0x8011, ASE_FP_SPEC, Floating-point operation speculatively executed, Advanced SIMD

The counter counts each [speculatively executed](#) floating-point operation counted by [ASE_SVE_FP_SPEC](#) due to an A64 Advanced SIMD instruction.

0x8013, ASE_SVE_FP_SPEC, Floating-point operation speculatively executed, Advanced SIMD or SVE

The counter counts each [speculatively executed](#) floating-point operation counted by [SE_FP_SPEC](#) due to an A64 Advanced SIMD instruction.

0x8014, FP_HP_SPEC, Floating-point operation speculatively executed, half-precision

The counter counts each [speculatively executed](#) floating-point operation counted by [FP_SPEC](#) where the largest type is half-precision.

0x8015, ASE_FP_HP_SPEC, Floating-point operation speculatively executed, Advanced SIMD half-precision, data-processing

The counter counts each [speculatively executed](#) half-precision floating-point data-processing operation counted by [ASE_SVE_FP_HP_SPEC](#) due to an Advanced SIMD instruction.

0x8017, ASE_SVE_FP_HP_SPEC, Floating-point operation speculatively executed, Advanced SIMD or SVE half-precision

The counter counts each [speculatively executed](#) half-precision floating-point operation counted by [FP_HP_SPEC](#) due to an Advanced SIMD.

0x8018, FP_SP_SPEC, Floating-point operation speculatively executed, single-precision

The counter counts each [speculatively executed](#) floating-point operation counted by [FP_SPEC](#) where the largest type is single-precision.

0x8019, ASE_FP_SP_SPEC, Floating-point operation speculatively executed, Advanced SIMD single-precision, data-processing

The counter counts each [speculatively executed](#) single-precision floating-point data-processing operation counted by [ASE_SVE_FP_SP_SPEC](#) due to an Advanced SIMD instruction.

0x801B, ASE_SVE_FP_SP_SPEC, Floating-point operation speculatively executed, Advanced SIMD or SVE single-precision, data-processing

The counter counts each [speculatively executed](#) single-precision floating-point data-processing operation counted by [FP_SP_SPEC](#) due to an Advanced SIMD.

0x801C, FP_DP_SPEC, Floating-point operation speculatively executed, double-precision, data-processing

The counter counts each [speculatively executed](#) floating-point data-processing operation counted by [FP_SPEC](#) where the largest type is double-precision.

0x801D, ASE_FP_DP_SPEC, Floating-point operation speculatively executed, Advanced SIMD double-precision, data-processing

The counter counts each [speculatively executed](#) double-precision floating-point data-processing operation counted by [ASE_SVE_FP_DP_SPEC](#) due to an Advanced SIMD instruction.

0x801F, ASE_SVE_FP_DP_SPEC, Floating-point operation speculatively executed, Advanced SIMD or SVE double-precision, data-processing

The counter counts each [speculatively executed](#) double-precision floating-point data-processing operation due to an Advanced SIMD.

0x8020, **FP_DIV_SPEC, Floating-point operation speculatively executed, divide**

The counter counts each [speculatively executed](#) floating-point divide operation counted by [FP_SPEC](#) due to any of the following A64 instructions:

- Scalar: FDIV.
- Advanced SIMD: FDIV.

0x8021, **ASE_FP_DIV_SPEC, Floating-point operation speculatively executed, Advanced SIMD divide**

The counter counts each [speculatively executed](#) floating-point divide operation counted by [ASE_SVE_FP_DIV_SPEC](#) due to any of the following A64 instructions:

- Advanced SIMD: FDIV.

0x8023, **ASE_SVE_FP_DIV_SPEC, Floating-point operation speculatively executed, Advanced SIMD or SVE divide**

The counter counts each [speculatively executed](#) floating-point divide operation counted by [FP_DIV_SPEC](#) due to any of the following A64 instructions:

- Advanced SIMD: FDIV.

0x8024, **FP_SQRT_SPEC, Floating-point operation speculatively executed, square root**

The counter counts each [speculatively executed](#) floating-point square-root operation counted by [FP_SPEC](#) due to any of the following A64 instructions:

- Scalar: FSQRT.
- Advanced SIMD: FSQRT.

0x8025, **ASE_FP_SQRT_SPEC, Floating-point operation speculatively executed, Advanced SIMD square root**

The counter counts each [speculatively executed](#) floating-point square-root operation counted by [ASE_SVE_FP_SQRT_SPEC](#) due to any of the following A64 instructions:

- Advanced SIMD: FSQRT.

0x8027, **ASE_SVE_FP_SQRT_SPEC, Floating-point operation speculatively executed, Advanced SIMD or SVE square-root**

The counter counts each [speculatively executed](#) floating-point square-root operation counted by [FP_SQRT_SPEC](#) due to any of the following A64 instructions:

- Advanced SIMD: FSQRT.

0x8028, **FP_FMA_SPEC, Floating-point operation speculatively executed, FMA**

The counter counts each [speculatively executed](#) floating-point fused multiply-add or multiply-subtract operation counted by [FP_SPEC](#) due to any of the following A64 instructions:

- Scalar: FMADD, FMSUB, FNMADD, or FNMSUB.
- Advanced SIMD: FMLA or FMLS.
- When FEAT_FCMA is implemented, Advanced SIMD: FCMLA.
- When FEAT_FHM is implemented, Advanced SIMD: FMLAL, FMLAL2, FMLSL, or FMLSL2.

0x8029, **ASE_FP_FMA_SPEC, Floating-point operation speculatively executed, Advanced SIMD FMA**

The counter counts each [speculatively executed](#) floating-point fused multiply-add or multiply-subtract operation counted by [ASE_SVE_FP_FMA_SPEC](#) due to any of the following A64 instructions:

- Advanced SIMD: FMLA or FMLS.
- When FEAT_FCMA is implemented, Advanced SIMD: FCMLA.
- When FEAT_FHM is implemented, Advanced SIMD: FMLAL, FMLAL2, FMLSL, or FMLSL2.

0x802B, **ASE_SVE_FP_FMA_SPEC, Floating-point operation speculatively executed, Advanced SIMD or SVE FMA**

The counter counts each [speculatively executed](#) floating-point fused multiply-add or multiply-subtract operation counted by [FP_FMA_SPEC](#) due to any of the following A64 instructions:

- Advanced SIMD: FMLA or FMLS.
- When FEAT_FCMA is implemented, Advanced SIMD: FCMLA.
- When FEAT_FHM is implemented, Advanced SIMD: FMLAL, FMLAL2, FMLSL, or FMLSL2.

0x802C, **FP_MUL_SPEC, Floating-point operation speculatively executed, multiply**

The counter counts each [speculatively executed](#) floating-point multiply operation counted by [FP_SPEC](#) due to any of the following A64 instructions:

- Scalar: FMUL or FMULX.
- Advanced SIMD: FMUL or FMULX.

0x802D, **ASE_FP_MUL_SPEC, Floating-point operation speculatively executed, Advanced SIMD multiply**

The counter counts each [speculatively executed](#) floating-point multiply operation counted by [ASE_SVE_FP_MUL_SPEC](#) due to any of the following A64 instructions:

- Advanced SIMD: FMUL or FMULX.

0x802F, **ASE_SVE_FP_MUL_SPEC, Floating-point operation speculatively executed, Advanced SIMD or SVE multiply**

The counter counts each [speculatively executed](#) floating-point fused multiply-add or multiply-subtract operation counted by [FP_MUL_SPEC](#) due to any of the following A64 instructions:

- Advanced SIMD: FMUL or FMULX.

0x8030, **FP_ADDSUB_SPEC, Floating-point operation speculatively executed, add or subtract**

The counter counts each [speculatively executed](#) floating-point add or subtract operation counted by [FP_SPEC](#) due to any of the following A64 instructions:

- Scalar: FADD or FSUB.
- Advanced SIMD: FABD, FADD, or FSUB.

0x8031, **ASE_FP_ADDSUB_SPEC, Floating-point operation speculatively executed, Advanced SIMD add or subtract**

The counter counts each [speculatively executed](#) floating-point add or subtract operation counted by [ASE_SVE_FP_ADDSUB_SPEC](#) due to any of the following A64 instructions:

- Advanced SIMD: FABD, FADD, or FSUB.

0x8033, ASE_SVE_FP_ADDSUB_SPEC, Floating-point operation speculatively executed, Advanced SIMD or SVE add or subtract

The counter counts each [speculatively executed](#) floating-point add or subtract operation counted by [FP_ADDSUB_SPEC](#) due to any of the following A64 instructions:

- Advanced SIMD: FABD, FADD, or FSUB.

0x8034, FP_RECPE_SPEC, Floating-point operation speculatively executed, reciprocal estimate

The counter counts each [speculatively executed](#) floating-point reciprocal estimate operation counted by [FP_SPEC](#) due to any of the following A64 instructions:

- Advanced SIMD: FRECPPE or FRSQRTE.

0x8035, ASE_FP_RECPE_SPEC, Floating-point operation speculatively executed, Advanced SIMD reciprocal estimate

The counter counts each [speculatively executed](#) floating-point reciprocal estimate operation counted by [ASE_SVE_FP_RECPE_SPEC](#) due to any of the following A64 instructions:

- Advanced SIMD: FRECPPE or FRSQRTE.

0x8037, ASE_SVE_FP_RECPE_SPEC, Floating-point operation speculatively executed, Advanced SIMD or SVE reciprocal estimate

The counter counts each [speculatively executed](#) floating-point reciprocal estimate operation counted by [FP_RECPE_SPEC](#) due to any of the following A64 instructions:

- Advanced SIMD: FRECPPE or FRSQRTE.

0x8038, FP_CVT_SPEC, Floating-point operation speculatively executed, convert

The counter counts each [speculatively executed](#) floating-point convert operation due to any of:

- An A64 scalar floating-point conversion instruction.
- An Advanced SIMD floating-point conversion instruction.
- An SVE floating-point conversion instruction.

This includes both conversions between floating-point types, and conversions between integer and floating-point types.

0x8039, ASE_FP_CVT_SPEC, Floating-point operation speculatively executed, Advanced SIMD convert

The counter counts each [speculatively executed](#) floating-point convert operation counted by [ASE_SVE_FP_CVT_SPEC](#) due to an A64 Advanced SIMD instruction.

0x803B, ASE_SVE_FP_CVT_SPEC, Floating-point operation speculatively executed, Advanced SIMD or SVE convert

The counter counts each [speculatively executed](#) floating-point convert operation counted by [FP_CVT_SPEC](#) due to an A64 Advanced SIMD instruction.

0x803D, ASE_FP_PREDUCE_SPEC, Floating-point operation speculatively executed, Advanced SIMD pairwise add step or pairwise reduce step

The counter counts each [speculatively executed](#) floating-point pairwise add step or pairwise reduce step operation counted by [ASE_FP_VREDUCE_SPEC](#) due to any of the following A64 instructions:

- Advanced SIMD: FADDP, FMAXNMP, FMAXP, FMINNMP, or FMINP.

0x803F, ASE_SVE_FP_VREDUCE_SPEC, Floating-point operation speculatively executed, Advanced SIMD or SVE vector reduction

The counter counts each [speculatively executed](#) floating-point reduction operation counted by [ASE_SVE_FP_SPEC](#) due to any of the following A64 instructions:

- Advanced SIMD: FADDP, FMAXNMP, FMAXNMV, FMAXP, FMAXV, FMINNMP, FMINNMV, FMINP, or FMINV.

0x8040, INT_SPEC, Integer operation speculatively executed

The counter counts each [speculatively executed](#) integer arithmetic operation due to any of:

- An A64 scalar data-processing instruction.
- An Advanced SIMD instruction.
- An SVE data-processing instruction.

It is IMPLEMENTATION DEFINED whether the counter counts any operation due to the following instructions:

- Scalar: FABS, FNEG (scalar).
- Advanced SIMD: FABS, FNEG (vector), FRECP, FRSQRT.
- Data movement instructions which move data without carrying out any operations on the data. This includes identity data-processing operations.
- Conditional select instructions.
- Floating-point conversion instructions.

Any operation counted by [FP_SPEC](#) is not counted.

0x8041, ASE_INT_SPEC, Integer operation speculatively executed, Advanced SIMD

The counter counts each [speculatively executed](#) integer operation counted by [ASE_SVE_INT_SPEC](#) due to an A64 Advanced SIMD instruction.

0x8043, ASE_SVE_INT_SPEC, Integer operation speculatively executed, Advanced SIMD or SVE

The counter counts each [speculatively executed](#) integer arithmetic operation counted by [SE_INT_SPEC](#) due to an A64 Advanced SIMD.

0x8044, INT_DIV_SPEC, Integer operation speculatively executed, divide

The counter counts each [speculatively executed](#) integer divide operation counted by [INT_SPEC](#) due to any of the following A64 instructions:

- Scalar: SDIV or UDIV.

0x8045, **INT_DIV64_SPEC, Integer operation speculatively executed, 64-bit divide**

The counter counts each [speculatively executed](#) integer divide operation counted by [INT_SPEC](#) due to any of the following A64 instructions:

- Scalar: SDIV or UDIV.

The counter only counts operations with 64-bit operands or vector elements.

0x8048, **INT_MUL_SPEC, Integer operation speculatively executed, multiply**

The counter counts each [speculatively executed](#) integer multiply or multiply-accumulate operation counted by [INT_SPEC](#) due to any of the following A64 instructions:

- Scalar: MADD, MSUB, MUL, SMADDL, SMULH, UMADDL, or UMULH.
- Advanced SIMD: MLA, MLS, MUL, PMUL, PMULL, PMULL2, SMLAL, SMLAL2, SMLSL, SMLSL2, SMULL, SMULL2, SQDMLAL, SQDMLAL2, SQDMLSL, SQDMLSL2, SQDMULH, SQDMULL, SQDMULL2, SQRDMULH, UMLAL, UMLAL2, UMLSL, UMLSL2, UMULL, or UMULL2.
- When FEAT_RDM is implemented, Advanced SIMD: SQRDMLAH or SQRDMLSH.

0x8049, **ASE_INT_MUL_SPEC, Integer operation speculatively executed, Advanced SIMD multiply**

The counter counts each [speculatively executed](#) integer multiply or multiply-accumulate operation counted by [ASE_SVE_INT_MUL_SPEC](#) due to any of the following A64 instructions:

- Advanced SIMD: MLA, MLS, MUL, PMUL, PMULL, PMULL2, SMLAL, SMLAL2, SMLSL, SMLSL2, SMULL, SMULL2, SQDMLAL, SQDMLAL2, SQDMLSL, SQDMLSL2, SQDMULH, SQDMULL, SQDMULL2, SQRDMULH, UMLAL, UMLAL2, UMLSL, UMLSL2, UMULL, or UMULL2.
- When FEAT_RDM is implemented, Advanced SIMD: SQRDMLAH or SQRDMLSH.

0x804B, **ASE_SVE_INT_MUL_SPEC, Integer operation speculatively executed, Advanced SIMD or SVE multiply**

The counter counts each [speculatively executed](#) integer multiply or multiply-accumulate operation counted by [INT_MUL_SPEC](#) due to any of the following A64 instructions:

- Advanced SIMD: MLA, MLS, MUL, PMUL, PMULL, PMULL2, SMLAL, SMLAL2, SMLSL, SMLSL2, SMULL, SMULL2, SQDMLAL, SQDMLAL2, SQDMLSL, SQDMLSL2, SQDMULH, SQDMULL, SQDMULL2, SQRDMULH, UMLAL, UMLAL2, UMLSL, UMLSL2, UMULL, or UMULL2.
- When FEAT_RDM is implemented, Advanced SIMD: SQRDMLAH or SQRDMLSH.

0x804C, **INT_MUL64_SPEC, Integer operation speculatively executed, 64×64 multiply**

The counter counts each [speculatively executed](#) 64×64 integer multiply operation counted by [INT_SPEC](#) due to any of the following A64 instructions:

- Scalar: MADD, MSUB, MUL, SMULH, or UMULH.

The counter only counts operations that perform a 64-bit × 64-bit integer multiply operations.

0x804E, **INT_MULH64_SPEC, Integer operation speculatively executed, 64×64 multiply returning high part**

The counter counts each [speculatively executed](#) widening 64×64 integer multiply operation counted by [INT_SPEC](#) due to any of the following A64 instructions:

- Scalar: SMULH or UMULH.

These instructions perform 64-bit × 64-bit integer multiply operations.

0x8053, ASE_SVE_FP_BF16_SPEC, Floating-point operation speculatively executed, SVE or Advanced SIMD BFloat16, data-processing

The counter counts each [speculatively executed](#) BFloat16 floating-point data-processing operation counted by FP_BF16_SPEC due to an Advanced SIMD.

0x8056, SVE_SPEC, Operation speculatively executed, SVE data processing

The counter counts each operation counted by [ASE_SVE_SPEC](#) that is an SVE data-processing operation.

An SVE data-processing operation is any operation due to an instruction that operates on the SVE scalable vector and predicate registers that is not any of the following:

- A load or store operation. These are counted by SVE_INST_SPEC.
- If the Cryptographic Extension is implemented, an operation counted by [CRYPTO_SPEC](#) as a Cryptographic data-processing operation.

If the Cryptographic Extension and FEAT_SVE2 are implemented, operations due to the SVE `PMULLB` and `PMULLT` (Q variants) instructions are not counted by [CRYPTO_SPEC](#) and are counted as SVE data-processing operations.

0x8057, ASE_SVE_SPEC, Operation speculatively executed, Advanced SIMD data processing or SVE data processing

The counter counts each operation counted by [INST_SPEC](#) that is an Advanced SIMD data-processing operation or an SVE data-processing operation.

See [ASE_SPEC](#) and [SVE_SPEC](#) for these classifications.

0x8058, NONFP_SPEC, Non-floating-point operation speculatively executed

The counter counts each [speculatively executed](#) data-processing operation due to any of:

- A scalar instruction that would be counted by the [DP_SPEC](#) event.
- An A64 Advanced SIMD data processing instruction defined in the section [Data processing - SIMD and floating-point](#) that would not be counted by [FP_SPEC](#).
- An SVE instruction with vector source or destination registers that would not be counted by [FP_SPEC](#).

0x8059, ASE_NONFP_SPEC, Non-floating-point operation speculatively executed, Advanced SIMD

The counter counts each [speculatively executed](#) non-floating-point operation counted by [ASE_SVE_NONFP_SPEC](#) due to an A64 Advanced SIMD instruction.

0x805B, ASE_SVE_NONFP_SPEC, Non-floating-point operation speculatively executed, Advanced SIMD or SVE

The counter counts each [speculatively executed](#) non-floating-point operation counted by [NONFP_SPEC](#) due to an A64 Advanced SIMD instruction.

0x805D, ASE_INT_VREDUCE_SPEC, Integer operation speculatively executed, Advanced SIMD reduction

The counter counts each [speculatively executed](#) across-vector and pairwise integer reduction operation counted by [ASE_SVE_INT_VREDUCE_SPEC](#) due to any of the following A64 instructions:

- Advanced SIMD: `ADDP`, `ADDV`, `SADALP`, `SADDLP`, `SADDLV`, `SMAXP`, `SMAXV`, `SMINP`, `SMINV`, `UADALP`, `UADDLP`, `UADDLV`, `UMAXP`, `UMAXV`, `UMINP`, or `UMINV`.

0x805F, **ASE_SVE_INT_VREDUCE_SPEC, Integer operation speculatively executed, Advanced SIMD or SVE reduction**

The counter counts each [speculatively executed](#) across-vector and pairwise integer reduction operation counted by [INT_SPEC](#) due to any of the following A64 instructions:

- Advanced SIMD: ADDP, ADDV, SADALP, SADDLP, SADDLV, SMAXP, SMAXV, SMINP, SMINV, UADALP, UADDLP, UADDLV, UMAXP, UMAXV, UMINP, or UMINV.

0x8084, **ASE_SVE_LDST_SPEC, Operation speculatively executed, Advanced SIMD or SVE load or store**

The counter counts each [speculatively executed](#) operation that reads from or writes to memory due to an A64 Advanced SIMD load, store, or prefetch instruction.

0x8085, **ASE_SVE_LD_SPEC, Operation speculatively executed, Advanced SIMD or SVE load**

The counter counts each [speculatively executed](#) operation that reads from memory counted by [ASE_SVE_LDST_SPEC](#) due to an A64 Advanced SIMD load instruction.

0x8086, **ASE_SVE_ST_SPEC, Operation speculatively executed, Advanced SIMD or SVE store**

The counter counts each [speculatively executed](#) operation that writes to memory counted by [ASE_SVE_LDST_SPEC](#) due to an A64 Advanced SIMD store instruction.

0x8087, **PRF_SPEC, Operation speculatively executed, prefetch**

The counter counts each [speculatively executed](#) prefetch operation due to any of the following A64 instructions:

- Scalar: PRFM, PRFUM, or RPRFM.

0x8088, **BASE_LDST_REG_SPEC, Operation speculatively executed, general-purpose register load, store, or prefetch**

The counter counts each [speculatively executed](#) operation that reads from or writes to memory due to a general-purpose register load, store, or prefetch instruction.

0x8089, **BASE_LD_REG_SPEC, Operation speculatively executed, general-purpose register load**

The counter counts each [speculatively executed](#) operation that reads from memory counted by [BASE_LDST_REG_SPEC](#) due to a general-purpose register load instruction.

0x808A, **BASE_ST_REG_SPEC, Operation speculatively executed, general-purpose register store**

The counter counts each [speculatively executed](#) operation that writes to memory counted by [BASE_LDST_REG_SPEC](#) due to a general-purpose register store instruction.

It is IMPLEMENTATION DEFINED whether the counter counts operations due to DC ZVA instructions.

0x808B, **BASE_PRF_SPEC, Operation speculatively executed, general-purpose register prefetch**

The counter counts each [speculatively executed](#) prefetch operation counted by [BASE_LDST_REG_SPEC](#) due to any of the following A64 instructions:

- Scalar: PRFM, PRFUM, or RPRFM.

0x808C, **FPASE_LDST_REG_SPEC, Operation speculatively executed, SIMD&FP register load or store**

The counter counts each [speculatively executed](#) operation that reads from or writes to memory due to any of the following A64 instructions:

- Scalar: LDP (SIMD&FP), LDR (SIMD&FP), STP (SIMD&FP), or STR (SIMD&FP).
- Advanced SIMD: LD1, LD1R, LDNP, LDP, LDR, LDUR, ST1, STNP, STP, STR, or STUR.

0x808D, **FPASE_LD_REG_SPEC, Operation speculatively executed, SIMD&FP register load**

The counter counts each [speculatively executed](#) operation that reads from memory counted by [FPASE_LDST_REG_SPEC](#) due to any of the following A64 instructions:

- Scalar: LDP (SIMD&FP) or LDR (SIMD&FP).
- Advanced SIMD: LD1, LD1R, LDNP, LDP, LDR, or LDUR.

0x808E, **FPASE_ST_REG_SPEC, Operation speculatively executed, SIMD&FP register store**

The counter counts each [speculatively executed](#) operation that writes to memory counted by [FPASE_LDST_REG_SPEC](#) due to any of the following A64 instructions:

- Scalar: STP (SIMD&FP) or STR (SIMD&FP).
- Advanced SIMD: ST1, STNP, STP, STR, or STUR.

0x80A4, **ASE_SVE_LDST_MULTI_SPEC, Operation speculatively executed, Advanced SIMD or SVE contiguous load or store multiple vector**

The counter counts each [speculatively executed](#) operation due to an A64 Advanced SIMD multiple vector contiguous structure load or store instruction.

0x80A5, **ASE_SVE_LD_MULTI_SPEC, Operation speculatively executed, Advanced SIMD or SVE contiguous load multiple vector**

The counter counts each [speculatively executed](#) operation that reads from memory counted by [ASE_SVE_LDST_MULTI_SPEC](#) due to an A64 Advanced SIMD multiple vector contiguous structure load instruction.

0x80A6, **ASE_SVE_ST_MULTI_SPEC, Operation speculatively executed, Advanced SIMD or SVE contiguous store multiple vector**

The counter counts each [speculatively executed](#) operation that writes to memory counted by [ASE_SVE_LDST_MULTI_SPEC](#) due to an A64 Advanced SIMD multiple vector contiguous structure store instruction.

0x80B4, **ASE_SVE_UNALIGNED_LDST_SPEC, Advanced SIMD or SVE unaligned access**

The counter counts each [speculatively executed](#) A64 Advanced SIMD load or store instruction where either:

- A contiguous vector address is not aligned to the minimum of the in-memory size of the vector and the cache line size, in bytes.
- A gather, scatter, or single element address is not aligned to the memory element access size, in bytes.

The unaligned access is counted even if it is subsequently converted into multiple aligned accesses.

0x80B5, **ASE_SVE_UNALIGNED_LD_SPEC, Advanced SIMD or SVE unaligned read**

The counter counts each unaligned memory access counted by [ASE_SVE_UNALIGNED_LDST_SPEC](#) due to an A64 Advanced SIMD load instruction.

The unaligned access is counted even if it is subsequently converted into multiple aligned accesses.

0x80B6, **ASE_SVE_UNALIGNED_ST_SPEC, Advanced SIMD or SVE unaligned write**

The counter counts each unaligned memory access counted by [ASE_SVE_UNALIGNED_LDST_SPEC](#) due to an A64 Advanced SIMD store instruction.

The unaligned access is counted even if it is subsequently converted into multiple aligned accesses.

0x80B8, **ASE_SVE_UNALIGNED_CONTIG_LDST_SPEC, Advanced SIMD or SVE unaligned contiguous access**

The counter counts each [speculatively executed](#) Advanced SIMD contiguous load or store operation where the address is not aligned to the minimum of the in-memory size of the vector and the cache line size, in bytes.

The unaligned access is counted even if it is subsequently converted into multiple aligned accesses.

0x80B9, **ASE_SVE_UNALIGNED_CONTIG_LD_SPEC, Advanced SIMD or SVE unaligned contiguous read**

The counter counts each unaligned memory access counted by [ASE_SVE_UNALIGNED_CONTIG_LDST_SPEC](#) due to an A64 Advanced SIMD load instruction.

The unaligned access is counted even if it is subsequently converted into multiple aligned accesses.

0x80BA, **ASE_SVE_UNALIGNED_CONTIG_ST_SPEC, Advanced SIMD or SVE unaligned contiguous write**

The counter counts each unaligned memory access counted by [ASE_SVE_UNALIGNED_CONTIG_LDST_SPEC](#) due to a A64 Advanced SIMD store instruction.

The unaligned access is counted even if it is subsequently converted into multiple aligned accesses.

0x80C1, **FP_FIXED_OPS_SPEC, Non-scalable element arithmetic operations speculatively executed, floating-point**

The counter increments by v for each [speculatively executed](#) non-scalable element arithmetic operation, due to an instruction where the type was floating-point.

Where v is the number of arithmetic operations carried out by the operation or instruction which causes the counter to increment.

The counter does not count operations that are counted by [FP_SCALE_OPS_SPEC](#).

0x80C3, **FP_HP_FIXED_OPS_SPEC, Non-scalable element arithmetic operations speculatively executed, largest type is half-precision floating-point**

The counter increments by v for each [speculatively executed](#) non-scalable element arithmetic operation, due to an instruction where the largest type was half-precision floating-point.

Where v is the number of arithmetic operations carried out by the operation or instruction which causes the counter to increment.

The counter does not count operations that are counted by [FP_SCALE_OPS_SPEC](#).

0x80C5, FP_SP_FIXED_OPS_SPEC, Non-scalable element arithmetic operations speculatively executed, largest type is single-precision floating-point

The counter increments by v for each [speculatively executed](#) non-scalable element arithmetic operation, due to an instruction where the largest type was single-precision floating-point.

Where v is the number of arithmetic operations carried out by the operation or instruction which causes the counter to increment.

The counter does not count operations that are counted by FP_SCALE_OPS_SPEC.

0x80C7, FP_DP_FIXED_OPS_SPEC, Non-scalable element arithmetic operations speculatively executed, largest type is double-precision floating-point

The counter increments by v for each [speculatively executed](#) non-scalable element arithmetic operation, due to an instruction where the largest type was double-precision floating-point.

Where v is the number of arithmetic operations carried out by the operation or instruction which causes the counter to increment.

The counter does not count operations that are counted by FP_SCALE_OPS_SPEC.

0x80C9, INT_FIXED_OPS_SPEC, Non-scalable element arithmetic operations speculatively executed, integer

The counter increments by v for each [speculatively executed](#) non-scalable element arithmetic operation, due to an instruction where the type was integer.

Where v is the number of arithmetic operations carried out by the operation or instruction which causes the counter to increment.

The counter does not count operations that are counted by FP_SCALE_OPS_SPEC.

0x80CB, LDST_FIXED_OPS_SPEC, Non-scalable load or store element operations speculatively executed

The counter counts each [speculatively executed Memory-read operation](#) or [Memory-write operation](#) due to any of:

- Any load, store, or atomic operation, other than loads and stores of the SVE P and Z registers.
- Any SVE non-vector load or store operation.
- An SVE load and replicate instruction, including: LD1R, LD1RB, LD1RD, LD1RH, LD1RQ, LD1RQB, LD1RQD, LD1RQH, LD1RQW, LD1RSB, LD1RSH, or LD1RSW.

For each instruction, the counter is incremented by the number of operations specified by the instruction. For example, the counter counts operations as follows:

- Non-SVE load and store of a single register instructions increment the counter by 1. This includes loads and stores of Sx, Dx, and Qx SIMD&FP registers.
- Non-SVE load and store of a pair of registers instructions increment the counter by 2. This includes loads and stores of Sx, Dx, and Qx SIMD&FP registers.
- Atomic store instructions increment the counter by 1. These are instructions that atomically update a value in memory without returning a value to a register.
- Atomic load, compare and swap of a single register, and swap instructions increment the counter by 2. Atomic load instructions are instructions that atomically update a value in memory, returning a value to a register.
- Compare and swap of a pair of registers increment the counter by 4.
- Advanced SIMD LD1R instructions increment the counter by 1.
- Advanced SIMD LD[1-4] and ST[1-4] instructions increment the counter by the number of elements transferred per vector multiplied by the number of transferred registers.
- DC ZVA and DC GZVA instructions increment by an IMPLEMENTATION DEFINED amount.

Note

When a replicating load instruction loads data of the same size as the vector length, which causes no replication to occur, the instruction is counted.

0x80CD, LD_FIXED_OPS_SPEC, Non-scalable load element operations speculatively executed

The counter counts each [speculatively executed Memory-read operation](#) counted by [LDST_FIXED_OPS_SPEC](#).

For each instruction, the counter is incremented by the number of operations specified by the instruction. That is, the counter is incremented by:

- Half the value that the [LDST_FIXED_OPS_SPEC](#) event counts if the operation is a load atomic, compare and swap, or swap operation.
- The same as for [LDST_FIXED_OPS_SPEC](#) if the operation is any other load operation.

0x80CF, ST_FIXED_OPS_SPEC, Non-scalable store element operations speculatively executed

The counter counts each [Memory-write operation](#) counted by [LDST_FIXED_OPS_SPEC](#).

For each instruction, the counter is incremented by the number of operations specified by the instruction. That is, the counter is incremented by:

- Half the value that the [LDST_FIXED_OPS_SPEC](#) event counts if the operation is a store atomic, compare and swap, or swap operation.
- The same as for [LDST_FIXED_OPS_SPEC](#) if the operation is any other store operation.

0x80DB, LDST_FIXED_BYTES_SPEC, Non-scalable load and store bytes speculatively executed

The counter counts each byte speculatively read or written due to any of:

- Any load, store, or atomic operation, other than loads and stores of the SVE P and Z registers.
- Any SVE non-vector load or store operation.
- An SVE load and replicate instruction, including: LD1R, LD1RB, LD1RD, LD1RH, LD1RQ, LD1RQB, LD1RQD, LD1RQH, LD1RQW, LD1RSB, LD1RSH, or LD1RSW.

For each instruction, the counter is incremented by the number of bytes transferred per register multiplied by the number of registers transferred multiplied by the number of transfers made per register. For example, the counter counts bytes as follows:

- Non-SVE load and store of a single register instructions increment the counter by $(MSIZE \div 8)$. This includes loads and stores of Sx, Dx, and Qx SIMD&FP registers.
- Non-SVE load and store of a pair of registers instructions increment the counter by $2 \times (MSIZE \div 8)$. This includes loads and stores of Sx, Dx, and Qx SIMD&FP registers.
- Atomic store instructions increment the counter by $(MSIZE \div 8)$. These are instructions that atomically update a value in memory without returning a value to a register.
- Atomic load, compare and swap of a single register, and swap instructions increment the counter by $2 \times (MSIZE \div 8)$. Atomic load instructions are instructions that atomically update a value in memory, returning a value to a register.
- Compare and swap of a pair of registers increment the counter by $4 \times (MSIZE \div 8)$.
- Advanced SIMD LD1R instructions increment the counter by $(MSIZE \div 8)$.
- Advanced SIMD LD[1-4] and ST[1-4] instructions increment the counter by the number of registers transferred multiplied by the number of bytes being transferred per register.
- DC ZVA instructions increment by the counter by $2^{(DCZID_EL0.BS)}$.

0x80DD, LD_FIXED_BYTES_SPEC, Non-scalable load bytes speculatively executed

The counter counts each speculatively read byte counted by [LDST_FIXED_BYTES_SPEC](#).

For each instruction, the counter is incremented by the number of bytes transferred per register multiplied by the number of registers transferred. That is, the counter is incremented by:

- Half the value that the [LDST_FIXED_BYTES_SPEC](#) event counts if the operation is a load atomic, compare and swap, or swap operation.
- The same as for [LDST_FIXED_BYTES_SPEC](#) if the operation is any other load operation.

0x80DF, ST_FIXED_BYTES_SPEC, Non-scalable store bytes speculatively executed

The counter counts each speculatively written byte counted by [LDST_FIXED_BYTES_SPEC](#).

For each instruction, the counter is incremented by the number of bytes transferred per register multiplied by the number of registers transferred. That is, the counter is incremented by:

- Half the value that the [LDST_FIXED_BYTES_SPEC](#) event counts if the operation is a swap, or compare and swap operation.
- The same as for [LDST_FIXED_BYTES_SPEC](#) if the operation is any other store operation, including an atomic store operation.

0x80E1, ASE_INT8_SPEC, Integer operation speculatively executed, Advanced SIMD 8-bit

The counter counts each operation counted by [ASE_SVE_INT8_SPEC](#) that is an Advanced SIMD operation.

0x80E3, ASE_SVE_INT8_SPEC, Integer operation speculatively executed, Advanced SIMD or SVE 8-bit

The counter counts each operation counted by [ASE_SVE_INT_SPEC](#) where the largest type is 8-bit integer.

0x80E5, ASE_INT16_SPEC, Integer operation speculatively executed, Advanced SIMD 16-bit

The counter counts each operation counted by [ASE_SVE_INT16_SPEC](#) that is an Advanced SIMD operation.

0x80E7, ASE_SVE_INT16_SPEC, Integer operation speculatively executed, Advanced SIMD or SVE 16-bit

The counter counts each operation counted by [ASE_SVE_INT_SPEC](#) where the largest type is 16-bit integer.

0x80E9, ASE_INT32_SPEC, Integer operation speculatively executed, Advanced SIMD 32-bit

The counter counts each operation counted by [ASE_SVE_INT32_SPEC](#) that is an Advanced SIMD operation.

0x80EB, ASE_SVE_INT32_SPEC, Integer operation speculatively executed, Advanced SIMD or SVE 32-bit

The counter counts each operation counted by [ASE_SVE_INT_SPEC](#) where the largest type is 32-bit integer.

0x80ED, ASE_INT64_SPEC, Integer operation speculatively executed, Advanced SIMD 64-bit

The counter counts each operation counted by [ASE_SVE_INT64_SPEC](#) that is an Advanced SIMD operation.

0x80EF, ASE_SVE_INT64_SPEC, Integer operation speculatively executed, Advanced SIMD or SVE 64-bit

The counter counts each operation counted by [ASE_SVE_INT_SPEC](#) where the largest type is 64-bit integer.

0x80F1, ASE_FP_DOT_SPEC, Floating-point operation speculatively executed, Advanced SIMD dot-product

The counter counts each dot-product operation counted by [ASE_SVE_FP_DOT_SPEC](#) due to any of the following A64 instructions:

0x80F3, ASE_SVE_FP_DOT_SPEC, Floating-point operation speculatively executed, Advanced SIMD or SVE dot-product

The counter counts each dot-product operation counted by [FP_SPEC](#) due to any of the following A64 instructions:

0x80F5, ASE_FP_MMLA_SPEC, Floating-point operation speculatively executed, Advanced SIMD matrix multiply

The counter counts each floating-point matrix multiply operation counted by [ASE_SVE_FP_MMLA_SPEC](#) due to any of the following A64 instructions:

0x80F7, ASE_SVE_FP_MMLA_SPEC, Floating-point operation speculatively executed, Advanced SIMD or SVE matrix multiply

The counter counts each floating-point matrix multiply operation counted by [FP_SPEC](#) due to any of the following A64 instructions:

0x80F9, ASE_INT_DOT_SPEC, Operation speculatively executed, Advanced SIMD integer dot-product

The counter counts each integer dot product operation counted by [ASE_SVE_INT_DOT_SPEC](#) due to any of the following A64 instructions:

- When FEAT_DotProd is implemented, Advanced SIMD: SDOT or UDOT.

0x80FB, ASE_SVE_INT_DOT_SPEC, Integer operation speculatively executed, Advanced SIMD or SVE dot-product

The counter counts each integer dot product operation counted by [INT_SPEC](#) due to any of the following A64 instructions:

- When FEAT_DotProd is implemented, Advanced SIMD: SDOT or UDOT.

0x80FD, ASE_INT_MMLA_SPEC, Integer operation speculatively executed, Advanced SIMD matrix multiply

The counter counts each integer matrix multiply operation counted by [ASE_SVE_INT_MMLA_SPEC](#) due to any of the following A64 instructions:

0x80FF, ASE_SVE_INT_MMLA_SPEC, Integer operation speculatively executed, Advanced SIMD or SVE matrix multiply

The counter counts each integer matrix multiply operation counted by [INT_SPEC](#) due to any of the following A64 instructions:

0x8110, BR_IMMED_PRED_RETIRED, Branch instruction architecturally executed, predicted immediate

The counter counts each instruction counted by both [BR_IMMED_RETIRED](#) and [BR_PRED_RETIRED](#).

These are all direct branch instructions on the architecturally executed path, where the branch is correctly predicted.

0x8111, BR_IMMED_MIS_PRED_RETIRED, Branch instruction architecturally executed, mispredicted immediate

The counter counts each instruction counted by both [BR_IMMED_RETIRED](#) and [BR_MIS_PRED_RETIRED](#).

These are all direct branch instructions on the architecturally executed path, where the branch is mispredicted.

0x8112, BR_IND_PRED_RETIRED, Branch instruction architecturally executed, predicted indirect

The counter counts each instruction counted by both [BR_IND_RETIRED](#) and [BR_PRED_RETIRED](#).

These are all indirect branch instructions, including return instructions, on the architecturally executed path, where the branch is correctly predicted.

0x8113, **BR_IND_MIS_PRED_RETIRE**D, Branch instruction architecturally executed, mispredicted indirect

The counter counts each instruction counted by both [BR_IND_RETIRE](#)D and [BR_MIS_PRED_RETIRE](#)D.

These are all indirect branch instructions, including return instructions, on the architecturally executed path, where the branch is mispredicted.

0x8114, **BR_RETURN_PRED_RETIRE**D, Branch instruction architecturally executed, predicted procedure return

The counter counts each instruction counted by [BR_IND_PRED_RETIRE](#)D where if taken, the branch would be counted by [BR_RETURN_RETIRE](#)D.

These are all return instructions on the architecturally executed path, where the branch is correctly predicted.

0x8115, **BR_RETURN_MIS_PRED_RETIRE**D, Branch instruction architecturally executed, mispredicted procedure return

The counter counts each instruction counted by [BR_IND_MIS_PRED_RETIRE](#)D where if taken, the branch would also be counted by [BR_RETURN_RETIRE](#)D.

These are all return instructions on the architecturally executed path, where the branch is mispredicted.

0x8116, **BR_INDNR_PRED_RETIRE**D, Branch instruction architecturally executed, predicted indirect excluding procedure return

The counter counts each instruction counted by [BR_IND_PRED_RETIRE](#)D where if taken, the branch would not be counted by [BR_RETURN_RETIRE](#)D.

These are all indirect branch instructions, excluding return instructions, on the architecturally executed path, where the branch is correctly predicted.

0x8117, **BR_INDNR_MIS_PRED_RETIRE**D, Branch instruction architecturally executed, mispredicted indirect excluding procedure return

The counter counts each instruction counted by [BR_IND_MIS_PRED_RETIRE](#)D where if taken, the branch would not be counted by [BR_RETURN_RETIRE](#)D.

These are all indirect branch instructions, excluding return instructions, on the architecturally executed path, where the branch is mispredicted.

0x8118, **BR_TAKEN_PRED_RETIRE**D, Branch instruction architecturally executed, predicted branch, taken

The counter counts each instruction counted by both [BR_PRED_RETIRE](#)D and [PC_WRITE_RETIRE](#)D.

These are all branch instructions on the architecturally executed path, where the branch is correctly predicted and taken.

0x8119, **BR_TAKEN_MIS_PRED_RETIRE**D, Branch instruction architecturally executed, mispredicted branch, taken

The counter counts each instruction counted by both [BR_MIS_PRED_RETIRE](#)D and [PC_WRITE_RETIRE](#)D.

These are all branch instructions on the architecturally executed path, where the branch is mispredicted and taken.

0x811A, **BR_SKIP_PRED_RETIRE**D, Branch instruction architecturally executed, predicted branch, not taken

The counter counts each instruction counted by both [BR_PRED_RETIRE](#)D and [BR_SKIP_RETIRE](#)D.

These are all branch instructions on the architecturally executed path, where the branch is correctly predicted and not taken.

0x811B, **BR_SKIP_MIS_PRED_RETIRE**, Branch instruction architecturally executed, mispredicted branch, not taken

The counter counts each instruction counted by both [BR_MIS_PRED_RETIRE](#) and [BR_SKIP_RETIRE](#).

These are all branch instructions on the architecturally executed path, where the branch is mispredicted and not taken.

0x811C, **BR_PRED_RETIRE**, Branch instruction architecturally executed, predicted branch

The counter counts each instruction counted by [BR_RETIRE](#) that is not counted by [BR_MIS_PRED_RETIRE](#).

These are all branch instructions on the architecturally executed path, where the branch is correctly predicted.

0x8120, **INST_FETCH_PERCYC**, Instruction fetches in progress

The counter increments by the number of instruction fetches counted by [INST_FETCH](#) in progress on each [Processor cycle](#).

The ratio $\text{INST_FETCH_PERCYC} \div \text{INST_FETCH}$ is the mean duration of instruction fetches in [Processor cycles](#).

0x8121, **MEM_ACCESS_RD_PERCYC**, Data memory reads in progress

The counter increments by the number of data memory reads counted by [MEM_ACCESS_RD](#) in progress on each [Processor cycle](#).

The ratio $\text{MEM_ACCESS_RD_PERCYC} \div \text{MEM_ACCESS_RD}$ is the mean duration of data memory reads in [Processor cycles](#).

0x8122, **SAMPLE_FEED_DS**, Statistical Profiling sample taken, selected Data Source

The counter counts each SPE sample that is a load operations where $\text{PMSDSFR_EL1}[s]$ is 1 and s is bits [5:0] of the sampled Data Source.

The values of PMSFCR_EL1.FDS are ignored when generating this event.

Samples that are removed by filtering, or discarded, and not written to the Profiling Buffer are counted.

0x8123, **SAMPLE_BUFFER_FULL**, Profiling Buffer full

The counter counts each Profiling Buffer full management event.

0x8124, **INST_FETCH**, Instruction memory access

The counter counts each [Instruction memory access](#).

The counter increments whether the access results in an access to a Level 1 instruction cache, a Level 2 instruction, data or unified cache, or none of these.

The counter does not increment as a result of:

- Data memory accesses.
- Translation table walks.
- Refilling of any cache.
- Accesses that result from cache maintenance instructions.

0x8125, **BUS_REQ_RD_PERCYC**, Bus read transactions in progress

The counter increments by the number of bus read transactions counted by **BUS_REQ_RD** in progress on each **Processor cycle**.

The ratio $\text{BUS_REQ_RD_PERCYC} \div \text{BUS_REQ_RD}$ is the mean duration of bus read transactions in **Processor cycles**.

A bus read transaction is in progress between the transaction starting and it completing. This includes cycles when the transaction is not occupying the bus.

If the bus is shared and the Effective value of **PMEVTYPER<n>_EL0.MT** for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the bus is shared by PEs other than the PEs in the multithreaded processor and the Effective value of **PMEVTYPER<n>_EL0.MT** for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of **PMEVTYPER<n>_EL0.MT**.

0x8126, **BUS_REQ_WR_PERCYC**, Bus write transactions in progress

The counter increments by the number of bus write transactions counted by **BUS_REQ_WR** in progress on each **Processor cycle**.

The ratio $\text{BUS_REQ_WR_PERCYC} \div \text{BUS_REQ_WR}$ is the mean duration of bus write transactions in **Processor cycles**.

A bus write transaction is in progress between the transaction starting and it completing. This includes cycles when the transaction is not occupying the bus.

A mean duration value calculated using this event only measures the latency from the perspective of the bus. This is not necessarily the same as the latency for the write to be Complete, as the write might be completed on the bus before reaching its endpoint.

For some bus implementations, writes are posted, meaning that, from the perspective of the bus, the write completes immediately. There is no response when the write reaches its Completion endpoint. This event is not included for such implementations.

If the bus is shared and the Effective value of **PMEVTYPER<n>_EL0.MT** for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the bus is shared by PEs other than the PEs in the multithreaded processor and the Effective value of **PMEVTYPER<n>_EL0.MT** for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of **PMEVTYPER<n>_EL0.MT**.

0x8127, **PMU_SNAPSHOT**, Successful PMU capture event

The counter counts each PMU snapshot Capture event that was successful, that is, **PMSSCR_EL1.NC** is set to 0.

It is CONSTRAINED UNPREDICTABLE whether the counter counts successful Capture events when the PE is in Debug state.

0x8128, **DTLB_WALK_PERCYC**, Data translation table walks in progress

The counter increments by the number of data translation table walks counted by **DTLB_WALK** in progress on each **Processor cycle**.

The ratio $\text{DTLB_WALK_PERCYC} \div \text{DTLB_WALK}$ is the mean duration of data translation table walks in **Processor cycles**.

If the TLB is shared and the Effective value of **PMEVTYPER<n>_EL0.MT** for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of **PMEVTYPER<n>_EL0.MT** for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of **PMEVTYPER<n>_EL0.MT**.

0x8129, **ITLB_WALK_PERCYC**, Instruction translation table walks in progress

The counter increments by the number of instruction translation table walks counted by **ITLB_WALK** in progress on each **Processor cycle**.

The ratio **ITLB_WALK_PERCYC** ÷ **ITLB_WALK** is the mean duration of instruction translation table walks in **Processor cycles**.

If the TLB is shared and the Effective value of **PMEVTYPER<n>_EL0.MT** for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of **PMEVTYPER<n>_EL0.MT** for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of **PMEVTYPER<n>_EL0.MT**.

0x8130, **L1D_TLB_RW**, Level 1 data TLB access, demand access

The counter counts each access counted by **L1D_TLB** that is due to a demand **Memory-read operation** or demand **Memory-write operation**.

If the TLB is shared and the Effective value of **PMEVTYPER<n>_EL0.MT** for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of **PMEVTYPER<n>_EL0.MT** for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of **PMEVTYPER<n>_EL0.MT**.

Arm recommends that this event is implemented if event **L1D_TLB_PRFM** is implemented.

0x8131, **L1I_TLB_RD**, Level 1 instruction TLB access, demand access

The counter counts each access counted by **L1I_TLB** that is due to a demand **Instruction memory access**.

If the TLB is shared and the Effective value of **PMEVTYPER<n>_EL0.MT** for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of **PMEVTYPER<n>_EL0.MT** for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of **PMEVTYPER<n>_EL0.MT**.

Arm recommends that this event is implemented if event **L1I_TLB_PRFM** is implemented.

0x8132, **L1D_TLB_PRFM**, Level 1 data TLB access, software prefetch

The counter counts each access counted by **L1D_TLB_PRF** that is due to a prefetch instruction.

If the TLB is shared and the Effective value of **PMEVTYPER<n>_EL0.MT** for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of **PMEVTYPER<n>_EL0.MT** for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of **PMEVTYPER<n>_EL0.MT**.

Arm recommends that this event is implemented if event **L1D_TLB_RW** is implemented.

0x8133, **L1I_TLB_PRFM**, Level 1 instruction TLB access, software prefetch

The counter counts each access counted by **L1I_TLB_PRF** that is due to a prefetch instruction.

If the TLB is shared and the Effective value of **PMEVTYPER<n>_EL0.MT** for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of **PMEVTYPER<n>_EL0.MT** for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other

cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of [PMEVTYPER<n>_EL0.MT](#).

Arm recommends that this event is implemented if event [L1I_TLB_RD](#) is implemented.

0x8134, **DTLB_HWUPD**, Data TLB hardware update of translation table

The counter counts each access counted by [L1D_TLB](#) that causes a hardware update of a translation table entry.

Each attempted hardware update of a translation table entry is counted once. If the PE requires multiple translation table walk accesses to perform an update, this counts as a single update. If the update fails because it would not be atomic and has to be retried, each retry is counted.

The counter does not count the access if any of the following are true:

- The access generates a Translation fault because the applicable [TCR_ELx.EPDy](#) bit is 1.
- The access is an unprivileged access that generates a Translation fault because the applicable [TCR_ELx.E0PDy](#) bit is 1.

It is IMPLEMENTATION DEFINED whether the counter counts the access if the access generates a Translation fault for any other reason.

If the TLB is shared and the Effective value of [PMEVTYPER<n>_EL0.MT](#) for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of [PMEVTYPER<n>_EL0.MT](#) for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of [PMEVTYPER<n>_EL0.MT](#).

0x8135, **ITLB_HWUPD**, Instruction TLB hardware update of translation table

The counter counts each access counted by [L1I_TLB](#) that causes a hardware update of a translation table entry.

Each attempted hardware update of a translation table entry is counted once. If the PE requires multiple translation table walk accesses to perform an update, this counts as a single update. If the update fails because it would not be atomic and has to be retried, each retry is counted.

The counter does not count the access if any of the following are true:

- The access generates a Translation fault because the applicable [TCR_ELx.EPDy](#) bit is 1.
- The access is an unprivileged access that generates a Translation fault because the applicable [TCR_ELx.E0PDy](#) bit is 1.

It is IMPLEMENTATION DEFINED whether the counter counts the access if the access generates a Translation fault for any other reason.

If the TLB is shared and the Effective value of [PMEVTYPER<n>_EL0.MT](#) for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of [PMEVTYPER<n>_EL0.MT](#) for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of [PMEVTYPER<n>_EL0.MT](#).

0x8136, **DTLB_STEP**, Data TLB translation table walk, step

The counter counts each translation table walk access due to a refill or update of a data or unified TLB.

The event is Attributable to the access that missed in the TLB and caused the walk, not to the owner of the translation tables being accessed. For example, this means that if an EL0 access causes a translation table walk consisting of accesses to both stage 1 and stage 2 translation tables, all accesses are counted if event counting is allowed at EL0, regardless of whether event counting is allowed at EL1 and/or EL2.

The counter does not count the translation table walk access if any of the following are true:

- The access causing the refill generates a Translation fault because the applicable [TCR_ELx.EPDy](#) bit is 1.
- The access causing the refill is an unprivileged access that generates a Translation fault because the applicable [TCR_ELx.E0PDy](#) bit is 1.

It is IMPLEMENTATION DEFINED whether the counter counts the translation table walk access if the access causing the refill generates a Translation fault for any other reason.

If the TLB is shared and the Effective value of [PMEVTYPER<n>_EL0.MT](#) for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of [PMEVTYPER<n>_EL0.MT](#) for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of [PMEVTYPER<n>_EL0.MT](#).

0x8137, [ITLB_STEP](#), Instruction TLB translation table walk, step

The counter counts each translation table walk access due to a refill or update of an instruction TLB.

The event is Attributable to the access that missed in the TLB and caused the walk, not to the owner of the translation tables being accessed. For example, this means that if an EL0 access causes a translation table walk consisting of accesses to both stage 1 and stage 2 translation tables, all accesses are counted if event counting is allowed at EL0, regardless of whether event counting is allowed at EL1 and/or EL2.

The counter does not count the translation table walk access if any of the following are true:

- The access causing the refill generates a Translation fault because the applicable [TCR_ELx.EPDy](#) bit is 1.
- The access causing the refill is an unprivileged access that generates a Translation fault because the applicable [TCR_ELx.E0PDy](#) bit is 1.

It is IMPLEMENTATION DEFINED whether the counter counts the translation table walk access if the access causing the refill generates a Translation fault for any other reason.

If the TLB is shared and the Effective value of [PMEVTYPER<n>_EL0.MT](#) for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of [PMEVTYPER<n>_EL0.MT](#) for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of [PMEVTYPER<n>_EL0.MT](#).

0x8138, [DTLB_WALK_LARGE](#), Data TLB large page translation table walk

The counter counts each translation table walk counted by [DTLB_WALK](#) where the result of the walk yields a large page size.

The set of large page sizes is the complement of the set of small page sizes defined by the [DTLB_WALK_SMALL](#) event. For example, these translations might be cached by dedicated TLB resources. This set is IMPLEMENTATION DEFINED and might differ between instruction and data TLBs.

The counter does not count the walk if the access generates a Translation fault.

If the TLB is shared and the Effective value of [PMEVTYPER<n>_EL0.MT](#) for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of [PMEVTYPER<n>_EL0.MT](#) for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of [PMEVTYPER<n>_EL0.MT](#).

0x8139, [ITLB_WALK_LARGE](#), Instruction TLB large page translation table walk

The counter counts each translation table walk counted by [ITLB_WALK](#) where the result of the walk yields a large page size.

The set of large page sizes is the complement of the set of small page sizes defined by the [ITLB_WALK_SMALL](#) event. For example, these translations might be cached by dedicated TLB resources. This set is IMPLEMENTATION DEFINED and might differ between instruction and data TLBs.

The counter does not count the walk if the access generates a Translation fault.

If the TLB is shared and the Effective value of [PMEVTYPER<n>_EL0.MT](#) for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of [PMEVTYPER<n>_EL0.MT](#) for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of [PMEVTYPER<n>_EL0.MT](#).

0x813A, [DTLB_WALK_SMALL](#), Data TLB small page translation table walk

The counter counts each translation table walk counted by [DTLB_WALK](#) where the result of the walk yields a small page size.

The set of small page sizes is the complement of the set of large page sizes defined by the [DTLB_WALK_LARGE](#) event. For example, these translations might be cached by dedicated TLB resources. This set is IMPLEMENTATION DEFINED and might differ between instruction and data TLBs.

The counter does not count the walk if the access generates a Translation fault.

If the TLB is shared and the Effective value of [PMEVTYPER<n>_EL0.MT](#) for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of [PMEVTYPER<n>_EL0.MT](#) for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of [PMEVTYPER<n>_EL0.MT](#).

0x813B, [ITLB_WALK_SMALL](#), Instruction TLB small page translation table walk

The counter counts each translation table walk counted by [ITLB_WALK](#) where the result of the walk yields a small page size.

The set of small page sizes is the complement of the set of large page sizes defined by the [ITLB_WALK_LARGE](#) event. For example, these translations might be cached by dedicated TLB resources. This set is IMPLEMENTATION DEFINED and might differ between instruction and data TLBs.

The counter does not count the walk if the access generates a Translation fault.

If the TLB is shared and the Effective value of [PMEVTYPER<n>_EL0.MT](#) for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of [PMEVTYPER<n>_EL0.MT](#) for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of [PMEVTYPER<n>_EL0.MT](#).

0x813C, [DTLB_WALK_RW](#), Data TLB demand access, with at least one translation table walk

The counter counts each demand access counted by [L1D_TLB_RW](#) that causes a refill or update of a data or unified TLB involving at least one translation table walk access.

The counter does not count the demand access if any of the following are true:

- The access is due to a TLB maintenance instruction.
- The access generates a Translation fault because the applicable [TCR_ELx.EPDy](#) bit is 1.
- FEAT_E0PD is implemented and the access is an unprivileged access that generates a Translation fault because the applicable [TCR_ELx.E0PDy](#) bit is 1.

It is IMPLEMENTATION DEFINED whether the counter counts the demand access if the access generates a Translation fault for any other reason.

If the TLB is shared and the Effective value of [PMEVTYPER<n>_EL0.MT](#) for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of [PMEVTYPER<n>_EL0.MT](#) for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of [PMEVTYPER<n>_EL0.MT](#).

0x813D, **ITLB_WALK_RD, Instruction TLB demand access, with at least one translation table walk**

The counter counts each demand access counted by [L1I_TLB_RD](#) that causes a refill or update of an instruction TLB involving at least one translation table walk access.

The counter does not count the demand access if any of the following are true:

- The access is due to a TLB maintenance instruction.
- The access generates a Translation fault because the applicable [TCR_ELx.EPDy](#) bit is 1.
- FEAT_EOPD is implemented and the access is an unprivileged access that generates a Translation fault because the applicable [TCR_ELx.EOPDy](#) bit is 1.

It is IMPLEMENTATION DEFINED whether the counter counts the demand access if the access generates a Translation fault for any other reason.

If the TLB is shared and the Effective value of [PMEVTYPER<n>_EL0.MT](#) for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of [PMEVTYPER<n>_EL0.MT](#) for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of [PMEVTYPER<n>_EL0.MT](#).

0x813E, **DTLB_WALK_PRFM, Data TLB software prefetch, with at least one translation table walk**

The counter counts each software prefetch access counted by [L1D_TLB_PRFM](#) that causes a refill or update of a data or unified TLB involving at least one translation table walk access.

The counter does not count the software prefetch access if any of the following are true:

- The access is due to a TLB maintenance instruction.
- The access generates a Translation fault because the applicable [TCR_ELx.EPDy](#) bit is 1.
- FEAT_EOPD is implemented and the access is an unprivileged access that generates a Translation fault because the applicable [TCR_ELx.EOPDy](#) bit is 1.

It is IMPLEMENTATION DEFINED whether the counter counts the software prefetch access if the access generates a Translation fault for any other reason.

If the TLB is shared and the Effective value of [PMEVTYPER<n>_EL0.MT](#) for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of [PMEVTYPER<n>_EL0.MT](#) for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of [PMEVTYPER<n>_EL0.MT](#).

0x813F, **ITLB_WALK_PRFM, Instruction TLB software prefetch, with at least one translation table walk**

The counter counts each software prefetch access counted by [L1I_TLB_PRFM](#) that causes a refill or update of an instruction TLB involving at least one translation table walk access.

The counter does not count the software prefetch access if any of the following are true:

- The access is due to a TLB maintenance instruction.
- The access generates a Translation fault because the applicable [TCR_ELx.EPDy](#) bit is 1.
- FEAT_EOPD is implemented and the access is an unprivileged access that generates a Translation fault because the applicable [TCR_ELx.EOPDy](#) bit is 1.

It is IMPLEMENTATION DEFINED whether the counter counts the software prefetch access if the access generates a Translation fault for any other reason.

If the TLB is shared and the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of `PMEVTYPER<n>_EL0.MT`.

0x8140, **L1D_CACHE_RW, Level 1 data cache demand access**

The counter counts each access counted by `L1D_CACHE` that is due to a demand [Memory-read operation](#) or demand [Memory-write operation](#).

This includes accesses made by [speculatively executed](#) instructions.

Arm recommends that this event is implemented if any of the following are true:

- Event `L1D_CACHE_PRFM` is implemented.
- Event `L1D_CACHE_HWPRF` is implemented.

0x8141, **L1I_CACHE_RD, Level 1 instruction cache demand fetch**

The counter counts each access counted by `L1I_CACHE` that is due to a demand [Instruction memory access](#).

This includes instruction prefetches made by the PE for [speculatively executed](#) instructions.

Arm recommends that this event is implemented if any of the following are true:

- Event `L1I_CACHE_PRFM` is implemented.
- Event `L1I_CACHE_HWPRF` is implemented.

0x8142, **L1D_CACHE_PRFM, Level 1 data cache software prefetch**

The counter counts each access counted by `L1D_CACHE_PRF` that is due to a prefetch instruction.

Arm recommends that this event is implemented if event `L1D_CACHE_RW` is implemented.

0x8143, **L1I_CACHE_PRFM, Level 1 instruction cache software prefetch**

The counter counts each access counted by `L1I_CACHE_PRF` that is due to a prefetch instruction.

Arm recommends that this event is implemented if event `L1I_CACHE_RD` is implemented.

0x8144, **L1D_CACHE_MISS, Level 1 data cache demand access miss**

The counter counts each demand access counted by `L1D_CACHE_RW` that misses in the Level 1 data or unified cache, causing an access to outside of the Level 1 caches of this PE.

0x8145, **L1I_CACHE_HWPRF, Level 1 instruction cache hardware prefetch**

The counter counts each access counted by `L1I_CACHE_PRF` that is due to a hardware prefetch.

The hardware prefetch is generated by a hardware prefetcher at the Level 1 instruction or unified cache.

The PE might prefetch instructions as part of instruction pipelining, and might do so for [speculatively executed](#) instruction paths. PE instruction prefetching is not counted as hardware prefetching. Unlike PE instruction prefetching, a hardware prefetch only allocates instructions into the cache.

0x8146, **L1D_CACHE_REFILL_PRFM, Level 1 data cache refill, software prefetch**

The counter counts each access counted by [L1D_CACHE_PRFM](#) that causes a refill of the Level 1 data or unified cache from outside of the Level 1 data or unified cache.

0x8147, **L1I_CACHE_REFILL_PRFM, Level 1 instruction cache refill, software prefetch**

The counter counts each access counted by [L1I_CACHE_PRFM](#) that causes a refill of the Level 1 instruction or unified cache from outside of the Level 1 instruction or unified cache.

0x8148, **L2D_CACHE_RW, Level 2 data cache demand access**

The counter counts each access counted by [L2D_CACHE](#) that is due to a demand [Memory-read operation](#) or demand [Memory-write operation](#).

This includes:

- Accesses made by [speculatively executed](#) instructions.
- Accesses to the Level 2 data or unified cache due to a refill of another cache caused by a demand [Memory-read operation](#) or demand [Memory-write operation](#).

Arm recommends that this event is implemented if any of the following are true:

- Event [L2D_CACHE_PRFM](#) is implemented.
- Event [L2D_CACHE_HWPRF](#) is implemented.

0x8149, **L2I_CACHE_RD, Level 2 instruction cache demand fetch**

The counter counts each access counted by [L2I_CACHE](#) that is due to a demand [Instruction memory access](#).

This includes:

- Instruction prefetches made by the PE for [speculatively executed](#) instructions.
- Accesses to the Level 2 instruction or unified cache due to a refill of another cache caused by a demand [Instruction memory access](#).

Arm recommends that this event is implemented if any of the following are true:

- Event [L2I_CACHE_PRFM](#) is implemented.
- Event [L2I_CACHE_HWPRF](#) is implemented.

0x814A, **L2D_CACHE_PRFM, Level 2 data cache software prefetch**

The counter counts each access counted by [L2D_CACHE_PRF](#) that is due to a prefetch instruction.

This includes accesses to the Level 2 data or unified cache due to a refill of another cache caused by a prefetch instruction.

Arm recommends that this event is implemented if event [L2D_CACHE_RW](#) is implemented.

0x814B, **L2I_CACHE_PRFM, Level 2 instruction cache software prefetch**

The counter counts each access counted by [L2I_CACHE_PRF](#) that is due to a prefetch instruction.

This includes accesses to the Level 2 instruction or unified cache due to a refill of another cache caused by a prefetch instruction.

Arm recommends that this event is implemented if event [L2I_CACHE_RD](#) is implemented.

0x814C, **L2D_CACHE_MISS, Level 2 data cache demand access miss**

The counter counts each demand access counted by [L2D_CACHE_RW](#) that misses in the Level 1 and Level 2 data or unified caches, causing an access to outside of the Level 1 and Level 2 caches of this PE.

0x814D, **L2I_CACHE_HWPRF, Level 2 instruction cache hardware prefetch**

The counter counts each access counted by [L2I_CACHE_PRF](#) that is due to a hardware prefetch.

The hardware prefetch is generated by a hardware prefetcher at the Level 2 instruction or unified cache.

0x814E, **L2D_CACHE_REFILL_PRFM, Level 2 data cache refill, software prefetch**

The counter counts each access counted by [L2D_CACHE_PRFM](#) that causes a refill of the Level 2 data or unified cache, or any Level 1 data, instruction, or unified cache of this PE, from outside of those caches.

0x814F, **L2I_CACHE_REFILL_PRFM, Level 2 instruction cache refill, software prefetch**

The counter counts each access counted by [L2I_CACHE_PRFM](#) that causes a refill of the Level 2 instruction or unified cache, or any Level 1 data, instruction, or unified cache of this PE, from outside of those caches.

0x8150, **L3D_CACHE_RW, Level 3 data cache demand access**

The counter counts each access counted by [L3D_CACHE](#) that is due to a demand [Memory-read operation](#) or demand [Memory-write operation](#).

This includes:

- Accesses made by [speculatively executed](#) instructions.
- Accesses to the Level 3 data or unified cache due to a refill of another cache caused by a demand [Memory-read operation](#) or demand [Memory-write operation](#).

Arm recommends that this event is implemented if any of the following are true:

- Event [L3D_CACHE_PRFM](#) is implemented.
- Event [L3D_CACHE_HWPRF](#) is implemented.

0x8151, **L3D_CACHE_PRFM, Level 3 data cache software prefetch**

The counter counts each access counted by [L3D_CACHE_PRF](#) that is due to a prefetch instruction.

This includes accesses to the Level 3 data or unified cache due to a refill of another cache caused by a prefetch instruction.

Arm recommends that this event is implemented if event [L3D_CACHE_RW](#) is implemented.

0x8152, **L3D_CACHE_MISS, Level 3 data cache demand access miss**

The counter counts each demand access counted by [L3D_CACHE_RW](#) that misses in the Level 1 to Level 3 data or unified caches, causing an access to outside of the Level 1 to Level 3 caches of this PE.

0x8153, **L3D_CACHE_REFILL_PRFM, Level 3 data cache refill, software prefetch**

The counter counts each access counted by [L3D_CACHE_PRFM](#) that causes a refill of the Level 3 data or unified cache, or any Level 1 or Level 2 data, instruction, or unified cache of this PE, from outside of those caches.

0x8154, **L1D_CACHE_HWPRF, Level 1 data cache hardware prefetch**

The counter counts each access counted by [L1D_CACHE_PRF](#) that is due to a hardware prefetch.

The hardware prefetch is generated by a hardware prefetcher at the Level 1 data or unified cache.

0x8155, **L2D_CACHE_HWPRF, Level 2 data cache hardware prefetch**

The counter counts each access counted by [L2D_CACHE_PRF](#) that is due to a hardware prefetch.

The hardware prefetch is generated by a hardware prefetcher at the Level 2 data or unified cache.

0x8156, **L3D_CACHE_HWPRF, Level 3 data cache hardware prefetch**

The counter counts each access counted by [L3D_CACHE_PRF](#) that is due to a hardware prefetch.

The hardware prefetch is generated by a hardware prefetcher at the Level 3 data or unified cache.

0x8157, **LL_CACHE_HWPRF, Last level cache hardware prefetch**

The counter counts each access counted by [LL_CACHE_PRF](#) that is due to a hardware prefetch.

The hardware prefetch is generated by a hardware prefetcher at the Last level cache.

0x8158, **STALL_FRONTEND_MEMBOUND, Frontend stall cycles, memory bound**

The counter counts each cycle counted by [STALL_FRONTEND](#) when no instructions are delivered from the memory system.

The counter counts each stall that occurs when the frontend interface to memory is busy or stalled.

This includes the stalls counted by [STALL_FRONTEND_L1I](#), [STALL_FRONTEND_L2I](#), [STALL_FRONTEND_MEM](#), and [STALL_FRONTEND_TLB](#), and any other IMPLEMENTATION DEFINED memory stalls.

It does not include stalls that are counted by [STALL_FRONTEND_CPUBOUND](#). However both events will count the same cycle counted by [STALL_FRONTEND](#) if there are both memory and processor-resource stall conditions active.

For a multithreaded processor implementation, if the Effective value of [PMEVTYPER<n>_EL0.MT](#) is 1, then the counter counts when no instructions are delivered from the memory system for any PE in the multithreaded processor.

0x8159, **STALL_FRONTEND_L1I, Frontend stall cycles, level 1 instruction cache**

The counter counts each cycle counted by [STALL_FRONTEND_MEMBOUND](#) when there is a demand instruction miss in the first level of instruction cache.

For a multithreaded processor implementation, if the Effective value of [PMEVTYPER<n>_EL0.MT](#) is 1, then the counter counts when there is a demand instruction miss in the first level of instruction cache for any PE in the multithreaded processor.

The counter does not count the cycle if any of the following are true:

- The [STALL_FRONTEND_L2I](#) event is implemented and there is a demand instruction miss in the second level of instruction cache, meaning the [STALL_FRONTEND_L2I](#) event counts the cycle.
- There is a demand instruction miss in the last level of instruction cache within the PE clock domain, meaning the [STALL_FRONTEND_MEM](#) event counts the cycle.

0x815A, **STALL_FRONTEND_L2I, Frontend stall cycles, level 2 instruction cache**

The counter counts each cycle counted by [STALL_FRONTEND_MEMBOUND](#) when there is a demand instruction miss in the second level of instruction or unified cache.

For a multithreaded processor implementation, if the Effective value of [PMEVTYPER<n>_EL0](#).MT is 1, then the counter counts when there is a demand instruction miss in the second level of instruction or unified cache for any PE in the multithreaded processor.

The counter does not count the cycle if there is a demand instruction miss in the last level of instruction cache within the PE clock domain, meaning the [STALL_FRONTEND_MEM](#) event counts the cycle.

0x815B, **STALL_FRONTEND_MEM, Frontend stall cycles, last level PE cache or memory**

The counter counts each cycle counted by [STALL_FRONTEND_MEMBOUND](#) when there is a demand instruction miss in the last level of instruction or unified cache within the PE clock domain or a non-cacheable instruction fetch in progress.

For a multithreaded processor implementation, if the Effective value of [PMEVTYPER<n>_EL0](#).MT is 1, then the counter counts when there is a demand instruction miss in the last level of instruction or unified cache within the PE clock domain or a non-cacheable instruction fetch in progress for any PE in the multithreaded processor.

0x815C, **STALL_FRONTEND_TLB, Frontend stall cycles, TLB**

The counter counts each cycle counted by [STALL_FRONTEND_MEMBOUND](#) when there is a demand instruction miss in the instruction or unified TLB.

For a multithreaded processor implementation, if the Effective value of [PMEVTYPER<n>_EL0](#).MT is 1, then the counter counts when there is a demand instruction miss in the instruction or unified TLB for any PE in the multithreaded processor.

0x8160, **STALL_FRONTEND_CPUBOUND, Frontend stall cycles, processor bound**

The counter counts each cycle counted by [STALL_FRONTEND](#) when the frontend is stalled on a frontend processor resource, not including memory.

The counter counts each stall that occurs when a frontend processor resource is busy.

This includes the stalls counted by [STALL_FRONTEND_FLOW](#), [STALL_FRONTEND_FLUSH](#), and [STALL_FRONTEND_RENAME](#), and any other IMPLEMENTATION DEFINED processor resource stalls.

It does not include stalls that are counted by [STALL_FRONTEND_MEMBOUND](#). However both events will count the same cycle counted by [STALL_FRONTEND](#) if there are both memory and processor-resource stall conditions active.

For a multithreaded processor implementation, if the Effective value of [PMEVTYPER<n>_EL0](#).MT is 1, then the counter counts when the frontend is stalled on a frontend processor resource, not including memory for any PE in the multithreaded processor.

0x8161, **STALL_FRONTEND_FLOW, Frontend stall cycles, flow control**

The counter counts each cycle counted by [STALL_FRONTEND_CPUBOUND](#) when the frontend is stalled on unavailability of prediction flow resources.

For a multithreaded processor implementation, if the Effective value of [PMEVTYPER<n>_EL0](#).MT is 1, then the counter counts when the frontend is stalled on unavailability of prediction flow resources for any PE in the multithreaded processor.

Note

This event is not counting stalls due to mispredictions, but rather stalls when the frontend is unable to make a prediction.

0x8162, **STALL_FRONTEND_FLUSH**, Frontend stall cycles, flush recovery

The counter counts each cycle counted by [STALL_FRONTEND_CPUBOUND](#) when the frontend is recovering from a pipeline flush.

The situations where the frontend is flushed are IMPLEMENTATION DEFINED. For example, the frontend might be flushed on a branch misprediction or on a Context synchronization event.

For a multithreaded processor implementation, if the Effective value of [PMEVTYPER<n>_EL0](#).MT is 1, then the counter counts when the frontend is recovering from a pipeline flush for any PE in the multithreaded processor.

0x8163, **STALL_FRONTEND_RENAME**, Frontend stall cycles, rename full

The counter counts each cycle counted by [STALL_FRONTEND_CPUBOUND](#) when operations are available from the frontend but at least one is not ready to be sent to the backend because no rename register is available.

If this event is implemented and counts such stalls then the [STALL_BACKEND_RENAME](#) event counts as zero.

For a multithreaded processor implementation, if the Effective value of [PMEVTYPER<n>_EL0](#).MT is 1, then the counter counts when operations are available from the frontend but at least one is not ready to be sent to the backend because no rename register is available for any PE in the multithreaded processor.

0x8164, **STALL_BACKEND_MEMBOUND**, Backend stall cycles, memory bound

The counter counts each cycle counted by [STALL_BACKEND](#) when the backend is waiting for a memory access to complete.

The counter counts each stall that occurs when the backend interface to memory is busy or stalled.

This includes the stalls counted by: [STALL_BACKEND_ATOMIC](#), [STALL_BACKEND_L1D](#), [STALL_BACKEND_L2D](#), [STALL_BACKEND_MEM](#), [STALL_BACKEND_ST](#), [STALL_BACKEND_TLB](#), and any other IMPLEMENTATION DEFINED memory stall events.

It does not include stalls that are counted by [STALL_BACKEND_CPUBOUND](#), although both events might count on the same cycle counted by [STALL_BACKEND](#) if there are both memory and processor-resource stall conditions active.

For a multithreaded processor implementation, if the Effective value of [PMEVTYPER<n>_EL0](#).MT is 1, then the counter counts when the backend is waiting for a memory access to complete for any PE in the multithreaded processor.

0x8165, **STALL_BACKEND_L1D**, Backend stall cycles, level 1 data cache

The counter counts each cycle counted by [STALL_BACKEND_MEMBOUND](#) when there is a demand data miss in the first level of data or unified cache.

For a multithreaded processor implementation, if the Effective value of [PMEVTYPER<n>_EL0](#).MT is 1, then the counter counts when there is a demand data miss in the first level of data or unified cache for any PE in the multithreaded processor.

The counter does not count the cycle if any of the following are true:

- The [STALL_BACKEND_L2D](#) event is implemented and there is a demand data miss in the second level of data or unified cache, meaning the [STALL_BACKEND_L2D](#) event counts the cycle.
- There is a demand data miss in the last level of data or unified cache within the PE clock domain, meaning the [STALL_BACKEND_MEM](#) event counts the cycle.

0x8166, **STALL_BACKEND_L2D**, Backend stall cycles, level 2 data cache

The counter counts each cycle counted by [STALL_BACKEND_MEMBOUND](#) when there is a demand data miss in the second level of data or unified cache.

For a multithreaded processor implementation, if the Effective value of [PMEVTYPER<n>_EL0](#).MT is 1, then the counter counts when there is a demand data miss in the second level of data or unified cache for any PE in the multithreaded processor.

The counter does not count the cycle if there is a demand data miss in the last level of data or unified cache within the PE clock domain, meaning the [STALL_BACKEND_MEM](#) event counts the cycle.

0x8167, **STALL_BACKEND_TLB**, Backend stall cycles, TLB

The counter counts each cycle counted by [STALL_BACKEND_MEMBOUND](#) when there is a demand data miss in the data or unified TLB.

For a multithreaded processor implementation, if the Effective value of [PMEVTYPER<n>_EL0](#).MT is 1, then the counter counts when there is a demand data miss in the data or unified TLB for any PE in the multithreaded processor.

0x8168, **STALL_BACKEND_ST**, Backend stall cycles, store

The counter counts each cycle counted by [STALL_BACKEND_MEMBOUND](#) when the backend is stalled waiting for a store.

For a multithreaded processor implementation, if the Effective value of [PMEVTYPER<n>_EL0](#).MT is 1, then the counter counts when the backend is stalled waiting for a store for any PE in the multithreaded processor.

0x816A, **STALL_BACKEND_CPUBOUND**, Backend stall cycles, processor bound

The counter counts each cycle counted by [STALL_BACKEND](#) when the backend is stalled on a processor resource, not including memory.

The counter counts each stall that occurs when a backend processor resource is busy. This includes the stalls counted by [STALL_BACKEND_RENAME](#), and any other IMPLEMENTATION DEFINED processor resource stalls.

It does not include stalls that are counted by [STALL_BACKEND_MEMBOUND](#), although both events might count on the same cycle counted by [STALL_BACKEND](#) if there are both memory and processor-resource stall conditions active.

For a multithreaded processor implementation, if the Effective value of [PMEVTYPER<n>_EL0](#).MT is 1, then the counter counts when the backend is stalled on a processor resource, not including memory for any PE in the multithreaded processor.

0x816B, **STALL_BACKEND_BUSY**, Backend stall cycles, backend busy

The counter counts each cycle counted by [STALL_BACKEND](#) when operations are available from the frontend but the backend is not able to accept an operation because an execution unit is busy.

For example a complex operation unit such as a divider is executing a previous operation and cannot accept a new operation.

For a multithreaded processor implementation, if the Effective value of [PMEVTYPER<n>_EL0](#).MT is 1, then the counter counts when operations are available from the frontend but the backend is not able to accept an operation because an execution unit is busy for any PE in the multithreaded processor.

0x816C, **STALL_BACKEND_ILOCK**, Backend stall cycles, input dependency

The counter counts each cycle counted by [STALL_BACKEND](#) when operations are available from the frontend but at least one is not ready to be sent to the backend because of an input dependency.

For a multithreaded processor implementation, if the Effective value of [PMEVTYPER<n>_EL0](#).MT is 1, then the counter counts when operations are available from the frontend but at least one is not ready to be sent to the backend because of an input dependency for any PE in the multithreaded processor.

0x816D, **STALL_BACKEND_RENAME**, Backend stall cycles, rename full

The counter counts each cycle counted by [STALL_BACKEND_CPUBOUND](#) when operations are available from the frontend but at least one is not ready to be sent to the backend because no rename register is available.

If this event is implemented and counts such stalls then the [STALL_FRONTEND_RENAME](#) event counts as zero.

For a multithreaded processor implementation, if the Effective value of [PMEVTYPER<n>_EL0](#).MT is 1, then the counter counts when operations are available from the frontend but at least one is not ready to be sent to the backend because no rename register is available for any PE in the multithreaded processor.

0x816E, **STALL_BACKEND_ATOMIC, Backend stall cycles, atomic operation**

The counter counts each cycle counted by [STALL_BACKEND_MEMBOUND](#) when the backend is processing an Atomic operation.

For a multithreaded processor implementation, if the Effective value of [PMEVTYPER<n>_EL0](#).MT is 1, then the counter counts when the backend is processing an Atomic operation for any PE in the multithreaded processor.

0x8170, **CAS_NEAR_FAIL, Atomic memory Operation speculatively executed, Compare and Swap fail**

The counter counts each Compare and Swap operation counted by [CAS_NEAR_SPEC](#) that does not update the location accessed.

0x8171, **CAS_NEAR_PASS, Atomic memory Operation speculatively executed, Compare and Swap pass**

The counter counts each Compare and Swap operation counted by [CAS_NEAR_SPEC](#) that updates the location accessed.

0x8172, **CAS_NEAR_SPEC, Atomic memory Operation speculatively executed, Compare and Swap near**

The counter counts each Compare and Swap operation counted by [CAS_SPEC](#) that executes locally to the PE.

The definition of locally is IMPLEMENTATION DEFINED. Operations counted by [CAS_NEAR_SPEC](#) also generate one of the [CAS_NEAR_PASS](#) or [CAS_NEAR_FAIL](#) events.

0x8173, **CAS_FAR_SPEC, Atomic memory Operation speculatively executed, Compare and Swap far**

The counter counts each Compare and Swap operation counted by [CAS_SPEC](#) that does not execute locally to the PE.

The definition of locally is IMPLEMENTATION DEFINED. Operations counted by [CAS_FAR_SPEC](#) do not generate [CAS_NEAR_PASS](#) or [CAS_NEAR_FAIL](#) events.

0x8174, **CAS_SPEC, Atomic memory Operation speculatively executed, Compare and Swap**

The counter counts each Compare and Swap operation.

0x8175, **LSE_LD_SPEC, Atomic memory Operation speculatively executed, load**

The counter counts each Atomic memory operation counted by [LSE_LDST_SPEC](#) that returns a value to the PE, including Swap and Compare-and-Swap operations.

0x8176, **LSE_ST_SPEC, Atomic memory Operation speculatively executed, store**

The counter counts each Atomic memory operation counted by [LSE_LDST_SPEC](#) that does not return a value to the PE.

0x8177, **LSE_LDST_SPEC, Atomic memory Operation speculatively executed, load or store**

The counter counts each operation counted by [LDST_SPEC](#) that is an Atomic memory operation.

0x8178, **REMOTE_ACCESS_WR, Access to a remote device, write**

The counter counts each access counted by [REMOTE_ACCESS](#) that is a [Memory-write operation](#).

0x8186, UOP_RETIRE, Micro-operation architecturally executed

The counter counts each micro-operation that would be executed in a Simple sequential execution of the program.

Unlike [OP_RETIRE](#), this event is not linked to the definition of [OP_SPEC](#), meaning it counts micro-operations that are created from other operations after those operations are counted by [OP_SPEC](#).

0x8188, DTLB_WALK_BLOCK, Data TLB block translation table walk

The counter counts each translation table walk counted by [DTLB_WALK](#) where the result of the walk yields a Block.

That is, the translation table walk ends at a Block descriptor, at other than the last level of translation table.

If two stages of translation are used and Stage 1 and Stage 2 yield different granule sizes, the counter counts the translation table walk only if both are a Block.

The counter does not count the walk if the access generates a Translation fault.

If the TLB is shared and the Effective value of [PMEVTYPER<n>_EL0.MT](#) for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of [PMEVTYPER<n>_EL0.MT](#) for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of [PMEVTYPER<n>_EL0.MT](#).

0x8189, ITLB_WALK_BLOCK, Instruction TLB block translation table walk

The counter counts each translation table walk counted by [ITLB_WALK](#) where the result of the walk yields a Block.

That is, the translation table walk ends at a Page descriptor, at other than the last level of translation table.

If two stages of translation are used and Stage 1 and Stage 2 yield different granule sizes, the counter counts the translation table walk only if both are a Block.

The counter does not count the walk if the access generates a Translation fault.

If the TLB is shared and the Effective value of [PMEVTYPER<n>_EL0.MT](#) for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of [PMEVTYPER<n>_EL0.MT](#) for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of [PMEVTYPER<n>_EL0.MT](#).

0x818A, DTLB_WALK_PAGE, Data TLB page translation table walk

The counter counts each translation table walk counted by [DTLB_WALK](#) where the result of the walk yields a Page.

That is, the translation table walk ends at a Block descriptor, at the last level of translation table.

If two stages of translation are used and Stage 1 and Stage 2 yield different granule sizes, the counter counts the translation table walk only if either is a Page.

The counter does not count the walk if the access generates a Translation fault.

If the TLB is shared and the Effective value of [PMEVTYPER<n>_EL0.MT](#) for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of [PMEVTYPER<n>_EL0.MT](#) for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of [PMEVTYPER<n>_EL0.MT](#).

0x818B, ITLB_WALK_PAGE, Instruction TLB page translation table walk

The counter counts each translation table walk counted by [ITLB_WALK](#) where the result of the walk yields a Page.

That is, the translation table walk ends at a Page descriptor, at the last level of translation table.

If two stages of translation are used and Stage 1 and Stage 2 yield different granule sizes, the counter counts the translation table walk only if either is a Page.

The counter does not count the walk if the access generates a Translation fault.

If the TLB is shared and the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of `PMEVTYPER<n>_EL0.MT`.

0x818D, **BUS_REQ_RD, Bus request, read**

The counter counts each transaction counted by `BUS_REQ` that is a [Memory-read operation](#).

0x818E, **BUS_REQ_WR, Bus request, write**

The counter counts each transaction counted by `BUS_REQ` that is a [Memory-write operation](#).

0x818F, **BUS_REQ, Bus request**

The counter counts each request generated by a [Memory-read operation](#) or [Memory-write operation](#) that accesses outside of the boundary of the PE and its closely-coupled caches.

Where this boundary lies with respect to any implemented caches is IMPLEMENTATION DEFINED. Where an implementation has multiple buses at this boundary, this event counts the sum of requests across all buses.

A bus request is the start of a bus transaction. The exact nature of a bus transaction is IMPLEMENTATION DEFINED, but for the purposes of event monitoring consists of a single access comprising one or more cycles, or beats, when the transaction occupies the bus. The `BUS_REQ` event therefore counts the number of transactions. The `BUS_ACCESS` event counts the occupancy of the transaction on the bus.

Bus transactions include refills of and write-backs from data, instruction, and unified caches. Whether bus transactions include operations that use the bus but do not explicitly transfer data is IMPLEMENTATION DEFINED. This must be the same for the `BUS_REQ` and `BUS_ACCESS` events.

An Unattributable bus transaction occurs when a requester outside the PE makes a request that results in a bus transaction, for example, a coherency request.

The maximum increment in any given cycle is IMPLEMENTATION DEFINED.

If the bus is shared and the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the bus is shared by PEs other than the PEs in the multithreaded processor and the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of `PMEVTYPER<n>_EL0.MT`.

0x8190, **ISNP_HIT_RD, Snoop hit, demand instruction fetch**

The counter counts each snoop generated by the PE in response to a demand [Instruction memory access](#) that hits in a cache outside of the cache hierarchy of this PE.

The event is counted by the PE generating the snoop, not the PE being snooped.

0x8191, **ISNP_HIT_NEAR_RD, Snoop hit in near local cache, demand instruction fetch**

The counter counts each snoop generated by the PE in response to a demand [Instruction memory access](#) counted by `ISNP_HIT_RD` that hits in a cache outside of the cache hierarchy of this PE in the local PE cluster.

The event is counted by the PE generating the snoop, not the PE being snooped.

0x8192, ISNP_HIT_FAR_RD, Snoop hit in far local cache, demand instruction fetch

The counter counts each snoop generated by the PE in response to a demand [Instruction memory access](#) counted by [ISNP_HIT_RD](#) that hits in a cache outside the local PE cluster on the same device.

The event is counted by the PE generating the snoop, not the PE being snooped.

0x8193, ISNP_HIT_REMOTE_RD, Snoop hit in remote cache, demand instruction fetch

The counter counts each snoop generated by the PE in response to a demand [Instruction memory access](#) counted by [ISNP_HIT_RD](#) that hits in a cache on a remote device.

The event is counted by the PE generating the snoop, not the PE being snooped.

0x8194, DSNP_HIT_RD, Snoop hit, demand data read

The counter counts each snoop generated by the PE in response to a demand [Memory-read operation](#) counted by [DSNP_HIT_RW](#) that hits in a cache outside of the cache hierarchy of this PE.

The event is counted by the PE generating the snoop, not the PE being snooped.

0x8195, DSNP_HIT_NEAR_RD, Snoop hit in near local cache, demand data read

The counter counts each snoop generated by the PE in response to a demand [Memory-read operation](#) counted by [DSNP_HIT_RD](#) that hits in a cache outside of the cache hierarchy of this PE in the local PE cluster.

The event is counted by the PE generating the snoop, not the PE being snooped.

0x8196, DSNP_HIT_FAR_RD, Snoop hit in far local cache, demand data read

The counter counts each snoop generated by the PE in response to a demand [Memory-read operation](#) counted by [DSNP_HIT_RD](#) that hits in a cache outside the local PE cluster on the same device.

The event is counted by the PE generating the snoop, not the PE being snooped.

0x8197, DSNP_HIT_REMOTE_RD, Snoop hit in remote cache, demand data read

The counter counts each snoop generated by the PE in response to a demand [Memory-read operation](#) counted by [DSNP_HIT_RD](#) that hits in a cache on a remote device.

The event is counted by the PE generating the snoop, not the PE being snooped.

0x8198, DSNP_HIT_WR, Snoop hit, demand data write

The counter counts each snoop generated by the PE in response to a demand [Memory-write operation](#) counted by [DSNP_HIT_RW](#) that hits in a cache outside of the cache hierarchy of this PE.

The event is counted by the PE generating the snoop, not the PE being snooped.

0x8199, DSNP_HIT_NEAR_WR, Snoop hit in near local cache, demand data write

The counter counts each snoop generated by the PE in response to a demand [Memory-write operation](#) counted by [DSNP_HIT_WR](#) that hits in a cache outside of the cache hierarchy of this PE in the local PE cluster.

The event is counted by the PE generating the snoop, not the PE being snooped.

0x819A, **DSNP_HIT_FAR_WR, Snoop hit in far local cache, demand data write**

The counter counts each snoop generated by the PE in response to a demand [Memory-write operation](#) counted by [DSNP_HIT_WR](#) that hits in a cache outside the local PE cluster on the same device.

The event is counted by the PE generating the snoop, not the PE being snooped.

0x819B, **DSNP_HIT_REMOTE_WR, Snoop hit in remote cache, demand data write**

The counter counts each snoop generated by the PE in response to a demand [Memory-write operation](#) counted by [DSNP_HIT_WR](#) that hits in a cache on a remote device.

The event is counted by the PE generating the snoop, not the PE being snooped.

0x819C, **DSNP_HIT_RW, Snoop hit, demand data access**

The counter counts each snoop generated by the PE in response to a demand [Memory-read operation](#) or demand [Memory-write operation](#) that hits in a cache outside of the cache hierarchy of this PE.

The event is counted by the PE generating the snoop, not the PE being snooped.

0x819D, **DSNP_HIT_NEAR_RW, Snoop hit in near local cache, demand data access**

The counter counts each snoop generated by the PE in response to a demand [Memory-read operation](#) or demand [Memory-write operation](#) counted by [DSNP_HIT_RW](#) that hits in a cache outside of the cache hierarchy of this PE in the local PE cluster.

The event is counted by the PE generating the snoop, not the PE being snooped.

0x819E, **DSNP_HIT_FAR_RW, Snoop hit in far local cache, demand data access**

The counter counts each snoop generated by the PE in response to a demand [Memory-read operation](#) or demand [Memory-write operation](#) counted by [DSNP_HIT_RW](#) that hits in a cache outside the local PE cluster on the same device.

The event is counted by the PE generating the snoop, not the PE being snooped.

0x819F, **DSNP_HIT_REMOTE_RW, Snoop hit in remote cache, demand data access**

The counter counts each snoop generated by the PE in response to a demand [Memory-read operation](#) or demand [Memory-write operation](#) counted by [DSNP_HIT_RW](#) that hits in a cache on a remote device.

The event is counted by the PE generating the snoop, not the PE being snooped.

0x81A0, **DSNP_HIT_PRFM, Snoop hit, software data prefetch**

The counter counts each snoop generated by the PE in response to a data prefetch instruction counted by [DSNP_HIT_PRF](#) that hits in a cache outside of the cache hierarchy of this PE.

The event is counted by the PE generating the snoop, not the PE being snooped.

0x81A1, **DSNP_HIT_NEAR_PRFM, Snoop hit in near local cache, software data prefetch**

The counter counts each snoop generated by the PE in response to a data prefetch instruction counted by [DSNP_HIT_PRFM](#) that hits in a cache outside of the cache hierarchy of this PE in the local PE cluster.

The event is counted by the PE generating the snoop, not the PE being snooped.

0x81A2, **DSNP_HIT_FAR_PRFM, Snoop hit in far local cache, software data prefetch**

The counter counts each snoop generated by the PE in response to a data prefetch instruction counted by [DSNP_HIT_PRFM](#) that hits in a cache outside the local PE cluster on the same device.

The event is counted by the PE generating the snoop, not the PE being snooped.

0x81A3, **DSNP_HIT_REMOTE_PRFM, Snoop hit in remote cache, software data prefetch**

The counter counts each snoop generated by the PE in response to a data prefetch instruction counted by [DSNP_HIT_PRFM](#) that hits in a cache on a remote device.

The event is counted by the PE generating the snoop, not the PE being snooped.

0x81A4, **DSNP_HIT_HWPRF, Snoop hit, hardware data prefetch**

The counter counts each snoop generated by a data hardware prefetch counted by [DSNP_HIT_PRF](#) that hits in a cache outside of the cache hierarchy of this PE.

The event is counted by the PE generating the snoop, not the PE being snooped.

0x81A5, **DSNP_HIT_NEAR_HWPRF, Snoop hit in near local cache, hardware data prefetch**

The counter counts each snoop generated by a data hardware prefetch counted by [DSNP_HIT_HWPRF](#) that hits in a cache outside of the cache hierarchy of this PE in the local PE cluster.

The event is counted by the PE generating the snoop, not the PE being snooped.

0x81A6, **DSNP_HIT_FAR_HWPRF, Snoop hit in far local cache, hardware data prefetch**

The counter counts each snoop generated by a data hardware prefetch counted by [DSNP_HIT_HWPRF](#) that hits in a cache outside the local PE cluster on the same device.

The event is counted by the PE generating the snoop, not the PE being snooped.

0x81A7, **DSNP_HIT_REMOTE_HWPRF, Snoop hit in remote cache, hardware data prefetch**

The counter counts each snoop generated by a data hardware prefetch counted by [DSNP_HIT_HWPRF](#) that hits in a cache on a remote device.

The event is counted by the PE generating the snoop, not the PE being snooped.

0x81A8, **ISNP_HIT_PRFM, Snoop hit, software instruction prefetch**

The counter counts each snoop generated by the PE in response to an instruction prefetch instruction counted by [ISNP_HIT_PRF](#) that hits in a cache outside of the cache hierarchy of this PE.

The event is counted by the PE generating the snoop, not the PE being snooped.

0x81A9, **ISNP_HIT_NEAR_PRFM, Snoop hit in near local cache, software instruction prefetch**

The counter counts each snoop generated by the PE in response to an instruction prefetch instruction counted by [ISNP_HIT_PRFM](#) that hits in a cache outside of the cache hierarchy of this PE in the local PE cluster.

The event is counted by the PE generating the snoop, not the PE being snooped.

0x81AA, ISNP_HIT_FAR_PRFM, Snoop hit in far local cache, software instruction prefetch

The counter counts each snoop generated by the PE in response to an instruction prefetch instruction counted by [ISNP_HIT_PRFM](#) that hits in a cache outside the local PE cluster on the same device.

The event is counted by the PE generating the snoop, not the PE being snooped.

0x81AB, ISNP_HIT_REMOTE_PRFM, Snoop hit in remote cache, software instruction prefetch

The counter counts each snoop generated by the PE in response to an instruction prefetch instruction counted by [ISNP_HIT_PRFM](#) that hits in a cache on a remote device.

The event is counted by the PE generating the snoop, not the PE being snooped.

0x81AC, ISNP_HIT_HWPRF, Snoop hit, hardware instruction prefetch

The counter counts each snoop generated by an instruction hardware prefetch counted by [ISNP_HIT_PRF](#) that hits in a cache outside of the cache hierarchy of this PE.

The event is counted by the PE generating the snoop, not the PE being snooped.

0x81AD, ISNP_HIT_NEAR_HWPRF, Snoop hit in near local cache, hardware instruction prefetch

The counter counts each snoop generated by an instruction hardware prefetch counted by [ISNP_HIT_HWPRF](#) that hits in a cache outside of the cache hierarchy of this PE in the local PE cluster.

The event is counted by the PE generating the snoop, not the PE being snooped.

0x81AE, ISNP_HIT_FAR_HWPRF, Snoop hit in far local cache, hardware instruction prefetch

The counter counts each snoop generated by an instruction hardware prefetch counted by [ISNP_HIT_HWPRF](#) that hits in a cache outside the local PE cluster on the same device.

The event is counted by the PE generating the snoop, not the PE being snooped.

0x81AF, ISNP_HIT_REMOTE_HWPRF, Snoop hit in remote cache, hardware instruction prefetch

The counter counts each snoop generated by an instruction hardware prefetch counted by [ISNP_HIT_HWPRF](#) that hits in a cache on a remote device.

The event is counted by the PE generating the snoop, not the PE being snooped.

0x81B0, ISNP_HIT, Snoop hit, instruction

The counter counts each snoop that hits in a cache outside of the cache hierarchy of this PE.

The event is counted by the PE generating the snoop, not the PE being snooped.

0x81B1, ISNP_HIT_NEAR, Snoop hit in near local cache, instruction access

The counter counts each snoop counted by [ISNP_HIT](#) that hits in a cache outside of the cache hierarchy of this PE in the local PE cluster.

The event is counted by the PE generating the snoop, not the PE being snooped.

0x81B2, ISNP_HIT_FAR, Snoop hit in far local cache, instruction access

The counter counts each snoop counted by [ISNP_HIT](#) that hits in a cache outside the local PE cluster on the same device.

The event is counted by the PE generating the snoop, not the PE being snooped.

0x81B3, ISNP_HIT_REMOTE, Snoop hit in remote cache, instruction access

The counter counts each snoop counted by [ISNP_HIT](#) that hits in a cache on a remote device.

The event is counted by the PE generating the snoop, not the PE being snooped.

0x81B4, DSNP_HIT, Snoop hit, data

The counter counts each snoop that hits in a cache outside of the cache hierarchy of this PE.

The event is counted by the PE generating the snoop, not the PE being snooped.

0x81B5, DSNP_HIT_NEAR, Snoop hit in near local cache, data access

The counter counts each snoop counted by [DSNP_HIT](#) that hits in a cache outside of the cache hierarchy of this PE in the local PE cluster.

The event is counted by the PE generating the snoop, not the PE being snooped.

0x81B6, DSNP_HIT_FAR, Snoop hit in far local cache, data access

The counter counts each snoop counted by [DSNP_HIT](#) that hits in a cache outside the local PE cluster on the same device.

The event is counted by the PE generating the snoop, not the PE being snooped.

0x81B7, DSNP_HIT_REMOTE, Snoop hit in remote cache, data access

The counter counts each snoop counted by [DSNP_HIT](#) that hits in a cache on a remote device.

The event is counted by the PE generating the snoop, not the PE being snooped.

0x81B8, L1I_CACHE_REFILL_HWPRF, Level 1 instruction cache refill, hardware prefetch

The counter counts each hardware prefetch counted by [L1I_CACHE_HWPRF](#) that causes a refill of the Level 1 instruction or unified cache from outside of the Level 1 instruction or unified cache.

0x81B9, L2I_CACHE_REFILL_HWPRF, Level 2 instruction cache refill, hardware prefetch

The counter counts each hardware prefetch counted by [L2I_CACHE_HWPRF](#) that causes a refill of the Level 2 instruction or unified cache, or any Level 1 data, instruction, or unified cache of this PE, from outside of those caches.

0x81BC, L1D_CACHE_REFILL_HWPRF, Level 1 data cache refill, hardware prefetch

The counter counts each hardware prefetch counted by [L1D_CACHE_HWPRF](#) that causes a refill of the Level 1 data or unified cache from outside of the Level 1 data or unified cache.

0x81BD, L2D_CACHE_REFILL_HWPRF, Level 2 data cache refill, hardware prefetch

The counter counts each hardware prefetch counted by [L2D_CACHE_HWPRF](#) that causes a refill of the Level 2 data or unified cache, or any Level 1 data, instruction, or unified cache of this PE, from outside of those caches.

0x81BE, L3D_CACHE_REFILL_HWPRF, Level 3 data cache refill, hardware prefetch

The counter counts each hardware prefetch counted by [L3D_CACHE_HWPRF](#) that causes a refill of the Level 3 data or unified cache, or any Level 1 or Level 2 data, instruction, or unified cache of this PE, from outside of those caches.

0x81BF, LL_CACHE_REFILL_HWPRF, Last level cache refill, hardware prefetch

The counter counts each hardware prefetch counted by [LL_CACHE_HWPRF](#) that causes a refill of the Last level cache, or any other data, instruction, or unified cache of this PE, from outside of those caches.

0x81C0, L1I_CACHE_HIT_RD, Level 1 instruction cache demand fetch hit

The counter counts each demand fetch counted by [L1I_CACHE_RD](#) that hits in the Level 1 instruction or unified cache.

0x81C1, L2I_CACHE_HIT_RD, Level 2 instruction cache demand fetch hit

The counter counts each demand fetch counted by [L2I_CACHE_RD](#) that hits in the Level 2 instruction or unified cache.

0x81C4, L1D_CACHE_HIT_RD, Level 1 data cache demand access hit, read

The counter counts each demand read counted by [L1D_CACHE_RD](#) that hits in the Level 1 data or unified cache.

0x81C5, L2D_CACHE_HIT_RD, Level 2 data cache demand access hit, read

The counter counts each demand read counted by [L2D_CACHE_RD](#) that hits in the Level 2 data or unified cache.

0x81C6, L3D_CACHE_HIT_RD, Level 3 data cache demand access hit, read

The counter counts each demand read counted by [L3D_CACHE_RD](#) that hits in the Level 3 data or unified cache.

0x81C7, LL_CACHE_HIT_RD, Last level cache demand access hit, read

The counter counts each demand read counted by [LL_CACHE_RD](#) that hits in the Last level cache.

0x81C8, L1D_CACHE_HIT_WR, Level 1 data cache demand access hit, write

The counter counts each demand write counted by [L1D_CACHE_WR](#) that hits in the Level 1 data or unified cache.

0x81C9, L2D_CACHE_HIT_WR, Level 2 data cache demand access hit, write

The counter counts each demand write counted by [L2D_CACHE_WR](#) that hits in the Level 2 data or unified cache.

0x81CA, L3D_CACHE_HIT_WR, Level 3 data cache demand access hit, write

The counter counts each demand write counted by [L3D_CACHE_WR](#) that hits in the Level 3 data or unified cache.

0x81CB, LL_CACHE_HIT_WR, Last level cache demand access hit, write

The counter counts each demand write counted by [LL_CACHE_WR](#) that hits in the Last level cache.

0x81CC, L1D_CACHE_HIT_RW, Level 1 data cache demand access hit

The counter counts each demand access counted by [L1D_CACHE_RW](#) that hits in the Level 1 data or unified cache.

0x81CD, L2D_CACHE_HIT_RW, Level 2 data cache demand access hit

The counter counts each demand access counted by [L2D_CACHE_RW](#) that hits in the Level 2 data or unified cache.

0x81CE, L3D_CACHE_HIT_RW, Level 3 data cache demand access hit

The counter counts each demand access counted by [L3D_CACHE_RW](#) that hits in the Level 3 data or unified cache.

0x81CF, LL_CACHE_HIT_RW, Last level cache demand access hit

The counter counts each demand access counted by [LL_CACHE_RW](#) that hits in the Last level cache.

0x81D0, L1I_CACHE_HIT_RD_FPRFM, Level 1 instruction cache demand fetch first hit, fetched by software prefetch

The counter counts each demand fetch first hit counted by [L1I_CACHE_HIT_RD_FPRF](#) where the cache line was fetched in response to a prefetch instruction.

That is, the [L1I_CACHE_REFILL_PRFM](#) event was generated when the cache line was fetched into the cache.

Only the first hit by a demand access is counted. After this event is generated for a cache line, the event is not generated again for the same cache line while it remains in the cache.

0x81D1, L2I_CACHE_HIT_RD_FPRFM, Level 2 instruction cache demand fetch first hit, fetched by software prefetch

The counter counts each demand fetch first hit counted by [L2I_CACHE_HIT_RD_FPRF](#) where the cache line was fetched in response to a prefetch instruction.

That is, the [L2I_CACHE_REFILL_PRFM](#) event was generated when the cache line was fetched into the cache.

Only the first hit by a demand access is counted. After this event is generated for a cache line, the event is not generated again for the same cache line while it remains in the cache.

0x81D4, L1D_CACHE_HIT_RD_FPRFM, Level 1 data cache demand access first hit, read, fetched by software prefetch

The counter counts each first hit counted by [L1D_CACHE_HIT_RW_FPRFM](#) that is due to a demand [Memory-read operation](#).

0x81D5, L2D_CACHE_HIT_RD_FPRFM, Level 2 data cache demand access first hit, read, fetched by software prefetch

The counter counts each first hit counted by [L2D_CACHE_HIT_RW_FPRFM](#) that is due to a demand [Memory-read operation](#).

0x81D6, L3D_CACHE_HIT_RD_FPRFM, Level 3 data cache demand access first hit, read, fetched by software prefetch

The counter counts each first hit counted by [L3D_CACHE_HIT_RW_FPRFM](#) that is due to a demand [Memory-read operation](#).

0x81D7, LL_CACHE_HIT_RD_FPRFM, Last level cache demand access first hit, read, fetched by software prefetch

The counter counts each first hit counted by [LL_CACHE_HIT_RW_FPRFM](#) that is due to a demand [Memory-read operation](#).

0x81D8, L1D_CACHE_HIT_WR_FPRFM, Level 1 data cache demand access first hit, write, fetched by software prefetch

The counter counts each first hit counted by [L1D_CACHE_HIT_RW_FPRFM](#) that is due to a demand [Memory-write operation](#).

0x81D9, L2D_CACHE_HIT_WR_FPRFM, Level 2 data cache demand access first hit, write, fetched by software prefetch

The counter counts each first hit counted by [L2D_CACHE_HIT_RW_FPRFM](#) that is due to a demand [Memory-write operation](#).

0x81DA, L3D_CACHE_HIT_WR_FPRFM, Level 3 data cache demand access first hit, write, fetched by software prefetch

The counter counts each first hit counted by [L3D_CACHE_HIT_RW_FPRFM](#) that is due to a demand [Memory-write operation](#).

0x81DB, LL_CACHE_HIT_WR_FPRFM, Last level cache demand access first hit, write, fetched by software prefetch

The counter counts each first hit counted by [LL_CACHE_HIT_RW_FPRFM](#) that is due to a demand [Memory-write operation](#).

0x81DC, L1D_CACHE_HIT_RW_FPRFM, Level 1 data cache demand access first hit, fetched by software prefetch

The counter counts each demand access first hit counted by [L1D_CACHE_HIT_RW_FPRF](#) where the cache line was fetched in response to a prefetch instruction.

That is, the [L1D_CACHE_REFILL_PRFM](#) event was generated when the cache line was fetched into the cache.

Only the first hit by a demand access is counted. After this event is generated for a cache line, the event is not generated again for the same cache line while it remains in the cache.

0x81DD, L2D_CACHE_HIT_RW_FPRFM, Level 2 data cache demand access first hit, fetched by software prefetch

The counter counts each demand access first hit counted by [L2D_CACHE_HIT_RW_FPRF](#) where the cache line was fetched in response to a prefetch instruction.

That is, the [L2D_CACHE_REFILL_PRFM](#) event was generated when the cache line was fetched into the cache.

Only the first hit by a demand access is counted. After this event is generated for a cache line, the event is not generated again for the same cache line while it remains in the cache.

0x81DE, L3D_CACHE_HIT_RW_FPRFM, Level 3 data cache demand access first hit, fetched by software prefetch

The counter counts each demand access first hit counted by [L3D_CACHE_HIT_RW_FPRF](#) where the cache line was fetched in response to a prefetch instruction.

That is, the [L3D_CACHE_REFILL_PRFM](#) event was generated when the cache line was fetched into the cache.

Only the first hit by a demand access is counted. After this event is generated for a cache line, the event is not generated again for the same cache line while it remains in the cache.

0x81DF, LL_CACHE_HIT_RW_FPRFM, Last level cache demand access first hit, fetched by software prefetch

The counter counts each demand access first hit counted by [LL_CACHE_HIT_RW_FPRF](#) where the cache line was fetched in response to a prefetch instruction.

That is, the [LL_CACHE_REFILL_PRFM](#) event was generated when the cache line was fetched into the cache.

Only the first hit by a demand access is counted. After this event is generated for a cache line, the event is not generated again for the same cache line while it remains in the cache.

0x81E0, L1I_CACHE_HIT_RD_FHWPRF, Level 1 instruction cache demand fetch first hit, fetched by hardware prefetcher

The counter counts each demand fetch first hit counted by [L1I_CACHE_HIT_RD_FPRF](#) where the cache line was fetched by a hardware prefetcher.

That is, the [L1I_CACHE_REFILL_HWPRF](#) event was generated when the cache line was fetched into the cache.

Only the first hit by a demand access is counted. After this event is generated for a cache line, the event is not generated again for the same cache line while it remains in the cache.

0x81E1, L2I_CACHE_HIT_RD_FHWPRF, Level 2 instruction cache demand fetch first hit, fetched by hardware prefetcher

The counter counts each demand fetch first hit counted by [L2I_CACHE_HIT_RD_FPRF](#) where the cache line was fetched by a hardware prefetcher.

That is, the [L2I_CACHE_REFILL_HWPRF](#) event was generated when the cache line was fetched into the cache.

Only the first hit by a demand access is counted. After this event is generated for a cache line, the event is not generated again for the same cache line while it remains in the cache.

0x81E4, L1D_CACHE_HIT_RD_FHWPRF, Level 1 data cache demand access first hit, read, fetched by hardware prefetcher

The counter counts each first hit counted by [L1D_CACHE_HIT_RW_FHWPRF](#) that is due to a demand [Memory-read operation](#).

0x81E5, L2D_CACHE_HIT_RD_FHWPRF, Level 2 data cache demand access first hit, read, fetched by hardware prefetcher

The counter counts each first hit counted by [L2D_CACHE_HIT_RW_FHWPRF](#) that is due to a demand [Memory-read operation](#).

0x81E6, L3D_CACHE_HIT_RD_FHWPRF, Level 3 data cache demand access first hit, read, fetched by hardware prefetcher

The counter counts each first hit counted by [L3D_CACHE_HIT_RW_FHWPRF](#) that is due to a demand [Memory-read operation](#).

0x81E7, LL_CACHE_HIT_RD_FHWPRF, Last level cache demand access first hit, read, fetched by hardware prefetcher

The counter counts each first hit counted by [LL_CACHE_HIT_RW_FHWPRF](#) that is due to a demand [Memory-read operation](#).

0x81E8, L1D_CACHE_HIT_WR_FHWPRF, Level 1 data cache demand access first hit, write, fetched by hardware prefetcher

The counter counts each first hit counted by [L1D_CACHE_HIT_RW_FHWPRF](#) that is due to a demand [Memory-write operation](#).

0x81E9, L2D_CACHE_HIT_WR_FHWPRF, Level 2 data cache demand access first hit, write, fetched by hardware prefetcher

The counter counts each first hit counted by [L2D_CACHE_HIT_RW_FHWPRF](#) that is due to a demand [Memory-write operation](#).

0x81EA, L3D_CACHE_HIT_WR_FHWPRF, Level 3 data cache demand access first hit, write, fetched by hardware prefetcher

The counter counts each first hit counted by [L3D_CACHE_HIT_RW_FHWPRF](#) that is due to a demand [Memory-write operation](#).

0x81EB, LL_CACHE_HIT_WR_FHWPRF, Last level cache demand access first hit, write, fetched by hardware prefetcher

The counter counts each first hit counted by [LL_CACHE_HIT_RW_FHWPRF](#) that is due to a demand [Memory-write operation](#).

0x81EC, L1D_CACHE_HIT_RW_FHWPRF, Level 1 data cache demand access first hit, fetched by hardware prefetcher

The counter counts each demand access first hit counted by [L1D_CACHE_HIT_RW_FPRF](#) where the cache line was fetched by a hardware prefetcher.

That is, the [L1D_CACHE_REFILL_HWPRF](#) event was generated when the cache line was fetched into the cache.

Only the first hit by a demand access is counted. After this event is generated for a cache line, the event is not generated again for the same cache line while it remains in the cache.

0x81ED, L2D_CACHE_HIT_RW_FHWPRF, Level 2 data cache demand access first hit, fetched by hardware prefetcher

The counter counts each demand access first hit counted by [L2D_CACHE_HIT_RW_FPRF](#) where the cache line was fetched by a hardware prefetcher.

That is, the [L2D_CACHE_REFILL_HWPRF](#) event was generated when the cache line was fetched into the cache.

Only the first hit by a demand access is counted. After this event is generated for a cache line, the event is not generated again for the same cache line while it remains in the cache.

0x81EE, L3D_CACHE_HIT_RW_FHWPRF, Level 3 data cache demand access first hit, fetched by hardware prefetcher

The counter counts each demand access first hit counted by [L3D_CACHE_HIT_RW_FPRF](#) where the cache line was fetched by a hardware prefetcher.

That is, the [L3D_CACHE_REFILL_HWPRF](#) event was generated when the cache line was fetched into the cache.

Only the first hit by a demand access is counted. After this event is generated for a cache line, the event is not generated again for the same cache line while it remains in the cache.

0x81EF, LL_CACHE_HIT_RW_FHWPRF, Last level cache demand access first hit, fetched by hardware prefetcher

The counter counts each demand access first hit counted by [LL_CACHE_HIT_RW_FPRF](#) where the cache line was fetched by a hardware prefetcher.

That is, the [LL_CACHE_REFILL_HWPRF](#) event was generated when the cache line was fetched into the cache.

Only the first hit by a demand access is counted. After this event is generated for a cache line, the event is not generated again for the same cache line while it remains in the cache.

0x81F0, L1I_CACHE_HIT_RD_FPRF, Level 1 instruction cache demand fetch first hit, fetched by prefetch

The counter counts each demand fetch first hit counted by [L1I_CACHE_HIT_RD](#) where the cache line was fetched in response to a prefetch instruction or by a hardware prefetcher.

That is, the [L1I_CACHE_REFILL_PRF](#) event was generated when the cache line was fetched into the cache.

Only the first hit by a demand access is counted. After this event is generated for a cache line, the event is not generated again for the same cache line while it remains in the cache.

0x81F1, L2I_CACHE_HIT_RD_FPRF, Level 2 instruction cache demand fetch first hit, fetched by prefetch

The counter counts each demand fetch first hit counted by [L2I_CACHE_HIT_RD](#) where the cache line was fetched in response to a prefetch instruction or by a hardware prefetcher.

That is, the [L2I_CACHE_REFILL_PRF](#) event was generated when the cache line was fetched into the cache.

Only the first hit by a demand access is counted. After this event is generated for a cache line, the event is not generated again for the same cache line while it remains in the cache.

0x81F4, L1D_CACHE_HIT_RD_FPRF, Level 1 data cache demand access first hit, read, fetched by prefetch

The counter counts each first hit counted by [L1D_CACHE_HIT_RW_FPRF](#) that is due to a demand [Memory-read operation](#).

0x81F5, L2D_CACHE_HIT_RD_FPRF, Level 2 data cache demand access first hit, read, fetched by prefetch

The counter counts each first hit counted by [L2D_CACHE_HIT_RW_FPRF](#) that is due to a demand [Memory-read operation](#).

0x81F6, L3D_CACHE_HIT_RD_FPRF, Level 3 data cache demand access first hit, read, fetched by prefetch

The counter counts each first hit counted by [L3D_CACHE_HIT_RW_FPRF](#) that is due to a demand [Memory-read operation](#).

0x81F7, LL_CACHE_HIT_RD_FPRF, Last level cache demand access first hit, read, fetched by prefetch

The counter counts each first hit counted by [LL_CACHE_HIT_RW_FPRF](#) that is due to a demand [Memory-read operation](#).

0x81F8, L1D_CACHE_HIT_WR_FPRF, Level 1 data cache demand access first hit, write, fetched by prefetch

The counter counts each first hit counted by [L1D_CACHE_HIT_RW_FPRF](#) that is due to a demand [Memory-write operation](#).

0x81F9, L2D_CACHE_HIT_WR_FPRF, Level 2 data cache demand access first hit, write, fetched by prefetch

The counter counts each first hit counted by [L2D_CACHE_HIT_RW_FPRF](#) that is due to a demand [Memory-write operation](#).

0x81FA, L3D_CACHE_HIT_WR_FPRF, Level 3 data cache demand access first hit, write, fetched by prefetch

The counter counts each first hit counted by [L3D_CACHE_HIT_RW_FPRF](#) that is due to a demand [Memory-write operation](#).

0x81FB, LL_CACHE_HIT_WR_FPRF, Last level cache demand access first hit, write, fetched by prefetch

The counter counts each first hit counted by [LL_CACHE_HIT_RW_FPRF](#) that is due to a demand [Memory-write operation](#).

0x81FC, L1D_CACHE_HIT_RW_FPRF, Level 1 data cache demand access first hit, fetched by prefetch

The counter counts each demand access first hit counted by [L1D_CACHE_HIT_RW](#) where the cache line was fetched in response to a prefetch instruction or by a hardware prefetcher.

That is, the [L1D_CACHE_REFILL_PRF](#) event was generated when the cache line was fetched into the cache.

Only the first hit by a demand access is counted. After this event is generated for a cache line, the event is not generated again for the same cache line while it remains in the cache.

0x81FD, L2D_CACHE_HIT_RW_FPRF, Level 2 data cache demand access first hit, fetched by prefetch

The counter counts each demand access first hit counted by [L2D_CACHE_HIT_RW](#) where the cache line was fetched in response to a prefetch instruction or by a hardware prefetcher.

That is, the [L2D_CACHE_REFILL_PRF](#) event was generated when the cache line was fetched into the cache.

Only the first hit by a demand access is counted. After this event is generated for a cache line, the event is not generated again for the same cache line while it remains in the cache.

0x81FE, L3D_CACHE_HIT_RW_FPRF, Level 3 data cache demand access first hit, fetched by prefetch

The counter counts each demand access first hit counted by [L3D_CACHE_HIT_RW](#) where the cache line was fetched in response to a prefetch instruction or by a hardware prefetcher.

That is, the [L3D_CACHE_REFILL_PRF](#) event was generated when the cache line was fetched into the cache.

Only the first hit by a demand access is counted. After this event is generated for a cache line, the event is not generated again for the same cache line while it remains in the cache.

0x81FF, LL_CACHE_HIT_RW_FPRF, Last level cache demand access first hit, fetched by prefetch

The counter counts each demand access first hit counted by [LL_CACHE_HIT_RW](#) where the cache line was fetched in response to a prefetch instruction or by a hardware prefetcher.

That is, the [LL_CACHE_REFILL_PRF](#) event was generated when the cache line was fetched into the cache.

Only the first hit by a demand access is counted. After this event is generated for a cache line, the event is not generated again for the same cache line while it remains in the cache.

0x8200, L1I_CACHE_HIT, Level 1 instruction cache hit

The counter counts each access counted by [L1I_CACHE](#) that hits in the Level 1 instruction or unified cache.

0x8201, L2I_CACHE_HIT, Level 2 instruction cache hit

The counter counts each access counted by [L2I_CACHE](#) that hits in the Level 2 instruction or unified cache.

0x8204, L1D_CACHE_HIT, Level 1 data cache hit

The counter counts each access counted by [L1D_CACHE](#) that hits in the Level 1 data or unified cache.

0x8205, L2D_CACHE_HIT, Level 2 data cache hit

The counter counts each access counted by [L2D_CACHE](#) that hits in the Level 2 data or unified cache.

0x8206, L3D_CACHE_HIT, Level 3 data cache hit

The counter counts each access counted by [L3D_CACHE](#) that hits in the Level 3 data or unified cache.

0x8207, LL_CACHE_HIT, Last level cache hit

The counter counts each access counted by [LL_CACHE](#) that hits in the Last level cache.

0x8208, L1I_CACHE_HIT_PRFM, Level 1 instruction cache software prefetch hit

The counter counts each software prefetch counted by [L1I_CACHE_PRFM](#) that hits in the Level 1 instruction or unified cache.

0x8209, L2I_CACHE_HIT_PRFM, Level 2 instruction cache software prefetch hit

The counter counts each software prefetch counted by [L2I_CACHE_PRFM](#) that hits in the Level 2 instruction or unified cache.

0x820C, L1D_CACHE_HIT_PRFM, Level 1 data cache software prefetch hit

The counter counts each software prefetch counted by [L1D_CACHE_PRFM](#) that hits in the Level 1 data or unified cache.

0x820D, L2D_CACHE_HIT_PRFM, Level 2 data cache software prefetch hit

The counter counts each software prefetch counted by [L2D_CACHE_PRFM](#) that hits in the Level 2 data or unified cache.

0x820E, L3D_CACHE_HIT_PRFM, Level 3 data cache software prefetch hit

The counter counts each software prefetch counted by [L3D_CACHE_PRFM](#) that hits in the Level 3 data or unified cache.

0x820F, LL_CACHE_HIT_PRFM, Last level cache software prefetch hit

The counter counts each software prefetch counted by [LL_CACHE_PRFM](#) that hits in the Last level cache.

0x8214, L1D_CACHE_HITM_RD, Level 1 data cache demand access hit modified, read

The counter counts each cache access counted by [L1D_CACHE_HIT_RD](#) that accesses a previously modified cache location.

0x8215, L2D_CACHE_HITM_RD, Level 2 data cache demand access hit modified, read

The counter counts each cache access counted by [L2D_CACHE_HIT_RD](#) that accesses a previously modified cache location.

0x8216, L3D_CACHE_HITM_RD, Level 3 data cache demand access hit modified, read

The counter counts each cache access counted by [L3D_CACHE_HIT_RD](#) that accesses a previously modified cache location.

0x8217, LL_CACHE_HITM_RD, Last level cache demand access hit modified, read

The counter counts each cache access counted by [LL_CACHE_HIT_RD](#) that accesses a previously modified cache location.

0x8218, L1D_CACHE_HITM_WR, Level 1 data cache demand access hit modified, write

The counter counts each cache access counted by [L1D_CACHE_HIT_WR](#) that accesses a previously modified cache location.

0x8219, L2D_CACHE_HITM_WR, Level 2 data cache demand access hit modified, write

The counter counts each cache access counted by [L2D_CACHE_HIT_WR](#) that accesses a previously modified cache location.

0x821A, L3D_CACHE_HITM_WR, Level 3 data cache demand access hit modified, write

The counter counts each cache access counted by [L3D_CACHE_HIT_WR](#) that accesses a previously modified cache location.

0x821B, LL_CACHE_HITM_WR, Last level cache demand access hit modified, write

The counter counts each cache access counted by [LL_CACHE_HIT_WR](#) that accesses a previously modified cache location.

0x821C, L1D_CACHE_HITM_RW, Level 1 data cache demand access hit modified

The counter counts each cache access counted by [L1D_CACHE_HIT_RW](#) that accesses a previously modified cache location.

0x821D, L2D_CACHE_HITM_RW, Level 2 data cache demand access hit modified

The counter counts each cache access counted by [L2D_CACHE_HIT_RW](#) that accesses a previously modified cache location.

0x821E, L3D_CACHE_HITM_RW, Level 3 data cache demand access hit modified

The counter counts each cache access counted by [L3D_CACHE_HIT_RW](#) that accesses a previously modified cache location.

0x821F, LL_CACHE_HITM_RW, Last level cache demand access hit modified

The counter counts each cache access counted by [LL_CACHE_HIT_RW](#) that accesses a previously modified cache location.

0x8224, DSNP_HITM_RD, Snoop hit, demand data read, modified

The counter counts each snoop generated by the PE in response to a demand [Memory-read operation](#) counted by [DSNP_HIT_RD](#) that accesses a previously modified cache location.

0x8225, DSNP_HITM_NEAR_RD, Snoop hit in near local cache, demand data read, modified

The counter counts each snoop generated by the PE in response to a demand [Memory-read operation](#) counted by [DSNP_HIT_NEAR_RD](#) that accesses a previously modified cache location.

0x8226, DSNP_HITM_FAR_RD, Snoop hit in far local cache, demand data read, modified

The counter counts each snoop generated by the PE in response to a demand [Memory-read operation](#) counted by [DSNP_HIT_FAR_RD](#) that accesses a previously modified cache location.

0x8227, DSNP_HITM_REMOTE_RD, Snoop hit in remote cache, demand data read, modified

The counter counts each snoop generated by the PE in response to a demand [Memory-read operation](#) counted by [DSNP_HIT_REMOTE_RD](#) that accesses a previously modified cache location.

0x8228, DSNP_HITM_WR, Snoop hit, demand data write, modified

The counter counts each snoop generated by the PE in response to a demand [Memory-write operation](#) counted by [DSNP_HIT_WR](#) that accesses a previously modified cache location.

0x8229, DSNP_HITM_NEAR_WR, Snoop hit in near local cache, demand data write, modified

The counter counts each snoop generated by the PE in response to a demand [Memory-write operation](#) counted by [DSNP_HIT_NEAR_WR](#) that accesses a previously modified cache location.

0x822A, DSNP_HITM_FAR_WR, Snoop hit in far local cache, demand data write, modified

The counter counts each snoop generated by the PE in response to a demand [Memory-write operation](#) counted by [DSNP_HIT_FAR_WR](#) that accesses a previously modified cache location.

0x822B, DSNP_HITM_REMOTE_WR, Snoop hit in remote cache, demand data write, modified

The counter counts each snoop generated by the PE in response to a demand [Memory-write operation](#) counted by [DSNP_HIT_REMOTE_WR](#) that accesses a previously modified cache location.

0x822C, **DSNP_HITM_RW, Snoop hit, demand data access, modified**

The counter counts each snoop generated by the PE in response to a demand [Memory-read operation](#) or demand [Memory-write operation](#) counted by [DSNP_HIT_RW](#) that accesses a previously modified cache location.

0x822D, **DSNP_HITM_NEAR_RW, Snoop hit in near local cache, demand data access, modified**

The counter counts each snoop generated by the PE in response to a demand [Memory-read operation](#) or demand [Memory-write operation](#) counted by [DSNP_HIT_NEAR_RW](#) that accesses a previously modified cache location.

0x822E, **DSNP_HITM_FAR_RW, Snoop hit in far local cache, demand data access, modified**

The counter counts each snoop generated by the PE in response to a demand [Memory-read operation](#) or demand [Memory-write operation](#) counted by [DSNP_HIT_FAR_RW](#) that accesses a previously modified cache location.

0x822F, **DSNP_HITM_REMOTE_RW, Snoop hit in remote cache, demand data access, modified**

The counter counts each snoop generated by the PE in response to a demand [Memory-read operation](#) or demand [Memory-write operation](#) counted by [DSNP_HIT_REMOTE_RW](#) that accesses a previously modified cache location.

0x8230, **LOCAL_MEM, Access to memory attached to this device**

The counter counts each [Memory-read operation](#) or [Memory-write operation](#) access to external memory attached to this device.

In a multi-socket system this means attached to the socket that contains the PE. For more information, see [REMOTE_ACCESS](#).

In systems where there multiple types of memory attached to this device with different performance characteristics, it is IMPLEMENTATION DEFINED whether accesses to all external memory types are counted by this event, or are classified as remote accesses and counted by [REMOTE_MEM](#).

For example, in a system with an expansion memory connected to the device that has significantly higher latency than the main system memory, accesses to the main system memory might be counted by this event and accesses to the expansion memory by [REMOTE_MEM](#).

0x8231, **LOCAL_MEM_RD, Access to memory attached to this device, demand access, read**

The counter counts each access counted by [LOCAL_MEM_RW](#) that is a demand [Memory-read operation](#).

0x8232, **LOCAL_MEM_WR, Access to memory attached to this device, demand access, write**

The counter counts each access counted by [LOCAL_MEM_RW](#) that is a demand [Memory-write operation](#).

0x8233, **LOCAL_MEM_RW, Access to memory attached to this device, demand access**

The counter counts each access counted by [LOCAL_MEM](#) that is a demand [Memory-read operation](#) or demand [Memory-write operation](#).

It is IMPLEMENTATION DEFINED whether an access to external memory due to a prefetch to a cache is counted by [LOCAL_MEM_RW](#) or [LOCAL_MEM_PRFM](#).

0x8234, **LOCAL_MEM_PRFM, Access to memory attached to this device, software prefetch**

The counter counts each access counted by [LOCAL_MEM](#) that is due to a prefetch instruction.

It is IMPLEMENTATION DEFINED whether an access to external memory due to a prefetch to a cache is counted by [LOCAL_MEM_RW](#) or [LOCAL_MEM_PRFM](#).

0x8235, **LOCAL_MEM_LD_RETIRED**, Load instruction architecturally executed, access to memory attached to this device

The counter counts each [architecturally executed](#) instruction counted by [LOCAL_MEM_LDST_RETIRED](#) that is a [Memory-reading instruction](#).

0x8236, **LOCAL_MEM_ST_RETIRED**, Store instruction architecturally executed, access to memory attached to this device

The counter counts each [architecturally executed](#) instruction counted by [LOCAL_MEM_LDST_RETIRED](#) that is a [Memory-writing instruction](#).

0x8237, **LOCAL_MEM_LDST_RETIRED**, Load or store instruction architecturally executed, access to memory attached to this device

The counter counts each [Memory-reading instruction](#) or [Memory-writing instruction architecturally executed](#) counted by [LDST_ANY_RETIRED](#) that accessed external memory attached to this device.

0x8238, **REMOTE_MEM**, Access to memory attached to a remote device

The counter counts each [Memory-read operation](#) or [Memory-write operation](#) access counted by [REMOTE_ACCESS](#) to external memory attached to a remote device.

The counter also counts any accesses to external memory that are not counted by [LOCAL_MEM](#) because the implementation classifies them as remote accesses. For example, accesses to expansion memory connected to the device that has significantly higher latency than the main system memory might be classified as remote accesses. For more information, see [LOCAL_MEM](#).

0x8239, **REMOTE_MEM_RD**, Access to memory attached to a remote device, demand access, read

The counter counts each access counted by [REMOTE_MEM_RW](#) that is a demand [Memory-read operation](#).

0x823A, **REMOTE_MEM_WR**, Access to memory attached to a remote device, demand access, write

The counter counts each access counted by [REMOTE_MEM_RW](#) that is a demand [Memory-write operation](#).

0x823B, **REMOTE_MEM_RW**, Access to memory attached to a remote device, demand access

The counter counts each access counted by [REMOTE_MEM](#) that is a demand [Memory-read operation](#) or demand [Memory-write operation](#).

0x823C, **REMOTE_MEM_PRFM**, Access to memory attached to a remote device, software prefetch

The counter counts each access counted by [REMOTE_MEM](#) that is due to a prefetch instruction.

0x823D, **REMOTE_MEM_LD_RETIRED**, Load instruction architecturally executed, access to memory attached to a remote device

The counter counts each [architecturally executed](#) instruction counted by [REMOTE_MEM_LDST_RETIRED](#) that is a [Memory-reading instruction](#).

0x823E, **REMOTE_MEM_ST_RETIRED**, Store instruction architecturally executed, access to memory attached to a remote device

The counter counts each [architecturally executed](#) instruction counted by [REMOTE_MEM_LDST_RETIRED](#) that is a [Memory-writing instruction](#).

0x823F, REMOTE_MEM_LDST_RETIRED, Load or store instruction architecturally executed, access to memory attached to a remote device

The counter counts each [Memory-reading instruction](#) or [Memory-writing instruction architecturally executed](#) counted by [LDST_ANY_RETIRED](#) that accessed external memory attached to a remote device.

0x8240, L1I_LFB_HIT_RD, Level 1 instruction cache demand fetch line-fill buffer hit

The counter counts each demand access counted by [L1I_CACHE_HIT_RD](#) that hits a recently fetched line in the Level 1 instruction or unified cache.

That is, the access hits a cache line that is in the process of being loaded into the Level 1 instruction or unified cache, and so does not generate a new refill, but has to wait for the previous refill to complete.

0x8241, L2I_LFB_HIT_RD, Level 2 instruction cache demand fetch line-fill buffer hit

The counter counts each demand access counted by [L2I_CACHE_HIT_RD](#) that hits a recently fetched line in the Level 2 instruction or unified cache.

That is, the access hits a cache line that is in the process of being loaded into the Level 2 instruction or unified cache, and so does not generate a new refill, but has to wait for the previous refill to complete.

0x8244, L1D_LFB_HIT_RD, Level 1 data cache demand access line-fill buffer hit, read

The counter counts each demand access counted by [L1D_CACHE_HIT_RD](#) that hits a recently fetched line in the Level 1 data or unified cache.

That is, the access hits a cache line that is in the process of being loaded into the Level 1 data or unified cache, and so does not generate a new refill, but has to wait for the previous refill to complete.

0x8245, L2D_LFB_HIT_RD, Level 2 data cache demand access line-fill buffer hit, read

The counter counts each demand access counted by [L2D_CACHE_HIT_RD](#) that hits a recently fetched line in the Level 2 data or unified cache.

That is, the access hits a cache line that is in the process of being loaded into the Level 2 data or unified cache, and so does not generate a new refill, but has to wait for the previous refill to complete.

0x8246, L3D_LFB_HIT_RD, Level 3 data cache demand access line-fill buffer hit, read

The counter counts each demand access counted by [L3D_CACHE_HIT_RD](#) that hits a recently fetched line in the Level 3 data or unified cache.

That is, the access hits a cache line that is in the process of being loaded into the Level 3 data or unified cache, and so does not generate a new refill, but has to wait for the previous refill to complete.

0x8247, LL_LFB_HIT_RD, Last level cache demand access line-fill buffer hit, read

The counter counts each demand access counted by [LL_CACHE_HIT_RD](#) that hits a recently fetched line in the Last level cache.

That is, the access hits a cache line that is in the process of being loaded into the Last level cache, and so does not generate a new refill, but has to wait for the previous refill to complete.

0x8248, L1D_LFB_HIT_WR, Level 1 data cache demand access line-fill buffer hit, write

The counter counts each demand access counted by [L1D_CACHE_HIT_WR](#) that hits a recently fetched line in the Level 1 data or unified cache.

That is, the access hits a cache line that is in the process of being loaded into the Level 1 data or unified cache, and so does not generate a new refill, but has to wait for the previous refill to complete.

0x8249, L2D_LFB_HIT_WR, Level 2 data cache demand access line-fill buffer hit, write

The counter counts each demand access counted by [L2D_CACHE_HIT_WR](#) that hits a recently fetched line in the Level 2 data or unified cache.

That is, the access hits a cache line that is in the process of being loaded into the Level 2 data or unified cache, and so does not generate a new refill, but has to wait for the previous refill to complete.

0x824A, L3D_LFB_HIT_WR, Level 3 data cache demand access line-fill buffer hit, write

The counter counts each demand access counted by [L3D_CACHE_HIT_WR](#) that hits a recently fetched line in the Level 3 data or unified cache.

That is, the access hits a cache line that is in the process of being loaded into the Level 3 data or unified cache, and so does not generate a new refill, but has to wait for the previous refill to complete.

0x824B, LL_LFB_HIT_WR, Last level cache demand access line-fill buffer hit, write

The counter counts each demand access counted by [LL_CACHE_HIT_WR](#) that hits a recently fetched line in the Last level cache.

That is, the access hits a cache line that is in the process of being loaded into the Last level cache, and so does not generate a new refill, but has to wait for the previous refill to complete.

0x824C, L1D_LFB_HIT_RW, Level 1 data cache demand access line-fill buffer hit

The counter counts each demand access counted by [L1D_CACHE_HIT_RW](#) that hits a recently fetched line in the Level 1 data or unified cache.

That is, the access hits a cache line that is in the process of being loaded into the Level 1 data or unified cache, and so does not generate a new refill, but has to wait for the previous refill to complete.

0x824D, L2D_LFB_HIT_RW, Level 2 data cache demand access line-fill buffer hit

The counter counts each demand access counted by [L2D_CACHE_HIT_RW](#) that hits a recently fetched line in the Level 2 data or unified cache.

That is, the access hits a cache line that is in the process of being loaded into the Level 2 data or unified cache, and so does not generate a new refill, but has to wait for the previous refill to complete.

0x824E, L3D_LFB_HIT_RW, Level 3 data cache demand access line-fill buffer hit

The counter counts each demand access counted by [L3D_CACHE_HIT_RW](#) that hits a recently fetched line in the Level 3 data or unified cache.

That is, the access hits a cache line that is in the process of being loaded into the Level 3 data or unified cache, and so does not generate a new refill, but has to wait for the previous refill to complete.

0x824F, LL_LFB_HIT_RW, Last level cache demand access line-fill buffer hit

The counter counts each demand access counted by [LL_CACHE_HIT_RW](#) that hits a recently fetched line in the Last level cache.

That is, the access hits a cache line that is in the process of being loaded into the Last level cache, and so does not generate a new refill, but has to wait for the previous refill to complete.

0x8250, L1I_LFB_HIT_RD_FPRFM, Level 1 instruction cache demand fetch line-fill buffer first hit, recently fetched by software prefetch

The counter counts each demand fetch line-fill buffer first hit counted by [L1I_LFB_HIT_RD_FPRF](#) where the cache line was fetched in response to a prefetch instruction.

That is, the fetch hits a cache line that is in the process of being loaded into the Level 1 instruction or unified cache, and so does not generate a new refill, but has to wait for the previous refill to complete, and the [L1I_CACHE_REFILL_PRFM](#) event was generated when the cache line was fetched into the cache.

Only the first hit by a demand access is counted. After this event is generated for a cache line, the event is not generated again for the same cache line while it remains in the cache.

0x8251, L2I_LFB_HIT_RD_FPRFM, Level 2 instruction cache demand fetch line-fill buffer first hit, recently fetched by software prefetch

The counter counts each demand fetch line-fill buffer first hit counted by [L2I_LFB_HIT_RD_FPRF](#) where the cache line was fetched in response to a prefetch instruction.

That is, the fetch hits a cache line that is in the process of being loaded into the Level 2 instruction or unified cache, and so does not generate a new refill, but has to wait for the previous refill to complete, and the [L2I_CACHE_REFILL_PRFM](#) event was generated when the cache line was fetched into the cache.

Only the first hit by a demand access is counted. After this event is generated for a cache line, the event is not generated again for the same cache line while it remains in the cache.

0x8254, L1D_LFB_HIT_RD_FPRFM, Level 1 data cache demand access line-fill buffer first hit, read, recently fetched by software prefetch

The counter counts each line-fill buffer first hit counted by [L1D_LFB_HIT_RW_FPRFM](#) that is due to a demand [Memory-read operation](#).

0x8255, L2D_LFB_HIT_RD_FPRFM, Level 2 data cache demand access line-fill buffer first hit, read, recently fetched by software prefetch

The counter counts each line-fill buffer first hit counted by [L2D_LFB_HIT_RW_FPRFM](#) that is due to a demand [Memory-read operation](#).

0x8256, L3D_LFB_HIT_RD_FPRFM, Level 3 data cache demand access line-fill buffer first hit, read, recently fetched by software prefetch

The counter counts each line-fill buffer first hit counted by [L3D_LFB_HIT_RW_FPRFM](#) that is due to a demand [Memory-read operation](#).

0x8257, LL_LFB_HIT_RD_FPRFM, Last level cache demand access line-fill buffer first hit, read, recently fetched by software prefetch

The counter counts each line-fill buffer first hit counted by [LL_LFB_HIT_RW_FPRFM](#) that is due to a demand [Memory-read operation](#).

0x8258, L1D_LFB_HIT_WR_FPRFM, Level 1 data cache demand access line-fill buffer first hit, write, recently fetched by software prefetch

The counter counts each line-fill buffer first hit counted by [L1D_LFB_HIT_RW_FPRFM](#) that is due to a demand [Memory-write operation](#).

0x8259, L2D_LFB_HIT_WR_FPRFM, Level 2 data cache demand access line-fill buffer first hit, write, recently fetched by software prefetch

The counter counts each line-fill buffer first hit counted by [L2D_LFB_HIT_RW_FPRFM](#) that is due to a demand Memory-write operation.

0x825A, L3D_LFB_HIT_WR_FPRFM, Level 3 data cache demand access line-fill buffer first hit, write, recently fetched by software prefetch

The counter counts each line-fill buffer first hit counted by [L3D_LFB_HIT_RW_FPRFM](#) that is due to a demand Memory-write operation.

0x825B, LL_LFB_HIT_WR_FPRFM, Last level cache demand access line-fill buffer first hit, write, recently fetched by software prefetch

The counter counts each line-fill buffer first hit counted by [LL_LFB_HIT_RW_FPRFM](#) that is due to a demand Memory-write operation.

0x825C, L1D_LFB_HIT_RW_FPRFM, Level 1 data cache demand access line-fill buffer first hit, recently fetched by software prefetch

The counter counts each demand access line-fill buffer first hit counted by [L1D_LFB_HIT_RW_FPRF](#) where the cache line was fetched in response to a prefetch instruction.

That is, the access hits a cache line that is in the process of being loaded into the Level 1 data or unified cache, and so does not generate a new refill, but has to wait for the previous refill to complete, and the [L1D_CACHE_REFILL_PRFM](#) event was generated when the cache line was fetched into the cache.

Only the first hit by a demand access is counted. After this event is generated for a cache line, the event is not generated again for the same cache line while it remains in the cache.

0x825D, L2D_LFB_HIT_RW_FPRFM, Level 2 data cache demand access line-fill buffer first hit, recently fetched by software prefetch

The counter counts each demand access line-fill buffer first hit counted by [L2D_LFB_HIT_RW_FPRF](#) where the cache line was fetched in response to a prefetch instruction.

That is, the access hits a cache line that is in the process of being loaded into the Level 2 data or unified cache, and so does not generate a new refill, but has to wait for the previous refill to complete, and the [L2D_CACHE_REFILL_PRFM](#) event was generated when the cache line was fetched into the cache.

Only the first hit by a demand access is counted. After this event is generated for a cache line, the event is not generated again for the same cache line while it remains in the cache.

0x825E, L3D_LFB_HIT_RW_FPRFM, Level 3 data cache demand access line-fill buffer first hit, recently fetched by software prefetch

The counter counts each demand access line-fill buffer first hit counted by [L3D_LFB_HIT_RW_FPRF](#) where the cache line was fetched in response to a prefetch instruction.

That is, the access hits a cache line that is in the process of being loaded into the Level 3 data or unified cache, and so does not generate a new refill, but has to wait for the previous refill to complete, and the [L3D_CACHE_REFILL_PRFM](#) event was generated when the cache line was fetched into the cache.

Only the first hit by a demand access is counted. After this event is generated for a cache line, the event is not generated again for the same cache line while it remains in the cache.

0x825F, LL_LFB_HIT_RW_FPRFM, Last level cache demand access line-fill buffer first hit, recently fetched by software prefetch

The counter counts each demand access line-fill buffer first hit counted by [LL_LFB_HIT_RW_FPRF](#) where the cache line was fetched in response to a prefetch instruction.

That is, the access hits a cache line that is in the process of being loaded into the Last level cache, and so does not generate a new refill, but has to wait for the previous refill to complete, and the [LL_CACHE_REFILL_PRFM](#) event was generated when the cache line was fetched into the cache.

Only the first hit by a demand access is counted. After this event is generated for a cache line, the event is not generated again for the same cache line while it remains in the cache.

0x8260, L1I_LFB_HIT_RD_FHWPRF, Level 1 instruction cache demand fetch line-fill buffer first hit, recently fetched by hardware prefetcher

The counter counts each demand fetch line-fill buffer first hit counted by [L1I_LFB_HIT_RD_FPRF](#) where the cache line was fetched by a hardware prefetcher.

That is, the fetch hits a cache line that is in the process of being loaded into the Level 1 instruction or unified cache, and so does not generate a new refill, but has to wait for the previous refill to complete, and the [L1I_CACHE_REFILL_HWPRF](#) event was generated when the cache line was fetched into the cache.

Only the first hit by a demand access is counted. After this event is generated for a cache line, the event is not generated again for the same cache line while it remains in the cache.

0x8261, L2I_LFB_HIT_RD_FHWPRF, Level 2 instruction cache demand fetch line-fill buffer first hit, recently fetched by hardware prefetcher

The counter counts each demand fetch line-fill buffer first hit counted by [L2I_LFB_HIT_RD_FPRF](#) where the cache line was fetched by a hardware prefetcher.

That is, the fetch hits a cache line that is in the process of being loaded into the Level 2 instruction or unified cache, and so does not generate a new refill, but has to wait for the previous refill to complete, and the [L2I_CACHE_REFILL_HWPRF](#) event was generated when the cache line was fetched into the cache.

Only the first hit by a demand access is counted. After this event is generated for a cache line, the event is not generated again for the same cache line while it remains in the cache.

0x8264, L1D_LFB_HIT_RD_FHWPRF, Level 1 data cache demand access line-fill buffer first hit, read, recently fetched by hardware prefetcher

The counter counts each line-fill buffer first hit counted by [L1D_LFB_HIT_RW_FHWPRF](#) that is due to a demand [Memory-read operation](#).

0x8265, L2D_LFB_HIT_RD_FHWPRF, Level 2 data cache demand access line-fill buffer first hit, read, recently fetched by hardware prefetcher

The counter counts each line-fill buffer first hit counted by [L2D_LFB_HIT_RW_FHWPRF](#) that is due to a demand [Memory-read operation](#).

0x8266, L3D_LFB_HIT_RD_FHWPRF, Level 3 data cache demand access line-fill buffer first hit, read, recently fetched by hardware prefetcher

The counter counts each line-fill buffer first hit counted by [L3D_LFB_HIT_RW_FHWPRF](#) that is due to a demand [Memory-read operation](#).

0x8267, LL_LFB_HIT_RD_FHWPRF, Last level cache demand access line-fill buffer first hit, read, recently fetched by hardware prefetcher

The counter counts each line-fill buffer first hit counted by [LL_LFB_HIT_RW_FHWPRF](#) that is due to a demand [Memory-read operation](#).

0x8268, L1D_LFB_HIT_WR_FHWPRF, Level 1 data cache demand access line-fill buffer first hit, write, recently fetched by hardware prefetcher

The counter counts each line-fill buffer first hit counted by [L1D_LFB_HIT_RW_FHWPRF](#) that is due to a demand [Memory-write operation](#).

0x8269, L2D_LFB_HIT_WR_FHWPRF, Level 2 data cache demand access line-fill buffer first hit, write, recently fetched by hardware prefetcher

The counter counts each line-fill buffer first hit counted by [L2D_LFB_HIT_RW_FHWPRF](#) that is due to a demand [Memory-write operation](#).

0x826A, L3D_LFB_HIT_WR_FHWPRF, Level 3 data cache demand access line-fill buffer first hit, write, recently fetched by hardware prefetcher

The counter counts each line-fill buffer first hit counted by [L3D_LFB_HIT_RW_FHWPRF](#) that is due to a demand [Memory-write operation](#).

0x826B, LL_LFB_HIT_WR_FHWPRF, Last level cache demand access line-fill buffer first hit, write, recently fetched by hardware prefetcher

The counter counts each line-fill buffer first hit counted by [LL_LFB_HIT_RW_FHWPRF](#) that is due to a demand [Memory-write operation](#).

0x826C, L1D_LFB_HIT_RW_FHWPRF, Level 1 data cache demand access line-fill buffer first hit, recently fetched by hardware prefetcher

The counter counts each demand access line-fill buffer first hit counted by [L1D_LFB_HIT_RW_FPRF](#) where the cache line was fetched by a hardware prefetcher.

That is, the access hits a cache line that is in the process of being loaded into the Level 1 data or unified cache, and so does not generate a new refill, but has to wait for the previous refill to complete, and the [L1D_CACHE_REFILL_HWPRF](#) event was generated when the cache line was fetched into the cache.

Only the first hit by a demand access is counted. After this event is generated for a cache line, the event is not generated again for the same cache line while it remains in the cache.

0x826D, L2D_LFB_HIT_RW_FHWPRF, Level 2 data cache demand access line-fill buffer first hit, recently fetched by hardware prefetcher

The counter counts each demand access line-fill buffer first hit counted by [L2D_LFB_HIT_RW_FPRF](#) where the cache line was fetched by a hardware prefetcher.

That is, the access hits a cache line that is in the process of being loaded into the Level 2 data or unified cache, and so does not generate a new refill, but has to wait for the previous refill to complete, and the [L2D_CACHE_REFILL_HWPRF](#) event was generated when the cache line was fetched into the cache.

Only the first hit by a demand access is counted. After this event is generated for a cache line, the event is not generated again for the same cache line while it remains in the cache.

0x826E, L3D_LFB_HIT_RW_FHWPFRF, Level 3 data cache demand access line-fill buffer first hit, recently fetched by hardware prefetcher

The counter counts each demand access line-fill buffer first hit counted by [L3D_LFB_HIT_RW_FPRF](#) where the cache line was fetched by a hardware prefetcher.

That is, the access hits a cache line that is in the process of being loaded into the Level 3 data or unified cache, and so does not generate a new refill, but has to wait for the previous refill to complete, and the [L3D_CACHE_REFILL_HWPFRF](#) event was generated when the cache line was fetched into the cache.

Only the first hit by a demand access is counted. After this event is generated for a cache line, the event is not generated again for the same cache line while it remains in the cache.

0x826F, LL_LFB_HIT_RW_FHWPFRF, Last level cache demand access line-fill buffer first hit, recently fetched by hardware prefetcher

The counter counts each demand access line-fill buffer first hit counted by [LL_LFB_HIT_RW_FPRF](#) where the cache line was fetched by a hardware prefetcher.

That is, the access hits a cache line that is in the process of being loaded into the Last level cache, and so does not generate a new refill, but has to wait for the previous refill to complete, and the [LL_CACHE_REFILL_HWPFRF](#) event was generated when the cache line was fetched into the cache.

Only the first hit by a demand access is counted. After this event is generated for a cache line, the event is not generated again for the same cache line while it remains in the cache.

0x8270, L1I_LFB_HIT_RD_FPRF, Level 1 instruction cache demand fetch line-fill buffer first hit, recently fetched by prefetch

The counter counts each demand fetch line-fill buffer first hit counted by [L1I_LFB_HIT_RD](#) where the cache line was fetched in response to a prefetch instruction or by a hardware prefetcher.

That is, the fetch hits a cache line that is in the process of being loaded into the Level 1 instruction or unified cache, and so does not generate a new refill, but has to wait for the previous refill to complete, and the [L1I_CACHE_REFILL_PRF](#) event was generated when the cache line was fetched into the cache.

Only the first hit by a demand access is counted. After this event is generated for a cache line, the event is not generated again for the same cache line while it remains in the cache.

0x8271, L2I_LFB_HIT_RD_FPRF, Level 2 instruction cache demand fetch line-fill buffer first hit, recently fetched by prefetch

The counter counts each demand fetch line-fill buffer first hit counted by [L2I_LFB_HIT_RD](#) where the cache line was fetched in response to a prefetch instruction or by a hardware prefetcher.

That is, the fetch hits a cache line that is in the process of being loaded into the Level 2 instruction or unified cache, and so does not generate a new refill, but has to wait for the previous refill to complete, and the [L2I_CACHE_REFILL_PRF](#) event was generated when the cache line was fetched into the cache.

Only the first hit by a demand access is counted. After this event is generated for a cache line, the event is not generated again for the same cache line while it remains in the cache.

0x8274, L1D_LFB_HIT_RD_FPRF, Level 1 data cache demand access line-fill buffer first hit, read, recently fetched by prefetch

The counter counts each line-fill buffer first hit counted by [L1D_LFB_HIT_RW_FPRF](#) that is due to a demand [Memory-read operation](#).

0x8275, **L2D_LFB_HIT_RD_FPRF**, Level 2 data cache demand access line-fill buffer first hit, read, recently fetched by prefetch

The counter counts each line-fill buffer first hit counted by [L2D_LFB_HIT_RW_FPRF](#) that is due to a demand Memory-read operation.

0x8276, **L3D_LFB_HIT_RD_FPRF**, Level 3 data cache demand access line-fill buffer first hit, read, recently fetched by prefetch

The counter counts each line-fill buffer first hit counted by [L3D_LFB_HIT_RW_FPRF](#) that is due to a demand Memory-read operation.

0x8277, **LL_LFB_HIT_RD_FPRF**, Last level cache demand access line-fill buffer first hit, read, recently fetched by prefetch

The counter counts each line-fill buffer first hit counted by [LL_LFB_HIT_RW_FPRF](#) that is due to a demand Memory-read operation.

0x8278, **L1D_LFB_HIT_WR_FPRF**, Level 1 data cache demand access line-fill buffer first hit, write, recently fetched by prefetch

The counter counts each line-fill buffer first hit counted by [L1D_LFB_HIT_RW_FPRF](#) that is due to a demand Memory-write operation.

0x8279, **L2D_LFB_HIT_WR_FPRF**, Level 2 data cache demand access line-fill buffer first hit, write, recently fetched by prefetch

The counter counts each line-fill buffer first hit counted by [L2D_LFB_HIT_RW_FPRF](#) that is due to a demand Memory-write operation.

0x827A, **L3D_LFB_HIT_WR_FPRF**, Level 3 data cache demand access line-fill buffer first hit, write, recently fetched by prefetch

The counter counts each line-fill buffer first hit counted by [L3D_LFB_HIT_RW_FPRF](#) that is due to a demand Memory-write operation.

0x827B, **LL_LFB_HIT_WR_FPRF**, Last level cache demand access line-fill buffer first hit, write, recently fetched by prefetch

The counter counts each line-fill buffer first hit counted by [LL_LFB_HIT_RW_FPRF](#) that is due to a demand Memory-write operation.

0x827C, **L1D_LFB_HIT_RW_FPRF**, Level 1 data cache demand access line-fill buffer first hit, recently fetched by prefetch

The counter counts each demand access line-fill buffer first hit counted by [L1D_LFB_HIT_RW](#) where the cache line was fetched in response to a prefetch instruction or by a hardware prefetcher.

That is, the access hits a cache line that is in the process of being loaded into the Level 1 data or unified cache, and so does not generate a new refill, but has to wait for the previous refill to complete, and the [L1D_CACHE_REFILL_PRF](#) event was generated when the cache line was fetched into the cache.

Only the first hit by a demand access is counted. After this event is generated for a cache line, the event is not generated again for the same cache line while it remains in the cache.

0x827D, L2D_LFB_HIT_RW_FPRF, Level 2 data cache demand access line-fill buffer first hit, recently fetched by prefetch

The counter counts each demand access line-fill buffer first hit counted by [L2D_LFB_HIT_RW](#) where the cache line was fetched in response to a prefetch instruction or by a hardware prefetcher.

That is, the access hits a cache line that is in the process of being loaded into the Level 2 data or unified cache, and so does not generate a new refill, but has to wait for the previous refill to complete, and the [L2D_CACHE_REFILL_PRF](#) event was generated when the cache line was fetched into the cache.

Only the first hit by a demand access is counted. After this event is generated for a cache line, the event is not generated again for the same cache line while it remains in the cache.

0x827E, L3D_LFB_HIT_RW_FPRF, Level 3 data cache demand access line-fill buffer first hit, recently fetched by prefetch

The counter counts each demand access line-fill buffer first hit counted by [L3D_LFB_HIT_RW](#) where the cache line was fetched in response to a prefetch instruction or by a hardware prefetcher.

That is, the access hits a cache line that is in the process of being loaded into the Level 3 data or unified cache, and so does not generate a new refill, but has to wait for the previous refill to complete, and the [L3D_CACHE_REFILL_PRF](#) event was generated when the cache line was fetched into the cache.

Only the first hit by a demand access is counted. After this event is generated for a cache line, the event is not generated again for the same cache line while it remains in the cache.

0x827F, LL_LFB_HIT_RW_FPRF, Last level cache demand access line-fill buffer first hit, recently fetched by prefetch

The counter counts each demand access line-fill buffer first hit counted by [LL_LFB_HIT_RW](#) where the cache line was fetched in response to a prefetch instruction or by a hardware prefetcher.

That is, the access hits a cache line that is in the process of being loaded into the Last level cache, and so does not generate a new refill, but has to wait for the previous refill to complete, and the [LL_CACHE_REFILL_PRF](#) event was generated when the cache line was fetched into the cache.

Only the first hit by a demand access is counted. After this event is generated for a cache line, the event is not generated again for the same cache line while it remains in the cache.

0x8280, L1I_CACHE_PRF, Level 1 instruction cache, prefetch hit

The counter counts each access counted by [L1I_CACHE](#) that is due to a prefetch instruction, or hardware prefetch.

0x8281, L2I_CACHE_PRF, Level 2 instruction cache, prefetch hit

The counter counts each access counted by [L2I_CACHE](#) that is due to a prefetch instruction, or hardware prefetch.

This includes accesses to the Level 2 instruction or unified cache due to a refill of another cache caused by a prefetch instruction, or hardware prefetch.

0x8284, L1D_CACHE_PRF, Level 1 data cache, prefetch hit

The counter counts each access counted by [L1D_CACHE](#) that is due to a prefetch instruction, or hardware prefetch.

0x8285, L2D_CACHE_PRF, Level 2 data cache, prefetch hit

The counter counts each access counted by [L2D_CACHE](#) that is due to a prefetch instruction, or hardware prefetch.

This includes accesses to the Level 2 data or unified cache due to a refill of another cache caused by a prefetch instruction, or hardware prefetch.

0x8286, L3D_CACHE_PRF, Level 3 data cache, prefetch hit

The counter counts each access counted by [L3D_CACHE](#) that is due to a prefetch instruction, or hardware prefetch.

This includes accesses to the Level 3 data or unified cache due to a refill of another cache caused by a prefetch instruction, or hardware prefetch.

0x8287, LL_CACHE_PRF, Last level cache, prefetch hit

The counter counts each access counted by [LL_CACHE](#) that is due to a prefetch instruction, or hardware prefetch.

This includes accesses to the Last level cache due to a refill of another cache caused by a prefetch instruction, or hardware prefetch.

0x8288, L1I_CACHE_REFILL_PRF, Level 1 instruction cache refill, prefetch hit

The counter counts each access counted by [L1I_CACHE_REFILL_PRF](#) that causes a refill of the Level 1 instruction or unified cache from outside of the Level 1 instruction or unified cache.

0x8289, L2I_CACHE_REFILL_PRF, Level 2 instruction cache refill, prefetch hit

The counter counts each access counted by [L2I_CACHE_REFILL_PRF](#) that causes a refill of the Level 2 instruction or unified cache, or any Level 1 data, instruction, or unified cache of this PE, from outside of those caches.

0x828C, L1D_CACHE_REFILL_PRF, Level 1 data cache refill, prefetch hit

The counter counts each access counted by [L1D_CACHE_REFILL_PRF](#) that causes a refill of the Level 1 data or unified cache from outside of the Level 1 data or unified cache.

0x828D, L2D_CACHE_REFILL_PRF, Level 2 data cache refill, prefetch hit

The counter counts each access counted by [L2D_CACHE_REFILL_PRF](#) that causes a refill of the Level 2 data or unified cache, or any Level 1 data, instruction, or unified cache of this PE, from outside of those caches.

0x828E, L3D_CACHE_REFILL_PRF, Level 3 data cache refill, prefetch hit

The counter counts each access counted by [L3D_CACHE_REFILL_PRF](#) that causes a refill of the Level 3 data or unified cache, or any Level 1 or Level 2 data, instruction, or unified cache of this PE, from outside of those caches.

0x828F, LL_CACHE_REFILL_PRF, Last level cache refill, prefetch hit

The counter counts each access counted by [LL_CACHE_REFILL_PRF](#) that causes a refill of the Last level cache, or any other data, instruction, or unified cache of this PE, from outside of those caches.

0x8290, ISNP_HIT_PRF, Snoop hit, instruction prefetch

The counter counts each snoop generated by the PE in response to an instruction prefetch instruction, or by an instruction hardware prefetch that hits in a cache outside of the cache hierarchy of this PE.

The event is counted by the PE generating the snoop, not the PE being snooped.

0x8291, ISNP_HIT_NEAR_PRF, Snoop hit in near local cache, instruction prefetch

The counter counts each snoop generated by the PE in response to an instruction prefetch instruction, or by an instruction hardware prefetch counted by [ISNP_HIT_PRF](#) that hits in a cache outside of the cache hierarchy of this PE in the local PE cluster.

The event is counted by the PE generating the snoop, not the PE being snooped.

0x8292, **ISNP_HIT_FAR_PRF, Snoop hit in far local cache, instruction prefetch**

The counter counts each snoop generated by the PE in response to an instruction prefetch instruction, or by an instruction hardware prefetch counted by [ISNP_HIT_PRF](#) that hits in a cache outside the local PE cluster on the same device.

The event is counted by the PE generating the snoop, not the PE being snooped.

0x8293, **ISNP_HIT_REMOTE_PRF, Snoop hit in remote cache, instruction prefetch**

The counter counts each snoop generated by the PE in response to an instruction prefetch instruction, or by an instruction hardware prefetch counted by [ISNP_HIT_PRF](#) that hits in a cache on a remote device.

The event is counted by the PE generating the snoop, not the PE being snooped.

0x8294, **DSNP_HIT_PRF, Snoop hit, data prefetch**

The counter counts each snoop generated by the PE in response to a data prefetch instruction, or by a data hardware prefetch that hits in a cache outside of the cache hierarchy of this PE.

The event is counted by the PE generating the snoop, not the PE being snooped.

0x8295, **DSNP_HIT_NEAR_PRF, Snoop hit in near local cache, data prefetch**

The counter counts each snoop generated by the PE in response to a data prefetch instruction, or by a data hardware prefetch counted by [DSNP_HIT_PRF](#) that hits in a cache outside of the cache hierarchy of this PE in the local PE cluster.

The event is counted by the PE generating the snoop, not the PE being snooped.

0x8296, **DSNP_HIT_FAR_PRF, Snoop hit in far local cache, data prefetch**

The counter counts each snoop generated by the PE in response to a data prefetch instruction, or by a data hardware prefetch counted by [DSNP_HIT_PRF](#) that hits in a cache outside the local PE cluster on the same device.

The event is counted by the PE generating the snoop, not the PE being snooped.

0x8297, **DSNP_HIT_REMOTE_PRF, Snoop hit in remote cache, data prefetch**

The counter counts each snoop generated by the PE in response to a data prefetch instruction, or by a data hardware prefetch counted by [DSNP_HIT_PRF](#) that hits in a cache on a remote device.

The event is counted by the PE generating the snoop, not the PE being snooped.

0x8298, **LL_CACHE_RW, Last level cache demand access**

The counter counts each access counted by [LL_CACHE](#) that is due to a demand [Memory-read operation](#) or demand [Memory-write operation](#).

This includes:

- Accesses made by [speculatively executed](#) instructions.
- Accesses to the Last level cache due to a refill of another cache caused by a demand [Memory-read operation](#) or demand [Memory-write operation](#).

Arm recommends that this event is implemented if any of the following are true:

- Event [LL_CACHE_PRFM](#) is implemented.
- Event [LL_CACHE_HWPRF](#) is implemented.

0x8299, **LL_CACHE_PRFM, Last level cache software prefetch**

The counter counts each access counted by [LL_CACHE_PRF](#) that is due to a prefetch instruction.

This includes accesses to the Last level cache due to a refill of another cache caused by a prefetch instruction.

Arm recommends that this event is implemented if event [LL_CACHE_RW](#) is implemented.

0x829A, **LL_CACHE_REFILL, Last level cache refill**

The counter counts each access counted by [LL_CACHE](#) that causes a refill of the Last level cache, or any other data, instruction, or unified cache of this PE, from outside of those caches.

A refill includes any access that causes data to be fetched from outside of the Level 1 to Last level caches, even if the data is ultimately not allocated into the Last level cache. For example, data might be fetched into a buffer but then discarded, rather than being allocated into a cache. These buffers are treated as part of the cache.

For example, the counter counts:

- Accesses to the Last level cache that cause a refill that is satisfied by fetching data from memory, or a Last level cache of another PE.
- Refills of and write-backs from any other data, instruction, or unified caches of this PE that cause a refill from outside of the Level 1 to Last level caches of this PE.
- Accesses to the Last level cache that cause a refill of a higher level cache of this PE from outside of the Level 1 to Last level caches of this PE, even if there is no refill of the Last level cache.

The counter does not count accesses that:

- Miss in the cache but are satisfied by the refill of a previous miss and do not cause a new refill, even if that previous refill is not complete at the time of the miss.
- Miss in the cache but do not generate a refill, such as a write through the cache.

It is IMPLEMENTATION DEFINED whether accesses that result from cache maintenance instructions are counted.

If the cache is shared and the Effective value of [PMEVTYPER<n>_EL0.MT](#) for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the cache is shared by PEs other than the PEs in the multithreaded processor and the Effective value of [PMEVTYPER<n>_EL0.MT](#) for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of [PMEVTYPER<n>_EL0.MT](#).

0x829B, **LL_CACHE_REFILL_PRFM, Last level cache refill, software prefetch**

The counter counts each access counted by [LL_CACHE_PRFM](#) that causes a refill of the Last level cache, or any other data, instruction, or unified cache of this PE, from outside of those caches.

0x829C, **LL_CACHE_WB, Last level cache write-back**

The counter counts each write-back of data from the Last level cache to outside of the Level 1 to Last level caches.

For example:

- A write-back of a cache line to memory.
- A write-back of a recently fetched cache line that has not been allocated to the Last level cache.

Each write-back is counted once, even if multiple accesses are required to complete the write-back.

It is IMPLEMENTATION DEFINED whether the counter counts:

- A transfer of a dirty cache line from the Last level cache to outside of Level 1 to Last level caches made as a result of a coherency request.
- Write-backs made as a result of cache maintenance instructions.

The counter does not count:

- The invalidation of a cache line without any write-back to outside of the Level 1 to Last level caches or memory.
- Writes that write through the Last level cache to outside of the Level 1 to Last level caches.
- Transfers of data from the Last level cache to another cache to satisfy a refill of the other cache.

A write-back is attributable to one of the following, and it is IMPLEMENTATION DEFINED which:

- The PE or other agent that generated the request that caused the write-back. This might not be the same agent that caused the data to be allocated into the cache.
- If the cache is shared, the PE or other agent that caused the data to be allocated into the cache.
- If the cache is shared, the PE or other agent that last accessed the data when it was in the cache. If the data has not been accessed since being allocated, then the PE or other agent that caused the data to be allocated into the cache.

If the cache is shared, then the write-back event is counted only if it is attributable to the PE counting the event.

If the cache is not shared, then the event is counted by the PE that the cache is attached to, even if the write-back is not attributable to that PE. For example, a requestor outside of the PE made a coherency request that resulted in write-back.

It is IMPLEMENTATION DEFINED whether a write of a whole cache line that is not the result of the eviction of a line from the cache, is counted. For example, this applies when the PE determines software is streaming writes to memory and does not allocate lines to the cache, or by a DC ZVA operation.

0x829D, LL_CACHE_WR, Last level cache access, write

If the LL_CACHE_RW event is implemented, the counter counts each access counted by LL_CACHE_RW that is a Memory-write operation.

If the LL_CACHE_RW event is not implemented, the counter counts each access counted by LL_CACHE that is a Memory-write operation.

If the cache is shared and the Effective value of PMEVTYPEPER<n>_EL0.MT for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the cache is shared by PEs other than the PEs in the multithreaded processor and the Effective value of PMEVTYPEPER<n>_EL0.MT for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of PMEVTYPEPER<n>_EL0.MT.

0x829F, LL_CACHE_REFILL_WR, Last level cache refill, write

The counter counts each access counted by both LL_CACHE_REFILL and LL_CACHE_WR.

That is, every refill of the Last level cache counted by LL_CACHE_REFILL that is caused by a Memory-write operation.

If the cache is shared and the Effective value of PMEVTYPEPER<n>_EL0.MT for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the cache is shared by PEs other than the PEs in the multithreaded processor and the Effective value of PMEVTYPEPER<n>_EL0.MT for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of PMEVTYPEPER<n>_EL0.MT.

0x82A0, MEM_ACCESS_RW, Data memory access, demand access

The counter counts each access counted by MEM_ACCESS that is a demand Memory-read operation or demand Memory-write operation.

This includes accesses made by speculative instructions.

0x82A1, **INST_FETCH_RD, Instruction memory access, demand fetch**

The counter counts each fetch counted by [INST_FETCH](#) that is a demand [Instruction memory access](#).

This includes any fetch made for a speculative instruction.

0x82A2, **MEM_ACCESS_PRFM, Data memory access, software prefetch**

The counter counts each access counted by [MEM_ACCESS](#) that is due to a prefetch instruction.

0x82A3, **INST_FETCH_PRFM, Instruction memory access, software prefetch**

The counter counts each fetch counted by [INST_FETCH](#) that is due to a prefetch instruction.

0x82B0, **L1I_CACHE_MISS_RETIRED, Instruction architecturally executed, miss in Level 1 instruction cache**

The counter counts each [instruction architecturally executed](#) counted by [INST_RETIRED](#) that missed in Level 1 instruction or unified cache when fetched.

0x82B1, **L2I_CACHE_MISS_RETIRED, Instruction architecturally executed, miss in Level 2 instruction cache**

The counter counts each [instruction architecturally executed](#) counted by [INST_RETIRED](#) that missed in Level 2 instruction or unified cache when fetched.

0x82B4, **L1D_CACHE_MISS_LD_RETIRED, Load instruction architecturally executed, miss in Level 1 data cache**

The counter counts each [architecturally executed](#) instruction counted by [L1D_CACHE_MISS_LDST_RETIRED](#) that is a [Memory-reading instruction](#).

0x82B5, **L2D_CACHE_MISS_LD_RETIRED, Load instruction architecturally executed, miss in Level 2 data cache**

The counter counts each [architecturally executed](#) instruction counted by [L2D_CACHE_MISS_LDST_RETIRED](#) that is a [Memory-reading instruction](#).

0x82B6, **L3D_CACHE_MISS_LD_RETIRED, Load instruction architecturally executed, miss in Level 3 data cache**

The counter counts each [architecturally executed](#) instruction counted by [L3D_CACHE_MISS_LDST_RETIRED](#) that is a [Memory-reading instruction](#).

0x82B7, **LL_CACHE_MISS_LD_RETIRED, Load instruction architecturally executed, miss in Last level cache**

The counter counts each [architecturally executed](#) instruction counted by [LL_CACHE_MISS_LDST_RETIRED](#) that is a [Memory-reading instruction](#).

0x82B8, **L1D_CACHE_MISS_ST_RETIRED, Store instruction architecturally executed, miss in Level 1 data cache**

The counter counts each [architecturally executed](#) instruction counted by [L1D_CACHE_MISS_LDST_RETIRED](#) that is a [Memory-writing instruction](#).

0x82B9, **L2D_CACHE_MISS_ST_RETIRED, Store instruction architecturally executed, miss in Level 2 data cache**

The counter counts each [architecturally executed](#) instruction counted by [L2D_CACHE_MISS_LDST_RETIRED](#) that is a [Memory-writing instruction](#).

0x82BA, L3D_CACHE_MISS_ST_RETIRED, Store instruction architecturally executed, miss in Level 3 data cache

The counter counts each [architecturally executed](#) instruction counted by [L3D_CACHE_MISS_LDST_RETIRED](#) that is a [Memory-writing instruction](#).

0x82BB, LL_CACHE_MISS_ST_RETIRED, Store instruction architecturally executed, miss in Last level cache

The counter counts each [architecturally executed](#) instruction counted by [LL_CACHE_MISS_LDST_RETIRED](#) that is a [Memory-writing instruction](#).

0x82BC, L1D_CACHE_MISS_LDST_RETIRED, Load or store instruction architecturally executed, miss in Level 1 data cache

The counter counts each [architecturally executed Memory-reading instruction](#) or [Memory-writing instruction](#) counted by [LDST_ANY_RETIRED](#) that missed in Level 1 data or unified cache.

0x82BD, L2D_CACHE_MISS_LDST_RETIRED, Load or store instruction architecturally executed, miss in Level 2 data cache

The counter counts each [architecturally executed Memory-reading instruction](#) or [Memory-writing instruction](#) counted by [LDST_ANY_RETIRED](#) that missed in Level 2 data or unified cache.

0x82BE, L3D_CACHE_MISS_LDST_RETIRED, Load or store instruction architecturally executed, miss in Level 3 data cache

The counter counts each [architecturally executed Memory-reading instruction](#) or [Memory-writing instruction](#) counted by [LDST_ANY_RETIRED](#) that missed in Level 3 data or unified cache.

0x82BF, LL_CACHE_MISS_LDST_RETIRED, Load or store instruction architecturally executed, miss in Last level cache

The counter counts each [architecturally executed Memory-reading instruction](#) or [Memory-writing instruction](#) counted by [LDST_ANY_RETIRED](#) that missed in Last level cache.

0x82C4, L1D_CACHE_HITM_LD_RETIRED, Load instruction architecturally executed, hit modified data in Level 1 data cache

The counter counts each [architecturally executed](#) instruction counted by [L1D_CACHE_HITM_LDST_RETIRED](#) that is a [Memory-reading instruction](#).

0x82C5, L2D_CACHE_HITM_LD_RETIRED, Load instruction architecturally executed, hit modified data in Level 2 data cache

The counter counts each [architecturally executed](#) instruction counted by [L2D_CACHE_HITM_LDST_RETIRED](#) that is a [Memory-reading instruction](#).

0x82C6, L3D_CACHE_HITM_LD_RETIRED, Load instruction architecturally executed, hit modified data in Level 3 data cache

The counter counts each [architecturally executed](#) instruction counted by [L3D_CACHE_HITM_LDST_RETIRED](#) that is a [Memory-reading instruction](#).

0x82C7, LL_CACHE_HITM_LD_RETIRED, Load instruction architecturally executed, hit modified data in Last level cache

The counter counts each [architecturally executed](#) instruction counted by [LL_CACHE_HITM_LDST_RETIRED](#) that is a [Memory-reading instruction](#).

0x82C8, L1D_CACHE_HITM_ST_RETIRED, Store instruction architecturally executed, hit modified data in Level 1 data cache

The counter counts each [architecturally executed](#) instruction counted by [L1D_CACHE_HITM_LDST_RETIRED](#) that is a [Memory-writing instruction](#).

0x82C9, L2D_CACHE_HITM_ST_RETIRED, Store instruction architecturally executed, hit modified data in Level 2 data cache

The counter counts each [architecturally executed](#) instruction counted by [L2D_CACHE_HITM_LDST_RETIRED](#) that is a [Memory-writing instruction](#).

0x82CA, L3D_CACHE_HITM_ST_RETIRED, Store instruction architecturally executed, hit modified data in Level 3 data cache

The counter counts each [architecturally executed](#) instruction counted by [L3D_CACHE_HITM_LDST_RETIRED](#) that is a [Memory-writing instruction](#).

0x82CB, LL_CACHE_HITM_ST_RETIRED, Store instruction architecturally executed, hit modified data in Last level cache

The counter counts each [architecturally executed](#) instruction counted by [LL_CACHE_HITM_LDST_RETIRED](#) that is a [Memory-writing instruction](#).

0x82CC, L1D_CACHE_HITM_LDST_RETIRED, Load or store instruction architecturally executed, hit modified data in Level 1 data cache

The counter counts each [architecturally executed Memory-reading instruction](#) or [Memory-writing instruction](#) counted by [L1D_CACHE_HIT_LDST_RETIRED](#) that hit modified data in Level 1 data or unified cache.

0x82CD, L2D_CACHE_HITM_LDST_RETIRED, Load or store instruction architecturally executed, hit modified data in Level 2 data cache

The counter counts each [architecturally executed Memory-reading instruction](#) or [Memory-writing instruction](#) counted by [L2D_CACHE_HIT_LDST_RETIRED](#) that hit modified data in Level 2 data or unified cache.

0x82CE, L3D_CACHE_HITM_LDST_RETIRED, Load or store instruction architecturally executed, hit modified data in Level 3 data cache

The counter counts each [architecturally executed Memory-reading instruction](#) or [Memory-writing instruction](#) counted by [L3D_CACHE_HIT_LDST_RETIRED](#) that hit modified data in Level 3 data or unified cache.

0x82CF, LL_CACHE_HITM_LDST_RETIRED, Load or store instruction architecturally executed, hit modified data in Last level cache

The counter counts each [architecturally executed Memory-reading instruction](#) or [Memory-writing instruction](#) counted by [LL_CACHE_HIT_LDST_RETIRED](#) that hit modified data in Last level cache.

0x82D0, L1I_LFB_HIT_RETIRED, Instruction architecturally executed, line-fill buffer hit in Level 1 instruction cache

The counter counts each [instruction architecturally executed](#) counted by [L1I_CACHE_HIT_RETIRED](#) that hit a recently fetched line in Level 1 instruction or unified cache when fetched.

0x82D1, L2I_LFB_HIT_RETIRE, Instruction architecturally executed, line-fill buffer hit in Level 2 instruction cache

The counter counts each [instruction architecturally executed](#) counted by [L2I_CACHE_HIT_RETIRE](#) that hit a recently fetched line in Level 2 instruction or unified cache when fetched.

0x82D4, L1D_LFB_HIT_LD_RETIRE, Load instruction architecturally executed, line-fill buffer hit in Level 1 data cache

The counter counts each [architecturally executed](#) instruction counted by [L1D_LFB_HIT_LDST_RETIRE](#) that is a [Memory-reading instruction](#).

0x82D5, L2D_LFB_HIT_LD_RETIRE, Load instruction architecturally executed, line-fill buffer hit in Level 2 data cache

The counter counts each [architecturally executed](#) instruction counted by [L2D_LFB_HIT_LDST_RETIRE](#) that is a [Memory-reading instruction](#).

0x82D6, L3D_LFB_HIT_LD_RETIRE, Load instruction architecturally executed, line-fill buffer hit in Level 3 data cache

The counter counts each [architecturally executed](#) instruction counted by [L3D_LFB_HIT_LDST_RETIRE](#) that is a [Memory-reading instruction](#).

0x82D7, LL_LFB_HIT_LD_RETIRE, Load instruction architecturally executed, line-fill buffer hit in Last level cache

The counter counts each [architecturally executed](#) instruction counted by [LL_LFB_HIT_LDST_RETIRE](#) that is a [Memory-reading instruction](#).

0x82D8, L1D_LFB_HIT_ST_RETIRE, Store instruction architecturally executed, line-fill buffer hit in Level 1 data cache

The counter counts each [architecturally executed](#) instruction counted by [L1D_LFB_HIT_LDST_RETIRE](#) that is a [Memory-writing instruction](#).

0x82D9, L2D_LFB_HIT_ST_RETIRE, Store instruction architecturally executed, line-fill buffer hit in Level 2 data cache

The counter counts each [architecturally executed](#) instruction counted by [L2D_LFB_HIT_LDST_RETIRE](#) that is a [Memory-writing instruction](#).

0x82DA, L3D_LFB_HIT_ST_RETIRE, Store instruction architecturally executed, line-fill buffer hit in Level 3 data cache

The counter counts each [architecturally executed](#) instruction counted by [L3D_LFB_HIT_LDST_RETIRE](#) that is a [Memory-writing instruction](#).

0x82DB, LL_LFB_HIT_ST_RETIRE, Store instruction architecturally executed, line-fill buffer hit in Last level cache

The counter counts each [architecturally executed](#) instruction counted by [LL_LFB_HIT_LDST_RETIRE](#) that is a [Memory-writing instruction](#).

0x82DC, L1D_LFB_HIT_LDST_RETIRE, Load or store instruction architecturally executed, line-fill buffer hit in Level 1 data cache

The counter counts each [architecturally executed Memory-reading instruction](#) or [Memory-writing instruction](#) counted by [L1D_CACHE_HIT_LDST_RETIRE](#) that hit a recently fetched line in Level 1 data or unified cache.

0x82DD, L2D_LFB_HIT_LDST_RETIRE, Load or store instruction architecturally executed, line-fill buffer hit in Level 2 data cache

The counter counts each [architecturally executed Memory-reading instruction](#) or [Memory-writing instruction](#) counted by [L2D_CACHE_HIT_LDST_RETIRE](#) that hit a recently fetched line in Level 2 data or unified cache.

0x82DE, L3D_LFB_HIT_LDST_RETIRED, Load or store instruction architecturally executed, line-fill buffer hit in Level 3 data cache

The counter counts each [architecturally executed Memory-reading instruction](#) or [Memory-writing instruction](#) counted by [L3D_CACHE_HIT_LDST_RETIRED](#) that hit a recently fetched line in Level 3 data or unified cache.

0x82DF, LL_LFB_HIT_LDST_RETIRED, Load or store instruction architecturally executed, line-fill buffer hit in Last level cache

The counter counts each [architecturally executed Memory-reading instruction](#) or [Memory-writing instruction](#) counted by [LL_CACHE_HIT_LDST_RETIRED](#) that hit a recently fetched line in Last level cache.

0x82E0, L1I_CACHE_HIT_RETIRED, Instruction architecturally executed, hit in Level 1 instruction cache

The counter counts each [instruction architecturally executed](#) counted by [INST_RETIRED](#) that hit in Level 1 instruction or unified cache when fetched.

0x82E1, L2I_CACHE_HIT_RETIRED, Instruction architecturally executed, hit in Level 2 instruction cache

The counter counts each [instruction architecturally executed](#) counted by [INST_RETIRED](#) that hit in Level 2 instruction or unified cache when fetched.

0x82E4, L1D_CACHE_HIT_LD_RETIRED, Load instruction architecturally executed, hit in Level 1 data cache

The counter counts each [architecturally executed](#) instruction counted by [L1D_CACHE_HIT_LDST_RETIRED](#) that is a [Memory-reading instruction](#).

0x82E5, L2D_CACHE_HIT_LD_RETIRED, Load instruction architecturally executed, hit in Level 2 data cache

The counter counts each [architecturally executed](#) instruction counted by [L2D_CACHE_HIT_LDST_RETIRED](#) that is a [Memory-reading instruction](#).

0x82E6, L3D_CACHE_HIT_LD_RETIRED, Load instruction architecturally executed, hit in Level 3 data cache

The counter counts each [architecturally executed](#) instruction counted by [L3D_CACHE_HIT_LDST_RETIRED](#) that is a [Memory-reading instruction](#).

0x82E7, LL_CACHE_HIT_LD_RETIRED, Load instruction architecturally executed, hit in Last level cache

The counter counts each [architecturally executed](#) instruction counted by [LL_CACHE_HIT_LDST_RETIRED](#) that is a [Memory-reading instruction](#).

0x82E8, L1D_CACHE_HIT_ST_RETIRED, Store instruction architecturally executed, hit in Level 1 data cache

The counter counts each [architecturally executed](#) instruction counted by [L1D_CACHE_HIT_LDST_RETIRED](#) that is a [Memory-writing instruction](#).

0x82E9, L2D_CACHE_HIT_ST_RETIRED, Store instruction architecturally executed, hit in Level 2 data cache

The counter counts each [architecturally executed](#) instruction counted by [L2D_CACHE_HIT_LDST_RETIRED](#) that is a [Memory-writing instruction](#).

0x82EA, L3D_CACHE_HIT_ST_RETIRED, Store instruction architecturally executed, hit in Level 3 data cache

The counter counts each [architecturally executed](#) instruction counted by [L3D_CACHE_HIT_LDST_RETIRED](#) that is a [Memory-writing instruction](#).

0x82EB, LL_CACHE_HIT_ST_RETIRED, Store instruction architecturally executed, hit in Last level cache

The counter counts each [architecturally executed](#) instruction counted by [LL_CACHE_HIT_LDST_RETIRED](#) that is a [Memory-writing instruction](#).

0x82EC, L1D_CACHE_HIT_LDST_RETIRED, Load or store instruction architecturally executed, hit in Level 1 data cache

The counter counts each [architecturally executed Memory-reading instruction](#) or [Memory-writing instruction](#) counted by [LDST_ANY_RETIRED](#) that hit in Level 1 data or unified cache.

0x82ED, L2D_CACHE_HIT_LDST_RETIRED, Load or store instruction architecturally executed, hit in Level 2 data cache

The counter counts each [architecturally executed Memory-reading instruction](#) or [Memory-writing instruction](#) counted by [LDST_ANY_RETIRED](#) that hit in Level 2 data or unified cache.

0x82EE, L3D_CACHE_HIT_LDST_RETIRED, Load or store instruction architecturally executed, hit in Level 3 data cache

The counter counts each [architecturally executed Memory-reading instruction](#) or [Memory-writing instruction](#) counted by [LDST_ANY_RETIRED](#) that hit in Level 3 data or unified cache.

0x82EF, LL_CACHE_HIT_LDST_RETIRED, Load or store instruction architecturally executed, hit in Last level cache

The counter counts each [architecturally executed Memory-reading instruction](#) or [Memory-writing instruction](#) counted by [LDST_ANY_RETIRED](#) that hit in Last level cache.

0x82F0, ITLB_HIT_RETIRED, Instruction architecturally executed, no translation table walk

The counter counts each instruction which was [architecturally executed](#) counted by [INST_RETIRED](#) that did not cause a refill of an instruction TLB involving at least one translation table walk access.

The counter does not count the instruction which was [architecturally executed](#) if any of the following are true:

- The access generates a Translation fault because the applicable [TCR_ELx.EPDy](#) bit is 1.
- FEAT_EOPD is implemented and the access is an unprivileged access that generates a Translation fault because the applicable [TCR_ELx.EOPDy](#) bit is 1.

It is IMPLEMENTATION DEFINED whether the counter counts the instruction which was [architecturally executed](#) if the access generates a Translation fault for any other reason.

0x82F1, DTLB_HIT_LD_RETIRED, Load instruction architecturally executed, no translation table walk

The counter counts each [Memory-reading instruction architecturally executed](#) counted by [DTLB_HIT_LDST_RETIRED](#) that did not cause a refill of a data TLB involving at least one translation table walk access.

0x82F2, DTLB_HIT_ST_RETIRED, Store instruction architecturally executed, no translation table walk

The counter counts each [Memory-writing instruction architecturally executed](#) counted by [DTLB_HIT_LDST_RETIRED](#) that did not cause a refill of a data TLB involving at least one translation table walk access.

0x82F3, DTLB_HIT_LDST_RETIRED, Load or store instruction architecturally executed, no translation table walk

The counter counts each [Memory-reading instruction](#) or [Memory-writing instruction architecturally executed](#) counted by [LDST_ANY_RETIRED](#) that did not cause a refill of a data TLB involving at least one translation table walk access.

0x82F4, ITLB_WALK_RETIRED, Instruction architecturally executed, at least one translation table walk

The counter counts each instruction which was [architecturally executed](#) counted by [INST_RETIRED](#) that caused a refill of an instruction TLB involving at least one translation table walk access.

The counter does not count the instruction which was [architecturally executed](#) if any of the following are true:

- The access generates a Translation fault because the applicable [TCR_ELx.EPDy](#) bit is 1.
- FEAT_EOPD is implemented and the access is an unprivileged access that generates a Translation fault because the applicable [TCR_ELx.EOPDy](#) bit is 1.

It is IMPLEMENTATION DEFINED whether the counter counts the instruction which was [architecturally executed](#) if the access generates a Translation fault for any other reason.

0x82F5, DTLB_WALK_LD_RETIRED, Load instruction architecturally executed, at least one translation table walk

The counter counts each [Memory-reading instruction architecturally executed](#) counted by [DTLB_WALK_LDST_RETIRED](#) that caused a refill of a data TLB involving at least one translation table walk access.

The counter does not count the [Memory-reading instruction architecturally executed](#) if any of the following are true:

- The access generates a Translation fault because the applicable [TCR_ELx.EPDy](#) bit is 1.
- FEAT_EOPD is implemented and the access is an unprivileged access that generates a Translation fault because the applicable [TCR_ELx.EOPDy](#) bit is 1.

It is IMPLEMENTATION DEFINED whether the counter counts the [Memory-reading instruction architecturally executed](#) if the access generates a Translation fault for any other reason.

0x82F6, DTLB_WALK_ST_RETIRED, Store instruction architecturally executed, at least one translation table walk

The counter counts each [Memory-writing instruction architecturally executed](#) counted by [DTLB_WALK_LDST_RETIRED](#) that caused a refill of a data TLB involving at least one translation table walk access.

The counter does not count the [Memory-writing instruction architecturally executed](#) if any of the following are true:

- The access generates a Translation fault because the applicable [TCR_ELx.EPDy](#) bit is 1.
- FEAT_EOPD is implemented and the access is an unprivileged access that generates a Translation fault because the applicable [TCR_ELx.EOPDy](#) bit is 1.

It is IMPLEMENTATION DEFINED whether the counter counts the [Memory-writing instruction architecturally executed](#) if the access generates a Translation fault for any other reason.

0x82F7, DTLB_WALK_LDST_RETIRED, Load or store instruction architecturally executed, at least one translation table walk

The counter counts each [Memory-reading instruction](#) or [Memory-writing instruction architecturally executed](#) counted by [LDST_ANY_RETIRED](#) that caused a refill of a data TLB involving at least one translation table walk access.

The counter does not count the [Memory-reading instruction](#) or [Memory-writing instruction architecturally executed](#) if any of the following are true:

- The access generates a Translation fault because the applicable [TCR_ELx.EPDy](#) bit is 1.
- FEAT_EOPD is implemented and the access is an unprivileged access that generates a Translation fault because the applicable [TCR_ELx.EOPDy](#) bit is 1.

It is IMPLEMENTATION DEFINED whether the counter counts the [Memory-reading instruction](#) or [Memory-writing instruction architecturally executed](#) if the access generates a Translation fault for any other reason.

0x82F8, DTLB_WALK_PRF, Data TLB prefetch, with at least one translation table walk

The counter counts each software prefetch or hardware prefetch access counted by [L1D_TLB_PRF](#) that causes a refill or update of a data or unified TLB involving at least one translation table walk access.

The counter does not count the software prefetch or hardware prefetch access if any of the following are true:

- The access is due to a TLB maintenance instruction.
- The access generates a Translation fault because the applicable [TCR_ELx.EPDy](#) bit is 1.
- FEAT_EOPD is implemented and the access is an unprivileged access that generates a Translation fault because the applicable [TCR_ELx.EOPDy](#) bit is 1.

It is IMPLEMENTATION DEFINED whether the counter counts the software prefetch or hardware prefetch access if the access generates a Translation fault for any other reason.

If the TLB is shared and the Effective value of [PMEVTYPER<n>_EL0.MT](#) for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of [PMEVTYPER<n>_EL0.MT](#) for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of [PMEVTYPER<n>_EL0.MT](#).

0x82F9, ITLB_WALK_PRF, Instruction TLB prefetch, with at least one translation table walk

The counter counts each software prefetch or hardware prefetch access counted by [L1I_TLB_PRF](#) that causes a refill or update of an instruction TLB involving at least one translation table walk access.

The counter does not count the software prefetch or hardware prefetch access if any of the following are true:

- The access is due to a TLB maintenance instruction.
- The access generates a Translation fault because the applicable [TCR_ELx.EPDy](#) bit is 1.
- FEAT_EOPD is implemented and the access is an unprivileged access that generates a Translation fault because the applicable [TCR_ELx.EOPDy](#) bit is 1.

It is IMPLEMENTATION DEFINED whether the counter counts the software prefetch or hardware prefetch access if the access generates a Translation fault for any other reason.

If the TLB is shared and the Effective value of [PMEVTYPER<n>_EL0.MT](#) for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of [PMEVTYPER<n>_EL0.MT](#) for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of [PMEVTYPER<n>_EL0.MT](#).

0x82FA, DTLB_WALK_HWPRF, Data TLB hardware prefetch, with at least one translation table walk

The counter counts each hardware prefetch access counted by [L1D_TLB_HWPRF](#) that causes a refill or update of a data or unified TLB involving at least one translation table walk access.

The counter does not count the hardware prefetch access if any of the following are true:

- The access is due to a TLB maintenance instruction.
- The access generates a Translation fault because the applicable [TCR_ELx.EPDy](#) bit is 1.
- FEAT_EOPD is implemented and the access is an unprivileged access that generates a Translation fault because the applicable [TCR_ELx.EOPDy](#) bit is 1.

It is IMPLEMENTATION DEFINED whether the counter counts the hardware prefetch access if the access generates a Translation fault for any other reason.

If the TLB is shared and the Effective value of [PMEVTYPER<n>_EL0.MT](#) for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of [PMEVTYPER<n>_EL0.MT](#) for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other

cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of [PMEVTYPER<n>_EL0.MT](#).

0x82FB, [ITLB_WALK_HWPRF](#), Instruction TLB hardware prefetch, with at least one translation table walk

The counter counts each hardware prefetch access counted by [L1I_TLB_HWPRF](#) that causes a refill or update of an instruction TLB involving at least one translation table walk access.

The counter does not count the hardware prefetch access if any of the following are true:

- The access is due to a TLB maintenance instruction.
- The access generates a Translation fault because the applicable [TCR_ELx.EPDy](#) bit is 1.
- FEAT_EOPD is implemented and the access is an unprivileged access that generates a Translation fault because the applicable [TCR_ELx.EOPDy](#) bit is 1.

It is IMPLEMENTATION DEFINED whether the counter counts the hardware prefetch access if the access generates a Translation fault for any other reason.

If the TLB is shared and the Effective value of [PMEVTYPER<n>_EL0.MT](#) for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of [PMEVTYPER<n>_EL0.MT](#) for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of [PMEVTYPER<n>_EL0.MT](#).

0x82FC, [L1D_TLB_PRF](#), Level 1 data TLB access, prefetch

The counter counts each access counted by [L1D_TLB](#) that is due to a prefetch instruction or hardware prefetch.

If the TLB is shared and the Effective value of [PMEVTYPER<n>_EL0.MT](#) for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of [PMEVTYPER<n>_EL0.MT](#) for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of [PMEVTYPER<n>_EL0.MT](#).

0x82FD, [L1I_TLB_PRF](#), Level 1 instruction TLB access, prefetch

The counter counts each access counted by [L1I_TLB](#) that is due to a prefetch instruction or hardware prefetch.

If the TLB is shared and the Effective value of [PMEVTYPER<n>_EL0.MT](#) for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of [PMEVTYPER<n>_EL0.MT](#) for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of [PMEVTYPER<n>_EL0.MT](#).

0x82FE, [L1D_TLB_HWPRF](#), Level 1 data TLB access, hardware prefetch

The counter counts each access counted by [L1D_TLB_PRF](#) that is due to a hardware prefetch.

If the TLB is shared and the Effective value of [PMEVTYPER<n>_EL0.MT](#) for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of [PMEVTYPER<n>_EL0.MT](#) for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of [PMEVTYPER<n>_EL0.MT](#).

0x82FF, L1I_TLB_HWPRF, Level 1 instruction TLB access, hardware prefetch

The counter counts each access counted by [L1I_TLB_PRF](#) that is due to a hardware prefetch.

If the TLB is shared and the Effective value of [PMEVTYPEPER<n>_EL0.MT](#) for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of [PMEVTYPEPER<n>_EL0.MT](#) for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of [PMEVTYPEPER<n>_EL0.MT](#).

0x8304, DSNP_HITM_LD_RETIRED, Load instruction architecturally executed, snoop hit

The counter counts each [architecturally executed](#) instruction counted by [DSNP_HITM_LDST_RETIRED](#) that is a [Memory-reading instruction](#).

0x8305, DSNP_HITM_NEAR_LD_RETIRED, Load instruction architecturally executed, snoop hit in near cache

The counter counts each [architecturally executed](#) instruction counted by [DSNP_HITM_NEAR_LDST_RETIRED](#) that is a [Memory-reading instruction](#).

0x8306, DSNP_HITM_FAR_LD_RETIRED, Load instruction architecturally executed, snoop hit in far cache

The counter counts each [architecturally executed](#) instruction counted by [DSNP_HITM_FAR_LDST_RETIRED](#) that is a [Memory-reading instruction](#).

0x8307, DSNP_HITM_REMOTE_LD_RETIRED, Load instruction architecturally executed, snoop hit in remote cache

The counter counts each [architecturally executed](#) instruction counted by [DSNP_HITM_REMOTE_LDST_RETIRED](#) that is a [Memory-reading instruction](#).

0x8308, DSNP_HITM_ST_RETIRED, Store instruction architecturally executed, snoop hit

The counter counts each [architecturally executed](#) instruction counted by [DSNP_HITM_LDST_RETIRED](#) that is a [Memory-writing instruction](#).

0x8309, DSNP_HITM_NEAR_ST_RETIRED, Store instruction architecturally executed, snoop hit in near cache

The counter counts each [architecturally executed](#) instruction counted by [DSNP_HITM_NEAR_LDST_RETIRED](#) that is a [Memory-writing instruction](#).

0x830A, DSNP_HITM_FAR_ST_RETIRED, Store instruction architecturally executed, snoop hit in far cache

The counter counts each [architecturally executed](#) instruction counted by [DSNP_HITM_FAR_LDST_RETIRED](#) that is a [Memory-writing instruction](#).

0x830B, DSNP_HITM_REMOTE_ST_RETIRED, Store instruction architecturally executed, snoop hit in remote cache

The counter counts each [architecturally executed](#) instruction counted by [DSNP_HITM_REMOTE_LDST_RETIRED](#) that is a [Memory-writing instruction](#).

0x830C, DSNP_HITM_LDST_RETIRED, Load or store instruction architecturally executed, snoop hit

The counter counts each [architecturally executed Memory-reading instruction](#) or [Memory-writing instruction](#) counted by [LDST_ANY_RETIRED](#) that hit modified data in a data cache outside the cache hierarchy of this PE.

0x830D, **DSNP_HITM_NEAR_LDST_RETIRED**, Load or store instruction architecturally executed, snoop hit in near cache

The counter counts each [architecturally executed Memory-reading instruction](#) or [Memory-writing instruction](#) counted by [DSNP_HITM_LDST_RETIRED](#) that hit modified data outside of the cache hierarchy of this PE in the local PE cluster.

0x830E, **DSNP_HITM_FAR_LDST_RETIRED**, Load or store instruction architecturally executed, snoop hit in far cache

The counter counts each [architecturally executed Memory-reading instruction](#) or [Memory-writing instruction](#) counted by [DSNP_HITM_LDST_RETIRED](#) that hit modified data outside the local PE cluster on the same device.

0x830F, **DSNP_HITM_REMOTE_LDST_RETIRED**, Load or store instruction architecturally executed, snoop hit in remote cache

The counter counts each [architecturally executed Memory-reading instruction](#) or [Memory-writing instruction](#) counted by [DSNP_HITM_LDST_RETIRED](#) that hit modified data on a remote device.

0x8310, **ISNP_HIT_RETIRED**, Instruction architecturally executed, instruction fetch snoop hit

The counter counts each [instruction architecturally executed](#) counted by [INST_RETIRED](#) that hit in an instruction cache outside the cache hierarchy of this PE when fetched.

0x8311, **ISNP_HIT_NEAR_RETIRED**, Instruction architecturally executed, instruction fetch snoop hit in near cache

The counter counts each [instruction architecturally executed](#) counted by [ISNP_HIT_RETIRED](#) that hit outside of the cache hierarchy of this PE in the local PE cluster when fetched.

0x8312, **ISNP_HIT_FAR_RETIRED**, Instruction architecturally executed, instruction fetch snoop hit in far cache

The counter counts each [instruction architecturally executed](#) counted by [ISNP_HIT_RETIRED](#) that hit outside the local PE cluster on the same device when fetched.

0x8313, **ISNP_HIT_REMOTE_RETIRED**, Instruction architecturally executed, instruction fetch snoop hit in remote cache

The counter counts each [instruction architecturally executed](#) counted by [ISNP_HIT_RETIRED](#) that hit on a remote device when fetched.

0x8314, **DSNP_HIT_LD_RETIRED**, Load instruction architecturally executed, snoop hit

The counter counts each [architecturally executed](#) instruction counted by [DSNP_HIT_LDST_RETIRED](#) that is a [Memory-reading instruction](#).

0x8315, **DSNP_HIT_NEAR_LD_RETIRED**, Load instruction architecturally executed, snoop hit in near cache

The counter counts each [architecturally executed](#) instruction counted by [DSNP_HIT_NEAR_LDST_RETIRED](#) that is a [Memory-reading instruction](#).

0x8316, **DSNP_HIT_FAR_LD_RETIRED**, Load instruction architecturally executed, snoop hit in far cache

The counter counts each [architecturally executed](#) instruction counted by [DSNP_HIT_FAR_LDST_RETIRED](#) that is a [Memory-reading instruction](#).

0x8317, **DSNP_HIT_REMOTE_LD_RETIRED**, Load instruction architecturally executed, snoop hit in remote cache

The counter counts each [architecturally executed](#) instruction counted by [DSNP_HIT_REMOTE_LDST_RETIRED](#) that is a [Memory-reading instruction](#).

0x8318, **DSNP_HIT_ST_RETIRED**, Store instruction architecturally executed, snoop hit

The counter counts each [architecturally executed](#) instruction counted by [DSNP_HIT_LDST_RETIRED](#) that is a [Memory-writing instruction](#).

0x8319, **DSNP_HIT_NEAR_ST_RETIRED**, Store instruction architecturally executed, snoop hit in near cache

The counter counts each [architecturally executed](#) instruction counted by [DSNP_HIT_NEAR_LDST_RETIRED](#) that is a [Memory-writing instruction](#).

0x831A, **DSNP_HIT_FAR_ST_RETIRED**, Store instruction architecturally executed, snoop hit in far cache

The counter counts each [architecturally executed](#) instruction counted by [DSNP_HIT_FAR_LDST_RETIRED](#) that is a [Memory-writing instruction](#).

0x831B, **DSNP_HIT_REMOTE_ST_RETIRED**, Store instruction architecturally executed, snoop hit in remote cache

The counter counts each [architecturally executed](#) instruction counted by [DSNP_HIT_REMOTE_LDST_RETIRED](#) that is a [Memory-writing instruction](#).

0x831C, **DSNP_HIT_LDST_RETIRED**, Load or store instruction architecturally executed, snoop hit

The counter counts each [architecturally executed Memory-reading instruction](#) or [Memory-writing instruction](#) counted by [LDST_ANY_RETIRED](#) that hit in a data cache outside the cache hierarchy of this PE.

0x831D, **DSNP_HIT_NEAR_LDST_RETIRED**, Load or store instruction architecturally executed, snoop hit in near cache

The counter counts each [architecturally executed Memory-reading instruction](#) or [Memory-writing instruction](#) counted by [DSNP_HIT_LDST_RETIRED](#) that hit outside of the cache hierarchy of this PE in the local PE cluster.

0x831E, **DSNP_HIT_FAR_LDST_RETIRED**, Load or store instruction architecturally executed, snoop hit in far cache

The counter counts each [architecturally executed Memory-reading instruction](#) or [Memory-writing instruction](#) counted by [DSNP_HIT_LDST_RETIRED](#) that hit outside the local PE cluster on the same device.

0x831F, **DSNP_HIT_REMOTE_LDST_RETIRED**, Load or store instruction architecturally executed, snoop hit in remote cache

The counter counts each [architecturally executed Memory-reading instruction](#) or [Memory-writing instruction](#) counted by [DSNP_HIT_LDST_RETIRED](#) that hit on a remote device.

0x8320, **L1D_CACHE_REFILL_PERCYC**, Level 1 data or unified cache refills in progress

The counter increments by the number of Level 1 data or unified cache refills counted by [L1D_CACHE_REFILL](#) in progress on each [Processor cycle](#).

The ratio $\text{L1D_CACHE_REFILL_PERCYC} \div \text{L1D_CACHE_REFILL}$ is the mean duration of Level 1 data or unified cache refills in [Processor cycles](#).

0x8321, **L2D_CACHE_REFILL_PERCYC**, Level 2 data or unified cache refills in progress

The counter increments by the number of Level 2 data or unified cache refills counted by [L2D_CACHE_REFILL](#) in progress on each [Processor cycle](#).

The ratio $\text{L2D_CACHE_REFILL_PERCYC} \div \text{L2D_CACHE_REFILL}$ is the mean duration of Level 2 data or unified cache refills in [Processor cycles](#).

0x8322, **L3D_CACHE_REFILL_PERCYC, Level 3 data or unified cache refills in progress**

The counter increments by the number of Level 3 data or unified cache refills counted by [L3D_CACHE_REFILL](#) in progress on each [Processor cycle](#).

The ratio $\text{L3D_CACHE_REFILL_PERCYC} \div \text{L3D_CACHE_REFILL}$ is the mean duration of Level 3 data or unified cache refills in [Processor cycles](#).

0x8324, **L1I_CACHE_REFILL_PERCYC, Level 1 instruction or unified cache refills in progress**

The counter increments by the number of Level 1 instruction or unified cache refills counted by [L1I_CACHE_REFILL](#) in progress on each [Processor cycle](#).

The ratio $\text{L1I_CACHE_REFILL_PERCYC} \div \text{L1I_CACHE_REFILL}$ is the mean duration of Level 1 instruction or unified cache refills in [Processor cycles](#).

0x8325, **L2I_CACHE_REFILL_PERCYC, Level 2 instruction or unified cache refills in progress**

The counter increments by the number of Level 2 instruction or unified cache refills counted by [L2I_CACHE_REFILL](#) in progress on each [Processor cycle](#).

The ratio $\text{L2I_CACHE_REFILL_PERCYC} \div \text{L2I_CACHE_REFILL}$ is the mean duration of Level 2 instruction or unified cache refills in [Processor cycles](#).

0x8328, **REMOTE_CACHE_HIT_RD, Remote cache demand access hit, read**

The counter counts each cache hit on a remote device due to a demand read.

0x8329, **REMOTE_CACHE_HITM_RD, Remote cache demand access hit modified, read**

The counter counts each cache hit on a remote device counted by [REMOTE_CACHE_HIT_RD](#) that accesses a previously modified location.

0x832A, **REMOTE_LFB_HIT_RD, Remote cache demand access line-fill buffer hit, read**

The counter counts each cache hit on a remote device counted by [REMOTE_CACHE_HIT_RD](#) that hits a recently fetched line.

That is, the read hits a cache line that is in the process of being loaded into the cache attached to a remote device, and so does not generate a new refill, but has to wait for the previous refill to complete.

0x832B, **REMOTE_CACHE_HIT_PFRM, Remote cache software prefetch hit**

The counter counts each cache hit on a remote device due to a software prefetch.

0x8330, **L1GCS_CACHE, Level 1 GCS cache access**

The counter counts each GCS data read operation or GCS data write operation that causes a cache access to at least a Level 1 cache.

Each access to a cache line is counted including the multiple accesses caused by single instructions such as [GCSPUSHX](#) or [GCSPOPX](#). Each access to other Level 1 memory structures, for example refill buffers, write buffers, and write-back buffers, is also counted.

Accesses to a Level 1 cache due to a GCS hardware prefetcher as well are counted.

When there are separate GCS caching structures implemented:

- It is IMPLEMENTATION DEFINED whether accesses that result from cache maintenance instructions are counted.
- Accesses that only update the cache status information for a cache entry without accessing the content of the cache entry are not counted.

0x8331, **L1GCS_CACHE_RW, Level 1 GCS cache demand access**

The counter counts each access counted by [L1GCS_CACHE](#) that is due to a demand Memory-read operation or demand Memory-write operation.

This includes accesses made by Speculatively executed instructions.

Arm recommends that this event is implemented if event [L1GCS_CACHE_HWPRF](#) is implemented.

0x8332, **L1GCS_CACHE_HWPRF, Level 1 GCS cache hardware prefetch**

The counter counts each access counted by [L1GCS_CACHE](#) that is due to a GCS hardware prefetcher.

0x8334, **L1GCS_CACHE_MISS, Level 1 GCS cache demand access miss**

The counter counts each access counted by [L1GCS_CACHE_RW](#) that misses in the Level 1 caches causing an access to outside of the Level 1 caches of this PE.

0x8335, **L1GCS_CACHE_MISS_RD, Level 1 GCS cache demand access read miss**

The counter counts each access counted by [L1GCS_CACHE_MISS](#) that is also a Memory-read operation.

It is IMPLEMENTATION DEFINED whether accesses that result from cache maintenance instructions are counted.

If the cache is shared and the Effective value of [PMEVTYPER<n>_EL0.MT](#) for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the cache is shared by PEs other than the PEs in the multithreaded processor and the Effective value of [PMEVTYPER<n>_EL0.MT](#) for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of [PMEVTYPER<n>_EL0.MT](#).

Arm recommends that this event is implemented if event [L1GCS_CACHE](#) is implemented.

0x8336, **L1GCS_CACHE_HIT_RW, Level 1 GCS cache demand access hit**

The counter counts each access counted by [L1GCS_CACHE_RW](#) that hits in a Level 1 cache.

0x8337, **L1GCS_CACHE_HIT_RW_FHWPRF, Level 1 GCS cache demand access first hit, fetched by GCS hardware prefetcher**

The counter counts each demand access first hit counted by [L1GCS_CACHE_HIT_RW](#) where the cache line was fetched by a GCS hardware prefetcher.

That is, the [L1GCS_CACHE_REFILL_HWPRF](#) event was generated when the cache line was fetched into the cache.

Only the first hit by a demand access is counted. After this event is generated for a cache line, the event is not generated again for the same cache line while it remains in the cache.

0x8338, **L1GCS_CACHE_REFILL, Level 1 GCS cache refill**

The counter counts each access counted by [L1GCS_CACHE](#) that causes a refill of a Level 1 cache from outside of the Level 1 cache.

A refill includes any access that causes data to be fetched from outside of the Level 1 caches, even if the data is ultimately not allocated into the Level 1 cache. For example, data might be fetched into a buffer but then discarded, rather than being allocated into a cache. These buffers are treated as part of the cache.

For example, the counter counts accesses to the Level 1 cache that cause a refill that is satisfied by fetching data from memory, a Level 2 cache, or a Level 1 cache of another PE.

The counter does not count accesses that:

- Miss in the cache but are satisfied by the refill of a previous miss and do not cause a new refill, even if that previous refill is not complete at the time of the miss.
- Miss in the cache but do not generate a refill, such as a write through the cache.

If the cache is shared and the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the cache is shared by PEs other than the PEs in the multithreaded processor and the Effective value of `PMEVTYPER<n>_EL0.MT` for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of `PMEVTYPER<n>_EL0.MT`.

0x8339, **L1GCS_CACHE_REFILL_HWPRF, Level 1 GCS cache refill, hardware prefetch**

The counter counts each hardware prefetch counted by `L1GCS_CACHE_HWPRF` that causes a refill of a Level 1 cache from outside of the Level 1 cache.

0x833A, **L1GCS_CACHE_REFILL_PERCYC, Level 1 GCS cache refills in progress**

The counter increments by the number of Level 1 GCS cache refills counted by `L1GCS_CACHE_REFILL` in progress on each `Processor cycle`.

The ratio `L1GCS_CACHE_REFILL_PERCYC ÷ L1GCS_CACHE_REFILL` is the mean duration of Level 1 GCS cache refills in `Processor cycles`.

0x833C, **L1GCS_LFB_HIT_RW, Level 1 GCS cache demand access line-fill buffer hit**

The counter counts each demand access counted by `L1GCS_CACHE_HIT_RW` that hits a recently fetched line in a Level 1 cache.

That is, the access hits a cache line that is in the process of being loaded into the Level 1 cache, and so does not generate a new refill, but has to wait for the previous refill to complete.

0x833D, **L1GCS_LFB_HIT_RW_FHWPRF, Level 1 GCS cache demand access line-fill buffer first hit, recently fetched by GCS hardware prefetcher**

The counter counts each demand access line-fill buffer first hit counted by `L1GCS_LFB_HIT_RW` where the cache line was fetched by a GCS hardware prefetcher.

That is, the access hits a cache line that is in the process of being loaded into the Level 1 cache, and so does not generate a new refill, but has to wait for the previous refill to complete, and the `L1GCS_CACHE_REFILL_HWPRF` event was generated when the cache line was fetched into the cache.

0x833E, **L1GCS_CACHE_INVALID, Level 1 GCS cache invalidate**

The counter counts each invalidation of a cache line in a Level 1 GCS cache.

For example:

- Invalidation of a cache line because of a GCSB effect.
- Transfer of ownership of a cache line to another cache because of a coherency or refill request.

The counter does not count events if a cache refill of the Level 1 cache invalidates a line in the Level 1 cache.

Note

Software that uses this event must know whether the Level 1 cache is shared with other PEs. This event does not follow the general rule of Level 1 cache events of only counting Attributable events.

0x8340, **L1GCS_TLB, Level 1 GCS TLB access**

The counter counts each GCS data read operation or GCS data write operation that causes a TLB access to at least a Level 1 TLB.

Each access to a TLB entry is counted including multiple accesses caused by single instructions such as GCSPUSHX or GCSPOPX.

The counter does not count the access if the access is due to a TLB maintenance instruction.

If the TLB is shared and the Effective value of [PMEVTYPER<n>_EL0.MT](#) for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of [PMEVTYPER<n>_EL0.MT](#) for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of [PMEVTYPER<n>_EL0.MT](#).

0x8341, **L1GCS_TLB_RW, Level 1 GCS demand TLB access**

The counter counts each access counted by [L1GCS_TLB](#) that is due to a demand Memory-read operation or demand Memory-write operation.

If the TLB is shared and the Effective value of [PMEVTYPER<n>_EL0.MT](#) for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of [PMEVTYPER<n>_EL0.MT](#) for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of [PMEVTYPER<n>_EL0.MT](#).

0x8342, **L1GCS_TLB_HWPRF, Level 1 GCS demand TLB access, GCS hardware prefetch**

The counter counts each access counted by [L1GCS_TLB](#) that is due to a GCS hardware prefetch.

If the TLB is shared and the Effective value of [PMEVTYPER<n>_EL0.MT](#) for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of [PMEVTYPER<n>_EL0.MT](#) for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of [PMEVTYPER<n>_EL0.MT](#).

0x8344, **GCSTLB_WALK, GCS TLB access with at least one translation table walk**

The counter counts each access counted by [L1GCS_TLB](#) that causes a refill of a TLB involving at least one translation table walk access.

This includes each complete or partial translation table walk that causes an access to memory, including to data or translation table walk caches.

Accesses that cause an update of an existing TLB entry involving at least one translation table walk access are counted.

The counter does not count the access if any of the following are true:

- FEAT_EOPD is implemented and the access is an unprivileged access that generates a Translation fault because the applicable [TCR_ELx.EOPDy](#) bit is 1.
- The access generates a Translation fault because the applicable [TCR_ELx.EPDy](#) bit is 1.
- The access is due to a TLB maintenance instruction.

It is IMPLEMENTATION DEFINED whether the counter counts the access if the access generates a Translation fault for any other reason.

The counter does not count the access if any of the following are true:

- The access generates a Translation fault because the applicable [TCR_ELx.EPDy](#) bit is 1.

- FEAT_E0PD is implemented and the access is an unprivileged access that generates a Translation fault because the applicable [TCR_ELx.E0PDy](#) bit is 1.

It is IMPLEMENTATION DEFINED whether the counter counts the access if the access generates a Translation fault for any other reason.

If the TLB is shared and the Effective value of [PMEVTYPER<n>_EL0.MT](#) for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of [PMEVTYPER<n>_EL0.MT](#) for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of [PMEVTYPER<n>_EL0.MT](#).

0x8345, **GCSTLB_WALK_RW, GCS TLB demand access with at least one translation table walk**

The counter counts each demand access counted by both [GCSTLB_WALK](#) and [LIGCS_TLB_RW](#).

If the TLB is shared and the Effective value of [PMEVTYPER<n>_EL0.MT](#) for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of [PMEVTYPER<n>_EL0.MT](#) for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of [PMEVTYPER<n>_EL0.MT](#).

0x8346, **GCSTLB_WALK_PERCYC, Translation table walks in progress**

The counter increments by the number of translation table walks counted by [GCSTLB_WALK](#) in progress on each [Processor cycle](#).

The ratio $\text{GCSTLB_WALK_PERCYC} \div \text{GCSTLB_WALK}$ is the mean duration of translation table walks in [Processor cycles](#).

If the TLB is shared and the Effective value of [PMEVTYPER<n>_EL0.MT](#) for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of [PMEVTYPER<n>_EL0.MT](#) for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of [PMEVTYPER<n>_EL0.MT](#).

0x8347, **GCSTLB_WALK_STEP, GCS TLB translation table walk, step**

The counter counts each translation table walk access due to a refill of a TLB.

The translation table walk must be due to either GCS data read operation or GCS data write operation.

The event is Attributable to the access that missed in the TLB and caused the walk, not to the owner of the translation tables being accessed. For example, this means that if an EL0 access causes a translation table walk consisting of accesses to both stage 1 and stage 2 translation tables, all accesses are counted if event counting is allowed at EL0, regardless of whether event counting is allowed at EL1 and/or EL2.

The counter does not count the event if any of the following are true:

- The access causing the refill generates a Translation fault because the applicable [TCR_ELx.EPDy](#) bit is 1.
- The access causing the refill is an unprivileged access that generates a Translation fault because the applicable [TCR_ELx.E0PDy](#) bit is 1.

It is IMPLEMENTATION DEFINED whether the counter counts the event if the access causing the refill generates a Translation fault for any other reason.

Implementation of this optional event requires that FEAT_E0PD is implemented.

If the TLB is shared and the Effective value of [PMEVTYPER<n>_EL0.MT](#) for the counter is 0, then the counter counts only events Attributable to the PE counting the event. For a multithreaded processor implementation, if the TLB is shared by PEs other than the PEs in the multithreaded processor and the Effective value of [PMEVTYPER<n>_EL0.MT](#)

for the counter is 1, then the counter counts only events Attributable to PEs in the multithreaded processor. In all other cases, it is IMPLEMENTATION DEFINED whether only events Attributable to the PE counting the event or all events are counted, and might depend on the Effective value of [PMEVTYPER<n>_EL0.MT](#).

0x8350, **STALL_BACKEND_L1GCS**, Backend stall cycles, Level 1 GCS cache

The counter counts each cycle counted by [STALL_BACKEND_MEMBOUND](#) when there is a demand data miss in a first level cache.

The demand data miss must be due to either GCS data read operation or GCS data write operation.

The counter does not count the cycle if any of the following are true:

- The [STALL_BACKEND_L2D](#) event is implemented and there is a demand data miss in the second level of data or unified cache, meaning the [STALL_BACKEND_L2D](#) event counts the cycle.
- There is a demand data miss in the last level of data or unified cache within the PE clock domain, meaning the [STALL_BACKEND_MEM](#) event counts the cycle.

Implementation of this optional event requires that the first level cache is implemented within the PE clock domain and is not the last level cache within the PE clock domain.

Implementation of this optional event requires implementing [L1GCS_CACHE](#) event.

For a multithreaded processor implementation, if the Effective value of [PMEVTYPER<n>_EL0.MT](#) is 1, then the counter counts when there is a demand data miss in a first level cache for any PE in the multithreaded processor.

———— **Note** ————

It is possible that both the events [STALL_BACKEND_L1GCS](#) and [STALL_BACKEND_L1D](#) events may be counted on a same cycle.

0x8351, **STALL_BACKEND_GCSTLB**, Backend stall cycles, GCS TLB

The counter counts each cycle counted by [STALL_BACKEND_MEMBOUND](#) when there is a demand data miss in a TLB.

The demand data miss must be due to translation of a GCS data read operation or GCS data write operation.

Implementation of this optional event requires implementing [L1GCS_TLB](#) event.

For a multithreaded processor implementation, if the Effective value of [PMEVTYPER<n>_EL0.MT](#) is 1, then the counter counts when there is a demand data miss in a TLB for any PE in the multithreaded processor.

0x8353, **SE_FP_SPEC**, Operation speculatively executed, Advanced SIMD, SVE, or SME SIMD floating-point, data-processing

The counter counts each [speculatively executed](#) floating-point data-processing operation counted by [FP_SPEC](#) due to an A64 Advanced SIMD, SVE, or SME operation.

That is, each operation counted by [ASE_FP_SPEC](#), [SVE_FP_SPEC](#), or [SME_FP_SPEC](#).

0x835D, **SE_SPEC**, Operation speculatively executed, Advanced SIMD, SVE, or SME data processing

The counter counts each operation counted by [INST_SPEC](#) that is an Advanced SIMD, SVE, or SME data-processing operation.

See [ASE_SVE_SPEC](#) and [SME_SPEC](#) for these classifications.

0x835F, SE_INST_SPEC, Operation speculatively executed, Advanced SIMD, SVE, or SME

The counter counts each [speculatively executed](#) operation counted by [INST_SPEC](#) that is classified as an Advanced SIMD, SVE, or SME operation.

See [ASE_SVE_INST_SPEC](#) and [SME_INST_SPEC](#) for these classifications.

0x8361, SE_INT8_SPEC, Operation speculatively executed, Advanced SIMD, SVE, or SME SIMD 8-bit integer, data-processing

The counter counts each [speculatively executed](#) 8-bit integer data-processing operation counted by [SE_INT_SPEC](#) due to an A64 Advanced SIMD, SVE, or SME operation.

That is, each operation counted by [ASE_INT8_SPEC](#), [SVE_INT8_SPEC](#), or [SME_INT8_SPEC](#).

0x8363, SE_FP_BF16_SPEC, Operation speculatively executed, Advanced SIMD, SVE, or SME SIMD BFloat16 floating-point, data-processing

The counter counts each [speculatively executed](#) BFloat16 floating-point data-processing operation counted by [SE_FP_SPEC](#) due to an A64 Advanced SIMD, SVE, or SME operation.

That is, each operation counted by [SVE_FP_BF16_SPEC](#), or [SME_FP_BF16_SPEC](#).

0x8365, SE_INT16_SPEC, Operation speculatively executed, Advanced SIMD, SVE, or SME SIMD 16-bit integer, data-processing

The counter counts each [speculatively executed](#) 16-bit integer data-processing operation counted by [SE_INT_SPEC](#) due to an A64 Advanced SIMD, SVE, or SME operation.

That is, each operation counted by [ASE_INT16_SPEC](#), [SVE_INT16_SPEC](#), or [SME_INT16_SPEC](#).

0x8367, SE_FP_HP_SPEC, Operation speculatively executed, Advanced SIMD, SVE, or SME SIMD half-precision floating-point, data-processing

The counter counts each [speculatively executed](#) half-precision floating-point data-processing operation counted by [SE_FP_SPEC](#) due to an A64 Advanced SIMD, SVE, or SME operation.

That is, each operation counted by [ASE_FP_HP_SPEC](#), [SVE_FP_HP_SPEC](#), or [SME_FP_HP_SPEC](#).

0x8369, SE_INT32_SPEC, Operation speculatively executed, Advanced SIMD, SVE, or SME SIMD 32-bit integer, data-processing

The counter counts each [speculatively executed](#) 32-bit integer data-processing operation counted by [SE_INT_SPEC](#) due to an A64 Advanced SIMD, SVE, or SME operation.

That is, each operation counted by [ASE_INT32_SPEC](#), [SVE_INT32_SPEC](#), or [SME_INT32_SPEC](#).

0x836B, SE_FP_SP_SPEC, Operation speculatively executed, Advanced SIMD, SVE, or SME SIMD single-precision floating-point, data-processing

The counter counts each [speculatively executed](#) single-precision floating-point data-processing operation counted by [SE_FP_SPEC](#) due to an A64 Advanced SIMD, SVE, or SME operation.

That is, each operation counted by [ASE_FP_SP_SPEC](#), [SVE_FP_SP_SPEC](#), or [SME_FP_SP_SPEC](#).

0x836D, SE_INT64_SPEC, Operation speculatively executed, Advanced SIMD, SVE, or SME SIMD 64-bit integer, data-processing

The counter counts each [speculatively executed](#) 64-bit integer data-processing operation counted by [SE_INT_SPEC](#) due to an A64 Advanced SIMD, SVE, or SME operation.

That is, each operation counted by [ASE_INT64_SPEC](#), [SVE_INT64_SPEC](#), or [SME_INT64_SPEC](#).

0x836F, SE_FP_DP_SPEC, Operation speculatively executed, Advanced SIMD, SVE, or SME SIMD double-precision floating-point, data-processing

The counter counts each [speculatively executed](#) double-precision floating-point data-processing operation counted by [SE_FP_SPEC](#) due to an A64 Advanced SIMD, SVE, or SME operation.

That is, each operation counted by [ASE_FP_DP_SPEC](#), [SVE_FP_DP_SPEC](#), or [SME_FP_DP_SPEC](#).

0x8371, SE_FP_ADDSUB_SPEC, Operation speculatively executed, Advanced SIMD, SVE, or SME SIMD floating-point addition or subtraction

The counter counts each [speculatively executed](#) floating-point addition or subtraction operation counted by [SE_FP_SPEC](#) due to an A64 Advanced SIMD, SVE, or SME operation.

That is, each operation counted by [ASE_FP_ADDSUB_SPEC](#), [SVE_FP_ADDSUB_SPEC](#), or [SME_FP_ADDSUB_SPEC](#).

0x8373, SE_FP_FMA_SPEC, Operation speculatively executed, Advanced SIMD, SVE, or SME SIMD floating-point multiply-add or multiply-subtract

The counter counts each [speculatively executed](#) floating-point multiply-add, multiply-add long, multiply-subtract, or multiply-subtract long operation counted by [SE_FP_SPEC](#) due to an A64 Advanced SIMD, SVE, or SME operation.

That is, each operation counted by [ASE_FP_FMA_SPEC](#), [SVE_FP_FMA_SPEC](#), or [SME_FP_FMA_SPEC](#).

0x8375, SE_FP_DOT_SPEC, Operation speculatively executed, Advanced SIMD, SVE, or SME SIMD floating-point dot product

The counter counts each [speculatively executed](#) floating-point dot product operation counted by [SE_FP_SPEC](#) due to any of the following A64 instructions:

That is, each operation counted by [ASE_FP_DOT_SPEC](#), [SVE_FP_DOT_SPEC](#), or [SME_FP_DOT_SPEC](#).

0x8379, SE_INT_SPEC, Operation speculatively executed, Advanced SIMD, SVE, or SME SIMD integer, data-processing

The counter counts each [speculatively executed](#) integer data-processing operation counted by [INT_SPEC](#) due to an A64 Advanced SIMD, SVE, or SME operation.

That is, each operation counted by [ASE_INT_SPEC](#), [SVE_INT_SPEC](#), or [SME_INT_SPEC](#).

0x837B, SE_INT_MUL_SPEC, Operation speculatively executed, Advanced SIMD, SVE, or SME SIMD integer multiply or multiply-accumulate

The counter counts each [speculatively executed](#) integer multiply, multiply-add, or multiply-subtract operation counted by [SE_INT_SPEC](#) due to an A64 Advanced SIMD, SVE, or SME operation.

