Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are [UNPREDICTABLE](#).

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

### Configurations

This register is always implemented.

### Attributes

32-bit write-only register located at 0xE000EF64.

Secure software can access the Non-secure version of this register via DCCMVAU\_NS located at 0xE002EF64. The location 0xE002EF64 is [RES0](#) to software executing in Non-secure state and the debugger.

This register is not banked between Security states.

## Field descriptions

The DCCMVAU bit assignments are:

### ADDRESS, bits [31:0]

Address. Writing to this field initiates the maintenance operation for the address written.

### D1.2.25 DCCSW, Data Cache Clean line by Set/Way

The DCCSW characteristics are:

## Purpose

Clean data or unified cache line by set/way.

## Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

## Configurations

This register is always implemented.

## Attributes

32-bit write-only register located at 0xE000EF6C.

Secure software can access the Non-secure version of this register via DCCSW\_NS located at 0xE002EF6C.

The location 0xE002EF6C is **RES0** to software executing in Non-secure state and the debugger.

This register is not banked between Security states.

## Field descriptions

The DCCSW bit assignments are:

**SetWay, bits [31:4]**

Cache set/way. Contains two fields: Way, bits [31:32-A], the number of the way to operate on. Set, bits [B-1:L], the number of the set to operate on. Bits [L-1:4] are [RES0](#).  $A = \text{Log}_2(\text{ASSOCIATIVITY})$ ,  $L = \text{Log}_2(\text{LINELEN})$ ,  $B = (L + S)$ ,  $S = \text{Log}_2(\text{NSETS})$ . ASSOCIATIVITY, LINELEN (line length, in bytes), and NSETS (number of sets) have their usual meanings and are the values for the cache level being operated on. The values of A and S are rounded up to the next integer.

**Level, bits [3:1]**

Cache level. Cache level to operate on, minus 1. For example, this field is 0 for operations on L1 cache, or 1 for operations on L2 cache.

**Bit [0]**

Reserved, RES0.

### D1.2.26 DCIDR0, SCS Component Identification Register 0

The DCIDR0 characteristics are:

## Purpose

Provides CoreSight Unique Component Identifier information for the SCS.

## Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

If the Main Extension is not implemented then it is **IMPLEMENTATION DEFINED** whether this register is accessible only to the debugger and **RES0** for software. Otherwise the register is accessible to the debugger and software.

## Configurations

Present only if CoreSight identification is implemented.

This register is **RES0** if CoreSight identification is not implemented.

Present only if Halting debug is implemented.

This register is **RES0** if Halting debug is not implemented.

## Attributes

32-bit read-only register located at 0xE000EFF0.

Secure software can access the Non-secure version of this register via DCIDR0\_NS located at 0xE002EFF0. The location 0xE002EFF0 is **RES0** to software executing in Non-secure state and the debugger.

This register is not banked between Security states.

## Field descriptions

The DCIDR0 bit assignments are:

**Bits [31:8]**

Reserved, RES0.

**PRMBL\_0, bits [7:0]**

CoreSight component identification preamble. See the *Arm® CoreSight™ Architecture Specification*.

This field reads as 0x0D.

## D1.2.27 DCIDR1, SCS Component Identification Register 1

The DCIDR1 characteristics are:

### Purpose

Provides CoreSight Unique Component Identifier information for the SCS.

### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

If the Main Extension is not implemented then it is **IMPLEMENTATION DEFINED** whether this register is accessible only to the debugger and **RES0** for software. Otherwise the register is accessible to the debugger and software.

### Configurations

Present only if CoreSight identification is implemented.

This register is **RES0** if CoreSight identification is not implemented.

Present only if Halting debug is implemented.

This register is **RES0** if Halting debug is not implemented.

### Attributes

32-bit read-only register located at 0xE000EFF4.

Secure software can access the Non-secure version of this register via DCIDR1\_NS located at 0xE002EFF4. The location 0xE002EFF4 is **RES0** to software executing in Non-secure state and the debugger.

This register is not banked between Security states.

## Field descriptions

The DCIDR1 bit assignments are:

### Bits [31:8]

Reserved, **RES0**.

### CLASS, bits [7:4]

CoreSight component class. See the *Arm® CoreSight™ Architecture Specification*.

This field reads as 0x9.

### PRMBL\_1, bits [3:0]

CoreSight component identification preamble. See the *Arm® CoreSight™ Architecture Specification*.

This field reads as 0x0.

### D1.2.28 DCIDR2, SCS Component Identification Register 2

The DCIDR2 characteristics are:

## Purpose

Provides CoreSight Unique Component Identifier information for the SCS.

## Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

If the Main Extension is not implemented then it is **IMPLEMENTATION DEFINED** whether this register is accessible only to the debugger and **RES0** for software. Otherwise the register is accessible to the debugger and software.

## Configurations

Present only if CoreSight identification is implemented.

This register is **RES0** if CoreSight identification is not implemented.

Present only if Halting debug is implemented.

This register is **RES0** if Halting debug is not implemented.

## Attributes

32-bit read-only register located at 0xE000EFF8.

Secure software can access the Non-secure version of this register via DCIDR2\_NS located at 0xE002EFF8. The location 0xE002EFF8 is **RES0** to software executing in Non-secure state and the debugger.

This register is not banked between Security states.

## Field descriptions

The DCIDR2 bit assignments are:

**Bits [31:8]**

Reserved, RES0.

**PRMBL\_2, bits [7:0]**

CoreSight component identification preamble. See the *Arm® CoreSight™ Architecture Specification*.

This field reads as 0x05.

### D1.2.29 DCIDR3, SCS Component Identification Register 3

The DCIDR3 characteristics are:

## Purpose

Provides CoreSight Unique Component Identifier information for the SCS.

## Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

If the Main Extension is not implemented then it is **IMPLEMENTATION DEFINED** whether this register is accessible only to the debugger and **RES0** for software. Otherwise the register is accessible to the debugger and software.

## Configurations

Present only if CoreSight identification is implemented.

This register is **RES0** if CoreSight identification is not implemented.

Present only if Halting debug is implemented.

This register is **RES0** if Halting debug is not implemented.

## Attributes

32-bit read-only register located at 0xE000EFC.

Secure software can access the Non-secure version of this register via DCIDR3\_NS located at 0xE002EFFC. The location 0xE002EFFC is **RES0** to software executing in Non-secure state and the debugger.

This register is not banked between Security states.

## Field descriptions

The DCIDR3 bit assignments are:

**Bits [31:8]**

Reserved, RES0.

**PRMBL\_3, bits [7:0]**

CoreSight component identification preamble. See the *Arm® CoreSight™ Architecture Specification*.

This field reads as 0xB1.

### D1.2.30 DCIMVAC, Data Cache line Invalidate by Address to PoC

The DCIMVAC characteristics are:

#### Purpose

Invalidate data or unified cache line by address to PoC.

#### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

This register is RAZ/WI if accessed via an unprivileged debugger. It is **IMPLEMENTATION DEFINED** whether a DAP error is generated.

#### Configurations

This register is always implemented.

#### Attributes

32-bit write-only register located at 0xE000EF5C.

Secure software can access the Non-secure version of this register via DCIMVAC\_NS located at 0xE002EF5C. The location 0xE002EF5C is **RES0** to software executing in Non-secure state and the debugger.

This register is not banked between Security states.

### Field descriptions

The DCIMVAC bit assignments are:

#### ADDRESS, bits [31:0]

Address. Writing to this field initiates the maintenance operation for the address written.

### D1.2.31 DCISW, Data Cache line Invalidate by Set/Way

The DCISW characteristics are:

## Purpose

Invalidate data or unified cache line by set/way.

## Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

This register is RAZ/WI if accessed via an unprivileged debugger. It is **IMPLEMENTATION DEFINED** whether a DAP error is generated.

## Configurations

This register is always implemented.

## Attributes

32-bit write-only register located at 0xE000EF60.

Secure software can access the Non-secure version of this register via DCISW\_NS located at 0xE002EF60. The location 0xE002EF60 is **RES0** to software executing in Non-secure state and the debugger.

This register is not banked between Security states.

## Field descriptions

The DCISW bit assignments are:

**SetWay, bits [31:4]**

Cache set/way. Contains two fields: Way, bits[31:32-A], the number of the way to operate on. Set, bits[B-1:L], the number of the set to operate on. Bits[L-1:4] are [RES0](#). A =  $\text{Log}_2(\text{ASSOCIATIVITY})$ , L =  $\text{Log}_2(\text{LINELEN})$ , B = (L + S), S =  $\text{Log}_2(\text{NSETS})$ . ASSOCIATIVITY, LINELEN (line length, in bytes), and NSETS (number of sets) have their usual meanings and are the values for the cache level being operated on. The values of A and S are rounded up to the next integer.

**Level, bits [3:1]**

Cache level. Cache level to operate on, minus 1. For example, this field is 0 for operations on L1 cache, or 1 for operations on L2 cache.

## Bit [0]

Reserved, RES0.

## D1.2.32 DCRDR, Debug Core Register Data Register

The DCRDR characteristics are:

### Purpose

With the DCRSR, provides debug access to the general-purpose registers, special-purpose registers, and the Floating-point Extension registers. If the Main Extension is implemented, it can also be used for message passing between an external debugger and a debug agent running on the PE.

### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

If the Main Extension is not implemented then this register is accessible only to the debugger and **UNKNOWN** to software.

### Configurations

Present only if Halting debug is implemented.

This register is **RES0** if Halting debug is not implemented.

### Attributes

32-bit read/write register located at 0xE000EDF8.

Secure software can access the Non-secure version of this register via DCRDR\_NS located at 0xE002EDF8. The location 0xE002EDF8 is **RES0** to software executing in Non-secure state and the debugger.

This register is not banked between Security states.

## Field descriptions

The DCRDR bit assignments are:

### DBGTMP, bits [31:0]

Data temporary buffer. Provides debug access for reading and writing the general-purpose registers, special-purpose registers, and Floating-point Extension registers.

The value of this register is **UNKNOWN** if the PE is in Debug state, the debugger has written to DCRSR since entering Debug state and DHCSR.S\_REGRDY is set to 0. The value of this register is **UNKNOWN** if the Main Extension is not implemented and the PE is in Non-debug state.

This field resets to an **UNKNOWN** value on a Warm reset.

### D1.2.33 DCRSR, Debug Core Register Select Register

The DCRSR characteristics are:

#### Purpose

With the DCRDR, provides debug access to the general-purpose registers, special-purpose registers, and the Floating-point Extension registers. A write to the DCRSR specifies the register to transfer, whether the transfer is a read or write, and starts the transfer.

#### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are [UNPREDICTABLE](#).

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

Writes to this register while the PE is in Non-debug state are ignored.

This register is accessible only to the debugger and [RES0](#) to software.

#### Configurations

Present only if Halting debug is implemented.

This register is [RES0](#) if Halting debug is not implemented.

#### Attributes

32-bit write-only register located at 0xE000EDF4.

This register is not banked between Security states.

### Field descriptions

The DCRSR bit assignments are:

#### Bits [31:17]

Reserved, [RES0](#).

#### REGWnR, bit [16]

Register write/not-read. Specifies the access type for the transfer.

The possible values of this bit are:

0

Read.

1

Write.

#### Bits [15:8]

Reserved, [RES0](#).

#### REGSEL, bits [7:0]

Register selector. Specifies the general-purpose register, special-purpose register, or Floating-point Extension register to transfer.

The possible values of this field are:

**0b00000000-0b00001100**

General-purpose registers R0-R12.

**0b00001101**

Current stack pointer, SP.

**0b00001110**

LR.

**0b00001111**

DebugReturnAddress.

**0b00010000**

XPSR / EAPSR, on a read accesses XPSR, otherwise EAPSR is accessed.

**0b00010001**

Current state main stack pointer, SP\_main.

Accessible only when privileged debug is permitted for the current state.

**0b00010010**

Current state process stack pointer, SP\_process.

**0b00010100**

Current state. The value corresponds to {CONTROL[7:0], FAULTMASK[7:0], BASEPRI[7:0], PRIMASK[7:0]}.

All bits are accessible except when one or more of the following restrictions apply.

If DHCSR.S\_SDE is 0 then the bit corresponding to CONTROL.SFPA is [RES0](#).

When only unprivileged debug is permitted for the current Security state, the bits corresponding to the following fields are [RES0](#):

- All fields corresponding to the Control register except CONTROL.FPCA and CONTROL.SFPA. Access to CONTROL.SFPA depends on DHCSR.S\_SDE as described above.
- FAULTMASK[7:0].
- BASEPRI[7:0].
- PRIMASK[7:0].

If the Main Extension is not implemented FAULTMASK[7:0] and BASEPRI[7:0] are [RES0](#).

**0b00011000**

Non-secure main stack pointer, MSP\_NS.

If the Security Extension is not implemented, this value is reserved.

Accessible only when DHCSR.S\_NSUIDE == 0.

**0b00011001**

Non-secure process stack pointer, PSP\_NS.

If the Security Extension is not implemented, this value is reserved.

**0b00011010**

Secure main stack pointer, MSP\_S.

If the Security Extension is not implemented, this value is reserved.

Accessible only when DHCSR.S\_SDE == 1 and DHCSR.S\_SUIDE == 0.

**0b00011011**

Secure process stack pointer, PSP\_S.

If the Security Extension is not implemented, this value is reserved.

Accessible only when `DHCSR.S_SDE == 1`.

**0b00011100**

Secure main stack limit, `MSPLIM_S`.

If the Security Extension is not implemented, this value is reserved.

Accessible only when `DHCSR.S_SDE == 1` and `DHCSR.S_SUIDE == 0`.

**0b00011101**

Secure process stack limit, `PSPLIM_S`.

If the Security Extension is not implemented, this value is reserved.

Accessible only when `DHCSR.S_SDE == 1`.

**0b00011110**

Non-secure main stack limit, `MSPLIM_NS`.

If the Main Extension is not implemented, this value is reserved.

Accessible only when `DHCSR.S_NSUIDE == 0`.

**0b00011111**

Non-secure process stack limit, `PSPLIM_NS`.

If the Main Extension is not implemented, this value is reserved.

**0b00100001**

`FPSCR`.

If MVE and the Floating-point Extension are not implemented, this value is reserved.

**0b00100010**

Secure state. The value corresponds to `{CONTROL_S[7:0], FAULTMASK_S[7:0], BASEPRI_S[7:0], PRIMASK_S[7:0]}`.

All bits are **RES0** when `DHCSR.S_SDE == 0`.

All bits are accessible when `DHCSR.S_SDE == 1` and `DHCSR.S_SUIDE == 0`.

When `DHCSR.S_SDE == 1` and `DHCSR.S_SUIDE == 1` the bits corresponding to the following fields are **RES0**:

- All fields corresponding to the `CONTROL_S` register except for `CONTROL_S.SFPA` and `CONTROL_S.FPCA`.
- `FAULTMASK_S[7:0]`.
- `BASEPRI_S[7:0]`.
- `PRIMASK_S[7:0]`.

If the Main Extension is not implemented, `FAULTMASK_S[7:0]` and `BASEPRI_S[7:0]` are **RES0**.

If the Security Extension is not implemented, this value is reserved.

**0b00100011**

Non-secure state. The value corresponds to `{CONTROL_NS[7:0], FAULTMASK_NS[7:0], BASEPRI_NS[7:0], PRIMASK_NS[7:0]}`. All bits are accessible when `DHCSR.S_NSUIDE == 0`.

When `DHCSR.S_NSUIDE == 1` the bits corresponding to following fields are **RES0**:

- All fields corresponding to the `CONTROL_NS` register except for `CONTROL_NS.FPCA`.
- `FAULTMASK_NS[7:0]`.
- `BASEPRI_NS[7:0]`.

- PRIMASK\_NS[7:0].

If the Main Extension is not implemented, FAULTMASK\_NS[7:0] and BASEPRI\_NS[7:0] are **RES0**.

If the Security Extension is not implemented, this value is reserved.

**0b00100100**

VPR.

If MVE is not implemented, this value is reserved.

**0b01000000-0b01011111**

Floating-point registers, S0-S31.

If MVE and the Floating-point Extension are not implemented, these values are reserved.

**0b10000000-0b10000011**

Current state PAC\_KEY\_P, word 0 to 3.

If the PACBTI Extension is not implemented, this value is reserved.

Accessible only when privileged debug is permitted for the current state.

**0b10000100-0b10000111**

Current state PAC\_KEY\_U, word 0 to 3.

If the PACBTI Extension is not implemented, this value is reserved.

Accessible only when privileged debug is permitted for the current state.

**0b10001000-0b10001011**

Secure PAC\_KEY\_P\_S, word 0 to 3.

Accessible only when DHCSR.S\_SDE == 1.

If the PACBTI or Security Extensions are not implemented, this value is reserved.

Accessible only when privileged debug is permitted for the Secure state.

**0b10001100-0b10001111**

Secure PAC\_KEY\_U\_S, word 0 to 3.

Accessible only when DHCSR.S\_SDE == 1.

If the PACBTI or Security Extensions are not implemented, this value is reserved.

Accessible only when privileged debug is permitted for the Secure state.

**0b10010000-0b10010011**

Non-secure PAC\_KEY\_P\_NS, word 0 to 3.

If the PACBTI or Security Extensions are not implemented, this value is reserved.

Accessible only when privileged debug is permitted for the Non-secure state.

**0b10010100-0b10010111**

Non-secure PAC\_KEY\_U\_NS, word 0 to 3.

If the PACBTI or Security Extensions are not implemented, this value is reserved.

Accessible only when privileged debug is permitted for the Non-secure state.

All other values are reserved.

If the Security Extension and either MVE or the Floating-point Extension are implemented, then FPSCR, VPR and S0-S31 are not accessible:

- From Non-secure state if DHCSR.S\_SDE == 0 and FPCCR indicates the registers contain values from Secure state.

- From Non-secure state if `DHCSR.S_SDE == 0` and `NSACR` prevents Non-secure access to the registers.
- `FPCCR.LSPACT`, the banked variant associated with the Floating-point context as indicated by `FPCCR.S.S`, is set and only unprivileged debug is permitted for the security state associated with the Floating-point state (as indicated by `FPCCR.S`).

Registers that are not accessible are RAZ/WI.

If this field is written with a reserved value, the PE might behave as if a defined value was written, or ignore the value written, and the value of `DCRDR` becomes `UNKNOWN`.

## D1.2.34 DDEVARCH, SCS Device Architecture Register

The DDEVARCH characteristics are:

### Purpose

Provides CoreSight Unique Component Identifier information for the SCS.

### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

If the Main Extension is not implemented then it is **IMPLEMENTATION DEFINED** whether this register is accessible only to the debugger and **RES0** for software. Otherwise the register is accessible to the debugger and software.

### Configurations

Present only if CoreSight identification is implemented.

This register is **RES0** if CoreSight identification is not implemented.

Present only if Halting debug is implemented.

This register is **RES0** if Halting debug is not implemented.

### Attributes

32-bit read-only register located at 0xE000EFBC.

Secure software can access the Non-secure version of this register via DDEVARCH\_NS located at 0xE002EFBC. The location 0xE002EFBC is **RES0** to software executing in Non-secure state and the debugger.

This register is not banked between Security states.

## Field descriptions

The DDEVARCH bit assignments are:

### ARCHITECT, bits [31:21]

Architect. Defines the architect of the component. Bits [31:28] are the JEP106 continuation code (JEP106 bank ID, minus 1) and bits [27:21] are the JEP106 ID code.

The possible values of this field are:

#### 0x23B

JEP106 continuation code 0x4, ID code 0x3B. Arm Limited.

Other values are defined by the JEDEC JEP106 standard.

This field reads as 0x23B.

### PRESENT, bit [20]

DEVARCH Present. Defines that the DEVARCH register is present.

The possible values of this bit are:

**1**

DEVARCH information present.

This bit reads as one.

**REVISION, bits [19:16]**

Revision. Defines the architecture revision of the component.

The possible values of this field are:

**0b0000**

M-Profile debug architecture v3.0.

This field reads as 0b0000.

**ARCHVER, bits [15:12]**

Architecture Version. Defines the architecture version of the component.

The possible values of this field are:

**0b0010**

M-Profile debug architecture v3.

ARCHVER and ARCHPART are also defined as a single field, ARCHID, so that ARCHVER is ARCHID[15:12].

This field reads as 0b0010.

**ARCHPART, bits [11:0]**

Architecture Part. Defines the architecture of the component.

The possible values of this field are:

**0xA04**

M-Profile debug architecture.

ARCHVER and ARCHPART are also defined as a single field, ARCHID, so that ARCHPART is ARCHID[11:0].

This field reads as 0xA04.

### D1.2.35 DDEVTYPE, SCS Device Type Register

The DDEVTYPE characteristics are:

#### Purpose

Provides CoreSight Unique Component Identifier information for the SCS.

#### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

If the Main Extension is not implemented then it is **IMPLEMENTATION DEFINED** whether this register is accessible only to the debugger and **RES0** for software. Otherwise the register is accessible to the debugger and software.

#### Configurations

Present only if CoreSight identification is implemented.

This register is **RES0** if CoreSight identification is not implemented.

Present only if Halting debug is implemented.

This register is **RES0** if Halting debug is not implemented.

#### Attributes

32-bit read-only register located at 0xE000EFCC.

Secure software can access the Non-secure version of this register via DDEVTYPE\_NS located at 0xE002EFCC. The location 0xE002EFCC is **RES0** to software executing in Non-secure state and the debugger.

This register is not banked between Security states.

### Field descriptions

The DDEVTYPE bit assignments are:

#### Bits [31:8]

Reserved, **RES0**.

#### SUB, bits [7:4]

Sub-type. Component sub-type.

The possible values of this field are:

**0x0**

Other.

This field reads as 0b0000.

#### MAJOR, bits [3:0]

Major type. CoreSight major type.

The possible values of this field are:

**0x0**

Miscellaneous.

This field reads as 0b0000.

## D1.2.36 DEMCR, Debug Exception and Monitor Control Register

The DEMCR characteristics are:

### Purpose

Manages vector catch behavior and DebugMonitor handling when debugging.

### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

If Armv8.1-M is implemented, this register is word, halfword and byte accessible.

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

If the Main Extension is not implemented then it is **IMPLEMENTATION DEFINED** whether this register is accessible only to the debugger and **RES0** for software. Otherwise the register is accessible to the debugger and software.

### Configurations

Present if Halting debug or the Main Extension is implemented.

This register is **RES0** if both Halting debug and Main Extension are not implemented.

### Attributes

32-bit read/write register located at 0xE000EDFC.

Secure software can access the Non-secure version of this register via DEMCR\_NS located at 0xE002EDFC.

The location 0xE002EDFC is **RES0** to software executing in Non-secure state and the debugger.

This register is not banked between Security states.

## Field descriptions

The DEMCR bit assignments are:

### Bits [31:25]

Reserved, **RES0**.

### TRCENA, bit [24]

Trace enable. Global enable for all DWT, PMU, and ITM features.

The possible values of this bit are:

**0**

DWT, PMU, and ITM features disabled.

**1**

DWT, PMU, and ITM features enabled.

If the DWT, PMU, and ITM units are not implemented, this bit is [RES0](#). See the descriptions of DWT, PMU, and ITM for details of which features this bit controls.

Setting this bit to 0 might not stop all events. To ensure that all events are stopped, software must set all DWT, PMU, and ITM feature enable bits to 0, and ensure that all trace generated by the DWT, PMU, and ITM has been flushed, before setting this bit to 0.

It is [IMPLEMENTATION DEFINED](#) whether this bit affects how the system processes trace.

Arm recommends that this bit is set to 1 when using an ETM even if any implemented DWT, PMU, and ITM are not being used.

This bit resets to zero on a Cold reset.

#### **MONPRKEY, bit [23]**

Monitor pend req key. Writes to the MON\_PEND and MON\_REQ fields are ignored unless MONPRKEY is concurrently written to zero.

The possible values of this bit are:

**0**

Concurrent write to MON\_PEND and MON\_REQ are not ignored.

**1**

Concurrent write to MON\_PEND and MON\_REQ are ignored.

This bit reads-as-zero.

If version Armv8.1-M of the architecture is not implemented, this bit is [RES0](#).

#### **Bit [22]**

Reserved, [RES0](#).

#### **UMON\_EN, bit [21]**

Unprivileged monitor enable. DebugMonitor pend enable when the PE is in an unprivileged mode.

The possible values of this bit are:

**0**

DebugMonitor exception controlled by DEMCR.MON\_EN.

**1**

DebugMonitor exception can be pended for unprivileged execution.

Writes to this field by unprivileged DAP accesses are ignored.

If DEMCR.SDME is one this bit is RAZ/WI from Non-secure state

If version Armv8.1 of the architecture and UDE are not implemented, this bit is [RES0](#).

This bit resets to zero on a Warm reset.

#### **SDME, bit [20]**

Secure DebugMonitor enable. Indicates whether the DebugMonitor targets the Secure or the Non-secure state and whether debug events are allowed in Secure state.

The possible values of this bit are:

**0**

Debug events prohibited in Secure state and the DebugMonitor exception targets Non-secure state.

**1**

Debug events allowed in Secure state and the DebugMonitor exception targets Secure state.

When DebugMonitor exception is not pending or active, this bit reflects the value of SecureDebugMonitorAllowed(), otherwise, the previous value is retained.

This bit is read-only.

If the Security Extension is not implemented, this bit is [RES0](#).

If the Main Extension is not implemented, this bit is [RES0](#).

#### **MON\_REQ, bit [19]**

Monitor request. DebugMonitor semaphore bit.

The PE does not use this bit. The monitor software defines the meaning and use of this bit.

If the Main Extension is not implemented, this bit is [RES0](#).

This bit resets to zero on a Warm reset.

#### **MON\_STEP, bit [18]**

Monitor step. Enable DebugMonitor exception stepping.

The possible values of this bit are:

**0**

Stepping disabled.

**1**

Stepping enabled.

The effect of changing this bit at an execution priority that is lower than the priority of the DebugMonitor exception is [UNPREDICTABLE](#).

The effect of a write to DEMCR.MON\_STEP is [CONSTRAINED UNPREDICTABLE](#) unless one of:

- The PE is executing at a priority that is greater than or the same as the priority of the DebugMonitor exception.
- Before the write, DEMCR.MON\_STEP == 0 and the write writes 0 to DEMCR.MON\_STEP.

The [CONSTRAINED UNPREDICTABLE](#) write does one of the following:

- The write is ignored.
- DEMCR.MON\_STEP is set to 1. The effect of the subsequent instruction is [UNPREDICTABLE](#), and the PE might generate a DebugMonitor exception at any time, if enabled and permitted.
- DEMCR.MON\_STEP is set to 0. It is [UNPREDICTABLE](#) whether an 'in progress' step completes.

If the Main Extension is not implemented, this bit is [RES0](#).

This bit resets to zero on a Warm reset.

#### **MON\_PEND, bit [17]**

Monitor pend. Sets or clears the pending state of the DebugMonitor exception.

The possible values of this bit are:

**0**

Clear the status of the DebugMonitor exception to not pending.

**1**

Set the status of the DebugMonitor exception to pending.

When the DebugMonitor exception is pending it becomes active subject to the exception priority rules. The effect of setting this bit to 1 is not affected by the value of the MON\_EN and UMON\_EN bits. This means that software or a debugger can set MON\_PEND to 1 and pend a DebugMonitor exception, even when MON\_EN and UMON\_EN are set to 0.

If the Main Extension is not implemented, this bit is [RES0](#).

This bit resets to zero on a Warm reset.

**MON\_EN, bit [16]**

Monitor enable. Enable the DebugMonitor exception.

The possible values of this bit are:

**0**

DebugMonitor exception disabled.

**1**

DebugMonitor exception enabled.

If a debug event halts the PE, the PE ignores the value of this bit. Unprivileged writes to this bit from the DAP are ignored.

If DEMCR.SDME is one this bit is RAZ/WI from Non-secure state

If the Main Extension is not implemented, this bit is [RES0](#).

This bit resets to zero on a Warm reset.

**Bits [15:12]**

Reserved, [RES0](#).

**VC\_SFERR, bit [11]**

Vector Catch SecureFault. SecureFault exception Halting debug vector catch enable.

The possible values of this bit are:

**0**

Halting debug trap on SecureFault disabled.

**1**

Halting debug trap on SecureFault enabled.

The PE ignores the value of this bit if any of the following are true:

- DHCSR.C\_DEBUGEN == 0.
- DHCSR.S\_NSUIDE == 1.
- HaltingDebugAllowed() == FALSE.
- DHCSR.S\_SDE == 0.
- DHCSR.S\_SUIDE == 1.

