 is implemented:

Controls exception catch on exception return to Secure EL0.

SR0	Meaning
0b0	Exception Catch debug events are disabled for Secure EL0.
0b1	Exception Catch debug events are enabled for exception returns to Secure EL0.

The reset behavior of this field is:

- On a Cold reset, this field resets to '0'.

Otherwise:

Reserved, RES0.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

NSE3, bit [7]

Access to this field is RES0.

NSE2, bit [6]

When FEAT_Debugv8p2 is implemented and Non-secure EL2 is implemented:

Controls exception catch on exception entry to Non-secure EL2. Also controls exception catch on exception return to Non-secure EL2 in conjunction with EDECCR.NSR2.

NSE2	Meaning
0b0	If EDECCR.NSR2 is 0, then Exception Catch debug events are disabled for Non-secure EL2. If EDECCR.NSR2 is 1, then Exception Catch debug events are enabled for exception returns to Non-secure EL2.
0b1	If EDECCR.NSR2 is 0, then Exception Catch debug events are enabled for exception entry, reset entry, and exception return to Non-secure EL2. If EDECCR.NSR2 is 1, then Exception Catch debug events are enabled for exception entry and reset entry to Non-secure EL2.

Note

It is IMPLEMENTATION DEFINED whether a reset entry to an Exception level will generate an Exception Catch debug event.

The reset behavior of this field is:

- On a Cold reset, this field resets to '0'.

When Non-secure EL2 is implemented:

Coarse-grained exception catch for Non-secure EL2. Controls Exception Catch debug events for Non-secure EL2.

NSE2	Meaning
0b0	Exception Catch debug events are disabled for Non-secure EL2.
0b1	Exception Catch debug events are enabled for Non-secure EL2.

The reset behavior of this field is:

- On a Cold reset, this field resets to '0'.

Otherwise:

Reserved, RES0.

NSE1, bit [5]

When FEAT_Debugv8p2 is implemented and Non-secure EL1 is implemented:

Controls exception catch on exception entry to Non-secure EL1. Also controls exception catch on exception return to Non-secure EL1 in conjunction with EDECCR.NSR1.

NSE1	Meaning
0b0	If EDECCR.NSR1 is 0, then Exception Catch debug events are disabled for Non-secure EL1. If EDECCR.NSR1 is 1, then Exception Catch debug events are enabled for exception returns to Non-secure EL1.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

NSE1	Meaning
0b1	If EDECCR.NSR1 is 0, then Exception Catch debug events are enabled for exception entry, reset entry, and exception return to Non-secure EL1. If EDECCR.NSR1 is 1, then Exception Catch debug events are enabled for exception entry and reset entry to Non-secure EL1.

Note

It is IMPLEMENTATION DEFINED whether a reset entry to an Exception level will generate an Exception Catch debug event.

The reset behavior of this field is:

- On a Cold reset, this field resets to '0'.

When Non-secure EL1 is implemented:

Coarse-grained exception catch for Non-secure EL1. Controls Exception Catch debug events for Non-secure EL1.

NSE1	Meaning
0b0	Exception Catch debug events are disabled for Non-secure EL1.
0b1	Exception Catch debug events are enabled for Non-secure EL1.

The reset behavior of this field is:

- On a Cold reset, this field resets to '0'.

Otherwise:

Reserved, RES0.

NSE0, bit [4]

Access to this field is RES0.

Bit [3]

Reserved, RES0.

SE2, bit [2]

When FEAT_Debugv8p2 is implemented and FEAT_SEL2 is implemented:

Controls exception catch on exception entry to Secure EL2. Also controls exception catch on exception return to Secure EL2 in conjunction with EDECCR.SR2.

SE2	Meaning
0b0	If EDECCR.SR2 is 0, then Exception Catch debug events are disabled for Secure EL2. If EDECCR.SR2 is 1, then Exception Catch debug events are enabled for exception returns to Secure EL2.
0b1	If EDECCR.SR2 is 0, then Exception Catch debug events are enabled for exception entry, reset entry, and exception return to Secure EL2. If EDECCR.SR2 is 1, then Exception Catch debug events are enabled for exception entry and reset entry to Secure EL2.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

It is IMPLEMENTATION DEFINED whether a reset entry to an Exception level will generate an Exception Catch debug event.

The reset behavior of this field is:

- On a Cold reset, this field resets to '0'.

Otherwise:

Reserved, RES0.

SE1, bit [1]

When FEAT_Debugv8p2 is implemented and Secure EL1 is implemented:

Controls exception catch on exception entry to Secure EL1. Also controls exception catch on exception return to Secure EL1 in conjunction with EDECCR.SR1.

SE1	Meaning
0b0	If EDECCR.SR1 is 0, then Exception Catch debug events are disabled for Secure EL1. If EDECCR.SR1 is 1, then Exception Catch debug events are enabled for exception returns to Secure EL1.
0b1	If EDECCR.SR1 is 0, then Exception Catch debug events are enabled for exception entry, reset entry, and exception return to Secure EL1. If EDECCR.SR1 is 1, then Exception Catch debug events are enabled for exception entry and reset entry to Secure EL1.

Note

It is IMPLEMENTATION DEFINED whether a reset entry to an Exception level will generate an Exception Catch debug event.

The reset behavior of this field is:

- On a Cold reset, this field resets to '0'.

When Secure EL1 is implemented:

Coarse-grained exception catch for Secure EL1. Controls Exception Catch debug events for Secure EL1.

SE1	Meaning
0b0	Exception Catch debug events are disabled for Secure EL1.
0b1	Exception Catch debug events are enabled for Secure EL1.

The reset behavior of this field is:

- On a Cold reset, this field resets to '0'.

Otherwise:

Reserved, RES0.

SE0, bit [0]

Access to this field is RES0.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Accessing EDECCR

EDECCR can be accessed through the external debug interface:

Component	Offset	Instance
Debug	0x098	EDECCR

Accessible as follows:

- When DoubleLockStatus(), or !IsCorePowered(), or OSLockStatus(), accesses to this register return an ERROR.
- When SoftwareLockStatus(), accesses to this register are RO.
- Otherwise, accesses to this register are RW.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

E9.2.25 EDECR, External Debug Execution Control Register

The EDECR characteristics are:

Purpose

Controls Halting debug events.

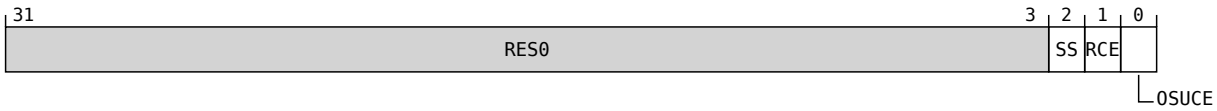
Configuration

When FEAT_DoPD is implemented, EDECR is in the Core power domain. Otherwise, EDECR is in the Debug power domain

Attributes

EDECR is a 32-bit register.

Field descriptions



Bits [31:3]

Reserved, RES0.

SS, bit [2]

Halting step enable. Possible values of this field are:

SS	Meaning
0b0	Halting step debug event disabled.
0b1	Halting step debug event enabled.

If the value of EDECR.SS is changed when the PE is in Non-debug state, behavior is CONSTRAINED UNPREDICTABLE as described in 'Changing the value of EDECR.SS when not in Debug state'.

The reset behavior of this field is:

- On a Cold reset:
  - When FEAT_DoPD is implemented, this field resets to '0'.
- On a External debug reset:
  - When FEAT_DoPD is not implemented, this field resets to '0'.

RCE, bit [1]

When FEAT_DoPD is not implemented:

Reset Catch Enable.

RCE	Meaning
0b0	Reset Catch debug event disabled.
0b1	Reset Catch debug event enabled.

The reset behavior of this field is:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- On a External debug reset, this field resets to '0'.

Otherwise:

Reserved, RES0.

OSUCE, bit [0]

When FEAT_DoPD is not implemented:

OS Unlock Catch Enable.

OSUCE	Meaning
0b0	OS Unlock Catch debug event disabled.
0b1	OS Unlock Catch debug event enabled.

The reset behavior of this field is:

- On a External debug reset, this field resets to '0'.

Otherwise:

Reserved, RES0.

Accessing EDECR

EDECR can be accessed through the external debug interface:

Component	Offset	Instance
Debug	0x024	EDECR

Accessible as follows:

- When FEAT_DoPD is implemented and !IsCorePowered(), accesses to this register return an ERROR.
- When SoftwareLockStatus(), accesses to this register are RO.
- Otherwise, accesses to this register are RW.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

E9.2.26 EDESR, External Debug Event Status Register

The EDESR characteristics are:

Purpose

Indicates the status of internally pending Halting debug events.

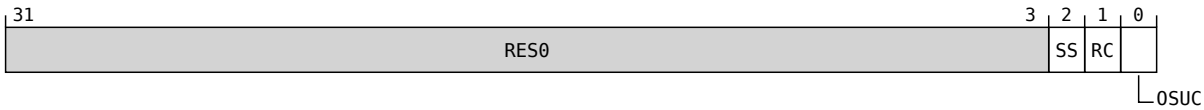
Configuration

EDESR is in the Core power domain

Attributes

EDESR is a 32-bit register.

Field descriptions



Bits [31:3]

Reserved, RES0.