That is, each operation counted by [ASE_INT_MUL_SPEC](#), [SVE_INT_MUL_SPEC](#), or [SME_INT_MUL_SPEC](#).

0x837D, SE_INT_DOT_SPEC, Operation speculatively executed, Advanced SIMD, SVE, or SME SIMD integer dot product

The counter counts each **speculatively executed** integer dot product operation counted by **SE_INT_SPEC** due to any of the following A64 instructions:

- When FEAT_DotProd is implemented, Advanced SIMD: SDOT or UDOT.

That is, each operation counted by **ASE_INT_DOT_SPEC**, **SVE_INT_DOT_SPEC**, or **SME_INT_DOT_SPEC**.

0x8380, ZA_ACTIVE, CPU cycles, ZA enabled

The counter counts each cycle counted by **CPU_CYCLES** when **PSTATE.ZA** is 1.

0x8398, ASE_LUT_SPEC, Lookup table operation speculatively executed, Advanced SIMD data processing

The counter counts each **speculatively executed** LUT operation counted by **SE_LUT_SPEC** that returns a value from a lookup table made up of a V register which is indexed by values from a V register.

0x8399, SVE_LUT_SPEC, Lookup table operation speculatively executed, SVE data processing

The counter counts each **speculatively executed** LUT operation counted by **SE_LUT_SPEC** that returns a value from a lookup table made up of a Z register which is indexed by values from a Z register.

That is, due to any of the following instructions:

0x839B, SE_LUT_SPEC, Lookup table operation speculatively executed, Advanced SIMD, SVE, or SME data processing

The counter counts each **speculatively executed** LUT operation counted by **SE_INST_SPEC** that returns a value from a lookup table made up of a ZT register, Z or V register which is indexed by values from a Z or V register.

0x83A0, N1_CACHE_HIT_RD, Cache at distance 1, demand access hit, read

The counter counts each cache hit at distance 1 due to a demand read.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

0x83A1, N2_CACHE_HIT_RD, Cache at distance 2, demand access hit, read

The counter counts each cache hit at distance 2 due to a demand read.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

Cache distance 2 represents a further distance of travel than cache distance 1.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

0x83A2, N3_CACHE_HIT_RD, Cache at distance 3, demand access hit, read

The counter counts each cache hit at distance 3 due to a demand read.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

Cache distance 3 represents a further distance of travel than cache distance 2.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

0x83A3, N4_CACHE_HIT_RD, Cache at distance 4, demand access hit, read

The counter counts each cache hit at distance 4 due to a demand read.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

Cache distance 4 represents a further distance of travel than cache distance 3.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

0x83A4, N1_CACHE_HIT_PRFM, Cache at distance 1, software prefetch hit

The counter counts each cache hit at distance 1 due to a software prefetch.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

0x83A5, N2_CACHE_HIT_PRFM, Cache at distance 2, software prefetch hit

The counter counts each cache hit at distance 2 due to a software prefetch.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

Cache distance 2 represents a further distance of travel than cache distance 1.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

0x83A6, N3_CACHE_HIT_PRFM, Cache at distance 3, software prefetch hit

The counter counts each cache hit at distance 3 due to a software prefetch.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

Cache distance 3 represents a further distance of travel than cache distance 2.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

0x83A7, N4_CACHE_HIT_PRFM, Cache at distance 4, software prefetch hit

The counter counts each cache hit at distance 4 due to a software prefetch.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

Cache distance 4 represents a further distance of travel than cache distance 3.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

0x83A8, N1_CACHE1_HIT_RD, Cache type 1 at distance 1 demand access hit, read

The counter counts each demand read counted by [N1_CACHE_HIT_RD](#) due to a demand read accessing a first cache type at distance 1.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

0x83A9, N2_CACHE1_HIT_RD, Cache type 1 at distance 2 demand access hit, read

The counter counts each demand read counted by [N2_CACHE_HIT_RD](#) due to a demand read accessing a first cache type at distance 2.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

0x83AA, N3_CACHE1_HIT_RD, Cache type 1 at distance 3 demand access hit, read

The counter counts each demand read counted by [N3_CACHE_HIT_RD](#) due to a demand read accessing a first cache type at distance 3.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

0x83AB, N4_CACHE1_HIT_RD, Cache type 1 at distance 4 demand access hit, read

The counter counts each demand read counted by [N4_CACHE_HIT_RD](#) due to a demand read accessing a first cache type at distance 4.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

0x83AC, N1_CACHE1_HIT_PRFM, Cache type 1 at distance 1 software prefetch hit

The counter counts each software prefetch counted by [N1_CACHE_HIT_PRFM](#) due to a software prefetch accessing a first cache type at distance 1.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

0x83AD, N2_CACHE1_HIT_PRFM, Cache type 1 at distance 2 software prefetch hit

The counter counts each software prefetch counted by [N2_CACHE_HIT_PRFM](#) due to a software prefetch accessing a first cache type at distance 2.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

0x83AE, N3_CACHE1_HIT_PRFM, Cache type 1 at distance 3 software prefetch hit

The counter counts each software prefetch counted by [N3_CACHE_HIT_PRFM](#) due to a software prefetch accessing a first cache type at distance 3.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

0x83AF, N4_CACHE1_HIT_PRFM, Cache type 1 at distance 4 software prefetch hit

The counter counts each software prefetch counted by [N4_CACHE_HIT_PRFM](#) due to a software prefetch accessing a first cache type at distance 4.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

0x83B0, N1_CACHE2_HIT_RD, Cache type 2 at distance 1 demand access hit, read

The counter counts each demand read counted by [N1_CACHE_HIT_RD](#) due to a demand read accessing a second cache type at distance 1.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

0x83B1, N2_CACHE2_HIT_RD, Cache type 2 at distance 2 demand access hit, read

The counter counts each demand read counted by [N2_CACHE_HIT_RD](#) due to a demand read accessing a second cache type at distance 2.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

0x83B2, N3_CACHE2_HIT_RD, Cache type 2 at distance 3 demand access hit, read

The counter counts each demand read counted by [N3_CACHE_HIT_RD](#) due to a demand read accessing a second cache type at distance 3.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

0x83B3, N4_CACHE2_HIT_RD, Cache type 2 at distance 4 demand access hit, read

The counter counts each demand read counted by [N4_CACHE_HIT_RD](#) due to a demand read accessing a second cache type at distance 4.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

0x83B4, N1_CACHE2_HIT_PRFM, Cache type 2 at distance 1 software prefetch hit

The counter counts each software prefetch counted by [N1_CACHE_HIT_PRFM](#) due to a software prefetch accessing a second cache type at distance 1.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

0x83B5, N2_CACHE2_HIT_PRFM, Cache type 2 at distance 2 software prefetch hit

The counter counts each software prefetch counted by [N2_CACHE_HIT_PRFM](#) due to a software prefetch accessing a second cache type at distance 2.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

0x83B6, N3_CACHE2_HIT_PRFM, Cache type 2 at distance 3 software prefetch hit

The counter counts each software prefetch counted by [N3_CACHE_HIT_PRFM](#) due to a software prefetch accessing a second cache type at distance 3.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

0x83B7, N4_CACHE2_HIT_PRFM, Cache type 2 at distance 4 software prefetch hit

The counter counts each software prefetch counted by [N4_CACHE_HIT_PRFM](#) due to a software prefetch accessing a second cache type at distance 4.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

0x83B8, N1_CACHE3_HIT_RD, Cache type 3 at distance 1 demand access hit, read

The counter counts each demand read counted by [N1_CACHE_HIT_RD](#) due to a demand read accessing a third cache type at distance 1.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

0x83B9, N2_CACHE3_HIT_RD, Cache type 3 at distance 2 demand access hit, read

The counter counts each demand read counted by [N2_CACHE_HIT_RD](#) due to a demand read accessing a third cache type at distance 2.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

0x83BA, N3_CACHE3_HIT_RD, Cache type 3 at distance 3 demand access hit, read

The counter counts each demand read counted by [N3_CACHE_HIT_RD](#) due to a demand read accessing a third cache type at distance 3.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

0x83BB, N4_CACHE3_HIT_RD, Cache type 3 at distance 4 demand access hit, read

The counter counts each demand read counted by [N4_CACHE_HIT_RD](#) due to a demand read accessing a third cache type at distance 4.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

0x83BC, N1_CACHE3_HIT_PRFM, Cache type 3 at distance 1 software prefetch hit

The counter counts each software prefetch counted by [N1_CACHE_HIT_PRFM](#) due to a software prefetch accessing a third cache type at distance 1.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

0x83BD, N2_CACHE3_HIT_PRFM, Cache type 3 at distance 2 software prefetch hit

The counter counts each software prefetch counted by [N2_CACHE_HIT_PRFM](#) due to a software prefetch accessing a third cache type at distance 2.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

0x83BE, N3_CACHE3_HIT_PRFM, Cache type 3 at distance 3 software prefetch hit

The counter counts each software prefetch counted by [N3_CACHE_HIT_PRFM](#) due to a software prefetch accessing a third cache type at distance 3.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

0x83BF, N4_CACHE3_HIT_PRFM, Cache type 3 at distance 4 software prefetch hit

The counter counts each software prefetch counted by [N4_CACHE_HIT_PRFM](#) due to a software prefetch accessing a third cache type at distance 4.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

0x83C0, N1_CACHE_HITM_RD, Cache at distance 1, demand access hit modified, read

The counter counts each demand read counted by [N1_CACHE_HIT_RD](#) that accesses a previously modified location in a cache at distance 1.

0x83C1, N2_CACHE_HITM_RD, Cache at distance 2, demand access hit modified, read

The counter counts each demand read counted by [N2_CACHE_HIT_RD](#) that accesses a previously modified location in a cache at distance 2.

0x83C2, N3_CACHE_HITM_RD, Cache at distance 3, demand access hit modified, read

The counter counts each demand read counted by [N3_CACHE_HIT_RD](#) that accesses a previously modified location in a cache at distance 3.

0x83C3, N4_CACHE_HITM_RD, Cache at distance 4, demand access hit modified, read

The counter counts each demand read counted by [N4_CACHE_HIT_RD](#) that accesses a previously modified location in a cache at distance 4.

0x83C4, N1_LFB_HIT_RD, Cache at distance 1 demand access line-fill buffer hit, read

The counter counts each demand read counted by [N1_CACHE_HIT_RD](#) that hits a recently fetched line in a cache at distance 1.

That is, the read hits a cache line that is in the process of being loaded into the cache at distance 1, and so does not generate a new refill, but has to wait for the previous refill to complete.

0x83C5, N2_LFB_HIT_RD, Cache at distance 2 demand access line-fill buffer hit, read

The counter counts each demand read counted by [N2_CACHE_HIT_RD](#) that hits a recently fetched line in a cache at distance 2.

That is, the read hits a cache line that is in the process of being loaded into the cache at distance 2, and so does not generate a new refill, but has to wait for the previous refill to complete.

0x83C6, N3_LFB_HIT_RD, Cache at distance 3 demand access line-fill buffer hit, read

The counter counts each demand read counted by [N3_CACHE_HIT_RD](#) that hits a recently fetched line in a cache at distance 3.

That is, the read hits a cache line that is in the process of being loaded into the cache at distance 3, and so does not generate a new refill, but has to wait for the previous refill to complete.

0x83C7, N4_LFB_HIT_RD, Cache at distance 4 demand access line-fill buffer hit, read

The counter counts each demand read counted by [N4_CACHE_HIT_RD](#) that hits a recently fetched line in a cache at distance 4.

That is, the read hits a cache line that is in the process of being loaded into the cache at distance 4, and so does not generate a new refill, but has to wait for the previous refill to complete.

0x83C8, N1_CACHE1_HITM_RD, Cache type 1 at distance 1 demand access hit modified, read

The counter counts each demand read counted by [N1_CACHE_HITM_RD](#) that accesses a previously modified location in a first cache type at distance 1.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

0x83C9, N2_CACHE1_HITM_RD, Cache type 1 at distance 2 demand access hit modified, read

The counter counts each demand read counted by [N2_CACHE_HITM_RD](#) that accesses a previously modified location in a first cache type at distance 2.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

0x83CA, N3_CACHE1_HITM_RD, Cache type 1 at distance 3 demand access hit modified, read

The counter counts each demand read counted by [N3_CACHE_HITM_RD](#) that accesses a previously modified location in a first cache type at distance 3.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

0x83CB, N4_CACHE1_HITM_RD, Cache type 1 at distance 4 demand access hit modified, read

The counter counts each demand read counted by [N4_CACHE_HITM_RD](#) that accesses a previously modified location in a first cache type at distance 4.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

0x83CC, N1_LFB1_HIT_RD, Cache type 1 at distance 1 demand access line-fill buffer hit, read

The counter counts each demand read counted by [N1_LFB_HIT_RD](#) that hits a recently fetched line in a first cache type at distance 1.

That is, the read hits a cache line that is in the process of being loaded into the cache at distance 1, and so does not generate a new refill, but has to wait for the previous refill to complete.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

0x83CD, N2_LFB1_HIT_RD, Cache type 1 at distance 2 demand access line-fill buffer hit, read

The counter counts each demand read counted by [N2_LFB_HIT_RD](#) that hits a recently fetched line in a first cache type at distance 2.

That is, the read hits a cache line that is in the process of being loaded into the cache at distance 2, and so does not generate a new refill, but has to wait for the previous refill to complete.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

0x83CE, N3_LFB1_HIT_RD, Cache type 1 at distance 3 demand access line-fill buffer hit, read

The counter counts each demand read counted by [N3_LFB_HIT_RD](#) that hits a recently fetched line in a first cache type at distance 3.

That is, the read hits a cache line that is in the process of being loaded into the cache at distance 3, and so does not generate a new refill, but has to wait for the previous refill to complete.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

0x83CF, N4_LFB1_HIT_RD, Cache type 1 at distance 4 demand access line-fill buffer hit, read

The counter counts each demand read counted by [N4_LFB_HIT_RD](#) that hits a recently fetched line in a first cache type at distance 4.

That is, the read hits a cache line that is in the process of being loaded into the cache at distance 4, and so does not generate a new refill, but has to wait for the previous refill to complete.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

0x83D0, N1_CACHE2_HITM_RD, Cache type 2 at distance 1 demand access hit modified, read

The counter counts each demand read counted by [N1_CACHE_HITM_RD](#) that accesses a previously modified location in a second cache type at distance 1.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

0x83D1, N2_CACHE2_HITM_RD, Cache type 2 at distance 2 demand access hit modified, read

The counter counts each demand read counted by [N2_CACHE_HITM_RD](#) that accesses a previously modified location in a second cache type at distance 2.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

0x83D2, N3_CACHE2_HITM_RD, Cache type 2 at distance 3 demand access hit modified, read

The counter counts each demand read counted by [N3_CACHE_HITM_RD](#) that accesses a previously modified location in a second cache type at distance 3.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

0x83D3, N4_CACHE2_HITM_RD, Cache type 2 at distance 4 demand access hit modified, read

The counter counts each demand read counted by [N4_CACHE_HITM_RD](#) that accesses a previously modified location in a second cache type at distance 4.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

0x83D4, N1_LFB2_HIT_RD, Cache type 2 at distance 1 demand access line-fill buffer hit, read

The counter counts each demand read counted by [N1_LFB_HIT_RD](#) that hits a recently fetched line in a second cache type at distance 1.

That is, the read hits a cache line that is in the process of being loaded into the cache at distance 1, and so does not generate a new refill, but has to wait for the previous refill to complete.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

0x83D5, N2_LFB2_HIT_RD, Cache type 2 at distance 2 demand access line-fill buffer hit, read

The counter counts each demand read counted by [N2_LFB_HIT_RD](#) that hits a recently fetched line in a second cache type at distance 2.

That is, the read hits a cache line that is in the process of being loaded into the cache at distance 2, and so does not generate a new refill, but has to wait for the previous refill to complete.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

0x83D6, N3_LFB2_HIT_RD, Cache type 2 at distance 3 demand access line-fill buffer hit, read

The counter counts each demand read counted by [N3_LFB_HIT_RD](#) that hits a recently fetched line in a second cache type at distance 3.

That is, the read hits a cache line that is in the process of being loaded into the cache at distance 3, and so does not generate a new refill, but has to wait for the previous refill to complete.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

0x83D7, N4_LFB2_HIT_RD, Cache type 2 at distance 4 demand access line-fill buffer hit, read

The counter counts each demand read counted by [N4_LFB_HIT_RD](#) that hits a recently fetched line in a second cache type at distance 4.

That is, the read hits a cache line that is in the process of being loaded into the cache at distance 4, and so does not generate a new refill, but has to wait for the previous refill to complete.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

0x83D8, N1_CACHE3_HITM_RD, Cache type 3 at distance 1 demand access hit modified, read

The counter counts each demand read counted by [N1_CACHE_HITM_RD](#) that accesses a previously modified location in a third cache type at distance 1.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

0x83D9, N2_CACHE3_HITM_RD, Cache type 3 at distance 2 demand access hit modified, read

The counter counts each demand read counted by [N2_CACHE_HITM_RD](#) that accesses a previously modified location in a third cache type at distance 2.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

0x83DA, N3_CACHE3_HITM_RD, Cache type 3 at distance 3 demand access hit modified, read

The counter counts each demand read counted by [N3_CACHE_HITM_RD](#) that accesses a previously modified location in a third cache type at distance 3.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

0x83DB, N4_CACHE3_HITM_RD, Cache type 3 at distance 4 demand access hit modified, read

The counter counts each demand read counted by [N4_CACHE_HITM_RD](#) that accesses a previously modified location in a third cache type at distance 4.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

0x83DC, N1_LFB3_HIT_RD, Cache type 3 at distance 1 demand access line-fill buffer hit, read

The counter counts each demand read counted by [N1_LFB_HIT_RD](#) that hits a recently fetched line in a third cache type at distance 1.

That is, the read hits a cache line that is in the process of being loaded into the cache at distance 1, and so does not generate a new refill, but has to wait for the previous refill to complete.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

0x83DD, N2_LFB3_HIT_RD, Cache type 3 at distance 2 demand access line-fill buffer hit, read

The counter counts each demand read counted by [N2_LFB_HIT_RD](#) that hits a recently fetched line in a third cache type at distance 2.

That is, the read hits a cache line that is in the process of being loaded into the cache at distance 2, and so does not generate a new refill, but has to wait for the previous refill to complete.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

0x83DE, N3_LFB3_HIT_RD, Cache type 3 at distance 3 demand access line-fill buffer hit, read

The counter counts each demand read counted by [N3_LFB_HIT_RD](#) that hits a recently fetched line in a third cache type at distance 3.

That is, the read hits a cache line that is in the process of being loaded into the cache at distance 3, and so does not generate a new refill, but has to wait for the previous refill to complete.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

0x83DF, N4_LFB3_HIT_RD, Cache type 3 at distance 4 demand access line-fill buffer hit, read

The counter counts each demand read counted by [N4_LFB_HIT_RD](#) that hits a recently fetched line in a third cache type at distance 4.

That is, the read hits a cache line that is in the process of being loaded into the cache at distance 4, and so does not generate a new refill, but has to wait for the previous refill to complete.

The definition of cache types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

0x83E0, N1_MEM_RD, Access to memory at distance 1, demand access, read

The counter counts each demand read to memory at distance 1.

The memory distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

0x83E1, N2_MEM_RD, Access to memory at distance 2, demand access, read

The counter counts each demand read to memory at distance 2.

The memory distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

Distance 2 represents a further distance of travel than distance 1.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

0x83E2, N3_MEM_RD, Access to memory at distance 3, demand access, read

The counter counts each demand read to memory at distance 3.

The memory distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

Distance 3 represents a further distance of travel than distance 2.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

0x83E3, N4_MEM_RD, Access to memory at distance 4, demand access, read

The counter counts each demand read to memory at distance 4.

The memory distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

Distance 4 represents a further distance of travel than distance 3.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

0x83E4, N1_MEM_PRFM, Access to memory at distance 1, software prefetch

The counter counts each software prefetch to memory at distance 1.

The memory distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

0x83E5, **N2_MEM_PRFM, Access to memory at distance 2, software prefetch**

The counter counts each software prefetch to memory at distance 2.

The memory distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

Distance 2 represents a further distance of travel than distance 1.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

0x83E6, **N3_MEM_PRFM, Access to memory at distance 3, software prefetch**

The counter counts each software prefetch to memory at distance 3.

The memory distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

Distance 3 represents a further distance of travel than distance 2.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

0x83E7, **N4_MEM_PRFM, Access to memory at distance 4, software prefetch**

The counter counts each software prefetch to memory at distance 4.

The memory distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

Distance 4 represents a further distance of travel than distance 3.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

0x83E8, **N1_MEM1_RD, Access to type 1 memory at distance 1, demand access, read**

The counter counts each demand read counted by [N1_MEM_RD](#) to a first memory type at distance 1.

The definition of memory types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system. See also [N1_MEM1_RD](#).

For example, the first memory type might be commodity DRAM connected to a device. However, this must be the same for all devices in the system, such that, for example, [N1_MEM1_RD](#) refers to commodity DRAM for a PE at distance 1 from the memory, regardless of which device the PE is located on, and [N4_MEM1_RD](#) refers to the same memory for any PE located at distance 4. This means that when a process counting the [N1_MEM1_RD](#) event migrates between PEs on different devices, its relative view of the first memory type remains unchanged, even if the distance changes.

0x83E9, **N2_MEM1_RD, Access to type 1 memory at distance 2, demand access, read**

The counter counts each demand read counted by [N2_MEM_RD](#) to a first memory type at distance 2.

The definition of memory types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system. See also [N1_MEM1_RD](#).

0x83EA, N3_MEM1_RD, Access to type 1 memory at distance 3, demand access, read

The counter counts each demand read counted by [N3_MEM_RD](#) to a first memory type at distance 3.

The definition of memory types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system. See also [N1_MEM1_RD](#).

0x83EB, N4_MEM1_RD, Access to type 1 memory at distance 4, demand access, read

The counter counts each demand read counted by [N4_MEM_RD](#) to a first memory type at distance 4.

The definition of memory types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system. See also [N1_MEM1_RD](#).

0x83EC, N1_MEM1_PRFM, Access to type 1 memory at distance 1, software prefetch

The counter counts each software prefetch counted by [N1_MEM_PRFM](#) to a first memory type at distance 1.

The definition of memory types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

0x83ED, N2_MEM1_PRFM, Access to type 1 memory at distance 2, software prefetch

The counter counts each software prefetch counted by [N2_MEM_PRFM](#) to a first memory type at distance 2.

The definition of memory types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

0x83EE, N3_MEM1_PRFM, Access to type 1 memory at distance 3, software prefetch

The counter counts each software prefetch counted by [N3_MEM_PRFM](#) to a first memory type at distance 3.

The definition of memory types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

0x83EF, N4_MEM1_PRFM, Access to type 1 memory at distance 4, software prefetch

The counter counts each software prefetch counted by [N4_MEM_PRFM](#) to a first memory type at distance 4.

The definition of memory types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

0x83F0, N1_MEM2_RD, Access to type 2 memory at distance 1, demand access, read

The counter counts each demand read counted by [N1_MEM_RD](#) to a second memory type at distance 1.

The definition of memory types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system. See also [N1_MEM2_RD](#).

For example, the second memory type might be bulk expansion memory connected to a device. However, this must be the same for all devices in the system, such that, for example, [N1_MEM2_RD](#) refers to bulk expansion memory for a PE at distance 1 from the memory, regardless of which device the PE is located on, and [N4_MEM2_RD](#) refers to the same memory for any PE located at distance 4. This means that when a process counting the [N1_MEM2_RD](#) event migrates between PEs on different devices, its relative view of the second memory type remains unchanged, even if the distance changes.

0x83F1, N2_MEM2_RD, Access to type 2 memory at distance 2, demand access, read

The counter counts each demand read counted by [N2_MEM_RD](#) to a second memory type at distance 2.

The definition of memory types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system. See also [N1_MEM2_RD](#).

0x83F2, N3_MEM2_RD, Access to type 2 memory at distance 3, demand access, read

The counter counts each demand read counted by [N3_MEM_RD](#) to a second memory type at distance 3.

The definition of memory types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system. See also [N1_MEM2_RD](#).

0x83F3, N4_MEM2_RD, Access to type 2 memory at distance 4, demand access, read

The counter counts each demand read counted by [N4_MEM_RD](#) to a second memory type at distance 4.

The definition of memory types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system. See also [N1_MEM2_RD](#).

0x83F4, N1_MEM2_PRFM, Access to type 2 memory at distance 1, software prefetch

The counter counts each software prefetch counted by [N1_MEM_PRFM](#) to a second memory type at distance 1.

The definition of memory types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

0x83F5, N2_MEM2_PRFM, Access to type 2 memory at distance 2, software prefetch

The counter counts each software prefetch counted by [N2_MEM_PRFM](#) to a second memory type at distance 2.

The definition of memory types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

0x83F6, N3_MEM2_PRFM, Access to type 2 memory at distance 3, software prefetch

The counter counts each software prefetch counted by [N3_MEM_PRFM](#) to a second memory type at distance 3.

The definition of memory types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

0x83F7, N4_MEM2_PRFM, Access to type 2 memory at distance 4, software prefetch

The counter counts each software prefetch counted by [N4_MEM_PRFM](#) to a second memory type at distance 4.

The definition of memory types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

0x83F8, N1_MEM3_RD, Access to type 3 memory at distance 1, demand access, read

The counter counts each demand read counted by [N1_MEM_RD](#) to a third memory type at distance 1.

The definition of memory types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system. See also [N1_MEM3_RD](#).

For example, the third memory type might be high-bandwidth memory connected to a device. However, this must be the same for all devices in the system, such that, for example, [N1_MEM3_RD](#) refers to high-bandwidth memory for a PE at distance 1 from the memory, regardless of which device the PE is located on, and [N4_MEM3_RD](#) refers to the same memory for any PE located at distance 4. This means that when a process counting the [N1_MEM3_RD](#) event migrates between PEs on different devices, its relative view of the third memory type remains unchanged, even if the distance changes.

0x83F9, N2_MEM3_RD, Access to type 3 memory at distance 2, demand access, read

The counter counts each demand read counted by [N2_MEM_RD](#) to a third memory type at distance 2.

The definition of memory types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system. See also [N1_MEM3_RD](#).

0x83FA, N3_MEM3_RD, Access to type 3 memory at distance 3, demand access, read

The counter counts each demand read counted by [N3_MEM_RD](#) to a third memory type at distance 3.

The definition of memory types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system. See also [N1_MEM3_RD](#).

0x83FB, N4_MEM3_RD, Access to type 3 memory at distance 4, demand access, read

The counter counts each demand read counted by [N4_MEM_RD](#) to a third memory type at distance 4.

The definition of memory types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system. See also [N1_MEM3_RD](#).

0x83FC, N1_MEM3_PRFM, Access to type 3 memory at distance 1, software prefetch

The counter counts each software prefetch counted by [N1_MEM_PRFM](#) to a third memory type at distance 1.

The definition of memory types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

0x83FD, N2_MEM3_PRFM, Access to type 3 memory at distance 2, software prefetch

The counter counts each software prefetch counted by [N2_MEM_PRFM](#) to a third memory type at distance 2.

The definition of memory types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

0x83FE, N3_MEM3_PRFM, Access to type 3 memory at distance 3, software prefetch

The counter counts each software prefetch counted by [N3_MEM_PRFM](#) to a third memory type at distance 3.

The definition of memory types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

0x83FF, N4_MEM3_PRFM, Access to type 3 memory at distance 4, software prefetch

The counter counts each software prefetch counted by [N4_MEM_PRFM](#) to a third memory type at distance 4.

The definition of memory types in the system is IMPLEMENTATION DEFINED, but must be similar for all devices in the system.

0x8400, ISNP_HIT_N1_RD, Snoop hit in cache at distance 1, demand instruction fetch

The counter counts each snoop generated by the PE in response to a demand [Instruction memory access](#) counted by [ISNP_HIT_RD](#) that hits in a cache at distance 1.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

0x8401, ISNP_HIT_N2_RD, Snoop hit in cache at distance 2, demand instruction fetch

The counter counts each snoop generated by the PE in response to a demand [Instruction memory access](#) counted by [ISNP_HIT_RD](#) that hits in a cache at distance 2.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

0x8402, ISNP_HIT_N3_RD, Snoop hit in cache at distance 3, demand instruction fetch

The counter counts each snoop generated by the PE in response to a demand [Instruction memory access](#) counted by [ISNP_HIT_RD](#) that hits in a cache at distance 3.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

0x8403, ISNP_HIT_N4_RD, Snoop hit in cache at distance 4, demand instruction fetch

The counter counts each snoop generated by the PE in response to a demand [Instruction memory access](#) counted by [ISNP_HIT_RD](#) that hits in a cache at distance 4.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

0x8404, DSNP_HIT_N1_RD, Snoop hit in cache at distance 1, demand data read

The counter counts each snoop generated by the PE in response to a demand [Memory-read operation](#) counted by [DSNP_HIT_RD](#) that hits in a cache at distance 1.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

0x8405, DSNP_HIT_N2_RD, Snoop hit in cache at distance 2, demand data read

The counter counts each snoop generated by the PE in response to a demand [Memory-read operation](#) counted by [DSNP_HIT_RD](#) that hits in a cache at distance 2.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

0x8406, **DSNP_HIT_N3_RD, Snoop hit in cache at distance 3, demand data read**

The counter counts each snoop generated by the PE in response to a demand [Memory-read operation](#) counted by [DSNP_HIT_RD](#) that hits in a cache at distance 3.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

0x8407, **DSNP_HIT_N4_RD, Snoop hit in cache at distance 4, demand data read**

The counter counts each snoop generated by the PE in response to a demand [Memory-read operation](#) counted by [DSNP_HIT_RD](#) that hits in a cache at distance 4.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

0x8408, **DSNP_HIT_N1_WR, Snoop hit in cache at distance 1, demand data write**

The counter counts each snoop generated by the PE in response to a demand [Memory-write operation](#) counted by [DSNP_HIT_WR](#) that hits in a cache at distance 1.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

0x8409, **DSNP_HIT_N2_WR, Snoop hit in cache at distance 2, demand data write**

The counter counts each snoop generated by the PE in response to a demand [Memory-write operation](#) counted by [DSNP_HIT_WR](#) that hits in a cache at distance 2.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

0x840A, **DSNP_HIT_N3_WR, Snoop hit in cache at distance 3, demand data write**

The counter counts each snoop generated by the PE in response to a demand [Memory-write operation](#) counted by [DSNP_HIT_WR](#) that hits in a cache at distance 3.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

0x840B, **DSNP_HIT_N4_WR, Snoop hit in cache at distance 4, demand data write**

The counter counts each snoop generated by the PE in response to a demand [Memory-write operation](#) counted by [DSNP_HIT_WR](#) that hits in a cache at distance 4.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

0x840C, **DSNP_HIT_N1_RW, Snoop hit in cache at distance 1, demand data access**

The counter counts each snoop generated by the PE in response to a demand [Memory-read operation](#) or demand [Memory-write operation](#) counted by [DSNP_HIT_RW](#) that hits in a cache at distance 1.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

0x840D, **DSNP_HIT_N2_RW, Snoop hit in cache at distance 2, demand data access**

The counter counts each snoop generated by the PE in response to a demand [Memory-read operation](#) or demand [Memory-write operation](#) counted by [DSNP_HIT_RW](#) that hits in a cache at distance 2.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

0x840E, **DSNP_HIT_N3_RW, Snoop hit in cache at distance 3, demand data access**

The counter counts each snoop generated by the PE in response to a demand [Memory-read operation](#) or demand [Memory-write operation](#) counted by [DSNP_HIT_RW](#) that hits in a cache at distance 3.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

0x840F, **DSNP_HIT_N4_RW, Snoop hit in cache at distance 4, demand data access**

The counter counts each snoop generated by the PE in response to a demand [Memory-read operation](#) or demand [Memory-write operation](#) counted by [DSNP_HIT_RW](#) that hits in a cache at distance 4.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

0x8410, **DSNP_HIT_N1_PRFM, Snoop hit in cache at distance 1, software data prefetch**

The counter counts each snoop generated by the PE in response to a data prefetch instruction counted by [DSNP_HIT_PRFM](#) that hits in a cache at distance 1.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

0x8411, **DSNP_HIT_N2_PRFM, Snoop hit in cache at distance 2, software data prefetch**

The counter counts each snoop generated by the PE in response to a data prefetch instruction counted by [DSNP_HIT_PRFM](#) that hits in a cache at distance 2.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

0x8412, **DSNP_HIT_N3_PRFM, Snoop hit in cache at distance 3, software data prefetch**

The counter counts each snoop generated by the PE in response to a data prefetch instruction counted by [DSNP_HIT_PRFM](#) that hits in a cache at distance 3.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

0x8413, **DSNP_HIT_N4_PRFM, Snoop hit in cache at distance 4, software data prefetch**

The counter counts each snoop generated by the PE in response to a data prefetch instruction counted by [DSNP_HIT_PRFM](#) that hits in a cache at distance 4.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

0x8414, **DSNP_HIT_N1_HWPRF, Snoop hit in cache at distance 1, hardware data prefetch**

The counter counts each snoop generated by a data hardware prefetch counted by [DSNP_HIT_HWPRF](#) that hits in a cache at distance 1.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

0x8415, **DSNP_HIT_N2_HWPRF, Snoop hit in cache at distance 2, hardware data prefetch**

The counter counts each snoop generated by a data hardware prefetch counted by [DSNP_HIT_HWPRF](#) that hits in a cache at distance 2.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

0x8416, **DSNP_HIT_N3_HWPRF, Snoop hit in cache at distance 3, hardware data prefetch**

The counter counts each snoop generated by a data hardware prefetch counted by [DSNP_HIT_HWPRF](#) that hits in a cache at distance 3.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

0x8417, **DSNP_HIT_N4_HWPRF, Snoop hit in cache at distance 4, hardware data prefetch**

The counter counts each snoop generated by a data hardware prefetch counted by [DSNP_HIT_HWPRF](#) that hits in a cache at distance 4.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

0x8418, **ISNP_HIT_N1_PRFM, Snoop hit in cache at distance 1, software instruction prefetch**

The counter counts each snoop generated by the PE in response to an instruction prefetch instruction counted by [ISNP_HIT_PRFM](#) that hits in a cache at distance 1.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

0x8419, **ISNP_HIT_N2_PRFM, Snoop hit in cache at distance 2, software instruction prefetch**

The counter counts each snoop generated by the PE in response to an instruction prefetch instruction counted by [ISNP_HIT_PRFM](#) that hits in a cache at distance 2.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

0x841A, ISNP_HIT_N3_PRFM, Snoop hit in cache at distance 3, software instruction prefetch

The counter counts each snoop generated by the PE in response to an instruction prefetch instruction counted by [ISNP_HIT_PRFM](#) that hits in a cache at distance 3.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

0x841B, ISNP_HIT_N4_PRFM, Snoop hit in cache at distance 4, software instruction prefetch

The counter counts each snoop generated by the PE in response to an instruction prefetch instruction counted by [ISNP_HIT_PRFM](#) that hits in a cache at distance 4.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

0x841C, ISNP_HIT_N1_HWPRF, Snoop hit in cache at distance 1, hardware instruction prefetch

The counter counts each snoop generated by an instruction hardware prefetch counted by [ISNP_HIT_HWPRF](#) that hits in a cache at distance 1.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

0x841D, ISNP_HIT_N2_HWPRF, Snoop hit in cache at distance 2, hardware instruction prefetch

The counter counts each snoop generated by an instruction hardware prefetch counted by [ISNP_HIT_HWPRF](#) that hits in a cache at distance 2.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

0x841E, ISNP_HIT_N3_HWPRF, Snoop hit in cache at distance 3, hardware instruction prefetch

The counter counts each snoop generated by an instruction hardware prefetch counted by [ISNP_HIT_HWPRF](#) that hits in a cache at distance 3.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

0x841F, **ISNP_HIT_N4_HWPRF, Snoop hit in cache at distance 4, hardware instruction prefetch**

The counter counts each snoop generated by an instruction hardware prefetch counted by [ISNP_HIT_HWPRF](#) that hits in a cache at distance 4.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

0x8420, **DSNP_HIT_N1_PRF, Snoop hit in cache at distance 1, data prefetch**

The counter counts each snoop generated by the PE in response to a data prefetch instruction, or by a data hardware prefetch counted by [DSNP_HIT_PRF](#) that hits in a cache at distance 1.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

0x8421, **DSNP_HIT_N2_PRF, Snoop hit in cache at distance 2, data prefetch**

The counter counts each snoop generated by the PE in response to a data prefetch instruction, or by a data hardware prefetch counted by [DSNP_HIT_PRF](#) that hits in a cache at distance 2.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

0x8422, **DSNP_HIT_N3_PRF, Snoop hit in cache at distance 3, data prefetch**

The counter counts each snoop generated by the PE in response to a data prefetch instruction, or by a data hardware prefetch counted by [DSNP_HIT_PRF](#) that hits in a cache at distance 3.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

0x8423, **DSNP_HIT_N4_PRF, Snoop hit in cache at distance 4, data prefetch**

The counter counts each snoop generated by the PE in response to a data prefetch instruction, or by a data hardware prefetch counted by [DSNP_HIT_PRF](#) that hits in a cache at distance 4.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

0x8424, ISNP_HIT_N1_PRF, Snoop hit in cache at distance 1, instruction prefetch

The counter counts each snoop generated by the PE in response to an instruction prefetch instruction, or by an instruction hardware prefetch counted by [ISNP_HIT_PRF](#) that hits in a cache at distance 1.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

0x8425, ISNP_HIT_N2_PRF, Snoop hit in cache at distance 2, instruction prefetch

The counter counts each snoop generated by the PE in response to an instruction prefetch instruction, or by an instruction hardware prefetch counted by [ISNP_HIT_PRF](#) that hits in a cache at distance 2.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

0x8426, ISNP_HIT_N3_PRF, Snoop hit in cache at distance 3, instruction prefetch

The counter counts each snoop generated by the PE in response to an instruction prefetch instruction, or by an instruction hardware prefetch counted by [ISNP_HIT_PRF](#) that hits in a cache at distance 3.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

0x8427, ISNP_HIT_N4_PRF, Snoop hit in cache at distance 4, instruction prefetch

The counter counts each snoop generated by the PE in response to an instruction prefetch instruction, or by an instruction hardware prefetch counted by [ISNP_HIT_PRF](#) that hits in a cache at distance 4.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

0x8428, ISNP_HIT_N1, Snoop hit in cache at distance 1, instruction access

The counter counts each snoop counted by [ISNP_HIT](#) that hits in a cache at distance 1.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

0x8429, ISNP_HIT_N2, Snoop hit in cache at distance 2, instruction access

The counter counts each snoop counted by [ISNP_HIT](#) that hits in a cache at distance 2.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

0x842A, ISNP_HIT_N3, Snoop hit in cache at distance 3, instruction access

The counter counts each snoop counted by [ISNP_HIT](#) that hits in a cache at distance 3.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

0x842B, ISNP_HIT_N4, Snoop hit in cache at distance 4, instruction access

The counter counts each snoop counted by [ISNP_HIT](#) that hits in a cache at distance 4.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

0x842C, DSNP_HIT_N1, Snoop hit in cache at distance 1, data access

The counter counts each snoop counted by [DSNP_HIT](#) that hits in a cache at distance 1.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

0x842D, DSNP_HIT_N2, Snoop hit in cache at distance 2, data access

The counter counts each snoop counted by [DSNP_HIT](#) that hits in a cache at distance 2.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

0x842E, DSNP_HIT_N3, Snoop hit in cache at distance 3, data access

The counter counts each snoop counted by [DSNP_HIT](#) that hits in a cache at distance 3.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

0x842F, **DSNP_HIT_N4, Snoop hit in cache at distance 4, data access**

The counter counts each snoop counted by [DSNP_HIT](#) that hits in a cache at distance 4.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

0x8431, **ASE_FP_VREDUCE_SPEC, Floating-point operation speculatively executed, Advanced SIMD pairwise or reduction**

The counter counts each [speculatively executed](#) floating-point treewise reduction or pairwise operation counted by [ASE_SVE_FP_VREDUCE_SPEC](#) due to any of the following A64 instructions:

- Advanced SIMD: FADDP, FMAXNMP, FMAXNMV, FMAXP, FMAXV, FMINNMP, FMINNMV, FMINP, or FMINV.

Note

Treewise reduction instructions might be executed and counted as multiple pairwise operations.

0x8432, **SVE_FP_PREDUCE_SPEC, Floating-point operation speculatively executed, SVE pairwise add step or pairwise reduce step**

The counter counts each [speculatively executed](#) floating-point pairwise add step or pairwise reduce step operation counted by [SVE_FP_VREDUCE_SPEC](#) due to any of the following instructions:

0x8434, **DSNP_HITM_N1_RD, Snoop hit in cache at distance 1, demand data read, modified**

The counter counts each snoop generated by the PE in response to a demand [Memory-read operation](#) counted by [DSNP_HIT_N1_RD](#) that accesses a previously modified cache location.

0x8435, **DSNP_HITM_N2_RD, Snoop hit in cache at distance 2, demand data read, modified**

The counter counts each snoop generated by the PE in response to a demand [Memory-read operation](#) counted by [DSNP_HIT_N2_RD](#) that accesses a previously modified cache location.

0x8436, **DSNP_HITM_N3_RD, Snoop hit in cache at distance 3, demand data read, modified**

The counter counts each snoop generated by the PE in response to a demand [Memory-read operation](#) counted by [DSNP_HIT_N3_RD](#) that accesses a previously modified cache location.

0x8437, **DSNP_HITM_N4_RD, Snoop hit in cache at distance 4, demand data read, modified**

The counter counts each snoop generated by the PE in response to a demand [Memory-read operation](#) counted by [DSNP_HIT_N4_RD](#) that accesses a previously modified cache location.

0x8438, **DSNP_HITM_N1_WR, Snoop hit in cache at distance 1, demand data write, modified**

The counter counts each snoop generated by the PE in response to a demand [Memory-write operation](#) counted by [DSNP_HIT_N1_WR](#) that accesses a previously modified cache location.

0x8439, **DSNP_HITM_N2_WR, Snoop hit in cache at distance 2, demand data write, modified**

The counter counts each snoop generated by the PE in response to a demand [Memory-write operation](#) counted by [DSNP_HIT_N2_WR](#) that accesses a previously modified cache location.

0x843A, **DSNP_HITM_N3_WR, Snoop hit in cache at distance 3, demand data write, modified**

The counter counts each snoop generated by the PE in response to a demand [Memory-write operation](#) counted by [DSNP_HIT_N3_WR](#) that accesses a previously modified cache location.

0x843B, **DSNP_HITM_N4_WR, Snoop hit in cache at distance 4, demand data write, modified**

The counter counts each snoop generated by the PE in response to a demand [Memory-write operation](#) counted by [DSNP_HIT_N4_WR](#) that accesses a previously modified cache location.

0x843C, **DSNP_HITM_N1_RW, Snoop hit in cache at distance 1, demand data access, modified**

The counter counts each snoop generated by the PE in response to a demand [Memory-read operation](#) or demand [Memory-write operation](#) counted by [DSNP_HIT_N1_RW](#) that accesses a previously modified cache location.

0x843D, **DSNP_HITM_N2_RW, Snoop hit in cache at distance 2, demand data access, modified**

The counter counts each snoop generated by the PE in response to a demand [Memory-read operation](#) or demand [Memory-write operation](#) counted by [DSNP_HIT_N2_RW](#) that accesses a previously modified cache location.

0x843E, **DSNP_HITM_N3_RW, Snoop hit in cache at distance 3, demand data access, modified**

The counter counts each snoop generated by the PE in response to a demand [Memory-read operation](#) or demand [Memory-write operation](#) counted by [DSNP_HIT_N3_RW](#) that accesses a previously modified cache location.

0x843F, **DSNP_HITM_N4_RW, Snoop hit in cache at distance 4, demand data access, modified**

The counter counts each snoop generated by the PE in response to a demand [Memory-read operation](#) or demand [Memory-write operation](#) counted by [DSNP_HIT_N4_RW](#) that accesses a previously modified cache location.

0x8440, **ASE_FP_SP_MIN_SPEC, Advanced SIMD data processing operation speculatively executed, smallest type is single-precision floating-point**

The counter counts each Advanced SIMD data-processing operation counted by [ASE_SVE_FP_SP_MIN_SPEC](#) due to an instruction where the smallest type was single-precision floating-point.

0x8442, **ASE_FP_HP_MIN_SPEC, Advanced SIMD data processing operation speculatively executed, smallest type is half-precision floating-point**

The counter counts each Advanced SIMD data-processing operation counted by [ASE_SVE_FP_HP_MIN_SPEC](#) due to an instruction where the smallest type was half-precision floating-point.

0x8443, **ASE_FP_BF16_MIN_SPEC, Advanced SIMD data processing operation speculatively executed, smallest type is BFloat16 floating-point**

The counter counts each Advanced SIMD data-processing operation counted by [ASE_SVE_FP_BF16_MIN_SPEC](#) due to an instruction where the smallest type was BFloat16 floating-point.

0x8444, **ASE_FP_FP8_MIN_SPEC, Advanced SIMD data processing operation speculatively executed, smallest type is 8-bit floating-point**

The counter counts each Advanced SIMD data-processing operation counted by [ASE_SVE_FP_FP8_MIN_SPEC](#) due to an instruction where the smallest type was 8-bit floating-point.

0x8448, **ASE_SVE_FP_SP_MIN_SPEC, Advanced SIMD data processing or SVE data processing operation speculatively executed, smallest type is single-precision floating-point**

The counter counts each Advanced SIMD or SVE data-processing operation counted by [SE_FP_SP_MIN_SPEC](#) due to an instruction where the smallest type was single-precision floating-point.

0x844A, **ASE_SVE_FP_HP_MIN_SPEC, Advanced SIMD data processing or SVE data processing operation speculatively executed, smallest type is half-precision floating-point**

The counter counts each Advanced SIMD or SVE data-processing operation counted by [SE_FP_HP_MIN_SPEC](#) due to an instruction where the smallest type was half-precision floating-point.

0x844B, **ASE_SVE_FP_BF16_MIN_SPEC, Advanced SIMD data processing or SVE data processing operation speculatively executed, smallest type is BFloat16 floating-point**

The counter counts each Advanced SIMD or SVE data-processing operation counted by [SE_FP_BF16_MIN_SPEC](#) due to an instruction where the smallest type was BFloat16 floating-point.

0x844C, **ASE_SVE_FP_FP8_MIN_SPEC, Advanced SIMD data processing or SVE data processing operation speculatively executed, smallest type is 8-bit floating-point**

The counter counts each Advanced SIMD or SVE data-processing operation counted by [SE_FP_FP8_MIN_SPEC](#) due to an instruction where the smallest type was 8-bit floating-point.

0x8450, **SE_FP_SP_MIN_SPEC, Advanced SIMD, SVE, or SME data processing operation speculatively executed, smallest type is single-precision floating-point**

The counter counts each Advanced SIMD, SVE, or SME data processing operation counted by [FP_SP_MIN_SPEC](#) due to an instruction where the smallest type was single-precision floating-point.

0x8452, **SE_FP_HP_MIN_SPEC, Advanced SIMD, SVE, or SME data processing operation speculatively executed, smallest type is half-precision floating-point**

The counter counts each Advanced SIMD, SVE, or SME data processing operation counted by [FP_HP_MIN_SPEC](#) due to an instruction where the smallest type was half-precision floating-point.

0x8453, **SE_FP_BF16_MIN_SPEC, Advanced SIMD, SVE, or SME data processing operation speculatively executed, smallest type is BFloat16 floating-point**

The counter counts each Advanced SIMD, SVE, or SME data processing operation counted by [FP_BF16_MIN_SPEC](#) due to an instruction where the smallest type was BFloat16 floating-point.

0x8454, **SE_FP_FP8_MIN_SPEC, Advanced SIMD, SVE, or SME data processing operation speculatively executed, smallest type is 8-bit floating-point**

The counter counts each Advanced SIMD, SVE, or SME data processing operation counted by [FP_FP8_MIN_SPEC](#) due to an instruction where the smallest type was 8-bit floating-point.

0x8458, **SME_FP_SP_MIN_SPEC, SME data processing operation speculatively executed, smallest type is single-precision floating-point**

The counter counts each SME data-processing operation counted by [SE_FP_SP_MIN_SPEC](#) due to an instruction where the smallest type was single-precision floating-point.

0x845A, **SME_FP_HP_MIN_SPEC, SME data processing operation speculatively executed, smallest type is half-precision floating-point**

The counter counts each SME data-processing operation counted by [SE_FP_HP_MIN_SPEC](#) due to an instruction where the smallest type was half-precision floating-point.

0x845B, **SME_FP_BF16_MIN_SPEC, SME data processing operation speculatively executed, smallest type is BFloat16 floating-point**

The counter counts each SME data-processing operation counted by [SE_FP_BF16_MIN_SPEC](#) due to an instruction where the smallest type was BFloat16 floating-point.

0x845C, **SME_FP_FP8_MIN_SPEC, SME data processing operation speculatively executed, smallest type is 8-bit floating-point**

The counter counts each SME data-processing operation counted by [SE_FP_FP8_MIN_SPEC](#) due to an instruction where the smallest type was 8-bit floating-point.

0x8460, **SVE_FP_SP_MIN_SPEC, SVE data processing operation speculatively executed, smallest type is single-precision floating-point**

The counter counts each SVE data-processing operation counted by [ASE_SVE_FP_SP_MIN_SPEC](#) due to an instruction where the smallest type was single-precision floating-point.

0x8462, **SVE_FP_HP_MIN_SPEC, SVE data processing operation speculatively executed, smallest type is half-precision floating-point**

The counter counts each SVE data-processing operation counted by [ASE_SVE_FP_HP_MIN_SPEC](#) due to an instruction where the smallest type was half-precision floating-point.

0x8463, **SVE_FP_BF16_MIN_SPEC, SVE data processing operation speculatively executed, smallest type is BFloat16 floating-point**

The counter counts each SVE data-processing operation counted by [ASE_SVE_FP_BF16_MIN_SPEC](#) due to an instruction where the smallest type was BFloat16 floating-point.

0x8464, **SVE_FP_FP8_MIN_SPEC, SVE data processing operation speculatively executed, smallest type is 8-bit floating-point**

The counter counts each SVE data-processing operation counted by [ASE_SVE_FP_FP8_MIN_SPEC](#) due to an instruction where the smallest type was 8-bit floating-point.

0x846B, FP_BF16_FIXED_OPS_SPEC, Non-scalable element arithmetic operations speculatively executed, largest type is BFloat16 floating-point

The counter increments by v for each [speculatively executed](#) non-scalable element arithmetic operation, due to an instruction where the largest type was BFloat16 floating-point.

Where v is the number of arithmetic operations carried out by the operation or instruction which causes the counter to increment.

The counter does not count operations that are counted by FP_SCALE_OPS_SPEC.

0x8470, FP_SP_MIN_SPEC, Floating-point operation speculatively executed, smallest type is single-precision floating-point

The counter counts each floating-point operation counted by [FP_SPEC](#) due to an instruction where the smallest type was single-precision floating-point.

0x8472, FP_HP_MIN_SPEC, Floating-point operation speculatively executed, smallest type is half-precision floating-point

The counter counts each floating-point operation counted by [FP_SPEC](#) due to an instruction where the smallest type was half-precision floating-point.

0x8473, FP_BF16_MIN_SPEC, Floating-point operation speculatively executed, smallest type is BFloat16 floating-point

The counter counts each floating-point operation counted by [FP_SPEC](#) due to an instruction where the smallest type was BFloat16 floating-point.

0x8474, FP_FP8_MIN_SPEC, Floating-point operation speculatively executed, smallest type is 8-bit floating-point

The counter counts each floating-point operation counted by [FP_SPEC](#) due to an instruction where the smallest type was 8-bit floating-point.

0x8480, FP_SP_FIXED_MIN_OPS_SPEC, Non-scalable element arithmetic operations speculatively executed, smallest type is single-precision floating-point

The counter increments by v for each [speculatively executed](#) non-scalable element arithmetic operation, due to an instruction where the smallest type was single-precision floating-point.

Where v is the number of arithmetic operations carried out by the operation or instruction which causes the counter to increment.

The counter does not count operations that are counted by FP_SCALE_OPS_SPEC.

0x8482, FP_HP_FIXED_MIN_OPS_SPEC, Non-scalable element arithmetic operations speculatively executed, smallest type is half-precision floating-point

The counter increments by v for each [speculatively executed](#) non-scalable element arithmetic operation, due to an instruction where the smallest type was half-precision floating-point.

Where v is the number of arithmetic operations carried out by the operation or instruction which causes the counter to increment.

The counter does not count operations that are counted by FP_SCALE_OPS_SPEC.

0x8483, FP_BF16_FIXED_MIN_OPS_SPEC, Non-scalable element arithmetic operations speculatively executed, smallest type is BFloat16 floating-point

The counter increments by v for each **speculatively executed** non-scalable element arithmetic operation, due to an instruction where the smallest type was BFloat16 floating-point.

Where v is the number of arithmetic operations carried out by the operation or instruction which causes the counter to increment.

The counter does not count operations that are counted by FP_SCALE_OPS_SPEC.

0x8484, FP_FP8_FIXED_MIN_OPS_SPEC, Non-scalable element arithmetic operations speculatively executed, smallest type is 8-bit floating-point

The counter increments by v for each **speculatively executed** non-scalable element arithmetic operation, due to an instruction where the smallest type was 8-bit floating-point.

Where v is the number of arithmetic operations carried out by the operation or instruction which causes the counter to increment.

The counter does not count operations that are counted by FP_SCALE_OPS_SPEC.

D9.4 Cycle event counting

The `CPU_CYCLES` event and the cycle counter, `PMCCNTR_EL0`, count cycles. The duration of a cycle is subject to any changes in clock frequency, including clock stopping caused by the WFI and WFE instructions.

It is IMPLEMENTATION SPECIFIC whether `CPU_CYCLES` and `PMCCNTR_EL0` count when the PE is in WFI or WFE state, even if the clocks are not stopped.

In addition, events such as `STALL`, `STALL_FRONTEND` and `STALL_BACKEND` that are defined to only count cycles that are counted by the `CPU_CYCLES` event have the same limitation.

D9.4.1 Cycle event counting in multithreaded implementations

Multithreaded implementations can have various forms, some examples of these are:

- *Simultaneous Multithreading* (SMT), where every PE thread is active on every [Processor cycle](#).
- *Fine-grained Multithreading* (FGMT), also known as a Barrel processor, where one PE thread is active on each [Processor cycle](#), and this changes regularly.
- *Switch on Event Multithreading* (SoEMT), also known as *Coarse-grained Multithreading* (CGMT), where high latency events cause the processor to switch the active PE thread.

In the above examples, active means that the PE might execute the instructions. A PE can be active but not executing instructions when no instruction is available or because of limited execution resources.

It is IMPLEMENTATION SPECIFIC whether a thread is active when the thread is in WFE or WFI state. This applies for all forms of multithreaded implementation.

When the PMU implementation supports multithreading, the [Effective value](#) of `PMEVTYPEPER<n>_EL0.MT` bit is 0, and the thread is not in WFE or WFI state, the `CPU_CYCLES` event only counts [Processor cycles](#) when the thread is active. For the example multithreaded implementations, this means that, if the event counter is enabled, event counting is not prohibited, and the thread is not in WFE or WFI state:

- For an SMT implementation, the `CPU_CYCLES` event counts every [Processor cycle](#).
- For a particular FGMT implementation, that alternates between two threads on each [Processor cycle](#), the `CPU_CYCLES` event counts every other [Processor cycle](#).
- For a particular SoEMT implementation, that is waiting for a long latency operation, the `CPU_CYCLES` event does not count [Processor cycles](#), as the PE thread is not active.

It is IMPLEMENTATION SPECIFIC whether `CPU_CYCLES` event counts [Processor cycles](#) when the [Effective value](#) of `PMEVTYPEPER<n>_EL0.MT` bit is 0, the thread is active, and the thread is in WFE or WFI state.

If the [Effective value](#) of `PMEVTYPEPER<n>_EL0.MT` bit is 1 and at least one thread is not in WFE or WFI state, then the `CPU_CYCLES` event counts each [Processor cycle](#), and can only count a maximum of one for each [Processor cycle](#).

If the [Effective value](#) of `PMEVTYPEPER<n>_EL0.MT` bit is 1, then all of the following apply for events that count PE cycles when a condition applies:

- The event does not count [Processor cycles](#) when all threads are in WFE or WFI state.
- If the event counts PE cycles when a stall condition is true and a second condition is true, then the counter counts [Processor cycles](#) when the stall condition is true for all of these PEs, and the second condition is true for any of these PEs.
- If the event counts PE cycles when any other condition is true, then the counter counts [Processor cycle](#) when the condition is true for any of these PEs.
- Otherwise, the event counts by the sum of the count across all of these PEs.

For the stall events, the stall condition means the applicable condition described by the `STALL`, `STALL_FRONTEND`, or `STALL_BACKEND` event. The second condition is any condition in addition to this. For example, for the `STALL_FRONTEND_L1I` event, the stall condition is `STALL_FRONTEND`, and the second condition is when there is a demand instruction miss in the first level of instruction cache. For the `STALL`, `STALL_FRONTEND`, and `STALL_BACKEND` events themselves, the second condition is the null TRUE condition.

Note

The cycle counter, [PMCCNTR_EL0](#), is not affected by whether the thread is active or inactive. When enabled, [PMCCNTR_EL0](#) counts every processor cycle.

D9.4.2 Time as measured by the Performance Monitors cycle counter

The Performance Monitors cycle counter, accessed through [PMCCNTR_EL0](#) increments from the hardware processor clock, not PE clock cycles.

The relationship between the count recorded by the Performance Monitors cycle counter and the passage of real time is IMPLEMENTATION DEFINED.

See [Controlling the PMU counters](#) for information about when the cycle counter does not increment.

Note

- This means that, in an implementation where PEs are multithreaded, when enabled, the cycle counter continues to increment across all PEs, rather than only counting cycles for which the current PE is active.
- Although the architecture requires that direct reads of [PMCCNTR_EL0](#) occur in program order, there is no requirement that the count increments between two such reads. Even when the counter is incrementing on every clock cycle, software might need check that the difference between two reads of the counter is nonzero.

The architecture requires that an indirect write to the [PMCCNTR_EL0](#) is observable to direct reads of the register in finite time. The counter increments from the hardware processor clock are indirect writes to these registers.

D9.5 Meaningful combinations of common events

The meaningful combinations listed in this section comprise a numerator event and a denominator event.

In many cases, the definition of the numerator event, <EVENT_NUMERATOR>, is defined such that it counts each event <X> counted by the denominator event, <EVENT_DENOMINATOR>, when some condition <COND> is true.

This means that there is a meaningful ratio between between <EVENT_NUMERATOR> and <EVENT_DENOMINATOR> that describes the proportion of <X> counted by <EVENT_DENOMINATOR> for which <COND> applies.

This does not mean that there is a requirement that if <EVENT_NUMERATOR> is implemented that <EVENT_DENOMINATOR> is also implemented.

A *meaningful combination* means that any microarchitectural conditions that affect the counting of events apply equally to all the events. This typically means that they are counted at the same place in the pipeline, so that, for example, they are equally affected by pipeline flushes to discard speculatively executed operations following a mispredicted branch.

The following tables list the highlighted combinations:

- [Table D9-4](#), REFILL events and associated access events.
- [Table D9-5](#), Meaningful combinations of latency events.
- [Table D9-6](#), Cache hit events and associated data source events.
- [Table D9-7](#), Meaningful combinations of cache line state tracking events.
- [Table D9-8](#), Meaningful combinations of TLB events.

D9.5.1 Refill events and associated access events

IGSMLS

The following are meaningful combinations of refill events and associated access events:

Table D9-4 Meaningful combinations of refill events and associated access events

Numerator	Denominator	Ratio
0x0001 L1I_CACHE_REFILL	0x0014 L1I_CACHE	Attributable Level 1 instruction cache refill rate
0x0002 L1I_TLB_REFILL	0x0026 L1I_TLB	Attributable Level 1 instruction TLB refill rate
0x0003 L1D_CACHE_REFILL	0x0004 L1D_CACHE	Attributable Level 1 data or unified cache refill rate
0x0005 L1D_TLB_REFILL	0x0025 L1D_TLB	Attributable Level 1 data or unified TLB refill rate
0x0017 L2D_CACHE_REFILL	0x0016 L2D_CACHE	Attributable Level 2 data or unified cache refill rate
0x0028 L2I_CACHE_REFILL	0x0027 L2I_CACHE	Attributable Level 2 instruction cache refill rate

0x00A3 L3D_CACHE_REFILL_WR	0x00A1 L3D_CACHE_WR	Attributable Level 3 data cache refill rate, write

D9.5.2 Latency events

I_{ZHFDC} The following are meaningful combination of latency events:

Table D9-5 Meaningful combinations of latency events

Numerator	Denominator	Ratio
0x8120 INST_FETCH_PERCYC	0x8124 INST_FETCH	Mean duration of instruction fetch events in processor cycles
0x8121 MEM_ACCESS_RD_PERCYC	0x0066 MEM_ACCESS_RD	Mean duration of memory read access events in processor cycles
0x8125, BUS_REQ_RD_PERCYC	0x818D, BUS_REQ_RD	Bus read transaction average latency
0x8128 DTLB_WALK_PERCYC	0x0034 DTLB_WALK	Mean duration of data or unified TLB walk events in processor cycles
0x8129 ITLB_WALK_PERCYC	0x0035 ITLB_WALK	Mean duration of instruction TLB walk events in processor cycles
0x8320, L1D_CACHE_REFILL_PERCYC	0x0003, L1D_CACHE_REFILL	Level 1 data cache refill average duration

D9.5.3 Cache hit events and associated data source events

I_{HMZQY} The following are meaningful combination of cache hit events:

Table D9-6 Meaningful combinations of cache hit events and associated data source events

Numerator	Denominator	Ratio
0x820C, L1D_CACHE_HIT_PRFM ^a	0x8142, L1D_CACHE_PRFM ^a	Level 1 data or unified cache software prefetch hit ratio ^a
0x81CC, L1D_CACHE_HIT_RW ^a	0x82A0, MEM_ACCESS_RW	Level 1 data or unified cache demand cache hit rate ^a
0x81CF, LL_CACHE_HIT_RW	0x82A0, MEM_ACCESS_RW	Last level cache demand cache hit rate

Numerator	Denominator	Ratio
0x8232, LOCAL_MEM_RW	0x82A0, MEM_ACCESS_RW	Local memory demand access rate
0x823B, REMOTE_MEM_RW	0x82A0, MEM_ACCESS_RW	Remote memory demand access rate
0x821D, L2D_CACHE_HITM_RW ^a	0x81CD, L2D_CACHE_HIT_RW ^a	Level 2 data or unified cache demand cache hit rate ^a

a. Similar ratios can be defined for other caches.

D9.5.4 Cache line state tracking events

I_{LGBBR}

The following are meaningful combination of cache line stake tracking events:

Table D9-7 Meaningful combinations of cache line state tracking events

Ratio	Meaning
$1 - (0x81EC, L1D_CACHE_HIT_RW_FWPRF \div 0x8154, L1D_CACHE_HWPRF)^a$	Level 1 data or unified cache data fetched by hardware prefetcher not used ^a
$1 - (0x81DC, L1D_CACHE_HIT_RW_FPRFM \div 0x8142, L1D_CACHE_PRFM)^a$	Level 1 data or unified cache data fetched by software prefetch not used ^a
$0x825C, L1D_LFB_HIT_RW_FPRFM \div 0x8142, L1D_CACHE_PRFM^a$	Level 1 data or unified cache data fetched late by software prefetch ^a

a. Similar ratios can be defined for other caches.

D9.5.5 TLB events

I_{PHZQV}

The following are meaningful combination of TLB events:

Table D9-8 Meaningful combinations of TLB events

Numerator	Denominator	Ratio
0x8188, DTLB_WALK_BLOCK ^a	0x0034, DTLB_WALK ^a	Data TLB block translation table walk fraction ^a
0x818A, DTLB_WALK_PAGE ^a	0x0034, DTLB_WALK ^a	Data TLB page translation table walk fraction ^a

a. Similar ratios can be defined for instruction TLB accesses.

D9.5.6 At-retirement events

I_{CYQZJ}

The following are meaningful combinations of at-retirement events:

Table D9-9 Meaningful combinations of at-retirement events

Numerator	Denominator	Ratio
0x82B0, L1I_CACHE_HIT_RETIRED	0x0008, INST_RETIRED	Architecturally executed instruction hit Level 1 instruction cache
0x82E0, L2I_CACHE_MISS_RETIRED	0x0008, INST_RETIRED	Architecturally executed instruction missed Level 2 instruction cache
0x82EC, L1D_CACHE_HIT_LDST_RETIRED	0x0008, INST_RETIRED	Architecturally executed load or store instruction hit in Level 1 data cache
0x82C9, L2D_CACHE_HITM_ST_RETIRED	0x0008, INST_RETIRED	Architecturally executed store instruction hit modified data in Level 2 data cache
0x82B7, LL_CACHE_MISS_LD_RETIRED	0x0008, INST_RETIRED	Architecturally executed load instruction missed in Last level cache
0x82F0, ITLB_HIT_RETIRED	0x0008, INST_RETIRED	Architecturally executed instruction which hit in the ITLB
0x82F7, DTLB_WALK_LDST_RETIRED	0x82AA, LDST_ANY_RETIRED	Architecturally executed LDST instructions DTLB miss fraction
0x82AF, CRYPTO_RETIRED	0x0008, INST_RETIRED	Architecturally executed cryptographic data processing fraction

D9.5.7 Speculatively executed operation events

I_{RDHPB}

The number of speculatively executed operations performed on individual scalar values can be determined from a pair of event counters. Combined multiply-add and multiply-subtract instructions are counted as two operations per element.

Table D9-10 Meaningful combinations of speculatively executed operation events

Ratio	Meaning
0x80C0, FP_SCALE_OPS_SPEC $\times$ VL $\div$ 128 + 0x80C1, FP_FIXED_OPS_SPEC	Total number of individual floating-point operations (any precision) performed
0x80C2, FP_HP_SCALE_OPS_SPEC $\times$ VL $\div$ 128 + 0x80C3, FP_HP_FIXED_OPS_SPEC	Total number of individual half-precision floating-point operations performed
0x80C4, FP_SP_SCALE_OPS_SPEC $\times$ VL $\div$ 128 + 0x80C5, FP_SP_FIXED_OPS_SPEC	Total number of individual single-precision floating-point operations performed
0x80C6, FP_DP_SCALE_OPS_SPEC $\times$ VL $\div$ 128 + 0x80C7, FP_DP_FIXED_OPS_SPEC	Total number of individual double-precision floating-point operations performed
0x80C8, INT_SCALE_OPS_SPEC $\times$ VL $\div$ 128 + 0x80C9, INT_FIXED_OPS_SPEC	Total number of individual integer operations performed
0x80CA, LDST_SCALE_OPS_SPEC $\times$ VL $\div$ 128 + 0x80CB, LDST_FIXED_OPS_SPEC	Total number of individual load/store accesses performed
0x80CC, LD_SCALE_OPS_SPEC $\times$ VL $\div$ 128 + 0x80CD, LD_FIXED_OPS_SPEC	Total number of individual load accesses performed
0x80CE, ST_SCALE_OPS_SPEC $\times$ VL $\div$ 128 + 0x80CF, ST_FIXED_OPS_SPEC	Total number of individual store accesses performed

D9.6 Required events

When at least one event counter is implemented, the following common events are implemented:

- 0x0000, [SW_INCR](#), Instruction architecturally executed, Condition code check pass, software increment.
- 0x0011, [CPU_CYCLES](#), Cycle.
- When the PE includes a Level 1 data or unified cache:
 - 0x0003, [L1D_CACHE_REFILL](#), Level 1 data cache refill.
 - 0x0004, [L1D_CACHE](#), Level 1 data cache access.
- If the implementation includes program-flow prediction:
 - At least one of the following is implemented:
 - 0x0012, [BR_PRED](#), Predictable branch [Speculatively executed](#).
 - 0x0021, [BR_RETIRED](#), Instruction architecturally executed, branch.
 - At least one of the following is implemented:
 - 0x0010, [BR_MIS_PRED](#), Mispredicted or not predicted branch [Speculatively executed](#).
 - 0x0022, [BR_MIS_PRED_RETIRED](#), Branch instruction architecturally executed, mispredicted.
 - At least one of the following applies:
 - Both [BR_PRED](#) and [BR_MIS_PRED](#) are implemented.
 - Both [BR_RETIRED](#) and [BR_MIS_PRED_RETIRED](#) are implemented.

Note

Arm strongly recommends that both [BR_RETIRED](#) and [BR_MIS_PRED_RETIRED](#) are implemented. If the implementation does not include program-flow prediction, Arm recommends that these events are implemented as described in [Common microarchitectural events](#).

- At least one of:
 - 0x0008, [INST_RETIRED](#), Instruction architecturally executed.
 - 0x001B, [INST_SPEC](#), Operation [Speculatively executed](#).

Note

Arm strongly recommends that event 0x0008 is implemented.

- When [FEAT_PMUv3p1](#) is implemented:
 - 0x0023, [STALL_FRONTEND](#), No operation issued due to the frontend.
 - 0x0024, [STALL_BACKEND](#), No operation issued due to the backend.
- When [FEAT_PMUv3p4](#) is implemented:
 - 0x003C, [STALL](#), No operation sent for execution.
 - When the PE includes a Level 1 data or unified cache:
 - 0x0039, [L1D_CACHE_LMISS_RD](#), Level 1 data cache long-latency read miss.
 - 0x0040, [L1D_CACHE_RD](#), Level 1 data cache read.
 - When the PE includes a Level 1 instruction cache:
 - 0x4006, [L1I_CACHE_LMISS](#), Level 1 instruction cache long-latency miss.

When any of the following common events are implemented, all three of them are implemented:

- 0x003D, [STALL_SLOT_BACKEND](#), No operation sent for execution on a [Slot](#) due to the backend.
- 0x003E, [STALL_SLOT_FRONTEND](#), No operation sent for execution on a [Slot](#) due to the frontend.
- 0x003F, [STALL_SLOT](#), No operation sent for execution on a [Slot](#).

Arm strongly recommends that the following events are implemented:

- 0x003A, [OP_RETIRED](#).
- 0x003B, [OP_SPEC](#).
- 0x003D, [STALL_SLOT_BACKEND](#).
- 0x003E, [STALL_SLOT_FRONTEND](#).
- 0x003F, [STALL_SLOT](#).

D9.7 IMPLEMENTATION DEFINED event numbers

Arm recommends that implementers establish a standardized numbering scheme for their IMPLEMENTATION DEFINED events, with common definitions, and common event numbers, applied to all of their implementations. In general, the recommended approach is for standardization across implementations with common features. However, Arm recognizes that attempting to standardize the encoding of microarchitectural features across too wide a range of implementations is not productive.

The Arm architecture guarantees not to define any event prefixed with *IMP_* as part of the standard Arm architecture.

Arm strongly recommends that at least the following classes of event are identified in the IMPLEMENTATION DEFINED events:

- Separating each of the [STALL_FRONTEND](#) and [STALL_SLOT_FRONTEND](#) events to count holes in instruction availability.
- Separating each of the [STALL_BACKEND](#) and [STALL_SLOT_BACKEND](#) events, to count, for example, cumulative duration of stalls, unavailability of execution resources, or missed superscalar issue opportunities.
- Miss rates for additional levels of caches and TLBs.
- Any external events passed to the PE through an IMPLEMENTATION DEFINED mechanism.
- Cumulative duration of a [PSTATE](#). {A, I, F} interrupt mask set to 1.
- Cumulative occupancy for resource queues, such as data access queues, and entry/exit counts, so that average latencies can be determined, separating out counts for key resources that might exist. An implementation might also provide registers in the IMPLEMENTATION DEFINED space to further extend such counts, for example by specifying a minimum latency for an event to be counted.
- Any other microarchitectural features that the implementer considers are valuable to count.

The range of possible IMPLEMENTATION DEFINED event numbers is described in [The PMU event number space and common events](#).

It is not required that implementations document the behavior of all IMPLEMENTATION DEFINED PMU events, including which PMU event numbers are used for these IMPLEMENTATION DEFINED events. However, Arm strongly recommends that implementations do include and document IMPLEMENTATION DEFINED PMU events. In particular events related to microarchitectural characteristics of the implementation not covered by Common events.

Chapter D10

RAS PE Architecture

This chapter describes the RAS Extension PE Architecture. It contains the following sections:

- [About the RAS Extension](#)
- [PE error handling](#)
- [Generating error exceptions](#)
- [Taking error exceptions](#)
- [Error synchronization event](#)
- [Virtual SError exceptions and delegated SError exceptions](#)
- [Error records in the PE](#)

D10.1 About the RAS Extension

I _{LBKPL}	The RAS Extension extends the exception syndrome registers to include fields that allow the PE to report a PE error state when an Error exception is taken.
I _{THGHB}	The RAS Extension defines System registers that are specific to RAS, including to access optional Error records defined by the RAS System Architecture. The format of the error record registers is defined in Error record System register view .
R _{YWXL}	The RAS Extension does not prescribe the level of reliability, availability, and serviceability in the PE. The RAS features that the system and PE include, for example to detect, correct, contain, or defer errors, are IMPLEMENTATION DEFINED. The RAS Extension defines a framework for building RAS features in a PE.

Example D10-1 Common error handling for RAS features

For a system with a requirement for high reliability and error containment:

- When errors are detected, they are recorded in error records. This includes both correctable and uncorrectable errors. Error correction and detection logic exists on all significant memory structures, and might include other non-memory structures.
- Most uncorrectable errors generate poison values to defer the error.
- On consuming poison from the memory system, a load instruction that would corrupt PE state generates a synchronous External Abort exception, regardless of the memory type.
- On taking error exceptions, the PE error state is [Recoverable state \(UER\)](#).

I _{QGLBZ}	See also <i>Arm® Reliability Availability and Serviceability (RAS) System Architecture, for A-profile architecture</i> (ARM IHI 0100) for more information about the framework for building RAS features in a system.
--------------------	---

D10.2 PE error handling

D10.2.1 PE error detection

I _{KRYQW}	When a PE accesses memory or other state, an error might be detected in that memory or state, and corrected, deferred, or signaled to the PE as a Detected error with an in-band error response. Note: • An error that is deferred might be signaled to the PE with an in-band error response. • An error might also be signaled to a PE by means other than an in-band error response.
I _{SLYLK}	The response from memory or other state is defined by Detecting and consuming errors. For more information, see <i>Arm[®] Reliability, Availability, and Serviceability (RAS) System Architecture, for A-profile architecture</i> (ARM IHI 0100).
I _{DWWQJ}	When an error is detected by a component on a read or a cache maintenance operation from the PE: • If the error can be corrected, it is corrected and corrected data is returned. • If the error cannot be corrected and can be deferred, it is deferred. For example, on a load by poisoning the PE state, if this is supported by the PE implementation. • If the error cannot be corrected and if implemented and enabled at the component, the Detected error is signaled to the PE as an in-band error response.
I _{BKVQP}	When an error is detected by a component consuming a write from the PE: • If the error can be corrected, it is corrected. • If the error cannot be corrected and can be deferred, it is deferred to the consumer. For example, by poisoning the location being written. • If the error cannot be corrected and if implemented and enabled at the component, the Detected error is signaled to the PE as an in-band error response.
I _{PDDNB}	The component might record the Detected error and generate a Fault handling interrupt and/or Error recovery interrupt.
I _{VRYYF}	If the component implements the RAS System Architecture, its behavior is defined by the RAS System Architecture, and depends on the nature of the error and IMPLEMENTATION DEFINED properties of the component. In each of these cases, the component might be a part of the processor, such as a cache, or might be outside of the processor. The component might also report the error to a RAS System Architecture node, which records the error and might generate one or more of a Fault handling interrupt, Error recovery interrupt, or Critical Error interrupt depending on the features and configuration of the node. See also Other errors.
I _{FLXTY}	An in-band error response is sometimes referred to as an <i>External abort</i>. To avoid confusion with the External abort <i>exception</i>, the RAS sections in this Manual use in-band error response to describe the response to the PE for a memory access. For more information, see <i>Arm[®] Reliability, Availability, and Serviceability (RAS) System Architecture, for A-profile architecture</i> (ARM IHI 0100).
R _{WLTPV}	The size of the protection granule for any implemented error detection mechanism in memory is IMPLEMENTATION DEFINED and might vary from moment to moment and instruction to instruction. For example, the size of the protection granule might depend on one or more of the following: • The physical address of the Location being accessed. • Whether a copy of the Location held in a cache is being accessed, and the cache it is held in. • The type of access being made. • If FEAT_SME is implemented, whether the PE is in Streaming SVE mode or is not in Streaming SVE mode.
I _{JJGW}	A system might implement multiple error detection mechanisms with differing protection granule sizes.
I _{YBRSM}	For a Deferred error, Clearing Deferred errors from poisoned Locations describes mechanisms to remove poison and clear the error. The architecture also permits IMPLEMENTATION DEFINED mechanisms for clearing an error or poison from memory.

D10.2.2 PE error propagation

I _{RPLQT}	The program-visible architectural state of the PE, referred to as the PE state, includes: • General-purpose and SIMD&FP registers. • System registers. • Special-purpose registers. • PSTATE.
R _{XMBNW}	An error is consumed by the PE by any of the following: • An instruction commits the corruption into the PE state. • The error is on an instruction fetch and the corrupt instruction is committed for execution. • The error is on a translation table walk for a committed load, store, or instruction fetch.
I _{HVFKW}	For a PE, Error propagation applies to the propagation of Detected error by the PE between the PE state, and any other PE state or memory. Note: <i>Memory</i> includes structures that cache the contents of memory, such as an instruction cache, data cache, or TLB.
R _{VGXBJ}	An error is propagated by the PE by one or more of the following occurring that would not have been permitted to occur had the fault not been activated: • Consumption of the corrupt value by any instruction, propagating the error to the target(s) of the instruction. This includes: — A store of a corrupt value. — A write of a corrupt value to a System register, Special-purpose register, or PSTATE. Infecting a System register state might mean that the PE generates transactions that would not otherwise be permitted. • Any operation occurring that should not have occurred, including: — A load, translation table walk, or instruction fetch that would not have been permitted, including those from hardware speculation or prefetching. — A store to an incorrect address, or a store that would not have been made or not permitted. — A direct or indirect write to a Special-purpose or System register that would not have been made or not permitted. — Assertion of any signal, such as an interrupt, that would not have been asserted. • Any operation not occurring that should have occurred. • Causing the PE to take an imprecise exception, other than an Error exception in response to the error itself. For more information, see Definition of a precise exception and imprecise exception. • The PE discarding data that it holds in a modified state. • Any other loss of required uniprocessor semantics, ordering, or coherency.
I _{RMZNK}	In R_{VGXBJ}, <i>not have been permitted to occur</i> means that the observable behavior of the PE is a deviation from the correct service of the PE, as defined by the architecture. Deviations from the normal behavior of the PE implementation that would otherwise be permitted by the architecture are not deviations from correct service.

Example D10-2

A PE takes an [Error exception](#) asynchronously as follows, in program order:

1. A load returns a corrupt value from a first location to a general-purpose register.
2. The PE suppresses a store of the register to a second memory location. In particular, the location is not updated and so retains its previous value.
3. The Error exception is taken.
4. At the point when the Error exception is taken, the ordering constraints imposed by the architecture have not been violated, in particular those relating to the observability of the store at step 2.

Although the error has not been propagated, the PE state is not consistent with the PE having executed all of the instructions up to the point when the Error exception is taken, and so it would be unlikely that software would be able to [recover execution](#).

R_{NQDWB}

An error [propagated by the PE](#) is silently propagated by the PE only if all of the following are true:

1. The propagation is not part of the required operation of the PE in taking an [Error exception](#) generated by the error.

2. The propagation is not part of the required operation of the PE executing an **ESB** instruction that **synchronizes** the error.
3. The error is not **signaled** to the consumer as a **Detected error** or **Deferred error**.
4. Any of the following are true:
 - The corrupt value is held in other than the general-purpose and SIMD&FP registers.
 - The error is propagated by an instruction in program order before either taking an **Error exception** generated by the error or executing an **ESB** instruction that **synchronizes** the error, and is propagated to outside of the general-purpose and SIMD&FP registers.
 - The error is propagated other than by an instruction that consumes the corrupt value as an input operand but otherwise behaves correctly.

I_{BRBFF}

In **R_{NQDWB}**, item 4 means that after taking the **Error exception** generated by the error, or an **ESB**, propagating an error by, for example, storing the corrupt value to memory, is not considered as silent propagation of the error by the PE.

Example D10-3

A PE takes an **Error exception** in response to a load that returns a corrupt value to a general-purpose register. The error is not silently propagated to outside of the general-purpose registers before the Error exception is taken.

Neither of the following are considered silent propagation of the error by the PE:

- Taking the Error exception causes the **ESR_ELx**, **ELR_ELx**, and **SPSR_ELx** registers to be updated. This is part of the required operation of the PE.
- After taking the Error exception, software stores the contents of the general-purpose register to memory, and this is not **signaled** to memory as a **Deferred error**. This happens in program order after the exception is taken.

The error is not silently propagated by the PE.

Example D10-4

Further to **Example D10-2**, if either of the following example additional operations occur between 2 and 3, then the PE has silently propagated the error:

- A second store to a third location is performed by the PE, and the architecture requires that the first store is ordered-before the second store. For example, the second store is a store-release operation. In this case, the PE violates the external ordering constraints for the two stores, and the error is silently propagated to any observer of the second store.
- A second load from the second location returns the previous value, and a second store writes that value to a third location. In this case, the PE violates the requirements of the **Coherence-before** relation because the second load cannot be Coherence-before the first store. The error silently propagates to any observer of the second store.

If instead of the PE suppressing the store at 2, the PE poisons the second memory location, and in the second example propagates that poison through the second load and second store, then the error is not silently propagated.

R_{DTRFQ}

The features that a PE includes to prevent silent propagation of an error are IMPLEMENTATION DEFINED.

Example D10-5

An implementation ensures that a corrupt value in a general-purpose or SIMD&FP register is not silently propagated, by **signaling** a **Deferred error** on any write of data to any memory location, such that the memory location is **poisoned**.

D10.2.3 Clearing Deferred errors from poisoned Locations

D10.2.3.1 Poison-atomicity of Memory Write Effects

D_{YQQLJ}

A Memory Write Effect is *poison-atomic* if the Memory Write Effect removes a **Deferred error (poison)** at all Locations written to by the Memory Write Effect.

R _{XVFDG}	For each store instruction with Explicit Memory Write Effects, it is IMPLEMENTATION DEFINED whether the Memory Write Effects are poison-atomic for a region of physical memory. This includes the DC ZVA and/or DC GZVA instructions.
R _{QSBKL}	If a Location in a region of physical memory supports the poison-atomic property for a store instruction, then all Locations in the same naturally-aligned region support this for the same store instruction, where the size of the region is the largest translation granule that the PE supports.
I _{CSJLP}	Support for the poison-atomic property for a store instruction is a property of both the PE as well as the system. That is, if the system includes a PE that supports the poison-atomic property for the instruction, then both the PE and the system support this instruction such that it is guaranteed to be poison-atomic. For example, the system should not split cache line writes of data to be smaller than the poison granule of the downstream component in order to preserve poison-atomicity of a DC {G}ZVA instruction.
I _{ZRSSM}	There is no architected means to discover the poison-atomic property for DC ZVA or DC GZVA for any region of physical memory.
I _{NXNTY}	When a Memory Write Effect to a Location is not poison-atomic, the Memory Write Effect propagates a Deferred error previously at the Location to the new value being written.

Example D10-6

A region of physical memory uses Error Correction Codes (ECC) to provide error detection and correction. The [protection granule](#) for this region of memory is the size of a range covered by a single ECC. The ECC is also used to encode a [poison](#) value. This means the [poison granule](#) is the same size as the [protection granule](#), for this region of physical memory.

A write that is smaller than the [protection granule](#) to this region of physical memory must read the [protection granule](#) containing the Location being written in order to calculate a new ECC for the [protection granule](#). If the [protection granule](#) contains [poison](#), then a [poisoned](#) value is written back, meaning the write is not poison-atomic.

If a write overwrites the entire [protection granule](#), then the system can calculate a new ECC for the [protection granule](#) without reading the previous contents, meaning the write can be poison-atomic.

I _{GLFCV}	A system might require software to stop using the protection granule until the Deferred error can be removed. For example, by not using the physical page containing the granule until the system is reset. The architecture does not set any limit on the size of a protection granule , and it might be larger than a translation granule.
I _{HPJFI}	The size of the poison granule is IMPLEMENTATION DEFINED and might vary from moment to moment, instruction to instruction, and by Location. The size of the poison granule might be the same as the size of the protection granule , but this is not guaranteed. See also RWLTPV .
I _{CBCMK}	The regions of physical memory that support the poison-atomic property are IMPLEMENTATION DEFINED. Systems might have multiple physical memory types, including multiple physical memory regions used for bulk memory.

D10.2.3.2 Removing poison

I _{VZRKL}	For guidance on mechanisms that software can use to remove poison from a Location, see Use of the RAS Extension.
I _{PSLGW}	In order to test that poison has been removed from a Location, after the Location has been overwritten by a known-good value, software must be able to read back the Location from physical memory to check that the poison has been removed and the error is not persistent. To do this, software must ensure that the Location has been cleaned and invalidated from all caches, so that the read returns a value from the Point of Physical Storage for the Location, and not any intermediate cache. The Point of Coherency might be before a transparent unified cache, meaning that it might be before the Point of Physical Storage for a Location. For more information on the Point of Physical Storage, see A64 Cache maintenance instructions .

D10.2.4 Other errors

I_{KRQMR}

The RAS Extension deals mostly with errors detected by components outside of the PE, such as memory, and [consumed by the PE](#).

Other errors might be detected from within the processor that implements the PE. If the error is not an error in the [PE state](#) then the error might be treated as an error detected by another component.

In the following examples, the *component* reports these errors to a RAS System Architecture node that implements Error records and records the errors, and might generate one or more of a Fault handling interrupt, Error recovery interrupt, or Critical Error interrupt depending on the features and configuration of the node.

Example D10-7

A processor cache can be treated as a component outside the PE.

The cache detects an error in the cache state that cannot be [corrected](#):

- If the error is detected in dirty cache data being evicted from the cache when the PE makes an access, then the error might be [deferred](#) by the cache writing [poison](#) in the evicted cache data.
- If the PE is performing a partial write that does not completely overwrite the protection granule, then the error might be [deferred](#) by the cache writing [poisoned](#) to the cache location, and/or evicting the cache line with [poison](#). Deferring the error means the error is not [consumed by the PE](#).

Otherwise, the cache component generates the [in-band error response](#) to the PE.

Example D10-8

A processor memory interface can be treated as a component outside the PE.

A processor detects a [corrupt](#) or [poisoned](#) value being returned on the interface that is not being [signaled](#) as an [in-band error response](#) and cannot be [corrected](#) or [deferred](#). For example, in response to a non-cacheable read or a cache refill.

The memory interface component generates the [in-band error response](#) to the PE.

I_{VNTWD}

An implementation might include error detection logic within the [PE state](#) itself. When the PE detects an error in the [PE state](#), the instruction that uses that state [consumes the error](#), and the PE generates an IMPLEMENTATION DEFINED [Error exception](#), taken as an SError exception. See [R_{FNVVJ}](#).

In this case, the processor that implements the PE includes a RAS System Architecture node that implements Error records that record these errors.

I_{JRQDM}

An implementation might support poisoning within the [PE state](#). When the PE consumes a [Deferred error](#), for example a [poisoned](#) value, from memory into the [PE state](#), the [PE state](#) becomes poisoned. Subsequent operations that read the poisoned value can continue to defer the error by poisoning the result of the operation.

However, if the PE attempts to execute an operation that reads the poisoned value and cannot defer the error further, the PE generates an IMPLEMENTATION DEFINED [Error exception](#), taken as an SError exception. See [R_{FNVVJ}](#).

In this case, the processor that implements the PE includes a RAS System Architecture node that implements Error records that record these errors.

I_{JHQVK}

Components outside of the PE might detect errors that are not [consumed by the PE](#). These components might report such errors to a PE using Error recovery interrupts.

I_{MJQQZ}

Errors from software faults are outside the scope of the RAS Extension. For more information, see *Arm® Reliability, Availability, and Serviceability (RAS) System Architecture, for A-profile architecture* (ARM IHI 0100).

D10.3 Generating error exceptions

R_VJRK_F	An Error exception is generated when a detected error is signaled to the PE as an in-band error response to an architecturally-executed memory access or cache maintenance operation. This includes any explicit data access, instruction fetch, translation table walk, or hardware update to the translation tables made by an architecturally-executed instruction.
I_PJHZ_S	An Error exception is taken as an asynchronous SError exception, a synchronous External Data Abort exception, or a synchronous External Instruction Abort exception.
R_MBNBH	It is IMPLEMENTATION DEFINED whether an Error exception can be generated for an error that is consumed by hardware speculation or prefetching by a PE, but that is not committed to the architecturally visible state of the PE.
R_SHKJB	It is IMPLEMENTATION DEFINED whether an Error exception can be generated for a detected error that is deferred .
R_GVWJD	It is IMPLEMENTATION DEFINED whether an Error exception can be generated for a detected error that is corrected .
R_FNVVJ	An Error exception can also be generated for IMPLEMENTATION DEFINED causes. An Error exception generated for an IMPLEMENTATION DEFINED cause is taken as an SError exception.

Example D10-9

An error is detected and neither [corrected](#) nor [deferred](#) to the PE, and [signaled](#) to the PE by means other than an [in-band error response](#), such as a wired SError exception pin. Asserting the SError exception pin causes the PE to generate an SError exception.

Example D10-10

An error is detected by the PE in the [PE state](#), or in the result of a calculation performed by the PE. The detected error generates an SError exception.

I_ZXHDP

See also:

- [Exceptions](#).
- [Taking error exceptions](#).

D10.4 Taking error exceptions

RPKGLV	For an error signaled on a non-speculative instruction fetch or a translation table walk or hardware update of translation tables, it is IMPLEMENTATION DEFINED whether an Error exception on these accesses is taken as a synchronous External Abort exception or as an asynchronous SError exception.
IYRSKT	For an error signaled on a fetch of GPT information to check an access, the Error exception generates a synchronous External abort on GPT fetch, which is taken as a GPC exception. For more information see GPC faults.
RVLFPT	Unless otherwise stated, it is IMPLEMENTATION DEFINED whether an Error exception is handled precisely and synchronously, or handled asynchronously for each non-speculative: • Explicit memory access made by an instruction. • Cache maintenance operation. • Translation table walk or hardware update of translation tables for a memory access made by an instruction.
DSRYHT	In this section, <i>Handled precisely and synchronously</i> means the error generates a precise synchronous Data Abort exception.
DTHFRY	In this section, <i>Handled asynchronously</i> means the error generates an asynchronous SError exception.
RCLFJM	All Error exceptions generated by speculative memory accesses are taken as an asynchronous SError exception.
RWFNJJ	When an Error exception is taken as an asynchronous SError exception, the exception is taken in finite time.
RBCXKN	When any of the following exceptions are taken, the PE records the PE error state in the exception syndrome register: • A synchronous External abort. • An SError exception.
IGGCQQ	The exception type and target Execution state determine the set of PE error state values the PE can record.
IWSYXB	The recorded PE error state informs software whether software can recover execution and, if so, whether any action by the recovery software to locate and repair the error is necessary first.
ITRWXF	Other than as described by IWBVYC , the PE error state recorded in the exception syndrome register describes the recovery of the PE state only. For example, the PE state might be recoverable when the state of system is such that system-level recovery is not possible. See also IZQRGL .
INFDSM	Software is only able to successfully recover execution and make progress from a restart address for the exception by executing an Exception Return instruction to branch to the instruction at this restart address if all of the following are true: • The error has not been silently propagated by the PE. • At the point when the Exception Return instruction is executed, the PE state and memory system state are consistent with the PE having executed all of the instructions up to but not including the instruction at the restart address, and none afterwards. That is, at least one of the following restart conditions is true: — The error has been not architecturally consumed by the PE and infected the PE state. — Executing the instruction at the restart address will not consume the error and will correct any corrupt state by overwriting it with the correct value or values.
RDCKHJ	On taking an Error exception , the PE determines that software is able to recover execution at the point where the exception is taken, with no additional action from software, if and only if all of the following are true: • The error has not been silently propagated by the PE. • The restart conditions are met because all of the following are true: — Either the error does not remain latent or executing the instruction at the restart address will not consume the error and will correct any corrupt PE state. — The restart address is the preferred return address for the exception. • The PE has not elected to determine that software is not able to recover execution, and has not elected to determine that software is able to recover execution if software takes action to locate and repair the error.

RJBHWY

On taking an [Error exception](#), the PE determines that software is able to [recover execution](#) if software takes action to locate and repair the error, to get the PE state and memory system state into this consistent state before attempting recovery, if and only if all the following are true:

- The error has not been [silently propagated by the PE](#).
- The [restart conditions](#) can be met because the restart address is the preferred return address for the exception and at least one of the following is true:
 - The error remains [latent](#) and executing the instruction at the restart address will access the corrupt state. If the error is removed then executing the instruction at the restart address will correct any corrupt PE state and/or corrupt memory state. For example, the instruction at the restart address is a load that will consume the error and corrupts PE state.
 - The error does not remain [latent](#) and the PE has elected to determine that software is able to [recover execution](#) if software takes action to [locate and repair](#) the error.
 - Executing the instruction at the restart address will not consume the error and the PE has elected to determine that software is able to [recover execution](#) if software takes action to [locate and repair](#) the error.
- The PE has not elected to determine that software is not able to [recover execution](#).

R_GJQWN

On taking an [Error exception](#), the PE determines that software is not able to [recover execution](#) if and only if one or more of the following are true:

- The error has been [silently propagated by the PE](#).
- The [restart conditions](#) cannot be met even if software takes action to [locate and repair](#) the error. This is because at least one of the following is true:
 - The error remains [latent](#) and executing the instruction at the restart address will consume the error and corrupt PE state. Either the error cannot be removed or executing the instruction at the restart address will not correct any corrupt PE state.
 - The restart address is not the preferred return address for the exception.
- The PE has elected to determine that software is not able to [recover execution](#).

I_XMCCR

That the PE determines that software is able to [recover execution](#) if software takes action to [locate and repair](#) the error does not mean that software can [locate and repair](#) the error. For example, the error in memory might be one which cannot be located or cannot be repaired. See [I_ZQGL](#).

Error recovery software might instead make the PE state and memory system state consistent with an *alternative execution* of the program.

Example D10-11

An [Error exception](#) is generated by a load from a location in a clean page of memory that is infected by an error. Software might be able to repair the error by:

- Reloading the page from a backing store. This makes the memory system state consistent with the uncorrupted view. Executing the instruction at the restart address will load the uncorrupted value into the PE state.
- Invalidating the clean page and marking it page as inaccessible. Executing the instruction at the restart address will result in a Translation fault being generated when the program tries to access the page. The target of the load will contain an UNKNOWN value, which is permitted by the architecture. The MMU fault handler can then reload the page from the backing store, as it would for a page that has not been previously accessed or has been paged out.

Either approach might result in the virtual address to physical address mapping for the page being changed by software, meaning the memory system state is not consistent with the previously executed instructions. However, the memory system state is consistent with a valid alternative view of the execution of the program that allows software to [recover execution](#).

This recovery is only possible if the error can be isolated to a location.

I_RHPPV

A PE might include additional IMPLEMENTATION DEFINED mechanisms to aid software [locate and repair](#) the error.

If software has to use IMPLEMENTATION DEFINED mechanisms to [locate and repair](#) the error, then the PE reports that it has determined that software is not able to [recover execution](#). The PE might use IMPLEMENTATION DEFINED additional syndrome registers to report that software is able to [recover execution](#) if software takes action to [locate and repair](#) the error using the IMPLEMENTATION DEFINED mechanisms.

I_RLQVJ

- PE error state recording in the exception syndrome.
- PE error state classification.

D10.4.1 PE error state recording in the exception syndrome

RWPKYM	When an asynchronous SError exception is taken to AArch64 state, the PE records the PE error state in the ESR_ELx exception syndrome register as the applicable one of: • Uncontainable (UC). • Unrecoverable state (UEU). • Recoverable state (UER). • Restartable state (UEO). • Corrected (CE). • Uncategorized error. • IMPLEMENTATION DEFINED syndrome.
ISDDL	When an asynchronous SError exception is taken to AArch64 state: • Uncategorized error is recorded by setting ESR_ELx.ISS to zero. This includes setting ESR_ELx.IDS and ESR_ELx.DFSC to zero. • IMPLEMENTATION DEFINED syndrome is recorded by setting ESR_ELx.IDS to 0b1. The remainder of the ESR_ELx.ISS syndrome is IMPLEMENTATION DEFINED. Other values for the PE error state are recorded in ESR_ELx.AET, by setting ESR_ELx.IDS to 0b0 and ESR_ELx.DFSC to the applicable nonzero fault status code, indicating ESR_ELx.AET is valid.
RFKHHF	When a synchronous External abort exception is taken, the PE records the PE error state in ESR_ELx.SET as the applicable one of the following: • Uncontainable (UC). • Recoverable state (UER). • Restartable state (UEO). Other values for the PE error state are not supported by synchronous External abort exceptions.
IQVSM	Table D10-1 summarizes the supported PE error state syndrome values for each type of Error exception.

Table D10-1 Summary of Error exception types and supported PE error state syndrome values

PE error state	External abort	SError exception
<i>Recorded in:</i>	ESR_ELx.SET	ESR_ELx.AET
Uncategorized error	No	Yes (ISS==0)
IMPLEMENTATION DEFINED syndrome	No	Yes (IDS==1)
Uncontainable (UC),	Yes (0b10)	Yes (0b000)
Unrecoverable state (UEU)	No	Yes (0b001)
Recoverable state (UER)	Yes (0b00)	Yes (0b011)
Restartable state (UEO)	Yes (0b11)	Yes (0b010)
Deferred (DE)	No	No
Corrected (CE)	No	Yes (0b110)

D10.4.2 PE error state classification

ICCKWK

The PE determines which **PE error state** to record based on the following criteria:

- The **PE error state** syndrome values supported by the type of **Error exception** being taken. See **PE error state recording in the exception syndrome**.
- The following IMPLEMENTATION SPECIFIC properties and behaviors of the PE on taking the exception:
 - Whether the error has been **silently propagated by the PE**.
 - Whether the PE determines that software is able to **recover execution** at the point where the exception is taken.
 - If the PE determines that software can recover execution, whether software needs **locate and repair** the error before attempting to recover. If software does not locate and repair the error, then attempting to recover execution might cause the **Error exception** to be generated again.
 - If the PE determines that software cannot recover execution, whether the error is a **synchronizable error**.
- Whether the implementation elects to record the **PE error state** as another state. The PE only does this when the criteria for the other, recorded state are met. The conditions under which the PE elects to record the **PE error state** as another state are IMPLEMENTATION DEFINED.

The recorded **PE error state** is defined by the rules in this section.

RQKZLB

If and only if all of the following are true, then on taking an **Error exception** the **PE error state** is recorded as Uncontainable (UC):

- One or more of the following are true:
 - The error has been **silently propagated by the PE**.
 - The PE determines that software is not able to **recover execution** from the preferred return address of the exception and the error is not a **synchronizable error**.
 - The PE determines that software is not able to **recover execution** from the preferred return address of the exception and the **Error exception** is taken as a synchronous External abort to AArch64 state. (That is, the type of **Error exception** does not support reporting the **PE error state** as **Unrecoverable state (UEU)**.)
 - The implementation has elected to record the **PE error state** as **Uncontainable (UC)**.
- The implementation has not elected to record the **PE error state** as **IMPLEMENTATION DEFINED syndrome** or **Uncategorized error**, or the type of **Error exception** does not support reporting the **PE error state** as **IMPLEMENTATION DEFINED syndrome** or **Uncategorized error**.

RQGNVD

If and only if all of the following are true, then on taking an **Error exception** the **PE error state** is recorded as Unrecoverable state (UEU):

- The error has not been **silently propagated by the PE**.
- The **Error exception** is taken as an SError exception.
- One or more of the following are true:
 - The PE determines that software is not able to **recover execution** from the preferred return address of the exception and the error is a **synchronizable error**.
 - The implementation has elected to record the **PE error state** as **Unrecoverable state (UEU)**.
- The implementation has not elected to record the **PE error state** as **Uncontainable (UC)**, **IMPLEMENTATION DEFINED syndrome**, or **Uncategorized error**.

IFJCZP

Error synchronization event defines **synchronizable error**.

RJHNVT

If and only if all of the following are true, then on taking an **Error exception** the **PE error state** is recorded as Recoverable state (UER):

- The error has not been **silently propagated by the PE**.
- The PE determines that software is able to **recover execution** from the preferred return address of the exception.
- One or more of the following are true:
 - The PE determines that software must take action to **locate and repair** the error to successfully **recover execution**. This might be because the exception was taken before the error was architecturally consumed by the PE, at the point when the PE was not be able to make correct progress without either consuming the error or otherwise making the state of the PE unrecoverable.
 - The implementation has elected to record the **PE error state** as **Recoverable state (UER)**.
- The implementation has not elected to record the **PE error state** as **Unrecoverable state (UEU)**, **Uncontainable (UC)**, **IMPLEMENTATION DEFINED syndrome**, or **Uncategorized error**.

R _{MBVCF}	If and only if all of the following are true, then on taking an Error exception the PE error state is recorded as Restartable state (UEO): • The error has not been silently propagated by the PE. • The PE determines that software can recover execution from the preferred return address of the exception without the need for software to take action to locate and repair the error first. • One or more of the following are true: — The error is an uncorrected error. This includes a deferred error. — The error is a corrected error and the Error exception is not taken as an SError exception taken to AArch64 state. — The implementation has elected to record the PE error state as Restartable state (UEO). • The implementation has not elected to record the PE error state as any of Recoverable state (UER), Unrecoverable state (UEU), Uncontainable (UC), IMPLEMENTATION DEFINED syndrome, or Uncategorized error.
R _{LFXRD}	If and only if all of the following are true, then on taking an Error exception the PE error state is recorded as Corrected (CE): • The error has been corrected and not silently propagated by the PE. • The Error exception is taken as an SError exception taken to AArch64 state. • Software can recover execution from the preferred return address of the exception. Because the error has been corrected, software does not need to take action to locate and repair the error. • The implementation has not elected to record the PE error state as any other type.
I _{BWPJZ}	Arm strongly recommends that a corrected error that is not silently propagated does not generate any Error exception at the PE. The producer of the data that corrected the error might still record the error in a RAS error record, and generate a fault handling interrupt, as described in the <i>Arm[®] Reliability, Availability, and Serviceability (RAS) System Architecture, for A-profile architecture</i> (ARM IHI 0100).
R _{NZYRP}	If and only if all the following are true, then on taking an Error exception the PE error state is recorded as an Uncategorized error: • The Error exception is taken as an asynchronous SError exception taken to AArch64 state. • The implementation has elected to record the PE error state as an Uncategorized error.
R _{VHWHID}	If and only if all the following are true, then on taking an Error exception the PE error state is recorded as an IMPLEMENTATION DEFINED syndrome: • The Error exception is taken as an asynchronous SError exception taken to AArch64 state. • The implementation has elected to record the PE error state as an IMPLEMENTATION DEFINED syndrome.
I _{SRPJD}	The IMPLEMENTATION DEFINED syndrome type might provide additional IMPLEMENTATION DEFINED syndrome recorded in the exception syndrome register. Software might be able to determine the state of the PE from this syndrome, or other IMPLEMENTATION DEFINED syndrome registers.
I _{WLZRP}	Uncategorized error and IMPLEMENTATION DEFINED syndrome are defined for backward compatibility with previous versions of the architecture. Arm does not recommend use of these PE error state values in new implementations that include other RAS features.
I _{VKMZB}	The PE error states for an Error exception generated when the PE consumes an uncorrected error are summarized by Figure D10-1. Figure D10-1 assumes the type of Error exception supports the resulting PE error state, that the error was neither corrected nor deferred, and the PE never elects to record an error as a different PE error state when permitted, an Uncategorized error syndrome, or an IMPLEMENTATION DEFINED syndrome.

Figure D10-1 PE error states

I_{ZQRGL}

If the **PE error state** reports that software can **recover execution**, or that software isolation might be possible because the error is a **synchronizable error**, then this does not necessarily mean that the error can be recovered from because the error in the system might be one which does not allow software to recover the operation. Rather, software *might* be able to recover if it can repair the error and continue.

Example D10-12

A component detects an error when accessed by a PE, and records in a RAS System Architecture node that the error is uncontainable at the component, meaning the system has to be shut down to avoid catastrophic failure. The component signals the error with an **in-band error response** to a PE, which does not report the severity of the error. The recorded **PE error state** refers only to the PE, not the system error state.

I_{WBVYC}

If the **in-band error response** can signal the severity of the error to the PE, then the PE might use this information to elect to report the **PE error state** as the severity of error reported to it, if permitted by the preceding rules. However, this is not required, and software must not rely on this behavior and should determine from the system whether the error is recoverable at the system level.

Example D10-13

A processor cache detects an uncontainable tag RAM error, and the PE reports the **PE error state** as **Uncontainable (UC)**, even though the state of the PE itself is **Recoverable state (UER)**. **R_{QKZLB}** allows this.

I_{TXFMY}

An Error exception that is masked when it is generated remains pending until taken later when no longer masked. In these cases, the PE error state is also unlikely to be *Restartable* or *Recoverable*.

I_{TGPQZ}

See also:

- **PE error propagation.**
- **Error synchronization event.**

D10.4.2.1 Using the PE error state classification

S_{XSXNS}

When the **PE error state** is recorded as **Uncontainable (UC)**:

- The error handling software must assume that either:
 - The error has been **silently propagated by the PE**.

- Software is not able to [recover execution](#) from the preferred return address of the exception and the error was not a [synchronizable error](#).
- If the error handling software cannot isolate the error to an application or VM, or both, by other means, then the system must be shut down by software to avoid catastrophic failure.

SHYWFL

When the **PE error state** is recorded as **Unrecoverable state (UEU)**:

- The error handling software can assume the error has not been [silently propagated by the PE](#).
- The error handler cannot safely [recover execution](#) from the preferred return address of the exception, even if it takes action to [locate and repair](#) the error. The state of the affected software is unrecoverable. However, if the software includes [Error synchronization events](#), the error handler can use the properties of the Error synchronization event to determine which software is affected by the error.
- The affected software cannot continue and must be isolated by the error handling software.

SLSFYM

When the **PE error state** is recorded as **Recoverable state (UER)**:

- The [uncorrected error](#) might remain [latent](#) in the system.
- If the error handling software takes action to [locate and repair](#) the [uncorrected error](#), then the error handler can safely [recover execution](#) from the preferred return address of the exception. Otherwise on restart of the affected software the PE might attempt to consume the error again, causing a further [Error exception](#). If the error handler cannot [locate and repair](#) the error, then the affected software must be isolated by the error handling software.

SGLPZY

When the **PE error state** is recorded as **Restartable state (UEO)**:

- The error might remain [latent](#) in the system.
- The error handling software might take action to [locate and repair](#) the error before it is consumed. However, the affected software can be safely restarted by the error handler without software taking any action to [locate and repair](#) the error.

For example, the error was [signaled](#) when the PE speculatively accessed corrupt data.

SGRZQS

When the **PE error state** is recorded as [IMPLEMENTATION DEFINED syndrome](#) or [Uncategorized error](#), if the error handling software is not able to determine the actual state of the PE and memory, it should treat [IMPLEMENTATION DEFINED syndrome](#) and [Uncategorized error](#) as [Uncontainable \(UC\)](#).

D10.4.3 Multiple SError exceptions

ICPJLW

Multiple physical and/or virtual SError exception conditions might be pending together. The architecture does not define relative priorities for asynchronous exceptions.

R_DHKQZ

If multiple physical and/or virtual SError exception conditions are pending, then it is [IMPLEMENTATION DEFINED](#) whether the multiple pending SError exception conditions are taken as a single SError exception.

R_JBQSC

On taking an SError exception for more than one SError condition:

- If the exception is taken and one or more pending SError conditions would be reported as [IMPLEMENTATION DEFINED syndrome](#) or [Uncategorized error](#), then the syndrome recorded in [ESR_ELx.ISS](#) is [IMPLEMENTATION DEFINED](#).
- Otherwise, the recorded **PE error state** applies recorded by combined effect of the errors.

I_GNHXJ

Any pending SError conditions that are not taken with other SError exceptions as a single SError exception remains pending after the SError exception is taken.

D10.4.4 Target Exception level for External abort and SError exceptions taken to AArch64 state

D_FWSVH

This section is included for completeness. It repeats the definitions from this Manual and so is *non-normative*.

I_NRZXZ

The default target Exception level for synchronous External abort exceptions is:

- EL1, if taken from EL0 or EL1.
- EL2, if taken from EL2.

The default target Exception level for SError exceptions is EL1.

However:

- If [HCR_EL2.AMO](#) is 0b1 or [HCR_EL2.TGE](#) is 0b1, then the target Exception level for SError exceptions is EL2.
- If [HCR_EL2.TEA](#) is 0b1 or [HCR_EL2.TGE](#) is 0b1, then the target Exception level for synchronous External abort exceptions taken from EL0 and EL1 is EL2.

When executing at a higher Exception level than the target Exception level for SError exceptions, SError exceptions are implicitly masked and not taken.

IBPGXV

See also [The AArch64 System Level Programmers' Model](#).

D10.5 Error synchronization event

R _{PMLNP}	An Error synchronization event is generated by any of the following: • Executing an ESB instruction. • When FEAT_IESB is implemented, and taking an exception in Non-debug state, when the appropriate SCTLR_ELx.IESB bits is 0b1. • When FEAT_IESB is implemented, executing an exception return instruction in Non-debug state and the appropriate SCTLR_ELx.IESB bit is 0b1.
R _{RKWPZ}	SCTLR_ELx.IESB is ignored in Debug state and treated as zero.
I _{XKTLN}	Because SError exceptions are masked in Debug state, and the effects of an implicit Error synchronization barrier could happen at any time regardless of the value of SCTLR_ELx.IESB, an implementation that honors SCTLR_ELx.IESB in Debug state is compliant with R_{RKWPZ} .
I _{PMGVM}	In addition to generating an Error synchronization event , the ESB instruction might additionally record and then clear a masked pending asynchronous SError exception. This is also referred to as deferring the pending asynchronous SError exception.
R _{WPPWC}	A synchronizable error is one of a subset of errors specific to the implementation that are synchronized by Error synchronization events, generated by an instruction executed on the same PE as the Error synchronization events. Note: Synchronizable error must not be confused with a synchronous error exception. An Error exception for a synchronizable error might be taken asynchronously.
R _{BZPTV}	If the Error exception for a synchronizable error is taken in program order after the Error synchronization event completes, and either physical SError exceptions are unmasked when the Error synchronization event occurs or the Error exception is taken synchronously, then all of the following are true: • The instruction that generated the synchronizable error is in program order after the Error synchronization event. • On completion of the Error synchronization event, the PE state and memory system state are consistent with the PE having executed all instructions in program order before the Error synchronization event.
R _{ZRHDD}	If the Error exception for a synchronizable error is taken asynchronously as an SError exception, physical SError exceptions are masked when the Error synchronization event occurs, and the SError exception is not pending when the Error synchronization event completes, then all of the following are true: • The instruction that generated the synchronizable error is in program order after the Error synchronization event. • On completion of the Error synchronization event, the PE state and memory system state are consistent with the PE having executed all instructions in program order before the Error synchronization event. The SError exception is not pending when the Error synchronization event completes if a subsequent read of ISR_EL1.A returns 0b0.
R _{YCJTN}	If the Error exception for a synchronizable error is taken asynchronously as an SError exception, the Error synchronization event is generated by an ESB instruction executed when physical SError exceptions are masked, and the ESB instruction does not set DISR_EL1.A to 0b1, then all of the following are true: • The instruction that generated the synchronizable error is in program order after the ESB. • On completion of the ESB, the PE state and memory system state are consistent with the PE having executed all instructions in program order before the ESB.
R _{NFKMQ}	Taken in program order after the Error synchronization event completes means: • For an Error synchronization event generated by an ESB instruction, the exception is taken in program order after the instruction. • For an Error synchronization event generated by an exception return instruction when FEAT_IESB implemented, the exception is taken in program order after the instruction. • For an Error synchronization event generated by an exception entry when FEAT_IESB is implemented, one of the following is true: — The exception is taken in program order strictly after the first instruction of the exception handler at the exception vector address. — The exception is taken from the first instruction of the exception handler at the exception vector address and the ESR_ELx.IESB syndrome bit is recorded as 0b0.

IQZSHG

The definition of [synchronizable error](#) means that if the error that is a [synchronizable error](#) is generated by an instruction in program order before the [Error synchronization event](#), then either the [Error exception](#) is taken before the [Error synchronization event](#), or on executing the [Error synchronization event](#) the following apply:

- If physical SError exceptions are unmasked or the Error exception is taken synchronously, then the [Error synchronization event](#) ensures that the Error exception is not taken in program order after the [Error synchronization event](#). This allows isolation of the software affected by the error.
- If physical SError exceptions are masked and the Error exception is taken asynchronously, then:
 - If the [Error synchronization event](#) was generated by an [ESB](#), then the error is recorded in [DISR_EL1](#). Software can use the [PE error state](#) recorded in [DISR_EL1](#) to determine what recovery is possible.
 - Otherwise, the Error exception is pending when the [Error synchronization event](#) completes.

The SError exception might have been pending before or made pending by the [Error synchronization event](#).

The definition does not mean that if the error is generated by a instruction in program order after the [Error synchronization event](#), then the [Error exception](#) will only be taken after the [Error synchronization event](#). The Error exception might be taken before the [Error synchronization event](#), if the PE speculated past the [Error synchronization event](#) and speculatively executed the instruction that generated the error. This might cause software to generate a false failure. [Error synchronization events](#) are not speculation barriers.

ISQCFG

The criteria for the [PE error state](#) mean that if the PE reports the [PE error state](#) as one of the following, then the error must be either explicitly or implicitly a [synchronizable error](#):

- [Unrecoverable state \(UEU\)](#).
- [Recoverable state \(UER\)](#).
- [Restartable state \(UEO\)](#).

This is because whether the error is a [synchronizable error](#) is a criterion for [Unrecoverable state \(UEU\)](#), and the criteria for [Recoverable state \(UER\)](#) and [Restartable state \(UEO\)](#) satisfy the definition of [synchronizable error](#).

For other physical errors:

- An error that has been [silently propagated by the PE](#) and is not reported as either [IMPLEMENTATION DEFINED syndrome](#) or [Uncategorized error](#) must be reported as [Uncontainable \(UC\)](#) and is not containable even if the error is a [synchronizable error](#). Software must assume the error has been silently propagated even if the error is a [synchronizable error](#).
- It is IMPLEMENTATION SPECIFIC whether an error reported with an [ESR_ELx.ISS](#) syndrome that is [IMPLEMENTATION DEFINED syndrome](#) or [Uncategorized error](#) is a [synchronizable error](#).
- The following errors have not been consumed by the PE:
 - A *Deferred error*.
 - A *Corrected error*.
 - An Error exception from a read by hardware speculation that does not corrupt the state of the PE. Software can [recover execution](#) from these errors regardless of whether the error is a [synchronizable error](#).
- An implementation might have other IMPLEMENTATION DEFINED [Error exception](#) and other sources of SError exception, see [R_FNVVJ](#). If an IMPLEMENTATION DEFINED SError exception is generated by a level-sensitive interrupt signal, then the SError exception cannot be a [synchronizable error](#).

IVFFYW

An [Error synchronization event](#) might operate as follows:

1. The PE ensures that any [synchronizable error](#) generated by an instruction in program order before the [Error synchronization event](#) has caused a physical SError exception to become pending.
2. If a physical SError exception is pending for a [synchronizable error](#) and generated by an instruction in program order before the [Error synchronization event](#), and physical SError exceptions are not masked at the current Exception level, then the physical SError exception is taken before completion of the [Error synchronization event](#). The SError exception might have been made pending by the [Error synchronization event](#), or might have been pending before the [Error synchronization event](#).

RNPPGJ

If a physical SError exception for a [synchronizable error](#) is pending after completing the [Error synchronization event](#) generated by an [ESB](#) instruction, and physical SError exceptions are masked at the current Exception level, then the [ESB](#) instruction performs the following steps:

1. The pending physical SError exception is recorded in [DISR_EL1](#). This includes the [PE error state](#) that the pending Error exception would record if taken.
2. The [DISR_EL1.A](#) bit is set to 0b1.
3. The pending state of the physical SError exception is cleared.

The SError exception might have been made pending by the [Error synchronization event](#), or might have been pending before the [Error synchronization event](#).

I _{BLRTM}	The criteria for ESB recording the PE error state in DISR_EL1 are the same as for that for recording the PE error state in ESR_ELx when an SError exception taken to the current execution state.
R _{KNWBN}	If an SError exception is taken as part of an Error synchronization event generated by an ESB instruction, then the ESB instruction address is the <i>preferred return address</i> of the exception. For the definition of the <i>preferred return address</i> for an exception, see Preferred return address .
R _{SFHDS}	On executing an ESB instruction when SError exceptions are masked, any pending SError exception generated by an error that is not a synchronizable error : • Remains pending after completion of the Error synchronization event. • Does not update DISR_EL1.
I _{CQKXL}	The Error recovery interrupt, Fault handling interrupt, and Critical Error interrupt interrupts described by RAS System Architecture are asynchronous interrupts, and so are not synchronizable errors .
I _{BGGXN}	If multiple SError exception conditions are pending, then an Error synchronization event synchronizes all errors that are synchronizable errors .
S _{VFHGT}	Software must be aware that an SError exception taken at an Error synchronization event or recorded in the DISR_EL1 register by an ESB instruction might have been generated by hardware speculation of an instruction in program order after the Error synchronization event .

D10.5.1 ESB and virtual SError exceptions

R _{TFVYW}	If VSESR_EL2 is writable, then an ESB instruction executed at EL0 or EL1 synchronizes a pending virtual SError exception. In these cases, a virtual SError exception is pending, and the following occur when an ESB instruction is executed at EL0 or EL1: • If the virtual SError exception is unmasked at the current Exception level, then the exception is taken before the completion of the ESB instruction. • If the virtual SError exception is masked at the current Exception level, then all the following occur: — HCR_EL2.VSE cleared to 0b0. — The virtual SError exception syndrome from VSESR_EL2 is recorded in VDISR_EL2. — VDISR_EL2.A is set to 0b1 to indicate the SError exception was pending prior to the execution of the ESB instruction.
R _{GXYHX}	If all of the following are true, then it is IMPLEMENTATION DEFINED whether or not an ESB instruction executed at EL0 or EL1 synchronizes a pending virtual SError exception: • EL2 is implemented and enabled in the current Security state. • EL2 is using AArch64, HCR_EL2.TGE is 0b0, HCR_EL2.VSE is 0b1 and either: — HCR_EL2.AMO is 0b1. • VSESR_EL2 is implemented as RAZ/WI. In these cases, a virtual SError exception is pending. If the IMPLEMENTATION DEFINED choice is that the ESB instruction synchronizes a pending virtual SError exception, then the following occur when an ESB instruction is executed at EL0 or EL1: • If the virtual SError exception is unmasked at the current Exception level, then the exception is taken before the completion of the ESB instruction. • If the virtual SError exception is masked at the current Exception level, then all the following occur: — HCR_EL2.VSE cleared to 0b0. — The virtual SError exception syndrome in VDISR_EL2 is set to zero. — VDISR_EL2.A is set to 0b1 to indicate the virtual SError exception was pending prior to the execution of the ESB instruction. If the IMPLEMENTATION DEFINED choice is that the ESB instruction does not synchronize a pending virtual SError exception, then an ESB instruction executed at EL0 or EL1 ignores the pending virtual SError exception and the virtual SError exception stays pending. See also Syndrome registers.

- I_VKQGL If both a virtual SError exception and a physical SError exception are pending as described in R_{TF}VYV and Error synchronization event, then the physical SError exception is not masked at the current Exception level, because this is not possible when a virtual SError exception is pending. This means that:
- If the virtual SError exception is masked at the current Exception level, then the physical SError exception will be taken before the ESB instruction completes and HCR_EL2.VSE and VDISR_EL2 are unchanged.
 - If the virtual SError exception is not masked at the current Exception level, then it is IMPLEMENTATION DEFINED which of the virtual SError or physical SError exceptions is taken before the ESB instruction completes. If the virtual SError exception is taken and, after taking the exception to EL1, the physical SError exception is still pending, then the physical SError exception is still not masked and will be taken.

D10.5.2 Extension for synchronization at exception entry and return

- D_{DP}SJR The rules in this section apply when FEAT_IESB is implemented.

- I_WDSBL An implicit Error synchronization event has no effect on DISR_EL1 or VDISR_EL2.

D10.5.2.1 Synchronization on exception entry

- R_{RN}ZWY For each value of ELx in EL1 or EL2, if all of the following are true, then each exception that is taken to ELx generates an Error synchronization event:

- The Effective value of SCTL_R_ELx.IESB is 0b1.

- R_{JQ}SKQ If an SError exception is taken to the Exception level ELy as a result of the Error synchronization event generated on exception entry by the FEAT_IESB mechanism, then all the following occur:

- The PE sets the ESR_ELy.IESB bit in the SError exception syndrome to 0b1.
- The preferred return address for the SError exception is the exception vector address for the original exception.

Note: ELy might be the same Exception level as ELx.

- I_{FW}ZHV If SError exceptions are masked at ELx, then any SError exception made pending by the Error synchronization event stays pending.

- I_{MM}VJW The prioritization of asynchronous exceptions is IMPLEMENTATION DEFINED. This means that an implementation might choose to behave as if the SError exception made pending by the Error synchronization event was taken before the implicit Error synchronization event, if the SError exception was not masked, taking the SError exception in place of the original exception, unless the original exception is also an SError exception.
In this case, ESR_ELy.IESB is cleared to 0 and the reported PE error state correctly indicates, for instance, whether software can recover execution from the preferred return address for the SError exception in ELR_ELy.

D10.5.2.2 Synchronization on exception return

- R_{SK}R_{CR} For each value of ELx in EL1 or EL2 if all of the following are true, then executing an exception return instruction at ELx generates an Error synchronization event:

- The instruction does not generate any exception.
- The Effective value of SCTL_R_ELx.IESB is 0b1.

- I_{GP}PXQ On an illegal return event, the exception return instruction sets PSTATE.IL to 0b1, which causes the next instruction to generate an Illegal State exception. The exception return instruction does not generate the exception.

- R_{GX}QYD Any SError exception taken as part of the Error synchronization event terminates execution of the instruction.

- R_{LP}KVM If an SError exception is taken to an Exception level, ELy, as a result of the Error synchronization event generated on exception return by the FEAT_IESB mechanism, then all the following occur:
- The PE sets the ESR_ELy.IESB bit in the SError exception syndrome to an IMPLEMENTATION DEFINED choice of 0b0 or 0b1.
 - The preferred return address for the SError exception is the address of the ERET instruction.

SMHCTH

[R1QSKQ](#) and [R1PKVM](#) describe how ESR_ELy.IESB records that an SError exception was taken because of an implicit [Error synchronization event](#) generated by the [FEAT_IESB](#) mechanism.

When ESR_ELy.IESB is 1, software can compare the value in ELR_ELy with the value of [VBAR_ELx](#), where ELx is the Exception level the SError exception was taken from, to confirm whether this is due to the exception entry or the exception return case.

If the error is also reported as a [synchronizable error](#), then:

- In the exception entry case:
 - ESR_ELy.IESB == 1 indicates that the error was generated by an instruction in program order before the exception was taken.
 - ELR_ELy will contain the address of an exception vector. See [Exception vectors](#).
 - Software can determine the Exception level the exception was taken from the value recorded in [SPSR_ELx](#), where ELx is the Exception level the SError was taken from.
- In the exception return case, software can ignore the value of ESR_ELy.IESB:
 - The value 1 indicates that the error was generated by an instruction in program order before the exception return.
 - However, this is indistinguishable from an SError taken before the exception return was executed. Hence the value of ESR_ELy.IESB is IMPLEMENTATION SPECIFIC in this case.

If [ID_AA64MMFR4_EL1](#).IESB indicates to software that implicit [Error synchronization events](#) are inserted before exceptions taken to ELy, then software can ignore the value in ESR_ELy.IESB, as it would only ever be set for the exception return case.

IJZHDB

If SError exceptions are masked at ELx, then any SError exception made pending by the [Error synchronization event](#) stays pending.

D10.5.3 Error synchronization barriers in a minimal implementation

IHQRLS

[Error synchronization events](#) and the [ESB](#) instruction can be implemented as no-ops if either there are no sources of SError exceptions, or all SError exceptions are reported as [Uncategorized error](#) and are not [synchronizable errors](#).

This allows for a very low cost implementation of the RAS Extension.

Such an implementation might include [FEAT_IESB](#), meaning the SCTL_R_ELx.IESB controls have no effect.

I_HSHJG

See also [Syndrome registers](#).

D10.6 Virtual SError exceptions and delegated SError exceptions

I_{LSSCN}

EL2 provides a virtual SError exception.

For more information, see:

- [Virtual asynchronous exceptions](#)
- Virtual exceptions when an implementation includes EL2.

I_{ZXMPL}

[FEAT_RAS](#) provides:

- Mechanisms to allow a hypervisor to specify the syndrome value reported to a guest Operating System on taking a virtual SError exception.
- Mechanisms to allow firmware to specify the syndrome value reported to a hypervisor or guest Operating System on taking a delegated SError exception.
- Support for EL0 or EL1 to isolate a virtual SError exception and for EL0, EL1, or EL2 to isolate a delegated SError exception as if it was a physical SError exception. See [ESB and virtual SError exceptions](#).

D10.7 Error records in the PE

I _{KMMPK}	A component that records detected errors is called a node by the RAS System Architecture. Each node implements one or more Error records.
R _{VNLPC}	It is IMPLEMENTATION DEFINED whether the processor that implements a PE implements any nodes.
R _{XKDRX}	A PE implementing the RAS Extension might implement the System register interface to nodes.
I _{SCVSB}	The System register interface to nodes is not restricted to accessing only PE nodes.
I _{ZRKKQ}	When an error is recorded by a PE node, one or more of the following might be generated, according to the configuration of the node: • A Fault handling interrupt. • An Error recovery interrupt. • A Critical Error interrupt. • An in-band error response.

D10.7.1 Error record System register view

I _{SLVDW}	If the System register interface to a node is implemented, then software can access the Error records of the node using Error record System registers.
R _{BYLZQ}	The number of Error records that can be accessed using the System registers is IMPLEMENTATION DEFINED, and might be zero. The ERRIDR_EL1 registers indicate the highest numbered index of the Error records that can be accessed using System registers, plus one.
I _{NWBNQ}	The AArch64 Error record System registers are those registers with an ERX*_EL1 mnemonic.
I _{BJNDF}	The following table describes the AArch64 Error record System registers. The descriptions in this section apply whether the Error record is accessed through the indirection mechanism, as described in Table D10-2, or as memory-mapped registers, as described in RAS registers summary.

Table D10-2 Using AArch64 System registers, System register map

Use	To Access	Access	Description
ERXADDR_EL1	ERR<n>ADDR	RW	Error Record <n> Address Register
ERXCTLR_EL1	ERR<n>CTLR	RW	Error Record <n> Control Register
ERXFR_EL1	ERR<n>FR	RO	Error Record <n> Feature Register
ERXMISC0_EL1	ERR<n>MISC0	RW	Error Record <n> Miscellaneous Register 0
ERXMISC1_EL1	ERR<n>MISC1	RW	Error Record <n> Miscellaneous Register 1
ERXMISC2_EL1^a	ERR<n>MISC2	RW	Error Record <n> Miscellaneous Register 2
ERXMISC3_EL1^a	ERR<n>MISC3	RW	Error Record <n> Miscellaneous Register 3
ERXPFGCDN_EL1	ERR<n>PFGCDN	RW	Error Record <n> Pseudo-fault Generation Countdown Register
ERXPFGCTL_EL1	ERR<n>PFGCTL	RW	Error Record <n> Pseudo-fault Generation Control Register
ERXPFGF_EL1	ERR<n>PFGF	RO	Error Record <n> Pseudo-fault Generation Feature Register
ERXSTATUS_EL1	ERR<n>STATUS	RW	Error Record <n> Primary Status Register

a. If [FEAT_RASv1p1](#) is implemented.

R _{ZBCFZ}	If FEAT_RASv1p1 is implemented, then all Error records accessible through System registers implement RAS System Architecture version 1.1.
--------------------	---

SVBBNY	To access an Error record, software: 1. Sets the error selection register, ERRSELR_EL1.SEL, to the index of the record being accessed. 2. Accesses the Error record using the ERX*_EL1 System registers, as described in IBJNDF.
IWKXSB	The Error records accessed through the System registers might be accessible only to the PE associated with those System registers, or they might be shared and therefore accessible to other PEs through either System registers or as a memory-mapped component.
IJMVVD	Direct reads of the System registers, including Error record System registers, can occur speculatively and out-of-order relative to other instructions executed on the same PE.
RWFPPF	Direct reads and writes of the Error records through the ERX*_EL1 AArch64 System registers, as described in IBJNDF , are indirect reads of ERRSELR_EL1 .

D10.7.1.1 Syndrome registers

IRGMHN	ESR_ELx is the exception syndrome registers. The PE records syndrome information in an exception syndrome register on taking a physical SError exception or synchronous External abort exception. ESR_ELx is also used by other exceptions. DISR_EL1 is the deferred error syndrome registers. The PE records syndrome information in a deferred error syndrome register on deferring a physical SError exception. The PE also records a virtual syndrome value in ESR_EL1 or DISR_EL1 on taking or deferring a virtual SError exception. The virtual syndrome value is provided by software in a corresponding virtual error syndrome register, VSESR_EL2 or VDISR_EL2 respectively. The PE also records a delegated syndrome value in ESR_EL2, ESR_EL1, VDISR_EL2, or DISR_EL1 on taking or deferring a delegated SError exception.
RSLNMV	For a given implementation: • If ESB never synchronizes any errors, then DISR_EL1.A might be RES0. • The deferred and virtual syndrome registers are capable of storing any syndrome value that might be recorded by the PE in an exception syndrome register on taking a physical SError exception or synchronous External abort exception. • If any of ESR_ELx[24:0] is not used and always set to zero by the PE on taking a physical SError exception or synchronous External abort exception, then that bit can be RES0 in that exception syndrome register. • A bit that is not used and always set to zero or always set to one by the PE on taking a physical SError exception is permitted to be RES0 or RES1 respectively in the corresponding deferred and virtual error syndrome registers. See Table D10-3. In Table D10-3, the deferred or virtual error syndrome register bit described in the left-hand column is permitted to be RES0 or RES1 only if the corresponding bit is always set to zero or always set to one (respectively) on taking a physical SError exception in all of the implemented exception syndrome registers listed in the other columns marked <i>Yes</i> on that row. Otherwise, the bit is read/write.

Table D10-3 Permitted relaxations for bits in deferred and virtual error syndrome registers

Bit is permitted to be res0 or res1	ESR_ELx[n] $n \in [24:0]$
VSESR_EL2[n]	Yes
VDISR_EL2[n]	Yes
DISR_EL1[n]	Yes

INQNWV	RSLNMV means that VSESR_EL2 can be implemented as RAZ/WI when ESR_ELx[24:0] are always set to zero by the PE on taking a physical SError exception or synchronous External abort exception. When this is the case, the PE error state is always reported as Uncategorized error when a physical SError exception is taken. IHQRLS, in Error synchronization barriers in a minimal implementation then further allows ESB to be executed as a NOP, meaning DISR_EL1 and VDISR_EL2 can also be implemented as RAZ/WI. This allows for a very low-cost implementation of the RAS Extension.
--------	---

Chapter D11

AArch64 System Register Encoding

This chapter describes the AArch64 System register encoding space. It contains the following sections:

- [The System register encoding space](#)
- [Moves to and from debug and trace System registers](#)
- [Moves to and from non-debug System registers, Special-purpose registers](#)

D11.1 The System register encoding space

The A64 instruction set includes instructions that access the System register encoding space. These instructions provide:

- Access to *System registers*, including the debug registers, that provide system control, and system status information.
- Access to Special-purpose registers such as [SPSR_ELx](#), [ELR_ELx](#), and the equivalent fields of the Process State.
- The cache and TLB maintenance instructions and address translation instructions.
- Barriers and the [CLREX](#) instruction.
- Architectural hint instructions.

This section describes the parts of the System register encoding space that provides access to the System registers described in [AArch64 System Register Descriptions](#).

Note

- See [Fixed values in AArch64 instruction and System register descriptions](#) for information about abbreviations used in the System instruction descriptions.
-

[Principles of the System instruction class encoding](#) describes some general properties of these encodings. [System instruction class encoding overview](#) then describes the top-level encoding of these instructions, identifying that:

- Entries in the encoding space are characterized by the parameter set $\{\text{op0}, \text{op1}, \text{CRn}, \text{CRm}, \text{op2}\}$.
- [op0](#) is the most significant parameter for determining allocations in this space.

Much of this encoding space is used for System instructions, as described in [The A64 System Instruction Class](#). This chapter describes only the part of the encoding space that is used for System registers, in the following sections:

- [Moves to and from debug and trace System registers](#).
- [Moves to and from non-debug System registers, Special-purpose registers](#).

D11.2 Moves to and from debug and trace System registers

The instructions that move data to and from the debug, execution environment, and trace System registers are encoded with $op0 == 0b10$. This means the encoding of these instructions is:

Note

- The section describes the use of all of the $op0 == 0b10$ region of the System register encoding space.
-

The value of $op1$ provides the next level of decode of these instructions, as follows:

$op1 == \{0b000, 0b011, 0b100, 0b101, 0b110, 0b111\}$

Debug, PMU, and System PMU registers.

Note

The standard encoding of debug System registers is $op0 == 0b10$, $op1 == \{0, 3, 4\}$. The registers in the $op0 == 0b11$ encoding space that are classified as debug System registers are [DLR_EL0](#), [DPSR_EL0](#), and [MDCR_EL2](#). See [Instructions for accessing non-debug System registers](#) for the encodings of these registers.

$op1 == \{0b001\}$ Trace and BRBE registers.

D11.2.1 Instructions for accessing debug System registers

The instructions for accessing debug System registers are:

```
MSR <System_register>, Xt    ; Write to System register
MRS Xt, <System_register>    ; Read from System register
```

Where <System_register> is the register name, for example [MDCCSR_EL0](#).

This section includes only the System register access encodings for which both:

- op0 is 0b10.
- The value of op1 is one of {0b000, 0b001, 0b011, 0b100, 0b101, 0b110, 0b111}.

[Table D11-1](#) shows the mapping of the System register encodings for debug System register access.

Table D11-1 Instruction encodings for debug System register access in the (op0==0b10) encoding space

op1	CRn	CRm	op2	Access	Mnemonic	Accesses
0b000	0b0000	0b0000	0b010	RW	OSDTRRX_EL1	OSDTRRX_EL1

0b000	0b0001	0b0011	0b100	RW	OSDLR_EL1	OSDLR_EL1
0b000	0b0001	0b0100	0b100	RW	DBGPRCR_EL1	DBGPRCR_EL1
0b000	0b0111	0b1000	0b110	RW	DBGCLAIMSET_EL1	DBGCLAIMSET_EL1
0b000	0b0111	0b1001	0b110	RW	DBGCLAIMCLR_EL1	DBGCLAIMCLR_EL1
0b000	0b0111	0b1110	0b110	RO	DBGAUTHSTATUS_EL1	DBGAUTHSTATUS_EL1
0b011	0b0000	0b0001	0b000	RO	MDCCSR_EL0	MDCCSR_EL0
0b011	0b0000	0b0100	0b000	RW	DBGDTR_EL0	DBGDTR_EL0
0b011	0b0000	0b0101	0b000	RO	DBGDTRRX_EL0	DBGDTRRX_EL0
0b011	0b0000	0b0101	0b000	WO	DBGDTRTX_EL0	DBGDTRTX_EL0

D11.3 Moves to and from non-debug System registers, Special-purpose registers

The instructions that move data to and from non-debug System registers are encoded with $op0 == 0b11$, except that some of this encoding space is reserved for IMPLEMENTATION DEFINED functionality. The encoding of these instructions is:

31	30	29	28	27	26	25	24	23	22	21	20	19	18	16	15	12	11	8	7	5	4	0
1	1	0	1	0	1	0	1	0	0	L	1	1	op1	CRn	CRm	op2	Rt					

op0

The value of CRn provides the next level of decode of these instructions, as follows:

$CRn == \{0b0000, 0b0001, 0b0010, 0b0011, 0b0101, 0b0110, 0b0111, 0b1001, 0b1010, 0b1100, 0b1101, 0b1110\}$

See [Instructions for accessing non-debug System registers](#).

$CRn == \{0b0100\}$

See [Instructions for accessing Special-purpose registers](#).

$CRn == \{0b1011, 0b1111\}$

See [Reserved encodings for IMPLEMENTATION DEFINED registers](#).

D11.3.1 Instructions for accessing non-debug System registers

The A64 instructions for accessing System registers are:

MSR <System_register>, Xt	; Write to 64-bit System register
MSRR <System_register>, Xt	; Write to 128-bit System register
MRS Xt, <System_register>	; Read from 64-bit System register
MRRS Xt, <System_register>	; Read from 128-bit System register

Where <System_register> is the register name, for example [MIDR_EL1](#).

This section includes only the System register access encodings for which both:

- $op0$ is $0b11$.
- The value of CRn is one of $\{0b0000, 0b0001, 0b0010, 0b0011, 0b0100, 0b0101, 0b0110, 0b0111, 0b1001, 0b1010, 0b1100, 0b1101, 0b1110\}$.

Direct accesses to some regions of the System register encoding space have a defined behavior even if no register is currently allocated or implemented for the encodings in those regions. The Feature ID space is the System register space in AArch64 with $op0 == 3$, $op1 == \{0, 1, 3\}$, $CRn == 0$, $CRm == \{0-7\}$, $op2 == \{0-7\}$. The properties for this space are that:

- For unused encodings in the part of the space that has $op1 == 0$ and $CRm == \{2-7\}$, the following apply:
 - It is IMPLEMENTATION DEFINED whether direct reads can be trapped by [HCR_EL2.TID3](#).
 - Direct reads that are not trapped behave as Reserved, RES0 to ensure correct behavior if the encodings are used for ID registers in the future.
- For unused encodings in the part of the space that has either $op1 == 0$ and $CRm == 0$, or $op1 == \{1, 3\}$, the following apply:
 - Direct reads are UNDEFINED and therefore generate exceptions reported with EC syndrome value 0×00 .

Note

- While this group is described as accessing the non-debug System registers, its correct characterization is by the {*op0*, *CRn*} values given in this subsection, and the group includes the debug System registers [DLR_EL0](#), [DPSR_EL0](#), [MDCR_EL2](#), [MDCR_EL3](#), and [SDER32_EL3](#) and [MDCR_EL3](#), which are described in [Debug System registers](#). These registers are exceptions to the standard encoding of debug registers, which has *op0* == 0b10, see [Instructions for accessing debug System registers](#).
- All unused encodings in the range *Op0* == 3, *op1* == 0, *CRn* == 0, *CRm* == {2-7}, *op2* == {0-7} are defined to be accessible as Reserved, RAZ to ensure correct behavior if the encodings are used for ID registers in the future.

The instruction encoding for these accesses is:

31	30	29	28	27	26	25	24	23	22	21	20	19	18	16	15	12	11	8	7	5	4	0
1	1	0	1	0	1	0	1	0	0	L	1	1	op1	CRn	CRm	op2	Rt					

op0

See text for permitted values of *CRn*

[Table D11-2](#) shows the encodings of the register access instructions.

See the register descriptions for information about the control that determines whether these accesses are permitted.

Table D11-2 Instruction encodings for non-debug System register access in the (*op0*==0b11) encoding space

op1	CRn	CRm	op2	Access	Mnemonic	Accesses
0b000	0b0000	0b0000	0b000	RO	MIDR_EL1	MIDR_EL1 VPIDR_EL2
0b000	0b0000	0b0000	0b100	RO	MPUIR_EL1	MPUIR_EL1

D11.3.1.1 About the GIC System registers

From version 3 of the GIC architecture, the specification defines three groups of System registers, identified by the prefix of the register name:

ICC_ GIC physical CPU interface System registers.

ICH_ GIC virtual interface control System registers.

ICV_ GIC Virtual CPU interface System registers.

Note

These registers are in addition to the GIC memory-mapped register groups GICC_, GICD_, GICH_, GICR_, GICV_, and GITS_.

When implemented, the GIC System registers form part of an Arm processor implementation, and therefore these registers are included in the register summaries. However, the registers are defined only in the GIC Architecture Specification.

As [Table D11-2](#) shows, the ICV_* registers have the same {op0, op1, CRn, CRm, op2} encodings as the corresponding ICC_* registers. For these encodings, GIC register configuration fields determine which register is accessed.

For more information, see the *Arm® Generic Interrupt Controller Architecture Specification, GIC architecture version 3 and version 4* (ARM IHI 0069).

D11.3.2 Reserved encodings for IMPLEMENTATION DEFINED registers

The System register encoding space with op0 == 0b11 reserves the following encodings for IMPLEMENTATION DEFINED registers:

The value of **L** defines the access type and the use of **Rt** as follows:

- 0** Write the value in **Rt** to the IMPLEMENTATION DEFINED register.
- 1** Read the value of the IMPLEMENTATION DEFINED register to **Rt**.

For more information about these encodings, see [S3_<op1>_<Cn>_<Cm>_<op2>](#), [IMPLEMENTATION DEFINED Registers](#).

As that section describes, any IMPLEMENTATION DEFINED registers are accessed in a similar way to architecturally-defined System registers, using **MRS**, and **MSR** instructions, see:

- [MRS](#).
- [MSR \(immediate\)](#).
- [MSR \(register\)](#).

Accesses to these registers that are not trapped are permitted to be UNDEFINED. Arm recommends that IMPLEMENTATION DEFINED registers that are not UNDEFINED follow the principles in [Principles of the System instruction class encoding](#).

The Arm architecture guarantees not to define any register name prefixed with **IMP_** as part of the standard Arm architecture.

Note

Arm strongly recommends that any register names created in the IMPLEMENTATION DEFINED register spaces be prefixed with **IMP_** and postfixed with **_ELx**, where appropriate.

Chapter D12

AArch64 System Register Descriptions

This chapter defines the AArch64 System registers. It contains the following sections:

- [About the AArch64 System registers](#)
- [General system control registers](#)
- [Debug System registers](#)
- [Trace registers](#)
- [Performance Monitors registers](#)
- [PMSA registers](#)
- [RAS registers](#)
- [Generic Timer registers](#)

D12.1 About the AArch64 System registers

The following sections describe common features of the AArch64 registers:

- [Reading the System register descriptions.](#)
- [General behavior of accesses to the AArch64 System registers.](#)
- [Principles of the ID scheme for fields in ID registers.](#)

D12.1.1 Reading the System register descriptions

D12.1.1.1 Registers and register names

The title of each section in [AArch64 System Register Descriptions](#) refers to a register.

An AArch64 register is accessed using one of the functions `MRS`, `MSR (register)`, `MSR (immediate)`, `MRRS`, or `MSRR`, using an encoding value.

The encoding value is associated with a mnemonic register name, which may not be the same as the name of the register. Tables listing all encodings, mnemonics and the register they access are found in [Table D11-1](#) and [Table D11-2](#).

Some registers can be accessed using multiple encodings.

For example:

- When virtualization is implemented, see System and Special-purpose register redirection.
- When there is an alias mnemonic, see System and Special-purpose register aliasing.
- When a mnemonic accesses a register in an array of registers, for example [PMXEVCNTR_EL0](#).

D12.1.1.2 Register arrays and names

Arrays of registers are indicated by an `<n>` or `<m>` in the title of the register. These are a shortcut for referencing a number of registers with identical field layout. The index letter is considered to be replaced by a number for each individual register in the array.

There are several different ways for a register in an array to be associated with an encoding:

- The same number of encodings as there are registers in the array. The mnemonic will include an index letter, which may not be the same as the register array index letter, and the encodings will be represented in terms of that index letter. For example, see `PMEVCNTR<n>`.
- One encoding for all registers in the array. Another register is used to select the register in the array to be accessed. For example, see [PMXEVCNTR_EL0](#).
- A group of encodings, used to access a subset of the register array, with another register used to select which bank of registers is accessed. For example, see `SPMEVCNTR<n>_EL0`.

D12.1.1.3 Multiple conditions in register fields, resets or accessors

Throughout the register descriptions, conditions are used to represent changes of behavior. If multiple conditions apply to the same item, they are not necessarily mutually exclusive. The conditions are ordered so that the first true condition applies, and no further conditions are considered.

D12.1.1.4 Direct register access

In the pseudocode representing access to a particular encoding, direct access to a register is represented by a function using the same name as the register.

On a direct read, the architecturally visible value includes any field-level access controls or conditional read constraints on the value read from the register using the function.

On a direct write, any field-level access controls and constraints are applied to the value before it is written to the register using the function.

The accessibility pseudocode in the register description represents the traps and redirections for read and write accesses, and in most cases, the function to read or write the register is simple. In a few cases, there are more complex behaviors that would not be possible to represent on the register page, and these are documented in [A-profile Architecture Pseudocode](#).

D12.1.1.5 Fixed values and reserved values in the System registers

Some fields or bit ranges in registers are described as reserved, or have a fixed value.

For information on the glossary terms [RAZ](#), [RES0](#), [RAO](#), and [RES1](#), see [Fixed values in AArch64 instruction and System register descriptions](#).

For information on the behavior of reserved values, see [Reserved values in System and memory-mapped registers and translation table entries](#).

D12.1.2 General behavior of accesses to the AArch64 System registers

The following subsections give general information about the behavior of accesses to the System registers:

- [Reset behavior of AArch64 System registers](#).
- [Synchronization requirements for AArch64 System registers](#).

D12.1.2.1 Reset behavior of AArch64 System registers

Reset values apply only to RW registers and fields, however:

- Some RO registers or fields, including feature ID registers and some status registers or register fields, always return a known value.
- Some RW and RO registers or register fields return status information about the PE. Unless the register description indicates that the value is UNKNOWN on reset, a read of the register immediately after a reset returns valid information.
- Some RW and RO registers and fields are aliases of other registers or fields. In these cases, the reset behavior of the aliased register or field determines the value returned by a read of the register immediately after a reset.
- WO registers that only have an effect on writes do not have meaningful reset values. However, an access to a WO register might affect underlying state, and that state might have a defined reset value.
- IMPLEMENTATION DEFINED registers have IMPLEMENTATION DEFINED reset behavior.

After a reset, only a limited subset of the PE state is guaranteed to be set to defined values. Also, for debug and trace System registers, reset requirements must take account of different levels of reset. For more information about the reset behavior of System registers when the PE resets into an Exception level that is using AArch64, see:

- [Reset behavior](#).
- The appropriate Trace architecture specification, for the Trace System registers.

For a PE reset into an Exception level that is using AArch64, the architecture defines which AArch64 System registers have a defined reset value, and when that defined reset value applies. The register descriptions include this information, and [Reset behavior](#) summarizes these architectural requirements. Otherwise, RW registers that have a meaningful reset value reset to an architecturally UNKNOWN value.

D12.1.2.1.1 Pseudocode description of resetting System registers

The `AArch64_ResetSystemRegisters()` pseudocode function resets all System registers, and register fields, that have defined reset values, as described in this section and [Reset behavior](#).

Note

For debug and trace System registers, this function resets registers as defined for the appropriate level of reset.

D12.1.2.2 Synchronization requirements for AArch64 System registers

Reads of the System registers can occur out of order with respect to earlier instructions executed on the same PE, provided that both:

- Any data dependencies between the instructions, including read-after-read dependencies, are respected.
- The reads to the register do not occur earlier than the most recent [Context Synchronization event](#) to its architectural position in the instruction stream.

Note

In particular, the values read from System registers that hold self-incrementing counts, such as the Performance Monitors counters or the Generic Timer counter or timers, could be accessed from any time after the previous [Context Synchronization event](#). For example, where a memory access is used to communicate a read of such a counter, an `ISB` must be inserted between the read of the memory location that is known to have returned its data, either as a result of a condition on that data or of the read having completed, and the read of the counter, if it is necessary that the counter returns a count value after the memory communication.

Unless otherwise stated in its System register definition, a direct write to a System register requires synchronization before software can rely on the effects of that write to affect instructions appearing in program order after the write. This does not apply to Special-purpose registers. For more information, see [Instructions for accessing Special-purpose registers](#). Direct writes to System registers are not allowed to affect any instructions appearing in program order before the direct write. The only exceptions are:

- All direct writes to the same register, that use the same encoding for that register, are guaranteed to occur in program order relative to each other.
- All direct writes to a register occur in program order with respect to all direct reads to the same register using the same encoding.
- Any System register access that an Arm *Architecture Specification* or equivalent specification defines as not requiring synchronization.
- When FEAT_BRBE is implemented, execution of `BRB INJ` does not require explicit synchronization to use the result of direct writes to the Branch record injection data registers in program order before `BRB INJ`.

Explicit synchronization occurs as a result of a [Context Synchronization event](#), which is one of the following events:

- Execution of an `ISB` instruction.
- Exception entry, if FEAT_ExS is not implemented, or if FEAT_ExS is implemented and defines that exception entries to this Exception level are [Context Synchronization events](#).
- Exception return, if FEAT_ExS is not implemented, or if FEAT_ExS is implemented and defines that exception returns from this Exception level are [Context Synchronization events](#).
- Execution of a `DCPS` instruction in Debug state.
- Execution of a `DRPS` instruction in Debug state.
- Exit from Debug state.

Note

The `ISB` and exception entry events are applicable both in Debug state and in Non-debug state.

The pseudocode for each of these events defines the point at which the explicit synchronization takes effect, as a result of a call to the `SynchronizeContext()` function or `InstructionSynchronizationBarrier()` function. The principle behind the position of the call to `SynchronizeContext()` or `InstructionSynchronizationBarrier()` is that it occurs before indirect reads of System registers that are used in the construction of the target context, but is permitted to occur after indirect reads of System registers that apply to the context in which the instruction is executed or from which the event is taken.

Note

For some instructions, this means that some System registers are indirectly read before the explicit synchronization, and therefore changes to those System registers might need an explicit Context synchronization event before the instruction. For example, changes to some fields of `HCR_EL2` at EL2 need an explicit `ISB` in program order before an `ERET` instruction.

In addition, any system instructions that cause a write to a System register must be synchronized before the result is guaranteed to be visible to subsequent direct reads of that System register.

Direct reads to any one of the following registers, using the same encoding, occur in program order relative to each other:

- [ISR_EL1](#).

- The Generic Timer registers, that is, [CNTPTCT_EL0](#) and [CNTVCT_EL0](#), and the Counter registers [CNTPT_TVAL_EL0](#), [CNTV_TVAL_EL0](#), [CNTHP_TVAL_EL2](#), and [CNTPTS_TVAL_EL1](#).
- [DBGCLAIMCLR_EL1](#).
- The PMU Counters, that is, [PMCCNTR_EL0](#), [PMEVCNTR<n>_EL0](#), [PMXEVCNTR_EL0](#), [PMOVSCLR_EL0](#), and [PMOVSSET_EL0](#).
- The System PMU Counters, that is, [SPMEVCNTR<n>_EL0](#), [SPMOVSCCLR_EL0](#), and [SPMOVSSSET_EL0](#).
- The Debug Communications Channel System registers, that is, [DBGDTRRX_EL0](#), [DBGDTR_EL0](#), and [MDCCSR_EL0](#).

All other direct reads of System registers can occur in any order if synchronization has not been performed.

[Table D12-1](#) describes the synchronization requirements between two successive read or write accesses to the same register, where the ordering of the read or write accesses is:

1. Program order, in the event that both the reads or writes are caused by an instruction executed on this PE, other than one caused by a memory access by this PE.
2. The order of arrival of asynchronous reads and writes at the PE relative to the execution of instructions that cause reads or writes.
3. The order of arrival of asynchronous reads and writes at the PE relative to each other.

Table D12-1 Synchronization requirements

First read/write	Second read/write	Synchronization requirement
Direct read	Direct read	None
	Direct write	None
	Indirect read	None
	Indirect write	None, see Notes
Direct write	Direct read	None
	Direct write	None
	Indirect read	Required
	Indirect write	None, see Notes
Indirect read	Direct read	None
	Direct write	None
	Indirect read	None
	Indirect write	None
Indirect write	Direct read	Required, see Notes
	Direct write	None, see Notes
	Indirect read	Required, see Notes
	Indirect write	None, see Notes

D12.1.2.2.1 Notes

The terms Direct read, Direct write, Indirect read, and Indirect write, as used in [Table D12-1](#), are defined as follows:

- Direct read** Where software uses an [MRS](#) or [MRRS](#) System register access instruction to read that register into a general purpose register.
- Where a direct read of a register has a side-effect that changes the contents of a register, the effect of a direct read on that register is defined to be an indirect write. In this case, the indirect write is only

guaranteed to have occurred, and be visible to subsequent direct or indirect reads or writes, if synchronization is performed after the direct read.

- Direct write** Where software uses an [MSR \(register\)](#) or MSRR access instruction to write to that register from a general purpose register.
- Where a direct write to a register has an effect on the register that means that the value in the register is not always the last value that is written (as is the case with set and clear registers), the effect of a direct write on that register is defined to be an indirect write. In this case, the indirect write is only guaranteed to be visible to subsequent direct or indirect reads or writes if synchronization is performed after the direct write and before the subsequent direct or indirect reads or writes.
- Indirect read** Where an instruction uses a System register to establish operating conditions for the instruction, for example, the [TTBR_ELx](#) address or whether memory accesses are forced to be Non-cacheable. This includes situations where the contents of one System register selects what value is read or written using a different register. Indirect reads also include reads of the System register by external agents such as debuggers. Instruction execution from MDSTEPOP_EL1 is an indirect read of MDSTEPOP_EL1. Where an indirect read of a register has a side-effect that changes the contents of that register, that is defined to be an indirect write.
- Indirect write** Where a System register is written as the consequence of some other instruction, exception, operation, or by the asynchronous operation of an external agent, including the passage of time as seen in counters, timers, or performance counters, the assertion of interrupts, or writes from an external debugger.

Note

Registers such as the Exception Syndrome registers that are indirectly written as part of exception entry do not require additional synchronization. This behavior is independent of the value of SCTLR_ELx.EIS, and the list of affected registers is described in the definition of that field.

The value of a System register does not change unless one of the following occurs:

- As the result of a direct write to the register, that is not specified as being trapped, UNDEFINED or IGNORED.
- As the result of one of the specified indirect writes to the register.
- A reset, if the register has a specified reset behavior for that reset.
- The register holds an UNKNOWN value as the result of one of the above.

Where a direct read or write to a register is followed by an indirect write caused by an external agent, autonomous asynchronous event, or as a result of memory mapped write, synchronization is required to guarantee the order of those two accesses.

Where an indirect write caused by a direct write is followed by an indirect write caused by an external agent, autonomous asynchronous event, or as a result of memory mapped write, synchronization is required to guarantee the order of those two indirect accesses.

Where a direct read to one register causes a bit or field in a different register (or the same register using a different encoding) to be updated, the change to the different register (or same register using a different encoding) is defined to be an indirect write. In this case, the indirect write is only guaranteed to be visible to subsequent direct or indirect reads or writes if synchronization is performed after the direct read and before the subsequent direct or indirect reads or writes.

Where a direct write to one register causes a bit or field in a different register (or the same register using a different encoding) to be updated as a side-effect of that direct write (as opposed to simply being a direct write to the different encoding), the change to the different register (or same register using a different encoding) is defined to be an indirect write. In this case, the indirect write is only guaranteed to be visible to subsequent direct or indirect reads or writes if synchronization is performed after the direct write and before the subsequent direct or indirect reads or writes.

Where indirect writes are caused by the actions of external agents such as debuggers, or by memory-mapped reads or writes by the PE, then an indirect write by that agent and mechanism to a register, followed by an indirect read by that agent and mechanism to the same register using the same address, does not require synchronization.

Where an indirect write occurs as a side-effect of an access, this happens atomically with the access, meaning no other accesses are allowed between the register access and its side-effect.

Note

Even though the 64-bit and 128-bit form of a System register share the same values of {op0, op1, CRn, CRm, op2}, they are considered to be distinct encodings. Therefore, explicit synchronization is required to guarantee ordering in all of the following cases:

- MSRR followed by an [MRS](#) from the same register.
- [MSR \(register\)](#) followed by an MRRS from the same register.

Where indirect writes to GCSPR_ELx are made by the following instructions, explicit synchronization is not required to be visible to direct reads, indirect reads, and indirect writes in program order after the initial indirect write:

- All Branch with Link instructions.
- All procedure return instructions.
- GCSPOPM and GCSPUSHM.
- GCSPOPX, GCSPOPCX, and GCSPUSHX.
- GCSSS1 and GCSSS2.

Indirect writes caused by external agents, autonomous asynchronous events, or as a result of memory-mapped writes, to the registers shown in [Table D12-2](#), are required to be observable to:

- Direct reads in finite time without explicit synchronization.
- Subsequent indirect reads without explicit synchronization.

Without explicit synchronization to guarantee the order of the accesses, where the same register is accessed by two or more of a System register access instruction, and external agent, and autonomous asynchronous event, or as a result of a memory-mapped access, the behavior must be as if the accesses occurred atomically and in any order. This applies even if the accesses occur simultaneously.

Table D12-2 Registers with a guarantee of observability, VMSAv8-64

Registers	Notes
ISR_EL1	Interrupt Status Register
DBGCLAIMCLR_EL1 , DBGCLAIMSET_EL1	Debug CLAIM registers
CNTPCT_EL0 , CNTVCT_EL0 , CNTP_TVAL_EL0 , CNTV_TVAL_EL0 , CNTHP_TVAL_EL2 , CNTPS_TVAL_EL1	Generic Timer registers
PMCCNTR_EL0 , PMEVCNTR<n>_EL0 , PMXVCNTR_EL0 , PMOVSLR_EL0 , PMOVSSET_EL0	PMU Counters
SPMEVCNTR<n>_EL0 , SPMOVSLR_EL0 , SPMOVSSET_EL0	System PMU Counters
DBGDTRTX_EL0 , DBGDTRRX_EL0 , DBGDTR_EL0 , and the DCC flags in MDCCSR_EL0 and EDSCR	Debug Communication Channel registers
EDSCR .PipeAdv	External Debug Status and Control Register

In addition to the requirements shown in [Table D12-2](#):

- Indirect writes to the following registers as a result of memory-mapped writes, including accesses by external agents, are required to be observable to the indirect read made in determining the response to a subsequent memory-mapped access without explicit synchronization:
 - [OSLAR_EL1](#). [OSLAR_EL1](#) is indirectly read to determine whether the subsequent access is permitted.
 - [EDLAR](#), if implemented. [EDLAR](#) is indirectly read to determine whether a subsequent write or side-effect of an access is ignored.

Note

This requirement is stricter than the general requirement for the observability of indirect writes.

- The requirement that an indirect write to the registers in [Table D12-2](#) is observable to direct reads in finite time does not imply that all observers will observe the indirect write at the same time.
For example, an increment of the system counter is an autonomous asynchronous event that performs an indirect write to the counter. This asynchronous event might generate a timer interrupt request, resulting in a [Context Synchronization event](#). When a GIC is used, the timer interrupt might arrive at the GIC after the PE has taken an interrupt request from another source, but before software reads the current interrupt ID from the GIC. This means that the GIC might identify the timer interrupt as the current interrupt. Software must not assume that a subsequent direct read of the counter register is guaranteed to observe the updated value of that register.
Although this example uses the counter-timer registers, it applies equally to other registers that might be linked to interrupt requests, including the PMU and Statistical Profiling status registers.
- When the PE is in Debug state, there are synchronization requirements for the Debug Communication Channel and Instruction Transfer registers. See [DCC and ITR access in Debug state](#).

Note

- The provision of explicit synchronization requirements to System registers is provided to allow the direct access to these registers to be implemented in a small number of cycles, and that updates to multiple registers can be performed quickly with the synchronization penalty being paid only when the updates have occurred.
 - Since toolkits might use registers such as the thread-local storage registers within compiled code, it is recommended that access to these registers is implemented to take a small number of cycles.
 - While no synchronization is required between a direct write and a direct read, or between a direct read and an indirect write, this does not imply that a direct read causes synchronization of a previous direct write. That is, the sequence direct write → direct read → indirect read, with no intervening context synchronization, does not guarantee that the indirect read observes the result of the direct write.
-

D12.1.3 Principles of the ID scheme for fields in ID registers

The Arm architecture specifies a number of *ID registers* that are characterized as comprising a set of 4-bit *ID fields*. Each ID field identifies the presence, and possibly the level of support for, a particular feature in an implementation of the architecture. These fields follow an architectural model that aids their use by software and provides future compatibility. This section describes that model. [ID registers to which this scheme applies](#) identifies the set of ID registers.

A small number of ID fields do not follow the scheme described in this section. In these cases, the field description states that it does not follow this scheme.

Note

- The ID fields described here are unlike the ones that enumerate the number of resources, such as the number of breakpoints, watchpoints, or performance monitors.
 - ID fields that do not follow this scheme include the [ID_AA64DFR0_EL1.PMUVer](#), [ID_DFR0_EL1.PerfMon](#), [ID_DFR0.PerfMon](#) and [EDDFR.PMUVer](#) fields, see [Alternative ID scheme used for the Performance Monitors Extension version](#).
 - The presence of an ID field for a feature does not imply that the feature is optional.
-

To provide forward compatibility, software can rely on the features of these fields that are described in this section.

The ID fields, which are either signed or unsigned, use increasing numerical values to indicate increases in functionality. Therefore, for an unsigned ID field, if the value 0×1 indicates the presence of some instructions, then the value 0×2 will indicate the presence of those instructions plus some additional instructions or functionality. This means software can be written in the form:

```
if (value >= number) {  
    // do something that relies on the value of the feature  
}
```

For ID fields where the value 0x0 defines that a feature is not present, the field holds an unsigned value. This covers the vast majority of such fields.

In a few cases, the architecture has been changed to permit implementations to exclude a feature that has previously been required and for which no ID field has been defined. In these cases, a new ID field is defined and:

- The field holds a signed value.
- The field value 0x0 indicates that the feature is implemented.
- The field value 0xF indicates that the feature is not implemented.
- Increasingly negative values indicate additional aspects of the architecture that are not implemented as a result of the feature not being implemented.
- Software that depends on the feature can use the test:

```
if value >= 0 {  
    // Software features that depend on the presence of the hardware feature  
}
```

In some cases, it has been decided retrospectively that the increase in functionality between two consecutive numerical values is too great, and it is desirable to permit an intermediate degree of functionality, and the means to discover this. This is done by the introduction of a *fractional* field that both:

- Is referred to in the definition of the original field.
- Applies only when the original field is at the lower value of the step.

In principle, a fractional field can be used for two different fractional steps, with different meanings associated with each of these steps. For this reason, a fractional field must be interpreted in the context of the field to which it relates and the value of that field. [Example D12-1](#) shows the use of such a field.

Example D12-1 Example of the use of a fractional field

For a field describing some class of functionality:

- The value 0x1 was defined as indicating that item A is present.
- The value 0x2 was defined as indicating that items B and C are present, in addition to item A.

Subsequently, it might be necessary to introduce a second ID field to indicate that A and B only are present. This new field is a fractional field, and might be defined as having the value 0x1 when A and B only are present. This fractional field is valid only when the original ID field has the value 0x1.

This approach means that:

- Software that depends on the test if (value >= 0x2) can rely on features A, B, and C being present,
- Software that depends on the test if (value >= 0x1) can rely on feature A being present.
- If new software needs to check only that features A and B are present, then it can test:

```
if (value >= 0x2 || (value == 0x1 && fractional_value >= 0x1)) {  
    // Software features that depend on A and B only  
}
```

A fractional field uses the same approach of increasing numerical values indicating increasing functionality, and the fractional approach can also be applied recursively to fractional fields.

Unused ID fields, and fractional fields that are not applicable, are RES0 to allow their future use when features, or fractional implementation options, are added.

D12.1.3.1 ID registers to which this scheme applies

This scheme applies to the following registers:

AArch64 System registers

- The Auxiliary Feature register [ID_AFR0_EL1](#).
- The Processor Feature registers [ID_PFR0_EL1](#), [ID_PFR1_EL1](#), and [ID_PFR2_EL1](#).
- The Debug Feature register [ID_DFR0_EL1](#) and [ID_DFR1_EL1](#).
- The Memory Model Feature registers [ID_MMFR0_EL1](#), [ID_MMFR1_EL1](#), [ID_MMFR2_EL1](#), [ID_MMFR3_EL1](#), [ID_MMFR4_EL1](#), and [ID_MMFR5_EL1](#).
- The Instruction Set Attribute registers [ID_ISAR0_EL1](#), [ID_ISAR1_EL1](#), [ID_ISAR2_EL1](#), [ID_ISAR3_EL1](#), [ID_ISAR4_EL1](#), [ID_ISAR5_EL1](#), and [ID_ISAR6_EL1](#).
- The Media and VFP Feature registers [MVFR0_EL1](#), [MVFR1_EL1](#), and [MVFR2_EL1](#).
- The AArch64 Auxiliary Feature registers [ID_AA64AFR0_EL1](#) and [ID_AA64AFR1_EL1](#).
- The AArch64 Processor Feature registers [ID_AA64PFR0_EL1](#), [ID_AA64PFR1_EL1](#), and [ID_AA64PFR2_EL1](#).
- The AArch64 Debug Feature registers [ID_AA64DFR0_EL1](#), [ID_AA64DFR1_EL1](#), and [ID_AA64DFR2_EL1](#).
- The AArch64 Memory Model Feature registers [ID_AA64MMFR0_EL1](#), [ID_AA64MMFR1_EL1](#), [ID_AA64MMFR2_EL1](#), [ID_AA64MMFR3_EL1](#), and [ID_AA64MMFR4_EL1](#).
- The AArch64 Instruction Set Attribute registers [ID_AA64ISAR0_EL1](#), [ID_AA64ISAR1_EL1](#), and [ID_AA64ISAR2_EL1](#).

Memory-mapped registers

- The External Debug Processor Feature register [EDPFR](#).
- The External Debug Feature register [EDDFR](#).
- The External Debug Auxiliary Processor Feature register [EDAA32PFR](#).

D12.1.3.2 Alternative ID scheme used for the Performance Monitors Extension version

The [ID_AA64DFR0_EL1](#).PMUVer, [ID_DFR0_EL1](#).PerfMon, [ID_DFR0](#).PerfMon and [EDDFR](#).PMUVer fields, that identify the version of the Performance Monitors Extension, do not follow the standard ID scheme. Software must treat these fields as follows:

- The value 0xF indicates that the Arm-architected Performance Monitors Extension is not implemented.
- If the field value is not 0xF, the field is treated as an unsigned value, as described for the standard ID scheme.

This means that software that depends on the implementation of a particular version of the Arm Performance Monitors Extension must be written in the form:

```
if (value != 0xF and value >= number) {
    // do something that relies on version 'number' of the feature
}
```

For these fields, Arm deprecates use of the value 0xF in new implementations.

D12.1.3.3 Alternative ID scheme used for ID_AA64MMFR0_EL1 stage 2 granule sizes

The [ID_AA64MMFR0_EL1](#).{TGran4_2, TGran64_2, TGran16_2} fields that identify the memory translation stage 2 granule size, do not follow the standard ID scheme. Software must treat these fields as follows:

- The value 0x0 indicates that support is identified by another field.
- If the field value is not 0x0, the value indicates the level of support provided.

This means that software should use a test of the form:

```
if (field != 0 and field > value) {
    // do something that relies on the value of the feature
}
```

D12.1.3.4 Alternative ID scheme used for ID_AA64SMFR0_EL1 and ID_AA64FPFR0_EL1

Apart from the ID_AA64SMFR0_EL1.SMEver field, which is a 4-bit unsigned integer conforming to the standard scheme, software must treat the other fields in these registers as follows:

- A 1-bit field value where the bit is 0b0 indicates that the specified feature or instructions described by this field are not implemented.
- A 1-bit field value where the bit is 0b1 indicates that the specified feature or instructions described by this field are implemented.
- In ID_AA64SMFR0_EL1, a 4-bit field indicates whether a group of related SME instructions is implemented, with permitted values defined in the field description. Bits within such a field which only permit the value 0b0000 might be used to identify new instructions in a future version of SME, without changing the meaning of those bits that permit the value 0b0001.

D12.2 General system control registers

This section lists the System registers in AArch64 that are not part of one of the other listed groups.

D12.2.1 ACTLR_EL1, Auxiliary Control Register (EL1)

The ACTLR_EL1 characteristics are:

Purpose

Provides IMPLEMENTATION DEFINED configuration and control options for execution at EL1 and EL0.

Configuration

There are no configuration notes.

Attributes

ACTLR_EL1 is a 64-bit register.

Field descriptions

IMPLEMENTATION DEFINED, bits [63:0]

IMPLEMENTATION DEFINED.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing ACTLR_EL1

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, ACTLR_EL1

op0	op1	CRn	CRm	op2
0b11	0b000	0b0001	0b0000	0b001

```
if PSTATE.EL == EL0 then
    Undefined();
elsif PSTATE.EL == EL1 then
    if HCR_EL2().TACR == '1' then
        AArch64_SystemAccessTrap(EL2, 0x18);
    else
        X{64}(t) = ACTLR_EL1();
    end;
elsif PSTATE.EL == EL2 then
    X{64}(t) = ACTLR_EL1();
end;
```

MSR ACTLR_EL1, <Xt>

op0	op1	CRn	CRm	op2
0b11	0b000	0b0001	0b0000	0b001

```
if PSTATE.EL == EL0 then
    Undefined();
elsif PSTATE.EL == EL1 then
    if HCR_EL2().TACR == '1' then
        AArch64_SystemAccessTrap(EL2, 0x18);
    else
        ACTLR_EL1() = X{64}(t);
    end;
elsif PSTATE.EL == EL2 then
    ACTLR_EL1() = X{64}(t);
end;
```

D12.2.2 ACTLR_EL2, Auxiliary Control Register (EL2)

The ACTLR_EL2 characteristics are:

Purpose

Provides IMPLEMENTATION DEFINED configuration and control options for EL2.

Configuration

There are no configuration notes.

Attributes

ACTLR_EL2 is a 64-bit register.

Field descriptions

IMPLEMENTATION DEFINED, bits [63:0]

IMPLEMENTATION DEFINED.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing ACTLR_EL2

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, ACTLR_EL2

op0	op1	CRn	CRm	op2
0b11	0b100	0b0001	0b0000	0b001

```
if PSTATE.EL == EL0 then
    Undefined();
elsif PSTATE.EL == EL1 then
    Undefined();
elsif PSTATE.EL == EL2 then
    X{64}(t) = ACTLR_EL2();
end;
```

MSR ACTLR_EL2, <Xt>

op0	op1	CRn	CRm	op2
0b11	0b100	0b0001	0b0000	0b001

```

if PSTATE.EL == EL0 then
    Undefined();
elseif PSTATE.EL == EL1 then
    Undefined();
elseif PSTATE.EL == EL2 then
    ACTLR_EL2() = X{64}(t);
end;

```

When an implementation implements ACTLR_ELx accessor behavior MRS <Xt>, ACTLR_EL1

op0	op1	CRn	CRm	op2
0b11	0b000	0b0001	0b0000	0b001

```

if PSTATE.EL == EL0 then
    Undefined();
elseif PSTATE.EL == EL1 then
    if HCR_EL2().TACR == '1' then
        AArch64_SystemAccessTrap(EL2, 0x18);
    else
        X{64}(t) = ACTLR_EL1();
    end;
elseif PSTATE.EL == EL2 then
    X{64}(t) = ACTLR_EL1();
end;

```

When an implementation implements ACTLR_ELx accessor behavior MSR ACTLR_EL1, <Xt>

op0	op1	CRn	CRm	op2
0b11	0b000	0b0001	0b0000	0b001

```

if PSTATE.EL == EL0 then
    Undefined();
elseif PSTATE.EL == EL1 then
    if HCR_EL2().TACR == '1' then
        AArch64_SystemAccessTrap(EL2, 0x18);
    else
        ACTLR_EL1() = X{64}(t);
    end;
elseif PSTATE.EL == EL2 then
    ACTLR_EL1() = X{64}(t);
end;

```

D12.2.3 AFSR0_EL1, Auxiliary Fault Status Register 0 (EL1)

The AFSR0_EL1 characteristics are:

Purpose

Provides additional IMPLEMENTATION DEFINED fault status information for exceptions taken to EL1.

Configuration

There are no configuration notes.

Attributes

AFSR0_EL1 is a 64-bit register.

Field descriptions

IMPLEMENTATION DEFINED, bits [63:0]

IMPLEMENTATION DEFINED.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing AFSR0_EL1

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, AFSR0_EL1

op0	op1	CRn	CRm	op2
0b11	0b000	0b0101	0b0001	0b000

```
if PSTATE.EL == EL0 then
    Undefined();
elsif PSTATE.EL == EL1 then
    if HCR_EL2().TRVM == '1' then
        AArch64_SystemAccessTrap(EL2, 0x18);
    else
        X{64}(t) = AFSR0_EL1();
    end;
elsif PSTATE.EL == EL2 then
    X{64}(t) = AFSR0_EL1();
end;
```

MSR AFSR0_EL1, <Xt>

op0	op1	CRn	CRm	op2
0b11	0b000	0b0101	0b0001	0b000

```
if PSTATE.EL == EL0 then
    Undefined();
elsif PSTATE.EL == EL1 then
    if HCR_EL2().TVM == '1' then
        AArch64_SystemAccessTrap(EL2, 0x18);
    else
        AFSR0_EL1() = X{64}(t);
    end;
elsif PSTATE.EL == EL2 then
    AFSR0_EL1() = X{64}(t);
end;
```

D12.2.4 AFSR0_EL2, Auxiliary Fault Status Register 0 (EL2)

The AFSR0_EL2 characteristics are:

Purpose

Provides additional IMPLEMENTATION DEFINED fault status information for exceptions taken to EL2.

Configuration

There are no configuration notes.

Attributes

AFSR0_EL2 is a 64-bit register.

Field descriptions

IMPLEMENTATION DEFINED, bits [63:0]

IMPLEMENTATION DEFINED.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing AFSR0_EL2

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, AFSR0_EL2

op0	op1	CRn	CRm	op2
0b11	0b100	0b0101	0b0001	0b000

```
if PSTATE.EL == EL0 then
    Undefined();
elsif PSTATE.EL == EL1 then
    Undefined();
elsif PSTATE.EL == EL2 then
    X{64}(t) = AFSR0_EL2();
end;
```

MSR AFSR0_EL2, <Xt>

op0	op1	CRn	CRm	op2
0b11	0b100	0b0101	0b0001	0b000

```
if PSTATE.EL == EL0 then
    Undefined();
elsif PSTATE.EL == EL1 then
    Undefined();
elsif PSTATE.EL == EL2 then
    AFSR0_EL2() = X{64}(t);
end;
```

D12.2.5 AFSR1_EL1, Auxiliary Fault Status Register 1 (EL1)

The AFSR1_EL1 characteristics are:

Purpose

Provides additional IMPLEMENTATION DEFINED fault status information for exceptions taken to EL1.

Configuration

There are no configuration notes.

Attributes

AFSR1_EL1 is a 64-bit register.

Field descriptions

IMPLEMENTATION DEFINED, bits [63:0]

IMPLEMENTATION DEFINED.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing AFSR1_EL1

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, AFSR1_EL1

op0	op1	CRn	CRm	op2
0b11	0b000	0b0101	0b0001	0b001

```
if PSTATE.EL == EL0 then
    Undefined();
elsif PSTATE.EL == EL1 then
    if HCR_EL2().TRVM == '1' then
        AArch64_SystemAccessTrap(EL2, 0x18);
    else
        X{64}(t) = AFSR1_EL1();
    end;
elsif PSTATE.EL == EL2 then
    X{64}(t) = AFSR1_EL1();
end;
```

MSR AFSR1_EL1, <Xt>

op0	op1	CRn	CRm	op2
0b11	0b000	0b0101	0b0001	0b001

```
if PSTATE.EL == EL0 then
    Undefined();
elsif PSTATE.EL == EL1 then
    if HCR_EL2().TVM == '1' then
        AArch64_SystemAccessTrap(EL2, 0x18);
    else
        AFSR1_EL1() = X{64}(t);
    end;
elsif PSTATE.EL == EL2 then
    AFSR1_EL1() = X{64}(t);
end;
```

D12.2.6 AFSR1_EL2, Auxiliary Fault Status Register 1 (EL2)

The AFSR1_EL2 characteristics are:

Purpose

Provides additional IMPLEMENTATION DEFINED fault status information for exceptions taken to EL2.

Configuration

There are no configuration notes.

Attributes

AFSR1_EL2 is a 64-bit register.

Field descriptions

IMPLEMENTATION DEFINED, bits [63:0]

IMPLEMENTATION DEFINED.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing AFSR1_EL2

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, AFSR1_EL2

op0	op1	CRn	CRm	op2
0b11	0b100	0b0101	0b0001	0b001

```
if PSTATE.EL == EL0 then
    Undefined();

    Undefined();
elsif PSTATE.EL == EL2 then
    X{64}(t) = AFSR1_EL2();
end;
```

MSR AFSR1_EL2, <Xt>

op0	op1	CRn	CRm	op2
0b11	0b100	0b0101	0b0001	0b001

```
if PSTATE.EL == EL0 then
    Undefined();
elsif PSTATE.EL == EL1 then
    Undefined();
elsif PSTATE.EL == EL2 then
    AFSR1_EL2() = X{64}(t);
end;
```

D12.2.7 AIDR_EL1, Auxiliary ID Register

The AIDR_EL1 characteristics are:

Purpose

Provides IMPLEMENTATION DEFINED identification information.

The value of this register must be interpreted in conjunction with the value of MIDR_EL1.

Configuration

There are no configuration notes.

Attributes

AIDR_EL1 is a 64-bit register.

Field descriptions

IMPLEMENTATION DEFINED, bits [63:0]

IMPLEMENTATION DEFINED.

Accessing AIDR_EL1

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, AIDR_EL1

op0	op1	CRn	CRm	op2
0b11	0b001	0b0000	0b0000	0b111

```
if PSTATE.EL == EL0 then
    if IsFeatureImplemented(FEAT_IDST) then
        AArch64_SystemAccessTrapToEL1orEL2(0x18);
    else
        Undefined();
    end;
elseif PSTATE.EL == EL1 then
    if HCR_EL2().TID1 == '1' then
        AArch64_SystemAccessTrap(EL2, 0x18);
    else
        X{64}(t) = AIDR_EL1();
    end;
elseif PSTATE.EL == EL2 then
    X{64}(t) = AIDR_EL1();
end;
```

D12.2.8 AMAIR_EL1, Auxiliary Memory Attribute Indirection Register (EL1)

The AMAIR_EL1 characteristics are:

Purpose

Provides IMPLEMENTATION DEFINED memory attributes for the memory regions specified by MAIR_EL1.

Configuration

There are no configuration notes.

Attributes

AMAIR_EL1 is a 64-bit register.

Field descriptions

AMAIR_EL1 is permitted to be cached in a TLB.

IMPLEMENTATION DEFINED, bits [63:0]

IMPLEMENTATION DEFINED.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing AMAIR_EL1

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, AMAIR_EL1

op0	op1	CRn	CRm	op2
0b11	0b000	0b1010	0b0011	0b000

```
if PSTATE.EL == EL0 then
    Undefined();
elsif PSTATE.EL == EL1 then
    if HCR_EL2().TRVM == '1' then
        AArch64_SystemAccessTrap(EL2, 0x18);
    else
        X{64}(t) = AMAIR_EL1();
    end;
elsif PSTATE.EL == EL2 then
    X{64}(t) = AMAIR_EL1();
end;
```

MSR AMAIR_EL1, <Xt>

op0	op1	CRn	CRm	op2
0b11	0b000	0b1010	0b0011	0b000

```
if PSTATE.EL == EL0 then
    Undefined();
elsif PSTATE.EL == EL1 then
    if HCR_EL2().TVM == '1' then
        AArch64_SystemAccessTrap(EL2, 0x18);
    else
        AMAIR_EL1() = X{64}(t);
    end;
elsif PSTATE.EL == EL2 then
    AMAIR_EL1() = X{64}(t);
end;
```

D12.2.9 AMAIR_EL2, Auxiliary Memory Attribute Indirection Register (EL2)

The AMAIR_EL2 characteristics are:

Purpose

Provides IMPLEMENTATION DEFINED memory attributes for the memory regions specified by MAIR_EL2.

Configuration

There are no configuration notes.

Attributes

AMAIR_EL2 is a 64-bit register.

Field descriptions

AMAIR_EL2 is permitted to be cached in a TLB.

IMPLEMENTATION DEFINED, bits [63:0]

IMPLEMENTATION DEFINED.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing AMAIR_EL2

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, AMAIR_EL2

op0	op1	CRn	CRm	op2
0b11	0b100	0b1010	0b0011	0b000

```
if PSTATE.EL == EL0 then

elsif PSTATE.EL == EL1 then
    Undefined();
elsif PSTATE.EL == EL2 then
    AMAIR_EL2() = X{64}(t);
end;
```

D12.2.10 APDAKeyHi_EL1, Pointer Authentication Key A for Data (bits[127:64])

The APDAKeyHi_EL1 characteristics are:

Purpose

Holds bits[127:64] of key A used for authentication of data pointer values.

Note

The term APDAKey_EL1 is used to describe the concatenation of [APDAKeyHi_EL1](#): [APDAKeyLo_EL1](#).

Configuration

This register is present only when FEAT_PAuth is implemented. Otherwise, direct accesses to APDAKeyHi_EL1 are UNDEFINED.

Attributes

APDAKeyHi_EL1 is a 64-bit register.

Field descriptions

APDAKeyHi, bits [63:0]

64 bit value, bits[127:64] of the 128 bit pointer authentication key value.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing APDAKeyHi_EL1

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, APDAKeyHi_EL1

op0	op1	CRn	CRm	op2
0b11	0b000	0b0010	0b0010	0b001

```
if !IsFeatureImplemented(FEAT_PAuth) then
    Undefined();
elsif PSTATE.EL == EL0 then
    Undefined();
elsif PSTATE.EL == EL1 then
    if HCR_EL2().APK == '0' then
        AArch64_SystemAccessTrap(EL2, 0x18);
    else
        X{64}(t) = APDAKeyHi_EL1();
    end;
end;
```

```
elseif PSTATE.EL == EL2 then
    X{64}(t) = APDAKeyHi_EL1();
end;

MSR APDAKeyHi_EL1, <Xt>

```

D12.2.11 APDAKeyLo_EL1, Pointer Authentication Key A for Data (bits[63:0])

The APDAKeyLo_EL1 characteristics are:

Purpose

Holds bits[63:0] of key A used for authentication of data pointer values.

Note

The term APDAKey_EL1 is used to describe the concatenation of [APDAKeyHi_EL1](#): [APDAKeyLo_EL1](#).

Configuration

This register is present only when FEAT_PAuth is implemented. Otherwise, direct accesses to APDAKeyLo_EL1 are UNDEFINED.

Attributes

APDAKeyLo_EL1 is a 64-bit register.

Field descriptions

APDAKeyLo, bits [63:0]

64 bit value, bits[63:0] of the 128 bit pointer authentication key value.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing APDAKeyLo_EL1

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, APDAKeyLo_EL1

op0	op1	CRn	CRm	op2
0b11	0b000	0b0010	0b0010	0b000

```
if !IsFeatureImplemented(FEAT_PAuth) then

D12.2.12 APDBKeyHi_EL1, Pointer Authentication Key B for Data (bits[127:64])

The APDBKeyHi_EL1 characteristics are:

Purpose

Holds bits[127:64] of key B used for authentication of data pointer values.

Note

The term APDBKey_EL1 is used to describe the concatenation of APDBKeyHi_EL1: APDBKeyLo_EL1.

Configuration

This register is present only when FEAT_PAuth is implemented. Otherwise, direct accesses to APDBKeyHi_EL1 are UNDEFINED.

Attributes

APDBKeyHi_EL1 is a 64-bit register.

Field descriptions

APDBKeyHi, bits [63:0]

64 bit value, bits[127:64] of the 128 bit pointer authentication key value.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing APDBKeyHi_EL1

Accesses to this register use the following encodings in the System register encoding space:

    APIBKeyLo_EL1() = X{64}(t);
end;
```

D12.2.20 CCSIDR2_EL1, Current Cache Size ID Register 2

The CCSIDR2_EL1 characteristics are:

Purpose

Provides the information about the architecture of the currently selected cache from bits[63:32] of [CCSIDR_EL1](#).

Configuration

In an implementation which does not support AArch32 at EL1, it is IMPLEMENTATION DEFINED whether reading this register gives an UNKNOWN value or is UNDEFINED.

The implementation includes one CCSIDR2_EL1 for each cache that it can access. [CSSELR_EL1](#) selects which Cache Size ID Register is accessible.

This register is present only when FEAT_CCIDX is implemented. Otherwise, direct accesses to CCSIDR2_EL1 are UNDEFINED.

Attributes

CCSIDR2_EL1 is a 64-bit register.

Field descriptions

Bits [63:24]

Reserved, RES0.

NumSets, bits [23:0]

(Number of sets in cache) - 1, therefore a value of 0 indicates 1 set in the cache. The number of sets does not have to be a power of 2.

Accessing CCSIDR2_EL1

If [CSSELR_EL1](#).{TnD, Level, InD} is programmed to a cache level that is not implemented, then on a read of the CCSIDR2_EL1 the behavior is CONSTRAINED UNPREDICTABLE, and can be one of the following:

- The CCSIDR2_EL1 read is treated as NOP.
- The CCSIDR2_EL1 read is UNDEFINED. If [FEAT_IDST](#) is implemented, this is permitted to be reported with EC syndrome value 0x18.
- The CCSIDR2_EL1 read returns an UNKNOWN value.

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, CCSIDR2_EL1

op0	op1	CRn	CRm	op2
0b11	0b001	0b0000	0b0000	0b010

```

if !IsFeatureImplemented(FEAT_CCIDX) then
    UnimplementedIDRegister();
elsif PSTATE.EL == EL0 then
    if IsFeatureImplemented(FEAT_IDST) then
        AArch64_SystemAccessTrapToEL1orEL2(0x18);
    else
        Undefined();
    end;
elsif PSTATE.EL == EL1 then
    if HCR_EL2().TID2 == '1' then
        AArch64_SystemAccessTrap(EL2, 0x18);
    else
        X{64}(t) = CCSIDR2_EL1();
    end;
elsif PSTATE.EL == EL2 then
    X{64}(t) = CCSIDR2_EL1();
end;

```

D12.2.21 CCSIDR_EL1, Current Cache Size ID Register

The CCSIDR_EL1 characteristics are:

Purpose

Provides information about the architecture of the currently selected cache.

Configuration

The implementation includes one CCSIDR_EL1 for each cache that it can access. [CSSELR_EL1](#) selects which Cache Size ID Register is accessible.

Attributes

CCSIDR_EL1 is a 64-bit register.

Field descriptions

When FEAT_CCIDX is implemented:

Note

The parameters NumSets, Associativity, and LineSize in these registers define the architecturally visible parameters that are required for the cache maintenance by Set/Way instructions. They are not guaranteed to represent the actual microarchitectural features of a design. You cannot make any inference about the actual sizes of caches based on these parameters.

Bits [63:56]

Reserved, RES0.

NumSets, bits [55:32]

(Number of sets in cache) - 1, therefore a value of 0 indicates 1 set in the cache. The number of sets does not have to be a power of 2.

Bits [31:24]

Reserved, RES0.

Associativity, bits [23:3]

(Associativity of cache) - 1, therefore a value of 0 indicates an associativity of 1. The associativity does not have to be a power of 2.

LineSize, bits [2:0]

($\log_2(\text{Number of bytes in cache line})$) - 4. For example:

- For a line length of 16 bytes: $\log_2(16) = 4$, LineSize entry = 0. This is the minimum line length.
- For a line length of 32 bytes: $\log_2(32) = 5$, LineSize entry = 1.

Note

The C++ 17 specification has two defined parameters relating to the granularity of memory that does not interfere. For generic software and tools, Arm will set the hardware_destructive_interference_size parameter to 256 bytes and the hardware_constructive_interference_size parameter to 64 bytes.

Otherwise:

Note

The parameters NumSets, Associativity, and LineSize in these registers define the architecturally visible parameters that are required for the cache maintenance by Set/Way instructions. They are not guaranteed to represent the actual microarchitectural features of a design. You cannot make any inference about the actual sizes of caches based on these parameters.

Bits [63:32]

Reserved, RES0.

Bits [31:28]

Reserved, UNKNOWN.

NumSets, bits [27:13]

(Number of sets in cache) - 1, therefore a value of 0 indicates 1 set in the cache. The number of sets does not have to be a power of 2.

Associativity, bits [12:3]

(Associativity of cache) - 1, therefore a value of 0 indicates an associativity of 1. The associativity does not have to be a power of 2.

LineSize, bits [2:0]

(Log₂(Number of bytes in cache line)) - 4. For example:

- For a line length of 16 bytes: Log₂(16) = 4, LineSize entry = 0. This is the minimum line length.
- For a line length of 32 bytes: Log₂(32) = 5, LineSize entry = 1.

Note

The C++ 17 specification has two defined parameters relating to the granularity of memory that does not interfere. For generic software and tools, Arm will set the hardware_destructive_interference_size parameter to 256 bytes and the hardware_constructive_interference_size parameter to 64 bytes.

Accessing CCSIDR_EL1

If [CSSELR_EL1](#).{TnD, Level, InD} is programmed to a cache level that is not implemented, then on a read of the CCSIDR_EL1 the behavior is CONSTRAINED UNPREDICTABLE, and can be one of the following:

- The CCSIDR_EL1 read is treated as NOP.
- The CCSIDR_EL1 read is UNDEFINED. If [FEAT_IDST](#) is implemented, this is permitted to be reported with EC syndrome value 0x18.

- The CCSIDR_EL1 read returns an UNKNOWN value.

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, CCSIDR_EL1

op0	op1	CRn	CRm	op2
0b11	0b001	0b0000	0b0000	0b000

```

if PSTATE.EL == EL0 then
    if IsFeatureImplemented(FEAT_IDST) then
        AArch64_SystemAccessTrapToEL1orEL2(0x18);
    else
        Undefined();
    end;
elseif PSTATE.EL == EL1 then
    if HCR_EL2().TID2 == '1' then
        AArch64_SystemAccessTrap(EL2, 0x18);
    else
        X{64}(t) = CCSIDR_EL1();
    end;
elseif PSTATE.EL == EL2 then
    X{64}(t) = CCSIDR_EL1();
end;

```

D12.2.22 CLIDR_EL1, Cache Level ID Register

The CLIDR_EL1 characteristics are:

Purpose

Identifies the type of cache, or caches, that are implemented at each level and can be managed using the architected cache maintenance instructions that operate by set/way, up to a maximum of seven levels. Also identifies the Level of Coherence (LoC) and Level of Unification (LoU) for the cache hierarchy.

Configuration

There are no configuration notes.

Attributes

CLIDR_EL1 is a 64-bit register.

Field descriptions

Bits [63:33]

Reserved, RES0.

ICB, bits [32:30]

Inner cache boundary. This field indicates the boundary for caching Inner Cacheable memory regions.

The value of this field is an IMPLEMENTATION DEFINED choice of:

ICB	Meaning
0b000	Not disclosed by this mechanism.
0b001	L1 cache is the highest Inner Cacheable level.
0b010	L2 cache is the highest Inner Cacheable level.
0b011	L3 cache is the highest Inner Cacheable level.
0b100	L4 cache is the highest Inner Cacheable level.
0b101	L5 cache is the highest Inner Cacheable level.
0b110	L6 cache is the highest Inner Cacheable level.
0b111	L7 cache is the highest Inner Cacheable level.

Access to this field is RO.

LoUU, bits [29:27]

Level of Unification Uniprocessor for the cache hierarchy.

For a description of the values of this field, see [Terminology for Clean, Invalidate, and Clean and Invalidate instructions](#).

Note

This field does not describe the requirements for instruction cache invalidation. See [CTR_EL0.DIC](#).

Note

When [FEAT_S2FWB](#) is implemented, the architecture requires that this field is zero so that no levels of data cache need to be cleaned in order to manage coherency with instruction fetches.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

LoC, bits [26:24]

Level of Coherence for the cache hierarchy.

For a description of the values of this field, see [Terminology for Clean, Invalidate, and Clean and Invalidate instructions](#).

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

LoUIS, bits [23:21]

Level of Unification Inner Shareable for the cache hierarchy.

For a description of the values of this field, see [Terminology for Clean, Invalidate, and Clean and Invalidate instructions](#).

Note

This field does not describe the requirements for instruction cache invalidation. See [CTR_EL0.DIC](#).

Note

When [FEAT_S2FWB](#) is implemented, the architecture requires that this field is zero so that no levels of data cache need to be cleaned in order to manage coherency with instruction fetches.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

Ctype<n> , bits [3(n-1)+2:3(n-1)], for n = 7 to 1

Cache Type fields. Indicate the type of cache that is implemented and can be managed using the architected cache maintenance instructions that operate by set/way at each level, from Level 1 up to a maximum of seven levels of cache hierarchy. Possible values of each field are:

Ctype<n>	Meaning
0b000	No cache.
0b001	Instruction cache only.
0b010	Data cache only.
0b011	Separate instruction and data caches.
0b100	Unified cache.

All other values are reserved.

If software reads the Cache Type fields from Ctype1 upwards, once it has seen a value of 0b000, no caches that can be managed using the architected cache maintenance instructions that operate by set/way exist at further-out levels of the hierarchy. So, for example, if Ctype3 is the first Cache Type field with a value of 0b000, the values of Ctype4 to Ctype7 must be ignored.

Accessing CLIDR_EL1

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, CLIDR_EL1

op0	op1	CRn	CRm	op2
0b11	0b001	0b0000	0b0000	0b001

```
if PSTATE.EL == EL0 then
    if IsFeatureImplemented(FEAT_IDST) then
        AArch64_SystemAccessTraptToEL1orEL2(0x18);
    else
        Undefined();
    end;
elseif PSTATE.EL == EL1 then
    if HCR_EL2().TID2 == '1' then
        AArch64_SystemAccessTrap(EL2, 0x18);
    else
        X{64}(t) = CLIDR_EL1();
    end;
elseif PSTATE.EL == EL2 then
    X{64}(t) = CLIDR_EL1();
end;
```

D12.2.23 CONTEXTIDR_EL1, Context ID Register (EL1)

The CONTEXTIDR_EL1 characteristics are:

Purpose

Identifies the current Process Identifier.

The value of the whole of this register is called the Context ID and is used by:

- The debug logic, for Linked and Unlinked Context ID matching.
- The trace logic, to identify the current process.

The significance of this register is for debug and trace use only.

Configuration

There are no configuration notes.

Attributes

CONTEXTIDR_EL1 is a 64-bit register.

Field descriptions

Bits [63:32]

Reserved, RES0.

PROCID, bits [31:0]

Process Identifier. This field must be programmed with a unique value that identifies the current process.

Note

In AArch64 state, CONTEXTIDR_EL1 is independent of the ASID, and for the EL1&0 translation regime either [TTBR0_EL1](#) or [TTBR1_EL1](#) holds the ASID.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing CONTEXTIDR_EL1

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, CONTEXTIDR_EL1

op0	op1	CRn	CRm	op2
0b11	0b000	0b1101	0b0000	0b001

```
if PSTATE.EL == EL0 then
    Undefined();
elseif PSTATE.EL == EL1 then
    if HCR_EL2().TRVM == '1' then
        AArch64_SystemAccessTrap(EL2, 0x18);
    else
        X{64}(t) = CONTEXTIDR_EL1();
    end;
elseif PSTATE.EL == EL2 then
    X{64}(t) = CONTEXTIDR_EL1();
end;
```

MSR CONTEXTIDR_EL1, <Xt>

op0	op1	CRn	CRm	op2
0b11	0b000	0b1101	0b0000	0b001

```
if PSTATE.EL == EL0 then
    Undefined();
elseif PSTATE.EL == EL1 then
    if HCR_EL2().TVM == '1' then
        AArch64_SystemAccessTrap(EL2, 0x18);
    else
        CONTEXTIDR_EL1() = X{64}(t);
    end;
elseif PSTATE.EL == EL2 then
    CONTEXTIDR_EL1() = X{64}(t);
end;
```

D12.2.24 CONTEXTIDR_EL2, Context ID Register (EL2)

The CONTEXTIDR_EL2 characteristics are:

Purpose

- Identifies the current Process Identifier for EL2.
- The value of the whole of this register is called the Context ID and is used by:
- The debug logic, for Linked and Unlinked Context ID matching.
 - The trace logic, to identify the current process.

The significance of this register is for debug and trace use only.

Configuration

This register is present only when FEAT_Debugv8p1 is implemented. Otherwise, direct accesses to CONTEXTIDR_EL2 are UNDEFINED.

Attributes

CONTEXTIDR_EL2 is a 64-bit register.

Field descriptions

Bits [63:32]

Reserved, RES0.

PROCID, bits [31:0]

- Process Identifier. This field must be programmed with a unique value that identifies the current process.
- The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing CONTEXTIDR_EL2

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, CONTEXTIDR_EL2

op0	op1	CRn	CRm	op2
0b11	0b100	0b1101	0b0000	0b001

```
if !IsFeatureImplemented(FEAT_Debugv8p1) then
    Undefined();
elseif PSTATE.EL == EL0 then
    Undefined();
elseif PSTATE.EL == EL1 then
    Undefined();
elseif PSTATE.EL == EL2 then
    X{64}(t) = CONTEXTIDR_EL2();
end;
```

MSR CONTEXTIDR_EL2, <Xt>

op0	op1	CRn	CRm	op2
0b11	0b100	0b1101	0b0000	0b001

```
if !IsFeatureImplemented(FEAT_Debugv8p1) then
    Undefined();
elseif PSTATE.EL == EL0 then
    Undefined();
elseif PSTATE.EL == EL1 then
    Undefined();
elseif PSTATE.EL == EL2 then
    CONTEXTIDR_EL2() = X{64}(t);
end;
```

D12.2.25 CPACR_EL1, Architectural Feature Access Control Register

The CPACR_EL1 characteristics are:

Purpose

Controls access to trace, and Advanced SIMD and floating-point functionality.

Configuration

There are no configuration notes.

Attributes

CPACR_EL1 is a 64-bit register.

Field descriptions

Bits [63:29]

Reserved, RES0.

TTA, bit [28]

When System register access to the trace unit registers is implemented:

Traps EL0 and EL1 System register accesses to all implemented trace System registers from both Execution states to EL1, or to EL2 when it is implemented and enabled in the current Security state and [HCR_EL2.TGE](#) is 1, as follows:

- In AArch64 state, accesses to trace System registers are trapped, reported using EC syndrome value 0x18.

TTA	Meaning
0b0	This control does not cause any instructions to be trapped.
0b1	This control causes EL0 and EL1 System register accesses to all implemented trace System registers to be trapped.

Note

- The ETMv4 architecture does not permit EL0 to access the trace System registers. If the trace unit implements FEAT_ETMv4, EL0 accesses to the trace System registers are UNDEFINED, and any resulting exception is higher priority than an exception that would be generated because the value of CPACR_EL1.TTA is 1.
- The Armv8-A architecture does not provide traps on trace register accesses through the optional memory-mapped interface.

System register accesses to the trace System registers can have side-effects. When a System register access is trapped, any side-effects that are normally associated with the access do not occur before the exception is taken.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bits [27:22]

Reserved, RES0.

FPEN, bits [21:20]

Traps execution at EL1 and EL0 of instructions that access the Advanced SIMD and floating-point registers from both Execution states to EL1, reported using EC syndrome value 0x07, or to EL2 reported using EC syndrome value 0x00 when EL2 is implemented and enabled in the current Security state and HCR_EL2.TGE is 1, as follows:

- In AArch64 state, accesses to FPCR, FPSR, and any of the SIMD and floating-point registers V0-V31, including their views as D0-D31 registers or S0-31 registers.

FPEN	Meaning
0b00	This control causes execution of these instructions at EL1 and EL0 to be trapped.
0b01	This control causes execution of these instructions at EL0 to be trapped, but does not cause execution of any instructions at EL1 to be trapped.
0b10	This control causes execution of these instructions at EL1 and EL0 to be trapped.
0b11	This control does not cause execution of any instructions to be trapped.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [19:0]

Reserved, RES0.

Accessing CPACR_EL1

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, CPACR_EL1

op0	op1	CRn	CRm	op2
0b11	0b000	0b0001	0b0000	0b010

```

if PSTATE.EL == EL0 then
    Undefined();
elseif PSTATE.EL == EL1 then
    if CPTR_EL2().TCPAC == '1' then

```

```
        AArch64_SystemAccessTrap(EL2, 0x18);
    else
        X{64}(t) = CPACR_EL1();
    end;
elseif PSTATE.EL == EL2 then
    X{64}(t) = CPACR_EL1();
end;
```

MSR CPACR_EL1, <Xt>

op0	op1	CRn	CRm	op2
0b11	0b000	0b0001	0b0000	0b010

```
if PSTATE.EL == EL0 then
    Undefined();
elseif PSTATE.EL == EL1 then
    if CPTR_EL2().TCPAC == '1' then
        AArch64_SystemAccessTrap(EL2, 0x18);
    else
        CPACR_EL1() = X{64}(t);
    end;
elseif PSTATE.EL == EL2 then
    CPACR_EL1() = X{64}(t);
end;
```

D12.2.26 CPTR_EL2, Architectural Feature Trap Register (EL2)

The CPTR_EL2 characteristics are:

Purpose

Controls trapping to EL2 of accesses to CPACR, CPACR_EL1, trace, Activity Monitor, and Advanced SIMD and floating-point functionality.

Configuration

There are no configuration notes.

Attributes

CPTR_EL2 is a 64-bit register.

Field descriptions

EffectiveHCR_EL2_E2H() == '0'

This format applies in all Armv8.0 implementations.

Bits [63:32]

Reserved, RES0.

TCPAC, bit [31]

In AArch64 state, traps accesses to CPACR_EL1 from EL1 to EL2, when EL2 is enabled in the current Security state. The exception is reported using EC syndrome value 0x18.

TCPAC	Meaning
0b0	This control does not cause any instructions to be trapped.
0b1	EL1 accesses to the following registers are trapped to EL2, when EL2 is enabled in the current Security state: CPACR_EL1.

When HCR_EL2.TGE is 1, this control does not cause any instructions to be trapped.

Note
CPACR_EL1 and CPACR are not accessible at EL0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [30:21]

Reserved, RES0.

TTA, bit [20]

When System register access to the trace unit registers is implemented:

Traps System register accesses to all implemented trace System registers from both Execution states to EL2, when EL2 is enabled in the current Security state, as follows:

- In AArch64 state, accesses to trace System registers with $op0=2$, $op1=1$, and $CRn<0b1000$ are trapped to EL2, reported using EC syndrome value 0×18 .

TTA	Meaning
0b0	This control does not cause any instructions to be trapped.
0b1	Any attempt at EL0, EL1, or EL2, to execute a System register access to an implemented trace System register is trapped to EL2, when EL2 is enabled in the current Security state, unless it is trapped by one of the following controls: • CPACR_EL1.TTA.

Note

- FEAT_ETMv4 and FEAT_ETE do not permit EL0 to access the trace System registers. EL0 accesses to the trace System registers are UNDEFINED, and any resulting exception is higher priority than an exception that would be generated because the value of CPTR_EL2.TTA is 1.
- EL2 does not provide traps on trace register accesses through the optional memory-mapped interface.

System register accesses to the trace System registers can have side-effects. When a System register access is trapped, any side-effects that are normally associated with the access do not occur before the exception is taken.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bits [19:14]

Reserved, RES0.

Bits [13:12]

Reserved, RES1.

Bit [11]

Reserved, RES0.

TFP, bit [10]

Traps execution of instructions which access the Advanced SIMD and floating-point functionality, from both Execution states to EL2, when EL2 is enabled in the current Security state, as follows:

- In AArch64 state, accesses to the following registers are trapped to EL2, reported using EC syndrome value 0×07 :
 - [FPCR](#), [FPSR](#), and any of the SIMD and floating-point registers V0-V31, including their views as D0-D31 registers or S0-31 registers.

TFP	Meaning
0b0	This control does not cause execution of any instructions to be trapped.
0b1	This control causes execution of these instructions at EL2, EL1, and EL0 to be trapped.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [9:0]

Reserved, RES1.

Accessing CPTR_EL2

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, CPTR_EL2

op0	op1	CRn	CRm	op2
0b11	0b100	0b0001	0b0001	0b010

```

if PSTATE.EL == EL0 then
    Undefined();
elsif PSTATE.EL == EL1 then
    Undefined();
elsif PSTATE.EL == EL2 then
    X{64}(t) = CPTR_EL2();
end;
```

MSR CPTR_EL2, <Xt>

op0	op1	CRn	CRm	op2
0b11	0b100	0b0001	0b0001	0b010

```

if PSTATE.EL == EL0 then
    Undefined();
elsif PSTATE.EL == EL1 then
    Undefined();
elsif PSTATE.EL == EL2 then
    CPTR_EL2() = X{64}(t);
end;
```

D12.2.27 CSSELR_EL1, Cache Size Selection Register

The CSSELR_EL1 characteristics are:

Purpose

Selects the current Cache Size ID Register, [CCSIDR_EL1](#), by specifying the required cache level and the cache type (either instruction or data cache).

Configuration

There are no configuration notes.

Attributes

CSSELR_EL1 is a 64-bit register.

Field descriptions

Bits [63:4]

Reserved, RES0.

Level, bits [3:1]

Cache level of required cache.

Level	Meaning
0b000	Level 1 cache.
0b001	Level 2 cache.
0b010	Level 3 cache.
0b011	Level 4 cache.
0b100	Level 5 cache.
0b101	Level 6 cache.
0b110	Level 7 cache.

All other values are reserved.

If CSSELR_EL1.{Level, InD} is programmed to a cache level that is not implemented, then the value for this field on a read of CSSELR_EL1 is UNKNOWN.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

InD, bit [0]

Instruction not Data bit.

InD	Meaning
0b0	Data or unified cache.
0b1	Instruction cache.

If CSSELR_EL1.{Level, InD} is programmed to a cache level that is not implemented, then a read of CSSELR_EL1 is CONSTRAINED UNPREDICTABLE, and returns UNKNOWN values for CSSELR_EL1.{Level, InD}.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing CSSELR_EL1

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, CSSELR_EL1

op0	op1	CRn	CRm	op2
0b11	0b010	0b0000	0b0000	0b000

```
if PSTATE.EL == EL0 then
    Undefined();
elsif PSTATE.EL == EL1 then
    if HCR_EL2().TID2 == '1' then
        AArch64_SystemAccessTrap(EL2, 0x18);
    else
        X{64}(t) = CSSELR_EL1();
    end;
elsif PSTATE.EL == EL2 then
    X{64}(t) = CSSELR_EL1();
end;
```

MSR CSSELR_EL1, <Xt>

op0	op1	CRn	CRm	op2
0b11	0b010	0b0000	0b0000	0b000

```
if PSTATE.EL == EL0 then
    Undefined();
elsif PSTATE.EL == EL1 then
    if HCR_EL2().TID2 == '1' then
        AArch64_SystemAccessTrap(EL2, 0x18);
    else
        CSSELR_EL1() = X{64}(t);
    end;
end;
```

```
elseif PSTATE.EL == EL2 then
    CSSELR_EL1() = X{64}(t);
end;
```

D12.2.28 CTR_EL0, Cache Type Register

The CTR_EL0 characteristics are:

Purpose

Provides information about the architecture of the caches.

Configuration

There are no configuration notes.

Attributes

CTR_EL0 is a 64-bit register.

Field descriptions

Bits [63:32]

Reserved, RES0.

Bit [31]

Reserved, RES1.

Bit [30]

Reserved, RES0.

DIC, bit [29]

Instruction cache invalidation requirements for data to instruction coherence.

The value of this field is an IMPLEMENTATION DEFINED choice of:

DIC	Meaning
0b0	Instruction cache invalidation to the Point of Unification is required for data to instruction coherence.
0b1	Instruction cache invalidation to the Point of Unification is not required for data to instruction coherence.

All PEs in the same Inner Shareable shareability domain must have a common value of this field.

Note
If CTR_EL0.DIC is 1, instruction cache maintenance is not required after overwriting instructions, including for different VA aliases of the affected Locations, regardless of the value of CTR_EL0.L1Ip.

Access to this field is RO.

IDC, bit [28]

Data cache clean requirements for instruction to data coherence. The meaning of this bit is:

The value of this field is an IMPLEMENTATION DEFINED choice of:

IDC	Meaning
0b0	Data cache clean to the Point of Unification is required for instruction to data coherence, unless CLIDR_EL1.LoC == 0b000 or (CLIDR_EL1.LoUIS == 0b000 and CLIDR_EL1.LoUU == 0b000).
0b1	Data cache clean to the Point of Unification is not required for instruction to data coherence.

If CTR_EL0.DIC is 1 then the value reported in this field must also be 1.

The Effective value of IDC is 1 if any of the following are true:

- CTR_EL0.IDC == 1.
- CLIDR_EL1.LoC == 0b000.
- CLIDR_EL1.LoUIS == 0b000 and CLIDR_EL1.LoUU == 0b000.

All PEs in the same Inner Shareable shareability domain must have a common Effective value of IDC.

Access to this field is RO.

CWG, bits [27:24]

Cache writeback granule. $\log_2$ of the number of words of the maximum size of memory that can be overwritten as a result of the eviction of a cache entry that has had a memory location in it modified.

A value of 0b0000 indicates that this register does not provide Cache writeback granule information and either:

- The architectural maximum of 512 words (2KB) must be assumed.
- The Cache writeback granule can be determined from maximum cache line size encoded in the Cache Size ID Registers.

Values greater than 0b1001 are reserved.

Arm recommends that an implementation that does not support cache write-back implements this field as 0b0001. This applies, for example, to an implementation that supports only write-through caches.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

ERG, bits [23:20]

Exclusives reservation granule. $\log_2$ of the number of words of the maximum size of the reservation granule that has been implemented for the Load-Exclusive and Store-Exclusive instructions.

The use of the value 0b0000 is deprecated.

The value 0b0001 and values greater than 0b1001 are reserved.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

DminLine, bits [19:16]

$\log_2$ of the number of words in the smallest cache line of all the data caches and unified caches that are controlled by the PE.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

L1Ip, bits [15:14]

Level 1 instruction cache policy. Indicates the indexing and tagging policy for the L1 instruction cache.

The value of this field is an IMPLEMENTATION DEFINED choice of:

L1Ip	Meaning
0b00	Reserved.
0b01	ASID-tagged Virtual Index, Virtual Tag (AIVIVT).
0b10	Virtual Index, Physical Tag (VIPT).
0b11	Physical Index, Physical Tag (PIPT).

From Armv8.0, the value 0b01 is reserved.

Access to this field is RO.

Bits [13:4]

Reserved, RES0.

IminLine, bits [3:0]

Log₂ of the number of words in the smallest cache line of all the instruction caches that are controlled by the PE.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

Accessing CTR_EL0

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, CTR_EL0

op0	op1	CRn	CRm	op2
0b11	0b011	0b0000	0b0000	0b001

```
if PSTATE.EL == EL0 then
    if EffectivelyAtEL0NotInHost() && SCTLR_EL1().UCT == '0' then
        AArch64_SystemAccessTrapToEL1orEL2(0x18);
    elsif EffectivelyAtEL0NotInHost() && HCR_EL2().TID2 == '1' then
        AArch64_SystemAccessTrap(EL2, 0x18);
    else
        X{64}(t) = CTR_EL0();
    end;
elsif PSTATE.EL == EL1 then
    if HCR_EL2().TID2 == '1' then
        AArch64_SystemAccessTrap(EL2, 0x18);
    else
        X{64}(t) = CTR_EL0();
    end;
elsif PSTATE.EL == EL2 then
    X{64}(t) = CTR_EL0();
end;
```

D12.2.29 DCZID_EL0, Data Cache Zero ID Register

The DCZID_EL0 characteristics are:

Purpose

Indicates the block size that is written with byte values of 0 by the [DC ZVA](#) (Data Cache Zero by Address) System instruction.

Configuration

There are no configuration notes.

Attributes

DCZID_EL0 is a 64-bit register.

Field descriptions

Bits [63:5]

Reserved, RES0.

DZP, bit [4]

Data Zero Prohibited. This field indicates whether use of [DC ZVA](#) instructions is permitted or prohibited.

DZP	Meaning
0b0	Instructions are permitted.
0b1	Instructions are prohibited.

The value read from this field is governed by the current Exception level and the values of the following fields:

- The Effective value of [HCR_EL2.TDZ](#).
- When the Effective value of [HCR_EL2.{E2H, TGE}](#) != ‘11’, [SCTLR_EL1.DZE](#).

BS, bits [3:0]

Log₂ of the block size in words written by a [DC ZVA](#) instruction. The maximum size supported is 2KB, indicated by value 0b1001.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

Accessing DCZID_EL0

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, DCZID_EL0

op0	op1	CRn	CRm	op2
0b11	0b011	0b0000	0b0000	0b111

```
if PSTATE.EL == EL0 then
    X{64}(t) = DCZID_EL0();
elsif PSTATE.EL == EL1 then
    X{64}(t) = DCZID_EL0();
elsif PSTATE.EL == EL2 then
    X{64}(t) = DCZID_EL0();
end;
```

D12.2.30 ESR_EL1, Exception Syndrome Register (EL1)

The ESR_EL1 characteristics are:

Purpose

Holds syndrome information for an exception taken to EL1.

Configuration

There are no configuration notes.

Attributes

ESR_EL1 is a 64-bit register.

Field descriptions

ESR_EL1 is made UNKNOWN as a result of an exception return from EL1.

When an UNPREDICTABLE instruction is treated as UNDEFINED, and the exception is taken to EL1, the value of ESR_EL1 is UNKNOWN. The value written to ESR_EL1 must be consistent with a value that could be created as a result of an exception from the same Exception level that generated the exception as a result of a situation that is not UNPREDICTABLE at that Exception level, in order to avoid the possibility of a privilege violation.

Bits [63:56]

Reserved, RES0.

ISS2, bits [55:32]

ISS2 encoding for an exception, the bit assignments are:

ISS2 encoding for an exception from a Data Abort

Bits [23:0]

Reserved, RES0.

ISS2 encoding for an exception from an Instruction Abort

Bits [23:0]

Reserved, RES0.

ISS2 encoding for an exception from a Watchpoint exception

Bits [23:0]

Reserved, RES0.

ISS2 encoding for all other exceptions

Bits [23:0]

Reserved, RES0.

EC, bits [31:26]

Exception Class. Indicates the reason for the exception that this register holds information about.

For each EC value, the table references a subsection that gives information about:

- The cause of the exception, for example the configuration required to enable the trap.
- The encoding of the associated ISS.

Possible values of the EC field are:

EC	Meaning	ISS	ISS2	Applies when
0b000000	Unknown reason.	ISS encoding for exceptions with an unknown reason	ISS2 encoding for all other exceptions	
0b000001	Trapped WF* instruction execution. Conditional WF* instructions that fail their condition code check do not cause an exception.	ISS encoding for an exception from a WF* instruction	ISS2 encoding for all other exceptions	

EC	Meaning	ISS	ISS2	Applies when
0b000111	Access to Advanced SIMD or floating-point functionality trapped by CPACR_EL1.FPEN , CPTR_EL2.FPEN or CPTR_EL2.TFP control. Excludes exceptions resulting from CPACR_EL1 when the value of HCR_EL2.TGE is 1, or because Advanced SIMD and floating-point are not implemented. These are reported with EC value 0b000000.	ISS encoding for an exception from an access to a register or instruction resulting from the FPEN and TFP traps	ISS2 encoding for all other exceptions	
0b001001	Trapped use of a Pointer authentication instruction.	ISS encoding for an exception from a trapped Pointer Authentication instruction	ISS2 encoding for all other exceptions	FEAT_PAuth is implemented
0b001110	Illegal Execution state.	ISS encoding for an exception from an Illegal Execution state, or a PC or SP alignment fault	ISS2 encoding for all other exceptions	
0b010101	SVC instruction execution in AArch64 state.	ISS encoding for an exception from HVC or SVC instruction execution	ISS2 encoding for all other exceptions	
0b011000	Trapped MSR, MRS or System instruction execution in AArch64 state, that is not reported using EC values 0b000000, 0b000001, or 0b000111. This includes all instructions that cause exceptions that are part of the encoding space defined in ‘ System instruction class encoding overview ’, except for those exceptions reported using EC values 0b000000, 0b000001, or 0b000111.	ISS encoding for an exception from MSR, MRS, or System instruction execution in AArch64 state	ISS2 encoding for all other exceptions	
0b011100	Exception from a PAC Fail	ISS encoding for a PAC Fail exception	ISS2 encoding for all other exceptions	FEAT_FPAC is implemented
0b100000	Instruction Abort from a lower Exception level. Used for MMU and MPU faults generated by instruction accesses and synchronous External aborts, including synchronous parity or ECC errors. Not used for debug-related exceptions.	ISS encoding for an exception from an Instruction Abort	ISS2 encoding for an exception from an Instruction Abort	
0b100001	Instruction Abort taken without a change in Exception level. Used for MMU and MPU faults generated by instruction accesses and synchronous External aborts, including synchronous parity or ECC errors. Not used for debug-related exceptions.	ISS encoding for an exception from an Instruction Abort	ISS2 encoding for an exception from an Instruction Abort	

EC	Meaning	ISS	ISS2	Applies when
0b100010	PC alignment fault exception.	ISS encoding for an exception from an Illegal Execution state, or a PC or SP alignment fault	ISS2 encoding for all other exceptions	
0b100100	Data Abort exception from a lower Exception level. Used for MMU and MPU faults generated by data accesses, alignment faults other than those caused by Stack Pointer misalignment, and synchronous External aborts, including synchronous parity or ECC errors. Not used for debug-related exceptions.	ISS encoding for an exception from a Data Abort	ISS2 encoding for an exception from a Data Abort	
0b100101	Data Abort exception taken without a change in Exception level. Used for MMU and MPU faults generated by instruction accesses and synchronous External aborts, including synchronous parity or ECC errors. Not used for debug-related exceptions.	ISS encoding for an exception from a Data Abort	ISS2 encoding for an exception from a Data Abort	
0b100110	SP alignment fault exception.	ISS encoding for an exception from an Illegal Execution state, or a PC or SP alignment fault	ISS2 encoding for all other exceptions	
0b101100	Trapped floating-point exception taken from AArch64 state. This EC value is valid if the implementation supports trapping of floating-point exceptions, otherwise it is reserved. Whether a floating-point implementation supports trapping of floating-point exceptions is IMPLEMENTATION DEFINED.	ISS encoding for an exception from a trapped floating-point exception	ISS2 encoding for all other exceptions	
0b101111	SError exception.	ISS encoding for an SError exception	ISS2 encoding for all other exceptions	
0b110000	Breakpoint exception from a lower Exception level.	ISS encoding for an exception from a Breakpoint or Vector Catch debug exception	ISS2 encoding for all other exceptions	
0b110001	Breakpoint exception taken without a change in Exception level.	ISS encoding for an exception from a Breakpoint or Vector Catch debug exception	ISS2 encoding for all other exceptions	
0b110010	Software Step exception from a lower Exception level.	ISS encoding for an exception from a Software Step exception	ISS2 encoding for all other exceptions	

EC	Meaning	ISS	ISS2	Applies when
0b110011	Software Step exception taken without a change in Exception level.	ISS encoding for an exception from a Software Step exception	ISS2 encoding for all other exceptions	
0b110100	Watchpoint exception from a lower Exception level.	ISS encoding for an exception from a Watchpoint exception	ISS2 encoding for an exception from a Watchpoint exception	
0b110101	Watchpoint exception taken without a change in Exception level.	ISS encoding for an exception from a Watchpoint exception	ISS2 encoding for an exception from a Watchpoint exception	
0b111100	BRK instruction execution in AArch64 state.	ISS encoding for an exception from execution of a Breakpoint instruction	ISS2 encoding for all other exceptions	

All other EC values are reserved by Arm, and:

- Unused values in the range 0b000000 - 0b101100 (0x00 - 0x2C) are reserved for future use for synchronous exceptions.
- Unused values in the range 0b101101 - 0b111111 (0x2D - 0x3F) are reserved for future use, and might be used for synchronous or asynchronous exceptions.

The effect of programming this field to a reserved value is that behavior is CONSTRAINED UNPREDICTABLE.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

IL, bit [25]

Instruction Length for synchronous exceptions. Possible values of this bit are:

IL	Meaning
0b0	16-bit instruction trapped.
0b1	32-bit instruction trapped. This value is also used when the exception is one of the following: • An SError exception. • An Instruction Abort exception. • A PC alignment fault exception. • An SP alignment fault exception. • A Data Abort exception for which the value of the ISV bit is 0. • An Illegal Execution state exception. • Any debug exception except for Breakpoint instruction exceptions, a BRK instruction. • An exception reported using EC value 0b000000.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

ISS, bits [24:0]

Instruction Specific Syndrome. Architecturally, this field can be defined independently for each defined Exception class. However, in practice, some ISS encodings are used for more than one Exception class.

Typically, an ISS encoding has a number of subfields. When an ISS subfield holds a register number, the value returned in that field is the AArch64 view of the register number.

ISS encoding for exceptions with an unknown reason

Bits [24:0]

Reserved, RES0.

Additional Information for ISS encoding for exceptions with an unknown reason

When an exception is reported using this EC value, the IL field is set to 1.

This EC value is used for all exceptions that are not covered by any other EC value. This includes exceptions that are generated in the following situations:

- The attempted execution of an instruction bit pattern that has no allocated instruction or that is not accessible at the current Exception level and Security state, including:
 - A read access using a System register pattern that is not allocated for reads or that does not permit reads at the current Exception level and Security state.
 - A write access using a System register pattern that is not allocated for writes or that does not permit writes at the current Exception level and Security state.
 - Instruction encodings that are unallocated.
 - Instruction encodings for instructions or System registers that are not implemented in the implementation.
- In Debug state, the attempted execution of an instruction bit pattern that is not accessible in Debug state.
- In Non-debug state, the attempted execution of an instruction bit pattern that is not accessible in Non-debug state.
- In an implementation that does not include Advanced SIMD and floating-point functionality, an attempted access to Advanced SIMD or floating-point functionality under conditions where that access would be permitted if that functionality was present. This includes the attempted execution of an Advanced SIMD or floating-point instruction, and attempted accesses to Advanced SIMD and floating-point System registers.
- An exception generated because of the value of one of the [SCTLR_EL1](#).{ITD, SED, CP15BEN} control bits.
- Attempted execution of:
 - An HVC instruction when disabled by [HCR_EL2](#).HCD.
 - An SMC instruction when disabled by [HCR_EL2](#).TSC.
 - An HLT instruction when disabled by [EDSCR](#).HDE.
- Attempted execution of an MSR or MRS instruction to access [SP_EL0](#) when the value of [SPSel.SP](#) is 0.
- Attempted execution of an MSR or MRS instruction using a [_EL12](#) register name.
- Attempted execution, in Debug state, of:
 - A DCPS1 instruction when the value of [HCR_EL2](#).TGE is 1.
 - A DCPS2 instruction from EL1 or EL0 when EL2 is disabled or not implemented in the current Security state.
 - A DCPS3 instruction when the value of [EDSCR](#).SDD is 1.
- In Debug state when the value of [EDSCR](#).SDD is 1, the attempted execution at EL1 or EL0 of an instruction that is configured to trap to EL2.
- An exception that is taken to EL2 because the value of [HCR_EL2](#).TGE is 1. If the value of [HCR_EL2](#).TGE is 0, this exception is reported using an [ESR_EL1.EC](#) value of 0b000111.

ISS encoding for an exception from a WF* instruction

**CV, bit [24]**

Condition code valid.

CV	Meaning
0b0	The COND field is not valid.
0b1	The COND field is valid.

For exceptions taken from AArch64, CV is set to 1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

COND, bits [23:20]

For exceptions taken from AArch64, this field is set to 0b1110.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [19:2]

Reserved, RES0.

TI, bits [1:0]

Trapped instruction. Possible values of this bit are:

TI	Meaning
0b00	WFI trapped.
0b01	WFE trapped.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Additional Information for ISS encoding for an exception from a WF* instruction

The following fields describe configuration settings for generating this exception:

- SCTRL_EL1.{nTWE, nTWI}.
- SCTRL_EL2.{nTWE, nTWI}.
- HCR_EL2.{TWE, TWI}.

ISS encoding for an exception from an access to a register or instruction resulting from the FPEN and TFP traps

The accesses covered by this trap include:

- Execution of Advanced SIMD and floating-point instructions.
- Accesses to the Advanced SIMD and floating-point System registers.

For an implementation that does not include support for Advanced SIMD and floating-point, the exception is reported using the EC value 0b000000.

CV, bit [24]

Condition code valid.

CV	Meaning
0b0	The COND field is not valid.
0b1	The COND field is valid.

For exceptions taken from AArch64, CV is set to 1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

COND, bits [23:20]

For exceptions taken from AArch64, this field is set to 0b1110.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [19:0]

Reserved, RES0.

Additional Information for ISS encoding for an exception from an access to a register or instruction resulting from the FPEN and TFP traps

The following fields describe the configuration settings for the traps that are reported using EC value 0b000111:

- [CPACR_EL1.FPEN](#), for accesses to SIMD and floating-point registers trapped to EL1.
- [CPTR_EL2.FPEN](#) and [CPTR_EL2.TFP](#), for accesses to SIMD and floating-point registers trapped to EL2.

ISS encoding for an exception from an Illegal Execution state, or a PC or SP alignment fault

Bits [24:0]

Reserved, RES0.

Additional Information for ISS encoding for an exception from an Illegal Execution state, or a PC or SP alignment fault

There are no configuration settings for generating Illegal Execution state exceptions and PC alignment fault exceptions. For more information about PC alignment fault exceptions, see [‘PC alignment checking’](#).