If the Security Extension is not implemented, this bit is [RES0](#).

If the Main Extension is not implemented, this bit is [RES0](#).

If Halting debug is not implemented, this bit is [RES0](#).

This bit resets to zero on a Cold reset.

**VC\_HARDERR, bit [10]**

Vector Catch HardFault errors. HardFault exception Halting debug vector catch enable.

The possible values of this bit are:

**0**

Halting debug trap on HardFault disabled.

**1**

Halting debug trap on HardFault enabled.

The PE ignores the value of this bit if any of the following are true:

- DHCSR.C\_DEBUGEN == 0.

- `DHCSR.S_NSUIDE == 1`.
- `HaltingDebugAllowed() == FALSE`.
- The Security Extension is implemented, either `DHCSR.S_SDE == 0` or `DHCSR.S_SUIDE == 1`, and the exception targets Secure state.

If Halting debug is not implemented, this bit is [RES0](#).

This bit resets to zero on a Cold reset.

#### **VC\_INTERR, bit [9]**

Vector Catch interrupt errors. Enable Halting debug vector catch for faults arising from lazy state preservation, stack violations and context stacking or unstacking during exception entry or return.

The possible values of this bit are:

**0**

Halting debug trap on faults disabled.

**1**

Halting debug trap on faults enabled.

The PE ignores the value of this bit if any of the following are true:

- `DHCSR.C_DEBUGEN == 0`.
- `DHCSR.S_NSUIDE == 1`.
- `HaltingDebugAllowed() == FALSE`.
- The Security Extension is implemented, `DHCSR.S_SDE == 0` or `DHCSR.S_SUIDE == 1`, and the exception targets Secure state.

If the Main Extension is not implemented, this bit is [RES0](#).

If Halting debug is not implemented, this bit is [RES0](#).

This bit resets to zero on a Cold reset.

#### **VC\_BUSERR, bit [8]**

Vector Catch BusFault errors. BusFault exception Halting debug vector catch enable.

The possible values of this bit are:

**0**

Halting debug trap on BusFault disabled.

**1**

Halting debug trap on BusFault enabled.

The PE ignores the value of this bit if any of the following are true:

- `DHCSR.C_DEBUGEN == 0`.
- `DHCSR.S_NSUIDE == 1`.
- `HaltingDebugAllowed() == FALSE`.
- The Security Extension is implemented, `DHCSR.S_SDE == 0` or `DHCSR.S_SUIDE == 1`, and the exception targets Secure state.

If the Main Extension is not implemented, this bit is [RES0](#).

If Halting debug is not implemented, this bit is [RES0](#).

This bit resets to zero on a Cold reset.

#### VC\_STATERR, bit [7]

Vector Catch state errors. Enable Halting debug trap on a UsageFault exception caused by a state information error, for example an Undefined Instruction exception.

The possible values of this bit are:

0

Halting debug trap on UsageFault caused by state information error disabled.

1

Halting debug trap on UsageFault caused by state information error enabled.

The PE ignores the value of this bit if any of the following are true:

- DHCSR.C\_DEBUGEN == 0.
- DHCSR.S\_NSUIDE == 1.
- HaltingDebugAllowed() == FALSE.
- The Security Extension is implemented, DHCSR.S\_SDE == 0 or DHCSR.S\_SUIDE == 1, and the exception targets Secure state.

If the Main Extension is not implemented, this bit is [RES0](#).

If Halting debug is not implemented, this bit is [RES0](#).

This bit resets to zero on a Cold reset.

#### VC\_CHKERR, bit [6]

Vector Catch check errors. Enable Halting debug trap on a UsageFault exception caused by an alignment check error or divide-by-zero trap.

The possible values of this bit are:

0

Halting debug trap on UsageFault caused by checking error disabled.

1

Halting debug trap on UsageFault caused by checking error enabled.

The PE ignores the value of this bit if any of the following are true:

- DHCSR.C\_DEBUGEN == 0.
- DHCSR.S\_NSUIDE == 1.
- HaltingDebugAllowed() == FALSE.
- The Security Extension is implemented, DHCSR.S\_SDE == 0 or DHCSR.S\_SUIDE == 1, and the exception targets Secure state.

If the Main Extension is not implemented, this bit is [RES0](#).

If Halting debug is not implemented, this bit is [RES0](#).

This bit resets to zero on a Cold reset.

#### VC\_NOCPPERR, bit [5]

Vector Catch NOCP errors. Enable Halting debug trap on a UsageFault caused by an access to a coprocessor.

The possible values of this bit are:

0

Halting debug trap on UsageFault caused by access to a coprocessor disabled.

1

Halting debug trap on UsageFault caused by access to a coprocessor enabled.

The PE ignores the value of this bit if any of the following are true:

- `DHCSR.C_DEBUGEN == 0`.
- `DHCSR.S_NSUIDE == 1`.
- `HaltingDebugAllowed() == FALSE`.
- The Security Extension is implemented, `DHCSR.S_SDE == 0` or `DHCSR.S_SUIDE == 1`, and the exception targets Secure state.

If the Main Extension is not implemented, this bit is [RES0](#).

If Halting debug is not implemented, this bit is [RES0](#).

This bit resets to zero on a Cold reset.

#### **VC\_MMERR, bit [4]**

Vector Catch MemManage errors. Enable Halting debug trap on a MemManage exception.

The possible values of this bit are:

- 0**  
Halting debug trap on MemManage disabled.
- 1**  
Halting debug trap on MemManage enabled.

The PE ignores the value of this bit if any of the following are true:

- `DHCSR.C_DEBUGEN == 0`.
- `DHCSR.S_NSUIDE == 1`.
- `HaltingDebugAllowed() == FALSE`.
- The Security Extension is implemented, `DHCSR.S_SDE == 0` or `DHCSR.S_SUIDE == 1`, and the exception targets Secure state.

If the Main Extension is not implemented, this bit is [RES0](#).

If Halting debug is not implemented, this bit is [RES0](#).

This bit resets to zero on a Cold reset.

#### **Bits [3:1]**

Reserved, [RES0](#).

#### **VC\_CORERESET, bit [0]**

Vector Catch Core reset. Enable Reset Vector Catch. This causes a Warm reset to halt a running system.

The possible values of this bit are:

- 0**  
Halting debug trap on reset disabled.
- 1**  
Halting debug trap on reset enabled.

If `DHCSR.C_DEBUGEN == 0`, the PE ignores the value of this bit. Otherwise, when this bit is set to 1 a Warm reset will pend a Vector Catch debug event. The debug event is pended regardless of debug permissions or the security state of the PE, and the PE will halt when it enters a mode or state where debug is enabled.

If Halting debug is not implemented, this bit is [RES0](#).

This bit resets to zero on a Cold reset.

### D1.2.37 DFSR, Debug Fault Status Register

The DFSR characteristics are:

## Purpose

Shows which debug event occurred.

## Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

If the Main Extension is not implemented then it is **IMPLEMENTATION DEFINED** whether this register is accessible only to the debugger and **RES0** for software. Otherwise the register is accessible to the debugger and software.

## Configurations

Present if Halting debug or the Main Extension is implemented.

This register is **RES0** if both Halting debug and Main Extension are not implemented.

## Attributes

32-bit read/write-one-to-clear register located at 0xE00ED30.

Secure software can access the Non-secure version of this register via DFSR\_NS located at 0xE002ED30. The location 0xE002ED30 is **RES0** to software executing in Non-secure state and the debugger.

This register is not banked between Security states.

## Field descriptions

The DFSSR bit assignments are:

**Bits [31:6]**

Reserved, RES0.

**PMU, bit [5]**

PMU event. Sticky flag indicating whether a PMU counter overflow event has occurred.

The possible values of this bit are:

0

PMU event has not occurred.

**1**

PMU event has occurred.

If version Armv8.1 of the architecture and PMU are not implemented, this bit is [RES0](#).

This bit resets to zero on a Cold reset.

**EXTERNAL, bit [4]**

External event. Sticky flag indicating whether an External debug request debug event has occurred.

The possible values of this bit are:

**0**

Debug event has not occurred.

**1**

Debug event has occurred.

This bit resets to zero on a Cold reset.

**VCATCH, bit [3]**

Vector Catch event. Sticky flag indicating whether a Vector catch debug event has occurred.

The possible values of this bit are:

**0**

Debug event has not occurred.

**1**

Debug event has occurred.

If Halting debug is not implemented, this bit is [RES0](#).

This bit resets to zero on a Cold reset.

**DWTTRAP, bit [2]**

Watchpoint event. Sticky flag indicating whether a Watchpoint debug event has occurred.

The possible values of this bit are:

**0**

Debug event has not occurred.

**1**

Debug event has occurred.

If the DWT is not implemented, this bit is [RES0](#).

This bit resets to zero on a Cold reset.

**BKPT, bit [1]**

Breakpoint event. Sticky flag indicating whether a Breakpoint debug event has occurred.

The possible values of this bit are:

**0**

Debug event has not occurred.

**1**

Debug event has occurred.

This bit resets to zero on a Cold reset.

**HALTED, bit [0]**

Halt or step event. Sticky flag indicating that a Halt request debug event or Step debug event has occurred.

The possible values of this bit are:

**0**

Debug event has not occurred.

**1**

Debug event has occurred.

This bit resets to zero on a Cold reset.

## D1.2.38 DHCSR, Debug Halting Control and Status Register

The DHCSR characteristics are:

### Purpose

Controls Halting debug.

### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

It is **IMPLEMENTATION DEFINED** whether this register is accessible only to the debugger and **RES0** for software.

### Configurations

Present only if Halting debug is implemented.

This register is **RES0** if Halting debug is not implemented.

### Attributes

32-bit read/write register located at 0xE000EDF0.

Secure software can access the Non-secure version of this register via DHCSR\_NS located at 0xE002EDF0. The location 0xE002EDF0 is **RES0** to software executing in Non-secure state and the debugger.

This register is not banked between Security states.

## Field descriptions

The DHCSR bit assignments are:

On a read:

On a write:

### DBGKEY, bits [31:16], on a write

Debug key. A debugger must write 0xA05F to this field to enable write access to the remaining bits, otherwise the PE ignores the write access.

The possible values of this field are:

**0xA05F**

Writes accompanied by this value update bits[15:0].

**Not 0xA05F**

Write ignored.

**Bits [31:27], on a read**

Reserved, [RES0](#).

**S\_RESTART\_ST, bit [26], on a read**

Restart sticky status. Indicates the PE has processed a request to clear DHCSR.C\_HALT to 0. That is, either a write to DHCSR that clears DHCSR.C\_HALT from 1 to 0, or an External Restart Request.

The possible values of this bit are:

**0**

PE has not left Debug state since the last read of DHCSR.

**1**

PE has left Debug state since the last read of DHCSR.

If the PE is not halted when C\_HALT is cleared to zero, it is [UNPREDICTABLE](#) whether this bit is set to 1. If DHCSR.C\_DEBUGEN == 0 this bit reads as an [UNKNOWN](#) value.

This bit clears to zero when read.

**Note**

If the request to clear C\_HALT is made simultaneously with a request to set C\_HALT, for example a restart request and external debug request occur together, then the PE notionally leaves Debug state and immediately halts again and S\_RESTART\_ST is set to 1.

**S\_RESET\_ST, bit [25], on a read**

Reset sticky status. Indicates whether the PE has been reset since the last read of the DHCSR.

The possible values of this bit are:

**0**

No reset since last DHCSR read.

**1**

At least one reset since last DHCSR read.

This bit clears to zero when read.

This bit resets to one on a Warm reset.

**S\_RETIRE\_ST, bit [24], on a read**

Retire sticky status. Set to 1 every time the PE retires one or more instructions.

The possible values of this bit are:

**0**

No instruction retired since last DHCSR read.

**1**

At least one instruction retired since last DHCSR read.

This bit clears to zero when read.

This bit resets to an [UNKNOWN](#) value on a Warm reset.

**S\_FPD, bit [23], on a read**

Floating-point registers Debuggable. Indicates that FPSCR, VPR, and the Floating-point registers are RAZ/WI in the current PE state when accessed via DCRSR. This reflects !CanDebugAccessFP().

The possible values of this bit are:

**0**

Floating-point registers accessible.

**1**

Floating-point registers are RAZ/WI.

If version Armv8.1-M of the architecture is not implemented, this bit is [RES0](#).

**S\_SUIDE, bit [22], on a read**

Secure unprivileged halting debug enabled. Indicates whether Secure unprivileged-only halting debug is allowed or active.

The possible values of this bit are:

**0**

Secure invasive halting debug prohibited or not restricted to an unprivileged mode.

**1**

Unprivileged Secure invasive halting debug enabled.

If the PE is in Non-debug state, this bit reflects the value of `UnprivHaltingDebugAllowed(TRUE) && !SecureHaltingDebugAllowed()`.

The value of this bit does not change whilst the PE remains in Debug state.

If the Security Extension is not implemented, this bit is [RES0](#).

If version Armv8.1 of the architecture and UDE are not implemented, this bit is [RES0](#).

**S\_NSUIDE, bit [21], on a read**

Non-secure unprivileged halting debug enabled. Indicates whether Non-secure unprivileged-only halting debug is allowed or active.

The possible values of this bit are:

**0**

Non-secure invasive halting debug prohibited or not restricted to an unprivileged mode.

**1**

Unprivileged Non-secure invasive halting debug enabled.

If the PE is in Non-debug state, this bit reflects the value of `UnprivHaltingDebugAllowed(FALSE) && !HaltingDebugAllowed()`.

The value of this bit does not change whilst the PE remains in Debug state.

If version Armv8.1 of the architecture and UDE are not implemented, this bit is [RES0](#).

**S\_SDE, bit [20], on a read**

Secure debug enabled. Indicates whether Secure invasive debug is allowed.

The possible values of this bit are:

**0**

Secure invasive debug prohibited.

**1**

Secure invasive debug allowed.

If the PE is in Non-debug state, this bit reflects the value of `SecureHaltingDebugAllowed()` or `UnprivHaltingDebugAllowed(TRUE)`.

The value of this bit does not change while the PE remains in Debug state.

If the Security Extension is not implemented, this bit is [RES0](#).

**S\_LOCKUP, bit [19], on a read**

Lockup status. Indicates whether the PE is in Lockup state.

The possible values of this bit are:

- 0**  
Not locked up.
- 1**  
Locked up.

This bit can only be read as 1 by a remote debugger, using the DAP. The value of 1 indicates that the PE is running but locked up. The bit clears to 0 when the PE enters Debug state.

**S\_SLEEP, bit [18], on a read**

Sleeping status. Indicates whether the PE is sleeping.

The possible values of this bit are:

- 0**  
Not sleeping.
- 1**  
Sleeping.

The debugger must set the C\_HALT bit to 1 to gain control, or wait for an interrupt or other wakeup event to wakeup the system.

**S\_HALT, bit [17], on a read**

Halted status. Indicates whether the PE is in Debug state.

The possible values of this bit are:

- 0**  
In Non-debug state.
- 1**  
In Debug state.

**S\_REGRDY, bit [16], on a read**

Register ready status. Handshake flag to transfers through the DCRDR.

The possible values of this bit are:

- 0**  
Write to DCRSR performed, but transfer not yet complete.
- 1**  
Transfer complete, or no outstanding transfer.

This bit is valid only when the PE is in Debug state, otherwise this bit is **UNKNOWN**.

This bit resets to an **UNKNOWN** value on a Warm reset.

**Bits [15:7]**

Reserved, **RES0**.

**C\_PMOV, bit [6]**

Halt on PMU overflow control. Request entry to Debug state when a PMU counter overflows.

The possible values of this bit are:

- 0**  
No action.

**1**

If C\_DEBUGEN is set to 1, then when a PMU counter is configured to generate an interrupt overflows, the PE sets DHCSR.C\_HALT to 1 and DFSR.PMU to 1.

PMU\_OVSSET and PMU\_OVSCLR indicate which counter or counters triggered the halt.

If the Main Extension is not implemented, this bit is [RES0](#).

If version Armv8.1 of the architecture and PMU are not implemented, this bit is [RES0](#).

This bit resets to zero on a Cold reset.

#### **C\_SNAPSTALL, bit [5]**

Snap stall control. Allow imprecise entry to Debug state.

The possible values of this bit are:

**0**

No action.

**1**

Allows imprecise entry to Debug state, for example by forcing any stalled load or store instruction to be abandoned.

Setting this bit to 1 allows a debugger to request an imprecise entry to Debug state. Writing 1 to this bit makes the state of the memory system [UNPREDICTABLE](#). Therefore if a debugger writes 1 to this bit it must reset the system before leaving Debug state.

The effect of setting this bit to 1 is [UNPREDICTABLE](#) unless the DHCSR write also sets C\_DEBUGEN and C\_HALT to 1. This means that if the PE is not already in Debug state, it enters Debug state when the stalled instruction completes.

If the Security Extension is implemented, then writes to this bit are ignored when DHCSR.S\_SDE == 0 or DHCSR.S\_SUIDE == 1.

If DHCSR.C\_DEBUGEN == 0, HaltingDebugAllowed() == FALSE, or DHCSR.S\_NSUIDE == 1, the PE ignores this bit and behaves as if it is set to 0.

If the Main Extension is not implemented, this bit is [RES0](#).

This bit resets to zero on a Cold reset.

#### **Note**

A debugger can write to the DHCSR to clear this bit to 0. However, this does not remove the [UNPREDICTABLE](#) state of the memory system caused by setting C\_SNAPSTALL to 1. The architecture does not guarantee that setting this bit to 1 will force an entry to Debug State. Arm strongly recommends that a value of 1 is never written to C\_SNAPSTALL when the PE is in Debug state. It is [IMPLEMENTATION DEFINED](#) whether this bit behaves as RAZ/WI.

#### **Bit [4]**

Reserved, [RES0](#).

#### **C\_MASKINTS, bit [3]**

Mask interrupts control. When debug is enabled, the debugger can write to this bit to mask PendSV, SysTick and external interrupts.

The possible values of this bit are:

**0**

Do not mask.

**1**

Mask PendSV, SysTick and external interrupts.

The effect of any single write to DHCSR that changes the value of this bit is [UNPREDICTABLE](#) unless one of:

- Before the write, DHCSR.{S\_HALT, C\_HALT} are both set to 1 and the write also writes 1 to DHCSR.C\_HALT.
- Before the write, DHCSR.C\_DEBUGEN == 0 or HaltingDebugAllowed() == FALSE, and the write writes 0 to DHCSR.C\_MASKINTS.

This means that a single write to DHCSR must not clear DHCSR.C\_HALT to 0 and change the value of the C\_MASKINTS bit.

If the Security Extension is implemented and either DHCSR.S\_SDE == 0 or DHCSR.S\_SUIDE == 1, this bit does not affect interrupts targeting Secure state.

If DHCSR.C\_DEBUGEN == 0, HaltingDebugAllowed() == FALSE, or DHCSR.S\_NSUIDE == 1, the PE ignores this bit and behaves as if it is set to 0.

If DHCSR.C\_DEBUGEN == 0 this bit reads as an UNKNOWN value.

This bit resets to an UNKNOWN value on a Cold reset.

#### Note

This bit does not affect NMI.

#### C\_STEP, bit [2]

Step control. Enable single instruction step.

The possible values of this bit are:

0

No effect.

1

Single step enabled.

The effect of a single write to DHCSR that changes the value of this bit is UNPREDICTABLE unless one of:

- Before the write, DHCSR.{S\_HALT, C\_HALT} are both set to 1.
- Before the write, DHCSR.C\_DEBUGEN == 0 or HaltingDebugAllowed() == FALSE or DHCSR.C\_STEP == 0, and the write writes 0 to DHCSR.C\_STEP.

The PE ignores this bit and behaves as if it set to 0 if any of:

- UnprivHaltingDebugAllowed(IsSecure()) == FALSE and either DHCSR.C\_DEBUGEN == 0 or HaltingDebugAllowed() == FALSE.
- The Security Extension is implemented, DHCSR.S\_SDE == 0 and the PE is in Secure state.

If DHCSR.C\_DEBUGEN == 0 this bit reads as an UNKNOWN value.

This bit resets to an UNKNOWN value on a Cold reset.

#### C\_HALT, bit [1]

Halt control. PE to enter Debug state halt request.

The possible values of this bit are:

0

Causes the PE to leave Debug state, if the PE is in Debug state.

1

Halt the PE.

The PE sets C\_HALT to 1 when a debug event pends an entry to Debug state.

The PE ignores this bit and behaves as if it is set to 0 if any of:

- `UnprivHaltingDebugAllowed(IsSecure()) == FALSE` and either `DHCSR.C_DEBUGEN == 0` or `HaltingDebugAllowed() == FALSE`.
- The Security Extension is implemented, `DHCSR.S_SDE == 0` and the PE is in Secure state.

If `DHCSR.C_DEBUGEN == 0` this bit reads as an **UNKNOWN** value.

This bit resets to zero on a Warm reset.

#### **C\_DEBUGEN, bit [0]**

Debug enable control. Enable Halting debug.

The possible values of this bit are:

**0**

Disabled.

**1**

Enabled.

If a debugger writes to `DHCSR` to change the value of this bit from 0 to 1, it must also write 0 to the `C_MASKINTS` bit, otherwise behavior is **UNPREDICTABLE**.

If this bit is set to 0:

- The PE behaves as if `DHCSR.{C_MASKINTS, C_STEP, C_HALT}` are all set to 0.
- `DHCSR.{S_RESTART_ST, C_MASKINTS, C_STEP, C_HALT}` are **UNKNOWN** on reads of `DHCSR`.

This bit is read/write to the debugger. Writes from software are ignored.

This bit resets to zero on a Cold reset.

### D1.2.39 DLAR, SCS Software Lock Access Register

The DLAR characteristics are:

## Purpose

Provides CoreSight Software Lock control for the SCS, see the *Arm® CoreSight™ Architecture Specification* for details.

## Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

This register is RAZ/WI if accessed via the debugger, regardless of DAUTHCTRL.UIDAPEN (either bank). It is **IMPLEMENTATION DEFINED** whether a DAP error is generated.

## Configurations

Present only if CoreSight identification is implemented.

This register is **RES0** if CoreSight identification is not implemented.

Present only if the optional Software Lock is implemented.

This register is RAZ/WI if the Software Lock is not implemented.

## Attributes

32-bit write-only register located at 0xE000EFB0.

Secure software can access the Non-secure version of this register via DLAR\_NS located at 0xE002EFB0. The location 0xE002EFB0 is **RES0** to software executing in Non-secure state and the debugger.

This register is not banked between Security states.

## Field descriptions

The DLAR bit assignments are:

**KEY, bits [31:0]**

### Lock Access control.

Writing the key value 0xC5ACCE55 to this field unlocks the lock, enabling write accesses to the registers of this component through a memory-mapped interface.

Writing any other value to this register locks the lock, disabling write accesses to the registers of this component through a memory mapped interface.

#### D1.2.40 DLSR, SCS Software Lock Status Register

The DLSR characteristics are:

## Purpose

Provides CoreSight Software Lock status information for the SCS, see the *Arm® CoreSight™ Architecture Specification* for details.

## Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

This register is RAZ/WI if accessed via the debugger, regardless of DAUTHCTRL.UIDAPEN (either bank). It is **IMPLEMENTATION DEFINED** whether a DAP error is generated.

## Configurations

Present only if CoreSight identification is implemented.

This register is **RES0** if CoreSight identification is not implemented.

Present only if the optional Software Lock is implemented.

This register is RAZ/WI if the Software Lock is not implemented.

## Attributes

32-bit read-only register located at 0xE000EFB4.

Secure software can access the Non-secure version of this register via DLSR\_NS located at 0xE002EFB4. The location 0xE002EFB4 is **RES0** to software executing in Non-secure state and the debugger.

This register is not banked between Security states.

## Field descriptions

The DLSR bit assignments are:

**Bits [31:3]**

Reserved, RES0.

**nTT, bit [2]**

Not thirty-two bit. See the *Arm® CoreSight™ Architecture Specification*.

This bit reads as zero.

**SLK, bit [1]**

Software Lock status. See the *Arm® CoreSight™ Architecture Specification*.

The possible values of this bit are:

0

Lock clear. Software writes are permitted to the registers of the component.

1

Lock set. Software writes to the registers of this component are ignored, and reads have no side effects.

For a debugger read of this register, or when the Software Lock is not implemented, this bit is [RES0](#).

This bit resets to one on a Warm reset.

**SLI, bit [0]**

Software Lock implemented. See the *Arm® CoreSight™ Architecture Specification*.

The possible values of this bit are:

**0**

Software Lock not implemented or debugger access.

**1**

Software Lock is implemented and software access.

For a debugger read of this register, or when the Software Lock is not implemented, this bit is RAZ.

This bit reads as an [IMPLEMENTATION DEFINED](#) value.

## D1.2.41 DPIDR0, SCS Peripheral Identification Register 0

The DPIDR0 characteristics are:

### Purpose

Provides CoreSight Unique Component Identifier information for the SCS.

### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

If the Main Extension is not implemented then it is **IMPLEMENTATION DEFINED** whether this register is accessible only to the debugger and **RES0** for software. Otherwise the register is accessible to the debugger and software.

### Configurations

Present only if CoreSight identification is implemented.

This register is **RES0** if CoreSight identification is not implemented.

Present only if Halting debug is implemented.

This register is **RES0** if Halting debug is not implemented.

### Attributes

32-bit read-only register located at 0xE000EFE0.

Secure software can access the Non-secure version of this register via DPIDR0\_NS located at 0xE002EFE0. The location 0xE002EFE0 is **RES0** to software executing in Non-secure state and the debugger.

This register is not banked between Security states.

## Field descriptions

The DPIDR0 bit assignments are:

### Bits [31:8]

Reserved, **RES0**.

### PART\_0, bits [7:0]

Part number bits [7:0]. See the *Arm® CoreSight™ Architecture Specification*.

This field reads as an **IMPLEMENTATION DEFINED** value.

## D1.2.42 DPIDR1, SCS Peripheral Identification Register 1

The DPIDR1 characteristics are:

### Purpose

Provides CoreSight Unique Component Identifier information for the SCS.

### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

If the Main Extension is not implemented then it is **IMPLEMENTATION DEFINED** whether this register is accessible only to the debugger and **RES0** for software. Otherwise the register is accessible to the debugger and software.

### Configurations

Present only if CoreSight identification is implemented.

This register is **RES0** if CoreSight identification is not implemented.

Present only if Halting debug is implemented.

This register is **RES0** if Halting debug is not implemented.

### Attributes

32-bit read-only register located at 0xE000EFE4.

Secure software can access the Non-secure version of this register via DPIDR1\_NS located at 0xE002EFE4. The location 0xE002EFE4 is **RES0** to software executing in Non-secure state and the debugger.

This register is not banked between Security states.

## Field descriptions

The DPIDR1 bit assignments are:

### Bits [31:8]

Reserved, **RES0**.

### DES\_0, bits [7:4]

JEP106 identification code bits [3:0]. See the *Arm® CoreSight™ Architecture Specification*.

This field reads as an **IMPLEMENTATION DEFINED** value.

### PART\_1, bits [3:0]

Part number bits [11:8]. See the *Arm® CoreSight™ Architecture Specification*.

This field reads as an **IMPLEMENTATION DEFINED** value.

### D1.2.43 DPIDR2, SCS Peripheral Identification Register 2

The DPIDR2 characteristics are:

#### Purpose

Provides CoreSight Unique Component Identifier information for the SCS.

#### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

If the Main Extension is not implemented then it is **IMPLEMENTATION DEFINED** whether this register is accessible only to the debugger and **RES0** for software. Otherwise the register is accessible to the debugger and software.

#### Configurations

Present only if CoreSight identification is implemented.

This register is **RES0** if CoreSight identification is not implemented.

Present only if Halting debug is implemented.

This register is **RES0** if Halting debug is not implemented.

#### Attributes

32-bit read-only register located at 0xE000EFE8.

Secure software can access the Non-secure version of this register via DPIDR2\_NS located at 0xE002EFE8. The location 0xE002EFE8 is **RES0** to software executing in Non-secure state and the debugger.

This register is not banked between Security states.

### Field descriptions

The DPIDR2 bit assignments are:

#### Bits [31:8]

Reserved, **RES0**.

#### REVISION, bits [7:4]

Component revision. See the *Arm® CoreSight™ Architecture Specification*.

This field reads as an **IMPLEMENTATION DEFINED** value.