SS, bit [2]

When FEAT_DoPD is implemented:

Halting step debug event pending. Possible values of this field are:

SS	Meaning
0b0	Reading this means that a Halting step debug event is not pending. Writing this means no action.
0b1	Reading this means that a Halting step debug event is pending. Writing this clears the pending Halting step debug event.

The reset behavior of this field is:

- On a Cold reset, this field resets to '0'.

Otherwise:

Halting step debug event pending. Possible values of this field are:

SS	Meaning
0b0	Reading this means that a Halting step debug event is not pending. Writing this means no action.
0b1	Reading this means that a Halting step debug event is pending. Writing this clears the pending Halting step debug event.

The reset behavior of this field is:

- On a Warm reset, this field resets to the value in EDECR.SS.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

RC, bit [1]

Reset Catch debug event pending. Possible values of this field are:

RC	Meaning
0b0	Reading this means that a Reset Catch debug event is not pending. Writing this means no action.
0b1	Reading this means that a Reset Catch debug event is pending. Writing this clears the pending Reset Catch debug event.

The reset behavior of this field is:

- On a Warm reset:
  - When FEAT_DoPD is implemented, this field resets to the value in CTIDEVCTL.RCE.
  - When FEAT_DoPD is not implemented, this field resets to the value in EDECR.RCE.

OSUC, bit [0]

OS Unlock Catch debug event pending. Possible values of this field are:

OSUC	Meaning
0b0	Reading this means that an OS Unlock Catch debug event is not pending. Writing this means no action.
0b1	Reading this means that an OS Unlock Catch debug event is pending. Writing this clears the pending OS Unlock Catch debug event.

The reset behavior of this field is:

- On a Warm reset, this field resets to '0'.

Accessing EDESR

If a request to clear a pending Halting debug event is received at or about the time when halting becomes allowed, it is CONSTRAINED UNPREDICTABLE whether the event is taken.

If Core power is removed while a Halting debug event is pending, it is lost. However, it might become pending again when the Core is powered back on and Cold reset.

EDESR can be accessed through the external debug interface:

Component	Offset	Instance
Debug	0x020	EDESR

Accessible as follows:

- When DoubleLockStatus() or !IsCorePowered(), accesses to this register return an ERROR.
- When SoftwareLockStatus(), accesses to this register are RO.
- Otherwise, accesses to this register are RW.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

E9.2.27 EDITCTRL, External Debug Integration mode Control register

The EDITCTRL characteristics are:

Purpose

Enables the external debug to switch from its default mode into integration mode, where test software can control directly the inputs and outputs of the PE, for integration testing or topology detection.

Configuration

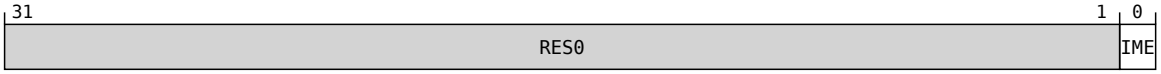
The power domain of EDITCTRL is IMPLEMENTATION DEFINED

Implementation of this register is OPTIONAL.

Attributes

EDITCTRL is a 32-bit register.

Field descriptions



Bits [31:1]

Reserved, RES0.

IME, bit [0]

Integration mode enable. When IME == 1, the device reverts to an integration mode to enable integration testing or topology detection.

IME	Meaning
0b0	Normal operation.
0b1	Integration mode enabled.

The integration mode behavior is IMPLEMENTATION DEFINED.

The following resets apply:

- Whichever power domain the register is implemented in, this field resets to 0.
- Otherwise, the value of this field is unchanged.

Accessing EDITCTRL

EDITCTRL can be accessed through the external debug interface:

Component	Offset	Instance
Debug	0xF00	EDITCTRL

Accessible as follows:

- When DoubleLockStatus(), or !IsCorePowered(), or OSLockStatus(), accesses to this register are IMPLEMENTATION DEFINED.
- When SoftwareLockStatus(), accesses to this register are RO.
- Otherwise, accesses to this register are RW.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

E9.2.28 EDITR, External Debug Instruction Transfer Register

The EDITR characteristics are:

Purpose

Used in Debug state for passing instructions to the PE for execution.

Configuration

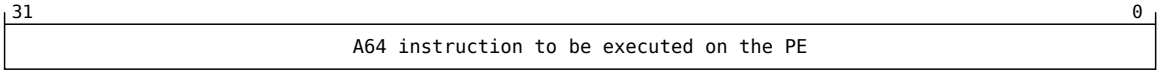
EDITR is in the Core power domain

Attributes

EDITR is a 32-bit register.

Field descriptions

When in AArch64 state:



A64_Instruction, bits [31:0]

A64 instruction to be executed on the PE.

Accessing EDITR

If EDSCR.ITE == 0 when the PE exits Debug state on receiving a Restart request trigger event, the behavior of any instruction issued through the ITR in Normal access mode that has not completed execution is CONSTRAINED UNPREDICTABLE, and must do one of the following:

- It must complete execution in Debug state before the PE executes the restart sequence.
- It must complete execution in Non-debug state before the PE executes the restart sequence.
- It must be abandoned. This means that the instruction does not execute. Any registers or memory accessed by the instruction are left in an UNKNOWN state.

EDITR ignores writes if the PE is in Non-debug state.

EDITR can be accessed through the external debug interface:

Component	Offset	Instance
Debug	0x084	EDITR

Accessible as follows:

- When DoubleLockStatus(), or !IsCorePowered(), or OSLockStatus(), accesses to this register return an ERROR.
- When SoftwareLockStatus(), accesses to this register are WI.
- Otherwise, accesses to this register are WO.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

E9.2.29 EDLAR, External Debug Lock Access Register

The EDLAR characteristics are:

Purpose

Allows or disallows access to the external debug registers through a memory-mapped interface.

The optional Software Lock provides a lock to prevent memory-mapped writes to the debug registers. Use of this lock mechanism reduces the risk of accidental damage to the contents of the debug registers. It does not, and cannot, prevent all accidental or malicious damage.

Configuration

When FEAT_DoPD is implemented, EDLAR is in the Core power domain. Otherwise, EDLAR is in the Debug power domain

If FEAT_DoPD is implemented, Software Lock is not implemented by the architecturally-defined debug components of the PE.

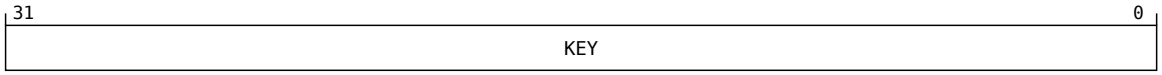
Software uses EDLAR to set or clear the lock, and EDLSR to check the current status of the lock.

Attributes

EDLAR is a 32-bit register.

Field descriptions

When Debug Software Lock is implemented:

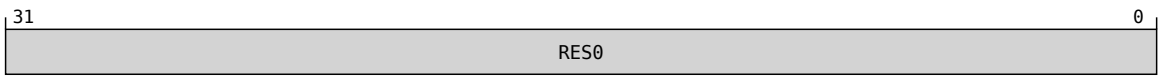


KEY, bits [31:0]

Lock Access control. Writing the key value `0xC5ACCE55` to this field unlocks the lock, enabling write accesses to this component's registers through a memory-mapped interface.

Writing any other value to this register locks the lock, disabling write accesses to this component's registers through a memory mapped interface.

Otherwise:



Otherwise

Bits [31:0]

Reserved, RES0.

Accessing EDLAR

EDLAR can be accessed through the memory-mapped interface:

Component	Offset	Instance
Debug	`0xFB0`	EDLAR

Accessible as follows:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- When FEAT_DoPD is implemented and !IsCorePowered(), accesses to this register return an ERROR.
- Otherwise, accesses to this register are WO.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

E9.2.30 EDLSR, External Debug Lock Status Register

The EDLSR characteristics are:

Purpose

Indicates the current status of the software lock for external debug registers.

The optional Software Lock provides a lock to prevent memory-mapped writes to the debug registers. Use of this lock mechanism reduces the risk of accidental damage to the contents of the debug registers. It does not, and cannot, prevent all accidental or malicious damage.

Configuration

When FEAT_DoPD is implemented, EDLSR is in the Core power domain. Otherwise, EDLSR is in the Debug power domain

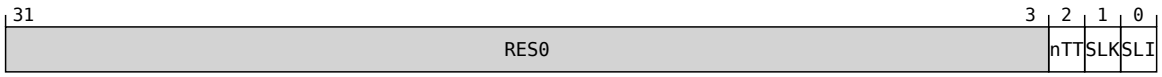
If FEAT_DoPD is implemented, Software Lock is not implemented by the architecturally-defined debug components of the PE.

Software uses EDLAR to set or clear the lock, and EDLSR to check the current status of the lock.

Attributes

EDLSR is a 32-bit register.

Field descriptions



Bits [31:3]

Reserved, RES0.

nTT, bit [2]

Not thirty-two bit access required. RAZ.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

SLK, bit [1]

When Debug Software Lock is implemented:

Software Lock status for this component. For an access to LSR that is not a memory-mapped access, or when Software Lock is not implemented, this field is RES0.

For memory-mapped accesses when Software Lock is implemented, possible values of this field are:

SLK	Meaning
0b0	Lock clear. Writes are permitted to this component's registers.
0b1	Lock set. Writes to this component's registers are ignored, and reads have no side effects.