[‘SP alignment checking’](#) describes the configuration settings for generating SP alignment fault exceptions.

ISS encoding for an exception from HVC or SVC instruction execution

Bits [24:16]

Reserved, RES0.

imm16, bits [15:0]

The value of the immediate field from the HVC or SVC instruction.

For an HVC instruction, and for an A64 SVC instruction, this is the value of the imm16 field of the issued instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Additional Information for ISS encoding for an exception from HVC or SVC instruction execution

For A64 instructions, see [‘SVC’](#) and [‘HVC’](#).

ISS encoding for an exception from MSR, MRS, or System instruction execution in AArch64 state

Bits [24:22]

Reserved, RES0.

Op0, bits [21:20]

The Op0 value from the issued instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Op2, bits [19:17]

The Op2 value from the issued instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Op1, bits [16:14]

The Op1 value from the issued instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

CRn, bits [13:10]

The CRn value from the issued instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Rt, bits [9:5]

The Rt value from the issued instruction, the general-purpose register used for the transfer.

For system instructions which require that the opcode Rt field is set to 0b11111, but where the trapped instruction has a different value of Rt, an implementation is permitted to return the value 0b11111, instead of the value of Rt from the trapped instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

CRm, bits [4:1]

The CRm value from the issued instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Direction, bit [0]

Indicates the direction of the trapped instruction.

Direction	Meaning
0b0	Write access, including MSR instructions.
0b1	Read access, including MRS instructions.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Additional Information for ISS encoding for an exception from MSR, MRS, or System instruction execution in AArch64 state

For exceptions caused by System instructions, see ‘[System instructions](#)’ subsection of ‘[Branches, exception generating and System instructions](#)’ for the encoding values returned by an instruction.

The following fields describe configuration settings for generating the exception that is reported using EC value 0b011000:

- [SCTLR_EL1](#).UCI, for execution of cache maintenance instructions using AArch64 state, execution is trapped to EL1 or EL2.
- [SCTLR_EL1](#).UCT, for accesses to [CTR_ELO](#) using AArch64 state, MSR or MRS access trapped to EL1 or EL2.
- [SCTLR_EL1](#).DZE, for execution of DC ZVA instructions using AArch64 state, execution is trapped to EL1 or EL2.
- [SCTLR_EL1](#).UMA, for accesses to the PSTATE interrupt masks using AArch64 state, MSR or MRS access trapped to EL1 or EL2.

- [CPACR_EL1](#).TTA, for accesses to the trace System registers using AArch64 state, MSR or MRS access trapped to EL1 or EL2.
- [MDSCR_EL1](#).TDCC, for accesses to the Debug Communications Channel (DCC) registers using AArch64 state, MSR or MRS access trapped to EL1 or EL2.
- [CNTKCTL_EL1](#).{EL0PTEN, EL0VTEN, EL0PCTEN, EL0VCTEN} accesses to the Generic Timer registers using AArch64 state, MSR or MRS access trapped to EL1 or EL2.
- [PMUSERENR_EL0](#), for accesses to the Performance Monitor System registers using AArch64 state, MSR or MRS access trapped to EL1 or EL2.
- [AMUSERENR_EL0](#).EN, for accesses to Activity Monitors System registers using AArch64 state, MSR or MRS access trapped to EL1 or EL2.
- [HCR_EL2](#).{TRVM, TVM}, for accesses to virtual memory control registers using AArch64 state, MSR or MRS access trapped to EL2.
- [HCR_EL2](#).TDZ, for execution of DC ZVA instructions using AArch64 state, execution is trapped to EL2.
- [HCR_EL2](#).TTLB, for execution of TLB maintenance instructions using AArch64 state, execution is trapped to EL2.
- [HCR_EL2](#).{TSW, TPC, TPU}, for execution of cache maintenance instructions using AArch64 state, execution is trapped to EL2.
- [HCR_EL2](#).TACR, for accesses to the Auxiliary Control Register, [ACTLR_EL1](#), using AArch64 state, MSR or MRS access trapped to EL2.
- [HCR_EL2](#).TIDCP, for accesses to lockdown, DMA, and TCM operations using AArch64 state, MSR or MRS access trapped to EL2.
- [HCR_EL2](#).{TID1, TID2, TID3}, for accesses to ID group 1, ID group 2 or ID group 3 registers, using AArch64 state, MSR or MRS access trapped to EL2.
- [CPTR_EL2](#).TCPAC, for accesses to [CPACR_EL1](#), using AArch64 state, MSR or MRS access trapped to EL2.
- [CPTR_EL2](#).TTA, for accesses to the trace System registers, using AArch64 state, MSR or MRS access trapped to EL2.
- [MDCR_EL2](#).TTRF, for accesses to the trace filter control register, [TRFCR_EL1](#), using AArch64 state, MSR or MRS access trapped to EL2.
- [MDCR_EL2](#).TDRA, for accesses to Debug ROM registers, using AArch64 state, MSR or MRS access trapped to EL2.
- [MDCR_EL2](#).TDOSA, for accesses to powerdown debug System registers using AArch64 state, MSR or MRS access trapped to EL2.
- [CNTHCTL_EL2](#).{EL1PCEN, EL1PCTEN}, for accesses to the Generic Timer registers using AArch64 state, MSR or MRS access trapped to EL2.
- [MDCR_EL2](#).TDA, for accesses to debug System registers using AArch64 state, MSR or MRS access trapped to EL2.
- [MDCR_EL2](#).{TPM, TPMCR}, for accesses to Performance Monitor System registers, using AArch64 state, MSR or MRS access trapped to EL2.
- [CPTR_EL2](#).TAM, for accesses to Activity Monitors System registers, using AArch64 state, MSR or MRS access trapped to EL2.
- [HCR_EL2](#).APK, for accesses to Pointer authentication key registers, using AArch64 state, MSR or MRS access trapped to EL2.
- [HCR_EL2](#).AT, for execution of AT S1E* instructions, using AArch64 state, execution is trapped to EL2.
- [HCR_EL2](#).{TERR, FIEN}, for accesses to RAS registers, using AArch64 state, MSR or MRS access, trapped to EL2.

ISS encoding for an exception from MSRR, MRRS, or 128-bit System instruction execution in AArch64 state

Bits [24:22]

Reserved, RES0.

Op0, bits [21:20]

The Op0 value from the issued instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Op2, bits [19:17]

The Op2 value from the issued instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Op1, bits [16:14]

The Op1 value from the issued instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

CRn, bits [13:10]

The CRn value from the issued instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Rt, bits [9:6]

The Rt value from the issued instruction, the general-purpose register used for the transfer.

Note

This value represents register pair of X[Rt:0], X[Rt:1].

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [5]

Reserved, RES0.

CRm, bits [4:1]

The CRm value from the issued instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Direction, bit [0]

Indicates the direction of the trapped instruction.

Direction	Meaning
0b0	Write access, MSRR instructions.
0b1	Read access, MRRS instructions.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Additional Information for ISS encoding for an exception from MSRR, MRRS, or 128-bit System instruction execution in AArch64 state

The following fields describe configuration settings for generating exceptions from an MSRR or MRRS access that are reported using EC value 0b010100:

ISS encoding for an exception from an Instruction Abort

Bits [24:13]

Reserved, RES0.

SET, bits [12:11]

When FEAT_RAS is implemented and GetESR_ELx_IFSC(EL1) IN {'010000', '01001x', '0101xx'}:

Synchronous Error Type. Describes the PE error state after taking the Instruction Abort exception.

SET	Meaning
0b00	Recoverable state (UER).
0b10	Uncontainable (UC).
0b11	Restartable state (UEO).

All other values are reserved.

Note
Software can use this information to determine what recovery might be possible. Taking a synchronous External abort exception might result in a PE state that is not recoverable.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

FnV, bit [10]

FAR not Valid, for a synchronous External abort other than a synchronous External abort on a translation table walk.

FnV	Meaning
0b0	FAR is valid.
0b1	FAR is not valid, and holds an UNKNOWN value.

This field is valid only if the IFSC code is 0b010000. It is RES0 for all other aborts.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

EA, bit [9]

External abort type. This bit can provide an IMPLEMENTATION DEFINED classification of External aborts.

For any abort other than an External abort this bit returns a value of 0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [8]

Reserved, RES0.

S1PTW, bit [7]

For a stage 2 fault, indicates whether the fault was a stage 2 fault on an access made for a stage 1 translation table walk:

S1PTW	Meaning
0b0	Fault not on a stage 2 translation for a stage 1 translation table walk.
0b1	Fault on the stage 2 translation of an access for a stage 1 translation table walk.

For any abort other than a stage 2 fault this bit is RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [6]

Reserved, RES0.

IFSC, bits [5:0]

Instruction Fault Status Code.

IFSC	Meaning	Applies when
0b000000	Address size fault, level 0 of translation or translation table base register.	
0b000001	Address size fault, level 1.	
0b000010	Address size fault, level 2.	
0b000011	Address size fault, level 3.	

IFSC	Meaning	Applies when
0b000100	Translation fault, level 0.	
0b000101	Translation fault, level 1.	
0b000110	Translation fault, level 2.	
0b000111	Translation fault, level 3.	
0b001001	Access flag fault, level 1.	
0b001010	Access flag fault, level 2.	
0b001011	Access flag fault, level 3.	
0b001100	Permission fault, level 0.	
0b001101	Permission fault, level 1.	
0b001110	Permission fault, level 2.	
0b001111	Permission fault, level 3.	
0b010000	Synchronous External abort, not on translation table walk or hardware update of translation table.	
0b010100	Synchronous External abort on translation table walk or hardware update of translation table, level 0.	
0b010101	Synchronous External abort on translation table walk or hardware update of translation table, level 1.	
0b010110	Synchronous External abort on translation table walk or hardware update of translation table, level 2.	
0b010111	Synchronous External abort on translation table walk or hardware update of translation table, level 3.	
0b011000	Synchronous parity or ECC error on memory access, not on translation table walk.	FEAT_RAS is not implemented
0b011100	Synchronous parity or ECC error on memory access on translation table walk or hardware update of translation table, level 0.	FEAT_RAS is not implemented
0b011101	Synchronous parity or ECC error on memory access on translation table walk or hardware update of translation table, level 1.	FEAT_RAS is not implemented
0b011110	Synchronous parity or ECC error on memory access on translation table walk or hardware update of translation table, level 2.	FEAT_RAS is not implemented
0b011111	Synchronous parity or ECC error on memory access on translation table walk or hardware update of translation table, level 3.	FEAT_RAS is not implemented
0b110000	TLB conflict abort.	
0b110001	Unsupported atomic hardware update fault.	FEAT_HAF is implemented

All other values are reserved.

For more information about the lookup level associated with a fault, see [‘The lookup level associated with MMU faults’](#).

If the S1PTW bit is set, then the level refers the level of the stage2 translation that is translating a stage 1

translation walk.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

ISS encoding for an exception from a Data Abort

ISV, bit [24]

Instruction Syndrome Valid. Indicates whether the syndrome information in ISS[23:14] represents the instruction syndrome fields {SAS, SSE, SRT, SF, AR}.

ISV	Meaning
0b0	No valid instruction syndrome. ISS[23:14] do not represent an instruction syndrome.
0b1	ISS[23:14] hold a valid instruction syndrome.

The ISV field is only relevant for the following instructions:

- An AArch64 load or store of a single general-purpose register (including the register specified with 0b11111, including those with Acquire/Release semantics, but excluding Load Exclusive or Store Exclusive and excluding those with writeback).

The ISV field is 1 if all of the following apply:

- The fault was not a stage 2 fault on a stage 1 translation table walk.
- If FEAT_RAS is implemented, the fault was not any kind of synchronous External abort.
- Any of the following apply:
 - The fault was generated by one of the described AArch64 load or store instructions that transfer a single general-purpose register, and any of the following apply:
 - The fault was a stage 2 fault.
 - The fault was generated by one of the FEAT_LS64, FEAT_LS64_V or FEAT_LS64_ACCDATA instructions and the fault was a Translation fault, Access flag fault or Permission fault.
- One of the following applies:
 - The address reported in FAR_EL1 is the lowest address accessed by the instruction.
 - The address reported in FAR_EL1 is not the lowest address accessed by the instruction, and the implementation reports ISV as 1 in this case. Arm recommends against this behavior.

The value of this field is UNKNOWN when the following occurs:

- Stage 2 faults when the exception was generated in Debug state, in memory access mode.

When FEAT_RAS is not implemented, it is IMPLEMENTATION DEFINED whether ISV is set to 1 or 0 on a synchronous External abort on a stage 2 translation table walk.

Otherwise the value of this field is 0.

Note

The value of this field is 0 if any of the following apply:

- FEAT_LSE is implemented and the fault was for an atomic instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

SAS, bits [23:22]

When ISV == '1':

Syndrome Access Size. Indicates the size of the access attempted by the faulting operation.

SAS	Meaning
0b00	Byte
0b01	Halfword
0b10	Word
0b11	Doubleword

This field is UNKNOWN when the value of ISV is UNKNOWN.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

SSE, bit [21]

When ISV == '1':

Syndrome Sign Extend. For a byte, halfword, or word load operation, indicates whether the data item must be sign extended.

SSE	Meaning
0b0	Sign-extension not required.
0b1	Data item must be sign-extended.

For all other operations, this field is 0.

This field is UNKNOWN when the value of ISV is UNKNOWN.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

SRT, bits [20:16]

When ISV == '1':

Syndrome Register Transfer. The register number of the Wt/Xt/Rt operand of the faulting instruction.

This field is UNKNOWN when the value of ISV is UNKNOWN.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bit [15]

When ISV == '1':

SF, bit [15]

Sixty Four bit general-purpose register transfer. Width of the register accessed by the instruction is 64-bit.

SF	Meaning
0b0	Instruction loads/stores a 32-bit general-purpose register.
0b1	Instruction loads/stores a 64-bit general-purpose register.

Note

This field specifies the register width identified by the instruction, not the Execution state.

This field is UNKNOWN when the value of ISV is UNKNOWN.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

FnP, bit [15]

FAR not Precise.

FnP	Meaning
0b0	The FAR holds the faulting virtual address that generated the Data Abort.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

AR, bit [14]

When ISV == '1':

Acquire/Release.

AR	Meaning
0b0	Instruction did not have acquire/release semantics.
0b1	Instruction did have acquire/release semantics.

This field is UNKNOWN when the value of ISV is UNKNOWN.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bit [13]

Reserved, RES0.

Bits [12:11]

When GetESR_ELx_DFSC(EL1) IN {'00xxx', '10101x'} and !(GetESR_ELx_DFSC(EL1) IN {'0000xx'}):

LST, bits [12:11]

Load/Store Type. Used when a Translation fault, Access flag fault, or Permission fault generates a Data Abort reported with ISV=1.

LST	Meaning
0b00	The instruction that generated the Data Abort is not specified by this field.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

When FEAT_RAS is implemented and GetESR_ELx_DFSC(EL1) == '010000':

SET, bits [12:11]

Synchronous Error Type. Used when a synchronous External abort, not on a Translation table walk or hardware update of the Translation table, generated the Data Abort. Describes the PE error state after taking the Data Abort exception.

SET	Meaning
0b00	Recoverable state (UER).
0b10	Uncontainable (UC).
0b11	Restartable state (UEO).

Note

Software can use this information to determine what recovery might be possible. Taking a synchronous External abort exception might result in a PE state that is not recoverable.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

FnV, bit [10]

FAR not Valid, for a synchronous External abort other than a synchronous External abort on a translation table walk.

FnV	Meaning
0b0	FAR is valid.
0b1	FAR is not valid, and holds an UNKNOWN value.

This field is valid only if the DFSC code is 0b010000. It is RES0 for all other aborts.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

EA, bit [9]

External abort type. This bit can provide an IMPLEMENTATION DEFINED classification of External aborts.

For any abort other than an External abort this bit returns a value of 0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

CM, bit [8]

Cache maintenance. Indicates whether the Data Abort came from a cache maintenance or address translation instruction:

CM	Meaning
0b0	The Data Abort was not generated by the execution of one of the System instructions identified in the description of value 1.
0b1	The Data Abort was generated by either the execution of a cache maintenance instruction or by a synchronous fault on the execution of an address translation instruction. The DC ZVA, DC GVA, and DC GZVA instructions are not classified as cache maintenance instructions, and therefore their execution cannot cause this field to be set to 1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

S1PTW, bit [7]

For a stage 2 fault, indicates whether the fault was a stage 2 fault on an access made for a stage 1 translation table walk:

S1PTW	Meaning
0b0	Fault not on a stage 2 translation for a stage 1 translation table walk.
0b1	Fault on the stage 2 translation of an access for a stage 1 translation table walk.

For any abort other than a stage 2 fault this bit is RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

WnR, bit [6]

Write not Read. Indicates whether a synchronous abort was caused by an instruction writing to a memory location, or by an instruction reading from a memory location.

WnR	Meaning
0b0	Abort caused by an instruction reading from a memory location.
0b1	Abort caused by an instruction writing to a memory location.

For faults on cache maintenance and address translation instructions, this bit always returns a value of 1.

For faults from an atomic instruction that both reads and writes from a memory location, this bit is set to 0 if a read of the address specified by the instruction would have generated the fault which is being reported, otherwise it is set to 1. The architecture permits, but does not require, a relaxation of this requirement such that for all stage 2 aborts on stage 1 translation table walks for atomic instructions, the WnR bit is always 0.

This field is UNKNOWN for:

- An External abort on an Atomic access.
- A fault reported using a DFSC value of 0b110101, indicating an unsupported Exclusive or atomic access.
- A fault reported using a DFSC value of 0b110001, indicating an unsupported atomic hardware update fault.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

DFSC, bits [5:0]

Data Fault Status Code.

DFSC	Meaning	Applies when
0b000000	Address size fault, level 0 of translation or translation table base register.	
0b000001	Address size fault, level 1.	
0b000010	Address size fault, level 2.	
0b000011	Address size fault, level 3.	
0b000100	Translation fault, level 0.	
0b000101	Translation fault, level 1.	
0b000110	Translation fault, level 2.	
0b000111	Translation fault, level 3.	
0b001001	Access flag fault, level 1.	
0b001010	Access flag fault, level 2.	
0b001011	Access flag fault, level 3.	
0b001100	Permission fault, level 0.	

DFSC	Meaning	Applies when
0b001101	Permission fault, level 1.	
0b001110	Permission fault, level 2.	
0b001111	Permission fault, level 3.	
0b010000	Synchronous External abort, not on translation table walk or hardware update of translation table.	
0b010100	Synchronous External abort on translation table walk or hardware update of translation table, level 0.	
0b010101	Synchronous External abort on translation table walk or hardware update of translation table, level 1.	
0b010110	Synchronous External abort on translation table walk or hardware update of translation table, level 2.	
0b010111	Synchronous External abort on translation table walk or hardware update of translation table, level 3.	
0b011000	Synchronous parity or ECC error on memory access, not on translation table walk.	FEAT_RAS is not implemented
0b011100	Synchronous parity or ECC error on memory access on translation table walk or hardware update of translation table, level 0.	FEAT_RAS is not implemented
0b011101	Synchronous parity or ECC error on memory access on translation table walk or hardware update of translation table, level 1.	FEAT_RAS is not implemented
0b011110	Synchronous parity or ECC error on memory access on translation table walk or hardware update of translation table, level 2.	FEAT_RAS is not implemented
0b011111	Synchronous parity or ECC error on memory access on translation table walk or hardware update of translation table, level 3.	FEAT_RAS is not implemented
0b100001	Alignment fault.	
0b110000	TLB conflict abort.	
0b110001	Unsupported atomic hardware update fault.	FEAT_HAF is implemented
0b110100	IMPLEMENTATION DEFINED fault (Lockdown).	
0b110101	IMPLEMENTATION DEFINED fault (Unsupported Exclusive or Atomic access).	

All other values are reserved.

For more information about the lookup level associated with a fault, see [‘The lookup level associated with MMU faults’](#).

If the S1PTW bit is set, then the level refers the level of the stage2 translation that is translating a stage 1 translation walk.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

ISS encoding for an exception from a trapped floating-point exception

Bit [24]

Reserved, RES0.

TFV, bit [23]

Trapped Fault Valid bit. Indicates whether the IDF, IXF, UFF, OFF, DZF, and IOF bits hold valid information about trapped floating-point exceptions.

TFV	Meaning
0b0	The IDF, IXF, UFF, OFF, DZF, and IOF bits do not hold valid information about trapped floating-point exceptions and are UNKNOWN.
0b1	One or more floating-point exceptions occurred during an operation performed while executing the reported instruction. The IDF, IXF, UFF, OFF, DZF, and IOF bits indicate trapped floating-point exceptions that occurred. For more information, see ‘Floating-point exceptions and exception traps’ .

It is IMPLEMENTATION DEFINED whether this field is set to 0 on an exception generated by a trapped floating-point exception from an instruction that is performing floating-point operations on more than one lane of a vector.

Note
This is not a requirement. Implementations can set this field to 1 on a trapped floating-point exception from an instruction and return valid information in the {IDF, IXF, UFF, OFF, DZF, IOF} fields.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [22:11]

Reserved, RES0.

VECITR, bits [10:8]

For a trapped floating-point exception from an instruction executed in AArch64 state this field is UNKNOWN.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

IDF, bit [7]

Input Denormal floating-point exception trapped bit. If the TFV field is 0, this bit is UNKNOWN. Otherwise, the possible values of this bit are:

IDF	Meaning
0b0	Input denormal floating-point exception has not occurred.
0b1	Input denormal floating-point exception occurred during execution of the reported instruction.

IDF	Meaning
-----	---------

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [6:5]

Reserved, RES0.

IXF, bit [4]

Inexact floating-point exception trapped bit. If the TFV field is 0, this bit is UNKNOWN. Otherwise, the possible values of this bit are:

IXF	Meaning
0b0	Inexact floating-point exception has not occurred.
0b1	Inexact floating-point exception occurred during execution of the reported instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

UFF, bit [3]

Underflow floating-point exception trapped bit. If the TFV field is 0, this bit is UNKNOWN. Otherwise, the possible values of this bit are:

UFF	Meaning
0b0	Underflow floating-point exception has not occurred.
0b1	Underflow floating-point exception occurred during execution of the reported instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

OFF, bit [2]

Overflow floating-point exception trapped bit. If the TFV field is 0, this bit is UNKNOWN. Otherwise, the possible values of this bit are:

OFF	Meaning
0b0	Overflow floating-point exception has not occurred.
0b1	Overflow floating-point exception occurred during execution of the reported instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

DZF, bit [1]

Divide by Zero floating-point exception trapped bit. If the TFV field is 0, this bit is UNKNOWN. Otherwise, the possible values of this bit are:

DZF	Meaning
0b0	Divide by Zero floating-point exception has not occurred.
0b1	Divide by Zero floating-point exception occurred during execution of the reported instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

IOF, bit [0]

Invalid Operation floating-point exception trapped bit. If the TFV field is 0, this bit is UNKNOWN. Otherwise, the possible values of this bit are:

IOF	Meaning
0b0	Invalid Operation floating-point exception has not occurred.
0b1	Invalid Operation floating-point exception occurred during execution of the reported instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Additional Information for ISS encoding for an exception from a trapped floating-point exception

In an implementation that supports the trapping of floating-point exceptions:

- From an Exception level using AArch64, the [FPCR](#). {IDE, IXE, UFE, OFE, DZE, IOE} bits enable each of the floating-point exception traps.

ISS encoding for an SError exception

Note

In earlier versions of the architecture, an SError exception is referred to as an SError interrupt or an asynchronous External abort exception.

IDS, bit [24]

IMPLEMENTATION DEFINED syndrome.

IDS	Meaning
0b0	Bits [23:0] of the ISS field holds the fields described in this encoding. Note If FEAT_RAS is not implemented, bits [23:0] of the ISS field are RES0.
0b1	Bits [23:0] of the ISS field holds IMPLEMENTATION DEFINED syndrome information that can be used to provide additional information about the SError exception.

Note

This field was previously called ISV.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [23:14]

Reserved, RES0.

IESB, bit [13]

When FEAT_IESB is implemented and GetESR_ELx_DFSC(EL1) == '010001':

Implicit error synchronization event.

IESB	Meaning
0b0	One of the following applies: • The SError exception was not synchronized by the implicit error synchronization event. • The SError exception was not taken immediately following an implicit error synchronization event. • The SError exception was either not synchronized by the implicit error synchronization event or not taken immediately. • The implicit error synchronization event was on an exception return, and implementation chose to set this field to 0.
0b1	The SError exception was synchronized by the implicit error synchronization event, taken immediately, and one of the following applies: • The implicit error synchronization event was on an exception entry. • The implicit error synchronization event was on an exception return, and implementation chose to set this field to 1.

When an SError exception is synchronized by an implicit error synchronization event on exception entry, and the exception is taken immediately after exception entry, this field is set to 1.

When an SError exception is synchronized by an implicit error synchronization event on exception return, and the exception is taken immediately before the exception return, this field is set to an IMPLEMENTATION SPECIFIC choice of 0 or 1.

For all other SError exceptions, this field is set to 0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

AET, bits [12:10]

When FEAT_RAS is implemented and GetESR_ELx_DFSC(EL1) == '010001':

Asynchronous Error Type.

Describes the PE error state after taking the SError exception.

AET	Meaning
0b000	Uncontainable (UC).
0b001	Unrecoverable state (UEU).
0b010	Restartable state (UEO).
0b011	Recoverable state (UER).
0b110	Corrected (CE).

All other values are reserved.

If multiple errors are taken as a single SError exception, the overall PE error state is reported.

Note

Software can use this information to determine what recovery might be possible. The recovery software must also examine any implemented fault records to determine the location and extent of the error.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

EA, bit [9]

When FEAT_RAS is implemented and GetESR_ELx_DFSC(EL1) == '010001':

External abort type. Provides an IMPLEMENTATION DEFINED classification of External aborts.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bits [8:6]

Reserved, RES0.

DFSC, bits [5:0]

When FEAT_RAS is implemented:

Data Fault Status Code.

DFSC	Meaning
0b000000	Uncategorized error.
0b010001	Asynchronous SError exception.

All other values are reserved.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

ISS encoding for an exception from a Breakpoint or Vector Catch debug exception

Bits [24:6]

Reserved, RES0.

IFSC, bits [5:0]

Instruction Fault Status Code.

IFSC	Meaning
0b100010	Debug exception.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Additional Information for ISS encoding for an exception from a Breakpoint or Vector Catch debug exception

For more information about generating these exceptions:

- For exceptions from AArch64, see [‘Breakpoint exceptions’](#).

ISS encoding for an exception from a Software Step exception

ISV, bit [24]

Instruction syndrome valid. Indicates whether the EX bit, ISS[6], is valid, as follows:

ISV	Meaning
0b0	EX bit is RES0.
0b1	EX bit is valid.

Arm deprecates software use of this field.

See the EX bit description for more information.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [23:7]

Reserved, RES0.

EX, bit [6]

Exclusive operation. If the ISV bit is set to 1, this bit indicates whether a Load-Exclusive instruction was stepped.

EX	Meaning
0b0	An instruction other than a Load-Exclusive instruction was stepped.
0b1	A Load-Exclusive instruction was stepped.

Arm deprecates software use of this field.

If the ISV bit is set to 0, this bit is RES0, indicating no syndrome data is available.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

IFSC, bits [5:0]

Instruction Fault Status Code.

IFSC	Meaning
0b100010	Debug exception.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Additional Information for ISS encoding for an exception from a Software Step exception

For more information about generating these exceptions, see [‘Software Step exceptions’](#).

ISS encoding for an exception from a Watchpoint exception

Bit [24]

Reserved, RES0.

WPT, bits [23:18]

When FEAT_Debugv8p2 is implemented:

Watchpoint number.

All other values are reserved.

Otherwise:

Reserved, RES0.

WPTV, bit [17]

When FEAT_Debugv8p2 is implemented:

Watchpoint number Valid.

WPTV	Meaning
0b0	The WPT field is invalid, and holds an UNKNOWN value.
0b1	The WPT field is valid, and holds the number of a watchpoint that triggered a Watchpoint exception.

When a Watchpoint exception is triggered by a watchpoint match:

- If the PE sets any of FnV, FnP, or WPF to 1, then the PE sets WPTV to 1.
- Otherwise, the PE sets WPTV to an IMPLEMENTATION DEFINED value, 0 or 1.

Otherwise:

Reserved, RES0.

Bits [16:9]

Reserved, RES0.

CM, bit [8]

Cache maintenance. Indicates whether the Watchpoint exception came from a cache maintenance instruction:

CM	Meaning
0b0	The Watchpoint exception was not generated by the execution of one of the System instructions identified in the description of value 1.
0b1	The Watchpoint exception was generated by the execution of a cache maintenance instruction. The DC ZVA instruction is not classified as a cache maintenance instruction, and therefore their execution does not cause this field to be set to 1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [7]

Reserved, RES0.

WnR, bit [6]

Write not Read. Indicates whether the Watchpoint exception was caused by an instruction writing to a memory location, or by an instruction reading from a memory location.

WnR	Meaning
0b0	Watchpoint exception caused by an instruction reading from a memory location.
0b1	Watchpoint exception caused by an instruction writing to a memory location.

For Watchpoint exceptions on cache maintenance instructions, this bit always returns a value of 1.

For Watchpoint exceptions from an atomic instruction, this field is set to 0 if a read of the location would have generated the Watchpoint exception, otherwise it is set to 1.

If multiple watchpoints match on the same access, it is UNPREDICTABLE which watchpoint generates the Watchpoint exception.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

DFSC, bits [5:0]

Data Fault Status Code.

DFSC	Meaning
0b100010	Debug exception.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Additional Information for ISS encoding for an exception from a Watchpoint exception

For more information about generating these exceptions, see [‘Watchpoint exceptions’](#).

ISS encoding for an exception from execution of a Breakpoint instruction

24	16	15	0
RES0		Comment	

Bits [24:16]

Reserved, RES0.

Comment, bits [15:0]

Set to the instruction comment field value, zero extended as necessary.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Additional Information for ISS encoding for an exception from execution of a Breakpoint instruction

For more information about generating these exceptions, see ‘Breakpoint instruction exceptions’.

ISS encoding for an exception from a trapped Pointer Authentication instruction

Bits [24:0]

Reserved, RES0.

Additional Information for ISS encoding for an exception from a trapped Pointer Authentication instruction

For more information about generating these exceptions, see:

- [HCR_EL2.API](#), for exceptions from Pointer authentication instructions, using AArch64 state, trapped to EL2.

ISS encoding for a PAC Fail exception

Bits [24:2]

Reserved, RES0.

DnI, bit [1]

This field indicates whether the exception is as a result of an Instruction key or a Data key.

DnI	Meaning
0b0	Instruction Key.
0b1	Data Key.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

BnA, bit [0]

This field indicates whether the exception is as a result of an A key or a B key.

BnA	Meaning
0b0	A key.

BnA	Meaning
0b1	B key.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Additional Information for ISS encoding for a PAC Fail exception

The following instructions generate a PAC Fail exception when the Pointer Authentication Code (PAC) is incorrect:

- AUTDA, AUTDZA.
- AUTDB, AUTDZB.
- AUTIA, AUTIA1716, AUTIASP, AUTIAZ, AUTIZA.
- AUTIB, AUTIB1716, AUTIBSP, AUTIBZ, AUTIZB.
- AUTIASPPC, AUTIASPPCR, AUTIA171615.
- AUTIBSPPC, AUTIBSPPCR, AUTIB171615.

If [FEAT_FPACCOMBINE](#) is implemented, the following instructions generate a PAC Fail exception when the Pointer Authentication Code (PAC) is incorrect:

- RETAA, RETAB.
- RETAASPPC, RETABSPPC.
- RETAASPPCR, RETABSPPCR.
- BLRAA, BLRAAZ, BLRAB, BLRABZ.
- BRAA, BRAB, BRAAZ, BRABZ.
- ERETAA, ERETAB.
- LDRAA, LDRAB, whether the authenticated address is written back to the base register or not.

Accessing ESR_EL1

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, ESR_EL1

op0	op1	CRn	CRm	op2
0b11	0b000	0b0101	0b0010	0b000

```
if PSTATE.EL == EL0 then
    Undefined();
elsif PSTATE.EL == EL1 then
    if HCR_EL2().TRVM == '1' then
        AArch64_SystemAccessTrap(EL2, 0x18);
    else
        X{64}(t) = ESR_EL1();
    end;
elsif PSTATE.EL == EL2 then
    X{64}(t) = ESR_EL1();
end;
```

MSR ESR_EL1, <Xt>

op0	op1	CRn	CRm	op2
0b11	0b000	0b0101	0b0010	0b000

```

if PSTATE.EL == EL0 then
    Undefined();
elsif PSTATE.EL == EL1 then
    if HCR_EL2().TVM == '1' then
        AArch64_SystemAccessTrap(EL2, 0x18);
    else
        ESR_EL1() = X{64}(t);
    end;
elsif PSTATE.EL == EL2 then
    ESR_EL1() = X{64}(t);
end;

```

MRS <Xt>, ESR_EL2

op0	op1	CRn	CRm	op2
0b11	0b100	0b0101	0b0010	0b000

```

if PSTATE.EL == EL0 then
    Undefined();
elsif PSTATE.EL == EL1 then
    Undefined();
elsif PSTATE.EL == EL2 then
    X{64}(t) = ESR_EL2();
end;

```

MSR ESR_EL2, <Xt>

op0	op1	CRn	CRm	op2
0b11	0b100	0b0101	0b0010	0b000

```

if PSTATE.EL == EL0 then
    Undefined();
elsif PSTATE.EL == EL1 then
    Undefined();
elsif PSTATE.EL == EL2 then
    ESR_EL2() = X{64}(t);
end;

```

D12.2.31 ESR_EL2, Exception Syndrome Register (EL2)

The ESR_EL2 characteristics are:

Purpose

Holds syndrome information for an exception taken to EL2.

Configuration

There are no configuration notes.

Attributes

ESR_EL2 is a 64-bit register.

Field descriptions

ESR_EL2 is made UNKNOWN as a result of an exception return from EL2.

When an UNPREDICTABLE instruction is treated as UNDEFINED, and the exception is taken to EL2, the value of ESR_EL2 is UNKNOWN. The value written to ESR_EL2 must be consistent with a value that could be created as a result of an exception from the same Exception level that generated the exception as a result of a situation that is not UNPREDICTABLE at that Exception level, in order to avoid the possibility of a privilege violation.

Bits [63:56]

Reserved, RES0.

ISS2, bits [55:32]

ISS2 encoding for an exception, the bit assignments are:

ISS2 encoding for an exception from a Data Abort

Bits [23:0]

Reserved, RES0.

ISS2 encoding for an exception from an Instruction Abort

Bits [23:0]

Reserved, RES0.

ISS2 encoding for an exception from a Watchpoint exception

Bits [23:0]

Reserved, RES0.

ISS2 encoding for all other exceptions

Bits [23:0]

Reserved, RES0.

EC, bits [31:26]

Exception Class. Indicates the reason for the exception that this register holds information about.

For each EC value, the table references a subsection that gives information about:

- The cause of the exception, for example the configuration required to enable the trap.
- The encoding of the associated ISS.

Possible values of the EC field are:

EC	Meaning	ISS	ISS2	Applies when
0b000000	Unknown reason.	ISS encoding for exceptions with an unknown reason	ISS2 encoding for all other exceptions	
0b000001	Trapped WF* instruction execution. Conditional WF* instructions that fail their condition code check do not cause an exception.	ISS encoding for an exception from a WF* instruction	ISS2 encoding for all other exceptions	

EC	Meaning	ISS	ISS2	Applies when
0b000111	Access to Advanced SIMD or floating-point functionality trapped by CPACR_EL1.FPEN , CPTR_EL2.FPEN , or CPTR_EL2.TFP control. Excludes exceptions resulting from CPACR_EL1 when the value of HCR_EL2.TGE is 1, or because Advanced SIMD and floating-point are not implemented. These are reported with EC value 0b000000.	ISS encoding for an exception from an access to a register or instruction resulting from the FPEN and TFP traps	ISS2 encoding for all other exceptions	
0b001001	Trapped use of a Pointer authentication instruction.	ISS encoding for an exception from a trapped Pointer Authentication instruction	ISS2 encoding for all other exceptions	FEAT_PAuth is implemented
0b001110	Illegal Execution state.	ISS encoding for an exception from an Illegal Execution state, or a PC or SP alignment fault	ISS2 encoding for all other exceptions	
0b010101	SVC instruction execution in AArch64 state.	ISS encoding for an exception from HVC or SVC instruction execution	ISS2 encoding for all other exceptions	
0b010110	HVC instruction execution in AArch64 state, when HVC is not disabled.	ISS encoding for an exception from HVC or SVC instruction execution	ISS2 encoding for all other exceptions	
0b010111	SMC instruction execution in AArch64 state, when SMC is not disabled. This is reported in ESR_EL2 only when the exception is generated because the value of HCR_EL2.TSC is 1.	ISS encoding for an exception from SMC instruction execution in AArch64 state	ISS2 encoding for all other exceptions	
0b011000	Trapped MSR, MRS or System instruction execution in AArch64 state, that is not reported using EC values 0b000000, 0b000001 or 0b000111. This includes all instructions that cause exceptions that are part of the encoding space defined in ‘ System instruction class encoding overview ’, except for those exceptions reported using EC values 0b000000, 0b000001, or 0b000111.	ISS encoding for an exception from MSR, MRS, or System instruction execution in AArch64 state	ISS2 encoding for all other exceptions	
0b011100	Exception from a PAC Fail	ISS encoding for a PAC Fail exception	ISS2 encoding for all other exceptions	FEAT_FPAC is implemented

EC	Meaning	ISS	ISS2	Applies when
0b100000	Instruction Abort from a lower Exception level. Used for MMU and MPU faults generated by instruction accesses and synchronous External aborts, including synchronous parity or ECC errors. Not used for debug-related exceptions.	ISS encoding for an exception from an Instruction Abort	ISS2 encoding for an exception from an Instruction Abort	
0b100001	Used for MMU and MPU faults generated by instruction accesses and synchronous External aborts, including synchronous parity or ECC errors. Not used for debug-related exceptions.	ISS encoding for an exception from an Instruction Abort	ISS2 encoding for an exception from an Instruction Abort	
0b100010	PC alignment fault exception.	ISS encoding for an exception from an Illegal Execution state, or a PC or SP alignment fault	ISS2 encoding for all other exceptions	
0b100100	Data Abort exception from a lower Exception level, excluding Data Abort exceptions taken to EL2 as a result of accesses generated associated with VNCR_EL2 as part of nested virtualization support. These Data Abort exceptions might be generated from Exception levels in any Execution state. Used for MMU and MPU faults generated by data accesses, alignment faults other than those caused by Stack Pointer misalignment, and synchronous External aborts, including synchronous parity or ECC errors. Not used for debug-related exceptions.	ISS encoding for an exception from a Data Abort	ISS2 encoding for an exception from a Data Abort	
0b100101	Data Abort exception without a change in Exception level, or Data Abort exceptions taken to EL2 as a result of accesses generated associated with VNCR_EL2 as part of nested virtualization support. Used for MMU and MPU faults generated by data accesses, alignment faults other than those caused by Stack Pointer misalignment, and synchronous External aborts, including synchronous parity or ECC errors. Not used for debug-related exceptions.	ISS encoding for an exception from a Data Abort	ISS2 encoding for an exception from a Data Abort	
0b100110	SP alignment fault exception.	ISS encoding for an exception from an Illegal Execution state, or a PC or SP alignment fault	ISS2 encoding for all other exceptions	

EC	Meaning	ISS	ISS2	Applies when
0b101100	Trapped floating-point exception taken from AArch64 state. This EC value is valid if the implementation supports trapping of floating-point exceptions, otherwise it is reserved. Whether a floating-point implementation supports trapping of floating-point exceptions is IMPLEMENTATION DEFINED.	ISS encoding for an exception from a trapped floating-point exception	ISS2 encoding for all other exceptions	
0b101111	SError exception.	ISS encoding for an SError exception	ISS2 encoding for all other exceptions	
0b110000	Breakpoint exception from a lower Exception level.	ISS encoding for an exception from a Breakpoint or Vector Catch debug exception	ISS2 encoding for all other exceptions	
0b110001	Breakpoint exception taken without a change in Exception level.	ISS encoding for an exception from a Breakpoint or Vector Catch debug exception	ISS2 encoding for all other exceptions	
0b110010	Software Step exception from a lower Exception level.	ISS encoding for an exception from a Software Step exception	ISS2 encoding for all other exceptions	
0b110011	Software Step exception taken without a change in Exception level.	ISS encoding for an exception from a Software Step exception	ISS2 encoding for all other exceptions	
0b110100	Watchpoint from a lower Exception level, excluding Watchpoint Exceptions taken to EL2 as a result of accesses generated associated with VNCR_EL2 as part of nested virtualization support. These Watchpoint Exceptions might be generated from Exception levels using any Execution state.	ISS encoding for an exception from a Watchpoint exception	ISS2 encoding for an exception from a Watchpoint exception	
0b110101	Watchpoint exceptions without a change in Exception level, or Watchpoint exceptions taken to EL2 as a result of accesses generated associated with VNCR_EL2 as part of nested virtualization support.	ISS encoding for an exception from a Watchpoint exception	ISS2 encoding for an exception from a Watchpoint exception	
0b111100	BRK instruction execution in AArch64 state.	ISS encoding for an exception from execution of a Breakpoint instruction	ISS2 encoding for all other exceptions	

All other EC values are reserved by Arm, and:

- Unused values in the range 0b000000 - 0b101100 (0x00 - 0x2C) are reserved for future use for synchronous exceptions.

- Unused values in the range 0b101101 - 0b111111 (0x2D - 0x3F) are reserved for future use, and might be used for synchronous or asynchronous exceptions.

The effect of programming this field to a reserved value is that behavior is **CONSTRAINED UNPREDICTABLE**.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally **UNKNOWN** value.

IL, bit [25]

Instruction Length for synchronous exceptions. Possible values of this bit are:

IL	Meaning
0b0	16-bit instruction trapped.
0b1	32-bit instruction trapped. This value is also used when the exception is one of the following: - An SError exception. - An Instruction Abort exception. - A PC alignment fault exception. - An SP alignment fault exception. - A Data Abort exception for which the value of the ISV bit is 0. - An Illegal Execution state exception. - Any debug exception except for Breakpoint instruction exceptions, a BRK instruction. - An exception reported using EC value 0b000000.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally **UNKNOWN** value.

ISS, bits [24:0]

Instruction Specific Syndrome. Architecturally, this field can be defined independently for each defined Exception class. However, in practice, some ISS encodings are used for more than one Exception class.

Typically, an ISS encoding has a number of subfields. When an ISS subfield holds a register number, the value returned in that field is the AArch64 view of the register number.

ISS encoding for exceptions with an unknown reason

Bits [24:0]

Reserved, RES0.

Additional Information for ISS encoding for exceptions with an unknown reason

When an exception is reported using this EC value, the IL field is set to 1.

This EC value is used for all exceptions that are not covered by any other EC value. This includes exceptions that are generated in the following situations:

- The attempted execution of an instruction bit pattern that has no allocated instruction or that is not accessible at the current Exception level and Security state, including:
 - A read access using a System register pattern that is not allocated for reads or that does not permit reads at the current Exception level and Security state.
 - A write access using a System register pattern that is not allocated for writes or that does not permit writes at the current Exception level and Security state.
 - Instruction encodings that are unallocated.
 - Instruction encodings for instructions or System registers that are not implemented in the implementation.
- In Debug state, the attempted execution of an instruction bit pattern that is not accessible in Debug state.
- In Non-debug state, the attempted execution of an instruction bit pattern that is not accessible in Non-debug state.
- In an implementation that does not include Advanced SIMD and floating-point functionality, an attempted access to Advanced SIMD or floating-point functionality under conditions where that access would be permitted if that functionality was present. This includes the attempted execution of an Advanced SIMD or floating-point instruction, and attempted accesses to Advanced SIMD and floating-point System registers.
- An exception generated because of the value of one of the [SCTLR_EL1](#).{ITD, SED, CP15BEN} control bits.
- Attempted execution of:
 - An HVC instruction when disabled by [HCR_EL2.HCD](#).
 - An SMC instruction when disabled by [HCR_EL2.TSC](#).
 - An HLT instruction when disabled by [EDSCR.HDE](#).
- Attempted execution of an MSR or MRS instruction to access [SP_EL0](#) when the value of [SPSel.SP](#) is 0.
- Attempted execution of an MSR or MRS instruction using a [_EL12](#) register name.
- Attempted execution, in Debug state, of:
 - A DCPS1 instruction when the value of [HCR_EL2.TGE](#) is 1.
 - A DCPS2 instruction from EL1 or EL0 when EL2 is disabled or not implemented in the current Security state.
 - A DCPS3 instruction when the value of [EDSCR.SDD](#) is 1.
- In Debug state when the value of [EDSCR.SDD](#) is 1, the attempted execution at EL1 or EL0 of an instruction that is configured to trap to EL2.
- An exception that is taken to EL2 because the value of [HCR_EL2.TGE](#) is 1. If the value of [HCR_EL2.TGE](#) is 0, this exception is reported using an [ESR_EL2.EC](#) value of 0b000111.

ISS encoding for an exception from a WF* instruction

24	23	20	19		2	1	0
CV	COND	RES0				TI	

CV, bit [24]

Condition code valid.

CV	Meaning
0b0	The COND field is not valid.
0b1	The COND field is valid.

For exceptions taken from AArch64, CV is set to 1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

COND, bits [23:20]

For exceptions taken from AArch64, this field is set to 0b1110.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [19:2]

Reserved, RES0.

TI, bits [1:0]

Trapped instruction. Possible values of this bit are:

TI	Meaning
0b00	WFI trapped.
0b01	WFE trapped.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Additional Information for ISS encoding for an exception from a WF* instruction

The following fields describe configuration settings for generating this exception:

- [SCTLR_EL1](#). {nTWE, nTWI}.
- [SCTLR_EL2](#). {nTWE, nTWI}.
- [HCR_EL2](#). {TWE, TWI}.

ISS encoding for an exception from an access to a register or instruction resulting from the FPEN and TFP traps

24	23	20	19	0
CV	COND	RES0		

The accesses covered by this trap include:

- Execution of Advanced SIMD and floating-point instructions.
- Accesses to the Advanced SIMD and floating-point System registers.

For an implementation that does not include support for Advanced SIMD and floating-point, the exception is reported using the EC value 0b000000.

CV, bit [24]

Condition code valid.

CV	Meaning
0b0	The COND field is not valid.

CV	Meaning
0b1	The COND field is valid.

For exceptions taken from AArch64, CV is set to 1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

COND, bits [23:20]

For exceptions taken from AArch64, this field is set to 0b1110.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [19:0]

Reserved, RES0.

Additional Information for ISS encoding for an exception from an access to a register or instruction resulting from the FPEN and TFP traps

The following fields describe the configuration settings for the traps that are reported using EC value 0b000111:

- [CPACR_EL1.FPEN](#), for accesses to SIMD and floating-point registers trapped to EL1.
- [CPTR_EL2.FPEN](#) and [CPTR_EL2.TFP](#), for accesses to SIMD and floating-point registers trapped to EL2.

ISS encoding for an exception from an Illegal Execution state, or a PC or SP alignment fault

**Bits [24:0]**

Reserved, RES0.

Additional Information for ISS encoding for an exception from an Illegal Execution state, or a PC or SP alignment fault

There are no configuration settings for generating Illegal Execution state exceptions and PC alignment fault exceptions. For more information about PC alignment fault exceptions, see [‘PC alignment checking’](#).

‘SP alignment checking’ describes the configuration settings for generating SP alignment fault exceptions.

ISS encoding for an exception from HVC or SVC instruction execution

**Bits [24:16]**

Reserved, RES0.

imm16, bits [15:0]

The value of the immediate field from the HVC or SVC instruction.

For an HVC instruction, and for an A64 SVC instruction, this is the value of the imm16 field of the issued instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Additional Information for ISS encoding for an exception from HVC or SVC instruction execution

For A64 instructions, see ‘[SVC](#)’ and ‘[HVC](#)’.

ISS encoding for an exception from SMC instruction execution in AArch64 state

Bits [24:16]

Reserved, RES0.

imm16, bits [15:0]

The value of the immediate field from the issued SMC instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Additional Information for ISS encoding for an exception from SMC instruction execution in AArch64 state

The value of ISS[24:0] when an SMC instruction is trapped from EL1 modes.

[HCR_EL2.TSC](#) describes the configuration settings for trapping SMC from EL1 modes.

ISS encoding for an exception from MSR, MRS, or System instruction execution in AArch64 state

Bits [24:22]

Reserved, RES0.

Op0, bits [21:20]

The Op0 value from the issued instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Op2, bits [19:17]

The Op2 value from the issued instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Op1, bits [16:14]

The Op1 value from the issued instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

CRn, bits [13:10]

The CRn value from the issued instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Rt, bits [9:5]

The Rt value from the issued instruction, the general-purpose register used for the transfer.

For system instructions which require that the opcode Rt field is set to 0b11111, but where the trapped instruction has a different value of Rt, an implementation is permitted to return the value 0b11111, instead of the value of Rt from the trapped instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

CRm, bits [4:1]

The CRm value from the issued instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Direction, bit [0]

Indicates the direction of the trapped instruction.

Direction	Meaning
0b0	Write access, including MSR instructions.
0b1	Read access, including MRS instructions.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Additional Information for ISS encoding for an exception from MSR, MRS, or System instruction execution in AArch64 state

For exceptions caused by System instructions, see ‘[System instructions](#)’ subsection of ‘[Branches, exception generating and System instructions](#)’ for the encoding values returned by an instruction.

The following fields describe configuration settings for generating the exception that is reported using EC value 0b011000:

- [SCTLR_EL1](#).UCI, for execution of cache maintenance instructions using AArch64 state, execution is trapped to EL1 or EL2.
- [SCTLR_EL1](#).UCT, for accesses to [CTR_EL0](#) using AArch64 state, MSR or MRS access trapped to EL1 or EL2.
- [SCTLR_EL1](#).DZE, for execution of DC ZVA instructions using AArch64 state, execution is trapped to EL1 or EL2.

- [SCTLR_EL1](#).UMA, for accesses to the PSTATE interrupt masks using AArch64 state, MSR or MRS access trapped to EL1 or EL2.
- [CPACR_EL1](#).TTA, for accesses to the trace System registers using AArch64 state, MSR or MRS access trapped to EL1 or EL2.
- [MDSCR_EL1](#).TDCC, for accesses to the Debug Communications Channel (DCC) registers using AArch64 state, MSR or MRS access trapped to EL1 or EL2.
- [CNTKCTL_EL1](#).{EL0PTEN, EL0VTEN, EL0PCTEN, EL0VCTEN} accesses to the Generic Timer registers using AArch64 state, MSR or MRS access trapped to EL1 or EL2.
- [PMUSERENR_EL0](#).EN, for accesses to the Performance Monitor System registers using AArch64 state, MSR or MRS access trapped to EL1 or EL2.
- [AMUSERENR_EL0](#).EN, for accesses to Activity Monitors System registers using AArch64 state, MSR or MRS access trapped to EL1 or EL2.
- [HCR_EL2](#).{TRVM, TVM}, for accesses to virtual memory control registers using AArch64 state, MSR or MRS access trapped to EL2.
- [HCR_EL2](#).TDZ, for execution of DC ZVA instructions using AArch64 state, execution is trapped to EL2.
- [HCR_EL2](#).TTLB, for execution of TLB maintenance instructions using AArch64 state, execution is trapped to EL2.
- [HCR_EL2](#).{TSW, TPC, TPU}, for execution of cache maintenance instructions using AArch64 state, execution is trapped to EL2.
- [HCR_EL2](#).TACR, for accesses to the Auxiliary Control Register, [ACTLR_EL1](#), using AArch64 state, MSR or MRS access trapped to EL2.
- [HCR_EL2](#).TIDCP, for accesses to lockdown, DMA, and TCM operations using AArch64 state, MSR or MRS access trapped to EL2.
- [HCR_EL2](#).{TID1, TID2, TID3}, for accesses to ID group 1, ID group 2 or ID group 3 registers, using AArch64 state, MSR or MRS access trapped to EL2.
- [CPTR_EL2](#).TCPAC, for accesses to [CPACR_EL1](#), using AArch64 state, MSR or MRS access trapped to EL2.
- [CPTR_EL2](#).TTA, for accesses to the trace System registers, using AArch64 state, MSR or MRS access trapped to EL2.
- [MDCR_EL2](#).TTRF, for accesses to the trace filter control register, [TRFCR_EL1](#), using AArch64 state, MSR or MRS access trapped to EL2.
- [MDCR_EL2](#).TDRA, for accesses to Debug ROM registers, using AArch64 state, MSR or MRS access trapped to EL2.
- [MDCR_EL2](#).TDOSA, for accesses to powerdown debug System registers using AArch64 state, MSR or MRS access trapped to EL2.
- [CNTHCTL_EL2](#).{EL1PCEN, EL1PCTEN}, for accesses to the Generic Timer registers using AArch64 state, MSR or MRS access trapped to EL2.
- [MDCR_EL2](#).TDA, for accesses to debug System registers using AArch64 state, MSR or MRS access trapped to EL2.
- [MDCR_EL2](#).{TPM, TPMCR}, for accesses to Performance Monitor System registers, using AArch64 state, MSR or MRS access trapped to EL2.
- [CPTR_EL2](#).TAM, for accesses to Activity Monitors System registers, using AArch64 state, MSR or MRS access trapped to EL2.
- [HCR_EL2](#).APK, for accesses to Pointer authentication key registers, using AArch64 state, MSR or MRS access trapped to EL2.
- [HCR_EL2](#).AT, for execution of AT S1E* instructions, using AArch64 state, execution is trapped to EL2.
- [HCR_EL2](#).{TERR, FIEN}, for accesses to RAS registers, using AArch64 state, MSR or MRS access, trapped to EL2.

ISS encoding for an exception from MSRR, MRRS, or 128-bit System instruction execution in AArch64 state

Bits [24:22]

Reserved, RES0.

Op0, bits [21:20]

The Op0 value from the issued instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Op2, bits [19:17]

The Op2 value from the issued instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Op1, bits [16:14]

The Op1 value from the issued instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

CRn, bits [13:10]

The CRn value from the issued instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Rt, bits [9:6]

The Rt value from the issued instruction, the general-purpose register used for the transfer.

Note

This value represents register pair of X[Rt:0], X[Rt:1].

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [5]

Reserved, RES0.

CRm, bits [4:1]

The CRm value from the issued instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Direction, bit [0]

Indicates the direction of the trapped instruction.

Direction	Meaning
0b0	Write access, MSRR instructions.
0b1	Read access, MRRS instructions.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Additional Information for ISS encoding for an exception from MSRR, MRRS, or 128-bit System instruction execution in AArch64 state

The following fields describe configuration settings for generating exceptions from an MSRR or MRRS access that are reported using EC value 0b010100:

ISS encoding for an exception from an Instruction Abort

The ISS2 encoding for an exception from an Instruction Abort includes further information about the exception if any of the following are true:

Bits [24:13]

Reserved, RES0.

SET, bits [12:11]

When FEAT_RAS is implemented and GetESR_ELx_IFSC(EL2) == '010000':

Synchronous Error Type. When IFSC is 0b010000, describes the PE error state after taking the Instruction Abort exception.

SET	Meaning
0b00	Recoverable state (UER).
0b10	Uncontainable (UC).
0b11	Restartable state (UEO).

All other values are reserved.

Note
Software can use this information to determine what recovery might be possible. Taking a synchronous External abort exception might result in a PE state that is not recoverable.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

FnV, bit [10]

When GetESR_ELx_IFSC(EL2) == '010000':

FAR not Valid, for a synchronous External abort other than a synchronous External abort on a translation table walk.

FnV	Meaning
0b0	FAR is valid.
0b1	FAR is not valid, and holds an UNKNOWN value.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

EA, bit [9]

External abort type. This bit can provide an IMPLEMENTATION DEFINED classification of External aborts.

For any abort other than an External abort this bit returns a value of 0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [8]

Reserved, RES0.

S1PTW, bit [7]

For a stage 2 fault, indicates whether the fault was a stage 2 fault on an access made for a stage 1 translation table walk:

S1PTW	Meaning
0b0	Fault not on a stage 2 translation for a stage 1 translation table walk.
0b1	Fault on the stage 2 translation of an access for a stage 1 translation table walk.

For any abort other than a stage 2 fault this bit is RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [6]

Reserved, RES0.

IFSC, bits [5:0]

Instruction Fault Status Code.

IFSC	Meaning	Applies when
0b000000	Address size fault, level 0 of translation or translation table base register.	
0b000001	Address size fault, level 1.	
0b000010	Address size fault, level 2.	

IFSC	Meaning	Applies when
0b000011	Address size fault, level 3.	
0b000100	Translation fault, level 0.	
0b000101	Translation fault, level 1.	
0b000110	Translation fault, level 2.	
0b000111	Translation fault, level 3.	
0b001001	Access flag fault, level 1.	
0b001010	Access flag fault, level 2.	
0b001011	Access flag fault, level 3.	
0b001100	Permission fault, level 0.	
0b001101	Permission fault, level 1.	
0b001110	Permission fault, level 2.	
0b001111	Permission fault, level 3.	
0b010000	Synchronous External abort, not on translation table walk or hardware update of translation table.	
0b010100	Synchronous External abort on translation table walk or hardware update of translation table, level 0.	
0b010101	Synchronous External abort on translation table walk or hardware update of translation table, level 1.	
0b010110	Synchronous External abort on translation table walk or hardware update of translation table, level 2.	
0b010111	Synchronous External abort on translation table walk or hardware update of translation table, level 3.	
0b011000	Synchronous parity or ECC error on memory access, not on translation table walk.	FEAT_RAS is not implemented
0b011100	Synchronous parity or ECC error on memory access on translation table walk or hardware update of translation table, level 0.	FEAT_RAS is not implemented
0b011101	Synchronous parity or ECC error on memory access on translation table walk or hardware update of translation table, level 1.	FEAT_RAS is not implemented
0b011110	Synchronous parity or ECC error on memory access on translation table walk or hardware update of translation table, level 2.	FEAT_RAS is not implemented
0b011111	Synchronous parity or ECC error on memory access on translation table walk or hardware update of translation table, level 3.	FEAT_RAS is not implemented
0b110000	TLB conflict abort.	
0b110001	Unsupported atomic hardware update fault.	FEAT_HAF is implemented

All other values are reserved.

For more information about the lookup level associated with a fault, see [‘The lookup level associated with MMU faults’](#).

If the S1PTW bit is set, then the level refers the level of the stage2 translation that is translating a stage 1 translation walk.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

ISS encoding for an exception from a Data Abort

ISV, bit [24]

Instruction Syndrome Valid. Indicates whether the syndrome information in ISS[23:14] represents the instruction syndrome fields {SAS, SSE, SRT, SF, AR}.

ISV	Meaning
0b0	No valid instruction syndrome. ISS[23:14] do not represent an instruction syndrome.
0b1	ISS[23:14] hold a valid instruction syndrome.

The ISV field is only relevant for the following instructions:

- An AArch64 load or store of a single general-purpose register (including the register specified with 0b11111, including those with Acquire/Release semantics, but excluding Load Exclusive or Store Exclusive and excluding those with writeback).

The ISV field is 1 if all of the following apply:

- The fault was not a stage 2 fault on a stage 1 translation table walk.
- If FEAT_RAS is implemented, the fault was not any kind of synchronous External abort.
- Any of the following apply:
 - The fault was generated by one of the described AArch64 load or store instructions that transfer a single general-purpose register, and any of the following apply:
 - The fault was a stage 2 fault.
 - The fault was generated by one of the FEAT_LS64, FEAT_LS64_V or FEAT_LS64_ACCDATA instructions and the fault was a Translation fault, Access flag fault or Permission fault.
- One of the following applies:
 - The address reported in FAR_EL2 is the lowest address accessed by the instruction.
 - The address reported in FAR_EL2 is not the lowest address accessed by the instruction, and the implementation reports ISV as 1 in this case. Arm recommends against this behavior.

The value of this field is UNKNOWN when the following occurs:

- Stage 2 faults when the exception was generated in Debug state, in memory access mode.

When FEAT_RAS is not implemented, it is IMPLEMENTATION DEFINED whether ISV is set to 1 or 0 on a synchronous External abort on a stage 2 translation table walk.

Otherwise the value of this field is 0.

Note

The value of this field is 0 if any of the following apply:

- FEAT_LSE is implemented and the fault was for an atomic instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

SAS, bits [23:22]

When ISV == '1':

Syndrome Access Size. Indicates the size of the access attempted by the faulting operation.

SAS	Meaning
0b00	Byte
0b01	Halfword
0b10	Word
0b11	Doubleword

This field is UNKNOWN when the value of ISV is UNKNOWN.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

SSE, bit [21]

When ISV == '1':

Syndrome Sign Extend. For a byte, halfword, or word load operation, indicates whether the data item must be sign extended.

SSE	Meaning
0b0	Sign-extension not required.
0b1	Data item must be sign-extended.

For all other operations, this field is 0.

This field is UNKNOWN when the value of ISV is UNKNOWN.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

SRT, bits [20:16]

When ISV == '1':

Syndrome Register Transfer. The register number of the Wt/Xt/Rt operand of the faulting instruction.

This field is UNKNOWN when the value of ISV is UNKNOWN.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bit [15]

When ISV == '1':

SF, bit [15]

Sixty Four bit general-purpose register transfer. Width of the register accessed by the instruction is 64-bit.

SF	Meaning
0b0	Instruction loads/stores a 32-bit general-purpose register.
0b1	Instruction loads/stores a 64-bit general-purpose register.

Note

This field specifies the register width identified by the instruction, not the Execution state.

This field is UNKNOWN when the value of ISV is UNKNOWN.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

FnP, bit [15]

FAR not Precise.

FnP	Meaning
0b0	The FAR holds the faulting virtual address that generated the Data Abort.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

AR, bit [14]

When ISV == '1':

Acquire/Release.

AR	Meaning
0b0	Instruction did not have acquire/release semantics.
0b1	Instruction did have acquire/release semantics.

This field is UNKNOWN when the value of ISV is UNKNOWN.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bit [13]

Reserved, RES0.

Bits [12:11]

When GetESR_ELx_DFSC(EL2) IN {'00xxxx', '10101x'} and !(GetESR_ELx_DFSC(EL2) IN {'0000xx'}):

LST, bits [12:11]

Load/Store Type. Used when a Translation fault, Access flag fault, or Permission fault generates a Data Abort reported with ISV=1.

LST	Meaning
0b00	The instruction that generated the Data Abort is not specified by this field.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

When FEAT_RAS is implemented and GetESR_ELx_DFSC(EL2) == '010000':

SET, bits [12:11]

Synchronous Error Type. Used when a synchronous External abort, not on a Translation table walk or hardware update of the Translation table, generated the Data Abort. Describes the PE error state after taking the Data Abort exception.

SET	Meaning
0b00	Recoverable state (UER).
0b11	Restartable state (UEO).

Note

Software can use this information to determine what recovery might be possible. Taking a synchronous External abort exception might result in a PE state that is not recoverable.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

FnV, bit [10]

FAR not Valid, for a synchronous External abort other than a synchronous External abort on a translation table walk.

FnV	Meaning
0b0	FAR is valid.
0b1	FAR is not valid, and holds an UNKNOWN value.

This field is valid only if the DFSC code is 0b010000. It is RES0 for all other aborts.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

EA, bit [9]

External abort type. This bit can provide an IMPLEMENTATION DEFINED classification of External aborts.

For any abort other than an External abort this bit returns a value of 0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

CM, bit [8]

Cache maintenance. Indicates whether the Data Abort came from a cache maintenance or address translation instruction:

CM	Meaning
0b0	The Data Abort was not generated by the execution of one of the System instructions identified in the description of value 1.
0b1	The Data Abort was generated by either the execution of a cache maintenance instruction or by a synchronous fault on the execution of an address translation instruction. The DC ZVA, DC GVA, and DC GZVA instructions are not classified as cache maintenance instructions, and therefore their execution cannot cause this field to be set to 1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

S1PTW, bit [7]

For a stage 2 fault, indicates whether the fault was a stage 2 fault on an access made for a stage 1 translation table walk:

S1PTW	Meaning
0b0	Fault not on a stage 2 translation for a stage 1 translation table walk.
0b1	Fault on the stage 2 translation of an access for a stage 1 translation table walk.

For any abort other than a stage 2 fault this bit is RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

WnR, bit [6]

Write not Read. Indicates whether a synchronous abort was caused by an instruction writing to a memory location, or by an instruction reading from a memory location.

WnR	Meaning
0b0	Abort caused by an instruction reading from a memory location.
0b1	Abort caused by an instruction writing to a memory location.

For faults on cache maintenance and address translation instructions, this bit always returns a value of 1.

For faults from an atomic instruction that both reads and writes from a memory location, this bit is set to 0 if a read of the address specified by the instruction would have generated the fault which is being reported, otherwise it is set to 1. The architecture permits, but does not require, a relaxation of this requirement such that for all stage 2 aborts on stage 1 translation table walks for atomic instructions, the WnR bit is always 0.

This field is UNKNOWN for:

- An External abort on an Atomic access.
- A fault reported using a DFSC value of 0b110101, indicating an unsupported Exclusive or atomic access.
- A fault reported using a DFSC value of 0b110001, indicating an unsupported atomic hardware update fault.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

DFSC, bits [5:0]

Data Fault Status Code.

DFSC	Meaning	Applies when
0b000000	Address size fault, level 0 of translation or translation table base register.	
0b000001	Address size fault, level 1.	
0b000010	Address size fault, level 2.	
0b000011	Address size fault, level 3.	
0b000100	Translation fault, level 0.	
0b000101	Translation fault, level 1.	
0b000110	Translation fault, level 2.	
0b000111	Translation fault, level 3.	
0b001001	Access flag fault, level 1.	
0b001010	Access flag fault, level 2.	
0b001011	Access flag fault, level 3.	
0b001100	Permission fault, level 0.	
0b001101	Permission fault, level 1.	

DFSC	Meaning	Applies when
0b001110	Permission fault, level 2.	
0b001111	Permission fault, level 3.	
0b010000	Synchronous External abort, not on translation table walk or hardware update of translation table.	
0b010100	Synchronous External abort on translation table walk or hardware update of translation table, level 0.	
0b010101	Synchronous External abort on translation table walk or hardware update of translation table, level 1.	
0b010110	Synchronous External abort on translation table walk or hardware update of translation table, level 2.	
0b010111	Synchronous External abort on translation table walk or hardware update of translation table, level 3.	
0b011000	Synchronous parity or ECC error on memory access, not on translation table walk.	FEAT_RAS is not implemented
0b011100	Synchronous parity or ECC error on memory access on translation table walk or hardware update of translation table, level 0.	FEAT_RAS is not implemented
0b011101	Synchronous parity or ECC error on memory access on translation table walk or hardware update of translation table, level 1.	FEAT_RAS is not implemented
0b011110	Synchronous parity or ECC error on memory access on translation table walk or hardware update of translation table, level 2.	FEAT_RAS is not implemented
0b011111	Synchronous parity or ECC error on memory access on translation table walk or hardware update of translation table, level 3.	FEAT_RAS is not implemented
0b100001	Alignment fault.	
0b110000	TLB conflict abort.	
0b110001	Unsupported atomic hardware update fault.	FEAT_HAF is implemented
0b110100	IMPLEMENTATION DEFINED fault (Lockdown).	
0b110101	IMPLEMENTATION DEFINED fault (Unsupported Exclusive or Atomic access).	

All other values are reserved.

For more information about the lookup level associated with a fault, see ‘[The lookup level associated with MMU faults](#)’.

If the S1PTW bit is set, then the level refers the level of the stage2 translation that is translating a stage 1 translation walk.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

ISS encoding for an exception from a trapped floating-point exception

Bit [24]

Reserved, RES0.

TFV, bit [23]

Trapped Fault Valid bit. Indicates whether the IDF, IXF, UFF, OFF, DZF, and IOF bits hold valid information about trapped floating-point exceptions.

TFV	Meaning
0b0	The IDF, IXF, UFF, OFF, DZF, and IOF bits do not hold valid information about trapped floating-point exceptions and are UNKNOWN.
0b1	One or more floating-point exceptions occurred during an operation performed while executing the reported instruction. The IDF, IXF, UFF, OFF, DZF, and IOF bits indicate trapped floating-point exceptions that occurred. For more information, see ‘Floating-point exceptions and exception traps’ .

It is IMPLEMENTATION DEFINED whether this field is set to 0 on an exception generated by a trapped floating-point exception from an instruction that is performing floating-point operations on more than one lane of a vector.

Note
This is not a requirement. Implementations can set this field to 1 on a trapped floating-point exception from an instruction and return valid information in the {IDF, IXF, UFF, OFF, DZF, IOF} fields.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [22:11]

Reserved, RES0.

VECITR, bits [10:8]

For a trapped floating-point exception from an instruction executed in AArch64 state this field is UNKNOWN.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

IDF, bit [7]

Input Denormal floating-point exception trapped bit. If the TFV field is 0, this bit is UNKNOWN. Otherwise, the possible values of this bit are:

IDF	Meaning
0b0	Input denormal floating-point exception has not occurred.
0b1	Input denormal floating-point exception occurred during execution of the reported instruction.

IDF	Meaning
-----	---------

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [6:5]

Reserved, RES0.

IXF, bit [4]

Inexact floating-point exception trapped bit. If the TFV field is 0, this bit is UNKNOWN. Otherwise, the possible values of this bit are:

IXF	Meaning
0b0	Inexact floating-point exception has not occurred.
0b1	Inexact floating-point exception occurred during execution of the reported instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

UFF, bit [3]

Underflow floating-point exception trapped bit. If the TFV field is 0, this bit is UNKNOWN. Otherwise, the possible values of this bit are:

UFF	Meaning
0b0	Underflow floating-point exception has not occurred.
0b1	Underflow floating-point exception occurred during execution of the reported instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

OFF, bit [2]

Overflow floating-point exception trapped bit. If the TFV field is 0, this bit is UNKNOWN. Otherwise, the possible values of this bit are:

OFF	Meaning
0b0	Overflow floating-point exception has not occurred.
0b1	Overflow floating-point exception occurred during execution of the reported instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

DZF, bit [1]

Divide by Zero floating-point exception trapped bit. If the TFV field is 0, this bit is UNKNOWN. Otherwise, the possible values of this bit are:

DZF	Meaning
0b0	Divide by Zero floating-point exception has not occurred.
0b1	Divide by Zero floating-point exception occurred during execution of the reported instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

IOF, bit [0]

Invalid Operation floating-point exception trapped bit. If the TFV field is 0, this bit is UNKNOWN. Otherwise, the possible values of this bit are:

IOF	Meaning
0b0	Invalid Operation floating-point exception has not occurred.
0b1	Invalid Operation floating-point exception occurred during execution of the reported instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Additional Information for ISS encoding for an exception from a trapped floating-point exception

In an implementation that supports the trapping of floating-point exceptions:

- From an Exception level using AArch64, the [FPCR](#). {IDE, IXE, UFE, OFE, DZE, IOE} bits enable each of the floating-point exception traps.

ISS encoding for an SError exception

Note

In earlier versions of the architecture, an SError exception is referred to as an SError interrupt or an asynchronous External abort exception.

IDS, bit [24]

IMPLEMENTATION DEFINED syndrome.

IDS	Meaning
0b0	Bits [23:0] of the ISS field holds the fields described in this encoding. ———— Note ———— If FEAT_RAS is not implemented, bits [23:0] of the ISS field are RES0.
0b1	Bits [23:0] of the ISS field holds IMPLEMENTATION DEFINED syndrome information that can be used to provide additional information about the SError exception.

———— **Note** ————
This field was previously called ISV.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [23:14]

Reserved, RES0.

IESB, bit [13]

When FEAT_IESB is implemented and GetESR_ELx_DFSC(EL2) == '010001':

Implicit error synchronization event.

IESB	Meaning
0b0	One of the following applies: • The SError exception was not synchronized by the implicit error synchronization event. • The SError exception was not taken immediately following an implicit error synchronization event. • The SError exception was either not synchronized by the implicit error synchronization event or not taken immediately. • The implicit error synchronization event was on an exception return, and implementation chose to set this field to 0.
0b1	The SError exception was synchronized by the implicit error synchronization event, taken immediately, and one of the following applies: • The implicit error synchronization event was on an exception entry. • The implicit error synchronization event was on an exception return, and implementation chose to set this field to 1.

When an SError exception is synchronized by an implicit error synchronization event on exception entry, and the exception is taken immediately after exception entry, this field is set to 1.

When an SError exception is synchronized by an implicit error synchronization event on exception return, and the exception is taken immediately before the exception return, this field is set to an IMPLEMENTATION SPECIFIC choice of 0 or 1.

For all other SError exceptions, this field is set to 0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

AET, bits [12:10]

When FEAT_RAS is implemented and GetESR_ELx_DFSC(EL2) == '010001':

Asynchronous Error Type.

Describes the PE error state after taking the SError exception.

AET	Meaning
0b000	Uncontainable (UC).
0b001	Unrecoverable state (UEU).
0b010	Restartable state (UEO).
0b011	Recoverable state (UER).
0b110	Corrected (CE).

All other values are reserved.

If multiple errors are taken as a single SError exception, the overall PE error state is reported.

Note

Software can use this information to determine what recovery might be possible. The recovery software must also examine any implemented fault records to determine the location and extent of the error.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

EA, bit [9]

When FEAT_RAS is implemented and GetESR_ELx_DFSC(EL2) == '010001':

External abort type. Provides an IMPLEMENTATION DEFINED classification of External aborts.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bits [8:6]

Reserved, RES0.

DFSC, bits [5:0]

When FEAT_RAS is implemented:

Data Fault Status Code.

DFSC	Meaning
0b000000	Uncategorized error.
0b010001	Asynchronous SError exception.

All other values are reserved.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

ISS encoding for an exception from a Breakpoint or Vector Catch debug exception

Bits [24:6]

Reserved, RES0.

IFSC, bits [5:0]

Instruction Fault Status Code.

IFSC	Meaning
0b100010	Debug exception.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Additional Information for ISS encoding for an exception from a Breakpoint or Vector Catch debug exception

For more information about generating these exceptions:

- For exceptions from AArch64, see '[Breakpoint exceptions](#)'.

ISS encoding for an exception from a Software Step exception

ISV, bit [24]

Instruction syndrome valid. Indicates whether the EX bit, ISS[6], is valid, as follows:

ISV	Meaning
0b0	EX bit is RES0.
0b1	EX bit is valid.

Arm deprecates software use of this field.

See the EX bit description for more information.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [23:7]

Reserved, RES0.

EX, bit [6]

Exclusive operation. If the ISV bit is set to 1, this bit indicates whether a Load-Exclusive instruction was stepped.

EX	Meaning
0b0	An instruction other than a Load-Exclusive instruction was stepped.
0b1	A Load-Exclusive instruction was stepped.

Arm deprecates software use of this field.

If the ISV bit is set to 0, this bit is RES0, indicating no syndrome data is available.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

IFSC, bits [5:0]

Instruction Fault Status Code.

IFSC	Meaning
0b100010	Debug exception.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Additional Information for ISS encoding for an exception from a Software Step exception

For more information about generating these exceptions, see '[Software Step exceptions](#)'.

ISS encoding for an exception from a Watchpoint exception

Bit [24]

Reserved, RES0.

WPT, bits [23:18]

When FEAT_Debugv8p2 is implemented:

Watchpoint number.

All other values are reserved.

Otherwise:

Reserved, RES0.

WPTV, bit [17]

When FEAT_Debugv8p2 is implemented:

Watchpoint number Valid.

WPTV	Meaning
0b0	The WPT field is invalid, and holds an UNKNOWN value.
0b1	The WPT field is valid, and holds the number of a watchpoint that triggered a Watchpoint exception.

When a Watchpoint exception is triggered by a watchpoint match:

- If the PE sets any of FnV, FnP, or WPF to 1, then the PE sets WPTV to 1.
- Otherwise, the PE sets WPTV to an IMPLEMENTATION DEFINED value, 0 or 1.

Otherwise:

Reserved, RES0.

Bits [16:9]

Reserved, RES0.

CM, bit [8]

Cache maintenance. Indicates whether the Watchpoint exception came from a cache maintenance instruction:

CM	Meaning
0b0	The Watchpoint exception was not generated by the execution of one of the System instructions identified in the description of value 1.
0b1	The Watchpoint exception was generated by the execution of a cache maintenance instruction. The DC ZVA instruction is not classified as a cache maintenance instruction, and therefore their execution does not cause this field to be set to 1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [7]

Reserved, RES0.

WnR, bit [6]

Write not Read. Indicates whether the Watchpoint exception was caused by an instruction writing to a memory location, or by an instruction reading from a memory location.

WnR	Meaning
0b0	Watchpoint exception caused by an instruction reading from a memory location.
0b1	Watchpoint exception caused by an instruction writing to a memory location.

For Watchpoint exceptions on cache maintenance instructions, this bit always returns a value of 1.

For Watchpoint exceptions from an atomic instruction, this field is set to 0 if a read of the location would have generated the Watchpoint exception, otherwise it is set to 1.

If multiple watchpoints match on the same access, it is UNPREDICTABLE which watchpoint generates the Watchpoint exception.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

DFSC, bits [5:0]

Data Fault Status Code.

DFSC	Meaning
0b100010	Debug exception.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Additional Information for ISS encoding for an exception from a Watchpoint exception

For more information about generating these exceptions, see [‘Watchpoint exceptions’](#).

ISS encoding for an exception from execution of a Breakpoint instruction

24	16	15	0
RES0		Comment	

Bits [24:16]

Reserved, RES0.

Comment, bits [15:0]

Set to the instruction comment field value, zero extended as necessary.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Additional Information for ISS encoding for an exception from execution of a Breakpoint instruction

For more information about generating these exceptions, see ‘Breakpoint instruction exceptions’.

ISS encoding for an exception from a trapped Pointer Authentication instruction

Bits [24:0]

Reserved, RES0.

Additional Information for ISS encoding for an exception from a trapped Pointer Authentication instruction

For more information about generating these exceptions, see:

- [HCR_EL2.API](#), for exceptions from Pointer authentication instructions, using AArch64 state, trapped to EL2.

ISS encoding for a PAC Fail exception

Bits [24:2]

Reserved, RES0.

DnI, bit [1]

This field indicates whether the exception is as a result of an Instruction key or a Data key.

DnI	Meaning
0b0	Instruction Key.
0b1	Data Key.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

BnA, bit [0]

This field indicates whether the exception is as a result of an A key or a B key.

BnA	Meaning
0b0	A key.

BnA	Meaning
0b1	B key.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Additional Information for ISS encoding for a PAC Fail exception

The following instructions generate a PAC Fail exception when the Pointer Authentication Code (PAC) is incorrect:

- AUTDA, AUTDZA.
- AUTDB, AUTDZB.
- AUTIA, AUTIA1716, AUTIASP, AUTIAZ, AUTIZA.
- AUTIB, AUTIB1716, AUTIBSP, AUTIBZ, AUTIZB.
- AUTIASPPC, AUTIASPPCR, AUTIA171615.
- AUTIBSPPC, AUTIBSPPCR, AUTIB171615.

If [FEAT_FPACCOMBINE](#) is implemented, the following instructions generate a PAC Fail exception when the Pointer Authentication Code (PAC) is incorrect:

- RETAA, RETAB.
- RETAASPPC, RETABSPPC.
- RETAASPPCR, RETABSPPCR.
- BLRAA, BLRAAZ, BLRAB, BLRABZ.
- BRAA, BRAB, BRAAZ, BRABZ.
- ERETAA, ERETAB.
- LDRAA, LDRAB, whether the authenticated address is written back to the base register or not.

Accessing ESR_EL2

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, ESR_EL2

op0	op1	CRn	CRm	op2
0b11	0b100	0b0101	0b0010	0b000

```
if PSTATE.EL == EL0 then
    Undefined();
elsif PSTATE.EL == EL1 then
    Undefined();
elsif PSTATE.EL == EL2 then
    X{64}(t) = ESR_EL2();
end;
```

MSR ESR_EL2, <Xt>

op0	op1	CRn	CRm	op2
0b11	0b100	0b0101	0b0010	0b000

```
if PSTATE.EL == EL0 then
    Undefined();
elseif PSTATE.EL == EL1 then
    Undefined();
elseif PSTATE.EL == EL2 then
    ESR_EL2() = X{64}(t);
end;
```

MRS <Xt>, ESR_EL1

op0	op1	CRn	CRm	op2
0b11	0b000	0b0101	0b0010	0b000

```
if PSTATE.EL == EL0 then
    Undefined();
elseif PSTATE.EL == EL1 then
    if HCR_EL2().TRVM == '1' then
        AArch64_SystemAccessTrap(EL2, 0x18);
    else
        X{64}(t) = ESR_EL1();
    end;
elseif PSTATE.EL == EL2 then
    X{64}(t) = ESR_EL1();
end;
```

MSR ESR_EL1, <Xt>

op0	op1	CRn	CRm	op2
0b11	0b000	0b0101	0b0010	0b000

```
if PSTATE.EL == EL0 then
    Undefined();
elseif PSTATE.EL == EL1 then
    if HCR_EL2().TVM == '1' then
        AArch64_SystemAccessTrap(EL2, 0x18);
    else
        ESR_EL1() = X{64}(t);
    end;
elseif PSTATE.EL == EL2 then
    ESR_EL1() = X{64}(t);
end;
```

D12.2.32 FAR_EL1, Fault Address Register (EL1)

The FAR_EL1 characteristics are:

Purpose

Holds the faulting Virtual Address for all synchronous Instruction Abort exceptions, Data Abort exceptions, PC alignment fault exceptions and Watchpoint exceptions that are taken to EL1.

Configuration

There are no configuration notes.

Attributes

FAR_EL1 is a 64-bit register.

Field descriptions

VA, bits [63:0]

Faulting Virtual Address for synchronous exceptions taken to EL1. Exceptions that set the FAR_EL1 are Instruction Aborts (EC 0x20 or 0x21), Data Aborts (EC 0x24 or 0x25), PC alignment faults (EC 0x22), and Watchpoints (EC 0x34 or 0x35). [ESR_EL1.EC](#) holds the EC syndrome value for the exception.

For a synchronous External abort:

- If the VA that generated the abort was from an address range for which Address tagging is enabled for the translation regime in use when the abort was generated, then bits[63:56] of FAR_EL1 are UNKNOWN.
- If the VA that generated the abort was from an address range for which Address tagging is disabled and Logical Address Tagging is enabled for the translation regime in use when the abort was generated, then bits[59:56] of FAR_EL1 are UNKNOWN.

For a synchronous External abort other than a synchronous External abort on a translation table walk, this field is valid only if [ESR_EL1.FnV](#) is 0, and FAR_EL1 is UNKNOWN if [ESR_EL1.FnV](#) is 1.

If a memory fault that sets FAR_EL1 is generated from a data cache maintenance or other DC instruction, this field holds the address specified in the register argument of the instruction.

When the PE sets [ESR_EL1.{FnV,FnP}](#) to {0,1} on taking a Watchpoint exception, the PE sets FAR_EL1 to any address within the naturally-aligned fault granule that contains the virtual address of the memory access that generated the Watchpoint exception.

For a Data Abort exception or Watchpoint exception, if address tagging is enabled for the address accessed by the data access that caused the exception, then this field includes the tag. For more information about address tagging, see ‘[Address tagging](#)’.

Execution at EL0 makes FAR_EL1 become UNKNOWN.

Note

The address held in this field is an address accessed by the instruction fetch or data access that caused the exception that actually gave rise to the instruction or Data Abort. It is the lower address that gave rise to the fault that is reported. Where different faults from different addresses arise from the same instruction, such as for an instruction that loads or stores an unaligned address that crosses a page boundary, the architecture does not prioritize which fault is reported.

For all other exceptions taken to EL1, FAR_EL1 is UNKNOWN.

FAR_EL1 is made UNKNOWN on an exception return from EL1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing FAR_EL1

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, FAR_EL1

op0	op1	CRn	CRm	op2
0b11	0b000	0b0110	0b0000	0b000

```

if PSTATE.EL == EL0 then
    Undefined();
elsif PSTATE.EL == EL1 then
    if HCR_EL2().TRVM == '1' then
        AArch64_SystemAccessTrap(EL2, 0x18);
    else
        X{64}(t) = FAR_EL1();
    end;
elsif PSTATE.EL == EL2 then
    X{64}(t) = FAR_EL1();
end;

```

MSR FAR_EL1, <Xt>

op0	op1	CRn	CRm	op2
0b11	0b000	0b0110	0b0000	0b000

```

if PSTATE.EL == EL0 then
    Undefined();
elsif PSTATE.EL == EL1 then
    if HCR_EL2().TVM == '1' then
        AArch64_SystemAccessTrap(EL2, 0x18);
    else
        FAR_EL1() = X{64}(t);
    end;
elsif PSTATE.EL == EL2 then
    FAR_EL1() = X{64}(t);
end;

```

D12.2.33 FAR_EL2, Fault Address Register (EL2)

The FAR_EL2 characteristics are:

Purpose

Holds the faulting Virtual Address for all synchronous Instruction Abort exceptions, Data Abort exceptions, PC alignment fault exceptions and Watchpoint exceptions that are taken to EL2.

Configuration

There are no configuration notes.

Attributes

FAR_EL2 is a 64-bit register.

Field descriptions

VA, bits [63:0]

Faulting Virtual Address for synchronous exceptions taken to EL2. Exceptions that set the FAR_EL2 are Instruction Aborts (EC 0x20 or 0x21), Data Aborts (EC 0x24 or 0x25), PC alignment faults (EC 0x22), and Watchpoints (EC 0x34 or 0x35). [ESR_EL2](#).EC holds the EC syndrome value for the exception.

For a synchronous External abort:

- If the VA that generated the abort was from an address range for which Address tagging is enabled for the translation regime in use when the abort was generated, then bits[63:56] of FAR_EL2 are UNKNOWN.
- If the VA that generated the abort was from an address range for which Address tagging is disabled and Logical Address Tagging is enabled for the translation regime in use when the abort was generated, then bits[59:56] of FAR_EL2 are UNKNOWN.

For a synchronous External abort other than a synchronous External abort on a translation table walk, this field is valid only if [ESR_EL2](#).FnV is 0, and FAR_EL2 is UNKNOWN if [ESR_EL2](#).FnV is 1.

If a memory fault that sets FAR_EL2 is generated from a data cache maintenance or other DC instruction, this field holds the address specified in the register argument of the instruction.

When the PE sets [ESR_EL2](#).{FnV,FnP} to {0,1} on taking a Watchpoint exception, the PE sets FAR_EL2 to any address within the naturally-aligned fault granule that contains the virtual address of the memory access that generated the Watchpoint exception.

For a Data Abort exception or Watchpoint exception, if address tagging is enabled for the address accessed by the data access that caused the exception, then this field includes the tag. For more information about address tagging, see ‘Address tagging’.

Execution at EL1 or EL0 makes FAR_EL2 become UNKNOWN.

Note

The address held in this field is an address accessed by the instruction fetch or data access that caused the exception that actually gave rise to the instruction or Data Abort. It is the lower address that gave rise to the fault that is reported. Where different faults from different addresses arise from the same instruction, such as for an instruction that loads or stores an unaligned address that crosses a page boundary, the architecture does not prioritize which fault is reported.

For all other exceptions taken to EL2, FAR_EL2 is UNKNOWN.

FAR_EL2 is made UNKNOWN on an exception return from EL2.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing FAR_EL2

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, FAR_EL2

op0	op1	CRn	CRm	op2
0b11	0b100	0b0110	0b0000	0b000

```

if PSTATE.EL == EL0 then
    Undefined();
elsif PSTATE.EL == EL1 then
    Undefined();
elsif PSTATE.EL == EL2 then
    X{64}(t) = FAR_EL2();
end;
```

MSR FAR_EL2, <Xt>

op0	op1	CRn	CRm	op2
0b11	0b100	0b0110	0b0000	0b000

```

if PSTATE.EL == EL0 then
    Undefined();
elsif PSTATE.EL == EL1 then
    Undefined();
elsif PSTATE.EL == EL2 then
    FAR_EL2() = X{64}(t);
end;
```

D12.2.34 HACR_EL2, Hypervisor Auxiliary Control Register

The HACR_EL2 characteristics are:

Purpose

Controls trapping to EL2 of IMPLEMENTATION DEFINED aspects of EL1 or EL0 operation.

Configuration

There are no configuration notes.

Attributes

HACR_EL2 is a 64-bit register.

Field descriptions

IMPLEMENTATION DEFINED, bits [63:0]

IMPLEMENTATION DEFINED.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing HACR_EL2

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, HACR_EL2

op0	op1	CRn	CRm	op2
0b11	0b100	0b0001	0b0001	0b111

```
if PSTATE.EL == EL0 then
    Undefined();
elsif PSTATE.EL == EL1 then
    Undefined();
elsif PSTATE.EL == EL2 then
    X{64}(t) = HACR_EL2();
end;
```

MSR HACR_EL2, <Xt>

op0	op1	CRn	CRm	op2
0b11	0b100	0b0001	0b0001	0b111

```
if PSTATE.EL == EL0 then
    Undefined();
elsif PSTATE.EL == EL1 then
    Undefined();
elsif PSTATE.EL == EL2 then
    HACR_EL2() = X{64}(t);
end;
```

D12.2.35 HCR_EL2, Hypervisor Configuration Register

The HCR_EL2 characteristics are:

Purpose

Provides configuration controls for virtualization, including defining whether various operations are trapped to EL2.

Configuration

There are no configuration notes.

Attributes

HCR_EL2 is a 64-bit register.

Field descriptions

Bits [63:54]

Reserved, RES0.

EnSCXT, bit [53]

When FEAT_CSV2_2 is implemented or FEAT_CSV2_1p2 is implemented:

Enable Access to the SCXTNUM_EL1 and SCXTNUM_EL0 registers. The defined values are:

EnSCXT	Meaning
0b0	When EL2 is enabled in the current Security state, EL1 accesses to SCXTNUM_EL0 and SCXTNUM_EL1 are disabled, causing an exception to EL2, and the value of the registers to be treated as 0. When EL2 is enabled in the current Security state, EL0 access to SCXTNUM_EL0 is disabled, causing an exception to EL2, and the value of the register to be treated as 0.
0b1	This control does not cause accesses to SCXTNUM_EL0 or SCXTNUM_EL1 to be trapped.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bits [52:48]

Reserved, RES0.

FIEN, bit [47]

When FEAT_RASv1p1 is implemented:

Fault Injection Enable. Unless this bit is set to 1, accesses to the [ERXPFBCDN_EL1](#), [ERXPFBCCTL_EL1](#), and [ERXPFBCF_EL1](#) registers from EL1 generate a Trap exception to EL2, reported using EC syndrome value 0x18.

FIEN	Meaning
0b0	Accesses to the specified registers from EL1 are trapped to EL2.
0b1	This control does not cause any instructions to be trapped.

If [ERRIDR_EL1.NUM](#) is zero, meaning no error records are implemented, or no error record accessible using System registers is owned by a node that implements the RAS Common Fault Injection Model Extension, then this bit might be RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

FWB, bit [46]

When FEAT_S2FWB is implemented:

Forced Write-Back. Defines the combined cacheability attributes in a 2 stage translation regime.

FWB	Meaning
0b0	When this bit is 0, then the combination of stage 1 and stage 2 translations on memory type and cacheability attributes are as described in the Armv8.0 architecture. For more information, see ‘Combining stage 1 and stage 2 memory type attributes’. For an R profile implementation: The encoding of the stage 2 memory type and cacheability attributes is derived from MAIR_EL2 register, as described in the Armv8-R AArch64 architecture.
0b1	When this bit is 1, then the encoding of the stage 2 memory type and cacheability attributes in bits[5:2] of the stage 2 Page or Block descriptors are as described in ‘Stage 2 memory type and Cacheability attributes when FEAT_S2FWB is enabled’. For an R profile implementation: - If the inner and outer memory attributes for stage 2 EL1&0 translation regime must be the same with the same encoding, otherwise, the combined attribute is UNKNOWN. - If the stage 2 EL1&0 translation regime memory attribute is Write-Back with MAIR_EL2.Attr[7:6] = 0b11, then the combined attribute is Normal Write-Back. For all other encodings, the combination of stage 1 and stage 2 translations on memory type and cacheability attributes are as described in the Armv8.0 architecture.

This bit is permitted to be cached in a TLB.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bits [45:42]

Reserved, RES0.

API, bit [41]

When FEAT_PAuth is implemented:

Controls the use of instructions related to Pointer Authentication:

- PACGA.
- AUTDA, AUTDB, AUTDZA, AUTDZB, AUTIA, AUTIA1716, AUTIASP, AUTIAZ, AUTIB, AUTIB1716, AUTIBSP, AUTIBZ, AUTIZA, AUTIZB.
- PACDA, PACDB, PACDZA, PACDZB, PACIA, PACIA1716, PACIASP, PACIAZ, PACIB, PACIB1716, PACIBSP, PACIBZ, PACIZA, PACIZB.
- RETAA, RETAB, BRAA, BRAB, BLRAA, BLRAB, BRAAZ, BRABZ, BLRAAZ, BLRABZ.
- ERETA, ERETAB, LDRAA, and LDRAB.

This field is ignored if the instruction is disabled as a result of the SCTLR_ELx.{EnIB, EnIA, EnDA, EnDB} fields.

API	Meaning
0b0	The instructions related to Pointer Authentication are trapped to EL2 and reported using EC syndrome value 0x09, when the instructions are enabled for the EL1&0 translation regime, from: • EL0. • EL1.
0b1	This control does not cause any instructions to be trapped.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

APK, bit [40]

When FEAT_PAuth is implemented:

Trap registers holding “key” values for Pointer Authentication. Traps accesses to the following registers from EL1 to EL2, reported using EC syndrome value 0x18:

- [APIAKeyLo_EL1](#), [APIAKeyHi_EL1](#), [APIBKeyLo_EL1](#), [APIBKeyHi_EL1](#), [APDAKeyLo_EL1](#), [APDAKeyHi_EL1](#), [APDBKeyLo_EL1](#), [APDBKeyHi_EL1](#), [APGAKeyLo_EL1](#), and [APGAKeyHi_EL1](#).

APK	Meaning
0b0	Access to the registers holding “key” values for pointer authentication from EL1 are trapped to EL2.

APK	Meaning
0b1	This control does not cause any instructions to be trapped.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bits [39:38]

Reserved, RES0.

TEA, bit [37]

When FEAT_RAS is implemented:

Route synchronous External abort exceptions to EL2.

TEA	Meaning
0b0	Synchronous External abort exceptions are unaffected by this mechanism. That is, synchronous External abort exceptions are not taken to EL2 unless routed to EL2 by another control.
0b1	When executing at Exception levels below EL2, synchronous External abort exceptions are taken to EL2.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

TERR, bit [36]

When FEAT_RAS is implemented:

Trap accesses of Error Record registers. Enables a trap to EL2 on accesses of Error Record registers.

TERR	Meaning
0b0	Accesses of the specified Error Record registers are not trapped by this mechanism.
0b1	Accesses of the specified Error Record registers at EL1 are trapped to EL2, unless the instruction generates a higher priority exception.

In AArch64 state, the instructions affected by this control are:

- MRS and MSR accesses to [ERRSELR_EL1](#), [ERXADDR_EL1](#), [ERXCTLR_EL1](#), [ERXMISC0_EL1](#), [ERXMISC1_EL1](#), and [ERXSTATUS_EL1](#).
- MRS accesses to [ERRIDR_EL1](#) and [ERXFR_EL1](#).
- If [FEAT_RASv1p1](#) is implemented, MRS and MSR accesses to [ERXMISC2_EL1](#) and [ERXMISC3_EL1](#).

Unless the instruction generates a higher priority exception, trapped instructions generate an exception to EL2.

Trapped AArch64 instructions are reported using EC syndrome value 0×18 .

Accessing this field has the following behavior:

- This field is permitted to be RES0 if all of the following are true:
 - [ERRSELR_EL1](#) and all ERX* registers are implemented as UNDEFINED or RAZ/WI.
 - [ERRIDR_EL1](#).NUM is zero.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bits [35:34]

Reserved, RES0.

ID, bit [33]

Stage 2 Instruction access cacheability disable. For the EL1&0 translation regime, when HCR_EL2.VM==1, this control forces all stage 2 translations for instruction accesses to Normal memory to be Non-cacheable.

Note

The behavior is the same irrespective of whether the instruction accesses are to an MPU region or Background region.

ID	Meaning
0b0	This control has no effect on stage 2 of the EL1&0 translation regime.
0b1	Forces all stage 2 translations for instruction accesses to Normal memory to be Non-cacheable. This applies regardless of the value of HCR_EL2.FWB.

This bit has no effect on the EL2 translation regime.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

CD, bit [32]

Stage 2 Data access cacheability disable. For the EL1&0 translation regime, when HCR_EL2.VM==1, this control forces all stage 2 translations for data accesses to Normal memory to be Non-cacheable.

Note

The behavior is same irrespective of whether the data accesses is to MPU region or Background region.

CD	Meaning
0b0	This control has no effect on stage 2 of the EL1&0 translation regime for data accesses and translation table walks.
0b1	Forces all stage 2 translations for data accesses and translation table walks to Normal memory to be Non-cacheable. This applies regardless of the value of HCR_EL2.FWB.

This bit has no effect on the EL2 translation regime.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [31]

Reserved, RAO/WI.

TRVM, bit [30]

Trap Reads of Virtual Memory controls. Traps reads of the virtual memory control registers to EL2 as follows:

- If EL1 is using AArch64, EL1 accesses to the following registers are trapped to EL2 and reported using EC syndrome value 0x18 for MRS:
 - [SCTLR_EL1](#), [TTBR0_EL1](#), [TTBR1_EL1](#), [TCR_EL1](#), [ESR_EL1](#), [FAR_EL1](#), [AFSR0_EL1](#), [AFSR1_EL1](#), [MAIR_EL1](#), [AMAIR_EL1](#), and [CONTEXTIDR_EL1](#).
- If EL1 is in PMSAv8-64 context, EL1 accesses to the following registers are also trapped to EL2 and reported using EC syndrome value 0x18 - [PRENR_EL1](#), [PRSELR_EL1](#), [PRBAR_EL1](#), [PRBARn_EL1](#), [PRLAR_EL1](#), and [PRLARn_EL1](#).

TRVM	Meaning
0b0	This control does not cause any instructions to be trapped.
0b1	Read accesses to the specified Virtual Memory control registers are trapped to EL2.

When HCR_EL2.TGE is 1, the PE ignores the value of this field for all purposes other than a direct read of this field.

Note

EL2 provides a second stage of address translation, that a hypervisor can use to remap the address map defined by a Guest OS. In addition, a hypervisor can trap attempts by a Guest OS to write to the registers that control the memory system. A hypervisor might use this trap as part of its virtualization of memory management.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

HCD, bit [29]

HVC instruction disable. Disables EL1 and EL2 execution of HVC instructions, from both Execution states, reported using EC syndrome value 0x00.

HCD	Meaning
0b0	HVC instruction execution is enabled at EL2 and EL1.
0b1	HVC instructions are UNDEFINED at EL2 and EL1. Any resulting exception is taken to the Exception level at which the HVC instruction is executed.

Note

HVC instructions are always UNDEFINED at EL0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

TDZ, bit [28]

Traps EL0 and EL1 execution of the following instructions to EL2 from AArch64 state only, reported using EC syndrome value 0×18 :

- [DC ZVA](#).

TDZ	Meaning
0b0	This control does not cause any instructions to be trapped.
0b1	In AArch64 state, any attempt to execute an instruction this trap applies to at EL1, or at EL0 when the instruction is not UNDEFINED at EL0, is trapped to EL2. Reading the DCZID_EL0 returns a value that indicates that the instructions this trap applies to are not supported.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

TGE, bit [27]

Trap General Exceptions, from EL0.

TGE	Meaning
0b0	This control has no effect on execution at EL0.

TGE	Meaning
0b1	When EL2 is not enabled in the current Security state, the Effective value of this field is 0 and this field have no effect on execution at EL0. When EL2 is enabled in the current Security state, in all cases: • All exceptions that would be routed to EL1 are routed to EL2. • If EL1 is using AArch64, the SCTLR_EL1.M field is treated as being 0 for all purposes other than returning the result of a direct read of SCTLR_EL1. • If stage 1 EL1&0 translation regime is in PMSAv8-64 context, the SCTLR_EL1.BR field is treated as being 0 for all purposes other than returning the result of a direct read of SCTLR_EL1. • All virtual interrupts and virtual exceptions are disabled. • Any IMPLEMENTATION DEFINED mechanisms for signaling virtual interrupts are disabled. • An exception return to EL1 is treated as an illegal exception return. • The MDCR_EL2.{TDRA, TDOSA, TDA, TDE} fields are treated as being 1 for all purposes other than returning the result of a direct read of MDCR_EL2. In addition, when EL2 is enabled in the current Security state, the Effective values of the HCR_EL2.{FMO, IMO, AMO} fields are 1.

[HCR_EL2.TGE](#) must not be cached in a TLB.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

TVM, bit [26]

Trap Virtual Memory controls. Traps writes to the virtual memory control registers to EL2 as follows:

- If EL1 is using AArch64, the following registers are trapped to EL2 and reported using EC syndrome value 0x18 for MSR:
 - [SCTLR_EL1](#), [TTBR0_EL1](#), [TTBR1_EL1](#), [TCR_EL1](#), [ESR_EL1](#), [FAR_EL1](#), [AFSR0_EL1](#), [AFSR1_EL1](#), [MAIR_EL1](#), [AMAIR_EL1](#), and [CONTEXTIDR_EL1](#).
- If EL1 is in PMSAv8-64 context, EL1 accesses to the following registers are also trapped to EL2 and reported using EC syndrome value 0x18 - [PRENR_EL1](#), [PRSELR_EL1](#), [PRBAR_EL1](#), [PRBARn_EL1](#), and [PRLAR_EL1](#), and [PRLARn_EL1](#).

TVM	Meaning
0b0	This control does not cause any instructions to be trapped.
0b1	Write accesses to the specified Virtual Memory control registers are trapped to EL2.

When [HCR_EL2.TGE](#) is 1, the PE ignores the value of this field for all purposes other than a direct read of this field.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

TTLB, bit [25]

Trap TLB maintenance instructions. Traps execution of TLB maintenance instructions at EL1 to EL2 as follows:

- If EL1 is using AArch64, then the following instructions are trapped to EL2 and reported using EC syndrome value 0x18:

- [TLBI VMALLE1](#), [TLBI VAE1](#), [TLBI ASIDE1](#), [TLBI VAAE1](#), [TLBI VALE1](#), and [TLBI VAALE1](#).
- [TLBI VMALLE1IS](#), [TLBI VAE1IS](#), [TLBI ASIDE1IS](#), [TLBI VAAE1IS](#), [TLBI VALE1IS](#), and [TLBI VAALE1IS](#).
- If [FEAT_TLBIOS](#) is implemented, [TLBI VMALLE1OS](#), [TLBI VAE1OS](#), [TLBI ASIDE1OS](#), [TLBI VAAE1OS](#), [TLBI VALE1OS](#), and [TLBI VAALE1OS](#).
- If [FEAT_TLBIRANGE](#) is implemented, [TLBI RVAE1](#), [TLBI RVAAE1](#), [TLBI RVALE1](#), [TLBI RVALE1IS](#), [TLBI RVAAE1IS](#), [TLBI RVALE1IS](#), and [TLBI RVAALE1IS](#).
- If [FEAT_TLBIOS](#) and [FEAT_TLBIRANGE](#) are implemented, [TLBI RVAE1OS](#), [TLBI RVAAE1OS](#), [TLBI RVALE1OS](#), and [TLBI RVAALE1OS](#).

TTLB	Meaning
0b0	This control does not cause any instructions to be trapped.
0b1	EL1 execution of the specified TLB maintenance instructions are trapped to EL2.

When [HCR_EL2.TGE](#) is 1, the PE ignores the value of this field for all purposes other than a direct read of this field.

Note

The TLB maintenance instructions are UNDEFINED at EL0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

TPU, bit [24]

Trap cache maintenance instructions that operate to the Point of Unification. Traps execution of those cache maintenance instructions at EL0 and EL1 to EL2 as follows:

- If EL0 is using AArch64 and the value of [SCTLR_EL1.UCI](#) is 1, then the following instructions at EL0 are trapped to EL2 and reported with EC syndrome value 0x18:
 - [IC IVAU](#) and [DC CVAU](#).
- If EL1 is using AArch64, then the following instructions at EL1 are trapped to EL2 and reported with EC syndrome value 0x18:
 - [IC IVAU](#), [IC IALLU](#), [IC IALLUIS](#), and [DC CVAU](#).

Note

When [SCTLR_EL1.UCI](#) is 0, the trap on execution of instructions at EL0 is higher priority than this control. An exception generated because an instruction is UNDEFINED at EL0 is higher priority than this trap to EL2. In addition:

- [IC IALLUIS](#) and [IC IALLU](#) are always UNDEFINED at EL0 using AArch64.

TPU	Meaning
0b0	This control does not cause any instructions to be trapped.
0b1	For each of the specified instructions, if the execution of the instruction can be trapped, access is trapped to EL2.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

TPCP, bit [23]

Trap data or unified cache maintenance instructions that operate to the Point of Coherency or Persistence. When EL2 is enabled in the current Security state, traps execution of cache maintenance instructions at EL0 and EL1 to EL2 as follows:

- If EL0 is using AArch64 and the value of [SCTLR_EL1.UCI](#) is 1, then the following instructions at EL0 are trapped to EL2 and reported using EC syndrome value 0x18:
 - [DC CIVAC](#) and [DC CVAC](#).
 - If [FEAT_DPB](#) is implemented, [DC CVAP](#).
 - If [FEAT_DPB2](#) is implemented, [DC CVADP](#).
- If EL1 is using AArch64, then the following instructions at EL1 are trapped to EL2 and reported using EC syndrome value 0x18:
 - [DC IVAC](#), [DC CIVAC](#) and [DC CVAC](#).
 - If [FEAT_DPB](#) is implemented, [DC CVAP](#).
 - If [FEAT_DPB2](#) is implemented, [DC CVADP](#).

Note

This field was previously named TPC.

When [SCTLR_EL1.UCI](#) is 0, the trap on execution of instructions at EL0 is higher priority than this control. An exception generated because an instruction is UNDEFINED at EL0 is higher priority than this trap to EL2. In addition:

- AArch64 instructions which invalidate by VA to the Point of Coherency are always UNDEFINED at EL0 using AArch64.
-

TPCP	Meaning
0b0	This control does not cause any instructions to be trapped.
0b1	For each of the specified instructions, if the execution of the instruction can be trapped, it is trapped to EL2.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

TSW, bit [22]

Trap data or unified cache maintenance instructions that operate by Set/Way. Traps execution of those cache maintenance instructions at EL1 to EL2 as follows:

- If EL1 is using AArch64, then the following instructions are trapped to EL2 and reported with EC syndrome value 0x18:
 - [DC ISW](#), [DC CSW](#), and [DC CISW](#).

Note

An exception generated because an instruction is UNDEFINED at EL0 is higher priority than this trap to EL2, and these instructions are always UNDEFINED at EL0.

TSW	Meaning
0b0	This control does not cause any instructions to be trapped.

0b1	Execution of the specified instructions is trapped to EL2.
-----	--

When HCR_EL2.TGE is 1, the PE ignores the value of this field for all purposes other than a direct read of this field.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

TACR, bit [21]

Trap Auxiliary Control Registers. Traps EL1 accesses to the Auxiliary Control Registers to EL2 as follows:

- If EL1 is using AArch64, accesses to [ACTLR_EL1](#) to EL2, are trapped to EL2 and reported using EC syndrome value 0x18.

TACR	Meaning
0b0	This control does not cause any instructions to be trapped.
0b1	EL1 accesses to the specified registers are trapped to EL2.

When HCR_EL2.TGE is 1, the PE ignores the value of this field for all purposes other than a direct read of this field.

Note

[ACTLR_EL1](#) is not accessible at EL0.

The Auxiliary Control Registers are IMPLEMENTATION DEFINED registers that might implement global control bits for the PE.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

TIDCP, bit [20]

Trap IMPLEMENTATION DEFINED functionality. Traps EL1 accesses to the encodings reserved for IMPLEMENTATION DEFINED functionality to EL2 as follows:

- In AArch64 state, EL1 access to the encodings in the following reserved encoding spaces are trapped:
 - IMPLEMENTATION DEFINED System instructions, which are accessed using SYS and SYSL, with CRn == {11, 15}, and are reported using EC syndrome value 0x18.
 - IMPLEMENTATION DEFINED System instructions, which are accessed using SYSP, with CRn == {11, 15}, and are reported using EC syndrome value 0x14.
 - IMPLEMENTATION DEFINED System registers, which are accessed using MRS and MSR with the [S3_<op1>_<Cn>_<Cm>_<op2>](#) register name, and are reported using EC syndrome 0x18.
 - IMPLEMENTATION DEFINED System registers, which are accessed using MRRS and MSRR with the [S3_<op1>_<Cn>_<Cm>_<op2>](#) register name, and are reported using EC syndrome 0x14.

For accesses to these regions of encoding space by EL0, all of the following apply:

- If FEAT_TIDCP1 is implemented, traps caused by [SCTLR_EL1.TIDCP](#) and [SCTLR_EL2.TIDCP](#) are reported with higher priority than traps caused by this control.
- If FEAT_TIDCP1 is not implemented, or the access is not trapped by SCTLR_ELx.TIDCP, one of the following applies:
 - If [HCR_EL2.TIDCP](#) is 0 then it is IMPLEMENTATION DEFINED, for each encoding, whether the access is performed, is UNDEFINED, or is trapped by an IMPLEMENTATION DEFINED mechanism.
 - If [HCR_EL2.TIDCP](#) is 1 then it is IMPLEMENTATION DEFINED, for each encoding, whether the access is trapped to EL2. If it is not trapped it is UNDEFINED.

TIDCP	Meaning
0b0	This control does not cause any instructions to be trapped.
0b1	EL1 accesses to or execution of the specified encodings reserved for IMPLEMENTATION DEFINED functionality are trapped to EL2.

An implementation can also include IMPLEMENTATION DEFINED registers that provide additional controls, to give finer-grained control of the trapping of IMPLEMENTATION DEFINED features.

Note

The trapping of accesses to these registers from EL1 is higher priority than an exception resulting from the register access being UNDEFINED.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

TSC, bit [19]

Trap SMC instructions. Traps EL1 execution of SMC instructions to EL2.

If execution is in AArch64 state, the trap is reported using EC syndrome value 0x17.

Note

HCR_EL2.TSC traps execution of the SMC instruction. It is not a routing control for the SMC exception. Trap exceptions and SMC exceptions have different preferred return addresses.

TSC	Meaning
0b0	This control does not cause any instructions to be trapped.
0b1	It is IMPLEMENTATION DEFINED whether: • Any attempt to execute an SMC instruction at EL1 is trapped to EL2. • Any attempt to execute an SMC instruction is UNDEFINED.

SMC instructions are UNDEFINED at EL0.

It is IMPLEMENTATION DEFINED whether this bit is:

- RES0.
- Implemented with the functionality as described in HCR_EL2.TSC.

When HCR_EL2.TGE is 1, the PE ignores the value of this field for all purposes other than a direct read of this field.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

TID3, bit [18]

Trap ID group 3. Traps EL1 reads of group 3 ID registers to EL2, when EL2 is enabled in the current Security state, as follows:

In AArch64 state:

- Reads of the following registers are trapped to EL2, reported using EC syndrome value 0×18 :
 - [ID_PFR0_EL1](#), [ID_PFR1_EL1](#), [ID_DFR0_EL1](#), [ID_AFR0_EL1](#), [ID_MMFR0_EL1](#), [ID_MMFR1_EL1](#), [ID_MMFR2_EL1](#), [ID_MMFR3_EL1](#), [ID_ISAR0_EL1](#), [ID_ISAR1_EL1](#), [ID_ISAR2_EL1](#), [ID_ISAR3_EL1](#), [ID_ISAR4_EL1](#), [ID_ISAR5_EL1](#), [MVFR0_EL1](#), [MVFR1_EL1](#), and [MVFR2_EL1](#).
 - [ID_AA64PFR0_EL1](#), [ID_AA64PFR1_EL1](#), [ID_AA64DFR0_EL1](#), [ID_AA64DFR1_EL1](#), [ID_AA64ISAR0_EL1](#), [ID_AA64ISAR1_EL1](#), [ID_AA64MMFR0_EL1](#), [ID_AA64MMFR1_EL1](#), [ID_AA64AFR0_EL1](#), and [ID_AA64AFR1_EL1](#).
- Reads of the following registers are trapped to EL2, unless the register is implemented as RAZ when it is IMPLEMENTATION DEFINED whether accesses are trapped to EL2.
 - [ID_PFR2_EL1](#), [ID_MMFR4_EL1](#) and [ID_MMFR5_EL1](#).
 - [ID_AA64MMFR4_EL1](#).
 - [ID_AA64MMFR2_EL1](#) and [ID_ISAR6_EL1](#).
- It is IMPLEMENTATION DEFINED whether this field traps MRS accesses to registers in the following range that are not already mentioned in this field description: $op0 = 3$, $op1 = 0$, $CRn = 0$, $CRm = \{2-7\}$, $op2 = \{0-7\}$.

TID3	Meaning
0b0	This control does not cause any instructions to be trapped.
0b1	The specified EL1 read accesses to ID group 3 registers are trapped to EL2.

When [HCR_EL2.TGE](#) is 1, the PE ignores the value of this field for all purposes other than a direct read of this field.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

TID2, bit [17]

Trap ID group 2. Traps the following register accesses to EL2 as follows:

- If EL1 is using AArch64, reads of [CTR_EL0](#), [CCSIDR_EL1](#), [CCSIDR2_EL1](#), [CLIDR_EL1](#), and [CSSELR_EL1](#) are trapped to EL2, reported using EC syndrome value 0×18 .
- If EL0 is using AArch64 and the value of [SCTLR_EL1.UCT](#) is not 0, reads of [CTR_EL0](#) are trapped to EL2, reported using EC syndrome value 0×18 . If the value of [SCTLR_EL1.UCT](#) is 0, then EL0 reads of [CTR_EL0](#) are trapped to EL1 and the resulting exception takes precedence over this trap.
- If EL1 is using AArch64, writes to [CSSELR_EL1](#) are trapped to EL2, reported using EC syndrome value 0×18 .

TID2	Meaning
0b0	This control does not cause any instructions to be trapped.
0b1	The specified EL1 and EL0 accesses to ID group 2 registers are trapped to EL2.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

TID1, bit [16]

Trap ID group 1. Traps EL1 reads of the following registers to EL2 as follows:

- In AArch64 state, accesses of [REVIDR_EL1](#) and [AIDR_EL1](#), reported using EC syndrome value 0×18 .

- When [FEAT_PMSAv64](#) is implemented, accesses of [MPUIR_EL1](#), reported using EC syndrome value 0x18.

TID1	Meaning
0b0	This control does not cause any instructions to be trapped.
0b1	The specified EL1 read accesses to ID group 1 registers are trapped to EL2.

When HCR_EL2.TGE is 1, the PE ignores the value of this field for all purposes other than a direct read of this field.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [15]

Reserved, RES0.

TWE, bit [14]

Traps EL0 and EL1 execution of WFE instructions to EL2 from both Execution states, reported using EC syndrome value 0x01.

TWE	Meaning
0b0	This control does not cause any instructions to be trapped.
0b1	Any attempt to execute a WFE instruction at EL1 or EL0 is trapped to EL2, if the instruction would otherwise have caused the PE to enter a low-power state and it is not trapped by SCTLR.nTWE or SCTLR_EL1.nTWE .

Note

Since a WFE can complete at any time, even without a Wakeup event, the traps on WFE are not guaranteed to be taken, even if the WFE is executed when there is no Wakeup event. The only guarantee is that if the instruction does not complete in finite time in the absence of a Wakeup event, the trap will be taken.

For more information about when WFE instructions can cause the PE to enter a low-power state, see ‘[Wait for Event mechanism and Send event](#)’.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

TWI, bit [13]

Traps EL0 and EL1 execution of WFI instructions to EL2 from both Execution states, reported using EC syndrome value 0x01.

TWI	Meaning
0b0	This control does not cause any instructions to be trapped.

TWI	Meaning
0b1	Any attempt to execute a WFI instruction at EL1 or EL0 is trapped to EL2, if the instruction would otherwise have caused the PE to enter a low-power state and it is not trapped by SCTLR.nTWI or SCTLR_EL1.nTWI.

Note

Since a WFI can complete at any time, even without a Wakeup event, the traps on WFI are not guaranteed to be taken, even if the WFI is executed when there is no Wakeup event. The only guarantee is that if the instruction does not complete in finite time in the absence of a Wakeup event, the trap will be taken.

For more information about when WFI instructions can cause the PE to enter a low-power state, see ‘Wait for Interrupt’.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

DC, bit [12]

Default Cacheability.

DC	Meaning
0b0	This control has no effect on the EL1&0 translation regime.
0b1	In both Security states: - When EL1 is using AArch64, the PE behaves as if the value of the SCTLR_EL1.M field is 0 for all purposes other than returning the value of a direct read of SCTLR_EL1. - If stage 1 EL1&0 translation regime is in PMSAv8-64 context, the PE behaves as if the value of the SCTLR_EL1.BR field is 0 for all purposes other than returning the value of a direct read of SCTLR_EL1. - The PE behaves as if the value of the HCR_EL2.VM field is 1 for all purposes other than returning the value of a direct read of HCR_EL2. - The memory type produced by stage 1 of the EL10 translation regime is Normal Non-Shareable, Inner Write-Back Read-Allocate Write-Allocate, Outer Write-Back Read-Allocate Write-Allocate.

This field has no effect on the EL2 translation regime.

This bit is permitted to be cached in a TLB.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

BSU, bits [11:10]

Barrier Shareability upgrade. This field determines the minimum shareability domain that is applied to any barrier instruction executed from EL1 or EL0:

BSU	Meaning
0b00	No effect.

BSU	Meaning
0b01	Inner Shareable.
0b10	Outer Shareable.
0b11	Full system.

This value is combined with the specified level of the barrier held in its instruction, using the same principles as combining the shareability attributes from two stages of address translation.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

FB, bit [9]

Force broadcast. Causes the following Non-shareable invalidate instructions to be broadcast within the Inner Shareable domain when executed from EL1:

- In AArch64 state:
 - All TLBI instructions that are executable at EL1 and do not specify IS or OS.
 - IC IALLU.

For more information, see ‘[A64 System instructions for TLB maintenance](#)’.

FB	Meaning
0b0	The specified instructions are not affected by this control.
0b1	When one of the specified Non-shareable instructions is executed at EL1, the operation is broadcast within the Inner Shareable shareability domain.

When HCR_EL2.TGE is 1, the PE ignores the value of this field for all purposes other than a direct read of this field.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

VSE, bit [8]

Virtual SError exception.

VSE	Meaning
0b0	This mechanism is not making a virtual SError exception pending.
0b1	A virtual SError exception is pending because of this mechanism.

The virtual SError exception is enabled only when HCR_EL2.{TGE, AMO} is {0, 1}.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

VI, bit [7]

Virtual IRQ Interrupt.

VI	Meaning
0b0	This mechanism is not making a virtual IRQ pending.
0b1	A virtual IRQ is pending because of this mechanism.

The virtual IRQ is enabled only when the value of HCR_EL2.{TGE, IMO} is {0, 1}.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

VF, bit [6]

Virtual FIQ Interrupt.

VF	Meaning
0b0	This mechanism is not making a virtual FIQ pending.
0b1	A virtual FIQ is pending because of this mechanism.

The virtual FIQ is enabled only when the value of HCR_EL2.{TGE, FMO} is {0, 1}.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

AMO, bit [5]

Physical SError exception routing.

AMO	Meaning
0b0	When executing at Exception levels below EL2, and EL2 is enabled in the current Security state, all of the following apply: - If HCR_EL2.TGE is 0, then the routing of physical SError exceptions is unaffected by this mechanism - If HCR_EL2.TGE is 1, then physical SError exceptions are taken to EL2. - Virtual SError exceptions are disabled.
0b1	When the Effective value of HCR_EL2.TGE is 0: - Physical SError exceptions are taken to EL2. - Virtual SError exceptions are enabled.

When the Effective value of HCR_EL2.TGE is 1, regardless of the value of the AMO bit, all of the following are true:

- Physical SError exceptions target EL2.
- Virtual SError exceptions are disabled.

When the Effective value of HCR_EL2.TGE is 0, it is IMPLEMENTATION DEFINED whether the Effective value of HCR_EL2.AMO is 1 or the value programmed.

For more information, see ‘[Asynchronous exception routing](#)’.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

IMO, bit [4]

Physical IRQ Routing.

IMO	Meaning
0b0	When the Effective value of HCR_EL2.TGE is 0: • Physical IRQ interrupts are not taken to EL2. • Virtual IRQ interrupts are disabled.
0b1	When the Effective value of HCR_EL2.TGE is 0: • Physical IRQ exceptions are taken to EL2. • Virtual IRQ interrupts are enabled.

When the Effective value of HCR_EL2.TGE is 1, regardless of the value of the IMO bit, all of the following are true:

- Physical IRQ Interrupts target EL2.
- Virtual IRQ interrupts are disabled.

When the Effective value of HCR_EL2.TGE is 0, it is IMPLEMENTATION DEFINED whether the Effective value of HCR_EL2.IMO is 1 or the value programmed.

For more information, see ‘[Asynchronous exception routing](#)’.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

FMO, bit [3]

Physical FIQ Routing.

FMO	Meaning
0b0	When the Effective value of HCR_EL2.TGE is 0: • Physical FIQ interrupts are not taken to EL2. • Virtual FIQ interrupts are disabled.
0b1	When the Effective value of HCR_EL2.TGE is 0: • Physical FIQ exceptions are taken to EL2. • Virtual FIQ interrupts are enabled.

When the Effective value of HCR_EL2.TGE is 1, regardless of the value of the FMO bit, all of the following are true:

- Physical FIQ Interrupts target EL2.
- Virtual FIQ interrupts are disabled.

When the Effective value of HCR_EL2.TGE is 0, it is IMPLEMENTATION DEFINED whether the Effective value of HCR_EL2.FMO is 1 or the value programmed.

For more information, see ‘[Asynchronous exception routing](#)’.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

PTW, bit [2]

Protected Table Walk. In the EL1&0 translation regime, a translation table access made as part of a stage 1 translation table walk is subject to a stage 2 translation. The combining of the memory type attributes from the two stages of translation means the access might be made to a type of Device memory. If this occurs, then the value of this bit determines the behavior:

PTW	Meaning
0b0	The translation table walk occurs as if it is to Normal Non-cacheable memory. This means it can be made speculatively.
0b1	The memory access generates a stage 2 Permission fault.

This bit is permitted to be cached in a TLB.

When HCR_EL2.TGE is 1, the PE ignores the value of this field for all purposes other than a direct read of this field.

In a PMSA-only implementation, this bit is permitted to be RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

SWIO, bit [1]

Set/Way Invalidation Override. Causes EL1 execution of the data cache invalidate by set/way instructions to perform a data cache clean and invalidate by set/way:

SWIO	Meaning
0b0	This control has no effect on the operation of data cache invalidate by set/way instructions.
0b1	Data cache invalidate by set/way instructions perform a data cache clean and invalidate by set/way.

When the value of this bit is 1:

AArch64: [DC ISW](#) performs the same invalidation as a [DC C1SW](#) instruction.

This bit can be implemented as RES1.

When HCR_EL2.TGE is 1, the PE ignores the value of this field for all purposes other than a direct read of this field.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

VM, bit [0]

Virtualization enable. Enables stage 2 address translation for the EL1&0 translation regime.

VM	Meaning
0b0	EL1&0 stage 2 address translation disabled.
0b1	EL1&0 stage 2 address translation enabled.

If HCR_EL2.VM is 1 and SCTL2_EL2.{M, BR} is {0, 0}, then the behavior is a CONSTRAINED UNPREDICTABLE choice of:

- The memory attribute becomes UNKNOWN.
- Raise stage 2 level 0 Translation fault.

When the value of this bit is 1, data cache invalidate instructions executed at EL1 perform a data cache clean and invalidate. For the invalidate by set/way instruction this behavior applies regardless of the value of the HCR_EL2.SWIO bit.

This bit is permitted to be cached in a TLB.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing HCR_EL2

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, HCR_EL2

op0	op1	CRn	CRm	op2
0b11	0b100	0b0001	0b0001	0b000

```

if PSTATE.EL == EL0 then
    Undefined();
elsif PSTATE.EL == EL1 then
    Undefined();
elsif PSTATE.EL == EL2 then
    X{64}(t) = HCR_EL2();
end;

```

MSR HCR_EL2, <Xt>

op0	op1	CRn	CRm	op2
0b11	0b100	0b0001	0b0001	0b000

```
if PSTATE.EL == EL0 then
    Undefined();
elsif PSTATE.EL == EL1 then
    Undefined();
elsif PSTATE.EL == EL2 then
    HCR_EL2() = X{64}(t);
end;
```

D12.2.36 HPFAR_EL2, Hypervisor IPA Fault Address Register

The HPFAR_EL2 characteristics are:

Purpose

Holds the faulting IPA for some aborts on a stage 2 translation taken to EL2 due to a fault on an access for a stage 2 translation.

Configuration

The HPFAR_EL2 is written for:

- A Translation fault, Access Flag fault, or Address Size fault on a stage 2 translation not on a stage 1 translation table walk.
- A Translation fault, Access Flag fault, Address Size fault, or Permission fault on stage 2 translation of an address accessed in a stage 1 translation table walk.

For all other exceptions taken to EL2, this register is UNKNOWN.

Note

The address held in this register is an address accessed by the instruction fetch or data access that caused the exception that gave rise to the Instruction Abort exception or Data Abort exception. It is the lower address that gave rise to the fault that is reported. Where different faults from different addresses arise from the same instruction, such as for an instruction that loads or stores an unaligned address that crosses a page boundary, the architecture does not prioritize which fault is reported.

Attributes

HPFAR_EL2 is a 64-bit register.

Field descriptions

Execution at EL1 or EL0 makes HPFAR_EL2 become UNKNOWN.

NS, bit [63]

When FEAT_SEL2 is implemented:

Faulting IPA address space.

NS	Meaning
0b0	Faulting IPA is from the Secure IPA space.
0b1	Faulting IPA is from the Non-secure IPA space.

For Data Abort exceptions or Instruction Abort exceptions taken to Non-secure EL2:

- This field is RES0.

- The address is from the Non-secure IPA space.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bits [62:48]

Reserved, RES0.

FIPA, bits [47:4]

When FEAT_LPA is implemented:

Bits [43:40]

Reserved, RES0.

FIPA, bits [39:0]

Bits [51:12] of the Faulting Intermediate Physical Address.

For implementations with fewer than 52 physical address bits, the corresponding upper bits in this field are RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

When FEAT_LPA is not implemented:

Bits [43:36]

Reserved, RES0.

FIPA, bits [35:0]

Bits[47:12] Faulting Intermediate Physical Address.

For implementations with fewer than 48 physical address bits, the corresponding upper bits in this field are RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [3:0]

Reserved, RES0.

Accessing HPFAR_EL2

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, HPFAR_EL2

op0	op1	CRn	CRm	op2
0b11	0b100	0b0110	0b0000	0b100

```
if PSTATE.EL == EL0 then
    Undefined();
elsif PSTATE.EL == EL1 then

0b11	0b100	0b0110	0b0000	0b100

```
if PSTATE.EL == EL0 then
    Undefined();
elsif PSTATE.EL == EL1 then
    Undefined();
elsif PSTATE.EL == EL2 then
    HPFAR_EL2() = X{64}(t);
end;
```

D12.2.37 HSTR_EL2, Hypervisor System Trap Register

The HSTR_EL2 characteristics are:

Purpose

Controls trapping to EL2 of EL1 or lower AArch32 accesses to the System register in the coproc == 0b1111 encoding space, by the CRn value used to access the register using MCR or MRC instruction. When the register is accessible using an MCRR or MRRC instruction, this is the CRm value used to access the register.

Configuration

There are no configuration notes.

Attributes

HSTR_EL2 is a 64-bit register.

Field descriptions

Bits [63:0]

Reserved, RES0.

Accessing HSTR_EL2

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, HSTR_EL2

op0	op1	CRn	CRm	op2
0b11	0b100	0b0001	0b0001	0b011

```
if PSTATE.EL == EL0 then
    Undefined();
elseif PSTATE.EL == EL1 then
    Undefined();
elseif PSTATE.EL == EL2 then
    X{64}(t) = HSTR_EL2();
end;
```

MSR HSTR_EL2, <Xt>

op0	op1	CRn	CRm	op2
0b11	0b100	0b0001	0b0001	0b011

```
if PSTATE.EL == EL0 then
    Undefined();
elsif PSTATE.EL == EL1 then
    Undefined();
elsif PSTATE.EL == EL2 then
    HSTR_EL2() = X{64}(t);
end;
```

D12.2.38 ID_AA64AFR0_EL1, AArch64 Auxiliary Feature Register 0

The ID_AA64AFR0_EL1 characteristics are:

Purpose

Provides information about the IMPLEMENTATION DEFINED features of the PE in AArch64 state.

For general information about the interpretation of the ID registers, see ‘[Principles of the ID scheme for fields in ID registers](#)’.

Configuration

There are no configuration notes.

Attributes

ID_AA64AFR0_EL1 is a 64-bit register.

```

D12.2.39 ID_AA64AFR1_EL1, AArch64 Auxiliary Feature Register 1

The ID_AA64AFR1_EL1 characteristics are:

Purpose

Reserved for future expansion of information about the IMPLEMENTATION DEFINED features of the PE in AArch64 state.

For general information about the interpretation of the ID registers, see ‘[Principles of the ID scheme for fields in ID registers](#)’.

Configuration

There are no configuration notes.

Attributes

ID_AA64AFR1_EL1 is a 64-bit register.

Field descriptions

Bits [63:0]

Reserved, RES0.

Accessing ID_AA64AFR1_EL1

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, ID_AA64AFR1_EL1

op0	op1	CRn	CRm	op2
0b11	0b000	0b0000	0b0101	0b101

    end;
elseif PSTATE.EL == EL2 then
    X{64}(t) = ID_AA64AFR1_EL1();
end;
```

D12.2.40 ID_AA64DFR0_EL1, AArch64 Debug Feature Register 0

The ID_AA64DFR0_EL1 characteristics are:

Purpose

Provides top-level information about the debug system in AArch64 state.

For general information about the interpretation of the ID registers, see ‘Principles of the ID scheme for fields in ID registers’.

Configuration

The external register EDDFR gives information from this register.

Attributes

ID_AA64DFR0_EL1 is a 64-bit register.

Field descriptions

Bits [63:44]

Reserved, RES0.

TraceFilt, bits [43:40]

Armv8.4 Self-hosted Trace Extension version.

The value of this field is an IMPLEMENTATION DEFINED choice of:

TraceFilt	Meaning
0b0000	Armv8.4 Self-hosted Trace Extension not implemented.
0b0001	Armv8.4 Self-hosted Trace Extension implemented.

All other values are reserved.

FEAT_TRF implements the functionality identified by the value 0b0001.

From Armv8.4, if FEAT_ETMv4 is implemented, the value 0b0000 is not permitted.

Access to this field is RO.

DoubleLock, bits [39:36]

OS Double Lock implemented.

The value of this field is an IMPLEMENTATION DEFINED choice of:

DoubleLock	Meaning
0b0000	OS Double Lock implemented. OSDLR_EL1 is RW.
0b1111	OS Double Lock not implemented. OSDLR_EL1 is RAZ/WI.

All other values are reserved.

[FEAT_DoubleLock](#) implements the functionality identified by the value 0b0000.

In Armv8.0, the only permitted value is 0b0000.

If [FEAT_Debugv8p2](#) is implemented and [FEAT_DoPD](#) is not implemented, the permitted values are 0b0000 and 0b1111.

If [FEAT_DoPD](#) is implemented, the only permitted value is 0b1111.

Access to this field is RO.

Bits [35:32]

Reserved, RES0.

CTX_CMPs, bits [31:28]

Number of context-aware breakpoints, minus 1.

The value of this field is an IMPLEMENTATION DEFINED choice of:

CTX_CMPs	Meaning
0b0000..0b1110	The number of context-aware breakpoints, minus 1.
0b1111	If ID_AA64DFR1_EL1.CTX_CMPs is zero, then 16 context-aware breakpoints are implemented. Otherwise, 16 or more context-aware breakpoints are implemented and ID_AA64DFR1_EL1.CTX_CMPs indicates how many.

Values greater than [ID_AA64DFR0_EL1.BRPs](#) are not permitted.

Access to this field is RO.

Bits [27:24]

Reserved, RES0.

WRPs, bits [23:20]

Number of watchpoints, minus 1.

The value of this field is an IMPLEMENTATION DEFINED choice of:

WRPs	Meaning
0b0001..0b1111	The number of watchpoints, minus 1.

The value 0b0000 is reserved.

Access to this field is RO.

Bits [19:16]

Reserved, RES0.

BRPs, bits [15:12]

Index of the highest numbered context-aware breakpoint. Identifies which of the implemented breakpoints are context-aware breakpoints.

The value of this field is an IMPLEMENTATION DEFINED choice of:

BRPs	Meaning
0b0001..0b1110	Index of the highest numbered context-aware breakpoint.
0b1111	If ID_AA64DFR0_EL1.CTX_CMPs and ID_AA64DFR1_EL1.CTX_CMPs indicate that 16 or fewer breakpoints are context-aware, then the index of the highest context-aware breakpoint is 15. Otherwise, the context-aware breakpoints are the lowest numbered breakpoints.

The value 0b0000 is reserved.

Access to this field is RO.

PMUVer, bits [11:8]

Performance Monitors Extension version.

This field does not follow the standard ID scheme, but uses the alternative ID scheme described in '[Alternative ID scheme used for the Performance Monitors Extension version](#)'.

The value of this field is an IMPLEMENTATION DEFINED choice of:

All other values are reserved.

[FEAT_PMUv3](#) implements the functionality identified by the value 0b0001.

[FEAT_PMUv3p1](#) implements the functionality identified by the value 0b0100.

[FEAT_PMUv3p4](#) implements the functionality identified by the value 0b0101.

From Armv8.1, if [FEAT_PMUv3](#) is implemented, the value 0b0001 is not permitted.

From Armv8.4, if [FEAT_PMUv3](#) is implemented, the value 0b0100 is not permitted.

Access to this field is RO.

TraceVer, bits [7:4]

Trace support. Indicates whether System register interface to a trace unit is implemented.

The value of this field is an IMPLEMENTATION DEFINED choice of:

TraceVer	Meaning
0b0000	Trace unit System registers not implemented.
0b0001	Trace unit System registers implemented.

All other values are reserved.

See the ETM Architecture Specification for more information.

A value of 0b0000 only indicates that no System register interface to a trace unit is implemented. A trace unit might nevertheless be implemented without a System register interface.

Access to this field is RO.

DebugVer, bits [3:0]

Debug architecture version. Indicates presence of Armv8 debug architecture.

The value of this field is an IMPLEMENTATION DEFINED choice of:

All other values are reserved.

[FEAT_Debugv8p1](#) implements the functionality identified by the value 0b0111.

[FEAT_Debugv8p2](#) implements the functionality identified by the value 0b1000.

[FEAT_Debugv8p4](#) implements the functionality identified by the value 0b1001.

From Armv8.1, when [FEAT_Debugv8p1](#) is implemented the value 0b0110 is not permitted.

From Armv8.2, the values 0b0110 and 0b0111 are not permitted.

From Armv8.4, the value 0b1000 is not permitted.

Access to this field is RO.

Accessing ID_AA64DFR0_EL1

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, ID_AA64DFR0_EL1

op0	op1	CRn	CRm	op2
0b11	0b000	0b0000	0b0101	0b000

```

if PSTATE.EL == EL0 then
    if IsFeatureImplemented(FEAT_IDST) then
        AArch64_SystemAccessTrapToEL1orEL2(0x18);
    else
        Undefined();
    end;
elseif PSTATE.EL == EL1 then
    if HCR_EL2().TID3 == '1' then
        AArch64_SystemAccessTrap(EL2, 0x18);
    else
        X{64}(t) = ID_AA64DFR0_EL1();
    end;
elseif PSTATE.EL == EL2 then
    X{64}(t) = ID_AA64DFR0_EL1();
end;

```

D12.2.41 ID_AA64DFR1_EL1, AArch64 Debug Feature Register 1

The ID_AA64DFR1_EL1 characteristics are:

Purpose

Provides top-level information about the debug system in AArch64.

Configuration

There are no configuration notes.

Attributes

ID_AA64DFR1_EL1 is a 64-bit register.

Field descriptions

Bits [63:0]

Reserved, RES0.

Accessing ID_AA64DFR1_EL1

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, ID_AA64DFR1_EL1

op0	op1	CRn	CRm	op2
0b11	0b000	0b0000	0b0101	0b001

```
if PSTATE.EL == EL0 then
    if IsFeatureImplemented(FEAT_IDST) then
        AArch64_SystemAccessTraptToEL1orEL2(0x18);
    else
        Undefined();
    end;
elseif PSTATE.EL == EL1 then
    if HCR_EL2().TID3 == '1' then
        AArch64_SystemAccessTrap(EL2, 0x18);
    else
        X{64}(t) = ID_AA64DFR1_EL1();
    end;
elseif PSTATE.EL == EL2 then
    X{64}(t) = ID_AA64DFR1_EL1();
end;
```

D12.2.42 ID_AA64DFR2_EL1, AArch64 Debug Feature Register 2

The ID_AA64DFR2_EL1 characteristics are:

Purpose

Provides top-level information about the debug system in AArch64.

For general information about the interpretation of the ID registers, see ‘[Principles of the ID scheme for fields in ID registers](#)’.

Configuration

Note
Prior to the introduction of the features described by this register, this register was unnamed and reserved, RES0 from EL1 and EL2.

Attributes

ID_AA64DFR2_EL1 is a 64-bit register.

Field descriptions

Bits [63:0]

Reserved, RES0.

Accessing ID_AA64DFR2_EL1

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, ID_AA64DFR2_EL1

op0	op1	CRn	CRm	op2
0b11	0b000	0b0000	0b0101	0b010

```
if PSTATE.EL == EL0 then
    if IsFeatureImplemented(FEAT_IDST) then
        AArch64_SystemAccessTraptoEL1orEL2(0x18);
    else
        Undefined();
    end;
elseif PSTATE.EL == EL1 then
    if (!IsZero(ID_AA64DFR2_EL1()) || ImpDefBool("ID_AA64DFR2_EL1 trapped by HCR_EL2.TID3")) &&
        ↪HCR_EL2().TID3 == '1' then
        AArch64_SystemAccessTrap(EL2, 0x18);
    else
        X{64}(t) = ID_AA64DFR2_EL1();
    end;
end;
```

```
elseif PSTATE.EL == EL2 then
    X{64}(t) = ID_AA64DFR2_EL1();
end;
```

D12.2.43 ID_AA64ISAR0_EL1, AArch64 Instruction Set Attribute Register 0

The ID_AA64ISAR0_EL1 characteristics are:

Purpose

Provides information about the instructions implemented in AArch64 state.

For general information about the interpretation of the ID registers, see ‘[Principles of the ID scheme for fields in ID registers](#)’.

Configuration

There are no configuration notes.

Attributes

ID_AA64ISAR0_EL1 is a 64-bit register.

Field descriptions

63	60	59	56	55	52	51	48	47	44	43	40	39	36	35	32
RES0	TLB			TS		FHM		DP		SM4		SM3		SHA3	
31	28	27	24	23	20	19	16	15	12	11	8	7	4	3	0
RDM		RES0		Atomic		CRC32		SHA2		SHA1		AES		RES0	

Bits [63:60]

Reserved, RES0.

TLB, bits [59:56]

Indicates support for Outer Shareable and TLB range maintenance instructions.

The value of this field is an IMPLEMENTATION DEFINED choice of:

TLB	Meaning
0b0000	Outer Shareable and TLB range maintenance instructions are not implemented.
0b0001	Outer Shareable TLB maintenance instructions are implemented.
0b0010	Outer Shareable and TLB range maintenance instructions are implemented.

All other values are reserved.

[FEAT_TLBIOS](#) implements the functionality identified by the values 0b0001 and 0b0010.

[FEAT_TLBI RANGE](#) implements the functionality identified by the value 0b0010.

From Armv8.4, the values 0b0000 and 0b0001 are not permitted.

Access to this field is RO.

TS, bits [55:52]

Indicates support for flag manipulation instructions.

The value of this field is an IMPLEMENTATION DEFINED choice of:

All other values are reserved.

[FEAT_FlagM](#) implements the functionality identified by the value 0b0001.

In Armv8.4, the value 0b0000 is not permitted.

Access to this field is RO.

FHM, bits [51:48]

Indicates support for the Advanced SIMD half-precision to single-precision multiply instructions.

The value of this field is an IMPLEMENTATION DEFINED choice of:

All other values are reserved.

[FEAT_FHM](#) implements the functionality identified by the value 0b0001.

From Armv8.4, if [FEAT_FP16](#) is implemented, the value 0b0000 is not permitted.

Access to this field is RO.

DP, bits [47:44]

Indicates support for Dot Product instructions in AArch64 state.

The value of this field is an IMPLEMENTATION DEFINED choice of:

DP	Meaning
0b0000	No Dot Product instructions implemented.
0b0001	UDOT and SDOT instructions implemented.

All other values are reserved.

[FEAT_DotProd](#) implements the functionality identified by the value 0b0001.

From Armv8.4, if [FEAT_AdvSIMD](#) is implemented, the value 0b0000 is not permitted.

Access to this field is RO.

SM4, bits [43:40]

Indicates support for SM4 instructions in AArch64 state.

The value of this field is an IMPLEMENTATION DEFINED choice of:

SM4	Meaning
0b0000	No SM4 instructions implemented.
0b0001	SM4E and SM4EKEY instructions implemented.

All other values are reserved.

If [FEAT_SM4](#) is not implemented, the value 0b0001 is reserved.

[FEAT_SM4](#) implements the functionality identified by the value 0b0001.

This field must have the same value as ID_AA64ISAR0_EL1.SM3.

Access to this field is RO.

SM3, bits [39:36]

Indicates support for the following SM3 instructions SM3SS1, SM3TT1A, SM3TT1B, SM3TT2A, SM3TT2B, SM3PARTW1, and SM3PARTW2 in AArch64 state.

The value of this field is an IMPLEMENTATION DEFINED choice of:

SM3	Meaning
0b0000	The specified instructions are not implemented.
0b0001	The specified instructions are implemented.

All other values are reserved.

If [FEAT_SM3](#) is not implemented, the value 0b0001 is reserved.

[FEAT_SM3](#) implements the functionality identified by the value 0b0001.

This field must have the same value as ID_AA64ISAR0_EL1.SM4.

Access to this field is RO.

SHA3, bits [35:32]

Indicates support for the following SHA3 instructions EOR3, RAX1, XAR, and BCAX in AArch64 state.

The value of this field is an IMPLEMENTATION DEFINED choice of:

SHA3	Meaning
0b0000	The specified instructions are not implemented.
0b0001	The specified instructions are implemented.

All other values are reserved.

If [FEAT_SHA3](#) is not implemented, the value 0b0001 is reserved.

[FEAT_SHA3](#) implements the functionality identified by the value 0b0001.

If the value of ID_AA64ISAR0_EL1.SHA1 is 0b0000, this field must have the value 0b0000.

If the value of this field is 0b0001, ID_AA64ISAR0_EL1.SHA2 must have the value 0b0010.

Access to this field is RO.

RDM, bits [31:28]

Indicates support for SQRDMLAH and SQRDMLSH instructions in AArch64 state.

The value of this field is an IMPLEMENTATION DEFINED choice of:

RDM	Meaning
0b0000	No RDMA instructions implemented.
0b0001	SQRDMLAH and SQRDMLSH instructions implemented.

All other values are reserved.

[FEAT_RDM](#) implements the functionality identified by the value 0b0001.

From Armv8.1, the value 0b0000 is not permitted.

Access to this field is RO.

Bits [27:24]

Reserved, RES0.

Atomic, bits [23:20]

Indicates support for Atomic instructions in AArch64 state.

The value of this field is an IMPLEMENTATION DEFINED choice of:

All other values are reserved.

[FEAT_LSE](#) implements the functionality identified by the value 0b0010.

From Armv8.1, the value 0b0000 is not permitted.

Access to this field is RO.

CRC32, bits [19:16]

Indicates support for the following CRC32 instructions CRC32B, CRC32H, CRC32W, CRC32X, CRC32CB, CRC32CH, CRC32CW, and CRC32CX in AArch64 state.

The value of this field is an IMPLEMENTATION DEFINED choice of:

CRC32	Meaning
0b0000	The specified instructions are not implemented.
0b0001	The specified instructions are implemented.

All other values are reserved.

[FEAT_CRC32](#) implements the functionality identified by the value 0b0001.

From Armv8.1, the value 0b0000 is not permitted.

Access to this field is RO.

SHA2, bits [15:12]

Indicates support for SHA2 instructions in AArch64 state.

The value of this field is an IMPLEMENTATION DEFINED choice of:

SHA2	Meaning
0b0000	No SHA2 instructions implemented.
0b0001	Implements instructions: SHA256H, SHA256H2, SHA256SU0, and SHA256SU1.
0b0010	Implements instructions: - SHA256H, SHA256H2, SHA256SU0, and SHA256SU1. - SHA512H, SHA512H2, SHA512SU0, and SHA512SU1.

All other values are reserved.

[FEAT_SHA256](#) implements the functionality identified by the value 0b0001.

[FEAT_SHA512](#) implements the functionality identified by the value 0b0010.

If the value of ID_AA64ISAR0_EL1.SHA1 is 0b0000, this field must have the value 0b0000.

If the value of this field is 0b0010, ID_AA64ISAR0_EL1.SHA3 must have the value 0b0001.

Access to this field is RO.

SHA1, bits [11:8]

Indicates support for the following SHA1 instructions SHA1C, SHA1P, SHA1M, SHA1H, SHA1SU0, and SHA1SU1 in AArch64 state.

The value of this field is an IMPLEMENTATION DEFINED choice of:

SHA1	Meaning
0b0000	The specified instructions are not implemented.
0b0001	The specified instructions are implemented.

All other values are reserved.

[FEAT_SHA1](#) implements the functionality identified by the value 0b0001.

If the value of ID_AA64ISAR0_EL1.SHA2 is 0b0000, this field must have the value 0b0000.

Access to this field is RO.

AES, bits [7:4]

Indicates support for AES instructions in AArch64 state.

The value of this field is an IMPLEMENTATION DEFINED choice of:

AES	Meaning
0b0000	No AES instructions implemented.
0b0001	AESE, AESD, AESMC, and AESIMC instructions implemented.
0b0010	As for 0b0001, plus PMULL and PMULL2 instructions operating on 64-bit source elements.

[FEAT_AES](#) implements the functionality identified by the value 0b0001.

FEAT_PMULL implements the functionality identified by the value 0b0010.

All other values are reserved.

Access to this field is RO.

Bits [3:0]

Reserved, RES0.

Accessing ID_AA64ISAR0_EL1

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, ID_AA64ISAR0_EL1

op0	op1	CRn	CRm	op2
0b11	0b000	0b0000	0b0110	0b000

```

if PSTATE.EL == EL0 then
    if IsFeatureImplemented(FEAT_IDST) then
        AArch64_SystemAccessTrapToEL1orEL2(0x18);
    else
        Undefined();
    end;
elseif PSTATE.EL == EL1 then
    if HCR_EL2().TID3 == '1' then
        AArch64_SystemAccessTrap(EL2, 0x18);
    else
        X{64}(t) = ID_AA64ISAR0_EL1();
    end;
elseif PSTATE.EL == EL2 then
    X{64}(t) = ID_AA64ISAR0_EL1();
end;

```

D12.2.44 ID_AA64ISAR1_EL1, AArch64 Instruction Set Attribute Register 1

The ID_AA64ISAR1_EL1 characteristics are:

Purpose

Provides information about the features and instructions implemented in AArch64 state.

For general information about the interpretation of the ID registers, see [‘Principles of the ID scheme for fields in ID registers’](#).

Configuration

There are no configuration notes.

Attributes

ID_AA64ISAR1_EL1 is a 64-bit register.

GPI				GPA				LRCPC				FCMA				JSCVT				API				APA				DPB					

Bits [63:52]

Reserved, RES0.

DGH, bits [51:48]

Indicates support for the Data Gathering Hint instruction.

The value of this field is an IMPLEMENTATION DEFINED choice of:

DGH	Meaning
0b0000	Data Gathering Hint is not implemented.
0b0001	Data Gathering Hint is implemented.

All other values are reserved.

FEAT_DGH implements the functionality identified by 0b0001.

From Armv8.0, the permitted values are 0b0000 and 0b0001.

If the DGH instruction has no effect in preventing the merging of memory accesses, the value of this field is 0b0000.

Access to this field is RO.

Bits [47:44]

Reserved, RES0.

SPECRES, bits [43:40]

Indicates support for prediction invalidation instructions in AArch64 state.

The value of this field is an IMPLEMENTATION DEFINED choice of:

All other values are reserved.

[FEAT_SPECRES](#) implements the functionality identified by 0b0001.

In Armv8-R, the permitted values are 0b0000 and 0b0001.

Access to this field is RO.

SB, bits [39:36]

Indicates support for SB instruction in AArch64 state.

The value of this field is an IMPLEMENTATION DEFINED choice of:

SB	Meaning
0b0000	SB instruction is not implemented.
0b0001	SB instruction is implemented.

All other values are reserved.

[FEAT_SB](#) implements the functionality identified by 0b0001.

In Armv8-R, the permitted values are 0b0000 and 0b0001.

Access to this field is RO.

Bits [35:32]

Reserved, RES0.

GPI, bits [31:28]

Indicates support for an IMPLEMENTATION DEFINED algorithm is implemented in the PE for generic code authentication in AArch64 state.

The value of this field is an IMPLEMENTATION DEFINED choice of:

GPI	Meaning
0b0000	Generic Authentication using an IMPLEMENTATION DEFINED algorithm is not implemented.
0b0001	Generic Authentication using an IMPLEMENTATION DEFINED algorithm is implemented. This includes the PACGA instruction.

All other values are reserved.

When this field is nonzero, [FEAT_PACIMP](#) is implemented.

From Armv8.3, the permitted values are 0b0000 and 0b0001.

If the value of ID_AA64ISAR1_EL1.GPA is nonzero, this field must have the value 0b0000.

Access to this field is RO.

GPA, bits [27:24]

Indicates whether the QARMA5 algorithm is implemented in the PE for generic code authentication in AArch64 state.

The value of this field is an IMPLEMENTATION DEFINED choice of:

GPA	Meaning
0b0000	Generic Authentication using the QARMA5 algorithm is not implemented.
0b0001	Generic Authentication using the QARMA5 algorithm is implemented. This includes the PACGA instruction.

All other values are reserved.

[FEAT_PACQARMA5](#) implements the functionality identified by 0b0001.

When this field is nonzero, [FEAT_PACQARMA5](#) is implemented.

From Armv8.3, the permitted values are 0b0000 and 0b0001.

If the value of ID_AA64ISAR1_EL1.GPI is nonzero, this field must have the value 0b0000.

Access to this field is RO.

LRCPC, bits [23:20]

Indicates support for weaker release consistency, RCpc, based model.

The value of this field is an IMPLEMENTATION DEFINED choice of:

All other values are reserved.

[FEAT_LRCPC](#) implements the functionality identified by the value 0b0001.

[FEAT_LRCPC2](#) implements the functionality identified by the value 0b0010.

From Armv8.3, the value 0b0000 is not permitted.

From Armv8.4, the value 0b0001 is not permitted.

Access to this field is RO.

FCMA, bits [19:16]

Indicates support for complex number addition and multiplication, where numbers are stored in vectors.

The value of this field is an IMPLEMENTATION DEFINED choice of:

FCMA	Meaning
0b0000	The FCMLA and FCADD instructions are not implemented.
0b0001	The FCMLA and FCADD instructions are implemented.

All other values are reserved.

[FEAT_FCMA](#) implements the functionality identified by the value 0b0001.

From Armv8.3, if Advanced SIMD or floating-point is implemented, the value 0b0000 is not permitted.

From Armv8.3, if Advanced SIMD or floating-point is not implemented, the only permitted value is 0b0000.

Access to this field is RO.

JSCVT, bits [15:12]

Indicates support for JavaScript conversion from double-precision floating-point values to integers in AArch64 state.

The value of this field is an IMPLEMENTATION DEFINED choice of:

JSCVT	Meaning
0b0000	The FJCVTZS instruction is not implemented.
0b0001	The FJCVTZS instruction is implemented.

All other values are reserved.

[FEAT_JSCVT](#) implements the functionality identified by 0b0001.

From Armv8.3, if Advanced SIMD or floating-point is implemented, the value 0b0000 is not permitted.

From Armv8.3, if Advanced SIMD or floating-point is not implemented, the only permitted value is 0b0000.

Access to this field is RO.

API, bits [11:8]

Indicates whether an IMPLEMENTATION DEFINED algorithm is implemented in the PE for address authentication, in AArch64 state. This applies to all Pointer Authentication instructions other than the PACGA instruction.

The value of this field is an IMPLEMENTATION DEFINED choice of:

All other values are reserved.

[FEAT_PAuth](#) implements the functionality identified by 0b0001.

[FEAT_EPAC](#) implements the functionality identified by 0b0010.

[FEAT_PAuth2](#) implements the functionality identified by 0b0011.

[FEAT_FPAC](#) implements the functionality identified by 0b0100.

[FEAT_FPACCOMBINE](#) implements the functionality identified by 0b0101.

When this field is nonzero, [FEAT_PACIMP](#) is implemented.

In Armv8-R, the permitted values are 0b0000, 0b0001, 0b0010, 0b0011, 0b0100, and 0b0101.

If the value of ID_AA64ISAR1_EL1.APA is nonzero, this field must have the value 0b0000.

Access to this field is RO.

APA, bits [7:4]

Indicates whether the QARMA5 algorithm is implemented in the PE for address authentication, in AArch64 state. This applies to all Pointer Authentication instructions other than the PACGA instruction.

The value of this field is an IMPLEMENTATION DEFINED choice of:

All other values are reserved.

[FEAT_PAuth](#) implements the functionality identified by 0b0001.

[FEAT_EPAC](#) implements the functionality identified by 0b0010.

[FEAT_PAuth2](#) implements the functionality identified by 0b0011.

[FEAT_FPAC](#) implements the functionality identified by 0b0100.

FEAT_FPACCOMBINE implements the functionality identified by 0b0101.

When this field is nonzero, **FEAT_PACQARMA5** is implemented.

In Armv8-R, the permitted values are 0b0000, 0b0001, 0b0010, 0b0011, 0b0100, and 0b0101.

If the value of ID_AA64ISAR1_EL1.API is nonzero, this field must have the value 0b0000.

Access to this field is RO.

DPB, bits [3:0]

Data Persistence writeback. Indicates support for the **DC CVAP** and **DC CVADP** instructions in AArch64 state.

The value of this field is an IMPLEMENTATION DEFINED choice of:

DPB	Meaning
0b0000	DC CVAP not supported.
0b0001	DC CVAP supported.
0b0010	DC CVAP and DC CVADP supported.

All other values are reserved.

FEAT_DPB implements the functionality identified by the value 0b0001.

FEAT_DPB2 implements the functionality identified by the value 0b0010.

In Armv8-R, the value 0b0000 is not permitted.

Access to this field is RO.

Accessing ID_AA64ISAR1_EL1

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, ID_AA64ISAR1_EL1

op0	op1	CRn	CRm	op2
0b11	0b000	0b0000	0b0110	0b001

```

if PSTATE.EL == EL0 then
    if IsFeatureImplemented(FEAT_IDST) then
        AArch64_SystemAccessTrapToEL1orEL2(0x18);
    else
        Undefined();
    end;
elseif PSTATE.EL == EL1 then
    if HCR_EL2().TID3 == '1' then
        AArch64_SystemAccessTrap(EL2, 0x18);
    else
        X{64}(t) = ID_AA64ISAR1_EL1();
    end;
elseif PSTATE.EL == EL2 then
    X{64}(t) = ID_AA64ISAR1_EL1();
end;

```

D12.2.45 ID_AA64ISAR2_EL1, AArch64 Instruction Set Attribute Register 2

The ID_AA64ISAR2_EL1 characteristics are:

Purpose

Provides information about the features and instructions implemented in AArch64 state.

For general information about the interpretation of the ID registers, see ‘Principles of the ID scheme for fields in ID registers’.

Configuration

Note
Prior to the introduction of the features described by this register, this register was unnamed and reserved, RES0 from EL1 and EL2.

Attributes

ID_AA64ISAR2_EL1 is a 64-bit register.

Field descriptions

Bits [63:28]

Reserved, RES0.

PAC_frac, bits [27:24]

Indicates which address bit is used to determine the size of the PAC field.

The value of this field is an IMPLEMENTATION DEFINED choice of:

PAC_frac	Meaning
0b0000	The address bit which is used to define the size of the PAC field is dependent on whether address tagging is used.
0b0001	The address bit which is used to define the size of the PAC field is fixed.

All other values are reserved.

[FEAT_CONSTPACFIELD](#) implements the functionality identified by the value 0b0001.

From Armv8.3, the permitted values are 0b0000 and 0b0001.

Access to this field is RO.

Bits [23:16]

Reserved, RES0.

APA3, bits [15:12]

Indicates whether the QARMA3 algorithm is implemented in the PE for address authentication in AArch64 state. This applies to all Pointer Authentication instructions other than the PACGA instruction.

The value of this field is an IMPLEMENTATION DEFINED choice of:

All other values are reserved.

[FEAT_PAuth](#) implements the functionality identified by the value 0b0001.

[FEAT_EPAC](#) implements the functionality identified by the value 0b0010.

[FEAT_PAuth2](#) implements the functionality identified by the value 0b0011.

[FEAT_FPAC](#) implements the functionality identified by the value 0b0100.

[FEAT_FPACCOMBINE](#) implements the functionality identified by the value 0b0101.

When this field is nonzero, [FEAT_PACQARMA3](#) is implemented.

In Armv8.3, the permitted values are 0b0000, 0b0001, 0b0010, 0b0011, 0b0100, and 0b0101.

From Armv8.6, the permitted values are 0b0000, 0b0011, 0b0100, and 0b0101.

If the value of [ID_AA64ISAR1_EL1.API](#) is nonzero, or the value of [ID_AA64ISAR1_EL1.APA](#) is nonzero, this field must have the value 0b0000.

Access to this field is RO.

GPA3, bits [11:8]

Indicates whether the QARMA3 algorithm is implemented in the PE for generic code authentication in AArch64 state.

The value of this field is an IMPLEMENTATION DEFINED choice of:

GPA3	Meaning
0b0000	Generic Authentication using the QARMA3 algorithm is not implemented.
0b0001	Generic Authentication using the QARMA3 algorithm is implemented. This includes the PACGA instruction.

All other values are reserved.

[FEAT_PACQARMA3](#) implements the functionality identified by the value 0b0001.

When this field is nonzero, [FEAT_PACQARMA3](#) is implemented.

From Armv8.3, the permitted values are 0b0000 and 0b0001.

If the value of [ID_AA64ISAR1_EL1.GPI](#) is nonzero, or the value of [ID_AA64ISAR1_EL1.GPA](#) is nonzero, this field must have the value 0b0000.

Access to this field is RO.

Bits [7:0]

Reserved, RES0.

Accessing ID_AA64ISAR2_EL1

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, ID_AA64ISAR2_EL1

op0	op1	CRn	CRm	op2
0b11	0b000	0b0000	0b0110	0b010

```
if PSTATE.EL == EL0 then
    if IsFeatureImplemented(FEAT_IDST) then
        AArch64_SystemAccessTrapToEL1orEL2(0x18);
    else
        Undefined();
    end;
elseif PSTATE.EL == EL1 then
    if (!IsZero(ID_AA64ISAR2_EL1()) || ImpDefBool("ID_AA64ISAR2_EL1 trapped by HCR_EL2.TID3")) &&
        ↪HCR_EL2().TID3 == '1' then
        AArch64_SystemAccessTrap(EL2, 0x18);
    else
        X{64}(t) = ID_AA64ISAR2_EL1();
    end;
elseif PSTATE.EL == EL2 then
    X{64}(t) = ID_AA64ISAR2_EL1();
end;
```

D12.2.46 ID_AA64MMFR0_EL1, AArch64 Memory Model Feature Register 0

The ID_AA64MMFR0_EL1 characteristics are:

Purpose

Provides information about the implemented memory model and memory management support in AArch64 state.

For general information about the interpretation of the ID registers, see ‘[Principles of the ID scheme for fields in ID registers](#)’.

Configuration

There are no configuration notes.

Attributes

ID_AA64MMFR0_EL1 is a 64-bit register.

Field descriptions

63	56	55	52	51	48	47	32
RES0			MSA_frac		MSA		RES0
31	28	27	24	23	20	19	16
15	12	11	8	7	4	3	0
TGran4		TGran64		TGran16		BigEndEL0	
SNSMem		BigEnd		ASIDBits		PARange	

Bits [63:56]

Reserved, RES0.

MSA_frac, bits [55:52]

Memory System Architecture fractional field. This holds the information on additional Memory System Architectures supported.

The value of this field is an IMPLEMENTATION DEFINED choice of:

MSA_frac	Meaning
0b0000	PMSAv8-64 not supported in any translation regime.
0b0001	PMSAv8-64 supported in all translation regimes. No support for VMSAv8-64.
0b0010	PMSAv8-64 supported in all translation regimes. In addition to PMSAv8-64, stage 1 EL1&0 translation regime also supports VMSAv8-64.

All other values are reserved.

The permitted values are 0b0001 and 0b0010.

This field is valid only when ID_AA64MMFR0_EL1.MSA is 0b1111.

Access to this field is RO.

MSA, bits [51:48]

Memory System Architecture ID field. This holds the information on Memory System Architectures supported.

The value of this field is an IMPLEMENTATION DEFINED choice of:

MSA	Meaning
0b0000	VMSAv8-64 supported in all translation regimes. No support for PMSAv8-64.
0b1111	See ID_AA64MMFR0_EL1.MSA_frac for the Memory System Architectures supported.

All other values are reserved.

In Armv8-R, the only permitted value is 0b1111.

Access to this field is RO.

Bits [47:32]

Reserved, RES0.

TGran4, bits [31:28]

Indicates support for 4KB memory translation granule size.

The value of this field is an IMPLEMENTATION DEFINED choice of:

TGran4	Meaning
0b0000	4KB granule supported.
0b1111	4KB granule not supported.

All other values are reserved.

Access to this field is RO.

TGran64, bits [27:24]

Indicates support for 64KB memory translation granule size.

The value of this field is an IMPLEMENTATION DEFINED choice of:

TGran64	Meaning
0b0000	64KB granule supported.
0b1111	64KB granule not supported.

All other values are reserved.

Access to this field is RO.

TGran16, bits [23:20]

Indicates support for 16KB memory translation granule size.

The value of this field is an IMPLEMENTATION DEFINED choice of:

TGran16	Meaning
0b0000	16KB granule not supported.
0b0001	16KB granule supported.

All other values are reserved.

Access to this field is RO.

BigEndEL0, bits [19:16]

Indicates support for mixed-endian at EL0 only.

The value of this field is an IMPLEMENTATION DEFINED choice of:

BigEndEL0	Meaning
0b0000	No mixed-endian support at EL0. The SCTLR_EL1.E0E bit has a fixed value.
0b0001	Mixed-endian support at EL0. The SCTLR_EL1.E0E bit can be configured.

[FEAT_MixedEndEL0](#) implements the functionality identified by the value 0b0001.

All other values are reserved.

This field is invalid and is RES0 if ID_AA64MMFR0_EL1.BigEnd is not 0b0000.

Access to this field is RO.

SNSMem, bits [15:12]

Indicates support for a distinction between Secure and Non-secure Memory.

The value of this field is an IMPLEMENTATION DEFINED choice of:

SNSMem	Meaning
0b0000	Does not support a distinction between Secure and Non-secure Memory.
0b0001	Does support a distinction between Secure and Non-secure Memory.

All other values are reserved.

Access to this field is RO.

BigEnd, bits [11:8]

Indicates support for mixed-endian configuration.

The value of this field is an IMPLEMENTATION DEFINED choice of:

BigEnd	Meaning
0b0000	No mixed-endian support. The SCTLR_ELx.EE bits have a fixed value. See the BigEndEL0 field, bits[19:16], for whether EL0 supports mixed-endian.
0b0001	Mixed-endian support. The SCTLR_ELx.EE and SCTLR_EL1.E0E bits can be configured.

[FEAT_MixedEnd](#) implements the functionality identified by the value 0b0001.

If this field is 0b0001, [FEAT_MixedEndEL0](#) is also implemented.

All other values are reserved.

Access to this field is RO.

ASIDBits, bits [7:4]

Number of ASID bits.

The value of this field is an IMPLEMENTATION DEFINED choice of:

ASIDBits	Meaning
0b0000	8 bits.
0b0010	16 bits.

All other values are reserved.

Access to this field is RO.

PARange, bits [3:0]

Physical Address range supported.

The value of this field is an IMPLEMENTATION DEFINED choice of:

PARange	Meaning	Applies when
0b0000	32 bits, 4GB.	
0b0001	36 bits, 64GB.	
0b0010	40 bits, 1TB.	
0b0011	42 bits, 4TB.	
0b0100	44 bits, 16TB.	
0b0101	48 bits, 256TB.	
0b0110	52 bits, 4PB.	FEAT_LPA is implemented

All other values are reserved.

Access to this field is RO.

Accessing ID_AA64MMFR0_EL1

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, ID_AA64MMFR0_EL1

op0	op1	CRn	CRm	op2
0b11	0b000	0b0000	0b0111	0b000

```
if PSTATE.EL == EL0 then
    if IsFeatureImplemented(FEAT_IDST) then
        AArch64_SystemAccessTrapToEL1orEL2(0x18);
    else
        Undefined();
    end;
elseif PSTATE.EL == EL1 then
    if HCR_EL2().TID3 == '1' then
        AArch64_SystemAccessTrap(EL2, 0x18);
    else
        X{64}(t) = ID_AA64MMFR0_EL1();
    end;
elseif PSTATE.EL == EL2 then
    X{64}(t) = ID_AA64MMFR0_EL1();
end;
```

D12.2.47 ID_AA64MMFR1_EL1, AArch64 Memory Model Feature Register 1

The ID_AA64MMFR1_EL1 characteristics are:

Purpose

Provides information about the implemented memory model and memory management support in AArch64 state.

For general information about the interpretation of the ID registers, see ‘[Principles of the ID scheme for fields in ID registers](#)’.

Configuration

There are no configuration notes.

Attributes

ID_AA64MMFR1_EL1 is a 64-bit register.

Field descriptions

63	52	51	48	47	32
RES0			nTLBPA		RES0
31	28	27	24	23	20
19	16	15	12	11	8
7	4	3	0		
XNX		SpecSEI		PAN	RES0
				HPDS	RES0
				VMIDBits	HAFDBS

Bits [63:52]

Reserved, RES0.

nTLBPA, bits [51:48]

Indicates support for intermediate caching of translation table walks.

The value of this field is an IMPLEMENTATION DEFINED choice of:

nTLBPA	Meaning
0b0000	The intermediate caching of translation table walks might include non-coherent physical translation caches.
0b0001	The intermediate caching of translation table walks does not include non-coherent physical translation caches.

Non-coherent physical translation caches are non-coherent caches of previous valid translation table entries since the last completed relevant TLBI applicable to the PE, where either:

- The caching is indexed by the physical address of the location holding the translation table entry.
- The caching is used for stage 1 translations and is indexed by the intermediate physical address of the location holding the translation table entry.

All other values are reserved.

FEAT_nTLBPA implements the functionality identified by the value 0b0001.

Access to this field is RO.

Bits [47:32]

Reserved, RES0.

XNX, bits [31:28]

Indicates support for execute-never control distinction by Exception level at stage 2.

The value of this field is an IMPLEMENTATION DEFINED choice of:

XNX	Meaning
0b0000	Distinction between EL0 and EL1 execute-never control at stage 2 not supported.
0b0001	Distinction between EL0 and EL1 execute-never control at stage 2 supported.

All other values are reserved.

[FEAT_XNX](#) implements the functionality identified by the value 0b0001.

From Armv8.2, the value 0b0000 is not permitted.

Access to this field is RO.

SpecSEI, bits [27:24]

When FEAT_RAS is implemented:

Describes whether the PE can generate SError exceptions from speculative reads of memory, including speculative instruction fetches.

The value of this field is an IMPLEMENTATION DEFINED choice of:

SpecSEI	Meaning
0b0000	The PE never generates an SError exception due to an External abort on a speculative read.
0b0001	The PE might generate an SError exception due to an External abort on a speculative read.

All other values are reserved.

[FEAT_SpecSEI](#) implements the functionality identified by the value 0b0001.

Access to this field is RO.

Otherwise:

Reserved, RES0.

PAN, bits [23:20]

Privileged Access Never. Indicates support for the PAN bit in PSTATE, [SPSR_EL1](#), [SPSR_EL2](#), and [DPSR_EL0](#).

The value of this field is an IMPLEMENTATION DEFINED choice of:

All other values are reserved.

[FEAT_PAN](#) implements the functionality identified by the value 0b0001.

[FEAT_PAN2](#) implements the functionality added by the value 0b0010.

From Armv8.1, the value 0b0000 is not permitted.

From Armv8.2, the value 0b0001 is not permitted.

Access to this field is RO.

Bits [19:16]

Reserved, RES0.

HPDS, bits [15:12]

Hierarchical Permission Disables. Indicates support for disabling hierarchical controls in translation tables.

The value of this field is an IMPLEMENTATION DEFINED choice of:

HPDS	Meaning
0b0000	Disabling of hierarchical controls not supported.
0b0001	Disabling of hierarchical controls supported with the TCR_EL1 .{HPD1, HPD0}, TCR_EL2 .HPD or TCR_EL2 .{HPD1, HPD0} bits.
0b0010	As for value 0b0001, and adds possible hardware allocation of bits[62:59] of the Translation table descriptors from the final lookup level for IMPLEMENTATION DEFINED use.

All other values are reserved.

[FEAT_HPDS](#) implements the functionality identified by the value 0b0001.

[FEAT_HPDS2](#) implements the functionality identified by the value 0b0010.

From Armv8.1, the value 0b0000 is not permitted.

Access to this field is RO.

Bits [11:8]

Reserved, RES0.

VMIDBits, bits [7:4]

Number of VMID bits.

The value of this field is an IMPLEMENTATION DEFINED choice of:

VMIDBits	Meaning
0b0000	8 bits
0b0010	16 bits

All other values are reserved.

[FEAT_VMID16](#) implements the functionality identified by the value 0b0010.

Access to this field is RO.

HAFDBS, bits [3:0]

Hardware updates to Access flag and Dirty state in translation tables.

The value of this field is an IMPLEMENTATION DEFINED choice of:

All other values are reserved.

[FEAT_HAF](#) implements the functionality identified by the value 0b0001.

[FEAT_HAFDBS](#) implements the functionality identified by the value 0b0010.

Access to this field is RO.

Accessing ID_AA64MMFR1_EL1

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, ID_AA64MMFR1_EL1

op0	op1	CRn	CRm	op2
0b11	0b000	0b0000	0b0111	0b001

```

if PSTATE.EL == EL0 then
    if IsFeatureImplemented(FEAT_IDST) then
        AArch64_SystemAccessTrapToEL1orEL2(0x18);
    else
        Undefined();
    end;
elseif PSTATE.EL == EL1 then
    if HCR_EL2().TID3 == '1' then
        AArch64_SystemAccessTrap(EL2, 0x18);
    else
        X{64}(t) = ID_AA64MMFR1_EL1();
    end;
elseif PSTATE.EL == EL2 then
    X{64}(t) = ID_AA64MMFR1_EL1();
end;

```

D12.2.48 ID_AA64MMFR2_EL1, AArch64 Memory Model Feature Register 2

The ID_AA64MMFR2_EL1 characteristics are:

Purpose

Provides information about the implemented memory model and memory management support in AArch64 state.

For general information about the interpretation of the ID registers, see ‘[Principles of the ID scheme for fields in ID registers](#)’.

Configuration

Note

Prior to the introduction of the features described by this register, this register was unnamed and reserved, RES0 from EL1 and EL2.

Attributes

ID_AA64MMFR2_EL1 is a 64-bit register.

Field descriptions

63	60	59	56	55	52	51	48	47	44	43	40	39	36	35	32
E0PD	RES0		BBM		TTL		RES0		FWB		IDS		AT		
31	28	27	24	23	20	19	16	15	12	11	8	7	4	3	0
ST	RES0		CCIDX		VARange		IESB		RES0		UA0		CnP		

E0PD, bits [63:60]

Indicates support for the E0PD mechanism.

The value of this field is an IMPLEMENTATION DEFINED choice of:

E0PD	Meaning
0b0000	E0PDx mechanism is not implemented.
0b0001	E0PDx mechanism is implemented.

All other values are reserved.

[FEAT_E0PD](#) implements the functionality identified by the value 0b0001.

In Armv8.4, the permitted values are 0b0000 and 0b0001.

If [FEAT_E0PD](#) is implemented, [FEAT_CSV3](#) must be implemented.

Access to this field is RO.

Bits [59:56]

Reserved, RES0.

BBM, bits [55:52]

Allows identification of the requirements of the hardware to have break-before-make sequences when changing block or table size for a translation.

The value of this field is an IMPLEMENTATION DEFINED choice of:

All other values are reserved.

[FEAT_BBML1](#) implements the functionality identified by the value 0b0001.

[FEAT_BBML2](#) implements the functionality identified by the value 0b0010.

Access to this field is RO.

TTL, bits [51:48]

Indicates support for TTL field in address operations.

The value of this field is an IMPLEMENTATION DEFINED choice of:

TTL	Meaning
0b0000	TLB maintenance instructions by address have bits[47:44] as RES0.
0b0001	TLB maintenance instructions by address have bits[47:44] holding the TTL field.

All other values are reserved.

[FEAT_TTL](#) implements the functionality identified by the value 0b0001.

This field affects [TLBI IPAS2E1](#), [TLBI IPAS2E1IS](#), [TLBI IPAS2E1OS](#), [TLBI IPAS2LE1](#), [TLBI IPAS2LE1IS](#), [TLBI IPAS2LE1OS](#), [TLBI VAAE1](#), [TLBI VAAE1IS](#), [TLBI VAAE1OS](#), [TLBI VAALE1](#), [TLBI VAALE1IS](#), [TLBI VAALE1OS](#), [TLBI VAE1](#), [TLBI VAE1IS](#), [TLBI VAE1OS](#), [TLBI VAE2](#), [TLBI VAE2IS](#), [TLBI VAE2OS](#), [TLBI VAE3](#), [TLBI VAE3IS](#), [TLBI VAE3OS](#), [TLBI VALE1](#), [TLBI VALE1IS](#), [TLBI VALE1OS](#), [TLBI VALE2](#), [TLBI VALE2IS](#), [TLBI VALE2OS](#), [TLBI VALE3](#), [TLBI VALE3IS](#), [TLBI VALE3OS](#).

From Armv8.4, the value 0b0000 is not permitted.

Access to this field is RO.

Bits [47:44]

Reserved, RES0.

FWB, bits [43:40]

Indicates support for [HCR_EL2.FWB](#).

The value of this field is an IMPLEMENTATION DEFINED choice of:

FWB	Meaning
0b0000	HCR_EL2.FWB bit is not supported.
0b0001	HCR_EL2.FWB is supported.

All other values are reserved.

[FEAT_S2FWB](#) implements the functionality identified by the value 0b0001.

From Armv8.4, the value 0b0000 is not permitted.

Access to this field is RO.

IDS, bits [39:36]

Indicates the EC syndrome value in [ESR_ELx.EC](#) that is reported if an exception is generated by a read access to the feature ID space.

The value of this field is an IMPLEMENTATION DEFINED choice of:

All other values are reserved.

The Feature ID space is defined as the System register space in AArch64 with $op0=3$, $op1=\{0, 1, 3\}$, $CRn=0$, $CRm=\{0-7\}$, $op2=\{0-7\}$.

[FEAT_IDST](#) implements the functionality identified by the value `0b0001`.

From Armv8.4, the value `0b0000` is not permitted.

Access to this field is RO.

AT, bits [35:32]

Identifies support for unaligned single-copy atomicity and atomic functions.

The value of this field is an IMPLEMENTATION DEFINED choice of:

AT	Meaning
0b0000	Unaligned single-copy atomicity and atomic functions are not supported.
0b0001	Unaligned single-copy atomicity and atomic functions with a 16-byte address range aligned to 16-bytes are supported.

All other values are reserved.

[FEAT_LSE2](#) implements the functionality identified by the value `0b0001`.

From Armv8.4, the value `0b0000` is not permitted.

Access to this field is RO.

ST, bits [31:28]

Identifies support for small translation tables.

The value of this field is an IMPLEMENTATION DEFINED choice of:

ST	Meaning
0b0000	The maximum value of the TCR_ELx.{T0SZ,T1SZ} and VTCR_EL2.T0SZ fields is 39.
0b0001	The maximum value of the TCR_ELx.{T0SZ,T1SZ} and VTCR_EL2.T0SZ fields is 48 for 4KB and 16KB granules, and 47 for 64KB granules.

All other values are reserved.

[FEAT_TTST](#) implements the functionality identified by the value `0b0001`.

When [FEAT_SEL2](#) is implemented, the value `0b0000` is not permitted.

Access to this field is RO.

Bits [27:24]

Reserved, RES0.

CCIDX, bits [23:20]

Support for the use of revised [CCSIDR_EL1](#) register format.

The value of this field is an IMPLEMENTATION DEFINED choice of:

CCIDX	Meaning
0b0000	32-bit format implemented for all levels of the CCSIDR_EL1 .
0b0001	64-bit format implemented for all levels of the CCSIDR_EL1 .

All other values are reserved.

[FEAT_CCIDX](#) implements the functionality identified by the value 0b0001.

From Armv8.3, the permitted values are 0b0000 and 0b0001.

Access to this field is RO.

VARange, bits [19:16]

Indicates support for a larger virtual address.

The value of this field is an IMPLEMENTATION DEFINED choice of:

All other values are reserved.

[FEAT_LVA](#) implements the functionality identified by the value 0b0001.

Access to this field is RO.

IESB, bits [15:12]

Indicates support for the IESB fields in the SCTLR_ELx and [ESR_ELx](#) registers.

The value of this field is an IMPLEMENTATION DEFINED choice of:

All other values are reserved.

[FEAT_IESB](#) implements the functionality identified by the value 0b0001.

Access to this field is RO.

Bits [11:8]

Reserved, RES0.

UAO, bits [7:4]

User Access Override.

The value of this field is an IMPLEMENTATION DEFINED choice of:

UAO	Meaning
0b0000	UAO not supported.
0b0001	UAO supported.

All other values are reserved.

[FEAT_UAO](#) implements the functionality identified by the value 0b0001.

From Armv8.2, the value 0b0000 is not permitted.

Access to this field is RO.

CnP, bits [3:0]

Indicates support for Common not Private translations.

The value of this field is an IMPLEMENTATION DEFINED choice of:

CnP	Meaning
0b0000	Common not Private translations not supported.
0b0001	Common not Private translations supported.

All other values are reserved.

FEAT_TTCNP implements the functionality identified by the value 0b0001.

From Armv8.2, the value 0b0000 is not permitted.

Access to this field is RO.

Accessing ID_AA64MMFR2_EL1

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, ID_AA64MMFR2_EL1

op0	op1	CRn	CRm	op2
0b11	0b000	0b0000	0b0111	0b010

```
if PSTATE.EL == EL0 then
    if IsFeatureImplemented(FEAT_IDST) then
        AArch64_SystemAccessTrapToEL1orEL2(0x18);
    else
        Undefined();
    end;
elseif PSTATE.EL == EL1 then
    if (!IsZero(ID_AA64MMFR2_EL1()) || ImpDefBool("ID_AA64MMFR2_EL1 trapped by HCR_EL2.TID3")) &&
        ↪HCR_EL2().TID3 == '1' then
        AArch64_SystemAccessTrap(EL2, 0x18);
    else
        X{64}(t) = ID_AA64MMFR2_EL1();
    end;
elseif PSTATE.EL == EL2 then
    X{64}(t) = ID_AA64MMFR2_EL1();
end;
```

D12.2.49 ID_AA64MMFR3_EL1, AArch64 Memory Model Feature Register 3

The ID_AA64MMFR3_EL1 characteristics are:

Purpose

Provides information about the implemented memory model and memory management support in AArch64 state.

Configuration

Note
Prior to the introduction of the features described by this register, this register was unnamed and reserved, RES0 from EL1 and EL2.

Attributes

ID_AA64MMFR3_EL1 is a 64-bit register.

Field descriptions

Spec_FPACC, bits [63:60]

When FEAT_FPACCOMBINE is implemented:

Speculative behavior in the event of a PAC authentication failure in an implementation that includes [FEAT_FPACCOMBINE](#).

The value of this field is an IMPLEMENTATION DEFINED choice of:

Spec_FPACC	Meaning
0b0000	The implementation does not disclose whether the speculative use of pointers processed by a PAC Authentication is materially different in terms of the impact on cached microarchitectural state between passing and failing of the PAC Authentication.
0b0001	The speculative use of pointers processed by a PAC Authentication is not materially different in terms of the impact on cached microarchitectural state between passing and failing of the PAC Authentication.

All other values are reserved.

For the purpose of this definition, cached microarchitecture state is the state of caching agents such as instruction caches, data caches and TLBs which can be altered as a result of speculation caused by a mispredicted execution, but is not restored to the state prior to the speculation when the misprediction is corrected.

Access to this field is RO.

Otherwise:

Reserved, RES0.

Bits [59:0]

Reserved, RES0.

Accessing ID_AA64MMFR3_EL1

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, ID_AA64MMFR3_EL1

op0	op1	CRn	CRm	op2
0b11	0b000	0b0000	0b0111	0b011

```
if PSTATE.EL == EL0 then
    if IsFeatureImplemented(FEAT_IDST) then
        AArch64_SystemAccessTrapToEL1orEL2(0x18);
    else
        Undefined();
    end;
elseif PSTATE.EL == EL1 then
    if (!IsZero(ID_AA64MMFR3_EL1()) || ImpDefBool("ID_AA64MMFR3_EL1 trapped by HCR_EL2.TID3")) &&
        ↪HCR_EL2().TID3 == '1' then
        AArch64_SystemAccessTrap(EL2, 0x18);
    else
        X{64}(t) = ID_AA64MMFR3_EL1();
    end;
elseif PSTATE.EL == EL2 then
    X{64}(t) = ID_AA64MMFR3_EL1();
end;
```

D12.2.50 ID_AA64MMFR4_EL1, AArch64 Memory Model Feature Register 4

The ID_AA64MMFR4_EL1 characteristics are:

Purpose

Provides additional information about implemented memory model and memory management support in AArch64.

Configuration

Note
Prior to the introduction of the features described by this register, this register was unnamed and reserved, RES0 from EL1 and EL2.

Attributes

ID_AA64MMFR4_EL1 is a 64-bit register.

Field descriptions

Bits [63:8]

Reserved, RES0.

EIESB, bits [7:4]

When FEAT_IESB is implemented:

Early Implicit Error Synchronization event. Indicates whether the implicit Error synchronization event inserted on taking an exception to ELx when SCTLR_ELx.IESB is 1 is inserted before or after the exception is taken.

The value of this field is an IMPLEMENTATION DEFINED choice of:

EIESB	Meaning
0b1111	When FEAT_IESB is implemented and enabled, SError exceptions are routed to EL3, and either FEAT_DoubleFault is not implemented or the Effective value of SCR_EL3.NMEA is 1, an implicit Error synchronization event might be inserted after an exception is taken to EL3, unless that exception is also an SError exception.
0b0000	FEAT_IESB is not implemented, or behavior is not described.
0b0001	When FEAT_IESB is implemented and enabled, SError exceptions are routed to EL3, and either FEAT_DoubleFault is not implemented or the Effective value of SCR_EL3.NMEA is 1, an implicit Error synchronization event is inserted before an exception taken to EL3, unless that exception is also an SError exception.

EIESB	Meaning
0b0010	As 0b0001, and also: - When FEAT_IESB is implemented and enabled, SError exceptions are routed to EL1, an implicit Error synchronization event is inserted before an exception taken to EL1, unless that exception is also an SError exception. - When FEAT_IESB is implemented and enabled, SError exceptions are routed to EL2, an implicit Error synchronization event is inserted before an exception taken to EL2, unless that exception is also an SError exception.
0b0011	When FEAT_IESB is implemented and enabled, an implicit Error synchronization event is inserted before taking an exception other than an SError exception.

All other values are reserved.

This field describes the PE behavior on taking an exception to ELx when SCTLR_ELx.IESB is 1. This field does not describe the behavior when SCTLR_ELx.IESB is 0.

Inserting the event before the exception is taken means that if the Error synchronization event causes an SError exception to become pending, and SError exceptions are not masked and not disabled, then the SError exception is taken in place of the original exception.

When [FEAT_IESB](#) is not implemented, the only permitted value of this field is 0b0000.

In Armv8-R AArch64, the permitted values are 0b0000, 0b0010 (excluding the behavior defined by 0b0001) and 0b0011.

Access to this field is RO.

Otherwise:

Reserved, RES0.

Bits [3:0]

Reserved, RES0.

Accessing ID_AA64MMFR4_EL1

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, ID_AA64MMFR4_EL1

op0	op1	CRn	CRm	op2
0b11	0b000	0b0000	0b0111	0b100

```

if PSTATE.EL == EL0 then
    if IsFeatureImplemented(FEAT_IDST) then
        AArch64_SystemAccessTrapToEL1orEL2(0x18);
    else
        Undefined();
    end;
elseif PSTATE.EL == EL1 then
    if (!IsZero(ID_AA64MMFR4_EL1()) || ImpDefBool("ID_AA64MMFR4_EL1 trapped by HCR_EL2.TID3")) &&
        ↪HCR_EL2().TID3 == '1' then
        AArch64_SystemAccessTrap(EL2, 0x18);
    else
        X{64}(t) = ID_AA64MMFR4_EL1();
    end;
elseif PSTATE.EL == EL2 then

```

```
X{64}(t) = ID_AA64MMFR4_EL1();  
end;
```

D12.2.51 ID_AA64PFR0_EL1, AArch64 Processor Feature Register 0

The ID_AA64PFR0_EL1 characteristics are:

Purpose

Provides additional information about implemented PE features in AArch64 state.

For general information about the interpretation of the ID registers, see ‘Principles of the ID scheme for fields in ID registers’.

Configuration

The external register EDPFR gives information from this register.

Attributes

ID_AA64PFR0_EL1 is a 64-bit register.

Field descriptions

CSV3, bits [63:60]

Speculative use of faulting data.

The value of this field is an IMPLEMENTATION DEFINED choice of:

CSV3	Meaning
0b0000	This PE does not disclose whether data loaded or read from a register under speculation where the data load or register read would not be permitted architecturally, can be used by instructions newer than the load or register read in a manner that allows the value of the inaccessible data to be recovered by code architecturally executed.
0b0001	Data loaded or read from a register under speculation where the data load or register read would not be permitted architecturally, cannot be used by instructions newer than the load or register read in a manner that allows the value of the inaccessible data to be recovered by code architecturally executed.

All other values are reserved.

FEAT_CSV3 implements the functionality identified by the value 0b0001.

If FEAT_E0PD is implemented, FEAT_CSV3 must be implemented.

From Armv8.5, the value 0b0000 is not permitted.

Access to this field is RO.

CSV2, bits [59:56]

Speculative use of out of context prediction resources.

The value of this field is an IMPLEMENTATION DEFINED choice of:

CSV2	Meaning
0b0000	The implementation does not disclose whether FEAT_CSV2 is implemented.
0b0001	FEAT_CSV2 is implemented, but FEAT_CSV2_2 and FEAT_CSV2_3 are not implemented. ID_AA64PFR1_EL1.CSV2_frac determines whether either or both of FEAT_CSV2_1p1 or FEAT_CSV2_1p2 are implemented.
0b0010	FEAT_CSV2_2 is implemented, but FEAT_CSV2_3 is not implemented.
0b0011	FEAT_CSV2_3 is implemented.

All other values are reserved.

FEAT_CSV2 implements the functionality identified by the value 0b0001.

FEAT_CSV2_2 implements the functionality identified by the value 0b0010.

FEAT_CSV2_3 implements the functionality identified by the feature 0b0011.

Access to this field is RO.

Bits [55:52]

Reserved, RES0.

DIT, bits [51:48]

Data Independent Timing.

The value of this field is an IMPLEMENTATION DEFINED choice of:

All other values are reserved.

FEAT_DIT implements the functionality identified by the value 0b0001.

From Armv8.4, the value 0b0000 is not permitted.

Access to this field is RO.

Bits [47:40]

Reserved, RES0.

SEL2, bits [39:36]

Secure EL2.

The value of this field is an IMPLEMENTATION DEFINED choice of:

SEL2	Meaning
0b0000	Secure EL2 is not implemented.
0b0001	Secure EL2 is implemented.

All other values are reserved.

FEAT_SEL2 implements the functionality identified by the value 0b0001.

From Armv8.4, if Secure state and EL2 are implemented, the value 0b0000 is not permitted.

From Armv8.4, if Secure state is not implemented, or if EL2 is not implemented, the only permitted value is 0b0000.

Access to this field is RO.

Bits [35:32]

Reserved, RES0.

RAS, bits [31:28]

RAS Extension version.

The value of this field is an IMPLEMENTATION DEFINED choice of:

All other values are reserved.

[FEAT_RAS](#) implements the functionality identified by the value 0b0001.

When [ERRIDR_EL1.NUM](#) is zero:

- This field is permitted to have the value 0b0001, regardless of the version of the RAS that is implemented.

When [ERRIDR_EL1.NUM](#) is nonzero:

- [FEAT_RASv1p1](#) implements the functionality identified by the value 0b0010.

From Armv8.2, the value 0b0000 is not permitted.

From Armv8.4, if [FEAT_DoubleFault](#) is implemented or [ERRIDR_EL1.NUM](#) is nonzero, the value 0b0001 is not permitted.

Note

When the value of this field is 0b0001, [ID_AA64PFR1_EL1.RAS_frac](#) indicates whether [FEAT_RASv1p1](#) is implemented.

Access to this field is RO.

GIC, bits [27:24]

System register GIC CPU interface.

The value of this field is an IMPLEMENTATION DEFINED choice of:

GIC	Meaning
0b0000	GIC CPU interface System registers not implemented.
0b0001	System register interface to versions 3.0 and 4.0 of the GIC CPU interface is supported.
0b0011	System register interface to version 4.1 of the GIC CPU interface is supported.

All other values are reserved.

Access to this field is RO.

AdvSIMD, bits [23:20]

Advanced SIMD.

If [FEAT_FP16](#) is implemented, indicates support for the half-precision floating-point arithmetic instructions.

The value of this field is an IMPLEMENTATION DEFINED choice of:

All other values are reserved.

This field must have the same value as the FP field.

[FEAT_AdvSIMD](#) implements the functionality identified by the value 0b0000.

[FEAT_FP16](#) implements the functionality identified by the value 0b0001.

Access to this field is RO.

FP, bits [19:16]

Indicates floating-point support.

If [FEAT_FP16](#) is implemented, indicates support for the half-precision floating-point arithmetic instructions.

The value of this field is an IMPLEMENTATION DEFINED choice of:

All other values are reserved.

This field must have the same value as the AdvSIMD field.

[FEAT_FP](#) implements the functionality identified by the value 0b0000.

[FEAT_FP16](#) implements the functionality identified by the value 0b0001.

Access to this field is RO.

EL3, bits [15:12]

EL3 Exception level handling. In Armv8-R, the only permitted value is 0b0000. All other values are reserved.

EL3	Meaning
0b0000	EL3 is not implemented.

Access to this field is RO.

EL2, bits [11:8]

EL2 Exception level handling. In Armv8-R, the only permitted value is 0b0001. All other values are reserved.

EL2	Meaning
0b0001	EL2 can be executed in AArch64 state only.

Access to this field is RO.

EL1, bits [7:4]

EL1 Exception level handling. In Armv8-R, the only permitted value is 0b0001. All other values are reserved.

EL1	Meaning
0b0001	EL1 can be executed in AArch64 state only.

Access to this field is RO.

EL0, bits [3:0]

EL0 Exception level handling. In Armv8-R, the only permitted value is 0b0001. All other values are reserved.

EL0	Meaning
0b0001	EL0 can be executed in AArch64 state only.

Access to this field is RO.

Accessing ID_AA64PFR0_EL1

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, ID_AA64PFR0_EL1

op0	op1	CRn	CRm	op2
0b11	0b000	0b0000	0b0100	0b000

```
if PSTATE.EL == EL0 then
    if IsFeatureImplemented(FEAT_IDST) then
        AArch64_SystemAccessTraptoEL1orEL2(0x18);
    else
        Undefined();
    end;
elseif PSTATE.EL == EL1 then
    if HCR_EL2().TID3 == '1' then
        AArch64_SystemAccessTrap(EL2, 0x18);
    else
        X{64}(t) = ID_AA64PFR0_EL1();
    end;
elseif PSTATE.EL == EL2 then
    X{64}(t) = ID_AA64PFR0_EL1();
end;
```

D12.2.52 ID_AA64PFR1_EL1, AArch64 Processor Feature Register 1

The ID_AA64PFR1_EL1 characteristics are:

Purpose

Provides additional information about implemented PE features in AArch64 state.

For general information about the interpretation of the ID registers, see ‘Principles of the ID scheme for fields in ID registers’.

Configuration

There are no configuration notes.

Attributes

ID_AA64PFR1_EL1 is a 64-bit register.

Field descriptions

Bits [63:36]

Reserved, RES0.

CSV2_frac, bits [35:32]

CSV2 fractional field.

The value of this field is an IMPLEMENTATION DEFINED choice of:

CSV2_frac	Meaning
0b0000	Either ID_AA64PFR0_EL1.CSV2 is not 0b0001, or the implementation does not disclose whether FEAT_CSV2_1p1 is implemented. FEAT_CSV2_1p2 is not implemented.
0b0001	FEAT_CSV2_1p1 is implemented, but FEAT_CSV2_1p2 is not implemented.
0b0010	FEAT_CSV2_1p2 is implemented.

All other values are reserved.

FEAT_CSV2_1p1 implements the functionality identified by the value 0b0001.

FEAT_CSV2_1p2 implements the functionality identified by the value 0b0010.

In Armv8-R, the permitted values are 0b0000, 0b0001, and 0b0010.

The values 0b0001 and 0b0010 are permitted only when ID_AA64PFR0_EL1.CSV2 is 0b0001.

Access to this field is RO.

Bits [31:16]

Reserved, RES0.

RAS_frac, bits [15:12]

RAS Extension fractional field.

The value of this field is an IMPLEMENTATION DEFINED choice of:

RAS_frac	Meaning
0b0000	If ID_AA64PFR0_EL1.RAS == 0b0001, support for the Reliability, Availability, and Serviceability Extension is implemented.
0b0001	If ID_AA64PFR0_EL1.RAS == 0b0001, as 0b0000 and adds support for: - Additional ERXMISC<m>_EL1 System registers. - Additional System registers ERXPGCDN_EL1, ERXPGCTL_EL1, and ERXPFGF_EL1, and the HCR_EL2.FIEN trap controls, to support the optional RAS Common Fault Injection Model Extension. Error records accessed through System registers conform to RAS System Architecture v1.1, which includes simplifications to ERR<n>STATUS, and support for the optional RAS Timestamp and RAS Common Fault Injection Model Extensions.

All other values are reserved.

[FEAT_RAS](#) implements the functionality identified by the value 0b0000.

When [ERRIDR_EL1.NUM](#) is zero, this field is permitted to have the value 0b0000, regardless of whether [FEAT_RASv1p1](#) is implemented.

When [ERRIDR_EL1.NUM](#) is nonzero, [FEAT_RASv1p1](#) implements the functionality identified by the value 0b0001.

This field is valid only if [ID_AA64PFR0_EL1.RAS](#) == 0b0001.

Access to this field is RO.

Bits [11:8]

Reserved, RES0.

SSBS, bits [7:4]

Speculative Store Bypassing controls in AArch64 state.

The value of this field is an IMPLEMENTATION DEFINED choice of:

SSBS	Meaning
0b0000	AArch64 provides no mechanism to control the use of Speculative Store Bypassing.
0b0001	AArch64 provides the PSTATE.SSBS mechanism to mark regions that are Speculative Store Bypass Safe.
0b0010	As 0b0001, and adds the MSR and MRS instructions to directly read and write the PSTATE.SSBS field.

All other values are reserved.

[FEAT_SSBS](#) implements the functionality identified by the value 0b0001.

[FEAT_SSBS2](#) implements the functionality identified by the value 0b0010.

Access to this field is RO.

Bits [3:0]

Reserved, RES0.

Accessing ID_AA64PFR1_EL1

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, ID_AA64PFR1_EL1

op0	op1	CRn	CRm	op2
0b11	0b000	0b0000	0b0100	0b001

```

if PSTATE.EL == EL0 then
    if IsFeatureImplemented(FEAT_IDST) then
        AArch64_SystemAccessTrapToEL1orEL2(0x18);
    else
        Undefined();
    end;
elseif PSTATE.EL == EL1 then
    if HCR_EL2().TID3 == '1' then
        AArch64_SystemAccessTrap(EL2, 0x18);

        X{64}(t) = ID_AA64PFR1_EL1();
    end;
elseif PSTATE.EL == EL2 then
    X{64}(t) = ID_AA64PFR1_EL1();
end;

```

D12.2.53 ID_AA64PFR2_EL1, AArch64 Processor Feature Register 2

The ID_AA64PFR2_EL1 characteristics are:

Purpose

Provides additional information about implemented PE features in AArch64 state.

For general information about the interpretation of the ID registers, see ‘[Principles of the ID scheme for fields in ID registers](#)’.

Configuration

Note
Prior to the introduction of the features described by this register, this register was unnamed and reserved, RES0 from EL1 and EL2.

Attributes

ID_AA64PFR2_EL1 is a 64-bit register.

Field descriptions

Bits [63:0]

Reserved, RES0.

Accessing ID_AA64PFR2_EL1

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, ID_AA64PFR2_EL1

op0	op1	CRn	CRm	op2
0b11	0b000	0b0000	0b0100	0b010

```
if PSTATE.EL == EL0 then
    if IsFeatureImplemented(FEAT_IDST) then
        AArch64_SystemAccessTrapToEL1orEL2(0x18);
    else
        Undefined();
    end;
elseif PSTATE.EL == EL1 then
    if (!IsZero(ID_AA64PFR2_EL1()) || ImpDefBool("ID_AA64PFR2_EL1 trapped by HCR_EL2.TID3")) &&
        ↪HCR_EL2().TID3 == '1' then
        AArch64_SystemAccessTrap(EL2, 0x18);
    else
        X{64}(t) = ID_AA64PFR2_EL1();
    end;
```

```
elseif PSTATE.EL == EL2 then
    X{64}(t) = ID_AA64PFR2_EL1();
end;
```

D12.2.54 ID_AFR0_EL1, AArch32 Auxiliary Feature Register 0

The ID_AFR0_EL1 characteristics are:

Purpose

Provides information about the IMPLEMENTATION DEFINED features of the PE in AArch32 state.

Must be interpreted with the Main ID Register, [MIDR_EL1](#).

For general information about the interpretation of the ID registers see ‘[Principles of the ID scheme for fields in ID registers](#)’.

Configuration

There are no configuration notes.

Attributes

ID_AFR0_EL1 is a 64-bit register.

Field descriptions

Bits [63:0]

Reserved, UNKNOWN.

Accessing ID_AFR0_EL1

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, ID_AFR0_EL1

op0	op1	CRn	CRm	op2
0b11	0b000	0b0000	0b0001	0b011

```
if PSTATE.EL == EL0 then
    if IsFeatureImplemented(FEAT_IDST) then
        AArch64_SystemAccessTrapToEL1orEL2(0x18);
    else
        Undefined();
    end;
elseif PSTATE.EL == EL1 then
    if HCR_EL2().TID3 == '1' then
        AArch64_SystemAccessTrap(EL2, 0x18);
    else
        X{64}(t) = ID_AFR0_EL1();
    end;
elseif PSTATE.EL == EL2 then
    X{64}(t) = ID_AFR0_EL1();
end;
```

D12.2.55 ID_DFR0_EL1, AArch32 Debug Feature Register 0

The ID_DFR0_EL1 characteristics are:

Purpose

Provides top-level information about the debug system in AArch32 state.

Must be interpreted with the Main ID Register, [MIDR_EL1](#).

For general information about the interpretation of the ID registers see ‘[Principles of the ID scheme for fields in ID registers](#)’.

Configuration

There are no configuration notes.

Attributes

ID_DFR0_EL1 is a 64-bit register.

Field descriptions

Bits [63:0]

Reserved, UNKNOWN.

Accessing ID_DFR0_EL1

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, ID_DFR0_EL1

op0	op1	CRn	CRm	op2
0b11	0b000	0b0000	0b0001	0b010

```
if PSTATE.EL == EL0 then

    else
        Undefined();
    end;
elseif PSTATE.EL == EL1 then
    if HCR_EL2().TID3 == '1' then
        AArch64_SystemAccessTrap(EL2, 0x18);
    else
        X{64}(t) = ID_DFR0_EL1();
    end;
elseif PSTATE.EL == EL2 then
    X{64}(t) = ID_DFR0_EL1();
end;
```

D12.2.56 ID_DFR1_EL1, AArch32 Debug Feature Register 1

The ID_DFR1_EL1 characteristics are:

Purpose

Provides top-level information about the debug system in AArch32.

For general information about the interpretation of the ID registers see ‘[Principles of the ID scheme for fields in ID registers](#)’.

Configuration

Note
Prior to the introduction of the features described by this register, this register was unnamed and reserved, RES0 from EL1 and EL2.

Attributes

ID_DFR1_EL1 is a 64-bit register.

Field descriptions

Bits [63:0]

Reserved, UNKNOWN.

Accessing ID_DFR1_EL1

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, ID_DFR1_EL1

op0	op1	CRn	CRm	op2
0b11	0b000	0b0000	0b0011	0b101

    end;
```

```
elseif PSTATE.EL == EL2 then
    X{64}(t) = ID_DFR1_EL1();
end;
```

D12.2.57 ID_ISAR0_EL1, AArch32 Instruction Set Attribute Register 0

The ID_ISAR0_EL1 characteristics are:

Purpose

Provides information about the instruction sets implemented by the PE in AArch32 state.

Must be interpreted with ID_ISAR1_EL1, ID_ISAR2_EL1, ID_ISAR3_EL1, ID_ISAR4_EL1, and ID_ISAR5_EL1.

For general information about the interpretation of the ID registers see ‘Principles of the ID scheme for fields in ID registers’.

Configuration

There are no configuration notes.

Attributes

ID_ISAR0_EL1 is a 64-bit register.

Field descriptions

Bits [63:0]

Reserved, UNKNOWN.

Accessing ID_ISAR0_EL1

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, ID_ISAR0_EL1

op0	op1	CRn	CRm	op2
0b11	0b000	0b0000	0b0010	0b000

```
if PSTATE.EL == EL0 then

        AArch64_SystemAccessTrap(EL2, 0x18);
    else
        X{64}(t) = ID_ISAR0_EL1();
    end;
elseif PSTATE.EL == EL2 then
```

```
X{64}(t) = ID_ISAR0_EL1();  
end;
```

D12.2.58 ID_ISAR1_EL1, AArch32 Instruction Set Attribute Register 1

The ID_ISAR1_EL1 characteristics are:

Purpose

Provides information about the instruction sets implemented by the PE in AArch32 state.

Must be interpreted with ID_ISAR0_EL1, ID_ISAR2_EL1, ID_ISAR3_EL1, ID_ISAR4_EL1, and ID_ISAR5_EL1.

For general information about the interpretation of the ID registers see ‘Principles of the ID scheme for fields in ID registers’.

Configuration

There are no configuration notes.

Attributes

ID_ISAR1_EL1 is a 64-bit register.

Field descriptions

Bits [63:0]

Reserved, UNKNOWN.

Accessing ID_ISAR1_EL1

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, ID_ISAR1_EL1

op0	op1	CRn	CRm	op2
0b11	0b000	0b0000	0b0010	0b001

```

    end;
elseif PSTATE.EL == EL2 then
```

```
X{64}(t) = ID_ISAR1_EL1();  
end;
```

D12.2.59 ID_ISAR2_EL1, AArch32 Instruction Set Attribute Register 2

The ID_ISAR2_EL1 characteristics are:

Purpose

Provides information about the instruction sets implemented by the PE in AArch32 state.

Must be interpreted with ID_ISAR0_EL1, ID_ISAR1_EL1, ID_ISAR3_EL1, ID_ISAR4_EL1, and ID_ISAR5_EL1.

For general information about the interpretation of the ID registers see ‘Principles of the ID scheme for fields in ID registers’.

Configuration

There are no configuration notes.

Attributes

ID_ISAR2_EL1 is a 64-bit register.

Field descriptions

Bits [63:0]

Reserved, UNKNOWN.

Accessing ID_ISAR2_EL1

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, ID_ISAR2_EL1

op0	op1	CRn	CRm	op2
0b11	0b000	0b0000	0b0010	0b010

```
if PSTATE.EL == EL0 then
    if IsFeatureImplemented(FEAT_IDST) then
        AArch64_SystemAccessTrapToEL1orEL2(0x18);

    end;
elseif PSTATE.EL == EL2 then
```

```
X{64}(t) = ID_ISAR2_EL1();  
end;
```

D12.2.60 ID_ISAR3_EL1, AArch32 Instruction Set Attribute Register 3

The ID_ISAR3_EL1 characteristics are:

Purpose

Provides information about the instruction sets implemented by the PE in AArch32 state.

Must be interpreted with ID_ISAR0_EL1, ID_ISAR1_EL1, ID_ISAR2_EL1, ID_ISAR4_EL1, and ID_ISAR5_EL1.

For general information about the interpretation of the ID registers see ‘Principles of the ID scheme for fields in ID registers’.

Configuration

There are no configuration notes.

Attributes

ID_ISAR3_EL1 is a 64-bit register.

Field descriptions

Bits [63:0]

Reserved, UNKNOWN.

Accessing ID_ISAR3_EL1

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, ID_ISAR3_EL1

op0	op1	CRn	CRm	op2
0b11	0b000	0b0000	0b0010	0b011

```
if PSTATE.EL == EL0 then
    if IsFeatureImplemented(FEAT_IDST) then
        AArch64_SystemAccessTrapToEL1orEL2(0x18);
    else

        X{64}(t) = ID_ISAR3_EL1();
    end;
elseif PSTATE.EL == EL2 then
```

```
X{64}(t) = ID_ISAR3_EL1();  
end;
```

D12.2.61 ID_ISAR4_EL1, AArch32 Instruction Set Attribute Register 4

The ID_ISAR4_EL1 characteristics are:

Purpose

Provides information about the instruction sets implemented by the PE in AArch32 state.

Must be interpreted with ID_ISAR0_EL1, ID_ISAR1_EL1, ID_ISAR2_EL1, ID_ISAR3_EL1, and ID_ISAR5_EL1.

For general information about the interpretation of the ID registers, see ‘Principles of the ID scheme for fields in ID registers’.

Configuration

There are no configuration notes.

Attributes

ID_ISAR4_EL1 is a 64-bit register.

Field descriptions

Bits [63:0]

Reserved, UNKNOWN.

Accessing ID_ISAR4_EL1

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, ID_ISAR4_EL1

op0	op1	CRn	CRm	op2
0b11	0b000	0b0000	0b0010	0b100

```
if PSTATE.EL == EL0 then
    if IsFeatureImplemented(FEAT_IDST) then
        AArch64_SystemAccessTrapToEL1orEL2(0x18);
    else

    end;
elseif PSTATE.EL == EL2 then
```

```
X{64}(t) = ID_ISAR4_EL1();  
end;
```

D12.2.62 ID_ISAR5_EL1, AArch32 Instruction Set Attribute Register 5

The ID_ISAR5_EL1 characteristics are:

Purpose

Provides information about the instruction sets implemented by the PE in AArch32 state.

Must be interpreted with ID_ISAR0_EL1, ID_ISAR1_EL1, ID_ISAR2_EL1, ID_ISAR3_EL1, and ID_ISAR4_EL1.

For general information about the interpretation of the ID registers see ‘Principles of the ID scheme for fields in ID registers’.

Configuration

There are no configuration notes.

Attributes

ID_ISAR5_EL1 is a 64-bit register.

Field descriptions

Bits [63:0]

Reserved, UNKNOWN.

Accessing ID_ISAR5_EL1

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, ID_ISAR5_EL1

op0	op1	CRn	CRm	op2
0b11	0b000	0b0000	0b0010	0b101

```
if PSTATE.EL == EL0 then

        X{64}(t) = ID_ISAR5_EL1();
    end;
elseif PSTATE.EL == EL2 then
```

```
X{64}(t) = ID_ISAR5_EL1();  
end;
```

D12.2.63 ID_ISAR6_EL1, AArch32 Instruction Set Attribute Register 6

The ID_ISAR6_EL1 characteristics are:

Purpose

Provides information about the instruction sets implemented by the PE in AArch32 state.

Must be interpreted with ID_ISAR0_EL1, ID_ISAR1_EL1, ID_ISAR2_EL1, ID_ISAR3_EL1, ID_ISAR4_EL1 and ID_ISAR5_EL1.

For general information about the interpretation of the ID registers see ‘Principles of the ID scheme for fields in ID registers’.

Configuration

Note
Prior to the introduction of the features described by this register, this register was unnamed and reserved, RES0 from EL1 and EL2.

Attributes

ID_ISAR6_EL1 is a 64-bit register.

Field descriptions

Bits [63:0]

Reserved, UNKNOWN.