#### JEDEC, bit [3]

JEDEC assignee value is used. See the *Arm® CoreSight™ Architecture Specification*.

This bit reads as one.

#### DES\_1, bits [2:0]

JEP106 identification code bits [6:4]. See the *Arm® CoreSight™ Architecture Specification*.

This field reads as an **IMPLEMENTATION DEFINED** value.

#### D1.2.44 DPIDR3, SCS Peripheral Identification Register 3

The DPIDR3 characteristics are:

## Purpose

Provides CoreSight Unique Component Identifier information for the SCS.

## Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

If the Main Extension is not implemented then it is **IMPLEMENTATION DEFINED** whether this register is accessible only to the debugger and **RES0** for software. Otherwise the register is accessible to the debugger and software.

## Configurations

Present only if CoreSight identification is implemented.

This register is **RES0** if CoreSight identification is not implemented.

Present only if Halting debug is implemented.

This register is **RES0** if Halting debug is not implemented.

## Attributes

32-bit read-only register located at 0xE000EFEC.

Secure software can access the Non-secure version of this register via DPIDR3\_NS located at 0xE002EFEC. The location 0xE002EFEC is **RES0** to software executing in Non-secure state and the debugger.

This register is not banked between Security states.

## Field descriptions

The DPIDR3 bit assignments are:

**Bits [31:8]**

Reserved, RES0.

**REVAND, bits [7:4]**

RevAnd. See the *Arm® CoreSight™ Architecture Specification*.

This field reads as an **IMPLEMENTATION DEFINED** value.

**CMOD, bits [3:0]**

Customer Modified. See the *Arm® CoreSight™ Architecture Specification*.

This field reads as an IMPLEMENTATION DEFINED value.

## D1.2.45 DPIDR4, SCS Peripheral Identification Register 4

The DPIDR4 characteristics are:

### Purpose

Provides CoreSight Unique Component Identifier information for the SCS.

### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

If the Main Extension is not implemented then it is **IMPLEMENTATION DEFINED** whether this register is accessible only to the debugger and **RES0** for software. Otherwise the register is accessible to the debugger and software.

### Configurations

Present only if CoreSight identification is implemented.

This register is **RES0** if CoreSight identification is not implemented.

Present only if Halting debug is implemented.

This register is **RES0** if Halting debug is not implemented.

### Attributes

32-bit read-only register located at 0xE000EFD0.

Secure software can access the Non-secure version of this register via DPIDR4\_NS located at 0xE002EFD0. The location 0xE002EFD0 is **RES0** to software executing in Non-secure state and the debugger.

This register is not banked between Security states.

## Field descriptions

The DPIDR4 bit assignments are:

### Bits [31:8]

Reserved, **RES0**.

### SIZE, bits [7:4]

4KB count. See the *Arm® CoreSight™ Architecture Specification*.

This field reads as zero.

### DES\_2, bits [3:0]

JEP106 continuation code. See the *Arm® CoreSight™ Architecture Specification*.

This field reads as an **IMPLEMENTATION DEFINED** value.

## D1.2.46 DPIDR5, SCS Peripheral Identification Register 5

The DPIDR5 characteristics are:

### Purpose

Provides CoreSight Unique Component Identifier information for the SCS.

### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

If the Main Extension is not implemented then it is **IMPLEMENTATION DEFINED** whether this register is accessible only to the debugger and **RES0** for software. Otherwise the register is accessible to the debugger and software.

### Configurations

Present only if CoreSight identification is implemented.

This register is **RES0** if CoreSight identification is not implemented.

Present only if Halting debug is implemented.

This register is **RES0** if Halting debug is not implemented.

### Attributes

32-bit read-only register located at 0xE000EFD4.

Secure software can access the Non-secure version of this register via DPIDR5\_NS located at 0xE002EFD4. The location 0xE002EFD4 is **RES0** to software executing in Non-secure state and the debugger.

This register is not banked between Security states.

## Field descriptions

The DPIDR5 bit assignments are:

### Bits [31:0]

Reserved, **RES0**.

## D1.2.47 DPIDR6, SCS Peripheral Identification Register 6

The DPIDR6 characteristics are:

### Purpose

Provides CoreSight Unique Component Identifier information for the SCS.

### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

If the Main Extension is not implemented then it is **IMPLEMENTATION DEFINED** whether this register is accessible only to the debugger and **RES0** for software. Otherwise the register is accessible to the debugger and software.

### Configurations

Present only if CoreSight identification is implemented.

This register is **RES0** if CoreSight identification is not implemented.

Present only if Halting debug is implemented.

This register is **RES0** if Halting debug is not implemented.

### Attributes

32-bit read-only register located at 0xE000EFD8.

Secure software can access the Non-secure version of this register via DPIDR6\_NS located at 0xE002EFD8. The location 0xE002EFD8 is **RES0** to software executing in Non-secure state and the debugger.

This register is not banked between Security states.

## Field descriptions

The DPIDR6 bit assignments are:

### Bits [31:0]

Reserved, **RES0**.

## D1.2.48 DPIDR7, SCS Peripheral Identification Register 7

The DPIDR7 characteristics are:

### Purpose

Provides CoreSight Unique Component Identifier information for the SCS.

### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

If the Main Extension is not implemented then it is **IMPLEMENTATION DEFINED** whether this register is accessible only to the debugger and **RES0** for software. Otherwise the register is accessible to the debugger and software.

### Configurations

Present only if CoreSight identification is implemented.

This register is **RES0** if CoreSight identification is not implemented.

Present only if Halting debug is implemented.

This register is **RES0** if Halting debug is not implemented.

### Attributes

32-bit read-only register located at 0xE000EFDC.

Secure software can access the Non-secure version of this register via DPIDR7\_NS located at 0xE002EFDC. The location 0xE002EFDC is **RES0** to software executing in Non-secure state and the debugger.

This register is not banked between Security states.

## Field descriptions

The DPIDR7 bit assignments are:

### Bits [31:0]

Reserved, **RES0**.

## D1.2.49 DSCEMCR, Debug Set Clear Exception and Monitor Control Register

The DSCEMCR characteristics are:

### Purpose

Atomically sets or clears selected fields in the DEMCR register.

### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

### Configurations

Present if Halting debug or the Main Extension is implemented.

This register is **RES0** if both Halting debug and Main Extension are not implemented.

Present only if version Armv8.1-M of the architecture is implemented.

This register is **RES0** if Armv8.1-M is not implemented.

### Attributes

32-bit write-only register located at 0xE000EE00.

Secure software can access the Non-secure version of this register via DSCEMCR\_NS located at 0xE002EE00. The location 0xE002EE00 is **RES0** to software executing in Non-secure state and the debugger.

This register is not banked between Security states.

## Field descriptions

The DSCEMCR bit assignments are:

### Bits [31:20]

Reserved, **RES0**.

### CLR\_MON\_REQ, bit [19]

Clear monitor request. Atomically clears the DEMCR.MON\_REQ field.

The possible values of this bit are:

**0**

No effect.

**1**

Clear DEMCR.MON\_REQ.

A write to this register with both SET\_MON\_REQ and CLR\_MON\_REQ set to 1 causes DEMCR.MON\_REQ to become **UNKNOWN**.

### Bit [18]

Reserved, **RES0**.

**CLR\_MON\_PEND, bit [17]**

Clear monitor pend. Atomically clears the DEMCR.MON\_PEND field.

The possible values of this bit are:

**0**

No effect.

**1**

Clear DEMCR.MON\_PEND.

A write to this register with both SET\_MON\_PEND and CLR\_MON\_PEND set to 1 causes DEMCR.MON\_PEND to become **UNKNOWN**.

**Bits [16:4]**

Reserved, **RES0**.

**SET\_MON\_REQ, bit [3]**

Set monitor request. Atomically sets the DEMCR.MON\_REQ field.

The possible values of this bit are:

**0**

No effect.

**1**

Sets DEMCR.MON\_REQ.

A write to this register with both SET\_MON\_REQ and CLR\_MON\_REQ set to 1 causes DEMCR.MON\_REQ to become **UNKNOWN**.

**Bit [2]**

Reserved, **RES0**.

**SET\_MON\_PEND, bit [1]**

Set monitor pend. Atomically sets the DEMCR.MON\_PEND field.

The possible values of this bit are:

**0**

No effect.

**1**

Sets DEMCR.MON\_PEND.

A write to this register with both SET\_MON\_PEND and CLR\_MON\_PEND set to 1 causes DEMCR.MON\_PEND to become **UNKNOWN**.

**Bit [0]**

Reserved, **RES0**.

## D1.2.50 DSCSR, Debug Security Control and Status Register

The DSCSR characteristics are:

### Purpose

Provides control and status information for Secure debug.

### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

Writes to this register while the PE is in Non-debug state are ignored.

This register is accessible only to the debugger and **RES0** to software.

### Configurations

Present only if the Security Extension is implemented.

This register is **RES0** if the Security Extension is not implemented.

Present only if Halting debug is implemented.

This register is **RES0** if Halting debug is not implemented.

### Attributes

32-bit read/write register located at 0xE000EE08.

This register is not banked between Security states.

## Field descriptions

The DSCSR bit assignments are:

### Bits [31:18]

Reserved, **RES0**.

### CDSKEY, bit [17]

CDS write-enable key. Writes to the CDS bit are ignored unless CDSKEY is concurrently written to zero.

The possible values of this bit are:

**0**

Concurrent write to CDS not ignored.

**1**

Concurrent write to CDS ignored.

This bit reads-as-one.

### CDS, bit [16]

Current domain Secure. This field indicates the current Security state of the processor.

The possible values of this bit are:

**0**  
PE is in Non-secure state.

**1**  
PE is in Secure state.

This bit is only writable if all of the following are true:

- DHCSR.S\_SDE is 1.
- The processor is in Secure state and either DHCSR.S\_NSUIDE == 0 or the current mode for the Non-secure state is unprivileged, or the processor is in Non-secure state and either DHCSR.S\_SUIDE == 0 or the current mode for the Secure state is unprivileged.
- The access to the register originates from the debugger.
- The PE is halted in Debug state.
- CDSKEY is concurrently written to zero.

**Bits [15:2]**  
Reserved, [RES0](#).

**SBRSEL, bit [1]**

Secure banked register select. If SBRSELEN is 1 this bit selects whether the Non-secure or the Secure versions of the memory-mapped banked registers are accessible to the debugger.

The possible values of this bit are:

**0**  
Selects the Non-secure versions.

**1**  
Selects the Secure versions.

This bit behaves as RAZ/WI if DHCSR.S\_SDE is 0.

This bit resets to zero on a Cold reset.

**SBRSELEN, bit [0]**

Secure banked register select enable. Controls whether the SBRSEL field or the current Security state of the processor selects which version of the memory-mapped banked registers are accessible to the debugger.

The possible values of this bit are:

**0**  
The current Security state of the PE determines which memory-mapped Banked registers are accessed by the debugger.

**1**  
DSCSR.SBRSEL selects which memory-mapped Banked registers are accessed by the debugger.

This bit behaves as RAO/WI if DHCSR.S\_SDE is 0.

This bit resets to zero on a Cold reset.

**Note**

This method of banked register selection means that the register aliasing is not used for accesses from the debugger. Accesses to the aliased addresses from the debugger have the same behavior as reserved addresses.

## D1.2.51 DWT\_CIDR0, DWT Component Identification Register 0

The DWT\_CIDR0 characteristics are:

### Purpose

Provides CoreSight Unique Component Identifier information for the DWT.

### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

If the Main Extension is not implemented then it is **IMPLEMENTATION DEFINED** whether this register is accessible only to the debugger and **RES0** for software. Otherwise the register is accessible to the debugger and software.

### Configurations

Present only if CoreSight identification is implemented.

This register is **RES0** if CoreSight identification is not implemented.

Present only if the DWT is implemented.

This register is **RES0** if the DWT is not implemented.

### Attributes

32-bit read-only register located at 0xE0001FF0.

This register is not banked between Security states.

## Field descriptions

The DWT\_CIDR0 bit assignments are:

### Bits [31:8]

Reserved, **RES0**.

### PRMBL\_0, bits [7:0]

CoreSight component identification preamble. See the *Arm® CoreSight™ Architecture Specification*.

This field reads as 0x0D.

## D1.2.52 DWT\_CIDR1, DWT Component Identification Register 1

The DWT\_CIDR1 characteristics are:

### Purpose

Provides CoreSight Unique Component Identifier information for the DWT.

### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

If the Main Extension is not implemented then it is **IMPLEMENTATION DEFINED** whether this register is accessible only to the debugger and **RES0** for software. Otherwise the register is accessible to the debugger and software.

### Configurations

Present only if CoreSight identification is implemented.

This register is **RES0** if CoreSight identification is not implemented.

Present only if the DWT is implemented.

This register is **RES0** if the DWT is not implemented.

### Attributes

32-bit read-only register located at 0xE0001FF4.

This register is not banked between Security states.

## Field descriptions

The DWT\_CIDR1 bit assignments are:

### Bits [31:8]

Reserved, **RES0**.

### CLASS, bits [7:4]

CoreSight component class. See the *Arm® CoreSight™ Architecture Specification*.

This field reads as 0x9.

### PRMBL\_1, bits [3:0]

CoreSight component identification preamble. See the *Arm® CoreSight™ Architecture Specification*.

This field reads as 0x0.

### D1.2.53 DWT\_CIDR2, DWT Component Identification Register 2

The DWT\_CIDR2 characteristics are:

#### Purpose

Provides CoreSight Unique Component Identifier information for the DWT.

#### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

If the Main Extension is not implemented then it is **IMPLEMENTATION DEFINED** whether this register is accessible only to the debugger and **RES0** for software. Otherwise the register is accessible to the debugger and software.

#### Configurations

Present only if CoreSight identification is implemented.

This register is **RES0** if CoreSight identification is not implemented.

Present only if the DWT is implemented.

This register is **RES0** if the DWT is not implemented.

#### Attributes

32-bit read-only register located at 0xE0001FF8.

This register is not banked between Security states.

#### Field descriptions

The DWT\_CIDR2 bit assignments are:

#### Bits [31:8]

Reserved, **RES0**.

#### PRMBL\_2, bits [7:0]

CoreSight component identification preamble. See the *Arm® CoreSight™ Architecture Specification*.

This field reads as 0x05.

### D1.2.54 DWT\_CIDR3, DWT Component Identification Register 3

The DWT\_CIDR3 characteristics are:

## Purpose

Provides CoreSight Unique Component Identifier information for the DWT.

## Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

If the Main Extension is not implemented then it is **IMPLEMENTATION DEFINED** whether this register is accessible only to the debugger and **RES0** for software. Otherwise the register is accessible to the debugger and software.

## Configurations

Present only if CoreSight identification is implemented.

This register is **RES0** if CoreSight identification is not implemented.

Present only if the DWT is implemented.

This register is **RES0** if the DWT is not implemented.

## Attributes

32-bit read-only register located at 0xE0001FFC.

This register is not banked between Security states.

## Field descriptions

The DWT\_CIDR3 bit assignments are:

**Bits [31:8]**

Reserved, RES0.

**PRMBL\_3, bits [7:0]**

CoreSight component identification preamble. See the *Arm® CoreSight™ Architecture Specification*.

This field reads as 0xB1.

## D1.2.55 DWT\_COMPn, DWT Comparator Register, n = 0 - 14

The DWT\_COMP{0..14} characteristics are:

### Purpose

Provides a reference value for use by watchpoint comparator *n*.

### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

If the Main Extension is not implemented then it is **IMPLEMENTATION DEFINED** whether this register is accessible only to the debugger and **RES0** for software. Otherwise the register is accessible to the debugger and software.

### Configurations

Present only if the DWT is implemented.

This register is **RES0** if the DWT is not implemented.

### Attributes

32-bit read/write register located at  $0xE0001020 + 16n$ .

This register is not banked between Security states.

## Field descriptions

The DWT\_COMP{0..14} bit assignments are:

**When DWT\_FUNCTIONn.MATCH == 0b0001:**

**When DWT\_FUNCTIONn.MATCH == 0b001x:**

**When DWT\_FUNCTIONn.MATCH == 0b10xx:**

**When DWT\_FUNCTIONn.MATCH == 0bx1xx:**

**CYCVALUE, bits [31:0], when DWT\_FUNCTIONn.MATCH == 0b0001**

Cycle value. Reference value for comparison with cycle count.

This field resets to an **UNKNOWN** value on a Cold reset.

**PCVALUE, bits [31:1], when DWT\_FUNCTIONn.MATCH == 0b001x**

PC value. Reference value for comparison with Program Counter.

This field resets to an **UNKNOWN** value on a Cold reset.

**Bit [0], when DWT\_FUNCTIONn.MATCH == 0b001x**

Reserved, **RES0**.

**DADDR, bits [31:0], when DWT\_FUNCTIONn.MATCH == 0bx1xx**

Data address. Reference value for comparison with load or store address.

For halfword address comparisons, DADDR[0] is **RES0**. For byte address comparisons, DADDR[1:0] are **RES0**.

This field resets to an **UNKNOWN** value on a Cold reset.

**DVALUE, bits [31:0], when DWT\_FUNCTIONn.MATCH == 0b10xx**

Data value. Reference value for comparison with load or store data.

For halfword or word comparisons, the data value is in little-endian order. That is, the least significant byte of this register is compared with the byte targeting the lowest address in memory.

For byte or halfword comparisons, if the value of the byte or halfword is not replicated across all byte or halfword lanes, the value used for the comparison is **UNKNOWN**.

This field resets to an **UNKNOWN** value on a Cold reset.

### D1.2.56 DWT\_CPICNT, DWT CPI Count Register

The DWT\_CPICNT characteristics are:

## Purpose

Counts additional cycles required to execute multicycle instructions and instruction fetch stalls.

## Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

## Configurations

Present only if the Main Extension is implemented.

This register is **RES0** if the Main Extension is not implemented.

Present only if the DWT is implemented.

This register is **RES0** if the DWT is not implemented.

Present only if DWT\_CTRL.NOPRFCNT == 0.

This register is **RES0** if DWT\_CTRL.NOPRFCNT == 1.

## Attributes

32-bit read/write register located at 0xE0001008.

This register is not banked between Security states.

## Field descriptions

The DWT\_CPICNT bit assignments are:

**RESERVED, bits [31:8]**

Reserved, RAZ/WI

**CPICNT, bits [7:0]**

Base instruction overhead counter.

Counts one on each cycle when all of the following are true:

- `DWT_CTRL.CPIEVTENA == 1` and `DEMCR.TRCENA == 1`.
- No instruction is executed.
- No load-store operation is in progress, see `DWT_LSUCNT`.
- No exception-entry or exception-exit operation is in progress, see `DWT_EXCCNT`.
- The PE is not in a power-saving mode, see `DWT_SLEPCNT`.
- Either `SecureNoninvasiveDebugAllowed() == TRUE`, or the PE is in Non-secure state and `NoninvasiveDebugAllowed() == TRUE`.

The definition of "no instruction is executed" is **IMPLEMENTATION DEFINED**. Arm recommends that this counts each cycle on which no instruction is retired.

Initialized to zero when the counter is disabled and DWT\_CTRL.CPIEVTENA is written with 1. An Event Counter packet is emitted on counter overflow.

This field resets to an **UNKNOWN** value on a Cold reset.

## D1.2.57 DWT\_CTRL, DWT Control Register

The DWT\_CTRL characteristics are:

### Purpose

Provides configuration and status information for the DWT unit, and used to control features of the unit.

### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

If the Main Extension is not implemented then it is **IMPLEMENTATION DEFINED** whether this register is accessible only to the debugger and **RES0** for software. Otherwise the register is accessible to the debugger and software.

### Configurations

Present only if the DWT is implemented.

This register is **RES0** if the DWT is not implemented.

### Attributes

32-bit read/write register located at 0xE0001000.

This register is not banked between Security states.

## Field descriptions

The DWT\_CTRL bit assignments are:

### NUMCOMP, bits [31:28]

Number of comparators. Number of DWT comparators implemented.

A value of zero indicates no comparator support.

This field reads as an **IMPLEMENTATION DEFINED** value.

### NOTRCPKT, bit [27]

No trace packets. Indicates whether the implementation does not support trace.

The possible values of this bit are:

**0**

Trace supported.

**1**

Trace not supported.

If this bit is RAZ, the NOCYCCNT bit must also RAZ.

If the Main Extension is not implemented, this bit is RES1.

This bit reads as an IMPLEMENTATION DEFINED value.

**NOEXTTRIG, bit [26]**

No External Triggers. Shows whether the implementation does not support external triggers.

Reserved, RES0.

**NOCYCCNT, bit [25]**

No cycle count. Indicates whether the implementation does not include a cycle counter.

The possible values of this bit are:

0

Cycle counter implemented.

1

Cycle counter not implemented.

If the Main Extension is not implemented, this bit is RES1.

This bit reads as an IMPLEMENTATION DEFINED value.

**NOPRFCNT, bit [24]**

No profile counters. Indicates whether the implementation does not include the profiling counters.

The possible values of this bit are:

0

Profiling counters implemented.

1

Profiling counters not implemented.

If the Main Extension is not implemented, this bit is RES1.

This bit reads as an IMPLEMENTATION DEFINED value.

**CYCDISS, bit [23]**

Cycle counter disabled secure. Controls whether the cycle counter is disabled in Secure state.

The possible values of this bit are:

0

No effect.

1

Disable incrementing of the cycle counter when the PE is in Secure state.

If the NOCYCCNT bit is RAO this bit is RES0.

If the Main Extension is not implemented, this bit is RES0.

This bit resets to zero on a Cold reset.

**CYCEVTENA, bit [22]**

Cycle event enable. Enables Event Counter packet generation on POSTCNT underflow.

The possible values of this bit are:

0

No Event Counter packets generated when POSTCNT underflows.

1

If PCSAMPLENA set to 0, an Event Counter packet is generated when POSTCNT underflows.

If the NOTRCPKT bit is RAO or the NOCYCCNT bit is RAO this bit is [RES0](#).

If the Main Extension is not implemented, this bit is [RES0](#).

This bit resets to zero on a Cold reset.

**FOLDEVTENA, bit [21]**

Fold event enable. Enables DWT\_FOLDCNT counter.

The possible values of this bit are:

**0**

DWT\_FOLDCNT disabled.

**1**

DWT\_FOLDCNT enabled.

If the NOPRFCNT bit is RAO this bit is [RES0](#). The reset value is 0.

If the Main Extension is not implemented, this bit is [RES0](#).

This bit resets to zero on a Cold reset.

**LSUEVTENA, bit [20]**

LSU event enable. Enables DWT\_LSUCNT counter.

The possible values of this bit are:

**0**

DWT\_LSUCNT disabled.

**1**

DWT\_LSUCNT enabled.

If the NOPRFCNT bit is RAO this bit is [RES0](#).

If the Main Extension is not implemented, this bit is [RES0](#).

This bit resets to zero on a Cold reset.

**SLEEPEVTENA, bit [19]**

Sleep event enable. Enable DWT\_SLEEPCNT counter.

The possible values of this bit are:

**0**

DWT\_SLEEPCNT disabled.

**1**

DWT\_SLEEPCNT enabled.

If the NOPRFCNT bit is RAO this bit is [RES0](#).

If the Main Extension is not implemented, this bit is [RES0](#).

This bit resets to zero on a Cold reset.

**EXCEVTENA, bit [18]**

Exception event enable. Enables DWT\_EXCCNT counter.

The possible values of this bit are:

**0**

DWT\_EXCCNT disabled.

**1**

DWT\_EXCCNT enabled.

If the NOPRFCNT bit is RAO this bit is **RES0**.

If the Main Extension is not implemented, this bit is **RES0**.

This bit resets to zero on a Cold reset.

**CPIEVTENA, bit [17]**

CPI event enable. Enables DWT\_CPICNT counter.

The possible values of this bit are:

**0**

DWT\_CPICNT disabled.

**1**

DWT\_CPICNT enabled.

If the NOPRFCNT bit is RAO this bit is **RES0**.

If the Main Extension is not implemented, this bit is **RES0**.

This bit resets to zero on a Cold reset.

**EXCTRCENA, bit [16]**

Exception trace enable. Enables generation of Exception Trace packets.

The possible values of this bit are:

**0**

Exception Trace packet generation disabled.

**1**

Exception Trace packet generation enabled.

If the NOTRCPKT bit is RAO this bit is **RES0**.

If the Main Extension is not implemented, this bit is **RES0**.

This bit resets to zero on a Cold reset.

**Bits [15:13]**

Reserved, **RES0**.

**PCSAMPLENA, bit [12]**

PC sample enable. Enables use of POSTCNT counter as a timer for Periodic PC Sample packet generation.

The possible values of this bit are:

**0**

Periodic PC Sample packet generation disabled.

**1**

Periodic PC Sample packet generated on POSTCNT underflow.

If the NOTRCPKT bit is RAO or the NOCYCCNT bit is RAO this bit is **RES0**.

If the Main Extension is not implemented, this bit is **RES0**.

This bit resets to zero on a Cold reset.

**SYNCTAP, bits [11:10]**

Synchronization tap. Selects the position of the synchronization packet request counter tap on the CYCCNT counter. This determines the rate of Synchronization packet requests made by the DWT.

The possible values of this field are:

**0b00**

Synchronization packet request disabled.

**0b01**

Synchronization counter tap at CYCCNT[24].

**0b10**

Synchronization counter tap at CYCCNT[26].

**0b11**

Synchronization counter tap at CYCCNT[28].

If the NOCYCCNT bit is RAO this bit is [RES0](#).

If the Main Extension is not implemented, this field is [RES0](#).

This field resets to an [UNKNOWN](#) value on a Cold reset.

**CYCTAP, bit [9]**

Cycle count tap. Selects the position of the POSTCNT tap on the CYCCNT counter.

The possible values of this bit are:

**0**

POSTCNT tap at CYCCNT[6].

**1**

POSTCNT tap at CYCCNT[10].

If the NOCYCCNT bit is RAO this bit is [RES0](#).

If the Main Extension is not implemented, this bit is [RES0](#).

This bit resets to an [UNKNOWN](#) value on a Cold reset.

**POSTINIT, bits [8:5]**

POSTCNT initial. Initial value for the POSTCNT counter.

If the NOCYCCNT bit is RAO this bit is [RES0](#).

If the Main Extension is not implemented, this field is [RES0](#).

This field resets to an [UNKNOWN](#) value on a Cold reset.

**POSTPRESET, bits [4:1]**

POSTCNT preset. Reload value for the POSTCNT counter.

If the NOCYCCNT bit is RAO this bit is [RES0](#).

If the Main Extension is not implemented, this field is [RES0](#).

This field resets to an [UNKNOWN](#) value on a Cold reset.

**CYCCNTENA, bit [0]**

CYCCNT enable. Enables CYCCNT.

The possible values of this bit are:

**0**

CYCCNT disabled.

**1**

CYCCNT enabled.

If the NOCYCCNT bit is RAO this bit is [RES0](#).

If the Main Extension is not implemented, this bit is [RES0](#).

This bit resets to zero on a Cold reset.

## D1.2.58 DWT\_CYCCNT, DWT Cycle Count Register

The DWT\_CYCCNT characteristics are:

### Purpose

Shows or sets the value of the processor cycle counter, CYCCNT.

### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are [UNPREDICTABLE](#).

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

### Configurations

Present only if the Main Extension is implemented.

This register is [RES0](#) if the Main Extension is not implemented.

Present only if the DWT is implemented.

This register is [RES0](#) if the DWT is not implemented.

Present only if DWT\_CTRL.NOCYCCNT == 0.

This register is [RES0](#) if DWT\_CTRL.NOCYCCNT == 1.

### Attributes

32-bit read/write register located at 0xE0001004.

This register is not banked between Security states.

### Preface

The PMU\_CCNTR register, if implemented, is an alias of this register.

### Field descriptions

The DWT\_CYCCNT bit assignments are:

### CYCCNT, bits [31:0]

Incrementing cycle counter value. Increments one on each processor clock cycle when DWT\_CTRL.CYCCNTENA == 1 and DEMCR.TRCENA == 1. On overflow, CYCCNT wraps to zero.

This field resets to an [UNKNOWN](#) value on a Cold reset.

## D1.2.59 DWT\_DEVARCH, DWT Device Architecture Register

The DWT\_DEVARCH characteristics are:

### Purpose

Provides CoreSight Unique Component Identifier information for the DWT.

### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

If the Main Extension is not implemented then it is **IMPLEMENTATION DEFINED** whether this register is accessible only to the debugger and **RES0** for software. Otherwise the register is accessible to the debugger and software.