The reset behavior of this field is:

- On a Cold reset:
  - When FEAT_DoPD is implemented, this field resets to '1'.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- On a External debug reset:
  - When FEAT_DoPD is not implemented, this field resets to `'1'`.

Otherwise:

Reserved, RAZ.

SLI, bit [0]

Software Lock implemented. For an access to LSR that is not a memory-mapped access, this field is RAZ.

The value of this field is an IMPLEMENTATION DEFINED choice of:

SLI	Meaning
`0b0`	Software Lock not implemented or not memory-mapped access.
`0b1`	Software Lock implemented and memory-mapped access.

Access to this field is RO.

Accessing EDLSR

EDLSR can be accessed through the memory-mapped interface:

Component	Offset	Instance
Debug	`0xFB4`	EDLSR

Accessible as follows:

- When FEAT_DoPD is implemented and !IsCorePowered(), accesses to this register return an ERROR.
- Otherwise, accesses to this register are RO.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

E9.2.31 EDPFR, External Debug Processor Feature Register

The EDPFR characteristics are:

Purpose

Provides information about implemented PE features.

For general information about the interpretation of the ID registers, see 'Principles of the ID scheme for fields in ID registers'.

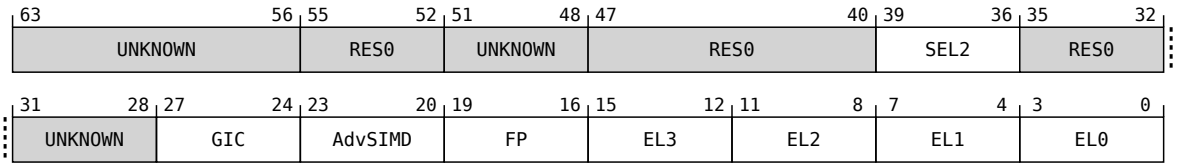
Configuration

There are no configuration notes.

Attributes

EDPFR is a 64-bit register.

Field descriptions



Bits [63:56]

Reserved, UNKNOWN.

Bits [55:52]

Reserved, RES0.

Bits [51:48]

Reserved, UNKNOWN.

Bits [47:40]

Reserved, RES0.

SEL2, bits [39:36]

Secure EL2.

The value of this field is an IMPLEMENTATION DEFINED choice of:

SEL2	Meaning
0b0000	Secure EL2 is not implemented.
0b0001	Secure EL2 is implemented.

FEAT_SEL2 implements the functionality identified by the value 0b0001

All other values are reserved.

Access to this field is RO.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Bits [35:32]

Reserved, RES0.

Bits [31:28]

Reserved, UNKNOWN.

GIC, bits [27:24]

System register GIC interface support.

The value of this field is an IMPLEMENTATION DEFINED choice of:

GIC	Meaning
0b0000	GIC CPU interface system registers not implemented.
0b0001	System register interface to versions 3.0 and 4.0 of the GIC CPU interface is supported.
0b0011	System register interface to version 4.1 of the GIC CPU interface is supported.

All other values are reserved.

In Armv8-R AArch64, this field returns the value of ID_AA64PFR0_EL1.GIC.

Access to this field is RO.

AdvSIMD, bits [23:20]

Advanced SIMD.

The value of this field is an IMPLEMENTATION DEFINED choice of:

AdvSIMD	Meaning
0b0000	Advanced SIMD is implemented, including support for the following SISD and SIMD operations: • Integer byte, halfword, word and doubleword element operations. • Single-precision and double-precision floating-point arithmetic. • Conversions between single-precision and half-precision data types, and double-precision and half-precision data types.
0b0001	As for 0b0000, and also includes support for half-precision floating-point arithmetic.
0b1111	Advanced SIMD is not implemented.

All other values are reserved.

This field must have the same value as the FP field.

The permitted values are:

- 0b0000 in an implementation with Advanced SIMD support, that does not include the FEAT_FP16 extension.
- 0b0001 in an implementation with Advanced SIMD support, that includes the FEAT_FP16 extension.
- 0b1111 in an implementation without Advanced SIMD support.

In Armv8-R AArch64, this field returns the value of ID_AA64PFR0_EL1.AdvSIMD.

Access to this field is RO.

FP, bits [19:16]

Floating-point.

The value of this field is an IMPLEMENTATION DEFINED choice of:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

FP	Meaning
0b0000	Floating-point is implemented, and includes support for: • Single-precision and double-precision floating-point types. • Conversions between single-precision and half-precision data types, and double-precision and half-precision data types.
0b0001	As for 0b0000, and also includes support for half-precision floating-point arithmetic.
0b1111	Floating-point is not implemented.

All other values are reserved.

This field must have the same value as the AdvSIMD field.

The permitted values are:

- 0b0000 in an implementation with floating-point support, that does not include the FEAT_FP16 extension.
- 0b0001 in an implementation with floating-point support, that includes the FEAT_FP16 extension.
- 0b1111 in an implementation without floating-point support.

In Armv8-R AArch64, this field returns the value of ID_AA64PFR0_EL1.FP.

Access to this field is RO.

EL3, bits [15:12]

AArch64 EL3 Exception level handling.

The value of this field is an IMPLEMENTATION DEFINED choice of:

EL3	Meaning
0b0000	EL3 is not implemented or cannot be executed in AArch64 state.
0b0001	EL3 can be executed in AArch64 state only.
0b0010	EL3 can be executed in both Execution states.

When the value of EDAA32PFR.EL3 is nonzero, this field must be 0b0000.

All other values are reserved.

In an Armv8-R AArch64 implementation this field returns the value of 0b0000.

Access to this field is RO.

EL2, bits [11:8]

AArch64 EL2 Exception level handling.

The value of this field is an IMPLEMENTATION DEFINED choice of:

EL2	Meaning
0b0000	EL2 is not implemented or cannot be executed in AArch64 state.
0b0001	EL2 can be executed in AArch64 state only.
0b0010	EL2 can be executed in both Execution states.

All other values are reserved.

In an Armv8-R AArch64 implementation this field returns the value of 0b0001.

Access to this field is RO.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

EL1, bits [7:4]

AArch64 EL1 Exception level handling.

The value of this field is an IMPLEMENTATION DEFINED choice of:

EL1	Meaning
0b0000	EL1 cannot be executed in AArch64 state.
0b0001	EL1 can be executed in AArch64 state only.
0b0010	EL1 can be executed in both Execution states.

All other values are reserved.

In Armv8-R AArch64, the only permitted values is 0b0001.

Access to this field is RO.

EL0, bits [3:0]

AArch64 EL0 Exception level handling.

The value of this field is an IMPLEMENTATION DEFINED choice of:

EL0	Meaning
0b0000	EL0 cannot be executed in AArch64 state.
0b0001	EL0 can be executed in AArch64 state only.
0b0010	EL0 can be executed in both Execution states.

All other values are reserved.

In Armv8-R AArch64 implementation, the only permitted value is 0b0001.

Access to this field is RO.

Accessing EDPFR

EDPFR can be accessed through the external debug interface:

Component	Offset	Instance
Debug	0xD20	EDPFR

Accessible as follows:

- When IsCorePowered() and !DoubleLockStatus(), accesses to this register are RO.
- When FEAT_DoPD is implemented and !IsCorePowered(), accesses to this register return an ERROR.
- Otherwise, accesses to this register are IMPLEMENTATION DEFINED.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

E9.2.32 EDPIDR0, External Debug Peripheral Identification Register 0

The EDPIDR0 characteristics are:

Purpose

Provides information to identify an external debug component.

For more information, see ‘About the Peripheral identification scheme’.

Configuration

When FEAT_DoPD is implemented, EDPIDR0 is in the Core power domain. Otherwise, EDPIDR0 is in the Debug power domain

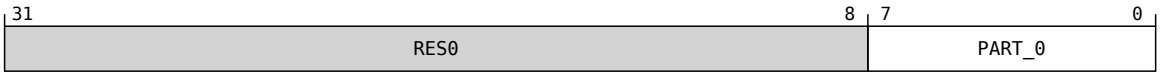
This register is required for CoreSight compliance.

Implementation of this register is OPTIONAL.

Attributes

EDPIDR0 is a 32-bit register.

Field descriptions



Bits [31:8]

Reserved, RES0.

PART_0, bits [7:0]

Part number, least significant byte.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

Accessing EDPIDR0

EDPIDR0 can be accessed through the external debug interface:

Component	Offset	Instance
Debug	0xFE0	EDPIDR0

Accessible as follows:

- When FEAT_DoPD is implemented and !IsCorePowered(), accesses to this register return an ERROR.
- Otherwise, accesses to this register are RO.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

E9.2.33 EDPIDR1, External Debug Peripheral Identification Register 1

The EDPIDR1 characteristics are:

Purpose

Provides information to identify an external debug component.

For more information, see ‘About the Peripheral identification scheme’.

Configuration

When FEAT_DoPD is implemented, EDPIDR1 is in the Core power domain. Otherwise, EDPIDR1 is in the Debug power domain

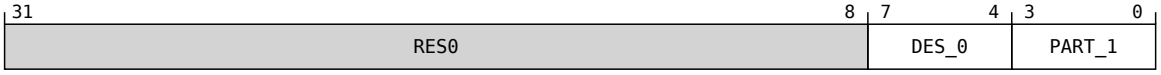
This register is required for CoreSight compliance.