Accessing ID_ISAR6_EL1

Accesses to this register use the following encodings in the System register encoding space:

```

D12.2.68 ID_MMFR4_EL1, AArch32 Memory Model Feature Register 4

The ID_MMFR4_EL1 characteristics are:

Purpose

Provides information about the implemented memory model and memory management support in AArch32 state.

For general information about the interpretation of the ID registers see ‘[Principles of the ID scheme for fields in ID registers](#)’.

Configuration

Note
Prior to the introduction of the features described by this register, this register was unnamed and reserved, RES0 from EL1 and EL2.

Attributes

ID_MMFR4_EL1 is a 64-bit register.

Field descriptions

Bits [63:0]

Reserved, UNKNOWN.

Accessing ID_MMFR4_EL1

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, ID_MMFR4_EL1

op0	op1	CRn	CRm	op2
0b11	0b000	0b0000	0b0010	0b110

```
if PSTATE.EL == EL0 then
    if IsFeatureImplemented(FEAT_IDST) then
        AArch64_SystemAccessTraptoEL1orEL2(0x18);
    else
        Undefined();
    end;
elseif PSTATE.EL == EL1 then
    if (!IsZero(ID_MMFR4_EL1()) || ImpDefBool("ID_MMFR4_EL1 trapped by HCR_EL2.TID3")) && HCR_EL2().TID3
        == '1' then
        AArch64_SystemAccessTrap(EL2, 0x18);
    else
        X{64}(t) = ID_MMFR4_EL1();
    end;
end;
```

```
elseif PSTATE.EL == EL2 then
    X{64}(t) = ID_MMFR4_EL1();
end;
```

D12.2.69 ID_MMFR5_EL1, AArch32 Memory Model Feature Register 5

The ID_MMFR5_EL1 characteristics are:

Purpose

Provides information about the implemented memory model and memory management support in AArch32 state.

For general information about the interpretation of the ID registers, see ‘[Principles of the ID scheme for fields in ID registers](#)’.

Configuration

Note

Prior to the introduction of the features described by this register, this register was unnamed and reserved, RES0 from EL1 and EL2.

Attributes

ID_MMFR5_EL1 is a 64-bit register.

Field descriptions

Bits [63:0]

Reserved, UNKNOWN.

Accessing ID_MMFR5_EL1

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, ID_MMFR5_EL1

op0	op1	CRn	CRm	op2
0b11	0b000	0b0000	0b0011	0b110

```
if PSTATE.EL == EL0 then
    if IsFeatureImplemented(FEAT_IDST) then
        AArch64_SystemAccessTrapToEL1orEL2(0x18);
    else
        Undefined();
    end;
elseif PSTATE.EL == EL1 then
    if (!IsZero(ID_MMFR5_EL1()) || ImpDefBool("ID_MMFR5_EL1 trapped by HCR_EL2.TID3")) && HCR_EL2().TID3
        == '1' then
        AArch64_SystemAccessTrap(EL2, 0x18);
    else
        X{64}(t) = ID_MMFR5_EL1();
    end;
end;
```

```
elseif PSTATE.EL == EL2 then
    X{64}(t) = ID_MMFR5_EL1();
end;
```

D12.2.70 ID_PFR0_EL1, AArch32 Processor Feature Register 0

The ID_PFR0_EL1 characteristics are:

Purpose

Gives top-level information about the instruction sets supported by the PE in AArch32 state.

Must be interpreted with ID_PFR1_EL1.

For general information about the interpretation of the ID registers, see ‘Principles of the ID scheme for fields in ID registers’.

Configuration

There are no configuration notes.

Attributes

ID_PFR0_EL1 is a 64-bit register.

Field descriptions

Bits [63:0]

Reserved, UNKNOWN.

Accessing ID_PFR0_EL1

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, ID_PFR0_EL1

op0	op1	CRn	CRm	op2
0b11	0b000	0b0000	0b0001	0b000

```
if PSTATE.EL == EL0 then
    if IsFeatureImplemented(FEAT_IDST) then
        AArch64_SystemAccessTrapToEL1orEL2(0x18);
    else
        Undefined();
    end;
elseif PSTATE.EL == EL1 then
    if HCR_EL2().TID3 == '1' then
        AArch64_SystemAccessTrap(EL2, 0x18);
    else
        X{64}(t) = ID_PFR0_EL1();
    end;
elseif PSTATE.EL == EL2 then
    X{64}(t) = ID_PFR0_EL1();
end;
```

D12.2.71 ID_PFR1_EL1, AArch32 Processor Feature Register 1

The ID_PFR1_EL1 characteristics are:

Purpose

Gives information about the AArch32 programmers' model.

Must be interpreted with [ID_PFR0_EL1](#).

For general information about the interpretation of the ID registers see 'Principles of the ID scheme for fields in ID registers'.

Configuration

There are no configuration notes.

Attributes

ID_PFR1_EL1 is a 64-bit register.

Field descriptions

Bits [63:0]

Reserved, UNKNOWN.

Accessing ID_PFR1_EL1

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, ID_PFR1_EL1

op0	op1	CRn	CRm	op2
0b11	0b000	0b0000	0b0001	0b001

```
if PSTATE.EL == EL0 then
    if IsFeatureImplemented(FEAT_IDST) then
        AArch64_SystemAccessTraptToEL1orEL2(0x18);
    else
        Undefined();
    end;
elseif PSTATE.EL == EL1 then
    if HCR_EL2().TID3 == '1' then
        AArch64_SystemAccessTrap(EL2, 0x18);
    else
        X{64}(t) = ID_PFR1_EL1();
    end;
elseif PSTATE.EL == EL2 then
    X{64}(t) = ID_PFR1_EL1();
end;
```

D12.2.72 ID_PFR2_EL1, AArch32 Processor Feature Register 2

The ID_PFR2_EL1 characteristics are:

Purpose

Gives information about the AArch32 programmers’ model.

Must be interpreted with ID_PFR0_EL1 and ID_PFR1_EL1.

For general information about the interpretation of the ID registers see ‘Principles of the ID scheme for fields in ID registers’.

Configuration

Note

Prior to the introduction of the features described by this register, this register was unnamed and reserved, RES0 from EL1 and EL2.

Attributes

ID_PFR2_EL1 is a 64-bit register.

Field descriptions

Bits [63:0]

Reserved, UNKNOWN.

Accessing ID_PFR2_EL1

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, ID_PFR2_EL1

op0	op1	CRn	CRm	op2
0b11	0b000	0b0000	0b0011	0b100

```
if PSTATE.EL == EL0 then
    if IsFeatureImplemented(FEAT_IDST) then
        AArch64_SystemAccessTrapToEL1orEL2(0x18);
    else
        Undefined();
    end;
elseif PSTATE.EL == EL1 then
    if (!IsZero(ID_PFR2_EL1()) || ImpDefBool("ID_PFR2_EL1 trapped by HCR_EL2.TID3")) && HCR_EL2().TID3
        == '1' then
        AArch64_SystemAccessTrap(EL2, 0x18);
    else
```

```
        X{64}(t) = ID_PFR2_EL1();  
    end;  
    elsif PSTATE.EL == EL2 then  
        X{64}(t) = ID_PFR2_EL1();  
    end;
```

D12.2.73 **ISR_EL1, Interrupt Status Register**

The ISR_EL1 characteristics are:

Purpose

Shows the pending status of IRQ and FIQ interrupts and SError exceptions.

Configuration

There are no configuration notes.

Attributes

ISR_EL1 is a 64-bit register.

Field descriptions

Bits [63:9]

Reserved, RES0.

A, bit [8]

SError exception pending bit. Indicates whether an SError exception is pending.

A	Meaning
0b0	No pending SError.
0b1	An SError exception is pending.

If all of the following apply, then this field shows the pending status of virtual SError exceptions:

- [HCR_EL2.AMO](#) is 1.
- The PE is executing at EL1.

Otherwise, this field shows the pending status of physical SError exceptions.

If the physical SError exception is edge-triggered, this field is cleared to zero when the physical SError exception is taken.

I, bit [7]

IRQ pending bit. Indicates whether an IRQ interrupt is pending.

I	Meaning
0b0	No pending IRQ.
0b1	An IRQ interrupt is pending.

If all of the following apply, then this field shows the pending status of virtual IRQ interrupts:

- [HCR_EL2](#).IMO is 1.
- The PE is executing at EL1.

Otherwise, this field shows the pending status of physical IRQ interrupts.

F, bit [6]

FIQ pending bit. Indicates whether an FIQ interrupt is pending.

F	Meaning
0b0	No pending FIQ.
0b1	An FIQ interrupt is pending.

If all of the following apply, then this field shows the pending status of virtual FIQ interrupts:

- [HCR_EL2](#).FMO is 1.
- The PE is executing at EL1.

Otherwise, this field shows the pending status of physical FIQ interrupts.

Bits [5:0]

Reserved, RES0.

Accessing ISR_EL1

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, ISR_EL1

op0	op1	CRn	CRm	op2
0b11	0b000	0b1100	0b0001	0b000

```

if PSTATE.EL == EL0 then
    Undefined();
elsif PSTATE.EL == EL1 then
    X{64}(t) = ISR_EL1();
elsif PSTATE.EL == EL2 then
    X{64}(t) = ISR_EL1();
end;
```

D12.2.74 MAIR_EL1, Memory Attribute Indirection Register (EL1)

The MAIR_EL1 characteristics are:

Purpose

If VMSAv8-64 is enabled at stage 1 of EL1&0 translation regime, this register provides the memory attribute encodings corresponding to the possible AttrIdx values in a Long-descriptor format translation table entry for stage 1 translations at EL1.

If PMSAv8-64 is enabled at stage 1 of EL1&0 translation regime, this register provides the memory attribute encodings corresponding to the possible AttrIdx values in [PRLAR_EL1](#) register for stage 1 translations.

Configuration

There are no configuration notes.

Attributes

MAIR_EL1 is a 64-bit register.

Field descriptions

MAIR_EL1 is permitted to be cached in a TLB.

Attr<n> , bits [8n+7:8n], for n = 7 to 0

The memory attribute encoding for an AttrIdx[2:0] gives the value of <n> in Attr<n>.

Attr is encoded as follows:

Attr	Meaning
‘0000dd00’	Device memory. See encoding of ‘dd’ for the type of Device memory.
‘0000ddxx’ where xx != 00	UNPREDICTABLE.
‘ooooiiii’ where oooo != 0000 and iiii != 0000	Normal memory. See encoding of ‘oooo’ and ‘iiii’ for the type of Normal memory.
‘xxxx0000’ where xxxx != 0000	UNPREDICTABLE.

dd is encoded as follows:

‘dd’	Meaning
‘00’	Device-nGnRnE memory.

'dd'	Meaning
'01'	Device-nGnRE memory.
'10'	Device-nGRE memory.
'11'	Device-GRE memory.

oooo is encoded as follows:

'oooo'		Meaning
'0000'		See encoding of Attr.
'00RW'	where RW != 00	Normal memory, Outer Write-Through Transient.
'0100'		Normal memory, Outer Non-cacheable.
'01RW'	where RW != 00	Normal memory, Outer Write-Back Transient.
'10RW'		Normal memory, Outer Write-Through Non-transient.
'11RW'		Normal memory, Outer Write-Back Non-transient.

R encodes the Outer Read-Allocate policy and W encodes the Outer Write-Allocate policy.

iiii is encoded as follows:

'iiii'		Meaning
'0000'		See encoding of Attr.
'00RW'	where RW != 00	Normal memory, Inner Write-Through Transient.
'0100'		Normal memory, Inner Non-cacheable.
'01RW'	where RW != 00	Normal memory, Inner Write-Back Transient.
'10RW'		Normal memory, Inner Write-Through Non-transient.
'11RW'		Normal memory, Inner Write-Back Non-transient.

R encodes the Inner Read-Allocate policy and W encodes the Inner Write-Allocate policy.

In oooo and iiii, R and W are encoded as follows:

'R' or 'W'	Meaning
'0'	No Allocate.
'1'	Allocate.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing MAIR_EL1

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, MAIR_EL1

op0	op1	CRn	CRm	op2
0b11	0b000	0b1010	0b0010	0b000

```

if PSTATE.EL == EL0 then
    Undefined();
elsif PSTATE.EL == EL1 then
    if HCR_EL2().TRVM == '1' then
        AArch64_SystemAccessTrap(EL2, 0x18);
    else
        X{64}(t) = MAIR_EL1();
    end;
elsif PSTATE.EL == EL2 then
    X{64}(t) = MAIR_EL1();
end;

```

MSR MAIR_EL1, <Xt>

op0	op1	CRn	CRm	op2
0b11	0b000	0b1010	0b0010	0b000

```

if PSTATE.EL == EL0 then
    Undefined();
elsif PSTATE.EL == EL1 then
    if HCR_EL2().TVM == '1' then
        AArch64_SystemAccessTrap(EL2, 0x18);
    else
        MAIR_EL1() = X{64}(t);
    end;
elsif PSTATE.EL == EL2 then
    MAIR_EL1() = X{64}(t);
end;

```

D12.2.75 MAIR_EL2, Memory Attribute Indirection Register (EL2)

The MAIR_EL2 characteristics are:

Purpose

Provides the memory attribute encodings corresponding to the possible AttrIdx values in [PRLAR_EL2](#) for stage 1 EL2 translation regime and for stage 2 EL1&0 translation regime.

For stage 2 EL1&0 translations, the memory attributes are derived from MAIR_EL2 register as described in the Armv8-R AArch64 architecture.

Configuration

There are no configuration notes.

Attributes

MAIR_EL2 is a 64-bit register.

Field descriptions

MAIR_EL2 is permitted to be cached in a TLB.

Attr<n>, bits [8n+7:8n], for n = 7 to 0

The memory attribute encoding for an AttrIdx[2:0] gives the value of <n> in Attr<n>.

Attr is encoded as follows:

Attr	Meaning
'0000dd00'	Device memory. See encoding of 'dd' for the type of Device memory.
'0000ddxx' where xx != 00	UNPREDICTABLE.
'ooooiiii' where oooo != 0000 and iiii != 0000	Normal memory. See encoding of 'oooo' and 'iiii' for the type of Normal memory.
'xxxx0000' where xxxx != 0000	UNPREDICTABLE.

dd is encoded as follows:

'dd'	Meaning
'00'	Device-nGnRnE memory.
'01'	Device-nGnRE memory.

'dd'	Meaning
'10'	Device-nGRE memory.
'11'	Device-GRE memory.

oooo is encoded as follows:

'oooo'		Meaning
'0000'		See encoding of Attr.
'00RW'	where RW != 00	Normal memory, Outer Write-Through Transient.
'0100'		Normal memory, Outer Non-cacheable.
'01RW'	where RW != 00	Normal memory, Outer Write-Back Transient.
'10RW'		Normal memory, Outer Write-Through Non-transient.
'11RW'		Normal memory, Outer Write-Back Non-transient.

R encodes the Outer Read-Allocate policy and W encodes the Outer Write-Allocate policy.

iiii is encoded as follows:

'iiii'		Meaning
'0000'		See encoding of Attr.
'00RW'	where RW != 00	Normal memory, Inner Write-Through Transient.
'0100'		Normal memory, Inner Non-cacheable.
'01RW'	where RW != 00	Normal memory, Inner Write-Back Transient.
'10RW'		Normal memory, Inner Write-Through Non-transient.
'11RW'		Normal memory, Inner Write-Back Non-transient.

R encodes the Inner Read-Allocate policy and W encodes the Inner Write-Allocate policy.

In oooo and iiii, R and W are encoded as follows:

'R' or 'W'	Meaning
'0'	No Allocate.
'1'	Allocate.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing MAIR_EL2

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, MAIR_EL2

op0	op1	CRn	CRm	op2
0b11	0b100	0b1010	0b0010	0b000

```

if PSTATE.EL == EL0 then
    Undefined();
elsif PSTATE.EL == EL1 then
    Undefined();
elsif PSTATE.EL == EL2 then
    X{64}(t) = MAIR_EL2();
end;

```

MSR MAIR_EL2, <Xt>

op0	op1	CRn	CRm	op2
0b11	0b100	0b1010	0b0010	0b000

```

if PSTATE.EL == EL0 then
    Undefined();
elsif PSTATE.EL == EL1 then
    Undefined();
elsif PSTATE.EL == EL2 then
    MAIR_EL2() = X{64}(t);
end;

```

MRS <Xt>, MAIR_EL1

op0	op1	CRn	CRm	op2
0b11	0b000	0b1010	0b0010	0b000

```

if PSTATE.EL == EL0 then
    Undefined();
elsif PSTATE.EL == EL1 then
    if HCR_EL2().TRVM == '1' then
        AArch64_SystemAccessTrap(EL2, 0x18);
    else
        X{64}(t) = MAIR_EL1();
    end;
elsif PSTATE.EL == EL2 then
    X{64}(t) = MAIR_EL1();
end;

```

MSR MAIR_EL1, <Xt>

op0	op1	CRn	CRm	op2
0b11	0b000	0b1010	0b0010	0b000

```
if PSTATE.EL == EL0 then
    Undefined();
elsif PSTATE.EL == EL1 then
    if HCR_EL2().TVM == '1' then
        AArch64_SystemAccessTrap(EL2, 0x18);
    else
        MAIR_EL1() = X{64}(t);
    end;
elsif PSTATE.EL == EL2 then
    MAIR_EL1() = X{64}(t);
end;
```

D12.2.76 MIDR_EL1, Main ID Register

The MIDR_EL1 characteristics are:

Purpose

Provides identification information for the PE, including an implementer code for the device and a device ID number.

Configuration

AArch64 System register MIDR_EL1 bits [31:0] are architecturally mapped to External register [MIDR_EL1](#)[31:0].

Attributes

MIDR_EL1 is a 64-bit register.

Field descriptions

Bits [63:32]

Reserved, RES0.

Implementer, bits [31:24]

The Implementer code. This field must hold an implementer code that has been assigned by Arm.

The value of this field is an IMPLEMENTATION DEFINED choice of:

Implementer	Meaning
0x00	Reserved for software use.
0x41	Arm Limited.
0x42	Broadcom Corporation.
0x43	Cavium Inc.
0x44	Digital Equipment Corporation.
0x46	Fujitsu Ltd.
0x49	Infineon Technologies AG.
0x4D	Motorola or Freescale Semiconductor Inc.
0x4E	NVIDIA Corporation.
0x50	Applied Micro Circuits Corporation.
0x51	Qualcomm Inc.
0x56	Marvell International Ltd.

Implementer	Meaning
0x69	Intel Corporation.
0xC0	Ampere Computing.

Arm can assign codes that are not published in this manual. All values not assigned by Arm are reserved and must not be used.

Access to this field is RO.

Variant, bits [23:20]

Variant number. Typically, this field is used to distinguish between different product variants, or major revisions of a product.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

Architecture, bits [19:16]

Architecture version.

The value of this field is an IMPLEMENTATION DEFINED choice of:

Architecture	Meaning
0b0001	Armv4.
0b0010	Armv4T.
0b0011	Armv5 (obsolete).
0b0100	Armv5T.
0b0101	Armv5TE.
0b0110	Armv5TEJ.
0b0111	Armv6.
0b1111	Architectural features are individually identified in the ID_* registers.

All other values are reserved.

Access to this field is RO.

PartNum, bits [15:4]

Primary Part Number for the device.

On processors implemented by Arm, if the top four bits of the primary part number are 0x0 or 0x7, the variant and architecture are encoded differently.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

Revision, bits [3:0]

Revision number for the device.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

Accessing MIDR_EL1

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, MIDR_EL1

op0	op1	CRn	CRm	op2
0b11	0b000	0b0000	0b0000	0b000

```
if PSTATE.EL == EL0 then
    if IsFeatureImplemented(FEAT_IDST) then
        AArch64_SystemAccessTraptToEL1orEL2(0x18);
    else
        Undefined();
    end;
elseif PSTATE.EL == EL1 then
    X{64}(t) = VPIDR_EL2();
elseif PSTATE.EL == EL2 then
    X{64}(t) = MIDR_EL1();
end;
```

D12.2.77 MPIDR_EL1, Multiprocessor Affinity Register

The MPIDR EL1 characteristics are:

Purpose

In a multiprocessor system, provides an additional PE identification mechanism.

Configuration

In a uniprocessor system, Arm recommends that each Aff<n> field of this register returns a value of 0.

Attributes

MPIDR_EL1 is a 64-bit register.

Field descriptions

**Bits [63:40]**

Reserved, RES0.

Aff3, bits [39:32]

Affinity level 3. See the description of Aff0 for more information.

Aff3 is not supported in AArch32 state.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

Bit [31]

Reserved, RES1.

U, bit [30]

Indicates a Uniprocessor system, as distinct from PE 0 in a multiprocessor system.

The value of this field is an IMPLEMENTATION DEFINED choice of:

U	Meaning
0b0	Processor is part of a multiprocessor system.
0b1	Processor is part of a uniprocessor system.

Access to this field is RO.

Bits [29:25]

Reserved, RES0.

MT, bit [24]

Indicates whether the lowest level of affinity consists of logical PEs that are implemented using an interdependent approach, such as multithreading. See the description of Aff0 for more information about affinity levels.

The value of this field is an IMPLEMENTATION DEFINED choice of:

MT	Meaning
0b0	Performance of PEs with different affinity level 0 values, and the same values for affinity level 1 and higher, is largely independent.
0b1	Performance of PEs with different affinity level 0 values, and the same values for affinity level 1 and higher, is very interdependent.

Note

This field does not indicate that multithreading is implemented and does not indicate that PEs with different affinity level 0 values, and the same values for affinity level 1 and higher are implemented.

Access to this field is RO.

Aff2, bits [23:16]

Affinity level 2. See the description of Aff0 for more information.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

Aff1, bits [15:8]

Affinity level 1. See the description of Aff0 for more information.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

Aff0, bits [7:0]

Affinity level 0. The value of the MPIDR.{Aff2, Aff1, Aff0} or [MPIDR_EL1](#).{Aff3, Aff2, Aff1, Aff0} set of fields of each PE must be unique within the system as a whole.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

Accessing MPIDR_EL1

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, MPIDR_EL1

op0	op1	CRn	CRm	op2
0b11	0b000	0b0000	0b0000	0b101

```
if PSTATE.EL == EL0 then
    if IsFeatureImplemented(FEAT_IDST) then
        AArch64_SystemAccessTrapToEL1orEL2(0x18);
    else
        Undefined();
    end;
elsif PSTATE.EL == EL1 then
    X{64}(t) = VMPIDR_EL2();
elsif PSTATE.EL == EL2 then
    X{64}(t) = MPIDR_EL1();
end;
```

D12.2.78 MVFR0_EL1, AArch32 Media and VFP Feature Register 0

The MVFR0_EL1 characteristics are:

Purpose

Describes the features provided by the AArch32 Advanced SIMD and floating-point implementation.

Must be interpreted with [MVFR1_EL1](#) and [MVFR2_EL1](#).

For general information about the interpretation of the ID registers see ‘[Principles of the ID scheme for fields in ID registers](#)’.

Configuration

In an implementation where at least one Exception level supports execution in AArch32 state, but there is no support for Advanced SIMD and floating-point operation, this register is RAZ.

Attributes

MVFR0_EL1 is a 64-bit register.

Field descriptions

Bits [63:0]

Reserved, UNKNOWN.

Accessing MVFR0_EL1

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, MVFR0_EL1

op0	op1	CRn	CRm	op2
0b11	0b000	0b0000	0b0011	0b000

```
if PSTATE.EL == EL0 then
    if IsFeatureImplemented(FEAT_IDST) then
        AArch64_SystemAccessTraptoEL1orEL2(0x18);
    else
        Undefined();
    end;
elseif PSTATE.EL == EL1 then
    if HCR_EL2().TID3 == '1' then
        AArch64_SystemAccessTrap(EL2, 0x18);
    else
        X{64}(t) = MVFR0_EL1();
    end;
elseif PSTATE.EL == EL2 then
```

```
X{64}(t) = MVFR0_EL1();  
end;
```

D12.2.79 MVFR1_EL1, AArch32 Media and VFP Feature Register 1

The MVFR1_EL1 characteristics are:

Purpose

Describes the features provided by the AArch32 Advanced SIMD and floating-point implementation.

Must be interpreted with [MVFR0_EL1](#) and [MVFR2_EL1](#).

For general information about the interpretation of the ID registers see ‘[Principles of the ID scheme for fields in ID registers](#)’.

Configuration

In an implementation where at least one Exception level supports execution in AArch32 state, but there is no support for Advanced SIMD and floating-point operation, this register is RAZ.

Attributes

MVFR1_EL1 is a 64-bit register.

Field descriptions

Bits [63:0]

Reserved, UNKNOWN.

Accessing MVFR1_EL1

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, MVFR1_EL1

op0	op1	CRn	CRm	op2
0b11	0b000	0b0000	0b0011	0b001

```
if PSTATE.EL == EL0 then
    if IsFeatureImplemented(FEAT_IDST) then
        AArch64_SystemAccessTrapToEL1orEL2(0x18);
    else
        Undefined();
    end;
elseif PSTATE.EL == EL1 then
    if HCR_EL2().TID3 == '1' then
        AArch64_SystemAccessTrap(EL2, 0x18);
    else
        X{64}(t) = MVFR1_EL1();
    end;
elseif PSTATE.EL == EL2 then
```

```
X{64}(t) = MVFR1_EL1();  
end;
```

D12.2.80 MVFR2_EL1, AArch32 Media and VFP Feature Register 2

The MVFR2_EL1 characteristics are:

Purpose

Describes the features provided by the AArch32 Advanced SIMD and floating-point implementation.

Must be interpreted with [MVFR0_EL1](#) and [MVFR1_EL1](#).

For general information about the interpretation of the ID registers, see [‘Principles of the ID scheme for fields in ID registers’](#).

Configuration

In an implementation where at least one Exception level supports execution in AArch32 state, but there is no support for Advanced SIMD and floating-point operation, this register is RAZ.

Attributes

MVFR2_EL1 is a 64-bit register.

Field descriptions

Bits [63:0]

Reserved, UNKNOWN.

Accessing MVFR2_EL1

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, MVFR2_EL1

op0	op1	CRn	CRm	op2
0b11	0b000	0b0000	0b0011	0b010

```
if PSTATE.EL == EL0 then
    if IsFeatureImplemented(FEAT_IDST) then
        AArch64_SystemAccessTraptoEL1orEL2(0x18);
    else
        Undefined();
    end;
elseif PSTATE.EL == EL1 then
    if HCR_EL2().TID3 == '1' then
        AArch64_SystemAccessTrap(EL2, 0x18);
    else
        X{64}(t) = MVFR2_EL1();
    end;
elseif PSTATE.EL == EL2 then
```

```
X{64}(t) = MVFR2_EL1();  
end;
```

D12.2.81 PAR_EL1, Physical Address Register

The PAR_EL1 characteristics are:

Purpose

Returns the output address (OA) from an Address translation instruction that executed successfully, or fault information if the instruction did not execute successfully.

Configuration

There are no configuration notes.

Attributes

PAR_EL1 is a 64-bit register.

Field descriptions

When `GetPAR_EL1_F() == '0'`:

This section describes the register value returned by the successful execution of an Address translation instruction. Software might subsequently write a different value to the register, and that write does not affect the operation of the PE.

On a successful conversion, the PAR_EL1 can return a value that indicates the resulting attributes, rather than the values that appear in the Translation table descriptors. More precisely:

- The PAR_EL1.{ATTR, SH} fields are permitted to report the resulting attributes, as determined by any permitted implementation choices and any applicable configuration bits, instead of reporting the values that appear in the Translation table descriptors.
- See the PAR_EL1.NS bit description for constraints on the value it returns.

ATTR, bits [63:56]

Memory attributes for the returned output address. This field uses the same encoding as the Attr<n> fields in [MAIR_EL1](#), and [MAIR_EL2](#).

The value returned in this field can be the resulting attribute that is actually implemented by the implementation, as determined by any permitted implementation choices and any applicable configuration bits, instead of the value that appears in the Translation table descriptor.

Note

The attributes presented are consistent with the stages of translation applied in the address translation instruction. If the instruction performed a stage 1 translation only, the attributes are from the stage 1 translation. If the instruction performed a stage 1 and stage 2 translation, the attributes are from the combined stage 1 and stage 2 translation.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [55:52, 6:4]

Reserved, RES0.

PA[51:48], bits [51:48]

When FEAT_LPA is implemented:

Extension to PA[47:12]. For more information, see PA[47:12].

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

PA[47:12], bits [47:12]

Output address. The output address (OA) corresponding to the supplied input address. This field returns address bits[47:12].

When [FEAT_LPA](#) is implemented and 52-bit addresses are in use, PA[51:48] forms the upper part of the address value. Otherwise, when 52-bit addresses are not in use, PA[51:48] is RES0.

For implementations with fewer than 48 physical address bits, the corresponding upper bits in this field are RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [11]

Reserved, RES1.

IMPLEMENTATION DEFINED, bit [10]

IMPLEMENTATION DEFINED.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

NS, bit [9]

Non-secure. The NS attribute for a translation table entry from a Secure translation regime.

This bit distinguishes between the Secure and Non-secure intermediate physical address space of the translation for the instructions:

- In AArch64 state: [AT S1E1R](#), [AT S1E1W](#), [AT S1E1RP](#), [AT S1E1WP](#), [AT S1E0R](#), and [AT S1E0W](#).

Otherwise, this bit reflects the Security state of the physical address space of the translation. This means it reflects the effect of the NSTable bits of earlier levels of the translation table walk if those NSTable bits have an effect on the translation.

For a result from a Non-secure translation regime, this bit is UNKNOWN.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

SH, bits [8:7]

Shareability attribute, for the returned output address.

SH	Meaning
0b00	Non-shareable.
0b10	Outer Shareable.
0b11	Inner Shareable.

The value 0b01 is reserved.

Note

This field returns the value 0b10 for:

- Any type of Device memory.
- Normal memory with both Inner Non-cacheable and Outer Non-cacheable attributes.

The value returned in this field can be the resulting attribute, as determined by any permitted implementation choices and any applicable configuration bits, instead of the value that appears in the Translation table descriptor.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [3:1]

Reserved, RES0.

F, bit [0]

Indicates whether the instruction performed a successful address translation.

F	Meaning
0b0	Address translation completed successfully.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

When GetPAR_EL1_F0 == '1':

This section describes the register value returned by a fault on the execution of an Address translation instruction. Software might subsequently write a different value to the register, and that write does not affect the operation of the PE.

IMPLEMENTATION DEFINED, bits [63:56]

IMPLEMENTATION DEFINED.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

IMPLEMENTATION DEFINED, bits [55:52]

IMPLEMENTATION DEFINED.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

IMPLEMENTATION DEFINED, bits [51:48]

IMPLEMENTATION DEFINED.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [47:12]

Reserved, RES0.

Bit [11]

Reserved, RES1.

Bit [10]

Reserved, RES0.

S, bit [9]

Indicates the translation stage at which the translation aborted:

S	Meaning
0b0	Translation aborted because of a fault in the stage 1 translation.
0b1	Translation aborted because of a fault in the stage 2 translation.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

PTW, bit [8]

If this bit is set to 1, it indicates the translation aborted because of a stage 2 fault during a stage 1 translation table walk.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [7]

Reserved, RES0.

FST, bits [6:1]

Fault status code, as shown in the Data Abort exception ESR encoding.

FST	Meaning	Applies when
0b000000	Address size fault, level 0 of translation or translation table base register.	
0b000001	Address size fault, level 1.	
0b000010	Address size fault, level 2.	
0b000011	Address size fault, level 3.	
0b000100	Translation fault, level 0.	
0b000101	Translation fault, level 1.	
0b000110	Translation fault, level 2.	
0b000111	Translation fault, level 3.	
0b001001	Access flag fault, level 1.	
0b001010	Access flag fault, level 2.	
0b001011	Access flag fault, level 3.	
0b001100	Permission fault, level 0.	
0b001101	Permission fault, level 1.	
0b001110	Permission fault, level 2.	
0b001111	Permission fault, level 3.	
0b011100	Synchronous parity or ECC error on memory access on translation table walk or hardware update of translation table, level 0.	FEAT_RAS is not implemented
0b011101	Synchronous parity or ECC error on memory access on translation table walk or hardware update of translation table, level 1.	FEAT_RAS is not implemented
0b011110	Synchronous parity or ECC error on memory access on translation table walk or hardware update of translation table, level 2.	FEAT_RAS is not implemented
0b011111	Synchronous parity or ECC error on memory access on translation table walk or hardware update of translation table, level 3.	FEAT_RAS is not implemented
0b110000	TLB conflict abort.	
0b110001	Unsupported atomic hardware update fault.	FEAT_HAF is implemented

Note

The encodings for FST do not include Synchronous External abort on translation table walk or hardware update of translation table, because these MMU faults are reported as a Data Abort exception instead of being recorded in PAR_EL1. See [Exceptions to reporting the fault in PAR_EL1](#).

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

F, bit [0]

Indicates whether the instruction performed a successful address translation.

F	Meaning
0b1	Address translation aborted.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing PAR_EL1

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, PAR_EL1

op0	op1	CRn	CRm	op2
0b11	0b000	0b0111	0b0100	0b000

```
if PSTATE.EL == EL0 then
    Undefined();
elsif PSTATE.EL == EL1 then
    X{64}(t) = PAR_EL1()[63:0];
elsif PSTATE.EL == EL2 then
    X{64}(t) = PAR_EL1()[63:0];
end;
```

MSR PAR_EL1, <Xt>

op0	op1	CRn	CRm	op2
0b11	0b000	0b0111	0b0100	0b000

```
if PSTATE.EL == EL0 then
    Undefined();
elsif PSTATE.EL == EL1 then
    PAR_EL1()[63:0] = X{64}(t);
elsif PSTATE.EL == EL2 then
    PAR_EL1()[63:0] = X{64}(t);
end;
```

D12.2.82 REVIDR_EL1, Revision ID Register

The REVIDR_EL1 characteristics are:

Purpose

Provides implementation-specific minor revision information.

Configuration

If REVIDR_EL1 has the same value as MIDR_EL1, then its contents have no significance.

Attributes

REVIDR_EL1 is a 64-bit register.

Field descriptions

IMPLEMENTATION DEFINED, bits [63:0]

IMPLEMENTATION DEFINED.

Accessing REVIDR_EL1

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, REVIDR_EL1

op0	op1	CRn	CRm	op2
0b11	0b000	0b0000	0b0000	0b110

```
if PSTATE.EL == EL0 then
    if IsFeatureImplemented(FEAT_IDST) then
        AArch64_SystemAccessTrapToEL1orEL2(0x18);
    else
        Undefined();
    end;
elseif PSTATE.EL == EL1 then
    if HCR_EL2().TID1 == '1' then
        AArch64_SystemAccessTrap(EL2, 0x18);
    else
        X{64}(t) = REVIDR_EL1();
    end;
elseif PSTATE.EL == EL2 then
    X{64}(t) = REVIDR_EL1();
end;
```

D12.2.83 RMR_EL2, Reset Management Register (EL2)

The RMR_EL2 characteristics are:

Purpose

When this register is implemented:

- A write to the register at EL2 can request a Warm reset.
- If EL2 can use all Execution states, this register specifies the Execution state that the PE boots into on a Warm reset.

Configuration

When EL2 is the highest implemented Exception level:

- If EL2 can use all Execution states then this register must be implemented.
- In an AArch64 only implementation it is IMPLEMENTATION DEFINED whether the register is implemented.

Attributes

RMR_EL2 is a 64-bit register.

Field descriptions

Bits [63:2]

Reserved, RES0.

RR, bit [1]

Reset Request. Setting this bit to 1 requests a Warm reset.

The reset behavior of this field is:

- On a Warm reset, this field resets to '0'.

Bit [0]

Reserved, RAO/WI.

Accessing RMR_EL2

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, RMR_EL2

op0	op1	CRn	CRm	op2
0b11	0b100	0b1100	0b0000	0b010

```
if PSTATE.EL == EL2 then
    X{64}(t) = RMR_EL2();
else
    Undefined();
end;
```

MSR RMR_EL2, <Xt>

op0	op1	CRn	CRm	op2
0b11	0b100	0b1100	0b0000	0b010

```
if PSTATE.EL == EL2 then
    RMR_EL2() = X{64}(t);
else
    Undefined();
end;
```

D12.2.84 RVBAR_EL2, Reset Vector Base Address Register (if EL3 not implemented)

The RVBAR_EL2 characteristics are:

Purpose

If EL2 is the highest Exception level implemented, contains the IMPLEMENTATION DEFINED address that execution starts from after reset when executing in AArch64 state.

Configuration

There are no configuration notes.

Attributes

RVBAR_EL2 is a 64-bit register.

Field descriptions

ResetAddress, bits [63:0]

The IMPLEMENTATION DEFINED address that execution starts from after reset when executing in 64-bit state. Bits[1:0] of this register are 00, as this address must be aligned, and the address must be within the physical address size supported by the PE.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

Accessing RVBAR_EL2

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, RVBAR_EL2

op0	op1	CRn	CRm	op2
0b11	0b100	0b1100	0b0000	0b001

```
if PSTATE.EL == EL2 then
    X{64}(t) = RVBAR_EL2();
else
    Undefined();
end;
```

D12.2.85 S3_<op1>_<Cn>_<Cm>_<op2>, IMPLEMENTATION DEFINED Registers

The S3_<op1><Cn><Cm>_<op2> characteristics are:

Purpose

This area of the instruction set space is reserved for IMPLEMENTATION DEFINED registers.

Configuration

There are no configuration notes.

Attributes

S3_<op1><Cn><Cm>_<op2> is a 64-bit register.

Field descriptions

IMPLEMENTATION DEFINED, bits [63:0]

IMPLEMENTATION DEFINED.

Accessing S3_<op1>_<Cn>_<Cm>_<op2>

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, S3_<op1>_C<Cn>_C<Cm>_<op2>

op0	op1	CRn	CRm	op2
0b11	op1[2:0]	0b1x11	Cm[3:0]	op2[2:0]

```
if PSTATE.EL == EL0 then
    AArch64_ImpDefSysRegRead(op0, op1, CRn, CRm, op2, t);
elsif PSTATE.EL == EL1 then
    if HCR_EL2().TIDCP == '1' then
        AArch64_SystemAccessTrap(EL2, 0x18);
    else
        AArch64_ImpDefSysRegRead(op0, op1, CRn, CRm, op2, t);
    end;
elsif PSTATE.EL == EL2 then
    AArch64_ImpDefSysRegRead(op0, op1, CRn, CRm, op2, t);
end;
```

MSR S3_<op1>_C<Cn>_C<Cm>_<op2>, <Xt>

op0	op1	CRn	CRm	op2
0b11	op1[2:0]	0b1x11	Cm[3:0]	op2[2:0]

```
if PSTATE.EL == EL0 then
    AArch64_ImpDefSysRegWrite(op0, op1, CRn, CRm, op2, t);
elsif PSTATE.EL == EL1 then
    if HCR_EL2().TIDCP == '1' then
        AArch64_SystemAccessTrap(EL2, 0x18);
    else
        AArch64_ImpDefSysRegWrite(op0, op1, CRn, CRm, op2, t);
    end;
elsif PSTATE.EL == EL2 then
    AArch64_ImpDefSysRegWrite(op0, op1, CRn, CRm, op2, t);
end;
```

D12.2.86 SCTLR_EL1, System Control Register (EL1)

The SCTLR_EL1 characteristics are:

Purpose

Provides top-level control of the system, including its memory system, at EL1 and EL0.

Configuration

There are no configuration notes.

Attributes

SCTLR_EL1 is a 64-bit register.

Field descriptions

Bits [63:45]

Reserved, RES0.

DSSBS, bit [44]

When FEAT_SSBS is implemented:

Default PSTATE.SSBS value on Exception Entry.

DSSBS	Meaning
0b0	PSTATE.SSBS is set to 0 on an exception to EL1.
0b1	PSTATE.SSBS is set to 1 on an exception to EL1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an IMPLEMENTATION DEFINED value.

Otherwise:

Reserved, RES0.

Bits [43:32]

Reserved, RES0.

EnIA, bit [31]

When FEAT_PAuth is implemented:

Controls enabling of pointer authentication of instruction addresses, using the APIAKey_EL1 key, at EL1 and at EL0 in the EL1&0 translation regime.

EnIA	Meaning
0b0	Pointer authentication of instruction addresses at EL1 and at EL0 in the EL1&0 translation regime, using the APIAKey_EL1 key, is not enabled.
0b1	Pointer authentication of instruction addresses at EL1 and at EL0 in the EL1&0 translation regime, using the APIAKey_EL1 key, is enabled.

Note

This field controls the behavior of the `AddPACIA()` and `AuthIA()` pseudocode functions. When pointer authentication is enabled, `AddPACIA()` returns a copy of a pointer to which a pointer authentication code has been added, and `AuthIA()` returns an authenticated copy of a pointer. When pointer authentication is disabled, both of these functions are NOP.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

EnIB, bit [30]

When FEAT_PAuth is implemented:

Controls enabling of pointer authentication of instruction addresses, using the APIBKey_EL1 key, at EL1 and at EL0 in the EL1&0 translation regime.

EnIB	Meaning
0b0	Pointer authentication of instruction addresses at EL1 and at EL0 in the EL1&0 translation regime, using the APIBKey_EL1 key, is not enabled.
0b1	Pointer authentication of instruction addresses at EL1 and at EL0 in the EL1&0 translation regime, using the APIBKey_EL1 key, is enabled.

Note

This field controls the behavior of the `AddPACIB()` and `AuthIB()` pseudocode functions. When pointer authentication is enabled, `AddPACIB()` returns a copy of a pointer to which a pointer authentication code has been added, and `AuthIB()` returns an authenticated copy of a pointer. When pointer authentication is disabled, both of these functions are NOP.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bits [29:28]

Reserved, RES1.

EnDA, bit [27]

When FEAT_PAuth is implemented:

Controls enabling of pointer authentication of data addresses, using the APDAKey_EL1 key, at EL1 and at EL0 in the EL1&0 translation regime.

EnDA	Meaning
0b0	Pointer authentication of data addresses at EL1 and at EL0 in the EL1&0 translation regime, using the APDAKey_EL1 key, is not enabled.
0b1	Pointer authentication of data addresses at EL1 and at EL0 in the EL1&0 translation regime, using the APDAKey_EL1 key, is enabled.

Note

This field controls the behavior of the `AddPACDA()` and `AuthDA()` pseudocode functions. When pointer authentication is enabled, `AddPACDA()` returns a copy of a pointer to which a pointer authentication code has been added, and `AuthDA()` returns an authenticated copy of a pointer. When pointer authentication is disabled, both of these functions are NOP.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

UCI, bit [26]

Traps EL0 execution of cache maintenance instructions, to EL1, or to EL2 when [HCR_EL2.TGE](#) is 1, from AArch64 state only, reported using EC syndrome value 0x18, as follows:

- [DC CVAU](#), [DC CIVAC](#), [DC CVAC](#), and [IC IVAU](#).
- If [FEAT_DPB](#) is implemented, [DC CVAP](#).
- If [FEAT_DPB2](#) is implemented, [DC CVADP](#).

UCI	Meaning
0b0	For each of the specified instructions, if the execution of the instruction can be trapped, access at EL0 using AArch64 is trapped.
0b1	This control does not cause any instructions to be trapped.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

EE, bit [25]

When FEAT_MixedEnd is implemented:

Endianness of data accesses at EL1, and stage 1 translation table walks in the EL1&0 translation regime.

EE	Meaning
0b0	Explicit data accesses at EL1, and stage 1 translation table walks in the EL1&0 translation regime are little-endian.
0b1	Explicit data accesses at EL1, and stage 1 translation table walks in the EL1&0 translation regime are big-endian.

The EE bit is permitted to be cached in a TLB.

The reset behavior of this field is:

- On a Warm reset, this field resets to an IMPLEMENTATION DEFINED value.

When FEAT_BigEnd is implemented:

Explicit data accesses at EL1, and stage 1 translation table walks in the EL1&0 translation regime are big-endian.

Reserved, RES1.

Otherwise:

Explicit data accesses at EL1, and stage 1 translation table walks in the EL1&0 translation regime are little-endian.

Reserved, RES0.

E0E, bit [24]

When FEAT_MixedEndEL0 is implemented:

Endianness of data accesses at EL0.

E0E	Meaning
0b0	Explicit data accesses at EL0 are little-endian.
0b1	Explicit data accesses at EL0 are big-endian.

This bit has no effect on the endianness of Explicit Memory Effects generated by unprivileged memory access instructions executed at EL1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

When FEAT_BigEndEL0 is implemented:

Explicit data accesses at EL0 are big-endian.

Reserved, RES1.

Otherwise:

Explicit data accesses at EL0 are little-endian.

Reserved, RES0.

SPAN, bit [23]

When FEAT_PAN is implemented:

Set Privileged Access Never, on taking an exception to EL1.

SPAN	Meaning
0b0	PSTATE.PAN is set to 1 on taking an exception to EL1.
0b1	The value of PSTATE.PAN is left unchanged on taking an exception to EL1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES1.

Bit [22]

Reserved, RES1.

IESB, bit [21]

When FEAT_IESB is implemented:

Implicit Error Synchronization event enable. Possible values are:

IESB	Meaning
0b0	Disabled.
0b1	An implicit error synchronization event is added: • At each exception taken to EL1. • Before the operational pseudocode of each Exception Return instruction executed at EL1.

The value of this field is ignored in Debug state and treated as zero.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

TSCXT, bit [20]

When FEAT_CSV2_2 is implemented or FEAT_CSV2_1p2 is implemented:

Trap EL0 Access to the [SCXTNUM_EL0](#) register, when EL0 is using AArch64.

TSCXT	Meaning
0b0	EL0 access to SCXTNUM_EL0 is not disabled by this mechanism.
0b1	EL0 access to SCXTNUM_EL0 is disabled, causing an exception to EL1, or to EL2 when HCR_EL2.TGE is 1. The value of SCXTNUM_EL0 is treated as 0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES1.

WXN, bit [19]

Write permission implies XN (Execute-never). For the EL1&0 translation regime, this bit can restrict execute permissions on writable pages.

WXN	Meaning
0b0	This control has no effect on memory access permissions.
0b1	In the EL1&0 translation regime, any region of memory that is writable at EL1 is XN at EL1, and any region of memory that is writable at EL0 is XN at EL0.

This bit applies only when [SCTLR_EL1.M](#) bit is set.

The WXN bit is permitted to be cached in a TLB.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

nTWE, bit [18]

Traps EL0 execution of WFE instructions to EL1, or to EL2 when [HCR_EL2.TGE](#) is 1, from both Execution states, reported using EC syndrome value 0x01.

nTWE	Meaning
0b0	Any attempt to execute a WFE instruction at EL0 is trapped, if the instruction would otherwise have caused the PE to enter a low-power state.
0b1	This control does not cause any instructions to be trapped.

Note

Since a WFE or WFI can complete at any time, even without a Wakeup event, the traps on WFE or WFI are not guaranteed to be taken, even if the WFE or WFI is executed when there is no Wakeup event. The only guarantee is that if the instruction does not complete in finite time in the absence of a Wakeup event, the trap will be taken.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

BR, bit [17]

When `VTCR_EL2.MSA == '0'`:

Background region enable for EL1 MPU memory regions.

BR	Meaning
0b0	Background region disabled for stage 1 EL1&0 translation regime.
0b1	Background region enabled for stage 1 EL1&0 translation regime.

If the value of `HCR_EL2.{DC, TGE}` is not `{0, 0}`, then PE behaves as if the value of the `SCTLR_EL1.BR` field is 0 for all purposes other than returning the value of a direct read of the field.

If EL1 MPU is enabled, then EL0 access that does not match an EL1 MPU region always results in a Translation fault.

The reset behavior of this field is:

- On a Warm reset, this field resets to '0'.

Otherwise:

Reserved, RES0.

nTWI, bit [16]

Traps EL0 execution of WFI instructions to EL1, or to EL2 when `HCR_EL2.TGE` is 1, from both Execution states, reported using EC syndrome value `0x01`.

nTWI	Meaning
0b0	Any attempt to execute a WFI instruction at EL0 is trapped, if the instruction would otherwise have caused the PE to enter a low-power state.
0b1	This control does not cause any instructions to be trapped.

Note

Since a WFE or WFI can complete at any time, even without a Wakeup event, the traps on WFE or WFI are not guaranteed to be taken, even if the WFE or WFI is executed when there is no Wakeup event. The only guarantee is that if the instruction does not complete in finite time in the absence of a Wakeup event, the trap will be taken.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

UCT, bit [15]

Traps EL0 accesses to the `CTR_EL0` to EL1, or to EL2 when `HCR_EL2.TGE` is 1, from AArch64 state only, reported using EC syndrome value `0x18`.

UCT	Meaning
0b0	Accesses to the CTR_EL0 from EL0 using AArch64 are trapped.
0b1	This control does not cause any instructions to be trapped.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

DZE, bit [14]

Traps EL0 execution of [DC ZVA](#) instructions to EL1, or to EL2 when [HCR_EL2.TGE](#) is 1, from AArch64 state only, reported using EC syndrome value 0x18.

DZE	Meaning
0b0	Any attempt to execute an instruction that this trap applies to at EL0 using AArch64 is trapped. Reading DCZID_EL0.DZP from EL0 returns 1, indicating that the instructions this trap applies to are not supported.
0b1	This control does not cause any instructions to be trapped.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

EnDB, bit [13]

When FEAT_PAuth is implemented:

Controls enabling of pointer authentication of data addresses, using the [APDBKey_EL1](#) key, at EL1 and at EL0 in the EL1&0 translation regime.

EnDB	Meaning
0b0	Pointer authentication of data addresses at EL1 and at EL0 in the EL1&0 translation regime, using the APDBKey_EL1 key, is not enabled.
0b1	Pointer authentication of data addresses at EL1 and at EL0 in the EL1&0 translation regime, using the APDBKey_EL1 key, is enabled.

Note

This field controls the behavior of the [AddPACDB\(\)](#) and [AuthDB\(\)](#) pseudocode functions. When pointer authentication is enabled, [AddPACDB\(\)](#) returns a copy of a pointer to which a pointer authentication code has been added, and [AuthDB\(\)](#) returns an authenticated copy of a pointer. When pointer authentication is disabled, both of these functions are NOP.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

I, bit [12]

Stage 1 instruction access Cacheability control, for accesses at EL0 and EL1:

I	Meaning
0b0	All instruction access to Stage 1 Normal memory from EL0 and EL1 are Stage 1 Non-cacheable. If stage 1 EL1&0 translation is in VMSAv8-64 context and the value of SCTLR_EL1.M is 0, then instruction accesses from stage 1 are to Normal, Outer Shareable, Inner Non-cacheable, Outer Non-cacheable memory. If stage 1 EL1&0 translation is in PMSAv8-64 context and the value of SCTLR_EL1.{BR, M} = {0, 0}, then instruction accesses from stage 1 are to Normal, Outer Shareable, Inner Non-cacheable, Outer Non-cacheable memory.
0b1	This control has no effect on the Stage 1 Cacheability of instruction access to Stage 1 Normal memory from EL0 and EL1. If stage 1 EL1&0 translation is in VMSAv8-64 context and the value of SCTLR_EL1.M is 0, then instruction accesses from stage 1 are to Normal, Outer Shareable, Inner Write-Through, Outer Write-Through memory. If stage 1 EL1&0 translation is in PMSAv8-64 context, and the value of SCTLR_EL1.{BR, M} = {0, 0}, then instruction accesses from stage 1 are to Normal, Outer Shareable, Inner Write-Through, Outer Write-Through memory.

When the value of the [HCR_EL2.DC](#) bit is 1, then instruction access to Normal memory from EL0 and EL1 are Cacheable regardless of the value of the SCTLR_EL1.I bit.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [11]

Reserved, RES1.

EnRCTX, bit [10]

When FEAT_SPECRES is implemented:

Enable EL0 access to the following System instructions:

- [CFP RCTX](#), [DVP RCTX](#) and [CPP RCTX](#) instructions.

EnRCTX	Meaning
0b0	EL0 access to these instructions is disabled, and these instructions are trapped to EL1, or to EL2 when it is implemented and enabled for the current Security state and HCR_EL2.TGE is 1.
0b1	EL0 access to these instructions is enabled.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

UMA, bit [9]

User Mask Access. Traps EL0 execution of MSR and MRS instructions that access the PSTATE.{D, A, I, F} masks to EL1, or to EL2 when [HCR_EL2.TGE](#) is 1, from AArch64 state only, reported using EC syndrome value 0x18.

UMA	Meaning
0b0	Any attempt at EL0 using AArch64 to execute an <code>MRS, MSR(register)</code> , or <code>MSR(immediate)</code> instruction that accesses the DAIF is trapped.
0b1	This control does not cause any instructions to be trapped.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [8:7]

Reserved, RES1.

nAA, bit [6]

When FEAT_LSE2 is implemented:

Non-aligned access. This bit controls generation of Alignment faults at EL1 and EL0 under certain conditions.

The following instructions generate an Alignment fault if all bytes being accessed are not within a single naturally aligned 16-byte quantity, for access:

- LDAPR, LDAPRH, LDAPUR, LDAPURH, LDAPURSH, LDAPURSW, LDAR, LDARH, LDLAR, LDLARH.
- STLLR, STLLRH, STLR, STLRH, STLUR, and STLURH.

nAA	Meaning
0b0	Unaligned accesses by the specified instructions generate an Alignment fault.
0b1	This control does not generate Alignment faults.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bit [5]

Reserved, RES0.

SA0, bit [4]

SP Alignment check enable for EL0. When set to 1, if a load or store instruction executed at EL0 uses the SP as the base address and the SP is not aligned to a 16-byte boundary, then an SP alignment fault exception is generated. For more information, see '[SP alignment checking](#)'.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

SA, bit [3]

SP Alignment check enable. When set to 1, if a load or store instruction executed at EL1 uses the SP as the base address and the SP is not aligned to a 16-byte boundary, then an SP alignment fault exception is generated. For more information, see ‘[SP alignment checking](#)’.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

C, bit [2]

Stage 1 Cacheability control, for data accesses.

C	Meaning
0b0	All data access to Stage 1 Normal memory from EL0 and EL1, and all Normal memory accesses from unified cache to the EL1&0 Stage 1 translation tables, are treated as Stage 1 Non-cacheable.
0b1	This control has no effect on the Stage 1 Cacheability of: • Data access to Normal memory from EL0 and EL1. • Normal memory accesses to the EL1&0 Stage 1 translation tables.

When the Effective value of the [HCR_EL2.DC](#) bit in the current Security state is 1, the PE ignores SCTLR_EL1.C. This means that EL0 and EL1 data accesses to Normal memory are Cacheable.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

A, bit [1]

Alignment check enable. This is the enable bit for Alignment fault checking at EL1 and EL0.

A	Meaning
0b0	Alignment fault checking is disabled when executing at EL1 or EL0. Alignment checks on some instructions are not disabled by this control. For more information, see ‘ Alignment of data accesses ’.
0b1	Alignment fault checking is enabled when executing at EL1 or EL0. All instructions that load or store one or more registers have an alignment check that the address being accessed is aligned to the size of the data element(s) being accessed. If this check fails it causes an Alignment fault, which is taken as a Data Abort exception.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

M, bit [0]

MMU or MPU enable for EL1&0 stage 1 address translation.

This is the enable bit for:

- MPU, if stage 1 EL1&0 translation is in PMSAv8-64 context.
- MMU, if stage 1 EL1&0 translation is in VMSAv8-64 context.

M	Meaning
0b0	EL1 MPU(PMSAv8-64) or MMU(VMSAv8-64) disabled See the SCTLR_EL1.I field for the behavior of instruction accesses to Normal memory.
0b1	EL1 MPU(PMSAv8-64) or MMU(VMSAv8-64) enabled

If the Effective value of [HCR_EL2](#).{DC, TGE} in the current Security state is not {0, 0}, then the PE behaves as if the value of the SCTLR_EL1.M field is 0 for all purposes other than returning the value of a direct read of the field.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing SCTLR_EL1

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, SCTLR_EL1

op0	op1	CRn	CRm	op2
0b11	0b000	0b0001	0b0000	0b000

```

if PSTATE.EL == EL0 then
    Undefined();
elsif PSTATE.EL == EL1 then
    if HCR_EL2().TRVM == '1' then
        AArch64_SystemAccessTrap(EL2, 0x18);
    else
        X{64}(t) = SCTLR_EL1();
    end;
elsif PSTATE.EL == EL2 then
    X{64}(t) = SCTLR_EL1();
end;

```

MSR SCTLR_EL1, <Xt>

op0	op1	CRn	CRm	op2
0b11	0b000	0b0001	0b0000	0b000

```

if PSTATE.EL == EL0 then
    Undefined();
elsif PSTATE.EL == EL1 then
    if HCR_EL2().TVM == '1' then
        AArch64_SystemAccessTrap(EL2, 0x18);
    else
        SCTLR_EL1() = X{64}(t);
    end;
elsif PSTATE.EL == EL2 then
    SCTLR_EL1() = X{64}(t);
end;

```

D12.2.87 SCTLR_EL2, System Control Register (EL2)

The SCTLR_EL2 characteristics are:

Purpose

Provides top-level control of the system, including its memory system, at EL2.

Configuration

There are no configuration notes.

Attributes

SCTLR_EL2 is a 64-bit register.

Field descriptions

Bits [63:45]

Reserved, RES0.

DSSBS, bit [44]

When FEAT_SSBS is implemented:

Default PSTATE.SSBS value on exception entry.

DSSBS	Meaning
0b0	PSTATE.SSBS is set to 0 on an exception to EL2.
0b1	PSTATE.SSBS is set to 1 on an exception to EL2.

The reset behavior of this field is:

- On a Warm reset, this field resets to an IMPLEMENTATION DEFINED value.

Otherwise:

Reserved, RES0.

Bits [43:32]

Reserved, RES0.

EnIA, bit [31]

When FEAT_PAuth is implemented:

Controls enabling of pointer authentication of instruction addresses, using the APIAKey_EL1 key, at EL2 and at EL0 in the EL2&0 translation regime.

EnIA	Meaning
0b0	Pointer authentication of instruction addresses at EL2 and at EL0 in the EL2&0 translation regime, using the APIAKey_EL1 key, is not enabled.
0b1	Pointer authentication of instruction addresses at EL2 and at EL0 in the EL2&0 translation regime, using the APIAKey_EL1 key, is enabled.

Note

This field controls the behavior of the `AddPACIA()` and `AuthIA()` pseudocode functions. When pointer authentication is enabled, `AddPACIA()` returns a copy of a pointer to which a pointer authentication code has been added, and `AuthIA()` returns an authenticated copy of a pointer. When pointer authentication is disabled, both of these functions are NOP.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

EnIB, bit [30]

When FEAT_PAuth is implemented:

Controls enabling of pointer authentication of instruction addresses, using the APIBKey_EL1 key, at EL2 and at EL0 in the EL2&0 translation regime.

EnIB	Meaning
0b0	Pointer authentication of instruction addresses at EL2 and at EL0 in the EL2&0 translation regime, using the APIBKey_EL1 key, is not enabled.
0b1	Pointer authentication of instruction addresses at EL2 and at EL0 in the EL2&0 translation regime, using the APIBKey_EL1 key, is enabled.

Note

This field controls the behavior of the `AddPACIB()` and `AuthIB()` pseudocode functions. When pointer authentication is enabled, `AddPACIB()` returns a copy of a pointer to which a pointer authentication code has been added, and `AuthIB()` returns an authenticated copy of a pointer. When pointer authentication is disabled, both of these functions are NOP.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bits [29:28]

Reserved, RES1.

EnDA, bit [27]

When FEAT_PAuth is implemented:

Controls enabling of pointer authentication of data addresses, using the APDAKey_EL1 key, at EL2 and at EL0 in the EL2&0 translation regime.

EnDA	Meaning
0b0	Pointer authentication of data addresses at EL2 and at EL0 in the EL2&0 translation regime, using the APDAKey_EL1 key, is not enabled.
0b1	Pointer authentication of data addresses at EL2 and at EL0 in the EL2&0 translation regime, using the APDAKey_EL1 key, is enabled.

Note

This field controls the behavior of the `AddPACDA()` and `AuthDA()` pseudocode functions. When pointer authentication is enabled, `AddPACDA()` returns a copy of a pointer to which a pointer authentication code has been added, and `AuthDA()` returns an authenticated copy of a pointer. When pointer authentication is disabled, both of these functions are NOP.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bit [26]

Reserved, RES0.

EE, bit [25]

When FEAT_MixedEnd is implemented:

Endianness of data accesses at EL2.

EE	Meaning
0b0	Explicit data accesses at EL2 are little-endian.
0b1	Explicit data accesses at EL2 are big-endian.

The EE bit is permitted to be cached in a TLB.

The reset behavior of this field is:

- On a Warm reset, this field resets to an IMPLEMENTATION DEFINED value.

When FEAT_BigEnd is implemented:

Explicit data accesses at EL1, and stage 1 translation table walks in the EL1&0 translation regime are big-endian.

Reserved, RES1.

Otherwise:

Explicit data accesses at EL1, and stage 1 translation table walks in the EL1&0 translation regime are little-endian.

Reserved, RES0.

E0E, bit [24]

When FEAT_MixedEndEL0 is implemented and EffectiveHCR_EL2_E2H() == '1':

Endianness of data accesses at EL0.

E0E	Meaning
0b0	Explicit data accesses at EL0 are little-endian.
0b1	Explicit data accesses at EL0 are big-endian.

If the [Effective value](#) of [HCR_EL2.TGE](#) is 0, the field is IGNORED for all purposes other than direct reads and writes of the register.

This bit has no effect on the endianness of Explicit Memory Effects generated by unprivileged memory access instructions executed at EL2.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

When FEAT_BigEndEL0 is implemented and EffectiveHCR_EL2_E2H() == '1':

Explicit data accesses at EL0 are big-endian.

Reserved, RES1.

When FEAT_LittleEndEL0 is implemented and EffectiveHCR_EL2_E2H() == '1':

Explicit data accesses at EL0 are little-endian.

Reserved, RES0.

Otherwise:

Reserved, RES0.

Bits [23:22]

Reserved, RES1.

IESB, bit [21]

When FEAT_IESB is implemented:

Implicit Error Synchronization event enable.

IESB	Meaning
0b0	Disabled.

IESB	Meaning
0b1	An implicit error synchronization event is added: - At each exception taken to EL2. - Before the operational pseudocode of each Exception Return instruction executed at EL2.

The value of this field is ignored in Debug state and treated as zero.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bit [20]

Reserved, RES0.

WXN, bit [19]

Write permission implies XN (Execute-never). For the EL2 or EL2&0 translation regime, this bit can restrict execute permissions on writable pages.

WXN	Meaning
0b0	This control has no effect on memory access permissions.
0b1	In the EL2 or EL2&0 translation regime, any region of memory that is writable at EL2 is XN at EL2. In the EL2&0 translation regime, any region of memory that is writable at EL0 is XN at EL0.

This bit applies only when SCTLR_EL2.M bit is set.

The WXN bit is permitted to be cached in a TLB.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [18]

Reserved, RES1.

BR, bit [17]

Background region enable for EL2 MPU memory regions.

BR	Meaning
0b0	Background region disabled for stage 1 EL2 translation regime and stage 2 EL1&0 translation regime.
0b1	Background region enabled for stage 1 EL2 translation regime and stage 2 EL1&0 translation regime.

If EL2 MPU is enabled, then EL0 and EL1 access that does not match an EL2 MPU region always results in a Translation fault.

The reset behavior of this field is:

- On a Warm reset, this field resets to '0'.

Bit [16]

Reserved, RES1.

Bits [15:14]

Reserved, RES0.

EnDB, bit [13]

When FEAT_PAuth is implemented:

Controls enabling of pointer authentication of data addresses, using the APDBKey_EL1 key, at EL2 and at EL0 in the EL2&0 translation regime.

EnDB	Meaning
0b0	Pointer authentication of data addresses at EL2 and at EL0 in the EL2&0 translation regime, using the APDBKey_EL1 key, is not enabled.
0b1	Pointer authentication of data addresses at EL2 and at EL0 in the EL2&0 translation regime, using the APDBKey_EL1 key, is enabled.

Note

This field controls the behavior of the `AddPACDB()` and `AuthDB()` pseudocode functions. When pointer authentication is enabled, `AddPACDB()` returns a copy of a pointer to which a pointer authentication code has been added, and `AuthDB()` returns an authenticated copy of a pointer. When pointer authentication is disabled, both of these functions are NOP.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

I, bit [12]

Instruction access Cacheability control, for accesses at EL2.

I	Meaning
0b0	All instruction accesses to Normal memory from EL2 are Non-cacheable for all levels of instruction and unified cache. If <code>SCTLR_EL2.{BR, M} = {0, 0}</code> , then instruction accesses from stage 1 of the EL2 translation regime are to Normal, Outer Shareable, Inner Non-cacheable, Outer Non-cacheable memory.
0b1	This control has no effect on the Cacheability of instruction access to Normal memory from EL2. If <code>SCTLR_EL2.{BR, M} = {0, 0}</code> , then instruction accesses from stage 1 of the EL2 translation regime are to Normal, Outer Shareable, Inner Write-Through, Outer Write-Through memory.

This bit has no effect on the EL1&0 translation regime.

The reset behavior of this field is:

- On a Warm reset, this field resets to '0'.

Bit [11]

Reserved, RES1.

Bits [10:8]

Reserved, RES0.

Bit [7]

Reserved, RES1.

nAA, bit [6]

When FEAT_LSE2 is implemented:

Non-aligned access. This bit controls generation of Alignment faults under certain conditions at EL2.

The following instructions generate an Alignment fault if all bytes being accessed are not within a single naturally aligned 16-byte quantity, for access:

- LDAPR, LDAPRH, LDAPUR, LDAPURH, LDAPURSH, LDAPURSW, LDAR, LDARH, LDLAR, LDLARH.
- STLLR, STLLRH, STLR, STLRH, STLUR, and STLURH.

nAA	Meaning
0b0	Unaligned accesses by the specified instructions generate an Alignment fault.
0b1	Unaligned accesses by the specified instructions do not generate an Alignment fault.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

CP15BEN, bit [5]

Access to this field is RES0.

Bit [4]

Reserved, RES1.

SA, bit [3]

SP Alignment check enable. When set to 1, if a load or store instruction executed at EL2 uses the SP as the base address and the SP is not aligned to a 16-byte boundary, then an SP alignment fault exception is generated. For more information, see '[SP alignment checking](#)'.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

C, bit [2]

Data access Cacheability control, for accesses at EL2.

C	Meaning
0b0	All data accesses to Normal memory from EL2 are Non-cacheable for all levels of data and unified cache.
0b1	This control has no effect on the Cacheability of data accesses to Normal memory from EL2.

This bit has no effect on the EL1&0 translation regime.

The reset behavior of this field is:

- On a Warm reset, this field resets to '0'.

A, bit [1]

Alignment check enable. This is the enable bit for Alignment fault checking at EL2.

A	Meaning
0b0	Alignment fault checking is disabled when executing at EL2. Alignment checks on some instructions are not disabled by this control. For more information, see ‘Alignment of data accesses’ .
0b1	Alignment fault checking is enabled when executing at EL2. All instructions that load or store one or more registers have an alignment check that the address being accessed is aligned to the size of the data element(s) being accessed. If this check fails it causes an Alignment fault, which is taken as a Data Abort exception.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

M, bit [0]

MPU enable for EL2 stage 1 and EL1&0 stage 2 address translation.

M	Meaning
0b0	MPU disabled for EL2 and EL1&0 stage 2 address translation. See the SCTLR_EL2.I field for the behavior of instruction accesses to Normal memory.
0b1	MPU enabled for EL2 and EL1&0 stage 2 address translation.

The reset behavior of this field is:

- On a Warm reset, this field resets to '0'.

Accessing SCTLR_EL2

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, SCTLR_EL2

op0	op1	CRn	CRm	op2
0b11	0b100	0b0001	0b0000	0b000

```
if PSTATE.EL == EL0 then
    Undefined();
elsif PSTATE.EL == EL1 then
    Undefined();
elsif PSTATE.EL == EL2 then
    X{64}(t) = SCTLR_EL2();
end;
```

MSR SCTLR_EL2, <Xt>

op0	op1	CRn	CRm	op2
0b11	0b100	0b0001	0b0000	0b000

```
if PSTATE.EL == EL0 then
    Undefined();
elsif PSTATE.EL == EL1 then
    Undefined();
elsif PSTATE.EL == EL2 then
    SCTLR_EL2() = X{64}(t);
end;
```

D12.2.88 SCXTNUM_EL0, EL0 Read/Write Software Context Number

The SCXTNUM_EL0 characteristics are:

Purpose

Provides a number that can be used to separate out different context numbers with the EL0 exception level, for the purpose of protecting against side-channels using branch prediction and similar resources.

Configuration

This register is present only when FEAT_CSV2_2 is implemented or FEAT_CSV2_1p2 is implemented. Otherwise, direct accesses to SCXTNUM_EL0 are UNDEFINED.

Attributes

SCXTNUM_EL0 is a 64-bit register.

Field descriptions

SCXTNUM, bits [63:0]

Software Context Number. A number to identify the context within the EL0 exception level.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing SCXTNUM_EL0

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, SCXTNUM_EL0

op0	op1	CRn	CRm	op2
0b11	0b011	0b1101	0b0000	0b111

D12.2.89 SCXTNUM_EL1, EL1 Read/Write Software Context Number

The SCXTNUM_EL1 characteristics are:

Purpose

Provides a number that can be used to separate out different context numbers with the EL1 exception level, for the purpose of protecting against side-channels using branch prediction and similar resources.

Configuration

This register is present only when FEAT_CSV2_2 is implemented or FEAT_CSV2_1p2 is implemented. Otherwise, direct accesses to SCXTNUM_EL1 are UNDEFINED.

Attributes

SCXTNUM_EL1 is a 64-bit register.

Field descriptions

SCXTNUM, bits [63:0]

Software Context Number. A number to identify the context within the EL1 exception level.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing SCXTNUM_EL1

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, SCXTNUM_EL1

op0	op1	CRn	CRm	op2
0b11	0b000	0b1101	0b0000	0b111

D12.2.90 SCXTNUM_EL2, EL2 Read/Write Software Context Number

The SCXTNUM_EL2 characteristics are:

Purpose

Provides a number that can be used to separate out different context numbers with the EL2 exception level, for the purpose of protecting against side-channels using branch prediction and similar resources.

Configuration

This register is present only when FEAT_CSV2_2 is implemented or FEAT_CSV2_1p2 is implemented. Otherwise, direct accesses to SCXTNUM_EL2 are UNDEFINED.

Attributes

SCXTNUM_EL2 is a 64-bit register.

Field descriptions

SCXTNUM, bits [63:0]

Software Context Number. A number to identify the context within the EL2 exception level.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

D12.2.91 TCR_EL1, Translation Control Register (EL1)

The TCR_EL1 characteristics are:

Purpose

The control register for stage 1 of the EL1&0 translation regime.

Configuration

There are no configuration notes.

Attributes

TCR_EL1 is a 64-bit register.

Field descriptions

Any of the bits in TCR_EL1, other than the EPDx bits when they have the value 1, and the A1 bit are permitted to be cached in a TLB.

Bits [63:57]

Reserved, RES0.

E0PD1, bit [56]

When VTCR_EL2.MSA == '1' and FEAT_E0PD is implemented:

Faulting control for unprivileged access to any address translated by [TTBR1_EL1](#).

E0PD1	Meaning
0b0	Unprivileged access to any address translated by TTBR1_EL1 will not generate a fault by this mechanism.
0b1	Unprivileged access to any address translated by TTBR1_EL1 will generate a level 0 Translation fault.

Level 0 Translation faults generated as a result of this field are not counted as TLB misses for performance monitoring. The fault should take the same time to generate, whether the address is present in the TLB or not, to mitigate attacks that use fault timing.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

E0PD0, bit [55]

When VTCR_EL2.MSA == '1' and FEAT_E0PD is implemented:

Faulting control for unprivileged access to any address translated by [TTBR0_EL1](#).

E0PD0	Meaning
0b0	Unprivileged access to any address translated by TTBR0_EL1 will not generate a fault by this mechanism.
0b1	Unprivileged access to any address translated by TTBR0_EL1 will generate a level 0 Translation fault.

Level 0 Translation faults generated as a result of this field are not counted as TLB misses for performance monitoring. The fault should take the same time to generate, whether the address is present in the TLB or not, to mitigate attacks that use fault timing.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bits [54:53]

Reserved, RES0.

TBID1, bit [52]

When VTCR_EL2.MSA == '1' and FEAT_PAuth is implemented:

Controls the use of the top byte of instruction addresses for address matching.

For the purpose of this field, all cache maintenance and address translation instructions that perform address translation are treated as data accesses.

For more information, see '[Address tagging](#)'.

TBID1	Meaning
0b0	TCR_EL1.TBI1 applies to Instruction and Data accesses.
0b1	TCR_EL1.TBI1 applies to Data accesses only.

This affects addresses where the address would be translated by tables pointed to by [TTBR1_EL1](#). It has an effect whether the EL1&0 translation regime is enabled or not.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

TBID0, bit [51]

When VTCR_EL2.MSA == '1' and FEAT_PAuth is implemented:

Controls the use of the top byte of instruction addresses for address matching.

For the purpose of this field, all cache maintenance and address translation instructions that perform address translation are treated as data accesses.

For more information, see [‘Address tagging’](#).

TBID0	Meaning
0b0	TCR_EL1.TBI0 applies to Instruction and Data accesses.
0b1	TCR_EL1.TBI0 applies to Data accesses only.

This affects addresses where the address would be translated by tables pointed to by [TTBR0_EL1](#). It has an effect whether the EL1&0 translation regime is enabled or not.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

When FEAT_PAuth is implemented and VTCR_EL2.MSA == '0':

Controls the use of the top byte of instruction addresses for address matching.

For the purpose of this field, all cache maintenance and address translation instructions that perform address translation are treated as data accesses.

For more information, see [‘Address tagging’](#).

TBID0	Meaning
0b0	TCR_EL1.TBI0 applies to Instruction and Data accesses.
0b1	TCR_EL1.TBI0 applies to Data accesses only.

This affects addresses where the address would be translated by EL1 MPU.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

HWU162, bit [50]

When VTCR_EL2.MSA == '1' and FEAT_HPDS2 is implemented:

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[62] of the stage 1 translation table Block or Page entry for translations using [TTBR1_EL1](#).

HWU162	Meaning
0b0	For translations using TTBR1_EL1 , bit[62] of each stage 1 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.
0b1	For translations using TTBR1_EL1 , bit[62] of each stage 1 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose if the value of TCR_EL1.HPD1 is 1.

The Effective value of this field is 0 if the value of TCR_EL1.HPD1 is 0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

HWU161, bit [49]

When VTCR_EL2.MSA == '1' and FEAT_HPDS2 is implemented:

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[61] of the stage 1 translation table Block or Page entry for translations using [TTBR1_EL1](#).

HWU161	Meaning
0b0	For translations using TTBR1_EL1 , bit[61] of each stage 1 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.
0b1	For translations using TTBR1_EL1 , bit[61] of each stage 1 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose if the value of TCR_EL1.HPD1 is 1.

The Effective value of this field is 0 if the value of TCR_EL1.HPD1 is 0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

HWU160, bit [48]

When VTCR_EL2.MSA == '1' and FEAT_HPDS2 is implemented:

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[60] of the stage 1 translation table Block or Page entry for translations using [TTBR1_EL1](#).

HWU160	Meaning
0b0	For translations using TTBR1_EL1 , bit[60] of each stage 1 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.

HWU160	Meaning
0b1	For translations using TTBR1_EL1 , bit[60] of each stage 1 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose if the value of TCR_EL1.HPD1 is 1.

The Effective value of this field is 0 if the value of TCR_EL1.HPD1 is 0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

HWU159, bit [47]

When VTCR_EL2.MSA == '1' and FEAT_HPDS2 is implemented:

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[59] of the stage 1 translation table Block or Page entry for translations using [TTBR1_EL1](#).

HWU159	Meaning
0b0	For translations using TTBR1_EL1 , bit[59] of each stage 1 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.
0b1	For translations using TTBR1_EL1 , bit[59] of each stage 1 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose if the value of TCR_EL1.HPD1 is 1.

The Effective value of this field is 0 if the value of TCR_EL1.HPD1 is 0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

HWU062, bit [46]

When VTCR_EL2.MSA == '1' and FEAT_HPDS2 is implemented:

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[62] of the stage 1 translation table Block or Page entry for translations using [TTBR0_EL1](#).

HWU062	Meaning
0b0	For translations using TTBR0_EL1 , bit[62] of each stage 1 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.
0b1	For translations using TTBR0_EL1 , bit[62] of each stage 1 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose if the value of TCR_EL1.HPD0 is 1.

The Effective value of this field is 0 if the value of TCR_EL1.HPD0 is 0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

HWU061, bit [45]

When VTCR_EL2.MSA == '1' and FEAT_HPDS2 is implemented:

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[61] of the stage 1 translation table Block or Page entry for translations using [TTBR0_EL1](#).

HWU061	Meaning
0b0	For translations using TTBR0_EL1 , bit[61] of each stage 1 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.
0b1	For translations using TTBR0_EL1 , bit[61] of each stage 1 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose if the value of TCR_EL1.HPD0 is 1.

The Effective value of this field is 0 if the value of TCR_EL1.HPD0 is 0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

HWU060, bit [44]

When VTCR_EL2.MSA == '1' and FEAT_HPDS2 is implemented:

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[60] of the stage 1 translation table Block or Page entry for translations using [TTBR0_EL1](#).

HWU060	Meaning
0b0	For translations using TTBR0_EL1 , bit[60] of each stage 1 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.
0b1	For translations using TTBR0_EL1 , bit[60] of each stage 1 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose if the value of TCR_EL1.HPD0 is 1.

The Effective value of this field is 0 if the value of TCR_EL1.HPD0 is 0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

HWU059, bit [43]

When VTCR_EL2.MSA == '1' and FEAT_HPDS2 is implemented:

Hardware Use. Indicates IMPLEMENTATION DEFINED hardware use of bit[59] of the stage 1 translation table Block or Page entry for translations using [TTBR0_EL1](#).

HWU059	Meaning
0b0	For translations using TTBR0_EL1 , bit[59] of each stage 1 translation table Block or Page entry cannot be used by hardware for an IMPLEMENTATION DEFINED purpose.
0b1	For translations using TTBR0_EL1 , bit[59] of each stage 1 translation table Block or Page entry can be used by hardware for an IMPLEMENTATION DEFINED purpose if the value of TCR_EL1.HPD0 is 1.

The Effective value of this field is 0 if the value of TCR_EL1.HPD0 is 0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

HPD1, bit [42]

When VTCR_EL2.MSA == '1' and FEAT_HPDS is implemented:

Hierarchical Permission Disables. This affects the hierarchical control bits, APTable, PXNTable, and UXNTable, except NSTable, in the translation tables pointed to by [TTBR1_EL1](#).

HPD1	Meaning
0b0	Hierarchical permissions are enabled.
0b1	Hierarchical permissions are disabled.

When disabled, the permissions are treated as if the bits are zero.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

HPD0, bit [41]

When VTCR_EL2.MSA == '1' and FEAT_HPDS is implemented:

Hierarchical Permission Disables. This affects the hierarchical control bits, APTable, PXNTable, and UXNTable, except NSTable, in the translation tables pointed to by [TTBR0_EL1](#).

HPD0	Meaning
0b0	Hierarchical permissions are enabled.
0b1	Hierarchical permissions are disabled.

When disabled, the permissions are treated as if the bits are zero.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

HD, bit [40]

When VTCR_EL2.MSA == '1' and FEAT_HAFDBS is implemented:

Hardware management of dirty state in stage 1 translations from EL0 and EL1.

HD	Meaning
0b0	Stage 1 hardware management of dirty state disabled.
0b1	Stage 1 hardware management of dirty state enabled.

When the [Effective value](#) of TCR_EL1.HA is 0, this field behaves as 0 for all purposes other than a direct read of the value of this field.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

HA, bit [39]

When VTCR_EL2.MSA == '1' and FEAT_HAF is implemented:

Hardware Access flag update in stage 1 translations from EL0 and EL1.

HA	Meaning
0b0	Stage 1 Access flag update disabled.
0b1	Stage 1 Access flag update enabled.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

When VTCR_EL2.MSA == '0':

Reserved, RES0.

Otherwise:

Reserved, RES0.

TBI1, bit [38]

When VTCR_EL2.MSA == '1':

Top Byte ignored. Indicates whether the top byte of an address is used for address match for the [TTBR1_EL1](#) region, or ignored and used for tagged addresses.

TBI1	Meaning
0b0	Top Byte used in the address calculation.
0b1	Top Byte ignored in the address calculation.

This affects addresses generated at EL0 and EL1 using AArch64 where the address would be translated by tables pointed to by [TTBR1_EL1](#). It has an effect whether the EL1&0 translation regime is enabled or not.

If [FEAT_PAuth](#) is implemented and TCR_EL1.TBID1 is 1, then this field only applies to Data accesses.

Otherwise, if the value of TBI1 is 1 and bit [55] of the target address to be stored to the PC is 1, then bits[63:56] of that target address are also set to 1 before the address is stored in the PC, in the following cases:

- A branch or procedure return within EL1 or EL0.
- An exception taken to EL1.
- An exception return to EL1 or EL0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

When VTCR_EL2.MSA == '0':

Reserved, RES0.

Otherwise:

Reserved, RES0.

TBI0, bit [37]

When VTCR_EL2.MSA == '1':

Top Byte ignored. Indicates whether the top byte of an address is used for address match for the [TTBR0_EL1](#) region, or ignored and used for tagged addresses.

TBI0	Meaning
0b0	Top Byte used in the address calculation.
0b1	Top Byte ignored in the address calculation.

This affects addresses generated at EL0 and EL1 using AArch64 where the address would be translated by tables pointed to by [TTBR0_EL1](#). It has an effect whether the EL1&0 translation regime is enabled or not.

If [FEAT_PAuth](#) is implemented and TCR_EL1.TBID0 is 1, then this field only applies to Data accesses.

Otherwise, if the value of TBI0 is 1 and bit [55] of the target address to be stored to the PC is 0, then bits[63:56] of that target address are also set to 0 before the address is stored in the PC, in the following cases:

- A branch or procedure return within EL1 or EL0.
- An exception taken to EL1.
- An exception return to EL1 or EL0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

When VTCR_EL2.MSA == '0':

Top Byte ignored. Indicates whether the top byte of an address is used for an address match for the EL1 MPU regions, or ignored and used for tagged addresses.

TBI0	Meaning
0b0	Top Byte used in the address calculation.
0b1	Top Byte ignored in the address calculation.

This affects addresses generated at EL0 and EL1, where the address would be translated by the EL1 MPU.

If [FEAT_PAuth](#) is implemented and TCR_EL1.TBID0 is 1, then this field only applies to Data accesses.

Otherwise, if the value of TBI0 is 1 and bit [55] of the target address to be stored to the PC is 0, then bits[63:56] of that target address are also set to 0 before the address is stored in the PC, in the following cases:

- A branch or procedure return within EL1 or EL0.
- An exception taken to EL1.
- An exception return to EL1 or EL0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

AS, bit [36]

When VTCR_EL2.MSA == '1':

ASID Size.

AS	Meaning
0b0	8 bit - the upper 8 bits of TTBR0_EL1 and TTBR1_EL1 are ignored by hardware for every purpose except reading back the register, and are treated as if they are all zeros for when used for allocation and matching entries in the TLB.
0b1	16 bit - the upper 16 bits of TTBR0_EL1 and TTBR1_EL1 are used for allocation and matching in the TLB.

If the implementation has only 8 bits of ASID, this field is RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

When VTCR_EL2.MSA == '0':

ASID Size.

AS	Meaning
0b0	8 bit - the upper 8 bits of TTBR0_EL1 are ignored by hardware for every purpose except reading back the register, and are treated as if they are all zeros when used for address matching.
0b1	16 bit - the upper 16 bits of TTBR0_EL1 are used for address matching.

If the implementation has only 8 bits of ASID, this field is RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bit [35]

Reserved, RES0.

IPS, bits [34:32]

When VTCR_EL2.MSA == '1':

Intermediate Physical Address Size.

IPS	Meaning
0b000	32 bits, 4GB.
0b001	36 bits, 64GB.
0b010	40 bits, 1TB.
0b011	42 bits, 4TB.
0b100	44 bits, 16TB.
0b101	48 bits, 256TB.
0b110	52 bits, 4PB.

All other values are reserved.

The reserved values behave in the same way as the 0b101 or 0b110 encoding, but software must not rely on this property as the behavior of the reserved values might change in a future revision of the architecture.

The values 0b110 and 0b111 represent different output address sizes depending on implementation choices and translation configuration.

The following table captures the output address size represented by the value 0b110:

Descriptor Format	ID_AA64MMFR0_EL1.PARange	Translation Granule	DS ¹	Represented OA size
Any	0b0101	Any	Any	48 bits, 256TB

Descriptor Format	ID_AA64MMFR0_EL1.PARange	Translation Granule	DS ¹	Represented OA size
VMSAv8-64	0b011x	4KB or 16KB	0	48 bits, 256TB
VMSAv8-64	0b011x	4KB or 16KB	1	52 bits, 4PB
VMSAv8-64	0b011x	64KB	N/A	52 bits, 4PB

¹ This column represents the value of [TCR_EL1.DS](#).

The following table captures the output address size represented by the value 0b111:

Descriptor Format	ID_AA64MMFR0_EL1.PARange	Translation Granule	Represented OA size
Any	0b0110	Any	OA size represented by 0b110
VMSAv8-64	0b0111	Any	OA size represented by 0b110

If 52-bit PA is supported, and the translation table descriptors cannot express an OA larger than 48-bits, then bits[51:48] of every translation table base address are treated as 0b0000 for the stage of translation controlled by [TCR_EL1](#).

If 56-bit PA is supported, and the translation table descriptors cannot express an OA larger than 52-bits, then bits[55:52] of every translation table base address are treated as 0b0000 for the stage of translation controlled by [TCR_EL1](#).

If the output address size represented by this field is larger than the supported PA size expressed in [ID_AA64MMFR0_EL1.PARange](#), then the output address size is treated as being the same as the supported PA size. Arm strongly recommends that software avoids configuring this field to a value representing an output address size larger than the supported PA size.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

TG1, bits [31:30]

When [VTCR_EL2.MSA](#) == '1':

Granule size for the [TTBR1_EL1](#).

TG1	Meaning
0b01	16KB.
0b10	4KB.
0b11	64KB.

Other values are reserved.

If the value is programmed to either a reserved value or a size that has not been implemented, then the hardware will treat the field as if it has been programmed to an IMPLEMENTATION DEFINED choice of the sizes that has been implemented for all purposes other than the value read back from this register.

It is IMPLEMENTATION DEFINED whether the value read back is the value programmed or the value that corresponds to the size chosen.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

SH1, bits [29:28]

When VTCR_EL2.MSA == '1':

Shareability attribute for memory associated with translation table walks using [TTBR1_EL1](#).

SH1	Meaning
0b00	Non-shareable.
0b10	Outer Shareable.
0b11	Inner Shareable.

Other values are reserved. The effect of programming this field to a Reserved value is that behavior is CONSTRAINED UNPREDICTABLE.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

ORGN1, bits [27:26]

When VTCR_EL2.MSA == '1':

Outer Cacheability attribute for memory associated with translation table walks using [TTBR1_EL1](#).

ORGN1	Meaning
0b00	Normal memory, Outer Non-cacheable.
0b01	Normal memory, Outer Write-Back Read-Allocate Write-Allocate Cacheable.
0b10	Normal memory, Outer Write-Through Read-Allocate No Write-Allocate Cacheable.
0b11	Normal memory, Outer Write-Back Read-Allocate No Write-Allocate Cacheable.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

IRGN1, bits [25:24]

When VTCR_EL2.MSA == '1':

Inner Cacheability attribute for memory associated with translation table walks using [TTBR1_EL1](#).

IRGN1	Meaning
0b00	Normal memory, Inner Non-cacheable.
0b01	Normal memory, Inner Write-Back Read-Allocate Write-Allocate Cacheable.
0b10	Normal memory, Inner Write-Through Read-Allocate No Write-Allocate Cacheable.
0b11	Normal memory, Inner Write-Back Read-Allocate No Write-Allocate Cacheable.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

EPD1, bit [23]

When VTCR_EL2.MSA == '1':

Translation table walk disable for translations using [TTBR1_EL1](#). This bit controls whether a translation table walk is performed on a TLB miss, for an address that is translated using [TTBR1_EL1](#). The encoding of this bit is:

EPD1	Meaning
0b0	Perform translation table walks using TTBR1_EL1 .
0b1	A TLB miss on an address that is translated using TTBR1_EL1 generates a Translation fault. No translation table walk is performed.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

A1, bit [22]

When VTCR_EL2.MSA == '1':

Selects whether [TTBR0_EL1](#) or [TTBR1_EL1](#) defines the ASID. The encoding of this bit is:

A1	Meaning
0b0	TTBR0_EL1 .ASID defines the ASID.
0b1	TTBR1_EL1 .ASID defines the ASID.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

T1SZ, bits [21:16]

When VTCR_EL2.MSA == '1':

The size offset of the memory region addressed by [TTBR1_EL1](#). The region size is $2^{(64-T1SZ)}$ bytes.

The maximum and minimum possible values for T1SZ depend on the level of translation table and the memory translation granule size, as described in the AArch64 Virtual Memory System Architecture chapter. It has an effect on computation of PAC whether the EL1&0 translation regime is enabled or not.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

TG0, bits [15:14]

When VTCR_EL2.MSA == '1':

Granule size for the [TTBR0_EL1](#).

TG0	Meaning
0b00	4KB
0b01	64KB
0b10	16KB

Other values are reserved.

If the value is programmed to either a reserved value or a size that has not been implemented, then the hardware will treat the field as if it has been programmed to an IMPLEMENTATION DEFINED choice of the sizes that has been implemented for all purposes other than the value read back from this register.

It is IMPLEMENTATION DEFINED whether the value read back is the value programmed or the value that corresponds to the size chosen.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

SH0, bits [13:12]

When VTCR_EL2.MSA == '1':

Shareability attribute for memory associated with translation table walks using [TTBR0_EL1](#).

SH0	Meaning
0b00	Non-shareable
0b10	Outer Shareable
0b11	Inner Shareable

Other values are reserved. The effect of programming this field to a Reserved value is that behavior is CONSTRAINED UNPREDICTABLE.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

ORGN0, bits [11:10]

When VTCR_EL2.MSA == '1':

Outer Cacheability attribute for memory associated with translation table walks using [TTBR0_EL1](#).

ORGN0	Meaning
0b00	Normal memory, Outer Non-cacheable.
0b01	Normal memory, Outer Write-Back Read-Allocate Write-Allocate Cacheable.
0b10	Normal memory, Outer Write-Through Read-Allocate No Write-Allocate Cacheable.
0b11	Normal memory, Outer Write-Back Read-Allocate No Write-Allocate Cacheable.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

IRGN0, bits [9:8]

When VTCR_EL2.MSA == '1':

Inner Cacheability attribute for memory associated with translation table walks using [TTBR0_EL1](#).

IRGN0	Meaning
0b00	Normal memory, Inner Non-cacheable.
0b01	Normal memory, Inner Write-Back Read-Allocate Write-Allocate Cacheable.
0b10	Normal memory, Inner Write-Through Read-Allocate No Write-Allocate Cacheable.
0b11	Normal memory, Inner Write-Back Read-Allocate No Write-Allocate Cacheable.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

EPD0, bit [7]

When VTCR_EL2.MSA == '1':

Translation table walk disable for translations using [TTBR0_EL1](#). This bit controls whether a translation table walk is performed on a TLB miss, for an address that is translated using [TTBR0_EL1](#). The encoding of this bit is:

EPD0	Meaning
0b0	Perform translation table walks using TTBR0_EL1 .
0b1	A TLB miss on an address that is translated using TTBR0_EL1 generates a Translation fault. No translation table walk is performed.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bit [6]

Reserved, RES0.

T0SZ, bits [5:0]

When VTCR_EL2.MSA == '1':

The size offset of the memory region addressed by [TTBR0_EL1](#). The region size is $2^{(64-T0SZ)}$ bytes.

The maximum and minimum possible values for T0SZ depend on the level of translation table and the memory translation granule size, as described in the AArch64 Virtual Memory System Architecture chapter. It has an effect on computation of PAC whether the EL1&0 translation regime is enabled or not.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Accessing TCR_EL1

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, TCR_EL1

op0	op1	CRn	CRm	op2
0b11	0b000	0b0010	0b0000	0b010

```
if PSTATE.EL == EL0 then
    Undefined();
elseif PSTATE.EL == EL1 then
    if HCR_EL2().TRVM == '1' then
        AArch64_SystemAccessTrap(EL2, 0x18);
    else
        X{64}(t) = TCR_EL1();
    end;
elseif PSTATE.EL == EL2 then
    X{64}(t) = TCR_EL1();
end;
```

MSR TCR_EL1, <Xt>

op0	op1	CRn	CRm	op2
0b11	0b000	0b0010	0b0000	0b010

```
if PSTATE.EL == EL0 then
    Undefined();
elseif PSTATE.EL == EL1 then
    if HCR_EL2().TVM == '1' then
        AArch64_SystemAccessTrap(EL2, 0x18);
    else
        TCR_EL1() = X{64}(t);
    end;
elseif PSTATE.EL == EL2 then
    TCR_EL1() = X{64}(t);
end;
```

D12.2.92 TCR_EL2, Translation Control Register (EL2)

The TCR_EL2 characteristics are:

Purpose

This register controls stage 1 of the EL2 translation regime, translated by the EL2-MPU.

Configuration

There are no configuration notes.

Attributes

TCR_EL2 is a 64-bit register.

Field descriptions

IsProfile(PROFILE_R)

Any of the bits in TCR_EL2 are permitted to be cached in a TLB.

Bits [63:32]

Reserved, RES0.

Bit [31]

Reserved, RES1.

Bit [30]

Reserved, RES0.

TBID, bit [29]

When FEAT_PAuth is implemented:

Controls the use of the top byte of instruction addresses for address matching.

For the purpose of this field, all cache maintenance and address translation instructions that perform address translation are treated as data accesses.

For more information, see [‘Address tagging’](#).

TBID	Meaning
0b0	TCR_EL2.TBI applies to Instruction and Data accesses.

0b1	TCR_EL2.TBI applies to Data accesses only.
-----	--

This affects addresses where the address would be translated by EL2 MPU.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bits [28:24]

Reserved, RES0.

Bit [23]

Reserved, RES1.

Bits [22:21]

Reserved, RES0.

TBI, bit [20]

Top Byte ignored. Indicates whether the top byte of an address is used for address match for the EL2 MPU regions, or ignored and used for tagged addresses.

For more information, see [‘Address tagging’](#).

TBI	Meaning
0b0	Top Byte used in the address calculation.
0b1	Top Byte ignored in the address calculation.

This affects addresses generated at EL2 using AArch64 where the address would be translated by the EL2 MPU. It has an effect whether the EL2 translation regime is enabled or not.

If [FEAT_PAuth](#) is implemented and TCR_EL2.TBID is 1, then this field only applies to Data accesses.

If the value of TBI is 1, then bits[63:56] of that target address are also set to 0 before the address is stored in the PC, in the following cases:

- A branch or procedure return within EL2.
- An exception taken to EL2.
- An exception return to EL2.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [19:0]

Reserved, RES0.

Accessing TCR_EL2

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, TCR_EL2

op0	op1	CRn	CRm	op2
0b11	0b100	0b0010	0b0000	0b010

```
if PSTATE.EL == EL0 then
    Undefined();
elsif PSTATE.EL == EL1 then
    Undefined();
elsif PSTATE.EL == EL2 then
    X{64}(t) = TCR_EL2();
end;
```

MSR TCR_EL2, <Xt>

op0	op1	CRn	CRm	op2
0b11	0b100	0b0010	0b0000	0b010

```
if PSTATE.EL == EL0 then
    Undefined();
elsif PSTATE.EL == EL1 then
    Undefined();
elsif PSTATE.EL == EL2 then
    TCR_EL2() = X{64}(t);
end;
```

D12.2.93 **TPIDR_EL0, EL0 Read/Write Software Thread ID Register**

The TPIDR_EL0 characteristics are:

Purpose

Provides a location where software executing at EL0 can store thread identifying information, for OS management purposes.

The PE makes no use of this register.

Configuration

There are no configuration notes.

Attributes

TPIDR_EL0 is a 64-bit register.

Field descriptions

ThreadID, bits [63:0]

Thread ID. Thread identifying information stored by software running at this Exception level.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing TPIDR_EL0

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, TPIDR_EL0

op0	op1	CRn	CRm	op2
0b11	0b011	0b1101	0b0000	0b010

```
if PSTATE.EL == EL0 then
    X{64}(t) = TPIDR_EL0();
elsif PSTATE.EL == EL1 then
    X{64}(t) = TPIDR_EL0();
elsif PSTATE.EL == EL2 then
    X{64}(t) = TPIDR_EL0();
end;
```

MSR TPIDR_EL0, <Xt>

op0	op1	CRn	CRm	op2
0b11	0b011	0b1101	0b0000	0b010

```
if PSTATE.EL == EL0 then
    TPIDR_EL0() = X{64}(t);
elsif PSTATE.EL == EL1 then
    TPIDR_EL0() = X{64}(t);
elsif PSTATE.EL == EL2 then
    TPIDR_EL0() = X{64}(t);
end;
```

D12.2.94 TPIDR_EL1, EL1 Software Thread ID Register

The TPIDR_EL1 characteristics are:

Purpose

Provides a location where software executing at EL1 can store thread identifying information, for OS management purposes.

The PE makes no use of this register.

Configuration

There are no configuration notes.

Attributes

TPIDR_EL1 is a 64-bit register.

Field descriptions

ThreadID, bits [63:0]

Thread ID. Thread identifying information stored by software running at this Exception level.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing TPIDR_EL1

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, TPIDR_EL1

op0	op1	CRn	CRm	op2
0b11	0b000	0b1101	0b0000	0b100

```
if PSTATE.EL == EL0 then
    Undefined();
elsif PSTATE.EL == EL1 then
    X{64}(t) = TPIDR_EL1();
elsif PSTATE.EL == EL2 then
    X{64}(t) = TPIDR_EL1();
end;
```

MSR TPIDR_EL1, <Xt>

op0	op1	CRn	CRm	op2
0b11	0b000	0b1101	0b0000	0b100

```
if PSTATE.EL == EL0 then
    Undefined();
elsif PSTATE.EL == EL1 then
    TPIDR_EL1() = X{64}(t);
elsif PSTATE.EL == EL2 then
    TPIDR_EL1() = X{64}(t);
end;
```

D12.2.95 TPIDR_EL2, EL2 Software Thread ID Register

The TPIDR_EL2 characteristics are:

Purpose

Provides a location where software executing at EL2 can store thread identifying information, for OS management purposes.

The PE makes no use of this register.

Configuration

There are no configuration notes.

Attributes

TPIDR_EL2 is a 64-bit register.

Field descriptions

ThreadID, bits [63:0]

Thread ID. Thread identifying information stored by software running at this Exception level.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing TPIDR_EL2

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, TPIDR_EL2

op0	op1	CRn	CRm	op2
0b11	0b100	0b1101	0b0000	0b010

```
if PSTATE.EL == EL0 then
    Undefined();
elsif PSTATE.EL == EL1 then
    Undefined();
elsif PSTATE.EL == EL2 then
    X{64}(t) = TPIDR_EL2();
end;
```

MSR TPIDR_EL2, <Xt>

op0	op1	CRn	CRm	op2
0b11	0b100	0b1101	0b0000	0b010

```
if PSTATE.EL == EL0 then
    Undefined();
elsif PSTATE.EL == EL1 then
    Undefined();
elsif PSTATE.EL == EL2 then
    TPIDR_EL2() = X{64}(t);
end;
```

D12.2.96 **TPIDRRO_EL0, EL0 Read-Only Software Thread ID Register**

The TPIDRRO_EL0 characteristics are:

Purpose

Provides a location where software executing at EL1 or higher can store thread identifying information that is visible to software executing at EL0, for OS management purposes.

The PE makes no use of this register.

Configuration

There are no configuration notes.

Attributes

TPIDRRO_EL0 is a 64-bit register.

Field descriptions

ThreadID, bits [63:0]

Thread ID. Thread identifying information stored by software running at this Exception level.

Accessing TPIDRRO_EL0

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, TPIDRRO_EL0

op0	op1	CRn	CRm	op2
0b11	0b011	0b1101	0b0000	0b011

```
if PSTATE.EL == EL0 then
    X{64}(t) = TPIDRRO_EL0();
elsif PSTATE.EL == EL1 then
    X{64}(t) = TPIDRRO_EL0();
elsif PSTATE.EL == EL2 then
    X{64}(t) = TPIDRRO_EL0();
end;
```

MSR TPIDRRO_EL0, <Xt>

op0	op1	CRn	CRm	op2
0b11	0b011	0b1101	0b0000	0b011

```
if PSTATE.EL == EL0 then
    Undefined();
elsif PSTATE.EL == EL1 then
    TPIDRRO_EL0() = X{64}(t);
elsif PSTATE.EL == EL2 then
    TPIDRRO_EL0() = X{64}(t);
end;
```

D12.2.97 TTBR0_EL1, Translation Table Base Register 0 (EL1)

The TTBR0_EL1 characteristics are:

Purpose

Holds the base address of the translation table for the initial lookup for stage 1 of the translation of an address from the lower VA range in the EL1&0 translation regime, and other information for this translation regime.

Configuration

There are no configuration notes.

Attributes

TTBR0_EL1 is a 64-bit register.

Field descriptions

ASID, bits [63:48]

When VTCR_EL2.MSA == '1':

An ASID for the translation table base address. The [TCR_EL1.A1](#) field selects either TTBR0_EL1.ASID or [TTBR1_EL1.ASID](#).

If the implementation has only 8 bits of ASID, then the upper 8 bits of this field are RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

When VTCR_EL2.MSA == '0':

An ASID for addresses defined by the current EL1 MPU configuration.

If the implementation has only 8 bits of ASID, then the upper 8 bits of this field are RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

BADDR[47:1], bits [47:1]

When VTCR_EL2.MSA == '1':

Translation table base address:

- Bits A[47:x] of the stage 1 translation table base address bits are in register bits[47:x].
- Bits A[(x-1):0] of the stage 1 translation table base address are zero.

Address bit x is the minimum address bit required to align the translation table to the size of the table. The AArch64 Virtual Memory System Architecture chapter describes how x is calculated based on the value of [TCR_EL1.T0SZ](#), the translation stage, and the translation granule size.

The BADDR field represents a 52-bit address if any of the following apply:

- The value of [TCR_EL1.IPS](#) represents an OA size of 52 bits.
- The Effective value of [TCR_EL1.DS](#) is 1.

When [TTBR0_EL1.BADDR](#) represents a 52-bit addresses, all of the following apply:

- Bits $A[51:48]$ of the stage 1 translation table base address bits are in register bits $[5:2]$.
- Register bit $[1]$ is RES0.
- The smallest permitted value of x is 6.
- When $x > 6$, register bits $[(x-1):6]$ are RES0.

Otherwise, all of the following apply:

- Register bits $[(x-1):1]$ are RES0.
- If 52-bit PA is supported, then bits $A[51:48]$ of the stage 1 translation table base address are treated as 0b0000.

Note

If BADDR represents a 52-bit address, and the translation table has fewer than eight entries, the table must be aligned to 64 bytes. Otherwise the translation table must be aligned to the size of the table.

For the 64KB granule, if 52-bit PA is not supported, and the value of [TCR_EL1.IPS](#) is 0b110 or 0b111, one of the following IMPLEMENTATION DEFINED behaviors occur:

- BADDR uses the extended format to represent a 52-bit base address.
 - BADDR does not use the extended format.
-

If any register bit $[47:1]$ that is defined as RES0 has the value 1 when a translation table walk is done using [TTBR0_EL1](#), then the translation table base address might be misaligned, with effects that are CONSTRAINED UNPREDICTABLE, and must be one of the following:

- Bits $A[(x-1):0]$ of the stage 1 translation table base address are treated as if all the bits are zero. The value read back from the corresponding register bits is either the value written to the register or zero.
- The result of the calculation of an address for a translation table walk using this register can be corrupted in those bits that are nonzero.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

CnP, bit [0]

When [VTCR_EL2.MSA](#) == '1' and [FEAT_TTCNP](#) is implemented:

Common not Private. This bit indicates whether each entry that is pointed to by [TTBR0_EL1](#) is a member of a common set that can be used by every PE in the Inner Shareable domain for which the value of [TTBR0_EL1.CnP](#) is 1.

CnP	Meaning
0b0	The translation table entries pointed to by TTBR0_EL1, for the current translation regime and ASID, are permitted to differ from corresponding entries for TTBR0_EL1 for other PEs in the Inner Shareable domain. This is not affected by: • The value of TTBR0_EL1.CnP on those other PEs. • The value of the current ASID. • If EL2 is implemented and enabled in the current Security state, the value of the current VMID.
0b1	The translation table entries pointed to by TTBR0_EL1 are the same as the translation table entries for every other PE in the Inner Shareable domain for which the value of TTBR0_EL1.CnP is 1 and all of the following apply: • The translation table entries are pointed to by TTBR0_EL1. • The translation tables relate to the same translation regime. • The ASID is the same as the current ASID. • If EL2 is implemented and enabled in the current Security state, the value of the current VMID.

This bit is permitted to be cached in a TLB.

When a TLB combines entries from stage 1 translation and stage 2 translation into a single entry, that entry can only be shared between different PEs if the value of the CnP bit is 1 for both stage 1 and stage 2.

Note

If the value of the TTBR0_EL1.CnP bit is 1 on multiple PEs in the same Inner Shareable domain and those TTBR0_EL1s do not point to the same translation table entries when the other conditions specified for the case when the value of CnP is 1 apply, then the results of translations are **CONSTRAINED UNPREDICTABLE**, see ‘[CONSTRAINED UNPREDICTABLE behaviors due to caching of control or data values](#)’.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

When VTCR_EL2.MSA == '0':

Reserved, RES0.

Otherwise:

Reserved, RES0.

Accessing TTBR0_EL1

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, TTBR0_EL1

op0	op1	CRn	CRm	op2
0b11	0b000	0b0010	0b0000	0b000

```

```

D12.2.98 TTBR1_EL1, Translation Table Base Register 1 (EL1)

The TTBR1_EL1 characteristics are:

Purpose

Holds the base address of the translation table for the initial lookup for stage 1 of the translation of an address from the higher VA range in the EL1&0 stage 1 translation regime, and other information for this translation regime.

Configuration

In a PMSAv8-64 only implementation, this register is UNDEFINED.

This register is present only when architecture implements VMSA extension. Otherwise, direct accesses to TTBR1_EL1 are UNDEFINED.

Attributes

TTBR1_EL1 is a 64-bit register.

Field descriptions

ASID, bits [63:48]

When VTCR_EL2.MSA == '1':

An ASID for the translation table base address. The [TCR_EL1.A1](#) field selects either [TTBR0_EL1.ASID](#) or [TTBR1_EL1.ASID](#).

If the implementation has only 8 bits of ASID, then the upper 8 bits of this field are RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

BADDR[47:1], bits [47:1]

When VTCR_EL2.MSA == '1':

Translation table base address:

- Bits A[47:x] of the stage 1 translation table base address bits are in register bits[47:x].
- Bits A[(x-1):0] of the stage 1 translation table base address are zero.

Address bit x is the minimum address bit required to align the translation table to the size of the table. The AArch64 Virtual Memory System Architecture chapter describes how x is calculated based on the value of [TCR_EL1.T1SZ](#), the translation stage, and the translation granule size.

The BADDR field represents a 52-bit address if any of the following apply:

- The value of [TCR_EL1.IPS](#) represents an OA size of 52 bits.
- The Effective value of [TCR_EL1.DS](#) is 1.

When TTBR1_EL1.BADDR represents a 52-bit addresses, all of the following apply:

- Bits A[51:48] of the stage 1 translation table base address bits are in register bits[5:2].
- Register bit[1] is RES0.
- The smallest permitted value of x is 6.
- When $x > 6$, register bits[(x-1):6] are RES0.

Otherwise, all of the following apply:

- Register bits[(x-1):1] are RES0.
- If 52-bit PA is supported, then bits A[51:48] of the stage 1 translation table base address are treated as 0b0000.

Note

If BADDR represents a 52-bit address, and the translation table has fewer than eight entries, the table must be aligned to 64 bytes. Otherwise the translation table must be aligned to the size of the table.

For the 64KB granule, if 52-bit PA is not supported, and the value of TCR_EL1.IPS is 0b110 or 0b111, one of the following IMPLEMENTATION DEFINED behaviors occur:

- BADDR uses the extended format to represent a 52-bit base address.
 - BADDR does not use the extended format.
-

If any register bit[47:1] that is defined as RES0 has the value 1 when a translation table walk is done using TTBR1_EL1, then the translation table base address might be misaligned, with effects that are CONSTRAINED UNPREDICTABLE, and must be one of the following:

- Bits A[(x-1):0] of the stage 1 translation table base address are treated as if all the bits are zero. The value read back from the corresponding register bits is either the value written to the register or zero.
- The result of the calculation of an address for a translation table walk using this register can be corrupted in those bits that are nonzero.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

CnP, bit [0]

When VTCR_EL2.MSA == '1' and FEAT_TTCNP is implemented:

Common not Private. This bit indicates whether each entry that is pointed to by TBR1_EL1 is a member of a common set that can be used by every PE in the Inner Shareable domain for which the value of TTBR1_EL1.CnP is 1.

CnP	Meaning
0b0	The translation table entries pointed to by TTBR1_EL1, for the current translation regime and ASID, are permitted to differ from corresponding entries for TTBR1_EL1 for other PEs in the Inner Shareable domain. This is not affected by: • The value of TTBR1_EL1.CnP on those other PEs. • The value of the current ASID. • The value of the current VMID.

CnP	Meaning
0b1	The translation table entries pointed to by TTBR1_EL1 are the same as the translation table entries for every other PE in the Inner Shareable domain for which the value of TTBR1_EL1.CnP is 1 and all of the following apply: • The translation table entries are pointed to by TTBR1_EL1. • The translation tables relate to the same translation regime. • The ASID is the same as the current ASID. • The value of the current VMID.

This bit is permitted to be cached in a TLB.

When a TLB combines entries from stage 1 translation and stage 2 translation into a single entry, that entry can only be shared between different PEs if the value of the CnP bit is 1 for both stage 1 and stage 2.

Note

If the value of the TTBR1_EL1.CnP bit is 1 on multiple PEs in the same Inner Shareable domain and those TTBR1_EL1s do not point to the same translation table entries when the other conditions specified for the case when the value of CnP is 1 apply, then the results of translations are **CONSTRAINED UNPREDICTABLE**, see ‘[CONSTRAINED UNPREDICTABLE behaviors due to caching of control or data values](#)’.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Accessing TTBR1_EL1

Accesses to this register use the following encodings in the System register encoding space:

```

D12.2.99 VBAR_EL1, Vector Base Address Register (EL1)

The VBAR_EL1 characteristics are:

Purpose

Holds the vector base address for any exception that is taken to EL1.

Configuration

There are no configuration notes.

Attributes

VBAR_EL1 is a 64-bit register.

Field descriptions

VBA, bits [63:11]

Vector Base Address. Base address of the exception vectors for exceptions taken to EL1.

Note

If the implementation supports [FEAT_LVA](#), then:

- If tagged addresses are being used, bits [55:52] of VBAR_EL1 must be the same or else the use of the vector address will result in a recursive exception.
- If tagged addresses are not being used, bits [63:52] of VBAR_EL1 must be the same or else the use of the vector address will result in a recursive exception.

If the implementation does not support [FEAT_LVA](#), then:

- If tagged addresses are being used, bits [55:48] of VBAR_EL1 must be the same or else the use of the vector address will result in a recursive exception.
- If tagged addresses are not being used, bits [63:48] of VBAR_EL1 must be the same or else the use of the vector address will result in a recursive exception.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [10:0]

Reserved, RES0.

Accessing VBAR_EL1

Accesses to this register use the following encodings in the System register encoding space:

end;

```

D12.2.100 **VBAR_EL2, Vector Base Address Register (EL2)**

The VBAR_EL2 characteristics are:

Purpose

Holds the vector base address for any exception that is taken to EL2.

Configuration

There are no configuration notes.

Attributes

VBAR_EL2 is a 64-bit register.

Field descriptions

VBA, bits [63:11]

Vector Base Address. Base address of the exception vectors for exceptions taken to EL2.

Note
If [FEAT_LVA](#) is implemented:

- If tagged addresses are being used, bits [55:52] of VBAR_EL2 must be 0 or else the use of the ↪vector address will result in a recursive exception.
- If tagged addresses are not being used, bits [63:52] of VBAR_EL2 must be 0 or else the use of the ↪vector address will result in a recursive exception.

If [FEAT_LVA](#) is not implemented:

- If tagged addresses are being used, bits [55:48] of VBAR_EL2 must be 0 or else the use of the ↪vector address will result in a recursive exception.
- If tagged addresses are not being used, bits [63:48] of VBAR_EL2 must be 0 or else the use of ↪the vector address will result in a recursive exception.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [10:0]

Reserved, RES0.

Accessing VBAR_EL2

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, VBAR_EL2

end;
```

D12.2.101 VMPIDR_EL2, Virtualization Multiprocessor ID Register

The VMPIDR_EL2 characteristics are:

Purpose

Holds the value of the Virtualization Multiprocessor ID. This is the value returned by EL1 reads of MPIDR_EL1, which in a multiprocessor system, provides an additional PE identification system.

Configuration

If EL2 is not implemented, reads of this register return the value of the MPIDR_EL1 and writes to the register are ignored.

This register has no effect if EL2 is not enabled in the current Security state.

Attributes

VMPIDR_EL2 is a 64-bit register.

Field descriptions

Bits [63:40]

Reserved, RES0.

Aff3, bits [39:32]

Affinity level 3. See the description of VMPIDR_EL2.Aff0 for more information.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [31]

Reserved, RES1.

U, bit [30]

Indicates a Uniprocessor system, as distinct from PE 0 in a multiprocessor system.

U	Meaning
0b0	Processor is part of a multiprocessor system.
0b1	Processor is part of a uniprocessor system.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [29:25]

Reserved, RES0.

MT, bit [24]

Indicates whether the lowest level of affinity consists of logical PEs that are implemented using a multithreading type approach. See the description of VMPIDR_EL2.Aff0 for more information about affinity levels.

MT	Meaning
0b0	Performance of PEs at the lowest affinity level is largely independent.
0b1	Performance of PEs at the lowest affinity level is very interdependent.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Aff2, bits [23:16]

Affinity level 2. See the description of VMPIDR_EL2.Aff0 for more information.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Aff1, bits [15:8]

Affinity level 1. See the description of VMPIDR_EL2.Aff0 for more information.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Aff0, bits [7:0]

Affinity level 0.

The assigned value of the [MPIDR_EL1](#).{Aff3, Aff2, Aff1, Aff0} set of fields of each PE must be unique within the system as a whole.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing VMPIDR_EL2

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, VMPIDR_EL2

op0	op1	CRn	CRm	op2
0b11	0b100	0b0000	0b0000	0b101

```

if PSTATE.EL == EL0 then
    Undefined();
elsif PSTATE.EL == EL1 then

```

if PSTATE.EL == EL0 then
    if IsFeatureImplemented(FEAT_IDST) then
        AArch64_SystemAccessTrapToEL1orEL2(0x18);
    else
        Undefined();
    end;
elsif PSTATE.EL == EL1 then
    X{64}(t) = VMPIDR_EL2();
elsif PSTATE.EL == EL2 then
    X{64}(t) = MPIDR_EL1();
end;

```

D12.2.102 **VPIDR_EL2, Virtualization Processor ID Register**

The VPIDR_EL2 characteristics are:

Purpose

Holds the value of the Virtualization Processor ID. This is the value returned by EL1 reads of [MIDR_EL1](#).

Configuration

If EL2 is not implemented, reads of this register return the value of the [MIDR_EL1](#) and writes to the register are ignored.

This register has no effect if EL2 is not enabled in the current Security state.

Attributes

VPIDR_EL2 is a 64-bit register.

Field descriptions

Bits [63:32]

Reserved, RES0.

Implementer, bits [31:24]

The Implementer code. This field must hold an implementer code that has been assigned by Arm.

Implementer	Meaning
0x00	Reserved for software use.
0x41	Arm Limited.
0x42	Broadcom Corporation.
0x43	Cavium Inc.
0x44	Digital Equipment Corporation.
0x46	Fujitsu Ltd.
0x49	Infineon Technologies AG.
0x4D	Motorola or Freescale Semiconductor Inc.
0x4E	NVIDIA Corporation.
0x50	Applied Micro Circuits Corporation.
0x51	Qualcomm Inc.
0x56	Marvell International Ltd.
0x69	Intel Corporation.

Implementer	Meaning
0xC0	Ampere Computing.

Arm can assign codes that are not published in this manual. All values not assigned by Arm are reserved and must not be used.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Variant, bits [23:20]

An IMPLEMENTATION DEFINED variant number. Typically, this field is used to distinguish between different product variants, or major revisions of a product.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Architecture, bits [19:16]

Architecture version.

Architecture	Meaning
0b0001	Armv4.
0b0010	Armv4T.
0b0011	Armv5 (obsolete).
0b0100	Armv5T.
0b0101	Armv5TE.
0b0110	Armv5TEJ.
0b0111	Armv6.
0b1111	Architectural features are individually identified in the ID_* registers.

All other values are reserved.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

PartNum, bits [15:4]

An IMPLEMENTATION DEFINED primary part number for the device.

On processors implemented by Arm, if the top four bits of the primary part number are 0x0 or 0x7, the variant and architecture are encoded differently.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Revision, bits [3:0]

An IMPLEMENTATION DEFINED revision number for the device.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing VPIDR_EL2

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, VPIDR_EL2

op0	op1	CRn	CRm	op2
0b11	0b100	0b0000	0b0000	0b000

```

if PSTATE.EL == EL0 then
    Undefined();
elsif PSTATE.EL == EL1 then
    Undefined();
elsif PSTATE.EL == EL2 then
    X{64}(t) = VPIDR_EL2();
end;

```

MSR VPIDR_EL2, <Xt>

op0	op1	CRn	CRm	op2
0b11	0b100	0b0000	0b0000	0b000

```

if PSTATE.EL == EL0 then
    Undefined();
elsif PSTATE.EL == EL1 then
    Undefined();
elsif PSTATE.EL == EL2 then
    VPIDR_EL2() = X{64}(t);
end;

```

MRS <Xt>, MIDR_EL1

op0	op1	CRn	CRm	op2
0b11	0b000	0b0000	0b0000	0b000

```

if PSTATE.EL == EL0 then
    if IsFeatureImplemented(FEAT_IDST) then
        AArch64_SystemAccessTrapToEL1orEL2(0x18);
    else
        Undefined();
    end;
elsif PSTATE.EL == EL1 then
    X{64}(t) = VPIDR_EL2();
elsif PSTATE.EL == EL2 then
    X{64}(t) = MIDR_EL1();
end;

```

D12.2.103 VSCTLR_EL2, Virtualization System Control Register (EL2)

The VSCTLR_EL2 characteristics are:

Purpose

Provides configuration information for VMSAv8-64 and PMSAv8-64 virtualization using stage 2 of EL1&0 translation regime.

Configuration

There are no configuration notes.

Attributes

VSCTLR_EL2 is a 64-bit register.

Field descriptions

VMID[15:8], bits [63:56]

When FEAT_VMID16 is implemented and VTCR_EL2.VS == '1':

Extension to VMID[7:0]. For more information, see VSCTLR_EL2.VMID[7:0].

If the implementation has an 8-bit VMID, this field is RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

VMID[7:0], bits [55:48]

The VMID for the EL1-Guest-OS.

The VMID is 8 bits when any of the following are true:

- The [VTCR_EL2.VS](#) is 0.
- [FEAT_VMID16](#) is not implemented.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [47:1]

Reserved, RES0.

CnP, bit [0]

When FEAT_TTCNP is implemented and VTCR_EL2.MSA == '1':

Common not Private. This bit indicates whether stage 2 of EL1&0 translations are a member of a common set that can be used by every PE in the Inner Shareable domain for which the value of VSCTLR_EL2.CnP is 1.

CnP	Meaning
0b0	The stage 2 translations of the EL1&0 translation regime are permitted to differ in other PEs in the Inner Shareable domain. This is not affected by the value of the current VMID.
0b1	The stage 2 translations of the EL1&0 translation regime are the same for every other PE in the Inner Shareable domain for which the value of VSCTLR_EL2.CnP is 1 and the VMID is the same as the current VMID.

Note

If the value of VSCTLR_EL2.CnP bit is 1 on multiple PEs in the same Inner Shareable domain and the stage 2 EL1&0 translation does not point to the same configurations when using the current VMID, then the results of the translations are CONSTRAINED UNPREDICTABLE, see ‘[CONSTRAINED UNPREDICTABLE behaviors due to caching of control or data values](#)’.

In an implementation that does not support VMSAv8-64 at stage 1 EL1&0 translation regime this field is RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Accessing VSCTLR_EL2

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, VSCTLR_EL2

op0	op1	CRn	CRm	op2
0b11	0b100	0b0010	0b0000	0b000

```

if PSTATE.EL == EL0 then
    Undefined();
elsif PSTATE.EL == EL1 then
    Undefined();
elsif PSTATE.EL == EL2 then
    X{64}(t) = VSCTLR_EL2();
end;
```

MSR VSCTLR_EL2, <Xt>

op0	op1	CRn	CRm	op2

```
if PSTATE.EL == EL0 then
    Undefined();
elsif PSTATE.EL == EL1 then
    Undefined();
elsif PSTATE.EL == EL2 then
    VSCTLR_EL2() = X{64}(t);
end;
```

D12.2.104 VSTCR_EL2, Virtualization Secure Translation Control Register

The VSTCR_EL2 characteristics are:

Purpose

The control register for stage 2 of the Secure EL1&0 translation regime.

Configuration

This register is present only when FEAT_SEL2 is implemented. Otherwise, direct accesses to VSTCR_EL2 are UNDEFINED.

Attributes

VSTCR_EL2 is a 64-bit register.

Field descriptions

Any of the bits in VSTCR_EL2 are permitted to be cached in a TLB.

Bits [63:32]

Reserved, RES0.

Bit [31]

Reserved, RES1.

SA, bit [30]

Secure stage 2 translation output address space.

SA	Meaning
0b0	All stage 2 translations for the Secure PA space access the Secure PA space.
0b1	All stage 2 translations for the Secure PA space access the Non-secure PA space.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [29:21]

Reserved, RES0.

SC, bit [20]

NS check enable bit.

SC	Meaning
0b0	Least secure NS configuration is selected from the stage 1 and stage 2 EL1&0 translation regime for the given address.
0b1	Stage 2 NS configuration is checked against stage 1 NS configuration at EL1&0 translation regime for the given address, and generate a fault if they are different.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [19:0]

Reserved, RES0.

Accessing VSTCR_EL2

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, VSTCR_EL2

op0	op1	CRn	CRm	op2
0b11	0b100	0b0010	0b0110	0b010

```
if !IsFeatureImplemented(FEAT_SEL2) then
    Undefined();
elsif PSTATE.EL == EL0 then
    Undefined();
elsif PSTATE.EL == EL1 then
    Undefined();
elsif PSTATE.EL == EL2 then
    X{64}(t) = VSTCR_EL2();
end;
```

MSR VSTCR_EL2, <Xt>

op0	op1	CRn	CRm	op2
0b11	0b100	0b0010	0b0110	0b010

```
if !IsFeatureImplemented(FEAT_SEL2) then
    Undefined();
elsif PSTATE.EL == EL0 then
    Undefined();
elsif PSTATE.EL == EL1 then
    Undefined();
elsif PSTATE.EL == EL2 then
    VSTCR_EL2() = X{64}(t);
end;
```

D12.2.105 VTCR_EL2, Virtualization Translation Control Register

The VTCR_EL2 characteristics are:

Purpose

The control register for stage 2 of the EL1&0 translation regime.

Configuration

There are no configuration notes.

Attributes

VTCR_EL2 is a 64-bit register.

Field descriptions

Any of the bits in VTCR_EL2 are permitted to be cached in a TLB.

Bits [63:32]

Reserved, RES0.

MSA, bit [31]

When ID_AA64MMFR0_EL1.MSA_frac == '0010':

Stage 1 EL1&0 translation regime memory system architecture.

MSA	Meaning
0b0	Stage 1 EL1&0 translation regime uses PMSAv8-64 memory architecture.
0b1	Stage 1 EL1&0 translation regime uses VMSAv8-64 memory architecture.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

When ID_AA64MMFR0_EL1.MSA_frac == '0001':

Reserved, RES0.

Otherwise:

Reserved, RES1.

NSA, bit [30]

When FEAT_SEL2 is implemented:

Non-secure stage 2 translation output address space.

NSA	Meaning
0b0	All stage 2 translations for the Non-secure PA space of the Secure EL1&0 translation regime access the Secure PA space.
0b1	All stage 2 translations for the Non-secure PA space of the Secure EL1&0 translation regime access the Non-secure PA space.

This bit behaves as 1 for all purposes other than reading back the value of the bit when the value of [VSTCR_EL2.SA](#) is 1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bits [29:20]

Reserved, RES0.

VS, bit [19]

When FEAT_VMID16 is implemented:

VMID Size.

VS	Meaning
0b0	8-bit VMID. The upper 8 bits of VSCTLR_EL2 are ignored by the hardware, and treated as if they are all zeros, for every purpose except when reading back the register.
0b1	16-bit VMID. The upper 8 bits of VSCTLR_EL2 are used for allocation and matching in the TLB.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bits [18:0]

Reserved, RES0.

Accessing VTCR_EL2

Unless stated otherwise, any of the bits in VTCR_EL2 are permitted to be cached in a TLB.

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, VTCR_EL2

op0	op1	CRn	CRm	op2
0b11	0b100	0b0010	0b0001	0b010

```
if PSTATE.EL == EL0 then
    Undefined();
elsif PSTATE.EL == EL1 then
    Undefined();
elsif PSTATE.EL == EL2 then
    X{64}(t) = VTCR_EL2();
end;
```

MSR VTCR_EL2, <Xt>

op0	op1	CRn	CRm	op2
0b11	0b100	0b0010	0b0001	0b010

```
if PSTATE.EL == EL0 then
    Undefined();
elsif PSTATE.EL == EL1 then
    Undefined();
elsif PSTATE.EL == EL2 then
    VTCR_EL2() = X{64}(t);
end;
```

D12.3 Debug System registers

This section lists the debug System registers in AArch64 state, in alphabetic order:

- The principal encoding space for debug System registers is $op0 == 0b10$, $op1 == \{0, 3, 4\}$. [Instructions for accessing debug System registers](#) summarizes the registers in this encoding space and lists them in order of their encodings.
- In addition, the following registers in the $op0 == 0b11$ encoding space are classified as debug System registers:
 - [DLR_EL0](#).
 - [DPSR_EL0](#).
 - [MDCR_EL2](#).
 - [MDCR_EL3](#).
 - [SDER32_EL3](#).

D12.3.1 DBGAUTHSTATUS_EL1, Debug Authentication Status Register

The DBGAUTHSTATUS_EL1 characteristics are:

Purpose

Provides information about the state of the IMPLEMENTATION DEFINED authentication interface for debug.

Configuration

AArch64 System register DBGAUTHSTATUS_EL1 bits [31:0] are architecturally mapped to External register [DBGAUTHSTATUS_EL1](#)[31:0].

Attributes

DBGAUTHSTATUS_EL1 is a 64-bit register.

Field descriptions

Bits [63:8]

Reserved, RES0.

SNID, bits [7:6]

When FEAT_Debugv8p4 is implemented:

Secure non-invasive debug.
This field has the same value as DBGAUTHSTATUS_EL1.SID.

Otherwise:

Secure non-invasive debug.

SNID	Meaning
0b00	Secure state is not implemented.
0b10	Implemented and disabled. ExternalSecureNoninvasiveDebugEnabled() == FALSE.
0b11	Implemented and enabled. ExternalSecureNoninvasiveDebugEnabled() == TRUE.

All other values are reserved.

SID, bits [5:4]

Secure invasive debug.

SID	Meaning
0b00	Secure state is not implemented.
0b10	Implemented and disabled. <code>ExternalSecureInvasiveDebugEnabled()</code> == FALSE.
0b11	Implemented and enabled. <code>ExternalSecureInvasiveDebugEnabled()</code> == TRUE.

All other values are reserved.

NSNID, bits [3:2]

When FEAT_Debugv8p4 is implemented:

Non-secure non-invasive debug.

NSNID	Meaning
0b00	Non-secure state is not implemented.
0b11	Implemented and enabled. EL3 is implemented or the Effective value of SCR_EL3.NS is 1.

All other values are reserved.

Otherwise:

Non-secure non-invasive debug.

NSNID	Meaning
0b00	Non-secure state is not implemented.
0b10	Implemented and disabled. <code>ExternalNoninvasiveDebugEnabled()</code> == FALSE.
0b11	Implemented and enabled. <code>ExternalNoninvasiveDebugEnabled()</code> == TRUE.

All other values are reserved.

NSID, bits [1:0]

Non-secure invasive debug.

NSID	Meaning
0b00	Non-secure state is not implemented.
0b10	Implemented and disabled. <code>ExternalInvasiveDebugEnabled()</code> == FALSE.
0b11	Implemented and enabled. <code>ExternalInvasiveDebugEnabled()</code> == TRUE.

All other values are reserved.

Accessing DBGAUTHSTATUS_EL1

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, DBGAUTHSTATUS_EL1

op0	op1	CRn	CRm	op2
0b10	0b000	0b0111	0b1110	0b110

```
if PSTATE.EL == EL0 then
    Undefined();
elsif PSTATE.EL == EL1 then
    if MDCR_EL2().[TDE,TDA] != '00' then
        AArch64_SystemAccessTrap(EL2, 0x18);
    else
        X{64}(t) = DBGAUTHSTATUS_EL1();
    end;
elsif PSTATE.EL == EL2 then
    X{64}(t) = DBGAUTHSTATUS_EL1();
end;
```

D12.3.2 DBGBCR<n>_EL1, Debug Breakpoint Control Registers, n = 0 - 63

The DBGBCR<n>_EL1 characteristics are:

Purpose

Holds control information for a breakpoint. Forms breakpoint n together with value register DBGBVR<n>_EL1.

Configuration

If breakpoint n is not implemented, accesses to this register are UNDEFINED.

AArch64 System register DBGBCR<n>_EL1 bits [31:0] are architecturally mapped to External register DBGBCR<n>_EL1[31:0].

Attributes

DBGBCR<n>_EL1 is a 64-bit register.

Field descriptions

Bits [63:24]

Reserved, RES0.

BT, bits [23:20]

Breakpoint Type.

Specifies breakpoint type.

BT	Meaning	Applies when
0b0000	Unlinked instruction address match. DBGBVR<n>_EL1 is the address of an instruction.	
0b0001	Linked instruction address match. As 0b0000, but linked to a breakpoint that has linking enabled.	
0b0010	Unlinked Context ID match. DBGBVR<n>_EL1.ContextID is compared against CONTEXTIDR_EL1.	breakpoint n is context-aware
0b0011	As 0b0010, with linking enabled.	breakpoint n is context-aware
0b0110	Unlinked CONTEXTIDR_EL1 match. DBGBVR<n>_EL1.ContextID is a Context ID compared against CONTEXTIDR_EL1.	FEAT_Debugv8p1 is implemented and breakpoint n is context-aware
0b0111	As 0b0110, with linking enabled.	FEAT_Debugv8p1 is implemented and breakpoint n is context-aware

BT	Meaning	Applies when
0b1000	Unlinked VMID match. DBGBVR<n>_EL1 .VMID is a VMID compared against VSCTLR_EL2 .VMID.	breakpoint n is context-aware
0b1001	As 0b1000, with linking enabled.	breakpoint n is context-aware
0b1010	Unlinked VMID and Context ID match. DBGBVR<n>_EL1 .ContextID is a Context ID compared against CONTEXTIDR_EL1 , and DBGBVR<n>_EL1 .VMID is a VMID compared against VSCTLR_EL2 .VMID.	breakpoint n is context-aware
0b1011	As 0b1010, with linking enabled.	breakpoint n is context-aware
0b1100	Unlinked CONTEXTIDR_EL2 match. DBGBVR<n>_EL1 .ContextID2 is a Context ID compared against CONTEXTIDR_EL2 .	FEAT_Debugv8p1 is implemented and breakpoint n is context-aware
0b1101	As 0b1100, with linking enabled.	FEAT_Debugv8p1 is implemented and breakpoint n is context-aware
0b1110	Unlinked Full Context ID match. DBGBVR<n>_EL1 .ContextID is compared against CONTEXTIDR_EL1 , and DBGBVR<n>_EL1 .ContextID2 is compared against CONTEXTIDR_EL2 .	FEAT_Debugv8p1 is implemented and breakpoint n is context-aware
0b1111	As 0b1110, with linking enabled.	FEAT_Debugv8p1 is implemented and breakpoint n is context-aware

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

LBN, bits [19:16]

Linked Breakpoint Number.

For Linked address matching breakpoints, specifies the index of the breakpoint linked to.

For all other breakpoint types, this field is ignored and reads of the register return an UNKNOWN value.

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

SSC, bits [15:14]

Security state control. Determines the Security states under which a Breakpoint debug event for breakpoint n is generated.

The fields that indicate when the breakpoint can be generated are: HMC, PMC, and SSC. These fields must be considered in combination, and the values that are permitted for these fields are constrained.

For more information on the operation of these fields, see ‘[Execution conditions for which a breakpoint generates Breakpoint exceptions](#)’.

For more information on the effect of programming the fields to a reserved set of values, see ‘[Reserved DBGBCR<n>_EL1.{SSC, HMC, PMC} values](#)’.

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

HMC, bit [13]

Higher mode control. Determines the debug perspective for deciding when a Breakpoint debug event for breakpoint n is generated.

The fields that indicate when the breakpoint can be generated are: HMC, PMC, and SSC. These fields must be considered in combination, and the values that are permitted for these fields are constrained.

For more information on the operation of these fields, see ‘[Execution conditions for which a breakpoint generates Breakpoint exceptions](#)’.

For more information, see DBGBCR<n>_EL1.SSC.

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

Bits [12:9]

Reserved, RES0.

Bits [8:5]

Reserved, RES1.

Bits [4:3]

Reserved, RES0.

PMC, bits [2:1]

Privilege mode control. Determines the Exception level or levels at which a Breakpoint debug event for breakpoint n is generated.

The fields that indicate when the breakpoint can be generated are: HMC, PMC, and SSC. These fields must be considered in combination, and the values that are permitted for these fields are constrained.

For more information on the operation of these fields, see ‘[Execution conditions for which a breakpoint generates Breakpoint exceptions](#)’.

For more information, see DBGBCR<n>_EL1.SSC.

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

E, bit [0]

Enable breakpoint n.

E	Meaning
0b0	Breakpoint n disabled.
0b1	Breakpoint n enabled.

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

Accessing DBGBCR<n>_EL1

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, DBGBCR<m>_EL1 ; Where m = 0-15

op0	op1	CRn	CRm	op2
0b10	0b000	0b0000	m[3:0]	0b101

```

let m:integer = UInt(CRm[3:0]);

if m >= NUM_BREAKPOINTS then
    Undefined();
elseif PSTATE.EL == EL0 then
    Undefined();
elseif PSTATE.EL == EL1 then
    if MDCR_EL2().[TDE,TDA] != '00' then
        AArch64_SystemAccessTrap(EL2, 0x18);
    elseif OSLSR_EL1().OSLK == '0' && HaltingAllowed() && EDSCR().TDA == '1' then
        Halt(DebugHalt_SoftwareAccess);
    else
        X{64}(t) = DBGBCR_EL1(m);
    end;
elseif PSTATE.EL == EL2 then
    if OSLSR_EL1().OSLK == '0' && HaltingAllowed() && EDSCR().TDA == '1' then
        Halt(DebugHalt_SoftwareAccess);
    else
        X{64}(t) = DBGBCR_EL1(m);
    end;
end;

```

MSR DBGBCR<m>_EL1, <Xt> ; Where m = 0-15

op0	op1	CRn	CRm	op2
0b10	0b000	0b0000	m[3:0]	0b101

```

let m:integer = UInt(CRm[3:0]);

if m >= NUM_BREAKPOINTS then
    Undefined();
elseif PSTATE.EL == EL0 then
    Undefined();
elseif PSTATE.EL == EL1 then
    if MDCR_EL2().[TDE,TDA] != '00' then
        AArch64_SystemAccessTrap(EL2, 0x18);
    elseif OSLSR_EL1().OSLK == '0' && HaltingAllowed() && EDSCR().TDA == '1' then
        Halt(DebugHalt_SoftwareAccess);
    else
        DBGBCR_EL1(m) = X{64}(t);
    end;
elseif PSTATE.EL == EL2 then
    if OSLSR_EL1().OSLK == '0' && HaltingAllowed() && EDSCR().TDA == '1' then
        Halt(DebugHalt_SoftwareAccess);
    else
        DBGBCR_EL1(m) = X{64}(t);
    end;
end;

```

D12.3.3 DBGBVR<n>_EL1, Debug Breakpoint Value Registers, n = 0 - 63

The DBGBVR<n>_EL1 characteristics are:

Purpose

Holds a virtual address, or a VMID and/or a context ID, for use in breakpoint matching. Forms breakpoint n together with control register [DBGBCR<n>_EL1](#).

Configuration

How this register is interpreted depends on the value of [DBGBCR<n>_EL1.BT](#).

- When [DBGBCR<n>_EL1.BT](#) is 0b000x, this register holds a virtual address.
- When [DBGBCR<n>_EL1.BT](#) is 0b001x, 0b011x, or 0b110x, this register holds a Context ID.
- When [DBGBCR<n>_EL1.BT](#) is 0b100x, this register holds a VMID.
- When [DBGBCR<n>_EL1.BT](#) is 0b101x, this register holds a VMID and a Context ID.
- When [DBGBCR<n>_EL1.BT](#) is 0b111x, this register holds two Context ID values.

For other values of [DBGBCR<n>_EL1.BT](#), this register is RES0.

If breakpoint n is not implemented then accesses to this register are UNDEFINED.

AArch64 System register DBGBVR<n>_EL1 bits [63:0] are architecturally mapped to External register [DBGBVR<n>_EL1](#)[63:0].

Attributes

DBGBVR<n>_EL1 is a 64-bit register.

Field descriptions

When [DBGBCR<n>_EL1.BT](#) IN {'000x'}:

RESS[14:8], bits [63:57]

Reserved, Sign extended. Software must set all bits in this field to the same value as the most significant bit of the VA field. If all bits in this field are not the same value as the most significant bit of the VA field, then all of the following apply:

- It is CONSTRAINED UNPREDICTABLE whether the PE ignores this field when comparing an address.
- If the breakpoint is not context-aware, it is IMPLEMENTATION DEFINED whether the value read back in each bit of this field is a copy of the most significant bit of the VA field or the value written.

RESS[7:4], bits [56:53]

Extension to RESS[14:8]. For more information, see RESS[14:8].

Bits [52:49]

When FEAT_LVA is implemented:

VA[52:49], bits [52:49]

Extension to VA[48:2]. For more information, see VA[48:2].

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

RESS[3:0], bits [52:49]

Extension to RESS[14:8]. For more information, see RESS[14:8].

VA[48:2], bits [48:2]

Bits[48:2] of the address value for comparison.

When [FEAT_LVA](#) is implemented, VA[52:49] forms the upper part of the address value. If FEAT_LVA is not implemented, bits [52:49] are part of the RESS field.

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

Bits [1:0]

Reserved, RES0.

When DBGBCR<n>_EL1.BT IN {'001x'}:

Bits [63:32]

Reserved, RES0.

ContextID, bits [31:0]

Context ID value for comparison.

The value is compared against [CONTEXTIDR_EL1](#).

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

When DBGBCR<n>_EL1.BT IN {'011x'} and FEAT_Debugv8p1 is implemented:

Bits [63:32]

Reserved, RES0.

ContextID, bits [31:0]

Context ID value for comparison against [CONTEXTIDR_EL1](#).

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

When DBGBCR<n>_EL1.BT IN {'100x'}:

Bits [63:48]

Reserved, RES0.

VMID[15:8], bits [47:40]

When FEAT_VMID16 is implemented and VTCR_EL2.VS == '1':

Extension to VMID[7:0]. For more information, see [DBGBVR<n>_EL1.VMID\[7:0\]](#).

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

VMID[7:0], bits [39:32]

VMID value for comparison.

The VMID is 8 bits when any of the following are true:

- [VTCR_EL2.VS](#) is 0.
- [FEAT_VMID16](#) is not implemented.

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

Bits [31:0]

Reserved, RES0.

When DBGBCR<n>_EL1.BT IN {'101x'}:

Bits [63:48]

Reserved, RES0.

VMID[15:8], bits [47:40]

When FEAT_VMID16 is implemented and VTCR_EL2.VS == '1':

Extension to VMID[7:0]. For more information, see [DBGBVR<n>_EL1.VMID\[7:0\]](#).

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

VMID[7:0], bits [39:32]

VMID value for comparison.

The VMID is 8 bits when any of the following are true:

- [VTCR_EL2.VS](#) is 0.
- [FEAT_VMID16](#) is not implemented.

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

ContextID, bits [31:0]

Context ID value for comparison against [CONTEXTIDR_EL1](#).

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

When DBGBCR<n>_EL1.BT IN {'110x'} and FEAT_Debugv8p1 is implemented:

ContextID2, bits [63:32]

Context ID value for comparison against [CONTEXTIDR_EL2](#).

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

Bits [31:0]

Reserved, RES0.

When DBGBCR<n>_EL1.BT IN {'111x'} and FEAT_Debugv8p1 is implemented:

ContextID2, bits [63:32]

Context ID value for comparison against [CONTEXTIDR_EL2](#).

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

ContextID, bits [31:0]

Context ID value for comparison against [CONTEXTIDR_EL1](#).

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

Accessing DBGVR<n>_EL1

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, DBGVR<m>_EL1 ; Where m = 0-15

op0	op1	CRn	CRm	op2
0b10	0b000	0b0000	m[3:0]	0b100

```
let m:integer = UInt(CRm[3:0]);

if m >= NUM_BREAKPOINTS then
    Undefined();
elseif PSTATE.EL == EL0 then

        Halt(DebugHalt_SoftwareAccess);
    else
        DBGVBVR_EL1(m) = X{64}(t);
    end;
end;

```

D12.3.4 DBGCLAIMCLR_EL1, Debug CLAIM Tag Clear Register

The DBGCLAIMCLR_EL1 characteristics are:

Purpose

Used by software to read the values of the CLAIM tag bits, and to clear CLAIM tag bits to 0.

The architecture does not define any functionality for the CLAIM tag bits.

Note

CLAIM tags are typically used for communication between the debugger and target software.

Used in conjunction with the [DBGCLAIMSET_EL1](#) register.

Configuration

An implementation must include eight CLAIM tag bits.

AArch64 System register DBGCLAIMCLR_EL1 bits [63:0] are architecturally mapped to AArch64 System register [DBGCLAIMSET_EL1](#)[63:0].

AArch64 System register DBGCLAIMCLR_EL1 bits [31:0] are architecturally mapped to External register [DBGCLAIMCLR_EL1](#)[31:0].

AArch64 System register DBGCLAIMCLR_EL1 bits [31:0] are architecturally mapped to External register [DBGCLAIMSET_EL1](#)[31:0].

Attributes

DBGCLAIMCLR_EL1 is a 64-bit register.

Field descriptions

Bits [63:32]

Reserved, RES0.

Bits [31:8]

Reserved, RAZ/WI.

CLAIM<m>, bits [m], for m = 7 to 0

Claim Tag Clear. Indicates the current status of Claim Tag bit <m>, and is used to clear Claim Tag bit <m> to 0.

CLAIM<m>	Meaning
0b0	On a read: Claim Tag bit <m> is not set. On a write: Ignored.
0b1	On a read: Claim Tag bit <m> is set. On a write: Clear Claim tag bit <m> to 0.

The reset behavior of this field is:

- On a Cold reset, this field resets to '0'.

Access to this field is W1C.

Accessing DBGCLAIMCLR_EL1

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, DBGCLAIMCLR_EL1

op0	op1	CRn	CRm	op2
0b10	0b000	0b0111	0b1001	0b110

```
if PSTATE.EL == EL0 then
    Undefined();
elsif PSTATE.EL == EL1 then
    if MDCR_EL2().[TDE,TDA] != '00' then
        AArch64_SystemAccessTrap(EL2, 0x18);
    else
        X{64}(t) = DBGCLAIMCLR_EL1();
    end;
elsif PSTATE.EL == EL2 then
    X{64}(t) = DBGCLAIMCLR_EL1();
end;
```

MSR DBGCLAIMCLR_EL1, <Xt>

0b10	0b000	0b0111	0b1001	0b110

```
if PSTATE.EL == EL0 then
    Undefined();
elsif PSTATE.EL == EL1 then
    if MDCR_EL2().[TDE,TDA] != '00' then
        AArch64_SystemAccessTrap(EL2, 0x18);
    else
        DBGCLAIMCLR_EL1() = X{64}(t);
    end;
elsif PSTATE.EL == EL2 then
    DBGCLAIMCLR_EL1() = X{64}(t);
end;
```

D12.3.5 DBGCLAIMSET_EL1, Debug CLAIM Tag Set Register

The DBGCLAIMSET_EL1 characteristics are:

Purpose

Used by software to set the CLAIM tag bits to 1.

The architecture does not define any functionality for the CLAIM tag bits.

Note

CLAIM tags are typically used for communication between the debugger and target software.

Used in conjunction with the [DBGCLAIMCLR_EL1](#) register.

Configuration

An implementation must include eight CLAIM tag bits.

AArch64 System register DBGCLAIMSET_EL1 bits [63:0] are architecturally mapped to AArch64 System register [DBGCLAIMCLR_EL1](#)[63:0].

AArch64 System register DBGCLAIMSET_EL1 bits [31:0] are architecturally mapped to External register [DBGCLAIMSET_EL1](#)[31:0].

AArch64 System register DBGCLAIMSET_EL1 bits [31:0] are architecturally mapped to External register [DBGCLAIMCLR_EL1](#)[31:0].

Attributes

DBGCLAIMSET_EL1 is a 64-bit register.

Field descriptions

Bits [63:32]

Reserved, RES0.

Bits [31:8]

Reserved, RAZ/WI.

CLAIM<m>, bits [m], for m = 7 to 0

Claim Tag Set. Used to set Claim Tag bit <m> to 1.

CLAIM<m>	Meaning
0b0	On a write: Ignored.
0b1	On a write: Set Claim Tag bit <m> to 1.

Access to this field is RAO/WIS.

Accessing DBGCLAIMSET_EL1

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, DBGCLAIMSET_EL1

op0	op1	CRn	CRm	op2
0b10	0b000	0b0111	0b1000	0b110

```
if PSTATE.EL == EL0 then
    Undefined();
elsif PSTATE.EL == EL1 then

elsif PSTATE.EL == EL2 then
    DBGCLAIMSET_EL1() = X{64}(t);
end;
```

D12.3.6 DBGDTR_EL0, Debug Data Transfer Register, half-duplex

The DBGDTR_EL0 characteristics are:

Purpose

Transfers 64 bits of data between the PE and an external debugger. Can transfer both ways using only a single register.

Configuration

When written, AArch64 System register DBGDTR_EL0 bits [63:32] are architecturally mapped to External register [DBGDTRRX_EL0](#)[31:0].

When written, AArch64 System register DBGDTR_EL0 bits [63:32] are architecturally mapped to AArch64 System register [DBGDTRRX_EL0](#)[31:0].

When written, AArch64 System register DBGDTR_EL0 bits [31:0] are architecturally mapped to External register [DBGDTRTX_EL0](#)[31:0].

When written, AArch64 System register DBGDTR_EL0 bits [31:0] are architecturally mapped to AArch64 System register [DBGDTRTX_EL0](#)[31:0].

When read, AArch64 System register DBGDTR_EL0 bits [63:32] are architecturally mapped to External register [DBGDTRTX_EL0](#)[31:0].

When read, AArch64 System register DBGDTR_EL0 bits [63:32] are architecturally mapped to AArch64 System register [DBGDTRTX_EL0](#)[31:0].

When read, AArch64 System register DBGDTR_EL0 bits [31:0] are architecturally mapped to External register [DBGDTRRX_EL0](#)[31:0].

When read, AArch64 System register DBGDTR_EL0 bits [31:0] are architecturally mapped to AArch64 System register [DBGDTRRX_EL0](#)[31:0].

Attributes

DBGDTR_EL0 is a 64-bit register.

Field descriptions

HighWord, bits [63:32]

If TXfull is 1, then writes to this register set DTRRX to an UNKNOWN value. Otherwise, writes to this register set DTRRX to the value in this field. Writes to this register do not change RXfull.

Reads of this register:

- If RXfull is 1, return the last value written to DTRTX.
- If RXfull is 0, return an UNKNOWN value.

After the read, RXfull is cleared to 0.

LowWord, bits [31:0]

If TXfull is 1, then writes to this register set DTRTX to an UNKNOWN value. Otherwise, writes to this register set DTRTX to the value in this field and set TXfull to 1.

Reads of this register:

- If RXfull is 1, return the last value written to DTRRX.
- If RXfull is 0, return an UNKNOWN value.

After the read, RXfull is cleared to 0.

Accessing DBGDTR_EL0

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, DBGDTR_EL0

op0	op1	CRn	CRm	op2
0b10	0b011	0b0000	0b0100	0b000

```

if Halted() then
    X{64}(t) = Read_DBGDTR_EL0{64}();

    end;
```

D12.3.7 DBGDTRRX_EL0, Debug Data Transfer Register, Receive

The DBGDTRRX_EL0 characteristics are:

Purpose

Transfers data from an external debugger to the PE. For example, it is used by a debugger transferring commands and data to a debug target. See [DBGDTR_EL0](#) for additional architectural mappings. It is a component of the Debug Communications Channel.

Configuration

AArch64 System register DBGDTRRX_EL0 bits [31:0] are architecturally mapped to External register [DBGDTRRX_EL0](#)[31:0].

Attributes

DBGDTRRX_EL0 is a 64-bit register.

Field descriptions

Bits [63:32]

Reserved, RES0.

DTRRX, bits [31:0]

DTRRX. Reads of this register:

- If RXfull is 1, return the last value written to DTRRX.
- If RXfull is 0, return an UNKNOWN value.

After the read, RXfull is cleared to 0.

For the full behavior of the Debug Communications Channel, see ‘[The Debug Communication Channel and Instruction Transfer Register](#)’.

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

Accessing DBGDTRRX_EL0

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, DBGDTRRX_EL0

op0	op1	CRn	CRm	op2
0b10	0b011	0b0000	0b0101	0b000

```
if Halted() then
    X{32}(t) = Read_DBGDTR_EL0{32}();
elsif PSTATE.EL == EL0 then
    if MDSCR_EL1().TDCC == '1' then
        AArch64_SystemAccessTrapToEL1orEL2(0x18);
    elsif EffectiveTGEforEL0Traps() == '1' || MDCR_EL2().[TDE,TDA] != '00' then
        AArch64_SystemAccessTrap(EL2, 0x18);
    else
        X{32}(t) = Read_DBGDTR_EL0{32}();
    end;
elsif PSTATE.EL == EL1 then
    if MDCR_EL2().[TDE,TDA] != '00' then
        AArch64_SystemAccessTrap(EL2, 0x18);
    else
        X{32}(t) = Read_DBGDTR_EL0{32}();
    end;
elsif PSTATE.EL == EL2 then
    X{32}(t) = Read_DBGDTR_EL0{32}();
end;
```

D12.3.8 DBGDTRTX_EL0, Debug Data Transfer Register, Transmit

The DBGDTRTX_EL0 characteristics are:

Purpose

Transfers data from the PE to an external debugger. For example, it is used by a debug target to transfer data to the debugger. See [DBGDTR_EL0](#) for additional architectural mappings. It is a component of the Debug Communication Channel.

Configuration

AArch64 System register DBGDTRTX_EL0 bits [31:0] are architecturally mapped to External register [DBGDTRTX_EL0](#)[31:0].

Attributes

DBGDTRTX_EL0 is a 64-bit register.

Field descriptions

Bits [63:32]

Reserved, RES0.

DTRTX, bits [31:0]

DTRTX. Writes to this register:

- If TXfull is 1, DTRTX is set to an UNKNOWN value.
- If TXfull is 0, update the value in DTRTX.

After the write, TXfull is set to 1.

For the full behavior of the Debug Communications Channel, see ‘[The Debug Communication Channel and Instruction Transfer Register](#)’.

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

Accessing DBGDTRTX_EL0

Accesses to this register use the following encodings in the System register encoding space:

MSR DBGDTRTX_EL0, <Xt>

op0	op1	CRn	CRm	op2
0b10	0b011	0b0000	0b0101	0b000

```
if Halted() then
    Write_DBGDTR_EL0{32}(X{32}(t));
elsif PSTATE.EL == EL0 then
    if MDSCR_EL1().TDCC == '1' then
        AArch64_SystemAccessTraptoEL1orEL2(0x18);
    elsif EffectiveTGEforEL0Traps() == '1' || MDSCR_EL2().[TDE,TDA] != '00' then
        AArch64_SystemAccessTrap(EL2, 0x18);
    else
        Write_DBGDTR_EL0{32}(X{32}(t));
    end;
elsif PSTATE.EL == EL1 then
    if MDSCR_EL2().[TDE,TDA] != '00' then
        AArch64_SystemAccessTrap(EL2, 0x18);
    else
        Write_DBGDTR_EL0{32}(X{32}(t));
    end;
elsif PSTATE.EL == EL2 then
    Write_DBGDTR_EL0{32}(X{32}(t));
end;
```

D12.3.9 DBGPRCR_EL1, Debug Power Control Register

The DBGPRCR_EL1 characteristics are:

Purpose

Controls behavior of the PE on powerdown request.

Configuration

AArch64 System register DBGPRCR_EL1 bit [0] is architecturally mapped to External register [EDPRCR](#)[0].

Attributes

DBGPRCR_EL1 is a 64-bit register.

Field descriptions

Bits [63:1]

Reserved, RES0.

CORENPD RQ, bit [0]

When FEAT_DoPD is implemented:

Core no powerdown request. Requests emulation of powerdown.

This request is typically passed to an external power controller. This means that whether a request causes power up is dependent on the IMPLEMENTATION DEFINED nature of the system. The power controller must not allow the Core power domain to switch off while this bit is 1.

CORENPD RQ	Meaning
0b0	If the system responds to a powerdown request, it powers down Core power domain.
0b1	If the system responds to a powerdown request, it does not powerdown the Core power domain, but instead emulates a powerdown of that domain.

In an implementation that includes the recommended external debug interface, this bit drives the **DBGNOPWRDWN** signal.

It is IMPLEMENTATION DEFINED whether this bit is reset to its Cold reset value on exit from an IMPLEMENTATION DEFINED software-visible retention state. For more information about retention states see ‘[Core power domain power states](#)’.

Note

Writes to this bit are not prohibited by the IMPLEMENTATION DEFINED authentication interface. This means that a debugger can request emulation of powerdown regardless of whether invasive debug is permitted.

On a Cold reset, if the powerup request is implemented and the powerup request has been asserted, this field is set to an IMPLEMENTATION DEFINED choice of 0 or 1. If the powerup request is not asserted, this field is set to 0.

Otherwise:

Core no powerdown request. Requests emulation of powerdown.

This request is typically passed to an external power controller. This means that whether a request causes power up is dependent on the IMPLEMENTATION DEFINED nature of the system. The power controller must not allow the Core power domain to switch off while this bit is 1.

CORENPDRQ	Meaning
0b0	If the system responds to a powerdown request, it powers down Core power domain.
0b1	If the system responds to a powerdown request, it does not powerdown the Core power domain, but instead emulates a powerdown of that domain.

In an implementation that includes the recommended external debug interface, this bit drives the **DBGNOPWRDWN** signal.

It is IMPLEMENTATION DEFINED whether this bit is reset to the value of **EDPRCR.COREPURQ** on exit from an IMPLEMENTATION DEFINED software-visible retention state. For more information about retention states see ‘Core power domain power states’.

Note

Writes to this bit are not prohibited by the IMPLEMENTATION DEFINED authentication interface. This means that a debugger can request emulation of powerdown regardless of whether invasive debug is permitted.

The reset behavior of this field is:

- On a Cold reset, this field resets to the value in **EDPRCR.COREPURQ**.

Accessing DBGPRCR_EL1

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, DBGPRCR_EL1

op0	op1	CRn	CRm	op2
0b10	0b000	0b0001	0b0100	0b100

```
if PSTATE.EL == EL0 then
    Undefined();
elsif PSTATE.EL == EL1 then
    if MDCR_EL2().[TDE,TDOSA] != '00' then
        AArch64_SystemAccessTrap(EL2, 0x18);
    else
```

```
        X{64}(t) = DBGPRCR_EL1();  
    end;  
    elsif PSTATE.EL == EL2 then  
        X{64}(t) = DBGPRCR_EL1();  
    end;
```

MSR DBGPRCR_EL1, <Xt>

op0	op1	CRn	CRm	op2
0b10	0b000	0b0001	0b0100	0b100

```
if PSTATE.EL == EL0 then  
    Undefined();  
elsif PSTATE.EL == EL1 then  
    if MDCR_EL2().[TDE,TDOSA] != '00' then  
        AArch64_SystemAccessTrap(EL2, 0x18);  
    else  
        DBGPRCR_EL1() = X{64}(t);  
    end;  
elsif PSTATE.EL == EL2 then  
    DBGPRCR_EL1() = X{64}(t);  
end;
```

D12.3.10 DBGWCR<n>_EL1, Debug Watchpoint Control Registers, n = 0 - 63

The DBGWCR<n>_EL1 characteristics are:

Purpose

Holds control information for a watchpoint. Forms watchpoint n together with value register DBGWVR<n>_EL1.

Configuration

If watchpoint n is not implemented then accesses to this register are UNDEFINED.

AArch64 System register DBGWCR<n>_EL1 bits [31:0] are architecturally mapped to External register DBGWCR<n>_EL1[31:0].

Attributes

DBGWCR<n>_EL1 is a 64-bit register.

Field descriptions

Bits [63:29]

Reserved, RES0.

MASK, bits [28:24]

Address Mask. Only address ranges up to 2GB can be watched using a single mask.

MASK	Meaning
0b00000	No mask.
0b00011..0b11111	Number of address bits masked.

All other values are reserved.

Indicates the number of masked address bits, from 0b00011 masking 3 address bits (0x00000007 mask for address) to 0b11111 masking 31 address bits (0x7FFFFFFF mask for address).

If programmed with a reserved value, the watchpoint behaves as if one of the following:

- DBGWCR<n>_EL1.MASK has been programmed with a defined value, which might be 0b00000 (no mask), other than for a direct read of DBGWCR<n>_EL1.
- The watchpoint is disabled.

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

Bits [23:21]

Reserved, RES0.

WT, bit [20]

Watchpoint type. Possible values are:

WT	Meaning
0b0	Unlinked watchpoint.
0b1	Linked watchpoint.

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

LBN, bits [19:16]

Linked Breakpoint Number.

For Linked data address watchpoints, specifies the index of the breakpoint linked to.

For all other watchpoint types, this field is ignored and reads of the register return an UNKNOWN value.

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

SSC, bits [15:14]

Security state control. Determines the Security states under which a Watchpoint debug event for watchpoint n is generated.

The fields that indicate when the watchpoint can be generated are: HMC, PAC, and SSC. These fields must be considered in combination, and the values that are permitted for these fields are constrained.

For more information on the operation of these fields, see [‘Execution conditions for which a watchpoint generates Watchpoint exceptions’](#).

For more information on the effect of programming the fields to a reserved value, see [‘Reserved DBGWCR<n>_EL1.{SSC, HMC, PAC} values’](#).

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

HMC, bit [13]

Higher mode control. Determines the debug perspective for deciding when a Watchpoint debug event for watchpoint n is generated.

The fields that indicate when the watchpoint can be generated are: HMC, PAC, and SSC. These fields must be considered in combination, and the values that are permitted for these fields are constrained.

For more information on the operation of these fields, see [‘Execution conditions for which a watchpoint generates Watchpoint exceptions’](#).

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

BAS, bits [12:5]

Byte address select. Each bit of this field selects whether a byte from within the word or doubleword addressed by [DBGWVR<n>_EL1](#) is being watched.

BAS	Description
xxxxxxx1	Match byte at DBGWVR<n>_EL1
xxxxxx1x	Match byte at DBGWVR<n>_EL1 + 1
xxxxx1xx	Match byte at DBGWVR<n>_EL1 + 2
xxxx1xxx	Match byte at DBGWVR<n>_EL1 + 3

In cases where [DBGWVR<n>_EL1](#) addresses a doubleword:

BAS	Description, if DBGWVR<n>_EL1[2] == 0
xxx1xxxx	Match byte at DBGWVR<n>_EL1 + 4
xx1xxxxx	Match byte at DBGWVR<n>_EL1 + 5
x1xxxxxx	Match byte at DBGWVR<n>_EL1 + 6
1xxxxxxx	Match byte at DBGWVR<n>_EL1 + 7

If [DBGWVR<n>_EL1\[2\] == 1](#), only BAS[3:0] are used and BAS[7:4] are ignored. Arm deprecates setting [DBGWVR<n>_EL1\[2\] == 1](#).

The valid values for BAS are nonzero binary numbers all of whose set bits are contiguous. All other values are reserved and must not be used by software. See '[Reserved DBGWVR<n>_EL1.BAS values](#)'.

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

LSC, bits [4:3]

Load/store control. This field enables watchpoint matching on the type of access being made. Possible values of this field are:

LSC	Meaning
0b01	Match instructions that load from a watchpointed address.
0b10	Match instructions that store to a watchpointed address.
0b11	Match instructions that load from or store to a watchpointed address.

All other values are reserved, but must behave as if the watchpoint is disabled. Software must not rely on this property as the behavior of reserved values might change in a future revision of the architecture.

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

PAC, bits [2:1]

Privilege of access control. Determines the Exception level or levels at which a Watchpoint debug event for watchpoint n is generated.

The fields that indicate when the watchpoint can be generated are: HMC, PAC, and SSC. These fields must be considered in combination, and the values that are permitted for these fields are constrained.

For more information on the operation of these fields, see ‘[Execution conditions for which a watchpoint generates Watchpoint exceptions](#)’.

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

E, bit [0]

Enable watchpoint n.

E	Meaning
0b0	Watchpoint n disabled.
0b1	Watchpoint n enabled.

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

Accessing DBGWCR<n>_EL1

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, DBGWCR<m>_EL1 ; Where m = 0-15

op0	op1	CRn	CRm	op2
0b10	0b000	0b0000	m[3:0]	0b111

```
let m:integer = UInt(CRm[3:0]);

    elseif OSLSR_EL1().OSLK == '0' && HaltingAllowed() && EDSCR().TDA == '1' then
        Halt(DebugHalt_SoftwareAccess);
    else
        DBGWCR_EL1(m) = X{64}(t);
    end;
elseif PSTATE.EL == EL2 then
    if OSLSR_EL1().OSLK == '0' && HaltingAllowed() && EDSCR().TDA == '1' then
        Halt(DebugHalt_SoftwareAccess);
    else
        DBGWCR_EL1(m) = X{64}(t);
    end;
end;

```

D12.3.11 DBGWVR<n>_EL1, Debug Watchpoint Value Registers, n = 0 - 63

The DBGWVR<n>_EL1 characteristics are:

Purpose

Holds a data address value for use in watchpoint matching. Forms watchpoint n together with control register `DBGWCR<n>_EL1`.

Configuration

If watchpoint n is not implemented then accesses to this register are UNDEFINED.

AArch64 System register DBGWVR<n>_EL1 bits [63:0] are architecturally mapped to External register DBGWVR<n>_EL1[63:0].

Attributes

DBGWVR<n>>_EL1 is a 64-bit register.

Field descriptions

**RESS[14:8], bits [63:57]**

Reserved, Sign extended. Software must set all bits in this field to the same value as the most significant bit of the VA field. If all bits in this field are not the same value as the most significant bit of the VA field, then all of the following apply:

- It is **CONSTRAINED UNPREDICTABLE** whether the PE ignores this field when comparing an address.
- It is **IMPLEMENTATION DEFINED** whether the value read back in each bit of this field is a copy of the most significant bit of the VA field or the value written.

RESS[7:4], bits [56:53]

Extension to RESS[14:8]. For more information, see RESS[14:8].

Bits [52:49]

When FEAT_LVA is implemented:

VA[52:49], bits [52:49]

Extension to VA[48:2]. For more information, see VA[48:2].

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

RESS[3:0], bits [52:49]

Extension to RESS[14:8]. For more information, see RESS[14:8].

VA[48:2], bits [48:2]

Bits[48:2] of the address value for comparison.

When [FEAT_LVA](#) is implemented, VA[52:49] forms the upper part of the address value. If FEAT_LVA is not implemented, bits [52:49] are part of the RESS field.

Arm deprecates setting DBGWVR<n>_EL1[2] == 1.

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

Bits [1:0]

Reserved, RES0.

Accessing DBGWVR<n>_EL1

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, DBGWVR<m>_EL1 ; Where m = 0-15

op0	op1	CRn	CRm	op2
0b10	0b000	0b0000	m[3:0]	0b110

```
let m:integer = UInt(CRm[3:0]);

if m >= NUM_WATCHPOINTS then
    Undefined();
elseif PSTATE.EL == EL0 then
    Undefined();
elseif PSTATE.EL == EL1 then
    if MDCR_EL2().[TDE,TDA] != '00' then
        AArch64_SystemAccessTrap(EL2, 0x18);
    elseif OSLSR_EL1().OSLK == '0' && HaltingAllowed() && EDSCR().TDA == '1' then
        Halt(DebugHalt_SoftwareAccess);
    else
        X{64}(t) = DBGWVR_EL1(m);
    end;
elseif PSTATE.EL == EL2 then
    if OSLSR_EL1().OSLK == '0' && HaltingAllowed() && EDSCR().TDA == '1' then
        Halt(DebugHalt_SoftwareAccess);
    else
        X{64}(t) = DBGWVR_EL1(m);
    end;
end;
```

MSR DBGWVR<m>_EL1, <Xt> ; Where m = 0-15

op0	op1	CRn	CRm	op2
0b10	0b000	0b0000	m[3:0]	0b110

```
let m:integer = UInt(CRM[3:0]);

if m >= NUM_WATCHPOINTS then
    Undefined();
elseif PSTATE.EL == EL0 then
    Undefined();
elseif PSTATE.EL == EL1 then
    if MDCR_EL2().[TDE,TDA] != '00' then
        AArch64_SystemAccessTrap(EL2, 0x18);
    elseif OSLSR_EL1().OSLK == '0' && HaltingAllowed() && EDSCR().TDA == '1' then
        Halt(DebugHalt_SoftwareAccess);
    else
        DBGWVR_EL1(m) = X{64}(t);
    end;
elseif PSTATE.EL == EL2 then
    if OSLSR_EL1().OSLK == '0' && HaltingAllowed() && EDSCR().TDA == '1' then
        Halt(DebugHalt_SoftwareAccess);
    else
        DBGWVR_EL1(m) = X{64}(t);
    end;
end;
```

D12.3.12 DLR_EL0, Debug Link Register

The DLR_EL0 characteristics are:

Purpose

In Debug state, holds the address to restart from.

Configuration

This register is a Special-purpose register.

Attributes

DLR_EL0 is a 64-bit register.

Field descriptions

ADDR, bits [63:0]

Restart address.

Accessing DLR_EL0

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, DLR_EL0

op0	op1	CRn	CRm	op2
0b11	0b011	0b0100	0b0101	0b001

```
if !Halted() then
    Undefined();
else
    X{64}(t) = DLR_EL0();
end;
```

MSR DLR_EL0, <Xt>

op0	op1	CRn	CRm	op2
0b11	0b011	0b0100	0b0101	0b001

```
if !Halted() then
    Undefined();
else
    DLR_EL0() = X{64}(t);
end;
```

D12.3.13 DSPSR_EL0, Debug Saved Program Status Register

The DSPSR_EL0 characteristics are:

Purpose

Holds the saved process state for Debug state. On entering Debug state, PSTATE information is written to this register. On exiting Debug state, values are copied from this register to PSTATE.

Configuration

This register is a Special-purpose register.

Attributes

DSPSR_EL0 is a 64-bit register.

Field descriptions

When entering or exiting Debug state from or to AArch64 state:

Bits [63:32]

Reserved, RES0.

N, bit [31]

Negative Condition flag. Set to the value of PSTATE.N on entering Debug state, and copied to PSTATE.N on exiting Debug state.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Z, bit [30]

Zero Condition flag. Set to the value of PSTATE.Z on entering Debug state, and copied to PSTATE.Z on exiting Debug state.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

C, bit [29]

Carry Condition flag. Set to the value of PSTATE.C on entering Debug state, and copied to PSTATE.C on exiting Debug state.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

V, bit [28]

Overflow Condition flag. Set to the value of PSTATE.V on entering Debug state, and copied to PSTATE.V on exiting Debug state.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [27:25]

Reserved, RES0.

DIT, bit [24]

When FEAT_DIT is implemented:

Data Independent Timing. Set to the value of PSTATE.DIT on entering Debug state, and copied to PSTATE.DIT on exiting Debug state.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

UAO, bit [23]

When FEAT_UAO is implemented:

User Access Override. Set to the value of PSTATE.UAO on entering Debug state, and copied to PSTATE.UAO on exiting Debug state.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

PAN, bit [22]

When FEAT_PAN is implemented:

Privileged Access Never. Set to the value of PSTATE.PAN on entering Debug state, and copied to PSTATE.PAN on exiting Debug state.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

SS, bit [21]

Software Step. Set to the value of PSTATE.SS on entering Debug state, and conditionally copied to PSTATE.SS on exiting Debug state.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

IL, bit [20]

Illegal Execution state. Set to the value of PSTATE.IL on entering Debug state, and copied to PSTATE.IL on exiting Debug state.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [19:13]

Reserved, RES0.

SSBS, bit [12]

When FEAT_SSBS is implemented:

Speculative Store Bypass. Set to the value of PSTATE.SSBS on entering Debug state, and copied to PSTATE.SSBS on exiting Debug state.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bits [11:10]

Reserved, RES0.

D, bit [9]

Debug exception mask. Set to the value of PSTATE.D on entering Debug state, and copied to PSTATE.D on exiting Debug state.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

A, bit [8]

SError exception mask. Set to the value of PSTATE.A on entering Debug state, and copied to PSTATE.A on exiting Debug state.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

I, bit [7]

IRQ interrupt mask. Set to the value of PSTATE.I on entering Debug state, and copied to PSTATE.I on exiting Debug state.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

F, bit [6]

FIQ interrupt mask. Set to the value of PSTATE.F on entering Debug state, and copied to PSTATE.F on exiting Debug state.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [5]

Reserved, RES0.

M[4], bit [4]

Execution state. Set to 0, the value of PSTATE.nRW, on entering Debug state from AArch64 state, and copied to PSTATE.nRW on exiting Debug state.

M[4]	Meaning
0b0	AArch64 execution state.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

M[3:0], bits [3:0]

AArch64 Exception level and selected Stack Pointer.

M[3:0]	Meaning
0b0000	EL0.
0b0100	EL1 with SP_EL0 (EL1t).
0b0101	EL1 with SP_EL1 (EL1h).
0b1000	EL2 with SP_EL0 (EL2t).
0b1001	EL2 with SP_EL2 (EL2h).

Other values are reserved. If DSPSR_EL0.M[3:0] has a Reserved value, or a value for an unimplemented Exception level, exiting Debug state is an illegal return event, as described in ‘[Illegal return events from AArch64 state](#)’.

The bits in this field are interpreted as follows:

- M[3:2] is set to the value of PSTATE.EL on entering Debug state and copied to PSTATE.EL on exiting Debug state.
- M[1] is unused and is 0 for all non-reserved values.
- M[0] is set to the value of PSTATE.SP on entering Debug state and copied to PSTATE.SP on exiting Debug state.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing DSPSR_EL0

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, DSPSR_EL0

op0	op1	CRn	CRm	op2
0b11	0b011	0b0100	0b0101	0b000

```
if !Halted() then
    Undefined();
else
    X{64}(t) = DSPSR_EL0();
end;
```

MSR DSPSR_EL0, <Xt>

op0	op1	CRn	CRm	op2
0b11	0b011	0b0100	0b0101	0b000

```
if !Halted() then
    Undefined();
else
    DSPSR_EL0() = X{64}(t);
end;
```

D12.3.14 MDCCINT_EL1, Monitor DCC Interrupt Enable Register

The MDCCINT_EL1 characteristics are:

Purpose

Enables interrupt requests to be signaled based on the DCC status flags.

Configuration

There are no configuration notes.

Attributes

MDCCINT_EL1 is a 64-bit register.

Field descriptions

Bits [63:31]

Reserved, RES0.

RX, bit [30]

DCC interrupt request enable control for DTRRX. Enables a common **COMMIRQ** interrupt request to be signaled based on the DCC status flags.

RX	Meaning
0b0	No interrupt request generated by DTRRX.
0b1	Interrupt request will be generated on RXfull == 1.

If legacy **COMMRX** and **COMMTX** signals are implemented, then these are not affected by the value of this bit.

The reset behavior of this field is:

- On a Warm reset, this field resets to '0'.

TX, bit [29]

DCC interrupt request enable control for DTRTX. Enables a common **COMMIRQ** interrupt request to be signaled based on the DCC status flags.

TX	Meaning
0b0	No interrupt request generated by DTRTX.
0b1	Interrupt request will be generated on TXfull == 0.

If legacy **COMMRX** and **COMMTX** signals are implemented, then these are not affected by the value of this bit.

The reset behavior of this field is:

- On a Warm reset, this field resets to '0'.

Bits [28:0]

Reserved, RES0.

Accessing MDCCINT_EL1

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, MDCCINT_EL1

op0	op1	CRn	CRm	op2
0b10	0b000	0b0000	0b0010	0b000

```

if Halted() && !(EffectivelyAtEL0InHost() || EffectivelyAtEL0NotInHost()) &&
    ↳ConstrainUnpredictableBool(Unpredictable_IGNORETRAPINDEBUG) then
    X{64}(t) = MDCCINT_EL1();
elseif PSTATE.EL == EL0 then
    Undefined();
elseif PSTATE.EL == EL1 then
    if MDCR_EL2().[TDE,TDA] != '00' then
        AArch64_SystemAccessTrap(EL2, 0x18);
    else
        X{64}(t) = MDCCINT_EL1();
    end;
elseif PSTATE.EL == EL2 then
    X{64}(t) = MDCCINT_EL1();
end;

```

MSR MDCCINT_EL1, <Xt>

op0	op1	CRn	CRm	op2
0b10	0b000	0b0000	0b0010	0b000

```

if Halted() && !(EffectivelyAtEL0InHost() || EffectivelyAtEL0NotInHost()) &&
    ↳ConstrainUnpredictableBool(Unpredictable_IGNORETRAPINDEBUG) then
    MDCCINT_EL1() = X{64}(t);
elseif PSTATE.EL == EL0 then
    Undefined();
elseif PSTATE.EL == EL1 then
    if MDCR_EL2().[TDE,TDA] != '00' then
        AArch64_SystemAccessTrap(EL2, 0x18);
    else

```

```
        MDCCINT_EL1() = X{64}(t);  
    end;  
    elsif PSTATE.EL == EL2 then  
        MDCCINT_EL1() = X{64}(t);  
    end;
```

D12.3.15 MDCCSR_EL0, Monitor DCC Status Register

The MDCCSR_EL0 characteristics are:

Purpose

Read-only register containing control status flags for the DCC.

Configuration

AArch64 System register MDCCSR_EL0 bits [30:29] are architecturally mapped to External register [EDSCR](#)[30:29].

Attributes

MDCCSR_EL0 is a 64-bit register.

Field descriptions

Bits [63:31]

Reserved, RES0.

RXfull, bit [30]

DTRRX full. Read-only view of the equivalent bit in the [EDSCR](#).

The reset behavior of this field is:

- On a Cold reset, this field resets to '0'.

TXfull, bit [29]

DTRTX full. Read-only view of the equivalent bit in the [EDSCR](#).

The reset behavior of this field is:

- On a Cold reset, this field resets to '0'.

Bits [28:19]

Reserved, RES0.

Bits [18:15]

Reserved, RAZ.

Bits [14:13]

Reserved, RES0.

Bit [12]

Reserved, RAZ.

Bits [11:6]

Reserved, RES0.

Bits [5:2]

Reserved, RAZ.

Bits [1:0]

Reserved, RES0.

Accessing MDCCSR_EL0

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, MDCCSR_EL0

op0	op1	CRn	CRm	op2
0b10	0b011	0b0000	0b0001	0b000

```
if Halted() && ConstrainUnpredictableBool(Unpredictable_IGNORETRAPINDEBUG) then
    X{64}(t) = MDCCSR_EL0();
elsif PSTATE.EL == EL0 then
    if MDSCR_EL1().TDCC == '1' then
        AArch64_SystemAccessTraptoEL1orEL2(0x18);
    elsif EffectiveTGEforEL0Traps() == '1' || MDCR_EL2().[TDE,TDA] != '00' then
        AArch64_SystemAccessTrap(EL2, 0x18);
    else
        X{64}(t) = MDCCSR_EL0();
    end;
elsif PSTATE.EL == EL1 then
    if MDCR_EL2().[TDE,TDA] != '00' then
        AArch64_SystemAccessTrap(EL2, 0x18);
    else
        X{64}(t) = MDCCSR_EL0();
    end;
elsif PSTATE.EL == EL2 then
    X{64}(t) = MDCCSR_EL0();
end;
```

D12.3.16 MDCR_EL2, Monitor Debug Configuration Register (EL2)

The MDCR_EL2 characteristics are:

Purpose

Provides EL2 configuration options for self-hosted debug and the Performance Monitors Extension.

Configuration

There are no configuration notes.

Attributes

MDCR_EL2 is a 64-bit register.

Field descriptions

Bits [63:20]

Reserved, RES0.

TTRF, bit [19]

When FEAT_TRF is implemented:

Traps use of the Trace Filter Control registers at EL1 to EL2, as follows:

- Access to [TRFCR_EL1](#) is trapped to EL2, reported using EC syndrome value 0x18.

TTRF	Meaning
0b0	Accesses to the specified registers at EL1 are not affected by this control.
0b1	Accesses to the specified registers at EL1 generate a trap exception to EL2 when EL2 is enabled in the current Security state.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bit [18]

Reserved, RES0.

HPMD, bit [17]

When FEAT_PMUv3p1 is implemented and FEAT_Debugv8p2 is implemented:

Guest Performance Monitors Disable. Controls PMU operation at EL2.

HPMD	Meaning
0b0	Counters are not affected by this mechanism.
0b1	Affected counters are prohibited from counting at EL2. If PMCR_EL0.DP is 1, then PMCCNTR_EL0 is disabled at EL2. Otherwise, PMCCNTR_EL0 is not affected by this mechanism.

The counters affected by this field are:

- Event counters in the first range.
- If [PMCR_EL0.DP](#) is 1, the cycle counter [PMCCNTR_EL0](#).

Other event counters are not affected by this field.

When [PMCR_EL0.DP](#) is 0, [PMCCNTR_EL0](#) is not affected by this field.

The reset behavior of this field is:

- On a Warm reset, this field resets to '0'.

When FEAT_PMUv3p1 is implemented:

Guest Performance Monitors Disable. Controls PMU operation at EL2 when `ExternalSecureNoninvasiveDebugEnabled()` is FALSE.

HPMD	Meaning
0b0	Counters are not affected by this mechanism.
0b1	If <code>ExternalSecureNoninvasiveDebugEnabled()</code> is FALSE, then all the following apply: • Affected event counters are prohibited from counting at EL2. • If PMCR_EL0.DP is 1, then PMCCNTR_EL0 is disabled at EL2. Otherwise, PMCCNTR_EL0 is not affected by this mechanism.

If `ExternalSecureNoninvasiveDebugEnabled()` is TRUE, then the event counters and [PMCCNTR_EL0](#) are not affected by this field.

Otherwise, the counters affected by this field are:

- Event counters in the first range.
- If [PMCR_EL0.DP](#) is 1, the cycle counter, [PMCCNTR_EL0](#).

Other event counters are not affected by this field. When [PMCR_EL0.DP](#) is 0, [PMCCNTR_EL0](#) is not affected by this field.

The reset behavior of this field is:

- On a Warm reset, this field resets to '0'.

Otherwise:

Reserved, RES0.

Bits [16:12]

Reserved, RES0.

TDRA, bit [11]

Trap Debug ROM Address register access. Traps System register accesses to the Debug ROM registers to EL2 when EL2 is enabled in the current Security state as follows:

- If EL1 is using AArch64, accesses to [MDRAR_EL1](#) are trapped to EL2, reported using EC syndrome value 0x18.

TDRA	Meaning
0b0	This control does not cause any instructions to be trapped.
0b1	EL0 and EL1 System register accesses to the Debug ROM registers are trapped to EL2 when EL2 is enabled in the current Security state, unless it is trapped by the following: • MDSCR_EL1.TDCC.

This field is treated as being 1 for all purposes other than a direct read when one or more of the following are true:

- The Effective value of [MDCR_EL2](#).TDE is 1.
- The [Effective value](#) of [HCR_EL2](#).TGE is 1.

Note

EL2 does not provide traps on debug register accesses through the optional memory-mapped external debug interfaces.

System register accesses to the debug System registers might have side-effects. When a System register access is trapped to EL2, no side-effects occur before the exception is taken to EL2.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

TDOSA, bit [10]

When FEAT_DoubleLock is implemented:

Trap debug OS-related register access. Traps EL1 System register accesses to the powerdown debug System registers to EL2, from both Execution states as follows:

- In AArch64 state, accesses to the following registers are trapped to EL2, reported using EC syndrome value 0x18:
 - [OSLAR_EL1](#), [OSLSR_EL1](#), [OSDLR_EL1](#), and [DBGPRCR_EL1](#).
 - Any IMPLEMENTATION DEFINED register with similar functionality that the implementation specifies as trapped by this bit.

TDOSA	Meaning
0b0	This control does not cause any instructions to be trapped.
0b1	EL1 System register accesses to the powerdown debug System registers are trapped to EL2 when EL2 is enabled in the current Security state.

Note

These registers are not accessible at EL0.

This field is treated as being 1 for all purposes other than a direct read when one or more of the following are true:

- The Effective value of [MDCR_EL2.TDE](#) is 1.
- The [Effective value](#) of [HCR_EL2.TGE](#) is 1.

System register accesses to the debug System registers might have side-effects. When a System register access is trapped to EL2, no side-effects occur before the exception is taken to EL2.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Trap debug OS-related register access. Traps EL1 System register accesses to the powerdown debug System registers to EL2, from both Execution states as follows:

- In AArch64 state, accesses to the following registers are trapped to EL2, reported using EC syndrome value 0x18:
 - [OSLAR_EL1](#), [OSLSR_EL1](#), and [DBGPRCR_EL1](#).
- Any IMPLEMENTATION DEFINED register with similar functionality that the implementation specifies as trapped by this bit.

It is IMPLEMENTATION DEFINED whether accesses to [OSDLR_EL1](#) are trapped.

TDOSA	Meaning
0b0	This control does not cause any instructions to be trapped.
0b1	EL1 System register accesses to the powerdown debug System registers are trapped to EL2 when EL2 is enabled in the current Security state.

Note

These registers are not accessible at EL0.

This field is treated as being 1 for all purposes other than a direct read when one or more of the following are true:

- The Effective value of [MDCR_EL2.TDE](#) is 1.
- The [Effective value](#) of [HCR_EL2.TGE](#) is 1.

Note

EL2 does not provide traps on debug register accesses through the optional memory-mapped external debug interfaces.

System register accesses to the debug System registers might have side-effects. When a System register access is trapped to EL2, no side-effects occur before the exception is taken to EL2.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

TDA, bit [9]

Trap accesses of debug System registers. Enables a trap to EL2 on accesses of debug System registers.

TDA	Meaning
0b0	Accesses of the specified debug System registers are not trapped by this mechanism.
0b1	Accesses of the specified debug System registers at EL1 and EL0 are trapped to EL2, unless the instruction generates a higher priority exception.

In AArch64 state, the instructions affected by this control are:

- MRS and MSR accesses to [DBGAUTHSTATUS_EL1](#), [DBGBCR<n>_EL1](#), [DBGBVR<n>_EL1](#), [DBGCLAIMCLR_EL1](#), [DBGCLAIMSET_EL1](#), [DBGWCR<n>_EL1](#), [DBGWVR<n>_EL1](#), [MDCCINT_EL1](#), [MDCCSR_EL0](#), [MDSCR_EL1](#), [OSDTRRX_EL1](#), [OSDTRTX_EL1](#), and [OSECCR_EL1](#).
- In Non-debug state, MRS accesses to [DBGDTRRX_EL0](#) and [DBGDTR_EL0](#) and MSR accesses to [DBGDTRTX_EL0](#) and [DBGDTR_EL0](#).

Trapped AArch64 instructions are reported using EC syndrome value 0×18 .

The AArch64 MRS accesses to [DBGDTRRX_EL0](#) and [DBGDTR_EL0](#) and MSR accesses to [DBGDTRTX_EL0](#) and [DBGDTR_EL0](#) are not trapped to Debug state.

This field is ignored by the PE and treated as one when any of the following are true:

- The Effective value of [MDCR_EL2.TDE](#) is 1.
- The [Effective value](#) of [HCR_EL2.TGE](#) is 1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

TDE, bit [8]

Trap Debug Exceptions. Controls routing of Debug exceptions, and defines the debug target Exception level, EL_D .

TDE	Meaning
0b0	The debug target Exception level is EL1.
0b1	If EL2 is enabled for the current Effective value of SCR_EL3.NS , the debug target Exception level is EL2, otherwise the debug target Exception level is EL1. The MDCR_EL2 .{TDRA, TDOSA, TDA} fields are treated as being 1 for all purposes other than returning the result of a direct read of the register.

For more information, see ‘[Routing debug exceptions](#)’.

This field is treated as being 1 for all purposes other than a direct read when the [Effective value](#) of [HCR_EL2.TGE](#) is 1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

HPME, bit [7]

When FEAT_PMUv3 is implemented:

Hyp Enable.

HPME	Meaning
0b0	Affected counters are disabled and do not count.
0b1	Affected counters are enabled by PMCNTENSET_EL0 .

The counters affected by this field are the event counters in the second range.

The following counters are not affected by this field:

- Other event counters.
- [PMCCNTR_EL0](#).

If MDCR_EL2.HPMN is equal to `GetNumEventCountersSelfHosted()`, then this field has no effect.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

TPM, bit [6]

When FEAT_PMUv3 is implemented:

Trap accesses of PMU System registers. Enables a trap to EL2 on accesses of PMU System registers.

TPM	Meaning
0b0	Accesses of the specified PMU System registers are not trapped by this mechanism.
0b1	Accesses of the specified PMU System registers at EL1 and EL0 are trapped to EL2, unless the instruction generates a higher priority exception.

In AArch64 state, the instructions affected by this control are:

- MRS and MSR accesses to [PMCCFILTR_EL0](#), [PMCCNTR_EL0](#), [PMCNTENCLR_EL0](#), [PMCNTENSET_EL0](#), [PMCR_EL0](#), [PMEVCNTR<n>_EL0](#), [PMEVTYPER<n>_EL0](#), [PMINTENCLR_EL1](#), [PMINTENSET_EL1](#), [PMOVSCLR_EL0](#), [PMOVSSET_EL0](#), [PMSELR_EL0](#), [PMSWINC_EL0](#), [PMUSERENR_EL0](#), [PMXEVCNTR_EL0](#), and [PMXEVTYPER_EL0](#).
- MRS accesses to [PMCEID0_EL0](#) and [PMCEID1_EL0](#).
- If [FEAT_PMUv3p4](#) is implemented, MRS accesses to [PMMIR_EL1](#).

Trapped AArch64 instructions are reported using EC syndrome value 0x18.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

TPMCR, bit [5]

When FEAT_PMUv3 is implemented:

Trap [PMCR_EL0](#) or PMCR accesses. Traps EL0 and EL1 accesses to EL2, when EL2 is enabled in the current Security state, as follows:

- In AArch64 state, accesses to [PMCR_EL0](#) are trapped to EL2, reported using EC syndrome value 0x18.

TPMCR	Meaning
0b0	This control does not cause any instructions to be trapped.
0b1	EL0 and EL1 accesses to the specified registers are trapped to EL2 when EL2 is enabled in the current Security state, unless they are trapped by the following: • PMUSERENR_EL0.EN.

Note

EL2 does not provide traps on Performance Monitor register accesses through the optional memory-mapped external debug interface.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

HPMN, bits [4:0]

When FEAT_PMUv3 is implemented:

Defines the number of event counters [PMEVCNTR<n>_EL0](#) that are accessible from EL1 and, if permitted, from EL0.

MDCR_EL2.HPMN divides the event counters into a first range and a second range.

If MDCR_EL2.HPMN is not 0 and is less than the number of PMU event counters implemented by the PE, `NUM_PMU_COUNTERS`, then event counters `[0..(MDCR_EL2.HPMN-1)]` are in the first range, and the remaining event counters `[MDCR_EL2.HPMN..(NUM_PMU_COUNTERS-1)]` are in the second range.

The pseudocode function `GetNumEventCountersSelfHosted()` returns the value `NUM_PMU_COUNTERS`.

If MDCR_EL2.HPMN is equal to `GetNumEventCountersSelfHosted()`, or EL2 is not implemented, then all of the following apply:

- All event counters are in the first range.
- No event counters are in the second range.

All of the following apply for an event counter [PMEVCNTR<n>_EL0](#) in the first range:

- The counter is accessible from EL1 and EL2.
- The counter is accessible from EL0 if permitted by [PMUSERENR_EL0](#) or [PMUSERENR](#).
- [PMCR_EL0.E](#) and [PMCNTENSET_EL0\[n\]](#) enable the operation of the event counter.

All of the following apply for an event counter [PMEVCNTR<n>_EL0](#) in the second range:

- The counter is only accessible from EL2.
- MDCR_EL2.HPME and [PMCNTENSET_EL0\[n\]](#) enable the operation of the event counter.

Values greater than `GetNumEventCountersSelfHosted()` and 0 are reserved.

If this field is set to a reserved value, then the following CONSTRAINED UNPREDICTABLE behaviors apply:

- The value returned by a direct read of MDCR_EL2.HPMN is UNKNOWN.
- The number of event counters in each of the first and second ranges is UNKNOWN. That is, either:
 - The PE behaves as if MDCR_EL2.HPMN is set to an UNKNOWN nonzero value less than or equal to `NUM_PMU_COUNTERS`.
 - All counters are in the second range and none are in the first range.

The reset behavior of this field is:

- On a Warm reset, this field resets to the expression `NUM_PMU_COUNTERS`.

Otherwise:

Reserved, RES0.

Accessing MDCR_EL2

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, MDCR_EL2

op0	op1	CRn	CRm	op2
0b11	0b100	0b0001	0b0001	0b001

```

if PSTATE.EL == EL0 then
    Undefined();
elsif PSTATE.EL == EL1 then
    Undefined();
elsif PSTATE.EL == EL2 then
    X{64}(t) = MDCR_EL2();
end;

```

MSR MDCR_EL2, <Xt>

op0	op1	CRn	CRm	op2
0b11	0b100	0b0001	0b0001	0b001

```

if PSTATE.EL == EL0 then
    Undefined();
elsif PSTATE.EL == EL1 then
    Undefined();
elsif PSTATE.EL == EL2 then
    MDCR_EL2() = X{64}(t);
end;

```

D12.3.17 MDRAR_EL1, Monitor Debug ROM Address Register

The MDRAR_EL1 characteristics are:

Purpose

Defines the base physical address of a 4KB-aligned memory-mapped debug component, usually a ROM table that locates and describes the memory-mapped debug components in the system. Use of this register is deprecated.

Configuration

There are no configuration notes.

Attributes

MDRAR_EL1 is a 64-bit register.

Field descriptions

Bits [63:56]

Reserved, RES0.

ROMADDR, bits [55:12]

When FEAT_LPA is implemented and MDRAR_EL1.Valid != '00':

Bits [43:40]

Reserved, RES0.

ROMADDR, bits [39:0]

Bits [51:12] of the ROM table physical address.

Bits [11:0] of the ROM table physical address are zero.

For implementations with fewer than 52 physical address bits, the corresponding upper bits of this field are RES0

In an implementation that includes EL3, ROMADDR is an address in Non-secure memory. It is IMPLEMENTATION DEFINED whether the ROM table is also accessible in Secure memory.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

When FEAT_LPA is not implemented and MDRAR_EL1.Valid != '00':

Bits [43:36]

Reserved, RES0.

ROMADDR, bits [35:0]

Bits [39:12] of the ROM table physical address.

Bits [11:0] of the ROM table physical address are zero.

For implementations with fewer than 48 physical address bits, the corresponding upper bits of this field are RES0

In an implementation that includes EL3, ROMADDR is an address in Non-secure memory. It is IMPLEMENTATION DEFINED whether the ROM table is also accessible in Secure memory.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

When MDRAR_EL1.Valid == '00':

Bits [43:0]

Reserved, UNKNOWN.

Bits [11:2]

Reserved, RES0.

Valid, bits [1:0]

This field indicates whether the ROM Table address is valid.

The value of this field is an IMPLEMENTATION DEFINED choice of:

Valid	Meaning
0b00	ROM Table address is not valid. Software must ignore ROMADDR.
0b11	ROM Table address is valid.

Valid	Meaning
-------	---------

Other values are reserved.

Arm recommends implementations set this field to zero.

Access to this field is RO.

Accessing MDRAR_EL1

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, MDRAR_EL1

op0	op1	CRn	CRm	op2
0b10	0b000	0b0001	0b0000	0b000

```

if PSTATE.EL == EL0 then
    Undefined();
elsif PSTATE.EL == EL1 then
    if MDCR_EL2().[TDE,TDRA] != '00' then
        AArch64_SystemAccessTrap(EL2, 0x18);
    else
        X{64}(t) = MDRAR_EL1();
    end;
elsif PSTATE.EL == EL2 then
    X{64}(t) = MDRAR_EL1();
end;

```

D12.3.18 MDSCR_EL1, Monitor Debug System Control Register

The MDSCR_EL1 characteristics are:

Purpose

Main control register for the debug implementation.

Configuration

AArch64 System register MDSCR_EL1 bits [31:29, 27:26, 23:21, 19, 14, 6] are architecturally mapped to External register [EDSCR](#)[31:29, 27:26, 23:21, 19, 14, 6].

Attributes

MDSCR_EL1 is a 64-bit register.

Field descriptions

Bits [63:32]

Reserved, RES0.

TFO, bit [31]

When FEAT_TRF is implemented:

Trace Filter override. Used for save/restore of [EDSCR](#).TFO.

When [OSLSR_EL1](#).OSLK = 0, software must treat this bit as UNK/SBZP.

When [OSLSR_EL1](#).OSLK = 1, this bit holds the value of [EDSCR](#).TFO. Reads and writes of this bit are indirect accesses to [EDSCR](#).TFO.

The reset behavior of this field is:

- On a Cold reset, this field resets to '0'.

Accessing this field has the following behavior:

- When [OSLSR_EL1](#).OSLK = '1', access to this field is RW.
- When [OSLSR_EL1](#).OSLK = '0', access to this field is RO.

Otherwise:

Reserved, RES0.

RXfull, bit [30]

Used for save/restore of [EDSCR](#).RXfull.

When [OSLSR_EL1](#).OSLK = 0, software must treat this bit as UNK/SBZP.

When [OSLSR_EL1](#).OSLK = 1, this bit holds the value of [EDSCR](#).RXfull. Reads and writes of this bit are indirect accesses to [EDSCR](#).RXfull.

The reset behavior of this field is:

- On a Cold reset, this field resets to '0'.

Accessing this field has the following behavior:

- When `OSLSR_EL1.OSLK == '1'`, access to this field is RW.
- When `OSLSR_EL1.OSLK == '0'`, access to this field is RO.

TXfull, bit [29]

Used for save/restore of `EDSCR.TXfull`.

When `OSLSR_EL1.OSLK == 0`, software must treat this bit as UNK/SBZP.

When `OSLSR_EL1.OSLK == 1`, this bit holds the value of `EDSCR.TXfull`. Reads and writes of this bit are indirect accesses to `EDSCR.TXfull`.

The reset behavior of this field is:

- On a Cold reset, this field resets to '0'.

Accessing this field has the following behavior:

- When `OSLSR_EL1.OSLK == '1'`, access to this field is RW.
- When `OSLSR_EL1.OSLK == '0'`, access to this field is RO.

Bit [28]

Reserved, RES0.

RXO, bit [27]

Used for save/restore of `EDSCR.RXO`.

When `OSLSR_EL1.OSLK == 0`, software must treat this bit as UNK/SBZP.

When `OSLSR_EL1.OSLK == 1`, this bit holds the value of `EDSCR.RXO`. Reads and writes of this bit are indirect accesses to `EDSCR.RXO`.

When `OSLSR_EL1.OSLK == 1`, if bits [27,6] of the value written to `MDSCR_EL1` are {1,0}, that is, the RXO bit is 1 and the ERR bit is 0, the PE sets `EDSCR.{RXO,ERR}` to UNKNOWN values.

The reset behavior of this field is:

- On a Cold reset, this field resets to '0'.

Accessing this field has the following behavior:

- When `OSLSR_EL1.OSLK == '1'`, access to this field is RW.
- When `OSLSR_EL1.OSLK == '0'`, access to this field is RO.

TXU, bit [26]

Used for save/restore of `EDSCR.TXU`.

When `OSLSR_EL1.OSLK == 0`, software must treat this bit as UNK/SBZP.

When `OSLSR_EL1.OSLK == 1`, this bit holds the value of `EDSCR.TXU`. Reads and writes of this bit are indirect accesses to `EDSCR.TXU`.

When `OSLSR_EL1.OSLK == 1`, if bits [26,6] of the value written to `MDSCR_EL1` are {1,0}, that is, the TXU bit is 1 and the ERR bit is 0, the PE sets `EDSCR.{TXU,ERR}` to UNKNOWN values.

The reset behavior of this field is:

- On a Cold reset, this field resets to '0'.

Accessing this field has the following behavior:

- When `OSLSR_EL1.OSLK == '1'`, access to this field is RW.

- When `OSLSR_EL1.OSLK == '0'`, access to this field is RO.

Bits [25:24]

Reserved, RES0.

INTdis, bits [23:22]

Used for save/restore of `EDSCR.INTdis`.

When `OSLSR_EL1.OSLK == 0`, software must treat this bit as UNK/SBZP.

When `OSLSR_EL1.OSLK == 1`, this field holds the value of `EDSCR.INTdis`. Reads and writes of this field are indirect accesses to `EDSCR.INTdis`.

The reset behavior of this field is:

- On a Cold reset, this field resets to '00'.

Accessing this field has the following behavior:

- When `OSLSR_EL1.OSLK == '1'`, access to this field is RW.
- When `OSLSR_EL1.OSLK == '0'`, access to this field is RO.

TDA, bit [21]

Used for save/restore of `EDSCR.TDA`.

When `OSLSR_EL1.OSLK == 0`, software must treat this bit as UNK/SBZP.

When `OSLSR_EL1.OSLK == 1`, this bit holds the value of `EDSCR.TDA`. Reads and writes of this bit are indirect accesses to `EDSCR.TDA`.

The reset behavior of this field is:

- On a Cold reset, this field resets to '0'.

Accessing this field has the following behavior:

- When `OSLSR_EL1.OSLK == '1'`, access to this field is RW.
- When `OSLSR_EL1.OSLK == '0'`, access to this field is RO.

Bits [20:19]

Reserved, RES0.

Bits [18:16]

Reserved, RAZ/WI.

Hardware must implement this field as RAZ/WI. Software must not rely on the register reading as zero, and must use a read-modify-write sequence to write to the register.

MDE, bit [15]

Monitor debug events. Enable Breakpoint, Watchpoint, and Vector Catch exceptions.

MDE	Meaning
0b0	Breakpoint, Watchpoint, and Vector Catch exceptions disabled.
0b1	Breakpoint, Watchpoint, and Vector Catch exceptions enabled.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

HDE, bit [14]

Used for save/restore of [EDSCR.HDE](#).

When [OSLSR_EL1.OSLK](#) = 0, software must treat this bit as UNK/SBZP.

When [OSLSR_EL1.OSLK](#) = 1, this bit holds the value of [EDSCR.HDE](#). Reads and writes of this bit are indirect accesses to [EDSCR.HDE](#).

The reset behavior of this field is:

- On a Cold reset, this field resets to '0'.

Accessing this field has the following behavior:

- When [OSLSR_EL1.OSLK](#) = '1', access to this field is RW.
- When [OSLSR_EL1.OSLK](#) = '0', access to this field is RO.

KDE, bit [13]

Local (kernel) debug enable. If EL_D is using AArch64, enable debug exceptions within EL_D . Permitted values are:

KDE	Meaning
0b0	Debug exceptions, other than Breakpoint Instruction exceptions, disabled within EL_D .
0b1	All debug exceptions enabled within EL_D .

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

TDCC, bit [12]

Traps EL_0 accesses to the Debug Communication Channel (DCC) registers to EL_1 , or to EL_2 when it is implemented and enabled for the current Security state and [HCR_EL2.TGE](#) is 1, from both Execution states, as follows:

- In AArch64 state, MRS or MSR accesses to the following DCC System registers are trapped, reported using EC syndrome value 0×18 :
 - [MDCCSR_EL0](#).
 - If not in Debug state, [DBGDTR_EL0](#), [DBGDTRTX_EL0](#), and [DBGDTRRX_EL0](#).

TDCC	Meaning
0b0	This control does not cause any instructions to be trapped.
0b1	EL_0 using AArch64: EL_0 accesses to the AArch64 DCC System registers are trapped.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [11:7]

Reserved, RES0.

ERR, bit [6]

Used for save/restore of [EDSCR.ERR](#).

When [OSLSR_EL1.OSLK](#) == 0, software must treat this bit as UNK/SBZP.

When [OSLSR_EL1.OSLK](#) == 1, this bit holds the value of [EDSCR.ERR](#). Reads and writes of this bit are indirect accesses to [EDSCR.ERR](#).

The reset behavior of this field is:

- On a Cold reset, this field resets to '0'.

Accessing this field has the following behavior:

- When [OSLSR_EL1.OSLK](#) == '1', access to this field is RW.
- When [OSLSR_EL1.OSLK](#) == '0', access to this field is RO.

Bits [5:1]

Reserved, RES0.

SS, bit [0]

Software step control bit. If [EL_D](#) is using AArch64, enable Software step. Permitted values are:

SS	Meaning
0b0	Software step disabled
0b1	Software step enabled.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing MDSCR_EL1

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, MDSCR_EL1

op0	op1	CRn	CRm	op2
0b10	0b000	0b0000	0b0010	0b010

```
if PSTATE.EL == EL0 then
    Undefined();
elsif PSTATE.EL == EL1 then
    if MDSCR_EL2().[TDE,TDA] != '00' then
        AArch64_SystemAccessTrap(EL2, 0x18);
    else
        X{64}(t) = MDSCR_EL1();
    end;
elsif PSTATE.EL == EL2 then
    X{64}(t) = MDSCR_EL1();
end;
```

MSR MDSCR_EL1, <Xt>

op0	op1	CRn	CRm	op2
0b10	0b000	0b0000	0b0010	0b010

```
if PSTATE.EL == EL0 then
    Undefined();
elsif PSTATE.EL == EL1 then
    if MDSCR_EL2().[TDE,TDA] != '00' then
        AArch64_SystemAccessTrap(EL2, 0x18);
    else
        MDSCR_EL1() = X{64}(t);
    end;
elsif PSTATE.EL == EL2 then
    MDSCR_EL1() = X{64}(t);
end;
```

D12.3.19 OSDLR_EL1, OS Double Lock Register

The OSDLR_EL1 characteristics are:

Purpose

Used to control the OS Double Lock.

Configuration

There are no configuration notes.

Attributes

OSDLR_EL1 is a 64-bit register.

Field descriptions

Bits [63:1]

Reserved, RES0.

DLK, bit [0]

When FEAT_DoubleLock is implemented:

OS Double Lock control bit.

DLK	Meaning
0b0	OS Double Lock unlocked.
0b1	OS Double Lock locked, if DBGPRCR_EL1 .CORENPDRQ (Core no powerdown request) bit is set to 0 and the PE is in Non-debug state.

The reset behavior of this field is:

- On a Warm reset, this field resets to '0'.

Otherwise:

Reserved, RAZ/WI.

Accessing OSDLR_EL1

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, OSDLR_EL1

op0	op1	CRn	CRm	op2
0b10	0b000	0b0001	0b0011	0b100

```
if PSTATE.EL == EL0 then
    Undefined();
elsif PSTATE.EL == EL1 then
    if MDCR_EL2().[TDE,TDOSA] != '00' && (IsFeatureImplemented(FEAT_DoubleLock) || ImpDefBool("Trapped
        ↳by MDCR_EL2.TDOSA")) then
        AArch64_SystemAccessTrap(EL2, 0x18);
    else
        X{64}(t) = OSDLR_EL1();
    end;
elsif PSTATE.EL == EL2 then
    X{64}(t) = OSDLR_EL1();
end;
```

MSR OSDLR_EL1, <Xt>

op0	op1	CRn	CRm	op2
0b10	0b000	0b0001	0b0011	0b100

```
if PSTATE.EL == EL0 then
    Undefined();
elsif PSTATE.EL == EL1 then
    if MDCR_EL2().[TDE,TDOSA] != '00' && (IsFeatureImplemented(FEAT_DoubleLock) || ImpDefBool("Trapped
        ↳by MDCR_EL2.TDOSA")) then
        AArch64_SystemAccessTrap(EL2, 0x18);
    else
        OSDLR_EL1() = X{64}(t);
    end;
elsif PSTATE.EL == EL2 then
    OSDLR_EL1() = X{64}(t);
end;
```

D12.3.20 OSDTRRX_EL1, OS Lock Data Transfer Register, Receive

The OSDTRRX_EL1 characteristics are:

Purpose

Used for save and restore of [DBGDTRRX_EL0](#). It is a component of the Debug Communications Channel.

Configuration

There are no configuration notes.

Attributes

OSDTRRX_EL1 is a 64-bit register.

Field descriptions

Bits [63:32]

Reserved, RES0.

DTRRX, bits [31:0]

Update DTRRX without side-effect.

Writes to this register update the value in DTRRX and do not change RXfull.

Reads of this register return the last value written to DTRRX and do not change RXfull.

For the full behavior of the Debug Communications Channel, see ‘[The Debug Communication Channel and Instruction Transfer Register](#)’.

Accessing OSDTRRX_EL1

Arm deprecates reads and writes of OSDTRRX_EL1 when the OS Lock is unlocked.

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, OSDTRRX_EL1

op0	op1	CRn	CRm	op2
0b10	0b000	0b0000	0b0000	0b010

```
if Halted() && !(EffectivelyAtEL0InHost() || EffectivelyAtEL0NotInHost()) &&
    ↳ConstrainUnpredictableBool(Unpredictable_IGNORETRAPINDEBUG) then
    X{64}(t) = OSDTRRX_EL1();
elseif PSTATE.EL == EL0 then
    Undefined();
elseif PSTATE.EL == EL1 then
```

```
if MDCR_EL2().[TDE,TDA] != '00' then
    AArch64_SystemAccessTrap(EL2, 0x18);
else
    X{64}(t) = OSDTRRX_EL1();
end;
elseif PSTATE.EL == EL2 then
    X{64}(t) = OSDTRRX_EL1();
end;
```

MSR OSDTRRX_EL1, <Xt>

op0	op1	CRn	CRm	op2
0b10	0b000	0b0000	0b0000	0b010

```
if Halted() && !(EffectivelyAtEL0InHost() || EffectivelyAtEL0NotInHost()) &&
    ↪ConstrainUnpredictableBool(Unpredictable_IGNORETRAPINDEBUG) then
    OSDTRRX_EL1() = X{64}(t);
elseif PSTATE.EL == EL0 then
    Undefined();
elseif PSTATE.EL == EL1 then
    if MDCR_EL2().[TDE,TDA] != '00' then
        AArch64_SystemAccessTrap(EL2, 0x18);
    else
        OSDTRRX_EL1() = X{64}(t);
    end;
elseif PSTATE.EL == EL2 then
    OSDTRRX_EL1() = X{64}(t);
end;
```

D12.3.21 OSDTRTX_EL1, OS Lock Data Transfer Register, Transmit

The OSDTRTX_EL1 characteristics are:

Purpose

Used for save/restore of [DBGDTRTX_EL0](#). It is a component of the Debug Communications Channel.

Configuration

There are no configuration notes.

Attributes

OSDTRTX_EL1 is a 64-bit register.

Field descriptions

Bits [63:32]

Reserved, RES0.

DTRTX, bits [31:0]

Return DTRTX without side-effect.

Reads of this register return the value in DTRTX and do not change TXfull.

Writes of this register update the value in DTRTX and do not change TXfull.

For the full behavior of the Debug Communications Channel, see ‘[The Debug Communication Channel and Instruction Transfer Register](#)’.

Accessing OSDTRTX_EL1

Arm deprecates reads and writes of OSDTRTX_EL1 when the OS Lock is unlocked.

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, OSDTRTX_EL1

op0	op1	CRn	CRm	op2
0b10	0b000	0b0000	0b0011	0b010

```
if Halted() && !(EffectivelyAtEL0InHost() || EffectivelyAtEL0NotInHost()) &&  
    ↳ConstrainUnpredictableBool(Unpredictable_IGNORETRAPINDEBUG) then  
    X{64}(t) = OSDTRTX_EL1();  
elseif PSTATE.EL == EL0 then  
    Undefined();  
elseif PSTATE.EL == EL1 then
```

```
if MDCR_EL2().[TDE,TDA] != '00' then

    OSDTRTX_EL1() = X{64}(t);
end;
```

D12.3.22 OSECCR_EL1, OS Lock Exception Catch Control Register

The OSECCR_EL1 characteristics are:

Purpose

Provides a mechanism for an operating system to access the contents of EDECCR that are otherwise invisible to software, so it can save/restore the contents of EDECCR over powerdown on behalf of the external debugger.

Configuration

If OSLSR_EL1.OSLK == 0, then OSECCR_EL1 returns an UNKNOWN value on reads and ignores writes.

AArch64 System register OSECCR_EL1 bits [31:0] are architecturally mapped to External register EDECCR[31:0].

Attributes

OSECCR_EL1 is a 64-bit register.

Field descriptions

When OSLSR_EL1.OSLK == '1':

Bits [63:32]

Reserved, RES0.

EDECCR, bits [31:0]

Used for save/restore to EDECCR over powerdown.

Reads or writes to this field are indirect accesses to EDECCR.

The reset behavior of this field is:

- On a Cold reset, this field resets to the expression 0x00.

Accessing OSECCR_EL1

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, OSECCR_EL1

op0	op1	CRn	CRm	op2
0b10	0b000	0b0000	0b0110	0b010

```
if PSTATE.EL == EL0 then
    Undefined();
elseif PSTATE.EL == EL1 then
    if MDCR_EL2().[TDE,TDA] != '00' then
        AArch64_SystemAccessTrap(EL2, 0x18);
    elseif OSLSR_EL1().OSLK == '0' then
        X{64}(t) = ARBITRARY:bits(64);
    else
        X{64}(t) = OSECCR_EL1();
    end;
elseif PSTATE.EL == EL2 then
    if OSLSR_EL1().OSLK == '0' then
        X{64}(t) = ARBITRARY:bits(64);
    else
        X{64}(t) = OSECCR_EL1();
    end;
end;
```

MSR OSECCR_EL1, <Xt>

op0	op1	CRn	CRm	op2
0b10	0b000	0b0000	0b0110	0b010

```
if PSTATE.EL == EL0 then
    Undefined();
elseif PSTATE.EL == EL1 then
    if MDCR_EL2().[TDE,TDA] != '00' then
        AArch64_SystemAccessTrap(EL2, 0x18);
    elseif OSLSR_EL1().OSLK == '0' then
        return;
    else
        OSECCR_EL1() = X{64}(t);
    end;
elseif PSTATE.EL == EL2 then
    if OSLSR_EL1().OSLK == '0' then
        return;
    else
        OSECCR_EL1() = X{64}(t);
    end;
end;
```

D12.3.23 OSLAR_EL1, OS Lock Access Register

The OSLAR_EL1 characteristics are:

Purpose

Used to lock or unlock the OS Lock.

Configuration

AArch64 System register OSLAR_EL1 bits [31:0] are architecturally mapped to External register [OSLAR_EL1](#)[31:0].

Attributes

OSLAR_EL1 is a 64-bit register.

Field descriptions

Bits [63:1]

Reserved, RES0.

OSLK, bit [0]

On writes to OSLAR_EL1, bit[0] is copied to the OS Lock.
Use [OSLSR_EL1](#).OSLK to check the current status of the lock.

Accessing OSLAR_EL1

Accesses to this register use the following encodings in the System register encoding space:

MSR OSLAR_EL1, <Xt>

op0	op1	CRn	CRm	op2
0b10	0b000	0b0001	0b0000	0b100

```
if PSTATE.EL == EL0 then
    Undefined();
elseif PSTATE.EL == EL1 then
    if MDCR_EL2().[TDE,TDOSA] != '00' then
        AArch64_SystemAccessTrap(EL2, 0x18);
    else
        OSLAR_EL1() = X{64}(t);
    end;
elseif PSTATE.EL == EL2 then
    OSLAR_EL1() = X{64}(t);
end;
```

D12.3.24 OSLSR_EL1, OS Lock Status Register

The OSLSR_EL1 characteristics are:

Purpose

Provides the status of the OS Lock.

Configuration

There are no configuration notes.

Attributes

OSLSR_EL1 is a 64-bit register.

Field descriptions

Bits [63:4]

Reserved, RES0.

OSLM, bits [3, 0]

OS Lock model implemented. Identifies the form of OS save and restore mechanism implemented.

The value of this field is an IMPLEMENTATION DEFINED choice of:

OSLM	Meaning
0b00	OS Lock not implemented.
0b10	OS Lock implemented.

All other values are reserved. In an Armv8 implementation the value 0b00 is not permitted.

Access to this field is RO.

nTT, bit [2]

Not 32-bit access. This bit is always RAZ. It indicates that a 32-bit access is needed to write the key to the OS Lock Access Register.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

OSLK, bit [1]

OS Lock Status.

OSLK	Meaning
0b0	OS Lock unlocked.
0b1	OS Lock locked.

The OS Lock is locked and unlocked by writing to the OS Lock Access Register.

The reset behavior of this field is:

- On a Cold reset, this field resets to '1'.

Accessing OSLSR_EL1

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, OSLSR_EL1

op0	op1	CRn	CRm	op2
0b10	0b000	0b0001	0b0001	0b100

```

if PSTATE.EL == EL0 then
    Undefined();
elsif PSTATE.EL == EL1 then
    if MDCR_EL2().[TDE,TDOSA] != '00' then
        AArch64_SystemAccessTrap(EL2, 0x18);
    else
        X{64}(t) = OSLSR_EL1();
    end;
elsif PSTATE.EL == EL2 then
    X{64}(t) = OSLSR_EL1();
end;

```

D12.4 Trace registers

This section lists the Trace registers in AArch64.

D12.4.1 TRFCR_EL1, Trace Filter Control Register (EL1)

The TRFCR_EL1 characteristics are:

Purpose

Provides EL1 controls for Trace.

Configuration

This register is present only when FEAT_TRF is implemented. Otherwise, direct accesses to TRFCR_EL1 are UNDEFINED.

Attributes

TRFCR_EL1 is a 64-bit register.

Field descriptions

Bits [63:7]

Reserved, RES0.

TS, bits [6:5]

Timestamp Control. Controls which timebase is used for trace timestamps.

TS	Meaning
0b01	Virtual timestamp. The traced timestamp is the physical counter value minus the value of CNTVOFF_EL2 .
0b11	Physical timestamp. The traced timestamp is the physical counter value.

All other values are reserved.

If any of the following are true, then this field is ignored by the PE:

- EL2 is implemented and [TRFCR_EL2](#).TS is not 0b00.
- SelfHostedTraceEnabled() == FALSE.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [4:2]

Reserved, RES0.

E1TRE, bit [1]

EL1 Trace Enable.

E1TRE	Meaning
0b0	Trace is prohibited at EL1.
0b1	Trace is allowed at EL1.

If any of the following are true, then this field is ignored by the PE:

- SelfHostedTraceEnabled() == FALSE.
- The Effective value of [HCR_EL2.TGE](#) is 1.

The reset behavior of this field is:

- On a Warm reset, this field resets to '0'.

E0TRE, bit [0]

EL0 Trace Enable.

E0TRE	Meaning
0b0	Trace is prohibited at EL0.
0b1	Trace is allowed at EL0.

If any of the following are true, then this field is ignored by the PE:

- SelfHostedTraceEnabled() == FALSE.
- The Effective value of [HCR_EL2.TGE](#) is 1.

The reset behavior of this field is:

- On a Warm reset, this field resets to '0'.

Accessing TRFCR_EL1

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, TRFCR_EL1

op0	op1	CRn	CRm	op2
0b11	0b000	0b0001	0b0010	0b001

```

if !IsFeatureImplemented(FEAT_TRF) then
    Undefined();
elseif PSTATE.EL == EL0 then
    Undefined();
elseif PSTATE.EL == EL1 then
    if MDCR_EL2().TTRF == '1' then
        AArch64_SystemAccessTrap(EL2, 0x18);

```

```
        else
            X{64}(t) = TRFCR_EL1();
        end;
    elsif PSTATE.EL == EL2 then
        X{64}(t) = TRFCR_EL1();
    end;
```

MSR TRFCR_EL1, <Xt>

op0	op1	CRn	CRm	op2
0b11	0b000	0b0001	0b0010	0b001

```
if !IsFeatureImplemented(FEAT_TRF) then
    Undefined();
elsif PSTATE.EL == EL0 then
    Undefined();
elsif PSTATE.EL == EL1 then
    if MDCR_EL2().TTRF == '1' then
        AArch64_SystemAccessTrap(EL2, 0x18);
    else
        TRFCR_EL1() = X{64}(t);
    end;
elsif PSTATE.EL == EL2 then
    TRFCR_EL1() = X{64}(t);
end;
```

D12.4.2 TRFCR_EL2, Trace Filter Control Register (EL2)

The TRFCR_EL2 characteristics are:

Purpose

Provides EL2 controls for Trace.

Configuration

This register is present only when FEAT_TRF is implemented. Otherwise, direct accesses to TRFCR_EL2 are UNDEFINED.

Attributes

TRFCR_EL2 is a 64-bit register.

Field descriptions

Bits [63:7]

Reserved, RES0.

TS, bits [6:5]

Timestamp Control. Controls which timebase is used for trace timestamps.

TS	Meaning
0b00	Timestamp controlled by TRFCR_EL1.TS .
0b01	Virtual timestamp. The traced timestamp is the physical counter value minus the value of CNTVOFF_EL2 .
0b11	Physical timestamp. The traced timestamp is the physical counter value.

If `SelfHostedTraceEnabled() == FALSE`, then this field is ignored by the PE.

The reset behavior of this field is:

- On a Warm reset, this field resets to '00'.

Bit [4]

Reserved, RES0.

CX, bit [3]

[CONTEXTIDR_EL2](#) and VMID trace enable.

CX	Meaning
0b0	CONTEXTIDR_EL2 and VMID trace prohibited.
0b1	CONTEXTIDR_EL2 and VMID trace allowed.

If `SelfHostedTraceEnabled() == FALSE`, then this field is ignored by the PE.

The reset behavior of this field is:

- On a Warm reset, this field resets to '0'.

Bit [2]

Reserved, RES0.

E2TRE, bit [1]

EL2 Trace Enable.

E2TRE	Meaning
0b0	Trace is prohibited at EL2.
0b1	Trace is allowed at EL2.

If `SelfHostedTraceEnabled() == FALSE`, then this field is ignored by the PE.

The reset behavior of this field is:

- On a Warm reset, this field resets to '0'.

E0HTRE, bit [0]

EL0 Trace Enable.

E0HTRE	Meaning
0b0	Trace is prohibited at EL0.
0b1	Trace is allowed at EL0.

If any of the following are true, then this field is ignored by the PE:

- `SelfHostedTraceEnabled() == FALSE`.
- The Effective value of [HCR_EL2.TGE](#) is 0.

The reset behavior of this field is:

- On a Warm reset, this field resets to '0'.

Accessing TRFCR_EL2

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, TRFCR_EL2

op0	op1	CRn	CRm	op2
0b11	0b100	0b0001	0b0010	0b001

```

D12.5 Performance Monitors registers

This section lists the Performance Monitoring registers in AArch64.

D12.5.1 PMCCFILTR_EL0, Performance Monitors Cycle Count Filter Register

The PMCCFILTR_EL0 characteristics are:

Purpose

Determines the modes in which the Cycle Counter, PMCCNTR_EL0, increments.

Configuration

AArch64 System register PMCCFILTR_EL0 bits [31:0] are architecturally mapped to External register PMCCFILTR_EL0[31:0].

This register is present only when FEAT_PMUv3 is implemented. Otherwise, direct accesses to PMCCFILTR_EL0 are UNDEFINED.

Attributes

PMCCFILTR_EL0 is a 64-bit register.

Field descriptions

Bits [63:32]

Reserved, RES0.

P, bit [31]

EL1 filtering. Controls counting cycles in EL1.

P	Meaning
0b0	This mechanism has no effect on filtering of cycles.
0b1	The PE does not count cycles in EL1.

If Secure and Non-secure states are implemented, then counting cycles in Non-secure EL1 is further controlled by PMCCFILTR_EL0.NSK.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

U, bit [30]

EL0 filtering. Controls counting cycles in EL0.

U	Meaning
0b0	This mechanism has no effect on filtering of cycles.
0b1	The PE does not count cycles in EL0.

If Secure and Non-secure states are implemented, then counting cycles in Non-secure EL0 is further controlled by PMCCFILTR_EL0.NSU.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [29:28]

Reserved, RES0.

NSH, bit [27]

EL2 filtering. Controls counting cycles in EL2.

NSH	Meaning
0b0	The PE does not count cycles in EL2.
0b1	This mechanism has no effect on filtering of cycles.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [26:0]

Reserved, RES0.

Accessing PMCCFILTR_EL0

PMCCFILTR_EL0 can also be accessed by using [PMXEVTYPYPER_EL0](#) with [PMSELR_EL0](#).SEL set to 0b111111.

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, PMCCFILTR_EL0

op0	op1	CRn	CRm	op2
0b11	0b011	0b1110	0b1111	0b111

```

if !IsFeatureImplemented(FEAT_PMUv3) then
    Undefined();
elsif PSTATE.EL == EL0 then

        AArch64_SystemAccessTrap(EL2, 0x18);
    else
        PMCCFILTR_EL0() = X{64}(t);
    end;
elseif PSTATE.EL == EL2 then
    PMCCFILTR_EL0() = X{64}(t);
end;
```

D12.5.2 PMCCNTR_EL0, Performance Monitors Cycle Count Register

The PMCCNTR_EL0 characteristics are:

Purpose

Holds the value of the processor Cycle Counter, CCNT, that counts processor clock cycles. See ‘Time as measured by the Performance Monitors cycle counter’ for more information.

PMCCFILTR_EL0 determines the modes and states in which the PMCCNTR_EL0 can increment.

Configuration

All counters are subject to any changes in clock frequency, including clock stopping caused by the WFI and WFE instructions. This means that it is CONSTRAINED UNPREDICTABLE whether or not PMCCNTR_EL0 continues to increment when clocks are stopped by WFI and WFE instructions.

AArch64 System register PMCCNTR_EL0 bits [63:0] are architecturally mapped to External register PMCCNTR_EL0[63:0].

This register is present only when FEAT_PMUv3 is implemented. Otherwise, direct accesses to PMCCNTR_EL0 are UNDEFINED.

Attributes

PMCCNTR_EL0 is a 64-bit register.

Field descriptions

CCNT, bits [63:0]

Cycle count. Depending on the values of PMCR_EL0.{LC,D}, this field increments in one of the following ways:

- Every processor clock cycle.
- Every 64th processor clock cycle.

Writing 1 to PMCR_EL0.C sets this field to 0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing PMCCNTR_EL0

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, PMCCNTR_EL0

op0	op1	CRn	CRm	op2
0b11	0b011	0b1001	0b1101	0b000

```

    PMCCNTR_EL0() = X{64}(t);
end;

```

D12.5.3 PMCEID0_EL0, Performance Monitors Common Event Identification Register 0

The PMCEID0_EL0 characteristics are:

Purpose

Defines which Common architectural events and Common microarchitectural events are implemented, or counted, using PMU events in the ranges 0x0000 to 0x001F and 0x4000 to 0x401F.

For more information about the Common events and the use of the PMCEID<n>_EL0 registers see ‘The PMU event number space and common events’.

Configuration

AArch64 System register PMCEID0_EL0 bits [31:0] are architecturally mapped to External register PMCEID0[31:0].

AArch64 System register PMCEID0_EL0 bits [63:32] are architecturally mapped to External register PMCEID2[31:0].

This register is present only when FEAT_PMUv3 is implemented. Otherwise, direct accesses to PMCEID0_EL0 are UNDEFINED.

Attributes

PMCEID0_EL0 is a 64-bit register.

Field descriptions

IDhi<n> , bits [n+32], for n = 31 to 0

When FEAT_PMUv3p1 is implemented:

IDhi[n] corresponds to Common event (0x4000 + n).

For each bit:

IDhi<n>	Meaning
0b0	The Common event is not implemented, or not counted.

0b1	The Common event is implemented.
-----	----------------------------------

When the value of a bit in the field is 1, the corresponding Common event is implemented and counted.

Note

Arm recommends that if a Common event is never counted, the value of the corresponding bit is 0.

A bit that corresponds to a reserved event number is reserved. The value might be used in a future revision of the architecture to identify an additional Common event.

Note

Such an event might be added retrospectively to an earlier version of the PMU architecture, provided the event does not require any additional PMU features and has an event number that can be represented in the PMCEID<n>_EL0 registers of that earlier version of the PMU architecture.

Otherwise:

Reserved, RES0.

ID<n> , bits [n], for n = 31 to 0

ID[n] corresponds to Common event n.

For each bit:

ID<n>	Meaning
0b0	The Common event is not implemented, or not counted.
0b1	The Common event is implemented.

When the value of a bit in the field is 1, the corresponding Common event is implemented and counted.

Note

Arm recommends that if a Common event is never counted, the value of the corresponding bit is 0.

A bit that corresponds to a reserved event number is reserved. The value might be used in a future revision of the architecture to identify an additional Common event.

Note

Such an event might be added retrospectively to an earlier version of the PMU architecture, provided the event does not require any additional PMU features and has an event number that can be represented in the PMCEID<n>_EL0 registers of that earlier version of the PMU architecture.

Accessing PMCEID0_EL0

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, PMCEID0_EL0

op0	op1	CRn	CRm	op2
0b11	0b011	0b1001	0b1100	0b110

```

    end;
elsif PSTATE.EL == EL2 then
    X{64}(t) = PMCEID0_EL0();
end;

```

D12.5.4 PMCEID1_EL0, Performance Monitors Common Event Identification Register 1

The PMCEID1_EL0 characteristics are:

Purpose

Defines which Common architectural events and Common microarchitectural events are implemented, or counted, using PMU events in the ranges 0x0020 to 0x003F and 0x4020 to 0x403F.

For more information about the Common events and the use of the PMCEID<n>_EL0 registers see ‘The PMU event number space and common events’.

Configuration

AArch64 System register PMCEID1_EL0 bits [31:0] are architecturally mapped to External register PMCEID1[31:0].

AArch64 System register PMCEID1_EL0 bits [63:32] are architecturally mapped to External register PMCEID3[31:0].

This register is present only when FEAT_PMUv3 is implemented. Otherwise, direct accesses to PMCEID1_EL0 are UNDEFINED.

Attributes

PMCEID1_EL0 is a 64-bit register.

Field descriptions

IDhi<n> , bits [n+32], for n = 31 to 0

When FEAT_PMUv3p1 is implemented:

IDhi[n] corresponds to Common event (0x4020 + n).

For each bit:

IDhi<n>	Meaning
0b0	The Common event is not implemented, or not counted.

0b1	The Common event is implemented.
-----	----------------------------------

When the value of a bit in the field is 1, the corresponding Common event is implemented and counted.

Note

Arm recommends that if a Common event is never counted, the value of the corresponding bit is 0.

A bit that corresponds to a reserved event number is reserved. The value might be used in a future revision of the architecture to identify an additional Common event.

Note

Such an event might be added retrospectively to an earlier version of the PMU architecture, provided the event does not require any additional PMU features and has an event number that can be represented in the PMCEID<n>_EL0 registers of that earlier version of the PMU architecture.

Otherwise:

Reserved, RES0.

ID<n> , bits [n], for n = 31 to 0

ID[n] corresponds to Common event (0x0020 + n).

For each bit:

ID<n>	Meaning
0b0	The Common event is not implemented, or not counted.
0b1	The Common event is implemented.

When the value of a bit in the field is 1, the corresponding Common event is implemented and counted.

Note

Arm recommends that if a Common event is never counted, the value of the corresponding bit is 0.

A bit that corresponds to a reserved event number is reserved. The value might be used in a future revision of the architecture to identify an additional Common event.

Note

Such an event might be added retrospectively to an earlier version of the PMU architecture, provided the event does not require any additional PMU features and has an event number that can be represented in the PMCEID<n>_EL0 registers of that earlier version of the PMU architecture.

Accessing PMCEID1_EL0

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, PMCEID1_EL0

op0	op1	CRn	CRm	op2
0b11	0b011	0b1001	0b1100	0b111

```

if !IsFeatureImplemented(FEAT_PMuV3) then
    Undefined();
elsif PSTATE.EL == EL0 then
    if PMUSERENR_EL0().EN == '0' then

    else
        X{64}(t) = PMCEID1_EL0();
    end;
elsif PSTATE.EL == EL1 then
    if MDCR_EL2().TPM == '1' then
        AArch64_SystemAccessTrap(EL2, 0x18);
    else
        X{64}(t) = PMCEID1_EL0();
    end;
elsif PSTATE.EL == EL2 then
    X{64}(t) = PMCEID1_EL0();
end;

```

D12.5.5 PMCNTENCLR_EL0, Performance Monitors Count Enable Clear Register

The PMCNTENCLR_EL0 characteristics are:

Purpose

Allows software to disable the following counters:

- The cycle counter [PMCCNTR_EL0](#).
- The event counters [PMEVCNTR<n>_EL0](#).

Reading from this register shows which counters are enabled.

Configuration

AArch64 System register PMCNTENCLR_EL0 bits [63:0] are architecturally mapped to AArch64 System register [PMCNTENSET_EL0](#)[63:0].

AArch64 System register PMCNTENCLR_EL0 bits [31:0] are architecturally mapped to External register [PMCNTENCLR_EL0](#)[31:0].

AArch64 System register PMCNTENCLR_EL0 bits [31:0] are architecturally mapped to External register [PMCNTENSET_EL0](#)[31:0].

This register is present only when FEAT_PMUv3 is implemented. Otherwise, direct accesses to PMCNTENCLR_EL0 are UNDEFINED.

Attributes

PMCNTENCLR_EL0 is a 64-bit register.

Field descriptions

Bits [63:32]

Reserved, RES0.

C, bit [31]

[PMCCNTR_EL0](#) disable. On writes, allows software to disable [PMCCNTR_EL0](#). On reads, returns the [PMCCNTR_EL0](#) enable status.

C	Meaning
0b0	PMCCNTR_EL0 disabled.
0b1	PMCCNTR_EL0 enabled.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Access to this field is W1C.

P<m> , bits [m], for m = 30 to 0

PMEVCNTR<m>_EL0 disable. On writes, allows software to disable PMEVCNTR<m>_EL0. On reads, returns the PMEVCNTR<m>_EL0 enable status.

P<m>	Meaning
0b0	PMEVCNTR<m>_EL0 disabled.
0b1	PMEVCNTR<m>_EL0 enabled.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing this field has the following behavior:

- When m ≥ GetNumEventCountersAccessible(), access to this field is RAZ/WI.
- Otherwise, access to this field is W1C.

Accessing PMCNTECLR_EL0

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, PMCNTECLR_EL0

op0	op1	CRn	CRm	op2
0b11	0b011	0b1001	0b1100	0b010

```

if !IsFeatureImplemented(FEAT_PMUv3) then

    else
        PMCNTENCLR_EL0() = X{64}(t);
    end;
elsif PSTATE.EL == EL1 then
    if MDCR_EL2().TPM == '1' then
        AArch64_SystemAccessTrap(EL2, 0x18);
    else
        PMCNTENCLR_EL0() = X{64}(t);
    end;
elsif PSTATE.EL == EL2 then
    PMCNTENCLR_EL0() = X{64}(t);
end;

```

D12.5.6 PMCNTESET_EL0, Performance Monitors Count Enable Set Register

The PMCNTESET_EL0 characteristics are:

Purpose

Allows software to enable the following counters:

- The cycle counter [PMCCNTR_EL0](#).
- The event counters [PMEVCNTR<n>_EL0](#).

Reading from this register shows which counters are enabled.

Configuration

AArch64 System register PMCNTESET_EL0 bits [63:0] are architecturally mapped to AArch64 System register [PMCNTECLR_EL0](#)[63:0].

AArch64 System register PMCNTESET_EL0 bits [31:0] are architecturally mapped to External register [PMCNTESET_EL0](#)[31:0].

AArch64 System register PMCNTESET_EL0 bits [31:0] are architecturally mapped to External register [PMCNTECLR_EL0](#)[31:0].

This register is present only when FEAT_PMUv3 is implemented. Otherwise, direct accesses to PMCNTESET_EL0 are UNDEFINED.

Attributes

PMCNTESET_EL0 is a 64-bit register.

Field descriptions

Bits [63:32]

Reserved, RES0.

C, bit [31]

[PMCCNTR_EL0](#) enable. On writes, allows software to enable [PMCCNTR_EL0](#). On reads, returns the [PMCCNTR_EL0](#) enable status.

C	Meaning
0b0	PMCCNTR_EL0 disabled.
0b1	PMCCNTR_EL0 enabled.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Access to this field is W1S.

P<m> , bits [m], for m = 30 to 0

PMEVCNTR<m>_EL0 enable. On writes, allows software to enable PMEVCNTR<m>_EL0. On reads, returns the PMEVCNTR<m>_EL0 enable status.

P<m>	Meaning
0b0	PMEVCNTR<m>_EL0 disabled.
0b1	PMEVCNTR<m>_EL0 enabled.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing this field has the following behavior:

- When m >= GetNumEventCountersAccessible(), access to this field is RAZ/WI.
- Otherwise, access to this field is W1S.

Accessing PMCNTENSET_EL0

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, PMCNTENSET_EL0

op0	op1	CRn	CRm	op2
0b11	0b011	0b1001	0b1100	0b001

```

    end;
elsif PSTATE.EL == EL2 then
    PMCNTENSET_EL0() = X{64}(t);
end;

```

D12.5.7 PMCR_EL0, Performance Monitors Control Register

The PMCR_EL0 characteristics are:

Purpose

Provides details of the Performance Monitors implementation, including the number of counters implemented, and configures and controls the counters.

Configuration

AArch64 System register PMCR_EL0 bits [31:0] are architecturally mapped to External register [PMCR_EL0](#)[31:0].

This register is present only when FEAT_PMUv3 is implemented. Otherwise, direct accesses to PMCR_EL0 are UNDEFINED.

Attributes

PMCR_EL0 is a 64-bit register.

Field descriptions

Bits [63:32]

Reserved, RES0.

IMP, bits [31:24]

Implementer code.

If this field is zero, then PMCR_EL0.IDCODE is RES0 and software must use [MIDR_EL1](#) to identify the PE.

Otherwise, this field and PMCR_EL0.IDCODE identify the PMU implementation to software. The implementer codes are allocated by Arm. A nonzero value has the same interpretation as [MIDR_EL1](#).Implementer.

Arm deprecates use of this field.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

IDCODE, bits [23:16]

When PMCR_EL0.IMP != '00000000':

Identification code. Arm deprecates use of this field.

Each implementer must maintain a list of identification codes that are specific to the implementer. A specific implementation is identified by the combination of the implementer code and the identification code.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

Otherwise:

Reserved, RES0.

N, bits [15:11]

Indicates the number of event counters implemented. This value is in the range of 0b000000-0b111111. If the value is 0b000000, then only [PMCCNTR_EL0](#) is implemented. If the value is 0b111111, then [PMCCNTR_EL0](#) and 31 event counters are implemented.

When EL2 is implemented and enabled for the current Security state, reads of this field from EL1 and EL0 return the Effective value of [MDCR_EL2](#).HPMN.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

Bits [10:7]

Reserved, RES0.

Bit [6]

Reserved, RES1.

DP, bit [5]

When FEAT_PMUv3p1 is implemented:

Disable cycle counter when event counting is prohibited.

DP	Meaning
0b0	Cycle counting by PMCCNTR_EL0 is not affected by this mechanism.
0b1	Cycle counting by PMCCNTR_EL0 is disabled in prohibited regions: If FEAT_PMUv3p1 is implemented, EL2 is implemented, and MDCR_EL2.HPMD is 1, then cycle counting by PMCCNTR_EL0 is disabled at EL2.

The conditions when this field disables the cycle counter are the same as when event counting by an event counter in the first range is prohibited. For more information about event counter ranges, see [MDCR_EL2](#).HPMN.

For more information, see ‘[Prohibiting event and cycle counting](#)’.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

X, bit [4]

When the implementation includes a PMU event export bus:

Enable export of events in an IMPLEMENTATION DEFINED PMU event export bus.

X	Meaning
0b0	Do not export events.
0b1	Export events where not prohibited.

This field enables the exporting of events over an IMPLEMENTATION DEFINED PMU event export bus to another device.

No events are exported when counting is prohibited.

This field does not affect the generation of Performance Monitors overflow interrupt requests or signaling to a cross-trigger interface (CTI) that can be implemented as signals exported from the PE.

If [FEAT_ETMv4](#) is implemented, this field does affect the use of PMU events as an External Input by the trace unit.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RAZ/WI.

Bit [3]

Reserved, RES0.

C, bit [2]

Cycle counter reset. The effects of writing to this field are:

C	Meaning
0b0	No action.
0b1	Reset PMCCNTR_EL0 to zero.

———— **Note** ————

Resetting [PMCCNTR_EL0](#) does not change the cycle counter overflow field. The value of PMCR_EL0.LC is ignored, and bits [63:0] of the cycle counter are reset.

Access to this field is WO/RAZ.

P, bit [1]

Event counter reset.

P	Meaning
0b0	No action.
0b1	Reset all affected event counters PMEVCNTR<n>_EL0 to zero.

The event counters affected by this field are:

- All event counters in the first range.

- If any of the following are true, all event counters in the second range:
 - EL2 is not implemented.
 - The PE is executing at EL2.

Writes to this field do not affect other event counters or the cycle counter [PMCCNTR_EL0](#).

For more information about event counter ranges, see [MDCR_EL2](#).HPMN.

Note

Resetting the event counters does not change the event counter overflow fields.

Access to this field is WO/RAZ.

E, bit [0]

Enable.

E	Meaning
0b0	Affected counters are disabled and do not count.
0b1	Affected counters are enabled by PMCNTENSET_EL0 .

The counters affected by this field are:

- The event counters in the first range. For more information about event counter ranges, see [MDCR_EL2](#).HPMN.
- The cycle counter [PMCCNTR_EL0](#).

Other event counters are not affected by this field.

The reset behavior of this field is:

- On a Warm reset, this field resets to '0'.