### Configurations

Present only if CoreSight identification is implemented.

This register is **RES0** if CoreSight identification is not implemented.

Present only if the DWT is implemented.

This register is **RES0** if the DWT is not implemented.

### Attributes

32-bit read-only register located at 0xE0001FBC.

This register is not banked between Security states.

## Field descriptions

The DWT\_DEVARCH bit assignments are:

### ARCHITECT, bits [31:21]

Architect. Defines the architect of the component. Bits [31:28] are the JEP106 continuation code (JEP106 bank ID, minus 1) and bits [27:21] are the JEP106 ID code.

The possible values of this field are:

#### 0x23B

JEP106 continuation code 0x4, ID code 0x3B. Arm Limited.

Other values are defined by the JEDEC JEP106 standard.

This field reads as 0x23B.

### PRESENT, bit [20]

DEVARCH Present. Defines that the DEVARCH register is present.

The possible values of this bit are:

#### 1

DEVARCH information present.

This bit reads as one.

**REVISION, bits [19:16]**

Revision. Defines the architecture revision of the component.

The possible values of this field are:

**0b0000**

DWT architecture v2.0.

**0b0001**

DWT architecture v2.1. The DWT\_VMASKn registers are implemented.

DWT architecture v2.1 is mandatory for a DWT implementation that includes data value comparators in a PE that implements v8.1-M and MVE. If the DWT implementation does not include data value comparators, it is IMPDEF whether it is v2.0 or v2.1.

This field reads as an **IMPLEMENTATION DEFINED** value.

**ARCHVER, bits [15:12]**

Architecture Version. Defines the architecture version of the component.

The possible values of this field are:

**0b0001**

DWT architecture v2.

ARCHVER and ARCHPART are also defined as a single field, ARCHID, so that ARCHVER is ARCHID[15:12].

This field reads as 0b0001.

**ARCHPART, bits [11:0]**

Architecture Part. Defines the architecture of the component.

The possible values of this field are:

**0xA02**

DWT architecture.

ARCHVER and ARCHPART are also defined as a single field, ARCHID, so that ARCHPART is ARCHID[11:0].

This field reads as 0xA02.

## D1.2.60 DWT\_DEVTYPE, DWT Device Type Register

The DWT\_DEVTYPE characteristics are:

### Purpose

Provides CoreSight Unique Component Identifier information for the DWT.

### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

If the Main Extension is not implemented then it is **IMPLEMENTATION DEFINED** whether this register is accessible only to the debugger and **RES0** for software. Otherwise the register is accessible to the debugger and software.

### Configurations

Present only if CoreSight identification is implemented.

This register is **RES0** if CoreSight identification is not implemented.

Present only if the DWT is implemented.

This register is **RES0** if the DWT is not implemented.

### Attributes

32-bit read-only register located at 0xE0001FCC.

This register is not banked between Security states.

## Field descriptions

The DWT\_DEVTYPE bit assignments are:

### Bits [31:8]

Reserved, **RES0**.

### SUB, bits [7:4]

Sub-type. Component sub-type.

The possible values of this field are:

**0x0**

Other.

This field reads as 0b0000.

### MAJOR, bits [3:0]

Major type. Component major type.

The possible values of this field are:

**0x0**

Miscellaneous.

This field reads as 0b0000.

## D1.2.61 DWT\_EXCCNT, DWT Exception Overhead Count Register

The DWT\_EXCCNT characteristics are:

### Purpose

Counts the total cycles spent in exception processing.

### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

### Configurations

Present only if the Main Extension is implemented.

This register is **RES0** if the Main Extension is not implemented.

Present only if the DWT is implemented.

This register is **RES0** if the DWT is not implemented.

Present only if DWT\_CTRL.NOPRFCNT == 0.

This register is **RES0** if DWT\_CTRL.NOPRFCNT == 1.

### Attributes

32-bit read/write register located at 0xE000100C.

This register is not banked between Security states.

## Field descriptions

The DWT\_EXCCNT bit assignments are:

### RESERVED, bits [31:8]

Reserved, RAZ/WI

### EXCCNT, bits [7:0]

The exception overhead counter.

Counts one on each cycle when all of the following are true:

- DWT\_CTRL.EXCEVTENA == 1 and DEMCR.TRCENA == 1.
- No instruction is executed, see DWT\_CPICNT.
- An exception-entry or exception-exit related operation is in progress.
- Either SecureNoninvasiveDebugAllowed() == TRUE, or NS-Req for the operation is set to Non-secure and NoninvasiveDebugAllowed() == TRUE.

Exception-entry or exception-exit related operations include the stacking of registers on exception entry, lazy state preservation, unstacking of registers on exception exit, and preemption.

Initialized to zero when the counter is disabled and DWT\_CTRL.EXCEVTENA is written with 1. An Event Counter packet is emitted on counter overflow.

This field resets to an **UNKNOWN** value on a Cold reset.

## D1.2.62 DWT\_FOLDCNT, DWT Folded Instruction Count Register

The DWT\_FOLDCNT characteristics are:

### Purpose

Increments for each additional instruction executed in the current cycle.

### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

### Configurations

Present only if the Main Extension is implemented.

This register is **RES0** if the Main Extension is not implemented.

Present only if the DWT is implemented.

This register is **RES0** if the DWT is not implemented.

Present only if DWT\_CTRL.NOPRFCNT == 0.

This register is **RES0** if DWT\_CTRL.NOPRFCNT == 1.

### Attributes

32-bit read/write register located at 0xE0001018.

This register is not banked between Security states.

## Field descriptions

The DWT\_FOLDCNT bit assignments are:

### RESERVED, bits [31:8]

Reserved, RAZ/WI

### FOLDCNT, bits [7:0]

Folded instruction counter.

Counts on each cycle when all of the following are true:

- DWT\_CTRL.FOLDEVTENA == 1 and DEMCR.TRCENA == 1.
- At least two instructions are executed, see DWT\_CPICNT.
- Either SecureNoninvasiveDebugAllowed() == TRUE, or the PE is in Non-secure state and NoninvasiveDebugAllowed() == TRUE.

The counter is incremented by the number of instructions executed, minus one.

Initialized to zero when the counter is disabled and DWT\_CTRL.FOLDEVTENA is written with 1. An event is emitted on counter overflow.

This field resets to an **UNKNOWN** value on a Cold reset.

### D1.2.63 DWT\_FUNCTIONn, DWT Comparator Function Register, n = 0 - 14

The DWT\_FUNCTION{0..14} characteristics are:

#### Purpose

Controls the operation of watchpoint comparator *n*.

#### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

If the Main Extension is not implemented then it is **IMPLEMENTATION DEFINED** whether this register is accessible only to the debugger and **RES0** for software. Otherwise the register is accessible to the debugger and software.

#### Configurations

Present only if the DWT is implemented.

This register is **RES0** if the DWT is not implemented.

#### Attributes

32-bit read/write register located at  $0xE0001028 + 16n$ .

This register is not banked between Security states.

### Field descriptions

The DWT\_FUNCTION{0..14} bit assignments are:

#### ID, bits [31:27]

Identify capability. Identifies the capabilities for MATCH for comparator *n*.

The possible values of this field are:

**0b00000**

Reserved.

**0b01000**

Data Address, and Data Address With Value.

**0b01001**

Cycle Counter, Data Address, and Data Address With Value.

**0b01010**

Instruction Address, Data Address, and Data Address With Value.

**0b01011**

Cycle Counter, Instruction Address, Data Address and Data Address With Value.

**0b11000**

Data Address, Data Address Limit, and Data Address With Value.

**0b11010**

Instruction Address, Instruction Address Limit, Data Address, Data Address Limit, and Data Address With Value.

**0b11100**

Data Address, Data Address Limit, Data Value, Linked Data Value, and Data Address With Value.

**0b11110**

Instruction Address, Instruction Address Limit, Data Address, Data Address Limit, Data value, Linked Data Value, and Data Address With Value.

All other values are reserved.

Comparator 0 never supports linking. If more than one comparator is implemented, then at least one comparator must support linking. Arm recommends that odd-numbered comparators support linking.

Cycle Counter matching is only supported if the Main Extension is implemented and `DWT_CTRL.NOCYCCNT == 0`, meaning the cycle counter is implemented. Comparator 0 must support Cycle Counter matching if the cycle counter is implemented.

Data Address With Value is supported for the first four comparators only, and only if the Main Extension and ITM are implemented, and `DWT_CTRL.NOTRCPKT == 0`. Data Value and Linked Data Value not supported if the Main Extension is not implemented.

This field is read-only.

This field reads as an **IMPLEMENTATION DEFINED** value.

**Bits [26:25]**

Reserved, **RES0**.

**MATCHED, bit [24]**

Comparator matched. Set to 1 when the comparator matches.

The possible values of this bit are:

**0**

No match.

**1**

Match. The comparator has matched since the last read of this register.

For an Instruction Address Limit or Data Address Limit comparator, this bit is **UNKNOWN** on reads.

This bit is read-only.

This bit clears to zero when read.

This bit resets to an **UNKNOWN** value on a Cold reset.

**Bits [23:12]**

Reserved, **RES0**.

**DATAVSIZE, bits [11:10]**

Data value size. Defines the size of the object being watched for by Data Value and Data Address comparators.

The possible values of this field are:

**0b00**

1 byte.

**0b01**

2 bytes.

**0b10**

4 bytes.

All other values are reserved.

For an Instruction Address or Instruction Address Limit comparator, DATAVSIZ must be 0b01 (2 bytes). If this comparator is part of an data address range pair, DATAVSIZ must be 0b00 (1 byte).

For a Data Address comparator, DWT\_COMP $n$  must be aligned to the size specified by DATAVSIZ. For a Data Value or Linked Data Value comparator:

- For halfword comparisons, DWT\_COMP $n$  [31:16] must be equal to DWT\_COMP $n$  [15:0].
- For byte comparisons, DWT\_COMP $n$  [31:24], DWT\_COMP $n$  [23:16], and DWT\_COMP $n$  [15:8] must be equal to DWT\_COMP $n$  [7:0].

This field resets to an UNKNOWN value on a Cold reset.

#### Bits [9:6]

Reserved, RES0.

#### ACTION, bits [5:4]

Action on match. Defines the action on a match. This field is ignored and the comparator generates no actions if it is disabled by MATCH.

The possible values of this field are:

##### 0b00

Trigger only.

##### 0b01

Generate debug event.

##### 0b10

For a Cycle Counter, Instruction Address, Data Address, Data Value or Linked Data Value comparator, generate a Data Trace Match packet.

For a Data Address With Value comparator, generate a Data Trace Data Value packet.

##### 0b11

For a Data Address Limit comparator, generate a Data Trace Data Address packet.

For a Cycle Counter, Instruction Address Limit, or Data Address comparator, generate a Data Trace PC Value packet.

For a Data Address With Value comparator, generate both a Data Trace PC Value packet and a Data Trace Data Value packet.

If the Main Extension is not implemented, the values 0b10 and 0b11 are reserved.

This field resets to an UNKNOWN value on a Cold reset.

#### MATCH, bits [3:0]

Match type. Controls the type of match generated by this comparator.

The possible values of this field are:

##### 0b0000

Disabled. Never generates a match.

##### 0b0001

Cycle Counter. Matches if DWT\_CYCCNT equals the comparator value. The comparator is checked each time DWT\_CYCCNT is written to, directly or indirectly.

Only supported if the Main Extension is implemented, DWT\_FUNCTION< $n$ >.ID<0> == 1 and DWT\_CTRL.NOCYCCNT == 0.

**0b0010**

Instruction Address. If not linked to, an instruction matches if the address of the first byte of the instruction matches the comparator address.

Only supported if DWT\_FUNCTION<n>.ID<1> == 1.

**0b0011**

Instruction Address Limit. When comparator <n-1> is configured as Instruction Address (0b0010) an access will generate a match if the first byte of the instruction lies between the lower address (specified by the comparator <n-1>) and the limit address (specified by this comparator, <n>). Both the lower address and the limit address are inclusive to the address range.

It is **UNPREDICTABLE** whether or not a match is generated on an access by any comparator when either:

- Comparator <n-1> is configured as a comparator type which is neither Instruction Address (0b0010) nor Disabled (0b0000).
- The lower address is unsigned greater-than-or-equal-to the limit address.

If comparator <n-1> is Disabled (0b0000) no access will generate a match for this comparator.

Only supported if DWT\_FUNCTION<n>.ID<4> == 1 and DWT\_FUNCTION<n>.ID<1> == 1.

**0b0100**

Data Address. If not linked to by a Data Address Limit comparator, an access matches if any accessed byte lies between the comparator address and a limit defined by the DATAVSIZE field. Supported for all comparators.

**0b0101**

Data Address, writes. As 0b0100, except that only write accesses generate a match.

**0b0110**

Data Address, reads. As 0b0100, except that only read accesses generate a match.

**0b0111**

Data Address Limit. An access will generate a match when all of the following are true:

- Comparator <n-1> is configured as one of Data Address (0b01xx, not 0b0111) or Data Address With Value (0b11xx, not 0b1111).
- Any accessed byte lies between the lower address (specified by comparator <n-1>) and the limit address (specified by this comparator <n>).
- Both the lower address and limit address are inclusive to the range.

It is **UNPREDICTABLE** whether or not a match is generated on an access by any comparator when either:

- Comparator <n-1> is not configured as one of Data Address (0b01xx, not 0b0111) nor Data Address With Value (0b11xx, not 0b1111).
- The lower address is unsigned greater-than-or-equal-to the limit address.

If comparator <n-1> is configured as Disabled (0b0000) no access will generate a match for this comparator.

Only supported if DWT\_FUNCTION<n>.ID<4> == 1.

**0b1000**

Data Value. An access matches if the value accessed matches the comparator value.

Only supported if the Main Extension is implemented and DWT\_FUNCTION<n>.ID<2> == 1.

**0b1001**

Data Value, writes. As 0b1000, except that only write accesses generate a match.

**0b1010**

Data Value, reads. As 0b1000, except that only read accesses generate a match.

**0b1011**

Linked Data Value. An access will generate a match when all of the following are true:

- Comparator  $\langle n-1 \rangle$  is configured as Data Address (0b01xx, not 0b0111), or Data Address With Value (0b11xx, not 0b1111).
- DATAVSIZE for the two comparators  $\langle n \rangle$  and  $\langle n-1 \rangle$  are equal.
- The value accessed matches the comparator value specified by comparator  $\langle n \rangle$ .
- Any accessed byte lies between the lower address (specified by comparator  $\langle n-1 \rangle$ ) and limit defined by the DATAVSIZE field.
- Both the lower address and the limit address are inclusive to the range.

It is **UNPREDICTABLE** whether or not any comparator generates a match if any of the following are true:

- Comparator  $\langle n-1 \rangle$  is not configured as one of Data Address (0b01xx, not 0b0111), Data Address With Value (0b11xx, not 0b1111), or Disabled (0b0000).
- DATAVSIZE for the two comparators  $\langle n-1 \rangle$  and  $\langle n \rangle$  are not equal.

If comparator  $\langle n-1 \rangle$  is programmed to Disabled (0b0000) no access will generate a match for this comparator.

Only supported if the Main Extension is implemented and  $\text{DWT\_FUNCTION}\langle n \rangle.\text{ID}\langle 4 \rangle == 1$  and  $\text{DWT\_FUNCTION}\langle n \rangle.\text{ID}\langle 2 \rangle == 1$ .

**0b1100**

Data Address With Value. As 0b01xx, except that the data value is traced.

Supported for the first four comparators only, and only if  $\text{DWT\_CTRL}.\text{NOTRCPKT} == 0$  and ITM is also implemented.

**0b1101**

Data Address With Value, writes. As 0b1100, except that only write accesses generate a match.

**0b1110**

Data Address With Value, reads. As 0b1100, except that only read accesses generate a match.

Any value not supported by the comparator is reserved. For a pair of linked comparators,  $\langle n \rangle$  and  $\langle n-1 \rangle$ ,  $\text{DWT\_FUNCTION}\langle n-1 \rangle.\text{MATCH}[1:0]$  determines the matching access types.

This field resets to zero on a Cold reset.

## D1.2.64 DWT\_LAR, DWT Software Lock Access Register

The DWT\_LAR characteristics are:

### Purpose

Provides CoreSight Software Lock control for the DWT, see the *Arm® CoreSight™ Architecture Specification* for details.

### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

This register is RAZ/WI if accessed via the debugger, regardless of DAUTHCTRL.UIDAPEN (either bank). It is **IMPLEMENTATION DEFINED** whether a DAP error is generated.

### Configurations

Present only if CoreSight identification is implemented.

This register is **RES0** if CoreSight identification is not implemented.

Present only if the DWT is implemented.

This register is **RES0** if the DWT is not implemented.

Present only if the optional Software Lock is implemented.

This register is RAZ/WI if the Software Lock is not implemented.

### Attributes

32-bit write-only register located at 0xE0001FB0.

This register is not banked between Security states.

## Field descriptions

The DWT\_LAR bit assignments are:

### KEY, bits [31:0]

Lock Access control.

Writing the key value 0xC5ACCE55 to this field unlocks the lock, enabling write accesses to the registers of this component through a memory-mapped interface.

Writing any other value to this register locks the lock, disabling write accesses to the registers of this component through a memory mapped interface.

## D1.2.65 DWT\_LSR, DWT Software Lock Status Register

The DWT\_LSR characteristics are:

### Purpose

Provides CoreSight Software Lock status information for the DWT, see the *Arm® CoreSight™ Architecture Specification* for details.

### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

This register is RAZ/WI if accessed via the debugger, regardless of DAUTHCTRL.UIDAPEN (either bank). It is **IMPLEMENTATION DEFINED** whether a DAP error is generated.

### Configurations

Present only if CoreSight identification is implemented.

This register is **RES0** if CoreSight identification is not implemented.

Present only if the DWT is implemented.

This register is **RES0** if the DWT is not implemented.

Present only if the optional Software Lock is implemented.

This register is RAZ/WI if the Software Lock is not implemented.

### Attributes

32-bit read-only register located at 0xE0001FB4.

This register is not banked between Security states.

## Field descriptions

The DWT\_LSR bit assignments are:

### Bits [31:3]

Reserved, **RES0**.

### nTT, bit [2]

Not thirty-two bit. See the *Arm® CoreSight™ Architecture Specification*.

This bit reads as zero.

### SLK, bit [1]

Software Lock status. See the *Arm® CoreSight™ Architecture Specification*.

The possible values of this bit are:

**0**

Lock clear. Software writes are permitted to the registers of this component.

**1**

Lock set. Software writes to the registers of this component are ignored, and reads have no side effects.

For a debugger read of this register, or when the Software Lock is not implemented, this bit is [RES0](#).

This bit resets to one on a Cold reset.

**SLI, bit [0]**

Software Lock implemented. See the *Arm® CoreSight™ Architecture Specification*.

The possible values of this bit are:

**0**

Software Lock not implemented or debugger access.

**1**

Software Lock is implemented and software access.

For a debugger read of this register, or when the Software Lock is not implemented, this bit is RAZ.

This bit reads as an [IMPLEMENTATION DEFINED](#) value.

## D1.2.66 DWT\_LSUCNT, DWT LSU Count Register

The DWT\_LSUCNT characteristics are:

### Purpose

Increments on the additional cycles required to execute all load or store instructions.

### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

### Configurations

Present only if the Main Extension is implemented.

This register is **RES0** if the Main Extension is not implemented.

Present only if the DWT is implemented.

This register is **RES0** if the DWT is not implemented.

Present only if DWT\_CTRL.NOPRFCNT == 0.

This register is **RES0** if DWT\_CTRL.NOPRFCNT == 1.

### Attributes

32-bit read/write register located at 0xE0001014.

This register is not banked between Security states.

## Field descriptions

The DWT\_LSUCNT bit assignments are:

### RESERVED, bits [31:8]

Reserved, RAZ/WI

### LSUCNT, bits [7:0]

Load-store overhead counter.

Counts one on each cycle when all of the following are true:

- DWT\_CTRL.LSUEVTENA == 1 and DEMCR.TRCENA == 1.
- No instruction is executed, see DWT\_CPICNT.
- No exception-entry or exception-exit operation is in progress, see DWT\_EXCCNT.
- A load-store operation is in progress.
- Either SecureNoninvasiveDebugAllowed() == TRUE, or NS-Req for the operation is set to Non-secure and NoninvasiveDebugAllowed() == TRUE.

Initialized to zero when the counter is disabled and DWT\_CTRL.LSUEVTENA is written with 1. An Event Counter packet is emitted on counter overflow.

This field resets to an **UNKNOWN** value on a Cold reset.

## D1.2.67 DWT\_PCSR, DWT Program Counter Sample Register

The DWT\_PCSR characteristics are:

### Purpose

Samples the current value of the Program Counter.

### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

If the Main Extension is not implemented then it is **IMPLEMENTATION DEFINED** whether this register is accessible only to the debugger and **RES0** for software. Otherwise the register is accessible to the debugger and software.

### Configurations

Present only if the DWT is implemented.

This register is **RES0** if the DWT is not implemented.

### Attributes

32-bit read-only register located at 0xE000101C.

This register is not banked between Security states.

## Field descriptions

The DWT\_PCSR bit assignments are:

### EIASAMPLE, bits [31:0]

Executed instruction address sample. Recently executed instruction address sample value.

The possible values of this field are:

#### 0xFFFFFFFF

One of the following is true:

- The PE is halted in Debug state.
- The Security Extension is implemented, the sampled instruction was executed in Secure state, and SecureNoninvasiveDebugAllowed() == FALSE.
- NoninvasiveDebugAllowed() == FALSE.
- DEMCR.TRCENA == 0.
- The address of a recently-executed instruction is not available.

#### Not 0xFFFFFFFF

Instruction address of a recently executed instruction. Bit [0] of the sample instruction address is 0.

The conditions when the address of a recently-executed instruction is not available are **IMPLEMENTATION DEFINED**.

## D1.2.68 DWT\_PIDR0, DWT Peripheral Identification Register 0

The DWT\_PIDR0 characteristics are:

### Purpose

Provides CoreSight Unique Component Identifier information for the DWT.

### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

If the Main Extension is not implemented then it is **IMPLEMENTATION DEFINED** whether this register is accessible only to the debugger and **RES0** for software. Otherwise the register is accessible to the debugger and software.

### Configurations

Present only if CoreSight identification is implemented.

This register is **RES0** if CoreSight identification is not implemented.

Present only if the DWT is implemented.

This register is **RES0** if the DWT is not implemented.

### Attributes

32-bit read-only register located at 0xE0001FE0.

This register is not banked between Security states.

## Field descriptions

The DWT\_PIDR0 bit assignments are:

### Bits [31:8]

Reserved, **RES0**.

### PART\_0, bits [7:0]

Part number bits [7:0]. See the *Arm® CoreSight™ Architecture Specification*.

This field reads as an **IMPLEMENTATION DEFINED** value.

## D1.2.69 DWT\_PIDR1, DWT Peripheral Identification Register 1

The DWT\_PIDR1 characteristics are:

### Purpose

Provides CoreSight Unique Component Identifier information for the DWT.

### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

If the Main Extension is not implemented then it is **IMPLEMENTATION DEFINED** whether this register is accessible only to the debugger and **RES0** for software. Otherwise the register is accessible to the debugger and software.

### Configurations

Present only if CoreSight identification is implemented.

This register is **RES0** if CoreSight identification is not implemented.

Present only if the DWT is implemented.

This register is **RES0** if the DWT is not implemented.

### Attributes

32-bit read-only register located at 0xE0001FE4.

This register is not banked between Security states.

## Field descriptions

The DWT\_PIDR1 bit assignments are:

### Bits [31:8]

Reserved, **RES0**.

### DES\_0, bits [7:4]

JEP106 identification code bits [3:0]. See the *Arm® CoreSight™ Architecture Specification*.

This field reads as an **IMPLEMENTATION DEFINED** value.

### PART\_1, bits [3:0]

Part number bits [11:8]. See the *Arm® CoreSight™ Architecture Specification*.

This field reads as an **IMPLEMENTATION DEFINED** value.

## D1.2.70 DWT\_PIDR2, DWT Peripheral Identification Register 2

The DWT\_PIDR2 characteristics are:

### Purpose

Provides CoreSight Unique Component Identifier information for the DWT.

### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

If the Main Extension is not implemented then it is **IMPLEMENTATION DEFINED** whether this register is accessible only to the debugger and **RES0** for software. Otherwise the register is accessible to the debugger and software.

### Configurations

Present only if CoreSight identification is implemented.

This register is **RES0** if CoreSight identification is not implemented.

Present only if the DWT is implemented.

This register is **RES0** if the DWT is not implemented.

### Attributes

32-bit read-only register located at 0xE0001FE8.

This register is not banked between Security states.

## Field descriptions

The DWT\_PIDR2 bit assignments are:

### Bits [31:8]

Reserved, **RES0**.

### REVISION, bits [7:4]

Component revision. See the *Arm® CoreSight™ Architecture Specification*.

This field reads as an **IMPLEMENTATION DEFINED** value.

### JEDEC, bit [3]

JEDEC assignee value is used. See the *Arm® CoreSight™ Architecture Specification*.

This bit reads as one.

### DES\_1, bits [2:0]

JEP106 identification code bits [6:4]. See the *Arm® CoreSight™ Architecture Specification*.

This field reads as an **IMPLEMENTATION DEFINED** value.

## D1.2.71 DWT\_PIDR3, DWT Peripheral Identification Register 3

The DWT\_PIDR3 characteristics are:

### Purpose

Provides CoreSight Unique Component Identifier information for the DWT.

### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

If the Main Extension is not implemented then it is **IMPLEMENTATION DEFINED** whether this register is accessible only to the debugger and **RES0** for software. Otherwise the register is accessible to the debugger and software.

### Configurations

Present only if CoreSight identification is implemented.

This register is **RES0** if CoreSight identification is not implemented.

Present only if the DWT is implemented.

This register is **RES0** if the DWT is not implemented.

### Attributes

32-bit read-only register located at 0xE0001FEC.

This register is not banked between Security states.

## Field descriptions

The DWT\_PIDR3 bit assignments are:

### Bits [31:8]

Reserved, **RES0**.

### REVAND, bits [7:4]

RevAnd. See the Arm® CoreSight™ Architecture Specification.

This field reads as an **IMPLEMENTATION DEFINED** value.

### CMOD, bits [3:0]

Customer Modified. See the Arm® CoreSight™ Architecture Specification.

This field reads as an **IMPLEMENTATION DEFINED** value.

## D1.2.72 DWT\_PIDR4, DWT Peripheral Identification Register 4

The DWT\_PIDR4 characteristics are:

### Purpose

Provides CoreSight Unique Component Identifier information for the DWT.

### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

If the Main Extension is not implemented then it is **IMPLEMENTATION DEFINED** whether this register is accessible only to the debugger and **RES0** for software. Otherwise the register is accessible to the debugger and software.

### Configurations

Present only if CoreSight identification is implemented.

This register is **RES0** if CoreSight identification is not implemented.

Present only if the DWT is implemented.

This register is **RES0** if the DWT is not implemented.

### Attributes

32-bit read-only register located at 0xE0001FD0.

This register is not banked between Security states.

## Field descriptions

The DWT\_PIDR4 bit assignments are:

### Bits [31:8]

Reserved, **RES0**.

### SIZE, bits [7:4]

4KB count. See the *Arm® CoreSight™ Architecture Specification*.

This field reads as zero.

### DES\_2, bits [3:0]

JEP106 continuation code. See the *Arm® CoreSight™ Architecture Specification*.

This field reads as an **IMPLEMENTATION DEFINED** value.

### D1.2.73 DWT\_PIDR5, DWT Peripheral Identification Register 5

The DWT\_PIDR5 characteristics are:

#### Purpose

Provides CoreSight Unique Component Identifier information for the DWT.

#### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

If the Main Extension is not implemented then it is **IMPLEMENTATION DEFINED** whether this register is accessible only to the debugger and **RES0** for software. Otherwise the register is accessible to the debugger and software.

#### Configurations

Present only if CoreSight identification is implemented.

This register is **RES0** if CoreSight identification is not implemented.

Present only if the DWT is implemented.

This register is **RES0** if the DWT is not implemented.

#### Attributes

32-bit read-only register located at 0xE0001FD4.

This register is not banked between Security states.

### Field descriptions

The DWT\_PIDR5 bit assignments are:

#### Bits [31:0]

Reserved, **RES0**.