Implementation of this register is OPTIONAL.

Attributes

EDPIDR1 is a 32-bit register.

Field descriptions



Bits [31:8]

Reserved, RES0.

DES_0, bits [7:4]

Designer, least significant nibble of JEP106 ID code. For Arm Limited, this field is `0b1011`.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

PART_1, bits [3:0]

Part number, most significant nibble.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

Accessing EDPIDR1

EDPIDR1 can be accessed through the external debug interface:

Component	Offset	Instance
Debug	`0xFE4`	EDPIDR1

Accessible as follows:

- When FEAT_DoPD is implemented and !IsCorePowered(), accesses to this register return an ERROR.
- Otherwise, accesses to this register are RO.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

E9.2.34 EDPIDR2, External Debug Peripheral Identification Register 2

The EDPIDR2 characteristics are:

Purpose

Provides information to identify an external debug component.

For more information, see ‘About the Peripheral identification scheme’.

Configuration

When FEAT_DoPD is implemented, EDPIDR2 is in the Core power domain. Otherwise, EDPIDR2 is in the Debug power domain

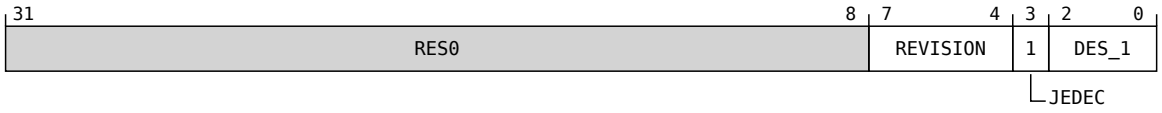
This register is required for CoreSight compliance.

Implementation of this register is OPTIONAL.

Attributes

EDPIDR2 is a 32-bit register.

Field descriptions



Bits [31:8]

Reserved, RES0.

REVISION, bits [7:4]

Part major revision. Parts can also use this field to extend Part number to 16-bits.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

JEDEC, bit [3]

Indicates a JEP106 identity code is used.

Reads as `0b1`

Access to this field is RO.

DES_1, bits [2:0]

Designer, most significant bits of JEP106 ID code. For Arm Limited, this field is `0b011`.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

Accessing EDPIDR2

EDPIDR2 can be accessed through the external debug interface:

Component	Offset	Instance
Debug	`0xFE8`	EDPIDR2

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Accessible as follows:

- When FEAT_DoPD is implemented and !IsCorePowered(), accesses to this register return an ERROR.
- Otherwise, accesses to this register are RO.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

E9.2.35 EDPIDR3, External Debug Peripheral Identification Register 3

The EDPIDR3 characteristics are:

Purpose

Provides information to identify an external debug component.

For more information, see ‘About the Peripheral identification scheme’.

Configuration

When FEAT_DoPD is implemented, EDPIDR3 is in the Core power domain. Otherwise, EDPIDR3 is in the Debug power domain

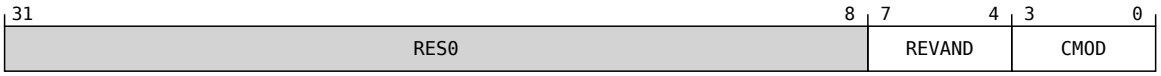
This register is required for CoreSight compliance.

Implementation of this register is OPTIONAL.

Attributes

EDPIDR3 is a 32-bit register.

Field descriptions



Bits [31:8]

Reserved, RES0.

REVAND, bits [7:4]

Part minor revision. Parts using EDPIDR2.REVISION as an extension to the Part number must use this field as a major revision number.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

CMOD, bits [3:0]

Customer modified. Indicates someone other than the Designer has modified the component.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

Accessing EDPIDR3

EDPIDR3 can be accessed through the external debug interface:

Component	Offset	Instance
Debug	0xFEC	EDPIDR3

Accessible as follows:

- When FEAT_DoPD is implemented and !IsCorePowered(), accesses to this register return an ERROR.
- Otherwise, accesses to this register are RO.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

E9.2.36 EDPIDR4, External Debug Peripheral Identification Register 4

The EDPIDR4 characteristics are:

Purpose

Provides information to identify an external debug component.

For more information, see ‘About the Peripheral identification scheme’.

Configuration

When FEAT_DoPD is implemented, EDPIDR4 is in the Core power domain. Otherwise, EDPIDR4 is in the Debug power domain

This register is required for CoreSight compliance.

Implementation of this register is OPTIONAL.

Attributes

EDPIDR4 is a 32-bit register.

Field descriptions

Bits [31:8]

Reserved, RES0.

SIZE, bits [7:4]

Size of the component. Log_2 of the number of 4KB pages from the start of the component to the end of the component ID registers.

Reads as `0b0000`

Access to this field is RO.

DES_2, bits [3:0]

Designer, JEP106 continuation code, least significant nibble. For Arm Limited, this field is `0b0100`.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

Accessing EDPIDR4

EDPIDR4 can be accessed through the external debug interface:

Component	Offset	Instance
Debug	`0xFD0`	EDPIDR4

Accessible as follows:

- When FEAT_DoPD is implemented and !IsCorePowered(), accesses to this register return an ERROR.
- Otherwise, accesses to this register are RO.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

E9.2.37 EDPRCR, External Debug Power/Reset Control Register

The EDPRCR characteristics are:

Purpose

Controls the PE functionality related to powerup, reset, and powerdown.

Configuration

When FEAT_DoPD is implemented, EDPRCR is in the Core power domain. Otherwise, EDPRCR contains fields that are in the Core power domain and fields that are in the Debug power domain

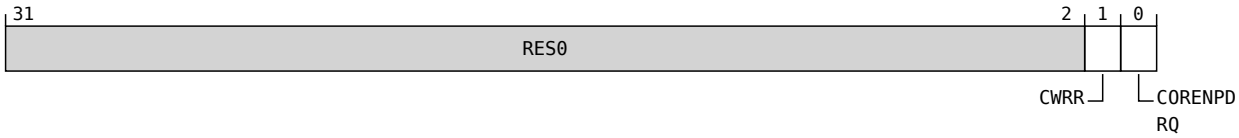
External register EDPRCR bit [0] is architecturally mapped to AArch64 System register DBGPRCR_EL1[0].

Attributes

EDPRCR is a 32-bit register.

Field descriptions

When FEAT_DoPD is implemented:



Bits [31:2]

Reserved, RES0.

CWRR, bit [1]

Warm reset request.

The extent of the reset is IMPLEMENTATION DEFINED, but must be one of:

- The request is ignored.
- Only this PE is Warm reset.
- This PE and other components of the system, possibly including other PEs, are Warm reset.

Arm deprecates use of this bit, and recommends that implementations ignore the request.

CWRR	Meaning
0b0	No action.
0b1	Request Warm reset.

This field is in the Core power domain

In an implementation that includes the recommended external debug interface, this bit drives the **DBGRSTREQ** signal.

The reset behavior of this field is:

- On a Warm reset, this field resets to '0'.

Accessing this field has the following behavior:

- Access to this field is RAZ/WI if any of the following are true:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- OSLockStatus()
- SoftwareLockStatus()

- Access to this field is RAZ/WI if all of the following are true:
  - !ExternalSecureInvasiveDebugEnabled()
  - FEAT_Secure is implemented
- Access to this field is RAZ/WI if all of the following are true:
  - !ExternalInvasiveDebugEnabled()
  - FEAT_Secure is not implemented
- Otherwise, access to this field is WO/RAZ.

CORENPDRQ, bit [0]

Core no powerdown request. Requests emulation of powerdown.

This request is typically passed to an external power controller. This means that whether a request causes power up is dependent on the IMPLEMENTATION DEFINED nature of the system. The power controller must not allow the Core power domain to switch off while this bit is 1.

CORENPDRQ	Meaning
0b0	If the system responds to a powerdown request, it powers down Core power domain.
0b1	If the system responds to a powerdown request, it does not powerdown the Core power domain, but instead emulates a powerdown of that domain.

When this bit reads as UNKNOWN, the PE ignores writes to this bit.

This field is in the Core power domain, and permitted accesses to this field map to the DBGPRCR.CORENPDRQ and DBGPRCR_EL1.CORENPDRQ fields.

In an implementation that includes the recommended external debug interface, this bit drives the **DBGNOPWRDWN** signal.

It is IMPLEMENTATION DEFINED whether this bit is reset to the Cold reset value on exit from an IMPLEMENTATION DEFINED software-visible retention state. For more information about retention states, see 'Core power domain power states'.

Note

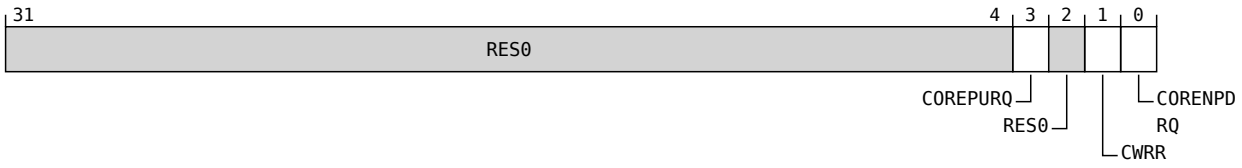
Writes to this bit are not prohibited by the IMPLEMENTATION DEFINED authentication interface. This means that a debugger can request emulation of powerdown regardless of whether invasive debug is permitted.