Accessing PMCR_EL0

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, PMCR_EL0

op0	op1	CRn	CRm	op2

    elseif MDCR_EL2().TPMCR == '1' then
        AArch64_SystemAccessTrap(EL2, 0x18);
    else
        PMCR_EL0() = X{64}(t);
    end;
elseif PSTATE.EL == EL2 then
    PMCR_EL0() = X{64}(t);
end;

```

D12.5.8 PMEVCNTR<n>_EL0, Performance Monitors Event Count Registers, n = 0 - 30

The PMEVCNTR<n>_EL0 characteristics are:

Purpose

Holds event counter n, which counts events, where n is 0 to 30.

Configuration

AArch64 System register PMEVCNTR<n>_EL0 bits [31:0] are architecturally mapped to External register [PMEVCNTR<n>_EL0](#)[31:0].

This register is present only when FEAT_PMUv3 is implemented. Otherwise, direct accesses to PMEVCNTR<n>_EL0 are UNDEFINED.

Attributes

PMEVCNTR<n>_EL0 is a 64-bit register.

Field descriptions

Bits [63:32]

Reserved, RES0.

EVCNT, bits [31:0]

Event counter n. Value of event counter n, where n is the number of this register and is a number from 0 to 30.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing PMEVCNTR<n>_EL0

PMEVCNTR<n>_EL0 can also be accessed by using [PMXEVCNTR_EL0](#) with [PMSELR_EL0](#).SEL set to the value of <n>.

If <n> is greater than or equal to the number of accessible event counters, then reads and writes of [PMEVCNTR<n>_EL0](#) are CONSTRAINED UNPREDICTABLE, and the following behaviors are permitted:

- Accesses to the register are UNDEFINED.
- Accesses to the register behave as RAZ/WI.
- Accesses to the register execute as a NOP.
- Accesses to the register behave as if <n> is an UNKNOWN value less-than-or-equal-to the index of the highest accessible event counter.
- If EL2 is implemented and enabled in the current Security state, and <n> is less than the number of implemented event counters, accesses from EL1 or permitted accesses from EL0 are trapped to EL2.

Note

In EL0, an access is permitted if it is enabled by [PMUSERENR_EL0](#).{ER,EN}.

In EL1 and EL0, [MDCR_EL2](#).HPMN identifies the number of accessible event counters. Otherwise, the number of accessible event counters is the number of implemented event counters. For more information, see [MDCR_EL2](#).HPMN.

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, PMEVCNTR<m>_EL0 ; Where m = 0-30

op0	op1	CRn	CRm	op2
0b11	0b011	0b1110	0b10:m[4:3]	m[2:0]

```

end;
```

D12.5.9 **PMEVTYPER<n>_EL0, Performance Monitors Event Type Registers, n = 0 - 30**

The PMEVTYPER<n>_EL0 characteristics are:

Purpose

Configures event counter n, where n is 0 to 30.

Configuration

AArch64 System register PMEVTYPER<n>_EL0 bits [31:0] are architecturally mapped to External register [PMEVTYPER<n>_EL0\[31:0\]](#).

This register is present only when FEAT_PMUv3 is implemented. Otherwise, direct accesses to PMEVTYPER<n>_EL0 are UNDEFINED.

Attributes

PMEVTYPER<n>_EL0 is a 64-bit register.

Field descriptions

Bits [63:32]

Reserved, RES0.

P, bit [31]

EL1 filtering. Controls counting events in EL1.

P	Meaning
0b0	This mechanism has no effect on filtering of events.
0b1	The PE does not count events in EL1.

If Secure and Non-secure states are implemented, then counting events in Non-secure EL1 is further controlled by PMEVTYPER<n>_EL0.NSK.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

U, bit [30]

EL0 filtering. Controls counting events in EL0.

U	Meaning
0b0	This mechanism has no effect on filtering of events.
0b1	The PE does not count events in EL0.

If Secure and Non-secure states are implemented, then counting events in Non-secure EL0 is further controlled by `PMEVTYPER<n>_EL0.NSU`.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [29:28]

Reserved, RES0.

NSH, bit [27]

EL2 filtering. Controls counting events in EL2.

NSH	Meaning
0b0	The PE does not count events in EL2.
0b1	This mechanism has no effect on filtering of events.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [26]

Reserved, RES0.

MT, bit [25]

When an IMPLEMENTATION DEFINED multi-threaded PMU extension is implemented:

Multithreading.

MT	Meaning
0b0	Count events only on controlling PE.
0b1	Count events from any PE with the same affinity at level 1 and above as this PE.

Unless otherwise stated:

- If the event counts PE cycles when a stall condition is true and a second condition is true, then the counter counts Processor cycles when the stall condition is true for all of these PEs, and the second condition is true for any of these PEs.
- If the event counts PE cycles when any other condition is true, then the counter counts Processor cycles when the condition is true for any of these PEs.
- Otherwise, the event counts by the sum of the count across all of these PEs.

For the stall events, the stall condition means the applicable condition described by the STALL, STALL_FRONTEND, or STALL_BACKEND event.

The second condition is any condition in addition to this.

For example, for the STALL_FRONTEND_L1I event, the stall condition is STALL_FRONTEND, and the second condition is when there is a demand instruction miss in the first level of instruction cache.

For the STALL, STALL_FRONTEND, and STALL_BACKEND events themselves, the second condition is the null TRUE condition.

See ‘[Multithreaded implementations](#)’ and ‘[Cycle event counting in multithreaded implementations](#)’.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bits [24:16]

Reserved, RES0.

evtCount[15:10], bits [15:10]

When FEAT_PMUv3p1 is implemented:

Extension to evtCount[9:0]. For more information, see evtCount[9:0].

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

evtCount[9:0], bits [9:0]

Event to count.

The event number of the event that is counted by event counter [PMEVCNTR<n>_EL0](#).

The ranges of event numbers allocated to each type of event are shown in ‘[Allocation of the PMU event number space](#)’.

If [PMEVTYPER<n>_EL0](#).evtCount is programmed to an event that is reserved or not supported by the PE, the behavior depends on the value written:

- For the range 0x0000 to 0x003F, no events are counted and the value returned by a direct or external read of the [PMEVTYPER<n>_EL0](#).evtCount field is the value written to the field.
- If [FEAT_PMUv3p1](#) is implemented, for the range 0x4000 to 0x403F, no events are counted and the value returned by a direct or external read of the [PMEVTYPER<n>_EL0](#).evtCount field is the value written to the field.
- For other values, it is UNPREDICTABLE what event, if any, is counted and the value returned by a direct or external read of the [PMEVTYPER<n>_EL0](#).evtCount field is UNKNOWN.

Note

UNPREDICTABLE means the event must not expose privileged information.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing [PMEVTYPER<n>_EL0](#)

[PMEVTYPER<n>_EL0](#) can also be accessed by using [PMXEVTYPER_EL0](#) with [PMSELR_EL0](#).SEL set to n.

If $\langle n \rangle$ is greater than or equal to the number of accessible event counters, then reads and writes of [PMEVTYPER \$\langle n \rangle\$ _EL0](#) are CONSTRAINED UNPREDICTABLE, and the following behaviors are permitted:

- Accesses to the register are UNDEFINED.
- Accesses to the register behave as RAZ/WI.
- Accesses to the register execute as a NOP.
- Accesses to the register behave as if $\langle n \rangle$ is an UNKNOWN value less-than-or-equal-to the index of the highest accessible event counter.
- If EL2 is implemented and enabled in the current Security state, and $\langle n \rangle$ is less than the number of implemented event counters, accesses from EL1 or permitted accesses from EL0 are trapped to EL2.

Note

In EL0, an access is permitted if it is enabled by [PMUSERENR_EL0.EN](#).

If EL2 is implemented and enabled in the current Security state, at EL1 and EL0, [MDCR_EL2.HPMN](#) identifies the number of accessible event counters. Otherwise, the number of accessible event counters is the number of implemented event counters. For more information, see [MDCR_EL2.HPMN](#).

Accesses to this register use the following encodings in the System register encoding space:

MRS $\langle Xt \rangle$, PMEVTYPER $\langle m \rangle$ _EL0 ; Where $m = 0-30$

D12.5.10 PMINTENCLR_EL1, Performance Monitors Interrupt Enable Clear Register

The PMINTENCLR_EL1 characteristics are:

Purpose

Allows software to disable the generation of interrupt requests on overflows from the following counters:

- The cycle counter [PMCCNTR_EL0](#).
- The event counters [PMEVCNTR<n>_EL0](#).

Reading from this register shows which overflow interrupt requests are enabled.

Configuration

AArch64 System register PMINTENCLR_EL1 bits [63:0] are architecturally mapped to AArch64 System register [PMINTENSET_EL1](#)[63:0].

AArch64 System register PMINTENCLR_EL1 bits [31:0] are architecturally mapped to External register [PMINTENCLR_EL1](#)[31:0].

AArch64 System register PMINTENCLR_EL1 bits [31:0] are architecturally mapped to External register [PMINTENSET_EL1](#)[31:0].

This register is present only when FEAT_PMUv3 is implemented. Otherwise, direct accesses to PMINTENCLR_EL1 are UNDEFINED.

Attributes

PMINTENCLR_EL1 is a 64-bit register.

Field descriptions

Bits [63:32]

Reserved, RES0.

C, bit [31]

Interrupt request on unsigned overflow of [PMCCNTR_EL0](#) disable. On writes, allows software to disable the interrupt request on unsigned overflow of [PMCCNTR_EL0](#). On reads, returns the interrupt request on unsigned overflow of [PMCCNTR_EL0](#) enable status.

C	Meaning
0b0	Interrupt request on unsigned overflow of PMCCNTR_EL0 disabled.
0b1	Interrupt request on unsigned overflow of PMCCNTR_EL0 enabled.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Access to this field is W1C.

P<m> , bits [m], for m = 30 to 0

Interrupt request on unsigned overflow of [PMEVCNTR<m>_EL0](#) disable. On writes, allows software to disable the interrupt request on unsigned overflow of [PMEVCNTR<m>_EL0](#). On reads, returns the interrupt request on unsigned overflow of [PMEVCNTR<m>_EL0](#) enable status.

P<m>	Meaning
0b0	Interrupt request on unsigned overflow of PMEVCNTR<m>_EL0 disabled.
0b1	Interrupt request on unsigned overflow of PMEVCNTR<m>_EL0 enabled.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing this field has the following behavior:

- When m >= GetNumEventCountersAccessible(), access to this field is RAZ/WI.
- Otherwise, access to this field is W1C.

Accessing PMINTENCLR_EL1

Accesses to this register use the following encodings in the System register encoding space:

```

D12.5.11 PMINTENSET_EL1, Performance Monitors Interrupt Enable Set Register

The PMINTENSET_EL1 characteristics are:

Purpose

Allows software to enable the generation of interrupt requests on overflows from the following counters:

- The cycle counter [PMCCNTR_EL0](#).
- The event counters [PMEVCNTR<n>_EL0](#).

Reading from this register shows which overflow interrupt requests are enabled.

Configuration

AArch64 System register PMINTENSET_EL1 bits [63:0] are architecturally mapped to AArch64 System register [PMINTENCLR_EL1](#)[63:0].

AArch64 System register PMINTENSET_EL1 bits [31:0] are architecturally mapped to External register [PMINTENSET_EL1](#)[31:0].

AArch64 System register PMINTENSET_EL1 bits [31:0] are architecturally mapped to External register [PMINTENCLR_EL1](#)[31:0].

This register is present only when FEAT_PMUv3 is implemented. Otherwise, direct accesses to PMINTENSET_EL1 are UNDEFINED.

Attributes

PMINTENSET_EL1 is a 64-bit register.

Field descriptions

Bits [63:32]

Reserved, RES0.

C, bit [31]

Interrupt request on unsigned overflow of [PMCCNTR_EL0](#) enable. On writes, allows software to enable the interrupt request on unsigned overflow of [PMCCNTR_EL0](#). On reads, returns the interrupt request on unsigned overflow of [PMCCNTR_EL0](#) enable status.

C	Meaning
0b0	Interrupt request on unsigned overflow of PMCCNTR_EL0 disabled.
0b1	Interrupt request on unsigned overflow of PMCCNTR_EL0 enabled.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Access to this field is W1S.

P<m> , bits [m], for m = 30 to 0

Interrupt request on unsigned overflow of [PMEVCNTR<m>_EL0](#) enable. On writes, allows software to enable the interrupt request on unsigned overflow of [PMEVCNTR<m>_EL0](#). On reads, returns the interrupt request on unsigned overflow of [PMEVCNTR<m>_EL0](#) enable status.

P<m>	Meaning
0b0	Interrupt request on unsigned overflow of PMEVCNTR<m>_EL0 disabled.
0b1	Interrupt request on unsigned overflow of PMEVCNTR<m>_EL0 enabled.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing this field has the following behavior:

- When m >= GetNumEventCountersAccessible(), access to this field is RAZ/WI.
- Otherwise, access to this field is W1S.

Accessing PMINTENSET_EL1

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, PMINTENSET_EL1

op0	op1	CRn	CRm	op2
0b11	0b000	0b1001	0b1110	0b001

```

if !IsFeatureImplemented(FEAT_PMUv3) then
    Undefined();
elsif PSTATE.EL == EL0 then

elsif PSTATE.EL == EL2 then
    PMINTENSET_EL1() = X{64}(t);
end;
```

D12.5.12 PMMIR_EL1, Performance Monitors Machine Identification Register

The PMMIR_EL1 characteristics are:

Purpose

Describes Performance Monitors parameters specific to the implementation to software.

Configuration

When FEAT_PMUv3_EXT is implemented and FEAT_PMUv3p4 is implemented, AArch64 System register PMMIR_EL1 bits [31:0] are architecturally mapped to External register [PMMIR](#)[31:0].

This register is present only when FEAT_PMUv3p4 is implemented. Otherwise, direct accesses to PMMIR_EL1 are UNDEFINED.

Attributes

PMMIR_EL1 is a 64-bit register.

Field descriptions

Bits [63:20]

Reserved, RES0.

BUS_WIDTH, bits [19:16]

Bus width. Indicates the number of bytes each BUS_ACCESS event relates to. Encoded as $\text{Log}_2(\text{number of bytes})$, plus one.

The value of this field is an IMPLEMENTATION DEFINED choice of:

BUS_WIDTH	Meaning
0b0000	The information is not available.
0b0011	Four bytes.
0b0100	8 bytes.
0b0101	16 bytes.
0b0110	32 bytes.
0b0111	64 bytes.
0b1000	128 bytes.
0b1001	256 bytes.
0b1010	512 bytes.
0b1011	1024 bytes.

0b1100

2048 bytes.

All other values are reserved.

Each transfer is up to this number of bytes. An access might be smaller than the bus width.

When this field is nonzero, each access counted by `BUS_ACCESS` is at most `BUS_WIDTH` bytes. An implementation might treat a wide bus as multiple narrower buses, such that a wide access on the bus increments the `BUS_ACCESS` counter by more than one.

Access to this field is RO.

BUS_SLOTS, bits [15:8]

Bus count. The largest value by which the `BUS_ACCESS` event might increment in a single `BUS_CYCLES` cycle.

When this field is nonzero, the largest value by which the `BUS_ACCESS` event might increment in a single `BUS_CYCLES` cycle is `BUS_SLOTS`.

If the bus count information is not available, this field will read as zero.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

SLOTS, bits [7:0]

Operation width. The largest value by which the `STALL_SLOT` event might increment in a single cycle. If the `STALL_SLOT` event is not implemented, this field might read as zero.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

Accessing PMMIR_EL1

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, PMMIR_EL1

op0	op1	CRn	CRm	op2
0b11	0b000	0b1001	0b1110	0b110

```

if !IsFeatureImplemented(FEAT_PMUv3p4) then
    Undefined();
elsif PSTATE.EL == EL0 then
    Undefined();
elsif PSTATE.EL == EL1 then
    if MDCR_EL2().TPM == '1' then
        AArch64_SystemAccessTrap(EL2, 0x18);
    else
        X{64}(t) = PMMIR_EL1();
    end;
elsif PSTATE.EL == EL2 then
    X{64}(t) = PMMIR_EL1();
end;

```

D12.5.13 PMOVSCLR_EL0, Performance Monitors Overflow Flag Status Clear Register

The PMOVSCLR_EL0 characteristics are:

Purpose

Allows software to clear the unsigned overflow flags for the following counters to 0:

- The cycle counter [PMCCNTR_EL0](#).
- The event counters [PMEVCNTR<n>_EL0](#).

Reading from this register shows the current unsigned overflow flag values.

Configuration

AArch64 System register PMOVSCLR_EL0 bits [63:0] are architecturally mapped to AArch64 System register [PMOVSSET_EL0](#)[63:0].

AArch64 System register PMOVSCLR_EL0 bits [31:0] are architecturally mapped to External register [PMOVSCLR_EL0](#)[31:0].

AArch64 System register PMOVSCLR_EL0 bits [31:0] are architecturally mapped to External register [PMOVSSET_EL0](#)[31:0].

This register is present only when FEAT_PMUv3 is implemented. Otherwise, direct accesses to PMOVSCLR_EL0 are UNDEFINED.

Attributes

PMOVSCLR_EL0 is a 64-bit register.

Field descriptions

Bits [63:32]

Reserved, RES0.

C, bit [31]

Unsigned overflow flag for [PMCCNTR_EL0](#) clear. On writes, allows software to clear the unsigned overflow flag for [PMCCNTR_EL0](#) to 0. On reads, returns the unsigned overflow flag for [PMCCNTR_EL0](#) overflow status.

C	Meaning
0b0	PMCCNTR_EL0 has not overflowed.
0b1	PMCCNTR_EL0 has overflowed.

[PMCR_EL0](#).LC controls whether an overflow is detected from unsigned overflow of [PMCCNTR_EL0](#)[31:0] or unsigned overflow of [PMCCNTR_EL0](#)[63:0].

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Access to this field is W1C.

P<m>, bits [m], for m = 30 to 0

Unsigned overflow flag for [PMEVCNTR<m>_EL0](#) clear. On writes, allows software to clear the unsigned overflow flag for [PMEVCNTR<m>_EL0](#) to 0. On reads, returns the unsigned overflow flag for [PMEVCNTR<m>_EL0](#) overflow status.

P<m>	Meaning
0b0	PMEVCNTR<m>_EL0 has not overflowed.
0b1	PMEVCNTR<m>_EL0 has overflowed.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing this field has the following behavior:

- When m >= GetNumEventCountersAccessible(), access to this field is RAZ/WI.
- Otherwise, access to this field is W1C.

Accessing PMOVSLR_EL0

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, PMOVSLR_EL0

op0	op1	CRn	CRm	op2

end;
```

D12.5.14 PMOVSET_EL0, Performance Monitors Overflow Flag Status Set Register

The PMOVSET_EL0 characteristics are:

Purpose

Allows software to set the unsigned overflow flags for the following counters to 1:

- The cycle counter [PMCCNTR_EL0](#).
- The event counters [PMEVCNTR<n>_EL0](#).

Reading from this register shows the current unsigned overflow flag values.

Configuration

AArch64 System register PMOVSET_EL0 bits [63:0] are architecturally mapped to AArch64 System register [PMOVCLR_EL0](#)[63:0].

AArch64 System register PMOVSET_EL0 bits [31:0] are architecturally mapped to External register [PMOVCLR_EL0](#)[31:0].

AArch64 System register PMOVSET_EL0 bits [31:0] are architecturally mapped to External register [PMOVSET_EL0](#)[31:0].

This register is present only when FEAT_PMUv3 is implemented. Otherwise, direct accesses to PMOVSET_EL0 are UNDEFINED.

Attributes

PMOVSET_EL0 is a 64-bit register.

Field descriptions

Bits [63:32]

Reserved, RES0.

C, bit [31]

Unsigned overflow flag for [PMCCNTR_EL0](#) set. On writes, allows software to set the unsigned overflow flag for [PMCCNTR_EL0](#) to 1. On reads, returns the unsigned overflow flag for [PMCCNTR_EL0](#) overflow status.

C	Meaning
0b0	PMCCNTR_EL0 has not overflowed.
0b1	PMCCNTR_EL0 has overflowed.

[PMCR_EL0](#).LC controls whether an overflow is detected from unsigned overflow of [PMCCNTR_EL0](#)[31:0] or unsigned overflow of [PMCCNTR_EL0](#)[63:0].

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Access to this field is W1S.

P<m>, bits [m], for m = 30 to 0

Unsigned overflow flag for [PMEVCNTR<m>_EL0](#) set. On writes, allows software to set the unsigned overflow flag for [PMEVCNTR<m>_EL0](#) to 1. On reads, returns the unsigned overflow flag for [PMEVCNTR<m>_EL0](#) overflow status.

P<m>	Meaning
0b0	PMEVCNTR<m>_EL0 has not overflowed.
0b1	PMEVCNTR<m>_EL0 has overflowed.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing this field has the following behavior:

- When $m \geq \text{GetNumEventCountersAccessible}()$, access to this field is RAZ/WI.
- Otherwise, access to this field is W1S.

Accessing PMOVSSET_EL0

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, PMOVSSET_EL0

op0	op1	CRn	CRm	op2
0b11	0b011	0b1001	0b1110	0b011

```

```

D12.5.15 PMSELR_EL0, Performance Monitors Event Counter Selection Register

The PMSELR_EL0 characteristics are:

Purpose

Selects the current event counter [PMEVCNTR<n>_EL0](#) or the cycle counter [PMCCNTR_EL0](#).

Used in conjunction with [PMXEVTYPER_EL0](#) to determine the event that increments a selected counter, and the modes and states in which the selected counter increments.

Used in conjunction with [PMXEVNTR_EL0](#) to determine the value of a selected counter.

Configuration

This register is present only when FEAT_PMUv3 is implemented. Otherwise, direct accesses to PMSELR_EL0 are UNDEFINED.

Attributes

PMSELR_EL0 is a 64-bit register.

Field descriptions

Bits [63:5]

Reserved, RES0.

SEL, bits [4:0]

Event counter select. Selects the counter accessed by subsequent accesses to [PMXEVTYPER_EL0](#) and [PMXEVNTR_EL0](#).

SEL	Meaning
0b00000..0b11110	Select event counter PMEVCNTR<n>_EL0 , where n is the value of this field: - MRS and MSR of PMXEVTYPER_EL0 access PMEVTYPER<n>_EL0. - MRS and MSR of PMXEVNTR_EL0 access PMEVCNTR<n>_EL0.
0b11111	Select the cycle counter, PMCCNTR_EL0 : - MRS and MSR of PMXEVTYPER_EL0 access PMCCFILTR_EL0. - MRS and MSR of PMXEVNTR_EL0 are CONSTRAINED UNPREDICTABLE. For more information, see PMXEVNTR_EL0.

If this field is set to a value greater than or equal to the number of implemented counters, but not equal to 31, then direct reads of this field return an UNKNOWN value.

For more information about the results of accesses to the event counters, including when PMSELR_EL0.SEL is set to the index of an unimplemented or inaccessible event counter, see [PMXEVTYPER_EL0](#) and [PMXVCNTR_EL0](#).

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing PMSELR_EL0

Accesses to this register use the following encodings in the System register encoding space:

    PMSELR_EL0() = X{64}(t);
end;
```

D12.5.16 PMSWINC_EL0, Performance Monitors Software Increment Register

The PMSWINC_EL0 characteristics are:

Purpose

Increments a counter that is configured to count the Software increment event, event 0x00. For more information, see ‘SW_INCR’.

Configuration

When FEAT_PMUv3_EXT32 is implemented, AArch64 System register PMSWINC_EL0 bits [31:0] are architecturally mapped to External register PMSWINC_EL0[31:0].

This register is present only when FEAT_PMUv3 is implemented. Otherwise, direct accesses to PMSWINC_EL0 are UNDEFINED.

Attributes

PMSWINC_EL0 is a 64-bit register.

Field descriptions

Bits [63:31]

Reserved, RES0.

P<m> , bits [m], for m = 30 to 0

Software increment.

P<m>	Meaning
0b0	Write is ignored.
0b1	Increment PMEVCNTR<m>_EL0, if PMEVCNTR<m>_EL0 is configured to count software increment events.

Accessing this field has the following behavior:

- When m >= GetNumEventCountersAccessible(), access to this field is RAZ/WI.
- Otherwise, access to this field is WO/RAZ.

Accessing PMSWINC_EL0

Accesses to this register use the following encodings in the System register encoding space:

MSR PMSWINC_EL0, <Xt>

op0	op1	CRn	CRm	op2
0b11	0b011	0b1001	0b1100	0b100

```

if !IsFeatureImplemented(FEAT_PMUv3) then
    Undefined();
elsif PSTATE.EL == EL0 then
    if PMUSERENR_EL0().[SW,EN] == '00' then
        AArch64_SystemAccessTrapToEL1orEL2(0x18);
    elsif MDCR_EL2().TPM == '1' then
        AArch64_SystemAccessTrap(EL2, 0x18);
    else
        PMSWINC_EL0() = X{64}(t);
    end;
elsif PSTATE.EL == EL1 then
    if MDCR_EL2().TPM == '1' then
        AArch64_SystemAccessTrap(EL2, 0x18);
    else
        PMSWINC_EL0() = X{64}(t);
    end;
elsif PSTATE.EL == EL2 then
    PMSWINC_EL0() = X{64}(t);
end;

```

D12.5.17 PMUSERENR_EL0, Performance Monitors User Enable Register

The PMUSERENR_EL0 characteristics are:

Purpose

Enables or disables EL0 access to the Performance Monitors.

Configuration

This register is present only when FEAT_PMuV3 is implemented. Otherwise, direct accesses to PMUSERENR_EL0 are UNDEFINED.

Attributes

PMUSERENR_EL0 is a 64-bit register.

Field descriptions

Bits [63:4]

Reserved, RES0.

ER, bit [3]

Event counters Read enable.

When PMUSERENR_EL0.EN is 0, PMUSERENR_EL0.ER enables EL0 reads of the event counters and EL0 reads and writes of the select register.

ER	Meaning
0b0	EL0 reads of the event counters and EL0 reads and writes of the select register are disabled, unless enabled by PMUSERENR_EL0.EN.
0b1	EL0 reads of the event counters and EL0 reads and writes of the select register are enabled, unless trapped by another control.

In AArch64 state, the register accesses affected by this control are:

- MRS reads of [PMEVCNTR<n>_EL0](#) and [PMXEVCNTR_EL0](#).
- MRS and MSR accesses to [PMSELR_EL0](#).

When disabled, reads and writes generate an exception to EL1, or to EL2 when EL2 is implemented and enabled for the current Security state and [HCR_EL2.TGE](#) is 1, and:

- AArch64 MRS and MSR accesses are reported using EC syndrome value 0x18.

This field is ignored by the PE when PMUSERENR_EL0.EN == 1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

CR, bit [2]

Cycle counter Read enable.

When PMUSERENR_EL0.EN is 0, PMUSERENR_EL0.CR enables EL0 reads of the cycle counter.

CR	Meaning
0b0	EL0 reads of the cycle counter are disabled, unless enabled by PMUSERENR_EL0.EN.
0b1	EL0 reads of the cycle counter are enabled, unless trapped by another control.

In AArch64 state, the register accesses affected by this control are:

- MRS reads of [PMCCNTR_EL0](#).

When disabled, reads generate an exception to EL1, or to EL2 when EL2 is implemented and enabled for the current Security state and [HCR_EL2.TGE](#) is 1, and:

- AArch64 MRS reads are reported using EC syndrome value 0x18.

This field is ignored by the PE when PMUSERENR_EL0.EN == 1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

SW, bit [1]

Software increment register Write enable.

When PMUSERENR_EL0.EN is 0, PMUSERENR_EL0.SW enables EL0 writes to the Software increment register.

SW	Meaning
0b0	EL0 writes to the Software increment register are disabled, unless enabled by PMUSERENR_EL0.EN.
0b1	EL0 writes to the Software increment register are enabled, unless trapped by another control.

In AArch64 state, the register accesses affected by this control are:

- MSR writes to [PMSWINC_EL0](#).

When disabled, writes generate an exception to EL1, or to EL2 when EL2 is implemented and enabled for the current Security state and [HCR_EL2.TGE](#) is 1, and:

- AArch64 MSR writes are reported using EC syndrome value 0x18.

This field is ignored by the PE when PMUSERENR_EL0.EN == 1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

EN, bit [0]

Enable.

Enables EL0 read/write access to PMU System registers.

EN	Meaning
0b0	EL0 accesses to the specified PMU System registers are trapped, unless enabled by PMUSERENR_EL0.{ER,CR,SW}.
0b1	EL0 accesses to the specified PMU System registers are enabled, unless trapped by another control.

In AArch64 state, the register accesses affected by this control are:

- MRS or MSR accesses to [PMCCFILTR_EL0](#), [PMCCNTR_EL0](#), [PMCNTENCLR_EL0](#), [PMCNTENSET_EL0](#), [PMCR_EL0](#), [PMEVCNTR<n>_EL0](#), [PMEVTYPER<n>_EL0](#), [PMOVSCCLR_EL0](#), [PMOVSSET_EL0](#), [PMSELR_EL0](#), [PMXEVCNTR_EL0](#), and [PMXEVTYPER_EL0](#).
- MRS reads of [PMCEID0_EL0](#) and [PMCEID1_EL0](#).
- MSR writes to [PMSWINC_EL0](#).

When trapped, reads and writes generate an exception to EL1, or to EL2 when EL2 is implemented and enabled for the current Security state and [HCR_EL2.TGE](#) is 1, and:

- AArch64 MRS and MSR accesses are reported using EC syndrome value 0x18.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing PMUSERENR_EL0

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, PMUSERENR_EL0

op0	op1	CRn	CRm	op2
0b11	0b011	0b1001	0b1110	0b000

```
if !IsFeatureImplemented(FEAT_PMUv3) then
    Undefined();
elsif PSTATE.EL == EL0 then

0b11	0b011	0b1001	0b1110	0b000

```
if !IsFeatureImplemented(FEAT_PMUv3) then
    Undefined();
elsif PSTATE.EL == EL0 then
    Undefined();
elsif PSTATE.EL == EL1 then
    if MDCR_EL2().TPM == '1' then
        AArch64_SystemAccessTrap(EL2, 0x18);
    else
        PMUSERENR_EL0() = X{64}(t);
    end;
elsif PSTATE.EL == EL2 then
    PMUSERENR_EL0() = X{64}(t);
end;
```

D12.5.18 PMXEVNTR_EL0, Performance Monitors Selected Event Count Register

The PMXEVNTR_EL0 characteristics are:

Purpose

Reads or writes the value of the selected event counter, [PMEVCNTR<n>_EL0](#). [PMSELR_EL0.SEL](#) determines which event counter is selected.

Configuration

This register is present only when FEAT_PMuV3 is implemented. Otherwise, direct accesses to PMXEVNTR_EL0 are UNDEFINED.

Attributes

PMXEVNTR_EL0 is a 64-bit register.

Field descriptions

Bits [63:32]

Reserved, RES0.

PMEVCNTR<n>, bits [31:0]

Value of the selected event counter, [PMEVCNTR<n>_EL0](#), where n is the value stored in [PMSELR_EL0.SEL](#).

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing PMXEVNTR_EL0

If [PMSELR_EL0.SEL](#) is greater than or equal to the number of accessible event counters, then reads and writes of PMXEVNTR_EL0 are CONSTRAINED UNPREDICTABLE, and the following behaviors are permitted:

- Accesses to the register are UNDEFINED.
- Accesses to the register behave as RAZ/WI.
- Accesses to the register execute as a NOP
- Accesses to the register behave as if [PMSELR_EL0.SEL](#) has an UNKNOWN value less than the number of counters accessible at the current Exception level and Security state.
- If EL2 is implemented and enabled in the current Security state, and [PMSELR_EL0.SEL](#) is less than the number of implemented event counters, accesses from EL1 or permitted accesses from EL0 are trapped to EL2.

Note

In EL0, an access is permitted if it is enabled by [PMUSERENR_EL0](#).{ER,EN}.

If EL2 is implemented and enabled in the current Security state, at EL1 and EL0, [MDCR_EL2.HPMN](#) identifies the number of accessible event counters.

Otherwise, the number of accessible event counters is the number of implemented event counters. For more information, see [MDCR_EL2.HPMN](#).

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, PMXEVNTR_EL0

op0	op1	CRn	CRm	op2
0b11	0b011	0b1001	0b1101	0b010

end;
```

D12.5.19 PMXEVTYPER_EL0, Performance Monitors Selected Event Type Register

The PMXEVTYPER_EL0 characteristics are:

Purpose

When [PMSELR_EL0.SEL](#) selects an event counter, this accesses a [PMEVTYPER<n>_EL0](#) register. When [PMSELR_EL0.SEL](#) selects the cycle counter, this accesses [PMCCFILTR_EL0](#).

Configuration

This register is present only when FEAT_PMuV3 is implemented. Otherwise, direct accesses to PMXEVTYPER_EL0 are UNDEFINED.

Attributes

PMXEVTYPER_EL0 is a 64-bit register.

Field descriptions

EVTYPERn, bits [63:0]

When [PMSELR_EL0.SEL](#) = 31, this register accesses [PMCCFILTR_EL0](#).

Otherwise, this register accesses [PMEVTYPER<n>_EL0](#) where n is the value in [PMSELR_EL0.SEL](#).

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing PMXEVTYPER_EL0

If [PMSELR_EL0.SEL](#) is not 31, and is greater than or equal to the number of accessible event counters, then reads and writes of PMXEVTYPER_EL0 are CONSTRAINED UNPREDICTABLE, and the following behaviors are permitted:

- Accesses to the register are UNDEFINED.
- Accesses to the register behave as RAZ/WI.
- Accesses to the register execute as a NOP.
- Accesses to the register behave as if [PMSELR_EL0.SEL](#) has an UNKNOWN value less than the number of event counters accessible at the current Exception level and Security state.
- Accesses to the register behave as if [PMSELR_EL0.SEL](#) is 31.
- If [PMSELR_EL0](#) is less than the number of implemented event counters, accesses from EL1 or permitted accesses from EL0 are trapped to EL2.

Note

In EL0, an access is permitted if it is enabled by [PMUSERENR_EL0.EN](#).

In in EL1 and EL0, [MDCR_EL2.HPMN](#) identifies the number of accessible event counters.

Otherwise, the number of accessible event counters is the number of implemented event counters. For more information, see [MDCR_EL2.HPMN](#).

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, PMXEVTYPER_EL0

op0	op1	CRn	CRm	op2

D12.6 PMSA registers

This section lists the PMSA registers in AArch64.

D12.6.1 MPUIR_EL1, MPU Type Register (EL1)

The MPUIR_EL1 characteristics are:

Purpose

Identifies the number of regions supported by the EL1 MPU.

Configuration

There are no configuration notes.

Attributes

MPUIR_EL1 is a 64-bit register.

Field descriptions

Bits [63:8]

Reserved, RES0.

REGION, bits [7:0]

The number of EL1 MPU regions supported.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

Accessing MPUIR_EL1

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, MPUIR_EL1

op0	op1	CRn	CRm	op2
0b11	0b000	0b0000	0b0000	0b100

```
if PSTATE.EL == EL0 then
    if IsFeatureImplemented(FEAT_IDST) then
        AArch64_SystemAccessTraptToEL1orEL2(0x18);
    else
        Undefined();
    end;
elseif PSTATE.EL == EL1 then
    if HCR_EL2().TID1 == '1' then
        AArch64_SystemAccessTrap(EL2, 0x18);
    elseif VTCR_EL2().MSA == '1' then
        Undefined();
    end;
end;
```

```
        else
            X{64}(t) = MPUIR_EL1();
        end;
    elsif PSTATE.EL == EL2 then
        X{64}(t) = MPUIR_EL1();
    end;
```

D12.6.2 MPUIR_EL2, MPU Type Register (EL2)

The MPUIR_EL2 characteristics are:

Purpose

Identifies the number of regions supported by the EL2 MPU.

Configuration

There are no configuration notes.

Attributes

MPUIR_EL2 is a 64-bit register.

Field descriptions

Bits [63:8]

Reserved, RES0.

REGION, bits [7:0]

The number of EL2 MPU regions supported.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

Accessing MPUIR_EL2

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, MPUIR_EL2

op0	op1	CRn	CRm	op2
0b11	0b100	0b0000	0b0000	0b100

```
if PSTATE.EL == EL0 then
    Undefined();
elseif PSTATE.EL == EL1 then
    Undefined();
elseif PSTATE.EL == EL2 then
    X{64}(t) = MPUIR_EL2();
end;
```

D12.6.3 PRBAR_EL1, Protection Region Base Address Register (EL1)

The PRBAR_EL1 characteristics are:

Purpose

Provides access to the base addresses for the EL1 MPU region. [PRSELR_EL1](#).REGION determines which MPU region is selected.

Configuration

All bits above implemented physical address range in this register should be treated as RES0.

Attributes

PRBAR_EL1 is a 64-bit register.

Field descriptions

Bits [63:52]

Reserved, RES0.

BASE[51:48], bits [51:48]

When FEAT_LPA is implemented:

Extension to BASE[47:6]. When [FEAT_LPA](#) is implemented, BASE[51:48] form the upper part of the address value. Otherwise, for implementations with fewer than 52 physical address bits, the upper bits of this field, corresponding to address bits that are not implemented, are RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

BASE[47:6], bits [47:6]

Bits[47:6] of the lower inclusive limit of the selected EL1 MPU memory region. This value is zero extended to provide the base address to be checked against.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

SH[1:0], bits [5:4]

Shareability attribute SH[1:0].

SH[1:0]	Meaning
0b00	Non-shareable
0b01	Reserved, CONSTRAINED UNPREDICTABLE
0b10	Outer Shareable
0b11	Inner Shareable

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

AP[2:1], bits [3:2]

Access Permission attributes AP[2:1].

AP[2:1]	Meaning
0b00	Read/write at EL1, no access at EL0
0b01	Read/write at EL1 and EL0
0b10	Read-only at EL1, no access at EL0
0b11	Read-only at EL1 and EL0

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

XN, bit [1]

Execute Never

XN	Meaning
0b0	Execution of instructions fetched from the region is permitted.
0b1	Execution of instructions fetched from the region is not permitted.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [0]

Reserved, RES0.

Accessing PRBAR_EL1

Any access to MPU region register PRBAR_EL1 above the number of implemented regions specified by [MPUIR_EL1.REGION](#) is CONSTRAINED UNPREDICTABLE.

CONSTRAINED UNPREDICTABLE behavior is defined as:

- Reads of unimplemented PRBAR_EL1 register return an UNKNOWN value.
- Writes to unimplemented PRBAR_EL1 register make all PRBAR_EL1 registers value UNKNOWN.

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, PRBAR_EL1

op0	op1	CRn	CRm	op2
0b11	0b000	0b0110	0b1000	0b000

```

if UInt(PRSELR_EL1().REGION) >= UInt(MPUIR_EL1().REGION) then
    ConstrainUnpredictableProcedure(Unpredictable_UnimplementedMPURRegion_RW_UNKNOWN);
elsif PSTATE.EL == EL0 then
    Undefined();
elsif PSTATE.EL == EL1 then
    if HCR_EL2().TRVM == '1' then
        AArch64_SystemAccessTrap(EL2, 0x18);
    elsif VTCR_EL2().MSA == '1' then
        Undefined();
    else
        X{64}(t) = PRBAR_EL1(UInt(PRSELR_EL1().REGION));
    end;
elsif PSTATE.EL == EL2 then
    X{64}(t) = PRBAR_EL1(UInt(PRSELR_EL1().REGION));
end;

```

MSR PRBAR_EL1, <Xt>

op0	op1	CRn	CRm	op2
0b11	0b000	0b0110	0b1000	0b000

```

if UInt(PRSELR_EL1().REGION) >= UInt(MPUIR_EL1().REGION) then
    ConstrainUnpredictableProcedure(Unpredictable_UnimplementedMPURRegion_RW_UNKNOWN);
elsif PSTATE.EL == EL0 then
    Undefined();
elsif PSTATE.EL == EL1 then
    if HCR_EL2().TVM == '1' then
        AArch64_SystemAccessTrap(EL2, 0x18);
    elsif VTCR_EL2().MSA == '1' then
        Undefined();
    else
        PRBAR_EL1(UInt(PRSELR_EL1().REGION)) = X{64}(t);
    end;
elsif PSTATE.EL == EL2 then
    PRBAR_EL1(UInt(PRSELR_EL1().REGION)) = X{64}(t);
end;

```

D12.6.4 PRBAR_EL2, Protection Region Base Address Register (EL2)

The PRBAR_EL2 characteristics are:

Purpose

Provides access to the base addresses for the EL2 MPU region. [PRSELR_EL2](#).REGION determines which MPU region is selected.

Configuration

All bits above implemented physical address range in this register should be treated as RES0.

Attributes

PRBAR_EL2 is a 64-bit register.

Field descriptions

Bits [63:52]

Reserved, RES0.

BASE[51:48], bits [51:48]

When FEAT_LPA is implemented:

Extension to BASE[47:6]. When [FEAT_LPA](#) is implemented, BASE[51:48] form the upper part of the address value. Otherwise, for implementations with fewer than 52 physical address bits, the upper bits of this field, corresponding to address bits that are not implemented, are RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

BASE[47:6], bits [47:6]

Bits[47:6] of the lower inclusive limit of the selected EL2 MPU memory region. This value is zero extended to provide the base address to be checked against.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

SH[1:0], bits [5:4]

Shareability attribute SH[1:0].

SH[1:0]	Meaning
0b00	Non-shareable
0b01	Reserved, CONSTRAINED UNPREDICTABLE
0b10	Outer Shareable
0b11	Inner Shareable

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

AP[2:1], bits [3:2]

Access Permission attributes AP[2:1].

AP[2:1]	Meaning
0b00	Read/write at EL2, no access at EL1 or EL0
0b01	Read/write at EL2, EL1 and EL0
0b10	Read-only at EL2, no access at EL1 or EL0
0b11	Read-only at EL2, EL1 and EL0

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

XN, bits [1:0]

Execute Never. For

- Stage 1 EL2 translation regime and
- Stage 2 EL1&0 translation regime when [FEAT_XNX](#) is not implemented

XN[1] determines whether execution of the instructions fetched from the MPU memory region is permitted. In this case, XN[0] is RES0

For stage 2 EL1&0 translation regime when [FEAT_XNX](#) is implemented, the behavior of XN[1:0] is same as that defined by VMSAv8-64 for EL1&0 stage 2 translation table XN[1:0],bits[54:53] field in Armv8-A architecture.

XN	Meaning
0b00	Execution of instructions fetched from the region is permitted.
0b01	Execution of instructions fetched from the region is not permitted.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing PRBAR_EL2

Any access to MPU region register PRBAR_EL2 above the number of implemented regions specified by [MPUIR_EL2.REGION](#) is CONSTRAINED UNPREDICTABLE.

CONSTRAINED UNPREDICTABLE behavior is defined as:

- Reads of unimplemented PRBAR_EL2 register return an UNKNOWN value.
- Writes to unimplemented PRBAR_EL2 register make all PRBAR_EL2 registers value UNKNOWN.

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, PRBAR_EL2

op0	op1	CRn	CRm	op2
0b11	0b100	0b0110	0b1000	0b000

```
if UInt(PRSELR_EL2().REGION) >= UInt(MPUIR_EL2().REGION) then
    ConstrainUnpredictableProcedure(Unpredictable_UnimplementedMPURegion_RW_UNKNOWN);
elsif PSTATE.EL == EL0 then
    Undefined();
elsif PSTATE.EL == EL1 then
    Undefined();
elsif PSTATE.EL == EL2 then
    X{64}(t) = PRBAR_EL2(UInt(PRSELR_EL2().REGION));
end;
```

MSR PRBAR_EL2, <Xt>

op0	op1	CRn	CRm	op2
0b11	0b100	0b0110	0b1000	0b000

```
if UInt(PRSELR_EL2().REGION) >= UInt(MPUIR_EL2().REGION) then
    ConstrainUnpredictableProcedure(Unpredictable_UnimplementedMPURegion_RW_UNKNOWN);
elsif PSTATE.EL == EL0 then
    Undefined();
elsif PSTATE.EL == EL1 then
    Undefined();
elsif PSTATE.EL == EL2 then

end;
```

D12.6.5 PRBAR<n>_EL1, Protection Region Base Address Register n (EL1), n = 1 - 15

The PRBAR<n>_EL1 characteristics are:

Purpose

Provides access to the base address for the MPU region determined by the value of ‘n’ and PRSELR_EL1.REGION as PRSELR_EL1.REGION<7:4>:n.

Configuration

All bits above implemented physical address range in this register should be treated as RES0.

Attributes

PRBAR<n>_EL1 is a 64-bit register.

Field descriptions

Bits [63:52]

Reserved, RES0.

BASE[51:48], bits [51:48]

When FEAT_LPA is implemented:

Extension to BASE[47:6]. When FEAT_LPA is implemented, BASE[51:48] form the upper part of the address value. Otherwise, for implementations with fewer than 52 physical address bits, the upper bits of this field, corresponding to address bits that are not implemented, are RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

BASE[47:6], bits [47:6]

Bits[47:6] of the lower inclusive limit of the selected EL1 MPU memory region. This value is zero extended to provide the base address to be checked against.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

SH[1:0], bits [5:4]

Shareability attribute SH[1:0].

SH[1:0]	Meaning
0b00	Non-shareable
0b01	Reserved, CONSTRAINED UNPREDICTABLE
0b10	Outer Shareable
0b11	Inner Shareable

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

AP[2:1], bits [3:2]

Access Permission attributes AP[2:1].

AP[2:1]	Meaning
0b00	Read/write at EL1, no access at EL0
0b01	Read/write at EL1 and EL0
0b10	Read-only at EL1, no access at EL0
0b11	Read-only at EL1 and EL0

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

XN, bit [1]

Execute Never

XN	Meaning
0b0	Execution of instructions fetched from the region is permitted.
0b1	Execution of instructions fetched from the region is not permitted.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [0]

Reserved, RES0.

Accessing PRBAR<n>_EL1

Any access to MPU region register PRBAR<n>_EL1 above the number of implemented regions specified by [MPUIR_EL1.REGION](#) is CONSTRAINED UNPREDICTABLE.

CONSTRAINED UNPREDICTABLE behavior is defined as:

- Reads of unimplemented PRBAR<n>_EL1 return an UNKNOWN value.
- Writes to unimplemented PRBAR<n>_EL1 register make all PRBAR_EL1 registers value UNKNOWN.

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, PRBAR<m>_EL1 ; Where m = 1-15

end;

```

D12.6.6 PRBAR<n>_EL2, Protection Region Base Address Register n (EL2), n = 1 - 15

The PRBAR<n>_EL2 characteristics are:

Purpose

Provides access to the base address for the MPU region determined by the value of ‘n’ and PRSELR_EL2.REGION as PRSELR_EL2.REGION<7:4>:n.

Configuration

All bits above implemented physical address range in this register should be treated as RES0.

Attributes

PRBAR<n>_EL2 is a 64-bit register.

Field descriptions

Bits [63:52]

Reserved, RES0.

BASE[51:48], bits [51:48]

When FEAT_LPA is implemented:

Extension to BASE[47:6]. When FEAT_LPA is implemented, BASE[51:48] form the upper part of the address value. Otherwise, for implementations with fewer than 52 physical address bits, the upper bits of this field, corresponding to address bits that are not implemented, are RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

BASE[47:6], bits [47:6]

Bits[47:6] of the lower inclusive limit of the selected EL2 MPU memory region. This value is zero extended to provide the base address to be checked against.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

SH[1:0], bits [5:4]

Shareability attribute SH[1:0].

SH[1:0]	Meaning
0b00	Non-shareable
0b01	Reserved, CONSTRAINED UNPREDICTABLE
0b10	Outer Shareable
0b11	Inner Shareable

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

AP[2:1], bits [3:2]

Access Permission attributes AP[2:1].

AP[2:1]	Meaning
0b00	Read/write at EL2, no access at EL1 or EL0
0b01	Read/write at EL2, EL1 and EL0
0b10	Read-only at EL2, no access at EL1 or EL0
0b11	Read-only at EL2, EL1 and EL0

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

XN, bits [1:0]

Execute Never. For

- Stage 1 EL2 translation regime and
- Stage 2 EL1&0 translation regime when [FEAT_XNX](#) is not implemented

XN[1] determines whether execution of the instructions fetched from the MPU memory region is permitted. In this case, XN[0] is RES0

For stage 2 EL1&0 translation regime when [FEAT_XNX](#) is implemented, the behavior of XN[1:0] is same as that defined by VMSAv8-64 for EL1&0 stage 2 translation table XN[1:0],bits[54:53] field in Armv8-A architecture.

XN	Meaning
0b00	Execution of instructions fetched from the region is permitted.
0b01	Execution of instructions fetched from the region is not permitted.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing PRBAR<n>_EL2

Any access to MPU region register PRBAR<n>_EL2 above the number of implemented regions specified by [MPUIR_EL2.REGION](#) is CONSTRAINED UNPREDICTABLE.

CONSTRAINED UNPREDICTABLE behavior is defined as:

- Reads of unimplemented PRBAR<n>_EL2 return an UNKNOWN value.
- Writes to unimplemented PRBAR<n>_EL2 register make all PRBAR_EL2 registers value UNKNOWN.

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, PRBAR<m>_EL2 ; Where m = 1-15

op0	op1	CRn	CRm	op2
0b11	0b100	0b0110	0b1:m[3:1]	m[0]:0b00

```
let m:integer = UInt(CRm[2:0] :: op2[2]);

if m + (UInt(PRSELR_EL2().REGION[7:4]) * 16) >= UInt(MPUIR_EL2().REGION) then

end;
```

D12.6.7 PRENR_EL1, Protection Region Enable Register (EL1)

The PRENR_EL1 characteristics are:

Purpose

Provides direct access to the PRLAR_EL1.EN bits of EL1 MPU regions from 0 to 31.

Configuration

There are no configuration notes.

Attributes

PRENR_EL1 is a 64-bit register.

Field descriptions

Bits [63:32]

Reserved, RES0.

ENABLE<n> , bits [n], for n = 31 to 0

Enable bit. Each bit, n, enables or disables the respective EL1 MPU region. The bits associated with the unimplemented MPU regions are RAZ/WI.

ENABLE<n>	Meaning
0b0	Disables the EL1 MPU n region.
0b1	Enables the EL1 MPU n region.

The reset behavior of this field is:

- On a Warm reset, this field resets to the expression 0x00000000.

Accessing PRENR_EL1

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, PRENR_EL1

op0	op1	CRn	CRm	op2
0b11	0b000	0b0110	0b0001	0b001

```

```

D12.6.8 PRENR_EL2, Protection Region Enable Register (EL2)

The PRENR_EL2 characteristics are:

Purpose

Provides direct access to the PRLAR_EL2.EN bits of EL2 MPU regions from 0 to 31.

Configuration

There are no configuration notes.

Attributes

PRENR_EL2 is a 64-bit register.

Field descriptions

Bits [63:32]

Reserved, RES0.

ENABLE<n> , bits [n], for n = 31 to 0

Enable bit. Each bit, n, enables or disables the respective EL2 MPU region. The bits associated with the unimplemented MPU regions are RAZ/WI.

ENABLE<n>	Meaning
0b0	Disables the EL2 MPU n region.
0b1	Enables the EL2 MPU n region.

The reset behavior of this field is:

- On a Warm reset, this field resets to the expression 0×00000000 .

Accessing PRENR_EL2

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, PRENR_EL2

op0	op1	CRn	CRm	op2
0b11	0b100	0b0110	0b0001	0b001

```

if PSTATE.EL == EL0 then

elsif PSTATE.EL == EL1 then
    Undefined();
elsif PSTATE.EL == EL2 then
    PRENR_EL2() = X{64}(t);
end;

```

D12.6.9 PRLAR_EL1, Protection Region Limit Address Register (EL1)

The PRLAR_EL1 characteristics are:

Purpose

Provides access to the limit addresses for the EL1 MPU region. [PRSELR_EL1](#).REGION determines which MPU region is selected.

Configuration

All bits above implemented physical address range in this register should be treated as RES0.

Attributes

PRLAR_EL1 is a 64-bit register.

Field descriptions

Bits [63:52]

Reserved, RES0.

LIMIT[51:48], bits [51:48]

When FEAT_LPA is implemented:

Extension to LIMIT[47:6]. When [FEAT_LPA](#) is implemented, LIMIT[51:48] form the upper part of the address value. Otherwise, for implementations with fewer than 52 physical address bits, the upper bits of this field, corresponding to address bits that are not implemented, are RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

LIMIT[47:6], bits [47:6]

Bits[47:6] of the upper inclusive limit of the selected EL1 MPU memory region. This value is concatenated with the value `0x3F` to provide the limit address to be checked against.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [5]

Reserved, RES0.

NS, bit [4]

Non-secure bit. Specifies whether the output address is in the Secure or Non-secure memory.

NS	Meaning
0b0	Output address is in Secure address space.
0b1	Output address is in Non-secure address space.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

AttrIdx[2:0], bits [3:1]

AttrIdx[2:0] selects attributes from within the associated Memory Attribute Indirection Register.

AttrIdx[2:0]	Meaning
0b000	Select the Attr0 field from MAIR_EL1.
0b001	Select the Attr1 field from MAIR_EL1.
0b010	Select the Attr2 field from MAIR_EL1.
0b011	Select the Attr3 field from MAIR_EL1.
0b100	Select the Attr4 field from MAIR_EL1.
0b101	Select the Attr5 field from MAIR_EL1.
0b110	Select the Attr6 field from MAIR_EL1.
0b111	Select the Attr7 field from MAIR_EL1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

EN, bit [0]

Region enable bit.

EN	Meaning
0b0	Region disabled.
0b1	Region enabled.

The reset behavior of this field is:

- On a Warm reset, this field resets to '0'.

Accessing PRLAR_EL1

Any access to MPU region register PRLAR_EL1 above the number of implemented regions specified by MPUIR_EL1.REGION is CONSTRAINED UNPREDICTABLE.

CONSTRAINED UNPREDICTABLE behavior is defined as:

- Reads of unimplemented PRLAR_EL1 register return an UNKNOWN value.
- Writes to unimplemented PRLAR_EL1 register make all PRLAR_EL1 registers value UNKNOWN.

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, PRLAR_EL1

op0	op1	CRn	CRm	op2
0b11	0b000	0b0110	0b1000	0b001

```
if UInt(PRSELR_EL1().REGION) >= UInt(MPUIR_EL1().REGION) then
    ConstrainUnpredictableProcedure(Unpredictable_UnimplementedMPURegion_RW_UNKNOWN);
elsif PSTATE.EL == EL0 then

        AArch64_SystemAccessTrap(EL2, 0x18);
    elsif VTCR_EL2().MSA == '1' then
        Undefined();
    else
        PRLAR_EL1(UInt(PRSELR_EL1().REGION)) = X{64}(t);
    end;
elsif PSTATE.EL == EL2 then
    PRLAR_EL1(UInt(PRSELR_EL1().REGION)) = X{64}(t);
end;
```

D12.6.10 PRLAR_EL2, Protection Region Limit Address Register (EL2)

The PRLAR_EL2 characteristics are:

Purpose

Provides access to the limit addresses for the EL2 MPU region. [PRSELR_EL2](#).REGION determines which MPU region is selected.

Configuration

All bits above implemented physical address range in this register should be treated as RES0.

Attributes

PRLAR_EL2 is a 64-bit register.

Field descriptions

Bits [63:52]

Reserved, RES0.

LIMIT[51:48], bits [51:48]

When FEAT_LPA is implemented:

Extension to LIMIT[47:6]. When [FEAT_LPA](#) is implemented, LIMIT[51:48] form the upper part of the address value. Otherwise, for implementations with fewer than 52 physical address bits, the upper bits of this field, corresponding to address bits that are not implemented, are RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

LIMIT[47:6], bits [47:6]

Bits[47:6] of the upper inclusive limit of the selected EL2 MPU memory region. This value is concatenated with the value 0x3F to provide the limit address to be checked against.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [5]

Reserved, RES0.

NS, bit [4]

Non-secure bit. Specifies whether the output address is in the Secure or Non-secure memory.

NS	Meaning
0b0	Output address is in Secure address space.
0b1	Output address is in Non-secure address space.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

AttrIdx[2:0], bits [3:1]

AttrIdx[2:0] selects attributes from within the associated Memory Attribute Indirection Register.

AttrIdx[2:0]	Meaning
0b000	Select the Attr0 field from MAIR_EL2.
0b001	Select the Attr1 field from MAIR_EL2.
0b010	Select the Attr2 field from MAIR_EL2.
0b011	Select the Attr3 field from MAIR_EL2.
0b100	Select the Attr4 field from MAIR_EL2.
0b101	Select the Attr5 field from MAIR_EL2.
0b110	Select the Attr6 field from MAIR_EL2.
0b111	Select the Attr7 field from MAIR_EL2.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

EN, bit [0]

Region enable bit.

EN	Meaning
0b0	Region disabled.
0b1	Region enabled.

The reset behavior of this field is:

- On a Warm reset, this field resets to '0'.

Accessing PRLAR_EL2

Any access to MPU region register PRLAR_EL2 above the number of implemented regions specified by MPUIR_EL2.REGION is CONSTRAINED UNPREDICTABLE.

CONSTRAINED UNPREDICTABLE behavior is defined as:

- Reads of unimplemented PRLAR_EL2 register return an UNKNOWN value.
- Writes to unimplemented PRLAR_EL2 register make all PRLAR_EL2 registers value UNKNOWN.

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, PRLAR_EL2

Bits [63:8]

Reserved, RES0.

REGION, bits [7:0]

The number of the current EL2 MPU region visible in [PRBAR_EL2](#) and [PRLAR_EL2](#). For N implemented MPU regions, memory region numbering starts at 0 and increments by 1 to the value N-1.

Writing a value greater than or equal to the number of implemented MPU regions specified by [MPUIR_EL2](#).REGION, results in CONSTRAINED UNPREDICTABLE behavior.

CONSTRAINED UNPREDICTABLE behavior is that PRSELR_EL2 register becomes UNKNOWN.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing PRSELR_EL2

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, PRSELR_EL2

op0	op1	CRn	CRm	op2
0b11	0b100	0b0110	0b0010	0b001

```

if PSTATE.EL == EL0 then
    Undefined();
elseif PSTATE.EL == EL1 then
    Undefined();
elseif PSTATE.EL == EL2 then

```

```
    X{64}(t) = PRSELR_EL2();  
end;
```

MSR PRSELR_EL2, <Xt>

op0	op1	CRn	CRm	op2
0b11	0b100	0b0110	0b0010	0b001

```
if PSTATE.EL == EL0 then  
    Undefined();  
elsif PSTATE.EL == EL1 then  
    Undefined();  
elsif PSTATE.EL == EL2 then  
    PRSELR_EL2() = X{64}(t);  
end;
```

D12.7 RAS registers

This section lists RAS registers in AArch64.

D12.7.1 DISR_EL1, Deferred Interrupt Status Register

The DISR_EL1 characteristics are:

Purpose

Records that an SError exception has been consumed by an ESB instruction.

Configuration

This register is present only when FEAT_RAS is implemented. Otherwise, direct accesses to DISR_EL1 are UNDEFINED.

Attributes

DISR_EL1 is a 64-bit register.

Field descriptions

When DISR_EL1.IDS == '0':

Bits [63:32]

Reserved, RES0.

A, bit [31]

Set to 1 when an ESB instruction defers an asynchronous SError exception. If the implementation does not include any sources of SError exception that can be synchronized by an Error Synchronization Barrier, then this bit is RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [30:25]

Reserved, RES0.

IDS, bit [24]

Indicates the deferred SError exception type.

IDS	Meaning
0b0	Deferred error uses architecturally-defined format.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [23:13]

Reserved, RES0.

AET, bits [12:10]

Asynchronous Error Type. See the description of [ESR_ELx.AET](#) for an SError exception.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

EA, bit [9]

External abort Type. See the description of [ESR_ELx.EA](#) for an SError exception.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [8:6]

Reserved, RES0.

DFSC, bits [5:0]

Fault Status Code. See the description of [ESR_ELx.DFSC](#) for an SError exception.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

When [DISR_EL1.IDS](#) == '1':

Bits [63:32]

Reserved, RES0.

A, bit [31]

Set to 1 when an [ESB](#) instruction defers an asynchronous SError exception. If the implementation does not include any sources of SError exception that can be synchronized by an Error Synchronization Barrier, then this bit is RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [30:25]

Reserved, RES0.

IDS, bit [24]

Indicates the deferred SError exception type.

IDS	Meaning
0b1	Deferred error uses IMPLEMENTATION DEFINED format.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

IMPLEMENTATION DEFINED, bits [23:0]

IMPLEMENTATION DEFINED syndrome. See the description of [ESR_ELx\[23:0\]](#) for an SError exception.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing DISR_EL1

An indirect write to DISR_EL1 made by an ESB instruction does not require an explicit synchronization operation for the value that is written to be observed by a direct read of DISR_EL1 occurring in program order after the ESB instruction.

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, DISR_EL1

op0	op1	CRn	CRm	op2
0b11	0b000	0b1100	0b0001	0b001

```
if !IsFeatureImplemented(FEAT_RAS) then
    Undefined();
elsif PSTATE.EL == EL0 then
    Undefined();
elsif PSTATE.EL == EL1 then
    if HCR_EL2().AMO == '1' then
        X{64}(t) = VDISR_EL2();
    else
        X{64}(t) = DISR_EL1();
    end;
elsif PSTATE.EL == EL2 then
    X{64}(t) = DISR_EL1();
end;
```

MSR DISR_EL1, <Xt>

op0	op1	CRn	CRm	op2
0b11	0b000	0b1100	0b0001	0b001

```
if !IsFeatureImplemented(FEAT_RAS) then
    Undefined();
elsif PSTATE.EL == EL0 then
    Undefined();
elsif PSTATE.EL == EL1 then
    if HCR_EL2().AMO == '1' then
        VDISR_EL2() = X{64}(t);
    end;
end;
```

```
        else
            DISR_EL1() = X{64}(t);
        end;
    elsif PSTATE.EL == EL2 then
        DISR_EL1() = X{64}(t);
    end;
```

D12.7.2 ERRIDR_EL1, Error Record ID Register

The ERRIDR_EL1 characteristics are:

Purpose

Defines the highest numbered index of the error records that can be accessed through the Error Record System registers.

Configuration

This register is present only when FEAT_RAS is implemented. Otherwise, direct accesses to ERRIDR_EL1 are UNDEFINED.

Attributes

ERRIDR_EL1 is a 64-bit register.

Field descriptions

Bits [63:16]

Reserved, RES0.

NUM, bits [15:0]

Highest numbered index of the records that can be accessed through the Error Record System registers plus one. Zero indicates no records can be accessed through the Error Record System registers.

Each implemented record is owned by a node. A node might own multiple records.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

Accessing ERRIDR_EL1

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, ERRIDR_EL1

op0	op1	CRn	CRm	op2
0b11	0b000	0b0101	0b0011	0b000

```
if !IsFeatureImplemented(FEAT_RAS) then
    Undefined();
elseif PSTATE.EL == EL0 then
    Undefined();
elseif PSTATE.EL == EL1 then
    if HCR_EL2().TERR == '1' then
```

```
        AArch64_SystemAccessTrap(EL2, 0x18);  
    else  
        X{64}(t) = ERRIDR_EL1();  
    end;  
elseif PSTATE.EL == EL2 then  
    X{64}(t) = ERRIDR_EL1();  
end;
```

D12.7.3 ERRSELR_EL1, Error Record Select Register

The ERRSELR_EL1 characteristics are:

Purpose

Selects an error record to be accessed through the Error Record System registers.

Configuration

If [ERRIDR_EL1](#) indicates that zero error records are implemented, then it is IMPLEMENTATION DEFINED whether ERRSELR_EL1 is UNDEFINED or RES0.

This register is present only when FEAT_RAS is implemented. Otherwise, direct accesses to ERRSELR_EL1 are UNDEFINED.

Attributes

ERRSELR_EL1 is a 64-bit register.

Field descriptions

Bits [63:16]

Reserved, RES0.

SEL, bits [15:0]

Selects the error record accessed through the ERX registers.

For example, if ERRSELR_EL1.SEL is 0x0004, then direct reads and writes of [ERXSTATUS_EL1](#) access ERR4STATUS.

If ERRSELR_EL1.SEL is greater than or equal to [ERRIDR_EL1.NUM](#), then all of the following apply:

- The value read back from ERRSELR_EL1.SEL is UNKNOWN.
- Unless the access to an ERX*_EL1 register generates a higher priority exception, one of the following occurs:
 - An UNKNOWN error record is selected.
 - The ERX*_EL1 registers are RAZ/WI.
 - ERX*_EL1 register reads and writes are NOPs.
 - ERX*_EL1 register reads and writes are UNDEFINED.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing ERRSELR_EL1

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, ERRSELR_EL1

op0	op1	CRn	CRm	op2
0b11	0b000	0b0101	0b0011	0b001

```

if !IsFeatureImplemented(FEAT_RAS) then
    Undefined();
elsif PSTATE.EL == EL0 then
    Undefined();
elsif PSTATE.EL == EL1 then
    if HCR_EL2().TERR == '1' then
        AArch64_SystemAccessTrap(EL2, 0x18);
    else
        X{64}(t) = ERRSELR_EL1();
    end;
elsif PSTATE.EL == EL2 then
    X{64}(t) = ERRSELR_EL1();
end;

```

MSR ERRSELR_EL1, <Xt>

op0	op1	CRn	CRm	op2
0b11	0b000	0b0101	0b0011	0b001

```

if !IsFeatureImplemented(FEAT_RAS) then
    Undefined();
elsif PSTATE.EL == EL0 then
    Undefined();
elsif PSTATE.EL == EL1 then
    if HCR_EL2().TERR == '1' then
        AArch64_SystemAccessTrap(EL2, 0x18);
    else
        ERRSELR_EL1() = X{64}(t);
    end;
elsif PSTATE.EL == EL2 then
    ERRSELR_EL1() = X{64}(t);
end;

```

D12.7.4 ERXADDR_EL1, Selected Error Record Address Register

The ERXADDR_EL1 characteristics are:

Purpose

Accesses ERR<n>ADDR for the error record <n> selected by ERRSELR_EL1.SEL.

Configuration

This register is present only when FEAT_RAS is implemented. Otherwise, direct accesses to ERXADDR_EL1 are UNDEFINED.

Attributes

ERXADDR_EL1 is a 64-bit register.

Field descriptions

ERRnADDR, bits [63:0]

ERXADDR_EL1 accesses ERR<n>ADDR, where <n> is the value in ERRSELR_EL1.SEL.

Accessing ERXADDR_EL1

If ERRIDR_EL1.NUM is 0x0000 or ERRSELR_EL1.SEL is greater than or equal to ERRIDR_EL1.NUM, then one of the following occurs:

- An UNKNOWN error record is selected.
- ERXADDR_EL1 is RAZ/WI.
- Direct reads and writes of ERXADDR_EL1 are NOPs.
- Direct reads and writes of ERXADDR_EL1 are UNDEFINED.

ERR<n>ADDR describes additional constraints that also apply when ERR<n>ADDR is accessed through ERXADDR_EL1.

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, ERXADDR_EL1

op0	op1	CRn	CRm	op2
0b11	0b000	0b0101	0b0100	0b011

```
if !IsFeatureImplemented(FEAT_RAS) then
    Undefined();
elseif PSTATE.EL == EL0 then
    Undefined();
elseif PSTATE.EL == EL1 then
    if HCR_EL2().TERR == '1' then
```

```
        AArch64_SystemAccessTrap(EL2, 0x18);
    else
        X{64}(t) = ERRADDR(UInt(ERRSELR_EL1().SEL));
    end;
elseif PSTATE.EL == EL2 then
    X{64}(t) = ERRADDR(UInt(ERRSELR_EL1().SEL));
end;
```

MSR ERXADDR_EL1, <Xt>

op0	op1	CRn	CRm	op2
0b11	0b000	0b0101	0b0100	0b011

```
if !IsFeatureImplemented(FEAT_RAS) then
    Undefined();
elseif PSTATE.EL == EL0 then
    Undefined();
elseif PSTATE.EL == EL1 then
    if HCR_EL2().TERR == '1' then
        AArch64_SystemAccessTrap(EL2, 0x18);
    else
        ERRADDR(UInt(ERRSELR_EL1().SEL)) = X{64}(t);
    end;
elseif PSTATE.EL == EL2 then
    ERRADDR(UInt(ERRSELR_EL1().SEL)) = X{64}(t);
end;
```

D12.7.5 ERXCTLR_EL1, Selected Error Record Control Register

The ERXCTLR_EL1 characteristics are:

Purpose

Accesses ERR<n>CTLR for the error record <n> selected by ERRSELR_EL1.SEL.

Configuration

This register is present only when FEAT_RAS is implemented. Otherwise, direct accesses to ERXCTLR_EL1 are UNDEFINED.

Attributes

ERXCTLR_EL1 is a 64-bit register.

Field descriptions

ERRnCTLR, bits [63:0]

ERXCTLR_EL1 accesses ERR<n>CTLR, where <n> is the value in ERRSELR_EL1.SEL.

Accessing ERXCTLR_EL1

If ERRIDR_EL1.NUM is 0x0000 or ERRSELR_EL1.SEL is greater than or equal to ERRIDR_EL1.NUM, then one of the following occurs:

- An UNKNOWN error record is selected.
- ERXCTLR_EL1 is RAZ/WI.
- Direct reads and writes of ERXCTLR_EL1 are NOPs.
- Direct reads and writes of ERXCTLR_EL1 are UNDEFINED.

If ERRSELR_EL1.SEL is not the index of the first error record owned by a node, then ERR<n>CTLR is not present, meaning reads and writes of ERXCTLR_EL1 are RES0.

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, ERXCTLR_EL1

op0	op1	CRn	CRm	op2
0b11	0b000	0b0101	0b0100	0b001

```
if !IsFeatureImplemented(FEAT_RAS) then
    Undefined();
elseif PSTATE.EL == EL0 then
    Undefined();
elseif PSTATE.EL == EL1 then
    if HCR_EL2().TERR == '1' then
```

```
        AArch64_SystemAccessTrap(EL2, 0x18);
    else
        X{64}(t) = ERRCTLR(UInt(ERRSELR_EL1().SEL));
    end;
elseif PSTATE.EL == EL2 then
    X{64}(t) = ERRCTLR(UInt(ERRSELR_EL1().SEL));
end;
```

MSR ERXCTLR_EL1, <Xt>

op0	op1	CRn	CRm	op2
0b11	0b000	0b0101	0b0100	0b001

```
if !IsFeatureImplemented(FEAT_RAS) then
    Undefined();
elseif PSTATE.EL == EL0 then
    Undefined();
elseif PSTATE.EL == EL1 then
    if HCR_EL2().TERR == '1' then
        AArch64_SystemAccessTrap(EL2, 0x18);
    else
        ERRCTLR(UInt(ERRSELR_EL1().SEL)) = X{64}(t);
    end;
elseif PSTATE.EL == EL2 then
    ERRCTLR(UInt(ERRSELR_EL1().SEL)) = X{64}(t);
end;
```

D12.7.6 ERXFR_EL1, Selected Error Record Feature Register

The ERXFR_EL1 characteristics are:

Purpose

Accesses ERR<n>FR for the error record <n> selected by ERRSELR_EL1.SEL.

Configuration

This register is present only when FEAT_RAS is implemented. Otherwise, direct accesses to ERXFR_EL1 are UNDEFINED.

Attributes

ERXFR_EL1 is a 64-bit register.

Field descriptions

ERRnFR, bits [63:0]

ERXFR_EL1 accesses ERR<n>FR, where <n> is the value in ERRSELR_EL1.SEL.

Accessing ERXFR_EL1

If ERRIDR_EL1.NUM is 0x0000 or ERRSELR_EL1.SEL is greater than or equal to ERRIDR_EL1.NUM, then one of the following occurs:

- An UNKNOWN error record is selected.
- ERXFR_EL1 is RAZ.
- Direct reads of ERXFR_EL1 are NOPs.
- Direct reads of ERXFR_EL1 are UNDEFINED.

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, ERXFR_EL1

op0	op1	CRn	CRm	op2
0b11	0b000	0b0101	0b0100	0b000

```
if !IsFeatureImplemented(FEAT_RAS) then
    Undefined();
elseif PSTATE.EL == EL0 then
    Undefined();
elseif PSTATE.EL == EL1 then
    if HCR_EL2().TERR == '1' then
        AArch64_SystemAccessTrap(EL2, 0x18);
    else
        X{64}(t) = ERRFR(UInt(ERRSELR_EL1().SEL));
```

```
end;  
elsif PSTATE.EL == EL2 then  
    X{64}(t) = ERRFR(ErrSelR_EL1().SEL);  
end;
```

D12.7.7 ERXMISC0_EL1, Selected Error Record Miscellaneous Register 0

The ERXMISC0_EL1 characteristics are:

Purpose

Accesses ERR<n>MISC0 for the error record <n> selected by ERRSELR_EL1.SEL.

Configuration

This register is present only when FEAT_RAS is implemented. Otherwise, direct accesses to ERXMISC0_EL1 are UNDEFINED.

Attributes

ERXMISC0_EL1 is a 64-bit register.

Field descriptions

ERRnMISC0, bits [63:0]

ERXMISC0_EL1 accesses ERR<n>MISC0, where <n> is the value in ERRSELR_EL1.SEL.

Accessing ERXMISC0_EL1

If ERRIDR_EL1.NUM is 0x0000 or ERRSELR_EL1.SEL is greater than or equal to ERRIDR_EL1.NUM, then one of the following occurs:

- An UNKNOWN error record is selected.
- ERXMISC0_EL1 is RAZ/WI.
- Direct reads and writes of ERXMISC0_EL1 are NOPs.
- Direct reads and writes of ERXMISC0_EL1 are UNDEFINED.

ERR<n>MISC0 describes additional constraints that also apply when ERR<n>MISC0 is accessed through ERXMISC0_EL1.

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, ERXMISC0_EL1

op0	op1	CRn	CRm	op2
0b11	0b000	0b0101	0b0101	0b000

```
if !IsFeatureImplemented(FEAT_RAS) then
    Undefined();

    Undefined();
elseif PSTATE.EL == EL1 then
    if HCR_EL2().TERR == '1' then
        AArch64_SystemAccessTrap(EL2, 0x18);
    else
        ERRMISC0( UInt( ERRSELR_EL1().SEL) ) = X{64}(t);
    end;
elseif PSTATE.EL == EL2 then
    ERRMISC0( UInt( ERRSELR_EL1().SEL) ) = X{64}(t);
end;
```

D12.7.8 ERXMISC1_EL1, Selected Error Record Miscellaneous Register 1

The ERXMISC1_EL1 characteristics are:

Purpose

Accesses ERR<n>MISC1 for the error record <n> selected by ERRSELR_EL1.SEL.

Configuration

This register is present only when FEAT_RAS is implemented. Otherwise, direct accesses to ERXMISC1_EL1 are UNDEFINED.

Attributes

ERXMISC1_EL1 is a 64-bit register.

Field descriptions

ERRnMISC1, bits [63:0]

ERXMISC1_EL1 accesses ERR<n>MISC1, where <n> is the value in ERRSELR_EL1.SEL.

Accessing ERXMISC1_EL1

If ERRIDR_EL1.NUM is 0x0000 or ERRSELR_EL1.SEL is greater than or equal to ERRIDR_EL1.NUM, then one of the following occurs:

- An UNKNOWN error record is selected.
- ERXMISC1_EL1 is RAZ/WI.
- Direct reads and writes of ERXMISC1_EL1 are NOPs.
- Direct reads and writes of ERXMISC1_EL1 are UNDEFINED.

ERR<n>MISC1 describes additional constraints that also apply when ERR<n>MISC1 is accessed through ERXMISC1_EL1.

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, ERXMISC1_EL1

op0	op1	CRn	CRm	op2

end;
```

D12.7.9 ERXMISC2_EL1, Selected Error Record Miscellaneous Register 2

The ERXMISC2_EL1 characteristics are:

Purpose

Accesses ERR<n>MISC2 for the error record <n> selected by [ERRSELR_EL1.SEL](#).

Configuration

This register is present only when FEAT_RASv1p1 is implemented. Otherwise, direct accesses to ERXMISC2_EL1 are UNDEFINED.

Attributes

ERXMISC2_EL1 is a 64-bit register.

Field descriptions

ERRnMISC2, bits [63:0]

ERXMISC2_EL1 accesses ERR<n>MISC2, where <n> is the value in [ERRSELR_EL1.SEL](#).

Accessing ERXMISC2_EL1

If [ERRIDR_EL1.NUM](#) is 0x0000 or [ERRSELR_EL1.SEL](#) is greater than or equal to [ERRIDR_EL1.NUM](#), then one of the following occurs:

- An UNKNOWN error record is selected.
- ERXMISC2_EL1 is RAZ/WI.
- Direct reads and writes of ERXMISC2_EL1 are NOPs.
- Direct reads and writes of ERXMISC2_EL1 are UNDEFINED.

ERR<n>MISC2 describes additional constraints that also apply when ERR<n>MISC2 is accessed through ERXMISC2_EL1.

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, ERXMISC2_EL1

op0	op1	CRn	CRm	op2
0b11	0b000	0b0101	0b0101	0b010

```

if !IsFeatureImplemented(FEAT_RASv1p1) then

    end;
elseif PSTATE.EL == EL2 then
    ERRMISC2( UInt( ERRSELR_EL1().SEL) ) = X{64}(t);
end;
```

D12.7.10 ERXMISC3_EL1, Selected Error Record Miscellaneous Register 3

The ERXMISC3_EL1 characteristics are:

Purpose

Accesses ERR<n>MISC3 for the error record <n> selected by ERRSELR_EL1.SEL.

Configuration

This register is present only when FEAT_RASv1p1 is implemented. Otherwise, direct accesses to ERXMISC3_EL1 are UNDEFINED.

Attributes

ERXMISC3_EL1 is a 64-bit register.

Field descriptions

ERRnMISC3, bits [63:0]

ERXMISC3_EL1 accesses ERR<n>MISC3, where <n> is the value in ERRSELR_EL1.SEL.

Accessing ERXMISC3_EL1

If ERRIDR_EL1.NUM is 0x0000 or ERRSELR_EL1.SEL is greater than or equal to ERRIDR_EL1.NUM, then one of the following occurs:

- An UNKNOWN error record is selected.
- ERXMISC3_EL1 is RAZ/WI.
- Direct reads and writes of ERXMISC3_EL1 are NOPs.
- Direct reads and writes of ERXMISC3_EL1 are UNDEFINED.

ERR<n>MISC3 describes additional constraints that also apply when ERR<n>MISC3 is accessed through ERXMISC3_EL1.

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, ERXMISC3_EL1

op0	op1	CRn	CRm	op2
0b11	0b000	0b0101	0b0101	0b011

```
if !IsFeatureImplemented(FEAT_RASv1p1) then

```

D12.7.11 ERXPFGCDN_EL1, Selected Pseudo-fault Generation Countdown Register

The ERXPFGCDN_EL1 characteristics are:

Purpose

Accesses ERR<n>PFGCDN for the error record <n> selected by [ERRSELR_EL1.SEL](#).

Configuration

This register is present only when FEAT_RASv1p1 is implemented. Otherwise, direct accesses to ERXPFGCDN_EL1 are UNDEFINED.

Attributes

ERXPFGCDN_EL1 is a 64-bit register.

Field descriptions

ERRnPFGCDN, bits [63:0]

ERXPFGCDN_EL1 accesses ERR<n>PFGCDN, where <n> is the value in [ERRSELR_EL1.SEL](#).

Accessing ERXPFGCDN_EL1

If [ERRIDR_EL1.NUM](#) is 0x0000 or [ERRSELR_EL1.SEL](#) is greater than or equal to [ERRIDR_EL1.NUM](#), then one of the following occurs:

- An UNKNOWN error record is selected.
- ERXPFGCDN_EL1 is RAZ/WI.
- Direct reads and writes of ERXPFGCDN_EL1 are NOPs.
- Direct reads and writes of ERXPFGCDN_EL1 are UNDEFINED.

If [ERRSELR_EL1.SEL](#) selects an error record owned by a node that does not implement the Common Fault Injection Model Extension, then one of the following occurs:

- ERXPFGCDN_EL1 is RAZ/WI.
- Direct reads and writes of ERXPFGCDN_EL1 are NOPs.
- Direct reads and writes of ERXPFGCDN_EL1 are UNDEFINED.

Note

A node does not implement the Common Fault Injection Model Extension if ERR<q>FR.INJ reads as 0b00. <q> is the index of the first error record owned by the same node as error record <n>, where <n> is the value in [ERRSELR_EL1.SEL](#). If the node owns a single record then q = n.

If [ERRSELR_EL1.SEL](#) is not the index of the first error record owned by a node, then ERR<n>PFGCDN is not present, meaning reads and writes of ERXPFGCDN_EL1 are RES0.

ERR<n>PFGCDN describes additional constraints that also apply when ERR<n>PFGCDN is accessed through ERXPFGCDN_EL1.

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, ERXPFPGCDN_EL1

op0	op1	CRn	CRm	op2

D12.7.12 ERXPFPGCTL_EL1, Selected Pseudo-fault Generation Control Register

The ERXPFPGCTL_EL1 characteristics are:

Purpose

Accesses ERR<n>PFGCTL for the error record <n> selected by [ERRSELR_EL1.SEL](#).

Configuration

This register is present only when FEAT_RASv1p1 is implemented. Otherwise, direct accesses to ERXPFPGCTL_EL1 are UNDEFINED.

Attributes

ERXPFPGCTL_EL1 is a 64-bit register.

Field descriptions

ERRnPFGCTL, bits [63:0]

ERXPFPGCTL_EL1 accesses ERR<n>PFGCTL, where <n> is the value in [ERRSELR_EL1.SEL](#).

Accessing ERXPFPGCTL_EL1

If [ERRIDR_EL1.NUM](#) is 0x0000 or [ERRSELR_EL1.SEL](#) is greater than or equal to [ERRIDR_EL1.NUM](#), then one of the following occurs:

- An UNKNOWN error record is selected.
- ERXPFPGCTL_EL1 is RAZ/WI.
- Direct reads and writes of ERXPFPGCTL_EL1 are NOPs.
- Direct reads and writes of ERXPFPGCTL_EL1 are UNDEFINED.

If [ERRSELR_EL1.SEL](#) selects an error record owned by a node that does not implement the Common Fault Injection Model Extension, then one of the following occurs:

- ERXPFPGCTL_EL1 is RAZ/WI.
- Direct reads and writes of ERXPFPGCTL_EL1 are NOPs.
- Direct reads and writes of ERXPFPGCTL_EL1 are UNDEFINED.

Note

A node does not implement the Common Fault Injection Model Extension if ERR<q>FR.INJ reads as 0b00. <q> is the index of the first error record owned by the same node as error record <n>, where <n> is the value in [ERRSELR_EL1.SEL](#). If the node owns a single record then q = n.

If [ERRSELR_EL1.SEL](#) is not the index of the first error record owned by a node, then ERR<n>PFGCTL is not present, meaning reads and writes of ERXPFPGCTL_EL1 are RES0.

ERR<n>PFGCTL describes additional constraints that also apply when ERR<n>PFGCTL is accessed through ERXPFPGCTL_EL1.

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, ERXPFPGCTL_EL1

op0	op1	CRn	CRm	op2

end;

```

D12.7.13 ERXPFGF_EL1, Selected Pseudo-fault Generation Feature Register

The ERXPFGF_EL1 characteristics are:

Purpose

Accesses ERR<n>PFGF for the error record <n> selected by [ERRSELR_EL1.SEL](#).

Configuration

This register is present only when FEAT_RASv1p1 is implemented. Otherwise, direct accesses to ERXPFGF_EL1 are UNDEFINED.

Attributes

ERXPFGF_EL1 is a 64-bit register.

Field descriptions

ERRnPFGF, bits [63:0]

ERXPFGF_EL1 accesses ERR<n>PFGF, where <n> is the value in [ERRSELR_EL1.SEL](#).

Accessing ERXPFGF_EL1

If [ERRIDR_EL1.NUM](#) is 0x0000 or [ERRSELR_EL1.SEL](#) is greater than or equal to [ERRIDR_EL1.NUM](#), then one of the following occurs:

- An UNKNOWN error record is selected.
- ERXPFGF_EL1 is RAZ.
- Direct reads of ERXPFGF_EL1 are NOPs.
- Direct reads of ERXPFGF_EL1 are UNDEFINED.

If [ERRSELR_EL1.SEL](#) selects an error record owned by a node that does not implement the Common Fault Injection Model Extension, then one of the following occurs:

- ERXPFGF_EL1 is RAZ.
- Direct reads of ERXPFGF_EL1 are NOPs.
- Direct reads of ERXPFGF_EL1 are UNDEFINED.

Note

A node does not implement the Common Fault Injection Model Extension if ERR<q>FR.INJ reads as 0b00. <q> is the index of the first error record owned by the same node as error record <n>, where <n> is the value in [ERRSELR_EL1.SEL](#). If the node owns a single record then q = n.

If [ERRSELR_EL1.SEL](#) is not the index of the first error record owned by a node, then ERR<n>PFGF is not present, meaning reads of ERXPFGF_EL1 are RES0.

ERR<n>PFGF describes additional constraints that also apply when ERR<n>PFGF is accessed through ERXPFGF_EL1.

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, ERXPFPGF_EL1

op0	op1	CRn	CRm	op2
0b11	0b000	0b0101	0b0100	0b100

```

if !IsFeatureImplemented(FEAT_RASv1p1) then
    Undefined();
elsif PSTATE.EL == EL0 then
    Undefined();
elsif PSTATE.EL == EL1 then
    if HCR_EL2().FIEN == '0' then
        AArch64_SystemAccessTrap(EL2, 0x18);
    else
        X{64}(t) = ERRPFPGF(UInt(ERRSELR_EL1().SEL));
    end;
elsif PSTATE.EL == EL2 then
    X{64}(t) = ERRPFPGF(UInt(ERRSELR_EL1().SEL));
end;

```

D12.7.14 ERXSTATUS_EL1, Selected Error Record Primary Status Register

The ERXSTATUS_EL1 characteristics are:

Purpose

Accesses ERR<n>STATUS for the error record <n> selected by ERRSELR_EL1.SEL.

Configuration

This register is present only when FEAT_RAS is implemented. Otherwise, direct accesses to ERXSTATUS_EL1 are UNDEFINED.

Attributes

ERXSTATUS_EL1 is a 64-bit register.

Field descriptions

ERRnSTATUS, bits [63:0]

ERXSTATUS_EL1 accesses ERR<n>STATUS, where <n> is the value in ERRSELR_EL1.SEL.

Accessing ERXSTATUS_EL1

If ERRIDR_EL1.NUM is 0x0000 or ERRSELR_EL1.SEL is greater than or equal to ERRIDR_EL1.NUM, then one of the following occurs:

- An UNKNOWN error record is selected.
- ERXSTATUS_EL1 is RAZ/WI.
- Direct reads and writes of ERXSTATUS_EL1 are NOPs.
- Direct reads and writes of ERXSTATUS_EL1 are UNDEFINED.

ERR<n>STATUS describes additional constraints that also apply when ERR<n>STATUS is accessed through ERXSTATUS_EL1.

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, ERXSTATUS_EL1

op0	op1	CRn	CRm	op2
0b11	0b000	0b0101	0b0100	0b010

```
if !IsFeatureImplemented(FEAT_RAS) then

end;
```

D12.7.15 VDISR_EL2, Virtual Deferred Interrupt Status Register (EL2)

The VDISR_EL2 characteristics are:

Purpose

Records that a virtual SError exception has been consumed by an ESB instruction executed at EL1 or EL0.

An indirect write to VDISR_EL2 made by an ESB instruction does not require an explicit synchronization operation for the value written to be observed by a direct read of one of the following registers occurring in program order after the ESB instruction:

- [DISR_EL1](#).

Configuration

If EL2 is not implemented, this register is RES0 from EL3.

This register has no effect if EL2 is not enabled in the current Security state.

This register is present only when FEAT_RAS is implemented. Otherwise, direct accesses to VDISR_EL2 are UNDEFINED.

Attributes

VDISR_EL2 is a 64-bit register.

Field descriptions

Bits [63:32]

Reserved, RES0.

A, bit [31]

Set to 1 when an ESB instruction defers a virtual SError exception.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [30:25]

Reserved, RES0.

IDS, bit [24]

The value copied from [VSESR_EL2](#).IDS.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

ISS, bits [23:0]

The value copied from [VSESR_EL2](#).ISS.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing VDISR_EL2

An indirect write to VDISR_EL2 made by an ESB instruction does not require an explicit synchronization operation for the value that is written to be observed by a direct read of one of the following registers occurring in program order after the ESB instruction:

- [DISR_EL1](#).

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, VDISR_EL2

    end;
elseif PSTATE.EL == EL2 then
    DISR_EL1() = X{64}(t);
end;
```

D12.7.16 VESR_EL2, Virtual SError Exception Syndrome Register (EL2)

The VESR_EL2 characteristics are:

Purpose

Provides the syndrome value reported to software on taking a virtual SError exception to EL1, or on executing an ESB instruction at EL1.

When the virtual SError exception injected using [HCR_EL2.VSE](#) is taken to EL1 using AArch64, then the syndrome value is reported in [ESR_EL1](#).

When the virtual SError exception injected using [HCR_EL2.VSE](#) is deferred by an ESB instruction, then the syndrome value is written to [VDISR_EL2](#).

Configuration

If EL2 is not implemented, this register is RES0 from EL3.

This register has no effect if EL2 is not enabled in the current Security state.

This register is present only when FEAT_RAS is implemented. Otherwise, direct accesses to VESR_EL2 are UNDEFINED.

Attributes

VESR_EL2 is a 64-bit register.

Field descriptions

Bits [63:25]

Reserved, RES0.

IDS, bit [24]

When a virtual SError exception is taken to EL1 using AArch64, [ESR_EL1\[24\]](#) is set to VESR_EL2.IDS.

When a virtual SError exception is deferred by an ESB instruction, [VDISR_EL2\[24\]](#) is set to VESR_EL2.IDS.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

ISS, bits [23:0]

When a virtual SError exception is taken to EL1 using AArch64, [ESR_EL1\[23:0\]](#) is set to VESR_EL2.ISS.

When a virtual SError exception is deferred by an ESB instruction, [VDISR_EL2\[23:0\]](#) is set to VESR_EL2.ISS.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing VESR_EL2

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, VSESR_EL2

op0	op1	CRn	CRm	op2
0b11	0b100	0b0101	0b0010	0b011

```

D12.8 Generic Timer registers

This section lists the Generic Timer registers in AArch64.

D12.8.1 CNTFRQ_EL0, Counter-timer Frequency Register

The CNTFRQ_EL0 characteristics are:

Purpose

This register is provided so that software can discover the [effective frequency](#) of the system counter. It must be programmed with this value as part of system initialization. The value of the register is not interpreted by hardware.

Configuration

There are no configuration notes.

Attributes

CNTFRQ_EL0 is a 64-bit register.

Field descriptions

Bits [63:32]

Reserved, RES0.

ClockFreq, bits [31:0]

Clock frequency. Indicates the [effective frequency](#) of the system counter, in Hz.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing CNTFRQ_EL0

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, CNTFRQ_EL0

op0	op1	CRn	CRm	op2
0b11	0b011	0b1110	0b0000	0b000

```
if PSTATE.EL == EL0 then
    if EffectivelyAtEL0NotInHost() && CNTKCTL_EL1().[EL0PCTEN,EL0VCTEN] == '00' then
        AArch64_SystemAccessTrapToEL1orEL2(0x18);
    else
        X{64}(t) = CNTFRQ_EL0();
    end;
elsif PSTATE.EL == EL1 then
    X{64}(t) = CNTFRQ_EL0();
elsif PSTATE.EL == EL2 then
```

```
    X{64}(t) = CNTFRQ_EL0();  
end;
```

```
MSR CNTFRQ_EL0, <Xt>
```

op0	op1	CRn	CRm	op2
0b11	0b011	0b1110	0b0000	0b000

```
if IsHighestEL(PSTATE.EL) then  
    CNTFRQ_EL0() = X{64}(t);  
else  
    Undefined();  
end;
```

D12.8.2 CNTHCTL_EL2, Counter-timer Hypervisor Control Register

The CNTHCTL_EL2 characteristics are:

Purpose

Controls the generation of an event stream from the physical counter, and access from EL1 to the physical counter and the EL1 physical timer.

Configuration

Fields that control the generation of events from the event stream have an effect regardless of the current Exception level and whether EL2 is enabled in the current Security state.

All other fields have no effect if EL2 is not enabled in the current Security state.

Attributes

CNTHCTL_EL2 is a 64-bit register.

Field descriptions

EffectiveHCR_EL2_E2H() == '0'

The following field descriptions apply in all Armv8.0 implementations.

Bits [63:8]

Reserved, RES0.

EVNTI, bits [7:4]

Selects which bit of [CNTPCT_EL0](#), as seen from EL2, is the trigger for the event stream generated from that counter when that stream is enabled.

This field selects a trigger bit in the range 0 to 15 of [CNTPCT_EL0](#).

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

EVNTDIR, bit [3]

Controls which transition of the [CNTPCT_EL0](#) trigger bit, as seen from EL2 and defined by EVNTI, generates an event when the event stream is enabled.

EVNTDIR	Meaning
0b0	A 0 to 1 transition of the trigger bit triggers an event.
0b1	A 1 to 0 transition of the trigger bit triggers an event.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

EVNTEN, bit [2]

Enables the generation of an event stream from [CNTPCT_EL0](#) as seen from EL2.

EVNTEN	Meaning
0b0	Disables the event stream.
0b1	Enables the event stream.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

EL1PCEN, bit [1]

Traps EL0 and EL1 accesses to the EL1 physical timer registers to EL2 when EL2 is enabled in the current Security state, as follows:

- In AArch64 state, accesses to [CNTP_CTL_EL0](#), [CNTP_CVAL_EL0](#), [CNTP_TVAL_EL0](#) are trapped to EL2, reported using EC syndrome value 0×18 , unless they are trapped by [CNTKCTL_EL1.EL0PTEN](#).

EL1PCEN	Meaning
0b0	EL0 and EL1 accesses to the specified registers are trapped to EL2.
0b1	This control does not cause any instructions to be trapped.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

EL1PCTEN, bit [0]

Traps EL0 and EL1 accesses to the EL1 physical counter registers to EL2 when EL2 is enabled in the current Security state, as follows:

- In AArch64 state, accesses to [CNTPCT_EL0](#) and [CNTPCTSS_EL0](#) are trapped to EL2 and reported using EC syndrome value 0×18 , unless they are trapped by [CNTKCTL_EL1.EL0PCTEN](#).

EL1PCTEN	Meaning
0b0	EL0 and EL1 accesses to the specified registers are trapped to EL2.

EL1PCTEN	Meaning
0b1	This control does not cause any instructions to be trapped.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing CNTHCTL_EL2

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, CNTHCTL_EL2

op0	op1	CRn	CRm	op2
0b11	0b100	0b1110	0b0001	0b000

```

if PSTATE.EL == EL0 then
    Undefined();
elsif PSTATE.EL == EL1 then
    Undefined();
elsif PSTATE.EL == EL2 then
    X{64}(t) = CNTHCTL_EL2();
end;

```

MSR CNTHCTL_EL2, <Xt>

op0	op1	CRn	CRm	op2
0b11	0b100	0b1110	0b0001	0b000

```

if PSTATE.EL == EL0 then
    Undefined();
elsif PSTATE.EL == EL1 then
    Undefined();
elsif PSTATE.EL == EL2 then
    CNTHCTL_EL2() = X{64}(t);
end;

```

D12.8.3 CNTHPS_CTL_EL2, Counter-timer Secure Physical Timer Control Register (EL2)

The CNTHPS_CTL_EL2 characteristics are:

Purpose

Control register for the Secure EL2 physical timer.

Configuration

This register is present only when FEAT_SEL2 is implemented. Otherwise, direct accesses to CNTHPS_CTL_EL2 are UNDEFINED.

Attributes

CNTHPS_CTL_EL2 is a 64-bit register.

Field descriptions

Bits [63:3]

Reserved, RES0.

ISTATUS, bit [2]

The status of the timer. This bit indicates whether the timer condition is met:

ISTATUS	Meaning
0b0	Timer condition is not met.
0b1	Timer condition is met.

When the value of the CNTHPS_CTL_EL2.ENABLE bit is 1, ISTATUS indicates whether the timer condition is met. ISTATUS takes no account of the value of the IMASK bit. If the value of ISTATUS is 1 and the value of IMASK is 0 then the timer interrupt is asserted.

When the value of the CNTHPS_CTL_EL2.ENABLE bit is 0, the ISTATUS field is UNKNOWN.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Access to this field is RO.

IMASK, bit [1]

Timer interrupt mask bit. Permitted values are:

IMASK	Meaning
0b0	Timer interrupt is not masked by the IMASK bit.
0b1	Timer interrupt is masked by the IMASK bit.

For more information, see the description of the ISTATUS bit.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

ENABLE, bit [0]

Enables the timer. Permitted values are:

ENABLE	Meaning
0b0	Timer disabled.
0b1	Timer enabled.

Setting this bit to 0 disables the timer output signal, but the timer value accessible from [CNTHPS_TVAL_EL2](#) continues to count down.

Note
Disabling the output signal might be a power-saving option.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing CNTHPS_CTL_EL2

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, CNTHPS_CTL_EL2

op0	op1	CRn	CRm	op2
0b11	0b100	0b1110	0b0101	0b001

```
if !IsFeatureImplemented(FEAT_SEL2) then
    Undefined();
elseif PSTATE.EL == EL0 then
    Undefined();
elseif PSTATE.EL == EL1 then
    Undefined();
elseif PSTATE.EL == EL2 then
    X{64}(t) = CNTHPS_CTL_EL2();
end;
```

MSR CNTHPS_CTL_EL2, <Xt>

op0	op1	CRn	CRm	op2
0b11	0b100	0b1110	0b0101	0b001

```
if !IsFeatureImplemented(FEAT_SEL2) then
    Undefined();
elsif PSTATE.EL == EL0 then
    Undefined();
elsif PSTATE.EL == EL1 then
    Undefined();
elsif PSTATE.EL == EL2 then
    CNTHPS_CTL_EL2() = X{64}(t);
end;
```

D12.8.4 CNTHPS_CVAL_EL2, Counter-timer Secure Physical Timer CompareValue Register (EL2)

The CNTHPS_CVAL_EL2 characteristics are:

Purpose

Holds the compare value for the Secure EL2 physical timer.

Configuration

This register is present only when FEAT_SEL2 is implemented. Otherwise, direct accesses to CNTHPS_CVAL_EL2 are UNDEFINED.

Attributes

CNTHPS_CVAL_EL2 is a 64-bit register.

Field descriptions

CompareValue, bits [63:0]

Holds the EL2 physical timer CompareValue.

When [CNTHPS_CTL_EL2.ENABLE](#) is 1, and TimerConditionMet is TRUE for the Secure EL2 physical timer, the timer condition is met and all of the following are true:

- [CNTHPS_CTL_EL2.ISTATUS](#) is set to 1.
- If [CNTHPS_CTL_EL2.IMASK](#) is 0, an interrupt is generated.

TimerConditionMet is defined by ‘[Operation of the CompareValue views of the timers](#)’.

The CompareValue view of the timer acts like a 64-bit upcounter timer.

When [CNTHPS_CTL_EL2.ENABLE](#) is 0, the timer condition is not met, but [CNTPCT_EL0](#) continues to count.

If the Generic counter is implemented at a size less than 64 bits, then this field is permitted to be implemented at the same width as the counter, and the upper bits are RES0.

The value of this field is treated as zero-extended in all counter calculations.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing CNTHPS_CVAL_EL2

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, CNTHPS_CVAL_EL2

op0	op1	CRn	CRm	op2
0b11	0b100	0b1110	0b0101	0b010

```

if !IsFeatureImplemented(FEAT_SEL2) then
    Undefined();
elsif PSTATE.EL == EL0 then
    Undefined();
elsif PSTATE.EL == EL1 then
    Undefined();
elsif PSTATE.EL == EL2 then
    X{64}(t) = CNTHPS_CVAL_EL2();
end;

```

MSR CNTHPS_CVAL_EL2, <Xt>

op0	op1	CRn	CRm	op2
0b11	0b100	0b1110	0b0101	0b010

```

if !IsFeatureImplemented(FEAT_SEL2) then
    Undefined();
elsif PSTATE.EL == EL0 then
    Undefined();
elsif PSTATE.EL == EL1 then
    Undefined();
elsif PSTATE.EL == EL2 then
    CNTHPS_CVAL_EL2() = X{64}(t);
end;

```

D12.8.5 CNTHPS_TVAL_EL2, Counter-timer Secure Physical Timer TimerValue Register (EL2)

The CNTHPS_TVAL_EL2 characteristics are:

Purpose

Holds the timer value for the Secure EL2 physical timer.

Configuration

This register is present only when FEAT_SEL2 is implemented. Otherwise, direct accesses to CNTHPS_TVAL_EL2 are UNDEFINED.

Attributes

CNTHPS_TVAL_EL2 is a 64-bit register.

Field descriptions

Bits [63:32]

Reserved, RES0.

TimerValue, bits [31:0]

The TimerValue view of the EL2 physical timer.

On a read of this register:

- If CNTHPS_CTL_EL2.ENABLE is 0, the value returned is UNKNOWN.
- If CNTHPS_CTL_EL2.ENABLE is 1, the value returned is (CNTHPS_CVAL_EL2 - CNTPCT_EL0).

On a write of this register, CNTHPS_CVAL_EL2 is set to (CNTPCT_EL0 + TimerValue), where TimerValue is treated as a signed 32-bit integer.

When CNTHPS_CTL_EL2.ENABLE is 1, the timer condition is met when (CNTPCT_EL0 - CNTHPS_CVAL_EL2) is greater than or equal to zero. This means that TimerValue acts like a 32-bit downcounter timer. When the timer condition is met:

- CNTHPS_CTL_EL2.ISTATUS is set to 1.
- If CNTHPS_CTL_EL2.IMASK is 0, an interrupt is generated.

When CNTHPS_CTL_EL2.ENABLE is 0, the TimerValue cannot be read but continues to decrement. When the timer is enabled, the TimerValue represents the elapsed time whether that time was spent enabled or disabled.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing CNTHPS_TVAL_EL2

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, CNTHPS_TVAL_EL2

op0	op1	CRn	CRm	op2
0b11	0b100	0b1110	0b0101	0b000

```

if !IsFeatureImplemented(FEAT_SEL2) then
    Undefined();
elsif PSTATE.EL == EL0 then
    Undefined();
elsif PSTATE.EL == EL1 then
    Undefined();
elsif PSTATE.EL == EL2 then
    if CNTHPS_CTL_EL2().ENABLE == '0' then
        X{64}(t) = ARBITRARY:bits(64);
    else
        X{64}(t) = ZeroExtend{64}((CNTHPS_CVAL_EL2() - PhysicalCountInt())[31:0]);
    end;
end;
end;

```

MSR CNTHPS_TVAL_EL2, <Xt>

op0	op1	CRn	CRm	op2
0b11	0b100	0b1110	0b0101	0b000

```

if !IsFeatureImplemented(FEAT_SEL2) then
    Undefined();
elsif PSTATE.EL == EL0 then
    Undefined();
elsif PSTATE.EL == EL1 then
    Undefined();
elsif PSTATE.EL == EL2 then
    CNTHPS_CVAL_EL2() = SignExtend{64}(X{64}(t)[31:0]) + PhysicalCountInt();
end;
end;

```

D12.8.6 CNTKCTL_EL1, Counter-timer Kernel Control Register

The CNTKCTL_EL1 characteristics are:

Purpose

This register controls the generation of an event stream from the virtual counter, and access from EL0 to the physical counter, virtual counter, EL1 physical timers, and the virtual timer.

Configuration

There are no configuration notes.

Attributes

CNTKCTL_EL1 is a 64-bit register.

Field descriptions

Bits [63:10]

Reserved, RES0.

ELOPTEN, bit [9]

Traps EL0 accesses to the physical timer registers to EL1, or to EL2 when it is implemented and enabled for the current Security state and [HCR_EL2.TGE](#) is 1, as follows:

- In AArch64 state, the following registers are trapped and reported using EC syndrome value 0x18:
 - [CNTP_CTL_EL0](#), [CNTP_CVAL_EL0](#), and [CNTP_TVAL_EL0](#).

ELOPTEN	Meaning
0b0	EL0 accesses to the physical timer registers are trapped to EL1.
0b1	This control does not cause any instructions to be trapped.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

ELOVTEN, bit [8]

Traps EL0 accesses to the virtual timer registers to EL1, or to EL2 when it is implemented and enabled for the current Security state and [HCR_EL2.TGE](#) is 1, as follows:

- In AArch64 state, accesses to the following registers are trapped and reported using EC syndrome value 0x18:
 - [CNTV_CTL_EL0](#), [CNTV_CVAL_EL0](#), and [CNTV_TVAL_EL0](#).

EL0VTEN	Meaning
0b0	EL0 accesses to the virtual timer registers are trapped.
0b1	This control does not cause any instructions to be trapped.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

EVNTI, bits [7:4]

Selects which bit of [CNTVCT_EL0](#), as seen from EL1, is the trigger for the event stream generated from that counter when that stream is enabled.

This field selects a trigger bit in the range 0 to 15 of [CNTVCT_EL0](#).

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

EVNTDIR, bit [3]

Controls which transition of the [CNTVCT_EL0](#) trigger bit, as seen from EL1 and defined by EVNTI, generates an event when the event stream is enabled.

EVNTDIR	Meaning
0b0	A 0 to 1 transition of the trigger bit triggers an event.
0b1	A 1 to 0 transition of the trigger bit triggers an event.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

EVNTEN, bit [2]

Enables the generation of an event stream from [CNTVCT_EL0](#) as seen from EL1.

EVNTEN	Meaning
0b0	Disables the event stream.
0b1	Enables the event stream.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

EL0VCTEN, bit [1]

Traps EL0 accesses to the frequency register and virtual counter registers to EL1, or to EL2 when it is implemented and enabled for the current Security state and [HCR_EL2.TGE](#) is 1, as follows:

- In AArch64 state, accesses to the following registers are trapped and reported using EC syndrome value 0x18:
 - [CNTVCT_EL0](#).
 - [CNTVCTSS_EL0](#).
 - If [CNTKCTL_EL1.EL0PCTEN](#) is 0, [CNTFRQ_EL0](#).

EL0VCTEN	Meaning
0b0	EL0 accesses to the frequency register and virtual counter registers are trapped.
0b1	This control does not cause any instructions to be trapped.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

EL0PCTEN, bit [0]

Traps EL0 accesses to the frequency register and physical counter register to EL1, or to EL2 when it is implemented and enabled for the current Security state and [HCR_EL2.TGE](#) is 1, as follows:

- In AArch64 state, the following registers are trapped and reported using EC syndrome value 0x18:
 - [CNTPCT_EL0](#)
 - [CNTPCTSS_EL0](#)
 - If [CNTKCTL_EL1.EL0VCTEN](#) is 0, [CNTFRQ_EL0](#).

EL0PCTEN	Meaning
0b0	EL0 accesses to the frequency register and physical counter register are trapped.
0b1	This control does not cause any instructions to be trapped.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing CNTKCTL_EL1

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, CNTKCTL_EL1

op0	op1	CRn	CRm	op2
0b11	0b000	0b11110	0b0001	0b000

```
if PSTATE.EL == EL0 then
    Undefined();
elsif PSTATE.EL == EL1 then
    X{64}(t) = CNTKCTL_EL1();
elsif PSTATE.EL == EL2 then
    X{64}(t) = CNTKCTL_EL1();
end;
```

MSR CNTKCTL_EL1, <Xt>

op0	op1	CRn	CRm	op2
0b11	0b000	0b1110	0b0001	0b000

```
if PSTATE.EL == EL0 then
    Undefined();
elsif PSTATE.EL == EL1 then
    CNTKCTL_EL1() = X{64}(t);
elsif PSTATE.EL == EL2 then
    CNTKCTL_EL1() = X{64}(t);
end;
```

D12.8.7 CNTPCT_EL0, Counter-timer Physical Count Register

The CNTPCT_EL0 characteristics are:

Purpose

Reads of CNTPCT_EL0 return the 64-bit physical count value minus a physical offset.

Configuration

There are no configuration notes.

Attributes

CNPCT_EL0 is a 64-bit register.

Field descriptions

PhysicalCount, bits [63:0]

Physical count value.

Reads of CNTPCT_EL0 return PhysicalCountInt<63:0>.

PhysicalCountInt is defined by ‘The Physical Counter’.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing CNTPCT_EL0

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, CNTPCT_EL0

op0	op1	CRn	CRm	op2
0b11	0b011	0b1110	0b0000	0b001

```
if PSTATE.EL == EL0 then
    if EffectivelyAtEL0NotInHost() && CNTKCTL_EL1().EL0PCTEN == '0' then
        AArch64_SystemAccessTrapToEL1orEL2(0x18);
    elseif !ELIsInHost(EL2) && CNTHCTL_EL2().EL1PCTEN == '0' then
        AArch64_SystemAccessTrap(EL2, 0x18);
    else
        X{64}(t) = PhysicalCountInt();
    end;
elseif PSTATE.EL == EL1 then
    if CNTHCTL_EL2().EL1PCTEN == '0' then
        AArch64_SystemAccessTrap(EL2, 0x18);
```

```
        else
            X{64}(t) = PhysicalCountInt();
        end;
    elsif PSTATE.EL == EL2 then
        X{64}(t) = PhysicalCountInt();
    end;
```

D12.8.8 CNTP_CTL_EL0, Counter-timer Physical Timer Control Register

The CNTP_CTL_EL0 characteristics are:

Purpose

Control register for the EL1 physical timer.

Configuration

There are no configuration notes.

Attributes

CNTP_CTL_EL0 is a 64-bit register.

Field descriptions

Bits [63:3]

Reserved, RES0.

ISTATUS, bit [2]

The status of the timer. This bit indicates whether the timer condition is met:

ISTATUS	Meaning
0b0	Timer condition is not met.
0b1	Timer condition is met.

When the value of the ENABLE bit is 1, ISTATUS indicates whether the timer condition is met. ISTATUS takes no account of the value of the IMASK bit. If the value of ISTATUS is 1 and the value of IMASK is 0 then the timer interrupt is asserted.

When the value of the ENABLE bit is 0, the ISTATUS field is UNKNOWN.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Access to this field is RO.

IMASK, bit [1]

Timer interrupt mask bit. Permitted values are:

IMASK	Meaning
0b0	Timer interrupt is not masked by the IMASK bit.
0b1	Timer interrupt is masked by the IMASK bit.

For more information, see the description of the ISTATUS bit.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

ENABLE, bit [0]

Enables the timer. Permitted values are:

ENABLE	Meaning
0b0	Timer disabled.
0b1	Timer enabled.

Setting this bit to 0 disables the timer output signal, but the timer value accessible from [CNTP_TVAL_ELO](#) continues to count down.

Note
Disabling the output signal might be a power-saving option.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing CNTP_CTL_ELO

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, CNTP_CTL_ELO

op0	op1	CRn	CRm	op2
0b11	0b011	0b1110	0b0010	0b001

```
if PSTATE.EL == EL0 then
    if EffectivelyAtEL0NotInHost() && CNTKCTL_EL1().ELOPTEN == '0' then
        AArch64_SystemAccessTrapToEL1orEL2(0x18);
    elseif !ELIsInHost(EL2) && CNTHCTL_EL2().EL1PCEN == '0' then
        AArch64_SystemAccessTrap(EL2, 0x18);
    else
        X{64}(t) = CNTP_CTL_ELO();
    end;
elseif PSTATE.EL == EL1 then
    if !ELIsInHost(EL2) && CNTHCTL_EL2().EL1PCEN == '0' then

    elseif ELIsInHost(EL2) then
        AArch64_SystemAccessTrap(EL2, 0x18);
    else
        CNTP_CTL_EL0() = X{64}(t);
    end;
elseif PSTATE.EL == EL2 then
    CNTP_CTL_EL0() = X{64}(t);
end;
```

D12.8.9 CNTP_CVAL_EL0, Counter-timer Physical Timer CompareValue Register

The CNTP_CVAL_EL0 characteristics are:

Purpose

Holds the compare value for the EL1 physical timer.

Configuration

There are no configuration notes.

Attributes

CNTP_CVAL_EL0 is a 64-bit register.

Field descriptions

CompareValue, bits [63:0]

Holds the EL1 physical timer CompareValue.

When [CNTP_CTL_EL0.ENABLE](#) is 1, and `TimerConditionMet` is TRUE for the EL1 physical timer, the timer condition is met and all of the following are true:

- [CNTP_CTL_EL0.ISTATUS](#) is set to 1.
- If [CNTP_CTL_EL0.IMASK](#) is 0, an interrupt is generated.

`TimerConditionMet` is defined by ‘[Operation of the CompareValue views of the timers](#)’.

The CompareValue view of the timer acts like a 64-bit upcounter timer.

When [CNTP_CTL_EL0.ENABLE](#) is 0, the timer condition is not met, but [CNTPCT_EL0](#) continues to count.

If the Generic counter is implemented at a size less than 64 bits, then this field is permitted to be implemented at the same width as the counter, and the upper bits are RES0.

The value of this field is treated as zero-extended in all counter calculations.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing CNTP_CVAL_EL0

Accesses to this register use the following encodings in the System register encoding space:

    else
        CNTP_CVAL_EL0() = X{64}(t);
    end;
elseif PSTATE.EL == EL2 then
    CNTP_CVAL_EL0() = X{64}(t);
end;

```

D12.8.10 CNTP_TVAL_EL0, Counter-timer Physical Timer TimerValue Register

The CNTP_TVAL_EL0 characteristics are:

Purpose

Holds the timer value for the EL1 physical timer.

Configuration

There are no configuration notes.

Attributes

CNTP_TVAL_EL0 is a 64-bit register.

Field descriptions

Bits [63:32]

Reserved, RES0.

TimerValue, bits [31:0]

The TimerValue view of the EL1 physical timer.

On a read of this register:

- If [CNTP_CTL_EL0.ENABLE](#) is 0, the value returned is UNKNOWN.
- If [CNTP_CTL_EL0.ENABLE](#) is 1, the value returned is ([CNTP_CVAL_EL0](#) - [CNTPCT_EL0](#)).

On a write of this register, [CNTP_CVAL_EL0](#) is set to ([CNTPCT_EL0](#) + TimerValue), where TimerValue is treated as a signed 32-bit integer.

When [CNTP_CTL_EL0.ENABLE](#) is 1, the timer condition is met when ([CNTPCT_EL0](#) - [CNTP_CVAL_EL0](#)) is greater than or equal to zero. This means that TimerValue acts like a 32-bit downcounter timer. When the timer condition is met:

- [CNTP_CTL_EL0.ISTATUS](#) is set to 1.
- If [CNTP_CTL_EL0.IMASK](#) is 0, an interrupt is generated.

When [CNTP_CTL_EL0.ENABLE](#) is 0, the TimerValue cannot be read but continues to decrement. When the timer is enabled, the TimerValue represents the elapsed time whether that time was spent enabled or disabled.

Note

The value of [CNTPCT_EL0](#) used in these calculations is the value seen at the Exception level that the [CNTPCT_EL0](#) register is being read or written from.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing CNTP_TVAL_EL0

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, CNTP_TVAL_EL0

op0	op1	CRn	CRm	op2
0b11	0b011	0b1110	0b0010	0b000

```

    elsif PSTATE.EL == EL2 then
        CNTP_CVAL_EL0() = SignExtend{64}(X{64}(t)[31:0]) + PhysicalCountInt();
    end;
```

D12.8.11 CNTVCT_EL0, Counter-timer Virtual Count Register

The CNTVCT_EL0 characteristics are:

Purpose

Reads of CNTVCT_EL0 return the 64-bit physical count value minus a virtual offset.

Configuration

There are no configuration notes.

Attributes

CNTVCT_EL0 is a 64-bit register.

Field descriptions

VirtualCount, bits [63:0]

Virtual count value.

Reads of CNTVCT_EL0 return PhysicalCountInt<63:0>.

PhysicalCountInt is defined by ‘The Physical Counter’.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing CNTVCT_EL0

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, CNTVCT_EL0

op0	op1	CRn	CRm	op2
0b11	0b011	0b1110	0b0000	0b010

```

            X{64}(t) = PhysicalCountInt() - CNTVOFF_EL2();
        else
            X{64}(t) = PhysicalCountInt();
        end;
    end;
elseif PSTATE.EL == EL1 then
```

```
        X{64}(t) = PhysicalCountInt() - CNTVOFF_EL2();  
    elsif PSTATE.EL == EL2 then  
        if !ELIsInHost(EL2) then  
            X{64}(t) = PhysicalCountInt() - CNTVOFF_EL2();  
        else  
            X{64}(t) = PhysicalCountInt();  
        end;  
    end;  
end;
```

D12.8.12 CNTVOFF_EL2, Counter-timer Virtual Offset Register

The CNTVOFF_EL2 characteristics are:

Purpose

Holds the 64-bit virtual offset. This is the offset for the AArch64 virtual timers and counters.

Configuration

The virtual offset applies to:

- Direct reads of [CNTVCT_EL0](#).
- Indirect reads of the virtual counter by the EL1 virtual timer. See ‘[The Generic Timer in AArch64 state](#)’.
- Indirect reads of the virtual counter for timestamps generated by profiling logic. See ‘[AArch64 Self-hosted Trace](#)’.

The virtual offset only applies under conditions described by the relevant sections.

Attributes

CNTVOFF_EL2 is a 64-bit register.

Field descriptions

VOffset, bits [63:0]

Virtual offset.

If the Generic counter is implemented at a size less than 64 bits, then this field is permitted to be implemented at the same width as the counter, and the upper bits are RES0.

The value of this field is treated as zero-extended in all counter calculations.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing CNTVOFF_EL2

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, CNTVOFF_EL2

op0	op1	CRn	CRm	op2
0b11	0b100	0b1110	0b0000	0b011

```
if PSTATE.EL == EL0 then
    Undefined();
elsif PSTATE.EL == EL1 then
    Undefined();
elsif PSTATE.EL == EL2 then
    X{64}(t) = CNTVOFF_EL2();
end;
```

MSR CNTVOFF_EL2, <Xt>

op0	op1	CRn	CRm	op2
0b11	0b100	0b1110	0b0000	0b011

```
if PSTATE.EL == EL0 then
    Undefined();
elsif PSTATE.EL == EL1 then
    Undefined();
elsif PSTATE.EL == EL2 then
    CNTVOFF_EL2() = X{64}(t);
end;
```

D12.8.13 CNTV_CTL_EL0, Counter-timer Virtual Timer Control Register

The CNTV_CTL_EL0 characteristics are:

Purpose

Control register for the virtual timer.

Configuration

There are no configuration notes.

Attributes

CNTV_CTL_EL0 is a 64-bit register.

Field descriptions

Bits [63:3]

Reserved, RES0.

ISTATUS, bit [2]

The status of the timer. This bit indicates whether the timer condition is met:

ISTATUS	Meaning
0b0	Timer condition is not met.
0b1	Timer condition is met.

When the value of the ENABLE bit is 1, ISTATUS indicates whether the timer condition is met. ISTATUS takes no account of the value of the IMASK bit. If the value of ISTATUS is 1 and the value of IMASK is 0 then the timer interrupt is asserted.

When the value of the ENABLE bit is 0, the ISTATUS field is UNKNOWN.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Access to this field is RO.

IMASK, bit [1]

Timer interrupt mask bit. Permitted values are:

IMASK	Meaning
0b0	Timer interrupt is not masked by the IMASK bit.
0b1	Timer interrupt is masked by the IMASK bit.

For more information, see the description of the ISTATUS bit.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

ENABLE, bit [0]

Enables the timer. Permitted values are:

ENABLE	Meaning
0b0	Timer disabled.
0b1	Timer enabled.

Setting this bit to 0 disables the timer output signal, but the timer value accessible from [CNTV_TVAL_ELO](#) continues to count down.

Note

Disabling the output signal might be a power-saving option.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing CNTV_CTL_ELO

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, CNTV_CTL_ELO

op0	op1	CRn	CRm	op2
0b11	0b011	0b1110	0b0011	0b001

```
if PSTATE.EL == EL0 then
    if EffectivelyAtEL0NotInHost() && CNTKCTL_EL1().ELOVTEN == '0' then
        AArch64_SystemAccessTrapToEL1orEL2(0x18);
    else
        X{64}(t) = CNTV_CTL_ELO();
    end;
elseif PSTATE.EL == EL1 then
    X{64}(t) = CNTV_CTL_ELO();
elseif PSTATE.EL == EL2 then
    X{64}(t) = CNTV_CTL_ELO();
end;
```

MSR CNTV_CTL_EL0, <Xt>

op0	op1	CRn	CRm	op2
0b11	0b011	0b1110	0b0011	0b001

```
if PSTATE.EL == EL0 then
    if EffectivelyAtEL0NotInHost() && CNTKCTL_EL1().ELOVTEN == '0' then
        AArch64_SystemAccessTrapToEL1orEL2(0x18);
    else
        CNTV_CTL_EL0() = X{64}(t);
    end;
elsif PSTATE.EL == EL1 then
    CNTV_CTL_EL0() = X{64}(t);
elsif PSTATE.EL == EL2 then
    CNTV_CTL_EL0() = X{64}(t);
end;
```

D12.8.14 CNTV_CVAL_EL0, Counter-timer Virtual Timer CompareValue Register

The CNTV_CVAL_EL0 characteristics are:

Purpose

Holds the compare value for the virtual timer.

Configuration

There are no configuration notes.

Attributes

CNTV_CVAL_EL0 is a 64-bit register.

Field descriptions

CompareValue, bits [63:0]

Holds the EL1 virtual timer CompareValue.

When [CNTV_CTL_EL0.ENABLE](#) is 1, and `TimerConditionMet` is TRUE for the EL1 virtual timer, the timer condition is met and all of the following are true:

- [CNTV_CTL_EL0.ISTATUS](#) is set to 1.
- If [CNTV_CTL_EL0.IMASK](#) is 0, an interrupt is generated.

`TimerConditionMet` is defined by ‘[Operation of the CompareValue views of the timers](#)’.

The CompareValue view of the timer acts like a 64-bit upcounter timer.

When [CNTV_CTL_EL0.ENABLE](#) is 0, the timer condition is not met, but [CNTVCT_EL0](#) continues to count.

If the Generic counter is implemented at a size less than 64 bits, then this field is permitted to be implemented at the same width as the counter, and the upper bits are RES0.

The value of this field is treated as zero-extended in all counter calculations.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing CNTV_CVAL_EL0

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, CNTV_CVAL_EL0

op0	op1	CRn	CRm	op2
0b11	0b011	0b1110	0b0011	0b010

```
if PSTATE.EL == EL0 then
    if EffectivelyAtEL0NotInHost() && CNTKCTL_EL1().EL0VTEN == '0' then
        AArch64_SystemAccessTrapToEL1orEL2(0x18);
    else
        X{64}(t) = CNTV_CVAL_EL0();
    end;
elseif PSTATE.EL == EL1 then
    X{64}(t) = CNTV_CVAL_EL0();
elseif PSTATE.EL == EL2 then
    X{64}(t) = CNTV_CVAL_EL0();
end;
```

MSR CNTV_CVAL_EL0, <Xt>

op0	op1	CRn	CRm	op2
0b11	0b011	0b1110	0b0011	0b010

```
if PSTATE.EL == EL0 then
    if EffectivelyAtEL0NotInHost() && CNTKCTL_EL1().EL0VTEN == '0' then
        AArch64_SystemAccessTrapToEL1orEL2(0x18);
    else
        CNTV_CVAL_EL0() = X{64}(t);
    end;
elseif PSTATE.EL == EL1 then
    CNTV_CVAL_EL0() = X{64}(t);
elseif PSTATE.EL == EL2 then
    CNTV_CVAL_EL0() = X{64}(t);
end;
```

D12.8.15 CNTV_TVAL_EL0, Counter-timer Virtual Timer TimerValue Register

The CNTV_TVAL_EL0 characteristics are:

Purpose

Holds the timer value for the EL1 virtual timer.

Configuration

There are no configuration notes.

Attributes

CNTV_TVAL_EL0 is a 64-bit register.

Field descriptions

Bits [63:32]

Reserved, RES0.

TimerValue, bits [31:0]

The TimerValue view of the EL1 virtual timer.

On a read of this register:

- If [CNTV_CTL_EL0.ENABLE](#) is 0, the value returned is UNKNOWN.
- If [CNTV_CTL_EL0.ENABLE](#) is 1, the value returned is ([CNTV_CVAL_EL0](#) - [CNTVCT_EL0](#)).

On a write of this register, [CNTV_CVAL_EL0](#) is set to ([CNTVCT_EL0](#) + TimerValue), where TimerValue is treated as a signed 32-bit integer.

When [CNTV_CTL_EL0.ENABLE](#) is 1, the timer condition is met when ([CNTVCT_EL0](#) - [CNTV_CVAL_EL0](#)) is greater than or equal to zero. This means that TimerValue acts like a 32-bit downcounter timer. When the timer condition is met:

- [CNTV_CTL_EL0.ISTATUS](#) is set to 1.
- If [CNTV_CTL_EL0.IMASK](#) is 0, an interrupt is generated.

When [CNTV_CTL_EL0.ENABLE](#) is 0, the TimerValue cannot be read but continues to decrement. When the timer is enabled, the TimerValue represents the elapsed time whether that time was spent enabled or disabled.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing CNTV_TVAL_EL0

Accesses to this register use the following encodings in the System register encoding space:

MRS <Xt>, CNTV_TVAL_EL0

op0	op1	CRn	CRm	op2
0b11	0b011	0b1110	0b0011	0b000

```

Part E

External Debug

Chapter E1

About External Debug

This chapter gives an overview of A-profile external debug and specifies the required debug authentication. It contains the following sections:

- [Introduction to external debug](#)
- [External debug](#)
- [Required debug authentication](#)

Note

For information about self-hosted debug, see [AArch64 Self-hosted Debug](#).

E1.1 Introduction to external debug

The architecture supports both:

Self-hosted debug

The PE itself hosts a debugger. That is, developers developing software to run on the PE use debugger software running on the same PE.

External debug

The debugger is external to the PE. The debugging might be either on-chip, for example in a second PE, or off-chip, for example a JTAG debugger that accesses the chip through a Debug Access Port.

External debug is particularly useful for:

- Hardware bring-up. That is, debugging during development when a system is first powered up and not all of the software functionality is available.
- PEs that are deeply embedded inside systems.

To support external debug, the Arm architecture defines required features that are called *external debug features*.

Note

An external debugger has a potentially high level of control over and visibility into the PE. The system sets this level using debug authentication. See [Required debug authentication](#).
If the debug authentication level is set too low, agents may be able to bypass elements of the security and privilege models. This includes both off-chip agents and on-chip agents such as unprivileged or Non-secure software.

E1.1.1 Definition and constraints of a debugger in the context of external debug

When the description of external debug in this Part of the manual describes a *debugger* as controlling external debug this debugger might be a second on-chip PE or an off-chip device such as a JTAG debugger using a Debug Access Port (DAP).

If a Debug Access Port is implemented:

- When debug is prohibited at the Debug Access Port, the port must not generate accesses to the external debug interface of the PE.
- When debug is prohibited for a Security state at the Debug Access Port, it must not be possible to generate accesses to PA spaces that are not accessible for that Security state.
- When accesses for a Security state are allowed at the Debug Access Port, the port must be able to generate accesses to PA spaces that are accessible for that Security state.

If [FEAT_Debugv8p4](#) is not implemented, accesses to the PE are controlled by the external authentication interface functions, [ExternalInvasiveDebugEnabled\(\)](#), [ExternalNoninvasiveDebugEnabled\(\)](#), [ExternalSecureNoninvasiveDebugEnabled\(\)](#), and [ExternalSecureInvasiveDebugEnabled\(\)](#).

The Debug Access Port is not required to use the same authentication interface as the PE.

Arm recommends that when [ExternalSecureInvasiveDebugEnabled\(\)](#) == FALSE at the PE, Secure debug is disabled at the DAP.

See also [Required debug authentication](#).

E1.2 External debug

Debug events allow an external debugger to halt the PE. The R-profile provides the following debug events:

- [Halting Step debug events:](#)
 - The debugger can use this resource to make the PE step through code one line at a time.
- [Halt Instruction debug event:](#)
 - This might occur when software executes the Halting breakpoint instruction, `HLT`.
- [Exception Catch debug event:](#)
 - This can be programmed to occur on all entries to a given Exception level.
- [External Debug Request debug event:](#)
 - An embedded cross-trigger can signal this debug event.
- [OS Unlock Catch debug event:](#)
 - This might occur when the state of the OS Lock changes from locked to unlocked.
- [Reset Catch debug events:](#)
 - This might occur when the PE exits reset state.
- [Software Access debug event:](#)
 - This can be programmed to occur when software tries to access the Breakpoint Value registers, the Breakpoint Control registers, the Watchpoint value registers, or the Watchpoint Control registers. It caused a trap to Debug state.

Breakpoints and watchpoints can also halt the PE.

When the PE is in Debug state:

- It stops executing instructions from the location indicated by the program counter, and is instead controlled through the external debug interface.
- The *Instruction Transfer Register*, ITR, passes instructions to the PE to execute in Debug state:
 - The ITR contains a single register, EDITR, and associated flow-control flags.
- The *Debug Communications Channel*, DCC, passes data between the PE and the debugger:
 - The DCC includes the data transfer registers, DTRRX and DTRTX, and associated flow-control flags.
 - Although the DCC is an essential part of Debug state operation, it can also be used in Non-debug state.
- The PE cannot service any interrupts in Debug state.

[Debug State](#) describes Debug state in more detail.

E1.3 Required debug authentication

A PE implements the debug authentication interface defined in this section. The debug authentication interface controls:

- Whether halting the PE and entering Debug state is allowed or prohibited.
- Whether some aspects of non-invasive debug are allowed or prohibited.

The pseudocode functions shown in [Table E1-1](#), and the conditions that follow that table, define the architectural requirements for debug authentication.

Table E1-1 Debug authentication functions

Pseudocode function	Description
ExternalNoninvasiveDebugEnabled()	Returns TRUE if Non-secure non-invasive debug is allowed.
ExternalInvasiveDebugEnabled()	Returns TRUE if Non-secure invasive debug is allowed.
ExternalSecureNoninvasiveDebugEnabled()	Returns TRUE if Secure non-invasive debug is allowed.
ExternalSecureInvasiveDebugEnabled()	Returns TRUE if Secure invasive debug is allowed.

The following conditions always apply:

- If [ExternalInvasiveDebugEnabled\(\)](#) is FALSE, then [ExternalSecureInvasiveDebugEnabled\(\)](#) is FALSE.
- If [ExternalNoninvasiveDebugEnabled\(\)](#) is FALSE, then [ExternalSecureNoninvasiveDebugEnabled\(\)](#) is FALSE.
- If [ExternalInvasiveDebugEnabled\(\)](#) is TRUE, then [ExternalNoninvasiveDebugEnabled\(\)](#) is TRUE.
- If [ExternalSecureInvasiveDebugEnabled\(\)](#) is TRUE, then [ExternalSecureNoninvasiveDebugEnabled\(\)](#) is TRUE.

If [FEAT_Debugv8p4](#) is implemented, then all of the following apply:

- [ExternalNoninvasiveDebugEnabled\(\)](#) always returns TRUE.
- [ExternalSecureNoninvasiveDebugEnabled\(\)](#) returns the same value as [ExternalSecureInvasiveDebugEnabled\(\)](#).

Arm recommends the use of the interface described in Recommended authentication interface to provide this debug authentication. The pseudocode functions in [R-profile Architecture Pseudocode](#), which are linked to by the entries in the [Pseudocode function](#) column of [Table E1-1](#), assume that this interface is implemented.

Chapter E2

Debug State

This chapter describes Debug state. It contains the following sections:

- [About Debug state](#)
- [Halting the PE on debug events](#)
- [Entering Debug state](#)
- [Behavior in Debug state](#)
- [Exiting Debug state](#)

E2.1 About Debug state

In external debug, debug events allow an external debugger to halt the PE. The PE then enters Debug state. When the PE is in Debug state:

- It stops executing instructions from the location indicated by the Program Counter, and is instead controlled through the external debug interface.
- The *Instruction Transfer Register*, ITR, passes instructions to the PE to execute in Debug state.
- The *Debug Communications Channel*, DCC, passes data between the PE and the debugger.

The PE cannot service any interrupts in Debug state.

E2.2 Halting the PE on debug events

For details of debug events, see [Introduction to Halting debug events](#) and [Breakpoint and Watchpoint debug events](#).

On a debug event, the PE must do one of the following:

- Enter Debug state.
- Pend the debug event.
- Generate a debug exception.
- Ignore the debug event.

This behavior depends on both:

- Whether halting is allowed by the current state of the debug authentication interface. See [Halting allowed and halting prohibited](#).
- The type of debug event and the programming of the debug control registers.
 - See [Halting debug events](#) for all Halting debug events.
 - See [Breakpoint and Watchpoint debug events](#) for Breakpoint and Watchpoint debug events.

See also [Other debug exceptions](#).

This means that behavior can be CONSTRAINED UNPREDICTABLE if the conditions change. See [Synchronization and Halting debug events](#).

[Table E3-1](#) summarizes the possible outcomes of each type of debug event.

E2.2.1 Halting allowed and halting prohibited

Halting can be either allowed or prohibited:

- Halting is always prohibited in Debug state.
- Halting is always prohibited when `DoubleLockStatus() == TRUE`.
 - This means that [FEAT_DoubleLock](#) is implemented and OS Double lock is locked.
- Halting is also controlled by the IMPLEMENTATION DEFINED authentication interface, and is prohibited when `ExternalSecureInvasiveDebugEnabled() == FALSE`.
- Otherwise, halting is allowed.

For more information, see:

- [Pseudocode description of Halting on debug events](#).
- [Required debug authentication](#).
- Recommended External Debug Interface.

E2.2.2 Halting debug events

The Halting debug events are described in [Halting Debug Events](#).

When a Halting debug event is generated, it causes entry to Debug state if all of the following are true:

- Halting is allowed. See [Halting allowed and halting prohibited](#).
- The Halting debug event is one of:
 - A Halt Instruction debug event and `EDSCR.HDE == 1`.
 - A Software Access debug event and `OSLSR_EL1.OSLK == 0`, meaning that the OS Lock is unlocked.
 - Neither a Halt Instruction debug event nor a Software Access debug event.

-
- Note**
-
- A Halt Instruction debug event is the only Halting debug event that relies on [EDSCR.HDE](#) == 1.
 - Halting on Breakpoint and Watchpoint debug events is also controlled by [EDSCR.HDE](#). See [Breakpoint and Watchpoint debug events](#).
 - [EDSCR.HDE](#) can be written by software when the OS Lock is locked. Privileged code can use [MDCR_EL2.TDOSA](#) to trap writes to OS Lock registers.
-

If a Halting debug event does not generate entry to Debug state because the conditions listed in this section do not hold, then:

- If the Halting debug event is a Halt Instruction debug event, the instruction that generated the Halting debug event is treated as UNDEFINED.
- If the Halting debug event is a Software Access debug event, it is ignored.
- If the Halting debug event is an Exception Catch debug event, it is ignored except when FEAT_Debugv8p8 is implemented, in which case the event might be pending.

In all other cases the Halting debug event is pending, see [Pending Halting debug events](#).

[Summary of actions from debug events](#) summarizes the possible outcome for each type of Debug event.

Note

Halting debug events never generate debug exceptions.

E2.2.3 Breakpoint and Watchpoint debug events

A breakpoint or watchpoint generates an entry to Debug state if all of the following conditions hold:

- Halting debug is enabled, that is [EDSCR.HDE](#) == 1.
- Halting is allowed. See [Halting allowed and halting prohibited](#).
- The OS Lock is unlocked, that is [OSLSR_EL1.OSLK](#) == 0.

The Address Mismatch breakpoint type is reserved when all of these conditions are met.

[MDSCR_EL1.MDE](#) is ignored when determining whether to enter Debug state. A breakpoint or watchpoint that generates entry to Debug state is a Breakpoint or Watchpoint debug event and does not generate a debug exception.

A breakpoint or watchpoint that does not generate an entry to Debug state either:

- Generates a Breakpoint or Watchpoint exception.
- Is ignored.

Note

[EDSCR.HDE](#) is ignored when determining whether to generate a debug exception. The debug exception is suppressed only if the PE enters Debug state. This means that the use of Halting debug mode in one Security state does not affect the Exception model in another Security state.

See [AArch64 Self-hosted Debug](#), and the Note in [Other debug exceptions](#).

E2.2.4 Other debug exceptions

The following events never generate entry to Debug state:

- Breakpoint Instruction exceptions.
- Software Step exceptions.

The behavior of these events is unchanged when Halting debug mode is enabled, that is when `EDSCR.HDE == 1`. This means that these events can do one of the following:

- They can generate a debug exception.
- They can be ignored.

For additional information, see [AArch64 Self-hosted Debug](#).

E2.2.5 Debug state entry and debug event prioritization

The following are synchronous debug events:

- Breakpoint debug event.
- Watchpoint debug event.
- Halting Step debug event.
- Halt Instruction debug event.
- Exception Catch debug event.
- Software Access debug event.
- Reset Catch debug event.

Each of these synchronous debug events are treated as a synchronous exception generated by an instruction, or by the taking of an exception or reset. That is, if halting is allowed, the synchronous debug event must be taken before any subsequent instructions are executed. Reset Catch debug events must be taken before the PE executes the instruction at the reset vector.

Note

- Reset Catch and Exception Catch debug events might be generated asynchronously, because they can result from an asynchronous exception. However, if halting is allowed after the reset or asynchronous exception has been processed, the Reset Catch or Exception Catch debug event is taken synchronously.
 - The Halting Step debug event is generated by the instruction after the stepped instruction. Therefore, if the stepped instruction generates any other synchronous exceptions or debug events these are taken first.
-

If halting is prohibited then Halting Step debug events and Reset Catch debug events might be pended and taken asynchronously. OS Unlock Catch debug events are always pended and taken asynchronously. See [Pending Halting debug events](#).

The architecture does not define when asynchronous debug events are taken, and therefore the prioritization of asynchronous debug events is IMPLEMENTATION DEFINED. See [Synchronization and Halting debug events](#).

The following list shows how the synchronous debug events are prioritized, with 1 being the highest priority.

Note

The priority numbering is the same as the numbering for AArch64 synchronous exception priorities listed in [Synchronous exception types](#), and in particular [Prioritization of asynchronous exceptions](#).

The priority for synchronous debug events is as follows:

- | | |
|---|--|
| 1 | Reset Catch debug event. See Reset Catch debug events .

This debug event has a higher priority than the synchronous exceptions listed in Synchronous exception types . |
| 2 | Exception Catch debug event if it has a priority of 2. See Exception Catch debug event .

This debug event can be assigned one of two priorities, 2 or 5. When it has a priority of 2, it has a higher priority than the synchronous exceptions listed in the Exception model. |
| 3 | Halting Step debug event. See Halting Step debug events .

This debug event has a higher priority than the synchronous exceptions listed in the Exception model. |

4	This event is not a debug event.
5	Exception Catch debug event if it has a priority of 5. See Exception Catch debug event . This debug event can be assigned one of two priorities, 2 or 5.
6-9	These events are not debug events.
10	Breakpoint debug events. See Breakpoint and Watchpoint debug events .
11-13	These events are not debug events.
14	Halt Instruction debug event. See Halt Instruction debug event .
15-40	These events are not debug events.
41	Software Access debug event. See Software Access debug event .
42-46	These events are not debug events.
47	Watchpoint debug events. See Breakpoint and Watchpoint debug events .
48-49	These events are not debug events.

For Reset Catch debug events and Halting Step debug events, the priorities listed in this section apply only when halting is allowed at the time the event is generated. This means that the event is taken synchronously and not pended.

For more information on the prioritization of exceptions, see:

- [Synchronous exception types](#).
- [Prioritization of asynchronous exceptions](#).

E2.2.6 Imprecise entry to Debug state

Debug state entry is normally *precise*. This means that the PE cannot enter Debug state if it can neither complete nor abandon all currently executing instructions and leave the PE in a precise state. See [Definition of a precise exception and imprecise exception](#).

A debugger can write a value of 1 to [EDRCCR.CBRRQ](#) to allow imprecise entry to Debug state. An External Debug Request debug event must be pending before writing 1 to this bit. If 1 is written when an External Debug Request debug event is not pending, and the PE does not ignore the write, then the resulting PE behavior is UNPREDICTABLE. Support for allowing imprecise entry to Debug state using [EDRCCR.CBRRQ](#) is OPTIONAL, and it is IMPLEMENTATION DEFINED when this mechanism is effective at forcing entry to Debug state.

The PE ignores writes to [EDRCCR.CBRRQ](#) if any of the following apply:

- `ExternalInvasiveDebugEnabled() == FALSE`.
- Any IMPLEMENTATION DEFINED reason.

Arm recommends that the PE ignores writes to [EDRCCR.CBRRQ](#) when an External Debug Request debug event is not pending.

If forcing this PE to enter Debug state imprecisely could have an adverse effect on the wider system, then Arm recommends that a write to [EDRCCR.CBRRQ](#) is ignored if the highest level of debug authentication is not enabled at the system level.

[Example E2-1](#) shows how entry to Debug state can be forced.

Example E2-1 Forcing entry to Debug state

The debugger pends an External Debug Request debug event through the CTI to halt a program that has stopped responding. However, the memory system is not responding and a memory access instruction cannot complete. This means that Debug state cannot be entered precisely. The debugger writes a value of 1 to [EDRCCR.CBRRQ](#). The PE cancels all outstanding memory accesses and enters Debug state. As some instructions might not have completed correctly, entry to Debug state is imprecise.

When Debug state is entered imprecisely, all memory access instructions executed through the ITR have **CONSTRAINED UNPREDICTABLE** behavior. The value of all registers is **UNKNOWN**, but might be useful for diagnostic purposes.

E2.2.7 Summary of actions from debug events

[Table E2-1](#) shows the Software and Halting debug events. In [Table E2-1](#), the columns have the following meaning:

Debug event type

This means the type of debug event where:

Other software Means one of:

- [Software Step exceptions](#).
- [Breakpoint Instruction exceptions](#).

Other Halting Means one of the following:

- [Halting Step debug events](#).
- [External Debug Request debug event](#).
- [Reset Catch debug events](#).
- [OS Unlock Catch debug event](#).

Other debug events are referred to explicitly.

Authentication

This means halting is allowed by the **IMPLEMENTATION DEFINED** external authentication interface. It is the result of [ExternalSecureInvasiveDebugEnabled\(\)](#).

DLK This indicates whether [FEAT_DoubleLock](#) is implemented and locked, [DoubleLockStatus\(\)](#) == TRUE.

OSLK This is the value of [OSLSR_EL1.OSLK](#). It indicates whether the OS Lock is locked.

HDE This is the value of [EDSCR.HDE](#). It indicates whether Halting debug is enabled.

The letter X in [Table E2-1](#) indicates that the value can be either 0 or 1.

Table E2-1 Debug authentication for external debug

Debug event type	Authentication	DLK	OSLK	HDE	Behavior
Other software	X	X	X	X	Handled by the Exception model
Breakpoint or Watchpoint debug event	X	TRUE	X	X	Handled by the Exception model (ignored)

Debug event type	Authentication	DLK	OSLK	HDE	Behavior
	X	FALSE	1	X	Handled by the Exception model (ignored)
	FALSE	FALSE	0	X	Handled by the Exception model
	TRUE	FALSE	0	0	Handled by the Exception model
	TRUE	FALSE	0	1	Entry to Debug state
Halt Instruction debug event	FALSE	X	X	X	UNDEFINED
	TRUE	TRUE	X	X	UNDEFINED
	TRUE	FALSE	X	0	UNDEFINED
	TRUE	FALSE	X	1	Entry to Debug state
Exception Catch debug event	FALSE	X	X	X	Might be pended ^a
	TRUE	TRUE	X	X	Ignored
	TRUE	FALSE	X	X	Entry to Debug state
Software Access debug event	FALSE	X	X	X	Ignored
	TRUE	TRUE	X	X	Ignored
	TRUE	FALSE	1	X	Ignored
	TRUE	FALSE	0	X	Entry to Debug state
Other Halting	FALSE	X	X	X	Debug event is pended
	TRUE	TRUE	X	X	Debug event is pended
	TRUE	FALSE	X	X	Entry to Debug state

a. See [Exception Catch debug event](#).

E2.2.8 Pseudocode description of Halting on debug events

The `Halted()`, `Restarting()`, `HaltingAllowed()`, and `HaltOnBreakpointOrWatchpoint()` functions are described in the pseudocode.

E2.3 Entering Debug state

On entry to Debug state, the preferred restart address and [PSTATE](#) are saved in [DLR_EL0](#) and [DSPSR_EL0](#). The PE remains in the mode and Security state from which it entered Debug state.

If [EDRCR.CBRRQ](#) has a value of 0, entry to Debug state is precise. If [EDRCR.CBRRQ](#) has a value of 1, then imprecise entry to Debug state is permitted.

If a Watchpoint debug event causes an entry to Debug state, the PE records all of the following:

- When [FEAT_EDHSR](#) is not implemented or the PE sets [EDHSR.FnV](#) to 0, the address of the access that generated the Watchpoint debug event is recorded in [EDWAR](#).

For more information, see:

- [Exception syndrome information, fault address information, and preferred return address](#) for a debug event taken from AArch64 state.

Other than the effect on [PSTATE](#) and [EDSCR](#), entry to Debug state is not a [Context Synchronization event](#). The effects of entry to Debug state on [PSTATE](#) and [EDSCR](#) are synchronized.

E2.3.1 Effect of Debug state entry on DLR and DSPSR

[DLR_EL0](#) is set to the preferred restart address for the debug event, which depends on the event type. The value of [PSTATE](#) is saved in [DSPSR_EL0](#).

For synchronous Halting debug events, the preferred restart address is the address of the instruction that generated the debug event.

For asynchronous Halting debug events, including pending Halting debug events taken asynchronously, the preferred restart address is the address of the first instruction that must be executed on exit from Debug state.

This means that:

- For Breakpoint and Watchpoint debug events, the preferred restart address is the same as the preferred return address for a debug exception, as described in [AArch64 Self-hosted Debug](#).
 - For Halt Instruction debug events, [DLR_EL0](#) is set to the address of the [HLT](#) instruction and [DSPSR_EL0.IT](#) is correct for the [HLT](#) instruction.
 - For Software Access debug events, [DLR_EL0](#) is set to the address of the accessing instruction and [DSPSR_EL0.IT](#) is correct for this instruction.
 - For Halting Step debug events taken synchronously, [DLR_EL0](#) and [DSPSR_EL0](#) are set as the ELR and SPSR would be set for a Software Step exception. This is usually the address of, and [PSTATE](#) for, the instruction after the one that was stepped.
 - For Exception Catch debug events, [DLR_EL0](#) is set to the address of the first instruction that must be executed on exit from Debug state, and [DSPSR_EL0](#) is correct for this instruction. This is the exception vector or reset vector address.
 - If the debug event is generated on taking an exception to a trapped Exception level, the [DLR_EL0](#) is set to the address of the exception vector the PE would have started fetching from. This is UNKNOWN if the VBAR for the Exception level has never been initialized. The [DSPSR_EL0](#) records the value of [PSTATE](#) after taking the exception. The Exception Catch occurs after the SPSR and the Link register are set, and the debugger can use these registers to determine where in the application program the exception occurred.
-
- Note**
-
- Depending on the target Exception level and Execution state for the exception, the Link register is one of [ELR_EL1](#), [ELR_EL2](#) or LR (R14).
-
- If the debug event is generated on an exception return to a trapped Exception level, the [DLR_EL0](#) is set to the target address of the exception return and the [DSPSR_EL0](#) records the value of [PSTATE](#) after the exception return.
 - Reset Catch debug events taken synchronously behave like Exception Catch debug events.

- For Reset Catch debug events and Exception Catch debug events generated on reset to a trapped Exception level, the [DLR_EL0](#) is set to the reset address and the [DSPSR_EL0](#) records the reset value of [PSTATE](#).
- For pending Halting debug events and External Debug Request debug events, [DLR_EL0](#) is set to the address of the first instruction that must be executed on exit from Debug state. See [Pending Halting debug events](#).

Normally [DLR_EL0](#) is aligned according to the instruction set state indicated in [DSPSR_EL0](#). However, a debug event might be taken at a point where the PC is not aligned.

E2.3.2 Effect of Debug state entry on System registers, the Event register, and Exclusives monitors

Entering Debug state has no effect on System registers other than [DLR_EL0](#) and [DSPSR_EL0](#). In particular, ESRs, FARs, and FSRs are not updated on entering Debug state.

Entering Debug state has no architecturally-defined effect on the Event Register and Exclusives monitors.

Entry to Debug state might set the Event Register or clear the Exclusives monitors, or both. However, this is not a requirement, and debuggers must not rely on any IMPLEMENTATION SPECIFIC behavior.

Unless otherwise described in this reference manual, instructions executed in Debug state have their architecturally-defined effects on the System registers, the Event register, and Exclusives monitors.

E2.3.3 Effect of entering Debug state on PSTATE

The effect of an entry to Debug state on [PSTATE](#) is described in [Entering Debug state](#).

On entry to Debug state after [PSTATE](#) is saved in [DSPSR_EL0](#):

- [PSTATE](#).IL is cleared to 0.
- [PSTATE](#).{SS, D, A, I, F, SSBS} are set to UNKNOWN values.

[PSTATE](#).{N, Z, C, V, Q, M, nRW, EL, SP, PAN, DIT} are unchanged.

For more information, see [PSTATE in Debug state](#).

E2.3.4 Entering Debug state during loads and stores

The PE can enter Debug state during instructions that perform a sequence of memory accesses, as opposed to a single single-copy atomic access, because of a Watchpoint debug event. The effect of entering Debug state on such an instruction is the same as taking a Data Abort exception during such an instruction.

In addition, the PE can enter Debug state because of an External Debug Request debug event during instructions that perform a sequence of memory accesses. The effect of entering Debug state on such an instruction is the same as taking an interrupt exception during such an instruction.

This applies to all memory types.

E2.3.5 Entering Debug state and Software Step

When Software Step is active, a debug event that causes entry to Debug state behaves like an exception taken to an Exception level above the debug target Exception level. That is:

- If the instruction that is stepped generates a synchronous debug event that causes entry to Debug state, or an asynchronous debug event is taken before the step completes, the PE enters Debug state with [DSPSR_EL0](#).SS set to 1.
- A pending Halting debug event or an asynchronous debug event can be taken after the step has completed. In this case the PE enters Debug state with [DSPSR_EL0](#).SS set to 0.

In addition:

- If the instruction that is stepped generates an exception trapped by an Exception Catch debug event, the PE enters Debug state at the exception vector with [DSPSR_EL0.SS](#) set to 0. This is because [PSTATE.SS](#) is set to 0 by taking the exception.
- If the PE is reset, [PSTATE.SS](#) is reset to 0. If the following debug events are enabled, and halting is allowed, the PE enters Debug state with [DSPSR_EL0.SS](#) set to 0:
 - Reset Catch debug event at the reset Exception level.
 - Exception Catch debug event at the reset Exception level.
 - Halting Step debug event.
- If Halting Step is also active, then Halting Step and Software Step operate in parallel and can both become active-pending. In this case Halting step has a higher priority than Software step. This means that the PE enters Debug state and [DSPSR_EL0.SS](#) is set to 0.

E2.3.6 Pseudocode description of entering Debug state

The `DebugHalt` constants are described in [shared/debug/halting/DebugHalt](#) in the pseudocode. The [UpdateEDSCRFields\(\)](#) and [Halt\(\)](#) functions are described in [R-profile Architecture Pseudocode](#).

E2.4 Behavior in Debug state

Instructions are executed in Debug state from the Instruction Transfer Register, ITR. The debugger controls which instructions are executed in Debug state by writing the instructions to the External Debug Instruction Transfer register, [EDITR](#).

Some instructions are available only in Debug state. See [Debug state operations, DCPS, DRPS, MRS, MSR](#). In Non-debug state these instructions are UNDEFINED.

The following sections describe behavior in Debug state:

- [PSTATE in Debug state](#).
- [Executing instructions in Debug state](#).
- [Decode tables](#).
- [Security in Debug state](#).
- [Privilege in Debug state](#).
- [Debug state operations, DCPS, DRPS, MRS, MSR](#).
- [Exceptions in Debug state](#).
- [Accessing registers in Debug state](#).
- [Accessing memory in Debug state](#).

This section specifies the CONSTRAINED UNPREDICTABLE behaviors that apply in Debug state, but see [Changing the value of EDECR.SS when not in Debug state](#) for a change in Non-debug state that causes CONSTRAINED UNPREDICTABLE behavior.

E2.4.1 PSTATE in Debug state

[PSTATE](#).{N, Z, C, V, Q, SS, SSBS, D, A, I, F, PM} are all ignored in Debug state:

- There are no conditional instructions in Debug state.
- Software step is inactive.
- Asynchronous exceptions and debug events are ignored.
- If [FEAT_SSBS](#) is implemented, then hardware is permitted to load or store speculatively, regardless of the value of [PSTATE.SSBS](#).

Instructions executed in Debug state indirectly read [PSTATE](#).{PAN, IL, nRW, EL, SP} as they would in Non-debug state.

Note

[PSTATE.DIT](#) is not guaranteed to have any effect in Debug state.

In Debug state:

- [PSTATE.PAN](#) is set to 1 by:
 - A [DCPS<n>](#) instruction to EL1 using AArch64 if [SCTLR_EL1.SPAN](#) == 0.
 - A [DCPS<n>](#) instruction to EL2 using AArch64 if [SCTLR_EL2.SPAN](#) == 0.
- [PSTATE.UAO](#) is set to 0 by a [DCPS<n>](#) instruction to AArch64 state.
- If [FEAT_SSBS](#) is implemented, the [DCPS<n>](#) instruction leaves the [PSTATE.SSBS](#) bit UNKNOWN.

[PSTATE](#) can also be changed by taking exceptions in Debug state, and by the execution of [DCPS<n>](#) and [DRPS](#) instructions.

E2.4.2 Executing instructions in Debug state

The instructions executed in Debug state must be either A64 instructions, depending on the current Execution state.

Each instruction falls into one of the following groups:

- Debug state instructions. These are instructions that are changed in Debug state. See [A64 instructions that are changed in Debug state](#).
- Instructions that are unchanged in Debug state. See [A64 instructions that are unchanged in Debug state](#). Where these sections describe the behavior of an instruction as unchanged in Debug state, or having the same behavior as in Non-debug state, and that instruction would generate an exception in Non-debug state, then the behavior of the exception is as described in [Exceptions in Debug state](#).
- Instructions that are UNPREDICTABLE or CONSTRAINED UNPREDICTABLE in Debug state. See [A64 instructions that are CONSTRAINED UNPREDICTABLE in Debug state](#).

If $EDSCR.SDD = 1$, then an exception from Non-secure state is never taken to Secure state.

See [Security in Debug state](#).

E2.4.2.1 Executing A64 instructions in Debug state

The following sections describe the behavior of the A64 instructions in Debug state:

- [A64 instructions that are changed in Debug state](#).
- [A64 instructions that are unchanged in Debug state](#).
- [A64 instructions that are CONSTRAINED UNPREDICTABLE in Debug state](#).

E2.4.2.1.1 A64 instructions that are changed in Debug state

The following instructions are defined in Debug state, but are UNDEFINED in Non-debug state:

- DCPS.

Note

DCPS can be UNDEFINED in certain conditions in Debug state. See [DCPS<n>](#).

- DRPS.
- MRS ([DLR_EL0](#)), MRS ([DPSR_EL0](#)), MSR ([DLR_EL0](#)), MSR ([DPSR_EL0](#))

For more information, see [Debug state operations](#), [DCPS](#), [DRPS](#), [MRS](#), [MSR](#).

E2.4.2.1.2 A64 instructions that are unchanged in Debug state

The following list shows the instructions that are unchanged in Debug state:

Any instruction that is UNDEFINED in Non-debug state

This list of instructions excludes:

- Any instruction listed in [A64 instructions that are changed in Debug state](#).
- Any instruction listed in [A64 instructions that are CONSTRAINED UNPREDICTABLE in Debug state](#) that is UNDEFINED because an enable or disable bit is not RES0 or RES1

Instructions that move System or Special-purpose registers to or from a general-purpose register

This list of instructions:

- Includes the instructions to transfer a general-purpose register to or from the DTR, which can be executed at any Exception level.
- Excludes [PSTATE](#) access instructions.

These instructions are:

- MRS <special_reg>, MSR <special_reg>.

Note

This does not include NZCV, DAIF, DAIFSet, DAIFClr, SPSel, CurrentEL, PAN, UAO and DIT.

- MRS <system_reg>, MSR <system_reg>.

Floating-point moves between a SIMD&FP register and a general-purpose register

These instructions are:

- FMOV (between a general-purpose register and a half-precision register).
- FMOV (between a general-purpose register and a single-precision register).
- FMOV (between a general-purpose register and a double-precision register).
- FMOV (between a general-purpose register and a SIMD element).

SIMD moves between a SIMD&FP register and a general-purpose register

These instructions are:

- INS (from a general-purpose register to a SIMD element).
- UMOV (from a SIMD element to a general-purpose register).

Barriers

These instructions are:

- DMB.
- DSB.
- ISB.
- CSDB.
- SSBB.
- PSSBB.
- If [FEAT_SB](#) is implemented, then SB.

Memory access instructions at various access sizes

The following constraints apply:

- General purpose-registers only.
- One of the following addressing modes:
 - Unscaled (9-bit signed) immediate offset.
 - Immediate (9-bit signed) post-indexed.
 - Immediate (9-bit signed) pre-indexed.
 - Unprivileged (9-bit signed).
- Not literal.
- One of the following types:
 - (Single) register.
 - Exclusive.
 - Exclusive pair.
 - Acquire/Release.
 - Acquire/Release Exclusive.
 - Acquire/Release Exclusive pair.
- 32-bit and 64-bit target register variants.

These instructions are:

- LDR, LDRB, LDRH, LDRSB, LDRSH, LDRSW (immediate, not literal).
- LDUR, LDURB, LDURH, LDURSB, LDURSH, LDURSW (immediate).
- LDTR, LDTRB, LDTRH, LDTRSB, LDTRSH, LDTRSW (immediate).
- LDAR, LDARB, LDARH, LDXR, LDXRB, LDXRH, LDAXR, LDAXRB, LDAXRH.
- LDXP, LDAXP.

- STR, STRB, STRH (immediate).
- STUR, STURB, STURH (immediate).
- STTR, STTRB, STTRH (immediate).
- STL, STLB, STLRH, STXR, STXRB, STXRH, STLXR, STLXRB, STLXRH.
- STXP, STLXP.
- If FEAT_LOR is implemented, then:
 - LDLAR, LDLARB, LDLARH.
 - STLLR, STLLRBB, STLLRH.
- If FEAT_LSE is implemented, then:
 - CAS, CASB, CASH, CASP.
 - SWP, SWPB, SWPH.
 - LDADD, LDADDB, LDADDH.
 - LDCLR, LDCLRB, LDCLRH.
 - LDEOR, LDEORB, LDEORH.
 - LDSET, LDSETB, LDSETH.
 - LDSMAX, LDSMAXB, LDSMAXH.
 - LDSMIN, LDSMINB, LDSMINH.
 - LDUMAX, LDUMAXB, LDUMAXH.
 - LDUMIN, LDUMINB, LDUMINH.
 - STADD, STADDB, STADDH.
 - STCLR, STCLB, STCLRH.
 - STEOR, STEORB, STEORH.
 - STSET, STSETB, STSETH.
 - STSMAX, STSMAXB, STSMAXH.
 - STSMIN, STSMINB, STSMINH.
 - STUMAX, STUMAXB, STUMAXH.
 - STUMIN, STUMINB, STUMINH.
- If FEAT_LRCPC is implemented, then LDAPR, LDAPRB, LDAPRH.
- If FEAT_LRCPC2 is implemented, then:
 - LDAPURH, LDAPURSH, LDAPUR, LDAPURSW, LDAPURSB, LDAPURB.
 - STLUR, STLURH, STLURB.

Move immediate to general-purpose register

These instructions are:

- MOVZ, MOVN, MOVK (immediate).
- MOV (between a general-purpose register and the stack pointer).

System instructions, Send Event, NOP, Clear Exclusive, and Prediction

In this context, the System instructions are the Cache maintenance instructions, TLB maintenance instructions, Address translation instructions, the prediction restriction instructions, and the check feature instruction.

These instructions are:

- IC.
- DC.
- TLBI.
- AT.
- SEV, SEVL.
- NOP.
- CLREX.
- CFP.
- CPP.
- DVP.

Pointer authentication instructions

These instructions are:

- If [FEAT_PAuth](#) is implemented, then:
 - [AUTIA](#), [AUTIAZ](#), [AUTIZA](#).
 - [AUTIB](#), [AUTIBZ](#), [AUTIZB](#).
 - [AUTDA](#), [AUTDZA](#).
 - [AUTDB](#), [AUTDZB](#).
 - [PACIA](#), [PACIAZ](#), [PACIZA](#).
 - [PACIB](#), [PACIBZ](#), [PACIZB](#).
 - [PACDA](#), [PACDZA](#).
 - [PACDB](#), [PACDZB](#).
 - [PACGA](#).
 - [XPACD](#), [XPACI](#), [XPACLRI](#).

E2.4.2.1.3 A64 instructions that are **CONSTRAINED UNPREDICTABLE** in Debug state

This subsection describes all instructions that are not listed in either:

- [A64 instructions that are changed in Debug state](#).
- [A64 instructions that are unchanged in Debug state](#).

These instructions are **CONSTRAINED UNPREDICTABLE** in Debug state. In general, the permissible behaviors are:

- The instruction is **UNDEFINED**.
- The instruction executes as a **NOP**.
- If the instruction reads the PC or [PSTATE](#), it uses an **UNKNOWN** value.
- If the instruction modifies the PC or [PSTATE](#), other than by advancing the PC to the sequentially next instruction, it sets [DLR_EL0](#) and [DPSR_EL0](#) to **UNKNOWN** values.
- If the instruction is similar to a Debug state instruction, it executes as that Debug state instruction.
- The instruction has the same behavior as in Non-debug state.

The following list shows the permissible behaviors for A64 instruction in Debug state. An instruction might appear multiple times in the list, in which case the choice of permissible behaviors is any of those listed. An example of this is [CCMP](#).

Exception-generating instructions

These instructions are:

- [SVC](#).
- [HVC](#).
- [SMC](#).
- [BRK](#).
- [HLT](#).

These instructions behave in one of the following ways:

- They are **UNDEFINED**.
- They execute as a **NOP**.
- [SVC](#) behaves as [DCPS1](#).
- [HVC](#) behaves as [DCPS2](#).
- They generate the exception that the instruction would generate in Non-debug state. The exception is taken as described in [Exceptions in Debug state](#).

Instructions that explicitly write to the PC (branches)

These instructions are:

- B, B.cond, BL, BLR, BR, CBZ, CBNZ, RET, TBZ, TBNZ.
- If [FEAT_PAuth](#) is implemented, then RETAA, RETAB, BRAA, BRAB, BLRAA, BLRAB, BLRAAZ, BLRABZ.

These instructions behave in one of the following ways:

- They are UNDEFINED.
- They execute as a NOP.
- They execute as in Non-debug state without branching and set [DPSR_EL0](#) and [DLR_EL0](#) to UNKNOWN values.

Exception return and related instructions

These instructions are:

- ERET.
- If [FEAT_PAuth](#) is implemented, then ERETAA, ERETAB.

These instructions behave in one of the following ways:

- They are UNDEFINED.
- They execute as a NOP.
- They execute as in Non-debug state without branching, set [DPSR_EL0](#) and [DLR_EL0](#) to UNKNOWN values, and either:
 - Execute the DRPS operation instead of performing an exception return, using UNKNOWN SPSR values.
 - Do not change the Exception level.

Instructions that request entry to a low-power state

These instructions are WFE, WFI.

These instructions behave in one of the following ways:

- They are UNDEFINED.
- They execute as a NOP.
- They generate a synchronous exception if the corresponding instruction would be trapped in Non-debug state. See [Configurable instruction controls](#).
- A WFE instruction clears the Event register if it is set.

Note

This means that these instructions must not suspend execution.

Instructions that read the PC

These instructions are:

- LDR (literal), LDRSW (literal).
- ADR, ADRP.
- PRFM (literal).

These instructions behave in one of the following ways:

- They are UNDEFINED.
- They execute as a NOP.
- They execute as in Non-debug state, using an UNKNOWN value for the PC operand.

Instructions that explicitly modify [PSTATE](#), other than DCPS and DRPS

These instructions are:

- ADDS, SUBS, ADCS, SBCS, ANDS, BICS, CCMN, CCMP.
- FCMP, FCMPE, FCCMP, FCCMPE.

- MSR DAIFSet (immediate), MSR DAIFClr (immediate), MSR SPSEL (immediate).
- MSR NZCV (register), MSR DAIF (register), MSR SPSEL (register).
- If FEAT_PAN is implemented, then:
 - MSR PAN (immediate).
 - MSR PAN (register).
- If FEAT_UAO is implemented, then:
 - MSR UAO (immediate).
 - MSR UAO (register).
- If FEAT_FlagM is implemented, then:
 - CFINV.
 - RMIF.
 - SETF8.
 - SETF16.
- If FEAT_DIT is implemented, then MSR DIT.

These instructions behave in one of the following ways:

- They are UNDEFINED.
- They execute as a NOP.
- They execute as in Non-debug state, setting DSPSR_ELO and DLR_ELO to UNKNOWN values.
- For the PACM instruction, PSTATE.PACM is set to an UNKNOWN value.

Instructions that read PSTATE.{N, Z, C, V} or other PSTATE fields

These instructions are:

- CSEL, CSINC, CSINV, CSNEG, CCMN, CCMP, FCSEL, FCCMP, FCCMPE.
- ADC, ADCS, SBC, SBCS.
- MRS NZCV, MRS DAIF, MRS SPSEL, MRS CurrentEL.
- If FEAT_PAN is implemented, then MRS PAN.
- If FEAT_UAO is implemented, then MRS UAO.
- If FEAT_FlagM is implemented, then CFINV.
- If FEAT_DIT is implemented, then MRS DIT.

These instructions behave in one of the following ways:

- They are UNDEFINED.
- They execute as a NOP.
- They execute as in Non-debug state:
 - For the conditional operations and those that use Condition flags as an input, these instructions use UNKNOWN values for the Condition flag.
 - For the MRS instruction, they return an UNKNOWN value.
 - For the RCW and RCWS instructions, they return an UNKNOWN value.
 - For the PACIASP and PACIBSP instructions when PSTATE.PACM is 1, they use an UNKNOWN value for the PC operand.

Hint instructions

If FEAT_DGH is implemented, then this instruction is:

- DGH.

This instruction behaves in one of the following ways:

- It executes as a NOP.
- It executes as in Non-debug state.

All other instructions

These instructions behave in one of the following ways:

- They are UNDEFINED.
- They execute as a NOP.
- They execute as in Non-debug state.

Note

This includes instructions defined as UNPREDICTABLE or CONSTRAINED UNPREDICTABLE in Non-debug state. These instructions are UNPREDICTABLE or CONSTRAINED UNPREDICTABLE in Debug state.

E2.4.3 Decode tables

The syntax in the decode tables is defined as follows:

1	The bit has a fixed value of 1.
0	The bit has a fixed value of 0.
!=	The field has any value other than the value or values specified. The field might be an encoding field in the instruction whose value is supplied by the debugger.

Note

The instruction encodings in [A64 Base Instruction Descriptions](#) might show these bits as (0) or (1). A debugger must set these bits to 0 or 1, as appropriate.

Any other value indicates an encoding field in the instruction whose value is supplied by the debugger. Some values might be reserved or UNDEFINED, in which case the instruction is UNDEFINED or CONSTRAINED UNPREDICTABLE in Debug state, as it is in Non-debug state.

For more information about the instruction encodings, see [A64 Base Instruction Descriptions](#).

For information about the syntax used in [Figure E2-1](#), and [Figure E2-2](#) see:

- [Common syntax terms](#).
- Assembler symbols.

E2.4.3.1 A64 instructions that are modified in Debug state

Figure E2-1 shows the A64 instructions that are modified in Debug state. For information of how these are packed in the EDITR, see the register description.

E2.4.4 Security in Debug state

On entry to Debug state

`EDSCR.SDD` is the Secure debug disabled flag. If entering Debug state from Secure state, `EDSCR.SDD` is set to 0.

Note

If halting is prohibited in a Security state, it is not possible to enter Debug state from that Security state. However, because changes to the authentication signals require a [Context Synchronization event](#) to guarantee their effect, there is a period during which the PE might halt even though the authentication signals prohibit halting.

In Debug state

The value of `EDSCR.SDD` does not change, even if `ExternalSecureInvasiveDebugEnabled()` changes.

Note

- `DBGAUTHSTATUS_EL1` is not frozen in Debug state. However, a Context Synchronization event is required to guarantee that changes are visible in `DBGAUTHSTATUS_EL1`.
 - If `EDSCR.SDD` is 1 in Debug state, there is no means to enter a Security state where halting was prohibited on entry to Debug state. This means that it is not possible for the PE to be in such a Security state when `EDSCR.SDD` is 1. This is a general principle of behavior in Debug state.
-

In Non-debug state

`EDSCR.SDD` returns the inverse of `ExternalSecureInvasiveDebugEnabled()`. If the authentication signals that control `ExternalSecureInvasiveDebugEnabled()` change, a [Context Synchronization event](#) is required to guarantee their effect.

Note

- A [Context Synchronization event](#) is also required to guarantee that changes in the authentication signals are visible in `DBGAUTHSTATUS_EL1`.
-

E2.4.5 Privilege in Debug state

The only additional privileges offered to Debug state are:

- The privilege to execute [Debug state operations, DCPS, DRPS, MRS, MSR](#).
- The privilege to execute DTR access instructions regardless of the Exception level and traps.

The DTR access instructions can be executed at any Exception level, including EL0, regardless of any control register settings that might force these instructions to be UNDEFINED or trapped in Non-debug state. These instruction are:

- The MRS and MSR instructions that access [DBGDTR_EL0](#), [DBGDTRTX_EL0](#), and [DBGDTRRX_EL0](#) in AArch64 state.

All other instructions operate with the privilege determined by the current Exception level and Security state. This applies to all Special-purpose and System registers accesses, memory accesses, and UNDEFINED instructions, and includes generating exceptions when the System registers trap or disable an instruction.

E2.4.6 Debug state operations, DCPS, DRPS, MRS, MSR

The architecture defines operations to change between Exception levels in Debug state. These operations can also change the mode at the current Exception level.

E2.4.6.1 DCPS<n>

Executing a DCPS<n> instruction in Debug state moves the PE to a higher Exception level.

The effect on endianness is the same as for exceptions and exception returns in Non-debug state. In AArch64 state the current endianness is determined by the value of SCTL_R_EL_x.EE for the target Exception level.

The DCPS<n> instructions are:

In AArch64 state

- [DCPS1](#)
- [DCPS2](#)
- [DCPS3](#)

The DCPS instructions are UNDEFINED in Non-debug state.

[Table E2-2](#) shows the target of the instruction. In [Table E2-2](#), the entries have the following meaning:

EL1h/Svc This means that the target is EL1h.

EL2h/Hyp This means that the target is EL2h.

Table E2-2 Target for DCPS instructions in Debug state

Instruction	Target when DCPS instruction executed at stated Exception level:		
	EL0	EL1	EL2
DCPS1	EL1h	EL1h	EL2h
DCPS2	EL2h	EL2h	EL2h
DCPS3	•	•	•

However:

- [DCPS1](#) is UNDEFINED at EL0 if EL2 is implemented and [HCR_EL2.TGE](#) == 1.
- [DCPS3](#) is UNDEFINED at all Exception levels.

On executing a [DCPS](#) instruction:

- If the target Exception level is using AArch64:
 - [ELR_ELx](#) of the target Exception level becomes UNKNOWN.
 - [SPSR_ELx](#) of the target Exception level becomes UNKNOWN.
 - [ESR_ELx](#) of the target Exception level becomes UNKNOWN.
 - [DLR_EL0](#) and [DPSPR_EL0](#) become UNKNOWN.

The [DCPSInstruction\(\)](#) function is described in [A-profile Architecture Pseudocode](#).

E2.4.6.2 DRPS

Executing the DRPS operation in Debug state moves the PE to a lower Exception level, or the current Exception level, by copying the current SPSR to [PSTATE](#).

If the target Exception level is the current Exception level, then the PE does not change Exception level.

The effect on endianness is the same as for exceptions and exception returns in Non-debug state.

Current endianness is set according to the Effective values of [SCTLR_ELx.EE](#), or [SCTLR_EL1.E0E](#) for the target Exception level.

For more information see [DRPS](#).

If the SPSR specifies an illegal exception return, then [PSTATE](#).{nRW, EL, SP} are unchanged and [PSTATE](#).IL is set to 1. For further information on illegal exception returns, see [Illegal exception returns from AArch64 state](#).

Some [PSTATE](#) fields are ignored in Debug state. The effect of the DRPS operation on them is to set them to an UNKNOWN value that might be the value from the SPSR. For more information, see [PSTATE in Debug state](#).

All other [PSTATE](#) fields are copied from SPSR.

[DRPS](#) is UNDEFINED at EL0 and in Non-debug state.

Unlike an exception return, the [DRPS](#) operation has no architecturally-defined effect on the Event Register and Exclusives monitors. [DRPS](#) might set the Event Register or clear the Exclusives monitors, or both, but this is not a requirement and debuggers must not rely on any IMPLEMENTATION SPECIFIC behavior.

On executing a [DRPS](#) instruction, then [DLR_EL0](#) and [DPSPR_EL0](#) become UNKNOWN.

The [DRPSInstruction\(\)](#) function is described in [R-profile Architecture Pseudocode](#).

E2.4.6.3 MRS and MSR

The other Debug state instructions are used to read or write [DLR_EL0](#) and [DPSPR_EL0](#).

These instructions are:

In AArch64 state

- [MRS](#)
- [MSR \(register\)](#)

[MRS](#) <Xt>, [DLR_EL0](#) ; Copy [DLR_EL0](#) to <Xt>

[MRS](#) <Xt>, [DPSPR_EL0](#) ; Copy [DPSPR_EL0](#) to <Xt>

[MSR](#) [DLR_EL0](#), <Xt> ; Copy <Xt> to [DLR_EL0](#)

[MSR](#) [DPSPR_EL0](#), <Xt> ; Copy <Xt> to [DPSPR_EL0](#)

These instructions can be executed at any Exception level when in Debug state, including EL0. They are UNDEFINED in Non-debug state.

E2.4.7 Exceptions in Debug state

The following sections describe how exceptions are handled in Debug state:

- [Generating exceptions when in Debug state.](#)
- [Taking exceptions when in Debug state.](#)
- [Reset in Debug state.](#)

E2.4.7.1 Generating exceptions when in Debug state

In Debug state:

- Instruction Abort exceptions cannot happen because instructions are not fetched from memory.
- Interrupts, including SError and virtual interrupts are ignored and remain pending:
 - The pending interrupt remains visible in [ISR_EL1](#).
- Debug exceptions and debug events are ignored.
- Any attempt to execute an instruction bit pattern that is an allocated instruction at the current Exception level, but is listed in [Executing instructions in Debug state](#) as UNDEFINED in Debug state, generates an exception. The priority and syndrome for these exceptions is the same as for executing an encoding that does not have an allocated instruction.

Otherwise, synchronous exceptions are generated as they would be in Non-debug state and taken to the appropriate Exception level in Debug state.

E2.4.7.2 Taking exceptions when in Debug state

When the PE is in Debug state, all exceptions are synchronous. When an exception is generated, it is taken to Debug state. This means that:

- The target Exception level is as defined for the exception in Non-debug state.
- The exception syndrome is reported as defined for the exception in Non-debug state, except for the case described in [Data Aborts in Memory access mode](#) for which the reporting requirements are relaxed. The exception syndrome is reported using the syndrome register or registers for the target Exception level. In AArch64 state, these are [ESR_ELx](#), and [FAR_ELx](#). For example, if an instruction is trapped to an Exception level using AArch64 due to a configurable trap, disable, or enable, the exception code reported is the same as it would be in Non-debug state.

The effect on auxiliary syndrome registers, such as AFSR, is IMPLEMENTATION DEFINED.

- The PE remains in Debug state and changes to the target mode.
- The endianness switches to that indicated by the EE bit of the System register for the target Exception level.
- The SPSR for the target Exception level or mode is corrupted and becomes UNKNOWN.
- If the target Exception level is using AArch64, [ELR_ELx](#) for the target Exception level becomes UNKNOWN.
- [DLR_EL0](#) and [DSPSR_EL0](#) become UNKNOWN.
- The cumulative error flag, [EDSCR.ERR](#), is set to 1. See [Cumulative error flag](#).
- [PSTATE.IL](#) is cleared to 0.
- [PSTATE](#).{IT, T, SS, D, A, I, F} are set to UNKNOWN values, and [PSTATE](#).{N, Z, C, V, Q, GE} are unchanged. However, these fields are ignored and are not observable in Debug state. For more information, see [PSTATE in Debug state](#).

The debugger must save any state that can be corrupted by an exception before executing an instruction that might generate another exception.

E2.4.7.3 Pseudocode description of taking exceptions in Debug state

[AArch64_TakeException\(\)](#) shows the behavior when the PE takes an exception to an Exception level using AArch64 in Non-debug state. In Debug state, this redirects to [AArch64_TakeExceptionInDebugState\(\)](#).

E2.4.7.4 Reset in Debug state

If the PE is reset when in Debug state, it exits Debug state and enters Non-debug reset state. When the PE is in reset state, `EDSCR.STATUS == 0b000010` and writes to `EDITR` are ignored.

Note

If `EDECR.RCE == 1` or `CTIDEVCTL.RCE == 1`, meaning that a Reset Catch debug event is programmed, and if halting is allowed on exiting reset state, then on exiting reset state the PE halts and reenters Debug state. See [Reset Catch debug events](#). All PE registers have taken their reset values, which might be UNKNOWN.

E2.4.8 Accessing registers in Debug state

Register accesses are unchanged in Debug state. The view of each register is determined by either the current Exception level or the mode, or both, and accesses might be disabled or trapped by controls at a higher Exception level.

E2.4.8.1 General-purpose register access, other than AArch64 state SP access

A single general-purpose register can be read by issuing an MSR instruction through the ITR to write `DBGDTR_EL0` in AArch64 state.

The debugger can then read the DTR register or registers through the external debug interface. The reverse sequence writes to a general-purpose register.

Figure E2-3 shows the reading and writing of general-purpose registers, other than SP, in Debug state in AArch64 state.

Figure E2-3 Reading and writing general-purpose registers, other than SP, in Debug state in AArch64 state

E2.4.8.2 PC and PSTATE access

The debugger reads the Program Counter and `PSTATE` of the process being debugged through the `DLR_EL0` and `DSPSR_EL0` System registers. The actual values of PC and `PSTATE` cannot be directly observed in Debug state:

- Instructions that are used for direct reads and writes of PC and `PSTATE` in Non-debug state are `CONSTRAINED UNPREDICTABLE` in Debug state.
- On taking an exception, `ELR_ELx` and `SPSR_ELx` at the target Exception level are `UNKNOWN`. They do not record the PC and `PSTATE`.

`PSTATE`. {UAO, PAN, IL, nRW, EL, M} are indirectly read by instructions executed in Debug state, but all other `PSTATE` fields are ignored and cannot be observed. See also:

- [PSTATE in Debug state.](#)
- [Executing instructions in Debug state.](#)
- [Exceptions in Debug state.](#)

E2.4.8.3 Other register accesses

To access other registers, the debugger can use the operations described in [General-purpose register access, other than AArch64 state SP access](#) and the operations described below to build a sequence of operations to move the registers to or from a general-purpose register.

To access a SIMD&FP, SP, or System register, the debugger can use an instruction from the following list to transfer the register to or from a general-purpose register:

- The `UMOV` instruction in AArch64 state for SIMD transfers from SIMD&FP registers.
- The `FMOV` instruction in AArch64 state for floating-point transfers to or from SIMD&FP registers.
- `MOV (to/from SP) SP, Xs` and `MOV (to/from SP) Xd, SP` instructions in AArch64 state for transfers to or from the SP register.
- `MSR`, `MSRR`, `MRRS`, and `MRS` instructions for transfers to or from System registers.

E2.4.9 Accessing memory in Debug state

How the PE accesses memory is unchanged in Debug state. This includes:

- The operation of the MMU and MPU, including address translation, access permissions, memory attribute determination, and the operation of any TLBs.
- The operation of any caches and coherency mechanisms.
- Alignment support.
- Endianness support.
- The Memory order model.
- The operation of the MPU, including access permissions and memory attribute determination.

E2.4.9.1 Simple memory transfers

Simple memory accesses can be performed in Debug state by issuing memory access instructions through the ITR and passing data through the DTR registers. [Executing instructions in Debug state](#) lists the memory access instructions that are supported in Debug state.

E2.4.9.2 Bulk memory transfers

Memory access mode can accelerate bulk memory transfers in Debug state. See [DCC and ITR access modes](#).

E2.5 Exiting Debug state

The PE exits Debug state when it receives a Restart request trigger event. If `EDSCR.ITE == 0`, when the PE receives a Restart Request trigger event, the behavior of any instruction issued through the ITR in Normal access mode or an operation issued by a DTR access in Memory access mode that has not completed execution is one of the following:

- The instruction completes execution in Debug state and the PE ignores the restart request and remains in Debug state.
- The instruction completes execution in Debug state before the PE executes the restart sequence.
- The instruction completes execution in Non-debug state after the PE executes the restart sequence.
- The instruction is abandoned. This means that the instruction does not execute. Any registers or memory accessed by the instruction are left in an UNKNOWN state.

Note

- Implementations can set `EDSCR.ITE` to 1 to indicate that further instructions can be accepted by ITR before the previous instructions have completed. If any previous instruction has not completed and `EDSCR.ITE == 1`, then the PE must complete these instructions in Debug state before executing the restart sequence. `EDSCR.ITE == 0` indicates that the PE is not ready to restart.
 - A debugger must observe that any instructions issued through `EDITR` that might generate a synchronous exception, as complete, before issuing a restart request. It can do this by observing the completion of a later instruction, as synchronous exceptions must occur in program order. For example, a debugger can observe that an instruction that reads or writes a DTR register is complete because of its effect on the `EDSCR.{TXfull, RXfull}` flags.
-

On exiting Debug state, the PE sets the Program Counter to the address in `DLR_EL0`, where:

- If exiting to AArch64 state:
 - Bits[63:56] of `DLR_EL0` might be ignored as part of tagged address handling. See [Address tagging](#).
 - Otherwise the PC is set from `DLR_EL0`.

Exit from Debug state can give rise to a PC alignment fault exception when the Program Counter is used. For more information, see [PC alignment checking](#).

On exiting Debug state, `PSTATE` is set from `DSPSR_EL0` in the same way that an exception return sets `PSTATE` from `SPSR_ELx`:

- The same illegal exception return checks that apply to an exception return also apply to exiting Debug state. If the return from Debug state is an illegal exception return then the effect on `PSTATE` and the PC is the same as for any other illegal exception return. See [Exception return](#).
- `PSTATE.SS` is copied from `DSPSR_EL0.SS` if all of the following hold:
 - `MDSCR_EL1.SS == 1`.
 - The debug target Exception level is using AArch64.
 - Software step exceptions from the restart Exception level are enabled.

Otherwise `PSTATE.SS` is set to 0.

Note

Unlike a return using `ERET`, `PSTATE.SS` must be restored from `DSPSR_EL0.SS` because otherwise it is UNKNOWN.

However, if `OSDLR_EL1.DLK == 1` and `DBGPRCR_EL1.CORENPDRQ == 0`, meaning `FEAT_DoubleLock` is implemented and locked in Non-debug state and therefore Software Step exceptions are disabled, but otherwise Software Step exceptions would be enabled from the restart Exception level, it is CONSTRAINED UNPREDICTABLE whether `PSTATE.SS` is copied from `DSPSR_EL0.SS`.

- If `FEAT_SSBS` is implemented, `DSPSR_EL0.SSBS` is copied to `PSTATE.SSBS`.
- If `FEAT_PAN` is implemented, `DSPSR_EL0.PAN` is copied to `PSTATE.PAN`.
- If `FEAT_UAO` is implemented, on exit from Debug state, `DSPSR_EL0.UAO` is copied to `PSTATE.UAO`.
- If `FEAT_DIT` is implemented, on exit from Debug state, `DSPSR_EL0.DIT` is copied to `PSTATE.DIT`.

- Exit from Debug state has no architecturally-defined effect on the Event Register and Exclusives monitors. An exit from Debug state might set the Event Register or clear the Exclusives monitors, or both, but this is not a requirement and debuggers must not rely on any IMPLEMENTATION SPECIFIC behavior.

Note

- One important difference between Debug state exit and an exception return is that the PE can exit Debug state at EL0. Despite this, the behavior of an exit from Debug state is similar to an exception return. For example, [PSTATE.{D, A, I, F}](#) is updated regardless of the value of [SCTLR_EL1.UMA](#).
-

The [ExitDebugState\(\)](#) function is described in [R-profile Architecture Pseudocode](#).

Chapter E3

Halting Debug Events

This chapter describes a particular class of debug events. It contains the following sections:

- [Introduction to Halting debug events](#)
- [Halting Step debug events](#)
- [Halt Instruction debug event](#)
- [Exception Catch debug event](#)
- [External Debug Request debug event](#)
- [OS Unlock Catch debug event](#)
- [Reset Catch debug events](#)
- [Software Access debug event](#)
- [Synchronization and Halting debug events](#)

E3.1 Introduction to Halting debug events

External debug defines Halting debug events. The following Halting debug events are available from the introduction of Armv8:

- [Halting Step debug events](#).
- [Halt Instruction debug event](#).
- [Exception Catch debug event](#).
- [External Debug Request debug event](#).
- [OS Unlock Catch debug event](#).
- [Reset Catch debug events](#).
- [Software Access debug event](#).

If halting is allowed, a Halting debug event halts the PE. The PE enters Debug state.

In addition, breakpoints and watchpoints might halt the PE if halting is allowed. See [Breakpoint and Watchpoint debug events](#). Because breakpoints and watchpoints can generate an exception or halt the PE, Breakpoint and Watchpoint debug events are not classified as Halting debug events.

For a definition of Debug state, see [Debug State](#). For a definition of halting allowed, see [Halting allowed and halting prohibited](#).

[Debug state entry and debug event prioritization](#) describes the behavior when multiple debug events are generated by an instruction.

See also [Synchronization and Halting debug events](#).

[Table E3-1](#) shows the behavior of Breakpoint, Watchpoint, and Halting debug events.

Table E3-1 Summary of debug events and possible outcomes

Debug event type	PE behavior when halting is:	
	Allowed	Prohibited
Breakpoint and Watchpoint debug events	Halt	See Table D2-1
Halt Instruction debug event	Halt	UNDEFINED
Software Access debug event	Halt	Ignored
Exception Catch debug event	Halt	Ignored or pended
Halting Step debug events	Halt	Pended
External Debug Request debug event	Halt	Pended
Reset Catch debug events	Halt	Pended
OS Unlock Catch debug event	Pended	Pended

[Table E3-2](#) shows where the pseudocode for each Halting debug event type is located.

Table E3-2 Pseudocode description of Halting debug events

Halting debug event type	Pseudocode
Halt Instruction debug event	HLT

Halting debug event type	Pseudocode
Software Access debug event	Pseudocode description of Software Access debug event
Exception Catch debug event	Pseudocode description of Exception Catch debug events
Halting Step debug events	Pseudocode description of Halting Step debug events
External Debug Request debug event	Pseudocode description of External Debug Request debug events
Reset Catch debug events	Pseudocode description of Reset Catch debug event
OS Unlock Catch debug event	Pseudocode description of OS Unlock Catch debug event

E3.2 Halting Step debug events

Halting Step is a debug resource that a debugger can use to make the PE step through code one instruction at a time. This section describes the Halting Step debug events. It is divided into the following sections:

- [Overview of a Halting Step debug event.](#)
- [The Halting Step state machine.](#)
- [Using Halting Step.](#)
- [Detailed Halting Step state machine behavior.](#)
- [Synchronization and the Halting Step state machine.](#)
- [Disabling interrupts while stepping.](#)
- [Syndrome information on Halting Step.](#)
- [Pseudocode description of Halting Step debug events.](#)

The architecture describes the behavior as a simple Halting Step state machine. See [The Halting Step state machine.](#)

E3.2.1 Overview of a Halting Step debug event

The behavior of Halting Step is defined by a state machine, shown in [Figure E3-1](#). A Halting Step debug event executes a single instruction and then returns control to the debugger. When the debugger software wants to execute a Halting Step:

1. With the PE in Debug state, the debugger activates Halting Step.
2. The debugger signals the PE to exit Debug state and return to the instruction that is to be stepped.
3. The PE executes that single instruction.
4. The PE enters Debug state before executing the next instruction.

However, an exception might be generated during this process. That is, one of the following occurs:

- A synchronous exception generated by the instruction being stepped.
- An asynchronous exception taken before or during the instruction being stepped, to the extent permitted by the definition of a precise exception, without completing execution of the instruction being stepped.
- An asynchronous exception taken after completing execution of the instruction being stepped, before the PE enters Debug state.

See also [Definition of a precise exception and imprecise exception.](#)

Halting Step has its own enable control bit, [EDECR.SS](#) and [EDES.R.SS](#).

Note	
Because the Halting Step state machine states occur as a result of normal PE operation, the states can be described as both:	
•	PE states.
•	Halting Step states.

E3.2.2 The Halting Step state machine

The state machine states are:

Inactive	Halting Step is inactive. No Halting Step debug events can be generated, therefore execution is not affected by Halting Step. The PE is in this state whenever either of the following is true: • Halting Step is disabled. That is, EDECR.SS is set to 0 and EDES.R.SS is set to 0. • Halting is prohibited. See Halting the PE on debug events. In this state, if EDECR.SS is set to 1, then a Halting Step debug event is pending.
-----------------	---

In [Figure E3-1](#), this state is shown in red.

Active-not-pending

Halting Step is enabled and active. This is the state in which the PE steps an instruction. [EDECR.SS](#) == 1 and [EDES.R.SS](#) == 0. Software must not set [EDECR.SS](#) to 1 unless the PE is in Debug state, otherwise behavior is CONSTRAINED UNPREDICTABLE, as described in [Changing the value of EDECR.SS when not in Debug state](#).

In [Figure E3-1](#), this state is shown in green.

Active-pending

Halting Step is enabled and active. The step has completed and the PE enters Debug state. [EDES.R.SS](#) == 1.

In [Figure E3-1](#), this state is shown in green.

Whenever Halting Step is enabled and active, whether the state machine is in the active-not-pending state or in the active-pending state depends on [EDES.R.SS](#). [Table E3-3](#) shows this.

In the simple sequential execution of the program, the PE executes the Halting Step state machine as follows:

1. Initially, Halting Step is inactive.
2. After exiting Debug state, Halting Step is active-not-pending.
3. The PE executes an instruction and Halting Step is active-pending.
4. The pending Debug state entry is taken on the next instruction and the step is complete.

Exceptions and other changes to the PE context can interrupt this sequence.

[Figure E3-1](#) shows a Halting Step state machine.

Halting step is disabled

Halting step is enabled

- a. Step completed occurs when:
- A debug event, other than a Halting Step debug event, causes entry into Debug state.
- b. Step completed occurs when:
- An instruction is executed without taking an exception.
 - An exception is taken to a state where halting is allowed.
 - A reset.
- c. An asynchronous exception taken to a state where halting is allowed.
- d. An asynchronous exception taken to Secure state where halting is prohibited.

Figure E3-1 Halting Step state machine

Note

Figure E3-1 describes only state transitions to and from the inactive state by exit from Debug state, executing an exception return, or taking an exception. Other changes to the PE context, including writes to registers such as EDECR and OSDLR_EL1 and changes to the authentication interface can also cause changes to the Halting Step state machine. These can lead to UNPREDICTABLE or CONSTRAINED UNPREDICTABLE behavior. See Synchronization and the Halting Step state machine.

The following bits control the state machine, as shown in Table E3-3:

- EDECR.SS. This is the Halting Step enable bit.
- EDESR.SS. This is the Halting Step debug event pending bit.

Table E3-3 shows the Halting Step state machine states. The letter X in a register column means that the relevant bit can be set to either zero or one.

Table E3-3 Halting Step state machine states

Halting	EDECR.SS	EDESR.SS	Halting Step state
Prohibited	X	X	Inactive (Halting Step debug even not pending)
Prohibited	X	1	Inactive (Halting Step debug event pending)
Allowed	0	0	Inactive
Allowed	1	0	Active-not-pending
Allowed	X	1	Active-pending

E3.2.3 Using Halting Step

To step a single instruction the PE must be in Debug state:

1. The debugger sets EDECR.SS to 1 to enable Halting step.
2. The debugger signals the PE to exit Debug state with DLR_EL0 set to the address of the instruction being stepped. The PE clears EDESR.SS to 0 and the Halting Step state machine enters the active-not-pending state.
3. The PE executes the instruction being stepped.
If an exception is taken to a state where halting is prohibited, then EDESR.SS is always correct for the preferred return address of the exception.
4. The PE enters Debug state before executing the next instruction and the step is complete.

Note

- If FEAT_DoPD is not implemented, EDECR.SS value is in the Debug power domain, meaning that the state machine is maintained over a powerdown of the Core power domain.
- If FEAT_DoPD is implemented, the values of EDECR.SS and EDESR.SS are set to 0 on a Cold reset, and, if the PE was stepping an instruction, EDESR.SS is effectively UNKNOWN after a Warm reset. A debugger must use a Reset Catch debug event to step over a powerdown state.
- A debugger must only change the value of EDECR.SS when the PE is in Debug state, otherwise behavior is CONSTRAINED UNPREDICTABLE as described in Changing the value of EDECR.SS when not in Debug state.

E3.2.4 Detailed Halting Step state machine behavior

The behavior of the Halting Step state machine is described in the following sections:

- [Entering the active-not-pending state.](#)
- [PE behavior in the active-not-pending state.](#)
- [Entering the active-pending state.](#)
- [PE behavior in the active-pending state.](#)
- [PE behavior in the inactive state when in Non-debug state.](#)
- [PE behavior in Debug state.](#)

E3.2.4.1 Entering the active-not-pending state

The PE enters the active-not-pending state:

- By exiting Debug state to a state where halting is allowed with `EDECR.SS == 1`.
- By an exception return from a state where halting is prohibited to a state where halting is allowed with `EDECR.SS == 1` and `EDESR.SS == 0`.
- As described in [Synchronization and the Halting Step state machine](#).

E3.2.4.2 PE behavior in the active-not-pending state

When the PE is in the active-not-pending state it does one of the following:

- It executes one instruction and does one of the following:
 - Completes it without taking a synchronous exception.
 - Takes a synchronous exception generated by the instruction.
 - Generates a debug event that causes entry to Debug state.
- It takes an asynchronous exception without completing execution of the instruction.
- It takes an asynchronous debug event into Debug state.

E3.2.4.2.1 If no exception or debug event is generated

If no exception or debug event is generated the PE sets `EDESR.SS` to 1. This means that the Halting Step state machine advances to the active-pending state.

E3.2.4.2.2 If an exception or debug event is generated

The PE sets `EDESR.SS` according to all of the following:

- The type of exception.
- The target Exception level of the exception.

If an exception or debug event is generated, the PE sets `EDESR.SS` to 1 if the exception is an SMC exception or is taken to a state where halting is allowed.

Otherwise, `EDESR.SS` is unchanged.

It is IMPLEMENTATION SPECIFIC whether `EDESR.SS` is set to 1 or unchanged when an SError exception is taken to EL2 without completing execution of the instruction, and halting is prohibited at EL2.

If halting is prohibited after taking the exception or debug event, then the Halting Step state machine advances to the inactive state. Otherwise, the Halting Step state machine advances to the active-pending state.

Note

The underlying criteria for the value of `EDESR.SS` on an exception are:

- Whether halting is allowed at the target of the exception. If halting is allowed, the PE must step into the exception. If halting is prohibited, the PE must step over the exception.
 - Whether the preferred return address of the exception is the instruction itself or the next instruction, if the PE steps over the exception.
-

Table E3-4 shows the behavior of the active-not-pending state.

Table E3-4 Summary of active-not-pending state behavior

Event	Target Exception level	Value written to EDESR.SS
No exception or debug event	Not applicable	1
SMC exception	EL2 if trapped	1
Reset	Highest	1
Exception, other than SMC exception	EL1	1
	EL2	1
Debug event	Debug state	Unchanged

E3.2.4.3 Entering the active-pending state

The PE enters the active-pending state by one of the following:

- From the active-not-pending state by:
 - Executing an instruction without taking an exception.
 - Taking an exception so that the PE remains in a state where halting is allowed.
- An exception return from a state where halting is prohibited when EDESR.SS == 1.
- A reset when the value of EDECR.SS == 1, regardless of the state the PE was in before the reset occurred.
- From the active-pending state by taking an asynchronous exception to a state where halting is allowed.
- Following the description in [Synchronization and the Halting Step state machine](#).

E3.2.4.4 PE behavior in the active-pending state

When the PE is in the active-pending state, it enters Debug state before executing an instruction.

The entry into Debug state has higher priority than all other types of synchronous debug event and synchronous exception. However, the architecture does not define the prioritization of this Debug state entry with respect to any unmasked pending asynchronous exception. If an asynchronous exception is prioritized over the entry to Debug state, then EDESR.SS is unchanged.

For more information on the prioritization of debug events, see [Debug state entry and debug event prioritization](#).

E3.2.4.5 PE behavior in the inactive state when in Non-debug state

EDESR.SS is not updated by the execution of an instruction or the taking of an exception when Halting Step is inactive. This means that EDESR.SS is not changed by an exception handled in a state where halting is prohibited.

On return to a state where halting is allowed, the Halting Step state machine is restored either to the active-pending state or the active-not-pending state, depending on the value of EDESR.SS. The return to a state where halting is allowed is normally by an exception return, which in some situations is a [Context Synchronization event](#).

See also [Synchronization and the Halting Step state machine](#).

E3.2.4.6 PE behavior in Debug state

Halting Step is inactive in Debug state because halting is prohibited, see [Halting allowed and halting prohibited](#).

Entry to Debug state does not change EDESR.SS.

EDESR.SS is cleared to 0 on exiting Debug state as the result of a restart request. If EDECR.SS == 1, Halting Step enters the active-not-pending state.

Note

This means that [EDES.R.SS](#) is never cleared to 0 by the execution of an instruction in Debug state, or by taking an exception when in Debug state as described in [PE behavior in the active-not-pending state](#), because the Halting Step state machine is not in the active-not-pending state. [EDES.R.SS](#) can be cleared by a write to [EDES.R](#), see the register description.

However, if the PE exits Debug state as the result of a PE reset and [EDECR.SS](#) = 1, then Halting Step immediately enters the active-pending state, as [EDES.R.SS](#) is set to the value of [EDECR.SS](#).

E3.2.5 Synchronization and the Halting Step state machine

The Halting Step state machine also changes state if:

- Halting becomes allowed or prohibited other than by exit from Debug state, an exception return, or taking an exception. This means that halting becomes allowed or prohibited because:
 - The Security state changes without an exception return. See State and mode changes without explicit Context Synchronization events.
 - The external authentication interface changes.
 - [FEAT_DoubleLock](#) is implemented and the status, [DoubleLockStatus\(\)](#), changes.
- A write to [EDECR](#) when the PE is in Non-debug state changes the value of [EDECR.SS](#).

Note

Behavior is CONSTRAINED UNPREDICTABLE if the value of [EDECR.SS](#) is changed when the PE is in Non-debug state, see [Changing the value of EDECR.SS when not in Debug state](#).

- A write to [EDES.R](#) when the PE is in Non-debug state clears [EDES.R.SS](#) to 0.

These operations are guaranteed to take effect only after a [Context Synchronization event](#). If the instruction being stepped generates a [Context Synchronization event](#), then the PE might use the old or new state.

The PE must perform the required behavior of the new state before or immediately following the next [Context Synchronization event](#), but it is not required to do so immediately. This means that the PE can perform the required behavior of the old state before the next [Context Synchronization event](#). This is illustrated in [Example E3-1](#) and [Example E3-2](#).

Example E3-1 Synchronization requirements 1

[EDECR.SS](#) is set to 1 in Debug state, requesting the active-not-pending state on exit from Debug state. On exit from Debug state the PE immediately takes an exception to EL2, where halting is prohibited. The PE does not step any instructions but executes the software at EL2 as normal. [EDES.R.SS](#) remains set to 0. If halting is subsequently allowed, the PE must perform the required behavior of the active-not-pending state before or immediately following the next [Context Synchronization event](#), but it is not required to do so immediately.

Example E3-2 Synchronization requirements 2

EDECR.SS is set to 1 in Debug state. On exit from Debug the PE executes an **MSR** instruction that sets **OSDLR_EL1.DLK** to 1 and **DoubleLockStatus()** becomes TRUE. This change requires a **Context Synchronization event** to guarantee its effect, meaning it is **CONSTRAINED UNPREDICTABLE** whether:

- Halting is allowed:
 - The PE enters Debug state on the next instruction.
- Halting is prohibited:
 - The PE does not enter Debug state.

The value in **EDES.R.SS** depends on whether halting was allowed or prohibited when the write to **OSDLR_EL1.DLK** completed, and so it might be 0 or 1. If a second **MSR** instruction clears **OSDLR_EL1.DLK** to 0, the PE must perform the required behavior of the state indicated by **EDES.R.SS** before or immediately following the next **Context Synchronization event**, but it is not required to do so immediately.

See also [Synchronization and Halting debug events](#).

E3.2.5.1 Changing the value of **EDECR.SS** when not in Debug state

If software changes the value of **EDECR.SS** when the PE is not in Debug state then behavior is **CONSTRAINED UNPREDICTABLE**, and one or more of the following behaviors occurs:

- The value of **EDECR.SS** becomes **UNKNOWN**.
- The state of the Halting Step state machine becomes **UNKNOWN**.
- On a reset of the PE, the value of **EDECR.SS** and the state of the Halting Step state machine are **UNKNOWN**.

E3.2.6 Disabling interrupts while stepping

When using Halting Step, the sequence of entering Debug state, interacting with the debugger, and then exiting Debug state for each instruction reduces the rate at which the PE executes instructions. However, the rate at which certain interrupts, such as timer interrupts, are generated might be fixed by the system. This means it might be necessary to disable interrupts while using Halting Step by setting **EDSCR.INTdis**, to allow the code being debugged to make forward progress.

E3.2.7 Syndrome information on Halting Step

On entering Debug state on a Halting Step debug event, the PE optionally records information about the debug event:

Halting Step, normal

An instruction other than a Load-Exclusive instruction was stepped.

Halting Step, exclusive

A Load-Exclusive instruction was stepped.

Halting Step, no syndrome

The syndrome data is not available.

If no syndrome is recorded, then **EDSCR.STATUS** is set to Halting Step, no syndrome.

If no instruction was stepped because Halting step entered the active-pending state from the inactive state without passing through the active-not-pending state, then no syndrome is recorded.

This happens when the active-pending state is entered for other reasons. See [Synchronization and the Halting Step state machine](#).

When a syndrome is recorded, **EDSCR.STATUS** is set to one of:

- Halting step, normal, if the stepped instruction was not a Load-Exclusive instruction.
- Halting step, exclusive, if the stepped instruction was a Load-Exclusive instruction.

Note

A Load-Exclusive instruction is any instruction that has a mnemonic starting with either `LDX` or `LDAX`.

Note

Arm deprecates the use of the Halting Step, normal and Halting Step, exclusive syndrome values, and recommends software treats these values as Halting Step, no syndrome.

Table E3-5 summarizes the possible values that the PE can record in `EDSCR.STATUS`.

Table E3-5 Values that the PE can record in `EDSCR.STATUS`

Description	<code>EDSCR.STATUS</code>
Syndrome data is not available.	Halting Step, no syndrome.
Syndrome data is available. The instruction stepped was an instruction other than a Load-Exclusive instruction.	Syndrome data is available. Halting Step, normal.
Syndrome data is available. The instruction stepped was a Load-Exclusive instruction.	Syndrome data is available. Halting Step, exclusive.

E3.2.8 Pseudocode description of Halting Step debug events

There are two pseudocode functions for Halting Step debug events:

- `HSAdvance()`. This is called after an instruction has executed and any exception generated by the instruction is taken, except for the case of an SMC exception, in which case it is called before the exception is taken. `HSAdvance()` affects the next instruction.
- `CheckHaltingStep()`. This is called before the next instruction is executed. If a step is pending, it generates the debug event.

E3.3 Halt Instruction debug event

A Halt Instruction debug event is generated when `EDSCR.HDE == 1`, halting is allowed, and the PE executes the Halt instruction, `HLT`.

The pseudocode for Halt Instruction debug events is described in [HLT](#).

`HLT` never generates a debug exception. It is treated as `UNDEFINED` if `EDSCR.HDE == 0`, or if halting is prohibited.

Note

A debugger can replace a program instruction with a Halt instruction to generate a Halt Instruction debug event. Debuggers that use the `HLT` instruction must be aware of the rules for concurrent modification of executable code, `CMODX`. The rules for concurrent modification and execution of instructions do not allow one thread of execution or an external debugger to replace an instruction with an `HLT` instruction when these same instructions are being executed by a different thread of execution. See [Concurrent modification and execution of instructions](#).

E3.4 Exception Catch debug event

Exception Catch debug events:

- Are generated when the corresponding bit in the Exception Catch Control Register, [EDECCR](#), is set to 1 on all entries to a given Exception level. This means:
 - Exceptions taken to the Exception level.
 - Exception returns to the Exception level.
 - It is IMPLEMENTATION DEFINED whether a reset into an Exception level generates an Exception Catch debug event.
- Might be taken synchronously, after the exception or reset entry or the exception return has been processed by the PE.
- Ignore the Execution state of the target Exception level.
- Might be ignored if halting is prohibited.

The [EDECCR](#) register contains fields that control when Exception Catch debug events are generated.

See [Controlling Exception Catch debug events when FEAT_Debugv8p2 is implemented](#) and [Controlling Exception Catch debug events when FEAT_Debugv8p2 is not implemented](#).

For exception returns, the final Exception level of the exception return determines whether an Exception Catch debug event is generated. On an illegal exception return, an Exception Catch debug event is generated only if EDECCR is programmed to generate an Exception Catch debug event for an exception return to the current Exception level.

E3.4.1 Prioritization of Exception Catch debug events

The following rules define the prioritization of Exception Catch debug events:

- It is IMPLEMENTATION DEFINED whether Exception Catch debug events are higher or lower priority than [Software Step exceptions](#) and [Halting Step debug events](#).
- Exception Catch debug events are higher priority than all synchronous exceptions other than [Software Step exceptions](#) and debug events other than [Halting Step debug events](#).
- Exception Catch debug events are lower priority than [Reset Catch debug events](#).
- When [FEAT_Debugv8p2](#) is implemented, Exception Catch debug events are higher priority than pending asynchronous exceptions. Otherwise, the prioritization between asynchronous exceptions, asynchronous debug events, and an Exception Catch debug event, is IMPLEMENTATION DEFINED.

Note

As described in [Prioritization of Synchronous exceptions taken to AArch64 state](#), an exception trapping form of a Vector Catch debug event might generate a second debug exception as part of the exception entry, before the Exception Catch debug event is taken. See [Vector Catch exceptions](#) or [Vector Catch exceptions](#).

E3.4.2 Generating Exception Catch debug events when FEAT_Debugv8p2 is not implemented

When an Exception Catch debug event is generated after exception entry and halting is allowed at the target of the exception, the PE halts and enters Debug state:

- The PE halts and enters Debug state before the first instruction at the handler is executed, after the exception entry has updated the program counter, [PSTATE](#), and syndrome registers for the exception.
- The PE does not fetch instructions from the vector address before entering Debug state, if address translation is disabled in the translation regime at the target Exception level.
- A second unmasked asynchronous exception can be taken before the PE enters Debug state. If this second exception does not generate an Exception Catch debug event, the exception handler executed at the higher Exception level later returns to the trapped Exception level, causing the Exception Catch debug event to be generated again.

When an Exception Catch debug event is generated on exception return and halting is allowed at the target of the exception return:

- There is no prioritization between asynchronous exceptions, asynchronous debug events, and an Exception Catch debug event generated on an exception return.
- The PE halts and enters Debug state after the exception return has updated the program counter and [PSTATE](#), and before the execution of the first instruction at the return address is completed.

Otherwise, when the PE is executing code at a given Exception level, and the corresponding [EDECCR](#) bit is 1, it is CONSTRAINED UNPREDICTABLE whether an Exception Catch debug event is generated.

Examples of this are:

- If the debugger writes to [EDECCR](#) so that the current Exception level is trapped.
- If the OS restore code writes to [OSECCR_EL1](#) so that the current Exception level is trapped.

See also [Debug state entry and debug event prioritization](#).

Note

It is possible to generate Exception Catch debug events:

- As a trap on all instruction fetches from the trapped Exception level as part of an instruction fetch.
- On entry to the Exception level, as described in [Detailed Halting Step state machine behavior](#).

This is similar to the implementation options allowed for Vector Catch debug events. The architecture does not require that the event is generated following an [ISB](#) operation executed at the Exception level.

E3.4.3 Controlling Exception Catch debug events when FEAT_Debugv8p2 is implemented

When [FEAT_Debugv8p2](#) is implemented the fields [EDECCR](#).{NSR, SR, NSE, SE} control generation of Exception Catch debug events:

- On exception entry but not on exception return.
- On exception return but not on exception entry.
- On exception entry and exception return.

Exception entry, reset and exception return Exception Catch debug events are enabled as shown in [Table E3-6](#).

Table E3-6 Summary of Exception Catch debug event control when FEAT_Debugv8p2 is implemented

(N)SR<n>	(N)SE<n>	Behavior on exception return to ELn	Behavior on exception taken to ELn, and if resets are Exception Catch debug events, reset into ELn
0	0	No action.	No action.
0	1	Halt if allowed.	Halt if allowed.
1	0	Halt if allowed.	No action.
1	1	No action.	Halt if allowed.

E3.4.4 Controlling Exception Catch debug events when FEAT_Debugv8p2 is not implemented

When [FEAT_Debugv8p2](#) is not implemented, all Exception Catch debug events are enabled by a combination of the fields NSE and SE in [EDECCR](#), as shown in [Table E3-7](#).

Table E3-7 Summary of Exception Catch debug event control when FEAT_Debugv8p2 is not implemented

(N)SE<n>	Behavior on exception taken to ELn, return to ELn, and if resets are Exception Catch debug events, reset into ELn
0	No action.
1	Halt if allowed.

E3.4.5 Examples of Exception Catch debug events

If `EDECCR == 0x0020`, meaning that the Exception Catch debug event is enabled for EL1, then the following exceptions generate Exception Catch debug events:

- An exception taken from EL0 to EL1.
- An exception return from EL2 to EL1.

For example, on taking a Data Abort exception from EL0 to EL1, using AArch64:

- `ELR_EL1` and `SPSR_EL1` are written with the preferred return address and PE state for a return to EL0.
- `ESR_EL1` and `FAR_EL1` are written with the syndrome information for the exception.
- `DLR_EL0` is set to `VBAR_EL1 + 0x400`, the synchronous exception vector.
- `DSPSR_EL0` is written with the PE state for an exit to EL1.

The following do not generate Exception Catch debug events:

- An exception taken from EL0 to EL2.
- An exception return from EL2 to EL0.
- An exception taken from EL0 to EL1.

E3.4.6 Pseudocode description of Exception Catch debug events

The pseudocode functions `CheckExceptionCatch()` and `CheckPendingExceptionCatch()` are described in [R-profile Architecture Pseudocode](#).

E3.5 External Debug Request debug event

External Debug Request debug events are asynchronous debug events.

An External Debug Request debug event can be generated by any of the following:

- When signaled by the embedded cross-trigger. See [The Embedded Cross-Trigger Interface](#).
- The Performance Monitoring Unit. See [PMU Overflow external debug request](#).
- An implementation might also support IMPLEMENTATION DEFINED ways of generating an External Debug Request debug event.

E3.5.1 Synchronization and External Debug Request debug events

For all Context synchronization events, if an External Debug Request debug event is asserted before the [Context Synchronization event](#), and the External Debug Request debug event remains asserted and halting is allowed after the Context synchronization event, then the debug event is taken and the PE enters Debug state before the first instruction following the Context synchronization event completes its execution.

An External Debug Request debug event that is being asserted when the PE comes out of reset is taken, and the PE enters Debug state before the first instruction after the reset completes its execution, provided that halting is allowed when the PE exits reset state.

If the first instruction after the [Context Synchronization event](#) or after coming out of reset generates a synchronous exception then the architecture does not define the order in which the debug event and the exception or exceptions are taken.

Otherwise, when all of the following are true, External Debug Request debug events must be taken in finite time, without requiring the synchronization of any necessary change to the external authentication interface:

- Halting is allowed.
- The PE is not in a low-power state that is not required to exit on an external debug request. See [Core power domain power states](#).

External debug request is a wakeup event for WFI, WFE, or WFET instructions. See [Mechanisms for entering a low-power state](#).

Note

These rules are based on the rules that apply when taking asynchronous exceptions. See [Asynchronous exception types](#).

If an unmasked External Debug Request debug event was pending but is changed to not pending before it is taken, then the architecture permits the External Debug Request debug event to be taken, but does not require this to happen. If the External Debug Request debug event is taken then it must be taken before the first [Context Synchronization event](#) after the External Debug Request debug event was changed to not pending.

[Example E3-3](#) shows an example of the synchronization requirements.

Example E3-3 Synchronization requirements

Secure software locks up in a tight loop, so it executes indefinitely without any synchronization operations. An External debug request must be able to break the PE out of that loop. This is a requirement even if **DBGEN** or **SPIDEN** or both are LOW on entry to the loop, meaning that halting is prohibited, and are only asserted HIGH later.

E3.5.2 PMU Overflow external debug request

When the PE halts and enters Debug state because of a PMU Overflow external debug request:

- [DLR_ELO](#) is set to the address of the first instruction that must be executed on exit from Debug state. [DSPSR_ELO](#) is correct for this instruction.

- [EDSCR.STATUS](#) is set to 0b010011, external debug request.

E3.5.3 Pseudocode description of External Debug Request debug events

The [ExternalDebugRequest \(\)](#) function is described in [R-profile Architecture Pseudocode](#).

E3.6 OS Unlock Catch debug event

An OS Unlock Catch debug event is generated when enabled and the state of the OS Lock changes from locked to unlocked. When [FEAT_DoPD](#) is implemented, [CTIDEVCTL.OSUCE](#) enables an OS Unlock Catch debug event, otherwise [EDECR.OSUCE](#) enables an OS Unlock Catch debug event.

When the OS Lock is unlocked, the PE sets [EDES.R.OSUC](#) to 1 if the OS Unlock Catch debug event is enabled, and the PE is in Non-debug state, meaning the OS Unlock Catch debug event becomes pending. However, this is an indirect write to [EDES.R.OSUC](#), meaning the OS Unlock Catch debug event is not guaranteed to be taken before a subsequent Context synchronization event. If the PE enters Debug state or the OS Unlock Catch debug event is disabled before [EDES.R.OSUC](#) becomes set to 1, then [EDES.R.OSUC](#) might not be set.

OS Unlock Catch debug events are not generated if the OS Lock is unlocked when the PE is in Debug state. See also [Synchronization and Halting debug events](#).

[EDES.R.OSUC](#) is cleared to 0 on a Warm reset and on exiting Debug state.

E3.6.1 Using the OS Unlock Catch debug event

When the Core power domain is completely off or in a low-power state, a debugger is permitted to access a debug register that is implemented in the External debug power domain. However, if a debugger attempts to access a debug register that is implemented in the Core power domain when the Core power domain registers cannot be accessed, and that access returns an error, the debugger must retry the access.

Regularly powering down the Core power domain can result in unreliable debugger behavior.

The debugger can program a Reset Catch debug event to halt the PE when it has powered up, and can program the debug registers from Debug state. However, if the PE boot software restores the debug registers, as described in [Debug OS Save and Restore sequences](#), then newly written values are overwritten by the restore sequence.

The debugger can program an OS Unlock Catch debug event to halt the PE after the restore sequence has completed, and program the debug registers from Debug state.

E3.6.2 Pseudocode description of OS Unlock Catch debug event

The [CheckOSUnlockCatch\(\)](#) function is called when the OS Lock is unlocked.

The [CheckPendingOSUnlockCatch\(\)](#) function is called before an instruction is executed. If an OS Unlock Catch is pending, it generates the debug event.

E3.7 Reset Catch debug events

A Reset Catch debug event is generated when enabled, and the PE exits reset state. When the Reset Catch debug event is generated, it is recorded by setting [EDES.RC](#) to 1. When [FEAT_DoPD](#) is implemented, [CTIDEVCTL.RCE](#) enables a Reset Catch debug event, otherwise [EDECR.RCE](#) enables a Reset Catch debug event.

If halting is allowed when the event is generated, the Reset Catch debug event is taken immediately and synchronously. On entering Debug state, [DLR_EL0](#) has the address of the reset vector. The PE must not fetch any instructions from memory.

Otherwise, the Reset Catch debug event is pended and taken when halting is allowed. See [Synchronization and Halting debug events](#) for more information.

This means that [EDES.RC](#) is set to the value of [EDECR.RCE](#) or [CTIDEVCTL.RCE](#) on a Warm reset. [EDES.RC](#) is cleared to 0 on exiting Debug state.

E3.7.1 Pseudocode description of Reset Catch debug event

The [CheckResetCatch\(\)](#) function is called after reset before executing any instruction.

The [CheckPendingResetCatch\(\)](#) function is called before an instruction is executed. If a Reset Catch is pending, it generates the Reset Catch debug event.

E3.8 Software Access debug event

When the value of [EDSCR.TDA](#) is 1, software access to the following AArch64 debug System registers generate a Software Access debug event:

- The Breakpoint Value Registers, [DBGBVR<n>_EL1](#).
- The Breakpoint Control Registers, [DBGBCR<n>_EL1](#).
- The Watchpoint Value Registers, [DBGWVR<n>_EL1](#).
- The Watchpoint Control Registers, [DBGWCR<n>_EL1](#).

However, [EDSCR.TDA](#) is ignored if any of the following applies:

- The value of [OSLSR_EL1.OSLK](#) == 1, meaning that the OS Lock is locked.
- Halting is prohibited. See [Halting allowed and halting prohibited](#).
- The register access generates a higher priority synchronous exception or debug event.

Note

- The only accesses to the specified registers that generate a Software Access debug event are accesses to System registers in AArch64 state.
 - Accesses by a PE using the external debug interface never generate a Software Access debug event.
-

E3.8.1 Pseudocode description of Software Access debug event

The [CheckSoftwareAccessToDebugRegisters\(\)](#) function is described in [R-profile Architecture Pseudocode](#).

E3.9 Synchronization and Halting debug events

The behavior of external debug depends on:

- Indirect reads of:
 - External debug registers.
 - System registers, including system debug registers.
 - Special-purpose registers.
- The state of the external authentication interface.

For some registers, all read and write accesses that update the register occur in program order, without any additional synchronization, but others require an explicit [Context Synchronization event](#). For more information on the synchronization of register updates, see:

- [Synchronization requirements for AArch64 System registers.](#)
- [Synchronization of changes to the external debug registers.](#)

Changes to the external authentication interface do not require explicit synchronization to affect External Debug Request debug events. See [Synchronization and External Debug Request debug events](#).

For changes that require explicit synchronization, it is **CONSTRAINED UNPREDICTABLE** whether instructions between the change and the [Context Synchronization event](#) observe the old state or the new state.

This means that any change to these registers or the external authentication interface requires explicit synchronization by a [Context Synchronization event](#) before the change takes effect. This ensures that for instructions appearing in program order after the change, the change affects the following:

- The generation and behavior of Breakpoint and Watchpoint debug events. See [Synchronization and debug exceptions](#) for exceptions taken from AArch64 state.
- The generation of all Halting debug events by instructions.
- Taking a pending Halting debug event or other asynchronous debug event. See:
 - [Pending Halting debug events.](#)
 - [Synchronization and External Debug Request debug events.](#)
- The behavior of the Halting Step state machine. See [Synchronization and the Halting Step state machine.](#)

E3.9.1 Pending Halting debug events

A Halting debug event might be pending:

- If Halting Step of an instruction sets [EDES.RC](#) to 1, and halting is prohibited following the step, then the Halting Step state machine is inactive but a Halting Step debug event is pending.
- If a Reset Catch debug event sets [EDES.RC](#) to 1, and halting is prohibited following reset, then a Reset Catch debug event is pending.
- If an OS Unlock Catch debug event sets [EDES.OSUC](#) to 1, then an OS Unlock Catch debug event is pending.

Pending Halting debug events are taken asynchronously when halting is allowed.

Pending Halting debug events are discarded by a Cold reset. The debugger can also force a pending event to be dropped by writing to [EDES](#).

Any Halting debug event that is observed as pending in the [EDES](#) before a [Context Synchronization event](#) is taken and the PE enters Debug state before the first instruction following the [Context Synchronization event](#) completes its execution. This is possible only if halting is allowed after completion of the [Context Synchronization event](#).

If the first instruction after the [Context Synchronization event](#) generates a synchronous exception then the architecture does not define the order in which the debug event and the exception or exceptions are taken, unless a Halting Step debug event is pending and [EDES.SS](#) == 1.

Chapter E4

The Debug Communication Channel and Instruction Transfer Register

This chapter describes communication between a debugger and the implemented debug logic, using the *Debug Communications Channel* (DCC) and the *Instruction Transfer Register* (ITR), and associated control flags. It contains the following sections:

- [Introduction](#)
- [DCC and ITR registers](#)
- [DCC and ITR access modes](#)
- [Flow control of the DCC and ITR registers](#)
- [Synchronization of DCC and ITR accesses](#)
- [Interrupt-driven use of the DCC](#)
- [Pseudocode description of the operation of the DCC and ITR registers](#)

E4.1 Introduction

The *Debug Communications Channel*, DCC, is a channel for passing data between the PE and an external agent, such as a debugger. The DCC provides a communications channel between:

- An external debugger, described as the *debug host*.
- The debug implementation on the PE, described as the *debug target*.

The DCC can be used:

- As a 32-bit full-duplex channel.
- As a 64-bit half-duplex channel.

The DCC is an essential part of Debug state operation and can also be used in Non-debug state.

The *Instruction Transfer Register*, ITR, passes instructions to the PE to execute in Debug state.

The PE includes flow-control mechanisms for both the DCC and ITR.

E4.2 DCC and ITR registers

The DCC comprises *data transfer registers*, the DTRs, and associated flow-control flags. The data transfer registers are DTRRX and DTRTX.

The ITR comprises a single register, [EDITR](#), and associated flow-control flags.

In AArch64 state, software can access the data transfer registers as:

- A receive and transmit pair for 32-bit full duplex operation:
 - The write-only [DBGDTRTX_EL0](#) register to transmit data.
 - The read-only [DBGDTRRX_EL0](#) register to receive data.
- A single 64-bit read/write register, [DBGDTR_EL0](#), for 64-bit half-duplex operation.
- The read/write [OSDTRTX_EL1](#) and [OSDTRRX_EL1](#) registers for save and restore.

The data transfer registers are also accessible by the external debug interface as a pair of 32-bit registers, [DBGDTRRX_EL0](#) and [DBGDTRTX_EL0](#). Both registers are read/write, allowing both 32-bit full-duplex and 64-bit half-duplex operation.

The DCC flow-control flags are [EDSCR](#). {RXfull, TXfull, RXO, TXU}:

- The RXfull and TXfull ready flags are used for flow-control and are visible to software in the Debug System registers in [MDCCSR_EL0](#).
- The RX overrun flag, RXO, and the TX underrun flag, TXU, report flow-control errors.
- The flow-control flags are also accessible by software as simple read/write bits for saving and restoring over a powerdown when the OS Lock is locked in [MDSCR_EL1](#).
- The flow-control flags are accessible from the external debug interface in [EDSCR](#).

[Figure E4-1](#) shows the System register and external debug interface views of the [EDSCR](#) and DTR registers. These figures do not include the save and restore views.

Figure E4-1 System register and external debug interface views of EDSCR and DTR registers, Normal access mode

EDITR and the ITR flow-control flags, **EDSCR**.{ITE, ITO} are accessible only by the external debug interface:

- The **EDITR** specifies an instruction to execute in Debug state.
- The ITR empty flag, ITE, is used for flow-control.
- The ITR overrun flag, ITO, reports flow-control errors.

Figure E4-2 External debug interface views of EDSCR and EDITR registers, Normal access mode

The sticky overflow flag, [EDSCR.ERR](#), is used by both the DCC and ITR to report flow-control errors.

To save and restore the DCC registers for an external debugger over powerdown, software uses:

- The [MDSCR_EL1](#), [OSDTRTX_EL1](#), and [OSDTRRX_EL1](#) registers in AArch64 state.

Note

There is no save and restore mechanism for the ITR registers as the ITR is used only in Debug state.

Figure E4-3 System register views of EDSCR and DTR registers for save and restore

E4.3 DCC and ITR access modes

The DCC and ITR support two access modes:

DCC and ITR access mode, links to description	Applies when:
Normal access mode	EDSCR .MA == 0 or the PE is in Non-debug state
Memory access mode	EDSCR .MA == 1 and the PE is in Debug state

E4.3.1 Normal access mode

The Normal access mode allows use of the DCC as a communications channel between target and host. It also allows the use of the ITR for issuing instructions to the PE in Debug state.

In Normal access mode, if there is no overrun or underrun, the following occurs:

For accesses by software:

- Direct writes to [DBGDTRTX_EL0](#) update the value in DTRTX and indirectly write 1 to TXfull.
- Direct reads from [DBGDTRRX_EL0](#) return the value in DTRRX and indirectly write 0 to RXfull.
- Direct writes to [DBGDTR_EL0](#) update both DTRTX and DTRRX, indirectly write 1 to TXfull, and do not change RXfull:
 - DTRTX is set from bits[31:0] of the transfer register.
 - DTRRX is set from bits[63:32] of the transfer register.
- In AArch64 state, direct reads from [DBGDTR_EL0](#) return the concatenation of DTRRX and DTRTX, indirectly write 0 to RXfull, and do not change TXfull:
 - Bits[31:0] of the transfer register are set from DTRRX.
 - Bits[63:32] of the transfer register are set from DTRTX.

Note
For [DBGDTR_EL0](#), the word order is reversed for reads with respect to writes.

Software reads TXfull and RXfull using [MDCCSR_EL0](#).

For accesses by the external debug interface:

- Writes to [EDITR](#) trigger the instruction to be executed if the PE is in Debug state, if the PE is in AArch64 state, this is an A64 instruction.
- Reads of [DBGDTRTX_EL0](#) return the value in DTRTX and indirectly write 0 to TXfull.
- Writes to [DBGDTRTX_EL0](#) update the value in DTRTX and do not change TXfull.
- Reads of [DBGDTRRX_EL0](#) return the value in DTRRX and do not change RXfull.
- Writes to [DBGDTRRX_EL0](#) update the value in DTRRX and indirectly write 1 to RXfull. TXfull and RXfull are visible to the external debug interface in [EDSCR](#). The PE detects overrun and underrun by the external debug interface, and records errors in [EDSCR](#).{TXU, RXO, ITO, ERR}. See [Flow control of the DCC and ITR registers](#).

See also [Synchronization of DCC and ITR accesses](#).

E4.3.2 Memory access mode

When the PE is in Debug state, *Memory access mode* can be selected to accelerate word-aligned block reads or writes of memory by an external debugger. Memory access mode can be enabled only in Debug state, and no instructions can be issued directly by the debugger when in Memory access mode.

If there is no overrun or underrun when in Memory access mode, an access by the external debug interface results in the following:

- External reads from [DBGDTRTX_EL0](#) cause:
 1. The existing value in DTRTX to be returned. This clears [EDSCR.TXfull](#) to 0.
 2. The equivalent of `LDR W1, [X0], #4` to be executed.
 3. The equivalent of the `MSR DBGDTRTX_EL0, X1` instruction to be executed.
 4. [EDSCR.{TXfull, ITE}](#) to be set to {1, 1}, and X1 or R1 to be set to an UNKNOWN value.
- External writes to [DBGDTRRX_EL0](#) cause:
 1. The value in DTRRX to be updated. This sets [EDSCR.RXfull](#) to 1.
 2. The equivalent of the instruction `MRS X1, DBGDTRRX_EL0` to be executed.
 3. The equivalent of the instruction `STR W1, [X0], #4` to be executed.
 4. [EDSCR.{RXfull, ITE}](#) to be set to {0, 1}, and X1 or R1 to be set to an UNKNOWN value.
- External reads from [DBGDTRRX_EL0](#) return the last value written to DTRRX.
- External writes to [EDITR](#) generate an overrun error.

During these accesses, [EDSCR.{TXfull, RXfull, ITE}](#) are used for flow control.

Note

An overrun or underrun might result in [EDSCR.ERR](#) being set to 1 asynchronously to the sequence of operations that are outlined in this section. As this is timing-dependent, it is UNPREDICTABLE when the [EDSCR.ERR](#) flag affects the instructions and therefore whether neither instruction, only the first instruction, or both instructions are executed. If the second instruction is executed, then the first instruction must have been executed. However, in each case X1 or R1 is set to an UNKNOWN value. This means that:

- In both cases, if the memory access instruction is not executed, then the base register X0 or R0 is not updated, meaning the debugger can determine the last accessed location.
- In the list describing External reads from [DBGDTRTX_EL0](#), DTRTX and [EDSCR.TXfull](#) get set to UNKNOWN values. If the load was executed, then the value that was read by the PE is lost. This means the operation might need to be repeated by the debugger, and it is not advisable to use Memory access mode to read from read-sensitive locations using the underrun and overrun detection for flow control.
- In the list describing External writes to [DBGDTRRX_EL0](#), [EDSCR.RXfull](#) is set to an UNKNOWN value.

A Data Abort from the memory access can also set [EDSCR.ERR](#) to 1. See [Data Aborts in Memory access mode](#).

The architecture does not require precisely when these flags are set or cleared by the sequence of operations outlined in this section.

For example, in the case of an external write to [DBGDTRRX_EL0](#), in AArch64 state, [RXfull](#) might be cleared after step 2, or it might not be cleared until after step 3, as an implementation is free to fuse these steps into a single operation.

The architecture does require that the flags are set as at step 4 when the PE is ready to accept a further read or write without causing an overrun error or an underrun error.

The process outlined in this section represents a simple sequential execution model of Memory access mode. An implementation is free to pipeline, buffer, and reorder instructions and transactions, as long as the following remain true:

- Data items are transferred into and out of the DTR in order and without loss of data, other than as a result of an overrun or an underrun.
- Data Aborts occur in order.
- The constraints of the memory type are met.
- In the list describing [External reads from](#):
 - The MSR equivalent operation at step 3 of the sequence reads the value loaded by step 2.

- If the list is performed in a loop, for all but the first iteration of this list, the value read by step 1 returns the values written by the MSR equivalent operation at the previous iteration of step 3.
- In the list describing [External writes to](#):
 - The MRS equivalent operation at step 2 of the sequence returns the value written at step 1.
 - The STR equivalent at step 3 of the sequence writes the value read at step 2.
- If the PE cannot accept a read or write, as applicable, during the sequence, then the flags are updated to indicate an overrun or underrun.

See [Flow control of the DCC and ITR registers](#) for more information on overrun and underrun.

E4.3.2.1 Ordering, access sizes and effect on Exclusives monitors

For the purposes of memory ordering, access sizes, and effect on the Exclusives monitor, accesses in Memory access mode are consistent with load/store word instructions executed by the PE.

The simple sequential access model of Memory access mode, as stated in [Memory access mode](#), must also be ordered with respect to instructions executed as a result of External writes to [EDITR](#) in Normal mode both before and after accesses to the DTR registers in Memory access mode.

E4.3.2.2 Data Aborts in Memory access mode

If a memory access generates a Data Abort, then:

- The Data Abort exception is taken. See [Exceptions in Debug state](#):
 - This means [EDSCR.ERR](#) is set to 1, see [Cumulative error flag](#).
 - If the Data Abort occurs on stage 2 of an address translation, then the values returned in the ISV field and in bits[23:14] of the ISS are UNKNOWN.
If this Data Abort is taken to EL2, the ISS is returned by [ESR_EL2](#). [ISS encoding for an exception from a Data Abort](#) describes the usual encoding of this ISS.
- Register R0 retains the address that generated the abort.
- Register R1 is set to an UNKNOWN value.
- [EDSCR.TXfull](#), for a load, or [EDSCR.RXfull](#), for a store, is set to an UNKNOWN value.
- DTRTX, for a load, or DTRRX, for a store, is set to an UNKNOWN value.
- [EDSCR.ITE](#) is set to 1.

E4.3.2.3 Illegal Execution state exception

If [PSTATE.IL](#) is set to 1 when [EDSCR.MA](#) = 1, then on an external write access to [DBGDTRRX_EL0](#) or an external read from [DBGDTRTX_EL0](#), it is CONSTRAINED UNPREDICTABLE whether the PE:

- Takes an Illegal Execution state exception without performing any operations. In this case:
 - [EDSCR.ERR](#) is set to 1, see [Cumulative error flag](#).
 - Register R0 is unchanged.
 - Register R1 is set to an UNKNOWN value.
 - [EDSCR.TXfull](#) or [EDSCR.RXfull](#), as applicable, is set to an UNKNOWN value.
 - DTRTX or DTRRX, as applicable, is set an UNKNOWN value.
 - [EDSCR.ITE](#) is set to 1.

See also [Exceptions in Debug state](#).

- Ignores [PSTATE.IL](#).

Note

The typical usage model for Memory access mode involves executing instructions in Normal access mode to set up X0 before setting [EDSCR.MA](#) to 1. These instructions generate an Illegal state exception if [PSTATE.IL](#) is set to 1.

E4.3.2.4 Alignment constraints

If the address in R0 is not aligned to a multiple of four, the behavior is as follows:

- For each external DTR access a CONSTRAINED UNPREDICTABLE choice of:
 1. The PE makes an unaligned memory access to R0. If alignment checking is enabled for the memory access, this generates an Alignment fault.
 2. The PE makes a memory access to $\text{Align}(X[0], 4)$.
 3. The PE generates an Alignment fault, regardless of whether alignment checking is enabled.
 4. The PE does nothing.
- Following each memory access, if there is no Data Abort, R0 is updated with an UNKNOWN value.
- For external writes to [DBGDTRRX_EL0](#), if the PE writes to memory, an UNKNOWN value is written.
- For external reads of [DBGDTRTX_EL0](#) an UNKNOWN value is returned.
- The RXfull and TXfull flags are left in an UNKNOWN state, meaning that a [DBGDTRTX_EL0](#) read can trigger a TX underrun, and a [DBGDTRTX_EL0](#) write can trigger an RX overrun.

E4.3.3 Memory-mapped accesses to the DCC and ITR

Writes to the flags in [EDSCR](#) by external debug interface accesses to the DCC and the ITR registers are indirect writes, because they are a side-effect of the access. The indirect write might not occur for a memory-mapped access to the external debug interface. For more information, see [Register access permissions for memory-mapped accesses](#).

E4.4 Flow control of the DCC and ITR registers

- Ready flags.
- Buffering writes to EDITR.
- Overrun and underrun flags.
- Cumulative error flag.

E4.4.1 Ready flags

In Normal access mode:

- For the DTR registers there are two ready flags:
 - `EDSCR.RXfull` == 1 indicates that `DBGDTRRX_ELO` contains a valid value that has been written by the external debugger and not yet read by software running on the target.
 - `EDSCR.TXfull` == 1 indicates that `DBGDTRTX_ELO` contains a valid value that has been written by software running on the target and not yet read by an external debugger.
- For the ITR register there is a single ready flag:
 - `EDSCR.ITE` == 1 indicates that the PE is ready to accept an instruction to the ITR.

Note

The architecture permits a PE to continue to accept and buffer instructions when previous instructions have not completed their architecturally defined behavior, as long as those instructions are discarded if `EDSCR.ERR` is 1, either by an underrun or overrun or by any of the other error conditions described in this architecture, such as an instruction generating an abort.

In Memory access mode:

- `EDSCR.{RXfull, ITE}` == {0, 1} indicates that `DBGDTRRX_ELO` is empty and the PE is ready to accept a word external write to `DBGDTRRX_ELO`.
- `EDSCR.{TXfull, ITE}` == {1, 1} indicates that `DBGDTRTX_ELO` is full and the PE is ready to accept a word external read from `DBGDTRTX_ELO`.

All other values indicate that the PE is not ready, and result in a DTR overrun or underrun error, an ITR overrun error, or both, as defined in [Overrun and underrun flags](#).

`EDSCR.{ITE, RXfull, TXfull}` shows the status of the ITR and DCC registers. It ignores the question of whether a read or write cannot be accepted because, for example, `EDSCR.ERR` is set or the OPTIONAL Software Lock is locked for memory-mapped accesses (`EDLSR.SLK` == 1).

E4.4.2 Buffering writes to EDITR

The architecture permits a processor to continue to accept and buffer instructions when previous instructions have not completed their architecturally defined behavior, provided that:

- Those instructions are discarded if `EDSCR.ERR` is set to 1, either by an underrun or an overrun, or by any other error conditions described in this architecture, such as an instruction generating an abort.
- The PE maintains the simple sequential execution model with the order of instructions determined by the order in which the PE accepts the EDITR writes. In particular, the buffered instructions must be executed in the Execution state consistent with a simple sequential execution of the instructions, even if one of the previous instructions is a state changing operation, such as `DCPS` or `DRPS`.

E4.4.3 Overrun and underrun flags

Each of the ready flags has a corresponding overrun or a corresponding underrun flag. These are sticky status flags that are set if the register is accessed using the external debug interface when the corresponding ready flag is not in the ready state.

If the PE is in Debug state and Memory access mode, the corresponding error flag is also set if the PE is not ready to accept an operation because a previous load or store is still in progress. The sticky status flag remains set until cleared by writing 1 to [EDSCR.CSE](#).

Note

The architecture permits a PE to continue to accept and buffer data to write to memory in Memory access mode.

[Table E4-2](#) shows DCC and ITR ready flags and the overrun and underrun flags associated with them.

Table E4-2 DCC and ITR ready flags and the associated overrun/underrun flags

External debug interface access	Overrun/Underrun condition	EDSCR flag
Write DBGDTRRX_EL0	<code>EDSCR.RXfull == '1' (Halted() && EDSCR.MA == '1' && EDSCR.ITE == '0')</code>	RXO
Read DBGDTRTX_EL0	<code>EDSCR.TXfull == '0' (Halted() && EDSCR.MA == '1' && EDSCR.ITE == '0')</code>	TXU
Write EDITR	<code>Halted() && (EDSCR.ITE == '0' EDSCR.MA == '1')</code>	ITO

When an overrun or underrun flag is set to 1, the cumulative error flag, [EDSCR.ERR](#), described in [Cumulative error flag](#), is also set to 1.

In the event of an external write to [DBGDTRRX_EL0](#) or [EDITR](#) generating an overrun, or an external read from [DBGDTRTX_EL0](#) generating an underrun:

- For a write, the written value is ignored.
- For a read, an UNKNOWN value is returned.
- [EDSCR.TXfull](#), [EDSCR.RXfull](#) or [EDSCR.ITE](#), as applicable, are not updated.

There is no overrun or underrun detection on external reads of [DBGDTRRX_EL0](#) or external writes of [DBGDTRTX_EL0](#).

There is no overrun or underrun detection of direct reads and direct writes of the DTR System registers by software:

- If `RXfull == 0`, a direct read of [DBGDTRRX_EL0](#) or [DBGDTR_EL0](#) returns UNKNOWN.
- If `TXfull == 1`, a direct write of:
 - [DBGDTRTX_EL0](#) sets DTRTX to UNKNOWN.
 - [DBGDTR_EL0](#) sets DTRRX and DTRTX to UNKNOWN.

See [DCC accesses in Non-debug state](#) for more information.

E4.4.3.1 Accessing 64-bit data

In AArch64 state, a software access to the [DBGDTR_EL0](#) register and an external debugger access to both [DBGDTRRX_EL0](#) and [DBGDTRTX_EL0](#) can perform a 64-bit half-duplex operation.

However, there is only overrun and underrun detection on one of the external debug registers. That is:

- If software directly writes a 64-bit value to [DBGDTR_EL0](#), only `TXfull` is set to 1, meaning:
 - A subsequent external write to [DBGDTRRX_EL0](#) would not be detected as an overrun.

- If the external debugger reads `DBGDTRTX_EL0` first, software might observe `MDCCSR_EL0.TXfull == 0` and send a second value before the external debugger reads `DBGDTRRX_EL0`, leading to an undetected overrun.
- On external writes to both `DBGDTRRX_EL0` and `DBGDTRTX_EL0`, only `RXfull` is set to 1, meaning:
 - A subsequent direct write of `DBGDTRTX_EL0` would not be detected as an overrun.
 - If the external debugger writes to `DBGDTRRX_EL0` first, software might observe `MDCCSR_EL0.RXfull == 1` and read a full 64-bit value, before the external debugger writes to `DBGDTRTX_EL0`, leading to an undetected underrun.

To avoid this, debuggers need to be aware of the data size used by software for transfers and ensure that 64-bit data is read or written in the correct order. If the PE is in Non-debug state, this order is as follows:

- The external debugger must check `EDSCR.{RXfull, TXfull}` before each transfer.
- To receive a 64-bit value from the target, the external debugger must read `DBGDTRRX_EL0` before reading `DBGDTRTX_EL0`.
- To send a 64-bit value to the target, the external debugger must write to `DBGDTRTX_EL0` before writing `DBGDTRRX_EL0`.

Because three accesses are required to transfer 64 bits of data, 64-bit transfers are not recommended for regular communication between host and target. The use of underrun and overrun detection means that only one access is required for 32 bits of data when using 32-bit transfers.

In Debug state, the debugger controls the instructions executed by the PE, so these limitations do not apply. 64-bit transfers provide a means to transfer a 64-bit general register between the host and the target in Debug state.

E4.4.4 Cumulative error flag

The cumulative error flag, `EDSCR.ERR`, is set to 1:

- On taking an exception from Debug state.
- On any signaled overrun or underrun in the DCC or ITR.

When `EDSCR.ERR == 1`:

- External reads of `DBGDTRTX_EL0` do not have any side-effects.
- External writes to `DBGDTRRX_EL0` are ignored.
- External writes to `EDITR` are ignored.
- No further instructions can be issued in Debug state. This includes any instructions previously accepted as external writes to `EDITR` that occur in program order after the instruction or access that caused the error.

This allows a debugger to stream data, or, in Debug state, instructions, to the target without having to:

- Check `EDSCR.{RXfull, TXfull, ITE}` before each access.
- Check `EDSCR.{ITO, RXO, TXU}` following each access, for overrun or underrun.
- Check `PSTATE` or other syndrome registers, or both, for an exception following each instruction executed in Debug state that might generate a synchronous exception.

The cumulative error flag remains set until cleared to 0 by writing 1 to `EDRCR.CSE`. However, the effect of writing 1 to `EDRCR.CSE` to clear `EDSCR.ERR` is **CONSTRAINED UNPREDICTABLE** when both of the following apply:

- The PE is in Debug state.
- The value of `EDSCR.ITE` is 0.

When these conditions apply and a value of 1 is written to `EDRCR.CSE`, either or both of the following might occur:

- `EDSCR.ERR` is not cleared to 0.
- Any instructions in `EDITR` that have not been executed might be executed subsequently, rather than being ignored.

Note

This means that a debugger must poll [EDSCR.ITE](#) until it has the value 1, indicating that [EDITR](#) is empty, before writing to [EDRCR.CSE](#) to clear the [EDSCR.ERR](#) flag to 0.

For overruns and underruns, [EDSCR.{ITO, RXO, TXU}](#) record the error type.

E4.4.4.1 Pseudocode description of clearing the error flag

The [ClearStickyErrors\(\)](#) pseudocode function is described in [R-profile Architecture Pseudocode](#).

E4.5 Synchronization of DCC and ITR accesses

In addition to the standard synchronization requirements for register accesses, the following subsections describe additional requirements that apply for the DCC and ITR registers:

- [Summary of System register accesses to the DCC.](#)
- [DCC accesses in Non-debug state.](#)
- [Synchronization of DCC interrupt request signals.](#)
- [DCC and ITR access in Debug state.](#)

In these sections, accesses by the external debug interface are referred to as external reads and external writes. Accesses to System registers are referred to as direct reads, direct writes, indirect reads, and indirect writes.

Note

In [Synchronization requirements for AArch64 System registers](#) external reads and external writes are described as forms of indirect access. This whole section uses more explicit terminology.

The DTR registers and the DCC flags, TXfull and RXfull, form a communication channel, with one end operating asynchronously to the other. Implementations must respect the ordering of accesses to these registers in order to maintain the correct behavior of the channel.

External reads of, and external writes to [DBGDTRRX_EL0](#) and [DBGDTRTX_EL0](#) are asynchronous to direct reads of, and direct writes to, [DBGDTRRX_EL0](#), [DBGDTRTX_EL0](#), and in AArch64 state [DBGDTR_EL0](#), made by software using System register access instructions. The direct reads and direct writes indirectly write to the DCC flags. The external reads and external writes indirectly read the DCC flags to check for underrun and overrun.

Throughout this section:

- | | |
|------------------|--|
| DCC flags | Means any or all of the following: <ul style="list-style-type: none"> • The EDSCR.{RXfull.TXfull} ready flags. • The EDSCR.RXO overrun flag. • The EDSCR.TXU underrun flag. • The EDSCR.ERR cumulative error flag. |
| ITR flags | Means any or all of the following: <ul style="list-style-type: none"> • The EDSCR.ITE ready flag. • The EDSCR.ITO overrun flag. • The EDSCR.ERR cumulative error flag. |

E4.5.1 Summary of System register accesses to the DCC

System register accesses to the DTR registers are direct reads and writes of those registers, as shown in [Table E4-3](#). Several of these instructions access the same registers using different encodings.

[DBGDTRRX_EL0](#) and [DBGDTRTX_EL0](#) are encoded as MRS and MSR accesses respectively to the same System register, even though they access different underlying register values. [DBGDTRRX_EL0](#) and [DBGDTRTX_EL0](#) are similarly encoded as MRC and MCR accesses respectively to the same System register. The encoding means that direct reads and writes using these encodings must be ordered with respect to each other. For more information, see [Synchronization requirements for AArch64 System registers](#).

[Table E4-3](#) shows a summary of System register accesses to the DCC.

Table E4-3 Summary of System register accesses to the DCC

Operation	OS Lock	AArch64 (MRS/MSR)	Description
Read	-	DBGDTRRX_EL0	Direct read of DTRRX. Indirect write to the DCC flags . An STC instruction that reads DBGDTRRXint makes an indirect write to DBGDSCRint.RXfull.
Write	-	DBGDTRTX_EL0	Direct read of DTRTX. Indirect write to the DCC flags . An LDC instruction that writes to DBGDTRTXint using a value read from memory is a direct write to DBGDTRTXint.
Read/write	-	DBGDTR_EL0	Direct read/write of both DTRRX and DTRTX. Indirect write to the DCC flags .
Read	-	MDCCSR_EL0	Direct read of the DCC flags .
Read/write	-	OSDTRRX_EL1	Direct read/write of DTRRX.
Read/write	-	OSDTRTX_EL1	Direct read/write of DTRTX.
Read	Unlocked	MDSCR_EL1	Direct read of DCC flags .
Read/write	Locked	MDSCR_EL1	Direct read/write of DCC flags .

E4.5.2 DCC accesses in Non-debug state

In Non-debug state DCC accesses are as described in [Normal access mode](#):

- If a direct read of [MDCCSR_EL0](#) returns $RXfull == 1$, then a following direct read of [DBGDTRRX_EL0](#), or in AArch64 state of [DBGDTR_EL0](#), returns valid data and indirectly writes 0 to [MDCCSR_EL0.RXfull](#) as a side-effect.
- If a direct read of [MDCCSR_EL0](#) returns $TXfull == 0$, then a following direct write to [DBGDTRTX_EL0](#), or in AArch64 state to [DBGDTR_EL0](#), writes the intended value, and indirectly writes 1 to [MDCCSR_EL0.TXfull](#) as a side-effect.

No [Context Synchronization event](#) is required between these two instructions. Overrun and underrun detection prevents intervening external reads and external writes affecting the outcome of the second instruction.

The indirect write to the [DCC flags](#) as part of the DTR access instruction is made atomically with the DTR access.

Because a direct read of [DBGDTRRX_EL0](#) is an indirect write to [MDCCSR_EL0.RXfull](#), it must occur in program order with respect to the direct read of [MDCCSR_EL0](#), meaning it must not return a speculative value for DTRRX that predates the $RXfull$ flag returned by the read of [MDCCSR_EL0](#). The direct write to [DBGDTRTX_EL0](#) must not be executed speculatively.

Direct reads of [DBGDTRRX_EL0](#), or in AArch64 state [DBGDTR_EL0](#), and [MDCCSR_EL0](#), must occur in program order with respect to other direct reads of the same register using the same encoding.

The following accesses have an implied order within the atomic access:

- In the simple sequential execution of the program the indirect write of the [DCC flags](#) occurs immediately after the direct DTR access.

Note

For an access to [DBGDTR_EL0](#), this means the indirect write happens after both [DBGDTRRX_EL0](#) and [DBGDTRTX_EL0](#) have been accessed.

- In the simple sequential execution model, for an external read of [DBGDTRTX_EL0](#) or an external write of [DBGDTRRX_EL0](#):
— The check of the [DCC flags](#) for overrun or underrun occurs immediately before the access.

- If there is no underrun or overrun, the update of the [DCC flags](#) occurs immediately after the access.
- If there is underrun or overrun, the update of the DCC underrun or overrun flags occurs immediately after the access.

All observers must observe the same order for accesses.

Note

These requirements do not create order where order does not otherwise exist. It applies only for ordered accesses.

Without explicit synchronization following external writes and external reads:

- The value written by the external write to [DBGDTRRX_EL0](#) that does not overrun, must be observable to direct reads of [DBGDTRRX_EL0](#) and [DBGDTR_EL0](#) in finite time.
- The [DCC flags](#) that are updated as a side-effect of the external write or external read must be observable:
 - To subsequent external reads of [EDSCR](#).
 - To subsequent external reads of [DBGDTRRX_EL0](#) when checking for underrun.
 - To subsequent external writes to [DBGDTRTX_EL0](#) when checking for overrun.
 - To direct reads of [MDCCSR_EL0](#) in finite time.

However, explicit synchronization is required to guarantee that a direct read of [MDCCSR_EL0](#) returns up-to-date [DCC flags](#). This means that if a signal is received from another agent that indicates that [MDCCSR_EL0](#) must be read, an [ISB](#) is required to ensure that the direct read of [MDCCSR_EL0](#) occurs after the signal has been received. This also synchronizes the value in [DBGDTRRX_EL0](#), if applicable. However, if that signal is an interrupt exception triggered by [COMMIQ](#), [COMMTX](#), or [COMMRX](#), the exception entry is sufficient synchronization. See [Synchronization of DCC interrupt request signals](#).

Explicit synchronization is required following a direct read or direct write:

- To ensure that a value directly written to [DBGDTRTX_EL0](#) is observable to external reads of [DBGDTRTX_EL0](#).
- To ensure that a value directly written to [DBGDTR_EL0](#) is observable to external reads of [DBGDTRTX_EL0](#) and [DBGDTRRX_EL0](#).
- To guarantee that the indirect writes to the [DCC flags](#) that were a side-effect of the direct read or direct write have occurred, and therefore that the updated values are:
 - Observable to external reads of [EDSCR](#).
 - Observable to external reads of [DBGDTRRX_EL0](#) when checking for underrun.
 - Observable to external writes of [DBGDTRTX_EL0](#) when checking for overrun.
 - Returned by a following direct read of [MDCCSR_EL0](#).

See also [Memory-mapped accesses to the DCC and ITR](#) and [Synchronization of changes to the external debug registers](#).

Note

These ordering rules mean that software:

- Must not read [DBGDTRRX_EL0](#) or [DBGDTR_EL0](#) without first checking [MDCCSR_EL0.RXfull](#) or if the previously-read value of [MDCCSR_EL0.RXfull](#) is 0.
It is not sufficient to read both registers and then later decide whether to discard the read value, as there might be an intervening write from the external debug interface.
 - Must not write [DBGDTRTX_EL0](#) or [DBGDTR_EL0](#) without first checking [MDCCSR_EL0.TXfull](#) or if the previously-read value of [MDCCSR_EL0.TXfull](#) is 1.
The write to [DBGDTRTX_EL0](#) overwrites the value in [DTRTX](#), and the external debugger might or might not have read this value.
 - Must ensure there is an explicit [Context Synchronization event](#) following a DTR access, even if not immediately returning to read [MDCCSR_EL0](#) again. This synchronization operation might be an exception return.
-

E4.5.2.1 Derived requirements

The rules for DCC accesses in Non-debug state are as follows:

- Following a direct read of `DBGDTRRX_EL0` when `RXfull` is 1:
 - If an external write to `DBGDTRRX_EL0` checks the `RXfull` flag for overrun and observes that the value of `RXfull` is 0, the value returned by the previous direct read must not be affected by the external write.
 - If an external read of `EDSCR` returns a `RXfull` value of 0, then the value returned by the previous direct read must not be affected by a following external write to `DBGDTRRX_EL0`, and the following external write does not overrun.
- Following a direct read of `DBGDTR_EL0`, when `RXfull` is 1:
 - If an external write to `DBGDTRRX_EL0` checks the `RXfull` flag for overrun and observes that the value of `RXfull` is 0, the value returned by the previous direct read must not be affected by the external write nor by a following direct write to `DBGDTRTX_EL0`.
 - If an external read of `EDSCR` returns a `RXfull` value of 0, then the value returned by the previous direct read must not be affected by subsequent external writes to `DBGDTRRX_EL0` and `DBGDTRTX_EL0` in any order, and the following external write of `DBGDTRRX_EL0` will not overrun.
- Following a direct write to `DBGDTRTX_EL0`, when `TXfull` is 0:
 - If an external read of `DBGDTRTX_EL0` checks the `TXfull` flag for underrun and observes that the value of `TXfull` is 1, the value returned by the external read must be the value written by the previous direct write.
 - If an external read of `EDSCR` returns a `TXfull` value of 1, then the value returned by a following external read of `DBGDTRRX_EL0` must be the value written by the previous direct read, and the subsequent external read will not underrun.
- Following a direct write to `DBGDTR_EL0`, when `TXfull` is 0:
 - If an external read of `DBGDTRTX_EL0` checks the `TXfull` flag for underrun and observes that the value of `TXfull` is 1, the values returned by the external read and by a subsequent external read of `DBGDTRRX_EL0` must be the value written by the previous direct write.
 - If an external read of `EDSCR` returns a `TXfull` value of 1, then the value returned by subsequent external reads of `DBGDTRRX_EL0` and `DBGDTRTX_EL0`, in any order, must be the value written by the previous direct read, and the subsequent external read of `DBGDTRTX_EL0` does not underrun.
- Following an external read of `DBGDTRTX_EL0` that does not underrun, if a direct read of `MDCCSR_EL0` returns a `TXfull` value of 0, then the value returned by the external read must not be affected by a following direct write to `DBGDTRTX_EL0`.
- Following a first external read `DBGDTRRX_EL0` and a following second external read of `DBGDTRTX_EL0` that does not underrun, if a direct read of `MDCCSR_EL0` returns a `TXfull` value of 0, then the values returned by the external reads must not be affected by a following direct write to `DBGDTR_EL0`.
- Following an external write to `DBGDTRRX_EL0` that does not overrun, if a direct read of `MDCCSR_EL0` returns an `RXfull` value of 1, then the value returned by a following direct read of `DBGDTRRX_EL0` or `DBGDTR_EL0` must be the value written by the previous external write.
- Following a first external write to `DBGDTRTX_EL0` and a following second external write to `DBGDTRRX_EL0` that does not overrun, if a direct read of `MDCCSR_EL0` returns an `RXfull` value of 1, then the value returned by a subsequent direct read of `DBGDTR_EL0` must return the values written by the previous external writes.

E4.5.3 Synchronization of DCC interrupt request signals

Following an external read or external write access to the DTR registers, the interrupt request signals, `COMMIRQ`, `COMMTX`, and `COMMRX`, must be updated in finite time without explicit synchronization.

The updated values must be observable to a direct read of `MDCCSR_EL0` or `DBGDTRRX_EL0`, or a direct write of `DBGDTRTX_EL0` executed after taking an interrupt exception generated by the interrupt request. The updated values must also be observable to a direct write of `DBGDTRTX_EL0` executed after taking an interrupt exception generated by the interrupt request.

Note

The requirement that indirect writes to registers are observable to direct reads in finite time does not imply that all observers will observe the indirect write at the same time. For more information, see [Synchronization requirements for AArch64 System registers](#).

Following a direct read of [DBGDTRRX_EL0](#) or a direct write to [DBGDTRRX_EL0](#), software must execute a [Context Synchronization event](#) to guarantee the interrupt request signals have been updated in finite time. This synchronization operation can be an exception return.

E4.5.4 DCC and ITR access in Debug state

In Debug state, stricter observability rules apply for instructions issued through the ITR, to maintain communication between a debugger and the PE, without requiring excessive explicit synchronization.

In Normal access mode, without explicit synchronization:

- A direct read or direct write of the DTR registers by an instruction written to [EDITR](#) must be observable to an external write or an external read in finite time:
 - A direct read of [DBGDTRRX_EL0](#) must be observable to an external write of [DBGDTRRX_EL0](#).
 - A direct read of [DBGDTR_EL0](#) must be observable to an external write of [DBGDTRRX_EL0](#) and [DBGDTRTX_EL0](#).
 - A direct write of [DBGDTRTX_EL0](#) must be observable to an external read of [DBGDTRTX_EL0](#).
 - A direct write of [DBGDTR_EL0](#) must be observable to an external read of [DBGDTRRX_EL0](#) and [DBGDTRTX_EL0](#).

This includes the indirect write to the [DCC flags](#) that occurs atomically with the access as described in [DCC accesses in Non-debug state](#).

The subsequent external write or external read must observe either the old or the new values of both the DTR contents and [DCC flags](#). If the old values are observed, this typically results in overrun or underrun, assuming the old values of the [DCC flags](#) indicate an overrun or underrun condition, as would normally be the case.

This means the debugger can observe the direct read or direct write without explicit synchronization and without explicitly testing the [DCC flags](#) in [EDSCR](#), because it can rely on overrun and underrun tests.

- External reads of [DBGDTRTX_EL0](#) that do not underrun and external writes to [DBGDTRRX_EL0](#) that do not overrun must be observable to an instruction subsequently written to [EDITR](#) on completion of the first external access. This includes the indirect write to the [DCC flags](#).

This means that without explicit synchronization and without the need to first check the [DCC flags](#) in [MDCCSR_EL0](#):

- If the instruction is a direct read of [DBGDTRRX_EL0](#), it observes the external write.
- If the instruction is a direct write of [DBGDTRTX_EL0](#), it observes the external read.
- Writes to [EDITR](#) that do not overrun commit an instruction for execution immediately. The instruction must complete execution in finite time without requiring any further operation by the debugger.
- After an external write to the [EDITR](#), the [ITR flags](#) that are updated as a side effect of that write must be observable by:
 - An external read of the [EDSCR](#) that follows the external write to the [EDITR](#).
 - When checking for overrun, another external write to the [EDITR](#) that follows the original external write to the [EDITR](#).

In Memory access mode, these requirements shift to the instructions implicitly executed by external reads and external writes of the DTR registers, as described in [Memory access mode](#).

E4.6 Interrupt-driven use of the DCC

Arm recommends implementations provide a level-sensitive DCC interrupt request through the IMPLEMENTATION DEFINED interrupt controller as a Private Peripheral Interrupt for the originating PE.

Note

- In addition to connection to the interrupt controller Arm also recommends **COMMIRQ**, **COMMTX**, and **COMMRX** signals that might be implemented for use by any legacy system peripherals.
 - GICv3 reserves a Private Peripheral Interrupt number for the **COMMIRQ** interrupt.
-

The [MDCCINT_EL1](#) register provides a first level of interrupt masking within the PE, meaning only a single interrupt source, **COMMIRQ**, is needed at the interrupt controller.

See also [Synchronization of DCC interrupt request signals](#).

E4.7 Pseudocode description of the operation of the DCC and ITR registers

The basic operation of the DCC and ITR registers is shown by the following pseudocode functions. These functions do not cover the behavior when [OSLSR_EL1.OSLK](#) == 1, meaning that the OS Lock is locked:

- `Write_DBGDTR_EL0()`.
- `Write_DBGDTRRX_EL0()`.
- `Write_DBGDTRTX_EL0()`.
- `Write_EDITR()`.
- `CheckForDCCInterrupts()`.

For the definition of the DTR Registers, see [shared/debug/dccanditr/DTR](#).

Chapter E5

The Embedded Cross-Trigger Interface

This chapter describes the Embedded Cross-Trigger interface. It contains the following sections:

- [About the Embedded Cross-Trigger](#)
- [Basic operation on the ECT](#)
- [Cross-triggers on a PE in an Arm R-profile implementation](#)
- [Description and allocation of CTI triggers](#)
- [CTI registers programmers' model](#)
- [Examples](#)

E5.1 About the Embedded Cross-Trigger

The *Embedded Cross-Trigger* (ECT) allows a debugger to:

- Send trigger events to a PE. For example, this might be done to halt the PE.
- Send a trigger event to one or more PEs, or other system components, when a trigger event occurs on another PE or system component. For example, this might be done to halt all PEs when one individual PE halts.

Figure E5-1 shows the logical structure of an ECT.

Figure E5-1 Structure of an Embedded Cross-Trigger

The ECT can deliver many types of trigger events, which are described in the following sections:

- [Debug request trigger event.](#)
- [Restart request trigger event.](#)
- [Cross-halt trigger event.](#)
- [Performance Monitors overflow trigger event.](#)
- [Generic trace external input trigger events.](#)
- [Generic trace external output trigger events.](#)
- [Generic CTI interrupt trigger event.](#)

From the introduction of Armv8, an implementation must:

- Include a Cross-Trigger interface, CTI.
- Implement at least the input and output triggers defined in this architecture.

In addition, see [Cross-triggers on a PE in an Arm R-profile implementation.](#)

Arm recommends that this Cross-Trigger interface includes:

- The ability to route trigger events between Trace Units, which typically have advanced event triggering logic.
- An output trigger to the interrupt controller.

Also, Arm recommends that the Embedded Cross-Trigger includes the capability to send and receive IMPLEMENTATION DEFINED system trigger events to and from other system components, including a system counter, using a system CTI. See [Halt-on-debug.](#)

Note

The ECT and CTI must only signal trigger events for external debugging. They must not route software events, such as interrupts. For example, the Performance Monitors overflow input trigger is provided to allow entry to Debug state on a counter overflow, and the output trigger to the interrupt controller is provided to generally allow events from the external debug subsystem to be routed to a software agent. However, the combination of the two must not be used as a mechanism to route Performance Monitors overflows to an interrupt controller.

Note

CTI version 1 (CTIv1) is defined by the *CoreSight™ SoC Technical Reference Manual*. CTIv2 extends CTIv1 with the addition of the input channel gate. See [Implementation with CTIv2](#).

E5.1.1 Implementation with a CoreSight CTI

For details of the recommended connections for an A-profile implementation, see Recommended External Debug Interface. See also *CoreSight™ SoC Technical Reference Manual*.

E5.1.2 Implementation with CTIv2

If the CTI implemented is CTIv2 then:

- The [CTIDEVARCH](#), [CTIDEVAFF0](#), and [CTIDEVAFF1](#) registers must be implemented.
- If the channel gate function is implemented, it applies to both input and output channels.
- The input channel gate function must be implemented if either of the following is true:
 - The CTM is implemented and the architecture variant is Armv8.5 or higher.
 - The [CTIDEVARCH](#).REVISION field reads as 0b0001 or higher.

Implementation of CTIv2 features in architecture variants below Armv8.5 is OPTIONAL, but Arm recommends that CTIv2 is implemented, CTIv2 must be implemented from Armv8.5.

E5.2 Basic operation on the ECT

The ECT comprises a Cross-Trigger Matrix, CTM, and one Cross-Trigger Interface, CTI, for each PE. The ECT might also include other CTIs for other system components. The CTM passes events between the CTI blocks over channels. The CTM can have a maximum of 32 channels.

The main interfaces of the Cross-Trigger interface, CTI, are:

- The input triggers:
 - These are trigger event inputs from the PE to the CTI.
- The output triggers:
 - These are trigger event outputs from the CTI to the PE.
- The input channels:
 - These are channel event inputs from the Cross-Trigger matrix, CTM, to the CTI.
- The output channels:
 - These are channel event outputs from the CTI to the CTM.

Each CTI block has:

- Up to 32 input triggers that come from the PE:
 - The input triggers are numbered 0-31.
- Up to 32 output triggers that go to the PE:
 - The output triggers are numbered 0-31.

If the CTI is not powered up when the Core power domain is powered up, the CTI ignores all input triggers and input channel events, and does not generate any output triggers or output channel events.

[Figure E5-2](#) shows the logical internal structure of a CTI.

Figure E5-2 Structure of a Cross-Trigger interface

Note

- The number of triggers is IMPLEMENTATION DEFINED. Figure E5-2 shows eight input and eight output triggers.
- The number of channels is IMPLEMENTATION DEFINED. Figure E5-2 shows four channels.
- In Figure E5-2 the input channel gate function is a CTIv2 feature.

When the CTI receives an input trigger event, this generates channel events on one or more internal channels, according to the *mapping function* defined by the *Input trigger→output channel mapping registers*, *CTIINEN<n>*.

The CTI also contains an *application trigger* and *channel pulse* to allow a debugger to create channel events directly on internal channels by writing to the CTI control registers.

Channel events on each internal channel are passed to a corresponding output channel that is controlled by a *channel gate*. The channel gate can block propagation of channel events from an internal channel to an output channel.

Note

If the CTM is implemented:

- The gate function must be implemented.
 - If the CTI is CTIv1, the gate function applies to output triggers only.
-

The output channels from a CTI are combined, using a logical OR function, with the output channels from all other CTIs to form the input channels on other CTIs. The input channels of this CTI are the logical OR of the output channels on all other CTIs. This is the *Cross-Trigger Matrix*, CTM. Therefore, the number of input channels must equal the number of output channels.

Note

The number of input triggers and output triggers is not required to be the same.

The internal channels form an internal Cross-Trigger matrix within the CTI. This delivers events directly from the input triggers to the output triggers. Therefore the number of internal channels is the same as the number of input and output channels on the external CTM, and there is a direct mapping between the two.

Channel events received on each input channel are passed to the corresponding internal channel. It is IMPLEMENTATION DEFINED whether the Cross-Trigger gate also blocks propagation of channel events from input channels to internal channels.

Note

If CTIv2 is implemented, the Cross-Trigger gate also blocks propagation of channel events from input channels to internal channels.

When the CTI receives a channel event on an internal channel this generates trigger events on one or more output triggers, according to the mapping function defined by the *Input channel* $\rightarrow$ *output trigger mapping registers*, [CTIOUTEN<n>](#).

The CTI contains the input and output trigger interfaces to the PE and the interface of the Cross-Trigger matrix. The architecture does not define the signal protocol used on the trigger interfaces, and:

- It is IMPLEMENTATION DEFINED whether the CTI supports multicycle input trigger events.
- It is IMPLEMENTATION DEFINED whether the CTM supports multicycle channel events.

See [Multicycle events](#).

However, an output trigger is asserted until acknowledged. The output trigger can be:

- Self-acknowledging. This means that no further action is required from the debugger.
- Acknowledged by the debugger writing 1 to the corresponding bit of [CTIINTACK](#).

The time taken to propagate a trigger event from the first PE, through its CTI, across the CTM to another CTI, and thereby to a second PE is IMPLEMENTATION DEFINED.

Note

Arm recommends that this path is not longer than the shortest software communication path between those PEs. This is because if the first PE halts, the Cross-halt trigger event can propagate through the ECT and halt the second PE without causing software on the second PE to malfunction because the first PE is in Debug state and is not responding.

E5.2.1 Multicycle events

A multicycle event is one with a continuous state that might persist over many cycles, as opposed to a discrete event. A typical implementation of a multicycle event is a level-based signal interface, whereas a discrete event might be implemented as a pulse signal or message.

CTI support for multicycle trigger events is IMPLEMENTATION DEFINED. Use of multicycle trigger events is deprecated. Of the architecturally defined input trigger events, the Performance Monitors overflow trigger event and Generic trace external output trigger events can be multicycle input triggers.

CTM support for multicycle channel events is IMPLEMENTATION DEFINED. A CTM that does not support multicycle channel events cannot propagate a multicycle trigger event between CTIs.

Note

A full ECT might comprise a mix of CTIs, some of which can support multicycle trigger events. In bridging these components, multicycle channel events become single channel events at the boundary between the CTIs.

E5.2.1.1 An ECT that supports multicycle trigger events

When an ECT supports multicycle trigger events, an input trigger event to the CTI continuously asserts channel events on all output channels mapped to it until either:

- The input trigger event is removed.
- The channel mapping function is disabled.

This means that an input trigger that is asserted for multiple cycles causes any channels that are mapped to it to become active for multiple cycles. Consequently, any output triggers mapped from that channel are asserted for multiple cycles.

Note

The output trigger remains asserted for at least as long as the channel remains active. This means that even if the output trigger is acknowledged, it remains asserted until the channel deactivates.

The CTI does not guarantee that these events have precisely the same duration, as the triggers and channels can cross between clock domains.

[CTIAPPSET](#) and [CTIAPPCLEAR](#) can set a channel active for multiple cycles. [CTIAPPULSE](#) generates a single channel event. [CTICHINSTATUS](#) and [CTICHOUTSTATUS](#) can report whether a channel is active.

E5.2.1.2 An ECT that does not support multicycle trigger events

When an ECT does not support multicycle trigger events, an input trigger event to the CTI generates a single channel event on all output channels mapped to it, regardless of how long the input trigger event is asserted.

This means that an input trigger event that is asserted for multiple cycles generates a single channel event on any channels mapped to it. Consequently any self-acknowledging output triggers mapped from those channels are single trigger events.

Note

A single event is typically a single cycle, but there is no guarantee that this is always the case.

[CTIAPPSET](#) and [CTIAPPCLEAR](#) can only generate a single channel event. [CTIAPPULSE](#) generates a single channel event. If the ECT does not support multicycle channel events, use of [CTIAPPSET](#) and [CTIAPPCLEAR](#) is deprecated, and the debugger must only use [CTIAPPULSE](#). [CTICHINSTATUS](#) and [CTICHOUTSTATUS](#) must be treated as UNKNOWN.

E5.3 Cross-triggers on a PE in an Arm R-profile implementation

An R-profile PE must include a Cross-Trigger interface, and the implementation must include at least the input and output triggers defined in this architecture. The number of channels in the Cross-Trigger matrix is IMPLEMENTATION DEFINED, but there must be a minimum of three. Software can read CTIDEVID.NUMCHAN to discover the number of implemented channels.

The CTM must connect to all PEs in the same Inner Shareability domain as the PE that includes the Cross-Trigger interface, but can also connect to additional PEs. Arm strongly recommends that the CTM connects all PEs implementing a CTI in the system. This includes other PEs that can be connected using a CoreSight CTI module.

Note

In a uniprocessor system the CTM is OPTIONAL. In a multiprocessor system the CTM is required. The CTM might be connected other CTI modules for non-PEs, such as triggers for system visibility components. Arm recommends that the CTM is implemented.

Any CTI connected to a PE that is not an Arm PE must implement at least:

- The Debug request trigger event.
- The Restart trigger event.
- The Cross-halt trigger event.

For more information about the CTI, see the *CoreSight™ SoC Technical Reference Manual*. Arm architecture refines the generic CTI by defining roles for each of the implemented input and output triggers.

E5.4 Description and allocation of CTI triggers

Table E5-1 shows the output trigger events defined by the architecture and the related trigger numbers.

Table E5-1 Allocation of CTI output trigger events

Number	Source	Destination	Event description
0	CTI	PE	Debug request trigger event
1	CTI	PE	Restart request trigger event
2	CTI	IRQ controller	Generic CTI interrupt trigger event
3	-	-	Reserved
4 - 7	CTI	Trace unit	OPTIONAL Generic trace external input trigger events
8 - 15	-	-	Reserved

Note
Output triggers from the CTI are inputs to other blocks.

Table E5-2 shows the input trigger events defined by the architecture and the related trigger numbers.

Table E5-2 Allocation of CTI input trigger events

Number	Source	Destination	Event description
0	PE	CTI	Cross-halt trigger event
1	PE	CTI	Performance Monitors overflow trigger event
2	-	-	Reserved
3	-	-	Reserved
4 - 7	Trace unit	CTI	OPTIONAL Generic trace external output trigger events
8 - 10	-	-	Reserved
11 - 15	-	-	IMPLEMENTATION DEFINED.

Note
Input triggers to the CTI are outputs from other blocks.

Table E5-1 and Table E5-2 show the minimum set of trigger events defined by the architecture. However:

- The Generic trace external input and output trigger events are required only if the OPTIONAL trace unit is implemented. If the OPTIONAL trace unit is not implemented, these trigger events are reserved.
- Support for the generic CTI interrupt trigger event is IMPLEMENTATION DEFINED because details of interrupt handling in the system, including any interrupt controllers, are IMPLEMENTATION DEFINED. Details regarding how the CTI interrupt is connected to an interrupt controller and its allocated interrupt number lie outside the scope of the architecture. Arm strongly recommends that implementations provide a means to generate interrupts based on external debug events.
- The other trigger events are required by the architecture.

An implementation can extend the CTI with additional triggers.

E5.4.1 Debug request trigger event

This is an output trigger event from the CTI, and an input trigger event to the PE, asserted by the CTI to force the PE into Debug state. The trigger event is asserted until acknowledged by the debugger. The debugger acknowledges the trigger event by writing 1 to [CTIINTACK](#)[0].

Note

A debugger must poll [CTITRIGOUTSTATUS](#)[0] until it reads as 0, to confirm that the output trigger has been deasserted before generating any event that must be ordered after the write to [CTIINTACK](#), such as a write to [CTIAPPPULSE](#) to activate another trigger.

If the PE is already in Debug state, the PE ignores the trigger event, but the CTI continues to assert it until it is removed by the debugger. See also [External Debug Request debug event](#).

E5.4.2 Restart request trigger event

This is an output trigger event from the CTI, and an input trigger event to the PE, asserted by the CTI to request the PE to exit Debug state. If the PE is in Non-debug state, the request is ignored by the PE.

If a Restart request trigger event is received at or about the same time as the PE enters Debug state, it is CONstrained UNPREDICTABLE whether:

- The request is ignored by the PE. In this case the PE enters Debug state and remains in Debug state.
- The PE enters Debug state and then immediately restarts.

Debuggers must program the CTI to send Restart request trigger events only to PEs that are halted. To enable the PE to disambiguate discrete Restart request trigger events, after sending a Restart request trigger event, the debugger must confirm that the PE has restarted and halted before sending another Restart request trigger event. Debuggers can use [EDPRSR](#).{SDR, HALTED} to determine the Execution state of the PE.

Note

Before generating a Restart request trigger event for a PE, a debugger must ensure any Debug request trigger event targeting that PE is cleared. [Debug request trigger event](#) describes how to do this.

The trigger event is self-acknowledging, meaning that the debugger requires no further action to remove the trigger event. The trigger event is acknowledged even if the request is ignored by the PE. See also [Exiting Debug state](#).

E5.4.3 Cross-halt trigger event

This is an input trigger event to the CTI, and an output trigger event from the PE, asserted by a PE when it is entering Debug state.

Note

To reduce the latency of halting, Arm recommends that an implementation issues the Cross-halt trigger event early in the committed process of entering Debug state. This means that there is no requirement to wait until all aspects of entry to Debug state have completed before issuing the trigger event. Speculative emission of Cross-halt trigger events is not allowed. The Cross-halt trigger event must not be issued early enough for a subsequent Debug request trigger event, which might be derived from the Cross-halt trigger event, to be recorded in the [EDSCR](#).STATUS field. This applies to Debug request trigger events that are acting as inputs to the PE.

E5.4.4 Performance Monitors overflow trigger event

This is an input trigger event to the CTI, and an output trigger event from the PE, asserted each time the PE records a Performance Monitors counter overflow. See [The Performance Monitors Extension](#).

If the CTI supports multicycle trigger events, then the trigger event remains asserted while any of the following are true, and deasserted otherwise:

- An event counter <n> is implemented, the global enable control for the event counter is 1, [PMINTENSET_EL1.P\[n\]](#) is 1, and [PMOVSSET_EL0.P\[n\]](#) is 1. The global enable control is defined in [Enabling PMU counters](#).
- [PMCR_EL0.E](#) is 1, [PMINTENSET_EL1.C](#) is 1, and [PMOVSSET_EL0.C](#) is 1.

Note

- This does not replace the recommended connection of Performance Monitors overflow trigger event to an interrupt controller. Software must be able to program an interrupt on Performance Monitors overflow without programming the CTI.
 - Events can be counted when [ExternalNoninvasiveDebugEnabled\(\)](#) == FALSE, and, in Secure state, when [ExternalSecureNoninvasiveDebugEnabled\(\)](#) == FALSE. Secure software must be aware that overflow trigger events are nevertheless visible to the CTI.
-

If the CTI does not support multicycle trigger events, then the trigger event is asserted whenever a counter overflows, causing the PE to set [PMOVSSET_EL0.P\[n\]](#) to 1, or a direct write to a System register means the above conditions become true.

For more information, see [An ECT that supports multicycle trigger events](#).

E5.4.5 Generic trace external input trigger events

These are output trigger events from the CTI, and input trigger events to the OPTIONAL trace unit, that are used in conjunction with the Generic trace external output trigger events to pass trigger events between:

- The PE and the OPTIONAL trace unit.
- The OPTIONAL trace unit and any other component attached to the CTM, including other Trace Units.

There are four Generic trace external input trigger events.

The trigger events are self-acknowledging. This means that the debugger does not have to take any further action to remove the events.

E5.4.6 Generic trace external output trigger events

These are input trigger events to the CTI, and output trigger events from the OPTIONAL trace unit, used in conjunction with the Generic trace external input trigger events to pass trigger events between:

- The PE and the OPTIONAL trace unit.
- The OPTIONAL trace unit and any other component attached to the CTM, including other Trace Units.

There are four Generic trace external output trigger events.

E5.4.7 Generic CTI interrupt trigger event

This is an output trigger event from the CTI, and an input to an IMPLEMENTATION DEFINED interrupt controller, and can transfer trigger events from the PE, trace units, or any other component attached to the CTI and CTM to software as an interrupt. The Generic CTI interrupt trigger event must be connected to the interrupt controller as an interrupt that can target the originating PE.

Note

- Arm recommends that the Generic CTI interrupt trigger event is a private peripheral interrupt, but implementations might instead make this trigger event available as a shared peripheral interrupt or a local peripheral interrupt.
 - GICv3 reserves a private peripheral interrupt number for this interrupt.
-

It is IMPLEMENTATION DEFINED whether this trigger event is:

- Self-acknowledging. This means that the debugger is not required to take any further action, and that the interrupt controller must treat the trigger event as a pulse or edge-triggered interrupt.
- Acknowledged by the debugger. The debugger acknowledges the trigger event by writing 1 to [CTINTACK\[2\]](#). This means that the interrupt controller must treat the trigger event as a level-sensitive interrupt.

Arm recommends that the Generic CTI interrupt trigger event is a self-acknowledging trigger event.

E5.5 CTI registers programmers' model

The CTI registers programmers' model is described in [About the External Debug Registers](#). The following sections contain information specific to the CTI:

- [External debug register resets](#).
- [External debug interface register access permissions](#).
- [Cross-trigger interface registers](#).
- The individual register descriptions in [Cross-Trigger Interface registers](#).

See also [Memory-mapped accesses to the external debug interface](#).

E5.5.1 CTI reset

An External Debug reset resets the CTI. See [External debug register resets](#) for details of CTI register resets. All CTI output triggers and output channels are deasserted on an External Debug reset.

Note

An indirect read of an output trigger might not observe the deasserted state until the processor is Cold reset. For more information, see [Synchronization of changes to the external debug registers](#).

E5.5.2 CTI authentication

The CTI ignores the state of the IMPLEMENTATION DEFINED authentication interface. This means that:

- [CTITRIGINSTATUS](#) shows the status of the input triggers and [CTICHINSTATUS](#) shows the status of the input channels, regardless of the value of [ExternalNoninvasiveDebugEnabled\(\)](#).

Note

The PE does not generate the Cross-halt trigger event and the trace unit does not generate Generic trace external output trigger events when [ExternalNoninvasiveDebugEnabled\(\)](#) == FALSE. However, the PE can generate Performance Monitors overflow trigger events.

- The CTI can generate external triggers regardless of the value of [ExternalInvasiveDebugEnabled\(\)](#) and [ExternalNoninvasiveDebugEnabled\(\)](#).

Note

The destination of the trigger is responsible for authenticating the trigger request:

- The PE ignores Debug request events when [ExternalInvasiveDebugEnabled\(\)](#) is FALSE.
 - It is IMPLEMENTATION DEFINED whether the PE ignores Restart request trigger events when [ExternalInvasiveDebugEnabled\(\)](#) is FALSE.
 - The trace unit ignores Generic trace external input trigger events when [ExternalNoninvasiveDebugEnabled\(\)](#) is FALSE.
 - The behavior of Generic CTI interrupt requests is part of the IMPLEMENTATION DEFINED handling of these interrupts, but it is permissible for an interrupt controller to receive these requests even when [ExternalInvasiveDebugEnabled\(\)](#) is FALSE, meaning software might need to configure the interrupt controller to ignore these requests.
-

E5.6 Examples

The CTI is fully programmable and allows for flexible cross-triggering of events within a PE and between PEs in a multiprocessor system. For example:

- The Cross-halt trigger event and the Debug request trigger event can be used for cross-triggering in a multiprocessor system.
- The Cross-halt trigger event and the Generic interrupt trigger event can be used for event-driven debugging in a multiprocessor system.
- The Performance Monitors overflow trigger event and the Debug request trigger event can force entry to Debug state on overflow of a Performance Monitors event counter, for event-driven profiling.

Note

This does not replace the recommended connection of Performance Monitors overflow trigger events to an interrupt controller. Software must be able to program an interrupt on Performance Monitors overflow without programming the CTI. Arm recommends that the Performance Monitors overflow signal is directly available as a local interrupt source.

- The Generic trace external input and Generic trace external output trigger events can pass trace events into and out of the event logic of the trace unit. They can do this:
 - To pass trace events between Trace Units.
 - In conjunction with the Performance Monitors overflow trigger event, to couple the Performance Monitors to the PE trace unit.
 - In conjunction with the Debug request trigger event, to trigger entry to Debug state on a trace event.
 - In conjunction with other CTIs, to signal a trace trigger event onto a CoreSight trace interconnect.

The following sections describe some examples in more detail:

- [Example E5-1.](#)
- [Example E5-2.](#)
- [Example E5-3.](#)
- [Example E5-4.](#)

Example E5-1 Halting a single PE

To halt a single PE, set:

1. [CTIGATE](#)[0] to 0, so that the CTI does not pass channel events on internal channel 0 to the CTM.
2. [CTIOUTEN0](#)[0] to 1, so that the CTI generates a Debug request trigger event in response to a channel event on channel 0.

Note

The Cross-halt trigger event is input trigger 0, meaning it is controlled by the instance of [CTIOUTEN<n>](#) for which <n> is 0.

3. [CTIAPPULSE](#)[0] to 1, to generate a channel event on channel 0.

When the PE has entered Debug state, clear the Debug request trigger event by writing 1 to [CTIINTACK](#)[0], before restarting the PE.

Example E5-2 Halting all PEs in a group when any one PE halts

To program a group of PEs so that when one PE in the group halts, all of the PEs in that group halt, set the following registers for each PE in the group:

1. **CTIGATE**[2] to 1, so that each CTI passes channel events on internal channel 2 to the CTM.
2. **CTIINEN0**[2] to 1, so that each CTI generates a channel event on channel 2 in response to a Cross-halt trigger event.
3. **CTIOUTEN0**[2] to 1, so that each CTI generates a Debug request trigger event in response to a channel event on channel 2.

Note

The Cross-halt trigger event is input trigger 0, meaning it is controlled by the instances of **CTIINEN**<n> and **CTIOUTEN**<n> for which <n> is 0.

When a PE has halted, clear the Debug request trigger event by writing a value of 1 to **CTIINTACK**[0], before restarting the PE.

Example E5-3 Synchronously restarting a group of PEs

To restart a group of PEs, for each PE in the group:

1. If the PE was halted because of a Debug request trigger event, the debugger must ensure the trigger event is deasserted. It can do this by:
 - a. Writing 1 to **CTIINTACK**[0] to clear the Debug request trigger event.
 - b. Polling **CTITRIGOUTSTATUS**[0], until it reads as 0, to confirm that the trigger event has been deasserted.
2. Set **CTIGATE**[1] to 1, so that each CTI passes channel events on internal channel 1 to the CTM.
3. Set **CTIOUTEN1**[1] to 1, so that each CTI generates a Restart request trigger event in response to a channel event on channel 1.

Note

This example must use the instance of **CTIOUTEN**<n> for which <n> is 1.

4. Set **CTIAPPPULSE**[1] to 1 on any one PE in the group, to generate a channel event on channel 1.

Example E5-4 Halting a single PE on Performance Monitors overflow

To halt a single PE on a Performance Monitors overflow set:

1. `CTIGATE[3]` to 0, so that the CTI does not pass channel events on internal channel 3 to the CTM.
2. `CTIINEN1[3]` to 1, so that the CTI generates a channel event on channel 3 in response to a Performance Monitors overflow trigger event.

Note

This step of this example must use the instance of `CTIINEN<n>` for which `<n>` is 1.

3. `CTIOUTEN0[3]` to 1, so that the CTI generates a Debug request trigger event in response to a channel event on channel 3.

Note

This step of this example must use the instance of `CTIOUTEN<n>` for which `<n>` is 0.

When the PE has entered Debug state, clear the Debug request trigger event by writing 1 to `CTIINTACK[0]`, before restarting the PE. Clear the overflow status by writing to `PMOVSCLR_EL0`.

Chapter E6

Debug Reset and Powerdown Support

This chapter describes the reset and powerdown support in the Debug architecture. It contains the following sections:

- [About Debug over powerdown](#)
- [Power domains and debug](#)
- [Core power domain power states](#)
- [Powerup request mechanism](#)
- [Emulating low-power states](#)
- [Debug OS Save and Restore sequences](#)
- [Reset and debug](#)

E6.1 About Debug over powerdown

Arm A-profile external debug defines a logical model for the hardware on which a PE executes. This hardware is logically split into the *Core power domain* and the *Debug power domain*, and the model contains descriptions of the states of those domains. See:

- [Power domains and debug.](#)
- [Core power domain power states.](#)

An implementation may allow power domains to be powered up and down independently. Debug over powerdown provides:

- A facility for software executing on the PE to save and restore the PE state on behalf of a self-hosted or external debugger or both. See [Debug OS Save and Restore sequences.](#)
- A facility for an external debugger to request power up of the Core power domain. See [Powerup request mechanism.](#)
- A facility for an external debugger, or software executing on the PE, to request emulation of powerdown of the Core power domain. See [Emulating low-power states.](#)

E6.2 Power domains and debug

Arm A-profile external debug has two logical power domains, each with its own reset:

- The Debug power domain contains the interface between the PE and the external debugger, and is powered up whenever an external debugger is connected to the SoC. It remains powered up while the external debugger is connected. When the Core power domain is completely off or in a low-power state, a debugger is permitted to access a register that is implemented in the Debug power domain. Registers in this domain are reset by an External Debug reset.
- The Core power domain contains the rest of the PE, and might be allowed to power up and power down independently of the Debug power domain.

Note

- The model of two logical power domains has an impact on the reset and access permission requirements of the debug programmers' model.
 - The power domains are described as logical because the architecture defines the requirements but does not require two physical power domains. Any power domain split that meets the requirements of the programmers' model is a valid implementation.
-

The Core power domain contains several types of registers:

- Non-debug logic refers to all registers and logic that are not associated with debug.
- Self-hosted debug logic refers to registers and logic associated solely with the self-hosted debug aspects of the architecture.
- Shared debug logic refers to registers and logic associated with both the self-hosted and external debug aspects of the architecture.
- External debug logic refers to registers and logic associated solely with the external debug aspects of the architecture.

For information about which groups of registers and components are in each power domain, and which registers change power domain if [FEAT_DoPD](#) is implemented, see:

- [Access permissions for the External debug interface registers.](#)
- [Cross-trigger interface registers.](#)
- Management register access permissions.
- [Access permissions for external views of the Performance Monitors.](#)

E6.3 Core power domain power states

The Arm architecture does not define the power states of the PE as these are not normally visible to software. However, they are visible to the external debugger. Arm A-profile external debug uses a four logical power states model for the Core power domain. [Mechanisms for entering a low-power state](#) describes the architectural mechanisms for entering low-power states.

When the PE enters a low-power state other than Powerdown by executing a `WFI` or `WFE` instruction, it remains in that low-power state until it receives a wakeup event. See [Mechanisms for entering a low-power state](#) for the definition of wakeup events. When halting is allowed, an External Debug Request is a wakeup event. In addition, if the PE enters the Standby state for any reason, it will leave that state to service an External Debug Request debug event.

The four logical power states are as follows:

Normal	The Core power domain is fully powered up and the debug registers are accessible.
Standby	The Core power domain is on, but there are measures to reduce energy consumption. There can be other IMPLEMENTATION DEFINED measures the OS can take to enter standby. The PE preserves the PE state, including the debug logic state. Changing from standby to normal operation does not involve a reset of the PE. Standby is the least invasive OS energy saving state. Standby implies only that the PE is unavailable and does not clear any debug settings. For standby, the Debug architecture requires only the following: • If the external debug interface is accessed, the PE must respond to that access. Arm recommends that, if the PE executed a <code>WFI</code> or <code>WFE</code> instruction to enter standby, then it does not retire that instruction. Standby is transparent, meaning that to software and to an external debugger it is indistinguishable from normal operation.
Retention	The PE state, including debug settings, is preserved in low-power structures, allowing the Core power domain to be at least partially turned off. Changing from low-power retention to normal operation does not involve a reset of the PE. The saved PE state is restored on changing from low-power retention state to normal operation. If software has to use an IMPLEMENTATION DEFINED code sequence before entering, or after leaving, a retention state, this is referred to as a <i>software-visible retention state</i>. It is IMPLEMENTATION DEFINED whether the value of <code>DBGPRCR.CORENPDRQ</code> is set to its Cold reset value on leaving the software-visible retention state. See the description of <code>DBGPRCR.CORENPDRQ</code> for more information. Note • This model of retention does not include implementations where the PE exits the state in response to a debug register access. From the Debug architecture perspective, implementations like this are forms of standby.
Powerdown	These measures must include the OS saving any PE state, including the debug settings, that must be preserved over powerdown. If FEAT_DoubleLock is implemented, it is used during powerdown. Changing from powerdown to normal operation must include: • A Cold reset of the PE after the power level has been restored. • The OS restoring the saved PE state. External Debug Request debug events stay pending and debug registers in the Core power domain cannot be accessed.

An implementation might support enabling and disabling threads, either dynamically or once at reset time. Threads that are disabled in this way must appear to the external debugger as either:

- Powered off, meaning they are either:
 - In a powerdown state.

- In a retention state.
- Held in reset state.

Arm A-profile external debug uses a simpler two states model for the Debug power domain. The two states are:

Off The Debug power domain is turned off.

On The Debug power domain is turned on.

The available power states, including the cross-product of Core power domain and Debug power domain power states is IMPLEMENTATION DEFINED. Implementations are not required to implement all of these states and might include additional states. These additional states must appear to the debugger as one of the logical power states defined by this model. The control of power states is IMPLEMENTATION DEFINED.

———— **Note** —————

As a result, it is IMPLEMENTATION DEFINED whether it is possible for the Debug power domain to be on when the Core power domain is off.

If the Debug power domain is implemented but is not powered up when the Core power domain is powered up, the Reset Catch debug event and the OS Unlock Catch debug event are disabled.

E6.4 Powerup request mechanism

If a powerup request mechanism is implemented, asserting the powerup request requests the power controller to power up the Core power domain, and to emulate any subsequent powerdown requests, until the powerup request mechanism is deasserted.

E6.4.1 Powerup request mechanism if FEAT_DoPD is implemented

If [FEAT_DoPD](#) is implemented, the external debug component implements an OPTIONAL powerup request mechanism.

If the powerup request mechanism is implemented, Arm strongly recommends that the powerup request is a CoreSight Class 0x9 ROM table block that contains both:

- A parent entry for the debug registers of the PE.
- A parent entry for the PMU registers of the PE, if the OPTIONAL PMU with an external debug interface is implemented.

A parent entry of a component is an entry in a ROM table that either locates the component, or locates another ROM table that contains the parent entry for the component.

Note

The ROM table and any descendants might describe other debug components, including debug components for other PEs. The ROM table might have a parent entry in a second ROM table and that parent entry might also have a powerup request mechanism in the second ROM table. This applies recursively.

The parent entries for the debug components have the following properties:

For the debug registers and Performance Monitors registers: These components are in the Core power domain.

The POWERIDVALID bit is 1.

All parent entries must have the same IMPLEMENTATION DEFINED POWERID value.

Note

The IMPLEMENTATION DEFINED POWERID value does not need to be unique for each PE.

For the CTI registers: This component is in the Debug power domain.

The POWERIDVALID bit is IMPLEMENTATION DEFINED.

If the POWERIDVALID bit is 1, the entries must have a valid POWERID value.

Note

If the Core power domain can be powered down independently of the Debug power domain, Arm recommends the system implements an external debug component with a powerup request mechanism which can request the Core power domain to be powered up.

For more information about Coresight Class 0x9 ROM Tables, see *ARM® CoreSight™ Architecture Specification*.

On a Cold reset, if [FEAT_DoPD](#) is implemented, [DBGPRCR_EL1.CORENPDRQ](#) is set to an IMPLEMENTATION DEFINED choice between 0 and 1 if the powerup request is implemented and asserted, and 0 otherwise.

E6.4.2 Powerup request mechanism if FEAT_DoPD is not implemented

If [FEAT_DoPD](#) is not implemented, the bit [EDPRCR.COREPURQ](#) is the powerup request mechanism.

The control registers [DBGPRCR_EL1.CORENPDRQ](#) and [EDPRCR.COREPURQ](#) provide an interface between the power controller and the PE. They typically map directly to signals in the recommended external debug interface.

On Cold reset, if [FEAT_DoPD](#) is not implemented, [DBGPRCR_EL1.CORENPDRQ](#) is set to the value of [EDPRCR.COREPURQ](#).

E6.5 Emulating low-power states

[DBGPRCR_EL1](#).CORENPDRQ and the powerup request mechanism can request the power controller to emulate states where the Core power domain is completely off or in a low-power state where the Core power domain registers cannot be accessed. This simplifies the requirements on software by sacrificing entirely realistic behavior.

If [FEAT_DoPD](#) is not implemented, [EDPRSR](#).{SPD, PU} indicates the Core power domain power state. For more information, see:

- The [DBGPRCR_EL1](#) and DBGPRCR System register descriptions.
- The [EDPRCR](#) and [EDPRSR](#) external debug register descriptions.
- Recommended External Debug Interface.

The measures to emulate powerdown are IMPLEMENTATION DEFINED. The ability of the debugger to access the state of the PE and the system might be limited as a result of the measures adopted.

In an emulated powerdown state, the debugger must be able to access all debug, PMU, CTI, and trace unit registers that are accessible on the external debug interface and are in one of:

- The Debug power domain.
- The Core power domain.
- When a trace unit with a separate trace unit Core power domain is implemented, and the trace unit Core power domain is powered on, the trace unit Core power domain.

That is, the debugger must be able to read and write to such registers without receiving errors. This allows an external debugger to debug the powerup sequence.

Arm recommends that any IMPLEMENTATION DEFINED registers that are on the external debug interface and in either the Core power domain or the Debug power domain are also accessible in an emulated powerdown state.

If [FEAT_DoubleLock](#) is implemented, `DoubleLockStatus() == FALSE` when [DBGPRCR_EL1](#).CORENPDRQ == 1.

Otherwise, the behavior of the PE in emulated powerdown must be similar to that in a real powerdown state. In particular, the PE must not respond to other system stimuli, such as interrupts.

[Example E6-1](#) and [Example E6-2](#) are examples of two approaches to emulating powerdown.

Example E6-1 An example of emulating powerdown

The PE is held in Standby state, isolated from any system stimuli. It is IMPLEMENTATION DEFINED whether the PE can respond to debug stimuli such as an External Debug Request debug event.

If the PE can enter Debug state, then the external debugger is able to use the ITR to execute instructions, such as loads and stores. This causes the external debugger to interact with the system. If the external debugger restarts the PE, the PE leaves Standby state and restarts fetching instructions from memory.

Example E6-2 Another example of emulating powerdown

The PE is held in Warm reset. This limits the ability of an external debugger to access the resources of the PE. For example, the PE cannot be put into Debug state.

On exit from emulated powerdown the PE is reset. However, the debug registers that are only reset by a Cold reset must not be reset. Typically this means that a Warm reset is substituted for the Cold reset. As such, the effect of accessing any register that is reset by a Warm reset while the PE is in the emulated powerdown state will have an IMPLEMENTATION DEFINED effect on that register.

Note

- Warm reset and Cold reset have different effects apart from resetting the debug registers. In particular, [RMR_ELx](#) is reset by a Cold reset and controls the reset state on a Warm reset. This means that if a Cold reset is substituted by a Warm reset, the behavior of the reset code might be different.
 - The timing effects of powering down are typically not factored in the powerdown emulation. Examples of these timing effects are clock and voltage stabilization.
 - Emulation does not model the state lost during powerdown, meaning that it might mask errors in the state storage and recovery routines.
-

E6.6 Debug OS Save and Restore sequences

From the introduction of Armv8-R, the following registers provide the OS Save and Restore mechanism:

- The *OS Lock Access Register*, [OSLSR_EL1](#), locks the OS Lock to restrict access to debug registers before starting an OS Save sequence, and unlocks the OS Lock after an OS Restore sequence.
- The *OS Lock Status Register*, [OSLSR_EL1](#), shows the status of the OS Lock.
- The PE can be configured to generate an [OS Unlock Catch debug event](#) when the OS Lock is unlocked.
- If [FEAT_DoubleLock](#) is implemented, the OS Double Lock locks out an external debug interface entirely. This is only used immediately before a powerdown sequence.

See also:

- [FEAT_DoubleLock](#)
- [Reset and debug](#)
- [Example OS Save and Restore sequences](#)

E6.6.1 EDPRSR.{DLK, SPD, PU} and the Core power domain

If [FEAT_DoPD](#) is not implemented, a debugger uses [EDPRSR.{DLK, SPD, PU}](#) to determine whether registers in the Core power domain can be accessed, and whether their state has been lost since the last time the register was read.

Table E6-1 Interpretation of the EDPRSR.{DLK, SPD, PU} bits

EDPRSR			Core power domain			Notes
DLK	SPD	PU	Power	Accesses	State lost	
0	0	1	On	OK	No	-
0	1	1	On	OK	Yes	SPD is cleared to 0 following the read.
1	X	1	On	Error	Not known	FEAT_DoubleLock is implemented and DoubleLockStatus() == TRUE. Software locks the OS Double Lock before removing power.
X	1	0	Off	Error	Yes	A Cold reset will be asserted on exiting powerdown state, but not on exiting low-power retention state.
X	0	0	Not known	Error	Not known	

If [FEAT_DoPD](#) is implemented, accesses to [EDPRSR](#) return an error when the Core power domain is off or in a retention state, meaning successful reads of [EDPRSR](#) always return 1 for [EDPRSR.PU](#).

When [FEAT_Debugv8p4](#) is implemented, and whenever [FEAT_DoubleLock](#) is not implemented, [EDPRSR.DLK](#) is always 0.

If [FEAT_DoubleLock](#) is not implemented, [DoubleLockStatus\(\)](#) always returns FALSE.

If the Core power domain is powered up and [DoubleLockStatus\(\)](#) == TRUE, then:

- When [FEAT_Debugv8p2](#) is not implemented, [EDPRSR.{DLK, SPD, PU}](#) can read either {1, UNKNOWN, 1} or {UNKNOWN, 0, 0}.
- When [FEAT_Debugv8p2](#) is implemented, and [FEAT_Debugv8p4](#) is not implemented, [EDPRSR.{DLK, SPD, PU}](#) can only read {UNKNOWN, 0, 0}.

E6.6.2 EDPRSR.SPD when the Core domain is in either retention or powerdown state

If [FEAT_DoPD](#) is not implemented, when the Core power domain is in either the retention or powerdown state, [EDPRSR.SPD](#) is not cleared following a read of [EDPRSR](#) and it is IMPLEMENTATION DEFINED whether:

- [EDPRSR.SPD](#) shows whether the state of the debug registers in the Core power domain has been lost since the last time that [EDPRSR](#) was read. This means that:
 - When the Core power domain is in the powerdown state, [EDPRSR.SPD](#) is RAO, this indicates that the state of the debug registers has been lost.
 - When the Core power domain is in the retention state, [EDPRSR.SPD](#) indicates whether the state of the debug registers was lost before the Core power domain entered retention state.
- [EDPRSR.SPD](#) is RAZ, and:
 - On leaving the powerdown state, [EDPRSR.SPD](#) is set to 1 which indicates that the state of the debug registers has been lost.
 - On leaving the retention state, [EDPRSR.SPD](#) reverts the value it had on entering the retention state.

Note

If [FEAT_DoPD](#) is implemented, accesses to [EDPRSR](#) return an error when the Core power domain is off or in a retention state.

E6.6.3 EDPRSR.{DLK, R} and reset state

If [FEAT_DoPD](#) is implemented, accesses to [EDPRSR](#) return an error when the Core power domain is off or in a retention state, meaning successful reads of [EDPRSR](#) always return 1 for [EDPRSR.PU](#).

When [FEAT_Debugv8p4](#) is implemented, and whenever [FEAT_DoubleLock](#) is not implemented, [EDPRSR.DLK](#) is always 0.

If [FEAT_DoubleLock](#) is not implemented, [DoubleLockStatus\(\)](#) always returns FALSE.

If [FEAT_DoubleLock](#) is implemented and enabled, the behavior of all registers and fields except [EDPRSR.DLK](#) is the same as their behavior if [FEAT_Debugv8p4](#) is not implemented.

If [FEAT_Debugv8p4](#) is implemented [EDPRSR.DLK](#) is always 0 and does not give any information about the OS Double Lock.

[EDPRSR.R](#) is UNKNOWN when [DoubleLockStatus\(\)](#) == TRUE. [OSDLR_EL1.DLK](#) is cleared to 0 by a reset. If the Core power domain is powered up and entered reset state with the OS Double Lock locked, it is CONSTRAINED UNPREDICTABLE whether a read of [EDPRSR](#) while the PE is in reset state returns:

- [EDPRSR](#).{DLK, R, PU} == {1, UNKNOWN, 1} indicating that the OS Double Lock is locked. This is not permitted from Armv8.2.
- [EDPRSR](#).{DLK, R, PU} == {0, 1, 1} indicating that the PE is in reset state.
- [EDPRSR](#).{DLK, R, PU} == {UNKNOWN, UNKNOWN, 0} indicating that the registers in the Core power domain cannot be accessed because the OS Double Lock is locked.

If the PE was powered up and the OS Double Lock was unlocked when the PE was reset, then [EDPRSR](#).{DLK, R, PU} reads as {0, 1, 1} while the PE is in reset state.

On leaving reset state, [EDPRSR](#).{DLK, R} reads as {0, 0}.

E6.6.4 Debug registers to save over powerdown

[Table E6-2](#) shows the different requirements for self-hosted debug over powerdown and external debug over powerdown:

- The column labeled Self-hosted lists registers that software must preserve over powerdown so that it can support self-hosted debug over powerdown. This does not require use of the OS Save and Restore mechanism.
- The column labeled External lists registers that software must preserve over powerdown so that it can support external debug over powerdown. This requires use of the OS Save and Restore mechanism:

- Some external debug registers are not normally accessible to software executing on the PE. Additional debug registers are provided that give software the required access to save and restore these external debug registers when [OSLSR_EL1](#).OSLK is locked. These registers include [OSECCR_EL1](#), [OSDTRRX_EL1](#), and [OSDTRTX_EL1](#).
- Some registers might only present in some implementations, or might not be accessible at all Exception levels or in Non-secure state. .

[Table E6-2](#) does not include registers for the OPTIONAL Trace and Performance Monitor extensions.

Table E6-2 Debug registers to save over powerdown

Register in AArch64 state	Self-hosted	External
MDSCR_EL1	Yes	Yes
DBGBVR<n>_EL1	Yes	Yes
DBGBCR<n>_EL1	Yes	Yes
DBGWVR<n>_EL1	Yes	Yes
DBGWCR<n>_EL1	Yes	Yes
MDCR_EL2	Yes	-
DBGCLAIMSET_EL1 DBGCLAIMCLR_EL1	-	Yes
OSECCR_EL1	-	Yes
OSDTRRX_EL1 OSDTRTX_EL1	-	Yes

E6.6.5 OS Save sequence

To preserve the debug logic state over a powerdown, the state must be saved to nonvolatile storage. This means the OS Save sequence must:

1. Lock the OS Lock by writing 1 to [OSLAR_EL1](#).OSLK.
2. Execute an `ISB` instruction.
3. Walk through the debug registers listed in [Debug registers to save over powerdown](#) and save the values to the nonvolatile storage.

If the [FEAT_DoubleLock](#) is implemented, before removing power from the Core power domain, software must:

1. Lock the OS Double Lock by writing 1 to [OSDLR_EL1](#).DLK.
If [FEAT_DoubleLock](#) is not implemented, [OSDLR_EL1](#) ignores writes.
2. Execute a [Context Synchronization event](#).

E6.6.6 OS Restore sequence

After a powerdown, the OS Restore sequence must perform the following steps to restore the debug logic state from the non-volatile storage:

1. Lock the OS Lock, as described in [OS Save sequence](#). The OS Lock is generally locked by the Cold reset, but this step ensures that it is locked.
2. Execute an `ISB` instruction.

3. Write 0 to [MDSCR_EL1](#) to ensure that, if an external debugger clears the OS Lock before the end of this sequence, no debug exceptions are generated.
4. Walk through the debug registers listed in [Debug registers to save over powerdown](#), and restore the values from the nonvolatile storage. The last register to be restored must be [MDSCR_EL1](#).
5. Execute an `ISB` instruction.
6. Unlock the OS Lock by writing 0 to [OSLAR_EL1](#).OSLK.
7. Execute a [Context Synchronization event](#).

Note

The OS Restore sequence overwrites the debug registers with the values that were saved. If there are valid values in these registers immediately before the restore sequence, then those values are lost.

E6.6.7 Debug behavior when the OS Lock is locked

The main purpose of the OS Lock is to prevent updates to debug registers during an OS Save or OS Restore operation. The OS Lock is locked on a Cold reset.

When the OS Lock is locked:

- Access to debug System registers through the System register interface is mainly unchanged except that:
 - Certain registers are read and written without side-effects.
 - Fields in [MDSCR_EL1](#) and [OSECCR_EL1](#) that are normally read-only become read/write.This allows the state to be saved or restored. For more information, see the relevant register description in [External Debug Register Descriptions](#).
- Access to debug registers by the external debug interface is restricted to prevent an external debugger modifying the registers that are being saved or restored. For more information, see [External debug interface register access permissions summary](#).
- Debug exceptions, other than Breakpoint Instruction exceptions are not generated.
- Breakpoint and Watchpoint debug events are not generated. The OS Lock has no effect on Breakpoint Instruction exceptions and other debug events.

E6.6.8 Debug behavior when the OS Lock is unlocked

When the OS Lock is unlocked, the PE sets [EDES.R.OSUC](#) to 1 if the OS Unlock Catch debug event is enabled and the PE is in Non-debug state, meaning the OS Unlock Catch debug event becomes pending. See [OS Unlock Catch debug event](#).

E6.6.9 Debug behavior when the OS Double Lock is locked

If the [FEAT_DoubleLock](#) is implemented, software locks the OS Double Lock immediately before a powerdown sequence.

The OS Double Lock ensures that it is safe to remove core power by forcing the debug interfaces to be quiescent.

When `DoubleLockStatus() == TRUE`:

- The external debug interface has only restricted access to the debug registers, so that it is quiescent before removing power. See [External debug interface register access permissions summary](#).
- Debug exceptions, other than Breakpoint Instruction exceptions, are not generated.
- Halting is prohibited. See [Halting allowed and halting prohibited](#).

Note

Pending Halting debug events might be lost when core power is removed.

- No asynchronous debug events are *WF** wakeup events.

If the `FEAT_DoubleLock` is not implemented, the PE ensures these conditions are met before allowing power to be removed.

Software must synchronize the update to `OSDLR_EL1` before it indicates to the system that core power can be removed. The interface between the PE and its power controller is IMPLEMENTATION DEFINED.

Typically software indicates that core power can be removed by entering the Wait For Interrupt state. This means that software must explicitly synchronize the `OSDLR_EL1` update before issuing the `WFI` instruction.

`OSDLR_EL1.DLK` is ignored and `DoubleLockStatus()` == FALSE if either:

- The PE is in Debug state.
- `DBGPRCR_EL1.CORENPDRQ` is set to 1.

Note

It is possible to enter Debug state with `OSDLR_EL1.DLK` set to 1. This is because a `Context Synchronization event` is required to ensure the OS Double Lock is locked, meaning that Debug state might be entered before the `OSDLR_EL1` update is synchronized.

Because `OSDLR_EL1.DLK` is ignored when `DBGPRCR_EL1.CORENPDRQ` is set to 1, an external debugger can write to `DBGPRCR_EL1.CORENPDRQ`, and the `FEAT_DoubleLock` is not always implemented, software must not rely on using the OS Double Lock to disable debug exceptions or to prohibit halting, or both. Arm deprecates use of the OS Double Lock for these purposes, and instead recommends that software:

- Uses the OS Lock to disable debug exceptions during save or restore sequences.
- Uses the debug authentication interface to prohibit halting and external debug access to debug registers at times other than immediately prior to removing power.

As the purpose of the OS Double Lock is to ensure that it is safe to remove core power, if the `FEAT_DoubleLock` is implemented, it is important to avoid race conditions that defeat this purpose. Arm recommends that:

- Once the write to `OSDLR_EL1.DLK` has been synchronized by a `Context Synchronization event` and `DoubleLockStatus()` == TRUE, a PE must:
 - Not allow a debug event generated before the `Context Synchronization event` to cause an entry to Debug state or act as a wakeup event for a `WFI` or `WFE` instruction after the `Context Synchronization event` has completed.
 - Complete any external debug access started before the `Context Synchronization event` by the time the `Context Synchronization event` completes.

Note

A debug register access might be in progress when software sets `OSDLR_EL1.DLK` to 1. An implementation must not permit the synchronization of locking the OS Double Lock to stall indefinitely while waiting for that access to complete. This means that any debug register access that is in progress when software sets `OSDLR_EL1.DLK` to 1 must complete or return an error in finite time.

- If a write to `DBGPRCR_EL1` or `EDPRCR` made when `OSDLR_EL1.DLK` == 1 changes `DBGPRCR_EL1.CORENPDRQ` or `EDPRCR.CORENPDRQ` from 1 to 0, meaning `DoubleLockStatus()` changes from FALSE to TRUE, then before signaling to the system that the `CORENPDRQ` field has been cleared and emulation of powerdown is no longer requested, meaning the system can remove core power, the PE must ensure that all the requirements for `DoubleLockStatus()` == TRUE listed in this section are met.

In a standard OS Save sequence, the OS Lock is locked before the OS Double Lock is locked. This means that writes to `CORENPDRQ` are ignored by the time the OS Double Lock is locked. However, if `DoubleLockStatus()` == FALSE, an external debugger can clear the OS Lock at any time, and then write to `EDPRCR`.

E6.7 Reset and debug

All registers in the Core power domain are either:

- Reset by both a Cold and a Warm reset.
- Reset only by a Cold reset and are not changed by a Warm reset.

For more information, see [Resets and power domains](#).

All registers in the Debug power domain are reset by an External Debug reset.

[Figure E6-1](#) shows this reset scheme. The following three reset signals are an example implementation of the reset scheme:

- **CORERESET**, which must be asserted for a Warm reset.
- **CPUPORESET**, which must be asserted for a Cold reset.
- **PRESETDBG**, which must be asserted for an External Debug reset.

As shown in the figure, the external debug logic is split between the Debug power domain and the Core power domain.

Figure E6-1 Power and reset domains

For more information about power domains and power states, see [Power domains and debug](#).

When power is first applied to the Debug power domain, **PRESETDBG** must be asserted.

When power is first applied to the Core power domain, **CPUPORESET** must be asserted.

Note

In this scheme, logic in the Warm reset domain is reset by asserting either **CORERESET** or **CPUPORESET**. This implies a particular implementation style that permits these approaches.

CPUPORESET is not normally asserted on moving from a low-power state, where power has not been removed, to a full-power state. This can occur, for example, on exiting a low-power retention state. See also [Emulating low-power states](#) and the [EDPRSR](#) register description.

E6.7.1 External debug interface accesses to registers in reset

If a reset signal is asserted and the external debug interface:

- Writes a register, or indirectly writes a register or register field as a side-effect of an access:

- Then, if the register or register field is reset by that reset signal, it is **CONSTRAINED UNPREDICTABLE** whether the register or register field takes the reset value or the value written. The reset value might be **UNKNOWN**.
- Otherwise, the register or register field takes the value that is written.
- Reads a register, or indirectly reads a register or register field, as part of an access:
 - Then, if the register or register field is reset by that reset signal, the value returned is **UNKNOWN**.
 - Otherwise, the value of the register or register field is returned.

It is **IMPLEMENTATION DEFINED** whether any register can be accessed when External Debug reset is being asserted. The result of these accesses is **IMPLEMENTATION DEFINED**.

Chapter E7

The PC Sample-based Profiling Extension

This chapter describes the OPTIONAL PC Sample-based Profiling Extension that provides a non-invasive external debug component.

It contains the following section:

- [About the PC Sample-based Profiling Extension](#)

E7.1 About the PC Sample-based Profiling Extension

The PC Sample-based Profiling Extension is an **OPTIONAL** extension that provides coarse-grained, non-invasive profiling by an external debugger. See also [Non-invasive behavior](#).

When the PC Sample-based Profiling Extension is implemented, the PE implements a PC sample register and one or more context sample registers as external registers. Reads of the PC sample register return a PC sample value and capture the PE context in the context sample registers. For example, tools can use these samples to populate a statistical model of the performance of software executing on the PE.

Note

Data returned by periodic sampling of PC Sample-based Profiling registers is sufficient to allow tools to estimate the distribution of time spent executing software on the PE.

The delay between an instruction being executed by the PE and its address appearing in the PC Sample Register is not defined, and the architecture does not require that the sampled instruction was recently executed. For example, if a piece of software executes a load instruction that reads the PC Sample Register of the PE it is running on, there is no guaranteed relationship between the address of the load instruction and the value read. The PC Sample Register is intended only for use by an external agent to provide statistical information for software profiling.

It must be possible to sample references to branch targets. It is **IMPLEMENTATION DEFINED** whether references to other instructions can be sampled. The branch target for a conditional branch instruction that fails its condition check is the instruction that follows the conditional branch instruction. The branch target for an exception is the exception vector address.

Note

In the Armv7 PC Sample-based Profiling Extension, an offset was applied to the sampled Program Counter value and this offset and the instruction set state indicated in bits [1:0] of the sampled value. From the introduction of the Armv8 PC Sample-based Profiling Extension, the sampled value is the address of an instruction that has executed, with no offset and no indication of the instruction set state.

- [Controlling the PC Sample-based Profiling Extension](#).
- [Registers implemented by the PC Sample-based Profiling Extension](#).
- [Permitted behavior that might make the PC Sample-based profiling registers UNKNOWN](#).
- [Pseudocode description of PC Sample-based Profiling](#).

E7.1.1 Controlling the PC Sample-based Profiling Extension

PC Sample-based Profiling is controlled by the **IMPLEMENTATION DEFINED** authentication interface [ExternalNoninvasiveDebugEnabled\(\)](#).

PC Sample-based Profiling is allowed if both of the following apply:

- [ExternalNoninvasiveDebugEnabled\(\)](#) == TRUE.
- [ExternalSecureNoninvasiveDebugEnabled\(\)](#) == TRUE.

The state of the **IMPLEMENTATION DEFINED** authentication interface is visible through [DBGAUTHSTATUS_EL1](#). See Recommended authentication interface.

E7.1.1.1 Suspending and activating PC Sample-based Profiling

The state of PC Sample-based Profiling at Warm reset is an **IMPLEMENTATION DEFINED** one of suspended or active.

When all of the following apply, reading [PMPCSR](#)[31:0] or [PMPCSR](#)[63:0] makes PC Sample-based Profiling active:

- PC Sample-based Profiling is suspended.
- PC sampling is allowed.

A subsequent external read of [PMPCSR](#) will observe the updated state.

Note

- A read of [PMPCSR](#)[63:32] in isolation does not make PC Sample-based Profiling active.
 - There is no mechanism to return to suspended state, other than Warm reset.
-

E7.1.2 Registers implemented by the PC Sample-based Profiling Extension

If [FEAT_PCSRv8p2](#) is implemented and the 64-bit external PMU programmers' model extension is not implemented, the following PC Sample-based Profiling Extension registers can be implemented in the Performance Monitors memory-mapped register space:

- [PMCID1SR](#) and [PMCID2SR](#).
- [PMPCSR](#).
- [PMVIDSR](#).

When the 64-bit external PMU programmers' model extension is implemented, the PC Sample-based Profiling Extension registers are:

- [PMCCIDSR](#).
- [PMPCSR](#).
- [PMVCIDSR](#).

See [Performance Monitors external register views](#).

If [FEAT_PCSRv8p2](#) is implemented but the Performance Monitors Extension is not implemented, then the PC Sample-based Profiling Extension registers are implemented in their own memory-mapped register space, within the area that is reserved for the Performance Monitors, see [Table E7-1](#). If CoreSight compliance is required:

- The management registers are defined as in The Arm[®] Architecture Reference Manual, for A-profile architecture.
- The support for PC Sample-based profiling is defined in the following registers:
 - [PMDEVTYPE](#).MAJOR has the value 0x0.
 - [PMDEVARCH](#).ARCHID has the value 0x0A10 or 0x0A20.

For more information, see [PMDEVARCH](#).

Table E7-1 PC Sample-based Profiling register map without the Performance Monitors Extension

Offset	Description
0x200	PMPCSR [31:0]
0x204	PMPCSR [63:32]
0x208	PMCID1SR
0x20C	PMVIDSR
0x220	PMPCSR [31:0] (alias)
0x224	PMPCSR [63:32] (alias)
0x228	PMCID1SR (alias)
0x22C	PMCID2SR
0x600-0x6FC	IMPLEMENTATION DEFINED
0xE80-0xEFC	IMPLEMENTATION DEFINED for CoreSight compliance

Offset	Description
0xFF0-0xFFC	Management and CoreSight compliance registers

E7.1.3 Permitted behavior that might make the PC Sample-based profiling registers UNKNOWN

The architecture permits IMPLEMENTATION DEFINED extensions to external debug to define mechanisms that make the values of the PC Sample-based profiling registers UNKNOWN. However, it requires that any such mechanism is disabled by default. This means that powerup or a hard reset of the PE must leave the PE in a state where the PC Sample-based Profiling Extension, if implemented, exhibits its architecturally-defined behavior.

Note

A mechanism that, when enabled, makes the PC Sample-based profiling registers UNKNOWN might use other sample-based profiling events that are appropriate for a use that is independent of PC Sample-based Profiling.

If no branch instruction has been retired since the PE left Debug state, suspended state, or a state where PC Sample-based profiling is prohibited, then the sampled value is UNKNOWN.

If all of the following apply, then a read of [PMPCSR](#)[31:0] or [PMPCSR](#)[63:0] is permitted but not required to return 0xFFFF_FFFF for [PMPCSR](#)[31:0].

- The PE has not retired any branch instruction since leaving a state where PC Sample-based Profiling was suspended.
- Sampling on reads is not disabled.

This includes a read of [PMPCSR](#)[31:0] or [PMPCSR](#)[63:0] that indirectly makes PC Sample-based Profiling active.

E7.1.4 Pseudocode description of PC Sample-based Profiling

When FEAT_PCSRv8 is implemented, the functionality is described by the pseudocode functions:

- [CreatePCSample\(\)](#), which populates a variable of type [PCSample](#).
- [Read_EDPCSRlo\(\)](#), which writes a PC sample to the EDPCSR and associated registers.

When FEAT_PCSRv8p2 is implemented, the functionality is described by the pseudocode functions:

- [CreatePCSample\(\)](#), which populates a variable of type [PCSample](#).
- [Read_PMPCSR\(\)](#), which writes a PC Sample to the [PMPCSR](#) and associated registers.

Chapter E8

About the External Debug Registers

This chapter provides some additional information about the external debug registers. It contains the following sections:

- [Relationship between external debug and System registers](#)
- [Endianness and supported access sizes](#)
- [Synchronization of changes to the external debug registers](#)
- [Memory-mapped accesses to the external debug interface](#)
- [External debug interface register access permissions](#)
- [External debug interface registers](#)
- [Cross-trigger interface registers](#)
- [External debug register resets](#)

E8.1 Relationship between external debug and System registers

Table E8-1 shows the relationship between external debug registers and System registers. Where no relationship exists, the registers are not listed.

Table E8-1 Equivalence between external debug and System registers

External debug register	System register	Notes
DBGDTRRX_EL0	DBGDTRRX_EL0	See also Summary of System register accesses to the DCC
DBGDTRTX_EL0	DBGDTRTX_EL0	
OSLAR_EL1	OSLAR_EL1	-
DBGBVR<n>_EL1[31:0] DBGBVR<n>_EL1[63:32]	DBGBVR<n>_EL1[31:0] DBGBVR<n>_EL1[63:32]	-
DBGBCR<n>_EL1[31:0] DBGBCR<n>_EL1[63:32]	DBGBCR<n>_EL1[31:0] DBGBCR<n>_EL1[63:32]	-
DBGWVR<n>_EL1[31:0] DBGWVR<n>_EL1[63:32]	DBGWVR<n>_EL1[31:0] DBGWVR<n>_EL1[63:32]	-
DBGWCR<n>_EL1[31:0] DBGWCR<n>_EL1[63:32]	DBGWCR<n>_EL1[31:0] DBGWCR<n>_EL1[63:32]	-
DBGCLAIMSET_EL1	DBGCLAIMSET_EL1	-
DBGCLAIMCLR_EL1	DBGCLAIMCLR_EL1	-
DBGAUTHSTATUS_EL1	DBGAUTHSTATUS_EL1	Read-only
EDSCR	MDSCR_EL1	
EDECCR	OSECCR_EL1	Applies when the OS Lock is locked
MIDR_EL1	MIDR_EL1	Read-only copies of Processor ID Registers
EDDEVAFF0 EDDEVAFF1	MPIDR_EL1[31:0] ^a MPIDR_EL1[63:32] ^a	Read-only copies of system ID registers

a. This is a word of a 64-bit register.

In addition:

- [EDSCR](#).{TXfull, RXfull} are read-only aliases for [MDCCSR_EL0](#).{TXfull, RXfull}.
- [EDPRCR](#).CORENPDRQ is a read/write alias for [DBGPRCR_EL1](#).CORENPDRQ.
- [EDPRSR](#).OSLK is a read-only alias for [OSLSR_EL1](#).OSLK.
- If the [FEAT_DoubleLock](#) is implemented, [EDPRSR](#).DLK is a read-only function of [OSDLR_EL1](#).DLK.

E8.2 Endianness and supported access sizes

The debug registers, Performance Monitors registers, and CTI registers are implemented as memory-mapped peripherals. The Arm architecture requires memory-mapped peripherals to be little-endian.

The memory access sizes supported by any peripheral is IMPLEMENTATION DEFINED by the peripheral. For accesses to the debug registers, Performance Monitors registers, and CTI registers, implementations must:

- Comply with the requirements of [Supported access sizes and Endianness](#).
- Support word-aligned 32-bit accesses to access 32-bit registers or either half of a 64-bit register, even if all components with direct memory access to the memory-mapped peripheral support making 64-bit accesses.

Note

These requirements mean that a system implementing the debug registers using a 32-bit bus, such as an AMBA APB3, with a wider system interconnect must implement a bridge between the system and the debug bus that can split 64-bit accesses.

For accesses from the external debug interface, the size of an access is determined by the interface. For an access from an ADiv5-compliant Memory Access Port, MEM-AP, this is specified by the MEM-AP CSW register.

E8.3 Synchronization of changes to the external debug registers

This section describes the synchronization requirements for the external debug interface.

For more information on how these requirements affect debug, see:

- [Synchronization and debug exceptions](#) for exceptions taken from AArch64 state.
- [Synchronization and Halting debug events](#).
- [Synchronization of DCC and ITR accesses](#).

This section refers to accesses from the external debug interface as external reads and external writes. It refers to accesses to System registers as direct reads, direct writes, indirect reads, and indirect writes.

Note

[Synchronization requirements for AArch64 System registers](#) define direct read, direct write, indirect read, and indirect write, and classifies external reads as indirect reads, and external writes as indirect writes.

For general information about synchronization, access completion, ordering, and observability, see [Synchronization of memory-mapped registers](#).

Writes to the same register are serialized, meaning they are observed in the same order by all observers, although some observers might not observe all of the writes. With the exception of [DBGBCR<n>_EL1](#), [DBGBVR<n>_EL1](#), [DBGWCR<n>_EL1](#), and [DBGWVR<n>_EL1](#), external writes to different registers are not necessarily observed in the same order by all observers as the order in which they complete.

[Synchronization of DCC and ITR accesses](#) describes the synchronization requirements for the DCC and ITR.

Changes to the IMPLEMENTATION DEFINED authentication interface are external writes to the authentication status registers by the Requester of the authentication interface. See [Synchronization and the authentication interface](#).

The external agent must be able to guarantee completion of a write. For example by:

- Marking the memory as Device-nGnRnE and executing a DSB barrier, if the system supports this property.
- Reading back the value written.
- Some guaranteed property of the connection between the PE and the external agent.

Note

For an external Debug Access Port, access completion is an IMPLEMENTATION DEFINED property. For a CoreSight system using APB-AP to access a debug APB, accesses complete in order.

However, the external agent cannot force synchronization of completed writes without halting the PE. Executing an ISB instruction, either in Debug state or in Non-debug state, and exiting from Debug state forces synchronization. If the PE is in Debug state, executing an ISB instruction is guaranteed to explicitly synchronize any external reads, external writes, and changes to the authentication interface that are ordered before the external write to [EDITR](#).

For any given observer, external writes to the following register groups are guaranteed to be observable in the same order in which they complete:

- The breakpoint registers, [DBGBCR<n>_EL1](#) and [DBGBVR<n>_EL1](#).
- The watchpoint registers, [DBGWCR<n>_EL1](#) and [DBGWVR<n>_EL1](#).

This guarantee applies only to external writes to registers within one of these groups. There is no guarantee regarding the ordering of the observability of external writes within these groups with respect to external writes to registers, for example [EDSCR](#), or between breakpoints and watchpoints, including watchpoints linked to context matching breakpoints.

Note

This means that a debugger can rely on the external writes to be observed in the same order in which they complete. It does not mean that a debugger can rely on the external writes being observed in finite time.

In a simple sequential execution an indirect write that occurs as a side-effect of an access happens atomically with the access, meaning no other accesses are allowed between the register access and its side-effect.

If two or more interfaces simultaneously access a register, the behavior must be as if the accesses occurred atomically and in any order. This is described in [Examples of the synchronization of changes to the external debug registers](#).

Note

Where simultaneous writes occur, once an order has been established by the implementation, some registers have behavior that is incompatible with the implementation simply dropping the older write and only performing the actions of the younger write. In these cases, the implementation must ensure that the register update is consistent with both writes having occurred. For example, writing one to write-one-to-clear or write-one-to-set fields in the older write can produce effects that persist even after writing zero to the same field in the younger write. Examples of registers with this behavior include [DBGCLAIMSET_EL1](#), [DBGCLAIMCLR_EL1](#), [PMCR_EL0](#), [PMOVSSET_EL0](#), [PMOVSCCLR_EL0](#), [PMCNTENSET_EL0](#), [PMCNTENCLR_EL0](#), [PMINTENSET_EL1](#), [PMINTENCLR_EL1](#), [PMSWINC_EL0](#), and [PMZR_EL0](#), all of which are simultaneously accessible through external debug and System register access.

E8.3.1 Synchronization and the authentication interface

Changes to the authentication interface are indirect writes to the state of the PE by the Requester of the authentication interface.

For an external debug interface read of any Authentication Status register, or an indirect read of the authentication interface made in determining the response to a subsequent external debug interface access, a change on the authentication interface must be observable following a subsequent explicit [Context Synchronization event](#), and:

- It is IMPLEMENTATION DEFINED whether a change is guaranteed to be observable in finite time.
- It is IMPLEMENTATION DEFINED whether a change is guaranteed to be observable following an entry to Debug state.

For a System register read of [DBGAUTHSTATUS_EL1](#), a change on the authentication interface is guaranteed to be observable only after a [Context Synchronization event](#).

Note

- In some systems, the authentication interface is fixed by configuration or is changed under the control of software. These systems can require explicit synchronization for any change to the authentication interface.
 - In other systems, the authentication interface is controlled dynamically by an external agent. In these systems, it is desirable that changes to the authentication interface do not require explicit synchronization by software executing on the PE to be observable by subsequent external debug interface accesses, and are either observable in finite time or are synchronized by entry to Debug state. Otherwise, there are scenarios where a debugger is not able to halt and debug the system.
-

E8.3.2 Examples of the synchronization of changes to the external debug registers

[Example E8-1](#), [Example E8-2](#), and [Example E8-3](#) show the synchronization of changes to the external debug registers.

Example E8-1 Order of synchronization of Breakpoint and Watchpoint register writes

Initially `DBGBVR<n>_EL1` is `0x8000` and `DBGBCR<n>_EL1` is `0x0181`. This means that a breakpoint is enabled on the halfword T32 instruction at address `0x8000`.

A sequence of external writes occurs in the following order:

1. `0x0000` is written to `DBGBCR<n>_EL1`, disabling the breakpoint.
2. `0x9000` is written to `DBGBVR<n>_EL1`[31:0].
3. `0x0061` is written to `DBGBCR<n>_EL1`, enabling a breakpoint on the halfword at address `0x9002`.

The external writes must be observable to indirect reads in the same order as the external writes complete. This means that at no point is there a breakpoint enabled on either of the halfwords at address `0x8002` and `0x9000`.

Similarly a breakpoint or watchpoint must be disabled:

- If both halves of a 64-bit address have to be updated.
- If any of the `DBGBCR<n>_EL1` or `DBGWCR<n>_EL1` fields are modified at the same time as updating the address.

Example E8-2 Simultaneous accesses to DTR registers

Initially `EDSCR.{TXfull, TXU, ERR}` are 0. Then:

- `0x0DCCDA7A` is directly written to `DBGDTRTX_EL0` by an MSR instruction.
- `DBGDTRTX_EL0` is indirectly read by the external debug interface.

These accesses might happen at the same time and in any order.

If the direct write of `0x0DCCDA7A` to `DBGDTRTX_EL0` is handled first, then:

- The external debug interface read of `DBGDTRTX_EL0` clears `EDSCR.TXfull` to 0.
- `EDSCR.{TXU, ERR}` are unchanged.
- The external debug interface read returns `0x0DCCDA7A`.

If the indirect read of `DBGDTRTX_EL0` by the external debug interface is handled first, then:

- The external debug interface read of `DBGDTRTX_EL0` causes an underrun and as a result `EDSCR.{TXU, ERR}` are both set to 1.
- The external debug interface returns an UNKNOWN value.
- Writing `0x0DCCDA7A` to `DBGDTRTX_EL0` sets `DTRTX` to `0x0DCCDA7A` and `EDSCR.TXfull` to 1.

Example E8-3 Simultaneous writes to CLAIM registers

Initially all CLAIM tag bits are 0. Then:

- 0x01 is written to [DBGCLAIMSET_EL1](#) by a direct write, followed by an explicit [Context Synchronization event](#).
- 0x02 is written to [DBGCLAIMSET_EL1](#) by an external write.

These events might happen at the same time and in either order.

After this:

- [DBGCLAIMCLR_EL1](#) is read by a direct read.
- [DBGCLAIMCLR_EL1](#) is read by an external read.

In this case, a direct read can return either 0x01 or 0x03, and the external read can return either 0x02 or 0x03.

The only permitted final result for the CLAIM tags is the value 0x03, because this would be the result regardless of whether 0x01 or 0x02 is written first. This is because the external write is guaranteed to be observable to a direct read in finite time. See [Synchronization requirements for AArch64 System registers](#).

It is not possible for a direct read to return 0x01 and the external read to return 0x02, because the writes to [DBGCLAIMCLR_EL1](#) are serialized.

In the following scenario, there is only one permitted result. Both observers observe the value 0x03, and then, at the same time, two writes occur:

- 0x04 is written to [DBGCLAIMSET_EL1](#) by a direct write, followed by an explicit [Context Synchronization event](#).
- 0x01 is written to [DBGCLAIMCLR_EL1](#) by an external write.

In this case, the only permitted final result for the CLAIM tags is the value 0x06.

E8.4 Memory-mapped accesses to the external debug interface

Support for memory-mapped access to the external debug interface is **OPTIONAL**. When memory-mapped access to the external debug interface is supported, the external debug interface is accessed as a little-endian memory-mapped peripheral.

If the external debug interface is CoreSight compliant, then an **OPTIONAL** Software Lock can be implemented for memory-mapped accesses to each component.

The Software Lock is **OPTIONAL** and deprecated. If **FEAT_Debugv8p4** is implemented, the Software Lock is not implemented. If it is not implemented, the behavior is as if it is unlocked. The Software Locks are controlled by **EDLSR** and **EDLAR**, **PMLSR** and **PMLAR**, and **CTILSR** and **CTILAR**. See Management registers and CoreSight compliance.

If **FEAT_DoPD** is implemented, Software Lock is not implemented by the architecturally-defined debug components in the Core power domain.

With the exception of these registers and the effect of the Software Lock, the behavior of the memory-mapped accesses is the same as for other accesses to the external debug interface.

Note

The recommended memory-mapped accesses to the external debug interface are not compatible with the memory-mapped interface defined in Armv7. In particular:

- The memory map is different.
 - Memory-mapped accesses do not behave differently to Debug Access Port accesses when **OSLSR_EL1.OSLK** == 1, meaning that the OS Lock is locked.
-

The following sections give more information about these memory-mapped accesses:

- [Register access permissions for memory-mapped accesses.](#)
- [Synchronization of memory-mapped accesses to external debug registers.](#)

See also [Supported access sizes and Endianness](#).

E8.4.1 Register access permissions for memory-mapped accesses

It is **IMPLEMENTATION DEFINED** whether unprivileged memory-mapped accesses are allowed. Privileged software is responsible for controlling memory-mapped accesses using the MMU and MPU.

If **FEAT_Debugv8p4** is implemented, the Security state view of a debug component is mapped into the physical memory for that Security state.

If **FEAT_Debugv8p4** is implemented, the access permissions are different in each Security state, but Secure and Non-secure views of the debug components are identical. Arm recommends the views are located at the same address in the Secure and Non-secure physical address maps.

If memory-mapped accesses are made through an ADiv5 interface, the Debug Access Port can block the access using **DBGSWENABLE**. This is outside the scope of the Arm architecture. See *Arm® Debug Interface Architecture Specification ADiv5.0 to ADiv5.2*.

E8.4.1.1 Effect of the **OPTIONAL** Software Lock on memory-mapped access

For memory-mapped accesses, if other controls permit access to a register, the **OPTIONAL** Software Lock is implemented, and **EDLSR.SLK**, **PMLSR.SLK**, or **CTILSR.SLK** is set to 1, meaning the Software Lock is locked, then with the exception of the LAR itself:

- If other controls permit access to a register, then writes are ignored. That is:
 - Read/write (RW) registers become read-only, writes ignored (RO/WI).
 - Write-only (WO) registers become writes ignored (WI).
- Reads and writes have no side-effects. A side-effect is where a direct read or a direct write of a register creates an indirect write of the same or another register. When the Software Lock is locked, the indirect write does not occur.

- Writes to [EDLAR](#), [PMLAR](#), and [CTILAR](#) are unaffected.

This behavior must also apply to all IMPLEMENTATION DEFINED registers.

For example, if [EDLSR.SLK](#) is set to 1:

- [EDSCR](#).{TXfull, TXU, ERR} are unchanged by a memory-mapped read from [DBGDTRTX_EL0](#).
- [EDSCR](#).{RXfull, RXO, ERR} are unchanged by a memory-mapped write to [DBGDTRRX_EL0](#) that is ignored.
- [EDSCR](#).{ITE, ITO, ERR} are unchanged by a memory-mapped write to [EDITR](#) that is ignored.
- [OSLSR_EL1](#).OSLK is unchanged by a memory-mapped write to [OSLAR_EL1](#) that is ignored.
- [EDPCSR](#)[63:32], [EDCIDSR](#), and [EDVIDSR](#) are unchanged by a memory-mapped read from [EDPCSR](#)[31:0].

Note

Updating [EDVIDSR](#), [EDCIDSR](#), and [EDPCSR](#)hi are side-effects of reading [EDPCSR](#)lo, such that these registers contain the matching context for [EDPCSR](#)lo. The process that updates [EDPCSR](#)lo with PC samples is not a side-effect of the access. Reads of [EDPCSR](#)lo made when the Software Lock is locked can be used to profile software.

- [PMPCSR](#)[63:32], [PMCID1SR/PMCID2SR](#), and [PMVIDSR](#) are unchanged by a memory-mapped read from [PMPCSR](#)[31:0].

Note

Updating [PMVIDSR](#), [PMCID1SR/PMCID2SR](#), and [PMPCSR](#)[31:0] are side-effects of reading [PMPCSR](#)[63:32], such that these registers contain the matching context for [PMPCSR](#)[63:32]. The process that updates [PMPCSR](#)[63:32] with PC samples is not a side-effect of the access. Reads of [PMPCSR](#)[63:32] made when the Software Lock is locked can be used to profile software.

- [EDPRSR](#).{SDR, SPMAD, SDAD, SR, SPD} are unchanged by a memory-mapped read from [EDPRSR](#).
- [EDPRSR](#).SDAD is not set if an error response is returned due to a memory-mapped read or write of any debug register as the result of the value of the EDAD field.
- The CLAIM tags are unchanged by memory-mapped writes to [DBGCLAIMSET_EL1](#) and [DBGCLAIMCLR_EL1](#) which are ignored.

Similarly, if [PMLSr.SLK](#) is set to 1, then [EDPRSR](#).SPMAD is not set if an error response is returned to a memory-mapped read or write of any Performance Monitors register due to the value of the EPMAD field.

E8.4.1.2 Behavior of a not permitted memory-mapped access

Where the architecture requires that an external debug interface access generates an error response, a memory-mapped access must also generate an error response. However, it is IMPLEMENTATION DEFINED how the error response is handled, as this depends on the system.

Arm recommends that the error is returned as either:

- A synchronous external Data Abort.
- An SError exception.

E8.4.2 Synchronization of memory-mapped accesses to external debug registers

The synchronization requirements for memory-mapped accesses to the external debug interface is described in [Synchronization of changes to the external debug registers](#) and [Synchronization of memory-mapped registers](#).

The synchronization requirements between different routes to the external debug interface, that is, between Debug Access Port accesses and memory-mapped accesses are IMPLEMENTATION DEFINED.

E8.5 External debug interface register access permissions

Some external accesses to debug registers and Performance Monitor registers are not permitted and return an error response if:

- The Core power domain is powered down or is in low-power state where the registers cannot be accessed.
- [OSLSR_EL1](#).OSLK == 1. The OS Lock is locked.
- [FEAT_DoubleLock](#) is implemented and [DoubleLockStatus\(\)](#) == TRUE. The OS Double Lock is locked.
- The access is disabled by either the authentication interface or secure monitor.

Not all registers are affected in all of these cases. For more information, see [External debug interface register access permissions summary](#).

E8.5.1 External debug over powerdown and locks

Accessing registers using the external debug interface is not possible when the Debug power domain is off. In this case, all accesses return an error.

External accesses to debug and Performance Monitors registers in the Core power domain are not permitted and return an error response if:

- The Core power domain is off or in low-power state where the registers cannot be accessed.
- [OSLSR_EL1](#).OSLK == 1, meaning that the OS Lock is locked. This allows software to prevent external debugger modification of the registers while it saves and restores them over powerdown.
- [FEAT_DoubleLock](#) is implemented and [DoubleLockStatus\(\)](#) == TRUE. This means that the OS Double Lock is locked. The OS Double Lock ensures that it is safe to remove Core power by forcing the debug interface to be quiescent.

If [FEAT_DoubleLock](#) is not implemented, the hardware must provide another method to safely remove Core power.

The OS Lock condition does not apply to the following debug registers:

- [OSLAR_EL1](#). This means that an external debugger can override this lock.
- [EDES](#). This means that an external debugger can program a debug event for when software unlocks the OS Lock. See [OS Unlock Catch debug event](#).
- The ID registers that describe the PE to the debugger.

See also [Debug registers to save over powerdown](#).

E8.5.2 External access disabled

Accesses are further controlled by the external authentication interface. An untrusted external debugger cannot program the breakpoint and watchpoint registers to generate spurious debug exceptions. If external invasive debugging is not enabled, these external accesses to the registers are disabled.

The disable applies to:

- The [DBGBVR<n>_EL1](#), [DBGBCR<n>_EL1](#), [DBGWVR<n>_EL1](#), and [DBGWCR<n>_EL1](#) registers.
- From Armv8.2, the [OSLAR_EL1](#) register.

If [FEAT_Debugv8p4](#) is implemented, accesses from the external debug interface to these registers are not permitted if the PE behaves as if the Security state is Secure, and the access is Non-secure.

PEs might also provide an OPTIONAL external debug interface to the Performance Monitor registers.

Note

Arm recommends that Secure software that is not making use of debug hardware does not lock out the external debug interface.

The [AllowExternalPMUAccess\(\)](#) pseudocode function describes these accessibility rules.

E8.5.3 Behavior of a not permitted access

For an external debug interface access by a Debug Access Port, the Debug Access Port receives the error response and must signal this to the external debugger. For an ADIV5 implementation of a Debug Access Port, the error sets a sticky error flag in the Debug Access Port that the debugger can poll, and that suppresses further accesses until it is explicitly cleared.

When an error is returned because external access is disabled, and this is the highest priority error condition, a sticky error flag in [EDPRSR](#) is indirectly written to 1 as a side-effect of the access:

- For a debug register access when `AllowExternalDebugAccess()` == FALSE, [EDPRSR.SDAD](#) is indirectly written to 1.
- For Performance Monitor register access when `AllowExternalPMUAccess()` == FALSE, [EDPRSR.SPMAD](#) is indirectly written to 1.

The indirect write might not occur for a memory-mapped access to the external debug interface. For more information, see [Register access permissions for memory-mapped accesses](#).

If no error is returned, or the error is returned because of a higher priority error condition, the flag in [EDPRSR](#) is unchanged.

See also [Behavior of a not permitted memory-mapped access](#).

For more information, see *Arm® Debug Interface Architecture Specification*.

E8.5.4 External debug interface register access permissions summary

For accesses to:

- IMPLEMENTATION DEFINED registers, see [IMPLEMENTATION DEFINED registers](#).
- OPTIONAL registers for CoreSight compliance, see *Arm® Architecture Reference Manual*, for A-profile architecture.
- Reserved, unallocated, or unimplemented registers, writes to read-only registers, and reads of write-only registers, see [Reserved and unallocated registers](#).

For all other external debug interface, CTI, and Performance Monitor registers, [Table E8-3](#), [Table E8-4](#), [Table E8-6](#) and [Table F3-1](#), show the response of the PE to accesses by the external debug interface.

E8.5.5 IMPLEMENTATION DEFINED registers

Register access permissions for IMPLEMENTATION DEFINED debug, Performance Monitors, and CTI registers are IMPLEMENTATION DEFINED, other than as follows:

- If [FEAT_DoPD](#) is implemented, then all of the following apply:
 - All debug and Performance Monitors registers, including IMPLEMENTATION DEFINED registers, are implemented in the Core power domain and accesses return an error when the Core power domain is off or in a low-power state.
 - CTI registers, including IMPLEMENTATION DEFINED registers, are implemented in the Debug power domain.
- When memory-mapped access to the external debug interface is supported, the additional constraints in [Register access permissions for memory-mapped accesses](#) apply to IMPLEMENTATION DEFINED registers.

E8.5.6 Reserved and unallocated registers

The default access requirements for reserved and unallocated registers are described in [Access requirements for reserved and unallocated registers](#).

Note

Reads of WO and writes to RO refers to the default access permissions for a register. For example, when the SLK field is 1, meaning that the relevant registers become RO, a memory-mapped write to a RW register is ignored, and not treated as a reserved access.

The following reserved registers are RES0 in all conditions, other than when debug power is off:

- All reserved CTI registers.
- For the debug registers, and Performance Monitors registers, if the implementation is CoreSight architecture compliant, and either [FEAT_DoPD](#) is not implemented or the Core power domain is on, all reserved registers in the range 0xF00 - 0xFFC. See Management register access permissions.

Otherwise, the architecture defines that:

1. If debug power is off, all register accesses, including reserved accesses, return an error.
2. For reserved debug registers and Performance Monitors registers, if [FEAT_DoPD](#) is implemented, and the Core power domain is off or in a low-power state, the response is an error. Otherwise, the response is a CONSTRAINED UNPREDICTABLE choice of error or RES0, when any of the following hold:
 - Off** The Core power domain is either completely off or in a low-power state in which the Core power domain registers cannot be accessed.
 - DLK** [FEAT_DoubleLock](#) is implemented and [DoubleLockStatus\(\)](#) == TRUE. The OS Double Lock is locked.
 - OSLK** [OSLSR_EL1.OSLK](#) == 1. The OS Lock is locked.
3. In addition, for reserved debug registers in the address ranges 0x400 - 0x4FC and 0x800 - 0x8FC, the response is a CONSTRAINED UNPREDICTABLE choice of error or RES0 when conditions 1 or 2 do not apply and:
 - EDAD** [AllowExternalDebugAccess\(\)](#) == FALSE. External debug is disabled.

Note

See also [Behavior of a not permitted access](#).

4. In addition, for reserved Performance Monitors registers in the address ranges 0x000 - 0xEFC, the response is a CONSTRAINED UNPREDICTABLE choice of error or RES0 when conditions 1 or 2 do not apply and:
 - EPMD** [AllowExternalPMUAccess\(\)](#) == FALSE. External Performance Monitor access is disabled.

Note

See also [Behavior of a not permitted access](#).

5. For reads of WO locations, the response is a CONSTRAINED UNPREDICTABLE choice of error or RES0 when the architecture permits or requires a write to the location to return an error.
6. For writes of RO locations, the response is a CONSTRAINED UNPREDICTABLE choice of error or RES0 when the architecture permits or requires a read to the location to return an error.
7. For reads and writes of locations for features that are not implemented, the response is a CONSTRAINED UNPREDICTABLE choice of error or RES0 when the architecture permits or requires an access to the location to return an error if the feature is implemented.

E8.6 External debug interface registers

The external debug interface register map is described by:

- [Summary of external debug registers.](#)
- [Cross-trigger interface registers.](#)
- [Performance Monitors external register views.](#)

Table E8-2 Summary of external debug registers

Offset	Name	Description	Access
0x020	EDES	External Debug Event Status Register	RW

E8.6.1 Access permissions for the External debug interface registers

Table E8-3 and Table E8-4 show the access permissions for the external debug interface registers in an Arm A-profile Debug implementation. The terms are defined as follows:

Domain	This describes the power domain in which the register is logically implemented. Registers described as implemented in the Core power domain might be implemented in the Debug power domain, as long as they exhibit the required behavior. If FEAT_DoPD is implemented, most External debug interface registers are in the Core power domain, as shown in Table E8-3. If FEAT_DoPD is not implemented, most of the registers are in the Debug Power Domain, as shown in Table E8-4.										
Conditions	This lists the conditions under which the access is attempted. To determine the access permissions for a register, read these columns from left to right, and stop at first column that lists the condition as being true. The conditions are: <table> <tr> <td>Off</td><td>The Core power domain is completely off, or in low-power state. In these cases the Core power domain registers cannot be accessed, and if FEAT_DoPD is not implemented, EDPRSR.PU will read as 0.</td></tr> <tr> <td colspan="2"> Note When the Core power domain is off, or in a low-power state, a debugger is permitted to access a debug register that is implemented in the external Debug power domain. When the Debug power domain is off, all accesses to the registers in the external Debug power domain return an error. </td></tr> <tr> <td>DLK</td><td>FEAT_DoubleLock is implemented and DoubleLockStatus() == TRUE. The OS Double Lock is locked. If FEAT_DoPD is implemented, FEAT_DoubleLock is not implemented and so Table E8-3 does not include this column.</td></tr> <tr> <td>OSLK</td><td>OSLSR_EL1.OSLK == 1. The OS Lock is locked.</td></tr> <tr> <td>EDAD</td><td>AllowExternalDebugAccess() == FALSE. External debug access is disabled for the access. See also Behavior of a not permitted access.</td></tr> </table>	Off	The Core power domain is completely off, or in low-power state. In these cases the Core power domain registers cannot be accessed, and if FEAT_DoPD is not implemented, EDPRSR.PU will read as 0.	Note When the Core power domain is off, or in a low-power state, a debugger is permitted to access a debug register that is implemented in the external Debug power domain. When the Debug power domain is off, all accesses to the registers in the external Debug power domain return an error.		DLK	FEAT_DoubleLock is implemented and DoubleLockStatus() == TRUE. The OS Double Lock is locked. If FEAT_DoPD is implemented, FEAT_DoubleLock is not implemented and so Table E8-3 does not include this column.	OSLK	OSLSR_EL1.OSLK == 1. The OS Lock is locked.	EDAD	AllowExternalDebugAccess() == FALSE. External debug access is disabled for the access. See also Behavior of a not permitted access .
Off	The Core power domain is completely off, or in low-power state. In these cases the Core power domain registers cannot be accessed, and if FEAT_DoPD is not implemented, EDPRSR.PU will read as 0.										
Note When the Core power domain is off, or in a low-power state, a debugger is permitted to access a debug register that is implemented in the external Debug power domain. When the Debug power domain is off, all accesses to the registers in the external Debug power domain return an error.											
DLK	FEAT_DoubleLock is implemented and DoubleLockStatus() == TRUE. The OS Double Lock is locked. If FEAT_DoPD is implemented, FEAT_DoubleLock is not implemented and so Table E8-3 does not include this column.										
OSLK	OSLSR_EL1.OSLK == 1. The OS Lock is locked.										
EDAD	AllowExternalDebugAccess() == FALSE. External debug access is disabled for the access. See also Behavior of a not permitted access .										

EPMA	AllowExternalPMUAccess() == FALSE. Access to the external Performance Monitors is disabled for the access. See also Behavior of a not permitted access .
SLK	The Software Lock is implemented and SoftwareLockStatus() == TRUE. This provides the modified default access permissions for OPTIONAL memory-mapped accesses to the external debug interface if the OPTIONAL Software Lock is locked for the access. See Register access permissions for memory-mapped accesses . If FEAT_DoPD is implemented, the Software Lock is not locked or not implemented, then this column is ignored.
Default	This provides the default access permissions, if there are no conditions that prevent access to the register.

The access permissions are:

-	This means that the default access permission applies. See the Default column, or the SLK column, if applicable.
RO	This means that the register or field is read-only, and: - Unless the register description states otherwise, a RO field in an RW register ignores writes. - Where the SLK control makes a RW register RO, the register ignores writes.
RW	This means that the register or field is read/write. Individual fields within the register might be RO or WO. See the relevant register description for details.
RC	This means that a read of the register bit clears the field to 0.
WO	This means that the register or field is write-only. Unless the register description states otherwise, a WO field in a RW register returns an UNKNOWN value on a read of the register.
WI	This means that the register or field ignores writes.
IMP DEF	This means that the access permissions are IMPLEMENTATION DEFINED.

[DBGBVR<n>_EL1](#) and [DBGWVR<n>_EL1](#), are 64-bit registers mapped to pairs of 32-bit locations in the external debug interface. Doubleword accesses to these register are not guaranteed to be 64-bit single copy atomic. Software must take care before altering the values of [DBGBVR<n>_EL1](#), [DBGWVR<n>_EL1](#), [DBGBCR<n>_EL1](#), and [DBGWCR<n>_EL1](#) to prevent UNPREDICTABLE behavior. See [Endianness and supported access sizes](#) for more information.

If OPTIONAL memory-mapped access to the external debug interface is supported, there might be additional constraints on memory-mapped accesses. See [Register access permissions for memory-mapped accesses](#).

For the reset values for the external debug interface registers, see [[@tbl:CIHCDIDH0](#)].

Table E8-3 Access permissions for the external debug interface registers if FEAT_DoPD is implemented

0xFAC	EDDEVAFF1	Debug	-	-	-	RO	RO
0xFB8	DBGAUTHSTATUS_EL1	Debug	-	-	-	RO	RO
0xFC0	EDDEVID2	Debug	-	-	-	RO	RO
0xFC4	EDDEVID1	Debug	-	-	-	RO	RO
0xFC8	EDDEVID	Debug	-	-	-	RO	RO

a. Some bits are in the Debug power domain and some bits are in the Core power domain. See register field descriptions for information.

b. Implemented breakpoints and watchpoints only. *n* is the breakpoint or watchpoint number.

c. It is IMPLEMENTATION DEFINED whether an error is returned. See [External debug over powerdown and locks](#). If no error is returned, the access is permitted.

E8.7 Cross-trigger interface registers

The Embedded Cross-Trigger Interface, CTI, is located within its own block of the external debug memory map. There must be one such block for each PE.

If the CTI of a PE does not implement the [CTIDEVAFF0](#) or [CTIDEVAFF1](#) registers it must be located 64KB above the debug registers in the external debug interface.

When [FEAT_Debugv8p4](#) is implemented, each debug component has a Secure and Non-secure view. The Secure view of a debug component is mapped into Secure physical memory and the Non-secure view of a debug component is mapped into Non-secure memory. Apart from access conditions, the Non-secure and Secure views of the debug components are identical.

[Table E8-5](#) shows the CTI register map.

Table E8-5 Summary of the Embedded Cross-Trigger Interface, CTI, registers

Offset	Name	Description	Access
0x000	CTICONTROL	CTI Control register	RW
0x010	CTIINTACK	CTI Output Trigger Acknowledge register	WO
0x014	CTIAPPSET	CTI Application Trigger Set register	RW
0x018	CTIAPPCLEAR	CTI Application Trigger Clear register	WO
0x01C	CTIAPPULSE	CTI Application Pulse register	WO
0x020 + (4 * n)	CTIINEN<n>	CTI Input Trigger to Output Channel Enable registers	RW
0x0A0 + (4 * n)	CTIOUTEN<n>	CTI Input Channel to Output Trigger Enable registers	RW
0x130	CTITRIGINSTATUS	CTI Trigger In Status register	RO

0xFC8	CTIDEVID	Debug	-	-	-	-	RO	RO

For the reset values of the CTI registers, see [Table E8-8](#).

E8.8 External debug register resets

Each register or field has a defined reset domain:

- Registers and fields in the Warm reset domain are also reset by a Cold reset and unchanged by an External Debug reset that is not coincident with a Cold reset or a Warm reset.
- Registers and fields in the Cold reset domain are unchanged by a Warm reset or an External Debug reset that is not coincident with a Cold reset.
- Registers and fields in the External Debug reset domain are unchanged by a Cold reset or a Warm reset that is not coincident with an External Debug reset.

A reset might change the value of a register. Specific rules apply to the observability of registers in the External Debug reset domain by indirect reads from the Core power domain when an External Debug reset is asserted without a coincident Cold reset. For more information, see [Synchronization of changes to the external debug registers](#).

[Table E8-7](#) and [Table E8-8](#) show the external debug register and CTI register resets. For other debug registers, see Management register resets.

Note

By reference to [Figure E6-1](#) the power domain can be deduced from the reset domain.

[Table E8-7](#) and [Table E8-8](#) do not include:

- Read-only identification registers, such as Processor ID Registers and [PMCFGR](#), that have a fixed value from reset.
- Read-only status registers, such as [EDSCR.RW](#), that are evaluated each time the register is read and that have no meaningful reset value.
- Write-only registers, such as [EDRCR](#), that only have an effect on writes, and have no meaningful reset value.
- Read/write registers, such as breakpoint and watchpoint registers, and [EDPRCR.CORENPDRQ](#), that alias other registers. The reset values are described by the descriptions of those other registers.
- IMPLEMENTATION DEFINED registers. The reset values and reset domains of these registers are also IMPLEMENTATION DEFINED and might be UNKNOWN.

All other fields in the registers are set to an IMPLEMENTATION DEFINED value that can be UNKNOWN. The register is in the specified reset domain.

Note

An IMPLEMENTATION DEFINED reset value, which can be UNKNOWN, means that hardware is not required to reset the register on the specified reset, but software must not rely on the register being preserved over reset.

Table E8-7 Summary of external debug register resets, debug registers

Register	Reset domain	Field	Value	Description
DBGPRCR_EL1	Cold	CORENPDRQ	The value of the powerup request ^a	Debug Power Control Register.
EDES R, if FEAT_DoPD is not implemented	Warm	SS	EDECR .SS	Halting Step debug event pending
		RC	EDECR .RCE	Reset Catch debug event pending
		OSUC	0	OS Unlock Catch debug event pending
EDES R, if FEAT_DoPD is implemented	Cold	SS	0	Halting Step debug event pending
	Warm	RC	CTIDEVCTL .RCE	Reset Catch debug event pending

Register	Reset domain	Field	Value	Description
		OSUC	0	OS Unlock Catch debug event pending
EDECR, if FEAT_DoPD is implemented	Cold	SS	0	Halting Step debug event enable
EDECR, if FEAT_DoPD is not implemented	External debug	SS	0	Halting Step debug event enable
		RCE	0	Reset Catch debug event enable
		OSUCE	0	OS Unlock Catch debug event enable
EDWAR	Cold	-	-	All fields
EDSCR	Cold	RXfull	0	DTRRX register full
		TXfull	0	DTRTX register full
		RXO	0	DTRRX overrun
		TXU	0	DTRTX underrun
		INTdis	0	Interrupt disable
		TDA	0	Trap debug register accesses to Debug state
		MA	0	Memory access mode in Debug state
		HDE	0	Halting debug mode enable
		ERR	0	Cumulative error flag
EDECCR	Cold	NSE[2:1]	0b00	Coarse-grained Non-secure Exception Catch
		SE[3,1]	0b00	Coarse-grained Secure Exception Catch
EDPRCR, if FEAT_DoPD is implemented	Cold	-	-	-
EDPRCR, if FEAT_DoPD is not implemented	External debug	COREPURQ ^b	-	Core powerup request
EDPRSR	Warm	SDR	-	Sticky debug restart
	Cold	SPMAD	0	Sticky EPMAD error
		SDAD	0	Sticky EDAD error
	Warm	SR	1	Sticky reset status
	Cold	SPD	1	Sticky powerdown status

a. If FEAT_DoPD is not implemented, the powerup request is the EDPRCR.COREPURQ control bit.

b. If FEAT_DoPD is not implemented, on a Cold reset, DBGPRCR_EL1.CORENPDRQ resets to the value of EDPRCR.COREPURQ. If an External Debug reset and a Cold reset coincide, both EDPRCR.COREPURQ and DBGPRCR_EL1.CORENPDRQ are reset to 0.

Table E8-5 shows the reset values for the CTI registers

Table E8-8 Summary of external debug register resets, CTI registers

Register	Reset domain	Field	Value	Description
CTICONTROL	External debug	GLBEN	0	CTI global enable

Register	Reset domain	Field	Value	Description
CTIDEVCTL	External debug	RCE	0	If FEAT_DoPD is implemented, Reset Catch debug event enable
		OSUCE	0	If FEAT_DoPD is implemented, OS Unlock Catch debug event enable
CTIAPPSET	External debug	-	-	All fields
CTIINEN<n>	External debug	-	-	All fields
CTIOUTEN<n>	External debug	-	-	All fields
CTIGATE	External debug	-	-	All fields
ASICCTL	IMPLEMENTATION DEFINED	-	IMPLEMENTATION DEFINED	All of register

Chapter E9

External Debug Register Descriptions

This chapter provides a description of the external debug registers. It contains the following sections:

- [About the external debug registers](#)
- [External debug registers](#)
- [External trace registers](#)
- [Cross-Trigger Interface registers](#)

E9.1 About the external debug registers

The following sections describe the registers that are accessible through the external debug interface:

- [External debug registers.](#)
- [External trace registers.](#)
- [Cross-Trigger Interface registers.](#)

E9.2 External debug registers

This section describes the debug registers that are accessible through the external debug interface and are used for external debug.

E9.2.1 DBGAUTHSTATUS_EL1, Debug Authentication Status Register

The DBGAUTHSTATUS_EL1 characteristics are:

Purpose

Provides information about the state of the IMPLEMENTATION DEFINED authentication interface for debug.

Configuration

When FEAT_DoPD is implemented, DBGAUTHSTATUS_EL1 is in the Core power domain. Otherwise, DBGAUTHSTATUS_EL1 is in the Debug power domain

External register DBGAUTHSTATUS_EL1 bits [31:0] are architecturally mapped to AArch64 System register [DBGAUTHSTATUS_EL1](#)[31:0].

Attributes

DBGAUTHSTATUS_EL1 is a 32-bit register.

Field descriptions

31	8	7	6	5	4	3	2	1	0
RES0								SNID	NSID

Bits [31:8]

Reserved, RES0.

SNID, bits [7:6]

When FEAT_Debugv8p4 is implemented:

Secure non-invasive debug.

This field has the same value as DBGAUTHSTATUS_EL1.SID.

Otherwise:

Secure non-invasive debug.

SNID	Meaning
0b00	Secure state is not implemented.
0b10	Implemented and disabled. <code>ExternalSecureNoninvasiveDebugEnabled() == FALSE</code> .
0b11	Implemented and enabled. <code>ExternalSecureNoninvasiveDebugEnabled() == TRUE</code> .

All other values are reserved.

SID, bits [5:4]

Secure invasive debug.

SID	Meaning
0b00	Secure state is not implemented.
0b10	Implemented and disabled. <code>ExternalSecureInvasiveDebugEnabled()</code> == FALSE.
0b11	Implemented and enabled. <code>ExternalSecureInvasiveDebugEnabled()</code> == TRUE.

All other values are reserved.

NSNID, bits [3:2]

When FEAT_Debugv8p4 is implemented:

Non-secure non-invasive debug.

NSNID	Meaning
0b00	Non-secure state is not implemented.
0b11	Implemented and enabled. <code>ExternalNoninvasiveDebugEnabled()</code> == TRUE.

All other values are reserved.

Otherwise:

Non-secure non-invasive debug.

NSNID	Meaning
0b00	Non-secure state is not implemented.
0b10	Implemented and disabled. <code>ExternalNoninvasiveDebugEnabled()</code> == FALSE.
0b11	Implemented and enabled. <code>ExternalNoninvasiveDebugEnabled()</code> == TRUE.

All other values are reserved.

NSID, bits [1:0]

Non-secure invasive debug.

NSID	Meaning
0b00	Non-secure state is not implemented.
0b10	Implemented and disabled. <code>ExternalInvasiveDebugEnabled()</code> == FALSE.
0b11	Implemented and enabled. <code>ExternalInvasiveDebugEnabled()</code> == TRUE.

All other values are reserved.

Accessing DBGAUTHSTATUS_EL1

DBGAUTHSTATUS_EL1 can be accessed through the external debug interface:

Component	Offset	Instance
Debug	0xFB8	DBGAUTHSTATUS_EL1

Accessible as follows:

- When FEAT_DoPD is implemented and !IsCorePowered(), accesses to this register return an ERROR.
- Otherwise, accesses to this register are RO.

E9.2.2 DBGBCR<n>_EL1, Debug Breakpoint Control Registers, n = 0 - 63

The DBGBCR<n>_EL1 characteristics are:

Purpose

Holds control information for a breakpoint. Forms breakpoint n together with value register DBGBVR<n>_EL1.

Configuration

DBGBCR<n>_EL1 is in the Core power domain

If breakpoint n is not implemented, then accesses to this register are:

- RES0 when IsCorePowered() && !DoubleLockStatus() && !OSLockStatus() && AllowExternalDebugAccess().
- A CONSTRAINED UNPREDICTABLE choice of RES0 or ERROR otherwise.

External register DBGBCR<n>_EL1 bits [31:0] are architecturally mapped to AArch64 System register DBGBCR<n>_EL1[31:0].

Attributes

DBGBCR<n>_EL1 is a 64-bit register.

Field descriptions

When the E field is zero, all the other fields in the register are ignored.

Bits [63:24]

Reserved, RES0.

BT, bits [23:20]

Breakpoint Type.

Specifies breakpoint type.

BT	Meaning	Applies when
0b0000	Unlinked instruction address match. DBGBVR<n>_EL1 is the address of an instruction.	
0b0001	Linked instruction address match. As 0b0000, but linked to a breakpoint that has linking enabled.	
0b0010	Unlinked Context ID match. DBGBVR<n>_EL1.ContextID is compared against CONTEXTIDR.	breakpoint n is context-aware
0b0011	As 0b0010, with linking enabled.	breakpoint n is context-aware

BT	Meaning	Applies when
0b0110	Unlinked CONTEXTIDR_EL1 match. DBGBVR<n>_EL1 .ContextID is a Context ID compared against CONTEXTIDR_EL1 .	FEAT_Debugv8p1 is implemented and breakpoint n is context-aware
0b0111	As 0b0110, with linking enabled.	FEAT_Debugv8p1 is implemented and breakpoint n is context-aware
0b1000	Unlinked VMID match. DBGBVR<n>_EL1 .VMID is a VMID compared against VSCTLR_EL2 .VMID.	breakpoint n is context-aware
0b1001	As 0b1000, with linking enabled.	breakpoint n is context-aware
0b1010	Unlinked VMID and Context ID match. DBGBVR<n>_EL1 .ContextID is a Context ID compared against CONTEXTIDR_EL1 , and DBGBVR<n>_EL1 .VMID is a VMID compared against VSCTLR_EL2 .VMID.	breakpoint n is context-aware
0b1011	As 0b1010, with linking enabled.	breakpoint n is context-aware
0b1100	Unlinked CONTEXTIDR_EL2 match. DBGBVR<n>_EL1 .ContextID2 is a Context ID compared against CONTEXTIDR_EL2 .	FEAT_Debugv8p1 is implemented and breakpoint n is context-aware
0b1101	As 0b1100, with linking enabled.	FEAT_Debugv8p1 is implemented and breakpoint n is context-aware
0b1110	Unlinked Full Context ID match. DBGBVR<n>_EL1 .ContextID is compared against CONTEXTIDR_EL1 , and DBGBVR<n>_EL1 .ContextID2 is compared against CONTEXTIDR_EL2 .	FEAT_Debugv8p1 is implemented and breakpoint n is context-aware
0b1111	As 0b1110, with linking enabled.	FEAT_Debugv8p1 is implemented and breakpoint n is context-aware

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

LBN, bits [19:16]

Linked Breakpoint Number.

For Linked address matching breakpoints, specifies the index of the breakpoint linked to.

For all other breakpoint types, this field is ignored and reads of the register return an UNKNOWN value.

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

SSC, bits [15:14]

Security state control. Determines the Security states under which a Breakpoint debug event for breakpoint n is generated. This field must be interpreted along with the HMC and PMC fields, and there are constraints on the permitted values of the {HMC, SSC, PMC} fields. For more information, including the effect of programming the fields to a reserved set of values, see '[Reserved DBGBCR<n>_EL1.{SSC, HMC, PMC} values](#)'.

For more information on the operation of the SSC, HMC, and PMC fields, see '[Execution conditions for which a breakpoint generates Breakpoint exceptions](#)'.

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

HMC, bit [13]

Higher mode control. Determines the debug perspective for deciding when a Breakpoint debug event for breakpoint *n* is generated. This field must be interpreted along with the SSC and PMC fields, and there are constraints on the permitted values of the {HMC, SSC, PMC} fields. For more information see [DBGBCR<n>_EL1](#).SSC description.

For more information on the operation of the SSC, HMC, and PMC fields, see ‘[Execution conditions for which a breakpoint generates Breakpoint exceptions](#)’.

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

Bits [12:9]

Reserved, RES0.

Bits [8:5]

Reserved, RES1.

Bits [4:3]

Reserved, RES0.

PMC, bits [2:1]

Privilege mode control. Determines the Exception level or levels at which a Breakpoint debug event for breakpoint *n* is generated. This field must be interpreted along with the SSC and HMC fields, and there are constraints on the permitted values of the {HMC, SSC, PMC} fields. For more information see the [DBGBCR<n>_EL1](#).SSC description.

For more information on the operation of the SSC, HMC, and PMC fields, see ‘[Execution conditions for which a breakpoint generates Breakpoint exceptions](#)’.

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

E, bit [0]

Enable breakpoint *n*.

E	Meaning
0b0	Breakpoint <i>n</i> disabled.
0b1	Breakpoint <i>n</i> enabled.

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

Accessing DBGBCR<n>_EL1

This register is 32-bits wide and offset $0 \times 40C + (16 * n)$ is reserved.

DBGBCR<n>_EL1 can be accessed through the external debug interface:

Component	Offset	Instance
Debug	$0x408 + (16 * n)$	DBGBCR<n>_EL1

Accessible as follows:

- When DoubleLockStatus(), or !IsCorePowered(), or OSLockStatus(), or !AllowExternalDebugAccess(addrdesc), accesses to this register return an ERROR.
- When SoftwareLockStatus(addrdesc), accesses to this register are RO.
- Otherwise, accesses to this register are RW.

E9.2.3 DBGBVR<n>_EL1, Debug Breakpoint Value Registers, n = 0 - 63

The DBGBVR<n>_EL1 characteristics are:

Purpose

Holds a virtual address, or a VMID and/or a context ID, for use in breakpoint matching. Forms breakpoint n together with control register [DBGBCR<n>_EL1](#).

Configuration

DBGBVR<n>_EL1 is in the Core power domain

How this register is interpreted depends on the value of [DBGBCR<n>_EL1.BT](#).

- When [DBGBCR<n>_EL1.BT](#) is 0b0x0x, this register holds a virtual address.
- When [DBGBCR<n>_EL1.BT](#) is 0b001x, 0b011x, or 0b110x, this register holds a Context ID.
- When [DBGBCR<n>_EL1.BT](#) is 0b100x, this register holds a VMID.
- When [DBGBCR<n>_EL1.BT](#) is 0b101x, this register holds a VMID and a Context ID.
- When [DBGBCR<n>_EL1.BT](#) is 0b111x, this register holds two Context ID values.

For other values of [DBGBCR<n>_EL1.BT](#), this register is RES0.

If breakpoint n is not implemented, then accesses to this register are:

- RES0 when `IsCorePowered() && !DoubleLockStatus() && !OSLockStatus() && AllowExternalDebugAccess()`.
- A CONSTRAINED UNPREDICTABLE choice of RES0 or ERROR otherwise.

External register DBGBVR<n>_EL1 bits [63:0] are architecturally mapped to AArch64 System register [DBGBVR<n>_EL1](#)[63:0].

Attributes

DBGBVR<n>_EL1 is a 64-bit register.

Field descriptions

When [DBGBCR<n>_EL1.BT](#) IN {'0x0x'}:

RESS[14:8], bits [63:57]

Reserved, Sign extended. Software must treat this field as RES0 if the most significant bit of VA is 0 or RES0, and as RES1 if the most significant bit of VA is 1.

Hardware always ignores the value of these bits and it is IMPLEMENTATION DEFINED whether:

- The bits are hardwired to a copy of the most significant bit of VA, meaning writes to these bits are ignored, and reads to the bits always return the hardwired value.
- The value in those bits can be written, and reads will return the last value written. The value held in those bits is ignored by hardware.

RESS[7:4], bits [56:53]

Extension to RESS[14:8]. For more information, see RESS[14:8].

Bits [52:49]

When FEAT_LVA is implemented:

VA[52:49], bits [52:49]

Extension to VA[48:2]. For more information, see VA[48:2].

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

RESS[3:0], bits [52:49]

Extension to RESS[14:8]. For more information, see RESS[14:8].

VA[48:2], bits [48:2]

If the address is being matched in an AArch64 stage 1 translation regime:

- This field contains bits[48:2] of the address for comparison.
- When [FEAT_LVA](#) is implemented, VA[52:49] forms the upper part of the address value. If FEAT_LVA is not implemented, bits [52:49] are part of the RESS field.

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

Bits [1:0]

Reserved, RES0.

When DBGBCR<n>_EL1.BT IN {'001x'}:

Bits [63:32]

Reserved, RES0.

ContextID, bits [31:0]

Context ID value for comparison.

The value is compared against the following:

- [CONTEXTIDR_EL1](#) when the PE is executing at AArch64.

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

When DBGBCR<n>_EL1.BT IN {'011x'} and FEAT_Debugv8p1 is implemented:

Bits [63:32]

Reserved, RES0.

ContextID, bits [31:0]

Context ID value for comparison against [CONTEXTIDR_EL1](#).

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

When `DBGBCR<n>_EL1.BT IN {'100x'}`:

Bits [63:48]

Reserved, RES0.

VMID[15:8], bits [47:40]

When `FEAT_VMID16` is implemented and `VTCR_EL2.VS == '1'`:

Extension to VMID[7:0]. For more information, see `DBGBVR<n>_EL1.VMID[7:0]`.

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

VMID[7:0], bits [39:32]

VMID value for comparison.

The VMID is 8 bits when any of the following are true:

- `VTCR_EL2.VS` is 0.
- `FEAT_VMID16` is not implemented.

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

Bits [31:0]

Reserved, RES0.

When **DBGBCR<n>_EL1.BT** IN {'101x'}:

Bits [63:48]

Reserved, RES0.

VMID[15:8], bits [47:40]

When **FEAT_VMID16** is implemented and **VTCR_EL2.VS == '1'**:

Extension to VMID[7:0]. For more information, see **DBGBVR<n>_EL1.VMID[7:0]**.

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

VMID[7:0], bits [39:32]

VMID value for comparison.

The VMID is 8 bits when any of the following are true:

- VTCR_EL2.VS** is 0.
- FEAT_VMID16** is not implemented.

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

ContextID, bits [31:0]

Context ID value for comparison against **CONTEXTIDR_EL1**.

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

When **DBGBCR<n>_EL1.BT** IN {'110x'} and **FEAT_Debug8p1** is implemented:

ContextID2, bits [63:32]

Context ID value for comparison against **CONTEXTIDR_EL2**.

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

Bits [31:0]

Reserved, RES0.

When DBGBCR<n>_EL1.BT IN {'111x'} and FEAT_Debugv8p1 is implemented:

ContextID2, bits [63:32]

Context ID value for comparison against [CONTEXTIDR_EL2](#).

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

ContextID, bits [31:0]

Context ID value for comparison against [CONTEXTIDR_EL1](#).

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

Accessing DBGBVR<n>_EL1

DBGBVR<n>_EL1 can be accessed through the external debug interface:

Component	Offset	Instance	Range
Debug	$0 \times 400 + (16 * n)$	DBGBVR<n>_EL1	63:0

Accessible as follows:

- When DoubleLockStatus(), or !IsCorePowered(), or OSLockStatus(), or !AllowExternalDebugAccess(addrdesc), accesses to this register return an ERROR.
- When SoftwareLockStatus(addrdesc), accesses to this register are RO.
- Otherwise, accesses to this register are RW.

E9.2.4 DBGCLAIMCLR_EL1, Debug CLAIM Tag Clear Register

The DBGCLAIMCLR_EL1 characteristics are:

Purpose

Used by software to read the values of the CLAIM tag bits, and to clear CLAIM tag bits to 0.
The architecture does not define any functionality for the CLAIM tag bits.

Note
CLAIM tags are typically used for communication between the debugger and target software.

Used in conjunction with the DBGCLAIMSET_EL1 register.

Configuration

DBGCLAIMCLR_EL1 is in the Core power domain
An implementation must include eight CLAIM tag bits.
External register DBGCLAIMCLR_EL1 bits [31:0] are architecturally mapped to AArch64 System register DBGCLAIMCLR_EL1[31:0].
External register DBGCLAIMCLR_EL1 bits [31:0] are architecturally mapped to AArch64 System register DBGCLAIMSET_EL1[31:0].
External register DBGCLAIMCLR_EL1 bits [31:0] are architecturally mapped to External register DBGCLAIMSET_EL1[31:0].

Attributes

DBGCLAIMCLR_EL1 is a 32-bit register.

Field descriptions

Bits [31:8]

Reserved, RAZ/WI.

CLAIM<m>, bits [m], for m = 7 to 0

Claim Tag Clear. Indicates the current status of Claim Tag bit <m>, and is used to clear Claim Tag bit <m> to 0.

CLAIM<m>	Meaning
0b0	On a read: Claim Tag bit <m> is not set. On a write: Ignored.

CLAIM<m>	Meaning
0b1	On a read: Claim Tag bit <m> is set. On a write: Clear Claim tag bit <m> to 0.

The reset behavior of this field is:

- On a Cold reset, this field resets to '0'.

Access to this field is W1C.

Accessing DBGCLAIMCLR_EL1

DBGCLAIMCLR_EL1 can be accessed through the external debug interface:

Component	Offset	Instance
Debug	0xFA4	DBGCLAIMCLR_EL1

Accessible as follows:

- When DoubleLockStatus(), or !IsCorePowered(), or OSLockStatus(), accesses to this register return an ERROR.
- When SoftwareLockStatus(addrdesc), accesses to this register are RO.
- Otherwise, accesses to this register are RW.

E9.2.5 **DBGCLAIMSET_EL1, Debug CLAIM Tag Set Register**

The DBGCLAIMSET_EL1 characteristics are:

Purpose

Used by software to set the CLAIM tag bits to 1.
The architecture does not define any functionality for the CLAIM tag bits.

———— **Note** —————
CLAIM tags are typically used for communication between the debugger and target software.

Used in conjunction with the [DBGCLAIMCLR_EL1](#) register.

Configuration

DBGCLAIMSET_EL1 is in the Core power domain
An implementation must include eight CLAIM tag bits.
External register DBGCLAIMSET_EL1 bits [31:0] are architecturally mapped to AArch64 System register [DBGCLAIMSET_EL1](#)[31:0].
External register DBGCLAIMSET_EL1 bits [31:0] are architecturally mapped to AArch64 System register [DBGCLAIMCLR_EL1](#)[31:0].
External register DBGCLAIMSET_EL1 bits [31:0] are architecturally mapped to External register [DBGCLAIMCLR_EL1](#)[31:0].

Attributes

DBGCLAIMSET_EL1 is a 32-bit register.

Field descriptions

Bits [31:8]

Reserved, RAZ/WI.

CLAIM<m>, bits [m], for m = 7 to 0

Claim Tag Set. Used to set Claim Tag bit <m> to 1.

CLAIM<m>	Meaning
0b0	On a write: Ignored.
0b1	On a write: Set Claim Tag bit <m> to 1.

Access to this field is RAO/WIS.

Accessing DBGCLAIMSET_EL1

DBGCLAIMSET_EL1 can be accessed through the external debug interface:

Component	Offset	Instance
Debug	0xFA0	DBGCLAIMSET_EL1

Accessible as follows:

- When DoubleLockStatus(), or !IsCorePowered(), or OSLockStatus(), accesses to this register return an ERROR.
- When SoftwareLockStatus(addrdesc), accesses to this register are RO.
- Otherwise, accesses to this register are RW.

E9.2.6 DBGDTRRX_EL0, Debug Data Transfer Register, Receive

The DBGDTRRX_EL0 characteristics are:

Purpose

Transfers data from an external debugger to the PE. For example, it is used by a debugger transferring commands and data to a debug target. See [DBGDTR_EL0](#) for additional architectural mappings. It is a component of the Debug Communications Channel.

Configuration

DBGDTRRX_EL0 is in the Core power domain

External register DBGDTRRX_EL0 bits [31:0] are architecturally mapped to AArch64 System register [DBGDTRRX_EL0](#)[31:0].

Attributes

DBGDTRRX_EL0 is a 32-bit register.

Field descriptions

DTRRX, bits [31:0]

Update DTRRX.

Writes to this register:

- If RXfull is 0, update the value in DTRRX and set RXfull to 1.
- If RXfull is 1, the written value is ignored and RXO is set to 1.

Reads of this register return the last value written to DTRRX and do not change RXfull.

For the full behavior of the Debug Communications Channel, see ‘[The Debug Communication Channel and Instruction Transfer Register](#)’.

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

Accessing DBGDTRRX_EL0

If [EDSCR.ITE](#) == 0 when the PE exits Debug state on receiving a Restart request trigger event, the behavior of any operation issued by a DTR access in Memory access mode that has not completed execution is CONSTRAINED UNPREDICTABLE, and must do one of the following:

- It must complete execution in Debug state before the PE executes the restart sequence.
- It must complete execution in Non-debug state before the PE executes the restart sequence.
- It must be abandoned. This means that the instruction does not execute. Any registers or memory accessed by the instruction are left in an UNKNOWN state.

DBGDTRRX_EL0 can be accessed through the external debug interface:

Component	Offset	Instance
Debug	0x080	DBGDTRRX_EL0

Accessible as follows:

- When DoubleLockStatus(), or !IsCorePowered(), or OSLockStatus(), accesses to this register return an ERROR.
- When SoftwareLockStatus(addrdesc), accesses to this register are RO.
- Otherwise, accesses to this register are RW.

E9.2.7 DBGDTRTX_EL0, Debug Data Transfer Register, Transmit

The DBGDTRTX_EL0 characteristics are:

Purpose

Transfers data from the PE to an external debugger. For example, it is used by a debug target to transfer data to the debugger. See [DBGDTR_EL0](#) for additional architectural mappings. It is a component of the Debug Communication Channel.

Configuration

DBGDTRTX_EL0 is in the Core power domain

External register DBGDTRTX_EL0 bits [31:0] are architecturally mapped to AArch64 System register [DBGDTRTX_EL0](#)[31:0].

Attributes

DBGDTRTX_EL0 is a 32-bit register.

Field descriptions

DTRTX, bits [31:0]

Return DTRTX.

Reads of this register:

- If TXfull is 1, return the value in DTRTX and clear TXfull to 0.
- If TXfull is 0, return an UNKNOWN value and set TXU to 1.

Writes of this register update the value in DTRTX and do not change TXfull.

For the full behavior of the Debug Communications Channel, see ‘[The Debug Communication Channel and Instruction Transfer Register](#)’.

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

Accessing DBGDTRTX_EL0

If [EDSCR.ITE](#) == 0 when the PE exits Debug state on receiving a Restart request trigger event, the behavior of any operation issued by a DTR access in Memory access mode that has not completed execution is CONSTRAINED UNPREDICTABLE, and must do one of the following:

- It must complete execution in Debug state before the PE executes the restart sequence.
- It must complete execution in Non-debug state before the PE executes the restart sequence.
- It must be abandoned. This means that the instruction does not execute. Any registers or memory accessed by the instruction are left in an UNKNOWN state.

DBGDTRTX_EL0 can be accessed through the external debug interface:

Component	Offset	Instance
Debug	0x08C	DBGDTRTX_EL0

Accessible as follows:

- When DoubleLockStatus(), or !IsCorePowered(), or OSLockStatus(), accesses to this register return an ERROR.
- When SoftwareLockStatus(addrdesc), accesses to this register are RO.
- Otherwise, accesses to this register are RW.

E9.2.8 DBGWCR<n>_EL1, Debug Watchpoint Control Registers, n = 0 - 63

The DBGWCR<n>_EL1 characteristics are:

Purpose

Holds control information for a watchpoint. Forms watchpoint n together with value register DBGWVR<n>_EL1.

Configuration

DBGWCR<n>_EL1 is in the Core power domain

If watchpoint n is not implemented, then accesses to this register are:

- When IsCorePowered() && !DoubleLockStatus() && !OSLockStatus() && AllowExternalDebugAccess(), RES0.
- Otherwise, a CONSTRAINED UNPREDICTABLE choice of RES0 or ERROR.

External register DBGWCR<n>_EL1 bits [31:0] are architecturally mapped to AArch64 System register DBGWCR<n>_EL1[31:0].

Attributes

DBGWCR<n>_EL1 is a 64-bit register.

Field descriptions

Bits [63:29]

Reserved, RES0.

MASK, bits [28:24]

Address Mask. Only address ranges up to 2GB can be watched using a single mask.

MASK	Meaning
0b00000	No mask.
0b00011..0b11111	Number of address bits masked.

All other values are reserved.

Indicates the number of masked address bits, from 0b00011 masking 3 address bits (0x00000007 mask for address) to 0b11111 masking 31 address bits (0x7FFFFFFF mask for address).

If programmed with a reserved value, the watchpoint behaves as if one of the following:

- DBGWCR<n>_EL1.MASK has been programmed with a defined value, which might be 0b00000 (no mask), other than for a direct read of DBGWCR<n>_EL1.
- The watchpoint is disabled.

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

Bits [23:21]

Reserved, RES0.

WT, bit [20]

Watchpoint type. Possible values are:

WT	Meaning
0b0	Unlinked data address match.
0b1	Linked data address match.

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

LBN, bits [19:16]

Linked Breakpoint Number.

For Linked data address watchpoints, specifies the index of the breakpoint linked to.

For all other watchpoint types, this field is ignored and reads of the register return an UNKNOWN value.

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

SSC, bits [15:14]

Security state control. Determines the Security states under which a Watchpoint debug event for watchpoint n is generated. This field must be interpreted along with the HMC and PAC fields.

For more information on the operation of the SSC, HMC, and PAC fields, see [‘Execution conditions for which a watchpoint generates Watchpoint exceptions’](#).

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

HMC, bit [13]

Higher mode control. Determines the debug perspective for deciding when a Watchpoint debug event for watchpoint n is generated. This field must be interpreted along with the SSC and PAC fields.

For more information on the operation of the SSC, HMC, and PAC fields, see [‘Execution conditions for which a watchpoint generates Watchpoint exceptions’](#).

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

BAS, bits [12:5]

Byte address select. Each bit of this field selects whether a byte from within the word or doubleword addressed by [DBGWVR<n>_EL1](#) is being watched.

BAS	Description
xxxxxxx1	Match byte at DBGWVR<n>_EL1
xxxxxx1x	Match byte at DBGWVR<n>_EL1 + 1
xxxxx1xx	Match byte at DBGWVR<n>_EL1 + 2
xxxx1xxx	Match byte at DBGWVR<n>_EL1 + 3

In cases where [DBGWVR<n>_EL1](#) addresses a doubleword:

BAS	Description, if DBGWVR<n>_EL1[2] == 0
xxx1xxxx	Match byte at DBGWVR<n>_EL1 + 4
xx1xxxxx	Match byte at DBGWVR<n>_EL1 + 5
x1xxxxxx	Match byte at DBGWVR<n>_EL1 + 6
1xxxxxxx	Match byte at DBGWVR<n>_EL1 + 7

If [DBGWVR<n>_EL1\[2\] == 1](#), only BAS[3:0] is used. Arm deprecates setting [DBGWVR<n>_EL1\[2\] == 1](#).

The valid values for BAS are nonzero binary number all of whose set bits are contiguous. All other values are reserved and must not be used by software. See ‘Reserved DBGWCR<n>.BAS values’.

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

LSC, bits [4:3]

Load/store control. This field enables watchpoint matching on the type of access being made. Possible values of this field are:

LSC	Meaning
0b01	Match instructions that load from a watchpointed address.
0b10	Match instructions that store to a watchpointed address.
0b11	Match instructions that load from or store to a watchpointed address.

All other values are reserved, but must behave as if the watchpoint is disabled. Software must not rely on this property as the behavior of reserved values might change in a future revision of the architecture.

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

PAC, bits [2:1]

Privilege of access control. Determines the Exception level or levels at which a Watchpoint debug event for watchpoint n is generated. This field must be interpreted along with the SSC and HMC fields.

For more information on the operation of the SSC, HMC, and PAC fields, see ‘[Execution conditions for which a watchpoint generates Watchpoint exceptions](#)’.

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

E, bit [0]

Enable watchpoint n.

E	Meaning
0b0	Watchpoint n disabled.
0b1	Watchpoint n enabled.

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

Accessing DBGWCR<n>_EL1

This register is 32-bits wide and offset $0 \times 80C + (16 * n)$ is reserved.

DBGWCR<n>_EL1 can be accessed through the external debug interface:

Component	Offset	Instance
Debug	$0 \times 808 + (16 * n)$	DBGWCR<n>_EL1

Accessible as follows:

- When DoubleLockStatus(), or !IsCorePowered(), or OSLockStatus(), or !AllowExternalDebugAccess(addrdesc), accesses to this register return an ERROR.
- When SoftwareLockStatus(addrdesc), accesses to this register are RO.
- Otherwise, accesses to this register are RW.

E9.2.9 DBGWVR<n>_EL1, Debug Watchpoint Value Registers, n = 0 - 63

The DBGWVR<n>_EL1 characteristics are:

Purpose

Holds a data address value for use in watchpoint matching. Forms watchpoint n together with control register [DBGWCR<n>_EL1](#).

Configuration

DBGWVR<n>_EL1 is in the Core power domain

If watchpoint n is not implemented, then accesses to this register are:

- When `IsCorePowered() && !DoubleLockStatus() && !OSLockStatus() && AllowExternalDebugAccess(), RES0`.
- Otherwise, a CONSTRAINED UNPREDICTABLE choice of RES0 or ERROR.

External register DBGWVR<n>_EL1 bits [63:0] are architecturally mapped to AArch64 System register [DBGWVR<n>_EL1](#)[63:0].

Attributes

DBGWVR<n>_EL1 is a 64-bit register.

Field descriptions

63				57		56		53		52		49		48		32																		
RESS[14:8]								RESS[7:4]				VA[52:49]				VA[48:2]																		
31																															2		1	0
VA[48:2]																												RES0						

RESS[14:8], bits [63:57]

Reserved, Sign extended. Hardware and software must treat this field as RES0 if the most significant bit of VA is 0 or RES1 if the most significant bit of VA is 1.

Hardware always ignores the value of these bits and it is IMPLEMENTATION DEFINED whether:

- The bits are hardwired to a copy of the most significant bit of VA, meaning writes to these bits are ignored, and reads to the bits always return the hardwired value.
- The value in those bits can be written, and reads will return the last value written. The value held in those bits is ignored by hardware.

RESS[7:4], bits [56:53]

Extension to RESS[14:8]. For more information, see RESS[14:8].

Bits [52:49]

When FEAT_LVA is implemented:

VA[52:49], bits [52:49]

Extension to VA[48:2]. For more information, see VA[48:2].

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

RESS[3:0], bits [52:49]

Extension to RESS[14:8]. For more information, see RESS[14:8].

VA[48:2], bits [48:2]

Bits[48:2] of the address value for comparison.

When [FEAT_LVA](#) is implemented, VA[52:49] forms the upper part of the address value. If FEAT_LVA is not implemented, bits [52:49] are part of the RESS field.

Arm deprecates setting [DBGWVR<n>_EL1](#)[2] == 1.

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

Bits [1:0]

Reserved, RES0.

Accessing DBGWVR<n>_EL1

DBGWVR<n>_EL1 can be accessed through the external debug interface:

Component	Offset	Instance	Range
Debug	$0 \times 800 + (16 * n)$	DBGWVR<n>_EL1	63:0

Accessible as follows:

- When DoubleLockStatus(), or !IsCorePowered(), or OSLockStatus(), or !AllowExternalDebugAccess(addrdesc), accesses to this register return an ERROR.
- When SoftwareLockStatus(addrdesc), accesses to this register are RO.
- Otherwise, accesses to this register are RW.

E9.2.10 EDAA32PFR, External Debug Auxiliary Processor Feature Register

The EDAA32PFR characteristics are:

Purpose

Provides information about implemented PE features.

Note
The register mnemonic, EDAA32PFR, is derived from previous definitions of this register that defined this register only when AArch64 was not supported.

For general information about the interpretation of the ID registers, see [‘Principles of the ID scheme for fields in ID registers’](#).

Configuration

There are no configuration notes.

Attributes

EDAA32PFR is a 64-bit register.

Field descriptions

Bits [63:20]

Reserved, RES0.

MSA_frac, bits [19:16]

When EDAA32PFR.PMSA == '0000' and EDAA32PFR.VMSA == '1111':

Memory System Architecture fractional field. This holds the information on additional Memory System Architectures supported.

The value of this field is an IMPLEMENTATION DEFINED choice of:

MSA_frac	Meaning
0b0001	PMSAv8-64 supported in all translation regimes. VMSAv8-64 not supported.
0b0010	PMSAv8-64 supported in all translation regimes. In addition to PMSAv8-64, stage 1 EL1&0 translation regime also supports VMSAv8-64.

All other values are reserved.

In Armv8-R AArch64, the only permitted values are 0b0001 and 0b0010.

Access to this field is RO.

Otherwise:

Reserved, RES0.

EL3, bits [15:12]

When EDPFR.EL3 == '0000':

AArch32 EL3 Exception level handling.

The value of this field is an IMPLEMENTATION DEFINED choice of:

EL3	Meaning
0b0000	EL3 is not implemented or can be executed in AArch64 state.
0b0001	EL3 can be executed in AArch32 state only.

All other values are reserved.

In an Armv8-R AArch64 implementation this field returns the value of 0b0000.

Access to this field is RO.

Otherwise:

Reserved, RAZ.

EL2, bits [11:8]

When EDPFR.EL2 == '0000':

AArch32 EL2 Exception level handling.

The value of this field is an IMPLEMENTATION DEFINED choice of:

EL2	Meaning
0b0000	EL2 is not implemented or can be executed in AArch64 state.
0b0001	EL2 can be executed in AArch32 state only.

All other values are reserved.

In an Armv8-R AArch64 implementation this field returns the value of 0b0000.

Access to this field is RO.

Otherwise:

Reserved, RAZ.

PMSA, bits [7:4]

Indicates support for a 32-bit PMSA.

The value of this field is an IMPLEMENTATION DEFINED choice of:

PMSA	Meaning
0b0000	PMSA-32 not supported.
0b0100	PMSAv8-32 supported.

Access to this field is RO.

VMSA, bits [3:0]

When EDAA32PFR.PMSA != '0000':

Indicates support for a VMSA in addition to a 32-bit PMSA.

VMSA	Meaning
0b0000	VMSA not supported.

All other values are reserved.

Access to this field is RO.

When EDAA32PFR.PMSA == '0000':

The value of this field is an IMPLEMENTATION DEFINED choice of:

VMSA	Meaning
0b0000	VMSAv8-64 supported. PMSAv8-64 not supported.
0b1111	Memory system architecture described by EDAA32PFR.MSA_frac.

All other values are reserved.

In Armv8-R AArch64, the only permitted value is 0b1111.

Access to this field is RO.

Otherwise:

Reserved, RAZ.

Accessing EDAA32PFR

EDAA32PFR can be accessed through the external debug interface:

Component	Offset	Instance
Debug	0xD60	EDAA32PFR

Accessible as follows:

- When IsCorePowered() and !DoubleLockStatus(), accesses to this register are RO.
- When FEAT_DoPD is implemented and !IsCorePowered(), accesses to this register return an ERROR.
- Otherwise, accesses to this register are IMPLEMENTATION DEFINED.

E9.2.11 EDACR, External Debug Auxiliary Control Register

The EDACR characteristics are:

Purpose

Allows implementations to support IMPLEMENTATION DEFINED controls.

Configuration

When FEAT_DoPD is implemented, EDACR is in the Core power domain. Otherwise, it is IMPLEMENTATION DEFINED whether EDACR is implemented in the Core power domain or in the Debug power domain

If this register is implemented, EDDEVID.AuxRegs == 0b0001.

If FEAT_DoPD is implemented, any mechanism to preserve control bits in EDACR over power down is optional and IMPLEMENTATION DEFINED.

If FEAT_DoPD is not implemented and EDACR contains any control bits that must be preserved over power down, then these bits must be accessible by the external debug interface when the OS Lock is locked, OSLSR_EL1.OSLK == 1, and when the Core is powered off.

Changing this register from its reset value causes IMPLEMENTATION DEFINED behavior, including possible deviation from the architecturally-defined behavior.

Implementation of this register is OPTIONAL.

Attributes

EDACR is a 32-bit register.

Field descriptions

IMPLEMENTATION DEFINED, bits [31:0]

IMPLEMENTATION DEFINED.

The following resets apply:

- If the register is implemented in the Core power domain:
 - On a Cold reset, this field resets to an architecturally UNKNOWN value.
 - On an External debug reset, the value of this field is unchanged.
 - On a Warm reset, the value of this field is unchanged.
- If the register is implemented in the External debug power domain:
 - On a Cold reset, the value of this field is unchanged.
 - On an External debug reset, this field resets to an architecturally UNKNOWN value.
 - On a Warm reset, the value of this field is unchanged.

Accessing EDACR

EDACR can be accessed through the external debug interface:

Component	Offset	Instance
Debug	0x094	EDACR

Accessible as follows:

- When DoubleLockStatus(), or !IsCorePowered(), or OSLockStatus(), accesses to this register are IMPLEMENTATION DEFINED.
- When SoftwareLockStatus(addrdesc), accesses to this register are RO.
- Otherwise, accesses to this register are RW.

E9.2.12 EDCIDR0, External Debug Component Identification Register 0

The EDCIDR0 characteristics are:

Purpose

Provides information to identify an external debug component.
For more information, see ‘About the Component Identification scheme’.

Configuration

When FEAT_DoPD is implemented, EDCIDR0 is in the Core power domain. Otherwise, EDCIDR0 is in the Debug power domain

Attributes

EDCIDR0 is a 32-bit register.

Field descriptions

Bits [31:8]

Reserved, RES0.

PRMBL_0, bits [7:0]

When FEAT_ED_PIDR is implemented:

Preamble.
Reads as 0x0D
Access to this field is RO.

Otherwise:

Reserved, RAZ.

Accessing EDCIDR0

EDCIDR0 can be accessed through the external debug interface:

Component	Offset	Instance
Debug	0xFF0	EDCIDR0

Accessible as follows:

- When FEAT_DoPD is implemented and !IsCorePowered(), accesses to this register return an ERROR.
- Otherwise, accesses to this register are RO.

E9.2.13 EDCIDR1, External Debug Component Identification Register 1

The EDCIDR1 characteristics are:

Purpose

Provides information to identify an external debug component.
For more information, see ‘About the Component Identification scheme’.

Configuration

When FEAT_DoPD is implemented, EDCIDR1 is in the Core power domain. Otherwise, EDCIDR1 is in the Debug power domain

Attributes

EDCIDR1 is a 32-bit register.

Field descriptions

Bits [31:8]

Reserved, RES0.

CLASS, bits [7:4]

When FEAT_ED_PIDR is implemented:

Component class.

CLASS	Meaning
0b1001	CoreSight component.

Other values are defined by the CoreSight Architecture.

This field reads as 0x9.

Access to this field is RO.

Otherwise:

Reserved, RAZ.

PRMBL_1, bits [3:0]

When FEAT_ED_PIDR is implemented:

Preamble.

Reads as 0b0000

Access to this field is RO.

Otherwise:

Reserved, RAZ.

Accessing EDCIDR1

EDCIDR1 can be accessed through the external debug interface:

Component	Offset	Instance
Debug	0xFF4	EDCIDR1

Accessible as follows:

- When FEAT_DoPD is implemented and !IsCorePowered(), accesses to this register return an ERROR.
- Otherwise, accesses to this register are RO.

E9.2.14 EDCIDR2, External Debug Component Identification Register 2

The EDCIDR2 characteristics are:

Purpose

Provides information to identify an external debug component.
For more information, see ‘About the Component Identification scheme’.

Configuration

When FEAT_DoPD is implemented, EDCIDR2 is in the Core power domain. Otherwise, EDCIDR2 is in the Debug power domain

Attributes

EDCIDR2 is a 32-bit register.

Field descriptions

Bits [31:8]

Reserved, RES0.

PRMBL_2, bits [7:0]

When FEAT_ED_PIDR is implemented:

Preamble.
Reads as 0x05
Access to this field is RO.

Otherwise:

Reserved, RAZ.

Accessing EDCIDR2

EDCIDR2 can be accessed through the external debug interface:

Component	Offset	Instance
Debug	0xFF8	EDCIDR2

Accessible as follows:

- When FEAT_DoPD is implemented and !IsCorePowered(), accesses to this register return an ERROR.
- Otherwise, accesses to this register are RO.

E9.2.15 EDCIDR3, External Debug Component Identification Register 3

The EDCIDR3 characteristics are:

Purpose

Provides information to identify an external debug component.
For more information, see ‘About the Component Identification scheme’.

Configuration

When FEAT_DoPD is implemented, EDCIDR3 is in the Core power domain. Otherwise, EDCIDR3 is in the Debug power domain

Attributes

EDCIDR3 is a 32-bit register.

Field descriptions

Bits [31:8]

Reserved, RES0.

PRMBL_3, bits [7:0]

When FEAT_ED_PIDR is implemented:

Preamble.
Reads as 0xB1
Access to this field is RO.

Otherwise:

Reserved, RAZ.

Accessing EDCIDR3

EDCIDR3 can be accessed through the external debug interface:

Component	Offset	Instance
Debug	0xFFC	EDCIDR3

Accessible as follows:

- When FEAT_DoPD is implemented and !IsCorePowered(), accesses to this register return an ERROR.
- Otherwise, accesses to this register are RO.

E9.2.16 EDDEVAFF0, External Debug Device Affinity register 0

The EDDEVAFF0 characteristics are:

Purpose

Copy of the low half of the PE MPIDR_EL1 register that allows a debugger to determine which PE in a multiprocessor system the external debug component relates to.

Configuration

When FEAT_DoPD is implemented, EDDEVAFF0 is in the Core power domain. Otherwise, EDDEVAFF0 is in the Debug power domain

Attributes

EDDEVAFF0 is a 32-bit register.

Field descriptions

Bit [31]

Reserved, RAO/WI.

U, bit [30]

Indicates a Uniprocessor system, as distinct from PE 0 in a multiprocessor system.

The value of this field is an IMPLEMENTATION DEFINED choice of:

U	Meaning
0b0	Processor is part of a multiprocessor system.
0b1	Processor is part of a uniprocessor system.

Access to this field is RO.

Bits [29:25]

Reserved, RES0.

MT, bit [24]

Indicates whether the lowest level of affinity consists of logical PEs that are implemented using an interdependent approach, such as multithreading. See the description of Aff0 for more information about affinity levels.

The value of this field is an IMPLEMENTATION DEFINED choice of:

MT	Meaning
0b0	Performance of PEs with different affinity level 0 values, and the same values for affinity level 1 and higher, is largely independent.
0b1	Performance of PEs with different affinity level 0 values, and the same values for affinity level 1 and higher, is very interdependent.

Note

This field does not indicate that multithreading is implemented and does not indicate that PEs with different affinity level 0 values, and the same values for affinity level 1 and higher are implemented.

Access to this field is RO.

Aff2, bits [23:16]

Affinity level 2. See the description of Aff0 for more information.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

Aff1, bits [15:8]

Affinity level 1. See the description of Aff0 for more information.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

Aff0, bits [7:0]

Affinity level 0. The value of the MPIDR.{Aff2, Aff1, Aff0} or [MPIDR_EL1](#).{Aff3, Aff2, Aff1, Aff0} set of fields of each PE must be unique within the system as a whole.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

Accessing EDDEVAFF0

EDDEVAFF0 can be accessed through the external debug interface:

Component	Offset	Instance
Debug	0xFA8	EDDEVAFF0

Accessible as follows:

- When FEAT_DoPD is implemented and !IsCorePowered(), accesses to this register return an ERROR.
- Otherwise, accesses to this register are RO.

E9.2.17 EDDEVAFF1, External Debug Device Affinity register 1

The EDDEVAFF1 characteristics are:

Purpose

Copy of the high half of the PE MPIDR_EL1 register that allows a debugger to determine which PE in a multiprocessor system the external debug component relates to.

Configuration

When FEAT_DoPD is implemented, EDDEVAFF1 is in the Core power domain. Otherwise, EDDEVAFF1 is in the Debug power domain

Attributes

EDDEVAFF1 is a 32-bit register.

Field descriptions

Bits [31:8]

Reserved, RES0.

Aff3, bits [7:0]

Affinity level 3. See the description of EDDEVAFF0.Aff0 for more information.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

Accessing EDDEVAFF1

EDDEVAFF1 can be accessed through the external debug interface:

Component	Offset	Instance
Debug	0xFAC	EDDEVAFF1

Accessible as follows:

- When FEAT_DoPD is implemented and !IsCorePowered(), accesses to this register return an ERROR.
- Otherwise, accesses to this register are RO.

E9.2.18 EDDEVARCH, External Debug Device Architecture Register

The EDDEVARCH characteristics are:

Purpose

Identifies the programmers' model architecture of the external debug component.

Configuration

When FEAT_DoPD is implemented, EDDEVARCH is in the Core power domain. Otherwise, EDDEVARCH is in the Debug power domain

Attributes

EDDEVARCH is a 32-bit register.

Field descriptions

When FEAT_ED_PIDR is implemented:

ARCHITECT, bits [31:21]

Defines the architect of the component. For External Debug, this is Arm Limited.

Bits [31:28] are the JEP106 continuation code, 0b0100.

Bits [27:21] are the JEP106 identification code, 0b0111011.

Reads as 0b01000111011

Access to this field is RO.

PRESENT, bit [20]

DEVARCH presence. Indicates that the EDDEVARCH register provides architecture information.

Reads as 0b1

Access to this field is RO.

REVISION, bits [19:16]

Defines the architecture revision. For architectures defined by Arm this is the minor revision.

For debug, the revision defined by Armv8 is 0x0.

All other values are reserved.

Reads as 0b0000

Access to this field is RO.

ARCHVER, bits [15:12]

Architecture Version. Defines the architecture version of the component.

The value of this field is an IMPLEMENTATION DEFINED choice of:

EDDEVARCH.ARCHVER and EDDEVARCH.ARCHPART are also defined as a single field, EDDEVARCH.ARCHID, so that EDDEVARCH.ARCHVER is EDDEVARCH.ARCHID[15:12].

[FEAT_Debugv8p1](#) implements the functionality identified by the value 0b0111.

[FEAT_Debugv8p2](#) implements the functionality identified by the value 0b1000.

[FEAT_Debugv8p4](#) implements the functionality identified by the value 0b1001.

From Armv8.1, when [FEAT_Debugv8p1](#) is implemented the value 0b0110 is not permitted.

From Armv8.2, the values 0b0110 and 0b0111 are not permitted.

From Armv8.4, the value 0b1000 is not permitted.

Access to this field is RO.

ARCHPART, bits [11:0]

Architecture Part. Defines the architecture of the component.

ARCHPART	Meaning
0xA05	Armv8-R AArch64 debug architecture.

EDDEVARCH.ARCHVER and EDDEVARCH.ARCHPART are also defined as a single field, EDDEVARCH.ARCHID, so that EDDEVARCH.ARCHPART is EDDEVARCH.ARCHID[11:0].

Armv8-R debug architecture.

Access to this field is RO.

Otherwise:

Bits [31:21]

Reserved, RES0.

PRESENT, bit [20]

DEVARCH presence. Indicates that the EDDEVARCH register does not provide architecture information.

Reads as 0b0

Access to this field is RO.

Bits [19:0]

Reserved, RES0.

Accessing EDDEVARCH

EDDEVARCH can be accessed through the external debug interface:

Component	Offset	Instance
Debug	0xFBC	EDDEVARCH

Accessible as follows:

- When FEAT_DoPD is implemented and !IsCorePowered(), accesses to this register return an ERROR.
- Otherwise, accesses to this register are RO.

E9.2.19 EDDEVID, External Debug Device ID register 0

The EDDEVID characteristics are:

Purpose

Provides extra information for external debuggers about features of the debug implementation.

Configuration

When FEAT_DoPD is implemented, EDDEVID is in the Core power domain. Otherwise, EDDEVID is in the Debug power domain

Attributes

EDDEVID is a 32-bit register.

Field descriptions

31	28	27	24	23	8	7	4	3	0
RES0		AuxRegs		RES0			DebugPower	PCSample	

Bits [31:28]

Reserved, RES0.

AuxRegs, bits [27:24]

Indicates support for Auxiliary registers.

The value of this field is an IMPLEMENTATION DEFINED choice of:

AuxRegs	Meaning
0b0000	None supported.
0b0001	Support for External Debug Auxiliary Control Register, EDACR .

All other values are reserved.

Access to this field is RO.

Bits [23:8]

Reserved, RES0.

DebugPower, bits [7:4]

Indicates support for the [FEAT_DoPD](#) feature.

The value of this field is an IMPLEMENTATION DEFINED choice of:

DebugPower	Meaning
0b0000	FEAT_DoPD not implemented. Registers in the external debug interface register map are implemented in a mix of the Debug and Core power domains.
0b0001	FEAT_DoPD implemented. All registers in the external debug interface register map are implemented in the Core power domain.

FEAT_DoPD implements the functionality added by the value 0b0001.

All other values are reserved.

Access to this field is RO.

PCSample, bits [3:0]

Indicates the level of PC Sample-based Profiling support using external debug registers.

The value of this field is an IMPLEMENTATION DEFINED choice of:

PCSample	Meaning
0b0000	PC Sample-based Profiling Extension is not implemented in the external debug registers space.
0b0010	Only EDPCSR and EDCIDSR are implemented. This option is only permitted if EL3 and EL2 are not implemented.
0b0011	EDPCSR, EDCIDSR, and EDVIDSR are implemented.

All other values are reserved.

When FEAT_PCSRv8p2 is implemented, the only permitted value is 0b0000.

Note

FEAT_PCSRv8p2 implements the PC Sample-based Profiling Extension in the Performance Monitors register space, as indicated by the value of PMDEVID.PCSample.

Access to this field is RO.

Accessing EDDEVID

EDDEVID can be accessed through the external debug interface:

Component	Offset	Instance
Debug	0xFC8	EDDEVID

Accessible as follows:

- When FEAT_DoPD is implemented and !IsCorePowered(), accesses to this register return an ERROR.
- Otherwise, accesses to this register are RO.

E9.2.20 EDDEVID1, External Debug Device ID Register 1

The EDDEVID1 characteristics are:

Purpose

Provides extra information for external debuggers about features of the debug implementation.

Configuration

When FEAT_DoPD is implemented, EDDEVID1 is in the Core power domain. Otherwise, EDDEVID1 is in the Debug power domain

Attributes

EDDEVID1 is a 32-bit register.

Field descriptions

Bits [31:4]

Reserved, RES0.

PCSROffset, bits [3:0]

Indicates the offset applied to PC samples returned by reads of EDPCSR.

The value of this field is an IMPLEMENTATION DEFINED choice of:

PCSROffset	Meaning
0b0000	EDPCSR not implemented.
0b0010	EDPCSR implemented, and samples have no offset applied.

When [FEAT_PCSRv8p2](#) is implemented, the only permitted value is 0b0000.

Note
[FEAT_PCSRv8p2](#) implements the PC Sample-based Profiling Extension in the Performance Monitors register space, as indicated by the value of [PMDEVID.PCSample](#).

Access to this field is RO.

Accessing EDDEVID1

EDDEVID1 can be accessed through the external debug interface:

Component	Offset	Instance
Debug	0xFC4	EDDEVID1

Accessible as follows:

- When FEAT_DoPD is implemented and !IsCorePowered(), accesses to this register return an ERROR.
- Otherwise, accesses to this register are RO.

E9.2.21 EDDEVID2, External Debug Device ID register 2

The EDDEVID2 characteristics are:

Purpose

Reserved for future descriptions of features of the debug implementation.

Configuration

When FEAT_DoPD is implemented, EDDEVID2 is in the Core power domain. Otherwise, EDDEVID2 is in the Debug power domain

Attributes

EDDEVID2 is a 32-bit register.

Field descriptions

Bits [31:0]

Reserved, RES0.

Accessing EDDEVID2

EDDEVID2 can be accessed through the external debug interface:

Component	Offset	Instance
Debug	0xFC0	EDDEVID2

Accessible as follows:

- When FEAT_DoPD is implemented and !IsCorePowered(), accesses to this register return an ERROR.
- Otherwise, accesses to this register are RO.

E9.2.22 EDDEVTTYPE, External Debug Device Type register

The EDDEVTTYPE characteristics are:

Purpose

Indicates to a debugger that this component is part of a PE's debug logic.

Configuration

When FEAT_DoPD is implemented, EDDEVTTYPE is in the Core power domain. Otherwise, EDDEVTTYPE is in the Debug power domain

Attributes

EDDEVTTYPE is a 32-bit register.

Field descriptions

When FEAT_ED_PIDR is implemented:

Bits [31:8]

Reserved, RES0.

SUB, bits [7:4]

Subtype. Indicates this is a component within a PE.

Reads as 0b0001

Access to this field is RO.

MAJOR, bits [3:0]

Major type. Indicates this is a debug logic component.

Reads as 0b0101

Access to this field is RO.

Otherwise:

Bits [31:0]

Reserved, RES0.

Accessing EDDEVTYPE

EDDEVTYPE can be accessed through the external debug interface:

Component	Offset	Instance
Debug	0xFCC	EDDEVTYPE

Accessible as follows:

- When FEAT_DoPD is implemented and !IsCorePowered(), accesses to this register return an ERROR.
- Otherwise, accesses to this register are RO.

E9.2.23 EDDFR, External Debug Feature Register

The EDDFR characteristics are:

Purpose

Provides top-level information about the debug system.

Note

Debuggers must use [EDDEVARCH](#) to determine the Debug architecture version.

For general information about the interpretation of the ID registers, see ‘[Principles of the ID scheme for fields in ID registers](#)’.

Configuration

There are no configuration notes.

Attributes

EDDFR is a 64-bit register.

Field descriptions

Bits [63:44]

Reserved, RES0.

TraceFilt, bits [43:40]

Armv8.4 Self-hosted Trace Extension version.

The value of this field is an IMPLEMENTATION DEFINED choice of:

TraceFilt	Meaning
0b0000	Armv8.4 Self-hosted Trace Extension not implemented.
0b0001	Armv8.4 Self-hosted Trace Extension implemented.

All other values are reserved.

[FEAT_TRF](#) implements the functionality identified by the value 0b0001.

From Armv8.4, if [FEAT_ETMv4](#) is implemented, the value 0b0000 is not permitted.

Access to this field is RO.

Bits [39:32]

Reserved, RES0.

CTX_CMPs, bits [31:28]

Number of context-aware breakpoints, minus 1.

The value of this field is an IMPLEMENTATION DEFINED choice of:

CTX_CMPs	Meaning
0b0000..0b1111	The number of context-aware breakpoints, minus 1.

The value of this field is never greater than EDDFR.BRPs.

This field has the same value as [ID_AA64DFR0_EL1.CTX_CMPs](#).

Access to this field is RO.

Bits [27:24]

Reserved, RES0.

WRPs, bits [23:20]

Number of watchpoints, minus 1.

The value of this field is an IMPLEMENTATION DEFINED choice of:

WRPs	Meaning
0b0001..0b1111	The number of watchpoints, minus 1.

This field has the same value as [ID_AA64DFR0_EL1.WRPs](#).

The value 0b0000 is reserved.

Access to this field is RO.

Bits [19:16]

Reserved, RES0.

BRPs, bits [15:12]

Number of breakpoints, minus 1.

The value of this field is an IMPLEMENTATION DEFINED choice of:

BRPs	Meaning
0b0001..0b1111	The number of breakpoints, minus 1.

This field has the same value as [ID_AA64DFR0_EL1.BRPs](#).

The value 0b0000 is reserved.

Access to this field is RO.

PMUVer, bits [11:8]

Performance Monitors Extension version.

This field does not follow the standard ID scheme, but uses the alternative ID scheme described in ‘[Alternative ID scheme used for the Performance Monitors Extension version](#)’

The value of this field is an IMPLEMENTATION DEFINED choice of:

All other values are reserved.

[FEAT_PMUv3](#) implements the functionality identified by the value 0b0001.

[FEAT_PMUv3p1](#) implements the functionality identified by the value 0b0100.

[FEAT_PMUv3p4](#) implements the functionality identified by the value 0b0101.

From Armv8.1, if [FEAT_PMUv3](#) is implemented, the value 0b0001 is not permitted.

From Armv8.4, if [FEAT_PMUv3](#) is implemented, the value 0b0100 is not permitted.

This field has the same value as [ID_AA64DFR0_EL1](#).PMUVer.

Access to this field is RO.

TraceVer, bits [7:4]

Trace support. Indicates whether System register interface to a trace unit is implemented.

The value of this field is an IMPLEMENTATION DEFINED choice of:

TraceVer	Meaning
0b0000	Trace unit System registers not implemented.
0b0001	Trace unit System registers implemented.

All other values are reserved.

A value of 0b0000 only indicates that no System register interface to a trace unit is implemented. A trace unit might nevertheless be implemented without a System register interface.

This field returns the value of [ID_AA64DFR0_EL1](#).TraceVer.

Access to this field is RO.

Bits [3:0]

Reserved, UNKNOWN.

Accessing EDDFR

EDDFR can be accessed through the external debug interface:

Component	Offset	Instance
Debug	0xD28	EDDFR

Accessible as follows:

- When IsCorePowered() and !DoubleLockStatus(), accesses to this register are RO.
- When FEAT_DoPD is implemented and !IsCorePowered(), accesses to this register return an ERROR.
- Otherwise, accesses to this register are IMPLEMENTATION DEFINED.

E9.2.24 EDECCR, External Debug Exception Catch Control Register

The EDECCR characteristics are:

Purpose

Controls Exception Catch debug events. For more information, see ‘Exception Catch debug event’.

Configuration

EDECCR is in the Core power domain

External register EDECCR bits [31:0] are architecturally mapped to AArch64 System register OSECCR_EL1[31:0].

Attributes

EDECCR is a 32-bit register.

Field descriptions

Bits [31:17]

Reserved, RES0.

RLE0, bit [16]

Access to this field is RES0.

NSR3, bit [15]

Access to this field is RES0.

NSR2, bit [14]

When FEAT_Debugv8p2 is implemented and Non-secure EL2 is implemented:

Controls exception catch on exception return to Non-secure EL2 in conjunction with EDECCR.NSE2.

NSR2	Meaning
0b0	If EDECCR.NSE2 is 0, then Exception Catch debug events are disabled for Non-secure EL2. If EDECCR.NSE2 is 1, then Exception Catch debug events are enabled for exception entry, reset entry, and exception return to Non-secure EL2.
0b1	If EDECCR.NSE2 is 0, then Exception Catch debug events are enabled for exception returns to Non-secure EL2. If EDECCR.NSE2 is 1, then Exception Catch debug events are enabled for exception entry and reset entry to Non-secure EL2.

The reset behavior of this field is:

- On a Cold reset, this field resets to '0'.

Otherwise:

Reserved, RES0.

NSR1, bit [13]

When FEAT_Debugv8p2 is implemented and Non-secure EL1 is implemented:

Controls exception catch on exception return to Non-secure EL1 in conjunction with EDECCR.NSE1.

NSR1	Meaning
0b0	If EDECCR.NSE1 is 0, then Exception Catch debug events are disabled for Non-secure EL1. If EDECCR.NSE1 is 1, then Exception Catch debug events are enabled for exception entry, reset entry, and exception return to Non-secure EL1.
0b1	If EDECCR.NSE1 is 0, then Exception Catch debug events are enabled for exception returns to Non-secure EL1. If EDECCR.NSE1 is 1, then Exception Catch debug events are enabled for exception entry and reset entry to Non-secure EL1.

The reset behavior of this field is:

- On a Cold reset, this field resets to '0'.

Otherwise:

Reserved, RES0.

NSR0, bit [12]

When FEAT_Debugv8p2 is implemented and Non-secure EL0 is implemented:

Controls exception catch on exception return to Non-secure EL0.

NSR0	Meaning
0b0	Exception Catch debug events are disabled for Non-secure EL0.
0b1	Exception Catch debug events are enabled for exception returns to Non-secure EL0.

The reset behavior of this field is:

- On a Cold reset, this field resets to '0'.

Otherwise:

Reserved, RES0.

Bit [11]

Reserved, RES0.

SR2, bit [10]

When FEAT_Debugv8p2 is implemented and FEAT_SEL2 is implemented:

Controls exception catch on exception return to Secure EL2 in conjunction with EDECCR.SE2.

SR2	Meaning
0b0	If EDECCR.SE2 is 0, then Exception Catch debug events are disabled for Secure EL2. If EDECCR.SE2 is 1, then Exception Catch debug events are enabled for exception entry, reset entry, and exception return to Secure EL2.
0b1	If EDECCR.SE2 is 0, then Exception Catch debug events are enabled for exception returns to Secure EL2. If EDECCR.SE2 is 1, then Exception Catch debug events are enabled for exception entry and reset entry to Secure EL2.

The reset behavior of this field is:

- On a Cold reset, this field resets to '0'.

Otherwise:

Reserved, RES0.

SR1, bit [9]

When FEAT_Debugv8p2 is implemented and Secure EL1 is implemented:

Controls exception catch on exception return to Secure EL1 in conjunction with EDECCR.SE1.

SR1	Meaning
0b0	If EDECCR.SE1 is 0, then Exception Catch debug events are disabled for Secure EL1. If EDECCR.SE1 is 1, then Exception Catch debug events are enabled for exception entry, reset entry, and exception return to Secure EL1.
0b1	If EDECCR.SE1 is 0, then Exception Catch debug events are enabled for exception returns to Secure EL1. If EDECCR.SE1 is 1, then Exception Catch debug events are enabled for exception entry and reset entry to Secure EL1.

The reset behavior of this field is:

- On a Cold reset, this field resets to '0'.

Otherwise:

Reserved, RES0.

SR0, bit [8]

When FEAT_Debugv8p2 is implemented and Secure EL0 is implemented:

Controls exception catch on exception return to Secure EL0.

SR0	Meaning
0b0	Exception Catch debug events are disabled for Secure EL0.
0b1	Exception Catch debug events are enabled for exception returns to Secure EL0.

The reset behavior of this field is:

- On a Cold reset, this field resets to '0'.

Otherwise:

Reserved, RES0.

NSE3, bit [7]

Access to this field is RES0.

NSE2, bit [6]

When FEAT_Debugv8p2 is implemented and Non-secure EL2 is implemented:

Controls exception catch on exception entry to Non-secure EL2. Also controls exception catch on exception return to Non-secure EL2 in conjunction with EDECCR.NSR2.

NSE2	Meaning
0b0	If EDECCR.NSR2 is 0, then Exception Catch debug events are disabled for Non-secure EL2. If EDECCR.NSR2 is 1, then Exception Catch debug events are enabled for exception returns to Non-secure EL2.
0b1	If EDECCR.NSR2 is 0, then Exception Catch debug events are enabled for exception entry, reset entry, and exception return to Non-secure EL2. If EDECCR.NSR2 is 1, then Exception Catch debug events are enabled for exception entry and reset entry to Non-secure EL2.

Note

It is IMPLEMENTATION DEFINED whether a reset entry to an Exception level will generate an Exception Catch debug event.

The reset behavior of this field is:

- On a Cold reset, this field resets to '0'.

When Non-secure EL2 is implemented:

Coarse-grained exception catch for Non-secure EL2. Controls Exception Catch debug events for Non-secure EL2.

NSE2	Meaning
0b0	Exception Catch debug events are disabled for Non-secure EL2.
0b1	Exception Catch debug events are enabled for Non-secure EL2.

The reset behavior of this field is:

- On a Cold reset, this field resets to '0'.

Otherwise:

Reserved, RES0.

NSE1, bit [5]

When FEAT_Debugv8p2 is implemented and Non-secure EL1 is implemented:

Controls exception catch on exception entry to Non-secure EL1. Also controls exception catch on exception return to Non-secure EL1 in conjunction with EDECCR.NSR1.

NSE1	Meaning
0b0	If EDECCR.NSR1 is 0, then Exception Catch debug events are disabled for Non-secure EL1. If EDECCR.NSR1 is 1, then Exception Catch debug events are enabled for exception returns to Non-secure EL1.
0b1	If EDECCR.NSR1 is 0, then Exception Catch debug events are enabled for exception entry, reset entry, and exception return to Non-secure EL1. If EDECCR.NSR1 is 1, then Exception Catch debug events are enabled for exception entry and reset entry to Non-secure EL1.

Note

It is IMPLEMENTATION DEFINED whether a reset entry to an Exception level will generate an Exception Catch debug event.

The reset behavior of this field is:

- On a Cold reset, this field resets to '0'.

When Non-secure EL1 is implemented:

Coarse-grained exception catch for Non-secure EL1. Controls Exception Catch debug events for Non-secure EL1.

NSE1	Meaning
0b0	Exception Catch debug events are disabled for Non-secure EL1.
0b1	Exception Catch debug events are enabled for Non-secure EL1.

The reset behavior of this field is:

- On a Cold reset, this field resets to '0'.

Otherwise:

Reserved, RES0.

NSE0, bit [4]

Access to this field is RES0.

Bit [3]

Reserved, RES0.

SE2, bit [2]

When FEAT_Debugv8p2 is implemented and FEAT_SEL2 is implemented:

Controls exception catch on exception entry to Secure EL2. Also controls exception catch on exception return to Secure EL2 in conjunction with EDECCR.SR2.

SE2	Meaning
0b0	If EDECCR.SR2 is 0, then Exception Catch debug events are disabled for Secure EL2. If EDECCR.SR2 is 1, then Exception Catch debug events are enabled for exception returns to Secure EL2.
0b1	If EDECCR.SR2 is 0, then Exception Catch debug events are enabled for exception entry, reset entry, and exception return to Secure EL2. If EDECCR.SR2 is 1, then Exception Catch debug events are enabled for exception entry and reset entry to Secure EL2.

Note

It is IMPLEMENTATION DEFINED whether a reset entry to an Exception level will generate an Exception Catch debug event.

The reset behavior of this field is:

- On a Cold reset, this field resets to '0'.

Otherwise:

Reserved, RES0.

SE1, bit [1]

When FEAT_Debugv8p2 is implemented and Secure EL1 is implemented:

Controls exception catch on exception entry to Secure EL1. Also controls exception catch on exception return to Secure EL1 in conjunction with EDECCR.SR1.

SE1	Meaning
0b0	If EDECCR.SR1 is 0, then Exception Catch debug events are disabled for Secure EL1. If EDECCR.SR1 is 1, then Exception Catch debug events are enabled for exception returns to Secure EL1.
0b1	If EDECCR.SR1 is 0, then Exception Catch debug events are enabled for exception entry, reset entry, and exception return to Secure EL1. If EDECCR.SR1 is 1, then Exception Catch debug events are enabled for exception entry and reset entry to Secure EL1.

Note

It is IMPLEMENTATION DEFINED whether a reset entry to an Exception level will generate an Exception Catch debug event.

The reset behavior of this field is:

- On a Cold reset, this field resets to '0'.

When Secure EL1 is implemented:

Coarse-grained exception catch for Secure EL1. Controls Exception Catch debug events for Secure EL1.

SE1	Meaning
0b0	Exception Catch debug events are disabled for Secure EL1.
0b1	Exception Catch debug events are enabled for Secure EL1.

The reset behavior of this field is:

- On a Cold reset, this field resets to '0'.

Otherwise:

Reserved, RES0.

SE0, bit [0]

Access to this field is RES0.

Accessing EDECCR

EDECCR can be accessed through the external debug interface:

Component	Offset	Instance
Debug	0x098	EDECCR

Accessible as follows:

- When DoubleLockStatus(), or !IsCorePowered(), or OSLockStatus(), accesses to this register return an ERROR.
- When SoftwareLockStatus(addrdesc), accesses to this register are RO.
- Otherwise, accesses to this register are RW.

E9.2.25 EDECR, External Debug Execution Control Register

The EDECR characteristics are:

Purpose

Controls Halting debug events.

Configuration

When FEAT_DoPD is implemented, EDECR is in the Core power domain. Otherwise, EDECR is in the Debug power domain

Attributes

EDECR is a 32-bit register.

Field descriptions

Bits [31:3]

Reserved, RES0.

SS, bit [2]

Halting step enable. Possible values of this field are:

SS	Meaning
0b0	Halting step debug event disabled.
0b1	Halting step debug event enabled.

If the value of EDECR.SS is changed when the PE is in Non-debug state, behavior is CONSTRAINED UNPREDICTABLE as described in [‘Changing the value of EDECR.SS when not in Debug state’](#).

The reset behavior of this field is:

- On a Cold reset:
 - When FEAT_DoPD is implemented, this field resets to '0'.
- On a External debug reset:
 - When FEAT_DoPD is not implemented, this field resets to '0'.

RCE, bit [1]

When FEAT_DoPD is not implemented:

Reset Catch Enable.

RCE	Meaning
0b0	Reset Catch debug event disabled.
0b1	Reset Catch debug event enabled.

The reset behavior of this field is:

- On a External debug reset, this field resets to '0'.

Otherwise:

Reserved, RES0.

OSUCE, bit [0]

When FEAT_DoPD is not implemented:

OS Unlock Catch Enable.

OSUCE	Meaning
0b0	OS Unlock Catch debug event disabled.
0b1	OS Unlock Catch debug event enabled.

The reset behavior of this field is:

- On a External debug reset, this field resets to '0'.

Otherwise:

Reserved, RES0.

Accessing EDECR

EDECR can be accessed through the external debug interface:

Component	Offset	Instance
Debug	0x024	EDECR

Accessible as follows:

- When FEAT_DoPD is implemented and !IsCorePowered(), accesses to this register return an ERROR.
- When SoftwareLockStatus(addrdesc), accesses to this register are RO.
- Otherwise, accesses to this register are RW.

E9.2.26 EDESR, External Debug Event Status Register

The EDESR characteristics are:

Purpose

Indicates the status of internally pending Halting debug events.

Configuration

EDESR is in the Core power domain

Attributes

EDESR is a 32-bit register.

Field descriptions

Bits [31:3]

Reserved, RES0.

SS, bit [2]

When FEAT_DoPD is implemented:

Halting step debug event pending. Possible values of this field are:

SS	Meaning
0b0	Reading this means that a Halting step debug event is not pending. Writing this means no action.
0b1	Reading this means that a Halting step debug event is pending. Writing this clears the pending Halting step debug event.

The reset behavior of this field is:

- On a Cold reset, this field resets to '0'.

Otherwise:

Halting step debug event pending. Possible values of this field are:

SS	Meaning
0b0	Reading this means that a Halting step debug event is not pending. Writing this means no action.

SS	Meaning
0b1	Reading this means that a Halting step debug event is pending. Writing this clears the pending Halting step debug event.

The reset behavior of this field is:

- On a Warm reset, this field resets to the value in [EDEC.R.SS](#).

RC, bit [1]

Reset Catch debug event pending. Possible values of this field are:

RC	Meaning
0b0	Reading this means that a Reset Catch debug event is not pending. Writing this means no action.
0b1	Reading this means that a Reset Catch debug event is pending. Writing this clears the pending Reset Catch debug event.

The reset behavior of this field is:

- On a Warm reset:
 - When FEAT_DoPD is implemented, this field resets to the value in [CTIDEVCTL.RCE](#).
 - When FEAT_DoPD is not implemented, this field resets to the value in [EDEC.RCE](#).

OSUC, bit [0]

OS Unlock Catch debug event pending. Possible values of this field are:

OSUC	Meaning
0b0	Reading this means that an OS Unlock Catch debug event is not pending. Writing this means no action.
0b1	Reading this means that an OS Unlock Catch debug event is pending. Writing this clears the pending OS Unlock Catch debug event.

The reset behavior of this field is:

- On a Warm reset, this field resets to '0'.

Accessing EDESR

If a request to clear a pending Halting debug event is received at or about the time when halting becomes allowed, it is **CONSTRAINED UNPREDICTABLE** whether the event is taken.

If Core power is removed while a Halting debug event is pending, it is lost. However, it might become pending again when the Core is powered back on and Cold reset.

EDESR can be accessed through the external debug interface:

Component	Offset	Instance
Debug	0x020	EDES

Accessible as follows:

- When DoubleLockStatus() or !IsCorePowered(), accesses to this register return an ERROR.
- When SoftwareLockStatus(addrdesc), accesses to this register are RO.
- Otherwise, accesses to this register are RW.

E9.2.27 EDITCTRL, External Debug Integration mode Control register

The EDITCTRL characteristics are:

Purpose

Enables the external debug to switch from its default mode into integration mode, where test software can control directly the inputs and outputs of the PE, for integration testing or topology detection.

Configuration

The power domain of EDITCTRL is IMPLEMENTATION DEFINED

Implementation of this register is OPTIONAL.

Attributes

EDITCTRL is a 32-bit register.

Field descriptions

Bits [31:1]

Reserved, RES0.

IME, bit [0]

Integration mode enable. When IME == 1, the device reverts to an integration mode to enable integration testing or topology detection.

IME	Meaning
0b0	Normal operation.
0b1	Integration mode enabled.

The integration mode behavior is IMPLEMENTATION DEFINED.

The following resets apply:

- Whichever power domain the register is implemented in, this field resets to 0.
- Otherwise, the value of this field is unchanged.

Accessing EDITCTRL

EDITCTRL can be accessed through the external debug interface:

Component	Offset	Instance
Debug	0xF00	EDITCTRL

Accessible as follows:

- When DoubleLockStatus(), or !IsCorePowered(), or OSLockStatus(), accesses to this register are IMPLEMENTATION DEFINED.
- When SoftwareLockStatus(addrdesc), accesses to this register are RO.
- Otherwise, accesses to this register are RW.

E9.2.28 EDITR, External Debug Instruction Transfer Register

The EDITR characteristics are:

Purpose

Used in Debug state for passing instructions to the PE for execution.

Configuration

EDITR is in the Core power domain

Attributes

EDITR is a 32-bit register.

Field descriptions

When !UsingAArch32():

A64_Instruction, bits [31:0]

A64 instruction to be executed on the PE.

Accessing EDITR

If `EDSCR.ITE == 0` when the PE exits Debug state on receiving a Restart request trigger event, the behavior of any instruction issued through the ITR in Normal access mode that has not completed execution is **CONSTRAINED UNPREDICTABLE**, and must do one of the following:

- It must complete execution in Debug state before the PE executes the restart sequence.
- It must complete execution in Non-debug state before the PE executes the restart sequence.
- It must be abandoned. This means that the instruction does not execute. Any registers or memory accessed by the instruction are left in an **UNKNOWN** state.

EDITR ignores writes if the PE is in Non-debug state.

EDITR can be accessed through the external debug interface:

Component	Offset	Instance
Debug	0x084	EDITR

Accessible as follows:

- When `DoubleLockStatus()`, or `!IsCorePowered()`, or `OSLockStatus()`, accesses to this register return an **ERROR**.
- When `SoftwareLockStatus(addrdesc)`, accesses to this register are **W1**.
- Otherwise, accesses to this register are **W0**.

E9.2.29 EDLAR, External Debug Lock Access Register

The EDLAR characteristics are:

Purpose

Allows or disallows access to the external debug registers through a memory-mapped interface.

The optional Software Lock provides a lock to prevent memory-mapped writes to the debug registers. Use of this lock mechanism reduces the risk of accidental damage to the contents of the debug registers. It does not, and cannot, prevent all accidental or malicious damage.

Configuration

When FEAT_DoPD is implemented, EDLAR is in the Core power domain. Otherwise, EDLAR is in the Debug power domain

If [FEAT_DoPD](#) is implemented, Software Lock is not implemented by the architecturally-defined debug components of the PE.

Software uses EDLAR to set or clear the lock, and [EDLSR](#) to check the current status of the lock.

Attributes

EDLAR is a 32-bit register.

Field descriptions

When Debug Software Lock is implemented:

KEY, bits [31:0]

Lock Access control. Writing the key value 0xC5ACCE55 to this field unlocks the lock, enabling write accesses to this component's registers through a memory-mapped interface.

Writing any other value to this register locks the lock, disabling write accesses to this component's registers through a memory mapped interface.

Otherwise:

Otherwise

Bits [31:0]

Reserved, RES0.

Accessing EDLAR

EDLAR can be accessed through the memory-mapped interface:

Component	Offset	Instance
Debug	0xFB0	EDLAR

Accessible as follows:

- When FEAT_DoPD is implemented and !IsCorePowered(), accesses to this register return an ERROR.
- Otherwise, accesses to this register are WO.

E9.2.30 EDLSR, External Debug Lock Status Register

The EDLSR characteristics are:

Purpose

Indicates the current status of the software lock for external debug registers.

The optional Software Lock provides a lock to prevent memory-mapped writes to the debug registers. Use of this lock mechanism reduces the risk of accidental damage to the contents of the debug registers. It does not, and cannot, prevent all accidental or malicious damage.

Configuration

When FEAT_DoPD is implemented, EDLSR is in the Core power domain. Otherwise, EDLSR is in the Debug power domain

If **FEAT_DoPD** is implemented, Software Lock is not implemented by the architecturally-defined debug components of the PE.

Software uses [EDLAR](#) to set or clear the lock, and EDLSR to check the current status of the lock.

Attributes

EDLSR is a 32-bit register.

Field descriptions

**Bits [31:3]**

Reserved, RES0.

nTT, bit [2]

Not thirty-two bit access required. RAZ.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

SLK, bit [1]

When Debug Software Lock is implemented:

Software Lock status for this component. For an access to LSR that is not a memory-mapped access, or when Software Lock is not implemented, this field is RES0.

For memory-mapped accesses when Software Lock is implemented, possible values of this field are:

SLK	Meaning
0b0	Lock clear. Writes are permitted to this component's registers.
0b1	Lock set. Writes to this component's registers are ignored, and reads have no side effects.

The reset behavior of this field is:

- On a Cold reset:
 - When FEAT_DoPD is implemented, this field resets to '1'.
- On a External debug reset:
 - When FEAT_DoPD is not implemented, this field resets to '1'.

Otherwise:

Reserved, RAZ.

SLI, bit [0]

Software Lock implemented. For an access to LSR that is not a memory-mapped access, this field is RAZ.

The value of this field is an IMPLEMENTATION DEFINED choice of:

SLI	Meaning
0b0	Software Lock not implemented or not memory-mapped access.
0b1	Software Lock implemented and memory-mapped access.

Access to this field is RO.

Accessing EDLSR

EDLSR can be accessed through the memory-mapped interface:

Component	Offset	Instance
Debug	0xFB4	EDLSR

Accessible as follows:

- When FEAT_DoPD is implemented and !IsCorePowered(), accesses to this register return an ERROR.
- Otherwise, accesses to this register are RO.

E9.2.31 EDPFR, External Debug Processor Feature Register

The EDPFR characteristics are:

Purpose

Provides information about implemented PE features.

For general information about the interpretation of the ID registers, see ‘[Principles of the ID scheme for fields in ID registers](#)’.

Configuration

There are no configuration notes.

Attributes

EDPFR is a 64-bit register.

Field descriptions

63	56	55	52	51	48	47	40	39	36	35	32	⋮				
UNKNOWN				RES0		UNKNOWN		RES0		SEL2			RES0			
31	28	27	24	23	20	19	16	15	12	11	8	7	4	3	0	⋮
UNKNOWN		GIC		AdvSIMD		FP		EL3		EL2		EL1		EL0		

Bits [63:56]

Reserved, UNKNOWN.

Bits [55:52]

Reserved, RES0.

Bits [51:48]

Reserved, UNKNOWN.

Bits [47:40]

Reserved, RES0.

SEL2, bits [39:36]

Secure EL2.

The value of this field is an IMPLEMENTATION DEFINED choice of:

SEL2	Meaning
0b0000	Secure EL2 is not implemented.
0b0001	Secure EL2 is implemented.

[FEAT_SEL2](#) implements the functionality identified by the value 0b0001

All other values are reserved.

Access to this field is RO.

Bits [35:32]

Reserved, RES0.

Bits [31:28]

Reserved, UNKNOWN.

GIC, bits [27:24]

System register GIC interface support.

The value of this field is an IMPLEMENTATION DEFINED choice of:

GIC	Meaning
0b0000	GIC CPU interface System registers not implemented.
0b0001	System register interface to versions 3.0 and 4.0 of the GIC CPU interface is supported.
0b0011	System register interface to version 4.1 of the GIC CPU interface is supported.

All other values are reserved.

This field returns the value of [ID_AA64PFR0_EL1](#).GIC.

Access to this field is RO.

AdvSIMD, bits [23:20]

Advanced SIMD.

If [FEAT_FP16](#) is implemented, indicates support for the half-precision floating-point arithmetic instructions.

The value of this field is an IMPLEMENTATION DEFINED choice of:

All other values are reserved.

This field must have the same value as the FP field.

[FEAT_AdvSIMD](#) implements the functionality identified by the value 0b0000.

[FEAT_FP16](#) implements the functionality identified by the value 0b0001.

This field returns the value of [ID_AA64PFR0_EL1](#).AdvSIMD.

Access to this field is RO.

FP, bits [19:16]

If [FEAT_FP16](#) is implemented, indicates support for the half-precision floating-point arithmetic instructions.

The value of this field is an IMPLEMENTATION DEFINED choice of:

All other values are reserved.

This field must have the same value as the AdvSIMD field.

[FEAT_FP](#) implements the functionality identified by the value 0b0000.

[FEAT_FP16](#) implements the functionality identified by the value 0b0001.

This field returns the value of [ID_AA64PFR0_EL1](#).FP.

Access to this field is RO.

EL3, bits [15:12]

AArch64 EL3 Exception level handling.

The value of this field is an IMPLEMENTATION DEFINED choice of:

EL3	Meaning
0b0000	EL3 is not implemented or cannot be executed in AArch64 state.
0b0001	EL3 can be executed in AArch64 state only.
0b0010	EL3 can be executed in both Execution states.

When the value of [EDAA32PFR](#).EL3 is nonzero, this field must be 0b0000.

All other values are reserved.

In an Armv8-R AArch64 implementation this field returns the value of 0b0000.

Access to this field is RO.

EL2, bits [11:8]

AArch64 EL2 Exception level handling.

The value of this field is an IMPLEMENTATION DEFINED choice of:

EL2	Meaning
0b0000	EL2 is not implemented or cannot be executed in AArch64 state.
0b0001	EL2 can be executed in AArch64 state only.
0b0010	EL2 can be executed in both Execution states.

All other values are reserved.

In an Armv8-R AArch64 implementation this field returns the value of 0b0001.

Access to this field is RO.

EL1, bits [7:4]

AArch64 EL1 Exception level handling.

The value of this field is an IMPLEMENTATION DEFINED choice of:

EL1	Meaning
0b0000	EL1 cannot be executed in AArch64 state.
0b0001	EL1 can be executed in AArch64 state only.
0b0010	EL1 can be executed in both Execution states.

All other values are reserved.

In Armv8-R AArch64, the only permitted values is 0b0001.

Access to this field is RO.

EL0, bits [3:0]

AArch64 EL0 Exception level handling.

The value of this field is an IMPLEMENTATION DEFINED choice of:

EL0	Meaning
0b0000	EL0 cannot be executed in AArch64 state.
0b0001	EL0 can be executed in AArch64 state only.
0b0010	EL0 can be executed in both Execution states.

All other values are reserved.

In Armv8-R AArch64 implementation, the only permitted value is 0b0001.

Access to this field is RO.

Accessing EDPFR

EDPFR can be accessed through the external debug interface:

Component	Offset	Instance
Debug	0xD20	EDPFR

Accessible as follows:

- When IsCorePowered() and !DoubleLockStatus(), accesses to this register are RO.
- When FEAT_DoPD is implemented and !IsCorePowered(), accesses to this register return an ERROR.
- Otherwise, accesses to this register are IMPLEMENTATION DEFINED.

E9.2.32 **EDPIDR0, External Debug Peripheral Identification Register 0**

The EDPIDR0 characteristics are:

Purpose

Provides information to identify an external debug component.
For more information, see ‘About the Peripheral identification scheme’.

Configuration

When FEAT_DoPD is implemented, EDPIDR0 is in the Core power domain. Otherwise, EDPIDR0 is in the Debug power domain

This register is present only when FEAT_ED_PIDR is implemented. Otherwise, direct accesses to EDPIDR0 are RES0.