## D1.2.74 DWT\_PIDR6, DWT Peripheral Identification Register 6

The DWT\_PIDR6 characteristics are:

### Purpose

Provides CoreSight Unique Component Identifier information for the DWT.

### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

If the Main Extension is not implemented then it is **IMPLEMENTATION DEFINED** whether this register is accessible only to the debugger and **RES0** for software. Otherwise the register is accessible to the debugger and software.

### Configurations

Present only if CoreSight identification is implemented.

This register is **RES0** if CoreSight identification is not implemented.

Present only if the DWT is implemented.

This register is **RES0** if the DWT is not implemented.

### Attributes

32-bit read-only register located at 0xE0001FD8.

This register is not banked between Security states.

## Field descriptions

The DWT\_PIDR6 bit assignments are:

### Bits [31:0]

Reserved, **RES0**.

## D1.2.75 DWT\_PIDR7, DWT Peripheral Identification Register 7

The DWT\_PIDR7 characteristics are:

### Purpose

Provides CoreSight Unique Component Identifier information for the DWT.

### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

If the Main Extension is not implemented then it is **IMPLEMENTATION DEFINED** whether this register is accessible only to the debugger and **RES0** for software. Otherwise the register is accessible to the debugger and software.

### Configurations

Present only if CoreSight identification is implemented.

This register is **RES0** if CoreSight identification is not implemented.

Present only if the DWT is implemented.

This register is **RES0** if the DWT is not implemented.

### Attributes

32-bit read-only register located at 0xE0001FDC.

This register is not banked between Security states.

### Field descriptions

The DWT\_PIDR7 bit assignments are:

### Bits [31:0]

Reserved, **RES0**.

## D1.2.76 DWT\_SLEEPCNT, DWT Sleep Count Register

The DWT\_SLEEPCNT characteristics are:

### Purpose

Counts the total number of cycles that the processor is sleeping.

### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

### Configurations

Present only if the Main Extension is implemented.

This register is **RES0** if the Main Extension is not implemented.

Present only if the DWT is implemented.

This register is **RES0** if the DWT is not implemented.

Present only if DWT\_CTRL.NOPRFCNT == 0.

This register is **RES0** if DWT\_CTRL.NOPRFCNT == 1.

### Attributes

32-bit read/write register located at 0xE0001010.

This register is not banked between Security states.

## Field descriptions

The DWT\_SLEEPCNT bit assignments are:

### RESERVED, bits [31:8]

Reserved, RAZ/WI

### SLEEPCNT, bits [7:0]

Sleep counter.

Counts one on each cycle when all of the following are true:

- DWT\_CTRL.SLEEPEVTENA == 1 and DEMCR.TRCENA == 1.
- No instruction is executed, see DWT\_CPICNT.
- No load-store operation is in progress, see DWT\_LSUCNT.
- No exception-entry or exception-exit operation is in progress, see DWT\_EXCCNT.
- The PE is in a power-saving mode.
- Either SecureNoninvasiveDebugAllowed() == TRUE, or the PE is in Non-secure state and NoninvasiveDebugAllowed() == TRUE.

Power-saving modes include WFI, WFE, and Sleep-on-exit.

All power-saving features are **IMPLEMENTATION DEFINED** and therefore when this counter counts is **IMPLEMENTATION DEFINED**. In particular, it is **IMPLEMENTATION DEFINED** whether the counter increments if the PE is in a power-saving mode and SCR.SLEEPDEEP is set.

Initialized to zero when the counter is disabled and DWT\_CTRL.SLEEPEVTENA is written with 1. An Event Counter packet is emitted on counter overflow.

This field resets to an **UNKNOWN** value on a Cold reset.

**Note**

Arm recommends that this counter counts all cycles when the PE is sleeping and SCR.SLEEPDEEP is clear, regardless of whether a WFI or WFE instruction, or Sleep-on-exit, caused the entry to the power-saving mode.

## D1.2.77 DWT\_VMASKn, DWT Comparator Value Mask Register, n = 0 - 14

The DWT\_VMASK{0..14} characteristics are:

### Purpose

Provides a mask value for use by watchpoint comparator *n* when comparing data values.

### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

If the Main Extension is not implemented then it is **IMPLEMENTATION DEFINED** whether this register is accessible only to the debugger and **RES0** for software. Otherwise the register is accessible to the debugger and software.

### Configurations

Present only if the DWT is implemented.

This register is **RES0** if the DWT is not implemented.

Present only if the DWT implements DWT architecture version 2.1 or later.

This register is **RES0** if the DWT implements DWT architecture version 2.0 or earlier.

### Attributes

32-bit read/write register located at  $0 \times \text{E000102C} + 16n$ .

This register is not banked between Security states.

### Field descriptions

The DWT\_VMASK{0..14} bit assignments are:

**When DWT\_FUNCTIONn.MATCH != 0b10xx:**

**When DWT\_FUNCTIONn.MATCH == 0b10xx:**

**Bits [31:0], when DWT\_FUNCTIONn.MATCH != 0b10xx**

Reserved, **RES0**.

**VMASK, bits [31:0], when DWT\_FUNCTIONn.MATCH == 0b10xx**

Data value mask. Mask value for use in the comparison with load or store data.

The possible values of each bit are:

**0**

The comparison matches only if DWT\_COMPn[m] matches bit [m] of the candidate data value.

**1**

The comparison ignores bit [m] of the candidate data value. If DWT\_COMPn[m] is not set to zero, the result of the comparison is **UNPREDICTABLE**.

For halfword or word comparisons, the mask is in little-endian order. That is, the least significant byte of this register masks the byte targeting the lowest address in memory.

For byte or halfword comparisons, if the value of the byte or halfword is not replicated across all byte or halfword lanes, the value used for the comparison is **UNKNOWN**.

This field resets to an **UNKNOWN** value on a Cold reset.

## D1.2.78 EPSR, Execution Program Status Register

The EPSR characteristics are:

### Purpose

Holds Execution state bits.

### Usage constraints

Privileged access only. Unprivileged access is RAZ/WI, unless otherwise stated.

### Configurations

This register is always implemented.

### Attributes

32-bit read/write special-purpose register.

This register is not banked between Security states.

## Field descriptions

The EPSR bit assignments are:

When {EPSR[26:25], EPSR[11:10]} != 0:

When {EPSR[26:25], EPSR[11:10]} == 0, and a multicycle load or store instruction is in progress:

When {EPSR[26:25], EPSR[11:10]} == 0, and beat-wise vector instructions are in progress:

### Bits [31:27]

Reserved, [RES0](#).

### T, bit [24]

T32 state bit. Determines the current instruction set state.

The possible values of this bit are:

**0**

Execution of any instruction generates an INVSTATE UsageFault.

**1**

Instructions decoded as T32 instructions.

This bit resets to an [UNKNOWN](#) value on a Warm reset.

### Bits [23:22]

Reserved, [RES0](#).

**B, bit [21]**

Branch target identification active. Unless otherwise stated, when this bit is set the next executed instruction must be a BTI clearing instruction otherwise an INVSTATE UsageFault is generated.

The possible values of this bit are:

**0**

Branch target identification inactive.

**1**

Branch target identification active.

If the PACBTI Extension is not implemented, this bit is [RES0](#).

This bit resets to zero on a Warm reset.

**Bits [20:16]**

Reserved, [RES0](#).

**IT, bits [15:10, 26:25]** , when [{EPSR[26:25], EPSR[11:10]} != 0]

If-then flags. This field encodes the current condition and position in an IT block sequence.

The field IT[7:0] is equivalent to EPSR[15:10,26:25].

If the Main Extension is not implemented, this field is [RES0](#).

This field resets to zero on a Warm reset.

**ICI, bits [26:25, 15:10]** , when [{EPSR[26:25], EPSR[11:10]} == 0, and a multicycle load or store instruction is in progress]

Interrupt continuation flags. This field encodes information on the outstanding register list for an interrupted exception-continuable multicycle load or store instruction.

The field ICI[7:0] is equivalent to EPSR[26:25,15:10].

If the Main Extension is not implemented, this field is [RES0](#).

This field resets to zero on a Warm reset.

**ECI, bits [26:25, 11:10, 15:12]** , when [{EPSR[26:25], EPSR[11:10]} == 0, and beat-wise vector instructions are in progress]

Exception continuation flags for beat-wise vector instructions. This field encodes which beats of the in-flight instructions have completed.

The possible values of this field are:

**0b00000000**

No completed beats.

**0b00000001**

Completed beats: A0.

**0b00000010**

Completed beats: A0 A1.

**0b00000011**

Reserved.

**0b00000100**

Completed beats: A0 A1 A2.

**0b00000101**

Completed beats: A0 A1 A2 B0.

**0b0000011X**

Reserved.

**0b00001xxx**

Reserved.

In the enumeration above the letters correspond to the instructions at the return address and beyond, whilst the numbers correspond to the beats of those instructions that have been completed. For example, the sequence A0 A1 A2 B0 means the first three beats of the instruction at the return address, plus the first beat of the instruction at the return address +4 have been completed. The field ECI[7:0] is equivalent to EPSR[26:25,11:10,15:12].

This field resets to zero on a Warm reset.

**Bits [9:0]**

Reserved, [RES0](#).

## D1.2.79 ERRADDRn, Error Record Address Register, n = 0 - 55

The ERRADDR{0..55} characteristics are:

### Purpose

If an error has an associated address, this must be written to the address register when the error is recorded. It is **IMPLEMENTATION DEFINED** how the recorded addresses map to the software-visible physical addresses. Software might have to reconstruct the actual physical addresses using the identity of the node and knowledge of the system. Ignores writes if ERR<n>STATUS.AV is set to 1.

### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

If AIRCR.BFHFNMINS is zero this register is RAZ/WI from Non-secure state.

### Configurations

Present only if version Armv8.1 of the architecture and RAS are implemented.

This register is **RES0** if RAS is not implemented.

### Attributes

32-bit read/write register located at  $0xE0005018 + 64n$ .

This register is not banked between Security states.

From Armv8.1-M onwards it is **IMPLEMENTATION DEFINED** whether a debugger write to this register is ignored when the PE is not in Debug state.

## Field descriptions

The ERRADDR{0..55} bit assignments are:

### PADDR, bits [31:0]

Address, bits [31:0]. Unimplemented bits are **RES0**.

This field is preserved on an Error Recovery reset.

This field resets to ERR\_RESET on an Error Recovery reset.

### D1.2.80 ERRADDR2n, Error Record Address 2 Register, n = 0 - 55

The ERRADDR2{0..55} characteristics are:

## Purpose

If an error has an associated address, this must be written to the address register when the error is recorded. It is **IMPLEMENTATION DEFINED** how the recorded addresses map to the software-visible physical addresses. Software might have to reconstruct the actual physical addresses using the identity of the node and knowledge of the system. Ignores writes if `ERR<n>STATUS.AV` is set to 1.

## Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

If AIRCR.BFHFNMIN is zero this register is RAZ/WI from Non-secure state.

## Configurations

Present only if version Armv8.1 of the architecture and RAS are implemented.

This register is **RES0** if RAS is not implemented.

## Attributes

32-bit read/write register located at 0xE000501C + 64n.

This register is not banked between Security states.

From Armv8.1-M onwards it is **IMPLEMENTATION DEFINED** whether a debugger write to this register is ignored when the PE is not in Debug state.

## Field descriptions

The ERRADDR2{0..55} bit assignments are:

**NS, bit [31]**

Non-secure attribute.

The possible values of this bit are:

0

The address is Secure.

**1**

The address is Non-secure.

It is **IMPLEMENTATION DEFINED** whether this bit is read-only or read/write.

This bit is preserved on an Error Recovery reset.

This bit resets to ERR RESET on an Error Recovery reset.

**SI, bit [30]**

Secure Incorrect. Indicates whether the NS bit is valid.

The possible values of this bit are:

**O**

The NS bit is correct. That is, it matches the programmers' view of the Non-secure attribute for this recorded location.

**1**

The NS bit might not be correct, and might not match the programmers' view of the Non-secure attribute for the recorded location.

It is **IMPLEMENTATION DEFINED** whether this bit is read-only or read/write.

This bit is preserved on an Error Recovery reset.

This bit resets to ERR\_RESET on an Error Recovery reset.

**AI, bit [29]**

Address Incomplete or incorrect. Indicates whether the PADDR field in ERR<n>ADDR and ERR<n>ADDR2 is a valid physical address.

The possible values of this bit are:

**0**

The PADDR field is a valid physical address. That is, it matches the programmers' view of the physical address for this recorded location.

**1**

The PADDR field might not be a valid physical address, and might not match the programmers' view of the physical address for the recorded location.

It is **IMPLEMENTATION DEFINED** whether this bit is read-only or read/write.

This bit is preserved on an Error Recovery reset.

This bit resets to ERR\_RESET on an Error Recovery reset.

**Bit [28]**

Reserved, **RES0**.

**Bits [27:24]**

Reserved, **RES0**.

**PADDR, bits [23:0]**

Address, bits [55:32]. Unimplemented bits are **RES0**.

This field is preserved on an Error Recovery reset.

This field resets to ERR\_RESET on an Error Recovery reset.

## D1.2.81 ERRCTRLn, Error Record Control Register, n = 0 - 55

The ERRCTRL{0..55} characteristics are:

### Purpose

The error control register contains enable bits for the node that writes to this record.

### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

If AIRCR.BFHFNMINS is zero this register is RAZ/WI from Non-secure state.

### Configurations

Present only if version Armv8.1 of the architecture and RAS are implemented.

This register is **RES0** if RAS is not implemented.

### Attributes

32-bit read/write register located at  $0xE0005008 + 64n$ .

This register is not banked between Security states.

From Armv8.1-M onwards it is **IMPLEMENTATION DEFINED** whether a debugger write to this register is ignored when the PE is not in Debug state.

## Field descriptions

The ERRCTRL{0..55} bit assignments are:

### Bits [31:14]

Reserved, **RES0**.

### CI, bit [13]

Critical error interrupt enable. When enabled the critical error interrupt is generated for a critical error condition.

The possible values of this bit are:

**0**

Critical error interrupt not generated for critical errors. Critical errors are treated as Uncontained errors.

**1**

Critical error interrupt generated for critical errors.

This bit is **RES0** if the node does not support this control.

This bit is preserved on an Error Recovery reset.

This bit resets to ERR\_RESET on an Error Recovery reset.

### Bits [12:11]

Reserved, **RES0**.

### DUI, bit [10]

Enable error recovery interrupt enable for deferred errors. When enabled the error recovery interrupt is generated for all detected Deferred errors.

The possible values of this bit are:

**0**

Error recovery interrupt not generated for deferred errors.

**1**

Error recovery interrupt generated for deferred errors.

The interrupt is generated even if the error syndrome is discarded because the error record already records a higher priority error. This bit is **RES0** if the node does not support this control.

**Bit [9]**

Reserved, **RES0**.

This bit is preserved on an Error Recovery reset.

This bit resets to ERR\_RESET on an Error Recovery reset.

**CFI, bit [8]**

Enable fault handling interrupt for corrected errors. When enabled, if the node implements a Corrected error counter, then the fault handling interrupt is generated when the counter overflows and the overflow bit is set. Otherwise the fault handling interrupt is also generated for all detected Corrected errors.

The possible values of this bit are:

**0**

Fault handling interrupt not generated for corrected errors.

**1**

Fault handling interrupt generated for corrected errors.

The interrupt is generated even if the error syndrome is discarded because the error record already records a higher priority error. This bit is **RES0** if the node does not support this control.

This bit is preserved on an Error Recovery reset.

This bit resets to ERR\_RESET on an Error Recovery reset.

**Bits [7:5]**

Reserved, **RES0**.

**UE, bit [4]**

Enable in-band uncorrected error reporting. When enabled, responses to transactions that detect an uncorrected error that cannot be deferred are signaled as a detected error (external abort).

The possible values of this bit are:

**0**

External abort response for uncorrected errors disabled.

**1**

External abort response for uncorrected errors enabled.

This bit is **RES0** if the node does not support this control.

This bit is preserved on an Error Recovery reset.

This bit resets to ERR\_RESET on an Error Recovery reset.

**FI, bit [3]**

Enable fault handling interrupt.

When enabled, the fault handling interrupt is generated for all detected Deferred errors and Uncorrected errors.

If the fault handling interrupt for corrected errors control is not implemented then:

- If the node implements a Corrected error counter then the fault handling interrupt is also generated when the counter overflows and the overflow bit is set.
- Otherwise the fault handling interrupt is also generated for all detected Corrected errors.

The possible values of this bit are:

**0**

Fault handling interrupt disabled.

**1**

Fault handling interrupt enabled.

This bit is **RES0** if the node does not support this control.

This bit is preserved on an Error Recovery reset.

This bit resets to ERR\_RESET on an Error Recovery reset.

#### **UI, bit [2]**

Enable error recovery interrupt. Uncorrected error recovery interrupt enable. When enabled, the error recovery interrupt is generated for all detected Uncorrected errors that are not deferred.

The possible values of this bit are:

**0**

Error recovery interrupt disabled.

**1**

Error recovery interrupt enabled.

The interrupt is generated even if the error syndrome is discarded because the error record already records a higher priority error. This bit is **RES0** if the node does not support this control.

This bit is preserved on an Error Recovery reset.

This bit resets to ERR\_RESET on an Error Recovery reset.

#### **Bit [1]**

Reserved for **IMPLEMENTATION DEFINED** controls. Must permit SBZP write policy for software. This bit reads as an **IMPLEMENTATION DEFINED** value and writes to this bit have **IMPLEMENTATION DEFINED** behavior.

Reserved, **RES0**.

#### **ED, bit [0]**

Error reporting and logging enable. When disabled, the node behaves as if error detection and correction are disabled, and no errors are recorded or signaled by the node. Arm recommends that, when disabled, correct error detection and correction codes are written for writes, unless disabled by an **IMPLEMENTATION DEFINED** control for error injection.

The possible values of this bit are:

**0**

Error reporting disabled.

**1**

Error reporting enabled.

It is **IMPLEMENTATION DEFINED** whether the node fully disables error detection and correction when reporting is disabled. That is, even with error reporting disabled, the node might continue to silently correct errors. Uncorrectable errors might result in corrupt data being silently propagated by the node. This bit is **RES1** if the node does not support this control.

This bit is preserved on an Error Recovery reset.

This bit resets to zero on a Cold reset.

## D1.2.82 ERRDEVID, Error Record Device ID Register

The ERRDEVID characteristics are:

### Purpose

Defines the number of error records that can be accessed through the Memory-mapped registers.

### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

### Configurations

Present only if version Armv8.1 of the architecture and RAS are implemented.

This register is **RES0** if RAS is not implemented.

### Attributes

32-bit read-only register located at 0xE0005FC8.

This register is not banked between Security states.

## Field descriptions

The ERRDEVID bit assignments are:

### Bits [31:16]

Reserved, **RES0**.

### NUM, bits [15:0]

Number of implemented error record indexes.

Highest numbered index of the error records in this group, plus one. Each implemented record is owned by a node. A node might own multiple records.

This manual describes the memory-mapped view of a group with up to 56 records, the most that can be contained in a 4KB component, meaning the highest value for this field is 56.

This field reads as an **IMPLEMENTATION DEFINED** value.

### D1.2.83 ERRFRn, Error Record Feature Register, n = 0 - 55

The ERRFR{0..55} characteristics are:

## Purpose

Identifies the features implemented by the associated record  $n$ , and of those features that are software programmable.

## Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

If AIRCR.BFHFNMINS is zero this register is RAZ/WI from Non-secure state.

## Configurations

Present only if version Armv8.1 of the architecture and RAS are implemented.

This register is **RES0** if RAS is not implemented.

## Attributes

32-bit read-only register located at  $0xE0005000 + 64n$ .

This register is not banked between Security states.

From Armv8.1-M onwards it is **IMPLEMENTATION DEFINED** whether a debugger write to this register is ignored when the PE is not in Debug state.

## Field descriptions

The ERRFR{0..55} bit assignments are:

|      |  |    |  |    |    |      |    |     |    |     |    |    |    |     |  |     |    |    |   |    |   |    |   |      |   |    |   |
|------|--|----|--|----|----|------|----|-----|----|-----|----|----|----|-----|--|-----|----|----|---|----|---|----|---|------|---|----|---|
| 31   |  | 24 |  | 23 | 22 | 21   | 20 | 19  | 18 | 17  | 16 | 15 | 14 | 12  |  | 11  | 10 | 9  | 8 | 7  | 6 | 5  | 4 | 3    | 2 | 1  | 0 |
| RES0 |  |    |  | CI |    | RES0 |    | CEO |    | DUI |    | RP |    | CEC |  | CFI |    | UE |   | FI |   | UI |   | RES0 |   | ED |   |

**Bits [31:24]**

Reserved, RES0.

**CI, bits [23:22]**

Critical Error Interrupt. Indicates whether the critical error interrupt and associated controls are implemented.

The possible values of this field are:

0b00

Does not support feature.

0b01

Feature always enabled.

0b10

Feature is controllable.

All other values are reserved.

This field reads as an IMPLEMENTATION DEFINED value.

**Bits [21:20]**

Reserved, RES0.

**CEO, bits [19:18]**

Corrected Error overwrite. Indicates the behavior when a second Corrected error is detected after a first Corrected error has been recorded by the node.

The possible values of this field are:

**0b00**

Count Corrected error if a counter is implemented. Keep the previous error syndrome. If the counter overflows, or no counter is implemented then ERR<n>STATUS.OF is set to 1.

**0b01**

Count Corrected error. If ERR<n>STATUS.OF == 1 before the Corrected error is counted then keep the previous syndrome. Otherwise the previous syndrome is overwritten. If the counter overflows then ERR<n>STATUS.OF is set to 1.

All other values are reserved.

This field reads as an **IMPLEMENTATION DEFINED** value.

**DUI, bits [17:16]**

Error recovery interrupt for deferred errors. Indicates whether the node implements a control for enabling error recovery interrupts on deferred errors.

The possible values of this field are:

**0b00**

Does not support feature. ERRCTLn.DUI is **RES0**.

**0b10**

Feature is controllable using ERRCTLn.DUI.

All other values are reserved.

This field reads as an **IMPLEMENTATION DEFINED** value.

**RP, bit [15]**

Repeat counter. Indicates whether the node implements a repeat Corrected error counter in ERR<n>MISC0.

The possible values of this bit are:

**0b0**

A single CE counter is implemented.

**0b1**

A first (repeat) counter and a second (other) counter are implemented. The repeat counter is the same size as the primary error counter.

This bit is **RES0** if ERR<n>FR.CEC == 0b000.

This bit reads as an **IMPLEMENTATION DEFINED** value.

**CEC, bits [14:12]**

Corrected Error Counter. Indicates whether the node implements a standard Corrected error (CE) counter mechanism in ERR<n>MISC0.

The possible values of this field are:

**0b000**

Does not implement the standard Corrected error counter model.

**0b010**

Implements an 8-bit Corrected error counter in ERR<n>MISC0[7:0].

**0b100**

Implements a 16-bit Corrected error counter in ERR<n>MISC0[15:0].

All other values are reserved.

This field reads as an **IMPLEMENTATION DEFINED** value.

**CFI, bits [11:10]**

Fault handling for Corrected errors. Indicates whether the node implements a control for enabling fault handling interrupts on Corrected errors.

The possible values of this field are:

**0b00**

Does not support feature, ERRCTLRn.CFI is [RES0](#).

**0b10**

Feature is controllable using ERRCTLRn.CFI.

All other values are reserved.

This bit is '[RES0](#)' if  $ERR<n>FR.FI == 0b00$ .

This field reads as an [IMPLEMENTATION DEFINED](#) value.

**UE, bits [9:8]**

In-band uncorrected error reporting. Indicates whether the node implements in-band uncorrected error reporting (external aborts), and, if so, whether it implements controls for enabling and disabling in-band uncorrected error reporting.

The possible values of this field are:

**0b00**

Does not support feature, ERRCTLRn.UE is [RES0](#).

**0b01**

Feature always enabled, ERRCTLRn.UE is [RES0](#).

**0b10**

Feature is controllable using ERRCTLRn.UE.

This field reads as an [IMPLEMENTATION DEFINED](#) value.

**FI, bits [7:6]**

Fault handling interrupt. Indicates whether the node implements a fault handling interrupt, and, if so, whether it implements controls for enabling and disabling the fault handling interrupt.

The possible values of this field are:

**0b00**

Does not support feature, ERRCTLRn.FI is [RES0](#).

**0b01**

Feature always enabled, ERRCTLRn.FI is [RES0](#).

**0b10**

Feature is controllable using ERRCTLRn.FI.

This field reads as an [IMPLEMENTATION DEFINED](#) value.

**UI, bits [5:4]**

Error recovery interrupt for uncorrected errors. Indicates whether the node implements an error recovery interrupt, and, if so, whether it implements controls for enabling and disabling the error recovery interrupt.

The possible values of this field are:

**0b00**

Does not support feature, ERRCTLRn.UI is [RES0](#).

**0b01**

Feature always enabled, ERRCTLRn.UI is [RES0](#).

**0b10**

Feature is controllable using ERRCTLRn.UI.

This field reads as an IMPLEMENTATION DEFINED value.

**Bits [3:2]**

Reserved, RES0.

**ED, bits [1:0]**

Error reporting and logging. Indicates whether the node implements controls for enabling and disabling error reporting and logging.

The possible values of this field are:

**0b01**

Feature always enabled, ERRCTLRn.ED is RES1.

**0b10**

Feature is controllable using ERRCTLRn.ED.

All other values are reserved.

This field reads as an IMPLEMENTATION DEFINED value.

## D1.2.84 ERRGSRn, RAS Fault Group Status Register

The ERRGSR{0..1} characteristics are:

### Purpose

Each ERR<n>GSR register shows the status for up to 32 records in the group. <n> selects the set of 32 records from the records in the group.

### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

If AIRCR.BFHFNMINS is zero this register is RAZ/WI from Non-secure state.

### Configurations

Present only if version Armv8.1 of the architecture and RAS are implemented.

This register is RES0 if RAS is not implemented.

### Attributes

32-bit read-only register located at  $0 \times \text{E0005E00} + 4n$ .

This register is not banked between Security states.

## Field descriptions

The ERRGSR{0..1} bit assignments are:

### S, bits [31:0]

Status for Error Record <m>. Each bit is a read-only copy of the corresponding ERR<m>STATUS.V field.

The possible values of this field are:

**0**

No error.

**1**

One or more errors.

This bit is RES0 if <m> is greater than or equal to the number of implemented records, or if the record does not support this type of reporting.

## D1.2.85 ERRIIDR, Error Implementer ID Register

The ERRIIDR characteristics are:

### Purpose

Defines the implementer of the component.

### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are [UNPREDICTABLE](#).

### Configurations

Present only if version Armv8.1 of the architecture and RAS are implemented.

This register is [RES0](#) if RAS is not implemented.

### Attributes

32-bit read-only register located at 0xE0005E10.

This register is not banked between Security states.

## Field descriptions

The ERRIIDR bit assignments are:

### ProductID, bits [31:20]

This field reads as an [IMPLEMENTATION DEFINED](#) value.

### Variant, bits [19:16]

Component Major Revision. This field distinguishes between variants or major revisions of the product.

This field reads as an [IMPLEMENTATION DEFINED](#) value.

### Revision, bits [15:12]

Component minor revision. This field distinguishes between minor revisions of the product.

This field reads as an [IMPLEMENTATION DEFINED](#) value.

### Architect, bits [11:0]

The possible values of this field are:

#### 0x43B

JEP106 continuation code 0x4, ID code 0x3B. Arm Limited.

Other values are defined by the JEDEC JEP106 standard.

This field reads as 0x43B.

## D1.2.86 ERRMISC0n, Error Record Miscellaneous 0 Register, n = 0 - 55

The ERRMISC0{0..55} characteristics are:

### Purpose

IMPLEMENTATION DEFINED error syndrome register.

### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

If AIRCR.BFHFNMINS is zero this register is RAZ/WI from Non-secure state.

### Configurations

Present only if version Armv8.1 of the architecture and RAS are implemented.

This register is RES0 if RAS is not implemented.

### Attributes

32-bit read/write register located at  $0xE0005020 + 64n$ .

This register is not banked between Security states.

From Armv8.1-M onwards it is IMPLEMENTATION DEFINED whether a debugger write to this register is ignored when the PE is not in Debug state.

### Preface

The miscellaneous syndrome registers contain:

- Corrected error counter or counters, if the node supports the counting of Corrected errors.
- Information to identify the Field Replaceable Unit (FRU) in which the error was detected, and might contain enough information to locate error within that FRU.
- Other state information not present in the corresponding status and address registers.