On a Cold reset, if the powerup request is implemented and the powerup request has been asserted, this field is an IMPLEMENTATION DEFINED choice of 0 or 1. If the powerup request is not asserted, this field is set to 0.

Accessing this field has the following behavior:

- When OSLockStatus(), access to this field is UNKNOWN/WI.
- When SoftwareLockStatus(), access to this field is RO.
- Otherwise, access to this field is RW.

Otherwise:



Bits [31:4]

Reserved, RES0.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

COREPURQ, bit [3]

Core powerup request. Allows a debugger to request that the power controller power up the core, enabling access to the debug register in the Core power domain, and that the power controller emulates powerdown.

This request is typically passed to an external power controller. This means that whether a request causes power up is dependent on the IMPLEMENTATION DEFINED nature of the system. The power controller must not allow the Core power domain to switch off while this bit is 1.

COREPURQ	Meaning
0b0	Do not request power up of the Core power domain.
0b1	Request power up of the Core power domain, and emulation of powerdown.

In an implementation that includes the recommended external debug interface, this bit drives the **DBGPWRUPREQ** signal.

This field is in the Debug power domain and can be read and written when the Core power domain is powered off.

Note

Writes to this bit are not prohibited by the IMPLEMENTATION DEFINED authentication interface. This means that a debugger can request emulation of powerdown regardless of whether invasive debug is permitted.

The reset behavior of this field is:

- On a External debug reset, this field resets to '0'.

Accessing this field has the following behavior:

- When SoftwareLockStatus(), access to this field is RO.
- Otherwise, access to this field is RW.

Bit [2]

Reserved, RES0.

CWRR, bit [1]

Warm reset request.

The extent of the reset is IMPLEMENTATION DEFINED, but must be one of:

- The request is ignored.
- Only this PE is Warm reset.
- This PE and other components of the system, possibly including other PEs, are Warm reset.

Arm deprecates use of this bit, and recommends that implementations ignore the request.

CWRR	Meaning
0b0	No action.
0b1	Request Warm reset.

This field is in the Core power domain

In an implementation that includes the recommended external debug interface, this bit drives the **DBGRSTREQ** signal.

The reset behavior of this field is:

- On a Warm reset, this field resets to '0'.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Accessing this field has the following behavior:

- Access to this field is RAZ/WI if any of the following are true:
  - !IsCorePowered()
  - DoubleLockStatus()
  - OSLockStatus()
  - SoftwareLockStatus()
- Access to this field is RAZ/WI if all of the following are true:
  - FEAT_Secure is implemented
  - !ExternalSecureInvasiveDebugEnabled()
- Access to this field is RAZ/WI if all of the following are true:
  - FEAT_Secure is not implemented
  - !ExternalInvasiveDebugEnabled()
- Otherwise, access to this field is WO/RAZ.

CORENPDRQ, bit [0]

Core no powerdown request. Requests emulation of powerdown.

This request is typically passed to an external power controller. This means that whether a request causes power up is dependent on the IMPLEMENTATION DEFINED nature of the system. The power controller must not allow the Core power domain to switch off while this bit is 1.

CORENPDRQ	Meaning
0b0	If the system responds to a powerdown request, it powers down Core power domain.
0b1	If the system responds to a powerdown request, it does not powerdown the Core power domain, but instead emulates a powerdown of that domain.

When this bit reads as UNKNOWN, the PE ignores writes to this bit.

This field is in the Core power domain, and permitted accesses to this field map to the DBGPRCR.CORENPDRQ and DBGPRCR_EL1.CORENPDRQ fields.

In an implementation that includes the recommended external debug interface, this bit drives the **DBGNOPWRDWN** signal.

It is IMPLEMENTATION DEFINED whether this bit is reset to the value of EDPRCR.COREPURQ on exit from an IMPLEMENTATION DEFINED software-visible retention state. For more information about retention states, see 'Core power domain power states'.

Note

Writes to this bit are not prohibited by the IMPLEMENTATION DEFINED authentication interface. This means that a debugger can request emulation of powerdown regardless of whether invasive debug is permitted.

The reset behavior of this field is:

- On a Cold reset, this field resets to the value in EDPRCR.COREPURQ.

Accessing this field has the following behavior:

- Access to this field is UNKNOWN/WI if any of the following are true:
  - !IsCorePowered()
  - DoubleLockStatus()
  - OSLockStatus()
- When SoftwareLockStatus(), access to this field is RO.
- Otherwise, access to this field is RW.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Accessing EDPRCR

On permitted accesses to the register, other access controls affect the behavior of some fields. See the field descriptions for more information.

EDPRCR can be accessed through the external debug interface:

Component	Offset	Instance
Debug	0x310	EDPRCR

Accessible as follows:

- When FEAT_DoPD is implemented and !IsCorePowered(), accesses to this register return an ERROR.
- When SoftwareLockStatus(), accesses to this register are RO.
- Otherwise, accesses to this register are RW.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

E9.2.38 EDPRSR, External Debug Processor Status Register

The EDPRSR characteristics are:

Purpose

Holds information about the reset and powerdown state of the PE.

Configuration

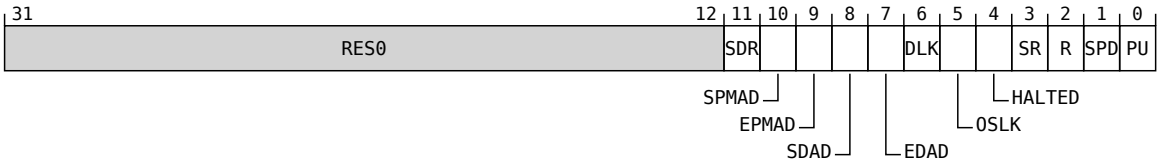
When FEAT_DoPD is implemented, EDPRSR is in the Core power domain. Otherwise, EDPRSR contains fields that are in the Core power domain and fields that are in the Debug power domain

If FEAT_DoPD is implemented, then all fields in this register are in the Core power domain.

Attributes

EDPRSR is a 32-bit register.

Field descriptions



Bits [31:12]

Reserved, RES0.

SDR, bit [11]

Sticky Debug Restart. Set to 1 when the PE exits Debug state.

SDR	Meaning
0b0	The PE has not restarted since EDPRSR was last read.
0b1	The PE has restarted since EDPRSR was last read.

Note

If a reset occurs when the PE is in Debug state, the PE exits Debug state. SDR is UNKNOWN on Warm reset, meaning a debugger must also use the SR bit to determine whether the PE has left Debug state.

If the Core power domain is powered up, then following a read of EDPRSR:

- If FEAT_DoubleLock is not implemented or `DoubleLockStatus()` == FALSE, this bit clears to 0.
- If FEAT_DoubleLock is implemented and `DoubleLockStatus()` == TRUE, it is CONSTRAINED UNPREDICTABLE whether this bit clears to 0 or is unchanged.

This field is in the Core power domain.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing this field has the following behavior:

- Access to this field is UNKNOWN/WI if all of the following are true:
  - FEAT_DoPD is not implemented

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- !IsCorePowered()
- When DoubleLockStatus(), access to this field is UNKNOWN/WI.
- When SoftwareLockStatus(), access to this field is RO.
- Otherwise, access to this field is RC/WI.

SPMAD, bit [10]

When FEAT_Debugv8p4 is implemented and FEAT_PMUv3_EXT is implemented:

Sticky EPMAD error. Set to 1 if an external debug interface access to a Performance Monitors register returns an error because `AllowExternalPMUAccess()` == FALSE.

SPMAD	Meaning
`0b0`	No Non-secure external debug interface accesses to the external Performance Monitors registers have failed because `AllowExternalPMUAccess()` == FALSE for the access since EDPRSR was last read.
`0b1`	At least one Non-secure external debug interface access to the external Performance Monitors register has failed and returned an error because `AllowExternalPMUAccess()` == FALSE for the access since EDPRSR was last read.

If the Core power domain is powered up, then following a read of EDPRSR:

- If FEAT_DoubleLock is not implemented or `DoubleLockStatus()` == FALSE, this bit clears to 0.
- If FEAT_DoubleLock is implemented and `DoubleLockStatus()` == TRUE, it is CONSTRAINED UNPREDICTABLE whether this bit clears to 0 or is unchanged.

This field is in the Core power domain.

The reset behavior of this field is:

- On a Cold reset, this field resets to `'0'`.

Accessing this field has the following behavior:

- Access to this field is UNKNOWN/WI if all of the following are true:
  - FEAT_DoPD is not implemented
  - !IsCorePowered()
- When DoubleLockStatus(), access to this field is UNKNOWN/WI.
- When SoftwareLockStatus(), access to this field is RO.
- Otherwise, access to this field is RC/WI.

When FEAT_PMUv3_EXT is implemented:

Sticky EPMAD error.

SPMAD	Meaning
`0b0`	No external debug interface accesses to the Performance Monitors registers have failed because `AllowExternalPMUAccess()` == FALSE since EDPRSR was last read.
`0b1`	At least one external debug interface access to the Performance Monitors registers has failed and returned an error because `AllowExternalPMUAccess()` == FALSE since EDPRSR was last read.