Attributes

EDPIDR0 is a 32-bit register.

Field descriptions

Bits [31:8]

Reserved, RES0.

PART_0, bits [7:0]

Part number, which is selected by the designer of the component and stored as follows:

- For a component with a 12-bit part number:
 - [EDPIDR1](#).PART_1 contains part number bits [11:8].
 - [EDPIDR0](#).PART_0 contains part number bits [7:0].
- For a component with a 16-bit part number:
 - [EDPIDR1](#).PART_1 contains part number bits [15:12].
 - [EDPIDR0](#).PART_0 contains part number bits [11:4].
 - [EDPIDR2](#).REVISION contains part number bits [3:0].

When a 12-bit part number is used, [EDPIDR2](#).REVISION indicates revision information.

The choice of using a 12-bit part number or 16-bit part number is specific to the designer of the component.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

Accessing EDPIDR0

EDPIDR0 can be accessed through the external debug interface:

Component	Offset	Instance
Debug	0xFE0	EDPIDR0

Accessible as follows:

- When FEAT_DoPD is implemented and !IsCorePowered(), accesses to this register return an ERROR.
- Otherwise, accesses to this register are RO.

E9.2.33 EDPIDR1, External Debug Peripheral Identification Register 1

The EDPIDR1 characteristics are:

Purpose

Provides information to identify an external debug component.

For more information, see ‘About the Peripheral identification scheme’.

Configuration

When FEAT_DoPD is implemented, EDPIDR1 is in the Core power domain. Otherwise, EDPIDR1 is in the Debug power domain

This register is present only when FEAT_ED_PIDR is implemented. Otherwise, direct accesses to EDPIDR1 are RES0.

Attributes

EDPIDR1 is a 32-bit register.

Field descriptions

31		8	7	4	3	0	
RES0							
DES_0							
PART_1							

Bits [31:8]

Reserved, RES0.

DES_0, bits [7:4]

Designer, JEP106 identification code, bits [3:0].

The JEP106 identification and continuation codes are stored as follows:

- [EDPIDR1.DES_0](#): JEP106 identification code bits[3:0].
- [EDPIDR2.DES_1](#): JEP106 identification code bits[6:4].
- [EDPIDR4.DES_2](#): JEP106 continuation code.

These codes indicate the designer of the component and not the implementer, except where the two are the same. To obtain a number, or to see the assignment of these codes, contact JEDEC <http://www.jedec.org>.

A JEP106 identification and continuation code takes the following form:

- A sequence of zero or more numbers, all having the value $0 \times 7F$.
- A following 8-bit number, that is not $0 \times 7F$, and where bit[7] is an odd parity bit.

The parity bit in the JEP106 identification code is not included.

Note

For example, Arm Limited is assigned the code $0 \times 7F \ 0 \times 7F \ 0 \times 7F \ 0 \times 7F \ 0 \times 3B$.

- The continuation code is the number of times $0 \times 7F$ appears before the final number. For example, a component designed by Arm Limited has the code 0×4 .
- The identification code is bits[6:0] of the final number. For example, a component designed by Arm Limited has the code $0 \times 3B$.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

PART_1, bits [3:0]

Part number, which is selected by the designer of the component and stored as follows:

- For a component with a 12-bit part number:
 - [EDPIDR1](#).PART_1 contains part number bits [11:8].
 - [EDPIDR0](#).PART_0 contains part number bits [7:0].
- For a component with a 16-bit part number:
 - [EDPIDR1](#).PART_1 contains part number bits [15:12].
 - [EDPIDR0](#).PART_0 contains part number bits [11:4].
 - [EDPIDR2](#).REVISION contains part number bits [3:0].

When a 12-bit part number is used, [EDPIDR2](#).REVISION indicates revision information.

The choice of using a 12-bit part number or 16-bit part number is specific to the designer of the component.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

Accessing EDPIDR1

EDPIDR1 can be accessed through the external debug interface:

Component	Offset	Instance
Debug	0xFE4	EDPIDR1

Accessible as follows:

- When FEAT_DoPD is implemented and !IsCorePowered(), accesses to this register return an ERROR.
- Otherwise, accesses to this register are RO.

E9.2.34 EDPIDR2, External Debug Peripheral Identification Register 2

The EDPIDR2 characteristics are:

Purpose

Provides information to identify an external debug component.

For more information, see ‘About the Peripheral identification scheme’.

Configuration

When FEAT_DoPD is implemented, EDPIDR2 is in the Core power domain. Otherwise, EDPIDR2 is in the Debug power domain

This register is present only when FEAT_ED_PIDR is implemented. Otherwise, direct accesses to EDPIDR2 are RES0.

Attributes

EDPIDR2 is a 32-bit register.

Field descriptions

Bits [31:8]

Reserved, RES0.

REVISION, bits [7:4]

Indicates either the revision of the component, or a portion of the part number of the component.

Where the component has a single 4-bit revision number, the revision number is an incremental value starting at zero for the first revision of the component.

Where the component has separate major and minor revision numbers, the major and minor revision numbers are each incremental values starting at zero for the first revision of the component. For each minor revision of the component, the minor revision number increments monotonically. For each major revision of the component, the major revision number increments monotonically and the minor revision begins again at zero.

For a component with a 12-bit part number with a single 4-bit revision number:

- [EDPIDR2.REVISION](#) indicates the 4-bit revision number.
- [EDPIDR3.REVAND](#) indicates component modifications.

For a component with a 12-bit part number with separate major and minor revision numbers:

- [EDPIDR2.REVISION](#) indicates the 4-bit major revision number.
- [EDPIDR3.REVAND](#) indicates the 4-bit minor revision number.

For a component with a 16-bit part number:

- [EDPIDR2.REVISION](#) contains part number bits [3:0].
- [EDPIDR3.REVAND](#) indicates the 4-bit revision number.

The choice of which style of revision information is used is specific to the designer of the component, and might also be specific to each individual component with a different part number.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

JEDEC, bit [3]

JEDEC-assigned JEP106 implementer code is used.

Reads as 0b1

Access to this field is RO.

DES_1, bits [2:0]

Designer, JEP106 identification code, bits [6:4].

The JEP106 identification and continuation codes are stored as follows:

- [EDPIDR1.DES_0](#): JEP106 identification code bits[3:0].
- [EDPIDR2.DES_1](#): JEP106 identification code bits[6:4].
- [EDPIDR4.DES_2](#): JEP106 continuation code.

These codes indicate the designer of the component and not the implementer, except where the two are the same. To obtain a number, or to see the assignment of these codes, contact JEDEC <http://www.jedec.org>.

A JEP106 identification and continuation code takes the following form:

- A sequence of zero or more numbers, all having the value 0x7F.
- A following 8-bit number, that is not 0x7F, and where bit[7] is an odd parity bit.

The parity bit in the JEP106 identification code is not included.

Note

For example, Arm Limited is assigned the code 0x7F 0x7F 0x7F 0x7F 0x3B.

- The continuation code is the number of times 0x7F appears before the final number. For example, a component designed by Arm Limited has the code 0x4.
 - The identification code is bits[6:0] of the final number. For example, a component designed by Arm Limited has the code 0x3B.
-

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

Accessing EDPIDR2

EDPIDR2 can be accessed through the external debug interface:

Component	Offset	Instance
Debug	0xFE8	EDPIDR2

Accessible as follows:

- When FEAT_DoPD is implemented and !IsCorePowered(), accesses to this register return an ERROR.
- Otherwise, accesses to this register are RO.

E9.2.35 EDPIDR3, External Debug Peripheral Identification Register 3

The EDPIDR3 characteristics are:

Purpose

Provides information to identify an external debug component.

For more information, see ‘About the Peripheral identification scheme’.

Configuration

When FEAT_DoPD is implemented, EDPIDR3 is in the Core power domain. Otherwise, EDPIDR3 is in the Debug power domain

This register is present only when FEAT_ED_PIDR is implemented. Otherwise, direct accesses to EDPIDR3 are RES0.

Attributes

EDPIDR3 is a 32-bit register.

Field descriptions

Bits [31:8]

Reserved, RES0.

REVAND, bits [7:4]

Indicates either the revision of the component, or whether the component has been modified.

Where the component has a single 4-bit revision number, the revision number is an incremental value starting at zero for the first revision of the component.

Where the component has separate major and minor revision numbers, the major and minor revision numbers are each incremental values starting at zero for the first revision of the component. For each minor revision of the component, the minor revision number increments monotonically. For each major revision of the component, the major revision number increments monotonically and the minor revision begins again at zero.

For a component with a 12-bit part number with a single 4-bit revision number:

- [EDPIDR2.REVISION](#) indicates the 4-bit revision number.
- [EDPIDR3.REVAND](#) indicates component modifications.

For a component with a 12-bit part number with separate major and minor revision numbers:

- [EDPIDR2.REVISION](#) indicates the 4-bit major revision number.
- [EDPIDR3.REVAND](#) indicates the 4-bit minor revision number.

For a component with a 16-bit part number:

- [EDPIDR2.REVISION](#) contains part number bits [3:0].
- [EDPIDR3.REVAND](#) indicates the 4-bit revision number.

The choice of which style of revision information is used is specific to the designer of the component, and might also be specific to each individual component with a different part number.

Where REVAND indicates component modifications, this indicates modifications such as errata fixes or metal fixes after implementation. Usually this value would be zero unless a modification has been performed. If the field

is required for indicating component modifications, Arm recommends that component designers ensure that it can be changed by a metal fix, for example by driving it from registers that reset to zero.

[EDPIDR3](#).CMOD might also indicate component modifications.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

CMOD, bits [3:0]

Indicates whether the component has been modified from its original behavior. Examples of modifications include errata fixes or metal fixes after implementation. Usually this value would be zero unless a modification has been performed. If the field is required for indicating component modifications, Arm recommends that component designers ensure that it can be changed by a metal fix, for example by driving it from registers that reset to zero.

A value of 0b0000 means the component is not modified from the original design.

Any other value means the component has been modified in an IMPLEMENTATION DEFINED way.

For any two components with the same Unique Component Identifier:

- If the value of the CMOD fields of both components equals zero, the components are identical.
- If the CMOD fields of both components have the same nonzero value, it does not necessarily mean that they have the same modifications.
- If the value of the CMOD field of either of the two components is nonzero, they might not be identical, even though they have the same Unique Component Identifier.

[EDPIDR3](#).REVAND might also indicate component modifications.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

Accessing EDPIDR3

EDPIDR3 can be accessed through the external debug interface:

Component	Offset	Instance
Debug	0xFEC	EDPIDR3

Accessible as follows:

- When FEAT_DoPD is implemented and !IsCorePowered(), accesses to this register return an ERROR.
- Otherwise, accesses to this register are RO.

E9.2.36 EDPIDR4, External Debug Peripheral Identification Register 4

The EDPIDR4 characteristics are:

Purpose

Provides information to identify an external debug component.

For more information, see ‘About the Peripheral identification scheme’.

Configuration

When FEAT_DoPD is implemented, EDPIDR4 is in the Core power domain. Otherwise, EDPIDR4 is in the Debug power domain

This register is present only when FEAT_ED_PIDR is implemented. Otherwise, direct accesses to EDPIDR4 are RES0.

Attributes

EDPIDR4 is a 32-bit register.

Field descriptions

Bits [31:8]

Reserved, RES0.

SIZE, bits [7:4]

Size of the component. $\log_2$ of the number of 4KB pages from the start of the component to the end of the component ID registers.

Reads as 0b0000

Access to this field is RO.

DES_2, bits [3:0]

Designer, JEP106 continuation code.

The JEP106 identification and continuation codes are stored as follows:

- [EDPIDR1.DES_0](#): JEP106 identification code bits[3:0].
- [EDPIDR2.DES_1](#): JEP106 identification code bits[6:4].
- [EDPIDR4.DES_2](#): JEP106 continuation code.

These codes indicate the designer of the component and not the implementer, except where the two are the same. To obtain a number, or to see the assignment of these codes, contact JEDEC <http://www.jedec.org>.

A JEP106 identification and continuation code takes the following form:

- A sequence of zero or more numbers, all having the value 0x7F.
- A following 8-bit number, that is not 0x7F, and where bit[7] is an odd parity bit.

The parity bit in the JEP106 identification code is not included.

Note

For example, Arm Limited is assigned the code 0x7F 0x7F 0x7F 0x7F 0x3B.

- The continuation code is the number of times 0x7F appears before the final number. For example, a component designed by Arm Limited has the code 0x4.
 - The identification code is bits[6:0] of the final number. For example, a component designed by Arm Limited has the code 0x3B.
-

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

Accessing EDPIDR4

EDPIDR4 can be accessed through the external debug interface:

Component	Offset	Instance
Debug	0xFD0	EDPIDR4

Accessible as follows:

- When FEAT_DoPD is implemented and !IsCorePowered(), accesses to this register return an ERROR.
- Otherwise, accesses to this register are RO.

E9.2.37 **EDPIDR5, External Debug Peripheral Identification Register 5**

The EDPIDR5 characteristics are:

Purpose

Provides information to identify an external debug component.
For more information, see ‘About the Peripheral identification scheme’.

Configuration

When FEAT_DoPD is implemented, EDPIDR5 is in the Core power domain. Otherwise, EDPIDR5 is in the Debug power domain
This register is present only when FEAT_ED_PIDR is implemented. Otherwise, direct accesses to EDPIDR5 are RES0.

Attributes

EDPIDR5 is a 32-bit register.

Field descriptions

Bits [31:0]

Reserved, RES0.

Accessing EDPIDR5

EDPIDR5 can be accessed through the external debug interface:

Component	Offset	Instance
Debug	0xFD4	EDPIDR5

Accessible as follows:

- When FEAT_DoPD is implemented and !IsCorePowered(), accesses to this register return an ERROR.
- Otherwise, accesses to this register are RO.

E9.2.38 **EDPIDR6, External Debug Peripheral Identification Register 6**

The EDPIDR6 characteristics are:

Purpose

Provides information to identify an external debug component.
For more information, see ‘About the Peripheral identification scheme’.

Configuration

When FEAT_DoPD is implemented, EDPIDR6 is in the Core power domain. Otherwise, EDPIDR6 is in the Debug power domain
This register is present only when FEAT_ED_PIDR is implemented. Otherwise, direct accesses to EDPIDR6 are RES0.

Attributes

EDPIDR6 is a 32-bit register.

Field descriptions

Bits [31:0]

Reserved, RES0.

Accessing EDPIDR6

EDPIDR6 can be accessed through the external debug interface:

Component	Offset	Instance
Debug	0xFD8	EDPIDR6

Accessible as follows:

- When FEAT_DoPD is implemented and !IsCorePowered(), accesses to this register return an ERROR.
- Otherwise, accesses to this register are RO.

E9.2.39 **EDPIDR7, External Debug Peripheral Identification Register 7**

The EDPIDR7 characteristics are:

Purpose

Provides information to identify an external debug component.
For more information, see ‘About the Peripheral identification scheme’.

Configuration

When FEAT_DoPD is implemented, EDPIDR7 is in the Core power domain. Otherwise, EDPIDR7 is in the Debug power domain

This register is present only when FEAT_ED_PIDR is implemented. Otherwise, direct accesses to EDPIDR7 are RES0.

Attributes

EDPIDR7 is a 32-bit register.

Field descriptions

Bits [31:0]

Reserved, RES0.

Accessing EDPIDR7

EDPIDR7 can be accessed through the external debug interface:

Component	Offset	Instance
Debug	0xFDC	EDPIDR7

Accessible as follows:

- When FEAT_DoPD is implemented and !IsCorePowered(), accesses to this register return an ERROR.
- Otherwise, accesses to this register are RO.

E9.2.40 EDPRCR, External Debug Power/Reset Control Register

The EDPRCR characteristics are:

Purpose

Controls the PE functionality related to powerup, reset, and powerdown.

Configuration

When FEAT_DoPD is implemented, EDPRCR is in the Core power domain. Otherwise, EDPRCR contains fields that are in the Core power domain and fields that are in the Debug power domain

External register EDPRCR bit [0] is architecturally mapped to AArch64 System register [DBGPRCR_EL1](#)[0].

Attributes

EDPRCR is a 32-bit register.

Field descriptions

When FEAT_DoPD is implemented:

Bits [31:2]

Reserved, RES0.

CWRR, bit [1]

Warm reset request.

The extent of the reset is IMPLEMENTATION DEFINED, but must be one of:

- The request is ignored.
- Only this PE is Warm reset.
- This PE and other components of the system, possibly including other PEs, are Warm reset.

Arm deprecates use of this bit, and recommends that implementations ignore the request.

CWRR	Meaning
0b0	No action.
0b1	Request Warm reset.

This field is in the Core power domain

In an implementation that includes the recommended external debug interface, this bit drives the **DBGIRSTREQ** signal.

The reset behavior of this field is:

- On a Warm reset, this field resets to '0'.

Accessing this field has the following behavior:

- Access to this field is RAZ/WI if any of the following are true:
 - OSLockStatus()
 - SoftwareLockStatus(addrdesc)
- Access to this field is RAZ/WI if all of the following are true:
 - !ExternalSecureInvasiveDebugEnabled()
 - FEAT_Secure is implemented
- Access to this field is RAZ/WI if all of the following are true:
 - !ExternalInvasiveDebugEnabled()
 - FEAT_Secure is not implemented
- Otherwise, access to this field is WO/RAZ.

CORENPDRQ, bit [0]

Core no powerdown request. Requests emulation of powerdown.

This request is typically passed to an external power controller. This means that whether a request causes power up is dependent on the IMPLEMENTATION DEFINED nature of the system. The power controller must not allow the Core power domain to switch off while this bit is 1.

CORENPDRQ	Meaning
0b0	If the system responds to a powerdown request, it powers down Core power domain.
0b1	If the system responds to a powerdown request, it does not powerdown the Core power domain, but instead emulates a powerdown of that domain.

When this bit reads as UNKNOWN, the PE ignores writes to this bit.

This field is in the Core power domain, and permitted accesses to this field map to the DBGPRCR.CORENPDRQ and [DBGPRCR_EL1.CORENPDRQ](#) fields.

In an implementation that includes the recommended external debug interface, this bit drives the **DBGNOPWRDWN** signal.

It is IMPLEMENTATION DEFINED whether this bit is reset to the Cold reset value on exit from an IMPLEMENTATION DEFINED software-visible retention state. For more information about retention states, see '[Core power domain power states](#)'.

Note

Writes to this bit are not prohibited by the IMPLEMENTATION DEFINED authentication interface. This means that a debugger can request emulation of powerdown regardless of whether invasive debug is permitted.

On a Cold reset, if the powerup request is implemented and the powerup request has been asserted, this field is an IMPLEMENTATION DEFINED choice of 0 or 1. If the powerup request is not asserted, this field is set to 0.

Accessing this field has the following behavior:

- When OSLockStatus(), access to this field is UNKNOWN/WI.
- When SoftwareLockStatus(addrdesc), access to this field is RO.
- Otherwise, access to this field is RW.

Otherwise:

Bits [31:4]

Reserved, RES0.

COREPURQ, bit [3]

Core powerup request. Allows a debugger to request that the power controller power up the core, enabling access to the debug register in the Core power domain, and that the power controller emulates powerdown.

This request is typically passed to an external power controller. This means that whether a request causes power up is dependent on the IMPLEMENTATION DEFINED nature of the system. The power controller must not allow the Core power domain to switch off while this bit is 1.

COREPURQ	Meaning
0b0	Do not request power up of the Core power domain.
0b1	Request power up of the Core power domain, and emulation of powerdown.

In an implementation that includes the recommended external debug interface, this bit drives the **DBGPWRUPREQ** signal.

This field is in the Debug power domain and can be read and written when the Core power domain is powered off.

Note

Writes to this bit are not prohibited by the IMPLEMENTATION DEFINED authentication interface. This means that a debugger can request emulation of powerdown regardless of whether invasive debug is permitted.

The reset behavior of this field is:

- On a External debug reset, this field resets to '0'.

Accessing this field has the following behavior:

- When SoftwareLockStatus(addrdesc), access to this field is RO.
- Otherwise, access to this field is RW.

Bit [2]

Reserved, RES0.

CWRR, bit [1]

Warm reset request.

The extent of the reset is IMPLEMENTATION DEFINED, but must be one of:

- The request is ignored.
- Only this PE is Warm reset.
- This PE and other components of the system, possibly including other PEs, are Warm reset.

Arm deprecates use of this bit, and recommends that implementations ignore the request.

CWRR	Meaning
0b0	No action.
0b1	Request Warm reset.

This field is in the Core power domain

In an implementation that includes the recommended external debug interface, this bit drives the **DBGSTREQ** signal.

The reset behavior of this field is:

- On a Warm reset, this field resets to '0'.

Accessing this field has the following behavior:

- Access to this field is RAZ/WI if any of the following are true:
 - !IsCorePowered()
 - DoubleLockStatus()
 - OSLockStatus()
 - SoftwareLockStatus(addrdesc)
- Access to this field is RAZ/WI if all of the following are true:
 - FEAT_Secure is implemented
 - !ExternalSecureInvasiveDebugEnabled()
- Access to this field is RAZ/WI if all of the following are true:
 - FEAT_Secure is not implemented
 - !ExternalInvasiveDebugEnabled()
- Otherwise, access to this field is WO/RAZ.

CORENPDRQ, bit [0]

Core no powerdown request. Requests emulation of powerdown.

This request is typically passed to an external power controller. This means that whether a request causes power up is dependent on the IMPLEMENTATION DEFINED nature of the system. The power controller must not allow the Core power domain to switch off while this bit is 1.

CORENPDRQ	Meaning
0b0	If the system responds to a powerdown request, it powers down Core power domain.
0b1	If the system responds to a powerdown request, it does not powerdown the Core power domain, but instead emulates a powerdown of that domain.

When this bit reads as UNKNOWN, the PE ignores writes to this bit.

This field is in the Core power domain, and permitted accesses to this field map to the **DBGPRCR.CORENPDRQ** and **DBGPRCR_EL1.CORENPDRQ** fields.

In an implementation that includes the recommended external debug interface, this bit drives the **DBGNOPWRDWN** signal.

It is IMPLEMENTATION DEFINED whether this bit is reset to the value of **EDPRCR.COREPURQ** on exit from an IMPLEMENTATION DEFINED software-visible retention state. For more information about retention states, see '[Core power domain power states](#)'.

Note

Writes to this bit are not prohibited by the IMPLEMENTATION DEFINED authentication interface. This means that a debugger can request emulation of powerdown regardless of whether invasive debug is permitted.

The reset behavior of this field is:

- On a Cold reset, this field resets to the value in [EDPRCR.COREPURQ](#).

Accessing this field has the following behavior:

- Access to this field is UNKNOWN/WI if any of the following are true:
 - !IsCorePowered()
 - DoubleLockStatus()
 - OSLockStatus()
- When SoftwareLockStatus(addrdesc), access to this field is RO.
- Otherwise, access to this field is RW.

Accessing EDPRCR

On permitted accesses to the register, other access controls affect the behavior of some fields. See the field descriptions for more information.

EDPRCR can be accessed through the external debug interface:

Component	Offset	Instance
Debug	0x310	EDPRCR

Accessible as follows:

- When FEAT_DoPD is implemented and !IsCorePowered(), accesses to this register return an ERROR.
- When SoftwareLockStatus(addrdesc), accesses to this register are RO.
- Otherwise, accesses to this register are RW.

E9.2.41 EDPRSR, External Debug Processor Status Register

The EDPRSR characteristics are:

Purpose

Holds information about the reset and powerdown state of the PE.

Configuration

When FEAT_DoPD is implemented, EDPRSR is in the Core power domain. Otherwise, EDPRSR contains fields that are in the Core power domain and fields that are in the Debug power domain

If FEAT_DoPD is implemented, then all fields in this register are in the Core power domain.

Attributes

EDPRSR is a 32-bit register.

Field descriptions

Bits [31:12]

Reserved, RES0.

SDR, bit [11]

Sticky Debug Restart. Set to 1 when the PE exits Debug state.

SDR	Meaning
0b0	The PE has not restarted since EDPRSR was last read.
0b1	The PE has restarted since EDPRSR was last read.

Note

If a reset occurs when the PE is in Debug state, the PE exits Debug state. SDR is UNKNOWN on Warm reset, meaning a debugger must also use the SR bit to determine whether the PE has left Debug state.

If the Core power domain is powered up, then following a read of EDPRSR:

- If FEAT_DoubleLock is not implemented or DoubleLockStatus() == FALSE, this bit clears to 0.
- If FEAT_DoubleLock is implemented and DoubleLockStatus() == TRUE, it is CONSTRAINED UNPREDICTABLE whether this bit clears to 0 or is unchanged.

This field is in the Core power domain.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing this field has the following behavior:

- Access to this field is UNKNOWN/WI if all of the following are true:
 - FEAT_DoPD is not implemented
 - !IsCorePowered()
- When DoubleLockStatus(), access to this field is UNKNOWN/WI.
- When SoftwareLockStatus(addrdesc), access to this field is RO.
- Otherwise, access to this field is RC/WI.

SPMAD, bit [10]

When FEAT_Debugv8p4 is implemented and FEAT_PMUv3_EXT is implemented:

Sticky EPMAD error. Set to 1 if an external debug interface access to a Performance Monitors register returns an error because `AllowExternalPMUAccess() == FALSE`.

SPMAD	Meaning
0b0	No Non-secure external debug interface accesses to the external Performance Monitors registers have failed because <code>AllowExternalPMUAccess() == FALSE</code> for the access since EDPRSR was last read.
0b1	At least one Non-secure external debug interface access to the external Performance Monitors register has failed and returned an error because <code>AllowExternalPMUAccess() == FALSE</code> for the access since EDPRSR was last read.

If the Core power domain is powered up, then following a read of EDPRSR:

- If [FEAT_DoubleLock](#) is not implemented or `DoubleLockStatus() == FALSE`, this bit clears to 0.
- If [FEAT_DoubleLock](#) is implemented and `DoubleLockStatus() == TRUE`, it is CONSTRAINED UNPREDICTABLE whether this bit clears to 0 or is unchanged.

This field is in the Core power domain.

The reset behavior of this field is:

- On a Cold reset, this field resets to '0'.

Accessing this field has the following behavior:

- Access to this field is UNKNOWN/WI if all of the following are true:
 - FEAT_DoPD is not implemented
 - !IsCorePowered()
- When DoubleLockStatus(), access to this field is UNKNOWN/WI.
- When SoftwareLockStatus(addrdesc), access to this field is RO.
- Otherwise, access to this field is RC/WI.

When FEAT_PMUv3_EXT is implemented:

Sticky EPMAD error.

SPMAD	Meaning
0b0	No external debug interface accesses to the Performance Monitors registers have failed because <code>AllowExternalPMUAccess() == FALSE</code> since EDPRSR was last read.
0b1	At least one external debug interface access to the Performance Monitors registers has failed and returned an error because <code>AllowExternalPMUAccess() == FALSE</code> since EDPRSR was last read.

If the Core power domain is powered up, then, following a read of EDPRSR:

- If `FEAT_DoubleLock` is not implemented or `DoubleLockStatus() == FALSE`, this bit clears to 0.
- If `FEAT_DoubleLock` is implemented, and `DoubleLockStatus() == TRUE`, it is CONstrained UNPREDICTABLE whether this bit clears to 0 or is unchanged.

This field is in the Core power domain.

The reset behavior of this field is:

- On a Cold reset, this field resets to '0'.

Accessing this field has the following behavior:

- Access to this field is UNKNOWN/WI if all of the following are true:
 - `FEAT_DoPD` is not implemented
 - `!IsCorePowered()`
- When `DoubleLockStatus()`, access to this field is UNKNOWN/WI.
- When `OSLockStatus()`, access to this field is UNKNOWN/WI.
- When `SoftwareLockStatus(addrdesc)`, access to this field is RO.
- Otherwise, access to this field is RC/WI.

Otherwise:

Reserved, RES0.

EPMAID, bit [9]

When `FEAT_Debugv8p4` is implemented and `FEAT_PMUv3_EXT` is implemented:

External Performance Monitors Access Disable status. Reports whether Non-secure access to Performance Monitor registers by an external debugger is prohibited by the `MDCR_EL3.EPMAID` control.

See `MDCR_EL3.EPMAID` for the list of affected external Performance Monitor registers.

EPMAID	Meaning
0b0	External Non-secure access to Performance Monitor registers not affected. <code>AllowExternalPMUAccess() == TRUE</code> for a Non-secure access.
0b1	External Non-secure access to affected Performance Monitor registers is prohibited. <code>AllowExternalPMUAccess() == FALSE</code> for a Non-secure access.

This field is in the Core power domain.

Accessing this field has the following behavior:

- Access to this field is UNKNOWN/WI if any of the following are true:
 - All of the following are true:
 - `FEAT_DoPD` is not implemented
 - `!IsCorePowered()`
 - `EDPRSR.R == '1'`
- When `DoubleLockStatus()`, access to this field is UNKNOWN/WI.
- Otherwise, access to this field is RO.

When `FEAT_PMUv3_EXT` is implemented:

External Performance Monitors Access Disable status. Reports whether access to Performance Monitor registers by an external debugger is prohibited by the `MDCR_EL3.EPMAID` control.

See `MDCR_EL3.EPMAID` for the list of affected external Performance Monitor registers.

EPMAID	Meaning
0b0	External access to Performance Monitor registers not affected. <code>AllowExternalPMUAccess()</code> == TRUE.
0b1	External access to affected Performance Monitor registers is prohibited. <code>AllowExternalPMUAccess()</code> == FALSE.

This field is in the Core power domain.

Accessing this field has the following behavior:

- Access to this field is UNKNOWN/WI if any of the following are true:
 - All of the following are true:
 - FEAT_DoPD is not implemented
 - !IsCorePowered()
 - EDPRSR.R == '1'
- When DoubleLockStatus(), access to this field is UNKNOWN/WI.
- When OSLockStatus(), access to this field is UNKNOWN/WI.
- Otherwise, access to this field is RO.

When FEAT_PMuV3 is implemented:

Reserved, UNKNOWN.

Otherwise:

Reserved, RES0.

SDAD, bit [8]

When FEAT_Debugv8p4 is implemented:

Sticky EDAD error. Set to 1 if an external debug interface access to a debug register returns an error because `AllowExternalDebugAccess()` == FALSE.

SDAD	Meaning
0b0	No Non-secure external debug interface accesses to the debug registers have failed because <code>AllowExternalDebugAccess()</code> == FALSE for the access since EDPRSR was last read.
0b1	At least one Non-secure external debug interface access to the debug registers has failed and returned an error because <code>AllowExternalDebugAccess()</code> == FALSE for the access since EDPRSR was last read.

If the Core power domain is powered up, then, following a read of EDPRSR:

- If FEAT_DoubleLock is not implemented or `DoubleLockStatus()` == FALSE, this bit clears to 0.
- If FEAT_DoubleLock is implemented and `DoubleLockStatus()` == TRUE, it is CONSTRAINED UNPREDICTABLE whether this bit clears to 0 or is unchanged.

This field is in the Core power domain.

The reset behavior of this field is:

- On a Cold reset, this field resets to '0'.

Accessing this field has the following behavior:

- Access to this field is UNKNOWN/WI if any of the following are true:
 - All of the following are true:
 - FEAT_DoPD is not implemented
 - !IsCorePowered()

- EDPRSR.R == '1'
- When DoubleLockStatus(), access to this field is UNKNOWN/WI.
- Otherwise, access to this field is RO.

Otherwise:

Sticky EDAD error. Set to 1 if an external debug interface access to a debug register returns an error because AllowExternalDebugAccess() == FALSE.

SDAD	Meaning
0b0	No external debug interface accesses to the debug registers have failed because AllowExternalDebugAccess() == FALSE since EDPRSR was last read.
0b1	At least one external debug interface access to the debug registers has failed and returned an error because AllowExternalDebugAccess() == FALSE since EDPRSR was last read.

If the Core power domain is powered up, then, following a read of EDPRSR:

- If FEAT_DoubleLock is not implemented or DoubleLockStatus() == FALSE, this bit clears to 0.
- If FEAT_DoubleLock is implemented and DoubleLockStatus() == TRUE, it is CONSTRAINED UNPREDICTABLE whether this bit clears to 0 or is unchanged.

This field is in the Core power domain.

The reset behavior of this field is:

- On a Cold reset, this field resets to '0'.

Accessing this field has the following behavior:

- Access to this field is UNKNOWN/WI if any of the following are true:
 - All of the following are true:
 - FEAT_DoPD is not implemented
 - !IsCorePowered()
 - EDPRSR.R == '1'
- When DoubleLockStatus(), access to this field is UNKNOWN/WI.
- Access to this field is UNKNOWN/WI if all of the following are true:
 - OSLockStatus()
 - external debug writes to OSLAR_EL1 do not return an error when AllowExternalDebugAccess(addrdesc) == FALSE
- Otherwise, access to this field is RO.

EDAD, bit [7]

When FEAT_Debugv8p4 is implemented:

External Debug Access Disable status. Reports whether Non-secure access to breakpoint registers, watchpoint registers, and OSLAR_EL1 by an external debugger is prohibited by the MDCR_EL3.EDAD control.

See MDCR_EL3.EDAD for the list of affected external debug registers.

EDAD	Meaning
0b0	External Non-secure access to debug registers not affected. AllowExternalDebugAccess() == TRUE for a Non-secure access.

EDAD	Meaning
0b1	External Non-secure access to affected debug registers is prohibited. <code>AllowExternalDebugAccess()</code> == FALSE for a Non-secure access.

This field is in the Core power domain.

Accessing this field has the following behavior:

- Access to this field is UNKNOWN/WI if any of the following are true:
 - All of the following are true:
 - FEAT_DoPD is not implemented
 - !IsCorePowered()
 - EDPRSR.R == '1'
- When DoubleLockStatus(), access to this field is UNKNOWN/WI.
- Otherwise, access to this field is RO.

When FEAT_Debugv8p2 is implemented:

External Debug Access Disable status. Reports whether access to breakpoint registers, watchpoint registers, and [OSLAR_EL1](#) by an external debugger is prohibited by the MDCR_EL3.EDAD control.

See MDCR_EL3.EDAD for the list of affected external debug registers.

EDAD	Meaning
0b0	External access to debug registers not affected. <code>AllowExternalDebugAccess()</code> == TRUE.
0b1	External access to affected debug registers is prohibited. <code>AllowExternalDebugAccess()</code> == FALSE.

This field is in the Core power domain.

Accessing this field has the following behavior:

- Access to this field is UNKNOWN/WI if any of the following are true:
 - All of the following are true:
 - FEAT_DoPD is not implemented
 - !IsCorePowered()
 - EDPRSR.R == '1'
- When DoubleLockStatus(), access to this field is UNKNOWN/WI.
- Access to this field is UNKNOWN/WI if all of the following are true:
 - OSLockStatus()
 - external debug writes to OSLAR_EL1 do not return an error when `AllowExternalDebugAccess(addrdesc)` == FALSE
- Otherwise, access to this field is RO.

Otherwise:

External Debug Access Disable status. Reports whether access to breakpoint registers, watchpoint registers, and optionally [OSLAR_EL1](#) by an external debugger is prohibited by the MDCR_EL3.EDAD control.

See MDCR_EL3.EDAD for the list of affected external debug registers.

EDAD	Meaning
0b0	External access to debug registers not affected. <code>AllowExternalDebugAccess()</code> == TRUE.

EDAD	Meaning
0b1	External access to affected debug registers is prohibited. <code>AllowExternalDebugAccess()</code> == FALSE.

This field is in the Core power domain.

Accessing this field has the following behavior:

- Access to this field is UNKNOWN/WI if any of the following are true:
 - All of the following are true:
 - `FEAT_DoPD` is not implemented
 - `!IsCorePowered()`
 - `EDPRSR.R` == '1'
- When `DoubleLockStatus()`, access to this field is UNKNOWN/WI.
- Otherwise, access to this field is RO.

DLK, bit [6]

When `FEAT_Debugv8p4` is implemented:

This field is RES0.

When `FEAT_Debugv8p2` is implemented and `FEAT_DoubleLock` is implemented:

Double Lock. From Armv8.2, use of this field is deprecated.

This field is in the Core power domain.

Accessing this field has the following behavior:

- Access to this field is UNKNOWN/WI if any of the following are true:
 - `!IsCorePowered()`
 - `DoubleLockStatus()`
- Otherwise, access to this field is RAZ/WI.

When `FEAT_DoubleLock` is implemented:

Double Lock.

This field returns the result of the pseudocode function `DoubleLockStatus()`.

If the Core power domain is powered up and `DoubleLockStatus() == TRUE`, it is IMPLEMENTATION DEFINED whether:

- `EDPRSR.PU` reads as 1, `EDPRSR.DLK` reads as 1, and `EDPRSR.SPD` is UNKNOWN.
- `EDPRSR.PU` reads as 0, `EDPRSR.DLK` is UNKNOWN, and `EDPRSR.SPD` reads as 0.

This field is in the Core power domain.

DLK	Meaning
0b0	<code>DoubleLockStatus()</code> returns FALSE.
0b1	<code>DoubleLockStatus()</code> returns TRUE and the Core power domain is powered up.

Accessing this field has the following behavior:

- When `!IsCorePowered()`, access to this field is UNKNOWN/WI.
- Otherwise, access to this field is RO.

Otherwise:

Reserved, RES0.

OSLK, bit [5]

OS Lock status bit.

A read of this bit returns the value of [OSLSR_EL1.OSLK](#).

This field is in the Core power domain.

Accessing this field has the following behavior:

- Access to this field is UNKNOWN/WI if any of the following are true:
 - All of the following are true:
 - FEAT_DoPD is not implemented
 - !IsCorePowered()
 - EDPRSR.R == '1'
- When DoubleLockStatus(), access to this field is UNKNOWN/WI.
- Otherwise, access to this field is RO.

HALTED, bit [4]

Halted status bit.

HALTED	Meaning
0b0	PE is in Non-debug state.
0b1	PE is in Debug state.

This field is in the Core power domain.

Accessing this field has the following behavior:

- Access to this field is UNKNOWN/WI if all of the following are true:
 - FEAT_DoPD is not implemented
 - !IsCorePowered()
- Otherwise, access to this field is RO.

SR, bit [3]

Sticky core Reset status bit.

SR	Meaning
0b0	The non-debug logic of the PE is not in reset state and has not been reset since the last time EDPRSR was read.
0b1	The non-debug logic of the PE is in reset state or has been reset since the last time EDPRSR was read.

If EDPRSR.PU reads as 1 and EDPRSR.R reads as 0, which means that the Core power domain is in a powerup state and that the non-debug logic of the PE is not in reset state, then following a read of EDPRSR:

- If [FEAT_DoubleLock](#) is not implemented or DoubleLockStatus() == FALSE, this bit clears to 0.
- If [FEAT_DoubleLock](#) is implemented and DoubleLockStatus() == TRUE, it is CONSTRAINED UNPREDICTABLE whether this bit clears to 0 or is unchanged.

This field is in the Core power domain.

The reset behavior of this field is:

- On a Warm reset, this field resets to '1'.

Accessing this field has the following behavior:

- Access to this field is UNKNOWN/WI if all of the following are true:
 - FEAT_DoPD is not implemented
 - !IsCorePowered()
- When DoubleLockStatus(), access to this field is UNKNOWN/WI.
- When SoftwareLockStatus(addrdesc), access to this field is RO.
- Otherwise, access to this field is RC/WI.

R, bit [2]

PE Reset status bit.

R	Meaning
0b0	The non-debug logic of the PE is not in reset state.
0b1	The non-debug logic of the PE is in reset state.

If [FEAT_DoubleLock](#) is implemented, the PE is in reset state, and the PE entered reset state with the OS Double Lock locked this bit has a CONSTRAINED UNPREDICTABLE value. For more information, see '[EDPRSR.{DLK, R} and reset state](#)'.

This field is in the Core power domain.

Accessing this field has the following behavior:

- Access to this field is UNKNOWN/WI if any of the following are true:
 - All of the following are true:
 - FEAT_DoPD is not implemented
 - !IsCorePowered()
 - DoubleLockStatus()
- Otherwise, access to this field is RO.

SPD, bit [1]

Sticky core Powerdown status bit.

If [FEAT_DoubleLock](#) is implemented and `DoubleLockStatus() == TRUE`, then:

- If [FEAT_Debugv8p2](#) is implemented, this bit reads as 0.
- If [FEAT_Debugv8p2](#) is not implemented, this bit might read as 0 or 1.

For more information, see '[EDPRSR.{DLK, SPD, PU} and the Core power domain](#)'.

SPD	Meaning
0b0	If EDPRSR.PU is 0, it is not known whether the state of the debug registers in the Core power domain is lost. If EDPRSR.PU is 1, the state of the debug registers in the Core power domain has not been lost.
0b1	The state of the debug registers in the Core power domain has been lost.

If the Core power domain is powered up, then, following a read of EDPRSR:

- If [FEAT_DoubleLock](#) is not implemented or `DoubleLockStatus() == FALSE`, this bit clears to 0.

- If **FEAT_DoubleLock** is implemented and `DoubleLockStatus() == TRUE`, it is CONSTRAINED UNPREDICTABLE whether this bit clears to 0 or is unchanged.

EDPRSR.{DLK, SPD, PU} describe whether registers in the Core power domain can be accessed, and whether their state has been lost since the last time the register was read. For more information, see ‘[EDPRSR.{DLK, SPD, PU} and the Core power domain](#)’.

When **FEAT_DoPD** is not implemented and the Core power domain is in either retention or powerdown state, the value of EDPRSR.SPD is IMPLEMENTATION DEFINED. For more information, see ‘[EDPRSR.SPD when the Core domain is in either retention or powerdown state](#)’.

The reset behavior of this field is:

- On a Cold reset, this field resets to '1'.

Accessing this field has the following behavior:

- Access to this field is RAZ/WI if all of the following are true:
 - FEAT_DoPD is not implemented
 - !IsCorePowered()
- Access to this field is UNKNOWN/WI if all of the following are true:
 - IsCorePowered()
 - DoubleLockStatus()
- Otherwise, access to this field is RC/WI.

PU, bit [0]

When FEAT_DoPD is implemented:

Core powerup status bit.

Access to this field is RAO/WI.

When FEAT_Debugv8p2 is implemented:

Core Powerup status bit. Indicates whether the debug registers in the Core power domain can be accessed.

PU	Meaning
0b0	Either the Core power domain is in a low-power or powerdown state, or FEAT_DoubleLock is implemented and <code>DoubleLockStatus() == TRUE</code> , meaning the debug registers in the Core power domain cannot be accessed.
0b1	The Core power domain is in a powerup state, and either FEAT_DoubleLock is not implemented or <code>DoubleLockStatus() == FALSE</code> , meaning the debug registers in the Core power domain can be accessed.

If **FEAT_DoubleLock** is implemented, the PE is in reset state, and the PE entered reset state with the OS Double Lock locked this bit has a CONSTRAINED UNPREDICTABLE value. For more information, see ‘[EDPRSR.{DLK, R} and reset state](#)’

EDPRSR.{DLK, SPD, PU} describe whether registers in the Core power domain can be accessed, and whether their state has been lost since the last time the register was read. For more information, see ‘[EDPRSR.{DLK, SPD, PU} and the Core power domain](#)’

Access to this field is RO.

Otherwise:

Core Powerup status bit. Indicates whether the debug registers in the Core power domain can be accessed.

PU	Meaning
0b0	Core power domain is in a low-power or powerdown state where the debug registers in the Core power domain cannot be accessed.
0b1	Core power domain is in a powerup state where the debug registers in the Core power domain can be accessed.

If [FEAT_DoubleLock](#) is implemented, the PE is in reset state, and the PE entered reset state with the OS Double Lock locked this bit has a CONSTRAINED UNPREDICTABLE value. For more information see ‘[EDPRSR.{DLK, R} and reset state](#)’

EDPRSR.{DLK, SPD, PU} describe whether registers in the Core power domain can be accessed, and whether their state has been lost since the last time the register was read. For more information, see ‘[EDPRSR.{DLK, SPD, PU} and the Core power domain](#)’.

When the Core power domain is powered-up and `DoubleLockStatus() == TRUE`, then the value of EDPRSR.PU is IMPLEMENTATION DEFINED. See the description of the DLK bit for more information.

If [FEAT_DoubleLock](#) is implemented, the Core power domain is powered up, and `DoubleLockStatus() == TRUE`, it is IMPLEMENTATION DEFINED whether this bit reads as 0 or 1.

Access to this field is RO.

Accessing EDPRSR

On permitted accesses to the register, other access controls affect the behavior of some fields. See the field descriptions for more information.

If the Core power domain is powered up (EDPRSR.PU == 1), then following a read of EDPRSR:

- If [FEAT_DoubleLock](#) is not implemented or `DoubleLockStatus() == FALSE`, then:
 - EDPRSR.{SDR, SPMAD, SDAD, SPD} are cleared to 0.
 - EDPRSR.SR is cleared to 0 if the non-debug logic of the PE is not in reset state (EDPRSR.R == 0).
- If [FEAT_DoubleLock](#) is implemented and `DoubleLockStatus() == TRUE`, it is CONSTRAINED UNPREDICTABLE whether or not this clearing occurs.

If [FEAT_DoPD](#) is not implemented and the Core power domain is powered down (EDPRSR.PU == 0), then:

- EDPRSR.{SDR, SPMAD, SDAD, SR} are all UNKNOWN, and are either reset or restored on being powered up.
- EDPRSR.SPD is not cleared following a read of EDPRSR. See the SPD bit description for more information.

The clearing of bits is an indirect write to EDPRSR.

EDPRSR can be accessed through the external debug interface:

Component	Offset	Instance
Debug	0x314	EDPRSR

Accessible as follows:

- When [FEAT_DoPD](#) is implemented and `!IsCorePowered()`, accesses to this register return an ERROR.
- Otherwise, accesses to this register are RO.

E9.2.42 EDRCR, External Debug Reserve Control Register

The EDRCR characteristics are:

Purpose

This register is used to allow imprecise entry to Debug state and clear sticky bits in [EDSCR](#).

Configuration

EDRCR is in the Core power domain

Attributes

EDRCR is a 32-bit register.

Field descriptions

Bits [31:5]

Reserved, RES0.

CBRRQ, bit [4]

Allow imprecise entry to Debug state. The actions on writing to this bit are:

CBRRQ	Meaning
0b0	No action.
0b1	Allow imprecise entry to Debug state, for example by canceling pending bus accesses.

Setting this bit to 1 allows a debugger to request imprecise entry to Debug state. An External Debug Request debug event must be pending before the debugger sets this bit to 1.

This feature is optional. If this feature is not implemented, writes to this bit are ignored.

CSPA, bit [3]

Clear Sticky Pipeline Advance. This bit is used to clear the [EDSCR](#).PipeAdv bit to 0. The actions on writing to this bit are:

CSPA	Meaning
0b0	No action.
0b1	Clear the EDSCR .PipeAdv bit to 0.

CSE, bit [2]

Clear Sticky Error. Used to clear the [EDSCR](#) cumulative error bits to 0. The actions on writing to this bit are:

CSE	Meaning
0b0	No action.
0b1	Clear the EDSCR .{TXU, RXO, ERR} bits, and, if the PE is in Debug state, the EDSCR .ITO bit, to 0.

Bits [1:0]

Reserved, RES0.

Accessing EDRCR

EDRCR can be accessed through the external debug interface:

Component	Offset	Instance
Debug	0x090	EDRCR

Accessible as follows:

- When DoubleLockStatus(), or !IsCorePowered(), or OSLockStatus(), accesses to this register return an ERROR.
- When SoftwareLockStatus(addrdesc), accesses to this register are WI.
- Otherwise, accesses to this register are WO.

E9.2.43 EDSCR, External Debug Status and Control Register

The EDSCR characteristics are:

Purpose

Main control register for the debug implementation.

Configuration

EDSCR is in the Core power domain

External register EDSCR bits [31:29, 27:26, 23:21, 19, 14, 6] are architecturally mapped to AArch64 System register [MDSCR_EL1](#)[31:29, 27:26, 23:21, 19, 14, 6].

External register EDSCR bits [30:29] are architecturally mapped to AArch64 System register [MDCCSR_EL0](#)[30:29].

Attributes

EDSCR is a 32-bit register.

Field descriptions

TFO, bit [31]

When FEAT_TRF is implemented:

Trace Filter Override. Overrides the Trace Filter controls allowing the external debugger to trace any visible Exception level.

TFO	Meaning
0b0	Trace Filter controls are not affected.
0b1	Trace Filter controls in TRFCR_EL1 and TRFCR_EL2 are ignored.

When [OSLSR_EL1](#).OSLK is 1, this bit can be indirectly read and written through [MDSCR_EL1](#).

This bit is ignored by the PE when `ExternalSecureNoninvasiveDebugEnabled()` is FALSE.

The reset behavior of this field is:

- On a Cold reset, this field resets to '0'.

Otherwise:

Reserved, RES0.

RXfull, bit [30]

DTRRX full.

When [OSLSR_EL1](#).OSLK is 1, this bit can be indirectly read and written through [MDSCR_EL1](#).

The reset behavior of this field is:

- On a Cold reset, this field resets to '0'.

Access to this field is RO.

TXfull, bit [29]

DTRTX full.

When [OSLSR_EL1](#).OSLK is 1, this bit can be indirectly read and written through [MDSCR_EL1](#).

The reset behavior of this field is:

- On a Cold reset, this field resets to '0'.

Access to this field is RO.

ITO, bit [28]

ITR overrun. Set to 0 on entry to Debug state.

Accessing this field has the following behavior:

- When the PE is in Non-debug state, access to this field is UNKNOWN/WI.
- Otherwise, access to this field is RO.

RXO, bit [27]

DTRRX overrun.

When [OSLSR_EL1](#).OSLK is 1, this bit can be indirectly read and written through [MDSCR_EL1](#).

The reset behavior of this field is:

- On a Cold reset, this field resets to '0'.

Access to this field is RO.

TXU, bit [26]

DTRTX underrun.

When [OSLSR_EL1](#).OSLK is 1, this bit can be indirectly read and written through [MDSCR_EL1](#).

The reset behavior of this field is:

- On a Cold reset, this field resets to '0'.

Access to this field is RO.

PipeAdv, bit [25]

Pipeline Advance. Indicates that software execution is progressing.

PipeAdv	Meaning
0b0	No progress has been made by the PE since the last time this field was cleared to zero by writing 1 to EDRCR.CSPA .
0b1	Progress has been made by the PE since the last time this field was cleared to zero by writing 1 to EDRCR.CSPA .

The architecture does not define precisely when this field is set to 1. It requires only that this happen periodically in Non-debug state to indicate that software execution is progressing. For example, a PE might set this field to 1 each time the PE retires one or more instructions, or at periodic intervals during the progression of an instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Access to this field is RO.

ITE, bit [24]

ITR empty.

Accessing this field has the following behavior:

- When the PE is in Non-debug state, access to this field is UNKNOWN/WI.
- Otherwise, access to this field is RO.

INTdis, bits [23:22]

When FEAT_Debugv8p4 is implemented:

Interrupt and SError exception disable. Disables taking interrupts and SError exceptions in Non-debug state.

INTdis	Meaning
0b00	Masking of interrupts and SError exceptions is controlled by PSTATE and interrupt routing controls.
0b01	If ExternalInvasiveDebugEnabled() is TRUE, then all interrupts and SError exceptions taken to Non-secure state are masked. If ExternalSecureInvasiveDebugEnabled() is TRUE, then all interrupts and SError exceptions taken to Secure state are masked.

Note

This control affects both physical and virtual interrupts and SError exceptions.

When [OSLSR_EL1](#).OSLK is 1, this field can be indirectly read and written through the following System registers:

- [MDSCR_EL1](#).

The Effective value of this field is 0b00 when ExternalInvasiveDebugEnabled() is FALSE.

When FEAT_Debugv8p4 is implemented, bit[23] of this register is RES0.

The reset behavior of this field is:

- On a Cold reset, this field resets to '00'.

Otherwise:

Interrupt and SError exception disable. Disables taking interrupts and SError exceptions in Non-debug state.

INTdis	Meaning
0b00	Masking of interrupts and SError exceptions is controlled by PSTATE and interrupt routing controls.
0b01	If ExternalInvasiveDebugEnabled() is TRUE, then all interrupts and SError exceptions taken to Non-secure EL1 are masked.
0b10	If ExternalInvasiveDebugEnabled() is TRUE, then all interrupts and SError exceptions taken to Non-secure state are masked. If ExternalSecureInvasiveDebugEnabled() is TRUE, then all interrupts and SError exceptions taken to Secure EL1 are masked.

INTdis	Meaning
0b11	If ExternalInvasiveDebugEnabled() is TRUE, then all interrupts and SError exceptions taken to Non-secure state are masked. If ExternalSecureInvasiveDebugEnabled() is TRUE, then all interrupts and SError exceptions taken to Secure state are masked.

———— **Note** ————

This control affects both physical and virtual interrupts and SError exceptions.

When [OSLSR_EL1.OSLK](#) is 1, this field can be indirectly read and written through the following System registers:

- [MDSCR_EL1](#).

The Effective value of this field is 0b00 when ExternalInvasiveDebugEnabled() is FALSE.

Support for the values 0b01 and 0b10 is IMPLEMENTATION DEFINED. If these values are not supported, they are reserved. If programmed with a reserved value, the PE behaves as if EDSCR.INTdis has been programmed with a defined value, other than for a direct read of EDSCR, and the value returned by a read of EDSCR.INTdis is UNKNOWN.

The reset behavior of this field is:

- On a Cold reset, this field resets to '00'.

TDA, bit [21]

Traps accesses to the following debug registers:

- AArch64: [DBGBCR<n>_EL1](#), [DBGBVR<n>_EL1](#), [DBGWCR<n>_EL1](#), [DBGWVR<n>_EL1](#).

TDA	Meaning
0b0	Accesses to debug registers do not generate a Software Access Debug event.
0b1	Accesses to debug registers generate a Software Access Debug event, if OSLSR_EL1.OSLK is 0 and if halting is allowed.

When [OSLSR_EL1.OSLK](#) is 1, this bit can be indirectly read and written through [MDSCR_EL1](#).

The reset behavior of this field is:

- On a Cold reset, this field resets to '0'.

MA, bit [20]

Memory access mode. Controls the use of Memory access mode for accessing ITR and the DCC. This bit is ignored if in Non-debug state and set to zero on entry to Debug state.

Possible values of this field are:

MA	Meaning
0b0	Normal access mode.

0b1	Memory access mode.
-----	---------------------

The reset behavior of this field is:

- On a Cold reset, this field resets to '0'.

Bit [19]

Reserved, RES0.

NS, bit [18]

Non-secure status. In Debug state, gives the current Security state:

NS	Meaning
0b0	Secure state.
0b1	Non-secure state.

Accessing this field has the following behavior:

- When the PE is in Non-debug state, access to this field is UNKNOWN/WI.
- Otherwise, access to this field is RO.

Bit [17]

Reserved, RES0.

SDD, bit [16]

When FEAT_Secure is implemented:

Secure debug disabled.

On entry to Debug state, SDD is set to 0.

In Debug state, the value of the SDD bit does not change, even if `ExternalSecureInvasiveDebugEnabled()` changes.

In Non-debug state, SDD returns the inverse of `ExternalSecureInvasiveDebugEnabled()`. If the authentication signals that control `ExternalSecureInvasiveDebugEnabled()` change, then a context synchronization event is required to guarantee their effect.

Access to this field is RO.

Otherwise:

Reserved, RES1.

Bit [15]

Reserved, RES0.

HDE, bit [14]

Halting debug enable.

HDE	Meaning
0b0	Halting disabled for Breakpoint, Watchpoint and Halt Instruction debug events.
0b1	Halting enabled for Breakpoint, Watchpoint and Halt Instruction debug events.

When [OSLSR_EL1](#).OSLK is 1, this bit can be indirectly read and written through [MDSCR_EL1](#).

The reset behavior of this field is:

- On a Cold reset, this field resets to '0'.

RW, bits [13:10]

Exception level Execution state status. In Debug state, each bit gives the current Execution state of each Exception level.

RW	Meaning
0b1111	Any of the following: - The PE is in Non-debug state. - The PE is at EL0 using AArch64. - The PE is not at EL0, and EL1 is using AArch64. If implemented and enabled in the current Security state, EL2 and EL3 are using AArch64.

Accessing this field has the following behavior:

- When the PE is in Non-debug state, access to this field is RAO/WI.
- Otherwise, access to this field is RO.

EL, bits [9:8]

Exception level. In Debug state, gives the current Exception level of the PE.

Accessing this field has the following behavior:

- When the PE is in Non-debug state, access to this field is RAZ/WI.
- Otherwise, access to this field is RO.

A, bit [7]

SError exception pending. In Debug state, indicates whether an SError exception is pending:

- If EL2 is enabled in the current Security state, the PE is executing at EL0 or EL1, and [HCR_EL2](#).{AMO, TGE} is {1, 0}, a virtual SError exception.
- Otherwise, a physical SError exception.

A	Meaning
0b0	No SError exception pending.
0b1	SError exception pending.

A debugger can read EDSCR to check whether an SError exception is pending without having to execute further instructions. A pending SError might indicate data from target memory is corrupted.

Accessing this field has the following behavior:

- When the PE is in Non-debug state, access to this field is UNKNOWN/WI.
- Otherwise, access to this field is RO.

ERR, bit [6]

Cumulative error flag. This bit is set to 1 following exceptions in Debug state and on any signaled overrun or underrun on the DTR or EDITR.

When [OSLSR_EL1.OSLK](#) is 1, this bit can be indirectly read and written through [MDSCR_EL1](#).

The reset behavior of this field is:

- On a Cold reset, this field resets to '0'.

Access to this field is RO.

STATUS, bits [5:0]

On entering Debug state, the PE sets this field to indicate the reason for halting.

STATUS	Meaning
0b000001	PE is restarting, exiting Debug state.
0b000010	PE is in Non-debug state.
0b000111	Breakpoint.
0b010011	External debug request.
0b011011	Halting step, normal.
0b011111	Halting step, exclusive.
0b100011	OS Unlock Catch.
0b100111	Reset Catch.
0b101011	Watchpoint.
0b101111	HLT instruction.
0b110011	Software access to debug register.
0b110111	Exception Catch.
0b111011	Halting step, no syndrome.

All other values are reserved.

The PE resets into Non-debug state. However, if the PE enters Debug state immediately after reset, then the reset value is overwritten with the reason for halting.

Arm deprecates software use of the Halting step, normal and Halting step, exclusive values.

The reset behavior of this field is:

- On a Cold reset, this field resets to '000010'.

Access to this field is RO.

Accessing EDSCR

EDSCR can be accessed through the external debug interface:

Component	Offset	Instance
Debug	0x088	EDSCR

Accessible as follows:

- When DoubleLockStatus(), or !IsCorePowered(), or OSLockStatus(), accesses to this register return an ERROR.
- When SoftwareLockStatus(addrdesc), accesses to this register are RO.
- Otherwise, accesses to this register are RW.

E9.2.44 EDWAR, External Debug Watchpoint Address Register

The EDWAR characteristics are:

Purpose

Returns the virtual data address being accessed when a Watchpoint Debug Event was triggered.

Configuration

EDWAR is in the Core power domain

The value of this register is UNKNOWN if the PE is in Non-debug state, or if [EDSCR.STATUS](#) is not 0b101011.

Attributes

EDWAR is a 64-bit register.

Field descriptions

ADDR, bits [63:0]

Watchpoint address. The data virtual address being accessed when a Watchpoint Debug Event was triggered and caused entry to Debug state. This address must be within a naturally-aligned block of memory of power-of-two size no larger than the [DC ZVA](#) block size.

The value of this register is UNKNOWN if the PE is in Non-debug state, or if Debug state was entered other than for a Watchpoint debug event.

The EDWAR is subject to the same alignment rules as the reporting of a watchpointed address in the FAR. See ‘[Exception syndrome information and preferred return address](#)’.

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

Accessing EDWAR

EDWAR can be accessed through the external debug interface:

Component	Offset	Instance
Debug	0x030	EDWAR

Accessible as follows:

- When DoubleLockStatus(), or !IsCorePowered(), or OSLockStatus(), accesses to this register return an ERROR.
- Otherwise, accesses to this register are RO.

E9.2.45 MIDR_EL1, Main ID Register

The MIDR_EL1 characteristics are:

Purpose

Provides identification information for the PE, including an implementer code for the device and a device ID number.

Configuration

The power domain of MIDR_EL1 is IMPLEMENTATION DEFINED

External register MIDR_EL1 bits [31:0] are architecturally mapped to AArch64 System register [MIDR_EL1](#)[31:0].

Attributes

MIDR_EL1 is a 32-bit register.

Field descriptions

31	24	23	20	19	16	15		4	3	0
Implementer			Variant		Architecture		PartNum			Revision

Implementer, bits [31:24]

The Implementer code. This field must hold an implementer code that has been assigned by Arm.

The value of this field is an IMPLEMENTATION DEFINED choice of:

Implementer	Meaning
0x00	Reserved for software use.
0x41	Arm Limited.
0x42	Broadcom Corporation.
0x43	Cavium Inc.
0x44	Digital Equipment Corporation.
0x46	Fujitsu Ltd.
0x49	Infineon Technologies AG.
0x4D	Motorola or Freescale Semiconductor Inc.
0x4E	NVIDIA Corporation.
0x50	Applied Micro Circuits Corporation.
0x51	Qualcomm Inc.
0x56	Marvell International Ltd.
0x69	Intel Corporation.
0xC0	Ampere Computing.

Arm can assign codes that are not published in this manual. All values not assigned by Arm are reserved and must not be used.

Access to this field is RO.

Variant, bits [23:20]

Variant number. Typically, this field is used to distinguish between different product variants, or major revisions of a product.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

Architecture, bits [19:16]

Architecture version.

The value of this field is an IMPLEMENTATION DEFINED choice of:

Architecture	Meaning
0b0001	Armv4.
0b0010	Armv4T.
0b0011	Armv5 (obsolete).
0b0100	Armv5T.
0b0101	Armv5TE.
0b0110	Armv5TEJ.
0b0111	Armv6.
0b1111	Architectural features are individually identified in the ID_* registers.

All other values are reserved.

Access to this field is RO.

PartNum, bits [15:4]

Primary Part Number for the device.

On processors implemented by Arm, if the top four bits of the primary part number are 0x0 or 0x7, the variant and architecture are encoded differently.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

Revision, bits [3:0]

Revision number for the device.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

Accessing MIDR_EL1

MIDR_EL1 can be accessed through the external debug interface:

Component	Offset	Instance
Debug	0xD00	MIDR_EL1

Accessible as follows:

- When DoubleLockStatus() or !IsCorePowered(), accesses to this register are IMPLEMENTATION DEFINED.
- Otherwise, accesses to this register are RO.

E9.2.46 OSLAR_EL1, OS Lock Access Register

The OSLAR_EL1 characteristics are:

Purpose

Used to lock or unlock the OS Lock.

Configuration

OSLAR_EL1 is in the Core power domain

If [FEAT_Debugv8p2](#) is not implemented, it is IMPLEMENTATION DEFINED whether external debug accesses to OSLAR_EL1 are ignored and return an error when `AllowExternalDebugAccess()` returns FALSE for the access.

If [FEAT_Debugv8p2](#) is implemented, external debug accesses to OSLAR_EL1 are ignored and return an error when `AllowExternalDebugAccess()` returns FALSE for the access.

External register OSLAR_EL1 bits [31:0] are architecturally mapped to AArch64 System register [OSLAR_EL1](#)[31:0].

Attributes

OSLAR_EL1 is a 32-bit register.

Field descriptions

Bits [31:1]

Reserved, RES0.

OSLK, bit [0]

On writes to OSLAR_EL1, bit[0] is copied to the OS Lock.

Use [EDPRSR.OSLK](#) to check the current status of the lock.

Accessing OSLAR_EL1

OSLAR_EL1 can be accessed through the external debug interface:

Component	Offset	Instance
Debug	0x300	OSLAR_EL1

Accessible as follows:

- When `(DoubleLockStatus() || (!IsCorePowered())) || ((!AllowExternalDebugAccess(addrdesc)) && IsFeatureImplemented(FEAT_Debugv8p2))`, accesses to this register return an ERROR.
- When `AllowExternalDebugAccess(addrdesc)` and `SoftwareLockStatus(addrdesc)`, accesses to this register are WI.
- When `AllowExternalDebugAccess(addrdesc)` and `!SoftwareLockStatus(addrdesc)`, accesses to this register are WO.
- Otherwise, accesses to this register are IMPLEMENTATION DEFINED.

E9.3 External trace registers

This section lists the external Trace unit registers.

E9.4 Cross-Trigger Interface registers

This section lists the Cross-Trigger Interface registers.

E9.4.1 ASICCTL, CTI External Multiplexer Control register

The ASICCTL characteristics are:

Purpose

Can be used to provide IMPLEMENTATION DEFINED controls for the CTI. For example, the register might be used to control multiplexors for additional IMPLEMENTATION DEFINED triggers. The IMPLEMENTATION DEFINED controls provided by this register might modify the architecturally defined behavior of the CTI.

Note

The architecturally-defined triggers must not be multiplexed.

Configuration

It is IMPLEMENTATION DEFINED whether ASICCTL is implemented in the Core power domain or in the Debug power domain

If it is implemented in the Core power domain, then it is IMPLEMENTATION DEFINED whether it is in the Cold reset domain or the Warm reset domain.

This register must reset to a value that supports the architecturally-defined behavior of the CTI. Changing the value of the register from its reset value causes IMPLEMENTATION DEFINED behavior that might differ from the architecturally-defined behavior of the CTI.

Other than the requirements listed in this register description, all aspects of the reset behavior of the ASICCTL are IMPLEMENTATION DEFINED.

Attributes

ASICCTL is a 32-bit register.

Field descriptions

IMPLEMENTATION DEFINED, bits [31:0]

IMPLEMENTATION DEFINED.

Accessing ASICCTL

ASICCTL can be accessed through the external debug interface:

Component	Offset	Instance
CTI	0x144	ASICCTL

Accessible as follows:

- When IsCorePowered(), !DoubleLockStatus(), !OSLockStatus(), AllowExternalDebugAccess(addrdesc), and SoftwareLockStatus(addrdesc), accesses to this register are RO.
- Otherwise, accesses to this register are IMPLEMENTATION DEFINED.

E9.4.2 CTIAPPCLEAR, CTI Application Trigger Clear register

The CTIAPPCLEAR characteristics are:

Purpose

Clears the application triggers.

Configuration

CTIAPPCLEAR is in the Debug power domain

External register CTIAPPCLEAR bits [31:0] are architecturally mapped to External register CTIAPPSET[31:0].

Attributes

CTIAPPCLEAR is a 32-bit register.

Field descriptions

APPCLEAR<x> , bits [x], for x = 31 to 0

Application trigger <x> disable.

Writing to this bit has the following effect:

APPCLEAR<x>	Meaning
0b0	No effect.
0b1	Clear corresponding application trigger to 0 and clear the corresponding channel event.

If the ECT does not support multicycle channel events, use of CTIAPPCLEAR is deprecated and the debugger must only use CTIAPPULSE.

Accessing this field has the following behavior:

- When $x \geq \text{UInt}(\text{CTIDEVID.NUMCHAN})$, access to this field is RAZ/WI.
- Otherwise, access to this field is RAZ/WIC.

Accessing CTIAPPCLEAR

CTIAPPCLEAR can be accessed through the external debug interface:

Component	Offset	Instance
CTI	0x018	CTIAPPCLEAR

Accessible as follows:

- When SoftwareLockStatus(addrdesc), accesses to this register are WI.
- Otherwise, accesses to this register are WO.

E9.4.3 CTIAPPPULSE, CTI Application Pulse register

The CTIAPPPULSE characteristics are:

Purpose

Causes event pulses to be generated on ECT channels.

Configuration

CTIAPPPULSE is in the Debug power domain

Attributes

CTIAPPPULSE is a 32-bit register.

Field descriptions

APPPULSE<x> , bits [x], for x = 31 to 0

Generate event pulse on ECT channel <x>.

APPPULSE<x>	Meaning
0b0	No effect.
0b1	Channel <x> event pulse generated.

Note

- The CTIAPPPULSE operation does not affect the state of the application trigger. If the channel is active, either because of an earlier event or from the application trigger, then the value written to CTIAPPPULSE might have no effect.
- Multiple pulse events that occur close together might be merged into a single pulse event.

Accessing this field has the following behavior:

- When $x \geq \text{UInt}(\text{CTIDEVID.NUMCHAN})$, access to this field is RAZ/WI.
- Otherwise, access to this field is WO/UNKNOWN.

Accessing CTIAPPPULSE

It is CONSTRAINED UNPREDICTABLE whether a write to CTIAPPPULSE generates an event on a channel if CTICONTROL.GLBEN is 0.

CTIAPPPULSE can be accessed through the external debug interface:

Component	Offset	Instance
CTI	0x01C	CTIAPPPULSE

Accessible as follows:

- When SoftwareLockStatus(addrdesc), accesses to this register are WI.
- Otherwise, accesses to this register are WO.

E9.4.4 CTIAPPSET, CTI Application Trigger Set register

The CTIAPPSET characteristics are:

Purpose

Sets the application triggers.

Configuration

CTIAPPSET is in the Debug power domain

External register CTIAPPSET bits [31:0] are architecturally mapped to External register CTIAPPCLEAR[31:0].

Attributes

CTIAPPSET is a 32-bit register.

Field descriptions

APPSET<x> , bits [x], for x = 31 to 0

Application trigger <x> enable.

APPSET<x>	Meaning
0b0	Reading this means the application trigger is inactive. Writing this has no effect.
0b1	Reading this means the application trigger is active. Writing this sets the corresponding application trigger to 1 and generates a channel event.

If the ECT does not support multicycle channel events, use of CTIAPPSET is deprecated and the debugger must only use CTIAPPULSE.

The reset behavior of this field is:

- On a External debug reset, this field resets to an architecturally UNKNOWN value.

Accessing this field has the following behavior:

- When $x \geq \text{UInt}(\text{CTIDEVID.NUMCHAN})$, access to this field is RAZ/WI.
- Otherwise, access to this field is WIS.

Accessing CTIAPPSET

CTIAPPSET can be accessed through the external debug interface:

Component	Offset	Instance
CTI	0x014	CTIAPPSET

Accessible as follows:

- When `SoftwareLockStatus(addrdesc)`, accesses to this register are RO.
- Otherwise, accesses to this register are RW.

E9.4.5 CTIAUTHSTATUS, CTI Authentication Status register

The CTIAUTHSTATUS characteristics are:

Purpose

Provides information about the state of the IMPLEMENTATION DEFINED authentication interface for CTI.

Configuration

CTIAUTHSTATUS is in the Debug power domain

This register is OPTIONAL, and is required for CoreSight compliance.

Attributes

CTIAUTHSTATUS is a 32-bit register.

Field descriptions

31	8	7	4	3	2	1	0
RES0							
RAZ				NSNID		NSID	

Bits [31:8]

Reserved, RES0.

Bits [7:4]

Reserved, RAZ.

NSNID, bits [3:2]

If the implemented Security state is Secure state, this field holds the same value as [DBGAUTHSTATUS_EL1.SNID](#).

NSID, bits [1:0]

If the implemented Security state is Secure state, this field holds the same value as [DBGAUTHSTATUS_EL1.SID](#).

Accessing CTIAUTHSTATUS

CTIAUTHSTATUS can be accessed through the external debug interface:

Component	Offset	Instance
CTI	0xFB8	CTIAUTHSTATUS

Accesses to this register are RO.

E9.4.6 CTICHINSTATUS, CTI Channel In Status register

The CTICHINSTATUS characteristics are:

Purpose

Provides the raw status of the ECT channel inputs to the CTI.

Configuration

CTICHINSTATUS is in the Debug power domain

Attributes

CTICHINSTATUS is a 32-bit register.

Field descriptions

CHIN<n> , bits [n], for n = 31 to 0

Input channel <n> status.

CHIN<n>	Meaning
0b0	Input channel <n> is inactive.
0b1	Input channel <n> is active.

If the ECT channels do not support multicycle events, then it is IMPLEMENTATION DEFINED whether an input channel can be observed as active.

Accessing this field has the following behavior:

- When $n \geq \text{UInt}(\text{CTIDEVID.NUMCHAN})$, access to this field is RAZ/WI.
- Otherwise, access to this field is RO.

Accessing CTICHINSTATUS

CTICHINSTATUS can be accessed through the external debug interface:

Component	Offset	Instance
CTI	0x138	CTICHINSTATUS

Accesses to this register are RO.

E9.4.7 CTICHOUTSTATUS, CTI Channel Out Status register

The CTICHOUTSTATUS characteristics are:

Purpose

Provides the status of the ECT channel outputs from the CTI.

Configuration

CTICHOUTSTATUS is in the Debug power domain

Attributes

CTICHOUTSTATUS is a 32-bit register.

Field descriptions

CHOUT<n> , bits [n], for n = 31 to 0

Output channel <n> status.

CHOUT<n>	Meaning
0b0	Output channel <n> is inactive.
0b1	Output channel <n> is active.

If the ECT channels do not support multicycle events, then it is IMPLEMENTATION DEFINED whether an output channel can be observed as active.

Note
The value in CTICHOUTSTATUS is after gating by the channel gate. For more information, see [CTIGATE](#).

Accessing this field has the following behavior:

- When $n \geq \text{UInt}(\text{CTIDEVID.NUMCHAN})$, access to this field is RAZ/WI.
- Otherwise, access to this field is RO.

Accessing CTICHOUTSTATUS

CTICHOUTSTATUS can be accessed through the external debug interface:

Component	Offset	Instance
CTI	0x13C	CTICHOUTSTATUS

Accesses to this register are RO.

E9.4.8 CTICIDR0, CTI Component Identification Register 0

The CTICIDR0 characteristics are:

Purpose

Provides information to identify a CTI component.
For more information, see ‘About the Component Identification scheme’.

Configuration

CTICIDR0 is in the Debug power domain

Attributes

CTICIDR0 is a 32-bit register.

Field descriptions

Bits [31:8]

Reserved, RES0.

PRMBL_0, bits [7:0]

When FEAT_CTI_PIDR is implemented:

Preamble.
Reads as 0x0D
Access to this field is RO.

Otherwise:

Reserved, RAZ.

Accessing CTICIDR0

CTICIDR0 can be accessed through the external debug interface:

Component	Offset	Instance
CTI	0xFF0	CTICIDR0

Accesses to this register are RO.

E9.4.9 CTICIDR1, CTI Component Identification Register 1

The CTICIDR1 characteristics are:

Purpose

Provides information to identify a CTI component.
For more information, see ‘About the Component Identification scheme’.

Configuration

CTICIDR1 is in the Debug power domain

Attributes

CTICIDR1 is a 32-bit register.

Field descriptions

Bits [31:8]

Reserved, RES0.

CLASS, bits [7:4]

When FEAT_CTI_PIDR is implemented:

Component class.

CLASS	Meaning
0b1001	CoreSight component.

Other values are defined by the CoreSight Architecture.

This field reads as 0x9.

Access to this field is RO.

Otherwise:

Reserved, RAZ.

PRMBL_1, bits [3:0]

When FEAT_CTI_PIDR is implemented:

Preamble.

Reads as 0b0000

Access to this field is RO.

Otherwise:

Reserved, RAZ.

Accessing CTICIDR1

CTICIDR1 can be accessed through the external debug interface:

Component	Offset	Instance
CTI	0xFF4	CTICIDR1

Accesses to this register are RO.

E9.4.10 CTICIDR2, CTI Component Identification Register 2

The CTICIDR2 characteristics are:

Purpose

Provides information to identify a CTI component.
For more information, see ‘About the Component Identification scheme’.

Configuration

CTICIDR2 is in the Debug power domain

Attributes

CTICIDR2 is a 32-bit register.

Field descriptions

Bits [31:8]

Reserved, RES0.

PRMBL_2, bits [7:0]

When FEAT_CTI_PIDR is implemented:

Preamble.
Reads as 0x05
Access to this field is RO.

Otherwise:

Reserved, RAZ.

Accessing CTICIDR2

CTICIDR2 can be accessed through the external debug interface:

Component	Offset	Instance
CTI	0xFF8	CTICIDR2

Accesses to this register are RO.

E9.4.11 CTICIDR3, CTI Component Identification Register 3

The CTICIDR3 characteristics are:

Purpose

Provides information to identify a CTI component.
For more information, see ‘About the Component Identification scheme’.

Configuration

CTICIDR3 is in the Debug power domain

Attributes

CTICIDR3 is a 32-bit register.

Field descriptions

Bits [31:8]

Reserved, RES0.

PRMBL_3, bits [7:0]

When FEAT_CTI_PIDR is implemented:

Preamble.
Reads as 0xB1
Access to this field is RO.

Otherwise:

Reserved, RAZ.

Accessing CTICIDR3

CTICIDR3 can be accessed through the external debug interface:

Component	Offset	Instance
CTI	0xFFC	CTICIDR3

Accesses to this register are RO.

E9.4.12 CTICLAIMCLR, CTI CLAIM Tag Clear register

The CTICLAIMCLR characteristics are:

Purpose

Used by software to read the values of the CLAIM bits, and to clear CLAIM tag bits to 0.

Configuration

CTICLAIMCLR is in the Debug power domain

External register CTICLAIMCLR bits [31:0] are architecturally mapped to External register [CTICLAIMSET](#)[31:0].

Implementation of this register is OPTIONAL.

Attributes

CTICLAIMCLR is a 32-bit register.

Field descriptions

CLAIM<m>, bits [m], for m = 31 to 0

Claim Tag Clear. Indicates the current status of Claim Tag bit <m>, and is used to clear Claim Tag bit <m> to 0.

CLAIM<m>	Meaning
0b0	On a read: Claim Tag bit <m> is not set. On a write: Ignored.
0b1	On a read: Claim Tag bit <m> is set. On a write: Clear Claim tag bit <m> to 0.

The number of Claim Tag bits implemented is indicated in [CTICLAIMSET](#).

An External Debug reset clears the CLAIM tag bits to 0.

Accessing this field has the following behavior:

- When $m \geq \text{NUM_CTI_CLAIM_TAGS}$, access to this field is RAZ/WI.
- Otherwise, access to this field is WIC.

Accessing CTICLAIMCLR

CTICLAIMCLR can be accessed through the external debug interface:

Component	Offset	Instance
CTI	0xFA4	CTICLAIMCLR

Accessible as follows:

- When SoftwareLockStatus(addrdesc), accesses to this register are RO.
- Otherwise, accesses to this register are RW.

E9.4.13 CTICLAIMSET, CTI CLAIM Tag Set register

The CTICLAIMSET characteristics are:

Purpose

Used by software to set CLAIM bits to 1.

Configuration

CTICLAIMSET is in the Debug power domain

External register CTICLAIMSET bits [31:0] are architecturally mapped to External register [CTICLAIMCLR](#)[31:0].

Implementation of this register is OPTIONAL.

Attributes

CTICLAIMSET is a 32-bit register.

Field descriptions

CLAIM<m> , bits [m], for m = 31 to 0

Claim Tag Set. Indicates whether Claim Tag bit <m> is implemented, and is used to set Claim Tag bit <m> to 1.

CLAIM<m>	Meaning
0b0	On a read: Claim Tag bit <m> is not implemented. On a write: Ignored.
0b1	On a read: Claim Tag bit <m> is implemented. On a write: Set Claim Tag bit <m> to 1.

An External Debug reset clears the CLAIM tag bits to 0.

Accessing this field has the following behavior:

- When $m \geq \text{NUM_CTI_CLAIM_TAGS}$, access to this field is RAZ/WI.
- Otherwise, access to this field is RAO/WIS.

Accessing CTICLAIMSET

CTICLAIMSET can be accessed through the external debug interface:

Component	Offset	Instance
CTI	0xFA0	CTICLAIMSET

Accessible as follows:

- When SoftwareLockStatus(addrdesc), accesses to this register are RO.
- Otherwise, accesses to this register are RW.

E9.4.14 CTICONTROL, CTI Control register

The CTICONTROL characteristics are:

Purpose

Controls whether the CTI is enabled.

Configuration

CTICONTROL is in the Debug power domain

Attributes

CTICONTROL is a 32-bit register.

Field descriptions

**Bits [31:1]**

Reserved, RES0.

GLBEN, bit [0]

Enables or disables the CTI mapping functions. Possible values of this field are:

GLBEN	Meaning
0b0	CTI mapping functions and application trigger disabled.
0b1	CTI mapping functions and application trigger enabled.

When GLBEN is 0, the input channel to output trigger, input trigger to output channel, and application trigger functions are disabled and do not signal new events on either output triggers or output channels. If a previously asserted output trigger has not been acknowledged, it is **CONSTRAINED UNPREDICTABLE** which of the following occurs:

- The output trigger remains asserted after the mapping functions are disabled.
- The output trigger is deasserted after the mapping functions are disabled.

All output triggers are disabled by CTI reset.

If the ECT supports multicycle channel events any existing output channel events will be terminated.

The reset behavior of this field is:

- On a External debug reset, this field resets to '0'.

Accessing CTICONTROL

CTICONTROL can be accessed through the external debug interface:

Component	Offset	Instance
CTI	0x000	CTICONTROL

Accessible as follows:

- When SoftwareLockStatus(addrdesc), accesses to this register are RO.
- Otherwise, accesses to this register are RW.

E9.4.15 CTIDEVAFF0, CTI Device Affinity register 0

The CTIDEVAFF0 characteristics are:

Purpose

Copy of the low half of the PE MPIDR_EL1 register that allows a debugger to determine which PE in a multiprocessor system the CTI component relates to.

Configuration

CTIDEVAFF0 is in the Debug power domain

If the CTI is CTIv1, this register is OPTIONAL. If the CTI is CTIv2, this register is mandatory.

Arm recommends that the CTI is CTIv2.

If this register is implemented, then CTIDEVAFF1 must also be implemented. If the CTI of a PE does not implement the CTI Device Affinity registers, the CTI block of the external debug memory map must be located 64KB above the debug registers in the external debug interface.

Attributes

CTIDEVAFF0 is a 32-bit register.

Field descriptions

Bit [31]

Reserved, RAO/WI.

U, bit [30]

Indicates a Uniprocessor system, as distinct from PE 0 in a multiprocessor system.

The value of this field is an IMPLEMENTATION DEFINED choice of:

U	Meaning
0b0	Processor is part of a multiprocessor system.
0b1	Processor is part of a uniprocessor system.

Access to this field is RO.

Bits [29:25]

Reserved, RES0.

MT, bit [24]

Indicates whether the lowest level of affinity consists of logical PEs that are implemented using an interdependent approach, such as multithreading. See the description of Aff0 for more information about affinity levels.

The value of this field is an IMPLEMENTATION DEFINED choice of:

MT	Meaning
0b0	Performance of PEs with different affinity level 0 values, and the same values for affinity level 1 and higher, is largely independent.
0b1	Performance of PEs with different affinity level 0 values, and the same values for affinity level 1 and higher, is very interdependent.

Note

This field does not indicate that multithreading is implemented and does not indicate that PEs with different affinity level 0 values, and the same values for affinity level 1 and higher are implemented.

Access to this field is RO.

Aff2, bits [23:16]

Affinity level 2. See the description of Aff0 for more information.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

Aff1, bits [15:8]

Affinity level 1. See the description of Aff0 for more information.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

Aff0, bits [7:0]

Affinity level 0. The value of the MPIDR.{Aff2, Aff1, Aff0} or [MPIDR_EL1](#).{Aff3, Aff2, Aff1, Aff0} set of fields of each PE must be unique within the system as a whole.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

Accessing CTIDEVAFF0

CTIDEVAFF0 can be accessed through the external debug interface:

Component	Offset	Instance
CTI	0xFA8	CTIDEVAFF0

Accesses to this register are RO.

E9.4.16 CTIDEVAFF1, CTI Device Affinity register 1

The CTIDEVAFF1 characteristics are:

Purpose

Copy of the high half of the PE [MPIDR_EL1](#) register that allows a debugger to determine which PE in a multiprocessor system the CTI component relates to.

Configuration

CTIDEVAFF1 is in the Debug power domain

If the CTI is CTIv1, this register is OPTIONAL. If the CTI is CTIv2, this register is mandatory.

Arm recommends that the CTI is CTIv2.

If this register is implemented, then [CTIDEVAFF0](#) must also be implemented. If the CTI of a PE does not implement the CTI Device Affinity registers, the CTI block of the external debug memory map must be located 64KB above the debug registers in the external debug interface.

Attributes

CTIDEVAFF1 is a 32-bit register.

Field descriptions

Bits [31:8]

Reserved, RES0.

Aff3, bits [7:0]

Affinity level 3. See the description of [CTIDEVAFF0.Aff0](#) for more information.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

Accessing CTIDEVAFF1

CTIDEVAFF1 can be accessed through the external debug interface:

Component	Offset	Instance
CTI	0xFAC	CTIDEVAFF1

Accesses to this register are RO.

E9.4.17 CTIDEVARCH, CTI Device Architecture register

The CTIDEVARCH characteristics are:

Purpose

Identifies the programmers’ model architecture of the CTI component.

Configuration

CTIDEVARCH is in the Debug power domain

If the CTI is CTIv1, this register is OPTIONAL. If the CTI is CTIv2, this register is mandatory.

Arm recommends that the CTI is CTIv2.

If this register is not implemented, CTIDEVAFF0 and CTIDEVAFF1 are also not implemented.

Attributes

CTIDEVARCH is a 32-bit register.

Field descriptions

ARCHITECT, bits [31:21]

Defines the architect of the component. For CTI, this is Arm Limited.

Bits [31:28] are the JEP106 continuation code, 0b0100.

Bits [27:21] are the JEP106 identification code, 0b0111011.

Reads as 0b01000111011

Access to this field is RO.

PRESENT, bit [20]

DEVARCH presence. Indicates that the CTIDEVARCH register provides architecture information.

Reads as 0b1

Access to this field is RO.

REVISION, bits [19:16]

Revision. Defines the architecture revision of the component.

The value of this field is an IMPLEMENTATION DEFINED choice of:

REVISION	Meaning
0b0000	First revision.
0b0001	As 0b0000, and also adds support for CTIDEVCTL.

All other values are reserved.

When [FEAT_DoPD](#) is implemented, the value 0b0000 is not permitted.

Access to this field is RO.

ARCHID, bits [15:0]

Defines this part to be an Armv8 debug component. For architectures defined by Arm this is further subdivided.

For CTI:

- Bits [15:12] are the architecture version, 0x1.
- Bits [11:0] are the architecture part number, 0xA14.

This corresponds to CTI architecture version CTIv2.

Reads as 0xA14

Access to this field is RO.

Accessing CTIDEVARCH

CTIDEVARCH can be accessed through the external debug interface:

Component	Offset	Instance
CTI	0xFBC	CTIDEVARCH

Accesses to this register are RO.

E9.4.18 CTIDEVCTL, CTI Device Control register

The CTIDEVCTL characteristics are:

Purpose

Provides target-specific device controls

Configuration

CTIDEVCTL is in the Debug power domain

This register is present only when FEAT_DoPD is implemented. Otherwise, direct accesses to CTIDEVCTL are RES0.

Attributes

CTIDEVCTL is a 32-bit register.

Field descriptions

Bits [31:2]

Reserved, RES0.

RCE, bit [1]

Reset Catch Enable.

RCE	Meaning
0b0	Reset Catch debug event disabled.
0b1	Reset Catch debug event enabled.

The reset behavior of this field is:

- On a External debug reset, this field resets to '0'.

OSUCE, bit [0]

OS Unlock Catch Enable

OSUCE	Meaning
0b0	OS Unlock Catch debug event disabled.
0b1	OS Unlock Catch debug event enabled.

The reset behavior of this field is:

- On a External debug reset, this field resets to '0'.

Accessing CTIDEVCTL

CTIDEVCTL can be accessed through the external debug interface:

Component	Offset	Instance
CTI	0x150	CTIDEVCTL

Accessible as follows:

- When SoftwareLockStatus(addrdesc), accesses to this register are RO.
- Otherwise, accesses to this register are RW.

E9.4.19 CTIDEVID, CTI Device ID register 0

The CTIDEVID characteristics are:

Purpose

Describes the CTI component to the debugger.

Configuration

CTIDEVID is in the Debug power domain

Attributes

CTIDEVID is a 32-bit register.

Field descriptions

31	26	25	24	23	22	21	16	15	14	13	8	7	5	4	0
RES0				INOUT	RES0	NUMCHAN				RES0	NUMTRIG			RES0	EXTMUXNUM

Bits [31:26]

Reserved, RES0.

INOUT, bits [25:24]

Input/output options. Indicates presence of the input gate. If the CTM is not implemented or CTIv2 is not implemented, this field is RAZ.

The value of this field is an IMPLEMENTATION DEFINED choice of:

INOUT	Meaning
0b00	CTIGATE does not mask propagation of input events from external channels.
0b01	CTIGATE masks propagation of input events from external channels.

All other values are reserved.

Access to this field is RO.

Bits [23:22]

Reserved, RES0.

NUMCHAN, bits [21:16]

Number of ECT channels implemented. For Armv8, valid values are:

- 0b000011 3 channels (0..2) implemented.
- 0b000100 4 channels (0..3) implemented.
- 0b000101 5 channels (0..4) implemented.
- 0b000110 6 channels (0..5) implemented.

and so on up to 0b100000, 32 channels (0..31) implemented.

All other values are reserved.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

Bits [15:14]

Reserved, RES0.

NUMTRIG, bits [13:8]

Upper bound for number of triggers. The indices of all implemented input and output triggers are less than this value.

There is no guarantee that all of the input and output triggers, including the highest numbered, are connected to any components, or that the implementation of input and output triggers is symmetrical.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

Bits [7:5]

Reserved, RES0.

EXTMUXNUM, bits [4:0]

Number of multiplexors available on triggers. This value is used in conjunction with External Control register, [ASICCTL](#).

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

Accessing CTIDEVID

CTIDEVID can be accessed through the external debug interface:

Component	Offset	Instance
CTI	0xFC8	CTIDEVID

Accesses to this register are RO.

E9.4.20 CTIDEVID1, CTI Device ID register 1

The CTIDEVID1 characteristics are:

Purpose

Reserved for future information about the CTI component to the debugger.

Configuration

CTIDEVID1 is in the Debug power domain

Attributes

CTIDEVID1 is a 32-bit register.

Field descriptions

Bits [31:0]

Reserved, RES0.

Accessing CTIDEVID1

CTIDEVID1 can be accessed through the external debug interface:

Component	Offset	Instance
CTI	0xFC4	CTIDEVID1

Accesses to this register are RO.

E9.4.21 CTIDEVID2, CTI Device ID register 2

The CTIDEVID2 characteristics are:

Purpose

Reserved for future information about the CTI component to the debugger.

Configuration

CTIDEVID2 is in the Debug power domain

Attributes

CTIDEVID2 is a 32-bit register.

Field descriptions

Bits [31:0]

Reserved, RES0.

Accessing CTIDEVID2

CTIDEVID2 can be accessed through the external debug interface:

Component	Offset	Instance
CTI	0xFC0	CTIDEVID2

Accesses to this register are RO.

E9.4.22 CTIDEVTYPE, CTI Device Type register

The CTIDEVTYPE characteristics are:

Purpose

Indicates to a debugger that this component is part of a PE’s cross-trigger interface.

Configuration

CTIDEVTYPE is in the Debug power domain

This register is present only when FEAT_CTI_PIDR is implemented. Otherwise, direct accesses to CTIDEVTYPE are RES0.

Attributes

CTIDEVTYPE is a 32-bit register.

Field descriptions

Bits [31:8]

Reserved, RES0.

SUB, bits [7:4]

Subtype. Indicates this is a component within a PE.

Reads as 0b0001

Access to this field is RO.

MAJOR, bits [3:0]

Major type. Indicates this is a cross-trigger component.

Reads as 0b0100

Access to this field is RO.

Accessing CTIDEVTYPE

CTIDEVTYPE can be accessed through the external debug interface:

Component	Offset	Instance
CTI	0xFCC	CTIDEVTYPE

Accesses to this register are RO.

E9.4.23 CTIGATE, CTI Channel Gate Enable register

The CTIGATE characteristics are:

Purpose

Determines whether events on channels propagate through the CTM to other ECT components, or from the CTM into the CTI.

Configuration

CTIGATE is in the Debug power domain

Attributes

CTIGATE is a 32-bit register.

Field descriptions

GATE<x> , bits [x], for x = 31 to 0

Channel <x> gate enable.

GATE<x>	Meaning
0b0	Disable output and, if CTIDEVID.INOUT == 0b01, input channel <x> propagation.
0b1	Enable output and, if CTIDEVID.INOUT == 0b01, input channel <x> propagation.

If GATE<x> is set to 0, no new events will be propagated to the ECT, and if the ECT supports multicycle channel events any existing output channel events will be terminated.

The reset behavior of this field is:

- On a External debug reset, this field resets to an architecturally UNKNOWN value.

Accessing this field has the following behavior:

- When $x \geq \text{UInt}(\text{CTIDEVID.NUMCHAN})$, access to this field is RAZ/WI.
- Otherwise, access to this field is RW.

Accessing CTIGATE

CTIGATE can be accessed through the external debug interface:

Component	Offset	Instance
CTI	0x140	CTIGATE

Accessible as follows:

- When SoftwareLockStatus(addrdesc), accesses to this register are RO.
- Otherwise, accesses to this register are RW.

E9.4.24 CTIINEN<n>, CTI Input Trigger to Output Channel Enable registers, n = 0 - 31

The CTIINEN<n> characteristics are:

Purpose

Enables the signaling of an event on output channels when input trigger event n is received by the CTI.

Configuration

CTIINEN<n> is in the Debug power domain

If input trigger n is not implemented or not connected, CTIINEN<n> is RES0.

Attributes

CTIINEN<n> is a 32-bit register.

Field descriptions

INEN<x> , bits [x], for x = 31 to 0

Input trigger <n> to output channel <x> enable.

INEN<x>	Meaning
0b0	Input trigger <n> will not generate an event on output channel <x>.
0b1	Input trigger <n> will generate an event on output channel <x>.

The reset behavior of this field is:

- On a External debug reset, this field resets to an architecturally UNKNOWN value.

Accessing this field has the following behavior:

- When x >= UInt(CTIDEVID.NUMCHAN), access to this field is RAZ/WI.
- Otherwise, access to this field is RW.

Accessing CTIINEN<n>

CTIINEN<n> can be accessed through the external debug interface:

Component	Offset	Instance
CTI	$0x020 + (4 * n)$	CTIINEN<n>

Accessible as follows:

- When SoftwareLockStatus(addrdesc), accesses to this register are RO.
- Otherwise, accesses to this register are RW.

E9.4.25 CTIINTACK, CTI Output Trigger Acknowledge register

The CTIINTACK characteristics are:

Purpose

Can be used to deactivate the output triggers.

Configuration

CTIINTACK is in the Debug power domain

Attributes

CTIINTACK is a 32-bit register.

Field descriptions

ACK<n>, bits [n], for n = 31 to 0

Acknowledge for output trigger <n>.

If any of the following is true, writes to ACK<n> are ignored:

- $n \geq \text{CTIDEVID.NUMTRIG}$, the number of implemented triggers.
- Output trigger n is not active.
- The channel mapping function output, as controlled by [CTIOUTEN<n>](#), is still active.

Otherwise, if any of the following are true, ACK<n> is RES0:

- Output trigger n is not implemented.
- Output trigger n is not connected.
- Output trigger n is self-acknowledging and does not require software acknowledge.

Otherwise, the behavior on writes to ACK<n> is as follows:

ACK<n>	Meaning
0b0	No effect
0b1	Deactivate the trigger.

Accessing this field has the following behavior:

- When $n \geq \text{UInt}(\text{CTIDEVID.NUMTRIG})$, access to this field is RAZ/WI.
- Otherwise, access to this field is WO/UNKNOWN.

Accessing CTIINTACK

A debugger must read [CTITRIGOUTSTATUS](#) to confirm that the output trigger has been acknowledged before generating any event that must be ordered after the write to CTIINTACK, such as a write to CTIAPPULSE to activate another trigger.

CTIINTACK can be accessed through the external debug interface:

Component	Offset	Instance
CTI	0x010	CTIINTACK

Accessible as follows:

- When `SoftwareLockStatus(addrdesc)`, accesses to this register are WI.
- Otherwise, accesses to this register are WO.

E9.4.26 CTIITCTRL, CTI Integration mode Control register

The CTIITCTRL characteristics are:

Purpose

Enables the CTI to switch from its default mode into integration mode, where test software can control directly the inputs and outputs of the PE, for integration testing or topology detection.

Configuration

The power domain of CTIITCTRL is IMPLEMENTATION DEFINED

Implementation of this register is OPTIONAL.

Attributes

CTIITCTRL is a 32-bit register.

Field descriptions

Bits [31:1]

Reserved, RES0.

IME, bit [0]

Integration mode enable. When IME == 1, the device reverts to an integration mode to enable integration testing or topology detection.

IME	Meaning
0b0	Normal operation.
0b1	Integration mode enabled.

The integration mode behavior is IMPLEMENTATION DEFINED.

The following resets apply:

- If the register is implemented in the Core power domain:
 - On a Cold reset, this field resets to 0.
 - On an External debug reset, the value of this field is unchanged.
 - On a Warm reset, the value of this field is unchanged.
- If the register is implemented in the External debug power domain:
 - On a Cold reset, the value of this field is unchanged.
 - On an External debug reset, this field resets to 0.
 - On a Warm reset, the value of this field is unchanged.

Accessing CTIITCTRL

CTIITCTRL can be accessed through the external debug interface:

Component	Offset	Instance
CTI	0xF00	CTIITCTRL

Accessible as follows:

- When DoubleLockStatus(), or !IsCorePowered(), or OSLockStatus(), accesses to this register are IMPLEMENTATION DEFINED.
- When SoftwareLockStatus(addrdesc), accesses to this register are RO.
- Otherwise, accesses to this register are RW.

E9.4.27 CTILAR, CTI Lock Access Register

The CTILAR characteristics are:

Purpose

Allows or disallows access to the CTI registers through a memory-mapped interface.

The optional Software Lock provides a lock to prevent memory-mapped writes to the Cross-Trigger Interface registers. Use of this lock mechanism reduces the risk of accidental damage to the contents of the Cross-Trigger Interface registers. It does not, and cannot, prevent all accidental or malicious damage.

Configuration

CTILAR is in the Debug power domain

If [FEAT_Debugv8p4](#) is implemented, the Software Lock is not implemented.

Software uses CTILAR to set or clear the lock, and [CTILSR](#) to check the current status of the lock.

Attributes

CTILAR is a 32-bit register.

Field descriptions

When CTI Software Lock is implemented:

KEY, bits [31:0]

Lock Access control. Writing the key value `0xC5ACCE55` to this field unlocks the lock, enabling write accesses to this component's registers through a memory-mapped interface.

Writing any other value to this register locks the lock, disabling write accesses to this component's registers through a memory mapped interface.

Otherwise:

Otherwise

Bits [31:0]

Reserved, RES0.

Accessing CTILAR

CTILAR can be accessed through the memory-mapped interface:

Component	Offset	Instance
CTI	0xFB0	CTILAR

Accesses to this register are WO.

E9.4.28 CTILSR, CTI Lock Status Register

The CTILSR characteristics are:

Purpose

Indicates the current status of the Software Lock for CTI registers.

The optional Software Lock provides a lock to prevent memory-mapped writes to the Cross-Trigger Interface registers. Use of this lock mechanism reduces the risk of accidental damage to the contents of the Cross-Trigger Interface registers. It does not, and cannot, prevent all accidental or malicious damage.

Configuration

CTILSR is in the Debug power domain

If [FEAT_Debugv8p4](#) is implemented, the Software Lock is not implemented.

Software uses **CTILAR** to set or clear the lock, and CTILSR to check the current status of the lock.

Attributes

CTILSR is a 32-bit register.

Field descriptions

31 3 2 1 0
RES0 nTTSLKSLI

Bits [31:3]

Reserved, RES0.

nTT, bit [2]

Not thirty-two bit access required. RAZ.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

SLK, bit [1]

When CTI Software Lock is implemented:

Software Lock status for this component. For an access to LSR that is not a memory-mapped access, or when the Software Lock is not implemented, this field is RES0.

For memory-mapped accesses when the Software Lock is implemented, possible values of this field are:

SLK	Meaning
0b0	Lock clear. Writes are permitted to this component's registers.
0b1	Lock set. Writes to this component's registers are ignored, and reads have no side effects.

The reset behavior of this field is:

- On a External debug reset, this field resets to '1'.

Otherwise:

Reserved, RAZ.

SLI, bit [0]

Software Lock implemented. For an access to LSR that is not a memory-mapped access, this field is RAZ.

The value of this field is an IMPLEMENTATION DEFINED choice of:

SLI	Meaning
0b0	Software Lock not implemented or not memory-mapped access.
0b1	Software Lock implemented and memory-mapped access.

Access to this field is RO.

Accessing CTILSR

CTILSR can be accessed through the memory-mapped interface:

Component	Offset	Instance
CTI	0xFB4	CTILSR

Accesses to this register are RO.

E9.4.29 CTIOUTEN<n>, CTI Input Channel to Output Trigger Enable registers, n = 0 - 31

The CTIOUTEN<n> characteristics are:

Purpose

Defines which input channels generate output trigger n.

Configuration

CTIOUTEN<n> is in the Debug power domain

If output trigger n is not implemented or not connected, CTIOUTEN<n> is RES0.

Attributes

CTIOUTEN<n> is a 32-bit register.

Field descriptions

OUTEN<x>, bits [x], for x = 31 to 0

Input channel <x> to output trigger <n> enable.

OUTEN<x>	Meaning
0b0	An event on input channel <x> will not cause output trigger <n> to be asserted.
0b1	An event on input channel <x> will cause output trigger <n> to be asserted.

The reset behavior of this field is:

- On a External debug reset, this field resets to an architecturally UNKNOWN value.

Accessing this field has the following behavior:

- When $x \geq \text{UInt}(\text{CTIDEVID.NUMCHAN})$, access to this field is RAZ/WI.
- Otherwise, access to this field is RW.

Accessing CTIOUTEN<n>

CTIOUTEN<n> can be accessed through the external debug interface:

Component	Offset	Instance
CTI	$0x0A0 + (4 * n)$	CTIOUTEN<n>

Accessible as follows:

- When SoftwareLockStatus(addrdesc), accesses to this register are RO.
- Otherwise, accesses to this register are RW.

E9.4.30 CTIPIDR0, CTI Peripheral Identification Register 0

The CTIPIDR0 characteristics are:

Purpose

Provides information to identify a CTI component.
For more information, see ‘About the Peripheral identification scheme’.

Configuration

CTIPIDR0 is in the Debug power domain
This register is present only when FEAT_CTI_PIDR is implemented. Otherwise, direct accesses to CTIPIDR0 are RES0.

Attributes

CTIPIDR0 is a 32-bit register.

Field descriptions

Bits [31:8]

Reserved, RES0.

PART_0, bits [7:0]

Part number, which is selected by the designer of the component and stored as follows:

- For a component with a 12-bit part number:
 - CTIPIDR1.PART_1 contains part number bits [11:8].
 - CTIPIDR0.PART_0 contains part number bits [7:0].
- For a component with a 16-bit part number:
 - CTIPIDR1.PART_1 contains part number bits [15:12].
 - CTIPIDR0.PART_0 contains part number bits [11:4].
 - CTIPIDR2.REVISION contains part number bits [3:0].

When a 12-bit part number is used, CTIPIDR2.REVISION indicates revision information.
The choice of using a 12-bit part number or 16-bit part number is specific to the designer of the component.
This field has an IMPLEMENTATION DEFINED value.
Access to this field is RO.

Accessing CTIPIDR0

CTIPIDR0 can be accessed through the external debug interface:

Component	Offset	Instance
CTI	0xFE0	CTIPIDR0

Accesses to this register are RO.

E9.4.31 CTIPIDR1, CTI Peripheral Identification Register 1

The CTIPIDR1 characteristics are:

Purpose

Provides information to identify a CTI component.

For more information, see ‘About the Peripheral identification scheme’.

Configuration

CTIPIDR1 is in the Debug power domain

This register is present only when FEAT_CTI_PIDR is implemented. Otherwise, direct accesses to CTIPIDR1 are RES0.

Attributes

CTIPIDR1 is a 32-bit register.

Field descriptions

31		8	7	4	3	0	
RES0						DES_0	PART_1

Bits [31:8]

Reserved, RES0.

DES_0, bits [7:4]

Designer, JEP106 identification code, bits [3:0].

The JEP106 identification and continuation codes are stored as follows:

- **CTIPIDR1**.DES_0: JEP106 identification code bits[3:0].
- **CTIPIDR2**.DES_1: JEP106 identification code bits[6:4].
- **CTIPIDR4**.DES_2: JEP106 continuation code.

These codes indicate the designer of the component and not the implementer, except where the two are the same. To obtain a number, or to see the assignment of these codes, contact JEDEC <http://www.jedec.org>.

A JEP106 identification and continuation code takes the following form:

- A sequence of zero or more numbers, all having the value 0x7F.
- A following 8-bit number, that is not 0x7F, and where bit[7] is an odd parity bit.

The parity bit in the JEP106 identification code is not included.

Note

For example, Arm Limited is assigned the code 0x7F 0x7F 0x7F 0x7F 0x3B.

- The continuation code is the number of times 0x7F appears before the final number. For example, a component designed by Arm Limited has the code 0x4.
 - The identification code is bits[6:0] of the final number. For example, a component designed by Arm Limited has the code 0x3B.
-

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

PART_1, bits [3:0]

Part number, which is selected by the designer of the component and stored as follows:

- For a component with a 12-bit part number:
 - CTIPIDR1.PART_1 contains part number bits [11:8].
 - CTIPIDR0.PART_0 contains part number bits [7:0].
- For a component with a 16-bit part number:
 - CTIPIDR1.PART_1 contains part number bits [15:12].
 - CTIPIDR0.PART_0 contains part number bits [11:4].
 - CTIPIDR2.REVISION contains part number bits [3:0].

When a 12-bit part number is used, CTIPIDR2.REVISION indicates revision information.

The choice of using a 12-bit part number or 16-bit part number is specific to the designer of the component.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

Accessing CTIPIDR1

CTIPIDR1 can be accessed through the external debug interface:

Component	Offset	Instance
CTI	0xFE4	CTIPIDR1

Accesses to this register are RO.

E9.4.32 CTIPIDR2, CTI Peripheral Identification Register 2

The CTIPIDR2 characteristics are:

Purpose

Provides information to identify a CTI component.

For more information, see ‘About the Peripheral identification scheme’.

Configuration

CTIPIDR2 is in the Debug power domain

This register is present only when FEAT_CTI_PIDR is implemented. Otherwise, direct accesses to CTIPIDR2 are RES0.

Attributes

CTIPIDR2 is a 32-bit register.

Field descriptions

Bits [31:8]

Reserved, RES0.

REVISION, bits [7:4]

Indicates either the revision of the component, or a portion of the part number of the component.

Where the component has a single 4-bit revision number, the revision number is an incremental value starting at zero for the first revision of the component.

Where the component has separate major and minor revision numbers, the major and minor revision numbers are each incremental values starting at zero for the first revision of the component. For each minor revision of the component, the minor revision number increments monotonically. For each major revision of the component, the major revision number increments monotonically and the minor revision begins again at zero.

For a component with a 12-bit part number with a single 4-bit revision number:

- [CTIPIDR2.REVISION](#) indicates the 4-bit revision number.
- [CTIPIDR3.REVAND](#) indicates component modifications.

For a component with a 12-bit part number with separate major and minor revision numbers:

- [CTIPIDR2.REVISION](#) indicates the 4-bit major revision number.
- [CTIPIDR3.REVAND](#) indicates the 4-bit minor revision number.

For a component with a 16-bit part number:

- [CTIPIDR2.REVISION](#) contains part number bits [3:0].
- [CTIPIDR3.REVAND](#) indicates the 4-bit revision number.

The choice of which style of revision information is used is specific to the designer of the component, and might also be specific to each individual component with a different part number.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

JEDEC, bit [3]

JEDEC-assigned JEP106 implementer code is used.

Reads as 0b1

Access to this field is RO.

DES_1, bits [2:0]

Designer, JEP106 identification code, bits [6:4].

The JEP106 identification and continuation codes are stored as follows:

- CTIPIDR1.DES_0: JEP106 identification code bits[3:0].
- CTIPIDR2.DES_1: JEP106 identification code bits[6:4].
- CTIPIDR4.DES_2: JEP106 continuation code.

These codes indicate the designer of the component and not the implementer, except where the two are the same. To obtain a number, or to see the assignment of these codes, contact JEDEC <http://www.jedec.org>.

A JEP106 identification and continuation code takes the following form:

- A sequence of zero or more numbers, all having the value 0x7F.
- A following 8-bit number, that is not 0x7F, and where bit[7] is an odd parity bit.

The parity bit in the JEP106 identification code is not included.

Note

For example, Arm Limited is assigned the code 0x7F 0x7F 0x7F 0x7F 0x3B.

- The continuation code is the number of times 0x7F appears before the final number. For example, a component designed by Arm Limited has the code 0x4.
 - The identification code is bits[6:0] of the final number. For example, a component designed by Arm Limited has the code 0x3B.
-

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

Accessing CTIPIDR2

CTIPIDR2 can be accessed through the external debug interface:

Component	Offset	Instance
CTI	0xFE8	CTIPIDR2

Accesses to this register are RO.

E9.4.33 CTIPIDR3, CTI Peripheral Identification Register 3

The CTIPIDR3 characteristics are:

Purpose

Provides information to identify a CTI component.

For more information, see ‘About the Peripheral identification scheme’.

Configuration

CTIPIDR3 is in the Debug power domain

This register is present only when FEAT_CTI_PIDR is implemented. Otherwise, direct accesses to CTIPIDR3 are RES0.

Attributes

CTIPIDR3 is a 32-bit register.

Field descriptions

31	8	7	4	3	0	
RES0					REVAND	CMOD

Bits [31:8]

Reserved, RES0.

REVAND, bits [7:4]

Indicates either the revision of the component, or whether the component has been modified.

Where the component has a single 4-bit revision number, the revision number is an incremental value starting at zero for the first revision of the component.

Where the component has separate major and minor revision numbers, the major and minor revision numbers are each incremental values starting at zero for the first revision of the component. For each minor revision of the component, the minor revision number increments monotonically. For each major revision of the component, the major revision number increments monotonically and the minor revision begins again at zero.

For a component with a 12-bit part number with a single 4-bit revision number:

- [CTIPIDR2.REVISION](#) indicates the 4-bit revision number.
- [CTIPIDR3.REVAND](#) indicates component modifications.

For a component with a 12-bit part number with separate major and minor revision numbers:

- [CTIPIDR2.REVISION](#) indicates the 4-bit major revision number.
- [CTIPIDR3.REVAND](#) indicates the 4-bit minor revision number.

For a component with a 16-bit part number:

- [CTIPIDR2.REVISION](#) contains part number bits [3:0].
- [CTIPIDR3.REVAND](#) indicates the 4-bit revision number.

The choice of which style of revision information is used is specific to the designer of the component, and might also be specific to each individual component with a different part number.

Where REVAND indicates component modifications, this indicates modifications such as errata fixes or metal fixes after implementation. Usually this value would be zero unless a modification has been performed. If the field

is required for indicating component modifications, Arm recommends that component designers ensure that it can be changed by a metal fix, for example by driving it from registers that reset to zero.

CTIPIDR3.CMOD might also indicate component modifications.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

CMOD, bits [3:0]

Indicates whether the component has been modified from its original behavior. Examples of modifications include errata fixes or metal fixes after implementation. Usually this value would be zero unless a modification has been performed. If the field is required for indicating component modifications, Arm recommends that component designers ensure that it can be changed by a metal fix, for example by driving it from registers that reset to zero.

A value of 0b0000 means the component is not modified from the original design.

Any other value means the component has been modified in an IMPLEMENTATION DEFINED way.

For any two components with the same Unique Component Identifier:

- If the value of the CMOD fields of both components equals zero, the components are identical.
- If the CMOD fields of both components have the same nonzero value, it does not necessarily mean that they have the same modifications.
- If the value of the CMOD field of either of the two components is nonzero, they might not be identical, even though they have the same Unique Component Identifier.

CTIPIDR3.REVAND might also indicate component modifications.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

Accessing CTIPIDR3

CTIPIDR3 can be accessed through the external debug interface:

Component	Offset	Instance
CTI	0xFEC	CTIPIDR3

Accesses to this register are RO.

E9.4.34 CTIPIDR4, CTI Peripheral Identification Register 4

The CTIPIDR4 characteristics are:

Purpose

Provides information to identify a CTI component.

For more information, see ‘About the Peripheral identification scheme’.

Configuration

CTIPIDR4 is in the Debug power domain

This register is present only when FEAT_CTI_PIDR is implemented. Otherwise, direct accesses to CTIPIDR4 are RES0.

Attributes

CTIPIDR4 is a 32-bit register.

Field descriptions

Bits [31:8]

Reserved, RES0.

SIZE, bits [7:4]

Size of the component. $\log_2$ of the number of 4KB pages from the start of the component to the end of the component ID registers.

Reads as 0b0000

Access to this field is RO.

DES_2, bits [3:0]

Designer, JEP106 continuation code.

The JEP106 identification and continuation codes are stored as follows:

- CTIPIDR1.DES_0: JEP106 identification code bits[3:0].
- CTIPIDR2.DES_1: JEP106 identification code bits[6:4].
- CTIPIDR4.DES_2: JEP106 continuation code.

These codes indicate the designer of the component and not the implementer, except where the two are the same. To obtain a number, or to see the assignment of these codes, contact JEDEC <http://www.jedec.org>.

A JEP106 identification and continuation code takes the following form:

- A sequence of zero or more numbers, all having the value 0x7F.
- A following 8-bit number, that is not 0x7F, and where bit[7] is an odd parity bit.

The parity bit in the JEP106 identification code is not included.

Note

For example, Arm Limited is assigned the code 0x7F 0x7F 0x7F 0x7F 0x3B.

- The continuation code is the number of times 0x7F appears before the final number. For example, a component designed by Arm Limited has the code 0x4.
 - The identification code is bits[6:0] of the final number. For example, a component designed by Arm Limited has the code 0x3B.
-

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

Accessing CTIPIDR4

CTIPIDR4 can be accessed through the external debug interface:

Component	Offset	Instance
CTI	0xFD0	CTIPIDR4

Accesses to this register are RO.

E9.4.35 CTIPIDR5, CTI Peripheral Identification Register 5

The CTIPIDR5 characteristics are:

Purpose

Provides information to identify a CTI component.
For more information, see ‘About the Peripheral identification scheme’.

Configuration

CTIPIDR5 is in the Debug power domain
This register is present only when FEAT_CTI_PIDR is implemented. Otherwise, direct accesses to CTIPIDR5 are RES0.

Attributes

CTIPIDR5 is a 32-bit register.

Field descriptions

Bits [31:0]

Reserved, RES0.

Accessing CTIPIDR5

CTIPIDR5 can be accessed through the external debug interface:

Component	Offset	Instance
CTI	0xFD4	CTIPIDR5

Accesses to this register are RO.

E9.4.36 CTIPIDR6, CTI Peripheral Identification Register 6

The CTIPIDR6 characteristics are:

Purpose

Provides information to identify a CTI component.
For more information, see ‘About the Peripheral identification scheme’.

Configuration

CTIPIDR6 is in the Debug power domain
This register is present only when FEAT_CTI_PIDR is implemented. Otherwise, direct accesses to CTIPIDR6 are RES0.

Attributes

CTIPIDR6 is a 32-bit register.

Field descriptions

Bits [31:0]

Reserved, RES0.

Accessing CTIPIDR6

CTIPIDR6 can be accessed through the external debug interface:

Component	Offset	Instance
CTI	0xFD8	CTIPIDR6

Accesses to this register are RO.

E9.4.37 CTIPIDR7, CTI Peripheral Identification Register 7

The CTIPIDR7 characteristics are:

Purpose

Provides information to identify a CTI component.
For more information, see ‘About the Peripheral identification scheme’.

Configuration

CTIPIDR7 is in the Debug power domain
This register is present only when FEAT_CTI_PIDR is implemented. Otherwise, direct accesses to CTIPIDR7 are RES0.

Attributes

CTIPIDR7 is a 32-bit register.

Field descriptions

Bits [31:0]

Reserved, RES0.

Accessing CTIPIDR7

CTIPIDR7 can be accessed through the external debug interface:

Component	Offset	Instance
CTI	0xFDC	CTIPIDR7

Accesses to this register are RO.

E9.4.38 CTITRIGINSTATUS, CTI Trigger In Status register

The CTITRIGINSTATUS characteristics are:

Purpose

Provides the status of the trigger inputs.

Configuration

CTITRIGINSTATUS is in the Debug power domain

Attributes

CTITRIGINSTATUS is a 32-bit register.

Field descriptions

TRIN<n> , bits [n], for n = 31 to 0

Trigger input <n> status.

TRIN<n>	Meaning
0b0	Input trigger n is inactive.
0b1	Input trigger n is active.

Not implemented and not-connected input triggers are always inactive.

It is IMPLEMENTATION DEFINED whether an input trigger that does not support multicyle events can be observed as active.

Accessing this field has the following behavior:

- When $n \geq \text{UInt}(\text{CTIDEVID.NUMTRIG})$, access to this field is RAZ/WI.
- Otherwise, access to this field is RO.

Accessing CTITRIGINSTATUS

CTITRIGINSTATUS can be accessed through the external debug interface:

Component	Offset	Instance
CTI	0x130	CTITRIGINSTATUS

Accesses to this register are RO.

E9.4.39 CTITRIGOUTSTATUS, CTI Trigger Out Status register

The CTITRIGOUTSTATUS characteristics are:

Purpose

Provides the raw status of the trigger outputs, after processing by any IMPLEMENTATION DEFINED trigger interface logic. For output triggers that are self-acknowledging, this is only meaningful if the CTI implements multicycle channel events.

Configuration

CTITRIGOUTSTATUS is in the Debug power domain

Attributes

CTITRIGOUTSTATUS is a 32-bit register.

Field descriptions

TROUT<n> , bits [n], for n = 31 to 0

Trigger output <n> status.

If n is less than [CTIDEVID.NUMTRIG](#), and output trigger <n> is implemented and connected, and either the trigger is not self-acknowledging or the CTI implements multicycle channel events, then permitted values for TROUT<n> are:

TROUT<n>	Meaning
0b0	Output trigger n is inactive.
0b1	Output trigger n is active.

Otherwise when n is less than [CTIDEVID.NUMTRIG](#), it is IMPLEMENTATION DEFINED whether TROUT<n> behaves as described here or is RAZ.

Accessing this field has the following behavior:

- When $n \geq \text{UInt}(\text{CTIDEVID.NUMTRIG})$, access to this field is RAZ/WI.
- Access to this field is RAZ/WI if all of the following are true:
 - Any of the following are true:
 - Output trigger $\langle n \rangle$ is not implemented or not connected
 - All of the following are true:
 - Output trigger $\langle n \rangle$ is self-acknowledging
 - CTI does not implement multicycle channel events
 - an implementation implements $\text{TROUT}\langle n \rangle$
- Otherwise, access to this field is RO.

Accessing CTITRIGOUTSTATUS

CTITRIGOUTSTATUS can be accessed through the external debug interface:

Component	Offset	Instance
CTI	0×134	CTITRIGOUTSTATUS

Accesses to this register are RO.

Part F
**Memory-mapped Components of the Arm
Architecture**

Chapter F1

Requirements for Memory-mapped Components

This chapter provides some additional information about memory-mapped components defined by the Armv8 and Armv9 architectures. Arm also recommends that memory-mapped components designed to support the Armv8 and Armv9 architectures use this section as guidance, other than where a conflicting behavior is required by some other standard that the component is designed to support. It contains the following sections:

- [Supported access sizes and Endianness](#)
- [Synchronization of memory-mapped registers](#)
- [Access requirements for reserved and unallocated registers](#)

F1.1 Supported access sizes and Endianness

The information in this section applies to all accesses to memory-mapped components of the Armv8 and later architectures, unless a register or component description explicitly states otherwise.

The memory access sizes that are supported by any peripheral are IMPLEMENTATION DEFINED by the peripheral.

All memory-mapped peripherals defined in the Arm architecture must be little-endian.

When [FEAT_Debugv8p4](#) is implemented, each debug component has a Secure and Non-secure view. The Secure view of a debug component is mapped into Secure physical memory and the Non-secure view of a debug component is mapped into Non-secure memory. Apart from access conditions, the Non-secure and Secure views of the debug components are identical.

An implementation of a memory-mapped component that is compatible with the Armv8 and later architectures must support the following:

- Word-aligned 32-bit accesses to access 32-bit registers.
- If the system includes any component with direct memory access to the memory-mapped component which needs to access the component but does not support making 64-bit accesses, word-aligned 32-bit accesses to either half of a 64-bit register. This includes, but is not limited to:
 - A PE that implements a 32-bit ISA that does not include 64-bit memory operations. For example, Armv8-M T32.
 - A Debug Access Port that cannot make 64-bit accesses.

Note

Some memory-mapped components of the Arm architecture require support for word-aligned 32-bit accesses to either half of a 64-bit memory mapped register even if all components with direct memory access to the memory-mapped component support making 64-bit accesses. These include:

- The memory-mapped interface to the external debug and CTI registers that are described in [External Debug Register Descriptions](#).
- The memory-mapped interfaces to the Generic Timer registers that are described in [System Level Implementation of the Generic Timer](#).
- When [FEAT_PMUv3_EXT32](#) is implemented, the memory-mapped interfaces to the Performance Monitors registers that are described in [Recommended External Interface to the Performance Monitors](#).

-
- Doubleword-aligned 64-bit accesses to access 64-bit registers that are mapped to a doubleword-aligned pair of adjacent 32-bit locations.

Unless otherwise specified, all registers are only single-copy atomic at word granularity. This means that for 64-bit accesses to a 64-bit register, the system might generate a pair of 32-bit accesses. The order in which the two halves are accessed is not specified.

The following accesses are not supported:

- Byte accesses.
- Halfword accesses.
- Unaligned word accesses. These accesses are not word single-copy atomic.
- Unaligned doubleword accesses. These accesses are not doubleword single-copy atomic.
- Doubleword accesses to a pair of 32-bit locations that are not a doubleword-aligned pair that forms a 64-bit register.
- Quadword accesses or higher accesses.
- Exclusive accesses.

For unsupported accesses, it is IMPLEMENTATION DEFINED and might be UNPREDICTABLE whether:

- The access generates an External abort or not.
- The defined side-effects of a read occur or not. A read returns an IMPLEMENTATION DEFINED value that might be UNKNOWN.

- A write is ignored or sets the accessed register or registers to UNKNOWN values.
- The access generates a fault handling interrupt or not.

Such accesses are often due to software faults. That is, software has accessed a location in a way that the component does not support. See also *Arm® Reliability, Availability, and Serviceability (RAS) System Architecture, for A-profile architecture* (ARM IHI 0100) for recommended behavior on accesses that constitute software faults.

For memory-mapped accesses from a PE that complies with an Arm architecture, the single-copy atomicity rules for the instruction, the type of instruction, and the type of memory that is accessed, determine the size of the access that is made by an instruction. [Example F1-1](#) shows this.

Example F1-1 Access sizes for memory-mapped accesses

Two Load Doubleword instructions that are made to consecutive doubleword-aligned locations generate a pair of single-copy atomic doubleword reads. However, if the accesses are made to Normal memory or Device-GRE memory they might appear as a single quadword access that is not supported by the peripheral.

The Arm architecture does not require the size of each element that is accessed by a multi-register load or store instruction to be identifiable by the memory system beyond the PE. Unless otherwise specified by the component, any access to a memory-mapped component of the Arm architecture is defined to be beyond the PE.

Software must use a Device-nGRE or stronger memory type, and only single register load and store instructions, to create memory accesses that are supported by the peripheral. For more information, see [Memory types and attributes](#).

F1.2 Synchronization of memory-mapped registers

This section describes the synchronization requirements for the memory-mapped accesses to System registers.

This section refers to accesses to external system control registers as external reads and external writes. It refers to accesses to System registers as direct reads, direct writes, indirect reads, and indirect writes.

Note

[Synchronization requirements for AArch64 System registers](#) define direct read, direct write, indirect read, and indirect write, and classifies external reads as indirect reads and external writes as indirect writes.

Writes to the same register are serialized, meaning they are observed in the same order by all observers, although some observers might not observe all of the writes. Unless otherwise stated, external writes to different registers are not necessarily observed in the same order by all observers as the order in which they complete.

Explicit synchronization is not required for an external read or an external write by an external agent to be observable to a following external read or external write by that agent to the same register using the same address, and so is never required for registers that are accessible as external system control registers.

Unless required to be observable to all observers in finite time, without explicit synchronization, explicit synchronization is normally required following an external write to any register for that write to be observable by:

- A direct access.
- An indirect read by an instruction.
- An external read of the register using a different address.

This means that an external write by an external agent is guaranteed to have an effect on subsequent instructions executed by the PE only if all of the following are true:

- The write has completed.
- The PE has executed a Context synchronization event.
- The Context synchronization event was executed after the write completed.

The order and synchronization of direct reads and direct writes of System registers is defined by [Synchronization requirements for AArch64 System registers](#).

The external agent must be able to guarantee completion of a write. For example, the agent can:

- Mark the memory as Device-nGnRnE and executing a DSB barrier, if the system supports this property.
- If the register is read/write and reads are not destructive, read back the value written.
- Use some guaranteed property of the connection between the PE and the external agent.

The external agent and PE can guarantee ordering by, for example, passing messages in an ordered way with respect to the external write and the Context synchronization event, and relying on the memory ordering rules provided by the memory model.

External reads and external write complete in the order in which they arrive at the PE. For accesses to different register locations, the external agent must create this order. The agent can:

- Mark the memory as Device-nGnRnE or Device-nGnRE.
- Use the appropriate memory barriers.
- Rely on some guaranteed property of the connection between the PE and the external agent.

However, the external agent cannot force the synchronization of completed writes.

In a simple sequential execution, an indirect write that occurs as a side-effect of an access happens atomically with the access, meaning no other accesses are allowed between the register access and its side-effect.

Without explicit synchronization to guarantee the order of the accesses, where the same register is accessed by two or more of a System register access instruction, and external agent, and autonomous asynchronous event, or as a result of a

memory-mapped access, the behavior must be as if the accesses occurred atomically and in any order. This applies even if the accesses occur simultaneously.

For example, some registers have the property that for certain bits a write of 0 is ignored and a write of 1 has an effect. This means the simultaneous writes must be merged.

F1.3 Access requirements for reserved and unallocated registers

This section describes the access requirements for reserved and unallocated memory-mapped components.

The following information relates to certain types of reserved accesses:

- Reads and writes of unallocated locations. These accesses are reserved for the architecture.
- Reads and writes of locations for features that are not implemented, including:
 - OPTIONAL features that are not implemented.
 - Breakpoints and watchpoints that are not implemented.
 - Performance Monitors counters that are not implemented.
 - CTI triggers that are not implemented.
 - Error records that are not implemented.

These accesses are reserved.

- Reads of WO locations. These accesses are reserved for the architecture.
- Writes to RO locations. These accesses are reserved for the architecture.

Reserved accesses are normally RAZ/WI. However, software must not rely on this property as the behavior of reserved values might change in a future revision of the architecture. Software must treat reserved accesses as RES0.

Chapter F2

System Level Implementation of the Generic Timer

This chapter defines the system level implementation of the Generic Timer. It contains the following sections:

- [About the Generic Timer specification](#)
- [Memory-mapped counter module](#)
- [Memory-mapped timer components](#)

Note

- [Generic Timer memory-mapped register descriptions](#) describes the System level Generic Timer registers. These registers are memory-mapped.
 - Additional Information for Implementations of the Generic Timer gives additional information, that does not form part of the architectural definition of a system level implementation of the Generic Timer.
 - [The Generic Timer in AArch64 state](#) gives a general description of the AArch64 state view of the Generic Timer, and describes the AArch64 System register interface to the Generic Timer.
-

F2.1 About the Generic Timer specification

[The Generic Timer in AArch64 state](#) describes the Arm Generic Timer and its implementation as seen from AArch64 state. These chapters include the definition of the low-latency System register interface to the Generic Timer. However, the Arm Generic Timer architecture also defines a memory-mapped component, that comprises:

- A memory-mapped counter module, that controls the generation of the Count value used by the Generic Timer. This memory-mapped counter module is required in any Arm Generic Timer implementation that requires software control of the Count value of the Generic Timer.
- Optional memory-mapped timer modules. These give a standardized way of providing timers for programmable system components other than PEs that implement the Arm architecture.

[The full set of Generic Timer components](#) summarizes these components as seen from AArch64 state. [The system level components of the Generic Timer](#) summarizes the system level components.

F2.1.1 Registers in the system level implementation of the Generic Timer

Registers that control components of the system level implementation of the Generic Timer are grouped into *frames*. This specification defines the registers in each frame, and their offsets within the frame. The system defines the position of each frame in the memory map. This means the base addresses for each frame are IMPLEMENTATION DEFINED.

Note

The final 12 words of the first or only 4KB block of a register memory frame is an ID block.

Each frame must be in its own memory page, or memory protection region, and must be aligned to the size of the translation granule or protection granule.

Note

When a system level implementation of the Generic Timer is accessed by a PE:

- Using a VMSA, each frame is in its own memory page, aligned to the size of the translation granule.
 - Using a PMSA, each frame is in its own memory protection region, aligned to the size of the memory protection granule.
-

The following sections give more information about the requirements for the system level Generic Timer component:

- [Supported access sizes](#).
- [Power and reset domains for the system level implementation of the Generic Timer](#).

F2.1.1.1 Supported access sizes

The memory access sizes supported by any peripheral is IMPLEMENTATION DEFINED by the peripheral. For accesses to the memory-mapped Generic Timer registers implementations must:

- Comply with the requirements of [Supported access sizes and Endianness](#).
- Support word-aligned 32-bit accesses to access 32-bit registers or either half of a 64-bit register, even if all components with direct memory access to the Generic Timer support making 64-bit accesses.

F2.1.1.2 Power and reset domains for the system level implementation of the Generic Timer

The power and reset domains of the system level implementation of the Generic Timer are IMPLEMENTATION DEFINED as part of the system implementation. In register descriptions, they are called Timer resets to indicate they can be outside the PE power and reset domains defined by the remainder of this manual.

The Arm architecture requires that the [CNTCR](#).{FCREQ, EN} and [CNTSR](#).FCACK fields reset to 0. These Timer reset values apply only on powerup of the power domain in which the registers are implemented or a reset of the reset domain in which they are implemented.

Every other register, or register field, of a system level implementation of the Generic Timer resets to a value that is architecturally UNKNOWN if it has a meaningful reset value. These Timer resets apply on powerup of the power domain in which the register is implemented, and on a reset of the reset domain in which it is implemented.

F2.1.2 The system level components of the Generic Timer

Each system level component has one or two register frames. The possible system level components are:

The memory-mapped counter module, required

This module controls the system counter. It has two frames:

- A control frame, [CNTControlBase](#).
- A status frame, [CNTReadBase](#).

[Memory-mapped counter module](#) describes this component.

The memory-mapped timer control module, required

The system level implementation of the Generic Timer can provide up to eight timers, and the memory-mapped timer control module identifies:

- Which timers are implemented.
- The features of each implemented timer.

This module has a single frame, [CNTCTLBase](#).

[The CNTCTLBase frame](#) describes this frame.

Memory-mapped timers, optional

An implemented memory-mapped timer:

- Must provide a privileged view of the timer, in the [CNTBase \$N\$](#) frame.
- Optionally provides an unprivileged view of the timer in the [CNTEL0Base \$N\$](#) frame.

N is the timer number, and the corresponding frame number, in the range 0-7.

[The CNTBase \$N\$ and CNTEL0Base \$N\$ frames](#) describes these frames.

F2.2 Memory-mapped counter module

The memory-mapped counter module provides top-level control of the system counter. The [CNTControlBase](#) frame holds the registers for the memory-mapped counter, and provides:

- An RW control register, [CNTCR](#), that provides:
 - An enable bit for the system counter.
 - An enable bit for Halt-on-debug. For more information, see [Halt-on-debug](#).
 - A field that can be written to request a change to the [Counter resolution](#). This mechanism means that, for example, if the [Counter resolution](#) is halved then the increment to the counter at each tick of the clock is doubled.
For more information, see [Control of counter resolution and increment](#).

Writes to this register are rare.

- A RO status register, [CNTSR](#), that provides:
 - A bit that indicates whether the system counter is halted because of an asserted Halt-on-debug signal.
 - A field that indicates whether a requested change to the [Counter resolution](#) has completed.
- Two contiguous 32-bit RW registers that hold the current system counter value, [CNTCV](#). If the system supports 64-bit atomic accesses, these two registers must be accessible by such accesses.
The system counter must be disabled before writing to these registers, otherwise the effect of the write is UNPREDICTABLE.
Writes to these registers are rare.
- A *Frequency modes table* of one or more 32-bit entries, where:
 - The first entry in the table defines the *base frequency* of the system counter. It is IMPLEMENTATION DEFINED whether the base frequency indicates the effective frequency of the counter, or the maximum [Counter resolution](#).
Arm recommends that the base frequency indicates the maximum [Counter resolution](#).
 - Each subsequent entry in the table defines an alternative frequency of the system counter, that must be an exact divisor of the base frequency.

A 32-bit zero entry immediately follows the last table entry.

This table can be RO or RW. For more information, see [The Frequency modes table](#).

In an implementation with multiple physical address spaces, [CNTControlBase](#) is only accessible by accesses from the most secure physical address space. For example, in a system with Secure and Non-secure memory maps, [CNTControlBase](#) is only accessible by Secure accesses.

In addition, the [CNTReadBase](#) frame includes a read-only copy of the system counter value, [CNTCV](#), as two contiguous 32-bit RO registers. If the system supports 64-bit atomic accesses, these two registers must be accessible by such accesses.

[Counter module control and status register summary](#) describes [CNTReadBase](#) and [CNTControlBase](#) memory maps, and the registers in each frame.

F2.2.1 Control of counter resolution and increment

The system counter has a fixed *base frequency*, and must maintain the required counter accuracy, meaning Arm recommends that it does not gain or lose more than ten seconds in a 24-hour period, see [The system counter](#). However, the counter can operate at a lower resolution than the base frequency, using a correspondingly larger increment. For example, it can increment by a value four times larger when running at a quarter of the base frequency. Any lower resolution operation, and any switching between resolutions, must not reduce the accuracy of the counter.

Control of the system [Counter resolution](#) and increment is provided only through the memory-mapped counter module. The following sections describe this control:

- [The Frequency modes table.](#)
- [Changing the system counter and increment.](#)

F2.2.1.1 The Frequency modes table

The Frequency modes table starts at offset `0x20` in the `CNTControlBase` frame.

Table entries are 32-bits, and each entry specifies a selected frequency, in Hz.

The first entry in the table specifies the base frequency of the system counter.

When the system counter is operating at a lower frequency than the base frequency, the increment applied at each counter update is increased by the ratio of the base frequency and the selected frequency.

Note

Where the [Effective frequency](#) and the base frequency are not the same, the increment is not solely defined by the ratio of the base frequency and the selected frequency. For example, a counter with an [Effective frequency](#) of 1GHz and a base frequency of 125MHz will increment by a value of 8 on each tick of the base frequency. If the Frequency modes table provides an additional selected frequency of 31.25MHz, then when this frequency is selected the counter increments by 32 on each tick of the selected frequency.

A 32-bit word of zero value marks the end of the table. That is, the word of memory immediately after the last entry in the table must be zero.

The only required entry in the table is the entry for the base frequency.

Typically, the Frequency modes table is in RO memory. However, a system implementation might use RW memory for the table, and initialize the table entries as part of its startup sequence. Therefore, the `CNTControlBase` memory map shows the table region as RO or RW.

A system might provide an IMPLEMENTATION DEFINED mechanism for selecting the current power mode and resolution of the counter, and such a mechanism is independent of the memory-mapped counter module. If such a mechanism is provided, typically the frequency modes table only includes a single entry to indicate the base frequency.

Arm strongly recommends that the Frequency modes table is not updated once the system is running.

The architecture can support up to 1004 entries in the Frequency modes table, including the zero-word end marker, and the number of entries is IMPLEMENTATION DEFINED, up to this limit.

Note

- Arm considers it likely that implementations will require significantly fewer entries than the architectural limit.
 - In the `CNTControlBase` frame, the offset range `0x0C0-0x0FC` can be used for IMPLEMENTATION DEFINED registers. If any registers are defined in this space, then the Frequency modes table cannot extend beyond offset `0x0B8`, with a zero word at offset `0x0BC`. This means that if any IMPLEMENTATION DEFINED registers are defined the maximum number of entries in the table is 40, including the zero-word end marker.
-

F2.2.1.2 Changing the system counter and increment

The value of the `CNTCR.FCREQ` field specifies which entry in the Frequency modes table specifies the selected frequency.

Changing the value of `CNTCR.FCREQ` requests a change to the selected frequency. To ensure the frequency change does not affect the overall accuracy of the counter, a change is made as follows:

- When changing from a higher frequency to a lower frequency, the counter:
 1. Continues running at the higher frequency until the count reaches an integer multiple of the required lower frequency.
 2. Switches to operating at the lower frequency.
- When changing from a lower frequency to a higher frequency, the counter:
 1. Waits until the end of the current lower-frequency cycle.
 2. Makes the counter increment required for operation at that lower frequency.
 3. Switches to operating at the higher frequency.

When the frequency has changed, [CNTSR](#) is updated to indicate the new selected frequency. Therefore, a system component that is waiting for a frequency change can poll [CNTSR](#) to detect the change.

F2.2.2 Halt-on-debug

The [CNTCR](#) register provides an enable bit for an OPTIONAL Halt-on-debug signal.

When the [CNTCR.HDBG](#) bit is set to 1, and the Halt-on-debug signal is implemented and asserted, the system counter is halted. Otherwise, the system counter ignores the state of this signal.

Where the system counter implements a Halt-on-debug signal and the system supports halting the system counter, Arm recommends that the Halt-on-debug signal can be controlled by a debugger using the Embedded Cross-Trigger (ECT) using a system-level cross-trigger interface that includes:

- A debug request output trigger event that asserts the Halt-on-debug signal.
- A restart request output trigger event that deasserts the Halt-on-debug signal.

For more information, see [About the Embedded Cross-Trigger](#).

Note

Software must use the Halt-on-debug enable bit to ensure that the timers cannot be halted maliciously in an attempt to prohibit progress.

For more information about Halt-on-debug, contact Arm.

F2.2.3 Counter module control and status register summary

The Counter module control and status registers are memory-mapped registers in the following register memory *frames*:

- A control frame, with base address [CNTControlBase](#).
- A status frame, with base address [CNTReadBase](#).

Each of these register memory frames is in its own [memory page](#) or [memory protection region](#), and the frame base address points to the start of this region. Each base address must be aligned to the size of the translation granule or protection granule.

Note

Each frame of a memory-mapped Generic Timer takes the name of its base address.

In each register memory frame, the memory at offset `0xFD0-0xFFF` is reserved for twelve 32-bit IMPLEMENTATION DEFINED ID registers, see the [CounterID<n>](#) register descriptions for more information.

Note

The Arm architecture requires memory-mapped peripherals to be little-endian, and therefore the counter is little-endian.

In an implementation with multiple physical address spaces, [CNTControlBase](#) is only accessible by accesses from the most secure physical address space. For example, in a system with Secure and Non-secure memory maps, [CNTControlBase](#) is only accessible by Secure accesses.

Table F2-1 shows the [CNTControlBase](#) control registers, in order of their offsets from the [CNTControlBase](#) base address, for an implementation that includes registers in the IMPLEMENTATION DEFINED register space 0x0C0-0x0FC, and also has fewer than 39 [CNTFID<n>](#) registers. The [Frequency modes table](#) describes how this memory map differs if more [CNTFID<n>](#) registers are implemented.

[Generic Timer memory-mapped register descriptions](#) describes each of these registers.

Table F2-1 CNTControlBase memory map

Offset	Name	Type	Description
0x000	CNTCR	RW	Counter Control Register.
0x004	CNTSR	RO	Counter Status Register.
0x008	CNTCV[31:0]	RW	Counter Count Value register.
0x00C	CNTCV[63:32]	RW	
0x010	CNTSCR^a	RW	Counter Scale Register.
0x014-0x018	-	RES0	Reserved.
0x01C	CNTID^a	RO	Counter Identification Register.
0x020	CNTFID0	RO or RW	Frequency modes table, and end marker. For more information, see The Frequency modes table .
0x020+4 <i>n</i>	CNTFID<n>	RO or RW	
0x024+4 <i>n</i>	-	RO or RW, RAZ	
(0x028+4 <i>n</i>)- 0x0BC	-	RO, RES0	Reserved.
0x0C0-0x0FC	-	IMPLEMENTATION DEFINED	Reserved for IMPLEMENTATION DEFINED registers.
0x100-0xFCC	-	RO, RES0	Reserved.
0xFD0-0xFFC	CounterID<n>	RO	Counter ID registers 0-11.

a. Implemented only if [FEAT_CNTSC](#) is implemented.

Table F2-2 shows the [CNTReadBase](#) control registers, in order of their offsets from the [CNTReadBase](#) base address. [Generic Timer memory-mapped register descriptions](#) describes each of these registers.

Table F2-2 CNTReadBase memory map

Offset	Name	Type	Description
0x000	CNTCV[31:0]	RO	Counter Count Value register
0x004	CNTCV[63:32]	RO	
0x008-0xFCC	-	RES0	Reserved
0xFD0-0xFFC	CounterID<n>	RO	Counter ID registers 0-11

F2.3 Memory-mapped timer components

This part of the Arm Generic Timer specification defines an optional memory-mapped timer component. This can be implemented as part of any programmable system component that does not incorporate a System register mapped Arm Generic Timer, to provide that system component with the timer functionality of an Arm Generic Timer.

The memory map consists of up to eight timer *frames*. The base address of a frame is `CNTBaseN`, where *N* numbers from 0 up to a maximum permitted value of 7.

Each `CNTBaseN` timer frame:

- Provides its own set of timers and associated interrupts.
- Is implemented in its own [memory page](#) or [memory protection region](#).
- Is implemented at a base address, identified as `CNTBaseN`, that is aligned to the size of the [translation granule](#) or [memory protection region](#).

For each implemented `CNTBaseN` frame the system can optionally provide an unprivileged view of the frame, described as the EL0 view of the frame. The base address of this second view of the `CNTBaseN` frame is `CNTELOBaseN`.

Note

In the naming of the registers associated with a `CNTBaseN` or `CNTELOBaseN` frame, the value of *N* is represented as `<n>`, for example `CNTACR<n>`.

If a `CNTELOBaseN` frame is implemented:

- Is implemented in its own [memory page](#) or [memory protection region](#) and is aligned to the size of the [translation granule](#) or [memory protection region](#).
- All registers visible in `CNTBaseN`, except for `CNTVOFF` and `CNTELOACR`, can be visible in `CNTELOBaseN`.
 - Control fields in `CNTELOACR` determine whether each register is visible.
- The offsets of all visible registers are the same as their offsets in the `CNTBaseN` frame.

In addition to the implemented `CNTBaseN` and `CNTELOBaseN` frames, the system must provide a single control frame at base address `CNTCTLBase`. `CNTCTLBase` must be implemented in its own [memory page](#) or [memory protection region](#) and is aligned to the size of the [translation granule](#) or [memory protection region](#).

The system defines the position of each frame in the memory map. This means the values of each of the `CNTBaseN`, `CNTELOBaseN`, and `CNTCTLBase` base addresses is IMPLEMENTATION DEFINED.

Note

The Arm architecture requires memory-mapped peripherals to be little-endian, and therefore the memory-mapped timers are little-endian.

The following sections describe the implementation of a memory-mapped view of the counter and timer:

- [The CNTCTLBase frame.](#)
- [The CNTBaseN and CNTELOBaseN frames.](#)

Note

Providing a complete set of features in a system level implementation gives an implementation example for a system level Generic Timer implementation that provides equivalent features to a System registers Generic Timer implementation in a PE that includes all of the Exception levels.

F2.3.1 The CNTCTLBase frame

The `CNTCTLBase` frame contains:

- An identification register for the features of the memory-mapped counter and timer implementation.

- Access controls for each [CNTBaseN](#) frame.
- A virtual offset register for frames that implement a virtual timer.

[Table F2-3](#) shows the [CNTCTLBase](#) registers, in order of their offsets from the [CNTCTLBase](#) base address.

Note

[CNTFRQ](#) and [CNTVOFF](#) registers are also implemented in a System register interface to the Generic Timer.

[Generic Timer memory-mapped register descriptions](#) describes each of these registers.

Table F2-3 CNTCTLBase memory map

Offset	Register	Type	Security ^a	Description
0x000	CNTFRQ^b	RW	Restricted	Counter Frequency register.
0x004	CNTNSAR	RW	Restricted	Counter Non-Secure Access register.
0x008	CNTTIDR	RO	No restrictions	Counter Timer ID register.
0x00C- 0x03F	-	RES0	-	Reserved.
0x040+4N ^c	CNTACR<n>	RW	Programmable ^d	Counter Access Control register <i>N</i> .
0x060- 0x07F	-	RES0	-	Reserved.
0x080+8N ^c	CNTVOFF<n>[31:0]^b	RW ^e	Programmable ^d	Virtual Offset register <i>N</i> . If the CNTBaseN frame has virtual timer capability then CNTVOFF<n> is implemented as an RW register, otherwise its location is RAZ/WI.
0x084+8N ^c	CNTVOFF<n>[63:32]^b	RW ^e		
0x0C0-0x0FC	-	RES0	-	Reserved.
0x100-0x7FC	-	-	-	IMPLEMENTATION DEFINED.
0x800-0xFBC	-	RES0	-	Reserved.
0xFC0-0xFCF	-	-	-	IMPLEMENTATION DEFINED.
0xFD0- 0xFFC	CounterID<n>	RO	No restrictions	Counter ID registers 0-11.

a. Access security restrictions in an implementation with multiple Security states. See the individual register descriptions and [CNTNSAR](#) for details on the restrictions. In an implementation that supports only a single Security state all registers are accessible as shown in the *Type* column.

b. These registers are also defined in the System register interface to the Generic Timer, and therefore are also described in [Generic Timer registers](#) and Generic Timer registers. The bit assignments of the registers are identical in the System register interface and in the memory-mapped system level interface.

c. Implemented for each value of *N* from 0 to 7 for which a [CNTBaseN](#) frame is implemented.

d. The [CNTNSAR](#) determines the Non-secure accessibility of the [CNTACR<n>](#) and the [CNTVOFF<n>](#) in the [CNTCTLBase](#) frame. For more information, see the register descriptions.

e. Address is reserved, RAZ/WI if register not implemented.

All implementations of the Generic Timer include the virtual counter. Therefore, conceptually, all implementations include the [CNTVOFF](#) register that defines the virtual offset between the physical count and the virtual count. If a memory-mapped Generic Timer component does not distinguish between real time and virtual time, then it can implement [CNTVOFF](#) as RAZ/WI. Otherwise [CNTVOFF](#) is an RW register, and Arm strongly recommends that the system only permits access to [CNTVOFF](#) from EL2 or higher.

F2.3.2 The CNTBaseN and CNTEL0BaseN frames

Each [CNTBaseN](#) frame, or {[CNTBaseN](#), [CNTEL0BaseN](#)} pair of frames, provides a memory-mapped counter and timer, see:

- The CNTBaseN frame.
- The CNTEL0BaseN frame.
- CNTCTLBase status and control fields for the CNTBaseN and CNTEL0BaseN frames.

F2.3.2.1 The CNTBaseN frame

Table F2-4 shows the CNTBaseN registers, in order of their offsets from the CNTBaseN base address. Whether a frame includes a virtual timer is IMPLEMENTATION DEFINED. If it does not, then memory at offsets 0x030-0x03C is RAZ/WI. Except for CNTEL0ACR and the CounterID<n> registers, equivalent registers are also implemented in a System register interface to the timer component of a Generic Timer.

Generic Timer memory-mapped register descriptions describes each of these registers.

Table F2-4 CNTBaseN memory map

Offset	Register	Type	Description
0x000	CNTPCT[31:0] ^a	RO	Physical Count register.
0x004	CNTPCT[63:32] ^a	RO	
0x008	CNTVCT[31:0] ^a	RO	Virtual Count register.
0x00C	CNTVCT[63:32] ^a	RO	
0x010	CNTRFQ ^a	RO ^c	Counter Frequency register.
0x014	CNTEL0ACR	RW ^b	Counter EL0 Access Control Register, optional in the CNTBaseN memory map.
0x018	CNTVOFF[31:0] ^a	RO ^c	Virtual Offset register. If CNTVOFF in the CNTCTLBase frame is an RW register, a read of this register returns the value of that register. Otherwise is RAZ.
0x01C	CNTVOFF[63:32] ^a	RO ^c	
0x020	CNTP_CVAL[31:0] ^a	RW	Physical Timer CompareValue register.
0x024	CNTP_CVAL[63:32] ^a	RW	
0x028	CNTP_TVAL ^a	RW	Physical TimerValue register.
0x02C	CNTP_CTL ^a	RW	Physical Timer Control register.
0x030	CNTV_CVAL[31:0] ^a	RW ^b	Virtual Timer CompareValue register, optional in the CNTBaseN memory map.
0x034	CNTV_CVAL[63:32] ^a	RW ^b	
0x038	CNTV_TVAL ^a	RW ^b	Virtual TimerValue register, optional in the CNTBaseN memory map.
0x03C	CNTV_CTL ^a	RW ^b	Virtual Timer Control register, optional in the CNTBaseN memory map.
0x040-0xFCF	-	RES0	Reserved.
0xFD0-0xFFC	CounterID<n>	RO	Counter ID registers 0-11.

a. These registers are also defined in the System register interface to the Generic Timer, and therefore are also described in [Generic Timer registers](#) and Generic Timer registers. The bit assignments of the registers are identical in the System register interface and in the memory-mapped system level interface.

b. Address is reserved, RAZ/WI if register not implemented.

c. The CNTCTLBase frame includes an RW view of this register.

F2.3.2.2 The CNTEL0BaseN frame

For any value of N, the layout of the registers in the CNTEL0BaseN frame is identical to the CNTBaseN frame, except that, in the CNTEL0BaseN frame:

- CNTVOFF is never visible, and the memory at 0x018-0x01C is RAZ/WI.

- **CNTELOACR** is never visible, and the memory at 0x014 is RAZ/WI.
- If implemented in the **CNTBaseN** frame, **CNTELOACR** controls whether **CNTPCT**, **CNTVCT**, **CNTRQ**, the Physical Timer, and the Virtual Timer registers are visible in the **CNTELOBaseN** frame. If **CNTELOACR** is not implemented then these registers are not visible in the **CNTELOBaseN** frame, and their addresses in that frame are RAZ/WI.

If an implementation supports 64-bit atomic accesses, then **CNTPCT**, **CNTVCT**, **CNTVOFF**, **CNTP_CVAL**, and **CNTV_CVAL** must be accessible as atomic 64-bit values.

F2.3.2.3 CNTCTLBase status and control fields for the CNTBaseN and CNTELOBaseN frames

In the **CNTCTLBase** frame:

CNTTIDR controls:

- Whether each **CNTBaseN** frame is implemented.
- If a **CNTBaseN** frame is implemented, whether:
 - That **CNTBaseN** frame has virtual timer capability.
 - A corresponding **CNTELOBaseN** frame is implemented.

CNTNSAR controls:

Whether all the following are accessible by Non-secure accesses:

- **CNTACR<n>**.
- **CNTVOFF<n>**.
- Each implemented **CNTBaseN** frame, and any corresponding **CNTELOBaseN** frame.

The **CNTACR<n>** registers control:

For each implemented **CNTBaseN** frame, the accessibility of the following registers in that frame:

- **CNTP_CTL**, **CNTP_CVAL**, and **CNTP_TVAL**.
- **CNTV_CTL**, **CNTV_CVAL**, and **CNTV_TVAL**.
- **CNTVOFF**.
- **CNTRQ**.
- **CNTPCT**.
- **CNTVCT**.

For **CNTACR<n>**, the value of <n> corresponds to the value of *N* for the controlled **CNTBaseN** frame.

The **CNTVOFF<n>** registers provide:

For each implemented **CNTBaseN** frame that has virtual capability, the RW copy of the **CNTVOFF** register for that frame.

Note

In a **CNTBaseN** frame that has virtual timer capability the **CNTVOFF** register is RO.

For **CNTVOFF<n>**, the value of <n> corresponds to the value of *N* for the controlled **CNTBaseN** frame.

Chapter F3

Recommended External Interface to the Performance Monitors

This chapter describes the recommended external interface to the Performance Monitors. It contains the following section:

- [About the external interface to the Performance Monitors registers](#)

Note

[Performance Monitors external register descriptions](#) describes the external view of the Performance Monitors registers.

F3.1 About the external interface to the Performance Monitors registers

Arm recommends that:

- An implementation provides the OPTIONAL external debug interface to the Performance Monitors registers, [FEAT_PMUv3_EXT](#).

Note

A debugger can use this interface to access counters in the Performance Monitors.

- The implementation includes the OPTIONAL support for memory-mapped access to the External debug interface.

Note

— Software running on any PE in a system can use this interface to access counters in the Performance Monitors.

— Privileged software should use the MMU or MPU to control access to this interface.

- The external debug interface is implemented as defined in Recommended External Debug Interface.

The following sections describe the memory-mapped views of the Performance Monitors registers:

- [Differences in the external views of the Performance Monitors registers](#).
- [Access permissions for external views of the Performance Monitors](#).

In this section, unless the context explicitly indicates otherwise, any reference to *a memory-mapped view* applies equally to a register view using:

- An access through an external debug interface.
- A memory-mapped access.

F3.1.1 Supported access sizes

[External Performance Monitors registers summary](#) gives the memory map of these registers.

The memory access sizes supported by any peripheral is IMPLEMENTATION DEFINED by the peripheral. For accesses to the external interface to the Performance Monitors registers implementations must:

- Comply with the requirements of [Supported access sizes and Endianness](#).
- When [FEAT_PMUv3_EXT32](#) is implemented, support word-aligned 32-bit accesses to access 32-bit registers or either half of a 64-bit register, even if all components with direct memory access to the PMU support making 64-bit accesses.

Permitted word-aligned 32-bit accesses are single-copy atomic at word granularity. When [FEAT_PMUv3_EXT64](#) is implemented, permitted doubleword-aligned 64-bit accesses are single-copy atomic at doubleword granularity.

F3.1.2 Differences in the external views of the Performance Monitors registers

An external view of the Performance Monitors registers accesses the same registers as the System registers interface described in [Performance Monitors Extension registers](#), except that:

- The PMSELR is accessible only in the System registers interface.
- The following registers are accessible only in external views:
 - [PMAUTHSTATUS](#).
 - [PMCCR](#).
 - [PMCFGR](#).
 - [PMCIDR0](#).
 - [PMCIDR1](#).

- [PMCIDR2](#).
- [PMCIDR3](#).
- [PMDEVARCH](#).
- [PMDEVTYPE](#).
- [PMEVFILT2R<n>](#).
- [PMIIDR](#).
- [PMLAR](#).
- [PMLSR](#).
- [PMPCCTL](#).
- [PMPCSR](#).
- [PMPIDR0](#).
- [PMPIDR1](#).
- [PMPIDR2](#).
- [PMPIDR3](#).
- [PMPIDR4](#).
- [PMPIDR5](#).
- [PMPIDR6](#).
- [PMPIDR7](#).

[Performance Monitors external register descriptions](#) describes these registers.

- The following registers are accessible only in the external view when [FEAT_PMUv3_EXT32](#) is implemented:

- [PMCID1SR](#).
- [PMCID2SR](#).
- [PMDEVAFF0](#).
- [PMDEVAFF1](#).
- [PMVIDSR](#).

[Performance Monitors external register descriptions](#) describes these registers.

- The following controls do not affect the external views:

- [PMSELR](#).
- [PMUSERENR](#).
- [HDCR](#). {TPM, TPMCR, HPMN}.

Instead, see the register descriptions in [External System Control Register Descriptions](#).

- The [PMSWINC_ELO](#) register is OPTIONAL in the external view when [FEAT_PMUv3_EXT32](#) is implemented.

F3.1.3 Access permissions for external views of the Performance Monitors

[IDZGKJ](#) For more information, see [External debug interface register access permissions](#).

[IYMBZZ](#) The following table shows the access permissions for the Performance Monitors registers in a Debug implementation for Armv8-R implementations.

The table uses the following terms:

DLK	When FEAT_DoubleLock is implemented and locked, DoubleLockStatus() == TRUE, accesses to some registers produce an error. Applies to both interfaces.
EPMAD	When AllowExternalPMUAccess() == FALSE, external debug access is disabled for the access. See also Behavior of a not permitted memory-mapped access .
Error	Indicates that the access gives an error response.
Def	This shows the default access permissions, if none of the conditions in this list prevent access to the register.
Off	The Core power domain is completely off, or in a low-power state where the Core power domain registers cannot be accessed, and EDPRSR.PU will read as zero.

Note

If debug power is off, then all external debug interface accesses return an error.

OSLK When the OS Lock is locked, [OSLSR_EL1](#).OSLK is 1, accesses to some registers produces an error. This column shows the effect of this control on accesses using the external debug interface.

SLK This indicates the modified default access permissions for OPTIONAL memory-mapped accesses to the external debug interface if the optional Software Lock is locked. See [Register access permissions for memory-mapped accesses](#).
For all other accesses, this column is ignored.

Note

When FEAT_PMUv3_EXT64 is implemented, the Software Lock is not implemented.

- Indicates that the control has no effect on the behavior of the access:

- If no other control affects the behavior, the Default access behavior applies.
- However, another control might determine the behavior.

Table F3-1 Access permissions for the Performance Monitors registers when FEAT_PMUv3_EXT32 is implemented

Offset	Register	Domain	Off	DLK	OSLK	EPMAD	EPMSSAD	Def	SLK

a. Implemented event counters only. *n* is the counter number.

b. See IMPLEMENTATION DEFINED registers.

Chapter F4

External System Control Register Descriptions

This chapter describes the external system control registers. It excludes the External debug registers that are described in [External Debug Register Descriptions](#). It contains the following sections:

- [About the external system control register descriptions](#)
- [External Performance Monitors registers summary](#)
- [Performance Monitors external register descriptions](#)
- [Generic Timer memory-mapped registers overview](#)
- [Generic Timer memory-mapped register descriptions](#)

F4.1 About the external system control register descriptions

This chapter describes the external system control registers other than the external debug registers. That is, it describes:

An external view of the Performance Monitors registers

Arm recommends that implementations provide access to the Performance Monitors registers through the OPTIONAL External debug interface, and provide the OPTIONAL memory-mapped interface to this interface:

- [External Performance Monitors registers summary](#) lists the registers that are accessible in this view of the Performance Monitors, and describes their memory map.
- [Performance Monitors external register descriptions](#) describes each of the memory-mapped registers.

[Recommended External Interface to the Performance Monitors](#) describes the recommended interface to these registers.

Note

[The Performance Monitors Extension](#) describes the Performance Monitors. The following section describes the System register interfaces to the Performance Monitors, [Performance Monitors registers](#), for accesses from an Exception level that is using AArch64.

The registers for the system level Generic Timer component

Any implementation that includes the Generic Timer must include the memory-mapped system level component described in [System Level Implementation of the Generic Timer](#). In this chapter:

- [Generic Timer memory-mapped registers overview](#) gives an overview of the registers, referring to [System Level Implementation of the Generic Timer](#) for more information.
- [Generic Timer memory-mapped register descriptions](#) describes each of the memory-mapped registers.

Note

[The Generic Timer in AArch64 state](#) describes the Generic Timer component that is accessible using the System registers. The following section describes the System register interfaces to that component [Generic Timer registers](#), for accesses from an Exception level that is using AArch64.

Note

[External Debug Register Descriptions](#) describes the external debug registers.

Arm® Reliability, Availability, and Serviceability (RAS) System Architecture, for A-profile architecture (ARM IHI 0100) describes the RAS memory-mapped registers.

F4.2 External Performance Monitors registers summary

When an implementation provides access to the Performance Monitors registers through the External debug interface, that interface provides access to:

- Performance Monitors registers.
- A read-only configuration register, [PMCFGR](#).
- The OPTIONAL CoreSight registers for the Performance Monitors, if they are implemented.

The locations of the registers are defined as offsets from a system-defined base address. [Performance Monitors external register views](#) defines this memory map.

F4.2.1 Performance Monitors external register views

The following tables show the external view of the Performance Monitors registers:

- [Table F4-1](#) when [FEAT_PMUv3_EXT32](#) is implemented.

All other entries are reserved.

-
- Note**
- Counters that are reserved because HDCR.HPMN has been changed from its reset value remain visible in any external view.
 - The registers that relate to an implemented event counter, PMNx, are PMEVCNTR<n> and PMEVTYPER<n>.
 - Tables in this section only list the Armv8 registers. For encoding information of the registers introduced by Armv9, see the individual register descriptions in this chapter.
-

Each entry in the Name column links to the register description in [Performance Monitors external register descriptions](#).

Table F4-1 Performance Monitors external register views when FEAT_PMUv3_EXT32 is implemented

PMCIDR1 ^d			0xFF4
PMCIDR2 ^d			0xFF8
PMCIDR3 ^d			0xFFC

a. The interface must support at least single-copy atomic 32-bit accesses. If single-copy atomic 64-bit access to the registers is not possible, software must use a high-low-high read access to read the counter value if the counter is enabled.

b. PC Sample-based Profiling Extension registers. Implemented only when [FEAT_PCSRv8p2](#) is implemented, except that from Armv8.2 [PMDEVID](#) is required regardless of whether [FEAT_PCSRv8p2](#) is implemented.

Before Armv8.2, the PC Sample-based Profiling Extension can, instead, be implemented in the memory-mapped debug registers space, see [The PC Sample-based Profiling Extension](#).

c. OPTIONAL.

d. CoreSight interface registers, see Management registers and CoreSight compliance.

e. The Software lock registers are defined as part of CoreSight compliance, but their contents depend on the type of access that is made and whether the OPTIONAL Software lock is implemented. See the register description for details.

F4.3 Performance Monitors external register descriptions

This section describes the external view of the Performance Monitors registers. [External Performance Monitors registers summary](#) lists these registers in offset order.

F4.3.1 PMAUTHSTATUS, Performance Monitors Authentication Status register

The PMAUTHSTATUS characteristics are:

Purpose

Provides information about the state of the IMPLEMENTATION DEFINED authentication interface for Performance Monitors.

Configuration

If FEAT_DoPD is implemented, this register is in the Core power domain. If FEAT_DoPD is not implemented, this register is in the Debug power domain.

This register is OPTIONAL, and is required for CoreSight compliance. Arm recommends that this register is implemented.

This register is present only when FEAT_PMUv3_EXT is implemented and FEAT_PMUv3 is implemented. Otherwise, direct accesses to PMAUTHSTATUS are RES0.

Attributes

PMAUTHSTATUS is a 32-bit register.

Field descriptions

Bits [31:8]

Reserved, RES0.

SNID, bits [7:6]

Holds the same value as DBGAUTHSTATUS_EL1.SNID.

SID, bits [5:4]

Secure invasive debug.

SID	Meaning
0b00	Not implemented.

All other values are reserved.

Access to this field is RO.

NSNID, bits [3:2]

Holds the same value as DBGAUTHSTATUS_EL1.NSNID.

NSID, bits [1:0]

Non-secure invasive debug.

NSID	Meaning
0b00	Not implemented.

All other values are reserved.

Access to this field is RO.

Accessing PMAUTHSTATUS

Accesses to this register use the following encodings:

When FEAT_PMUv3_EXT is implemented

Accessible at offset 0xFB8 from PMU

- When FEAT_DoPD is implemented and !IsCorePowered(), accesses to this register generate an error response.
- Otherwise, accesses to this register are RO.

F4.3.2 PMCCFILTR_EL0, Performance Monitors Cycle Counter Filter Register

The PMCCFILTR_EL0 characteristics are:

Purpose

Determines the modes in which the Cycle Counter, PMCCNTR_EL0, increments.

Configuration

PMCCFILTR_EL0 is in the Core power domain.

When FEAT_PMUv3_EXT32 is implemented, External register PMCCFILTR_EL0 bits [31:0] are architecturally mapped to AArch64 System register PMCCFILTR_EL0[31:0].

This register is present only when FEAT_PMUv3_EXT is implemented and FEAT_PMUv3 is implemented. Otherwise, direct accesses to PMCCFILTR_EL0 are RES0.

Attributes

PMCCFILTR_EL0 is a 64-bit register.

Field descriptions

Bits [63:32]

Reserved, RES0.

P, bit [31]

EL1 filtering. Controls counting cycles in EL1.

P	Meaning
0b0	This mechanism has no effect on filtering of cycles.
0b1	The PE does not count cycles in EL1.

If Secure and Non-secure states are implemented, then counting cycles in Non-secure EL1 is further controlled by PMCCFILTR_EL0.NSK.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

U, bit [30]

EL0 filtering. Controls counting cycles in EL0.

U	Meaning
0b0	This mechanism has no effect on filtering of cycles.
0b1	The PE does not count cycles in EL0.

If Secure and Non-secure states are implemented, then counting cycles in Non-secure EL0 is further controlled by PMCCFILTR_EL0.NSU.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [29:28]

Reserved, RES0.

NSH, bit [27]

EL2 filtering. Controls counting cycles in EL2.

NSH	Meaning
0b0	The PE does not count cycles in EL2.
0b1	This mechanism has no effect on filtering of cycles.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [26:0]

Reserved, RES0.

Accessing PMCCFILTR_EL0

Accesses to this register use the following encodings:

When FEAT_PMuV3_EXT32 is implemented

[31:0] Accessible at offset 0x47C from PMU

- When DoubleLockStatus(), or !IsCorePowered(), or !AllowExternalPMUAccess(addrdesc), accesses to this register generate an error response.
- When OSLockStatus(), accesses to this register generate an error response.
- When SoftwareLockStatus(addrdesc), accesses to this register are RO.
- Otherwise, accesses to this register are RW.

F4.3.3 PMCCNTR_EL0, Performance Monitors Cycle Counter

The PMCCNTR_EL0 characteristics are:

Purpose

Holds the value of the processor Cycle Counter, CCNT, that counts processor clock cycles. For more information, see ‘Time as measured by the Performance Monitors cycle counter’.

PMCCFILTR_EL0 determines the modes and states in which the PMCCNTR_EL0 can increment.

Configuration

PMCCNTR_EL0 is in the Core power domain.

External register PMCCNTR_EL0 bits [63:0] are architecturally mapped to AArch64 System register PMCCNTR_EL0[63:0].

This register is present only when FEAT_PMUv3_EXT is implemented and FEAT_PMUv3 is implemented. Otherwise, direct accesses to PMCCNTR_EL0 are RES0.

Attributes

PMCCNTR_EL0 is a 64-bit register.

Field descriptions

CCNT, bits [63:0]

Cycle count. Depending on the values of PMCR_EL0.{LC,D}, the cycle count increments in one of the following ways:

- Every processor clock cycle.
- Every 64th processor clock cycle.

Writing 1 to PMCR_EL0.C sets this field to 0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing PMCCNTR_EL0

Accesses to this register use the following encodings:

When FEAT_PMUv3_EXT32 is implemented

[63:0] Accessible at offset 0x0F8 from PMU

- When DoubleLockStatus(), or !IsCorePowered(), or !AllowExternalPMUAccess(addrdesc), accesses to this register generate an error response.
- When OSLockStatus(), accesses to this register generate an error response.
- When SoftwareLockStatus(addrdesc), accesses to this register are RO.
- Otherwise, accesses to this register are RW.

F4.3.4 PMCEID0, Performance Monitors Common Event Identification register 0

The PMCEID0 characteristics are:

Purpose

Defines which Common architectural events and Common microarchitectural events are implemented, or counted, using PMU events in the range 0x0000 to 0x001F.

For more information about the Common events and the use of the PMCEIDn registers, see ‘[The PMU event number space and common events](#)’.

Use of this register is deprecated.

Note

This view of the register was previously called PMCEID0_EL0.

Configuration

PMCEID0 is in the Core power domain.

When FEAT_PMUv3_EXT32 is implemented, External register PMCEID0 bits [31:0] are architecturally mapped to AArch64 System register [PMCEID0_EL0](#)[31:0].

This register is present only when FEAT_PMUv3_EXT32 is implemented and FEAT_PMUv3 is implemented. Otherwise, direct accesses to PMCEID0 are RES0.

Attributes

PMCEID0 is a 32-bit register.

Field descriptions

ID<n> , bits [n], for n = 31 to 0

ID[n] corresponds to Common event n.

For each bit:

ID<n>	Meaning
0b0	The Common event is not implemented, or not counted.

0b1

The Common event is implemented.

When the value of a bit in the field is 1, the corresponding Common event is implemented and counted.

Note

Arm recommends that if a Common event is never counted, the value of the corresponding bit is 0.

A bit that corresponds to a reserved event number is reserved. The value might be used in a future revision of the architecture to identify an additional Common event.

Note

Such an event might be added retrospectively to an earlier version of the PMU architecture, provided the event does not require any additional PMU features and has an event number that can be represented in the PMCEID<n> registers of that earlier version of the PMU architecture.

Accessing PMCEID0

Note

`AllowExternalPMUAccess()` has a new definition from Armv8.4. Refer to the Pseudocode definitions for more information.

Accesses to this register use the following encodings:

When FEAT_PMUv3_EXT32 is implemented

Accessible at offset 0xE20 from PMU

- When `DoubleLockStatus()`, or `!IsCorePowered()`, or `!AllowExternalPMUAccess(addrdesc)`, accesses to this register generate an error response.
- When `OSLockStatus()`, accesses to this register generate an error response.
- Otherwise, accesses to this register are RO.

F4.3.5 PMCEID1, Performance Monitors Common Event Identification register 1

The PMCEID1 characteristics are:

Purpose

Defines which Common architectural events and Common microarchitectural events are implemented, or counted, using PMU events in the range 0×020 to $0 \times 03F$.

For more information about the Common events and the use of the PMCEIDn registers, see ‘[The PMU event number space and common events](#)’.

Use of this register is deprecated.

Note

This view of the register was previously called PMCEID1_EL0.

Configuration

PMCEID1 is in the Core power domain.

When FEAT_PMUv3_EXT32 is implemented, External register PMCEID1 bits [31:0] are architecturally mapped to AArch64 System register [PMCEID1_EL0](#)[31:0].

This register is present only when FEAT_PMUv3_EXT32 is implemented and FEAT_PMUv3 is implemented. Otherwise, direct accesses to PMCEID1 are RES0.

Attributes

PMCEID1 is a 32-bit register.

Field descriptions

ID<n> , bits [n], for n = 31 to 0

ID[n] corresponds to Common event ($0 \times 0020 + n$).

For each bit:

ID<n>	Meaning
0b0	The Common event is not implemented, or not counted.

0b1

The Common event is implemented.

When the value of a bit in the field is 1, the corresponding Common event is implemented and counted.

Note

Arm recommends that if a Common event is never counted, the value of the corresponding bit is 0.

A bit that corresponds to a reserved event number is reserved. The value might be used in a future revision of the architecture to identify an additional Common event.

Note

Such an event might be added retrospectively to an earlier version of the PMU architecture, provided the event does not require any additional PMU features and has an event number that can be represented in the PMCEID<n> registers of that earlier version of the PMU architecture.

Accessing PMCEID1

Note

`AllowExternalPMUAccess()` has a new definition from Armv8.4. Refer to the Pseudocode definitions for more information.

Accesses to this register use the following encodings:

When FEAT_PMUv3_EXT32 is implemented

Accessible at offset 0xE24 from PMU

- When `DoubleLockStatus()`, or `!IsCorePowered()`, or `!AllowExternalPMUAccess(addrdesc)`, accesses to this register generate an error response.
- When `OSLockStatus()`, accesses to this register generate an error response.
- Otherwise, accesses to this register are RO.

F4.3.6 PMCEID2, Performance Monitors Common Event Identification register 2

The PMCEID2 characteristics are:

Purpose

Defines which Common architectural events and Common microarchitectural events are implemented, or counted, using PMU events in the range 0×4000 to $0 \times 401F$.

For more information about the Common events and the use of the PMCEID n registers, see ‘[The PMU event number space and common events](#)’.

Use of this register is deprecated.

Configuration

PMCEID2 is in the Core power domain.

When FEAT_PMUv3_EXT32 is implemented, External register PMCEID2 bits [31:0] are architecturally mapped to AArch64 System register [PMCEID0_EL0](#)[63:32].

This register is present only when FEAT_PMUv3_EXT32 is implemented and FEAT_PMUv3p1 is implemented. Otherwise, direct accesses to PMCEID2 are RES0.

Attributes

PMCEID2 is a 32-bit register.

Field descriptions

IDhi<n> , bits [n], for n = 31 to 0

IDhi[n] corresponds to Common event ($0 \times 4000 + n$).

For each bit:

IDhi<n>	Meaning
0b0	The Common event is not implemented, or not counted.
0b1	The Common event is implemented.

IDhi<n>	Meaning
---------	---------

When the value of a bit in the field is 1, the corresponding Common event is implemented and counted.

Note

Arm recommends that if a Common event is never counted, the value of the corresponding bit is 0.

A bit that corresponds to a reserved event number is reserved. The value might be used in a future revision of the architecture to identify an additional Common event.

Note

Such an event might be added retrospectively to an earlier version of the PMU architecture, provided the event does not require any additional PMU features and has an event number that can be represented in the PMCEID<n> registers of that earlier version of the PMU architecture.

Accessing PMCEID2

Note

`AllowExternalPMUAccess()` has a new definition from Armv8.4. Refer to the Pseudocode definitions for more information.

Accesses to this register use the following encodings:

When FEAT_PMuV3_EXT32 is implemented and FEAT_PMuV3p1 is implemented

Accessible at offset `0xE28` from PMU

- When `DoubleLockStatus()`, or `!IsCorePowered()`, or `!AllowExternalPMUAccess(addrdesc)`, accesses to this register generate an error response.
- When `OSLockStatus()`, accesses to this register generate an error response.
- Otherwise, accesses to this register are RO.

F4.3.7 PMCEID3, Performance Monitors Common Event Identification register 3

The PMCEID3 characteristics are:

Purpose

Defines which Common architectural events and Common microarchitectural events are implemented, or counted, using PMU events in the range 0×4020 to $0 \times 403F$.

For more information about the Common events and the use of the PMCEID $_n$ registers, see ‘[The PMU event number space and common events](#)’.

Use of this register is deprecated.

Configuration

PMCEID3 is in the Core power domain.

When FEAT_PMUv3_EXT32 is implemented, External register PMCEID3 bits [31:0] are architecturally mapped to AArch64 System register [PMCEID1_EL0](#)[63:32].

This register is present only when FEAT_PMUv3_EXT32 is implemented and FEAT_PMUv3p1 is implemented. Otherwise, direct accesses to PMCEID3 are RES0.

Attributes

PMCEID3 is a 32-bit register.

Field descriptions

IDhi<n> , bits [n], for n = 31 to 0

IDhi[n] corresponds to Common event ($0 \times 4020 + n$).

For each bit:

IDhi<n>	Meaning
0b0	The Common event is not implemented, or not counted.
0b1	The Common event is implemented.

IDhi<n>	Meaning
---------	---------

When the value of a bit in the field is 1, the corresponding Common event is implemented and counted.

Note

Arm recommends that if a Common event is never counted, the value of the corresponding bit is 0.

A bit that corresponds to a reserved event number is reserved. The value might be used in a future revision of the architecture to identify an additional Common event.

Note

Such an event might be added retrospectively to an earlier version of the PMU architecture, provided the event does not require any additional PMU features and has an event number that can be represented in the PMCEID<n> registers of that earlier version of the PMU architecture.

Accessing PMCEID3

Note

`AllowExternalPMUAccess()` has a new definition from Armv8.4. Refer to the Pseudocode definitions for more information.

Accesses to this register use the following encodings:

When FEAT_PMuV3_EXT32 is implemented and FEAT_PMuV3p1 is implemented

Accessible at offset `0xE2C` from PMU

- When `DoubleLockStatus()`, or `!IsCorePowered()`, or `!AllowExternalPMUAccess(addrdesc)`, accesses to this register generate an error response.
- When `OSLockStatus()`, accesses to this register generate an error response.
- Otherwise, accesses to this register are RO.

F4.3.8 PMCFGR, Performance Monitors Configuration Register

The PMCFGR characteristics are:

Purpose

Contains PMU-specific configuration data.

Configuration

PMCFGR is in the Core power domain.

This register is present only when FEAT_PMuV3_EXT is implemented and FEAT_PMuV3 is implemented. Otherwise, direct accesses to PMCFGR are RES0.

Attributes

PMCFGR is a 32-bit register.

Field descriptions

NCG, bits [31:28]

Defines the number of counter groups implemented, minus one.

NCG	Meaning
0b0000	One counter group implemented.

All other values are reserved.

Access to this field is RO.

Bits [27:23]

Reserved, RES0.

SS, bit [22]

Snapshot supported.

The value of this field is an IMPLEMENTATION DEFINED choice of:

SS	Meaning
0b0	Snapshot mechanism not supported. The locations 0x600-0x7FC and 0xE30-0xE3C are IMPLEMENTATION DEFINED.

SS	Meaning
0b1	Snapshot mechanism supported. Locations 0x600-0x7FC and 0xE30-0xE3C contain IMPLEMENTATION DEFINED snapshot registers.

A PMU might include an IMPLEMENTATION DEFINED snapshot mechanism, including one using the IMPLEMENTATION DEFINED registers 0x600-0x7FC and 0xE30-0xE3C.

Access to this field is RO.

Bits [21:20]

Reserved, RES0.

UEN, bit [19]

User-mode Enable Register supported. [PMUSERENR_EL0](#) is not visible in the external debug interface, so this bit is RAZ.

Reads as 0b0

Access to this field is RO.

WT, bit [18]

This feature is not supported, so this bit is RAZ.

Reads as 0b0

Access to this field is RO.

NA, bit [17]

This feature is not supported, so this bit is RAZ.

Reads as 0b0

Access to this field is RO.

EX, bit [16]

Export supported.

The value of this field is an IMPLEMENTATION DEFINED choice of:

EX	Meaning
0b0	PMCR_EL0.X is RES0.
0b1	PMCR_EL0.X is read/write.

Access to this field is RO.

CCD, bit [15]

Cycle counter has prescale.

This field is RAZ

The value of this field is an IMPLEMENTATION DEFINED choice of:

CCD	Meaning
0b0	PMCR_EL0.D is RES0.
0b1	PMCR_EL0.D is read/write.

Access to this field is RO.

CC, bit [14]

Dedicated cycle counter (counter 31) supported.

Reads as 0b1

Access to this field is RO.

SIZE, bits [13:8]

Size of counters, minus one. This field defines the size of the largest counter implemented by the Performance Monitors Unit.

From Armv8.0, the largest counter is 64-bits, so the value of this field is 0b111111.

This field is used by software to determine the spacing of the counters in the memory-map. From Armv8.0, the counters are a doubleword-aligned addresses.

Reads as 0b111111

Access to this field is RO.

N, bits [7:0]

Number of counters implemented, minus one.

The value of this field is an IMPLEMENTATION DEFINED choice of:

N	Meaning
0x00	Only PMCCNTR_EL0 implemented.
0x01..0x1F	Number of counters implemented, 2 to 32, minus one.

All other values are reserved.

The count includes the cycle counter, [PMCCNTR_EL0](#).

For example, if PMCFGR.N == 0x07, then:

- There are eight counters in total.
- This comprises 7 event counters and the cycle counter.

The maximum number of event counters is 31.

Access to this field is RO.

Accessing PMCFGR

Note

`AllowExternalPMUAccess()` has a new definition from Armv8.4. Refer to the Pseudocode definitions for more information.

Accesses to this register use the following encodings:

When FEAT_PMuV3_EXT32 is implemented

[31:0] Accessible at offset 0xE00 from PMU

- When DoubleLockStatus(), or !IsCorePowered(), or !AllowExternalPMUAccess(addrdesc), accesses to this register generate an error response.
- When OSLockStatus(), accesses to this register generate an error response.
- Otherwise, accesses to this register are RO.

F4.3.9 PMCID1SR, CONTEXTIDR_EL1 Sample Register

The PMCID1SR characteristics are:

Purpose

PC Sample-based Profiling Extension register that contains the sampled value of [CONTEXTIDR_EL1](#), captured on reading [PMPCSR](#)[31:0].

Configuration

PMCID1SR is in the Core power domain.

This register is present only when FEAT_PMuV3_EXT32 is implemented and FEAT_PCSRv8p2 is implemented.

Attributes

PMCID1SR is a 32-bit register.

Field descriptions

CONTEXTIDR_EL1, bits [31:0]

Context ID. The value of CONTEXTIDR that is associated with the most recent [PMPCSR](#) sample. When the most recent [PMPCSR](#) sample is generated:

- If EL1 is using AArch64, then the Context ID is sampled from [CONTEXTIDR_EL1](#).

Because the value written to this register is an indirect read of CONTEXTIDR, it is CONSTRAINED UNPREDICTABLE whether this register is set to the original or new value if [PMPCSR](#) samples:

- An instruction that writes to CONTEXTIDR.
- The next Context synchronization event.
- Any instruction executed between these two instructions.

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

Accessing PMCID1SR

IMPLEMENTATION DEFINED extensions to external debug might make the value of this register UNKNOWN, see ‘[Permitted behavior that might make the PC Sample-based profiling registers UNKNOWN](#)’.

Accesses to this register use the following encodings:

When FEAT_PMuV3_EXT32 is implemented and FEAT_PCSRv8p2 is implemented

Accessible at offset 0x208 from PMU

- When DoubleLockStatus() or !IsCorePowered(), accesses to this register generate an error response.
- When OSLockStatus(), accesses to this register generate an error response.
- Otherwise, accesses to this register are RO.

When FEAT_PMuV3_EXT32 is implemented and FEAT_PCSRv8p2 is implemented

Accessible at offset 0x228 from PMU

- When DoubleLockStatus() or !IsCorePowered(), accesses to this register generate an error response.
- When OSLockStatus(), accesses to this register generate an error response.
- Otherwise, accesses to this register are RO.

F4.3.10 PMCID2SR, CONTEXTIDR_EL2 Sample Register

The PMCID2SR characteristics are:

Purpose

PC Sample-based Profiling Extension register that contains the sampled value of [CONTEXTIDR_EL2](#), captured on reading [PMPCSR](#)[31:0].

Configuration

PMCID2SR is in the Core power domain.

This register is present only when FEAT_PMUv3_EXT32 is implemented and FEAT_PCSRv8p2 is implemented.

Attributes

PMCID2SR is a 32-bit register.

Field descriptions

CONTEXTIDR_EL2, bits [31:0]

Context ID. The value of [CONTEXTIDR_EL2](#) that is associated with the most recent [PMPCSR](#) sample. When the most recent [PMPCSR](#) sample is generated:

- If the PE is not executing at EL3, EL2 is using AArch64, and EL2 is enabled in the current Security state, then this field is set to the Context ID sampled from [CONTEXTIDR_EL2](#).
- Otherwise, this field is set to an UNKNOWN value.

Because the value written to this field is an indirect read of [CONTEXTIDR_EL2](#), it is CONSTRAINED UNPREDICTABLE whether this field is set to the original or new value if [PMPCSR](#) samples:

- An instruction that writes to [CONTEXTIDR_EL2](#).
- The next Context synchronization event.
- Any instruction executed between these two instructions.

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

Accessing PMCID2SR

IMPLEMENTATION DEFINED extensions to external debug might make the value of this register UNKNOWN, see ‘[Permitted behavior that might make the PC Sample-based profiling registers UNKNOWN](#)’.

Accesses to this register use the following encodings:

When FEAT_PMUv3_EXT32 is implemented and FEAT_PCSRv8p2 is implemented

Accessible at offset 0x22C from PMU

- When DoubleLockStatus() or !IsCorePowered(), accesses to this register generate an error response.
- When OSLockStatus(), accesses to this register generate an error response.
- Otherwise, accesses to this register are RO.

F4.3.11 PMCIDR0, Performance Monitors Component Identification Register 0

The PMCIDR0 characteristics are:

Purpose

Provides information to identify a Performance Monitor component.

For more information, see ‘About the Component Identification scheme’.

Configuration

If [FEAT_DoPD](#) is implemented, this register is in the Core power domain. If [FEAT_DoPD](#) is not implemented, this register is in the Debug power domain.

This register is present only when FEAT_PMuV3_EXT is implemented. Otherwise, direct accesses to PMCIDR0 are RES0.

Attributes

PMCIDR0 is a 32-bit register.

Field descriptions

Bits [31:8]

Reserved, RES0.

PRMBL_0, bits [7:0]

When FEAT_PMu_PIDR is implemented:

Preamble.

Reads as 0x0D

Access to this field is RO.

Otherwise:

Reserved, RAZ.

Accessing PMCIDR0

Accesses to this register use the following encodings:

When FEAT_PMuV3_EXT is implemented

Accessible at offset 0xFF0 from PMU

- When FEAT_DoPD is implemented and !IsCorePowered(), accesses to this register generate an error response.
- Otherwise, accesses to this register are RO.

F4.3.12 PMCIDR1, Performance Monitors Component Identification Register 1

The PMCIDR1 characteristics are:

Purpose

Provides information to identify a Performance Monitor component.
For more information, see ‘About the Component Identification scheme’.

Configuration

If FEAT_DoPD is implemented, this register is in the Core power domain. If FEAT_DoPD is not implemented, this register is in the Debug power domain.

This register is present only when FEAT_PMUv3_EXT is implemented. Otherwise, direct accesses to PMCIDR1 are RES0.

Attributes

PMCIDR1 is a 32-bit register.

Field descriptions

Bits [31:8]

Reserved, RES0.

CLASS, bits [7:4]

When FEAT_PMU_PIDR is implemented:
Component class.

CLASS	Meaning
0b1001	CoreSight component.

Other values are defined by the CoreSight Architecture.

This field reads as 0x9.

Access to this field is RO.

Otherwise:

Reserved, RAZ.

PRMBL_1, bits [3:0]

When FEAT_PMU_PIDR is implemented:

Preamble.

Reads as 0b0000

Access to this field is RO.

Otherwise:

Reserved, RAZ.

Accessing PMCIDR1

Accesses to this register use the following encodings:

When FEAT_PMuV3_EXT is implemented

Accessible at offset 0xFF4 from PMU

- When FEAT_DoPD is implemented and !IsCorePowered(), accesses to this register generate an error response.
- Otherwise, accesses to this register are RO.

F4.3.13 PMCIDR2, Performance Monitors Component Identification Register 2

The PMCIDR2 characteristics are:

Purpose

Provides information to identify a Performance Monitor component.

For more information, see ‘About the Component Identification scheme’.

Configuration

If [FEAT_DoPD](#) is implemented, this register is in the Core power domain. If [FEAT_DoPD](#) is not implemented, this register is in the Debug power domain.

This register is present only when [FEAT_PMuV3_EXT](#) is implemented. Otherwise, direct accesses to PMCIDR2 are RES0.

Attributes

PMCIDR2 is a 32-bit register.

Field descriptions

Bits [31:8]

Reserved, RES0.

PRMBL_2, bits [7:0]

When [FEAT_PMu_PIDR](#) is implemented:

Preamble.

Reads as 0x05

Access to this field is RO.

Otherwise:

Reserved, RAZ.

Accessing PMCIDR2

Accesses to this register use the following encodings:

When [FEAT_PMuV3_EXT](#) is implemented

Accessible at offset 0xFF8 from PMU

- When [FEAT_DoPD](#) is implemented and !IsCorePowered(), accesses to this register generate an error response.
- Otherwise, accesses to this register are RO.

F4.3.14 PMCIDR3, Performance Monitors Component Identification Register 3

The PMCIDR3 characteristics are:

Purpose

Provides information to identify a Performance Monitor component.

For more information, see ‘About the Component Identification scheme’.

Configuration

If [FEAT_DoPD](#) is implemented, this register is in the Core power domain. If [FEAT_DoPD](#) is not implemented, this register is in the Debug power domain.

This register is present only when [FEAT_PMuV3_EXT](#) is implemented. Otherwise, direct accesses to PMCIDR3 are RES0.

Attributes

PMCIDR3 is a 32-bit register.

Field descriptions

Bits [31:8]

Reserved, RES0.

PRMBL_3, bits [7:0]

When [FEAT_PMu_PIDR](#) is implemented:

Preamble.

Reads as 0xB1

Access to this field is RO.

Otherwise:

Reserved, RAZ.

Accessing PMCIDR3

Accesses to this register use the following encodings:

When [FEAT_PMuV3_EXT](#) is implemented

Accessible at offset 0xFFC from PMU

- When [FEAT_DoPD](#) is implemented and `!IsCorePowered()`, accesses to this register generate an error response.
- Otherwise, accesses to this register are RO.

F4.3.15 PMCNTENCLR_EL0, Performance Monitors Count Enable Clear Register

The PMCNTENCLR_EL0 characteristics are:

Purpose

Allows software to disable the following counters:

- The cycle counter [PMCCNTR_EL0](#).
- The event counters [PMEVCNTR<n>_EL0](#).

Reading from this register shows which counters are enabled.

Configuration

PMCNTENCLR_EL0 is in the Core power domain.

When FEAT_PMUv3_EXT32 is implemented, External register PMCNTENCLR_EL0 bits [31:0] are architecturally mapped to AArch64 System register [PMCNTENCLR_EL0](#)[31:0].

When FEAT_PMUv3_EXT32 is implemented, External register PMCNTENCLR_EL0 bits [31:0] are architecturally mapped to AArch64 System register [PMCNTENSET_EL0](#)[31:0].

This register is present only when FEAT_PMUv3_EXT is implemented and FEAT_PMUv3 is implemented. Otherwise, direct accesses to PMCNTENCLR_EL0 are RES0.

Attributes

PMCNTENCLR_EL0 is a 32-bit register.

Field descriptions

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
C	P30	P29	P28	P27	P26	P25	P24	P23	P22	P21	P20	P19	P18	P17	P16	P15	P14	P13	P12	P11	P10	P9	P8	P7	P6	P5	P4	P3	P2	P1	P0

C, bit [31]

[PMCCNTR_EL0](#) disable. On writes, allows software to disable [PMCCNTR_EL0](#). On reads, returns the [PMCCNTR_EL0](#) enable status.

C	Meaning
0b0	PMCCNTR_EL0 disabled.
0b1	PMCCNTR_EL0 enabled.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing this field has the following behavior:

- When SoftwareLockStatus(addrdesc), access to this field is RO.
- Otherwise, access to this field is W1C.

P<m>, bits [m], for m = 30 to 0

[PMEVCNTR<m>_EL0](#) disable. On writes, allows software to disable [PMEVCNTR<m>_EL0](#). On reads, returns the [PMEVCNTR<m>_EL0](#) enable status.

P<m>	Meaning
0b0	PMEVCNTR<m>_EL0 disabled.
0b1	PMEVCNTR<m>_EL0 enabled.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing this field has the following behavior:

- When $m \geq \text{NUM_PMU_COUNTERS}$, access to this field is RAZ/WI.
- When `SoftwareLockStatus(addrdesc)`, access to this field is RO.
- Otherwise, access to this field is WIC.

Accessing PMCNTENCLR_EL0

Accesses to this register use the following encodings:

When FEAT_PMUv3_EXT32 is implemented

[31:0] Accessible at offset 0xC20 from PMU

- When `DoubleLockStatus()`, or `!IsCorePowered()`, or `!AllowExternalPMUAccess(addrdesc)`, accesses to this register generate an error response.
- When `OSLockStatus()`, accesses to this register generate an error response.
- When `SoftwareLockStatus(addrdesc)`, accesses to this register are RO.
- Otherwise, accesses to this register are RW.

F4.3.16 PMCNTESET_EL0, Performance Monitors Count Enable Set Register

The PMCNTESET_EL0 characteristics are:

Purpose

Allows software to enable the following counters:

- The cycle counter [PMCCNTR_EL0](#).
- The event counters [PMEVCNTR<n>_EL0](#).

Reading from this register shows which counters are enabled.

Configuration

PMCNTESET_EL0 is in the Core power domain.

When FEAT_PMUv3_EXT32 is implemented, External register PMCNTESET_EL0 bits [31:0] are architecturally mapped to AArch64 System register [PMCNTESET_EL0](#)[31:0].

When FEAT_PMUv3_EXT32 is implemented, External register PMCNTESET_EL0 bits [31:0] are architecturally mapped to AArch64 System register [PMCNTECLR_EL0](#)[31:0].

This register is present only when FEAT_PMUv3_EXT is implemented and FEAT_PMUv3 is implemented. Otherwise, direct accesses to PMCNTESET_EL0 are RES0.

Attributes

PMCNTESET_EL0 is a 32-bit register.

Field descriptions

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
C	P30	P29	P28	P27	P26	P25	P24	P23	P22	P21	P20	P19	P18	P17	P16	P15	P14	P13	P12	P11	P10	P9	P8	P7	P6	P5	P4	P3	P2	P1	P0

C, bit [31]

[PMCCNTR_EL0](#) enable. On writes, allows software to enable [PMCCNTR_EL0](#). On reads, returns the [PMCCNTR_EL0](#) enable status.

C	Meaning
0b0	PMCCNTR_EL0 disabled.
0b1	PMCCNTR_EL0 enabled.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing this field has the following behavior:

- When SoftwareLockStatus(addrdesc), access to this field is RO.
- Otherwise, access to this field is WIS.

P<m>, bits [m], for m = 30 to 0

[PMEVCNTR<m>_EL0](#) enable. On writes, allows software to enable [PMEVCNTR<m>_EL0](#). On reads, returns the [PMEVCNTR<m>_EL0](#) enable status.

P<m>	Meaning
0b0	PMEVCNTR<m>_EL0 disabled.
0b1	PMEVCNTR<m>_EL0 enabled.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing this field has the following behavior:

- When $m \geq \text{NUM_PMU_COUNTERS}$, access to this field is RAZ/WI.
- When `SoftwareLockStatus(addrdesc)`, access to this field is RO.
- Otherwise, access to this field is WIS.

Accessing PMCNTENSET_EL0

Accesses to this register use the following encodings:

When FEAT_PMUv3_EXT32 is implemented

[31:0] Accessible at offset 0xC00 from PMU

- When `DoubleLockStatus()`, or `!IsCorePowered()`, or `!AllowExternalPMUAccess(addrdesc)`, accesses to this register generate an error response.
- When `OSLockStatus()`, accesses to this register generate an error response.
- When `SoftwareLockStatus(addrdesc)`, accesses to this register are RO.
- Otherwise, accesses to this register are RW.

F4.3.17 PMCR_EL0, Performance Monitors Control Register

The PMCR_EL0 characteristics are:

Purpose

Configures and controls the Performance Monitors counters.

Configuration

PMCR_EL0 is in the Core power domain.

External register PMCR_EL0 bits [31:0] are architecturally mapped to AArch64 System register [PMCR_EL0](#)[31:0].

This register is present only when FEAT_PMUv3_EXT is implemented and FEAT_PMUv3 is implemented. Otherwise, direct accesses to PMCR_EL0 are RES0.

Attributes

PMCR_EL0 is a 32-bit register.

Field descriptions

Bits [31:11]

Reserved, RAZ/WI.

Hardware must implement this field as RAZ/WI. Software must not rely on the register reading as zero, and must use a read-modify-write sequence to write to the register.

Bits [10:7]

Reserved, RES0.

Bit [6]

Reserved, RES1.

DP, bit [5]

When FEAT_PMUv3p1 is implemented:

Disable cycle counter when event counting is prohibited.

DP	Meaning
0b0	Cycle counting by PMCCNTR_EL0 is not affected by this mechanism.
0b1	Cycle counting by PMCCNTR_EL0 is disabled in prohibited regions: If FEAT_PMUv3p1 is implemented, EL2 is implemented, and MDCR_EL2.HPMD or HDCR.HPMD is 1, then cycle counting by PMCCNTR_EL0 is disabled at EL2.

The conditions when this field disables the cycle counter are the same as when event counting by an event counter in the first range is prohibited. For more information about event counter ranges, see [MDCR_EL2.HPMN](#).

For more information, see ‘[Prohibiting event and cycle counting](#)’.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

X, bit [4]

When the implementation includes a PMU event export bus:

Enable export of events in an IMPLEMENTATION DEFINED PMU event export bus.

X	Meaning
0b0	Do not export events.
0b1	Export events where not prohibited.

This field enables the exporting of events over an IMPLEMENTATION DEFINED PMU event export bus to another device.

No events are exported when counting is prohibited.

This field does not affect the generation of Performance Monitors overflow interrupt requests or signaling to a cross-trigger interface (CTI) that can be implemented as signals exported from the PE.

If [FEAT_ETMv4](#) is implemented, this field does affect the use of PMU events as an External Input by the trace unit.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RAZ/WI.

Bit [3]

Reserved, RES0.

C, bit [2]

Cycle counter reset. The effects of writing to this field are:

C	Meaning
0b0	No action.
0b1	Reset PMCCNTR_EL0 to zero.

Note

Resetting [PMCCNTR_EL0](#) does not change the cycle counter overflow field. The value of PMCR_EL0.LC is ignored, and bits [63:0] of the cycle counter are reset.

Access to this field is WO/RAZ.

P, bit [1]

Event counter reset.

P	Meaning
0b0	No action.
0b1	Reset all event counters PMEVCNTR<n>_EL0 to zero.

Writes to this field do not affect the cycle counter [PMCCNTR_EL0](#).

Note
Resetting the event counters does not change the event counter overflow fields.

Access to this field is WO/RAZ.

E, bit [0]

Enable.

E	Meaning
0b0	Affected counters are disabled and do not count.
0b1	Affected counters are enabled by PMCNTENSET_EL0 .

The counters affected by this field are:

- The event counters in the first range. For more information about event counter ranges, see [MDCR_EL2.HPMN](#).
- The cycle counter [PMCCNTR_EL0](#).

Other event counters are not affected by this field.

The reset behavior of this field is:

- On a Warm reset, this field resets to '0'.

Accessing PMCR_EL0

Accesses to this register use the following encodings:

When FEAT_PMUv3_EXT32 is implemented

Accessible at offset 0xE04 from PMU

- When DoubleLockStatus(), or !IsCorePowered(), or !AllowExternalPMUAccess(addrdesc), accesses to this register generate an error response.
- When OSLockStatus(), accesses to this register generate an error response.
- When SoftwareLockStatus(addrdesc), accesses to this register are RO.
- Otherwise, accesses to this register are RW.

F4.3.18 PMDEVAFF0, Performance Monitors Device Affinity register 0

The PMDEVAFF0 characteristics are:

Purpose

Copy of the low half of the PE MPIDR_EL1 register that allows a debugger to determine which PE in a multiprocessor system the Performance Monitor component relates to.

Configuration

If FEAT_DoPD is implemented, this register is in the Core power domain. If FEAT_DoPD is not implemented, this register is in the Debug power domain.

This register is present only when FEAT_PMUv3_EXT32 is implemented.

Attributes

PMDEVAFF0 is a 32-bit register.

Field descriptions

Bit [31]

Reserved, RAO/WI.

U, bit [30]

Indicates a Uniprocessor system, as distinct from PE 0 in a multiprocessor system.

The value of this field is an IMPLEMENTATION DEFINED choice of:

U	Meaning
0b0	Processor is part of a multiprocessor system.
0b1	Processor is part of a uniprocessor system.

Access to this field is RO.

Bits [29:25]

Reserved, RES0.

MT, bit [24]

Indicates whether the lowest level of affinity consists of logical PEs that are implemented using an interdependent approach, such as multithreading. See the description of Aff0 for more information about affinity levels.

The value of this field is an IMPLEMENTATION DEFINED choice of:

MT	Meaning
0b0	Performance of PEs with different affinity level 0 values, and the same values for affinity level 1 and higher, is largely independent.
0b1	Performance of PEs with different affinity level 0 values, and the same values for affinity level 1 and higher, is very interdependent.

Note

This field does not indicate that multithreading is implemented and does not indicate that PEs with different affinity level 0 values, and the same values for affinity level 1 and higher are implemented.

Access to this field is RO.

Aff2, bits [23:16]

Affinity level 2. See the description of Aff0 for more information.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

Aff1, bits [15:8]

Affinity level 1. See the description of Aff0 for more information.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

Aff0, bits [7:0]

Affinity level 0. The value of the MPIDR.{Aff2, Aff1, Aff0} or [MPIDR_EL1](#).{Aff3, Aff2, Aff1, Aff0} set of fields of each PE must be unique within the system as a whole.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

Accessing PMDEVAFF0

Accesses to this register use the following encodings:

When FEAT_PMUv3_EXT32 is implemented

Accessible at offset 0xFA8 from PMU

- When FEAT_DoPD is implemented and !IsCorePowered(), accesses to this register generate an error response.
- Otherwise, accesses to this register are RO.

F4.3.19 PMDEVAFF1, Performance Monitors Device Affinity register 1

The PMDEVAFF1 characteristics are:

Purpose

Copy of the high half of the PE [MPIDR_EL1](#) register that allows a debugger to determine which PE in a multiprocessor system the Performance Monitor component relates to.

Configuration

If [FEAT_DoPD](#) is implemented, this register is in the Core power domain. If [FEAT_DoPD](#) is not implemented, this register is in the Debug power domain.

This register is present only when [FEAT_PMUv3_EXT32](#) is implemented.

Attributes

PMDEVAFF1 is a 32-bit register.

Field descriptions

Bits [31:8]

Reserved, RES0.

Aff3, bits [7:0]

Affinity level 3. See the description of [PMDEVAFF0.Aff0](#) for more information.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

Accessing PMDEVAFF1

Accesses to this register use the following encodings:

When FEAT_PMUv3_EXT32 is implemented

Accessible at offset 0xFAC from PMU

- When [FEAT_DoPD](#) is implemented and `!IsCorePowered()`, accesses to this register generate an error response.
- Otherwise, accesses to this register are RO.

F4.3.20 PMDEVARCH, Performance Monitors Device Architecture register

The PMDEVARCH characteristics are:

Purpose

Identifies the programmers' model architecture of the Performance Monitor component.

Configuration

If **FEAT_DoPD** is implemented, this register is in the Core power domain. If **FEAT_DoPD** is not implemented, this register is in the Debug power domain.

This register is present only when **FEAT_PMUv3_EXT** is implemented. Otherwise, direct accesses to PMDEVARCH are RES0.

Attributes

PMDEVARCH is a 32-bit register.

Field descriptions

ARCHITECT, bits [31:21]

Defines the architect of the component. For Performance Monitors, this is Arm Limited.

Bits [31:28] are the JEP106 continuation code, 0b0100.

Bits [27:21] are the JEP106 identification code, 0b0111011.

Reads as 0b01000111011

Access to this field is RO.

PRESENT, bit [20]

DEVARCH presence. Indicates that the PMDEVARCH register provides architecture information.

Reads as 0b1

Access to this field is RO.

REVISION, bits [19:16]

Defines the architecture revision. For architectures defined by Arm this is the minor revision.

For Performance Monitors, the revision defined by Armv8 is 0x0.

All other values are reserved.

Reads as 0b0000

Access to this field is RO.

ARCHVER, bits [15:12]

When **UInt(PMU.PMDEVARCH.ARCHPART) == 0xA16**:

Architecture Version. Defines the architecture version of the component.

ARCHVER	Meaning
0b0010	Performance Monitors Extension version 3, PMUv3.

All other values are reserved.

PMDEVARCH.ARCHVER and PMDEVARCH.ARCHPART are also defined as a single field, PMDEVARCH.ARCHID, so that PMDEVARCH.ARCHVER is PMDEVARCH.ARCHID[15:12].

Access to this field is RO.

Otherwise:

Architecture Version. Defines the architecture version of the component.

ARCHVER	Meaning
0b0000	PC Sample-based Profiling version 2, FEAT_PCSRv8p2 .

All other values are reserved.

PMDEVARCH.ARCHVER and PMDEVARCH.ARCHPART are also defined as a single field, PMDEVARCH.ARCHID, so that PMDEVARCH.ARCHVER is PMDEVARCH.ARCHID[15:12].

ARCHPART, bits [11:0]

Architecture Part. Defines the architecture of the component.

The value of this field is an IMPLEMENTATION DEFINED choice of:

ARCHPART	Meaning
0xA10	PC Sample-based Profiling, including the 32-bit programmers' model extension.
0xA16	Armv8-A PE performance monitors, including the 32-bit programmers' model extension.

[FEAT_PMUv3_EXT32](#) implements the functionality described by the values 0xA10 and 0xA16.

The values 0xA10 and 0xA20 indicate that [FEAT_PCSRv8p2](#) is implemented but the Performance Monitors Extension is not implemented.

PMDEVARCH.ARCHVER and PMDEVARCH.ARCHPART are also defined as a single field, PMDEVARCH.ARCHID, so that PMDEVARCH.ARCHPART is PMDEVARCH.ARCHID[11:0].

Access to this field is RO.

Accessing PMDEVARCH

Accesses to this register use the following encodings:

When FEAT_PMUv3_EXT is implemented

Accessible at offset 0xFBC from PMU

- When FEAT_DoPD is implemented and !IsCorePowered(), accesses to this register generate an error response.
- Otherwise, accesses to this register are RO.

F4.3.21 PMDEVID, Performance Monitors Device ID register

The PMDEVID characteristics are:

Purpose

Provides information about features of the Performance Monitors implementation.

Configuration

If FEAT_DoPD is implemented, this register is in the Core power domain. If FEAT_DoPD is not implemented, this register is in the Debug power domain.

This register is present only when (Armv8.2 or FEAT_PCSRv8p2 is implemented) and FEAT_PMUv3_EXT is implemented. Otherwise, direct accesses to PMDEVID are RES0.

Attributes

PMDEVID is a 32-bit register.

Field descriptions

Bits [31:4]

Reserved, RES0.

PCSample, bits [3:0]

Indicates the level of PC Sample-based Profiling support using Performance Monitors registers.

The value of this field is an IMPLEMENTATION DEFINED choice of:

PCSample	Meaning
0b0000	PC Sample-based Profiling Extension is not implemented in the Performance Monitors register space.
0b0001	PC Sample-based Profiling Extension is implemented in the Performance Monitors register space.

All other values are reserved.

FEAT_PCSRv8p2 implements the functionality identified by the value 0b0001.

If FEAT_PCSRv8p2 is not implemented, then the only permitted value is 0b0000.

From Armv8.2, when FEAT_PCSRv8p2 is implemented, the value 0b0000 is not permitted.

Access to this field is RO.

Accessing PMDEVID

Accesses to this register use the following encodings:

When FEAT_PMUv3_EXT is implemented and (Armv8.2 or FEAT_PCSRv8p2 is implemented)

Accessible at offset 0xFC8 from PMU

- When FEAT_DoPD is implemented and !IsCorePowered(), accesses to this register generate an error response.
- Otherwise, accesses to this register are RO.

F4.3.22 PMDEVTYPE, Performance Monitors Device Type register

The PMDEVTYPE characteristics are:

Purpose

Indicates to a debugger that this component is part of a PE’s performance monitor interface.

Configuration

If FEAT_DoPD is implemented, this register is in the Core power domain. If FEAT_DoPD is not implemented, this register is in the Debug power domain.

This register is present only when FEAT_PMUv3_EXT is implemented and FEAT_PMU_PIDR is implemented. Otherwise, direct accesses to PMDEVTYPE are RES0.

Attributes

PMDEVTYPE is a 32-bit register.

Field descriptions

Bits [31:8]

Reserved, RES0.

SUB, bits [7:4]

Subtype. Indicates this is a component within a PE.

Reads as 0b0001

Access to this field is RO.

MAJOR, bits [3:0]

Major type.

The value of this field is an IMPLEMENTATION DEFINED choice of:

MAJOR	Meaning
0b0000	Unspecified.
0b0110	Performance monitor component.

FEAT_PMUv3 implements the functionality described by the value 0b0110.

Access to this field is RO.

Accessing PMDEVTYPE

Accesses to this register use the following encodings:

When FEAT_PMUv3_EXT is implemented

Accessible at offset 0xFCC from PMU

- When FEAT_DoPD is implemented and !IsCorePowered(), accesses to this register generate an error response.
- Otherwise, accesses to this register are RO.

F4.3.23 PMEVCNTR<n>_EL0, Performance Monitors Event Count Registers, n = 0 - 30

The PMEVCNTR<n>_EL0 characteristics are:

Purpose

Holds event counter <n>, which counts events, where <n> is 0 to 30.

Configuration

PMEVCNTR<n>_EL0 is in the Core power domain.

When FEAT_PMUv3_EXT32 is implemented, External register PMEVCNTR<n>_EL0 bits [31:0] are architecturally mapped to AArch64 System register [PMEVCNTR<n>_EL0](#)[31:0].

This register is present only when FEAT_PMUv3_EXT is implemented and FEAT_PMUv3 is implemented. Otherwise, direct accesses to PMEVCNTR<n>_EL0 are RES0.

Attributes

PMEVCNTR<n>_EL0 is a 32-bit register.

Field descriptions

31	0
Event counter n	

EVCNT, bits [31:0]

Event counter n. Value of event counter n, where n is the number of this register and is a number from 0 to 30.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing PMEVCNTR<n>_EL0

Accesses to this register use the following encodings:

When FEAT_PMUv3_EXT32 is implemented

[31:0] Accessible at offset $0 \times 000 + (8 * n)$ from PMU

- When DoubleLockStatus(), or !IsCorePowered(), or !AllowExternalPMUAccess(addrdesc), accesses to this register generate an error response.
- When OSLockStatus(), accesses to this register generate an error response.
- When SoftwareLockStatus(addrdesc), accesses to this register are RO.
- Otherwise, accesses to this register are RW.

F4.3.24 PMEVFILT2R<n>, Performance Monitors Event Filter Registers, n = 0 - 63

The PMEVFILT2R<n> characteristics are:

Purpose

Provides additional IMPLEMENTATION DEFINED configuration controls for PMU counters.

Each PMEVFILT2R<n> register can provide additional configuration controls for a PMU counter, where:

- For values of n less than 31, if event counter n is implemented, then the controls are for PMU event counter <n>.
- For n equal to 31, the controls are for the cycle counter, [PMCCNTR_ELO](#);
- For all other values of n, PMEVFILT2R<n> is not implemented.

Although this mapping is recommended, it is not required and the function of each register is IMPLEMENTATION DEFINED.

Configuration

PMEVFILT2R<n> is in the Core power domain.

If PMEVFILT2R<n> is not implemented:

- When `IsCorePowered() && !DoubleLockStatus() && !OSLockStatus() && AllowExternalPMUAccess()`, accesses are RES0.
- Otherwise, it is CONSTRAINED UNPREDICTABLE whether accesses to this register are RES0 or generate an error response.

This register is present only when FEAT_PMUv3_EXT is implemented, FEAT_PMUv3 is implemented, and an implementation implements PMEVFILT2R<n>. Otherwise, direct accesses to PMEVFILT2R<n> are RES0.

Attributes

PMEVFILT2R<n> is a 32-bit register.

Field descriptions

31	IMPLEMENTATION DEFINED	0
----	------------------------	---

IMPLEMENTATION DEFINED, bits [31:0]

IMPLEMENTATION DEFINED.

Accessing PMEVFILT2R<n>

Accesses to this register use the following encodings:

When FEAT_PMUv3_EXT32 is implemented

[31:0] Accessible at offset $0 \times 800 + (4 * n)$ from PMU

- When `DoubleLockStatus()`, or `!IsCorePowered()`, or `!AllowExternalPMUAccess(addrdesc)`, accesses to this register generate an error response.
- When `OSLockStatus()`, accesses to this register generate an error response.
- When `SoftwareLockStatus(addrdesc)`, accesses to this register are RO.
- Otherwise, accesses to this register are RW.

F4.3.25 **PMEVTYPER<n>_EL0, Performance Monitors Event Type Registers, n = 0 - 30**

The PMEVTYPER<n>_EL0 characteristics are:

Purpose

Configures event counter n, where n is 0 to 30.

Configuration

PMEVTYPER<n>_EL0 is in the Core power domain.

If event counter n is not implemented:

- When `IsCorePowered()` `&& !DoubleLockStatus()` `&& !OSLockStatus()` `&& AllowExternalPMUAccess()`, accesses are RES0.
- Otherwise, it is CONSTRAINED UNPREDICTABLE whether accesses to this register are RES0 or generate an error response.

External register PMEVTYPER<n>_EL0 bits [31:0] are architecturally mapped to AArch64 System register [PMEVTYPER<n>_EL0](#)[31:0].

This register is present only when FEAT_PMuV3_EXT is implemented and FEAT_PMuV3 is implemented. Otherwise, direct accesses to PMEVTYPER<n>_EL0 are RES0.

Attributes

PMEVTYPER<n>_EL0 is a 64-bit register.

Field descriptions

Bits [63:32]

Reserved, RES0.

P, bit [31]

EL1 filtering. Controls counting events in EL1.

P	Meaning
0b0	This mechanism has no effect on filtering of events.
0b1	The PE does not count events in EL1.

If Secure and Non-secure states are implemented, then counting events in Non-secure EL1 is further controlled by PMEVTYPER<n>_EL0.NSK.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

U, bit [30]

EL0 filtering. Controls counting events in EL0.

U	Meaning
0b0	This mechanism has no effect on filtering of events.
0b1	The PE does not count events in EL0.

If Secure and Non-secure states are implemented, then counting events in Non-secure EL0 is further controlled by PMEVTYP<n>_EL0.NSU.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [29:28]

Reserved, RES0.

NSH, bit [27]

EL2 filtering. Controls counting events in EL2.

NSH	Meaning
0b0	The PE does not count events in EL2.
0b1	This mechanism has no effect on filtering of events.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [26]

Reserved, RES0.

MT, bit [25]

When an IMPLEMENTATION DEFINED multi-threaded PMU extension is implemented:

Multithreading.

MT	Meaning
0b0	Count events only on controlling PE.
0b1	Count events from any PE with the same affinity at level 1 and above as this PE.

Unless otherwise stated:

- If the event counts PE cycles when a stall condition is true and a second condition is true, then the counter counts Processor cycles when the stall condition is true for all of these PEs, and the second condition is true for any of these PEs.

- If the event counts PE cycles when any other condition is true, then the counter counts Processor cycles when the condition is true for any of these PEs.
- Otherwise, the event counts by the sum of the count across all of these PEs.

For the stall events, the stall condition means the applicable condition described by the STALL, STALL_FRONTEND, or STALL_BACKEND event.

The second condition is any condition in addition to this.

For example, for the STALL_FRONTEND_L1I event, the stall condition is STALL_FRONTEND, and the second condition is when there is a demand instruction miss in the first level of instruction cache.

For the STALL, STALL_FRONTEND, and STALL_BACKEND events themselves, the second condition is the null TRUE condition.

See ‘[Multithreaded implementations](#)’ and ‘[Cycle event counting in multithreaded implementations](#)’.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bits [24:16]

Reserved, RES0.

evtCount[15:10], bits [15:10]

When FEAT_PMUv3p1 is implemented:

Extension to evtCount[9:0]. For more information, see evtCount[9:0].

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

evtCount[9:0], bits [9:0]

Event to count.

The event number of the event that is counted by event counter PMU.PMEVCNTR<n>_EL0.

The ranges of event numbers allocated to each type of event are shown in ‘[Allocation of the PMU event number space](#)’.

If PMEVTYPEPER<n>_EL0.evtCount is programmed to an event that is reserved or not supported by the PE, the behavior depends on the value written:

- For the range 0x0000 to 0x003F, no events are counted and the value returned by a direct or external read of the PMEVTYPEPER<n>_EL0.evtCount field is the value written to the field.
- If [FEAT_PMUv3p1](#) is implemented, for the range 0x4000 to 0x403F, no events are counted and the value returned by a direct or external read of the PMEVTYPEPER<n>_EL0.evtCount field is the value written to the field.
- For other values, it is UNPREDICTABLE what event, if any, is counted and the value returned by a direct or external read of the PMEVTYPEPER<n>_EL0.evtCount field is UNKNOWN.

Note

UNPREDICTABLE means the event must not expose privileged information.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing PMEVTYPER<n>_ELO

Accesses to this register use the following encodings:

When FEAT_PMUv3_EXT32 is implemented

[31:0] Accessible at offset $0x400 + (4 * n)$ from PMU

- When DoubleLockStatus(), or !IsCorePowered(), or !AllowExternalPMUAccess(addrdesc), accesses to this register generate an error response.
- When OSLockStatus(), accesses to this register generate an error response.
- When SoftwareLockStatus(addrdesc), accesses to this register are RO.
- Otherwise, accesses to this register are RW.

F4.3.26 PMIIDR, Performance Monitors Implementation Identification Register

The PMIIDR characteristics are:

Purpose

Provides discovery information about the Performance Monitor component.

Configuration

This register is present only when FEAT_PMUv3_EXT32 is implemented and an implementation implements PMIIDR. Otherwise, direct accesses to PMIIDR are RES0.

Attributes

PMIIDR is a 32-bit register.

Field descriptions

31	20	19	16	15	12	11	0
ProductID		Variant		Revision		Implementer	

ProductID, bits [31:20]

Part number, bits [11:0]. The part number is selected by the designer of the component.

Matches the part number represented in the Peripheral ID registers PMPIDRn, if those registers are present.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

Variant, bits [19:16]

Component major revision.

Defines either a variant of the component defined by PMIIDR.ProductID, or the major revision of the component.

When defining a major revision, PMIIDR.Variant and PMIIDR.Revision together form the revision number of the component, with this field being the most significant part.

When a component is changed, PMIIDR.Variant or PMIIDR.Revision is increased to ensure that software can differentiate between different revisions of the component. If this field is increased, PMIIDR.Revision should be set to 0b0000.

Arm recommends this field matches the [PMPIDR2.REVISION](#) field, if present.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

Revision, bits [15:12]

Component minor revision.

PMIIDR.Variant and PMIIDR.Revision together form the revision number of the component, with this field being the least significant part.

When a component is changed, PMIIDR.Variant or PMIIDR.Revision is increased to ensure that software can differentiate between different revisions of the component. If PMIIDR.Variant field is increased, this field should be set to 0b0000, otherwise the value in this field should be increased.

Arm recommends this field matches the [PMPIDR3.REVAND](#) field, if present.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

Implementer, bits [11:0]

Contains the JEP106 manufacturer's identification code of the designer of the PMU.

The code identifies the designer of the component, which might not be the same as the implementer of the device containing the component.

Zero is not a valid JEP106 identification code, meaning a value of zero for PMIIDR indicates this register is not implemented.

For an implementation designed by Arm, this field reads as 0x43B.

Bits [11:8] contain the JEP106 bank identifier of the designer minus 1.

Bit 7 is RES0.

Bits [6:0] contain bits [6:0] of the JEP106 manufacturer's identification code of the designer.

If [PMPIDR4](#) is implemented, [PMPIDR4.DES_2](#) matches bits [11:8] of this field.

If [PMPIDR2](#) is implemented, [PMPIDR2.DES_1](#) matches bits [6:4] of this field.

If [PMPIDR1](#) is implemented, [PMPIDR1.DES_0](#) matches bits [3:0] of this field.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

Accessing PMIIDR

Accesses to this register use the following encodings:

When FEAT_PMUv3_EXT is implemented

Accessible at offset 0xE08 from PMU

- When DoubleLockStatus(), or !IsCorePowered(), or !AllowExternalPMUAccess(addrdesc), accesses to this register generate an error response.
- When OSLockStatus(), accesses to this register generate an error response.
- Otherwise, accesses to this register are RO.

F4.3.27 PMINTENCLR_EL1, Performance Monitors Interrupt Enable Clear Register

The PMINTENCLR_EL1 characteristics are:

Purpose

Allows software to disable the generation of interrupt requests on overflows from the following counters:

- The cycle counter [PMCCNTR_EL0](#).
- The event counters [PMEVCNTR<n>_EL0](#).

Reading from this register shows which overflow interrupt requests are enabled.

Configuration

PMINTENCLR_EL1 is in the Core power domain.

When FEAT_PMUv3_EXT32 is implemented, External register PMINTENCLR_EL1 bits [31:0] are architecturally mapped to AArch64 System register [PMINTENCLR_EL1](#)[31:0].

When FEAT_PMUv3_EXT32 is implemented, External register PMINTENCLR_EL1 bits [31:0] are architecturally mapped to AArch64 System register [PMINTENSET_EL1](#)[31:0].

This register is present only when FEAT_PMUv3_EXT is implemented and FEAT_PMUv3 is implemented. Otherwise, direct accesses to PMINTENCLR_EL1 are RES0.

Attributes

PMINTENCLR_EL1 is a 32-bit register.

Field descriptions

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
C	P30	P29	P28	P27	P26	P25	P24	P23	P22	P21	P20	P19	P18	P17	P16	P15	P14	P13	P12	P11	P10	P9	P8	P7	P6	P5	P4	P3	P2	P1	P0

C, bit [31]

Interrupt request on unsigned overflow of [PMCCNTR_EL0](#) disable. On writes, allows software to disable the interrupt request on unsigned overflow of [PMCCNTR_EL0](#). On reads, returns the interrupt request on unsigned overflow of [PMCCNTR_EL0](#) enable status.

C	Meaning
0b0	Interrupt request on unsigned overflow of PMCCNTR_EL0 disabled.
0b1	Interrupt request on unsigned overflow of PMCCNTR_EL0 enabled.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing this field has the following behavior:

- When SoftwareLockStatus(addrdesc), access to this field is RO.
- Otherwise, access to this field is WIC.

P<m> , bits [m], for m = 30 to 0

Interrupt request on unsigned overflow of [PMEVCNTR<m>_EL0](#) disable. On writes, allows software to disable the interrupt request on unsigned overflow of [PMEVCNTR<m>_EL0](#). On reads, returns the interrupt request on unsigned overflow of [PMEVCNTR<m>_EL0](#) enable status.

P<m>	Meaning
0b0	Interrupt request on unsigned overflow of PMEVCNTR<m>_EL0 disabled.
0b1	Interrupt request on unsigned overflow of PMEVCNTR<m>_EL0 enabled.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing this field has the following behavior:

- When $m \geq \text{NUM_PMU_COUNTERS}$, access to this field is RAZ/WI.
- When `SoftwareLockStatus(addrdesc)`, access to this field is RO.
- Otherwise, access to this field is W1C.

Accessing PMINTENCLR_EL1

Accesses to this register use the following encodings:

When FEAT_PMUv3_EXT32 is implemented

[31:0] Accessible at offset 0xC60 from PMU

- When `DoubleLockStatus()`, or `!IsCorePowered()`, or `!AllowExternalPMUAccess(addrdesc)`, accesses to this register generate an error response.
- When `OSLockStatus()`, accesses to this register generate an error response.
- When `SoftwareLockStatus(addrdesc)`, accesses to this register are RO.
- Otherwise, accesses to this register are RW.

F4.3.28 PMINTENSET_EL1, Performance Monitors Interrupt Enable Set Register

The PMINTENSET_EL1 characteristics are:

Purpose

Allows software to enable the generation of interrupt requests on overflows from the following counters:

- The cycle counter [PMCCNTR_EL0](#).
- The event counters [PMEVCNTR<n>_EL0](#).

Reading from this register shows which overflow interrupt requests are enabled.

Configuration

PMINTENSET_EL1 is in the Core power domain.

When FEAT_PMUv3_EXT32 is implemented, External register PMINTENSET_EL1 bits [31:0] are architecturally mapped to AArch64 System register [PMINTENSET_EL1](#)[31:0].

When FEAT_PMUv3_EXT32 is implemented, External register PMINTENSET_EL1 bits [31:0] are architecturally mapped to AArch64 System register [PMINTENCLR_EL1](#)[31:0].

This register is present only when FEAT_PMUv3_EXT is implemented and FEAT_PMUv3 is implemented. Otherwise, direct accesses to PMINTENSET_EL1 are RES0.

Attributes

PMINTENSET_EL1 is a 32-bit register.

Field descriptions

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
C	P30	P29	P28	P27	P26	P25	P24	P23	P22	P21	P20	P19	P18	P17	P16	P15	P14	P13	P12	P11	P10	P9	P8	P7	P6	P5	P4	P3	P2	P1	P0

C, bit [31]

Interrupt request on unsigned overflow of [PMCCNTR_EL0](#) enable. On writes, allows software to enable the interrupt request on unsigned overflow of [PMCCNTR_EL0](#). On reads, returns the interrupt request on unsigned overflow of [PMCCNTR_EL0](#) enable status.

C	Meaning
0b0	Interrupt request on unsigned overflow of PMCCNTR_EL0 disabled.
0b1	Interrupt request on unsigned overflow of PMCCNTR_EL0 enabled.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing this field has the following behavior:

- When SoftwareLockStatus(addrdesc), access to this field is RO.
- Otherwise, access to this field is WIS.

P<m> , bits [m], for m = 30 to 0

Interrupt request on unsigned overflow of [PMEVCNTR<m>_EL0](#) enable. On writes, allows software to enable the interrupt request on unsigned overflow of [PMEVCNTR<m>_EL0](#). On reads, returns the interrupt request on unsigned overflow of [PMEVCNTR<m>_EL0](#) enable status.

P<m>	Meaning
0b0	Interrupt request on unsigned overflow of PMEVCNTR<m>_EL0 disabled.
0b1	Interrupt request on unsigned overflow of PMEVCNTR<m>_EL0 enabled.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing this field has the following behavior:

- When $m \geq \text{NUM_PMU_COUNTERS}$, access to this field is RAZ/WI.
- When `SoftwareLockStatus(addrdesc)`, access to this field is RO.
- Otherwise, access to this field is WIS.

Accessing PMINTENSET_EL1

Accesses to this register use the following encodings:

When FEAT_PMUv3_EXT32 is implemented

[31:0] Accessible at offset `0xC40` from PMU

- When `DoubleLockStatus()`, or `!IsCorePowered()`, or `!AllowExternalPMUAccess(addrdesc)`, accesses to this register generate an error response.
- When `OSLockStatus()`, accesses to this register generate an error response.
- When `SoftwareLockStatus(addrdesc)`, accesses to this register are RO.
- Otherwise, accesses to this register are RW.

F4.3.29 PMITCTRL, Performance Monitors Integration mode Control register

The PMITCTRL characteristics are:

Purpose

Enables the Performance Monitors to switch from default mode into integration mode, where test software can control directly the inputs and outputs of the PE, for integration testing or topology detection.

Configuration

This register is present only when FEAT_PMUv3_EXT is implemented, FEAT_PMUv3 is implemented, and an implementation implements PMITCTRL. Otherwise, direct accesses to PMITCTRL are RES0.

Attributes

PMITCTRL is a 32-bit register.

Field descriptions

Bits [31:1]

Reserved, RES0.

IME, bit [0]

Integration mode enable. When IME == 1, the device reverts to an integration mode to enable integration testing or topology detection.

IME	Meaning
0b0	Normal operation.
0b1	Integration mode enabled.

The integration mode behavior is IMPLEMENTATION DEFINED.

The following resets apply:

- If the register is implemented in the Core power domain:
 - On a Cold reset, this field resets to 0.
 - On an External debug reset, the value of this field is unchanged.
 - On a Warm reset, the value of this field is unchanged.
- If the register is implemented in the External debug power domain:
 - On a Cold reset, the value of this field is unchanged.
 - On an External debug reset, this field resets to 0.
 - On a Warm reset, the value of this field is unchanged.

Accessing PMITCTRL

Accesses to this register use the following encodings:

When FEAT_PMUv3_EXT is implemented

Accessible at offset 0xF00 from PMU

- When DoubleLockStatus(), or !IsCorePowered(), or !AllowExternalPMUAccess(addrdesc), accesses to this register generate an error response.
- When OSLockStatus(), accesses to this register generate an error response.
- When SoftwareLockStatus(addrdesc), accesses to this register are RO.
- Otherwise, accesses to this register are RW.

F4.3.30 PMLAR, Performance Monitors Lock Access Register

The PMLAR characteristics are:

Purpose

Allows or disallows access to the Performance Monitors registers through a memory-mapped interface.

The optional Software Lock provides a lock to prevent memory-mapped writes to the Performance Monitors registers. Use of this lock mechanism reduces the risk of accidental damage to the contents of the Performance Monitors registers. It does not, and cannot, prevent all accidental or malicious damage.

Configuration

If [FEAT_DoPD](#) is implemented, Software Lock is not implemented by the architecturally-defined debug components of the PE in the Core power domain.

If [FEAT_DoPD](#) is not implemented, this register is in the Debug power domain.

Software uses PMLAR to set or clear the lock, and [PMLSR](#) to check the current status of the lock.

This register is present only when [FEAT_PMUv3_EXT](#) is implemented and [FEAT_PMUv3](#) is implemented. Otherwise, direct accesses to PMLAR are RES0.

Attributes

PMLAR is a 32-bit register.

Field descriptions

When PMU Software Lock is implemented:

KEY, bits [31:0]

Lock Access control. Writing the key value `0xC5ACCE55` to this field unlocks the lock, enabling write accesses to this component's registers through a memory-mapped interface.

Writing any other value to this register locks the lock, disabling write accesses to this component's registers through a memory mapped interface.

Otherwise:

Otherwise

Bits [31:0]

Reserved, RES0.

Accessing PMLAR

Accesses to this register use the following encodings:

When FEAT_PMUv3_EXT is implemented

Accessible at offset 0x`FB0` from PMU

- When FEAT_DoPD is implemented and !IsCorePowered(), accesses to this register generate an error response.
- Otherwise, accesses to this register are WO.

F4.3.31 PMLSR, Performance Monitors Lock Status Register

The PMLSR characteristics are:

Purpose

Indicates the current status of the software lock for Performance Monitors registers.

The optional Software Lock provides a lock to prevent memory-mapped writes to the Performance Monitors registers. Use of this lock mechanism reduces the risk of accidental damage to the contents of the Performance Monitors registers. It does not, and cannot, prevent all accidental or malicious damage.

Configuration

If FEAT_DoPD is implemented, Software Lock is not implemented by the architecturally-defined debug components of the PE in the Core power domain.

If FEAT_DoPD is not implemented, this register is in the Debug power domain.

Software uses PMLAR to set or clear the lock, and PMLSR to check the current status of the lock.

This register is present only when FEAT_PMuV3_EXT is implemented and FEAT_PMuV3 is implemented. Otherwise, direct accesses to PMLSR are RES0.

Attributes

PMLSR is a 32-bit register.

Field descriptions

Bits [31:3]

Reserved, RES0.

nTT, bit [2]

Not thirty-two bit access required.

Reads as 0b0

Access to this field is RO.

SLK, bit [1]

When PMU Software Lock is implemented and FEAT_DoPD is not implemented:

Software Lock status for this component. For an access to LSR that is not a memory-mapped access, or when Software Lock is not implemented, this field is RES0.

For memory-mapped accesses when Software Lock is implemented, possible values of this field are:

SLK	Meaning
0b0	Lock clear. Writes are permitted to this component’s registers.

0b1

Lock set. Writes to this component's registers are ignored, and reads have no side effects.

The reset behavior of this field is:

- On a External debug reset, this field resets to '1'.

Otherwise:

Reserved, RAZ.

SLI, bit [0]

Software Lock implemented. For an access to LSR that is not a memory-mapped access, this field is RAZ.

The value of this field is an IMPLEMENTATION DEFINED choice of:

SLI	Meaning
0b0	Software Lock not implemented or not memory-mapped access.
0b1	Software Lock implemented and memory-mapped access.

Access to this field is RO.

Accessing PMLSR

Accesses to this register use the following encodings:

When FEAT_PMUv3_EXT is implemented

Accessible at offset 0xFB4 from PMU

- When FEAT_DoPD is implemented and !IsCorePowered(), accesses to this register generate an error response.
- Otherwise, accesses to this register are RO.

F4.3.32 PMMIR, Performance Monitors Machine Identification Register

The PMMIR characteristics are:

Purpose

Describes Performance Monitors parameters specific to the implementation.

Configuration

PMMIR is in the Core power domain.

When FEAT_PMUv3_EXT is implemented and FEAT_PMUv3p4 is implemented, External register PMMIR bits [31:0] are architecturally mapped to AArch64 System register [PMMIR_EL1](#)[31:0].

This register is present only when FEAT_PMUv3_EXT is implemented and FEAT_PMUv3p4 is implemented. Otherwise, direct accesses to PMMIR are RES0.

Attributes

PMMIR is a 32-bit register.

Field descriptions

31	20	19	16	15	8	7	0
RES0				BUS_WIDTH	BUS_SLOTS		SLOTS

Bits [31:20]

Reserved, RES0.

BUS_WIDTH, bits [19:16]

Bus width. Indicates the number of bytes each BUS_ACCESS event relates to. Encoded as Log₂(number of bytes), plus one.

The value of this field is an IMPLEMENTATION DEFINED choice of:

BUS_WIDTH	Meaning
0b0000	The information is not available.
0b0011	Four bytes.
0b0100	8 bytes.
0b0101	16 bytes.
0b0110	32 bytes.
0b0111	64 bytes.
0b1000	128 bytes.
0b1001	256 bytes.
0b1010	512 bytes.
0b1011	1024 bytes.
0b1100	2048 bytes.

All other values are reserved.

Each transfer is up to this number of bytes. An access might be smaller than the bus width.

When this field is nonzero, each access counted by BUS_ACCESS is at most BUS_WIDTH bytes. An implementation might treat a wide bus as multiple narrower buses, such that a wide access on the bus increments the BUS_ACCESS counter by more than one.

Access to this field is RO.

BUS_SLOTS, bits [15:8]

Bus count. The largest value by which the BUS_ACCESS event might increment in a single BUS_CYCLES cycle.

When this field is nonzero, the largest value by which the BUS_ACCESS event might increment in a single BUS_CYCLES cycle is BUS_SLOTS.

If the bus count information is not available, this field will read as zero.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

SLOTS, bits [7:0]

Operation width. The largest value by which the STALL_SLOT event might increment in a single cycle. If the STALL_SLOT event is not implemented, this field might read as zero.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

Accessing PMMIR

If the Core power domain is off or in a low-power state, access to this register returns an Error.

Accesses to this register use the following encodings:

When FEAT_PMUv3p4 is implemented and FEAT_PMUv3_EXT32 is implemented

[31:0] Accessible at offset 0xE40 from PMU

- When DoubleLockStatus(), or !IsCorePowered(), or !AllowExternalPMUAccess(addrdesc), accesses to this register generate an error response.
- When OSLockStatus(), accesses to this register generate an error response.
- Otherwise, accesses to this register are RO.

F4.3.33 PMOVSCLR_EL0, Performance Monitors Overflow Flag Status Clear register

The PMOVSCLR_EL0 characteristics are:

Purpose

Allows software to clear the unsigned overflow flags for the following counters to 0:

- The cycle counter [PMCCNTR_EL0](#).
- The event counters [PMEVCNTR<n>_EL0](#).

Reading from this register shows the current unsigned overflow flag values.

Configuration

PMOVSCLR_EL0 is in the Core power domain.

When FEAT_PMUv3_EXT32 is implemented, External register PMOVSCLR_EL0 bits [31:0] are architecturally mapped to AArch64 System register [PMOVSSET_EL0](#)[31:0].

When FEAT_PMUv3_EXT32 is implemented, External register PMOVSCLR_EL0 bits [31:0] are architecturally mapped to AArch64 System register [PMOVSCLR_EL0](#)[31:0].

This register is present only when FEAT_PMUv3_EXT is implemented and FEAT_PMUv3 is implemented. Otherwise, direct accesses to PMOVSCLR_EL0 are RES0.

Attributes

PMOVSCLR_EL0 is a 32-bit register.

Field descriptions

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
C	P30	P29	P28	P27	P26	P25	P24	P23	P22	P21	P20	P19	P18	P17	P16	P15	P14	P13	P12	P11	P10	P9	P8	P7	P6	P5	P4	P3	P2	P1	P0

C, bit [31]

Unsigned overflow flag for [PMCCNTR_EL0](#) clear. On writes, allows software to clear the unsigned overflow flag for [PMCCNTR_EL0](#) to 0. On reads, returns the unsigned overflow flag for [PMCCNTR_EL0](#) overflow status.

C	Meaning
0b0	PMCCNTR_EL0 has not overflowed.
0b1	PMCCNTR_EL0 has overflowed.

[PMCR_EL0](#).LC controls whether an overflow is detected from unsigned overflow of [PMCCNTR_EL0](#)[31:0] or unsigned overflow of [PMCCNTR_EL0](#)[63:0].

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing this field has the following behavior:

- When SoftwareLockStatus(addrdesc), access to this field is RO.
- Otherwise, access to this field is WIC.

P<m> , bits [m], for m = 30 to 0

Unsigned overflow flag for [PMEVCNTR<m>_EL0](#) clear. On writes, allows software to clear the unsigned overflow flag for [PMEVCNTR<m>_EL0](#) to 0. On reads, returns the unsigned overflow flag for [PMEVCNTR<m>_EL0](#) overflow status.

P<m>	Meaning
0b0	PMEVCNTR<m>_EL0 has not overflowed.
0b1	PMEVCNTR<m>_EL0 has overflowed.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing this field has the following behavior:

- When m >= NUM_PMU_COUNTERS, access to this field is RAZ/WI.
- When SoftwareLockStatus(addrdesc), access to this field is RO.
- Otherwise, access to this field is W1C.

Accessing PMOVSLR_EL0

Accesses to this register use the following encodings:

When FEAT_PMUv3_EXT32 is implemented

[31:0] Accessible at offset 0xC80 from PMU

- When DoubleLockStatus(), or !IsCorePowered(), or !AllowExternalPMUAccess(addrdesc), accesses to this register generate an error response.
- When OSLockStatus(), accesses to this register generate an error response.
- When SoftwareLockStatus(addrdesc), accesses to this register are RO.
- Otherwise, accesses to this register are RW.

F4.3.34 PMOVSSET_EL0, Performance Monitors Overflow Flag Status Set Register

The PMOVSSET_EL0 characteristics are:

Purpose

Allows software to set the unsigned overflow flags for the following counters to 1:

- The cycle counter [PMCCNTR_EL0](#).
- The event counters [PMEVCNTR<n>_EL0](#).

Reading from this register shows the current unsigned overflow flag values.

Configuration

PMOVSSET_EL0 is in the Core power domain.

When FEAT_PMUv3_EXT32 is implemented, External register PMOVSSET_EL0 bits [31:0] are architecturally mapped to AArch64 System register [PMOVSSET_EL0](#)[31:0].

When FEAT_PMUv3_EXT32 is implemented, External register PMOVSSET_EL0 bits [31:0] are architecturally mapped to AArch64 System register [PMOVSCCLR_EL0](#)[31:0].

This register is present only when FEAT_PMUv3_EXT is implemented and FEAT_PMUv3 is implemented. Otherwise, direct accesses to PMOVSSET_EL0 are RES0.

Attributes

PMOVSSET_EL0 is a 32-bit register.

Field descriptions

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
C	P30	P29	P28	P27	P26	P25	P24	P23	P22	P21	P20	P19	P18	P17	P16	P15	P14	P13	P12	P11	P10	P9	P8	P7	P6	P5	P4	P3	P2	P1	P0

C, bit [31]

Unsigned overflow flag for [PMCCNTR_EL0](#) set. On writes, allows software to set the unsigned overflow flag for [PMCCNTR_EL0](#) to 1. On reads, returns the unsigned overflow flag for [PMCCNTR_EL0](#) overflow status.

C	Meaning
0b0	PMCCNTR_EL0 has not overflowed.
0b1	PMCCNTR_EL0 has overflowed.

[PMCR_EL0](#).LC controls whether an overflow is detected from unsigned overflow of [PMCCNTR_EL0](#)[31:0] or unsigned overflow of [PMCCNTR_EL0](#)[63:0].

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing this field has the following behavior:

- When SoftwareLockStatus(addrdesc), access to this field is RO.
- Otherwise, access to this field is WIS.

P<m> , bits [m], for m = 30 to 0

Unsigned overflow flag for [PMEVCNTR<m>_EL0](#) set. On writes, allows software to set the unsigned overflow flag for [PMEVCNTR<m>_EL0](#) to 1. On reads, returns the unsigned overflow flag for [PMEVCNTR<m>_EL0](#) overflow status.

P<m>	Meaning
0b0	PMEVCNTR<m>_EL0 has not overflowed.
0b1	PMEVCNTR<m>_EL0 has overflowed.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing this field has the following behavior:

- When $m \geq \text{NUM_PMU_COUNTERS}$, access to this field is RAZ/WI.
- When `SoftwareLockStatus(addrdesc)`, access to this field is RO.
- Otherwise, access to this field is WIS.

Accessing PMOVSSET_EL0

Accesses to this register use the following encodings:

When FEAT_PMUv3_EXT32 is implemented

[31:0] Accessible at offset 0xCC0 from PMU

- When `DoubleLockStatus()`, or `!IsCorePowered()`, or `!AllowExternalPMUAccess(addrdesc)`, accesses to this register generate an error response.
- When `OSLockStatus()`, accesses to this register generate an error response.
- When `SoftwareLockStatus(addrdesc)`, accesses to this register are RO.
- Otherwise, accesses to this register are RW.

F4.3.35 PMPCSR, Program Counter Sample Register

The PMPCSR characteristics are:

Purpose

PC Sample-based Profiling Extension register that holds a sampled instruction address value.

Configuration

PMPCSR is in the Core power domain.

If FEAT_PMUv3_EXT32 is implemented, support for 64-bit atomic reads is IMPLEMENTATION DEFINED. If 64-bit atomic reads are implemented, a 64-bit read of PMPCSR has the same side-effect as a 32-bit read of PMCSR[31:0] followed by a 32-bit read of PMPCSR[63:32], returning the combined value. For example, if the PE is in Debug state, then a 64-bit atomic read returns bits[31:0] == 0xFFFFFFFF and bits[63:32] UNKNOWN.

This register is present only when FEAT_PMUv3_EXT is implemented and FEAT_PCSRv8p2 is implemented. Otherwise, direct accesses to PMPCSR are RES0.

Attributes

PMPCSR is a 64-bit register.

Field descriptions

NS, bit [63]

Non-secure state sample. Indicates the Security state that is associated with the most recent PMPCSR sample or, when it is read as a single atomic 64-bit read, the current PMPCSR sample.

This bit indicates the Effective value of SCR.NS.

NS	Meaning
0b0	Sample is from Secure state.
0b1	Sample is from Non-secure state.

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

EL, bits [62:61]

Exception level status sample. Indicates the Exception level that is associated with the most recent PMPCSR sample or, when it is read as a single atomic 64-bit read, the current PMPCSR sample.

EL	Meaning
0b00	Sample is from EL0.
0b01	Sample is from EL1.
0b10	Sample is from EL2.
0b11	Sample is from EL3.

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

Bits [60:56]

Reserved, RES0.

PCSample[55:32], bits [55:32]

Bits[55:32] of the sampled instruction address value. The translation regime that PMPCSR samples can be determined from PMPCSR.{NS,EL}.

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

PCSample[31:0], bits [31:0]

Bits[31:0] of the sampled instruction address value.

PMPCSR[31:0] reads as 0xFFFFFFFF when any of the following are true:

- The PE is in Debug state.
- PC Sample-based profiling is prohibited.

If a branch instruction has retired since the PE left reset state, then the first read of PMPCSR[31:0] is permitted but not required to return 0xFFFFFFFF.

PMPCSR[31:0] reads as an UNKNOWN value when any of the following are true:

- The PE is in reset state.
- No branch instruction has retired since the PE left reset state, Debug state, or a state where PC Sample-based Profiling is prohibited.
- No branch instruction has retired since the last read of PMPCSR[31:0].

For the cases where a read of PMPCSR[31:0] returns 0xFFFFFFFF or an UNKNOWN value, the read has the side-effect of setting PMPCSR[63:32], [PMCID1SR](#), [PMCID2SR](#), and [PMVIDSR](#) to UNKNOWN values.

Otherwise, a read of PMPCSR[31:0] returns bits [31:0] of the sampled instruction address value and has the side-effect of indirectly writing to PMPCSR[63:32], [PMCID1SR](#), [PMCID2SR](#), and [PMVIDSR](#). The translation regime that PMPCSR samples can be determined from PMPCSR.{NS,EL}.

For a read of PMPCSR[31:0] from the memory-mapped interface, if PMLSR.SLK == 1, meaning the OPTIONAL Software Lock is locked, then the side-effect of the access does not occur and PMPCSR[63:32], [PMCID1SR](#), [PMCID2SR](#), and [PMVIDSR](#) are unchanged.

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

Accessing PMPCSR

IMPLEMENTATION DEFINED extensions to external debug might make the value of this register UNKNOWN, see ‘[Permitted behavior that might make the PC Sample-based profiling registers UNKNOWN](#)’.

Note

A 32-bit access to PMPCSR[63:32] does not update the PC sample registers. Only a 64-bit access to PMPCSR[63:0] or a 32-bit access to PMPCSR[31:0] updates the PC sample registers. This includes the value a subsequent 32-bit read of PMPCSR[63:32] will return.

Accesses to this register use the following encodings:

When FEAT_PMuV3_EXT is implemented and FEAT_PCSRv8p2 is implemented

[63:0] Accessible at offset 0x200 from PMU

- When DoubleLockStatus() or !IsCorePowered(), accesses to this register generate an error response.
- When OSLockStatus(), accesses to this register generate an error response.
- Otherwise, accesses to this register are RO.

When FEAT_PMuV3_EXT is implemented and FEAT_PCSRv8p2 is implemented

[63:0] Accessible at offset 0x220 from PMU

- When DoubleLockStatus() or !IsCorePowered(), accesses to this register generate an error response.
- When OSLockStatus(), accesses to this register generate an error response.
- Otherwise, accesses to this register are RO.

F4.3.36 PMPIDR0, Performance Monitors Peripheral Identification Register 0

The PMPIDR0 characteristics are:

Purpose

Provides information to identify a Performance Monitor component.

For more information, see ‘About the Peripheral identification scheme’.

Configuration

If [FEAT_DoPD](#) is implemented, this register is in the Core power domain. If [FEAT_DoPD](#) is not implemented, this register is in the Debug power domain.

This register is present only when [FEAT_PMUv3_EXT](#) is implemented and [FEAT_PMU_PIDR](#) is implemented. Otherwise, direct accesses to PMPIDR0 are RES0.

Attributes

PMPIDR0 is a 32-bit register.

Field descriptions

Bits [31:8]

Reserved, RES0.

PART_0, bits [7:0]

Part number, which is selected by the designer of the component and stored as follows:

- For a component with a 12-bit part number:
 - [PMPIDR1](#).PART_1 contains part number bits [11:8].
 - [PMPIDR0](#).PART_0 contains part number bits [7:0].
- For a component with a 16-bit part number:
 - [PMPIDR1](#).PART_1 contains part number bits [15:12].
 - [PMPIDR0](#).PART_0 contains part number bits [11:4].
 - [PMPIDR2](#).REVISION contains part number bits [3:0].

When a 12-bit part number is used, [PMPIDR2](#).REVISION indicates revision information.

The choice of using a 12-bit part number or 16-bit part number is specific to the designer of the component.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

Accessing PMPIDR0

Accesses to this register use the following encodings:

When FEAT_PMUv3_EXT is implemented

Accessible at offset 0xFE0 from PMU

- When [FEAT_DoPD](#) is implemented and `!IsCorePowered()`, accesses to this register generate an error response.
- Otherwise, accesses to this register are RO.

F4.3.37 PMPIDR1, Performance Monitors Peripheral Identification Register 1

The PMPIDR1 characteristics are:

Purpose

Provides information to identify a Performance Monitor component.

For more information, see ‘About the Peripheral identification scheme’.

Configuration

If **FEAT_DoPD** is implemented, this register is in the Core power domain. If **FEAT_DoPD** is not implemented, this register is in the Debug power domain.

This register is present only when **FEAT_PMuV3_EXT** is implemented and **FEAT_PMu_PIDR** is implemented. Otherwise, direct accesses to PMPIDR1 are RES0.

Attributes

PMPIDR1 is a 32-bit register.

Field descriptions

31		8	7	4	3	0	
RES0							
				DES_0		PART_1	

Bits [31:8]

Reserved, RES0.

DES_0, bits [7:4]

Designer, JEP106 identification code, bits [3:0].

The JEP106 identification and continuation codes are stored as follows:

- **PMPIDR1.DES_0**: JEP106 identification code bits[3:0].
- **PMPIDR2.DES_1**: JEP106 identification code bits[6:4].
- **PMPIDR4.DES_2**: JEP106 continuation code.

These codes indicate the designer of the component and not the implementer, except where the two are the same. To obtain a number, or to see the assignment of these codes, contact JEDEC <http://www.jedec.org>.

A JEP106 identification and continuation code takes the following form:

- A sequence of zero or more numbers, all having the value $0 \times 7F$.
- A following 8-bit number, that is not $0 \times 7F$, and where bit[7] is an odd parity bit.

The parity bit in the JEP106 identification code is not included.

Note

For example, Arm Limited is assigned the code $0 \times 7F \ 0 \times 7F \ 0 \times 7F \ 0 \times 7F \ 0 \times 3B$.

- The continuation code is the number of times $0 \times 7F$ appears before the final number. For example, a component designed by Arm Limited has the code 0×4 .
- The identification code is bits[6:0] of the final number. For example, a component designed by Arm Limited has the code $0 \times 3B$.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

PART_1, bits [3:0]

Part number, which is selected by the designer of the component and stored as follows:

- For a component with a 12-bit part number:
 - [PMPIDR1](#).PART_1 contains part number bits [11:8].
 - [PMPIDR0](#).PART_0 contains part number bits [7:0].
- For a component with a 16-bit part number:
 - [PMPIDR1](#).PART_1 contains part number bits [15:12].
 - [PMPIDR0](#).PART_0 contains part number bits [11:4].
 - [PMPIDR2](#).REVISION contains part number bits [3:0].

When a 12-bit part number is used, [PMPIDR2](#).REVISION indicates revision information.

The choice of using a 12-bit part number or 16-bit part number is specific to the designer of the component.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

Accessing PMPIDR1

Accesses to this register use the following encodings:

When FEAT_PMUv3_EXT is implemented

Accessible at offset 0xFE4 from PMU

- When FEAT_DoPD is implemented and !IsCorePowered(), accesses to this register generate an error response.
- Otherwise, accesses to this register are RO.

F4.3.38 PMPIDR2, Performance Monitors Peripheral Identification Register 2

The PMPIDR2 characteristics are:

Purpose

Provides information to identify a Performance Monitor component.

For more information, see ‘About the Peripheral identification scheme’.

Configuration

If [FEAT_DoPD](#) is implemented, this register is in the Core power domain. If [FEAT_DoPD](#) is not implemented, this register is in the Debug power domain.

This register is present only when [FEAT_PMUv3_EXT](#) is implemented and [FEAT_PMU_PIDR](#) is implemented. Otherwise, direct accesses to PMPIDR2 are RES0.

Attributes

PMPIDR2 is a 32-bit register.

Field descriptions

Bits [31:8]

Reserved, RES0.

REVISION, bits [7:4]

Indicates either the revision of the component, or a portion of the part number of the component.

Where the component has a single 4-bit revision number, the revision number is an incremental value starting at zero for the first revision of the component.

Where the component has separate major and minor revision numbers, the major and minor revision numbers are each incremental values starting at zero for the first revision of the component. For each minor revision of the component, the minor revision number increments monotonically. For each major revision of the component, the major revision number increments monotonically and the minor revision begins again at zero.

For a component with a 12-bit part number with a single 4-bit revision number:

- [PMPIDR2.REVISION](#) indicates the 4-bit revision number.
- [PMPIDR3.REVAND](#) indicates component modifications.

For a component with a 12-bit part number with separate major and minor revision numbers:

- [PMPIDR2.REVISION](#) indicates the 4-bit major revision number.
- [PMPIDR3.REVAND](#) indicates the 4-bit minor revision number.

For a component with a 16-bit part number:

- [PMPIDR2.REVISION](#) contains part number bits [3:0].
- [PMPIDR3.REVAND](#) indicates the 4-bit revision number.

The choice of which style of revision information is used is specific to the designer of the component, and might also be specific to each individual component with a different part number.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

JEDEC, bit [3]

JEDEC-assigned JEP106 implementer code is used.

Reads as 0b1

Access to this field is RO.

DES_1, bits [2:0]

Designer, JEP106 identification code, bits [6:4].

The JEP106 identification and continuation codes are stored as follows:

- **PMPIDR1.DES_0**: JEP106 identification code bits[3:0].
- **PMPIDR2.DES_1**: JEP106 identification code bits[6:4].
- **PMPIDR4.DES_2**: JEP106 continuation code.

These codes indicate the designer of the component and not the implementer, except where the two are the same. To obtain a number, or to see the assignment of these codes, contact JEDEC <http://www.jedec.org>.

A JEP106 identification and continuation code takes the following form:

- A sequence of zero or more numbers, all having the value 0x7F.
- A following 8-bit number, that is not 0x7F, and where bit[7] is an odd parity bit.

The parity bit in the JEP106 identification code is not included.

Note

For example, Arm Limited is assigned the code 0x7F 0x7F 0x7F 0x7F 0x3B.

- The continuation code is the number of times 0x7F appears before the final number. For example, a component designed by Arm Limited has the code 0x4.
 - The identification code is bits[6:0] of the final number. For example, a component designed by Arm Limited has the code 0x3B.
-

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

Accessing PMPIDR2

Accesses to this register use the following encodings:

When FEAT_PMUv3_EXT is implemented

Accessible at offset 0xFE8 from PMU

- When FEAT_DoPD is implemented and !IsCorePowered(), accesses to this register generate an error response.
- Otherwise, accesses to this register are RO.

F4.3.39 PMPIDR3, Performance Monitors Peripheral Identification Register 3

The PMPIDR3 characteristics are:

Purpose

Provides information to identify a Performance Monitor component.

For more information, see ‘About the Peripheral identification scheme’.

Configuration

If [FEAT_DoPD](#) is implemented, this register is in the Core power domain. If [FEAT_DoPD](#) is not implemented, this register is in the Debug power domain.

This register is present only when [FEAT_PMUv3_EXT](#) is implemented and [FEAT_PMU_PIDR](#) is implemented. Otherwise, direct accesses to PMPIDR3 are RES0.

Attributes

PMPIDR3 is a 32-bit register.

Field descriptions

31	8	7	4	3	0	
RES0					REVAND	CMOD

Bits [31:8]

Reserved, RES0.

REVAND, bits [7:4]

Indicates either the revision of the component, or whether the component has been modified.

Where the component has a single 4-bit revision number, the revision number is an incremental value starting at zero for the first revision of the component.

Where the component has separate major and minor revision numbers, the major and minor revision numbers are each incremental values starting at zero for the first revision of the component. For each minor revision of the component, the minor revision number increments monotonically. For each major revision of the component, the major revision number increments monotonically and the minor revision begins again at zero.

For a component with a 12-bit part number with a single 4-bit revision number:

- [PMPIDR2](#).REVISION indicates the 4-bit revision number.
- [PMPIDR3](#).REVAND indicates component modifications.

For a component with a 12-bit part number with separate major and minor revision numbers:

- [PMPIDR2](#).REVISION indicates the 4-bit major revision number.
- [PMPIDR3](#).REVAND indicates the 4-bit minor revision number.

For a component with a 16-bit part number:

- [PMPIDR2](#).REVISION contains part number bits [3:0].
- [PMPIDR3](#).REVAND indicates the 4-bit revision number.

The choice of which style of revision information is used is specific to the designer of the component, and might also be specific to each individual component with a different part number.

Where REVAND indicates component modifications, this indicates modifications such as errata fixes or metal fixes after implementation. Usually this value would be zero unless a modification has been performed. If the field

is required for indicating component modifications, Arm recommends that component designers ensure that it can be changed by a metal fix, for example by driving it from registers that reset to zero.

[PMPIDR3](#).CMOD might also indicate component modifications.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

CMOD, bits [3:0]

Indicates whether the component has been modified from its original behavior. Examples of modifications include errata fixes or metal fixes after implementation. Usually this value would be zero unless a modification has been performed. If the field is required for indicating component modifications, Arm recommends that component designers ensure that it can be changed by a metal fix, for example by driving it from registers that reset to zero.

A value of 0b0000 means the component is not modified from the original design.

Any other value means the component has been modified in an IMPLEMENTATION DEFINED way.

For any two components with the same Unique Component Identifier:

- If the value of the CMOD fields of both components equals zero, the components are identical.
- If the CMOD fields of both components have the same nonzero value, it does not necessarily mean that they have the same modifications.
- If the value of the CMOD field of either of the two components is nonzero, they might not be identical, even though they have the same Unique Component Identifier.

[PMPIDR3](#).REVAND might also indicate component modifications.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

Accessing PMPIDR3

Accesses to this register use the following encodings:

When FEAT_PMUv3_EXT is implemented

Accessible at offset 0xFEC from PMU

- When FEAT_DoPD is implemented and !IsCorePowered(), accesses to this register generate an error response.
- Otherwise, accesses to this register are RO.

F4.3.40 PMPIDR4, Performance Monitors Peripheral Identification Register 4

The PMPIDR4 characteristics are:

Purpose

Provides information to identify a Performance Monitor component.

For more information, see ‘About the Peripheral identification scheme’.

Configuration

If **FEAT_DoPD** is implemented, this register is in the Core power domain. If **FEAT_DoPD** is not implemented, this register is in the Debug power domain.

This register is present only when **FEAT_PMUv3_EXT** is implemented and **FEAT_PMU_PIDR** is implemented. Otherwise, direct accesses to PMPIDR4 are RES0.

Attributes

PMPIDR4 is a 32-bit register.

Field descriptions

Bits [31:8]

Reserved, RES0.

SIZE, bits [7:4]

Size of the component. $\log_2$ of the number of 4KB pages from the start of the component to the end of the component ID registers.

Reads as 0b0000

Access to this field is RO.

DES_2, bits [3:0]

Designer, JEP106 continuation code.

The JEP106 identification and continuation codes are stored as follows:

- **PMPIDR1.DES_0**: JEP106 identification code bits[3:0].
- **PMPIDR2.DES_1**: JEP106 identification code bits[6:4].
- **PMPIDR4.DES_2**: JEP106 continuation code.

These codes indicate the designer of the component and not the implementer, except where the two are the same. To obtain a number, or to see the assignment of these codes, contact JEDEC <http://www.jedec.org>.

A JEP106 identification and continuation code takes the following form:

- A sequence of zero or more numbers, all having the value 0x7F.
- A following 8-bit number, that is not 0x7F, and where bit[7] is an odd parity bit.

The parity bit in the JEP106 identification code is not included.

Note

For example, Arm Limited is assigned the code 0x7F 0x7F 0x7F 0x7F 0x3B.

- The continuation code is the number of times 0x7F appears before the final number. For example, a component designed by Arm Limited has the code 0x4.
 - The identification code is bits[6:0] of the final number. For example, a component designed by Arm Limited has the code 0x3B.
-

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

Accessing PMPIDR4

Accesses to this register use the following encodings:

When FEAT_PMUv3_EXT is implemented

Accessible at offset 0xFD0 from PMU

- When FEAT_DoPD is implemented and !IsCorePowered(), accesses to this register generate an error response.
- Otherwise, accesses to this register are RO.

F4.3.41 PMPIDR5, Performance Monitors Peripheral Identification Register 5

The PMPIDR5 characteristics are:

Purpose

Provides information to identify a Performance Monitor component.

For more information, see ‘About the Peripheral identification scheme’.

Configuration

If [FEAT_DoPD](#) is implemented, this register is in the Core power domain. If [FEAT_DoPD](#) is not implemented, this register is in the Debug power domain.

This register is present only when [FEAT_PMuV3_EXT](#) is implemented and [FEAT_PMu_PIDR](#) is implemented. Otherwise, direct accesses to PMPIDR5 are RES0.

Attributes

PMPIDR5 is a 32-bit register.

Field descriptions

Bits [31:0]

Reserved, RES0.

Accessing PMPIDR5

Accesses to this register use the following encodings:

When [FEAT_PMuV3_EXT](#) is implemented

Accessible at offset `0xFD4` from PMU

- When [FEAT_DoPD](#) is implemented and `!IsCorePowered()`, accesses to this register generate an error response.
- Otherwise, accesses to this register are RO.

F4.3.42 PMPIDR6, Performance Monitors Peripheral Identification Register 6

The PMPIDR6 characteristics are:

Purpose

Provides information to identify a Performance Monitor component.

For more information, see ‘About the Peripheral identification scheme’.

Configuration

If [FEAT_DoPD](#) is implemented, this register is in the Core power domain. If [FEAT_DoPD](#) is not implemented, this register is in the Debug power domain.

This register is present only when [FEAT_PMUv3_EXT](#) is implemented and [FEAT_PMU_PIDR](#) is implemented. Otherwise, direct accesses to PMPIDR6 are RES0.

Attributes

PMPIDR6 is a 32-bit register.

Field descriptions

Bits [31:0]

Reserved, RES0.

Accessing PMPIDR6

Accesses to this register use the following encodings:

When [FEAT_PMUv3_EXT](#) is implemented

Accessible at offset `0xFD8` from PMU

- When [FEAT_DoPD](#) is implemented and `!IsCorePowered()`, accesses to this register generate an error response.
- Otherwise, accesses to this register are RO.

F4.3.43 PMPIDR7, Performance Monitors Peripheral Identification Register 7

The PMPIDR7 characteristics are:

Purpose

Provides information to identify a Performance Monitor component.

For more information, see ‘About the Peripheral identification scheme’.

Configuration

If [FEAT_DoPD](#) is implemented, this register is in the Core power domain. If [FEAT_DoPD](#) is not implemented, this register is in the Debug power domain.

This register is present only when [FEAT_PMUv3_EXT](#) is implemented and [FEAT_PMU_PIDR](#) is implemented. Otherwise, direct accesses to PMPIDR7 are RES0.

Attributes

PMPIDR7 is a 32-bit register.

Field descriptions

Bits [31:0]

Reserved, RES0.

Accessing PMPIDR7

Accesses to this register use the following encodings:

When [FEAT_PMUv3_EXT](#) is implemented

Accessible at offset `0xFDC` from PMU

- When [FEAT_DoPD](#) is implemented and `!IsCorePowered()`, accesses to this register generate an error response.
- Otherwise, accesses to this register are RO.

F4.3.44 PMSWINC_EL0, Performance Monitors Software Increment Register

The PMSWINC_EL0 characteristics are:

Purpose

Increments a counter that is configured to count the Software increment event, event 0x00. For more information, see ‘SW_INCR’.

Configuration

PMSWINC_EL0 is in the Core power domain.

If this register is implemented, use of it is deprecated.

If 1 is written to bit [n] from the external debug interface, it is CONSTRAINED UNPREDICTABLE whether or not a SW_INCR event is created for counter n. This is consistent with not implementing the register in the external debug interface.

When FEAT_PMUv3_EXT32 is implemented, External register PMSWINC_EL0 bits [31:0] are architecturally mapped to AArch64 System register [PMSWINC_EL0](#)[31:0].

This register is present only when FEAT_PMUv3_EXT32 is implemented and an implementation implements PMSWINC_EL0.

Attributes

PMSWINC_EL0 is a 32-bit register.

Field descriptions

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	P30	P29	P28	P27	P26	P25	P24	P23	P22	P21	P20	P19	P18	P17	P16	P15	P14	P13	P12	P11	P10	P9	P8	P7	P6	P5	P4	P3	P2	P1	P0

RES0

Bit [31]

Reserved, RES0.

P<m> , bits [m], for m = 30 to 0

Event counter software increment bit for [PMEVCNTR<m>_EL0](#).

P<m>	Meaning
0b0	No action. The write to this bit is ignored.
0b1	It is CONSTRAINED UNPREDICTABLE whether a SW_INCR event is generated for event counter m.

Accessing this field has the following behavior:

- When m >= NUM_PMU_COUNTERS, access to this field is RAZ/WI.
- When SoftwareLockStatus(addrdesc), access to this field is RAZ/WI.
- Otherwise, access to this field is WO/RAZ.

Accessing PMSWINC_EL0

Accesses to this register use the following encodings:

When FEAT_PMUv3_EXT32 is implemented

Accessible at offset 0xCA0 from PMU

- When DoubleLockStatus(), or !IsCorePowered(), or !AllowExternalPMUAccess(addrdesc), accesses to this register generate an error response.
- When OSLockStatus(), accesses to this register generate an error response.
- When SoftwareLockStatus(addrdesc), accesses to this register are WI.
- Otherwise, accesses to this register are WO.

F4.3.45 PMVIDSR, VMID Sample Register

The PMVIDSR characteristics are:

Purpose

PC Sample-based Profiling Extension register that contains the sampled VMID value that is captured on reading [PMPCSR](#)[31:0].

Configuration

PMVIDSR is in the Core power domain.

This register is present only when FEAT_PMuV3_EXT32 is implemented and FEAT_PCSRv8p2 is implemented.

Attributes

PMVIDSR is a 32-bit register.

Field descriptions

31	16	15	8	7	0
RES0		VMID[15:8]		VMID	

Bits [31:16]

Reserved, RES0.

VMID[15:8], bits [15:8]

When FEAT_VMID16 is implemented:

Extension to VMID[7:0]. For more information, see VMID[7:0].

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

VMID, bits [7:0]

VMID sample. The VMID associated with the most recent [PMPCSR](#) sample. When the most recent [PMPCSR](#) sample was generated:

- This field is set to an UNKNOWN value if any of the following apply:
 - The PE is executing at EL2.
- Otherwise:
 - If EL2 is using AArch64 and either [FEAT_VMID16](#) is not implemented or [VTCR_EL2.VS](#) is 1, this field is set to [VSCTLR_EL2.VMID](#).
 - If EL2 is using AArch64, [FEAT_VMID16](#) is implemented, and [VTCR_EL2.VS](#) is 0, PMVIDSR.VMID[7:0] is set to [VSCTLR_EL2.VMID\[7:0\]](#) and PMVIDSR.VMID[15:8] is RES0.

Because the value written to PMVIDSR is an indirect read of the VMID value, it is CONSTRAINED UNPREDICTABLE whether PMVIDSR is set to the original or new value if [PMPCSR](#) samples:

- An instruction that writes to the VMID value.
- The next Context synchronization event.
- Any instruction executed between these two instructions.

The reset behavior of this field is:

- On a Cold reset, this field resets to an architecturally UNKNOWN value.

Accessing PMVIDSR

IMPLEMENTATION DEFINED extensions to external debug might make the value of this register UNKNOWN, see [‘Permitted behavior that might make the PC Sample-based profiling registers UNKNOWN’](#).

Accesses to this register use the following encodings:

When FEAT_PMUv3_EXT32 is implemented and FEAT_PCSRv8p2 is implemented

Accessible at offset 0x20C from PMU

- When DoubleLockStatus() or !IsCorePowered(), accesses to this register generate an error response.
- When OSLockStatus(), accesses to this register generate an error response.
- Otherwise, accesses to this register are RO.

F4.4 Generic Timer memory-mapped registers overview

The Generic Timer memory-mapped registers are implemented as multiple register frames, with each register frame having its own base address, as follows:

- A single CNTCTLBase register frame, at base address CNTCTLBase.
- Between one and seven CNTBaseN register frames, each with its own base address CNTBaseN.
- For each CNTBaseN register frame, if required, a CNTEL0BaseN register frame, at base address CNTEL0BaseN, that provides an EL0 view of the CNTBaseN register frame.

For more information, see:

- [Memory-mapped timer components](#).
- [The CNTBaseN and CNTEL0BaseN frames](#). This section includes the memory map of the CNTBaseN and CNTEL0BaseN register frames.
- [The CNTCTLBase frame](#). This section includes the memory map of the CNTCTLBase register frame.

Note

Providing a complete set of features in a system level implementation gives an implementation example for a system level implementation of the Generic Timer.

F4.5 Generic Timer memory-mapped register descriptions

This section describes the Generic Timer registers. [Generic Timer memory-mapped registers overview](#) gives an overview of these registers, and includes links to their memory maps.

F4.5.1 CNTACR<n>, Counter-timer Access Control Registers, n = 0 - 7

The CNTACR<n> characteristics are:

Purpose

Provides top-level access controls for the elements of a timer frame. CNTACR<n> provides the controls for frame CNTBaseN.

In addition to the CNTACR<n> control:

- [CNTNSAR](#) controls whether CNTACR<n> is accessible by Non-secure accesses.
- If frame CNTELOBaseN is implemented, the [CNTELOACR](#) in frame CNTBaseN provides additional control of accesses to frame CNTELOBaseN.

Configuration

It is IMPLEMENTATION DEFINED whether CNTACR<n> is implemented in the Core power domain or in the Debug power domain

For more information, see ‘[Power and reset domains for the system level implementation of the Generic Timer](#)’.

Implemented only if the value of [CNTTIDR.Frame<n>](#) is 1.

An implementation of the counters might not provide configurable access to some or all of the features. In this case, the associated field in the CNTACR<n> register is:

- RAZ/WI if access is always denied.
- RAO/WI if access is always permitted.

Attributes

CNTACR<n> is a 32-bit register.

Field descriptions

Bits [31:6]

Reserved, RES0.

RWPT, bit [5]

Read/write access to the EL1 Physical Timer registers [CNTP_CVAL](#), [CNTP_TVAL](#), and [CNTP_CTL](#), in frame <n>.

RWPT	Meaning
0b0	No access to the EL1 Physical Timer registers in frame <n>. The registers are RES0.
0b1	Read/write access to the EL1 Physical Timer registers in frame <n>.

The reset behavior of this field is:

- On a Timer reset, this field resets to an architecturally UNKNOWN value.

RWVT, bit [4]

Read/write access to the Virtual Timer register [CNTV_CVAL](#), [CNTV_TVAL](#), and [CNTV_CTL](#), in frame <n>.

RWVT	Meaning
0b0	No access to the Virtual Timer registers in frame <n>. The registers are RES0.
0b1	Read/write access to the Virtual Timer registers in frame <n>.

The reset behavior of this field is:

- On a Timer reset, this field resets to an architecturally UNKNOWN value.

RVOFF, bit [3]

Read-only access to [CNTVOFF](#), in frame <n>.

RVOFF	Meaning
0b0	No access to CNTVOFF in frame <n>. The register is RES0.
0b1	Read-only access to CNTVOFF in frame <n>.

The reset behavior of this field is:

- On a Timer reset, this field resets to an architecturally UNKNOWN value.

RFRQ, bit [2]

Read-only access to [CNTFRQ](#), in frame <n>.

RFRQ	Meaning
0b0	No access to CNTFRQ in frame <n>. The register is RES0.
0b1	Read-only access to CNTFRQ in frame <n>.

The reset behavior of this field is:

- On a Timer reset, this field resets to an architecturally UNKNOWN value.

RVCT, bit [1]

Read-only access to [CNTVCT](#), in frame <n>.

RVCT	Meaning
0b0	No access to CNTVCT in frame <n>. The register is RES0.
0b1	Read-only access to CNTVCT in frame <n>.

The reset behavior of this field is:

- On a Timer reset, this field resets to an architecturally UNKNOWN value.

RPCT, bit [0]

Read-only access to [CNTPCT](#), in frame <n>.

RPCT	Meaning
0b0	No access to CNTPCT in frame <n>. The register is RES0.
0b1	Read-only access to CNTPCT in frame <n>.

The reset behavior of this field is:

- On a Timer reset, this field resets to an architecturally UNKNOWN value.

Accessing CNTACR<n>

In a system that recognizes two Security states:

- CNTACR<n> is always accessible by Secure accesses.
- [CNTNSAR.NS<n>](#) determines whether CNTACR<n> is accessible by Non-secure accesses.

CNTACR<n> can be accessed through the memory-mapped interface:

Component	Frame	Offset	Instance
Timer	CNTCTLBase	$0 \times 040 + (4 * n)$	CNTACR<n>

Accesses to this register are RW.

F4.5.2 CNTCR, Counter Control Register

The CNTCR characteristics are:

Purpose

Enables the counter, controls the [counter resolution](#), and controls counter behavior during debug.

Configuration

It is IMPLEMENTATION DEFINED whether CNTCR is implemented in the Core power domain or in the Debug power domain

For more information, see [‘Power and reset domains for the system level implementation of the Generic Timer’](#).

Attributes

CNTCR is a 32-bit register.

Field descriptions

Bits [31:18]

Reserved, RES0.

FCREQ, bits [17:8]

Frequency change request. Indicates the number of the entry in the Frequency modes table to select.

Selecting an unimplemented entry, or an entry that contains 0, has no effect on the counter.

The maximum number of entries in the Frequency modes table is IMPLEMENTATION DEFINED up to a maximum of 1004 entries, see [‘The Frequency modes table’](#). An implementation is only required to implement an FCREQ field that can hold values from 0 to the highest supported Frequency modes table entry. Any unrequired most-significant bits of FCREQ can be implemented as RES0.

The reset behavior of this field is:

- On a Timer reset, this field resets to the expression 0×0.

Bits [7:3]

Reserved, RES0.

SCEN, bit [2]

When FEAT_CNTSC is implemented:

Scale Enable.

SCEN	Meaning
0b0	Scaling is not enabled. The counter value is incremented by 0×1.0000000 for each counter tick.

0b1

Scaling is enabled. The counter is incremented by [CNTSCR.ScaleVal](#) for each counter tick.

The SCEN bit can only be changed when the counter is disabled, when $\text{CNTCR.EN} = 0$.

If the value of CNTCR.SCEN changes when $\text{CNTCR.EN} = 1$, then:

- The counter value becomes UNKNOWN.
- The counter value remains UNKNOWN on future ticks of the clock.

When the [CNTCV](#) register in the CNTControlBase frame of the memory mapped counter module is written to, the accumulated fraction information is reset to zero.

The reset behavior of this field is:

- On a Timer reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

HDBG, bit [1]

Halt-on-debug. Controls whether a Halt-on-debug signal halts the system counter:

HDBG	Meaning
0b0	System counter ignores Halt-on-debug.
0b1	Asserted Halt-on-debug signal halts system counter update.

The reset behavior of this field is:

- On a Timer reset, this field resets to an architecturally UNKNOWN value.

EN, bit [0]

Enables the counter:

EN	Meaning
0b0	System counter disabled.
0b1	System counter enabled.

The reset behavior of this field is:

- On a Timer reset, this field resets to '0'.

Accessing CNTCR

In a system that supports Secure and Non-secure physical address spaces, the CNTControlBase frame, which includes this register, is implemented only in the Secure physical address space.

CNTCR can be accessed through the memory-mapped interface:

Component	Frame	Offset	Instance
Timer	CNTControlBase	0x000	CNTCR

Accesses to this register are RW.

F4.5.3 CNTCV, Counter Count Value register

The CNTCV characteristics are:

Purpose

Indicates the current count value.

Configuration

It is IMPLEMENTATION DEFINED whether CNTCV is implemented in the Core power domain or in the Debug power domain

For more information, see [‘Power and reset domains for the system level implementation of the Generic Timer’](#).

Attributes

CNTCV is a 64-bit register.

Field descriptions

CountValue, bits [63:0]

Indicates the counter value.

The reset behavior of this field is:

- On a Timer reset, this field resets to an architecturally UNKNOWN value.

Accessing CNTCV

Frame	Accessibility
CNTControlBase	RW
CNTReadBase	RO

A write to CNTCV must be visible in the [CNTPCT](#) register of each running processor in a finite time.

For the instance of the register in the CNTControlBase frame:

- In a system that supports Secure and Non-secure physical address spaces, this register is implemented only in the Secure physical address space.
- If the counter is enabled, the effect of writing to the register is UNKNOWN.

For the instance of the register in the CNTReadBase frame, this register is accessible in all physical address spaces.

In an implementation that supports 64-bit atomic memory accesses, this register must be accessible using a 64-bit atomic access.

CNTCV can be accessed through the memory-mapped interface:

Component	Frame	Offset	Instance	Range
Timer	CNTControlBase	0x008	CNTCV	63:0

Accesses to this register are RW.

Component	Frame	Offset	Instance	Range
Timer	CNTReadBase	0x000	CNTCV	63:0

Accesses to this register are RO.

F4.5.4 CNTEL0ACR, Counter-timer EL0 Access Control Register

The CNTEL0ACR characteristics are:

Purpose

An implementation of CNTEL0ACR in the frame at CNTBaseN controls whether the [CNTPCT](#), [CNTVCT](#), [CNTFRQ](#), EL1 Physical Timer, and Virtual Timer registers are visible in the frame at CNTEL0BaseN.

Configuration

It is IMPLEMENTATION DEFINED whether CNTEL0ACR is implemented in the Core power domain or in the Debug power domain

For more information, see ‘[Power and reset domains for the system level implementation of the Generic Timer](#)’.

Implementation of this register is OPTIONAL.

Attributes

CNTEL0ACR is a 32-bit register.

Field descriptions

Bits [31:10]

Reserved, RES0.

EL0PTEN, bit [9]

Second view read/write access control for the EL1 Physical Timer registers. This bit controls whether the [CNTP_CVAL](#), [CNTP_TVAL](#), and [CNTP_CTL](#) registers in the current CNTBaseN frame are also accessible in the corresponding CNTEL0BaseN frame.

EL0PTEN	Meaning
0b0	No access. Registers are RES0 in the second view.
0b1	Access permitted. If the registers are accessible in the current frame, then they are accessible in the second view.

The reset behavior of this field is:

- On a Timer reset, this field resets to an architecturally UNKNOWN value.

EL0VTEN, bit [8]

Second view read/write access control for the Virtual Timer registers. This bit controls whether the [CNTV_CVAL](#), [CNTV_TVAL](#), and [CNTV_CTL](#) registers in the current CNTBaseN frame are also accessible in the corresponding CNTEL0BaseN frame.

EL0VTEN	Meaning
0b0	No access. Registers are RES0 in the second view.
0b1	Access permitted. If the registers are accessible in the current frame, then they are accessible in the second view.

The definition of this bit means that, if the Virtual Timer registers are not implemented in the current CNTBaseN frame, then the Virtual Timer register addresses are RES0 in the corresponding CNTEL0BaseN frame, regardless of the value of this bit.

The reset behavior of this field is:

- On a Timer reset, this field resets to an architecturally UNKNOWN value.

Bits [7:2]

Reserved, RES0.

EL0VCTEN, bit [1]

Second view read access control for [CNTVCT](#) and [CNTFRQ](#).

EL0VCTEN	Meaning
0b0	CNTVCT is not visible in the second view. If EL0PCTEN is set to 0, CNTFRQ is not visible in the second view.
0b1	Access permitted. If CNTVCT and CNTFRQ are visible in the current frame, then they are visible in the second view.

The reset behavior of this field is:

- On a Timer reset, this field resets to an architecturally UNKNOWN value.

EL0PCTEN, bit [0]

Second view read access control for [CNTPCT](#) and [CNTFRQ](#).

EL0PCTEN	Meaning
0b0	CNTPCT is not visible in the second view. If EL0VCTEN is set to 0, CNTFRQ is not visible in the second view.
0b1	Access permitted. If CNTPCT and CNTFRQ are visible in the current frame, then they are visible in the second view.

The reset behavior of this field is:

- On a Timer reset, this field resets to an architecturally UNKNOWN value.

Accessing CNTEL0ACR

CNTEL0ACR can be implemented in any implemented CNTBaseN frame.

‘[CNTCTLBase status and control fields for the CNTBaseN and CNTEL0BaseN frames](#)’ describes the status fields that identify whether a CNTBaseN frame is implemented, and for an implemented frame:

- Whether the CNTBaseN frame has virtual timer capability.
- Whether the corresponding CNTEL0BaseN frame is implemented.
- For an implementation that recognizes two Security states, whether the CNTBaseN frame, and any corresponding CNTEL0BaseN frame, is accessible by Non-secure accesses. The CNTBaseN frame is always accessible by Secure accesses.

If CNTEL0ACR is not implemented in an implemented CNTBaseN frame:

- The register location in that frame is RAZ/WI.
- If the corresponding CNTEL0BaseN frame is implemented, the registers [CNTFRQ](#), [CNTP_CTL](#), [CNTP_CVAL](#), [CNTP_TVAL](#), [CNTPCT](#), [CNTV_CTL](#), [CNTV_CVAL](#), [CNTV_TVAL](#), and [CNTVCT](#) are not visible and accesses are RAZ/WI in that frame.

CNTEL0ACR can be accessed through the memory-mapped interface:

Component	Frame	Offset	Instance
Timer	CNTBaseN	0x014	CNTEL0ACR

Accesses to this register are RW.

F4.5.5 CNTFID0, Counter Frequency ID

The CNTFID0 characteristics are:

Purpose

Indicates the base frequency of the system counter.

Configuration

It is IMPLEMENTATION DEFINED whether CNTFID0 is implemented in the Core power domain or in the Debug power domain

For more information, see [‘Power and reset domains for the system level implementation of the Generic Timer’](#).

The possible frequencies for the system counter are stored in the Frequency modes table as 32-bit words starting with the base frequency, CNTFID0. For more information, see [‘The Frequency modes table’](#).

The final entry in the Frequency modes table must be followed by a 32-bit word of zero value, to mark the end of the table.

Typically, the Frequency modes table will be in read-only memory. However, a system implementation might use read/write memory for the table, and initialize the table entries as part of its start-up sequence.

If the Frequency modes table is in read/write memory, Arm strongly recommends that the table is not updated once the system is running.

Attributes

CNTFID0 is a 32-bit register.

Field descriptions

Frequency, bits [31:0]

The base frequency of the system counter, in Hz.

The reset behavior of this field is:

- On a Timer reset, this field resets to an architecturally UNKNOWN value.

Accessing CNTFID0

It is IMPLEMENTATION DEFINED whether this register is RO or RW

In a system that supports Secure and Non-secure physical address spaces, the CNTControlBase frame, which includes this register, is implemented only in the Secure physical address space.

CNTFID0 can be accessed through the memory-mapped interface:

Component	Frame	Offset	Instance
Timer	CNTControlBase	0x020	CNTFID0

Accesses to this register are IMPLEMENTATION DEFINED.

F4.5.6 CNTFID<n>, Counter Frequency IDs, $n > 0$, $n = 1 - 1003$

The CNTFID<n> characteristics are:

Purpose

Indicates alternative system counter frequencies.

Configuration

It is IMPLEMENTATION DEFINED whether CNTFID<n> is implemented in the Core power domain or in the Debug power domain

For more information, see [‘Power and reset domains for the system level implementation of the Generic Timer’](#).

The possible frequencies for the system counter are stored in the Frequency modes table as 32-bit words starting with the base frequency, CNTFID0, see [‘The Frequency modes table’](#).

The number of CNTFID<n> registers is IMPLEMENTATION DEFINED, and the only required CNTFID<n> register is CNTFID0.

The final entry in the Frequency modes table must be followed by a 32-bit word of zero value, to mark the end of the table.

The architecture can support up to 1004 entries in the Frequency modes table, including the zero-word end marker, and the number of entries is IMPLEMENTATION DEFINED up to this limit. For an implementation that includes registers in the IMPLEMENTATION DEFINED register space 0x0C0-0x0FC, the maximum number of entries in the Frequency modes table is 40, including the zero-word end marker.

Typically, the Frequency modes table will be in read-only memory. However, a system implementation might use read/write memory for the table, and initialize the table entries as part of its start-up sequence.

If the Frequency modes table is in read/write memory, Arm strongly recommends that the table is not updated once the system is running.

Attributes

CNTFID<n> is a 32-bit register.

Field descriptions

Frequency, bits [31:0]

A system counter frequency, in Hz. Must be an exact divisor of the base frequency. Arm strongly recommends that all frequency values in the Frequency modes table are integer power-of-two divisors of the base frequency.

When the system timer is operating at a lower frequency than the base frequency, the increment applied at each counter update is increased by the ratio of the base frequency and the selected frequency.

The reset behavior of this field is:

- On a Timer reset, this field resets to an architecturally UNKNOWN value.

Accessing CNTFID<n>

It is IMPLEMENTATION DEFINED whether this register is RO or RW

In a system that supports Secure and Non-secure physical address spaces, the CNTControlBase frame, which includes these registers, is implemented only in the Secure physical address space.

CNTFID<n> can be accessed through the memory-mapped interface:

Component	Frame	Offset	Instance
Timer	CNTControlBase	$0 \times 020 + (4 * n)$	CNTFID<n>

Accesses to this register are IMPLEMENTATION DEFINED.

F4.5.7 CNTFRQ, Counter-timer Frequency

The CNTFRQ characteristics are:

Purpose

This register is provided so that software can discover the [effective frequency](#) of the system counter. The instance of the register in the CNTCTLBBase frame must be programmed with this value as part of system initialization. The value of the register is not interpreted by hardware.

Configuration

It is IMPLEMENTATION DEFINED whether CNTFRQ is implemented in the Core power domain or in the Debug power domain

For more information see [‘Power and reset domains for the system level implementation of the Generic Timer’](#).

Attributes

CNTFRQ is a 32-bit register.

Field descriptions

ClockFreq, bits [31:0]

Clock frequency. Indicates the [effective frequency](#) of the system counter, in Hz.

The reset behavior of this field is:

- On a Timer reset, this field resets to an architecturally UNKNOWN value.

Accessing CNTFRQ

CNTFRQ must be implemented as an RW register in the CNTCTLBBase frame.

In a system that recognizes two Security states, the instance of the register in the CNTCTLBBase frame is only accessible by Secure accesses.

CNTFRQ can be implemented as a RO register in any implemented CNTBaseN frame, and in the corresponding CNTEL0BaseN frame.

[‘CNTCTLBBase status and control fields for the CNTBaseN and CNTEL0BaseN frames’](#) describes the status fields that identify whether a CNTBaseN frame is implemented, and for an implemented frame:

- Whether the CNTBaseN frame has virtual timer capability.
- Whether the corresponding CNTEL0BaseN frame is implemented.
- For an implementation that recognizes two Security states, whether the CNTBaseN frame, and any corresponding CNTEL0BaseN frame, is accessible by Non-secure accesses. The CNTBaseN frame is always accessible by Secure accesses.

For an implemented CNTBaseN frame:

- CNTFRQ is accessible in that frame, as a RO register, if the value of [CNTACR<n>.RFRQ](#) is 1.
- Otherwise, the CNTFRQ address in that frame is RAZ/WI.

For an implemented CNTEL0BaseN frame:

- CNTFRQ is accessible as a RO register in that frame if both:

- CNTFRQ is accessible in the corresponding CNTBaseN frame.
- Either the value of CNTEL0ACR.EL0VCTEN is 1 or the value of CNTEL0ACR.EL0PCTEN is 1.
- Otherwise, the CNTFRQ address in that frame is RAZ/WI.

CNTFRQ can be accessed through the memory-mapped interface:

Component	Frame	Offset	Instance
Timer	CNTBaseN	0x010	CNTFRQ

Accesses to this register are RO.

Component	Frame	Offset	Instance
Timer	CNTEL0BaseN	0x010	CNTFRQ

Accesses to this register are RO.

Component	Frame	Offset	Instance
Timer	CNTCTLBase	0x000	CNTFRQ

Accesses to this register are RO.

F4.5.8 CNTID, Counter Identification Register

The CNTID characteristics are:

Purpose

Indicates whether counter scaling is implemented.

Configuration

It is IMPLEMENTATION DEFINED whether CNTID is implemented in the Core power domain or in the Debug power domain

This register is present only when FEAT_CNTSC is implemented. Otherwise, direct accesses to CNTID are RES0.

Attributes

CNTID is a 32-bit register.

Field descriptions

Bits [31:4]

Reserved, RES0.

CNTSC, bits [3:0]

Indicates whether Counter Scaling is implemented.

The value of this field is an IMPLEMENTATION DEFINED choice of:

CNTSC	Meaning
0b0000	Counter scaling is not implemented.
0b0001	Counter scaling is implemented.

All other values are reserved.

Access to this field is RO.

Accessing CNTID

In a system that supports Secure and Non-secure physical address spaces, the CNTControlBase frame, which includes this register, is implemented only in the Secure physical address space.

CNTID can be accessed through the memory-mapped interface:

Component	Frame	Offset	Instance
Timer	CNTControlBase	0x1C	CNTID

Accesses to this register are RO.

F4.5.9 CNTNSAR, Counter-timer Non-secure Access Register

The CNTNSAR characteristics are:

Purpose

Provides the highest-level control of whether frames CNTBaseN and CNTEL0BaseN are accessible by Non-secure accesses.

Configuration

It is IMPLEMENTATION DEFINED whether CNTNSAR is implemented in the Core power domain or in the Debug power domain

For more information, see [‘Power and reset domains for the system level implementation of the Generic Timer’](#).

Attributes

CNTNSAR is a 32-bit register.

Field descriptions

Bits [31:8]

Reserved, RES0.

NS<n> , bits [n], for n = 7 to 0

Non-secure access to frame n.

NS<n>	Meaning
0b0	Secure access only. Behaves as RES0 to Non-secure accesses.
0b1	Secure and Non-secure accesses permitted.

This bit also determines whether, in the CNTCTLBase frame, [CNTACR<n>](#) and [CNTVOFF<n>](#) are accessible to Non-secure accesses.

If frame CNTBase<n>:

- Is not implemented, then NS<n> is RES0.
- Is not Configurable access, and is accessible only by Secure accesses, then NS<n> is RES0.
- Is not Configurable access, and is accessible by both Secure and Non-secure accesses, then NS<n> is RES1.

The reset behavior of this field is:

- On a Timer reset, this field resets to an architecturally UNKNOWN value.

Accessing CNTNSAR

In a system that recognizes two Security states, this register is only accessible by Secure accesses.

CNTNSAR can be accessed through the memory-mapped interface:

Component	Frame	Offset	Instance
Timer	CNTCTLBase	0x004	CNTNSAR

Accesses to this register are RW.

F4.5.10 CNTPCT, Counter-timer Physical Count

The CNTPCT characteristics are:

Purpose

Holds the 64-bit physical count value.

Configuration

It is IMPLEMENTATION DEFINED whether CNTPCT is implemented in the Core power domain or in the Debug power domain

For more information, see [‘Power and reset domains for the system level implementation of the Generic Timer’](#).

Attributes

CNPCT is a 64-bit register.

Field descriptions

PhysicalCount, bits [63:0]

Physical count value.

The reset behavior of this field is:

- On a Timer reset, this field resets to an architecturally UNKNOWN value.

Accessing CNTPCT

CNPCT can be implemented in any implemented CNTBaseN frame, and in the corresponding CNTEL0BaseN frame, as a RO register.

[‘CNTCTLBase status and control fields for the CNTBaseN and CNTEL0BaseN frames’](#) describes the status fields that identify whether a CNTBaseN frame is implemented, and for an implemented frame:

- Whether the CNTBaseN frame has virtual timer capability.
- Whether the corresponding CNTEL0BaseN frame is implemented.
- For an implementation that recognizes two Security states, whether the CNTBaseN frame, and any corresponding CNTEL0BaseN frame, is accessible by Non-secure accesses. The CNTBaseN frame is always accessible by Secure accesses.

For an implemented CNTBaseN frame:

- CNTPCT is accessible in that frame, as a RO register, if the value of [CNTACR<n>.RPCT](#) is 1.
- Otherwise, the CNTPCT address in that frame is RAZ/WI.

For an implemented CNTEL0BaseN frame:

- CNTPCT is accessible in that frame if both:
 - CNTPCT is accessible in the corresponding CNTBaseN frame.
 - The value of [CNTEL0ACR.EL0PCTEN](#) is 1.

- Otherwise, the CNTPCT address in that frame is RAZ/WI.

If the implementation supports 64-bit atomic accesses, then the CNTPCT register must be accessible as an atomic 64-bit value.

CNTPCT can be accessed through the memory-mapped interface:

Component	Frame	Offset	Instance	Range
Timer	CNTBaseN	0x000	CNTPCT	31:0

Accesses to this register are RO.

Component	Frame	Offset	Instance	Range
Timer	CNTBaseN	0x004	CNTPCT	63:32

Accesses to this register are RO.

Component	Frame	Offset	Instance	Range
Timer	CNTEL0BaseN	0x000	CNTPCT	31:0

Accesses to this register are RO.

Component	Frame	Offset	Instance	Range
Timer	CNTEL0BaseN	0x004	CNTPCT	63:32

Accesses to this register are RO.

F4.5.11 CNTP_CTL, Counter-timer Physical Timer Control

The CNTP_CTL characteristics are:

Purpose

Control register for the EL1 physical timer.

Configuration

It is IMPLEMENTATION DEFINED whether CNTP_CTL is implemented in the Core power domain or in the Debug power domain

For more information, see ‘[Power and reset domains for the system level implementation of the Generic Timer](#)’.

Attributes

CNTP_CTL is a 32-bit register.

Field descriptions

Bits [31:3]

Reserved, RES0.

ISTATUS, bit [2]

The status of the timer. This bit indicates whether the timer condition is met:

ISTATUS	Meaning
0b0	Timer condition is not met.
0b1	Timer condition is met.

When the value of the ENABLE bit is 1, ISTATUS indicates whether the timer condition is met. ISTATUS takes no account of the value of the IMASK bit. If the value of ISTATUS is 1 and the value of IMASK is 0, then the timer interrupt is asserted.

When the value of the ENABLE bit is 0, the ISTATUS field is UNKNOWN.

The reset behavior of this field is:

- On a Timer reset, this field resets to an architecturally UNKNOWN value.

Access to this field is RO.

IMASK, bit [1]

Timer interrupt mask bit. Permitted values are:

IMASK	Meaning
0b0	Timer interrupt is not masked by the IMASK bit.
0b1	Timer interrupt is masked by the IMASK bit.

For more information, see the description of the ISTATUS bit.

The reset behavior of this field is:

- On a Timer reset, this field resets to an architecturally UNKNOWN value.

ENABLE, bit [0]

Enables the timer. Permitted values are:

ENABLE	Meaning
0b0	Timer disabled.
0b1	Timer enabled.

Setting this bit to 0 disables the timer output signal, but the timer value accessible from [CNTP_TVAL](#) continues to count down.

Note

Disabling the output signal might be a power-saving option.

The reset behavior of this field is:

- On a Timer reset, this field resets to an architecturally UNKNOWN value.

Accessing CNTP_CTL

CNTP_CTL can be implemented in any implemented CNTBaseN frame, and in the corresponding CNTEL0BaseN frame.

‘[CNTCTLBase status and control fields for the CNTBaseN and CNTEL0BaseN frames](#)’ describes the status fields that identify whether a CNTBaseN frame is implemented, and for an implemented frame:

- Whether the CNTBaseN frame has virtual timer capability.
- Whether the corresponding CNTEL0BaseN frame is implemented.
- For an implementation that recognizes two Security states, whether the CNTBaseN frame, and any corresponding CNTEL0BaseN frame, is accessible by Non-secure accesses. The CNTBaseN frame is always accessible by Secure accesses.

For an implemented CNTBaseN frame:

- CNTP_CTL is accessible in that frame if the value of [CNTACR<n>.RWPT](#) is 1.
- Otherwise, the CNTP_CTL address in that frame is RAZ/WI.

For an implemented CNTEL0BaseN frame:

- CNTP_CTL is accessible in that frame if both:
 - CNTP_CTL is accessible in the corresponding CNTBaseN frame:
 - The value of [CNTEL0ACR.ELOPTEN](#) is 1.
- Otherwise, the CNTP_CTL address in that frame is RAZ/WI.

CNTP_CTL can be accessed through the memory-mapped interface:

Component	Frame	Offset	Instance
Timer	CNTBaseN	0x02C	CNTP_CTL

Accesses to this register are RW.

Component	Frame	Offset	Instance
Timer	CNTELOBaseN	0x02C	CNTP_CTL

Accesses to this register are RW.

F4.5.12 CNTP_CVAL, Counter-timer Physical Timer CompareValue

The CNTP_CVAL characteristics are:

Purpose

Holds the 64-bit compare value for the EL1 physical timer.

Configuration

It is IMPLEMENTATION DEFINED whether CNTP_CVAL is implemented in the Core power domain or in the Debug power domain

For more information, see ‘[Power and reset domains for the system level implementation of the Generic Timer](#)’.

Attributes

CNTP_CVAL is a 64-bit register.

Field descriptions

CompareValue, bits [63:0]

Holds the EL1 physical timer CompareValue.

When [CNTP_CTL.ENABLE](#) is 1, the timer condition is met when ([CNTPCT](#) - CompareValue) is greater than or equal to zero. This means that CompareValue acts like a 64-bit upcounter timer. When the timer condition is met:

- [CNTP_CTL.ISTATUS](#) is set to 1.
- An interrupt is generated if [CNTP_CTL.IMASK](#) is 0.

When [CNTP_CTL.ENABLE](#) is 0, the timer condition is not met, but [CNTPCT](#) continues to count.

The reset behavior of this field is:

- On a Timer reset, this field resets to an architecturally UNKNOWN value.

Accessing CNTP_CVAL

CNTP_CVAL can be implemented in any implemented CNTBaseN frame, and in the corresponding CNTEL0BaseN frame.

‘[CNTCTLBase status and control fields for the CNTBaseN and CNTEL0BaseN frames](#)’ describes the status fields that identify whether a CNTBaseN frame is implemented, and for an implemented frame:

- Whether the CNTBaseN frame has virtual timer capability.
- Whether the corresponding CNTEL0BaseN frame is implemented.
- For an implementation that recognizes two Security states, whether the CNTBaseN frame, and any corresponding CNTEL0BaseN frame, is accessible by Non-secure accesses. The CNTBaseN frame is always accessible by Secure accesses.

For an implemented CNTBaseN frame:

- CNTP_CVAL is accessible in that frame if the value of [CNTACR<n>.RWPT](#) is 1.
- Otherwise, the CNTP_CVAL address in that frame is RAZ/WI.

For an implemented CNTEL0BaseN frame:

- CNTP_CVAL is accessible in that frame if both:
 - CNTP_CVAL is accessible in the corresponding CNTBaseN frame:
 - The value of CNTEL0ACR.EL0PTEN is 1.
- Otherwise, the CNTP_CVAL address in that frame is RAZ/WI.

If the implementation supports 64-bit atomic accesses, then the CNTP_CVAL register must be accessible as an atomic 64-bit value.

CNTP_CVAL can be accessed through the memory-mapped interface:

Component	Frame	Offset	Instance	Range
Timer	CNTBaseN	0x020	CNTP_CVAL	31:0

Accesses to this register are RW.

Component	Frame	Offset	Instance	Range
Timer	CNTBaseN	0x024	CNTP_CVAL	63:32

Accesses to this register are RW.

Component	Frame	Offset	Instance	Range
Timer	CNTEL0BaseN	0x020	CNTP_CVAL	31:0

Accesses to this register are RW.

Component	Frame	Offset	Instance	Range
Timer	CNTEL0BaseN	0x024	CNTP_CVAL	63:32

Accesses to this register are RW.

F4.5.13 CNTP_TVAL, Counter-timer Physical Timer TimerValue

The CNTP_TVAL characteristics are:

Purpose

Holds the timer value for the EL1 physical timer.

Configuration

It is IMPLEMENTATION DEFINED whether CNTP_TVAL is implemented in the Core power domain or in the Debug power domain

For more information, see [‘Power and reset domains for the system level implementation of the Generic Timer’](#).

Attributes

CNTP_TVAL is a 32-bit register.

Field descriptions

TimerValue, bits [31:0]

The TimerValue view of the EL1 physical timer.

On a read of this register:

- If [CNTP_CTL.ENABLE](#) is 0, the value returned is UNKNOWN.
- If [CNTP_CTL.ENABLE](#) is 1, the value returned is (CompareValue - [CNTPCT](#)).

On a write of this register, CompareValue is set to ([CNTPCT](#) + TimerValue), where TimerValue is treated as a signed 32-bit integer.

When [CNTP_CTL.ENABLE](#) is 1, the timer condition is met when ([CNTPCT](#) - CompareValue) is greater than or equal to zero. This means that TimerValue acts like a 32-bit downcounter timer. When the timer condition is met:

- [CNTP_CTL.ISTATUS](#) is set to 1.
- If [CNTP_CTL.IMASK](#) is 0, an interrupt is generated.

When [CNTP_CTL.ENABLE](#) is 0, the timer condition is not met, but [CNTPCT](#) continues to count, so the TimerValue view appears to continue to count down.

The reset behavior of this field is:

- On a Timer reset, this field resets to an architecturally UNKNOWN value.

Accessing CNTP_TVAL

CNTP_TVAL can be implemented in any implemented CNTBaseN frame, and in the corresponding CNTEL0BaseN frame.

[‘CNTCTLBase status and control fields for the CNTBaseN and CNTEL0BaseN frames’](#) describes the status fields that identify whether a CNTBaseN frame is implemented, and for an implemented frame:

- Whether the CNTBaseN frame has virtual timer capability.
- Whether the corresponding CNTEL0BaseN frame is implemented.
- For an implementation that recognizes two Security states, whether the CNTBaseN frame, and any corresponding CNTEL0BaseN frame, is accessible by Non-secure accesses. The CNTBaseN frame is always accessible by Secure accesses.

For an implemented CNTBaseN frame:

- CNTP_TVAL is accessible in that frame if the value of CNTACR<n>.RWPT is 1.
- Otherwise, the CNTP_TVAL address in that frame is RAZ/WI.

For an implemented CNTEL0BaseN frame:

- CNTP_TVAL is accessible in that frame if both:
 - CNTP_TVAL is accessible in the corresponding CNTBaseN frame:
 - The value of CNTEL0ACR.EL0PTEN is 1.
- Otherwise, the CNTP_TVAL address in that frame is RAZ/WI.

CNTP_TVAL can be accessed through the memory-mapped interface:

Component	Frame	Offset	Instance
Timer	CNTBaseN	0x028	CNTP_TVAL

Accesses to this register are RW.

Component	Frame	Offset	Instance
Timer	CNTEL0BaseN	0x028	CNTP_TVAL

Accesses to this register are RW.

F4.5.14 CNTSCR, Counter Scale Register

The CNTSCR characteristics are:

Purpose

Enables the counter, controls the counter [effective frequency](#) setting, and controls counter behavior during debug.

Configuration

It is IMPLEMENTATION DEFINED whether CNTSCR is implemented in the Core power domain or in the Debug power domain

For more information, see [‘Power and reset domains for the system level implementation of the Generic Timer’](#).

This register is present only when FEAT_CNTSC is implemented. Otherwise, direct accesses to CNTSCR are RES0.

Attributes

CNTSCR is a 32-bit register.

Field descriptions

ScaleVal, bits [31:0]

Scale Value

When counter scaling is enabled, ScaleVal is the average amount added to the counter value for one period of the frequency of the Generic counter as described in the [CNTFRQ](#) register.

The actual rate of update of the counter value is determined by the [counter resolution](#).

ScaleVal is expressed as an unsigned fixed point number with an 8-bit integer value and a 24-bit fractional value.

CNTSCR.ScaleVal can only be changed when [CNTCR.EN](#) == 0. If the value of this field is changed when [CNTCR.EN](#) == 1:

- The counter value becomes UNKNOWN.
- The counter value remains UNKNOWN on future ticks of the clock.

The reset behavior of this field is:

- On a Timer reset, this field resets to an architecturally UNKNOWN value.

Accessing CNTSCR

In a system that supports Secure and Non-secure physical address spaces, the CNTControlBase frame, which includes this register, is implemented only in the Secure physical address space.

CNTSCR can be accessed through the memory-mapped interface:

Component	Frame	Offset	Instance
Timer	CNTControlBase	0x10	CNTSCR

Accesses to this register are RW.

F4.5.15 CNTSR, Counter Status Register

The CNTSR characteristics are:

Purpose

Provides counter resolution status information.

Configuration

It is IMPLEMENTATION DEFINED whether CNTSR is implemented in the Core power domain or in the Debug power domain

For more information, see ‘Power and reset domains for the system level implementation of the Generic Timer’.

Attributes

CNTSR is a 32-bit register.

Field descriptions

Bits [31:18]

Reserved, RES0.

FCACK, bits [17:8]

Frequency Change Acknowledge. Indicates the currently selected entry in the Frequency modes table, see ‘The Frequency modes table’.

The reset behavior of this field is:

- On a Timer reset, this field resets to the expression 0x000000.

Bits [7:2]

Reserved, RES0.

DBGH, bit [1]

Indicates whether the counter is halted because the Halt-on-debug signal is asserted:

DBGH	Meaning
0b0	Counter is not halted.
0b1	Counter is halted.

The reset behavior of this field is:

- On a Timer reset, this field resets to an architecturally UNKNOWN value.

Bit [0]

Reserved, RES0.

Accessing CNTSR

In a system that supports Secure and Non-secure physical address spaces, the CNTControlBase frame, which includes this register, is implemented only in the Secure physical address space.

CNTSR can be accessed through the memory-mapped interface:

Component	Frame	Offset	Instance
Timer	CNTControlBase	0x004	CNTSR

Accesses to this register are RO.

F4.5.16 CNTTIDR, Counter-timer Timer ID Register

The CNTTIDR characteristics are:

Purpose

Indicates the implemented timers in the physical address space, and their features. For each value of N from 0 to 7 it indicates whether:

- Frame CNTBaseN is a view of an implemented timer.
- Frame CNTBaseN has a second view, CNTEL0BaseN.
- Frame CNTBaseN has a virtual timer capability.

Configuration

It is IMPLEMENTATION DEFINED whether CNTTIDR is implemented in the Core power domain or in the Debug power domain

For more information, see [‘Power and reset domains for the system level implementation of the Generic Timer’](#).

Attributes

CNTTIDR is a 32-bit register.

Field descriptions

31	28	27	24	23	20	19	16	15	12	11	8	7	4	3	0
Frame7	Frame6	Frame5	Frame4	Frame3	Frame2	Frame1	Frame0								

Frame<n>, bits [4n+3:4n], for n = 7 to 0

A 4-bit field indicating the features of frame CNTBase<n>.

Bit[3] of the field is RES0.

Bit[2], the FEL0 subfield, indicates whether frame CNTBase<n> has a second view, CNTEL0Base<n>. The possible values of this bit are:

Bit[2]	Meaning
0b0	Frame<n> does not have a second view. The CNTEL0ACR register in the first view of the frame is RES0.
0b1	Frame<n> has a second view, CNTEL0Base<n>.

If bit[0] is 0, bit[2] is RES0.

Bit[1], the FVI subfield, indicates whether both:

- Frame CNTBase<n> implements the virtual timer registers [CNTV_CVAL](#), [CNTV_TVAL](#), and [CNTV_CTL](#).
- This CNTCTLBase frame implements the virtual timer offset register [CNTVOFF<n>](#).

The possible values of bit[1] are:

Bit[1]	Meaning
0b0	Frame<n> does not have virtual capability. The virtual time and offset registers are RES0.
0b1	Frame<n> has virtual capability. The virtual time and offset registers are implemented.

If bit[0] is 0, bit[1] is RES0.

Bit[0], the FI subfield, indicates whether frame CNTBase<n> is implemented. The possible values of this bit are:

Bit[0]	Meaning
0b0	Frame<n> is not implemented. All registers associated with the frame are RES0.
0b1	Frame<n> is implemented.

Accessing CNTTIDR

In a system that recognizes two Security states, this register is accessible by both Secure and Non-secure accesses.

CNTTIDR can be accessed through the memory-mapped interface:

Component	Frame	Offset	Instance
Timer	CNTCTLBase	0x008	CNTTIDR

Accesses to this register are RO.

F4.5.17 CNTVCT, Counter-timer Virtual Count

The CNTVCT characteristics are:

Purpose

Holds the 64-bit virtual count value.

Configuration

It is IMPLEMENTATION DEFINED whether CNTVCT is implemented in the Core power domain or in the Debug power domain

For more information, see [‘Power and reset domains for the system level implementation of the Generic Timer’](#).

Attributes

CNTVCT is a 64-bit register.

Field descriptions

VirtualCount, bits [63:0]

Virtual count value.

The reset behavior of this field is:

- On a Timer reset, this field resets to an architecturally UNKNOWN value.

Accessing CNTVCT

CNTVCT can be implemented in any implemented CNTBaseN frame, and in the corresponding CNTEL0BaseN frame, as a RO register.

[‘CNTCTLBase status and control fields for the CNTBaseN and CNTEL0BaseN frames’](#) describes the status fields that identify whether a CNTBaseN frame is implemented, and for an implemented frame:

- Whether the CNTBaseN frame has virtual timer capability.
- Whether the corresponding CNTEL0BaseN frame is implemented.
- For an implementation that recognizes two Security states, whether the CNTBaseN frame, and any corresponding CNTEL0BaseN frame, is accessible by Non-secure accesses. The CNTBaseN frame is always accessible by Secure accesses.

For an implemented CNTBaseN frame:

- CNTVCT is accessible in that frame, as a RO register, if the value of [CNTACR<n>.RVCT](#) is 1.
- Otherwise, the CNTVCT address in that frame is RAZ/WI.

For an implemented CNTEL0BaseN frame:

- CNTVCT is accessible in that frame if both:
 - CNTVCT is accessible in the corresponding CNTBaseN frame.
 - The value of [CNTEL0ACR.EL0VCTEN](#) is 1.

- Otherwise, the CNTVCT address in that frame is RAZ/WI.

If the implementation supports 64-bit atomic accesses, then the CNTVCT register must be accessible as an atomic 64-bit value.

CNTVCT can be accessed through the memory-mapped interface:

Component	Frame	Offset	Instance	Range
Timer	CNTBaseN	0x008	CNTVCT	31:0

Accesses to this register are RO.

Component	Frame	Offset	Instance	Range
Timer	CNTBaseN	0x00C	CNTVCT	63:32

Accesses to this register are RO.

Component	Frame	Offset	Instance	Range
Timer	CNTEL0BaseN	0x008	CNTVCT	31:0

Accesses to this register are RO.

Component	Frame	Offset	Instance	Range
Timer	CNTEL0BaseN	0x00C	CNTVCT	63:32

Accesses to this register are RO.

F4.5.18 CNTVOFF, Counter-timer Virtual Offset

The CNTVOFF characteristics are:

Purpose

Holds the 64-bit virtual offset for a CNTBaseN frame that has virtual timer capability. This is the offset between real time and virtual time.

Configuration

It is IMPLEMENTATION DEFINED whether CNTVOFF is implemented in the Core power domain or in the Debug power domain

For more information, see [‘Power and reset domains for the system level implementation of the Generic Timer’](#).

Attributes

CNTVOFF is a 64-bit register.

Field descriptions

VOffset, bits [63:0]

Virtual offset.

The reset behavior of this field is:

- On a Timer reset, this field resets to an architecturally UNKNOWN value.

Accessing CNTVOFF

CNTVOFF is implemented, as a RO register, in any implemented CNTBaseN frame that has virtual timer capability.

[‘CNTCTLBase status and control fields for the CNTBaseN and CNTEL0BaseN frames’](#) describes the status fields that identify whether a CNTBaseN frame is implemented, and for an implemented frame:

- Whether the CNTBaseN frame has virtual timer capability.
- Whether the corresponding CNTEL0BaseN frame is implemented.
- For an implementation that recognizes two Security states, whether the CNTBaseN frame, and any corresponding CNTEL0BaseN frame, is accessible by Non-secure accesses. The CNTBaseN frame is always accessible by Secure accesses.

For an implemented CNTBaseN frame that has virtual timer capability:

- CNTVOFF is accessible in that frame, as a RO register, if the value of [CNTACR<n>.RVOFF](#) is 1.
- Otherwise, the CNTVOFF address in that frame is RAZ/WI.

Note

CNTVOFF is never visible in any CNTEL0BaseN frame. This means that the CNTVOFF address in any implemented CNTEL0BaseN frame is RAZ/WI.

In an implementation that supports 64-bit atomic accesses, then the CNTVOFF register must be accessible as an atomic 64-bit value.

CNTVOFF can be accessed through the memory-mapped interface:

Component	Frame	Offset	Range
Timer	CNTBaseN	0x018	31:0

Accesses to this register are RO.

Component	Frame	Offset	Range
Timer	CNTBaseN	0x01C	63:32

Accesses to this register are RO.

F4.5.19 CNTVOFF<n>, Counter-timer Virtual Offsets, n = 0 - 7

The CNTVOFF<n> characteristics are:

Purpose

Holds the 64-bit virtual offset for frame CNTBase<n>. This is the offset between real time and virtual time.

Configuration

It is IMPLEMENTATION DEFINED whether CNTVOFF<n> is implemented in the Core power domain or in the Debug power domain

For more information, see [‘Power and reset domains for the system level implementation of the Generic Timer’](#).

Implementation of this register is OPTIONAL.

Attributes

CNTVOFF<n> is a 64-bit register.

Field descriptions

VOffset, bits [63:0]

Virtual offset.

The reset behavior of this field is:

- On a Timer reset, this field resets to an architecturally UNKNOWN value.

Accessing CNTVOFF<n>

In the CNTCTBase frame a CNTVOFF<n> register must be implemented, as a RW register, for each CNTBaseN frame that has virtual timer capability. For more information, see [‘CNTCTBase status and control fields for the CNTBaseN and CNTEL0BaseN frames’](#).

Note

The value of <n> in an instance of CNTVOFF<n> specifies the value of N for the associated CNTBaseN frame.

In a system that recognizes two Security states, for any CNTVOFF<n> register in the CNTCTBase frame:

- CNTVOFF<n> is always accessible by Secure accesses.
- [CNTNSAR.NS<n>](#) determines whether CNTVOFF<n> is accessible by Non-secure accesses.

The register location of any unimplemented CNTVOFF<n> register in the CNTCTBase frame is RAZ/WI.

The CNTVOFF<n> register is accessible in the CNTBaseN frame using [CNTVOFF](#).

In an implementation that supports 64-bit atomic accesses, then the CNTVOFF<n> registers must be accessible as atomic 64-bit values.

CNTVOFF<n> can be accessed through the memory-mapped interface:

Component	Frame	Offset	Range
Timer	CNTCTLBase	$0 \times 080 + (8 * n)$	31:0

Accesses to this register are RW.

Component	Frame	Offset	Range
Timer	CNTCTLBase	$0 \times 084 + (8 * n)$	63:32

Accesses to this register are RW.

F4.5.20 CNTV_CTL, Counter-timer Virtual Timer Control

The CNTV_CTL characteristics are:

Purpose

Control register for the virtual timer.

Configuration

It is IMPLEMENTATION DEFINED whether CNTV_CTL is implemented in the Core power domain or in the Debug power domain

For more information, see ‘Power and reset domains for the system level implementation of the Generic Timer’.

Attributes

CNTV_CTL is a 32-bit register.

Field descriptions

Bits [31:3]

Reserved, RES0.

ISTATUS, bit [2]

The status of the timer. This bit indicates whether the timer condition is met:

ISTATUS	Meaning
0b0	Timer condition is not met.
0b1	Timer condition is met.

When the value of the ENABLE bit is 1, ISTATUS indicates whether the timer condition is met. ISTATUS takes no account of the value of the IMASK bit. If the value of ISTATUS is 1 and the value of IMASK is 0, then the timer interrupt is asserted.

When the value of the ENABLE bit is 0, the ISTATUS field is UNKNOWN.

The reset behavior of this field is:

- On a Timer reset, this field resets to an architecturally UNKNOWN value.

Access to this field is RO.

IMASK, bit [1]

Timer interrupt mask bit. Permitted values are:

IMASK	Meaning
0b0	Timer interrupt is not masked by the IMASK bit.
0b1	Timer interrupt is masked by the IMASK bit.

For more information, see the description of the ISTATUS bit.

The reset behavior of this field is:

- On a Timer reset, this field resets to an architecturally UNKNOWN value.

ENABLE, bit [0]

Enables the timer. Permitted values are:

ENABLE	Meaning
0b0	Timer disabled.
0b1	Timer enabled.

Setting this bit to 0 disables the timer output signal, but the timer value accessible from [CNTV_TVAL](#) continues to count down.

Note

Disabling the output signal might be a power-saving option.

The reset behavior of this field is:

- On a Timer reset, this field resets to an architecturally UNKNOWN value.

Accessing CNTV_CTL

CNTV_CTL can be implemented in any implemented CNTBaseN frame that has virtual timer capability, and in the corresponding CNTEL0BaseN frame.

‘[CNTCTLBase status and control fields for the CNTBaseN and CNTEL0BaseN frames](#)’ describes the status fields that identify whether a CNTBaseN frame is implemented, and for an implemented frame:

- Whether the CNTBaseN frame has virtual timer capability.
- Whether the corresponding CNTEL0BaseN frame is implemented.
- For an implementation that recognizes two Security states, whether the CNTBaseN frame, and any corresponding CNTEL0BaseN frame, is accessible by Non-secure accesses. The CNTBaseN frame is always accessible by Secure accesses.

For an implemented CNTBaseN frame that has virtual timer capability:

- CNTV_CTL is accessible in that frame if the value of [CNTACR<n>.RWVT](#) is 1.
- Otherwise, the CNTV_CTL address in that frame is RAZ/WI.

For an implemented CNTEL0BaseN frame:

- CNTV_CTL is accessible in that frame if both:
 - CNTV_CTL is accessible in the corresponding CNTBaseN frame:
 - The value of [CNTEL0ACR.EL0VTEN](#) is 1.
- Otherwise, the CNTV_CTL address in that frame is RAZ/WI.

CNTV_CTL can be accessed through the memory-mapped interface:

Component	Frame	Offset	Instance
Timer	CNTBaseN	0x03C	CNTV_CTL

Accesses to this register are RW.

Component	Frame	Offset	Instance
Timer	CNTEL0BaseN	0x03C	CNTV_CTL

Accesses to this register are RW.

F4.5.21 CNTV_CVAL, Counter-timer Virtual Timer CompareValue

The CNTV_CVAL characteristics are:

Purpose

Holds the 64-bit compare value for the virtual timer.

Configuration

It is IMPLEMENTATION DEFINED whether CNTV_CVAL is implemented in the Core power domain or in the Debug power domain

For more information, see ‘[Power and reset domains for the system level implementation of the Generic Timer](#)’.

Attributes

CNTV_CVAL is a 64-bit register.

Field descriptions

CompareValue, bits [63:0]

Holds the virtual timer CompareValue.

When [CNTV_CTL.ENABLE](#) is 1, the timer condition is met when ([CNTVCT](#) - CompareValue) is greater than or equal to zero. This means that CompareValue acts like a 64-bit upcounter timer. When the timer condition is met:

- [CNTV_CTL.ISTATUS](#) is set to 1.
- An interrupt is generated if [CNTV_CTL.IMASK](#) is 0.

When [CNTV_CTL.ENABLE](#) is 0, the timer condition is not met, but [CNTVCT](#) continues to count.

The reset behavior of this field is:

- On a Timer reset, this field resets to an architecturally UNKNOWN value.

Accessing CNTV_CVAL

CNTV_CVAL can be implemented in any implemented CNTBaseN frame that has virtual timer capability, and in the corresponding CNTEL0BaseN frame.

‘[CNTCTLBase status and control fields for the CNTBaseN and CNTEL0BaseN frames](#)’ describes the status fields that identify whether a CNTBaseN frame is implemented, and for an implemented frame:

- Whether the CNTBaseN frame has virtual timer capability.
- Whether the corresponding CNTEL0BaseN frame is implemented.
- For an implementation that recognizes two Security states, whether the CNTBaseN frame, and any corresponding CNTEL0BaseN frame, is accessible by Non-secure accesses. The CNTBaseN frame is always accessible by Secure accesses.

For an implemented CNTBaseN frame that has virtual timer capability:

- CNTV_CVAL is accessible in that frame if the value of [CNTACR<n>.RWVT](#) is 1.
- Otherwise, the CNTV_CVAL address in that frame is RAZ/WI.

For an implemented CNTEL0BaseN frame:

- CNTV_CVAL is accessible in that frame if both:
 - CNTV_CVAL is accessible in the corresponding CNTBaseN frame:
 - The value of CNTEL0ACR.EL0VTEN is 1.
- Otherwise, the CNTV_CVAL address in that frame is RAZ/WI.

If the implementation supports 64-bit atomic accesses, then the CNTV_CVAL register must be accessible as an atomic 64-bit value.

CNTV_CVAL can be accessed through the memory-mapped interface:

Component	Frame	Offset	Instance	Range
Timer	CNTBaseN	0x030	CNTV_CVAL	31:0

Accesses to this register are RW.

Component	Frame	Offset	Instance	Range
Timer	CNTBaseN	0x034	CNTV_CVAL	63:32

Accesses to this register are RW.

Component	Frame	Offset	Instance	Range
Timer	CNTEL0BaseN	0x030	CNTV_CVAL	31:0

Accesses to this register are RW.

Component	Frame	Offset	Instance	Range
Timer	CNTEL0BaseN	0x034	CNTV_CVAL	63:32

Accesses to this register are RW.

F4.5.22 CNTV_TVAL, Counter-timer Virtual Timer TimerValue

The CNTV_TVAL characteristics are:

Purpose

Holds the timer value for the virtual timer.

Configuration

It is IMPLEMENTATION DEFINED whether CNTV_TVAL is implemented in the Core power domain or in the Debug power domain

For more information, see [‘Power and reset domains for the system level implementation of the Generic Timer’](#).

Attributes

CNTV_TVAL is a 32-bit register.

Field descriptions

TimerValue, bits [31:0]

The TimerValue view of the virtual timer.

On a read of this register:

- If [CNTV_CTL.ENABLE](#) is 0, the value returned is UNKNOWN.
- If [CNTV_CTL.ENABLE](#) is 1, the value returned is (CompareValue - [CNTVCT](#)).

On a write of this register, CompareValue is set to ([CNTVCT](#) + TimerValue), where TimerValue is treated as a signed 32-bit integer.

When [CNTV_CTL.ENABLE](#) is 1, the timer condition is met when ([CNTVCT](#) - CompareValue) is greater than or equal to zero. This means that TimerValue acts like a 32-bit downcounter timer. When the timer condition is met:

- [CNTV_CTL.ISTATUS](#) is set to 1.
- If [CNTV_CTL.IMASK](#) is 0, an interrupt is generated.

When [CNTV_CTL.ENABLE](#) is 0, the timer condition is not met, but [CNTVCT](#) continues to count, so the TimerValue view appears to continue to count down.

The reset behavior of this field is:

- On a Timer reset, this field resets to an architecturally UNKNOWN value.

Accessing CNTV_TVAL

CNTV_TVAL can be implemented in any implemented CNTBaseN frame that has virtual timer capability, and in the corresponding CNTEL0BaseN frame.

[‘CNTCTLBase status and control fields for the CNTBaseN and CNTEL0BaseN frames’](#) describes the status fields that identify whether a CNTBaseN frame is implemented, and for an implemented frame:

- Whether the CNTBaseN frame has virtual timer capability.
- Whether the corresponding CNTEL0BaseN frame is implemented.
- For an implementation that recognizes two Security states, whether the CNTBaseN frame, and any corresponding CNTEL0BaseN frame, is accessible by Non-secure accesses. The CNTBaseN frame is always accessible by Secure accesses.

For an implemented CNTBaseN frame that has virtual timer capability:

- CNTV_TVAL is accessible in that frame if the value of CNTACR<n>.RWVT is 1.
- Otherwise, the CNTV_TVAL address in that frame is RAZ/WI.

For an implemented CNTEL0BaseN frame:

- CNTV_TVAL is accessible in that frame if both:
 - CNTV_TVAL is accessible in the corresponding CNTBaseN frame.
 - The value of CNTEL0ACR.EL0VTEN is 1.
- Otherwise, the CNTV_TVAL address in that frame is RAZ/WI.

CNTV_TVAL can be accessed through the memory-mapped interface:

Component	Frame	Offset	Instance
Timer	CNTBaseN	0x038	CNTV_TVAL

Accesses to this register are RW.

Component	Frame	Offset	Instance
Timer	CNTEL0BaseN	0x038	CNTV_TVAL

Accesses to this register are RW.

F4.5.23 CounterID<n>, Counter ID registers, n = 0 - 11

The CounterID<n> characteristics are:

Purpose

IMPLEMENTATION DEFINED identification registers 0 to 11 for the memory-mapped Generic Timer.

Configuration

It is IMPLEMENTATION DEFINED whether CounterID<n> is implemented in the Core power domain or in the Debug power domain

For more information, see [‘Power and reset domains for the system level implementation of the Generic Timer’](#).

These registers are implemented independently in each of the implemented Generic Timer memory-mapped frames.

If the implementation of the Counter ID registers requires an architecture version, the value for this version of the Arm Generic Timer is version 0.

The Counter ID registers can be implemented as a set of CoreSight ID registers, comprising Peripheral ID Registers and Component ID Registers. An implementation of these registers for the Generic Timer must use a Component class value of 0xF.

Attributes

CounterID<n> is a 32-bit register.

Field descriptions

31	IMPLEMENTATION DEFINED	0
----	------------------------	---

IMPLEMENTATION DEFINED, bits [31:0]

IMPLEMENTATION DEFINED.

Accessing CounterID<n>

These registers must be implemented, as RO registers, in every implemented Generic Timer memory-mapped frame.

For the CNTCTLBase frame, in a system that recognizes two Security states these registers are accessible by both Secure and Non-secure accesses.

For the CNTControlBase frame, in a system that supports Secure and Non-secure physical address spaces, the frame is implemented only in the Secure physical address space, meaning these registers are implemented only in the Secure physical address space.

For the CNTReadBase frame, these registers are accessible in all physical address spaces.

For the CNTBaseN frames, [‘CNTCTLBase status and control fields for the CNTBaseN and CNTEL0BaseN frames’](#) describes the status fields that identify whether a frame is implemented, and for an implemented frame:

- Whether the CNTBaseN frame has virtual timer capability.
- Whether the corresponding CNTEL0BaseN frame is implemented.
- For an implementation that recognizes two Security states, whether the CNTBaseN frame, and any corresponding CNTEL0BaseN frame, is accessible by Non-secure accesses. The CNTBaseN frame is always accessible by Secure accesses.

CounterID<n> can be accessed through the memory-mapped interface:

Component	Frame	Offset	Instance
Timer	CNTControlBase	$0 \times \text{FD0} + (4 * n)$	CounterID<n>

Accesses to this register are RO.

Component	Frame	Offset	Instance
Timer	CNTReadBase	$0 \times \text{FD0} + (4 * n)$	CounterID<n>

Accesses to this register are RO.

Component	Frame	Offset	Instance
Timer	CNTBaseN	$0 \times \text{FD0} + (4 * n)$	CounterID<n>

Accesses to this register are RO.

Component	Frame	Offset	Instance
Timer	CNTEL0BaseN	$0 \times \text{FD0} + (4 * n)$	CounterID<n>

Accesses to this register are RO.

Component	Frame	Offset	Instance
Timer	CNTCTLBase	$0 \times \text{FD0} + (4 * n)$	CounterID<n>

Accesses to this register are RO.

Part G
Architectural Pseudocode

Chapter G1

R-profile Architecture Pseudocode

This chapter contains pseudocode that describes many features of the R-profile architecture. It contains the following sections:

- [Standard library](#)
- [Pseudocode for AArch64 operation](#)
- [Shared pseudocode](#)

G1.1 Standard library

The pseudocode in this manual is written in the Architecture Specification Language (ASL). The ASL makes use of a standard library.

Implementations of the standard library functions can be found within the [herdtools7 github repository](#).

The standard library implements the following functions:

- `Abs(x: integer) => integer`
- `Abs(x: real) => real`
- `AlignDown{N}(x: bits(N), y: integer{1..N}) => bits(N)`
- `AlignDownP2(x: integer, p2: integer) => integer`
- `AlignDownP2{N}(x: bits(N), p2: integer{0..N}) => bits(N)`
- `AlignDownSize(x: integer, size: integer) => integer`
- `AlignDownSize{N}(x: bits(N), size: integer{1..2^N}) => bits(N)`
- `AlignUp{N}(x: bits(N), y: integer{1..N}) => bits(N)`
- `AlignUpP2(x: integer, p2: integer) => integer`
- `AlignUpP2{N}(x: bits(N), p2: integer{0..N}) => bits(N)`
- `AlignUpSize(x: integer, size: integer) => integer`
- `AlignUpSize{N}(x: bits(N), size: integer{1..2^N}) => bits(N)`
- `ASR_C{N}(x: bits(N), shift: integer) => (bits(N), bit)`
- `ASR{N}(x: bits(N), shift: integer) => bits(N)`
- `BitCount{N}(x: bits(N)) => integer{0..N}`
- `CeilLog2(a: integer) => integer`
- `CeilPow2(x : integer) => integer`
- `CountLeadingSignBits{N}(x: bits(N)) => integer{0..N-1}`
- `CountLeadingZeroBits{N}(x: bits(N)) => integer{0..N}`
- `Extend{N,M}(x: bits(M), unsigned: boolean) => bits(N)`
- `FloorLog2(a: integer) => integer`
- `FloorPow2(x : integer) => integer`
- `HighestSetBit{N}(x: bits(N)) => integer{-1..N-1}`
- `HighestSetBitNZ{N}(x: bits(N)) => integer{0..N-1}`
- `ILog2(value : real) => integer`
- `IsAlignedP2(x: integer, p2: integer) => boolean`
- `IsAlignedP2{N}(x: bits(N), p2: integer{0..N}) => boolean`
- `IsAlignedSize(x: integer, size: integer) => boolean`
- `IsAlignedSize{N}(x: bits(N), size: integer{1..2^N}) => boolean`
- `IsEven(a: integer) => boolean`
- `IsOdd(a: integer) => boolean`
- `IsOnes{N}(x: bits(N)) => boolean`
- `IsPow2(x : integer) => boolean`
- `IsZero{N}(x: bits(N)) => boolean`
- `Len{N}(x: bits(N)) => integer{N}`
- `LowestSetBit{N}(x: bits(N)) => integer{0..N}`
- `LowestSetBitNZ{N}(x: bits(N)) => integer{0..N-1}`
- `LSL_C{N}(x: bits(N), shift: integer) => (bits(N), bit)`
- `LSL{N}(x: bits(N), shift: integer) => bits(N)`
- `LSR_C{N}(x: bits(N), shift: integer) => (bits(N), bit)`
- `LSR{N}(x: bits(N), shift: integer) => bits(N)`
- `Max(a: integer, b: integer) => integer`
- `Max(a: real, b: real) => real`
- `Min(a: integer, b: integer) => integer`
- `Min(a: real, b: real) => real`
- `Ones{N}() => bits(N)`
- `Real(x: integer) => real`
- `Replicate{N,M}(x: bits(M)) => bits(N)`
- `ReplicateBit{N}(isZero: boolean) => bits(N)`
- `ROL_C{N}(x: bits(N), shift: integer) => (bits(N), bit)`

G1.2 Pseudocode for AArch64 operation

This section holds the pseudocode for execution in AArch64 state. Functions that are listed in this section are identified as `AArch64.FunctionName`. Some of these functions have an equivalent AArch32 function, `AArch32.FunctionName`. This section is organized by functional groups, with the functional groups being indicated by hierarchical path names, for example `aarch64/debug/breakpoint`.

The top-level sections of the AArch64 pseudocode hierarchy are:

- [aarch64/debug](#).
- [aarch64/exceptions](#).
- [aarch64/functions](#).
- [aarch64/translation](#).

G1.2.1 aarch64/debug

This section includes the following pseudocode functions:

- [AArch64_BreakpointMatch](#)
- [AArch64_BreakpointValueMatch](#)
- [AArch64_ReservedBreakpointType](#)
- [AArch64_StateMatch](#)
- [DebugAddrTop](#)
- [IsAddressLinkingBreakpoint](#)
- [IsBreakpointEnabled](#)
- [NumAddressLinkingBreakpointsImplemented](#)
- [AArch64_GenerateDebugExceptions](#)
- [AArch64_GenerateDebugExceptionsFrom](#)
- [AArch64_IncrementCycleCounter](#)
- [AArch64_IncrementEventCounter](#)
- [AArch64_PMUCycle](#)
- [TimeStamp](#)
- [AArch64_TakeExceptionInDebugState](#)
- [AArch64_WatchpointByteMatch](#)
- [AArch64_WatchpointMatch](#)
- [IsWatchpointEnabled](#)

G1.2.1.1 AArch64_BreakpointMatch