If the node supports the architecturally-defined error counter then it is implemented in ERR<n>MISC0.

If ERR<n>STATUS.MV is set to 1 then it is IMPLEMENTATION DEFINED whether fields of ERR<n>MISC0 ignores writes. Arm recommends that miscellaneous syndrome for multiple errors, such as a Corrected error counter, is read/write. This allows a counter to be reset in the presence of a persistent error. Miscellaneous syndrome for the most recently recorded error, such as information locating a FRU for that error, must ignore writes. This prevents the loss of information if an error is detected whilst the previous error is being logged.

### Field descriptions

The ERRMISC0{0..55} bit assignments are:

When Contents are IMPLEMENTATION DEFINED:

When Standard 16-bit CE counter:

**When Standard 16-bit CE counter pair:**

**When Standard 8-bit CE counter:**

**Bits [31:0], when Contents are IMPLEMENTATION DEFINED**

IMPLEMENTATION DEFINED.

**Bits [31:8], when Standard 8-bit CE counter**

IMPLEMENTATION DEFINED.

**OF8, bit [7], when Standard 8-bit CE counter**

Overflow. Sticky overflow bit.

The possible values of this bit are:

**0**

Counter has not overflowed.

**1**

Counter has overflowed.

Set to 1 when the Corrected error count field is incremented and wraps through zero.

A direct write that modifies this bit might indirectly set ERR<n>STATUS.OF to an UNKNOWN value and a direct write to ERR<n>STATUS.OF that clears it to zero might indirectly set this bit to an UNKNOWN value.

This bit is preserved on an Error Recovery reset.

This bit resets to ERR\_RESET on an Error Recovery reset.

**CEC8, bits [6:0], when Standard 8-bit CE counter**

Corrected error count.

This field is preserved on an Error Recovery reset.

This field resets to ERR\_RESET on an Error Recovery reset.

**Bits [31:16], when Standard 16-bit CE counter**

IMPLEMENTATION DEFINED.

**OF16, bit [15], when Standard 16-bit CE counter**

Overflow. Sticky overflow bit.

The possible values of this bit are:

**0**

Counter has not overflowed.

**1**

Counter has overflowed.

Set to 1 when the Corrected error count field is incremented and wraps through zero.

A direct write that modifies this bit might indirectly set ERR<n>STATUS.OF to an UNKNOWN value and a direct write to ERR<n>STATUS.OF that clears it to zero might indirectly set this bit to an UNKNOWN value.

This bit is preserved on an Error Recovery reset.

This bit resets to ERR\_RESET on an Error Recovery reset.

**CEC16, bits [14:0], when Standard 16-bit CE counter**

Corrected error count.

This field is preserved on an Error Recovery reset.

This field resets to ERR\_RESET on an Error Recovery reset.

**OFO, bit [31], when Standard 16-bit CE counter pair**

Overflow Other. Sticky overflow bit, other.

The possible values of this bit are:

**0**

Other Counter has not overflowed.

**1**

Other Counter has overflowed.

Set to 1 when the Corrected error count, other, field is incremented and wraps through zero.

A direct write that modifies this bit might indirectly set ERR<n>STATUS.OF to an UNKNOWN value and a direct write to ERR<n>STATUS.OF that clears it to zero might indirectly set this bit to an UNKNOWN value.

This bit is preserved on an Error Recovery reset.

This bit resets to ERR\_RESET on an Error Recovery reset.

**CECO, bits [30:16], when Standard 16-bit CE counter pair**

Corrected error count, other. Incremented for each countable error that is not accounted for by incrementing CECR.

This field is preserved on an Error Recovery reset.

This field resets to ERR\_RESET on an Error Recovery reset.

**OFR, bit [15], when Standard 16-bit CE counter pair**

Overflow Repeat. Sticky overflow bit, repeat.

The possible values of this bit are:

**0**

Repeat Counter has not overflowed.

**1**

Repeat Counter has overflowed.

Set to 1 when the Corrected error count, repeat, field is incremented and wraps through zero.

A direct write that modifies this bit might indirectly set ERR<n>STATUS.OF to an UNKNOWN value and a direct write to ERR<n>STATUS.OF that clears it to zero might indirectly set this bit to an UNKNOWN value.

This bit is preserved on an Error Recovery reset.

This bit resets to ERR\_RESET on an Error Recovery reset.

**CECR, bits [14:0], when Standard 16-bit CE counter pair**

Corrected error count. Incremented for the first detected countable error, which also records other syndrome for the error, and subsequently for each countable error that matches the recorded other syndrome. Corrected

errors are countable errors. Is is **IMPLEMENTATION DEFINED** and might be **UNPREDICTABLE** whether Deferred and Uncorrected errors are countable errors.

This field is preserved on an Error Recovery reset.

This field resets to ERR\_RESET on an Error Recovery reset.

## D1.2.87 ERRMISC1n, Error Record Miscellaneous 1 Register, n = 0 - 55

The ERRMISC1{0..55} characteristics are:

### Purpose

IMPLEMENTATION DEFINED error syndrome register.

### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

If AIRCR.BFHFNMINS is zero this register is RAZ/WI from Non-secure state.

### Configurations

Present only if version Armv8.1 of the architecture and RAS are implemented.

This register is RES0 if RAS is not implemented.

### Attributes

32-bit read/write register located at  $0xE0005024 + 64n$ .

This register is not banked between Security states.

From Armv8.1-M onwards it is IMPLEMENTATION DEFINED whether a debugger write to this register is ignored when the PE is not in Debug state.

### Preface

The miscellaneous syndrome registers contain:

- Corrected error counter or counters, if the node supports the counting of Corrected errors.
- Information to identify the Field Replaceable Unit (FRU) in which the error was detected, and might contain enough information to locate error within that FRU.
- Other state information not present in the corresponding status and address registers.

If ERR<n>STATUS.MV is set to 1 then it is IMPLEMENTATION DEFINED whether fields of ERR<n>MISC1 ignores writes. Arm recommends that miscellaneous syndrome for multiple errors, such as a corrected error counter, is read/write. This allows a counter to be reset in the presence of a persistent error. Miscellaneous syndrome for the most recently recorded error, such as information locating a FRU for that error, should ignore writes. This prevents information being lost if an error is detected whilst the previous error is being logged.

### Field descriptions

The ERRMISC1{0..55} bit assignments are:

### Bits [31:0]

IMPLEMENTATION DEFINED.

### D1.2.88 ERRMISC2n, Error Record Miscellaneous 2 Register, n = 0 - 55

The ERRMISC2{0..55} characteristics are:

## Purpose

IMPLEMENTATION DEFINED error syndrome register.

## Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

If AIRCR.BFHFNMINS is zero this register is RAZ/WI from Non-secure state.

## Configurations

Present only if version Armv8.1 of the architecture and RAS are implemented.

This register is **RES0** if RAS is not implemented.

## Attributes

32-bit read/write register located at  $0xE005028 + 64n$ .

This register is not banked between Security states.

From Armv8.1-M onwards it is **IMPLEMENTATION DEFINED** whether a debugger write to this register is ignored when the PE is not in Debug state.

## Preface

The miscellaneous syndrome registers contain:

- Corrected error counter or counters, if the node supports the counting of Corrected errors.
- Information to identify the Field Replaceable Unit (FRU) in which the error was detected, and might contain enough information to locate error within that FRU.
- Other state information not present in the corresponding status and address registers.

If `ERR<n>STATUS.MV` is set to 1 then it is **IMPLEMENTATION DEFINED** whether fields of `ERR<n>MISC2` ignores writes. Arm recommends that miscellaneous syndrome for multiple errors, such as a corrected error counter, is read/write. This allows a counter to be reset in the presence of a persistent error. Miscellaneous syndrome for the most recently recorded error, such as information locating a FRU for that error, should ignore writes. This prevents information being lost if an error is detected whilst the previous error is being logged.

## Field descriptions

The ERRMISC2{0..55} bit assignments are:

**Bits [31:0]**

## IMPLEMENTATION DEFINED.

## D1.2.89 ERRMISC3n, Error Record Miscellaneous 3 Register, n = 0 - 55

The ERRMISC3{0..55} characteristics are:

### Purpose

IMPLEMENTATION DEFINED error syndrome register.

### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

If AIRCR.BFHFNMINS is zero this register is RAZ/WI from Non-secure state.

### Configurations

Present only if version Armv8.1 of the architecture and RAS are implemented.

This register is RES0 if RAS is not implemented.

### Attributes

32-bit read/write register located at  $0xE000502C + 64n$ .

This register is not banked between Security states.

From Armv8.1-M onwards it is IMPLEMENTATION DEFINED whether a debugger write to this register is ignored when the PE is not in Debug state.

### Preface

The miscellaneous syndrome registers contain:

- Corrected error counter or counters, if the node supports the counting of Corrected errors.
- Information to identify the Field Replaceable Unit (FRU) in which the error was detected, and might contain enough information to locate error within that FRU.
- Other state information not present in the corresponding status and address registers.

If ERR<n>STATUS.MV is set to 1 then it is IMPLEMENTATION DEFINED whether fields of ERR<n>MISC3 ignores writes. Arm recommends that miscellaneous syndrome for multiple errors, such as a corrected error counter, is read/write. This allows a counter to be reset in the presence of a persistent error. Miscellaneous syndrome for the most recently recorded error, such as information locating a FRU for that error, should ignore writes. This prevents information being lost if an error is detected whilst the previous error is being logged.

### Field descriptions

The ERRMISC3{0..55} bit assignments are:

### Bits [31:0]

IMPLEMENTATION DEFINED.

## D1.2.90 ERRMISC4n, Error Record Miscellaneous 4 Register, n = 0 - 55

The ERRMISC4{0..55} characteristics are:

### Purpose

IMPLEMENTATION DEFINED error syndrome register.

### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

If AIRCR.BFHFNMINS is zero this register is RAZ/WI from Non-secure state.

### Configurations

Present only if version Armv8.1 of the architecture and RAS are implemented.

This register is RES0 if RAS is not implemented.

### Attributes

32-bit read/write register located at  $0xE0005030 + 64n$ .

This register is not banked between Security states.

From Armv8.1-M onwards it is IMPLEMENTATION DEFINED whether a debugger write to this register is ignored when the PE is not in Debug state.

## Preface

The miscellaneous syndrome registers contain:

- Corrected error counter or counters, if the node supports the counting of Corrected errors.
- Information to identify the Field Replaceable Unit (FRU) in which the error was detected, and might contain enough information to locate error within that FRU.
- Other state information not present in the corresponding status and address registers.

If ERR<n>STATUS.MV is set to 1 then it is IMPLEMENTATION DEFINED whether fields of ERR<n>MISC4 ignores writes. Arm recommends that miscellaneous syndrome for multiple errors, such as a corrected error counter, is read/write. This allows a counter to be reset in the presence of a persistent error. Miscellaneous syndrome for the most recently recorded error, such as information locating a FRU for that error, should ignore writes. This prevents information being lost if an error is detected whilst the previous error is being logged.

## Field descriptions

The ERRMISC4{0..55} bit assignments are:

### Bits [31:0]

IMPLEMENTATION DEFINED.

## D1.2.91 ERRMISC5n, Error Record Miscellaneous 5 Register, n = 0 - 55

The ERRMISC5{0..55} characteristics are:

### Purpose

IMPLEMENTATION DEFINED error syndrome register.

### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

If AIRCR.BFHFNMINS is zero this register is RAZ/WI from Non-secure state.

### Configurations

Present only if version Armv8.1 of the architecture and RAS are implemented.

This register is RES0 if RAS is not implemented.

### Attributes

32-bit read/write register located at  $0xE0005034 + 64n$ .

This register is not banked between Security states.

From Armv8.1-M onwards it is IMPLEMENTATION DEFINED whether a debugger write to this register is ignored when the PE is not in Debug state.

## Preface

The miscellaneous syndrome registers contain:

- Corrected error counter or counters, if the node supports the counting of Corrected errors.
- Information to identify the Field Replaceable Unit (FRU) in which the error was detected, and might contain enough information to locate error within that FRU.
- Other state information not present in the corresponding status and address registers.

If ERR<n>STATUS.MV is set to 1 then it is IMPLEMENTATION DEFINED whether fields of ERR<n>MISC5 ignores writes. Arm recommends that miscellaneous syndrome for multiple errors, such as a corrected error counter, is read/write. This allows a counter to be reset in the presence of a persistent error. Miscellaneous syndrome for the most recently recorded error, such as information locating a FRU for that error, should ignore writes. This prevents information being lost if an error is detected whilst the previous error is being logged.

The ERRMISC5{0..55} bit assignments are:

### Bits [31:0]

IMPLEMENTATION DEFINED.

## D1.2.92 ERRMISC6n, Error Record Miscellaneous 6 Register, n = 0 - 55

The ERRMISC6{0..55} characteristics are:

### Purpose

IMPLEMENTATION DEFINED error syndrome register.

### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

If AIRCR.BFHFNMINS is zero this register is RAZ/WI from Non-secure state.

### Configurations

Present only if version Armv8.1 of the architecture and RAS are implemented.

This register is RES0 if RAS is not implemented.

### Attributes

32-bit read/write register located at  $0xE0005038 + 64n$ .

This register is not banked between Security states.

From Armv8.1-M onwards it is IMPLEMENTATION DEFINED whether a debugger write to this register is ignored when the PE is not in Debug state.

## Preface

The miscellaneous syndrome registers contain:

- Corrected error counter or counters, if the node supports the counting of Corrected errors.
- Information to identify the Field Replaceable Unit (FRU) in which the error was detected, and might contain enough information to locate error within that FRU.
- Other state information not present in the corresponding status and address registers.

If ERR<n>STATUS.MV is set to 1 then it is IMPLEMENTATION DEFINED whether fields of ERR<n>MISC6 ignores writes. Arm recommends that miscellaneous syndrome for multiple errors, such as a corrected error counter, is read/write. This allows a counter to be reset in the presence of a persistent error. Miscellaneous syndrome for the most recently recorded error, such as information locating a FRU for that error, should ignore writes. This prevents information being lost if an error is detected whilst the previous error is being logged.

## Field descriptions

The ERRMISC6{0..55} bit assignments are:

### Bits [31:0]

IMPLEMENTATION DEFINED.

### D1.2.93 ERRMISC7n, Error Record Miscellaneous 7 Register, n = 0 - 55

The ERRMISC7{0..55} characteristics are:

## Purpose

IMPLEMENTATION DEFINED error syndrome register.

## Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

If AIRCR.BFHFNMIN is zero this register is RAZ/WI from Non-secure state.

## Configurations

Present only if version Armv8.1 of the architecture and RAS are implemented.

This register is **RES0** if RAS is not implemented.

## Attributes

32-bit read/write register located at  $0xE000503C + 64n$ .

This register is not banked between Security states.

From Armv8.1-M onwards it is **IMPLEMENTATION DEFINED** whether a debugger write to this register is ignored when the PE is not in Debug state.

# Preface

The miscellaneous syndrome registers contain:

- Corrected error counter or counters, if the node supports the counting of Corrected errors.
- Information to identify the Field Replaceable Unit (FRU) in which the error was detected, and might contain enough information to locate error within that FRU.
- Other state information not present in the corresponding status and address registers.

If ERR<n>STATUS.MV is set to 1 then it is **IMPLEMENTATION DEFINED** whether fields of ERR<n>MISC7 ignores writes. Arm recommends that miscellaneous syndrome for multiple errors, such as a corrected error counter, is read/write. This allows a counter to be reset in the presence of a persistent error. Miscellaneous syndrome for the most recently recorded error, such as information locating a FRU for that error, should ignore writes. This prevents information being lost if an error is detected whilst the previous error is being logged.

## Field descriptions

The ERRMISC7{0..55} bit assignments are:

**Bits [31:0]**

## IMPLEMENTATION DEFINED.

## D1.2.94 ERRSTATUS<sub>n</sub>, Error Record Primary Status Register, n = 0 - 55

The ERRSTATUS{0..55} characteristics are:

### Purpose

Contains status information for the error record.

### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

If AIRCR.BFHFNMINS is zero this register is RAZ/WI from Non-secure state.

### Configurations

Present only if version Armv8.1 of the architecture and RAS are implemented.

This register is RES0 if RAS is not implemented.

### Attributes

32-bit read/write register located at  $0xE0005010 + 64n$ .

This register is not banked between Security states.

From Armv8.1-M onwards it is IMPLEMENTATION DEFINED whether a debugger write to this register is ignored when the PE is not in Debug state.

## Preface

This register contains the following information:

- Whether any error has been detected (valid).
- Whether any detected error was not corrected, and returned to a Requester.
- Whether any detected error was not corrected and deferred.
- Whether an error record has been discarded because additional errors have been detected before the first error was handled by software (overflow).
- Whether any error has been reported.
- Whether the other error record registers contain valid information.
- Whether the error was reported because poison data was detected or because a corrupt value was detected by an error detection code.
- A primary error code.
- An IMPLEMENTATION DEFINED extended error code.

Within this register:

- The {AV, V, MV} bits are valid bits that define whether the error record registers are valid.
- The {UE, OF, CE, DE, UET} bits encode the type of error or errors recorded.
- The {CI, ER, PN, IERR, SERR} fields are syndrome fields.

After reading the status register, software must clear the valid bits to allow new errors to be recorded. Between reading the register and clearing the valid bits, a new error might have overwritten the register. To prevent this error being lost, a write to ERR<n>STATUS is ignored if all of:

- Any of the ERR<n>STATUS.{V, UE, OF, CE, DE} fields are nonzero before the write.
- The write does not clear the nonzero ERR<n>STATUS.{V, UE, OF, CE, DE} field(s) to zero by writing one(s) to the applicable field(s).

## Field descriptions

The ERRSTATUS{0..55} bit assignments are:

### AV, bit [31]

Address Valid.

The possible values of this bit are:

**0**

ERR<n>ADDR and ERR<n>ADDR2 not valid.

**1**

ERR<n>ADDR and ERR<n>ADDR2 contain an address associated with the highest priority error recorded by this record.

This bit is read/write-one-to-clear.

This bit is preserved on an Error Recovery reset.

This bit resets to zero on a Cold reset.

### V, bit [30]

Status Register valid.

The possible values of this bit are:

**0**

ERR<n>STATUS not valid.

**1**

ERR<n>STATUS valid. At least one error has been recorded.

This bit is read/write-one-to-clear.

This bit is preserved on an Error Recovery reset.

This bit resets to zero on a Cold reset.

### UE, bit [29]

Uncorrected error or errors.

The possible values of this bit are:

**0**

No errors that could neither be corrected nor deferred.

**1**

At least one error that has neither been corrected nor deferred.

This bit reads as **UNKNOWN** if ERR<n>STATUS.V is set to 0. This bit is read/write-one-to-clear.

This bit is preserved on an Error Recovery reset.

This bit resets to ERR\_RESET on an Error Recovery reset.

### ER, bit [28]

Error Reported.

The possible values of this bit are:

**0**

No in-band error (external abort) reported.

**1**

An external abort was signaled by the node to the Requester making the access or other transaction. This can be because any of:

- ERR<n>CTLR.UE is implemented and was set to 1 when an Uncorrected error was detected.
- ERR<n>CTLR.UE is not implemented and the node always reports errors.

It is **IMPLEMENTATION DEFINED** whether this bit can be set to 1 by a Deferred error. This bit is not valid and reads **UNKNOWN** if any of:

- ERR<n>STATUS.UE is set to 0 and this bit is only set to 1 by Uncorrected errors.
- ERR<n>STATUS.{UE, DE} are both set to 0 and this bit can be set to 1 by Deferred errors.
- ERR<n>STATUS.V is set to 0.

This bit is read/write-one-to-clear.

This bit is preserved on an Error Recovery reset.

This bit resets to ERR\_RESET on an Error Recovery reset.

#### **OF, bit [27]**

Overflow.

Indicates that multiple errors have been detected. This bit is set to 1 when one of the following occurs:

- A corrected error counter is implemented, an error is counted, and the counter overflows.
- A corrected error counter is not implemented, a corrected error is recorded, and ERR<n>STATUS.V was previously set to 1.

A type of error other than a corrected error is recorded and ERR<n>STATUS.V was previously set to 1.

Otherwise, this bit is unchanged when an error is recorded.

If a corrected error counter is implemented:

- A direct write that modifies the counter overflow flag indirectly might set this bit to an **UNKNOWN** value.
- A direct write to this bit that clears this bit to zero might indirectly set the counter overflow flag to an **UNKNOWN** value.

The possible values of this bit are:

**0**

No error syndrome has been discarded and, if a Corrected error counter is implemented, it has not overflowed since this bit was last cleared to zero.

**1**

At least one error syndrome has been discarded or, if a Corrected error counter is implemented, it might have overflowed, since this bit was last cleared to zero.

This bit is not valid and reads **UNKNOWN** if ERR<n>STATUS.V is set to 0.

This bit is read/write-one-to-clear.

This bit is preserved on an Error Recovery reset.

This bit resets to ERR\_RESET on an Error Recovery reset.

#### **MV, bit [26]**

Miscellaneous Registers Valid.

The possible values of this bit are:

**0**  
ERR<n>MISC\* not valid.

**1**  
The **IMPLEMENTATION DEFINED** contents of the ERR<n>MISC\* registers contains additional information for an error recorded by this record.

This bit is not valid and reads **UNKNOWN** if ERR<n>STATUS.V is set to 0.

This bit is read/write-one-to-clear.

This bit is preserved on an Error Recovery reset.

This bit resets to ERR\_RESET on an Error Recovery reset.

**CE, bits [25:24]**

Corrected error or errors.

The possible values of this field are:

**0b00**  
No errors were corrected.

**0b01**  
At least one transient error was corrected.

**0b10**  
At least one error was corrected.

**0b11**  
At least one persistent error was corrected.

The mechanism by which a node detects whether a correctable error is transient or persistent is **IMPLEMENTATION DEFINED**. If no such mechanism is implemented then the node sets this field to 0b10 when an error is corrected.

This field is not valid and reads **UNKNOWN** if ERR<n>STATUS.V is set to 0.

This field is read/write-ones-to-clear. Writing a value other than all-zeros or all-ones sets this field to an **UNKNOWN** value.

This field is preserved on an Error Recovery reset.

This field resets to ERR\_RESET on an Error Recovery reset.

**DE, bit [23]**

Deferred error or errors.

The possible values of this bit are:

**0**  
No errors were deferred.

**1**  
At least one error was not corrected and deferred.

Support for deferring errors is **IMPLEMENTATION DEFINED**.

This bit is not valid and reads **UNKNOWN** if ERR<n>STATUS.V is set to 0.

This bit is read/write-one-to-clear.

This bit is preserved on an Error Recovery reset.

This bit resets to ERR\_RESET on an Error Recovery reset.

**PN, bit [22]**

Poison.

The possible values of this bit are:

**0**

Uncorrected or deferred error from a corrupted value.

**1**

Uncorrected error or Deferred error from a poisoned value. Indicates that an error occurred because of the detection of a poison value rather because of the detection of a corrupted value.

It is **IMPLEMENTATION DEFINED** whether a node can distinguish a poisoned value from a corrupted value.

This bit is not valid and reads **UNKNOWN** if any of:

- ERR<n>STATUS.V is set to 0.
- ERR<n>STATUS.{CE, UE} are both set to 0.

This bit is read/write-one-to-clear.

This bit is preserved on an Error Recovery reset.

This bit resets to ERR\_RESET on an Error Recovery reset.

**Note**

If a node detects a corrupted value and defers the error by producing poison then this bit is set to 0b0 at the producer node. The value 0b1 might only be an indication of a poisoned value. As in some EDC schemes, it is possible to mistake a corrupted value for a poisoned value.

**UET, bits [21:20]**

Uncorrected Error Type. Describes the state of the component after detecting or consuming an Uncorrected error.

The possible values of this field are:

**0b00**

Uncorrected error, Uncontainable error (UC).

**0b01**

Uncorrected error, Unrecoverable error (UEU).

**0b10**

Uncorrected error, Latent or Restartable error (UEO).

**0b11**

Uncorrected error, Signaled or Recoverable error (UER).

This field is not valid and reads **UNKNOWN** if any of:

- ERR<n>STATUS.V is set to 0.
- ERR<n>STATUS.UE is set to 0.

This field is read/write-ones-to-clear. Writing a value other than all-zeros or all-ones sets this field to an **UNKNOWN** value.

Note: Software might use the information in the error record registers to determine what recovery is necessary.

This field is preserved on an Error Recovery reset.

This field resets to ERR\_RESET on an Error Recovery reset.

**CI, bit [19]**

Critical error. Indicates whether a critical error condition has been recorded.

The possible values of this bit are:

**0**

No critical error condition.

**1**

Critical error condition.

This bit is not valid and reads **UNKNOWN** if ERR<n>STATUS.V is set to 0.

This bit is read/write-one-to-clear.

This bit is preserved on an Error Recovery reset.

This bit resets to ERR\_RESET on an Error Recovery reset.

#### Bits [18:16]

Reserved, **RES0**.

#### IERR, bits [15:8]

**IMPLEMENTATION DEFINED** error code.

Used with any primary error code SERR value. Further **IMPLEMENTATION DEFINED** information can be placed in the MISC registers.

The subset of architecturally-defined values that this field can take is **IMPLEMENTATION DEFINED**. If any value not in this set is written to this register then the value read back from this field is **UNKNOWN**.

This field is not valid and reads **UNKNOWN** if ERR<n>STATUS.V is set to 0.

This field is preserved on an Error Recovery reset.

This field resets to ERR\_RESET on an Error Recovery reset.

#### Note

One or more bits of this field might be implemented as fixed read-as-zero or read-as-one values.

#### SERR, bits [7:0]

Architecturally-defined primary error code. The primary error code might be used by a fault handling agent to triage an error without requiring device-specific code. For example, to count and threshold corrected errors in software, or generate a short log entry.

The possible values of this field are:

**0**

No error.

**1**

**IMPLEMENTATION DEFINED** error.

**2**

Data value from (non-associative) internal memory. For example, ECC from on-chip SRAM or buffer.

**3**

**IMPLEMENTATION DEFINED** pin.

**4**

Assertion failure. For example, consistency failure.

**5**

Internal data path. For example, parity on ALU result.

**6**

Data value from associative memory. For example, ECC error on cache data.

- 7** Address/control value or values from associative memory. For example, ECC error on cache tag.
- 10** Data value from producer. For example, parity error on write data bus.
- 11** Address/control value or values from producer. For example, parity error on address bus.
- 12** Data value from (non-associative) external memory. For example, ECC error in SDRAM.
- 13** Illegal address (software fault). For example, access to unpopulated memory.
- 14** Illegal access (software fault). For example, byte write to word register.
- 15** Illegal state (software fault). For example, device not ready.
- 16** Internal data register. For example, parity on a floating-point or MVE register. For a PE, all general-purpose, stack pointer, and floating-point or MVE registers are data registers.
- 17** Internal control register. For example, parity on a system register. For a PE, all registers other than general-purpose, stack pointer, and floating-point or MVE registers are control registers.
- 18** Error response from Completer of access. For example, error response from cache write-back.
- 19** External timeout. For example, timeout on interaction with another node.
- 20** Internal timeout. For example, timeout on interface within the node.
- 21** Deferred error from Completer not supported at Requester. For example, poisoned data received from a Completer of an access by a Requester that cannot defer the error further.

All other values are reserved.

The subset of architecturally-defined values that this field can take is **IMPLEMENTATION DEFINED**. If any value not in this set is written to this register then the value read back from this field is **UNKNOWN**.

This field is not valid and reads **UNKNOWN** if ERR<n>STATUS.V is set to 0.

Note: one or more bits of this field might be implemented as fixed read-as-zero or read-as-one values.

This field is preserved on an Error Recovery reset.

This field resets to ERR\_RESET on an Error Recovery reset.

## D1.2.95 EXC\_RETURN, Exception Return Payload

The EXC\_RETURN characteristics are:

### Purpose

Value provided in LR on entry to an exception, and used with a BX or load to PC to perform an exception return.

### Usage constraints

None.

### Configurations

All.

### Attributes

32-bit payload.

## Field descriptions

The EXC\_RETURN bit assignments are:

### PREFIX, bits [31:24]

Prefix. Indicates that this is an EXC\_RETURN value.

This field reads as 0b11111111.

### Bits [23:7]

Reserved, [RES1](#).

### S, bit [6]

Secure or Non-secure stack. Indicates whether a Secure or Non-secure stack is used to restore stack frame on exception return.