If the Core power domain is powered up, then, following a read of EDPRSR:

- If FEAT_DoubleLock is not implemented or `DoubleLockStatus()` == FALSE, this bit clears to 0.
- If FEAT_DoubleLock is implemented, and `DoubleLockStatus()` == TRUE, it is CONSTRAINED UNPREDICTABLE whether this bit clears to 0 or is unchanged.

This field is in the Core power domain.

The reset behavior of this field is:

- On a Cold reset, this field resets to `'0'`.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Accessing this field has the following behavior:

- Access to this field is UNKNOWN/WI if all of the following are true:
  - FEAT_DoPD is not implemented
  - !IsCorePowered()
- When DoubleLockStatus(), access to this field is UNKNOWN/WI.
- When OSLockStatus(), access to this field is UNKNOWN/WI.
- When SoftwareLockStatus(), access to this field is RO.
- Otherwise, access to this field is RC/WI.

Otherwise:

Reserved, RES0.

EPMAD, bit [9]

When FEAT_Debugv8p4 is implemented and FEAT_PMUv3_EXT is implemented:

External Performance Monitors Access Disable status. Reports whether Non-secure access to Performance Monitor registers by an external debugger is prohibited by the MDCR_EL3.EPMAD control.

See MDCR_EL3.EPMAD for the list of affected external Performance Monitor registers.

EPMAD	Meaning
0b0	External Non-secure access to Performance Monitor registers not affected. AllowExternalPMUAccess() == TRUE for a Non-secure access.
0b1	External Non-secure access to affected Performance Monitor registers is prohibited. AllowExternalPMUAccess() == FALSE for a Non-secure access.

This field is in the Core power domain.

Accessing this field has the following behavior:

- Access to this field is UNKNOWN/WI if any of the following are true:
  - All of the following are true:
    - FEAT_DoPD is not implemented
    - !IsCorePowered()
  - EDPRSR.R == '1'
- When DoubleLockStatus(), access to this field is UNKNOWN/WI.
- Otherwise, access to this field is RO.

When FEAT_PMUv3_EXT is implemented:

External Performance Monitors Access Disable status. Reports whether access to Performance Monitor registers by an external debugger is prohibited by the MDCR_EL3.EPMAD control.

See MDCR_EL3.EPMAD for the list of affected external Performance Monitor registers.

EPMAD	Meaning
0b0	External access to Performance Monitor registers not affected. AllowExternalPMUAccess() == TRUE.
0b1	External access to affected Performance Monitor registers is prohibited. AllowExternalPMUAccess() == FALSE.

This field is in the Core power domain.

Accessing this field has the following behavior:

- Access to this field is UNKNOWN/WI if any of the following are true:
  - All of the following are true:
    - FEAT_DoPD is not implemented

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

— !IsCorePowered()
- EDPRSR.R == '1'

- When DoubleLockStatus(), access to this field is UNKNOWN/WI.
- When OSLockStatus(), access to this field is UNKNOWN/WI.
- Otherwise, access to this field is RO.

When FEAT_PMUv3 is implemented:

Reserved, UNKNOWN.

Otherwise:

Reserved, RES0.

SDAD, bit [8]

When FEAT_Debugv8p4 is implemented:

Sticky EDAD error. Set to 1 if an external debug interface access to a debug register returns an error because `AllowExternalDebugAccess()` == FALSE.

SDAD	Meaning
`0b0`	No Non-secure external debug interface accesses to the debug registers have failed because `AllowExternalDebugAccess()` == FALSE for the access since EDPRSR was last read.
`0b1`	At least one Non-secure external debug interface access to the debug registers has failed and returned an error because `AllowExternalDebugAccess()` == FALSE for the access since EDPRSR was last read.

If the Core power domain is powered up, then, following a read of EDPRSR:

- If FEAT_DoubleLock is not implemented or `DoubleLockStatus()` == FALSE, this bit clears to 0.
- If FEAT_DoubleLock is implemented and `DoubleLockStatus()` == TRUE, it is CONSTRAINED UNPREDICTABLE whether this bit clears to 0 or is unchanged.

This field is in the Core power domain.

The reset behavior of this field is:

- On a Cold reset, this field resets to `'0'`.

Accessing this field has the following behavior:

- Access to this field is UNKNOWN/WI if any of the following are true:
  - All of the following are true:
    — FEAT_DoPD is not implemented
    — !IsCorePowered()
  - EDPRSR.R == '1'
- When DoubleLockStatus(), access to this field is UNKNOWN/WI.
- Otherwise, access to this field is RO.

Otherwise:

Sticky EDAD error. Set to 1 if an external debug interface access to a debug register returns an error because `AllowExternalDebugAccess()` == FALSE.

SDAD	Meaning
`0b0`	No external debug interface accesses to the debug registers have failed because `AllowExternalDebugAccess()` == FALSE since EDPRSR was last read.
`0b1`	At least one external debug interface access to the debug registers has failed and returned an error because `AllowExternalDebugAccess()` == FALSE since EDPRSR was last read.

If the Core power domain is powered up, then, following a read of EDPRSR:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- If FEAT_DoubleLock is not implemented or `DoubleLockStatus()` == FALSE, this bit clears to 0.
- If FEAT_DoubleLock is implemented and `DoubleLockStatus()` == TRUE, it is CONSTRAINED UNPREDICTABLE whether this bit clears to 0 or is unchanged.

This field is in the Core power domain.

The reset behavior of this field is:

- On a Cold reset, this field resets to `'0'`.

Accessing this field has the following behavior:

- Access to this field is UNKNOWN/WI if any of the following are true:
  - All of the following are true:
    — FEAT_DoPD is not implemented
    — !IsCorePowered()
  - EDPRSR.R == '1'
- When DoubleLockStatus(), access to this field is UNKNOWN/WI.
- Access to this field is UNKNOWN/WI if all of the following are true:
  - OSLockStatus()
  - external debug writes to OSLAR_EL1 do not return an error when AllowExternalDebugAccess(addrdesc) == FALSE
- Otherwise, access to this field is RO.

EDAD, bit [7]

When FEAT_Debugv8p4 is implemented:

External Debug Access Disable status. Reports whether Non-secure access to breakpoint registers, watchpoint registers, and OSLAR_EL1 by an external debugger is prohibited by the MDCR_EL3.EDAD control.

See MDCR_EL3.EDAD for the list of affected external debug registers.

EDAD	Meaning
`0b0`	External Non-secure access to debug registers not affected. `AllowExternalDebugAccess()` == TRUE for a Non-secure access.
`0b1`	External Non-secure access to affected debug registers is prohibited. `AllowExternalDebugAccess()` == FALSE for a Non-secure access.

This field is in the Core power domain.

Accessing this field has the following behavior:

- Access to this field is UNKNOWN/WI if any of the following are true:
  - All of the following are true:
    — FEAT_DoPD is not implemented
    — !IsCorePowered()
  - EDPRSR.R == '1'
- When DoubleLockStatus(), access to this field is UNKNOWN/WI.
- Otherwise, access to this field is RO.

When FEAT_Debugv8p2 is implemented:

External Debug Access Disable status. Reports whether access to breakpoint registers, watchpoint registers, and OSLAR_EL1 by an external debugger is prohibited by the MDCR_EL3.EDAD control.

See MDCR_EL3.EDAD for the list of affected external debug registers.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

EDAD	Meaning
0b0	External access to debug registers not affected. AllowExternalDebugAccess() == TRUE.
0b1	External access to affected debug registers is prohibited. AllowExternalDebugAccess() == FALSE.

This field is in the Core power domain.

Accessing this field has the following behavior:

- Access to this field is UNKNOWN/WI if any of the following are true:
  - All of the following are true:
    - FEAT_DoPD is not implemented
    - !IsCorePowered()
  - EDPRSR.R == '1'
- When DoubleLockStatus(), access to this field is UNKNOWN/WI.
- Access to this field is UNKNOWN/WI if all of the following are true:
  - OSLockStatus()
  - external debug writes to OSLAR_EL1 do not return an error when AllowExternalDebugAccess(addrdesc) == FALSE
- Otherwise, access to this field is RO.

Otherwise:

External Debug Access Disable status. Reports whether access to breakpoint registers, watchpoint registers, and optionally OSLAR_EL1 by an external debugger is prohibited by the MDCR_EL3.EDAD control.

See MDCR_EL3.EDAD for the list of affected external debug registers.

EDAD	Meaning
0b0	External access to debug registers not affected. AllowExternalDebugAccess() == TRUE.
0b1	External access to affected debug registers is prohibited. AllowExternalDebugAccess() == FALSE.

This field is in the Core power domain.

Accessing this field has the following behavior:

- Access to this field is UNKNOWN/WI if any of the following are true:
  - All of the following are true:
    - FEAT_DoPD is not implemented
    - !IsCorePowered()
  - EDPRSR.R == '1'
- When DoubleLockStatus(), access to this field is UNKNOWN/WI.
- Otherwise, access to this field is RO.

DLK, bit [6]

When FEAT_Debugv8p4 is implemented:

This field is RES0.

When FEAT_Debugv8p2 is implemented and FEAT_DoubleLock is implemented:

Double Lock. From Armv8.2, use of this field is deprecated.

This field is in the Core power domain.

Accessing this field has the following behavior:

- Access to this field is UNKNOWN/WI if any of the following are true:
  - !IsCorePowered()
  - DoubleLockStatus()

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- Otherwise, access to this field is RAZ/WI.