```
// AArch64_BreakpointMatch()
// =====
// Breakpoint matching in an AArch64 translation regime.
// Returns BreakpointInfo structure that contains a boolean indicating if the match is successful
// and the matched address.
func AArch64_BreakpointMatch(n : integer, vaddress : bits(64), accdesc : AccessDescriptor,
                             size : integer) => BreakpointInfo
begin

G1.3 Shared pseudocode

This section holds the pseudocode that is common to execution in AArch64 state and in AArch32 state. Functions listed in this section are identified only by a `FunctionName`, without an `AArch64.` or `AArch32.` prefix. This section is organized by functional groups, with the functional groups being indicated by hierarchical path names, for example `shared/debug/DebugTarget`.

The top-level sections of the shared pseudocode hierarchy are:

- [shared/debug.](#)
- [shared/exceptions.](#)
- [shared/functions.](#)
- [shared/trace.](#)
- [shared/translation.](#)

G1.3.1 shared/debug

G1.3.3.193 Hint_Prefetch

```
// Hint_Prefetch()
// =====
// Signals the memory system that memory accesses of type HINT to or from the specified address are
// likely in the near future. The memory system may take some action to speed up the memory
// accesses when they do occur, such as pre-loading the specified address into one or more
// caches as indicated by the innermost cache level target (0=L1, 1=L2, etc) and non-temporal hint
// stream. Any or all prefetch hints may be treated as a NOP. A prefetch hint must not cause a
// synchronous abort due to Alignment or Translation faults and the like. Its only effect on
// software-visible state should be on caches and TLBs associated with address, which must be
// accessible by reads, writes or execution, as defined in the translation regime of the current
// Exception level. It is guaranteed not to access Device memory.
// A Prefetch_EXEC hint must not result in an access that could not be performed by a speculative
// instruction fetch, therefore if all associated MMUs are disabled, then it cannot access any
// memory location that cannot be accessed by instruction fetches.

impdef func Hint_Prefetch(address : bits(64),

Architectural Constraints on UNPREDICTABLE Behaviors

This chapter describes the architectural constraints on UNPREDICTABLE behaviors in the Armv8 and later architectures. It contains the following sections:

- [AArch64 CONSTRAINED UNPREDICTABLE behaviors](#)

H1.1 AArch64 CONSTRAINED UNPREDICTABLE behaviors

It contains the following sections:

- [Overview of the constraints on AArch64 UNPREDICTABLE behaviors.](#)
- [SBZ or SBO fields in A64 instructions.](#)
- [CONSTRAINED UNPREDICTABLE behaviors due to caching of control or data values.](#)
- [CONSTRAINED UNPREDICTABLE behavior due to inadequate context synchronization.](#)
- [Translation table base address alignment.](#)
- [The Performance Monitors Extension.](#)
- [Syndrome register handling for CONSTRAINED UNPREDICTABLE instructions treated as UNDEFINED.](#)
- [Out of range virtual address.](#)
- [Mapping of non-idempotent memory locations using the Normal memory type.](#)
- [Instruction fetches from Device memory.](#)
- [Programming the CSSELR_EL1. {Level, InD, TnD} for a cache level that is not implemented.](#)
- [Crossing a page boundary with different memory types or Shareability attributes.](#)
- [Crossing a peripheral boundary with a Device access.](#)
- [CONSTRAINED UNPREDICTABLE behaviors with Load-Exclusive/Store-Exclusive pairs.](#)
- [CONSTRAINED UNPREDICTABLE behavior for A64 instructions.](#)
- [Out of range values of the Set/Way/Index fields in cache maintenance instructions.](#)
- [Reserved values in System and memory-mapped registers and translation table entries.](#)
- [CONSTRAINED UNPREDICTABLE behavior in Debug state.](#)

H1.1.1 Overview of the constraints on AArch64 UNPREDICTABLE behaviors

The term UNPREDICTABLE describes a number of cases where the architecture has a feature that software must not use. For execution in AArch64 state, the Armv8-A and later architectures specify a narrow range of permitted behaviors. This range is the range of CONSTRAINED UNPREDICTABLE behavior. All implementations that are compliant with the architecture must follow the CONSTRAINED UNPREDICTABLE behavior.

Note

Software designed to be compatible with the Armv8-A and later architectures must not rely on these CONSTRAINED UNPREDICTABLE cases being handled in any way other than those listed under the heading CONSTRAINED UNPREDICTABLE.

H1.1.2 SBZ or SBO fields in A64 instructions

Some A64 instructions have (0) or (1) in the instruction decode to indicate *Should-Be-Zero*, SBZ, or *Should-Be-One*, SBO, as described in [Fixed values in AArch64 instruction and System register descriptions](#). Except for specific cases identified in [CONSTRAINED UNPREDICTABLE behaviors with Load-Exclusive/Store-Exclusive pairs](#), if the instruction bit pattern of an instruction is executed with these fields not having the *should be* values, one of the following must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction operates as if the bit had the *should-be* value.
- Any destination registers of the instruction become UNKNOWN.

H1.1.3 CONSTRAINED UNPREDICTABLE behaviors due to caching of control or data values

The Arm architecture allows copies of control values or data values to be cached in a cache or TLB. This can lead to UNPREDICTABLE behavior if the cache or TLB has not been correctly invalidated following a change of the control or data values.

Unless explicitly stated otherwise, the behavior of the PE is consistent with one of:

- The old data or control value.
- The new data or control value.
- An amalgamation of the old and new data or control values.

In an implementation that includes [FEAT_TTCNP](#), this CONSTRAINED UNPREDICTABLE case can arise from misprogramming when setting TTBR.CnP to 1, as identified in the descriptions of the TTBR.CnP field. In this case, for a particular TTBR, the behavior of the PE is consistent with one of:

- The value of the translation table entry pointed to by that TTBR on one of the PEs within the Inner Shareable domain for which both the value of TTBR.CnP is 1 and the other conditions for sharing translation table entries pointed to by that TTBR are met.
- An amalgamation of the values of the translation table entries pointed to by that TTBR on two or more of the PEs within the Inner Shareable domain for which both the value of TTBR.CnP is 1 and the other conditions for sharing translation table entries pointed to by that TTBR are met.

Note

If the [Effective value](#) of a control or data value that determines the behavior of the PE results from the amalgamation of two or more values, then that [Effective value](#) must not generate a privilege violation. So, for example:

- Where the CONSTRAINED UNPREDICTABLE behavior occurs because inadequate invalidation of the TLB causes multiple hits in the TLB, the failure to invalidate the TLB by software executing at a given Exception level and Security state must not make it possible to access regions of memory with permissions or attributes that could not be accessed at that Exception level and Security state.
 - Where the CONSTRAINED UNPREDICTABLE behavior occurs because of a programming error, on one or more PEs in the Inner Shareable domain, when using a TTBR.CnP value of 1 to share translation table entries, the misprogramming must not make it possible to access regions of memory with permissions or attributes that could not be accessed at the Exception level of that TTBR and the Security state corresponding to the translation table entries being shared.
-

Alternatively to this CONSTRAINED UNPREDICTABLE behavior, an implementation detecting multiple hits in a TLB might generate an exception, reporting the exception using the TLB conflict fault code, see [TLB conflict abort](#).

The choice between the behaviors might, in some implementations, vary for each use of a control or data value.

H1.1.4 CONSTRAINED UNPREDICTABLE behavior due to inadequate context synchronization

The Arm architecture requires that changes to System registers must be synchronized before they take effect. This can lead to UNPREDICTABLE behavior if the synchronization has not been performed.

In these cases, the behavior of the PE is consistent with the unsynchronized control value being either the old value or the new value.

Where multiple control values are updated but not yet synchronized, each control value might independently be the old value or the new value.

In addition, where the unsynchronized control value applies to different areas of functionality, or what an implementation has constructed as different areas of functionality, those areas might independently treat the control value as being either the old value or the new value.

The choice between these behaviors might, in some implementations, vary for each use of a control value.

H1.1.5 Translation table base address alignment

In the translation table base registers [TTBR0_EL1](#), [TTBR1_EL1](#), register bits[48:*x*] hold the translation table base address, where *x* depends on the translation table granule size and the size of the addressed translation table, as described in [Translation granules](#). Register bits[(*x*-1):0], unless redefined for another purpose, correspond to bits[(*x*-1):0] of the translation table base address and therefore are RES0.

Note

- When [FEAT_LPA](#) is implemented and the 64KB granule size is used, register bits[5:2] are redefined to hold bits[51:48] of the translation table base address.
 - When [FEAT_TTCNP](#) is implemented register bit[0] is redefined as the CnP bit.
-

For these registers, if one or more RES0 bits in register bits [(x-1):0] does not have a value of 0, this can result in a misaligned translation table base address. In this case, one of the following behaviors must occur:

- The field that is defined to be RES0 is treated as if all the bits had a value of 0:
 - The value read back might be the value written or it might be zero.
- The calculation of an address for a translation table walk using those registers might be corrupted in those bits that are nonzero.

For more information, see the appropriate TTBR.BADDR field description.

H1.1.6 The Performance Monitors Extension

IGTRGP

The following subsections describe CONSTRAINED UNPREDICTABLE behaviors when accessing the Performance Monitors Extension in AArch64 state:

- [CONSTRAINED UNPREDICTABLE](#) accesses to [PMXEVTYPER_EL0](#) or [PMXEVCNTR_EL0](#).
- [CONSTRAINED UNPREDICTABLE](#) accesses to [PMEVCNTR<n>_EL0](#) and [PMEVTYPER<n>_EL0](#).
- [CONSTRAINED UNPREDICTABLE](#) behavior caused by [MDCR_EL2.HPMN](#).

H1.1.6.1 CONSTRAINED UNPREDICTABLE accesses to [PMXEVTYPER_EL0](#) or [PMXEVCNTR_EL0](#)

RTVKJV

If [PMSELR_EL0.SEL](#) is greater than the number of event counters accessible at the current Exception level, then accesses to [PMXEVTYPER_EL0](#) and [PMXEVCNTR_EL0](#) can cause CONSTRAINED UNPREDICTABLE behavior. This occurs when any of the following is true:

- If [PMSELR_EL0.SEL](#) is not equal to 31, and [PMSELR_EL0.SEL](#) is greater than or equal to [PMCR_EL0.N](#), and the PE is executing in EL2 or EL3.
- If [FEAT_SEL2](#) is disabled or is not implemented, [PMSELR_EL0.SEL](#) is not 31, and [PMSELR_EL0.SEL](#) is greater than or equal to [PMCR_EL0.N](#), and the PE is executing in Secure EL1 or Secure EL0.
- If [PMSELR_EL0.SEL](#) is not 31, and [PMSELR_EL0.SEL](#) is greater than or equal to [MDCR_EL2.HPMN](#), and the PE is executing in EL0 or EL1.

In these cases, the PE does one of the following:

- Accesses to [PMXEVTYPER_EL0](#) or [PMXEVCNTR_EL0](#) are UNDEFINED.
- Accesses to [PMXEVTYPER_EL0](#) or [PMXEVCNTR_EL0](#) behave as RAZ/WI.
- Accesses to [PMXEVTYPER_EL0](#) or [PMXEVCNTR_EL0](#) execute as NOPs.
- Accesses to [PMXEVTYPER_EL0](#) or [PMXEVCNTR_EL0](#) behave as if [PMSELR_EL0.SEL](#) contains an UNKNOWN value that is less than the number of counters accessible at the current Exception level and Security state.
- Accesses to [PMXEVTYPER_EL0](#) or [PMXEVCNTR_EL0](#) behave as if [PMSELR_EL0.SEL](#) is 31.
- If EL2 is implemented and enabled in the current Security state, and [PMSELR_EL0.SEL](#) is less than the number of accessible event counters but greater than or equal to the number of accessible counters at this Exception level, access to [PMXEVTYPER_EL0](#) or [PMXEVCNTR_EL0](#) from EL1 or a permitted access from EL0 is trapped to EL2.

RCJXGK

If [PMSELR_EL0.SEL](#) is equal to 31, the PE does one of the following:

- Accesses to [PMXEVCNTR_EL0](#) are UNDEFINED.
- Accesses to [PMXEVCNTR_EL0](#) behave as RAZ/WI.
- Accesses to [PMXEVCNTR_EL0](#) execute as NOPs.
- Accesses to [PMXEVCNTR_EL0](#) behave as if [PMSELR_EL0.SEL](#) contains an unknown value that is less than the number of counters accessible at the current Exception level and Security state.

R_QRHGP

H1.1.6.2 CONSTRAINED UNPREDICTABLE accesses to PMEVCNTR<n>_EL0 and PMEVTPER<n>_EL0

If <n> is greater than the number of event counters available in the current Exception level and state, reads and writes of [PMEVCNTR<n>_EL0](#) and [PMEVTPER<n>_EL0](#) are CONSTRAINED UNPREDICTABLE, and the PE does one of the following:

- Accesses to the register are UNDEFINED.
- Accesses to the register behave as RAZ/WI.
- Accesses to the register execute as a NOP.
- If EL2 is implemented and enabled in the current Security state, for an access to [PMEVCNTR<n>_EL0](#) or [PMEVTPER<n>_EL0](#) from EL1 or a permitted access from EL0, if the counter is implemented but not accessible at the current Exception level, the register access is trapped to EL2.
Accesses from EL0 to [PMEVCNTR<n>_EL0](#) are permitted when EL1 is using AArch64 and the value of [PMUSERENR_EL0](#).{ER, EN} are both 1.
Accesses from EL0 to [PMEVTPER<n>_EL0](#) are permitted when EL1 is using AArch64 and the value of [PMUSERENR_EL0](#).EN is 1.

R_LGBTC

H1.1.6.3 CONSTRAINED UNPREDICTABLE behavior caused by MDCR_EL2.HPMN

If EL2 is implemented, NUM_PMU_COUNTERS is nonzero, and any of the following is true:

- FEAT_HPMN0 is not implemented and [MDCR_EL2.HPMN](#) is 0.
- FEAT_PMUv3_EXTPMN is not implemented and [MDCR_EL2.HPMN](#) is greater than NUM_PMU_COUNTERS.

Then the following CONSTRAINED UNPREDICTABLE behaviors apply:

- The value returned by a direct read of [MDCR_EL2.HPMN](#) is UNKNOWN.
- Either:
 - An UNKNOWN number of counters are reserved for EL2 use. That is, the PE behaves as if [MDCR_EL2.HPMN](#) is an UNKNOWN nonzero value less than or equal to NUM_PMU_COUNTERS.
 - All counters are reserved for EL2 and EL3 use, meaning no counters are accessible from EL1 and EL0.

H1.1.7 Syndrome register handling for CONSTRAINED UNPREDICTABLE instructions treated as UNDEFINED

When a CONSTRAINED UNPREDICTABLE instruction is treated as UNDEFINED, [ESR_ELx](#) is UNKNOWN.

Note

The value written to [ESR_ELx](#) must be consistent with a value that could be created as the result of an exception from the same Exception level that generated the exception, but was the result of a situation that is not CONSTRAINED UNPREDICTABLE at that Exception level. This is to avoid a possible privilege violation.

H1.1.8 Out of range virtual address

If the PE executes a load or store instruction with tagged addressing disabled in the current translation regime, and where the calculated virtual address, total access size, and alignment mean that it accesses the bytes at [0xFFFF_FFFF_FFFF_FFFF](#) and [0x0000_0000_0000_0000](#), then the bytes that appear to be from [0x0000_0000_0000_0000](#) onwards are accessed at an UNKNOWN address. It is permitted for the UNKNOWN address used to be a fixed value such that it always generates an [MMU fault](#).

If the PE executes a load or store instruction with tagged addressing enabled in the current translation regime, and where the calculated address, total access size, and alignment mean that it accesses the bytes at [0xFFFF_FFFF_FFFF_FFFF](#) and [0x0000_0000_0000_0000](#), then the bytes that appear to be from [0x0000_0000_0000_0000](#) onwards are accessed at an UNKNOWN address and the tags associated with address also become UNKNOWN. It is permitted for the UNKNOWN address used to be a fixed value such that it always generates an [MMU fault](#).

Note

Because of Program Counter alignment constraints, it is impossible for a PE to fetch an A64 instruction that includes both the byte at virtual address [0xFFFF_FFFF_FFFF_FFFF](#) and the byte at virtual address [0x0000_0000_0000_0000](#).

H1.1.9 Mapping of non-idempotent memory locations using the Normal memory type

If non-idempotent memory locations are mapped using the Normal memory type, the state of the non-idempotent memory location may become corrupted in following circumstances:

- Speculative read accesses may cause accesses to the non-idempotent memory locations that would not occur as part of a simple sequential execution.
- Writes to non-idempotent memory locations might be merged or split. In this case, the number and size of writes seen by the memory location might not be the number and size that occur as part of a simple sequential execution.

H1.1.10 Instruction fetches from Device memory

Instruction fetches from Device memory are CONSTRAINED UNPREDICTABLE.

If a location in memory has the Device attribute and is not marked as execute-never, then an implementation might perform speculative instruction accesses to this memory location at times when address translation is enabled.

For an instruction fetch from a memory location with the Device attribute that is not marked as execute-never for the current Exception level, an implementation can either:

- Treat the instruction fetch as if it were to a memory location with the Normal, Non-cacheable attribute.
- Take a Permission fault.

H1.1.11 Programming the CSSELR_EL1.{Level, InD, TnD} for a cache level that is not implemented

If the CSSELR_EL1.{Level, InD, TnD} is programmed to a cache level that is not implemented, then a read of CSSELR_EL1 returns an UNKNOWN value in CSSELR_EL1.{Level, InD, TnD}.

If CSSELR_EL1.{Level, InD, TnD} is programmed to a cache level that is not implemented, then on a read of CCSIDR_EL1 an implementation must perform one of the following behaviors:

- The CCSIDR_EL1 read is treated as a NOP.
- The CCSIDR_EL1 read is UNDEFINED.
- The CCSIDR_EL1 read returns an UNKNOWN value.

When FEAT_CCIDX is implemented, CCSIDR2_EL1 is implemented. If CSSELR_EL1.{Level, InD, TnD} is programmed to a cache level that is not implemented, then on a read of CCSIDR2_EL1 an implementation must perform one of the following behaviors:

- The CCSIDR2_EL1 read is treated as a NOP.
- The CCSIDR2_EL1 read is UNDEFINED.
- The CCSIDR2_EL1 read returns an UNKNOWN value.

H1.1.12 Crossing a page boundary with different memory types or Shareability attributes

If a single load or store instruction generates multiple memory accesses, such that the total set of accesses crosses a page boundary to a memory location that has a different memory type, Normal or Device, or Shareability attribute results in CONSTRAINED UNPREDICTABLE behavior. In this case, the implementation must perform one of the following behaviors:

- Each memory access generated by the instruction uses the memory type and Shareability attribute associated with its own address.
- The instruction generates an Alignment fault caused by the memory type.
For the EL1&0 translation regime, if the stage 1 translation generated the mismatch, the resulting exception is taken to EL1.
- The instruction executes as a NOP.

H1.1.13 Crossing a peripheral boundary with a Device access

Performing memory accesses from one load or store instruction to Device memory that crosses a boundary corresponding to the smallest translation granule size of the implementation causes CONSTRAINED UNPREDICTABLE behavior. In this case, the implementation performs one of the following behaviors:

- All memory accesses generated by the instruction are performed as if the boundary has no effect on the memory accesses.
- All memory accesses generated by the instruction are performed as if the boundary has no effect on the memory accesses except that there is no guarantee of ordering between memory accesses.
- The instruction generates an Alignment fault caused by the memory type.
For the EL1&0 translation regime, if the stage 1 translation generated the mismatch, the resulting exception is taken to EL1.
- The instruction executes as a NOP.

Note

The boundary referred to is between two Device memory regions that are both:

- Of the size of the smallest implemented translation granule.
 - Aligned to the size of the smallest implemented translation granule.
-

H1.1.14 CONSTRAINED UNPREDICTABLE behaviors with SVE memory accesses

The CONSTRAINED UNPREDICTABLE behaviors that are associated with memory accesses due to loads and stores also apply to SVE vector load and store instructions. The CONSTRAINED UNPREDICTABLE behaviors are described in [Crossing a page boundary with different memory types or Shareability attributes](#) and [Crossing a peripheral boundary with a Device access](#).

The CONSTRAINED UNPREDICTABLE behaviors apply to the following SVE memory accesses:

- When an SVE unpredicated contiguous load or store instruction accesses an address range that crosses a boundary between memory types, Shareability attributes, or peripherals.
- When an SVE predicated contiguous load or store instruction performs memory accesses that are associated with Active elements on both sides of a boundary between different memory types, Shareability attributes, or peripherals.
- When an SVE predicated non-contiguous load or store instruction performs a memory access that is associated with an Active element that crosses a boundary between memory types, Shareability attributes, or peripherals.

Memory addresses that are associated with *Inactive elements* cannot trigger CONSTRAINED UNPREDICTABLE behaviors.

If SVE vector loads and stores trigger a CONSTRAINED UNPREDICTABLE behavior that then generates an alignment fault, the fault is handled in the same as any other synchronous memory fault caused by an SVE load or store instruction.

H1.1.15 CONSTRAINED UNPREDICTABLE behaviors with Load-Exclusive/Store-Exclusive pairs

[Load-Exclusive and Store-Exclusive instruction usage restrictions](#) defines a Load-Exclusive/Store-Exclusive pair, and identifies various CONSTRAINED UNPREDICTABLE behaviors associated with using Load-Exclusive/Store-Exclusive pairs. In summary, these cases are:

- The target virtual address of a `StoreExcl` instruction is different from the virtual address of the preceding `LoadExcl` instruction in the same thread of execution.
- The transaction size of a `StoreExcl` instruction is different from the transaction size of the preceding `LoadExcl` instruction in the same thread of execution.
- The `StoreExcl` instruction accesses a different number of registers than the preceding `LoadExcl` instruction in the same thread of execution.
- The memory attributes for a `StoreExcl` instruction are different from the memory attributes for the preceding `LoadExcl` instruction in the same thread of execution, either:

- Because the translation of the accessed address changes between the `LoadExcl` instruction and the `StoreExcl` instruction.
- Because the `LoadExcl` instruction and the `StoreExcl` instruction use different virtual addresses, with different attributes, that point to the same physical address.

In addition, the effect of a data or unified cache invalidate, clean, or clean and invalidate instruction on a local or global Exclusives monitor that is in the Exclusive Access state is CONSTRAINED UNPREDICTABLE.

See the descriptions in [Load-Exclusive and Store-Exclusive instruction usage restrictions](#) for the permitted behavior in each of these cases, and any constraints that might apply to whether the case is CONSTRAINED UNPREDICTABLE.

H1.1.16 CONSTRAINED UNPREDICTABLE behavior for A64 instructions

This section lists the CONSTRAINED UNPREDICTABLE behavior for the different A64 instructions listed in [A64 Base Instruction Descriptions](#) and [A64 Advanced SIMD and Floating-point Instruction Descriptions](#).

H1.1.16.1 Memory Copy and Memory Set CPY*

For a list of these instructions, see Memory Copy and Memory Set instructions.

H1.1.16.1.1 CONSTRAINED UNPREDICTABLE behavior

If `s == n || s == d || n == d || d == 31 || s == 31 || n == 31`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- For execution at EL0 or EL1, when EL2 is implemented and enabled for the current Security state and `HCR_EL2.TIDCP` is 1, the instruction is trapped to EL2 with EC syndrome value `0x0`. When `FEAT_TIDCP1` is implemented, for execution at EL0, this also applies when `SCTLR_EL1.TIDCP` or `SCTLR_EL2.TIDCP` is 1.

H1.1.16.2 LD64B

For a description of this instruction and encoding, see LD64B.

H1.1.16.2.1 CONSTRAINED UNPREDICTABLE behavior

If a memory location does not support this instruction, then one of the following behaviors must occur:

- A stage 1 Data Abort, reported using the DFSC code of `110101`, is generated.
- The instruction performs the memory accesses, but the accesses are not single-copy atomic above the byte level.

H1.1.16.3 LDAXP

For a description of this instruction and the encoding, see LDAXP.

H1.1.16.3.1 CONSTRAINED UNPREDICTABLE behavior

If `t == t2`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs a load using the specified addressing mode, and the transfer register is set to an UNKNOWN value.

H1.1.16.4 LDNP

For a description of this instruction and the encoding, see LDNP.

H1.1.16.4.1 CONSTRAINED UNPREDICTABLE behavior

If $t == t2$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs a load using the specified addressing mode, and the transfer register is set to an UNKNOWN value.

H1.1.16.5 LDNP (SIMD&FP)

For a description of this instruction and the encoding, see [LDNP \(SIMD&FP\)](#).

H1.1.16.5.1 CONSTRAINED UNPREDICTABLE behavior

If $t == t2$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs a load using the specified addressing mode, and the transfer register is set to an UNKNOWN value.

H1.1.16.6 LDP and LDIAPP

For a description of these instructions and the encoding, see [LDP](#) and [LDIAPP](#).

H1.1.16.6.1 CONSTRAINED UNPREDICTABLE behavior

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and $(t == n \mid t2 == n) \& n \neq 31$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs a load using the specified addressing mode, and the base register is set to an UNKNOWN value. In addition, if an exception occurs during such an instruction, the base register might be corrupted so that the instruction cannot be repeated.

If $t == t2$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs all of the loads using the specified addressing mode, and the transfer register is set to an UNKNOWN value.

———— Note ————

Pre-indexed addressing and post-indexed addressing imply writeback.

H1.1.16.7 LDP (SIMD&FP)

For a description of this instruction and the encoding, see [LDP \(SIMD&FP\)](#).

H1.1.16.7.1 CONSTRAINED UNPREDICTABLE behavior

If $t == t2$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs a load using the specified addressing mode, and the transfer register is set to an UNKNOWN value.

H1.1.16.8 LDPSW

For a description of this instruction and the encoding, see [LDPSW](#).

H1.1.16.8.1 CONSTRAINED UNPREDICTABLE behavior

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and $(t == n \mid t2 == n) \&\& n != 31$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs a load using the specified addressing mode, and the base register is set to an UNKNOWN value. In addition, if an exception occurs during such an instruction, the base register might be corrupted so that the instruction cannot be repeated.

If $t == t2$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs all of the loads using the specified addressing mode, and the register loaded is set to an UNKNOWN value.

Note

Pre-indexed addressing and post-indexed addressing imply writeback.

H1.1.16.9 LDR (immediate)

For a description of this instruction and the encoding, see [LDR \(immediate\)](#).

H1.1.16.9.1 CONSTRAINED UNPREDICTABLE behavior

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and $n == t \&\& n != 31$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the load using the specified addressing mode, and the base register is set to an UNKNOWN value. In addition, if an exception occurs during such an instruction, the base register might be corrupted so that the instruction cannot be repeated.

Note

Pre-indexed addressing and post-indexed addressing imply writeback.

H1.1.16.10 LDRB (immediate)

For a description of this instruction and the encoding, see [LDRB \(immediate\)](#).

H1.1.16.10.1 CONSTRAINED UNPREDICTABLE behavior

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and $n == t \&\& n != 31$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the load using the specified addressing mode, and the base register is set to an UNKNOWN value. In addition, if an exception occurs during such an instruction, the base register might be corrupted so that the instruction cannot be repeated.

Note

Pre-indexed addressing and post-indexed addressing imply writeback.

H1.1.16.11 LDRH (immediate)

For a description of this instruction and the encoding, see [LDRH \(immediate\)](#).

H1.1.16.11.1 CONSTRAINED UNPREDICTABLE behavior

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and $n == t \ \&\& \ n != 31$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the load using the specified addressing mode, and the base register is set to an UNKNOWN value. In addition, if an exception occurs during such an instruction, the base register might be corrupted so that the instruction cannot be repeated.

Note

Pre-indexed addressing and post-indexed addressing imply writeback.

H1.1.16.12 LDRSB (immediate)

For a description of this instruction and the encoding, see [LDRSB \(immediate\)](#).

H1.1.16.12.1 CONSTRAINED UNPREDICTABLE behavior

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and $n == t \ \&\& \ n != 31$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the load using the specified addressing mode, and the base register is set to an UNKNOWN value. In addition, if an exception occurs during such an instruction, the base register might be corrupted so that the instruction cannot be repeated.

Note

Pre-indexed addressing and post-indexed addressing imply writeback.

H1.1.16.13 LDRSH (immediate)

For a description of this instruction and the encoding, see [LDRSH \(immediate\)](#).

H1.1.16.13.1 CONSTRAINED UNPREDICTABLE behavior

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and $n == t \ \&\& \ n != 31$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the load using the specified addressing mode, and the base register is set to an UNKNOWN value. In addition, if an exception occurs during such an instruction, the base register might be corrupted so that the instruction cannot be repeated.

Note

Pre-indexed addressing and post-indexed addressing imply writeback.

H1.1.16.14 LDRSW (immediate)

For a description of this instruction and the encoding, see [LDRSW \(immediate\)](#).

H1.1.16.14.1 CONSTRAINED UNPREDICTABLE behavior

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and $n == t \ \&\& \ n \neq 31$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the load using the specified addressing mode, and the base register is set to an UNKNOWN value. In addition, if an exception occurs during such an instruction, the base register might be corrupted so that the instruction cannot be repeated.

Note

Pre-indexed addressing and post-indexed addressing imply writeback.

H1.1.16.15 LDXP

For a description of this instruction and the encoding, see [LDXP](#).

H1.1.16.15.1 CONSTRAINED UNPREDICTABLE behavior

If $t == t2$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs a load using the specified addressing mode, and the transfer register is set to an UNKNOWN value.

H1.1.16.16 ST64B

For a description of this instruction and encoding, see ST64B.

H1.1.16.16.1 CONSTRAINED UNPREDICTABLE behavior

If a memory location does not support this instruction, then one of the following behaviors must occur:

- A stage 1 Data Abort, reported using the DFSC code of 110101, is generated.
- The instruction performs the memory accesses, but the accesses are not single-copy atomic above the byte level.

H1.1.16.17 STP and STILP

For a description of these instructions and the encoding, see [STP](#) and STILP.

H1.1.16.17.1 CONSTRAINED UNPREDICTABLE behavior

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and $(t == n \ || \ t2 == n) \ \&\& \ n \neq 31$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs a store using the specified addressing mode but the value stored is UNKNOWN.

Note

Pre-indexed addressing and post-indexed addressing imply writeback.

H1.1.16.18 STLXP

For a description of this instruction and the encoding, see [STLXP](#).

H1.1.16.18.1 CONSTRAINED UNPREDICTABLE behavior

If $s == t \mid (s == t2)$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the store to the specified address, but the value stored is UNKNOWN.

If $s == n \ \&\& \ n != 31$ then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the store to an UNKNOWN address.

H1.1.16.19 STLXR

For a description of this instruction and the encoding, see [STLXR](#).

H1.1.16.19.1 CONSTRAINED UNPREDICTABLE behavior

If $s == t$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the store to the specified address, but the value stored is UNKNOWN.

If $s == n \ \&\& \ n != 31$ then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the store to an UNKNOWN address.

H1.1.16.20 STLXRB

For a description of this instruction and the encoding, see [STLXRB](#).

H1.1.16.20.1 CONSTRAINED UNPREDICTABLE behavior

If $s == t$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the store to the specified address, but the value stored is UNKNOWN.

If $s == n \ \&\& \ n != 31$ then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the store to an UNKNOWN address.

H1.1.16.21 STLXRH

For a description of this instruction and the encoding, see [STLXRH](#).

H1.1.16.21.1 CONSTRAINED UNPREDICTABLE behavior

If $s == t$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the store to the specified address, but the value stored is UNKNOWN.

If $s == n$ && $n != 31$ then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the store to an UNKNOWN address.

H1.1.16.22 STR (immediate)

For a description of this instruction and the encoding, see [STR \(immediate\)](#).

H1.1.16.22.1 CONSTRAINED UNPREDICTABLE behavior

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and $n == t$ && $n != 31$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs a store using the specified addressing mode but the value stored is UNKNOWN.

———— Note ————

Pre-indexed addressing and post-indexed addressing imply writeback.

H1.1.16.23 STRB (immediate)

For a description of this instruction and the encoding, see [STRB \(immediate\)](#).

H1.1.16.23.1 CONSTRAINED UNPREDICTABLE behavior

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and $n == t$ && $n != 31$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs a store using the specified addressing mode but the value stored is UNKNOWN.

———— Note ————

Pre-indexed addressing and post-indexed addressing imply writeback.

H1.1.16.24 STRH (immediate)

For a description of this instruction and the encoding, see [STRH \(immediate\)](#).

H1.1.16.24.1 CONSTRAINED UNPREDICTABLE behavior

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and $n == t$ && $n != 31$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs a store using the specified addressing mode but the value stored is UNKNOWN.

———— Note ————

Pre-indexed addressing and post-indexed addressing imply writeback.

H1.1.16.25 STXP

For a description of this instruction and the encoding, see [STXP](#).

H1.1.16.25.1 CONSTRAINED UNPREDICTABLE behavior

If $s == t \mid (s == t2)$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the store to the specified address, but the value stored is UNKNOWN.

If $s == n \ \&\& \ n != 31$ then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the store to an UNKNOWN address.

H1.1.16.26 STXR

For a description of this instruction and the encoding, see [STXR](#).

H1.1.16.26.1 CONSTRAINED UNPREDICTABLE behavior

If $s == t$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the store to the specified address, but the value stored is UNKNOWN.

If $s == n \ \&\& \ n != 31$ then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the store to an UNKNOWN address.

H1.1.16.27 STXRB

For a description of this instruction and the encoding, see [STXRB](#).

H1.1.16.27.1 CONSTRAINED UNPREDICTABLE behavior

If $s == t$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the store to the specified address, but the value stored is UNKNOWN.

If $s == n \ \&\& \ n != 31$ then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the store to an UNKNOWN address.

H1.1.16.28 STXRH

For a description of this instruction and the encoding, see [STXRH](#).

H1.1.16.28.1 CONSTRAINED UNPREDICTABLE behavior

If $s == t$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the store to the specified address, but the value stored is UNKNOWN.

If $s == n$ && $n != 31$ then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the store to an UNKNOWN address.

H1.1.17 Out of range values of the Set/Way/Index fields in cache maintenance instructions

In the cache maintenance by set/way instructions [DC C1SW](#), [DC CSW](#), and [DC ISW](#), if any set/way/index argument is larger than the value supported by the implementation, then the behavior is CONSTRAINED UNPREDICTABLE and one of the following occurs:

- The instruction is UNDEFINED.
- The instruction performs cache maintenance on one of:
 - No cache lines.
 - A single arbitrary cache line.
 - Multiple arbitrary cache lines.

H1.1.18 Reserved values in System and memory-mapped registers and translation table entries

Unless otherwise stated in this manual, all unallocated or reserved values of fields, or combinations of fields, with allocated values within AArch64 System registers, memory-mapped registers, and translation table entries behave in one of the following ways:

- The unallocated value or values maps onto any of the allocated values, but otherwise does not cause CONSTRAINED UNPREDICTABLE behavior.
- The unallocated value or values causes effects that could be achieved by a combination of more than one of the allocated values.
- The unallocated value or values causes the field or fields to have no functional effect.

Unless otherwise stated, when a direct write of a System register or memory-mapped register writes an unallocated value to a field, if that value is unallocated in all contexts then a subsequent read of the field returns an UNKNOWN value.

H1.1.19 CONSTRAINED UNPREDICTABLE behavior in Debug state

[Behavior in Debug state](#) of this manual describes the CONSTRAINED UNPREDICTABLE behaviors that are specifically associated with Debug state.

H1.1.20 PMSAv64 CONSTRAINED UNPREDICTABLE behavior

This section lists the CONSTRAINED UNPREDICTABLE behaviors of the MPUs in PMSAv64.

If [HCR_EL2.VM](#) is 1 and [SCTLR_EL2.{M, BR}](#) is {0, 0}, then the behavior is CONSTRAINED UNPREDICTABLE with the following permitted behaviors:

- The stage 2 memory attribute becomes UNKNOWN.
- Raises a stage 2 level 0 translation fault.

Any accesses to an MPU base address register [PRBAR_ELx](#), limit address register [PRLAR_ELx](#), or select register [PSERLR_ELx](#) above the number of implemented regions specified by [MPUIR_ELx](#).REGION is CONSTRAINED UNPREDICTABLE. The CONSTAINED UNPREDICTABLE behavior is one of:

- Reads of base, limit or select registers for an unimplemented region returns an UNKNOWN value.
- Writes to base, limit or select registers for an unimplemented region causes those registers to become UNKNOWN.

Appendix H2

Recommendations for Reporting Memory Attributes on an Interconnect

This appendix describes the Arm recommendations for reporting the memory attributes that are assigned by the PE. It contains the following section:

- [Arm recommendations for reporting memory attributes on an interconnect](#)

H2.1 Arm recommendations for reporting memory attributes on an interconnect

The Arm architecture defines the architectural interface between software and the PE hardware. This means the mechanisms by which different memory type and Cacheability attributes are presented on an interface to an interconnect fabric such as AMBA[®] AXI are, strictly, outside the scope of the architecture. This appendix describes an approach for the interface between a PE implementation and an interconnect fabric that Arm strongly recommends, but these recommendations do not form part of the Arm architecture.

H2.1.1 Effect of microarchitectural choices on memory attributes

Implementations of the Arm architecture permit considerable variability in the presentation of memory attributes on the interconnect fabric, particularly in cases where the PE implementation does not provide optimized support for a memory type. For example, an implementation might treat Write-Through locations as Non-cacheable at some level of cache, because functionally this is consistent with the definition of Write-Through, but for the particular implementation the performance trade-off does not merit the hardware directly providing Write-Through capability. However, in such implementations, the assigned memory attributes are not changed by the microarchitectural choices. The microarchitecture simply implements different ways of handling some memory attributes.

Therefore, Arm strongly recommended that where any or all of the following memory attributes are presented on the interface between a PE and an interconnect fabric, the attributes that are presented are completely consistent with the attributes defined by the translation system:

- The memory type, Normal or Device.
- The Early Write Acknowledgment attribute.
- The ordering requirements.
- The Shareability.
- The Cacheability, including where practicable, the allocation hints.

H2.1.1.1 Effect when memory accesses are forced to be Non-cacheable

Arm also strongly recommends that the effects of forcing accesses to Normal memory to be Non-cacheable, as described in [Enabling and disabling the caching of memory accesses](#) for AArch64, are reflected on the interconnect by the memory type and attributes used for memory transactions generated while the cache is disabled.

Appendix H3

Arm Pseudocode Definition

The *Architecture Specification Language* (ASL) is defined in *Arm[®] Architecture Specification Language Reference* (ARM DDI 0626).

This appendix provides further information about the pseudocode used in this manual. It contains the following sections:

- [About the Arm pseudocode](#)
- [Pseudocode for instruction descriptions](#)

H3.1 About the Arm pseudocode

The Arm pseudocode provides precise descriptions of some areas of the Arm architecture. This includes description of the decoding and operation of all valid instructions. [Pseudocode for instruction descriptions](#) gives general information about this instruction pseudocode, including its limitations.

H3.1.1 General limitations of Arm pseudocode

The pseudocode statements `IMPLEMENTATION_DEFINED`, `SEE`, `UNDEFINED`, and `UNPREDICTABLE` indicate behavior that differs from that indicated by the pseudocode being executed. If one of them is encountered:

- Earlier behavior indicated by the pseudocode is only specified as occurring to the extent required to determine that the statement is executed.
- No subsequent behavior indicated by the pseudocode occurs.

H3.2 Pseudocode for instruction descriptions

Each instruction description includes pseudocode that provides a precise description of what the instruction does, subject to the limitations described in [General limitations of Arm pseudocode](#) and Limitations of the instruction pseudocode.

In the instruction pseudocode, instruction fields are referred to by the names shown in the encoding diagram for the instruction. Instruction encoding diagrams and instruction pseudocode gives more information about the pseudocode provided for each instruction.

Appendix H4

Registers Index

This appendix provides indexes to the register descriptions in this manual. It contains the following sections:

- [Introduction and register disambiguation](#)
- [Alphabetical index of AArch64 registers and System instructions](#)
- [Functional index of AArch64 registers and System instructions](#)
- [Alphabetical index of memory-mapped registers](#)
- [Functional index of memory-mapped registers](#)

H4.1 Introduction and register disambiguation

In some sections of this manual, registers are referred to by a *general name*, where the description applies to more than one context. In an AArch64 only implementation the description applies to multiple Exception levels, and therefore at a particular Exception level the register names need to take the appropriate Exception level suffix, _EL0, _EL1, or _EL2.

The following section disambiguates the general register names:

- [Register name disambiguation by Exception level.](#)

H4.1.1 Register name disambiguation by Exception level

[Table H4-1](#) disambiguates the general names of the AArch64 System registers by Exception level.

Table H4-1 Disambiguation of AArch64 System registers by Exception level

General form	EL0	EL1	EL2

VSTCR_EL2	Virtualization Secure Translation Control Register
VTCCR_EL2	Virtualization Translation Control Register

H4.3 Functional index of AArch64 registers and System instructions

This section is an index of the AArch64 registers and System instructions, divided by functional group. Each of the following sections lists the registers for a functional group:

- [Special-purpose registers.](#)
- [VMSA-specific registers.](#)
- [ID registers.](#)
- [Performance monitors System registers.](#)
- [Debug System registers.](#)
- [RAS registers.](#)
- [Generic timer registers.](#)
- [Cache maintenance System instructions.](#)
- [Address translation System instructions.](#)
- [TLB maintenance System instructions.](#)
- [Prediction restriction System instructions.](#)
- [Base System registers.](#)

H4.3.1 Special-purpose registers

This section is an index to the registers in the Special-purpose registers functional group.

Table H4-3 Special-purpose registers

Register	Description, see
CurrentEL	Current Exception Level
DAIF	Interrupt Mask Bits
DIT	Data Independent Timing
DLR_EL0	Debug Link Register
DSPSR_EL0	Debug Saved Program Status Register
ELR_EL1	Exception Link Register (EL1)
ELR_EL2	Exception Link Register (EL2)
FPCR	Floating-point Control Register
FPSR	Floating-point Status Register
NZCV	Condition Flags
PAN	Privileged Access Never
SP_EL0	Stack Pointer (EL0)
SP_EL1	Stack Pointer (EL1)
SP_EL2	Stack Pointer (EL2)
SPSel	Stack Pointer Select
SPSR_abt	Saved Program Status Register (Abort mode)
SPSR_EL1	Saved Program Status Register (EL1)
SPSR_EL2	Saved Program Status Register (EL2)
SPSR_fiq	Saved Program Status Register (FIQ mode)

Register	Description, see
SPSR_irq	Saved Program Status Register (IRQ mode)
SPSR_und	Saved Program Status Register (Undefined mode)
SSBS	Speculative Store Bypass Safe
UAO	User Access Override

H4.3.2 VMSA-specific registers

This section is an index to the registers in the Virtual memory control registers functional group.

Table H4-4 VMSA-specific registers

Register	Description, see
AMAIR_EL1	Auxiliary Memory Attribute Indirection Register (EL1)
AMAIR_EL2	Auxiliary Memory Attribute Indirection Register (EL2)
CONTEXTIDR_EL1	Context ID Register (EL1)
CONTEXTIDR_EL2	Context ID Register (EL2)
MAIR_EL1	Memory Attribute Indirection Register (EL1)
MAIR_EL2	Memory Attribute Indirection Register (EL2)
TCR_EL1	Translation Control Register (EL1)
TCR_EL2	Translation Control Register (EL2)
TTBR0_EL1	Translation Table Base Register 0 (EL1)
TTBR1_EL1	Translation Table Base Register 1 (EL1)
VTCR_EL2	Virtualization Translation Control Register

H4.3.3 ID registers

This section is an index to the registers in the Identification registers functional group.

Table H4-5 ID registers

Register	Description, see
CCSIDR2_EL1	Current Cache Size ID Register 2
CCSIDR_EL1	Current Cache Size ID Register
CLIDR_EL1	Cache Level ID Register
CSSELR_EL1	Cache Size Selection Register
CTR_EL0	Cache Type Register
DCZID_EL0	Data Cache Zero ID Register

Register	Description, see
ID_AA64AFR0_EL1	AArch64 Auxiliary Feature Register 0
ID_AA64AFR1_EL1	AArch64 Auxiliary Feature Register 1
ID_AA64DFR0_EL1	AArch64 Debug Feature Register 0
ID_AA64DFR1_EL1	AArch64 Debug Feature Register 1
ID_AA64DFR2_EL1	AArch64 Debug Feature Register 2
ID_AA64ISAR0_EL1	AArch64 Instruction Set Attribute Register 0
ID_AA64ISAR1_EL1	AArch64 Instruction Set Attribute Register 1
ID_AA64ISAR2_EL1	AArch64 Instruction Set Attribute Register 2
ID_AA64MMFR0_EL1	AArch64 Memory Model Feature Register 0
ID_AA64MMFR1_EL1	AArch64 Memory Model Feature Register 1
ID_AA64MMFR2_EL1	AArch64 Memory Model Feature Register 2
ID_AA64MMFR3_EL1	AArch64 Memory Model Feature Register 3
ID_AA64MMFR4_EL1	AArch64 Memory Model Feature Register 4
ID_AA64PFR0_EL1	AArch64 Processor Feature Register 0
ID_AA64PFR1_EL1	AArch64 Processor Feature Register 1
ID_AA64PFR2_EL1	AArch64 Processor Feature Register 2
ID_AFR0_EL1	AArch32 Auxiliary Feature Register 0
ID_DFR0_EL1	AArch32 Debug Feature Register 0
ID_DFR1_EL1	AArch32 Debug Feature Register 1
ID_ISAR0_EL1	AArch32 Instruction Set Attribute Register 0
ID_ISAR1_EL1	AArch32 Instruction Set Attribute Register 1
ID_ISAR2_EL1	AArch32 Instruction Set Attribute Register 2
ID_ISAR3_EL1	AArch32 Instruction Set Attribute Register 3
ID_ISAR4_EL1	AArch32 Instruction Set Attribute Register 4
ID_ISAR5_EL1	AArch32 Instruction Set Attribute Register 5
ID_ISAR6_EL1	AArch32 Instruction Set Attribute Register 6
ID_MMFR0_EL1	AArch32 Memory Model Feature Register 0
ID_MMFR1_EL1	AArch32 Memory Model Feature Register 1
ID_MMFR2_EL1	AArch32 Memory Model Feature Register 2
ID_MMFR3_EL1	AArch32 Memory Model Feature Register 3
ID_MMFR4_EL1	AArch32 Memory Model Feature Register 4
ID_MMFR5_EL1	AArch32 Memory Model Feature Register 5
ID_PFR0_EL1	AArch32 Processor Feature Register 0
ID_PFR1_EL1	AArch32 Processor Feature Register 1
ID_PFR2_EL1	AArch32 Processor Feature Register 2
MIDR_EL1	Main ID Register
MPIDR_EL1	Multiprocessor Affinity Register
MVFR0_EL1	AArch32 Media and VFP Feature Register 0
MVFR1_EL1	AArch32 Media and VFP Feature Register 1
MVFR2_EL1	AArch32 Media and VFP Feature Register 2

Register	Description, see
REVIDR_EL1	Revision ID Register
VMPIDR_EL2	Virtualization Multiprocessor ID Register
VPIDR_EL2	Virtualization Processor ID Register

H4.3.4 Performance monitors System registers

This section is an index to the System registers in the Performance Monitors registers functional group.

Table H4-6 Performance monitors registers

Register	Description, see
PMCCFILTR_EL0	Performance Monitors Cycle Count Filter Register
PMCCNTR_EL0	Performance Monitors Cycle Count Register
PMCEID0_EL0	Performance Monitors Common Event Identification Register 0
PMCEID1_EL0	Performance Monitors Common Event Identification Register 1
PMCNTENCLR_EL0	Performance Monitors Count Enable Clear Register
PMCNTENSET_EL0	Performance Monitors Count Enable Set Register
PMCR_EL0	Performance Monitors Control Register
PMINTENCLR_EL1	Performance Monitors Interrupt Enable Clear Register
PMINTENSET_EL1	Performance Monitors Interrupt Enable Set Register
PMMIR_EL1	Performance Monitors Machine Identification Register
PMOVSCLR_EL0	Performance Monitors Overflow Flag Status Clear Register
PMOVSSET_EL0	Performance Monitors Overflow Flag Status Set Register
PMSELR_EL0	Performance Monitors Event Counter Selection Register
PMSWINC_EL0	Performance Monitors Software Increment Register
PMUSERENR_EL0	Performance Monitors User Enable Register
PMXEVCNTR_EL0	Performance Monitors Selected Event Count Register
PMXEVTPER_EL0	Performance Monitors Selected Event Type Register

H4.3.5 Debug System registers

This section is an index to the System registers in the Debug registers functional group.

Table H4-7 Debug registers

Register	Description, see
DBGAUTHSTATUS_EL1	Debug Authentication Status Register
DBGCLAIMCLR_EL1	Debug CLAIM Tag Clear Register
DBGCLAIMSET_EL1	Debug CLAIM Tag Set Register
DBGDTR_EL0	Debug Data Transfer Register, half-duplex
DBGDTRRX_EL0	Debug Data Transfer Register, Receive
DBGDTRTX_EL0	Debug Data Transfer Register, Transmit
DBGPRCR_EL1	Debug Power Control Register
MDCCINT_EL1	Monitor DCC Interrupt Enable Register
MDCCSR_EL0	Monitor DCC Status Register
MDCR_EL2	Monitor Debug Configuration Register (EL2)
MDRAR_EL1	Monitor Debug ROM Address Register
MDSCR_EL1	Monitor Debug System Control Register
OSDLR_EL1	OS Double Lock Register
OSDTRRX_EL1	OS Lock Data Transfer Register, Receive
OSDTRTX_EL1	OS Lock Data Transfer Register, Transmit
OSECCR_EL1	OS Lock Exception Catch Control Register
OSLAR_EL1	OS Lock Access Register
OSLSR_EL1	OS Lock Status Register
TRFCR_EL1	Trace Filter Control Register (EL1)
TRFCR_EL2	Trace Filter Control Register (EL2)

H4.3.6 RAS registers

This section is an index to the registers in the RAS registers functional group.

Table H4-8 RAS registers

Register	Description, see
DISR_EL1	Deferred Interrupt Status Register
ERRIDR_EL1	Error Record ID Register
ERRSELR_EL1	Error Record Select Register
ERXADDR_EL1	Selected Error Record Address Register
ERXCTLR_EL1	Selected Error Record Control Register
ERXFR_EL1	Selected Error Record Feature Register
ERXMISC0_EL1	Selected Error Record Miscellaneous Register 0
ERXMISC1_EL1	Selected Error Record Miscellaneous Register 1

Register	Description, see
ERXMISC2_EL1	Selected Error Record Miscellaneous Register 2
ERXMISC3_EL1	Selected Error Record Miscellaneous Register 3
ERXPFGCDN_EL1	Selected Pseudo-fault Generation Countdown Register
ERXPFGCTL_EL1	Selected Pseudo-fault Generation Control Register
ERXPFGF_EL1	Selected Pseudo-fault Generation Feature Register
ERXSTATUS_EL1	Selected Error Record Primary Status Register
VDISR_EL2	Virtual Deferred Interrupt Status Register (EL2)
VSESR_EL2	Virtual SErrors Exception Syndrome Register (EL2)

H4.3.7 Generic timer registers

This section is an index to the registers in the Generic Timer registers functional group.

Table H4-9 Generic timer registers

Register	Description, see
CNTRQ_EL0	Counter-timer Frequency Register
CNTHCTL_EL2	Counter-timer Hypervisor Control Register
CNTHPS_CTL_EL2	Counter-timer Secure Physical Timer Control Register (EL2)
CNTHPS_CVAL_EL2	Counter-timer Secure Physical Timer CompareValue Register (EL2)
CNTHPS_TVAL_EL2	Counter-timer Secure Physical Timer TimerValue Register (EL2)
CNTKCTL_EL1	Counter-timer Kernel Control Register
CNTP_CTL_EL0	Counter-timer Physical Timer Control Register
CNTP_CVAL_EL0	Counter-timer Physical Timer CompareValue Register
CNTP_TVAL_EL0	Counter-timer Physical Timer TimerValue Register
CNTPCT_EL0	Counter-timer Physical Count Register
CNTV_CTL_EL0	Counter-timer Virtual Timer Control Register
CNTV_CVAL_EL0	Counter-timer Virtual Timer CompareValue Register
CNTV_TVAL_EL0	Counter-timer Virtual Timer TimerValue Register
CNTVCT_EL0	Counter-timer Virtual Count Register
CNTVOFF_EL2	Counter-timer Virtual Offset Register

H4.3.8 Cache maintenance System instructions

This section is an index to the System instructions in the Cache maintenance instructions functional group.

Table H4-10 Cache maintenance system instructions

System instruction	Description, see
DC CISW	Data or unified Cache line Clean and Invalidate by Set-Way
DC CIVAC	Data or unified Cache line Clean and Invalidate by VA to PoC
DC CSW	Data or unified Cache line Clean by Set-Way
DC CVAC	Data or unified Cache line Clean by VA to PoC
DC CVADP	Data or unified Cache line Clean by VA to PoDP
DC CVAP	Data or unified Cache line Clean by VA to PoP
DC CVAU	Data or unified Cache line Clean by VA to PoU
DC ISW	Data or unified Cache line Invalidate by Set-Way
DC IVAC	Data or unified Cache line Invalidate by VA to PoC
DC ZVA	Data Cache Zero by VA
IC IALLU	Instruction Cache Invalidate All to PoU
IC IALLUIS	Instruction Cache Invalidate All to PoU, Inner Shareable
IC IVAU	Instruction Cache line Invalidate by VA to PoU

H4.3.9 Address translation System instructions

This section is an index to the System instructions in the Address translation instructions functional group.

Table H4-11 Address translation system instructions

System instruction	Description, see
AT S12E0R	Address Translate Stages 1 and 2 EL0 Read
AT S12E0W	Address Translate Stages 1 and 2 EL0 Write
AT S12E1R	Address Translate Stages 1 and 2 EL1 Read
AT S12E1W	Address Translate Stages 1 and 2 EL1 Write
AT S1E0R	Address Translate Stage 1 EL0 Read
AT S1E0W	Address Translate Stage 1 EL0 Write
AT S1E1R	Address Translate Stage 1 EL1 Read
AT S1E1RP	Address Translate Stage 1 EL1 Read PAN
AT S1E1W	Address Translate Stage 1 EL1 Write
AT S1E1WP	Address Translate Stage 1 EL1 Write PAN
AT S1E2R	Address Translate Stage 1 EL2 Read
AT S1E2W	Address Translate Stage 1 EL2 Write
AT S1E3R	Address Translate Stage 1 EL3 Read
AT S1E3W	Address Translate Stage 1 EL3 Write

H4.3.10 TLB maintenance System instructions

This section is an index to the System instructions in the TLB maintenance instructions functional group.

Table H4-12 TLB maintenance system instructions

System instruction	Description, see
TLBI ALLE1	TLB Invalidate All, EL1
TLBI ALLE1IS	TLB Invalidate All, EL1, Inner Shareable
TLBI ALLE1OS	TLB Invalidate All, EL1, Outer Shareable
TLBI ALLE2	TLB Invalidate All, EL2
TLBI ALLE2IS	TLB Invalidate All, EL2, Inner Shareable
TLBI ALLE2OS	TLB Invalidate All, EL2, Outer Shareable
TLBI ALLE3	TLB Invalidate All, EL3
TLBI ALLE3IS	TLB Invalidate All, EL3, Inner Shareable
TLBI ALLE3OS	TLB Invalidate All, EL3, Outer Shareable
TLBI ASIDE1	TLB Invalidate by ASID, EL1
TLBI ASIDE1IS	TLB Invalidate by ASID, EL1, Inner Shareable
TLBI ASIDE1OS	TLB Invalidate by ASID, EL1, Outer Shareable
TLBI IPAS2E1	TLB Invalidate by Intermediate Physical Address, Stage 2, EL1
TLBI IPAS2E1IS	TLB Invalidate by Intermediate Physical Address, Stage 2, EL1, Inner Shareable
TLBI IPAS2E1OS	TLB Invalidate by Intermediate Physical Address, Stage 2, EL1, Outer Shareable
TLBI IPAS2LE1	TLB Invalidate by Intermediate Physical Address, Stage 2, Last level, EL1
TLBI IPAS2LE1IS	TLB Invalidate by Intermediate Physical Address, Stage 2, Last level, EL1, Inner Shareable
TLBI IPAS2LE1OS	TLB Invalidate by Intermediate Physical Address, Stage 2, Last level, EL1, Outer Shareable
TLBI RIPAS2E1	TLB Range Invalidate by Intermediate Physical Address, Stage 2, EL1
TLBI RIPAS2E1IS	TLB Range Invalidate by Intermediate Physical Address, Stage 2, EL1, Inner Shareable
TLBI RIPAS2E1OS	TLB Range Invalidate by Intermediate Physical Address, Stage 2, EL1, Outer Shareable
TLBI RIPAS2LE1	TLB Range Invalidate by Intermediate Physical Address, Stage 2, Last level, EL1
TLBI RIPAS2LE1IS	TLB Range Invalidate by Intermediate Physical Address, Stage 2, Last level, EL1, Inner Shareable
TLBI RIPAS2LE1OS	TLB Range Invalidate by Intermediate Physical Address, Stage 2, Last level, EL1, Outer Shareable
TLBI RVAAE1	TLB Range Invalidate by VA, All ASID, EL1
TLBI RVAAE1IS	TLB Range Invalidate by VA, All ASID, EL1, Inner Shareable
TLBI RVAAE1OS	TLB Range Invalidate by VA, All ASID, EL1, Outer Shareable

System instruction	Description, see
TLBI RVAALE1	TLB Range Invalidate by VA, All ASID, Last level, EL1
TLBI RVAALE1IS	TLB Range Invalidate by VA, All ASID, Last Level, EL1, Inner Shareable
TLBI RVAALE1OS	TLB Range Invalidate by VA, All ASID, Last Level, EL1, Outer Shareable
TLBI RVAE1	TLB Range Invalidate by VA, EL1
TLBI RVAE1IS	TLB Range Invalidate by VA, EL1, Inner Shareable
TLBI RVAE1OS	TLB Range Invalidate by VA, EL1, Outer Shareable
TLBI RVAE2	TLB Range Invalidate by VA, EL2
TLBI RVAE2IS	TLB Range Invalidate by VA, EL2, Inner Shareable
TLBI RVAE2OS	TLB Range Invalidate by VA, EL2, Outer Shareable
TLBI RVAE3	TLB Range Invalidate by VA, EL3
TLBI RVAE3IS	TLB Range Invalidate by VA, EL3, Inner Shareable
TLBI RVAE3OS	TLB Range Invalidate by VA, EL3, Outer Shareable
TLBI RVALE1	TLB Range Invalidate by VA, Last level, EL1
TLBI RVALE1IS	TLB Range Invalidate by VA, Last level, EL1, Inner Shareable
TLBI RVALE1OS	TLB Range Invalidate by VA, Last level, EL1, Outer Shareable
TLBI RVALE2	TLB Range Invalidate by VA, Last level, EL2
TLBI RVALE2IS	TLB Range Invalidate by VA, Last level, EL2, Inner Shareable
TLBI RVALE2OS	TLB Range Invalidate by VA, Last level, EL2, Outer Shareable
TLBI RVALE3	TLB Range Invalidate by VA, Last level, EL3
TLBI RVALE3IS	TLB Range Invalidate by VA, Last level, EL3, Inner Shareable
TLBI RVALE3OS	TLB Range Invalidate by VA, Last level, EL3, Outer Shareable
TLBI VAAE1	TLB Invalidate by VA, All ASID, EL1
TLBI VAAE1IS	TLB Invalidate by VA, All ASID, EL1, Inner Shareable
TLBI VAAE1OS	TLB Invalidate by VA, All ASID, EL1, Outer Shareable
TLBI VAALE1	TLB Invalidate by VA, All ASID, Last level, EL1
TLBI VAALE1IS	TLB Invalidate by VA, All ASID, Last Level, EL1, Inner Shareable
TLBI VAALE1OS	TLB Invalidate by VA, All ASID, Last Level, EL1, Outer Shareable
TLBI VAE1	TLB Invalidate by VA, EL1
TLBI VAE1IS	TLB Invalidate by VA, EL1, Inner Shareable
TLBI VAE1OS	TLB Invalidate by VA, EL1, Outer Shareable
TLBI VAE2	TLB Invalidate by VA, EL2
TLBI VAE2IS	TLB Invalidate by VA, EL2, Inner Shareable
TLBI VAE2OS	TLB Invalidate by VA, EL2, Outer Shareable
TLBI VAE3	TLB Invalidate by VA, EL3
TLBI VAE3IS	TLB Invalidate by VA, EL3, Inner Shareable
TLBI VAE3OS	TLB Invalidate by VA, EL3, Outer Shareable
TLBI VALE1	TLB Invalidate by VA, Last level, EL1

System instruction	Description, see
TLBI VALE1IS	TLB Invalidate by VA, Last level, EL1, Inner Shareable
TLBI VALE1OS	TLB Invalidate by VA, Last level, EL1, Outer Shareable
TLBI VALE2	TLB Invalidate by VA, Last level, EL2
TLBI VALE2IS	TLB Invalidate by VA, Last level, EL2, Inner Shareable
TLBI VALE2OS	TLB Invalidate by VA, Last level, EL2, Outer Shareable
TLBI VALE3	TLB Invalidate by VA, Last level, EL3
TLBI VALE3IS	TLB Invalidate by VA, Last level, EL3, Inner Shareable
TLBI VALE3OS	TLB Invalidate by VA, Last level, EL3, Outer Shareable
TLBI VMALLE1	TLB Invalidate by VMID, All at stage 1, EL1
TLBI VMALLE1IS	TLB Invalidate by VMID, All at stage 1, EL1, Inner Shareable
TLBI VMALLE1OS	TLB Invalidate by VMID, All at stage 1, EL1, Outer Shareable
TLBI VMALLS12E1	TLB Invalidate by VMID, All at Stage 1 and 2, EL1
TLBI VMALLS12E1IS	TLB Invalidate by VMID, All at Stage 1 and 2, EL1, Inner Shareable
TLBI VMALLS12E1OS	TLB Invalidate by VMID, All at Stage 1 and 2, EL1, Outer Shareable

H4.3.11 Prediction restriction System instructions

This section is an index to the registers in the Prediction restriction instructions functional group.

Table H4-13 Cache maintenance system instructions

System instruction	Description, see
CFP RCTX	Control Flow Prediction Restriction by Context
CPP RCTX	Cache Prefetch Prediction Restriction by Context
DVP RCTX	Data Value Prediction Restriction by Context

H4.3.12 Base System registers

This section is an index to the System registers in the Base System registers functional group.

Table H4-14 Base System registers

Register	Description, see
CPACR_EL1	Architectural Feature Access Control Register
SCTLR_EL1	System Control Register (EL1)
SCTLR_EL2	System Control Register (EL2)

H4.4 Alphabetical index of memory-mapped registers

This section is an index of memory-mapped registers in alphabetical order.

Table H4-15 Alphabetical index of Memory-Mapped Registers

Register	Description, see
ASICCTL	CTI External Multiplexer Control register
CNTCR	Counter Control Register
CNTCV	Counter Count Value register
CNTEL0ACR	Counter-timer EL0 Access Control Register
CNTFID0	Counter Frequency ID
CNTFRQ	Counter-timer Frequency
CNTID	Counter Identification Register
CNTNSAR	Counter-timer Non-secure Access Register
CNTP_CTL	Counter-timer Physical Timer Control
CNTP_CVAL	Counter-timer Physical Timer CompareValue
CNTP_TVAL	Counter-timer Physical Timer TimerValue
CNTPCT	Counter-timer Physical Count
CNTSCR	Counter Scale Register
CNTSR	Counter Status Register
CNTTIDR	Counter-timer Timer ID Register
CNTV_CTL	Counter-timer Virtual Timer Control
CNTV_CVAL	Counter-timer Virtual Timer CompareValue
CNTV_TVAL	Counter-timer Virtual Timer TimerValue
CNTVCT	Counter-timer Virtual Count
CNTVOFF	Counter-timer Virtual Offset
CTIAPPCLEAR	CTI Application Trigger Clear register
CTIAPPPULSE	CTI Application Pulse register
CTIAPPSET	CTI Application Trigger Set register
CTIAUTHSTATUS	CTI Authentication Status register
CTICHINSTATUS	CTI Channel In Status register
CTICHOUTSTATUS	CTI Channel Out Status register
CTICIDR0	CTI Component Identification Register 0
CTICIDR1	CTI Component Identification Register 1
CTICIDR2	CTI Component Identification Register 2
CTICIDR3	CTI Component Identification Register 3
CTICLAIMCLR	CTI CLAIM Tag Clear register
CTICLAIMSET	CTI CLAIM Tag Set register
CTICONTROL	CTI Control register
CTIDEVAFF0	CTI Device Affinity register 0

Register	Description, see
CTIDEVAFF1	CTI Device Affinity register 1
CTIDEVARCH	CTI Device Architecture register
CTIDEVCTL	CTI Device Control register
CTIDEVID	CTI Device ID register 0
CTIDEVID1	CTI Device ID register 1
CTIDEVID2	CTI Device ID register 2
CTIDEVTYPE	CTI Device Type register
CTIGATE	CTI Channel Gate Enable register
CTIINTACK	CTI Output Trigger Acknowledge register
CTIITCTRL	CTI Integration mode Control register
CTILAR	CTI Lock Access Register
CTILSR	CTI Lock Status Register
CTIPIDR0	CTI Peripheral Identification Register 0
CTIPIDR1	CTI Peripheral Identification Register 1
CTIPIDR2	CTI Peripheral Identification Register 2
CTIPIDR3	CTI Peripheral Identification Register 3
CTIPIDR4	CTI Peripheral Identification Register 4
CTIPIDR5	CTI Peripheral Identification Register 5

H4.5 Functional index of memory-mapped registers

This section is an index of the memory-mapped registers, divided by functional group. Each of the following sections lists the registers for a functional group:

- [ID registers.](#)
- [Memory-mapped Performance monitors registers.](#)
- Generic timer registers.
- [Debug registers.](#)
- [Cross-trigger interface registers.](#)

H4.5.1 ID registers

This section is an index to the registers in the Identification registers functional group.

Table H4-16 ID registers

Register	Description, see
EDAA32PFR	External Debug Auxiliary Processor Feature Register
EDDFR	External Debug Feature Register
EDPFR	External Debug Processor Feature Register
MIDR_EL1	Main ID Register

H4.5.2 Memory-mapped Performance monitors registers

This section is an index to the memory-mapped registers in the Performance Monitors registers functional group.

Table H4-17 Performance monitors registers

Register	Description, see
PMAUTHSTATUS	Performance Monitors Authentication Status register
PMCCFILTR_EL0	Performance Monitors Cycle Counter Filter Register
PMCCNTR_EL0	Performance Monitors Cycle Counter
PMCEID0	Performance Monitors Common Event Identification register 0
PMCEID1	Performance Monitors Common Event Identification register 1
PMCEID2	Performance Monitors Common Event Identification register 2
PMCEID3	Performance Monitors Common Event Identification register 3
PMCFGR	Performance Monitors Configuration Register
PMCID1SR	CONTEXTIDR_EL1 Sample Register

Register	Description, see
PMCID2SR	CONTEXTIDR_EL2 Sample Register
PMCIDR0	Performance Monitors Component Identification Register 0
PMCIDR1	Performance Monitors Component Identification Register 1
PMCIDR2	Performance Monitors Component Identification Register 2
PMCIDR3	Performance Monitors Component Identification Register 3

H4.5.4 Cross-trigger interface registers

This section is an index to the registers in the Cross-Trigger Interface registers functional group.

Table H4-19 Cross-trigger interface registers

Register	Description, see
ASICCTL	CTI External Multiplexer Control register
CTIAPPCLEAR	CTI Application Trigger Clear register
CTIAPPPULSE	CTI Application Pulse register
CTIAPPSET	CTI Application Trigger Set register
CTIAUTHSTATUS	CTI Authentication Status register
CTICHINSTATUS	CTI Channel In Status register
CTICHOUTSTATUS	CTI Channel Out Status register
CTICIDR0	CTI Component Identification Register 0
CTICIDR1	CTI Component Identification Register 1
CTICIDR2	CTI Component Identification Register 2
CTICIDR3	CTI Component Identification Register 3
CTICLAIMCLR	CTI CLAIM Tag Clear register
CTICLAIMSET	CTI CLAIM Tag Set register
CTICONTROL	CTI Control register
CTIDEVAFF0	CTI Device Affinity register 0
CTIDEVAFF1	CTI Device Affinity register 1
CTIDEVARCH	CTI Device Architecture register
CTIDEVCTL	CTI Device Control register
CTIDEVID	CTI Device ID register 0
CTIDEVID1	CTI Device ID register 1

Register	Description, see
CTIDEVID2	CTI Device ID register 2
CTIDEVTYPE	CTI Device Type register
CTIGATE	CTI Channel Gate Enable register
CTIINTACK	CTI Output Trigger Acknowledge register
CTIITCTRL	CTI Integration mode Control register
CTILAR	CTI Lock Access Register
CTILSR	CTI Lock Status Register
CTIPIDR0	CTI Peripheral Identification Register 0
CTIPIDR1	CTI Peripheral Identification Register 1
CTIPIDR2	CTI Peripheral Identification Register 2
CTIPIDR3	CTI Peripheral Identification Register 3
CTIPIDR4	CTI Peripheral Identification Register 4
CTIPIDR5	CTI Peripheral Identification Register 5
CTIPIDR6	CTI Peripheral Identification Register 6
CTIPIDR7	CTI Peripheral Identification Register 7
CTITRIGINSTATUS	CTI Trigger In Status register
CTITRIGOUTSTATUS	CTI Trigger Out Status register

Glossary

- A64 instruction** A word that specifies an operation to be performed by a PE that is executing in an Exception level that is using AArch64. A64 instructions must be word-aligned.
- AArch32** The 32-bit Execution state. AArch32 state and the associated instruction sets, T32 and A32, are not described in this Manual. See *Arm® Architecture Reference Manual for R-profile AArch32 architecture* (ARM DDI 111353).
- AArch64** The 64-bit Execution state. In AArch64 state, addresses are held in 64-bit registers, and instructions in the base instruction set can use 64-bit registers for their processing. AArch64 state supports the A64 instruction set.
- See also [A64 instruction](#).
- Abort** An exception caused by an illegal memory access. Aborts can be caused by the external memory system or the MMU.
- Active element** An Active element is an SVE vector element or predicate element that is a source register element or destination register element used by an SVE instruction. When the corresponding element in the instruction's Governing predicate is TRUE, the element is Active. If an instruction is unpredicated, all of the vector elements or predicate elements are implicitly Active.
- Addressing mode** Means a method for generating the memory address used by a load/store instruction.
- Advanced SIMD** A feature of the Arm architecture that provides SIMD operations on a register file of SIMD and floating-point registers. Where an implementation supports both Advanced SIMD and floating-point instructions, these instructions operate on the same register file.
- Aligned** A data item stored at an address that is exactly divisible by the highest power of 2 that divides exactly into its size in bytes. Aligned halfwords, words and doublewords therefore have addresses that are divisible by 2, 4 and 8 respectively.
- An aligned access is one where the address of the access is aligned to the size of each element of the access.
- AMBA** Advanced Microcontroller Bus Architecture. The AMBA family of protocol specifications is the Arm open standard for on-chip buses. AMBA provides solutions for the interconnection and management of the functional blocks that make up a *System-on-Chip* (SoC). Applications include the development of embedded systems with one or more processors or signal processors and multiple peripherals.
- Analysis of the trace element stream** Refers to the process of:

- Tracing elements that carry information that a trace analyzer requires to enable it to analyze the trace successfully.
- Tracing elements that either directly indicate program execution, or carry information about program execution.

A trace element stream might also contain trace elements that contain timing information. This term is distinct from analysis of program execution.

Architecturally executed An instruction is architecturally executed only if it would be executed in a simple sequential execution of the program. When such an instruction has been executed and retired, it has been *architecturally executed*. Any instruction that, in a simple sequential execution of a program, is treated as a `NOF` because it fails its condition code check, is an architecturally executed instruction.

In a PE that performs speculative execution, an instruction is not architecturally executed if the PE discards the results of a speculative execution.

See also [Condition code check](#), [Simple sequential execution](#).

Architecturally mapped Where this manual describes a register as being *architecturally mapped* to another register, this indicates that, in an implementation that supports both of the registers, the two registers access the same state.

Architecturally resolved The architectural state (S) associated with an operation (O) is architecturally resolved when S is determined to be identical to the architectural state of O that is visible to the programmer through the execution of the program.

Architecturally UNKNOWN An architecturally UNKNOWN value is a value that is not defined by the architecture but must meet the requirements of the definition of [UNKNOWN](#). Implementations can define the value of the field, but are not required to do so.

See also [IMPLEMENTATION DEFINED](#).

Architecturally Allowed Execution An *Architecturally Allowed Execution* must satisfy the [External visibility requirement](#).

Associativity See [Cache associativity](#).

Asynchronous accumulation Faults that are accumulated in a status register, where the update to the register is asynchronous to the instruction that causes the fault.

Atomicity Describes either single-copy atomicity or multi-copy atomicity. [Atomicity in the Arm architecture](#) defines these forms of atomicity for the Arm architecture.

See also [Multi-copy atomicity](#) and [Single-copy atomicity](#).

Might also refer to poison-atomicity. See [Poison atomicity](#).

Availability Readiness for correct service.

Banked register A register that has multiple instances, with the instance that is in use depending on the PE mode, Security state, or other PE state.

Baseboard Management Controller A PE dedicated to system control and monitoring.

Base register A register specified by a load/store instruction that is used as the base value for the address calculation for the instruction. Depending on the instruction and its addressing mode, an offset can be added to or subtracted from the base register value to form the virtual address that is sent to memory.

Base register writeback Describes writing back a modified value to the base register used in an address calculation.

Behaves as if Where this manual indicates that a PE *behaves as if* a certain condition applies, all descriptions of the operation of the PE must be re-evaluated taking account of that condition, together with any other conditions that affect operation.

Big-endian memory Means that, for example:

- A byte or halfword at a word-aligned address is the most significant byte or halfword in the word at that address.

- A byte at a halfword-aligned address is the most significant byte in the halfword at that address.

See also [Endianness](#), [Little-endian memory](#).

Blocking	Describes an operation that does not permit following instructions to be executed before the operation completes. A non-blocking operation can permit following instructions to be executed before the operation completes, and in the event of encountering an exception does not signal an exception to the PE. This enables implementations to retire following instructions while the non-blocking operation is executing, without the need to retain precise PE state.
Branch History Buffer (BHB)	The Branch History Buffer is an internal structure that stores branch instruction information including the history of previously executed branches.
Branch prediction	Is where a PE selects a future execution path to fetch along. For example, after a branch instruction, the PE can choose to speculatively fetch either the instruction following the branch or the instruction at the branch target. See also Prefetching .
Breakpoint	A debug event triggered by the execution of a particular instruction, specified by one or both of the address of the instruction and the state of the PE when the instruction is executed.
Built-in self test (BIST)	A mechanism that permits a machine to test itself.
Burst	A group of transfers that form a single transaction.
BWA	BandWidth Allocation.
BWPBM	BandWidth Portion Bit Map.
Byte	An 8-bit data item.
CE	See Corrected Error .
Cache associativity	The number of locations in a cache set to which an address can be assigned. Each location is identified by its <i>way</i> value.
Cache level	The position of a cache in the cache hierarchy. In the Arm architecture, the lower numbered levels are those closest to the PE. For more information, see Terms used in describing the cache maintenance instructions .
Cache line	The basic unit of storage in a cache. Its size in words is always a power of two, usually 4 or 8 words. A cache line must be aligned to a suitable memory boundary. A <i>memory cache line</i> is a block of memory locations with the same size and alignment as a cache line. Memory cache lines are sometimes loosely called cache lines.
Cache lockdown	Enables critical software and data to be loaded into the cache so that the cache lines containing them are not subsequently reallocated. It alleviates the delays caused by accessing a cache in a worst-case situation. This ensures that all subsequent accesses to the software and data concerned are cache hits and so complete quickly.
Cache miss	A memory access that cannot be processed at high speed because the data it addresses is not in the cache.
Cache sets	Areas of a cache, divided up to simplify and speed up the process of determining whether a cache hit occurs. The number of cache sets is always a power of two.
Cache way	A cache way consists of one cache line from each cache set. The cache ways are indexed from 0 to (Associativity-1). Each cache line in a cache way is chosen to have the same index as the cache way. For example, cache way <i>n</i> consists of the cache line with index <i>n</i> from each cache set.
Coherence order	See Coherent .
Coherent	Data accesses from a set of observers to a byte in memory are coherent if accesses to that byte in memory by the members of that set of observers are consistent with there being a single total order of all writes to that byte in memory by all members of the set of observers. This single total order of all to writes to that memory location is the <i>coherence order</i> for that byte in memory.

Commit window The Commit window defines the range of *P0 elements* that are committed by a *Commit element*. The oldest *P0 element* in the Commit window is the first *P0 element* committed when a *Commit element* occurs. By default, the Commit window starts on the oldest uncommitted *P0 element* and moves forward to the next uncommitted *P0 element*, with each *P0 element* committed by a *Commit element*. The Commit Window Move element moves the start of the Commit window by a number of *P0 elements*, to allow a *Commit element* to commit *P0 elements* that are younger than the oldest uncommitted *P0 elements*, leaving these older *P0 elements* uncommitted.

Completer An agent in a computing system that responds to and completes a memory transaction that was initiated by a Requester.

See also [Requester](#).

Constructive instruction encoding A constructive instruction encoding is an instruction encoding where the destination register is encoded independently of the source registers.

Condition code check The process of determining whether a conditional instruction executes normally or is treated as a *NOP*. For an instruction that includes a condition code field, that field is compared with the condition flags to determine whether the instruction is executed normally.

See also [Condition code field](#), [Condition flags](#), [Conditional execution](#).

Condition code field A 4-bit field in an instruction that specifies the condition under which the instruction executes.

See also [Condition code check](#).

Condition flags The N, Z, C, and V bits of PSTATE, an SPSR, or FPSCR. See the register descriptions for more information.

See also [Condition code check](#), [PSTATE](#).

Conditional execution When a conditional instruction starts executing, if the condition code check returns TRUE, the instruction executes normally. Otherwise, it is treated as a *NOP*.

See also [Condition code check](#).

CONSTRAINED UNPREDICTABLE Where an instruction can result in UNPREDICTABLE behavior, the Armv8 and later architectures specify a narrow range of permitted behaviors. This range is the range of CONSTRAINED UNPREDICTABLE behavior. All implementations that are compliant with the architecture must follow the CONSTRAINED UNPREDICTABLE behavior.

Execution at Non-secure EL1 or EL0 of an instruction that is CONSTRAINED UNPREDICTABLE can be implemented as generating a trap exception that is taken to EL2, provided that at least one instruction that is not UNPREDICTABLE and is not CONSTRAINED UNPREDICTABLE causes a trap exception that is taken to EL2.

In body text, the term CONSTRAINED UNPREDICTABLE is shown in SMALL CAPITALS.

See also [UNPREDICTABLE](#).

Containable error See [Contained error](#).

Contained error An error that is not uncontained or uncontainable.

Context switch The saving and restoring of computational state when switching between different threads or processes. In this manual, the term context switch describes any situation where the context is switched by an operating system and might or might not include changes to the address space.

Context Synchronization event One of:

- Performing an ISB operation. An ISB operation is performed when an *ISB* instruction is executed and does not fail its condition code check.
- Exception entry.
- Return from an exception.
- Exit from Debug state.
- Executing a *DCPS* instruction.
- Executing a *DRPS* instruction.

The effects of a Context synchronization event are:

- All unmasked interrupts that are pending at the time of the Context synchronization event are taken before the first instruction after the Context synchronization event.
- If halting is allowed, all Halting debug events that are pending at the time of the Context synchronization event are taken before the first instruction after the Context synchronization event.
- No instructions appearing in program order after an instruction that causes a Context synchronization event will have performed any part of their functionality until the Context synchronization event has occurred.
- All direct and indirect writes to System registers that are made before the Context synchronization event affect any instruction, including a direct read, that appears in program order after the instruction causing the Context synchronization event.
- All completed changes to the translation tables for entries that, before the change, were not permitted to be cached in a TLB, affect all instruction fetches that appear in program order after the instruction causing the Context synchronization event.
- The following invalidations, if completed before the Context synchronization event will affect all instructions that appear in program order after the Context synchronization event:
 - TLBs.
 - Instruction caches.
- Changes to the Debug external authentication interfaces that are made before the Context synchronization event affect any instruction that appears in program order after the instruction causing the Context synchronization event.
- The effect of the completion of any of the instructions added by [FEAT_SPECRES](#) is synchronized to the current execution context.
- Restrictions on the effects of speculation (as described in [Restrictions on the effects of speculation](#)) are observed.
- Ensuring that the `TSB` instruction is executed in the necessary order with respect to other instructions.
- Profiling operations for all instructions that are executed in program order are synchronized by execution of a `PSB` instruction before the Context synchronization event.
- See also:
 - [Restrictions on the effects of speculation](#).
 - [Trace Synchronization Barrier](#).
 - [Synchronization and debug exceptions](#).
 - [Synchronization in self-hosted trace](#).
 - [Execution, data prediction and prefetching restriction System instructions](#).
 - [Synchronization and Halting debug events](#).
 - [Synchronization of memory-mapped registers](#).
 - [CONSTRAINED UNPREDICTABLE behavior due to inadequate context synchronization](#).

Note

- The architecture requires that instructions that generate Context synchronization events do not appear to be executed speculatively, except that the performance monitor counters are permitted to reveal such speculation.
 - *Context synchronization events* were previously described as *context synchronization operations*.
-

Conventional memory Memory locations from which generic OSs and application runtimes expect to create allocations for general software use.

Core See [Processing element \(PE\)](#).

CoreSight Address Translation Unit A form of System MMU for trace streams.

Corrected error An error that is detected by hardware and that hardware has corrected.

Counter resolution See [Counter resolution](#).

CPBM Cache-Portion Bit Map.

CSU	Cache-Storage Usage.
Data independent timing (DIT)	The time that it takes to execute a piece of code where the time is not a function of the data being operated on. For more information, see About PSTATE.DIT and About the DIT bit.
Debugger	In most of this manual, <i>debugger</i> refers to any agent that is performing debug. However, some chapters or parts of this manual require a more rigorous definition, and define debugger locally. See: • Definition of a debugger in the context of self-hosted debug. • Definition of a debugger in the context of self-hosted debug. • Definition and constraints of a debugger in the context of external debug.
Deferred error	An error that has not been silently propagated but does not require immediate action at the producer. The error might have passed from the producer to a consumer.
Deprecated	Something that is present in the Arm architecture for backward compatibility. Features that are deprecated but are not OPTIONAL are present in current implementations of the Arm architecture, but might not be present, or might be deprecated and OPTIONAL, in future versions of the Arm architecture. Arm strongly recommends software to avoid using deprecated features. Where a feature is deprecated for performance reasons, Arm strongly recommends software to avoid using that feature because of the likelihood of the significant negative impact on performance. See also OPTIONAL.
Destructive instruction encoding	A destructive instruction encoding is an instruction encoding where one of the source registers is also used as the destination register.
Detected error	An error that has been detected and signaled to a consumer.
Detected Uncorrected error	A detected error that has not been corrected and causes failure.
Digital signal processing (DSP)	Algorithms for processing signals that have been sampled and converted to digital form. DSP algorithms often use saturated arithmetic.
Direct branch	Branch instructions whose target is relative to the PC of the branch and the offset is determined solely from the opcode of the executed instruction. See also Indirect branch.
Direct Memory Access (DMA)	An operation that accesses main memory directly, without the PE performing any accesses to the data concerned.
Direct read	A direct read of a System register is a read performed by a System register access instruction in which the contents of the System Register addressed by {op1, Crm, Crn, op2} For more information, see Direct read. See also Direct write, Indirect read, Indirect write.
Direct write	A direct write of a System register is a write performed by a System register access instruction. For more information, see Direct write. See also Direct read, Indirect read, Indirect write.
DMA	See Direct Memory Access (DMA) .
DNM	See Do-Not-Modify (DNM) .
Domain	In the Arm architecture, <i>domain</i> is used in the following contexts. Shareability domain Defines a set of observers for which the Shareability attributes make the data or unified caches transparent for data accesses. Power domain Defines a block of logic with a single, common, power supply.

Memory regions domain

When using the Short-descriptor translation table format, defines a collection of Sections, Large pages and Small pages of memory, that can have their access permissions switched rapidly by writing to the *Domain Access Control Register* (DACR). Arm deprecates any use of memory regions domains.

Do-Not-Modify (DNM) Means the value must not be altered by software. DNM fields read as UNKNOWN values, and must only be written with the value read from the same field on the same PE.

Double-precision value Consists of two consecutive 32-bit words that are interpreted as a basic double-precision floating-point number according to the *IEEE Standard for Floating-point Arithmetic*.

Doubleword A 64-bit data item. Doublewords are normally at least word-aligned in Arm systems.

Doubleword-aligned Means that the address is divisible by 8.

Downstream The direction from Requesters to Completers.

DSB Data Synchronization Barrier.

DSP See [Digital signal processing \(DSP\)](#).

DUE See [Detected Uncorrected error](#).

DUE FIT RATE The FIT rate for failures from a DUE.

ECC See [Error Correction Code \(ECC\)](#).

EDAC See [Error Correction Code \(ECC\)](#).

EDC See [Error Detection Code \(EDC\)](#).

Effective frequency See [Effective frequency](#).

Effective value A register control field, meaning a field in a register that controls some aspect of the behavior, can be described as having an *Effective value*:

- In some cases, the description of a control *a* specifies that when control *a* is active it causes a register control field *b* to be treated as having a fixed value for all purposes other than direct reads, or direct reads and direct writes, of the register containing control field *b*. When control *a* is active that fixed value is described as the *Effective value* of register control field *b*. In other cases, in some contexts a register control field *b* is not implemented or is not accessible, but behavior of the PE is as if control field *b* was implemented and accessible, and had a particular value. In this case, that value is the *Effective value* of register control field *b*.

Note

Where a register control field is introduced in a particular version of the architecture, and is not implemented in an earlier version of the architecture, typically it will have an *Effective value* in that earlier version of the architecture.

- Otherwise, the *Effective value* of a register control field is the value of that field.

Endianness An aspect of the system memory mapping.

See also [Big-endian memory](#) and [Little-endian memory](#).

Error Correction Code (ECC) A code capable of detecting and correcting a number of errors.

Error Detection Code (EDC) A code capable of detecting, but not correcting, errors.

Error propagation Passing an error from a producer to a consumer.

Error record Data recorded about an error, usually by hardware.

Exception Handles an event. For example, an exception could handle an external interrupt or an undefined instruction.

Exception vector A fixed address that contains the address of the first instruction of the corresponding exception handler.

Executing processing element (PEe) The name given to an example PE that executes a specified instruction.

See also [Processing element \(PE\)](#).

Execution stream The stream of instructions that would have been executed by sequential execution of the program.

External abort An abort that is generated by the external memory system.

Fault An event that causes the program to deviate from the intended behavior, for example an invalid translation.

Field Replaceable Unit (FRU) A component or unit in a system that can be replaced without return to base.

First active element The First active element of an SVE vector or predicate register is the lowest numbered element that is an Active element.

Flat address mapping Is where the physical address for every access is equal to its virtual address.

Flush-to-zero mode A processing mode that optimizes the performance of some floating-point algorithms by replacing the denormalized operands and Intermediate results with zeros, without significantly affecting the accuracy of their final results.

FRU See [Field Replaceable Unit \(FRU\)](#).

General-purpose registers The registers that the base instructions use for processing:

- In AArch64 state the general-purpose registers are:
 - W0-W30 when accessed as 32-bit registers.
 - X0-X30 when accessed as 64-bit registers.

Generic Interrupt Controller (GIC) Arm system architecture interrupt controller for IRQ and FIQ interrupt exceptions.

Governing predicate The predicate register that is used to determine the Active elements of a predicated instruction is known as the Governing predicate for that instruction.

GIC See [Generic Interrupt Controller \(GIC\)](#).

Halfword A 16-bit data item. Halfwords are normally halfword-aligned in Arm systems.

Halfword-aligned Means that the address is divisible by 2.

High vectors An alternative location for the exception vectors. The high vector address range is near the top of the address space, rather than at the bottom.

ICN InterConnect Network.

IGNORED Indicates that the architecture guarantees that the bit or field is not interpreted or modified by hardware. In body text, the term IGNORED is shown in SMALL CAPITALS.

Immediate and offset fields Are unsigned unless otherwise stated.

Immediate value A value that is encoded directly in the instruction and used as numeric data when the instruction is executed. Many instructions can be used with an immediate argument.

IMP An abbreviation used in diagrams to indicate that one or more bits have IMPLEMENTATION DEFINED behavior.

IMPLEMENTATION DEFINED Means that the behavior is not architecturally defined, but must be defined and documented by individual implementations.

In body text, the term IMPLEMENTATION DEFINED is shown in SMALL CAPITALS.

IMPLEMENTATION SPECIFIC Means that the behavior is not architecturally defined, and might not be documented by an individual implementation. Used when there are several implementation options available and the option chosen does not affect software compatibility.

In body text, the term IMPLEMENTATION SPECIFIC is shown in SMALL CAPITALS.

Imprecise exception An exception that is not precise.

Index register A register specified in some load and store instructions. The value of this register is used as an offset to be added to or subtracted from the base register value to form the virtual address that is sent to memory. Some instruction forms permit the index register value to be shifted before the addition or subtraction.

Indirect branch Branch instructions that are not direct branches.

See also [Direct branch](#).

Indirect read An Indirect System Register Read is a System Register Read which is not a Direct System Register Read Effect. For example, when an instruction uses a System register value to establish operating conditions, that use of the System register is an indirect read of the System register.

For more information, including additional examples of indirect reads, see [Indirect read](#).

See also [Direct read](#), [Direct write](#), [Indirect write](#).

Indirect write An indirect write of a System register occurs when the contents of a register are updated by some mechanism other than a [Direct write](#) to that register. For example, an indirect write to a register might occur as a side-effect of executing an instruction that does not perform a direct write to the register, or because of some operation performed by an external agent.

For more information, see [Indirect write](#).

See also [Direct read](#), [Direct write](#), [Indirect read](#).

Inline literals These are constant addresses and other data items held in the same area as the software itself. They are automatically generated by compilers, and can also appear in assembler code.

Intermediate physical address (IPA) An implementation of virtualization, the address to which a Guest OS maps a VA. A hypervisor might then map the IPA to a PA. Typically, the Guest OS is unaware of the translation from IPA to PA.

See also [Physical address \(PA\)](#), [Virtual address \(VA\)](#).

Interrupt In a PE context, an asynchronous exception. There are three interrupt exceptions: IRQ, FIQ, and SError. IRQ and FIQ are always precise. In a system architecture context, an asynchronous event sent to a PE or GIC for processing as an interrupt exception.

IPA See [Intermediate physical address \(IPA\)](#).

kvm Kernel-based Virtual Machine, an open-source software package that implements a type-2 hypervisor within Linux.

Latent error An error that is present in a system but not yet detected.

Last active element The Last active element of an SVE vector or predicate register is the highest numbered element that is an Active element.

Level See [Cache level](#).

Level of Coherence (LoC) The last level of cache that must be cleaned or invalidated when cleaning or invalidating to the point of coherency. For more information, see [Terms used in describing the cache maintenance instructions](#).

See also [Cache level](#), [Point of coherency \(PoC\)](#).

Level of Unification, Inner Shareable (LoUIS) The last level of cache that must be cleaned or invalidated when cleaning or invalidating to the point of unification for the Inner Shareable Shareability domain. For more information, see [Terms used in describing the cache maintenance instructions](#).

See also [Cache level](#), [Point of unification \(PoU\)](#).

Level of Unification, uniprocessor (LoUU) For a PE, the last level of cache that must be cleaned or invalidated when cleaning or invalidating to the point of unification for that PE. For more information, see [Terms used in describing the cache maintenance instructions](#).

See also [Cache level](#), [Point of unification \(PoU\)](#).

Line See [Cache line](#).

Little-endian memory Means that, for example:

- A byte or halfword at a word-aligned address is the least significant byte or halfword in the word at that address.
- A byte at a halfword-aligned address is the least significant byte in the halfword at that address.

See also [Big-endian memory](#), [Endianness](#).

Load/store architecture An architecture where data-processing operations only operate on register contents, not directly on memory contents.

LoC See [Level of Coherence \(LoC\)](#).

LoUIS See [Level of Unification, Inner Shareable \(LoUIS\)](#).

LoUU See [Level of Unification, uniprocessor \(LoUU\)](#).

Lockdown See [Cache lockdown](#).

MBWU Memory BandWidth Usage.

Memory barrier See [Memory barriers](#).

Memory coherency The problem of ensuring that when a memory location is read, either by a data read or an instruction fetch, the value actually obtained is always the value that was most recently written to the location. This can be difficult when there are multiple possible physical locations, such as main memory and at least one of a write buffer and one or more levels of cache.

Memory element An item of data in memory that is transferred to or from a vector element by an SVE load or store instruction. Each memory element has an access size and a type. The memory element access size is specified by each load and store instruction independently of the vector element size.

Memory Management Unit (MMU) Provides detailed control of the part of a memory system that provides a single stage of address translation. Most of the control is provided using translation tables that are held in memory, and define the attributes of different regions of the physical memory map.

Memory Protection Unit (MPU) A hardware unit whose registers provide simple control of a limited number of protection regions in memory.

Merging predication When a predicated SVE instruction specifies merging predication, the Inactive elements of the destination register remain unchanged.

Memory system component MSC. A function, unit, or design block in a memory system that can have partitionable resources. MSCs consist of all units that handle load or store requests issued by any MPAM Requester. These can include cache memories, interconnects, memory management units, memory channel controllers, queues, buffers, and rate adapters. An MSC can contain one or more resources that each can have zero or more resource partitioning controls. For example, a PE can contain several caches, each of which might have zero or more resource partitioning controls.

Memory system resource A resource that affects the performance of software's use of the memory system and is either local to an MSC (such as cache-memory capacity) or non-local (such as memory bandwidth, which is present over an entire path, from Requester to Completer, that can pass through multiple MSCs).

MMR Memory-mapped Register.

Microarchitecturally-finished An operation that has finished all of its operational pseudocode, although the results of any memory accesses, including translation table walks and updates, are not yet coherent with other observers.

Microarchitecturally-unfinished An operation that has not completed all of its operational pseudocode.

Miss See [Cache miss](#).

MMU See [Memory Management Unit \(MMU\)](#).

MPU See [Memory Protection Unit \(MPU\)](#).

Multi-copy atomicity The form of atomicity described in [Requirements for multi-copy atomicity](#).

See also [Atomicity](#), [Single-copy atomicity](#).

NaN Not a Number. A floating-point value that can be used when neither a numeric value nor an infinity is appropriate. A NaN can be a *quiet* NaN, that propagate through most floating-point operations, or a *signaling* NaN, that causes an Invalid Operation floating-point exception when used. For more information, see the *IEEE Standard for Floating-point Arithmetic*.

See also [Quiet NaN](#), [Signaling NaN](#).

Natural eviction A natural eviction is an eviction that occurs in the course of the normal operation of the memory system, rather than because of an operation that explicitly causes an eviction from the cache, such as the execution of a cache maintenance instruction. Typically, a natural eviction occurs when the caching algorithm requires data to be cached but the cache does not have room for that data.

Non-fault load SVE provides a Non-fault option for some SVE vector load instructions. This option causes all memory access faults to be suppressed. Instead, the FFR is updated to indicate which of the Active elements were not successfully loaded.

Observer An observer is one of:

- The mechanism inside a PE that generates Implicit Translation Table Descriptor (TTD) Memory Effects.
- The mechanism inside a PE that generates Implicit Instruction Memory Read Effects.
- The mechanism inside a PE that generates Explicit Memory Effects, Tag Memory Effects, Barrier Effects, Instruction Fetch Barrier Effects, TLBI Effects, DC Effects, IC Effects, Fault Effects, or GCS Effects.
- The mechanism inside a PE that generates Memory Effects for SPE.
- The mechanism inside a PE that generates Memory Effects for TRBE.
- The mechanism inside a PE that generates Memory Effects for HDBSS.
- The mechanism inside a PE that generates Memory Effects for HACDBS.
- Any mechanism outside the PE that can generate Memory Effects, for example, a peripheral device, an SMMU, or a GIC.

Obsolete Obsolete indicates something that is no longer supported by Arm. When an architectural feature is described as obsolete, this indicates that the architecture has no support for that feature, although an earlier version of the architecture did support it.

Offset addressing Means that the memory address is formed by adding or subtracting an offset to or from the base register value.

OPTIONAL When applied to a feature of the architecture, OPTIONAL indicates a feature that is not required in an implementation of the Arm architecture:

- If a feature is OPTIONAL and deprecated, this indicates that the feature is being phased out of the architecture. Arm expects such a features to be included in a new implementation only if there is a known backward-compatibility reason for the inclusion of the feature.
A feature that is OPTIONAL and deprecated might not be present in future versions of the architecture.
- A feature that is OPTIONAL but not deprecated is, typically, a feature added to a version of the Arm architecture after the initial release of that version of the architecture. Arm recommends that such features are included in all new implementations of the architecture.

In body text, these meanings of the term OPTIONAL are shown in SMALL CAPITALS.

Note

Do not confuse these Arm-specific uses of **OPTIONAL** with other uses of *optional*, where it has its usual meaning. These include:

- Optional arguments in the syntax of many instructions.
 - Behavior determined by an implementation choice
-

See also [Deprecated](#).

Other-multi-copy atomic This is a Memory Write effect from an observer that, if observed by a different observer, is then observed by all other observers that access the location coherently.

PA See [Physical address \(PA\)](#).

PCIe See [Peripheral Component Interconnect Express \(PCI Express or PCIe\)](#).

PE See [Processing element \(PE\)](#).

Peripheral Component Interconnect Express (PCI Express or PCIe) A high-speed serial computer expansion bus standard maintained and developed by the PCI Special Interest Group.

PEe The executing processing element. See [Executing processing element](#).

PFA See Predictive Failure Analysis (PFA).

Physical address (PA) An address that identifies a location in the physical memory map.

See also [Intermediate physical address \(IPA\)](#), [Virtual address \(VA\)](#).

Point of coherency (PoC) See [Terms used in describing the cache maintenance instructions](#) for the AArch64 state and Terminology for Clean, Invalidate, and Clean and Invalidate instructions for the AArch32 state.

Point of Deep Persistence (PoDP) See [Terms used in describing the cache maintenance instructions](#).

Point of encryption (PoE) See [Terms used in describing the cache maintenance instructions](#).

Point of persistence (PoP) See [Terms used in describing the cache maintenance instructions](#).

Point of physical aliasing (PoPA) See [Terms used in describing the cache maintenance instructions](#).

Point of physical storage (PoPS) See [Terms used in describing the cache maintenance instructions](#).

Point of unification (PoU) See [Terms used in describing the cache maintenance instructions](#) for the AArch64 state and Terminology for Clean, Invalidate, and Clean and Invalidate instructions for the AArch32 state.

Poison atomicity The form of atomicity described in [Clearing Deferred errors from poisoned Locations](#).

See also [Atomicity](#).

Poison granule A region of naturally-aligned memory affected by poison.

See [Error propagation](#) for information on poison.

Post-indexed addressing Means that the memory address is the base register value, but an offset is added to or subtracted from the base register value and the result is written back to the base register.

Precise exception An exception where the exception handler receives the state of the PE and the state of the memory system consistent with the PE having executed all of the instructions up to, but not including, the point in the instruction stream where the exception was taken. The state of the PE and the state of the memory do not include instructions that occurred after this point.

Prefetching Prefetching refers to speculatively fetching instructions or data from the memory system. In particular, instruction prefetching is the process of fetching instructions from memory before the instructions that precede them, in simple sequential execution of the program, have finished executing. Prefetching an instruction does not mean that the instruction has to be executed.

In this manual, references to instruction or data fetching apply also to prefetching, unless the context explicitly indicates otherwise.

Note

The Prefetch Abort exception can be generated on any instruction fetch, and is not limited to speculative instruction fetches.

See also [Simple sequential execution](#).

Prefixed instruction The instruction that immediately follows a MOVPRFX instruction in program order.

Pre-indexed addressing Means that the memory address is formed in the same way as for offset addressing, but the memory address is also written back to the base register.

Processing element (PE) The abstract machine defined in the Arm architecture, as documented in an Arm Architecture Reference Manual. A PE implementation compliant with the Arm architecture must conform with the behaviors described in the corresponding Arm Architecture Reference Manual.

Protection granule A quantum of memory for which an EDC or ECC provides detection or correction. For example, a 72/64 SECDED ECC scheme has a 64-bit protection granule.

Protection region A memory region whose position, size, and other properties are defined by Memory Protection Unit registers.

Protection Unit See [Memory Protection Unit \(MPU\)](#).

Pseudo-instruction UAL assembler syntax that assembles to an instruction encoding that is expected to disassemble to a different assembler syntax, and is described in this manual under that other syntax. For example, `MOV <Rd>, <Rm>, LSL #<n>` is a pseudo-instruction that is expected to disassemble as `LSL <Rd>, <Rm>, #<n>`.

PSTATE An abstraction of process state information. All of the instruction sets provide instructions that operate on elements of PSTATE.

See also [Condition flags](#).

Quadword A 128-bit data item. Quadwords are normally at least word-aligned in Arm systems.

Quadword-aligned Means that the address is divisible by 16.

Quiet NaN A NaN that propagates unchanged through most floating-point operations.

See also [NaN](#), [Signaling NaN](#).

RAO See [Read-As-One \(RAO\)](#).

RAZ See [Read-As-Zero \(RAZ\)](#).

RAO/SBOP In versions of the Arm architecture before Armv8, Read-As-One, Should-Be-One-or-Preserved on writes.

From the introduction of the Armv8 architecture, RES1 replaces this description.

See also [UNK/SBOP](#), [Read-As-One \(RAO\)](#), [RES1](#), [Should-Be-One-or-Preserved \(SBOP\)](#).

RAO/WI Read-As-One, Writes Ignored.

Hardware must implement the field as Read-As-One, and must ignore writes to the field.

Software can rely on the field reading as all 1s, and on writes being ignored.

This description can apply to a single bit that reads as 1, or to a field that reads as all 1s.

See also [Read-As-One \(RAO\)](#).

RAZ/SBZP In versions of the Arm architecture before Armv8, Read-As-Zero, Should-Be-Zero-or-Preserved on writes.

From the introduction of the Armv8 architecture, RES0 replaces this description.

See also [UNK/SBZP](#), [Read-As-Zero \(RAZ\)](#), [RES0](#), [Should-Be-Zero-or-Preserved \(SBZP\)](#).

RAZ/WI	Read-As-Zero, Writes Ignored. Hardware must implement the field as Read-As-Zero, and must ignore writes to the field. Software can rely on the field reading as all 0s, and on writes being ignored. This description can apply to a single bit that reads as 0, or to a field that reads as all 0s. See also Read-As-Zero (RAZ).
Read-allocate cache	A cache in which a cache miss on reading data causes a cache line to be allocated into the cache.
Read-As-One (RAO)	Hardware must implement the field as reading as all 1s. Software: • Can rely on the field reading as all 1s. • Must use a SBOP policy to write to the field. This description can apply to a single bit that reads as 1, or to a field that reads as all 1s. See also RAO/SBOP, RAO/WI, RES1.
Read-As-Zero (RAZ)	Hardware must implement the field as reading as all 0s. Software: • Can rely on the field reading as all 0s • Must use a SBZP policy to write to the field. This description can apply to a single bit that reads as 0, or to a field that reads as all 0s. See also RAZ/SBZP, RAZ/WI, RES0.
Read-to-Clear (RC)	A read of the field clears the field to 0 once the read is complete.
Read, modify, write	In a read, modify, write instruction sequence, a value is read to a general-purpose register, the relevant fields updated in that register, and the new value written back.
Recoverable error	A contained error that must be corrected to allow the correct operation of the system or smaller parts of the system to continue.
Reliability	Continuity of correct service.
Requester	An agent in a computing system that is capable of initiating memory transactions. See also Completer.
RES0	A reserved bit. Used for fields in register descriptions, and for fields in architecturally-defined data structures that are held in memory, for example in translation table descriptors. Within the architecture, there are some cases where a register bit or field: • Is RES0 in some defined architectural context. • Has different defined behavior in a different architectural context. This means the definition of RES0 for fields in read/write registers is: If a bit is RES0 in all contexts For a bit in a read/write register, it is IMPLEMENTATION DEFINED whether: 1. The bit is hardwired to 0. In this case: • Reads of the bit always return 0. • Writes to the bit are ignored. 2. The bit can be written. In this case: • An indirect write to the register sets the bit to 0.

- A read of the bit returns the last value successfully written, by either a direct or an indirect write, to the bit.
If the bit has not been successfully written since reset, then the read of the bit returns the reset value if there is one, or otherwise returns an UNKNOWN value.
- A direct write to the bit must update a storage location associated with the bit.
- The value of the bit must have no effect on the operation of the PE, other than determining the value read back from the bit, unless this Manual explicitly defines additional properties for the bit.

Whether RES0 bits or fields follow behavior 1 or behavior 2 is IMPLEMENTATION DEFINED on a bit-by-bit basis.

If a bit is RES0 only in some contexts

For a bit in a read/write register, when the bit is described as RES0:

- An indirect write to the register sets the bit to 0.
- A read of the bit must return the value last successfully written to the bit, by either a direct or an indirect write, regardless of the use of the register when the bit was written.
If the bit has not been successfully written since reset, then the read of the bit returns the reset value if there is one, or otherwise returns an UNKNOWN value.
- A direct write to the bit must update a storage location associated with the bit.
- While the use of the register is such that the bit is described as RES0, the value of the bit must have no effect on the operation of the PE, other than determining the value read back from that bit, unless this Manual explicitly defines additional properties for the bit.

Considering only contexts that apply to a particular implementation, if there is a context in which a bit is defined as RES0, another context in which the same bit is defined as RES1, and no context in which the bit is defined as a functional bit, then it is IMPLEMENTATION DEFINED whether:

- Writes to the bit are ignored, and reads of the bit return an UNKNOWN value.
- The value of the bit can be written, and a read returns the last value written to the bit.

The RES0 description can apply to bits or fields that are read-only, or are write-only:

- For a read-only bit, RES0 indicates that the bit reads as 0, but software must treat the bit as UNKNOWN.
- For a write-only bit, RES0 indicates that software must treat the bit as SBZ.

A bit that is RES0 in a context is reserved for possible future use in that context. To preserve forward compatibility, software:

- Must not rely on the bit reading as 0.
- Must use an SBZP policy to write to the bit.

The definition of a RES0 field in an architecturally-defined data structure that is held in memory is:

- A read of a RES0 bit returns the value last written.
- The value of a RES0 bit has no effect on the operation of the PE or any other hardware implementing the architecture such as the GIC or the SMMU, other than determining the value read back from that bit, unless this Manual explicitly defines additional properties for the bit.
- For an implicit memory write effect to the field by a PE or for a write to the field by any other hardware implementing the architecture such as the GIC or the SMMU, each bit defined as RES0 is set to 0.

- For a write to the data structure by a PE, or any other hardware implementing the architecture such as the GIC or the SMMU, if the write is specified to only update specific fields, the hardware preserves the value of other RES0 bits in the same data structure. This applies, for example, to Hardware updates to the translation tables.

This RES0 description can apply to a single bit, or to a field for which each bit of the field must be treated as RES0.

In body text, the term RES0 is shown in SMALL CAPITALS.

See also [Read-As-Zero \(RAZ\)](#), [RES0H](#), [RES1](#), [Should-Be-Zero-or-Preserved \(SBZP\)](#), [UNKNOWN](#).

RES0H A reserved bit or field with [SBZP](#). This behavior uses the hardwired to 0 subset of the RES0 definition.

See also [Read-As-Zero \(RAZ\)](#), [RES0](#), [RES1](#), [Should-Be-Zero-or-Preserved \(SBZP\)](#).

RES1 A reserved bit. Used for fields in register descriptions, and for fields in architecturally-defined data structures that are held in memory, for example in translation table descriptors.

Within the architecture, there are some cases where a register bit or field:

- Is RES1 in some defined architectural context.
- Has different defined behavior in a different architectural context.

This means the definition of RES1 for fields in read/write registers is:

If a bit is RES1 in all contexts

For a bit in a read/write register, it is IMPLEMENTATION DEFINED whether:

1. The bit is hardwired to 1. In this case:

- Reads of the bit always return 1.
- Writes to the bit are ignored.

2. The bit can be written. In this case:

- An indirect write to the register sets the bit to 1.
- A read of the bit returns the last value successfully written, by either a direct or an indirect write, to the bit.

If the bit has not been successfully written since reset, then the read of the bit returns the reset value if there is one, or otherwise returns an UNKNOWN value.

- A direct write to the bit must update a storage location associated with the bit.
- The value of the bit must have no effect on the operation of the PE, other than determining the value read back from the bit, unless this Manual explicitly defines additional properties for the bit.

Whether RES1 bits or fields follow behavior 1 or behavior 2 is IMPLEMENTATION DEFINED on a bit-by-bit basis.

If a bit is RES1 only in some contexts

For a bit in a read/write register, when the bit is described as RES1:

- An indirect write to the register sets the bit to 1.
- A read of the bit must return the value last successfully written to the bit, regardless of the use of the register when the bit was written.

Note

As indicated in this list, this value might be written by an indirect write to the register.

If the bit has not been successfully written since reset, then the read of the bit returns the reset value if there is one, or otherwise returns an UNKNOWN value.

- A direct write to the bit must update a storage location associated with the bit.
- While the use of the register is such that the bit is described as RES1, the value of the bit must have no effect on the operation of the PE, other than determining the value read back from that bit, unless this Manual explicitly defines additional properties for the bit.

Considering only contexts that apply to a particular implementation, if there is a context in which a bit is defined as RES0, another context in which the same bit is defined as RES1, and no context in which the bit is defined as a functional bit, then it is IMPLEMENTATION DEFINED whether:

- Writes to the bit are ignored, and reads of the bit return an UNKNOWN value.
- The value of the bit can be written, and a read returns the last value written to the bit.

The RES1 description can apply to bits or fields that are read-only, or are write-only:

- For a read-only bit, RES1 indicates that the bit reads as 1, but software must treat the bit as UNKNOWN.
- For a write-only bit, RES1 indicates that software must treat the bit as SBO.

A bit that is RES1 in a context is reserved for possible future use in that context. To preserve forward compatibility, software:

- Must not rely on the bit reading as 1.
- Must use an SBOP policy to write to the bit.

The definition of a RES1 field in an architecturally-defined data structure that is held in memory is:

- A read of a RES1 bit returns the value last written.
- The value of a RES1 bit has no effect on the operation of the PE or any other hardware implementing the architecture such as the GIC or the SMMU, other than determining the value read back from that bit, unless this Manual explicitly defines additional properties for the bit.
- For an implicit memory write effect to the field by a PE or for a write to the field by any other hardware implementing the architecture such as the GIC or the SMMU, each bit defined as RES1 is set to 1.
- For a write to the data structure by a PE, or any other hardware implementing the architecture such as the GIC or the SMMU, if the write is specified to only update specific fields, the hardware preserves the value of other RES1 bits in the same data structure. This applies, for example, to Hardware updates to the translation tables.

This RES1 description can apply to a single bit, or to a field for which each bit of the field must be treated as RES1.

In body text, the term RES1 is shown in SMALL CAPITALS.

See also [Read-As-One \(RAO\)](#), [RES0](#), [RES0H](#), [Should-Be-One-or-Preserved \(SBOP\)](#), [UNKNOWN](#).

Reserved

Unless otherwise stated:

- Instructions that are reserved or that access reserved registers have UNPREDICTABLE or CONSTRAINED UNPREDICTABLE behavior.
- Bit positions described as reserved are:
 - In an RW or WO register, RES0.
 - In an RO register, UNK.

See also [CONSTRAINED UNPREDICTABLE](#), [RES0](#), [RES0H](#), [RES1](#), [UNDEFINED](#), [UNK](#), [UNPREDICTABLE](#).

Resource partition The collection of MPAM resource control settings associated with a software environment and identified by the combination of a physical PARTID space and a partition number.

RESS

Reserved, Sign extended. A register value is extended by copying the sign bit into all of the reserved bits to the left of the most significant bit of the field. The values of these bits are identical to the most significant bit of the value being extended.

Within the architecture, a register bit or field can be treated:

- As RESS in few defined architectural contexts.
- In a different defined behavior in other architectural contexts.

This means the definition of RESS for fields in read/write registers is:

If a field [Q:P] is RESS in all contexts

For a bit in a read/write register, it is IMPLEMENTATION DEFINED whether:

1. The bit is hardwired as a sign-extension of bit [P-1]. In this case:

- Reads of the bit always return the value of bit [P-1].
- Writes to the bit are ignored.

2. The bit can be written. In this case:

- An indirect write to the register sets the bit to the same value as bit [P-1].
- A read of the bit returns the last value successfully written, by either a direct or an indirect write, to the bit.

If the bit has not been successfully written since reset, then the read of the bit returns the reset value if there is one, or otherwise returns an UNKNOWN value.

- A direct write to the bit must update a storage location associated with the bit.
- The value of the bit must have no effect on the operation of the PE, other than determining the value read back from the bit, unless this Manual explicitly defines additional properties for the bit.

Whether RESS bits or fields follow behavior 1 or behavior 2 is IMPLEMENTATION DEFINED on a bit-by-bit basis.

If a field [Q:P] is RESS only in some contexts

For a bit in a read/write register, when the bit is described as RESS:

- An indirect write to the register sets the bit to the same value as bit [P-1].
- A read of the bit must return the value last successfully written to the bit, regardless of the use of the register when the bit was written.

Note

As indicated in this list, this value might be written by an indirect write to the register.

If the bit has not been successfully written since reset, then the read of the bit returns the reset value if there is one, or otherwise returns an UNKNOWN value.

- A direct write to the bit must update a storage location associated with the bit.
- While the use of the register is such that the bit is described as RESS, the value of the bit must have no effect on the operation of the PE, other than determining the value read back from that bit, unless this Manual explicitly defines additional properties for the bit.

Considering only contexts that apply to a particular implementation, if there is a context in which a bit is defined as RES0, another context in which the same bit is

defined as RES1, and no context in which the bit is defined as a functional bit, then it is IMPLEMENTATION DEFINED whether:

- Writes to the bit are ignored, and reads of the bit return an UNKNOWN value.
- The value of the bit can be written, and a read returns the last value written to the bit.

The RESS description can apply to bits or fields that are read-only, or are write-only:

- For a read-only bit, RESS indicates that the bit reads as the value of bit [P-1], but software must treat the bit as UNKNOWN.
- For a write-only bit, RESS indicates that software must treat the bit as [SBO](#) or [SBZ](#) as necessary.

A bit that is RESS in a context is reserved for possible future use in that context. To preserve forward compatibility, software:

- Must not rely on the bit reading as [P-1].
- Must use a [SBOP](#) or [SBZP](#) policy to write to the bit.

This RESS description can apply to a single bit, or to a field for which each bit of the field must be treated as RESS.

Rewind point A rewind point is a point in the program flow to which execution can return if all subsequent execution is found to have been incorrectly speculatively executed.

RISC Reduced Instruction Set Computer.

Rounding error The value of the rounded result of an arithmetic operation minus the exact result of the operation.

Rounding mode Specifies how the exact result of a floating-point operation is rounded to a value that is representable in the destination format. The rounding modes are defined by the *IEEE Standard for Floating-point Arithmetic*, see [Floating-point standards, and terminology](#).

Saturated arithmetic Integer arithmetic in which a result that would be greater than the largest representable number is set to the largest representable number, and a result that would be less than the smallest representable number is set to the smallest representable number. Signed saturated arithmetic is often used in DSP algorithms. It contrasts with the normal signed integer arithmetic used in Arm processors, in which overflowing results wrap around from $+2^{31}-1$ to -2^{31} or vice versa.

SBO See [Should-Be-One \(SBO\)](#).

SBOP See [Should-Be-One-or-Preserved \(SBOP\)](#).

SBZ See [Should-Be-Zero \(SBZ\)](#).

SBZP See [Should-Be-Zero-or-Preserved \(SBZP\)](#).

Scalar base register A scalar base register refers to an AArch64 general-purpose register, X0-X30, or the current stack pointer, SP.

Scalar index register A scalar index register refers to an AArch64 general-purpose register, X0-X30, or for certain instructions, XZR.

SDC See [Silent Data Corruption \(SDC\)](#).

SDC FIT rate The FIT rate for failures because of SDC.

SDEC Single device error correction EDAC. This can detect and correct multiple clustered errors in a protection granule, such as the types of errors that might be seen if a protection granule is striped across multiple devices and multiple errors come from a single device.

SEDED Single error correct, double error detect EDAC. This can detect a single or double bit error and correct a single bit error in a protection granule.

SED Single error detect EDC. This can detect a single bit error in a protection granule.

Security hole A mechanism by which execution at the current level of privilege can achieve an outcome that cannot be achieved at the current or a lower level of privilege using instructions that are not UNPREDICTABLE and are not CONSTRAINED UNPREDICTABLE. The Arm architecture forbids security holes.

See also [CONSTRAINED UNPREDICTABLE](#), [UNPREDICTABLE](#).

Self-modifying code Code that writes one or more instructions to memory and then executes them. When using self-modifying code, you must use cache maintenance and barrier instructions to ensure synchronization. For more information, see [Caches and memory hierarchy](#).

SError exception An asynchronous exception in the Arm architecture.

Serviceability The ability to undergo modifications and repairs.

Service failure mode A mode entered to reduce the severity of an error.

Set See [Cache sets](#).

Should-Be-One (SBO) Hardware must ignore writes to the field.

Arm strongly recommends that software writes the field as all 1s. If software writes a value that is not all 1s, it must expect an UNPREDICTABLE or CONSTRAINED UNPREDICTABLE result.

This description can apply to a single bit that should be written as 1, or to a field that should be written as all 1s.

See also [CONSTRAINED UNPREDICTABLE](#), [UNPREDICTABLE](#).

Should-Be-One-or-Preserved (SBOP) From the introduction of the Armv8 architecture, the description [Should-Be-One-or-Preserved \(SBOP\)](#) is superseded by [RES1](#).

Hardware must ignore writes to the field.

When writing this field, software must either write all 1s to this field or, if the register is being restored from a previously read state, write the previously read value to this field. If this is not done, then the result is unpredictable.

This description can apply to a single bit that should be written as its preserved value or as 1, or to a field that should be written as its preserved value or as all 1s.

See also [CONSTRAINED UNPREDICTABLE](#), [UNPREDICTABLE](#).

Should-Be-Zero (SBZ) Hardware must ignore writes to the field.

Arm strongly recommends that software writes the field as all 0s. If software writes a value that is not all 0s, it must expect an UNPREDICTABLE or CONSTRAINED UNPREDICTABLE result.

This description can apply to a single bit that should be written as 0, or to a field that should be written as all 0s.

See also [CONSTRAINED UNPREDICTABLE](#), [UNPREDICTABLE](#).

Should-Be-Zero-or-Preserved (SBZP) From the introduction of the Armv8 architecture, the description [Should-Be-Zero-or-Preserved \(SBZP\)](#) is superseded by [RES0](#).

Hardware must ignore writes to the field.

When writing this field, software must either write all 0s to this field or, if the register is being restored from a previously read state, write the previously read value to this field. If this is not done, then the result is unpredictable.

This description can apply to a single bit that should be written as its preserved value or as 0, or to a field that should be written as its preserved value or as all 0s.

See also [CONSTRAINED UNPREDICTABLE](#), [UNPREDICTABLE](#).

Signaling NaN An Invalid Operation floating-point exception occurs whenever any floating-point operation receives a signaling NaN as an operand. Signaling NaNs can be used in debugging, to track down some uses of uninitialized variables.

See also [NaN](#), [Quiet NaN](#).

Signed immediate and offset fields Are encoded in two's complement notation unless otherwise stated.

Silent Data Corruption (SDC) An error that is not detected by hardware or software.

SIMD Single-Instruction, Multiple-Data.

Simple sequential execution The behavior of an implementation that fetches, decodes and completely executes each instruction before proceeding to the next instruction. Such an implementation performs no speculative accesses to memory, including to instruction memory. The implementation does not pipeline any phase of execution. In practice, this is the theoretical execution model that the architecture is based on, and Arm does not expect this model to correspond to a realistic implementation of the architecture.

Single-copy atomicity The form of atomicity described in [Properties of single-copy atomic accesses](#).

See also [Atomicity](#), [Multi-copy atomicity](#).

Single-precision value A 32-bit word that is interpreted as a basic single-precision floating-point number according to the *IEEE Standard for Floating-point Arithmetic*.

SMMU System Memory Management Unit.

Spatial locality The observed effect that after a program has accessed a memory location, it is likely to also access nearby memory locations in the near future. Caches with multi-word cache lines exploit this effect to improve performance.

Special-purpose register One of the [Special purpose registers](#) for which all direct and indirect reads and writes to the register appear to occur in program order relative to other instructions, without the need for any explicit synchronization.

Speculative A speculative operation is any of the following:

- An operation performed by the PE before the PE has determined that the operation is required to be performed in a simple sequential execution.
- An operation performed by the PE that is not required to be performed in a simple sequential execution.
- An operation performed by the PE before the PE has architecturally resolved the architectural state of inputs or outputs of the operation.

Examples of speculative operations are:

- Operations that are generated by instructions that appear in the Execution stream after a branch that is not architecturally resolved.
- Operations that are generated by instructions that appear in the Execution stream after an instruction where a synchronous exception condition has not been architecturally resolved.
- Operations that are generated by conditional instructions for which the conditions for the instruction have not been architecturally resolved.
- Operations that are generated by instructions that appear in the Execution stream after the point at which a precise asynchronous exception will be taken.
- Operations generated by instructions for which one or more of the arguments come from a register that has not been architecturally resolved.
- Operations generated by the hardware that are not directly generated by any instructions appearing in the Execution stream.
- A memory effect (M2) that appears in program order after a memory effect (M1) where all of the following apply:
 - M1 is locally-ordered-before M2.
 - M1 has not been architecturally resolved.
- Read accesses generated for a translation table walk for which the granule protection check for the address being accessed has not been architecturally resolved.

See also [Execution stream](#).

SPI Shared Peripheral Interrupt.

Superpriority	An attribute that is used to denote virtual and physical IRQ and FIQ interrupts as non-maskable. IRQ and FIQ interrupts with Superpriority can be taken under certain conditions where usually they would be masked by the PSTATE.{I, F} bits.
System Control Processor	A PE dedicated to system control and monitoring.
Temporal locality	The observed effect that after a program has accesses a memory location, it is likely to access the same memory location again in the near future. Caches exploit this effect to improve performance.
TLB	See Translation Lookaside Buffer (TLB) .
TLB lockdown	A way to prevent specific translation table entries from being evicted from a TLB. This ensures that accesses to the associated regions of virtual memory never cause a translation table walk.
Translation context	The context information used to uniquely identify a cached copy of a translation. See TLB maintenance .
Translation Lookaside Buffer (TLB)	A microarchitectural structure containing the results of translation table walks. They help to reduce the average cost of a memory access.
Translation table	A table held in memory that defines the properties of regions of virtual memory.
Translation table walk	The process of doing a full translation table lookup. It is performed automatically by hardware.
Trap enable bits	In VFPv2, VFPv3U, and VFPv4U, determine whether trapped or untrapped exception handling is selected. If trapped exception handling is selected, the way it is carried out is IMPLEMENTATION DEFINED.
Unaligned	An unaligned access is an access where the address of the access is not aligned to the size of an element of the access.
Unaligned memory accesses	Are memory accesses that are not, or might not be, appropriately halfword-aligned, word-aligned, or doubleword-aligned.
Unallocated	Except where otherwise stated in this manual, an instruction encoding is unallocated if the architecture does not assign a specific function to the entire bit pattern of the instruction, but instead describes it as CONSTRAINED UNPREDICTABLE, UNDEFINED, UNPREDICTABLE, or as an unallocated hint instruction. A bit in a register is unallocated if the architecture does not assign a function to that bit. See also CONSTRAINED UNPREDICTABLE, UNDEFINED, UNPREDICTABLE.
Uncontainable error	See Uncontained error .
Uncontained error	An error that has been, or might have been, silently propagated.
Uncorrected error	An error caused by a fault which was not removed.
UNDEFINED	Indicates cases where an attempt to execute a particular encoding bit pattern generates an exception, that is taken to the current Exception level, or to the default Exception level for taking exceptions if the UNDEFINED encoding was executed at EL0. This applies to: - Any encoding that is not allocated to any instruction. - Any encoding that is defined as never accessible at the current Exception level. - Some cases where an enable, disable, or trap control means an encoding is not accessible at the current Exception level. Note On reset, the default Exception level for taking exceptions from EL0 is EL1. However, an implementation might include controls that can change this, effectively making EL1 inactive. See the description of the Exception model for more information In body text, the term UNDEFINED is shown in SMALL CAPITALS. See also Undefined Instruction exception.

Undetected error See [Latent error](#).

Unified cache Is a cache used for both processing instruction fetches and processing data loads and stores.

Unindexed addressing Means addressing in which the base register value is used directly as the virtual address to send to memory, without adding or subtracting an offset. In most types of load/store instruction, unindexed addressing is performed by using offset addressing with an immediate offset of 0.

UNK An abbreviation indicating that software must treat a field as containing an UNKNOWN value.

Hardware must implement the bit as read as 0, or all 0s for a multi-bit field. Software must not rely on the field reading as zero.

See also [UNKNOWN](#).

UNK/SBOP Hardware must implement the field as Read-As-One, and must ignore writes to the field.

Software must not rely on the field reading as all 1s, and except for writing back to the register it must treat the value as if it is UNKNOWN. Software must use an SBOP policy to write to the field.

This description can apply to a single bit that should be written as its preserved value or as 1, or to a field that should be written as its preserved value or as all 1s.

See also [Read-As-One \(RAO\)](#), [Should-Be-One-or-Preserved \(SBOP\)](#), [UNKNOWN](#).

UNK/SBZP Hardware must implement the bit as Read-As-Zero, and must ignore writes to the field.

Software must not rely on the field reading as all 0s, and except for writing back to the register must treat the value as if it is UNKNOWN. Software must use an SBZP policy to write to the field.

This description can apply to a single bit that should be written as its preserved value or as 0, or to a field that should be written as its preserved value or as all 0s.

See also [Read-As-Zero \(RAZ\)](#), [Should-Be-Zero-or-Preserved \(SBZP\)](#), [UNKNOWN](#).

UNKNOWN An UNKNOWN value does not contain valid data, and can vary from implementation to implementation. An UNKNOWN value must not return information that cannot be accessed at the current or a lower level of privilege using instructions that are not UNPREDICTABLE, are not CONSTRAINED UNPREDICTABLE, and do not return UNKNOWN values.

An UNKNOWN value can vary from moment to moment, and instruction to instruction, unless it has previously been assigned, other than at reset, to one of the following registers:

- Any of the general-purpose registers.
- Any of the Advanced SIMD and floating-point registers.
- Any of the Scalable Vector Extension registers.
- Any of the PSTATE N, Z, C, or V flags.

An UNKNOWN value must not be documented or promoted as having a defined value or effect.

In body text, the term UNKNOWN is shown in SMALL CAPITALS.

See also [CONSTRAINED UNPREDICTABLE](#), [UNDEFINED](#), [UNK](#), [UNPREDICTABLE](#).

UNPREDICTABLE Means the behavior cannot be relied upon. UNPREDICTABLE behavior must not perform any function that cannot be performed at the current or a lower level of privilege using instructions that are not UNPREDICTABLE.

UNPREDICTABLE behavior must not be documented or promoted as having a defined effect.

An instruction that is UNPREDICTABLE can be implemented as UNDEFINED.

Execution at Non-secure EL1 or EL0 of an instruction that is UNPREDICTABLE can be implemented as generating a trap exception that is taken to EL2, provided that at least one instruction that is not UNPREDICTABLE and is not CONSTRAINED UNPREDICTABLE causes a trap exception that is taken to EL2.

In body text, the term UNPREDICTABLE is shown in SMALL CAPITALS.

See also [CONSTRAINED UNPREDICTABLE](#), [UNDEFINED](#).

Unrecoverable error	A contained error that is not recoverable. Continued correct operation is generally not possible. Usually this means correct operation of the system, but it can also be used in other contexts to describe correct operation of a smaller part. Systems might use high-level recovery techniques to work around an unrecoverable yet contained error in a component so that the system recovers from the error.
Upstream	The direction from Completers to Requesters.
VA	See Virtual address (VA) .
VFP	In Armv7, an extension to the Arm architecture, that provides single-precision and double-precision floating-point arithmetic.
Vector	A one-dimensional array of vector elements of the same size and data type.
Vector element	Individual subdivisions of a vector register that can be 8, 16, 32, 64 or 128 bits in size. The vector element size and data type is specified independently by each instruction.
Virtual address (VA)	An address generated by an Arm PE. This means it is an address that might be held in the program counter of the PE. For a PMSA implementation, the virtual address is identical to the physical address. See also Intermediate physical address (IPA) , Physical address (PA) .
VM	Virtual Machine.
VMM	Virtual Machine Monitor. An alias for “hypervisor”.
Virtual PARTID	A PARTID in MPAM that can be used by a virtual machine (VM). Virtual PARTIDs are mapped into physical PARTIDs using the virtual partition mapping entries in the MPAMVPM0 - MPAMVPM7 registers.
Watchpoint	A debug event triggered by an access to memory, specified in terms of the address of the location in memory being accessed.
Way	See Cache way .
WI	Writes Ignored. In a register that software can write to, a WI attribute applied to a bit or field indicates that the bit or field ignores the value written by software and retains the value it had before that write. See also RAO/WI , RAZ/WI , RES0 , RES1 .
Word	A 32-bit data item. Words are normally word-aligned in Arm systems.
Word-aligned	Means that the address is divisible by 4.
Write-allocate cache	A cache in which a cache miss on storing data causes a cache line to be allocated into the cache.
Write-back cache	A cache in which when a cache hit occurs on a write access, the data is only written to the cache. Data in the cache can therefore be more up-to-date than data in the next level of cache or memory. Any such data is written back to the next level of cache or memory when the cache line is cleaned. Another common term for a write-back cache is a <i>copy-back cache</i> .
Write-One-to-Clear (W1C)	Writes of 0 to the bit are ignored. A write of 1 clears the bit to 0.
Write-One-to-Set (W1S)	Writes of 0 to the bit are ignored. A write of 1 sets the bit to 1.
Write-Through cache	A cache in which when a cache hit occurs on a write access, the data is written both to the cache and to the next level of cache or memory.
Write buffer	A block of high-speed memory that optimizes stores to main memory.