When FEAT_DoubleLock is implemented:

Double Lock.

This field returns the result of the pseudocode function `DoubleLockStatus()`.

If the Core power domain is powered up and `DoubleLockStatus()` == TRUE, it is IMPLEMENTATION DEFINED whether:

- EDPRSR.PU reads as 1, EDPRSR.DLK reads as 1, and EDPRSR.SPD is UNKNOWN.
- EDPRSR.PU reads as 0, EDPRSR.DLK is UNKNOWN, and EDPRSR.SPD reads as 0.

This field is in the Core power domain.

DLK	Meaning
0b0	`DoubleLockStatus()` returns FALSE.
0b1	`DoubleLockStatus()` returns TRUE and the Core power domain is powered up.

Accessing this field has the following behavior:

- When !IsCorePowered(), access to this field is UNKNOWN/WI.
- Otherwise, access to this field is RO.

Otherwise:

Reserved, RES0.

OSLK, bit [5]

OS Lock status bit.

A read of this bit returns the value of OSLSR_EL1.OSLK.

This field is in the Core power domain.

Accessing this field has the following behavior:

- Access to this field is UNKNOWN/WI if any of the following are true:
  - All of the following are true:
    - FEAT_DoPD is not implemented
    - !IsCorePowered()
  - EDPRSR.R == '1'
- When DoubleLockStatus(), access to this field is UNKNOWN/WI.
- Otherwise, access to this field is RO.

HALTED, bit [4]

Halted status bit.

HALTED	Meaning
0b0	PE is in Non-debug state.
0b1	PE is in Debug state.

This field is in the Core power domain.

Accessing this field has the following behavior:

- Access to this field is UNKNOWN/WI if all of the following are true:
  - FEAT_DoPD is not implemented

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- !IsCorePowered()
- Otherwise, access to this field is RO.

SR, bit [3]

Sticky core Reset status bit.

SR	Meaning
0b0	The non-debug logic of the PE is not in reset state and has not been reset since the last time EDPRSR was read.
0b1	The non-debug logic of the PE is in reset state or has been reset since the last time EDPRSR was read.

If EDPRSR.PU reads as 1 and EDPRSR.R reads as 0, which means that the Core power domain is in a powerup state and that the non-debug logic of the PE is not in reset state, then following a read of EDPRSR:

- If FEAT_DoubleLock is not implemented or `DoubleLockStatus()` == FALSE, this bit clears to 0.
- If FEAT_DoubleLock is implemented and `DoubleLockStatus()` == TRUE, it is CONSTRAINED UNPREDICTABLE whether this bit clears to 0 or is unchanged.

This field is in the Core power domain.

The reset behavior of this field is:

- On a Warm reset, this field resets to `'1'`.

Accessing this field has the following behavior:

- Access to this field is UNKNOWN/WI if all of the following are true:
  - FEAT_DoPD is not implemented
  - !IsCorePowered()
- When DoubleLockStatus(), access to this field is UNKNOWN/WI.
- When SoftwareLockStatus(), access to this field is RO.
- Otherwise, access to this field is RC/WI.

R, bit [2]

PE Reset status bit.

R	Meaning
0b0	The non-debug logic of the PE is not in reset state.
0b1	The non-debug logic of the PE is in reset state.

If FEAT_DoubleLock is implemented, the PE is in reset state, and the PE entered reset state with the OS Double Lock locked this bit has a CONSTRAINED UNPREDICTABLE value. For more information, see ‘EDPRSR.{DLK, R} and reset state’.

This field is in the Core power domain.

Accessing this field has the following behavior:

- Access to this field is UNKNOWN/WI if any of the following are true:
  - All of the following are true:
    - FEAT_DoPD is not implemented
    - !IsCorePowered()
  - DoubleLockStatus()
- Otherwise, access to this field is RO.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

SPD, bit [1]

Sticky core Powerdown status bit.

If FEAT_DoubleLock is implemented and `DoubleLockStatus()` == TRUE, then:

- If FEAT_Debugv8p2 is implemented, this bit reads as 0.
- If FEAT_Debugv8p2 is not implemented, this bit might read as 0 or 1.

For more information, see 'EDPRSR.{DLK, SPD, PU} and the Core power domain'.

SPD	Meaning
`0b0`	If EDPRSR.PU is 0, it is not known whether the state of the debug registers in the Core power domain is lost. If EDPRSR.PU is 1, the state of the debug registers in the Core power domain has not been lost.
`0b1`	The state of the debug registers in the Core power domain has been lost.

If the Core power domain is powered up, then, following a read of EDPRSR:

- If FEAT_DoubleLock is not implemented or `DoubleLockStatus()` == FALSE, this bit clears to 0.
- If FEAT_DoubleLock is implemented and `DoubleLockStatus()` == TRUE, it is CONSTRAINED UNPREDICTABLE whether this bit clears to 0 or is unchanged.

EDPRSR.{DLK, SPD, PU} describe whether registers in the Core power domain can be accessed, and whether their state has been lost since the last time the register was read. For more information, see 'EDPRSR.{DLK, SPD, PU} and the Core power domain'.

When FEAT_DoPD is not implemented and the Core power domain is in either retention or powerdown state, the value of EDPRSR.SPD is IMPLEMENTATION DEFINED. For more information, see 'EDPRSR.SPD when the Core domain is in either retention or powerdown state'.

The reset behavior of this field is:

- On a Cold reset, this field resets to `'1'`.

Accessing this field has the following behavior:

- Access to this field is RAZ/WI if all of the following are true:
  - FEAT_DoPD is not implemented
  - !IsCorePowered()
- Access to this field is UNKNOWN/WI if all of the following are true:
  - IsCorePowered()
  - DoubleLockStatus()
- Otherwise, access to this field is RC/WI.

PU, bit [0]

When FEAT_DoPD is implemented:

Core powerup status bit.

Access to this field is RAO/WI.

When FEAT_Debugv8p2 is implemented:

Core Powerup status bit. Indicates whether the debug registers in the Core power domain can be accessed.

PU	Meaning
`0b0`	Either the Core power domain is in a low-power or powerdown state, or FEAT_DoubleLock is implemented and `DoubleLockStatus()` == TRUE, meaning the debug registers in the Core power domain cannot be accessed.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

PU	Meaning
0b1	The Core power domain is in a powerup state, and either FEAT_DoubleLock is not implemented or DoubleLockStatus() == FALSE, meaning the debug registers in the Core power domain can be accessed.

If FEAT_DoubleLock is implemented, the PE is in reset state, and the PE entered reset state with the OS Double Lock locked this bit has a CONSTRAINED UNPREDICTABLE value. For more information, see 'EDPRSR.{DLK, R} and reset state'

EDPRSR.{DLK, SPD, PU} describe whether registers in the Core power domain can be accessed, and whether their state has been lost since the last time the register was read. For more information, see 'EDPRSR.{DLK, SPD, PU} and the Core power domain'

Access to this field is RO.

Otherwise:

Core Powerup status bit. Indicates whether the debug registers in the Core power domain can be accessed.

PU	Meaning
0b0	Core power domain is in a low-power or powerdown state where the debug registers in the Core power domain cannot be accessed.
0b1	Core power domain is in a powerup state where the debug registers in the Core power domain can be accessed.

If FEAT_DoubleLock is implemented, the PE is in reset state, and the PE entered reset state with the OS Double Lock locked this bit has a CONSTRAINED UNPREDICTABLE value. For more information see 'EDPRSR.{DLK, R} and reset state'

EDPRSR.{DLK, SPD, PU} describe whether registers in the Core power domain can be accessed, and whether their state has been lost since the last time the register was read. For more information, see 'EDPRSR.{DLK, SPD, PU} and the Core power domain'.

When the Core power domain is powered-up and DoubleLockStatus() == TRUE, then the value of EDPRSR.PU is IMPLEMENTATION DEFINED. See the description of the DLK bit for more information.

If FEAT_DoubleLock is implemented, the Core power domain is powered up, and DoubleLockStatus() == TRUE, it is IMPLEMENTATION DEFINED whether this bit reads as 0 or 1.

Access to this field is RO.

Accessing EDPRSR

On permitted accesses to the register, other access controls affect the behavior of some fields. See the field descriptions for more information.

If the Core power domain is powered up (EDPRSR.PU == 1), then following a read of EDPRSR:

- If FEAT_DoubleLock is not implemented or DoubleLockStatus() == FALSE, then:
  - EDPRSR.{SDR, SPMAD, SDAD, SPD} are cleared to 0.
  - EDPRSR.SR is cleared to 0 if the non-debug logic of the PE is not in reset state (EDPRSR.R == 0).
- If FEAT_DoubleLock is implemented and DoubleLockStatus() == TRUE, it is CONSTRAINED UNPREDICTABLE whether or not this clearing occurs.

If FEAT_DoPD is not implemented and the Core power domain is powered down (EDPRSR.PU == 0), then:

- EDPRSR.{SDR, SPMAD, SDAD, SR} are all UNKNOWN, and are either reset or restored on being powered up.
- EDPRSR.SPD is not cleared following a read of EDPRSR. See the SPD bit description for more information.

The clearing of bits is an indirect write to EDPRSR.

EDPRSR can be accessed through the external debug interface:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Component	Offset	Instance
Debug	0x314	EDPRSR

Accessible as follows:

- When FEAT_DoPD is implemented and !IsCorePowered(), accesses to this register return an ERROR.
- Otherwise, accesses to this register are RO.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

E9.2.39 EDRCR, External Debug Reserve Control Register

The EDRCR characteristics are:

Purpose

This register is used to allow imprecise entry to Debug state and clear sticky bits in EDSCR.

Configuration

EDRCR is in the Core power domain

Attributes

EDRCR is a 32-bit register.

Field descriptions

Bits [31:5]

Reserved, RES0.

CBRRQ, bit [4]

Allow imprecise entry to Debug state. The actions on writing to this bit are:

CBRRQ	Meaning
0b0	No action.
0b1	Allow imprecise entry to Debug state, for example by canceling pending bus accesses.

Setting this bit to 1 allows a debugger to request imprecise entry to Debug state. An External Debug Request debug event must be pending before the debugger sets this bit to 1.

This feature is optional. If this feature is not implemented, writes to this bit are ignored.

CSPA, bit [3]

Clear Sticky Pipeline Advance. This bit is used to clear the EDSCR.PipeAdv bit to 0. The actions on writing to this bit are:

CSPA	Meaning
0b0	No action.
0b1	Clear the EDSCR.PipeAdv bit to 0.

CSE, bit [2]

Clear Sticky Error. Used to clear the EDSCR cumulative error bits to 0. The actions on writing to this bit are:

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

CSE	Meaning
0b0	No action.
0b1	Clear the EDSCR.{TXU, RXO, ERR} bits, and, if the PE is in Debug state, the EDSCR.ITO bit, to 0.

Bits [1:0]

Reserved, RES0.

Accessing EDRCR

EDRCR can be accessed through the external debug interface:

Component	Offset	Instance
Debug	0x090	EDRCR

Accessible as follows:

- When DoubleLockStatus(), or !IsCorePowered(), or OSLockStatus(), accesses to this register return an ERROR.
- When SoftwareLockStatus(), accesses to this register are WI.
- Otherwise, accesses to this register are WO.

Non-Confidential

E9.2.40 EDSCR, External Debug Status and Control Register

The EDSCR characteristics are:

Purpose

Main control register for the debug implementation.

Configuration

EDSCR is in the Core power domain

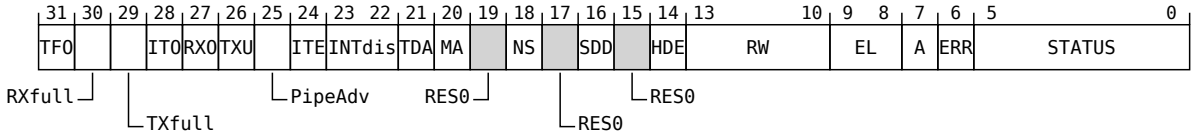
External register EDSCR bits [31:29, 27:26, 23:21, 19, 14, 6] are architecturally mapped to AArch64 System register MDSCR_EL1[31:29, 27:26, 23:21, 19, 14, 6].

External register EDSCR bits [30:29] are architecturally mapped to AArch64 System register MDCCSR_EL0[30:29].

Attributes

EDSCR is a 32-bit register.

Field descriptions



TFO, bit [31]

When FEAT_TRF is implemented:

Trace Filter Override. Overrides the Trace Filter controls allowing the external debugger to trace any visible Exception level.

TFO	Meaning
0b0	Trace Filter controls are not affected.
0b1	Trace Filter controls in TRFCR_EL1 and TRFCR_EL2 are ignored.

When OSLSR_EL1.OSLK is 1, this bit can be indirectly read and written through MDSCR_EL1.

This bit is ignored by the PE when ExternalSecureNoninvasiveDebugEnabled() is FALSE and the Effective value of MDCR_EL3.STE is 1.

The reset behavior of this field is:

- On a Cold reset, this field resets to '0'.

Otherwise:

Reserved, RES0.

RXfull, bit [30]

DTRRX full.

When OSLSR_EL1.OSLK is 1, this bit can be indirectly read and written through MDSCR_EL1.

The reset behavior of this field is:

- On a Cold reset, this field resets to '0'.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Access to this field is RO.

TXfull, bit [29]

DTRTX full.

When OSLSR_EL1.OSLK is 1, this bit can be indirectly read and written through MDSCR_EL1.

The reset behavior of this field is:

- On a Cold reset, this field resets to '0'.

Access to this field is RO.

ITO, bit [28]

ITR overrun. Set to 0 on entry to Debug state.

Accessing this field has the following behavior:

- When the PE is in Non-debug state, access to this field is UNKNOWN/WI.
- Otherwise, access to this field is RO.

RXO, bit [27]

DTRRX overrun.

When OSLSR_EL1.OSLK is 1, this bit can be indirectly read and written through MDSCR_EL1.

The reset behavior of this field is:

- On a Cold reset, this field resets to '0'.

Access to this field is RO.

TXU, bit [26]

DTRTX underrun.

When OSLSR_EL1.OSLK is 1, this bit can be indirectly read and written through MDSCR_EL1.

The reset behavior of this field is:

- On a Cold reset, this field resets to '0'.

Access to this field is RO.

PipeAdv, bit [25]

Pipeline Advance. Indicates that software execution is progressing.

PipeAdv	Meaning
0b0	No progress has been made by the PE since the last time this field was cleared to zero by writing 1 to EDRCR.CSPA.
0b1	Progress has been made by the PE since the last time this field was cleared to zero by writing 1 to EDRCR.CSPA.

The architecture does not define precisely when this field is set to 1. It requires only that this happen periodically in Non-debug state to indicate that software execution is progressing. For example, a PE might set this field to 1 each time the PE retires one or more instructions, or at periodic intervals during the progression of an instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Access to this field is RO.

Copyright © 2025 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

ITE, bit [24]

ITR empty.

Accessing this field has the following behavior:

- When the PE is in Non-debug state, access to this field is UNKNOWN/WI.
- Otherwise, access to this field is RO.

INTdis, bits [23:22]

When FEAT_Debugv8p4 is implemented:

Interrupt and SError exception disable. Disables taking interrupts and SError exceptions in Non-debug state.

INTdis	Meaning
0b00	Masking of interrupts and SError exceptions is controlled by PSTATE and interrupt routing controls.
0b01	If ExternalInvasiveDebugEnabled() is TRUE, then all interrupts and SError exceptions taken to Non-secure state are masked. If ExternalSecureInvasiveDebugEnabled() is TRUE, then all interrupts and SError exceptions taken to Secure state are masked.

Note

This control affects both physical and virtual interrupts and SError exceptions.

When OSLSR_EL1.OSLK is 1, this field can be indirectly read and written through the following System registers:

- MDSCR_EL1.

The Effective value of this field is 0b00 when ExternalInvasiveDebugEnabled() is FALSE.

When FEAT_Debugv8p4 is implemented, bit[23] of this register is RES0.

The reset behavior of this field is:

- On a Cold reset, this field resets to '00'.

Otherwise:

Interrupt and SError exception disable. Disables taking interrupts and SError exceptions in Non-debug state.

INTdis	Meaning
0b00	Masking of interrupts and SError exceptions is controlled by PSTATE and interrupt routing controls.
0b01	If ExternalInvasiveDebugEnabled() is TRUE, then all interrupts and SError exceptions taken to Non-secure EL1 are masked.
0b10	If ExternalInvasiveDebugEnabled() is TRUE, then all interrupts and SError exceptions taken to Non-secure state are masked. If ExternalSecureInvasiveDebugEnabled() is TRUE, then all interrupts and SError exceptions taken to Secure EL1 are masked.
0b11	If ExternalInvasiveDebugEnabled() is TRUE, then all interrupts and SError exceptions taken to Non-secure state are masked. If ExternalSecureInvasiveDebugEnabled() is TRUE, then all interrupts and SError exceptions taken to Secure state are masked.

Note

This control affects both physical and virtual interrupts and SError exceptions.

Non-Confidential

When OSLSR_EL1.OSLK is 1, this field can be indirectly read and written through the following System registers:

- MDSCR_EL1.

The Effective value of this field is 0b00 when ExternalInvasiveDebugEnabled() is FALSE.

Support for the values 0b01 and 0b10 is IMPLEMENTATION DEFINED. If these values are not supported, they are reserved. If programmed with a reserved value, the PE behaves as if EDSCR.INTdis has been programmed with a defined value, other than for a direct read of EDSCR, and the value returned by a read of EDSCR.INTdis is UNKNOWN.

The reset behavior of this field is:

- On a Cold reset, this field resets to '00'.

TDA, bit [21]

Traps accesses to the following debug System registers:

- AArch64: DBGBCR<n>_EL1, DBGBVR<n>_EL1, DBGWCR<n>_EL1, DBGWVR<n>_EL1.

TDA	Meaning
0b0	Accesses to debug System registers do not generate a Software Access Debug event.
0b1	Accesses to debug System registers generate a Software Access Debug event, if OSLSR_EL1.OSLK is 0 and if halting is allowed.

When OSLSR_EL1.OSLK is 1, this bit can be indirectly read and written through MDSCR_EL1.

The reset behavior of this field is:

- On a Cold reset, this field resets to '0'.

MA, bit [20]