The possible values of this bit are:

**0**

Non-secure stack used.

**1**

Secure stack used.

If the Security Extension is not implemented, this bit is [RES0](#).

### DCRS, bit [5]

Default callee register stacking. Indicates whether the default stacking rules apply, or whether the callee registers are already on the stack.

The possible values of this bit are:

**0**

Stacking of the callee saved registers skipped.

**1**

Default rules for stacking the callee registers followed.

If the Security Extension is not implemented, this bit is [RES1](#).

**FType, bit [4]**

Stack frame type. Indicates whether the stack frame is a standard integer only stack frame or an extended Floating-point stack frame.

The possible values of this bit are:

- 0**  
Extended stack frame.
- 1**  
Standard stack frame.

**Mode, bit [3]**

Mode. Indicates the Mode that was stacked from.

The possible values of this bit are:

- 0**  
Handler mode.
- 1**  
Thread mode.

**SPSEL, bit [2]**

Stack pointer selection. The value of this bit indicates the transitory value of the CONTROL.SPSEL bit associated with the Security state of the exception as indicated by EXC\_RETURN.ES.

The possible values of this bit are:

- 0**  
Main stack pointer.
- 1**  
Process stack pointer.

**Bit [1]**

Reserved, [RES0](#).

**ES, bit [0]**

Exception Secure. The security domain the exception was taken to.

The possible values of this bit are:

- 0**  
Non-secure.
- 1**  
Secure.

If the Security Extension is not implemented, this bit is [RES0](#).

### D1.2.96 FAULTMASK, Fault Mask Register

The FAULTMASK characteristics are:

## Purpose

Provides access to the PE FAULTMASK register.

## Usage constraints

Privileged access only. Unprivileged access is RAZ/WI, unless otherwise stated.

## Configurations

Present only if the Main Extension is implemented.

This register is **RES0** if the Main Extension is not implemented.

## Attributes

32-bit read/write special-purpose register.

This register is banked between Security states.

## Field descriptions

The FAULTMASK bit assignments are:

**Bits [31:1]**

Reserved, RES0.

**FM, bit [0]**

Fault mask enable.

The Secure and Non-secure FAULTMASK registers individually boost the current execution priority based on the settings of AIRCR.PRIS and AIRCR.BFHFNMINS.

If AIRCR.BFHFNMINS is zero, AIRCR.PRIS is zero, and FAULTMASK\_NS.FM is one, the execution priority is boosted to 0.

If AIRCR.BFHFNMINS is zero, AIRCR.PRIS is one, and FAULTMASK\_NS.FM is one, the execution priority is boosted to  $0 \times 80$ .

If AIRCR.BFHFNMINS is zero and FAULTMASK\_S is one, the execution priority is boosted to -1.

If AIRCR.BFHFNMINS is one and FAULTMASK\_NS is one, the execution priority is boosted to -1.

If AIRCR.BFHFNMINS is one and FAULTMASK\_S is one, the execution priority is boosted to -3.

The possible values of this bit are:

**O**

No effect.

1

Boost priority.

On an exception return from a raw execution priority greater or equal to zero, the FM bit corresponding to EXC\_RETURN.ES is cleared.

This bit resets to zero on a Warm reset.

## D1.2.97 FNC\_RETURN, Function Return Payload

The FNC\_RETURN characteristics are:

### Purpose

Value provided in LR on entry to Non-secure state from a Secure BLXNS.

### Usage constraints

None.

### Configurations

All.

### Attributes

32-bit payload.

## Field descriptions

The FNC\_RETURN bit assignments are:

### PREFIX, bits [31:24]

This field reads as 0b11111110.

### ONES, bits [23:1]

This field reads as 0b111111111111111111111111.

### S, bit [0]

Secure. Indicates whether the function call was from the Non-secure or Secure state. Because FNC\_RETURN is only used when calling from the Secure state, this bit is always set to 1. However, some function chaining cases can result in an SG instruction clearing this bit, so the architecture ignores the state of this bit when processing a branch to FNC\_RETURN.

The possible values of this bit are:

**0**

From Non-secure state.

**1**

From Secure state.

### D1.2.98 FPCAR, Floating-Point Context Address Register

The FPCAR characteristics are:

## Purpose

Holds the location of the unpopulated Floating-point register space allocated on an exception stack frame.

## Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

## Configurations

Present if the Floating-point Extension, or MVE, or both are implemented.

This register is **RES0** if neither the Floating-point Extension nor MVE are implemented.

## Attributes

32-bit read/write register located at 0xE000EF38.

Secure software can access the Non-secure version of this register via FPCAR\_NS located at 0xE002EF38. The location 0xE002EF38 is **RES0** to software executing in Non-secure state and the debugger.

This register is banked between Security states.

From Armv8.1-M onwards it is **IMPLEMENTATION DEFINED** whether a debugger write to this register is ignored when the PE is not in Debug state.

## Field descriptions

The FPCAR bit assignments are:

**ADDRESS, bits [31:3]**

Address. The location of the unpopulated Floating-point register space allocated on an exception stack frame.

This field resets to an **UNKNOWN** value on a Warm reset.

**Bits [2:0]**

Reserved, RES0.

## D1.2.99 FPCCR, Floating-Point Context Control Register

The FPCCR characteristics are:

### Purpose

Holds control data for the Floating Point Unit.

### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

### Configurations

Present if the Floating-point Extension, or MVE, or both are implemented.

This register is **RES0** if neither the Floating-point Extension nor MVE are implemented.

### Attributes

32-bit read/write register located at 0xE000EF34.

Secure software can access the Non-secure version of this register via FPCCR\_NS located at 0xE002EF34. The location 0xE002EF34 is **RES0** to software executing in Non-secure state and the debugger.

This register is banked between Security states on a bit by bit basis.

From Armv8.1-M onwards it is **IMPLEMENTATION DEFINED** whether a debugger write to this register is ignored when the PE is not in Debug state.

## Field descriptions

The FPCCR bit assignments are:

### ASPEN, bit [31]

Automatic state preservation enable. When this bit is set to 1, execution of a Floating-point instruction sets the CONTROL.FPCA bit to 1.

This bit is banked between Security states.

The possible values of this bit are:

**0**

Executing a floating-point instruction has no effect on CONTROL.FPCA.

**1**

Executing a floating-point instruction sets CONTROL.FPCA to 1.

Setting this bit to 1 means the hardware automatically preserves Floating-point context on exception entry and restores it on exception return. As of version Armv8.1-M of the architecture Arm deprecates setting this field to 0.

This bit resets to one on a Warm reset.

**LSPEN, bit [30]**

Lazy state preservation enable. Enables lazy context save of Floating-point state.

This bit is not banked between Security states.

The possible values of this bit are:

**0**

Disable automatic lazy context save.

**1**

Enable automatic lazy context save.

Writes to this bit from Non-secure state are ignored if LSPENS is set to 1.

This bit resets to one on a Warm reset.

**LSPENS, bit [29]**

Lazy state preservation enable Secure. This bit controls whether the LSPEN bit is writable from the Non-secure state. This behaves as RAZ/WI when accessed from the Non-secure state.

This bit is not banked between Security states.

The possible values of this bit are:

**0**

LSPEN is readable and writable from both Security states.

**1**

LSPEN is readable from both Security states, but writes to LSPEN are ignored from the Non-secure state.

This bit is RAZ/WI from Non-secure state.

This bit resets to zero on a Warm reset.

**CLRONRET, bit [28]**

Clear on return. Clear Floating-point caller saved registers on exception return.

This bit is not banked between Security states.

The possible values of this bit are:

**0**

Disabled.

**1**

Enabled.

When set to 1 the caller saved Floating-point registers (S0 to S15, FPSCR, and VPR) are cleared on exception return (including tail chaining) if CONTROL.FPCA is set to 1 and FPCCR\_S.LSPACT is set to 0. Writes to this bit from Non-secure state are ignored if CLRONRETS is set to one.

This bit resets to zero on a Warm reset.

**CLRONRETS, bit [27]**

Clear on return, Secure only. This bit controls whether the CLRONRET bit is writable from the Non-secure state.

This bit is not banked between Security states.

The possible values of this bit are:

**0**

The CLRONRET field is accessibly from both Security states.

**1**

The Non-secure view of the CLRONRET field is read-only.

This bit is RAZ/WI from Non-secure state.

This bit resets to zero on a Warm reset.

**TS, bit [26]**

Treat as Secure. Treat Floating-point registers as Secure enable.

This bit is not banked between Security states.

The possible values of this bit are:

**0**

Disabled.

**1**

Enabled.

When set to 0 the Floating-point registers are treated as Non-secure even when the PE is in Secure state and, therefore, the callee saved registers are never pushed to the stack. If the Floating-point registers never contain data that needs to be protected, clearing this flag can reduce interrupt latency. As this field changes how secure stack frames are interpreted, **UNPREDICTABLE** behavior can result if the state of this bit is not consistent with the current Secure stacks. Therefore, firmware must take care when modifying this value. This field behaves as RAZ/WI from the Non-secure state.

This bit is RAZ/WI from Non-secure state.

This bit resets to zero on a Warm reset.

**Bits [25:11]**

Reserved, **RES0**.

**UFRDY, bit [10]**

UsageFault enable. Indicates whether the software executing, when the PE allocated the Floating-point stack frame, was able to set the UsageFault exception to pending.

This bit is banked between Security states.

The possible values of this bit are:

**0**

Not able to set the UsageFault exception to pending.

**1**

Able to set the UsageFault exception to pending.

This bit resets to an **UNKNOWN** value on a Warm reset.

**SPLIMVIOL, bit [9]**

Stack pointer limit violation. This bit indicates whether the Floating-point context violates the stack pointer limit that was active when lazy state preservation was activated. SPLIMVIOL modifies the lazy Floating-point state preservation behavior.

This bit is banked between Security states.

The possible values of this bit are:

**0**

The existing behavior is retained.

**1**

The memory accesses associated with the Floating-point state preservation are not performed. However if the Floating-point state is Secure and FPCCR.TS is set to 1 the registers are still zeroed and the Floating-point state is lost.

This bit resets to an **UNKNOWN** value on a Warm reset.

**MONRDY, bit [8]**

DebugMonitor ready. Indicates whether the software executing, when the PE allocated the Floating-point stack frame, was able to set the DebugMonitor exception to pending.

This bit is not banked between Security states.

The possible values of this bit are:

**0**

Not able to set the DebugMonitor exception to pending.

**1**

Able to set the DebugMonitor exception to pending.

If DEMCR.SDME is one this bit is RAZ/WI from Non-secure state

This bit resets to an **UNKNOWN** value on a Warm reset.

**SFRDY, bit [7]**

SecureFault ready. Indicates whether the software executing, when the PE allocated the Floating-point stack frame, was able to set the SecureFault exception to pending.

This bit is not banked between Security states.

This bit is RAZ/WI from Non-secure state.

This bit resets to an **UNKNOWN** value on a Warm reset.

**BFRDY, bit [6]**

BusFault ready. Indicates whether the software executing, when the PE allocated the Floating-point stack frame, was able to set the BusFault exception to pending.

This bit is not banked between Security states.

The possible values of this bit are:

**0**

Not able to set the BusFault exception to pending.

**1**

Able to set the BusFault exception to pending.

If AIRCR.BFHFNMINS is zero this bit is RAZ/WI from Non-secure state.

This bit resets to an **UNKNOWN** value on a Warm reset.

**MMRDY, bit [5]**

MemManage ready. Indicates whether the software executing, when the PE allocated the Floating-point stack frame, was able to set the MemManage exception to pending.

This bit is banked between Security states.

The possible values of this bit are:

**0**

Not able to set the MemManage exception to pending.

**1**

Able to set the MemManage exception to pending.

This bit resets to an **UNKNOWN** value on a Warm reset.

**HFRDY, bit [4]**

HardFault ready. Indicates whether the software executing, when the PE allocated the Floating-point stack

frame, was able to set the HardFault exception to pending. If there is both a Secure HardFault and a Non-secure HardFault, this bit only applies to the Non-secure HardFault.

This bit is not banked between Security states.

The possible values of this bit are:

**0**

Not able to set the HardFault exception to pending.

**1**

Able to set the HardFault exception to pending.

If AIRCR.BFHFNMINS is zero this bit is RAZ/WI from Non-secure state.

This bit resets to an **UNKNOWN** value on a Warm reset.

#### **THREAD, bit [3]**

Thread mode. Indicates the PE mode when it allocated the Floating-point stack frame.

This bit is banked between Security states.

The possible values of this bit are:

**0**

Handler mode.

**1**

Thread mode.

This bit is for fault handler information only and does not interact with the exception model.

This bit resets to an **UNKNOWN** value on a Warm reset.

#### **S, bit [2]**

Security. Security status of the Floating-point context. This bit is only present in the Secure version of the register. This bit is updated whenever lazy state preservation is activated, or when a Floating-point instruction is executed.

This bit is not banked between Security states.

The possible values of this bit are:

**0**

Indicates the Floating-point context belongs to the Non-secure state.

**1**

Indicates the Floating-point context belongs to the Secure state.

This bit is RAZ/WI from Non-secure state.

This bit resets to one on a Warm reset.

#### **USER, bit [1]**

User privilege. Indicates the privilege level of the software executing when the PE allocated the Floating-point stack frame.

This bit is banked between Security states.

The possible values of this bit are:

**0**

Privileged.

**1**

Unprivileged.

This bit resets to an **UNKNOWN** value on a Warm reset.

**LSPACT, bit [0]**

Lazy state preservation active. Indicates whether lazy preservation of the Floating-point state is active.

This bit is banked between Security states.

The possible values of this bit are:

**0**

Lazy state preservation is not active.

**1**

Lazy state preservation is active.

This bit resets to zero on a Warm reset.

## D1.2.100 FPCXT, Floating-point context payload

The FPCXT characteristics are:

### Purpose

Values produced or consumed by instructions that provide access to the Floating-point context.

### Usage constraints

None.

### Configurations

All.

### Attributes

32-bit payload.

## Field descriptions

The FPCXT bit assignments are:

### SFPA, bit [31]

Secure Floating-point active. The value corresponds to CONTROL.SFPA.

### Bits [30:28]

Reserved, [RES0](#).

### QC, bit [27]

Cumulative saturation bit. The value corresponds to FPSCR.QC.

### AHP, bit [26]

Alternative half-precision control bit. The value corresponds to FPSCR.AHP.

### DN, bit [25]

Default NaN mode control bit. The value corresponds to FPSCR.DN.

### FZ, bit [24]

Flush-to-zero mode control for single and double precision Floating-point. The value corresponds to FPSCR.FZ.

### RMode, bits [23:22]

Rounding mode control field. The value corresponds to FPSCR.RMode.

### Bits [21:20]

Reserved, [RES0](#).

### FZ16, bit [19]

Flush-to-zero mode control bit on half-precision data-processing instructions. The value corresponds to FPSCR.FZ16.

### LTFSIZE, bits [18:16]

The vector element size that is used when applying low-overhead-loop tail predication to vector instructions.

**Bits [15:8]**

Reserved, [RES0](#).

**IDC, bit [7]**

Input Denormal cumulative exception bit. The value corresponds to FPSCR.IDC.

**Bits [6:5]**

Reserved, [RES0](#).

**IXC, bit [4]**

Inexact cumulative exception bit. The value corresponds to FPSCR.IXC.

**UFC, bit [3]**

Underflow cumulative exception bit. The value corresponds to FPSCR.UFC.

**OFC, bit [2]**

Overflow cumulative exception bit. The value corresponds to FPSCR.OFC.

**DZC, bit [1]**

Divide by Zero cumulative exception bit. The value corresponds to FPSCR.DZC.

**IOC, bit [0]**

Invalid Operation cumulative exception bit. The value corresponds to FPSCR.IOC.

## D1.2.101 FPDSCR, Floating-Point Default Status Control Register

The FPDSCR characteristics are:

### Purpose

Holds the default values for the Floating-point status control data that the PE assigns to FPSCR when it creates a new Floating-point context.

### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

### Configurations

Present if the Floating-point Extension, or MVE, or both are implemented.

This register is **RES0** if neither the Floating-point Extension nor MVE are implemented.

### Attributes

32-bit read/write register located at 0xE000EF3C.

Secure software can access the Non-secure version of this register via FPDSCR\_NS located at 0xE002EF3C. The location 0xE002EF3C is **RES0** to software executing in Non-secure state and the debugger.

This register is banked between Security states.

From Armv8.1-M onwards it is **IMPLEMENTATION DEFINED** whether a debugger write to this register is ignored when the PE is not in Debug state.

## Field descriptions

The FPDSCR bit assignments are:

### Bits [31:27]

Reserved, **RES0**.

### AHP, bit [26]

Alternative half-precision. Default value for FPSCR.AHP.

If the Floating-point Extension is not implemented, this bit is **RES0**.

This bit resets to zero on a Warm reset.

### DN, bit [25]

Default NaN. Default value for FPSCR.DN.

If the Floating-point Extension is not implemented, this bit is **RES0**.

This bit resets to zero on a Warm reset.

### FZ, bit [24]

Flush-to-zero. Default value for FPSCR.FZ.

If the Floating-point Extension is not implemented, this bit is **RES0**.

This bit resets to zero on a Warm reset.

**RMode, bits [23:22]**

Rounding mode. Default value for FPSCR.RMode.

If the Floating-point Extension is not implemented, this field is [RES0](#).

This field resets to zero on a Warm reset.

**Bits [21:20]**

Reserved, [RES0](#).

**FZ16, bit [19]**

Flush-to-zero mode control bit on half-precision data-processing instructions. Default value for FPSCR.FZ16.

If the Floating-point Extension is not implemented, this bit is RAZ/WI.

This bit resets to zero on a Warm reset.

**LTFSIZE, bits [18:16]**

The vector element size used when applying low-overhead-loop tail predication to vector instructions. Default value for FPSCR.LTFSIZE.

If the Low Overhead Branch Extension is not implemented, this field is [RES0](#).

This field reads as  $0 \times 4$ .

**Bits [15:0]**

Reserved, [RES0](#).

## D1.2.102 FPSCR, Floating-point Status and Control Register

The FPSCR characteristics are:

### Purpose

Provides control of the Floating-point unit.

### Usage constraints

Privileged and unprivileged access permitted.

### Configurations

Present if the Floating-point Extension, or MVE, or both are implemented.

This register is [RES0](#) if neither the Floating-point Extension nor MVE are implemented.

### Attributes

32-bit read/write special-purpose register.

This register is not banked between Security states.

## Preface

Writes to FPSCR can have side effects on various aspects of processor operation. All of these side effects are synchronous to FPSCR write. This means that they are guaranteed not to be visible to earlier instructions in the execution stream, and they are guaranteed to be visible to later instructions in the execution stream.

## Field descriptions

The FPSCR bit assignments are:

### N, bit [31]

Negative condition flag. When updated by a VCMP instruction, this bit indicates whether the result was less than.

The possible values of this bit are:

**0**

Compare result was not less than.

**1**

Compare result was less than.

See VCMP for details.

If the Floating-point Extension is not implemented, this bit is RAZ/WI.

This bit resets to an [UNKNOWN](#) value on a Warm reset.

### Z, bit [30]

Zero condition flag. When updated by a VCMP instruction, this bit indicates whether the result was equal.

The possible values of this bit are:

**0**  
Compare result was not equal.

**1**  
Compare result was equal.

See VCMP for details.

If the Floating-point Extension is not implemented, this bit is RAZ/WI.

This bit resets to an **UNKNOWN** value on a Warm reset.

**C, bit [29]**

Carry condition flag. Accessed by the VCMP, VADC, and VSBC instructions. For VCMP this bit indicates whether the result was not less than. In VADC and VSBC this bit is used to hold the carry in/out flag.

The possible values of this bit are:

**0**  
Compare result was less than.

**1**  
Compare result was not less than.

See VCMP, VADC, and VSBC for details.

This bit resets to an **UNKNOWN** value on a Warm reset.

**V, bit [28]**

Overflow condition flag. When updated by a VCMP instruction, this bit indicates whether the result was unordered.

The possible values of this bit are:

**0**  
Compare result was not unordered.

**1**  
Compare result was unordered.

See VCMP for details.

If the Floating-point Extension is not implemented, this bit is RAZ/WI.

This bit resets to an **UNKNOWN** value on a Warm reset.

**QC, bit [27]**

Cumulative saturation bit. This bit is set to 1 to indicate that an MVE integer operation has saturated since 0 was last written to this bit.

If MVE is not implemented, this bit is **RES0**.

This bit resets to an **UNKNOWN** value on a Warm reset.

**AHP, bit [26]**

Alternative half-precision control bit. This bit controls how the PE interprets 16-bit Floating-point values.

The possible values of this bit are:

**0**  
IEEE half-precision format selected.

**1**  
Alternative half-precision format selected.

If the Floating-point Extension is not implemented, this bit is RAZ/WI.

This bit resets to an **UNKNOWN** value on a Warm reset.

**DN, bit [25]**

Default NaN mode control bit. This bit determines whether Floating-point operations propagate NaNs or use the Default NaN.

The possible values of this bit are:

**0**

NaN operands propagate through to the output of a Floating-point operation.

**1**

Any operation involving one of more NaNs returns the Default NaN.

If the Floating-point Extension is not implemented, this bit is RAZ/WI.

This bit resets to an **UNKNOWN** value on a Warm reset.

**FZ, bit [24]**

Flush-to-zero mode control for single and double precision Floating-point. This bit determines whether denormal Floating-point values are treated as though they are zero.

The possible values of this bit are:

**0**

Flush-to-zero mode disabled. Behavior of the Floating-point unit is fully compliant with the IEEE754 standard.

**1**

Flush-to-zero mode enabled.

If the Floating-point Extension is not implemented, this bit is RAZ/WI.

This bit resets to an **UNKNOWN** value on a Warm reset.

**RMode, bits [23:22]**

Rounding mode control field. This field determines what rounding mode is applied to Floating-point operations.

The possible values of this field are:

**0b00**

Round to Nearest (RN) mode.

**0b01**

Round towards Plus Infinity (RP) mode.

**0b10**

Round towards Minus Infinity (RM) mode.

**0b11**

Round towards Zero (RZ) mode.

If the Floating-point Extension is not implemented, this field is RAZ/WI.

This field resets to an **UNKNOWN** value on a Warm reset.

**Bits [21:20]**

Reserved, **RES0**.

**FZ16, bit [19]**

Flush-to-zero mode control bit on half-precision data-processing instructions.

The possible values of this bit are:

**0**

Flush-to-zero mode disabled. Behavior of the Floating-point unit is fully compliant with the IEEE 754 standard.

**1**

Flush-to-zero mode enabled.

The value of this bit applies to both scalar and MVE Floating-point half-precision calculations.

If the Floating-point Extension is not implemented, this bit is RAZ/WI.

This bit resets to an **UNKNOWN** value on a Warm reset.

**LTPSIZE, bits [18:16]**

The vector element size used when applying low-overhead-loop tail predication to vector instructions.

The possible values of this field are:

**0b000**

8 bits.

**0b001**

16 bits.

**0b010**

32 bits.

**0b011**

64 bits.

**0b100**

Tail predication not applied.

All other values are reserved.

The loop hardware behaves as if this field had the value 4 (indicating no low-overhead-loop predication) if no floating-point context is active. This field reads as 4 and ignores writes if MVE is not implemented.

If the Low Overhead Branch Extension is not implemented, this field is **RES0**.

This field resets to an **UNKNOWN** value on a Warm reset.

**Bits [15:8]**

Reserved, **RES0**.

**IDC, bit [7]**

Input Denormal cumulative exception bit. This sticky flag records whether a Floating-point input denormal exception has been detected since last cleared.

The possible values of this bit are:

**0**

Input Denormal exception has not occurred since 0 was last written to this bit.

**1**

Input Denormal exception has occurred since 0 was last written to this bit.

If the Floating-point Extension is not implemented, this bit is **RES0**.

This bit resets to an **UNKNOWN** value on a Warm reset.

**Bits [6:5]**

Reserved, **RES0**.

**IXC, bit [4]**

Inexact cumulative exception bit. This sticky flag records whether a Floating-point inexact exception has been detected since last cleared.

The possible values of this bit are:

**0**  
Inexact exception has not occurred since 0 was last written to this bit.

**1**  
Inexact exception has occurred since 0 was last written to this bit.

If the Floating-point Extension is not implemented, this bit is **RES0**.

This bit resets to an **UNKNOWN** value on a Warm reset.

**UFC, bit [3]**

Underflow cumulative exception bit. This sticky flag records whether a Floating-point Underflow exception has been detected since last cleared.

The possible values of this bit are:

**0**  
Underflow exception has not occurred since 0 was last written to this bit.

**1**  
Underflow exception has occurred since 0 was last written to this bit.

If the Floating-point Extension is not implemented, this bit is **RES0**.

**OFC, bit [2]**

Overflow cumulative exception bit. This sticky flag records whether a Floating-point overflow exception has been detected since last cleared.

The possible values of this bit are:

**0**  
Overflow exception has not occurred since 0 was last written to this bit.

**1**  
Overflow exception has occurred since 0 was last written to this bit.

If the Floating-point Extension is not implemented, this bit is **RES0**.

This bit resets to an **UNKNOWN** value on a Warm reset.

**DZC, bit [1]**

Divide by Zero cumulative exception bit. This sticky flag records whether a Floating-point divide by zero exception has been detected since last cleared.

The possible values of this bit are:

**0**  
Division by Zero exception has not occurred since 0 was last written to this bit.

**1**  
Division by Zero exception has occurred since 0 was last written to this bit.

If the Floating-point Extension is not implemented, this bit is **RES0**.

This bit resets to an **UNKNOWN** value on a Warm reset.

**IOC, bit [0]**

Invalid Operation cumulative exception bit. This sticky flag records whether a Floating-point invalid operation exception has been detected since last cleared.

The possible values of this bit are:

**0**  
Invalid Operation exception has not occurred since 0 was last written to this bit.

**1**  
Invalid Operation exception has occurred since 0 was last written to this bit.

If the Floating-point Extension is not implemented, this bit is [RES0](#).

This bit resets to an [UNKNOWN](#) value on a Warm reset.

### D1.2.103 FP\_CIDR0, FP Component Identification Register 0

The FP\_CIDR0 characteristics are:

#### Purpose

Provides CoreSight Unique Component Identifier information for the Flash Patch and Breakpoint Unit.

#### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

If the Main Extension is not implemented then it is **IMPLEMENTATION DEFINED** whether this register is accessible only to the debugger and **RES0** for software. Otherwise the register is accessible to the debugger and software.

#### Configurations

Present only if CoreSight identification is implemented.

This register is **RES0** if CoreSight identification is not implemented.

Present only if the FPB is implemented.

This register is **RES0** if the FPB is not implemented.

#### Attributes

32-bit read-only register located at 0xE0002FF0.

This register is not banked between Security states.

### Field descriptions

The FP\_CIDR0 bit assignments are:

#### Bits [31:8]

Reserved, **RES0**.

#### PRMBL\_0, bits [7:0]

CoreSight component identification preamble. See the *Arm® CoreSight™ Architecture Specification*.

This field reads as 0x0D.

## D1.2.104 FP\_CIDR1, FP Component Identification Register 1

The FP\_CIDR1 characteristics are:

### Purpose

Provides CoreSight Unique Component Identifier information for the Flash Patch and Breakpoint Unit.

### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

If the Main Extension is not implemented then it is **IMPLEMENTATION DEFINED** whether this register is accessible only to the debugger and **RES0** for software. Otherwise the register is accessible to the debugger and software.

### Configurations

Present only if CoreSight identification is implemented.

This register is **RES0** if CoreSight identification is not implemented.

Present only if the FPB is implemented.

This register is **RES0** if the FPB is not implemented.

### Attributes

32-bit read-only register located at 0xE0002FF4.

This register is not banked between Security states.

## Field descriptions

The FP\_CIDR1 bit assignments are:

### Bits [31:8]

Reserved, **RES0**.

### CLASS, bits [7:4]

CoreSight component class. See the *Arm® CoreSight™ Architecture Specification*.

This field reads as 0x9.

### PRMBL\_1, bits [3:0]

CoreSight component identification preamble. See the *Arm® CoreSight™ Architecture Specification*.

This field reads as 0x0.

### D1.2.105 FP\_CIDR2, FP Component Identification Register 2

The FP\_CIDR2 characteristics are:

#### Purpose

Provides CoreSight Unique Component Identifier information for the Flash Patch and Breakpoint Unit.

#### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

If the Main Extension is not implemented then it is **IMPLEMENTATION DEFINED** whether this register is accessible only to the debugger and **RES0** for software. Otherwise the register is accessible to the debugger and software.

#### Configurations

Present only if CoreSight identification is implemented.

This register is **RES0** if CoreSight identification is not implemented.

Present only if the FPB is implemented.

This register is **RES0** if the FPB is not implemented.

#### Attributes

32-bit read-only register located at 0xE0002FF8.

This register is not banked between Security states.

### Field descriptions

The FP\_CIDR2 bit assignments are:

#### Bits [31:8]

Reserved, **RES0**.

#### PRMBL\_2, bits [7:0]

CoreSight component identification preamble. See the *Arm® CoreSight™ Architecture Specification*.

This field reads as 0x05.

### D1.2.106 FP\_CIDR3, FP Component Identification Register 3

The FP\_CIDR3 characteristics are:

#### Purpose

Provides CoreSight Unique Component Identifier information for the Flash Patch and Breakpoint Unit.

#### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

If the Main Extension is not implemented then it is **IMPLEMENTATION DEFINED** whether this register is accessible only to the debugger and **RES0** for software. Otherwise the register is accessible to the debugger and software.

#### Configurations

Present only if CoreSight identification is implemented.

This register is **RES0** if CoreSight identification is not implemented.

Present only if the FPB is implemented.

This register is **RES0** if the FPB is not implemented.

#### Attributes

32-bit read-only register located at 0xE0002FFC.

This register is not banked between Security states.

### Field descriptions

The FP\_CIDR3 bit assignments are:

#### Bits [31:8]

Reserved, **RES0**.

#### PRMBL\_3, bits [7:0]

CoreSight component identification preamble. See the *Arm® CoreSight™ Architecture Specification*.

This field reads as 0xB1.

### D1.2.107 FP\_COMPn, Flash Patch Comparator Register, n = 0 - 125

The FP\_COMP{0..125} characteristics are:

## Purpose

Holds an address for comparison.

## Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

If the Main Extension is not implemented then it is **IMPLEMENTATION DEFINED** whether this register is accessible only to the debugger and **RES0** for software. Otherwise the register is accessible to the debugger and software.

## Configurations

Present only if the FPB is implemented.

This register is **RES0** if the FPB is not implemented.

## Attributes

32-bit read/write register located at  $0xE002008 + 4n$ .

This register is not banked between Security states.

## Field descriptions

The FP\_COMP{0..125} bit assignments are:

**BPADDR, bits [31:1]**

Breakpoint address. Specifies bits[31:1] of the breakpoint instruction address.

**BE, bit [0]**

Breakpoint enable. Selects between remapping and breakpoint functionality.

The possible values of this bit are:

0

Breakpoint disabled.

**1**

Breakpoint enabled.

For backwards compatibility, when disabling a breakpoint software must write zero to the whole register.

This bit resets to zero on a Cold reset.

## D1.2.108 FP\_CTRL, Flash Patch Control Register

The FP\_CTRL characteristics are:

### Purpose

Provides FPB implementation information, and the global enable for the FPB unit.

### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

If the Main Extension is not implemented then it is **IMPLEMENTATION DEFINED** whether this register is accessible only to the debugger and **RES0** for software. Otherwise the register is accessible to the debugger and software.

### Configurations

Present only if the FPB is implemented.

This register is **RES0** if the FPB is not implemented.

### Attributes

32-bit read/write register located at 0xE0002000.

This register is not banked between Security states.

## Field descriptions

The FP\_CTRL bit assignments are:

### REV, bits [31:28]

Revision. Flash Patch and Breakpoint Unit architecture revision.

The possible values of this field are:

**0b0001**

Flash Patch Breakpoint version 2 implemented.

All other values are reserved.

This field is read-only.

This field reads as 0b0001.

### Bits [27:15]

Reserved, **RES0**.

### NUM\_CODE, bits [14:12,7:4]

Number of implemented code comparators. Indicates the number of implemented instruction address comparators. Zero indicates no Instruction Address comparators are implemented. The Instruction Address comparators are numbered from 0 to NUM\_CODE - 1.

This field is read-only.

This field reads as an **IMPLEMENTATION DEFINED** value.

**NUM\_LIT, bits [11:8]**

Number of literal comparators. This field is RAZ/WI. Remapping is not supported in Armv8-M.

Reserved, RAZ/WI

**Bits [3:2]**

Reserved, RES0.

**KEY, bit [1]**

FP\_CTRL write-enable key. Writes to the FP\_CTRL are ignored unless KEY is concurrently written to one.

The possible values of this bit are:

**0**

Concurrent write to FP\_CTRL ignored.

**1**

Concurrent write to FP\_CTRL permitted.

This bit reads-as-zero.

**ENABLE, bit [0]**

Flash Patch global enable. Enables the FPB.

The possible values of this bit are:

**0**

All FPB functionality disabled.

**1**

FPB enabled.

This bit resets to zero on a Cold reset.

## D1.2.109 FP\_DEVARCH, FPB Device Architecture Register

The FP\_DEVARCH characteristics are:

### Purpose

Provides CoreSight Unique Component Identifier information for the Flash Patch and Breakpoint Unit.

### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

If the Main Extension is not implemented then it is **IMPLEMENTATION DEFINED** whether this register is accessible only to the debugger and **RES0** for software. Otherwise the register is accessible to the debugger and software.

### Configurations

Present only if CoreSight identification is implemented.

This register is **RES0** if CoreSight identification is not implemented.

Present only if the FPB is implemented.

This register is **RES0** if the FPB is not implemented.

### Attributes

32-bit read-only register located at 0xE0002FBC.

This register is not banked between Security states.

## Field descriptions

The FP\_DEVARCH bit assignments are:

### ARCHITECT, bits [31:21]

Architect. Defines the architect of the component. Bits [31:28] are the JEP106 continuation code (JEP106 bank ID, minus 1) and bits [27:21] are the JEP106 ID code.

The possible values of this field are:

#### 0x23B

JEP106 continuation code 0x4, ID code 0x3B. Arm Limited.

Other values are defined by the JEDEC JEP106 standard.

This field reads as 0x23B.

### PRESENT, bit [20]

DEVARCH Present. Defines that the DEVARCH register is present.

The possible values of this bit are:

#### 1

DEVARCH information present.

This bit reads as one.

**REVISION, bits [19:16]**

Revision. Defines the architecture revision of the component.

The possible values of this field are:

**0b0000**

FPB architecture v2.0.

This field reads as 0b0000.

**ARCHVER, bits [15:12]**

Architecture Version. Defines the architecture version of the component.

The possible values of this field are:

**0b0001**

FPB architecture v2.

ARCHVER and ARCHPART are also defined as a single field, ARCHID, so that ARCHVER is ARCHID[15:12].

This field reads as 0b0001.

**ARCHPART, bits [11:0]**

Architecture Part. Defines the architecture of the component.

The possible values of this field are:

**0xA03**

FPB architecture.

ARCHVER and ARCHPART are also defined as a single field, ARCHID, so that ARCHPART is ARCHID[11:0].

This field reads as 0xA03.

### D1.2.110 FP\_DEVTYPE, FPB Device Type Register

The FP\_DEVTYPE characteristics are:

#### Purpose

Provides CoreSight Unique Component Identifier information for the Flash Patch and Breakpoint Unit.

#### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

If the Main Extension is not implemented then it is IMPLEMENTATION DEFINED whether this register is accessible only to the debugger and RES0 for software. Otherwise the register is accessible to the debugger and software.

#### Configurations

Present only if CoreSight identification is implemented.

This register is RES0 if CoreSight identification is not implemented.

Present only if the FPB is implemented.

This register is RES0 if the FPB is not implemented.

#### Attributes

32-bit read-only register located at 0xE0002FCC.

This register is not banked between Security states.

### Field descriptions

The FP\_DEVTYPE bit assignments are:

#### Bits [31:8]

Reserved, RES0.

#### SUB, bits [7:4]

Sub-type. Component sub-type.

The possible values of this field are:

0x0

Other.

This field reads as 0b0000.

#### MAJOR, bits [3:0]

Major type. Component major type.

The possible values of this field are:

0x0

Miscellaneous.

This field reads as 0b0000.

### D1.2.111 FP\_LAR, FPB Software Lock Access Register

The FP\_LAR characteristics are:

#### Purpose

Provides CoreSight Software Lock control for the FPB, see the *Arm® CoreSight™ Architecture Specification* for details.

#### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

This register is RAZ/WI if accessed via the debugger, regardless of DAUTHCTRL.UIDAPEN (either bank). It is **IMPLEMENTATION DEFINED** whether a DAP error is generated.

#### Configurations

Present only if CoreSight identification is implemented.

This register is **RES0** if CoreSight identification is not implemented.

Present only if the FPB is implemented.

This register is **RES0** if the FPB is not implemented.

Present only if the optional Software Lock is implemented.

This register is RAZ/WI if the Software Lock is not implemented.

#### Attributes

32-bit write-only register located at 0xE0002FB0.

This register is not banked between Security states.

### Field descriptions

The FP\_LAR bit assignments are:

#### KEY, bits [31:0]

Lock Access control.

Writing the key value 0xC5ACCE55 to this field unlocks the lock, enabling write accesses to the registers of this component through a memory-mapped interface.

Writing any other value to this register locks the lock, disabling write accesses to the registers of this component through a memory mapped interface.

### D1.2.112 FP\_LSR, FPB Software Lock Status Register

The FP\_LSR characteristics are:

#### Purpose

Provides CoreSight Software Lock status information for the FPB, see the *Arm® CoreSight™ Architecture Specification* for details.

#### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

This register is RAZ/WI if accessed via the debugger, regardless of DAUTHCTRL.UIDAPEN (either bank). It is **IMPLEMENTATION DEFINED** whether a DAP error is generated.

#### Configurations

Present only if CoreSight identification is implemented.

This register is **RES0** if CoreSight identification is not implemented.

Present only if the FPB is implemented.

This register is **RES0** if the FPB is not implemented.

Present only if the optional Software Lock is implemented.

This register is RAZ/WI if the Software Lock is not implemented.

#### Attributes

32-bit read-only register located at 0xE0002FB4.

This register is not banked between Security states.

### Field descriptions

The FP\_LSR bit assignments are:

#### Bits [31:3]

Reserved, **RES0**.

#### nTT, bit [2]

Not thirty-two bit. See the *Arm® CoreSight™ Architecture Specification*.

This bit reads as zero.

#### SLK, bit [1]

Software Lock status. See the *Arm® CoreSight™ Architecture Specification*.

The possible values of this bit are:

**0**

Lock clear. Software writes are permitted to the registers of this component.

**1**

Lock set. Software writes to the registers of this component are ignored, and reads have no side effects.

For a debugger read of this register, or when the Software Lock is not implemented, this bit is [RES0](#).

This bit resets to one on a Cold reset.

**SLI, bit [0]**

Software Lock implemented. See the *Arm® CoreSight™ Architecture Specification*.

The possible values of this bit are:

**0**

Software Lock not implemented or debugger access.

**1**

Software Lock is implemented and software access.

For a debugger read of this register, or when the Software Lock is not implemented, this bit is RAZ.

This bit reads as an [IMPLEMENTATION DEFINED](#) value.

### D1.2.113 FP\_PIDR0, FP Peripheral Identification Register 0

The FP\_PIDR0 characteristics are:

#### Purpose

Provides CoreSight Unique Component Identifier information for the Flash Patch and Breakpoint Unit.

#### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

If the Main Extension is not implemented then it is **IMPLEMENTATION DEFINED** whether this register is accessible only to the debugger and **RES0** for software. Otherwise the register is accessible to the debugger and software.

#### Configurations

Present only if CoreSight identification is implemented.

This register is **RES0** if CoreSight identification is not implemented.

Present only if the FPB is implemented.

This register is **RES0** if the FPB is not implemented.

#### Attributes

32-bit read-only register located at 0xE0002FE0.

This register is not banked between Security states.

### Field descriptions

The FP\_PIDR0 bit assignments are:

#### Bits [31:8]

Reserved, **RES0**.

#### PART\_0, bits [7:0]

Part number bits [7:0]. See the *Arm® CoreSight™ Architecture Specification*.

This field reads as an **IMPLEMENTATION DEFINED** value.

### D1.2.114 FP\_PIDR1, FP Peripheral Identification Register 1

The FP\_PIDR1 characteristics are:

## Purpose

Provides CoreSight Unique Component Identifier information for the Flash Patch and Breakpoint Unit.

## Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

If the Main Extension is not implemented then it is **IMPLEMENTATION DEFINED** whether this register is accessible only to the debugger and **RES0** for software. Otherwise the register is accessible to the debugger and software.

## Configurations

Present only if CoreSight identification is implemented.

This register is **RES0** if CoreSight identification is not implemented.

Present only if the FPB is implemented.

This register is **RES0** if the FPB is not implemented.

## Attributes

32-bit read-only register located at 0xE0002FE4.

This register is not banked between Security states.

## Field descriptions

The FP\_PIDR1 bit assignments are:

**Bits [31:8]**

Reserved, RES0.

**DES\_0, bits [7:4]**

JEP106 identification code bits [3:0]. See the *Arm® CoreSight™ Architecture Specification*.

This field reads as an IMPLEMENTATION DEFINED value.

**PART\_1, bits [3:0]**

Part number bits [11:8]. See the *Arm® CoreSight™ Architecture Specification*.

This field reads as an IMPLEMENTATION DEFINED value.

### D1.2.115 FP\_PIDR2, FP Peripheral Identification Register 2

The FP\_PIDR2 characteristics are:

#### Purpose

Provides CoreSight Unique Component Identifier information for the Flash Patch and Breakpoint Unit.

#### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

If the Main Extension is not implemented then it is **IMPLEMENTATION DEFINED** whether this register is accessible only to the debugger and **RES0** for software. Otherwise the register is accessible to the debugger and software.

#### Configurations

Present only if CoreSight identification is implemented.

This register is **RES0** if CoreSight identification is not implemented.

Present only if the FPB is implemented.

This register is **RES0** if the FPB is not implemented.

#### Attributes

32-bit read-only register located at 0xE0002FE8.

This register is not banked between Security states.

### Field descriptions

The FP\_PIDR2 bit assignments are:

#### Bits [31:8]

Reserved, **RES0**.

#### REVISION, bits [7:4]

Component revision. See the *Arm® CoreSight™ Architecture Specification*.

This field reads as an **IMPLEMENTATION DEFINED** value.

#### JEDEC, bit [3]

JEDEC assignee value is used. See the *Arm® CoreSight™ Architecture Specification*.

This bit reads as one.

#### DES\_1, bits [2:0]

JEP106 identification code bits [6:4]. See the *Arm® CoreSight™ Architecture Specification*.

This field reads as an **IMPLEMENTATION DEFINED** value.

## D1.2.116 FP\_PIDR3, FP Peripheral Identification Register 3

The FP\_PIDR3 characteristics are:

### Purpose

Provides CoreSight Unique Component Identifier information for the Flash Patch and Breakpoint Unit.

### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

If the Main Extension is not implemented then it is **IMPLEMENTATION DEFINED** whether this register is accessible only to the debugger and **RES0** for software. Otherwise the register is accessible to the debugger and software.

### Configurations

Present only if CoreSight identification is implemented.

This register is **RES0** if CoreSight identification is not implemented.

Present only if the FPB is implemented.

This register is **RES0** if the FPB is not implemented.

### Attributes

32-bit read-only register located at 0xE0002FEC.

This register is not banked between Security states.

## Field descriptions

The FP\_PIDR3 bit assignments are:

### Bits [31:8]

Reserved, **RES0**.

### REVAND, bits [7:4]

RevAnd. See the *Arm® CoreSight™ Architecture Specification*.

This field reads as an **IMPLEMENTATION DEFINED** value.

### CMOD, bits [3:0]

Customer Modified. See the *Arm® CoreSight™ Architecture Specification*.

This field reads as an **IMPLEMENTATION DEFINED** value.

## D1.2.117 FP\_PIDR4, FP Peripheral Identification Register 4

The FP\_PIDR4 characteristics are:

### Purpose

Provides CoreSight Unique Component Identifier information for the Flash Patch and Breakpoint Unit.

### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

If the Main Extension is not implemented then it is **IMPLEMENTATION DEFINED** whether this register is accessible only to the debugger and **RES0** for software. Otherwise the register is accessible to the debugger and software.

### Configurations

Present only if CoreSight identification is implemented.

This register is **RES0** if CoreSight identification is not implemented.

Present only if the FPB is implemented.

This register is **RES0** if the FPB is not implemented.

### Attributes

32-bit read-only register located at 0xE0002FD0.

This register is not banked between Security states.

## Field descriptions

The FP\_PIDR4 bit assignments are:

### Bits [31:8]

Reserved, **RES0**.

### SIZE, bits [7:4]

4KB count. See the *Arm® CoreSight™ Architecture Specification*.

This field reads as zero.

### DES\_2, bits [3:0]

JEP106 continuation code. See the *Arm® CoreSight™ Architecture Specification*.

This field reads as an **IMPLEMENTATION DEFINED** value.

### D1.2.118 FP\_PIDR5, FP Peripheral Identification Register 5

The FP\_PIDR5 characteristics are:

#### Purpose

Provides CoreSight Unique Component Identifier information for the Flash Patch and Breakpoint Unit.

#### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

If the Main Extension is not implemented then it is **IMPLEMENTATION DEFINED** whether this register is accessible only to the debugger and **RES0** for software. Otherwise the register is accessible to the debugger and software.

#### Configurations

Present only if CoreSight identification is implemented.

This register is **RES0** if CoreSight identification is not implemented.

Present only if the FPB is implemented.

This register is **RES0** if the FPB is not implemented.

#### Attributes

32-bit read-only register located at 0xE0002FD4.

This register is not banked between Security states.

### Field descriptions

The FP\_PIDR5 bit assignments are:

#### Bits [31:0]

Reserved, **RES0**.

### D1.2.119 FP\_PIDR6, FP Peripheral Identification Register 6

The FP\_PIDR6 characteristics are:

#### Purpose

Provides CoreSight Unique Component Identifier information for the Flash Patch and Breakpoint Unit.

#### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

If the Main Extension is not implemented then it is **IMPLEMENTATION DEFINED** whether this register is accessible only to the debugger and **RES0** for software. Otherwise the register is accessible to the debugger and software.

#### Configurations

Present only if CoreSight identification is implemented.

This register is **RES0** if CoreSight identification is not implemented.

Present only if the FPB is implemented.

This register is **RES0** if the FPB is not implemented.

#### Attributes

32-bit read-only register located at 0xE0002FD8.

This register is not banked between Security states.

#### Field descriptions

The FP\_PIDR6 bit assignments are:

#### Bits [31:0]

Reserved, **RES0**.

## D1.2.120 FP\_PIDR7, FP Peripheral Identification Register 7

The FP\_PIDR7 characteristics are:

### Purpose

Provides CoreSight Unique Component Identifier information for the Flash Patch and Breakpoint Unit.

### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

If the Main Extension is not implemented then it is **IMPLEMENTATION DEFINED** whether this register is accessible only to the debugger and **RES0** for software. Otherwise the register is accessible to the debugger and software.

### Configurations

Present only if CoreSight identification is implemented.

This register is **RES0** if CoreSight identification is not implemented.

Present only if the FPB is implemented.

This register is **RES0** if the FPB is not implemented.

### Attributes

32-bit read-only register located at 0xE0002FDC.

This register is not banked between Security states.

## Field descriptions

The FP\_PIDR7 bit assignments are:

### Bits [31:0]

Reserved, **RES0**.

### D1.2.121 FP\_REMAP, Flash Patch Remap Register

The FP REMAP characteristics are:

## Purpose

Indicates whether the implementation supports Flash Patch remap and, if it does, holds the target address for remap.

## Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

If the Main Extension is not implemented then it is **IMPLEMENTATION DEFINED** whether this register is accessible only to the debugger and **RES0** for software. Otherwise the register is accessible to the debugger and software.

## Configurations

Present only if the FPB is implemented.

This register is **RES0** if the FPB is not implemented.

## Attributes

32-bit read-only register located at 0xE0002004.

This register is not banked between Security states.

## Field descriptions

The FP\_REMAP bit assignments are:

**Bits [31:30]**

Reserved, RES0.

## RMPSPT, bit [29]

Remap supported. This field is RAZ. Remapping is not supported in Armv8-M.

**REMAP, bits [28:5]**

Remap address.

Reserved, RES0.

**Bits [4:0]**

Reserved, RES0.

## D1.2.122 HFSR, HardFault Status Register

The HFSR characteristics are:

### Purpose

Shows the cause of any HardFaults.

### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

### Configurations

Present only if the Main Extension is implemented.

This register is **RES0** if the Main Extension is not implemented.

### Attributes

32-bit read/write-one-to-clear register located at 0xE000ED2C.

Secure software can access the Non-secure version of this register via HFSR\_NS located at 0xE002ED2C. The location 0xE002ED2C is **RES0** to software executing in Non-secure state and the debugger.

This register is not banked between Security states.

From Armv8.1-M onwards it is **IMPLEMENTATION DEFINED** whether a debugger write to this register is ignored when the PE is not in Debug state.

## Field descriptions

The HFSR bit assignments are:

### DEBUGEVT, bit [31]

Debug event. Indicates when a debug event has occurred.

The possible values of this bit are:

**0**

No debug event has occurred.

**1**

Debug event has occurred. The Debug Fault Status Register has been updated.

The PE sets this bit to 1 when a breakpoint is encountered and Halting debug is disabled and a DebugMonitor exception cannot be taken.

If AIRCR.BFHFNMINS is zero this bit is RAZ/WI from Non-secure state.

This bit resets to zero on a Warm reset.

### FORCED, bit [30]

Forced. Indicates that a fault with configurable priority has been escalated to a HardFault exception, because it could not be made active, because of priority, or because it was disabled.

The possible values of this bit are:

**0**  
No priority escalation has occurred.

**1**  
Processor has escalated a configurable-priority exception to HardFault.  
If AIRCR.BFHFNMINS is zero this bit is RAZ/WI from Non-secure state.  
This bit resets to zero on a Warm reset.

**Bits [29:2]**  
Reserved, [RES0](#).

**VECTTBL, bit [1]**  
Vector table. Indicates when a fault has occurred because of a vector table read error on exception processing.  
The possible values of this bit are:

**0**  
No vector table read fault has occurred.

**1**  
Vector table read fault has occurred.  
If AIRCR.BFHFNMINS is zero this bit is RAZ/WI from Non-secure state.  
This bit resets to zero on a Warm reset.

**Bit [0]**  
Reserved, [RES0](#).

### D1.2.123 ICIALLU, Instruction Cache Invalidate All to PoU

The ICIALLU characteristics are:

#### Purpose

Invalidate all instruction caches to PoU.

#### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are [UNPREDICTABLE](#).

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

#### Configurations

This register is always implemented.

#### Attributes

32-bit write-only register located at 0xE000EF50.

Secure software can access the Non-secure version of this register via ICIALLU\_NS located at 0xE002EF50.

The location 0xE002EF50 is [RES0](#) to software executing in Non-secure state and the debugger.

This register is not banked between Security states.

### Field descriptions

The ICIALLU bit assignments are:

#### Ignored, bits [31:0]

The value written to this field is ignored. Ignored.

## D1.2.124 ICIMVAU, Instruction Cache line Invalidate by Address to PoU

The ICIMVAU characteristics are:

### Purpose

Invalidate instruction cache line by address to PoU.

### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

### Configurations

This register is always implemented.

### Attributes

32-bit write-only register located at 0xE000EF58.

Secure software can access the Non-secure version of this register via ICIMVAU\_NS located at 0xE002EF58. The location 0xE002EF58 is **RES0** to software executing in Non-secure state and the debugger.

This register is not banked between Security states.

## Field descriptions

The ICIMVAU bit assignments are:

### ADDRESS, bits [31:0]

Address. Writing to this field initiates the maintenance operation for the address written.

## D1.2.125 ICSR, Interrupt Control and State Register

The ICSR characteristics are:

### Purpose

Controls and provides status information for NMI, PendSV, SysTick and interrupts.

### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

### Configurations

This register is always implemented.

### Attributes

32-bit read/write register located at 0xE000ED04.

Secure software can access the Non-secure version of this register via ICSR\_NS located at 0xE002ED04. The location 0xE002ED04 is **RES0** to software executing in Non-secure state and the debugger.

This register is banked between Security states on a bit by bit basis.

## Field descriptions

The ICSR bit assignments are:

### PENDNMISET, bit [31], on a write

Pend NMI set. Allows the NMI exception to be set as pending.

This bit is not banked between Security states.

The possible values of this bit are:

**0**

No effect.

**1**

Sets the NMI exception pending.

If both PENDNMISET and PENDNMICLR are written to one simultaneously, the pending state of the NMI exception becomes **UNKNOWN**.

This bit is write-one-to-set. Writes of zero are ignored.

If AIRCR.BFHFNMINS is zero this bit is RAZ/WI from Non-secure state.

### PENDNMISET, bit [31], on a read

Pend NMI set. Indicates whether the NMI exception is pending.

This bit is not banked between Security states.

The possible values of this bit are:

**0**  
NMI exception not pending.

**1**  
NMI exception pending.

If AIRCR.BFHFNMINS is zero this bit is RAZ/WI from Non-secure state.

This bit resets to zero on a Warm reset.

**PENDNMICLR, bit [30]**

Pend NMI clear. Allows the NMI exception pending state to be cleared.

This bit is not banked between Security states.

The possible values of this bit are:

**0**  
No effect.

**1**  
Clear pending status.

This bit is write-only, and reads-as-zero.

This bit is write-one-to-clear. Writes of zero are ignored.

If AIRCR.BFHFNMINS is zero this bit is RAZ/WI from Non-secure state.

**Bit [29]**

Reserved, [RES0](#).

**PENDSVSET, bit [28], on a write**

Pend PendSV set. Allows the PendSV exception for the selected Security state to be set as pending.

This bit is banked between Security states.

The possible values of this bit are:

**0**  
No effect.

**1**  
Sets the PendSV exception pending.

If both PENDSVSET and PENDSVCLR are written to one simultaneously, the pending state of the associated PendSV exception becomes [UNKNOWN](#).

This bit is write-one-to-set. Writes of zero are ignored.

**PENDSVSET, bit [28], on a read**

Pend PendSV set. Indicates whether the PendSV for the selected Security state exception is pending.

This bit is banked between Security states.

The possible values of this bit are:

**0**  
PendSV exception not pending.

**1**  
PendSV exception pending.

This bit resets to zero on a Warm reset.

**PENDSVCLR, bit [27]**

Pend PendSV clear. Allows the PendSV exception pending state to be cleared for the selected Security state.

This bit is banked between Security states.

The possible values of this bit are:

**0**

No effect.

**1**

Clear pending status.

This bit is write-only, and reads-as-zero.

This bit is write-one-to-clear. Writes of zero are ignored.

**PENDSTSET, bit [26], on a write**

Pend SysTick set. Allows the SysTick for the selected Security state exception to be set as pending.

If two SysTick timers are implemented this bit is banked between Security states.

If less than two SysTick timers are implemented this bit is not banked between Security states.

The possible values of this bit are:

**0**

No effect.

**1**

Sets the SysTick exception for the selected Security state pending.

If only one SysTick timer is implemented and ICSR.STTNS is clear, this bit is RAZ/WI from Non-secure state.

If no SysTick timer is implemented this bit is [RES0](#).

**PENDSTSET, bit [26], on a read**

Pend SysTick set. Indicates whether the SysTick for the selected Security state exception is pending.

If two SysTick timers are implemented this bit is banked between Security states.

If less than two SysTick timers are implemented this bit is not banked between Security states.

The possible values of this bit are:

**0**

SysTick exception not pending.

**1**

SysTick exception pending.

If both PENDSTSET and PENDSTCLR are written to one simultaneously, the pending state of the associated SysTick exception becomes [UNKNOWN](#).

If only one SysTick timer is implemented and ICSR.STTNS is clear, this bit is RAZ/WI from Non-secure state.

If no SysTick timer is implemented this bit is [RES0](#).

This bit resets to zero on a Warm reset.

**PENDSTCLR, bit [25]**

Pend SysTick clear. Allows the SysTick exception pending state to be cleared for the selected Security state.

If two SysTick timers are implemented this bit is banked between Security states.

If less than two SysTick timers are implemented this bit is not banked between Security states.

The possible values of this bit are:

**0**  
No effect.

**1**  
Clear pending status.

This bit is write-only, and reads-as-zero.

This bit is write-one-to-clear. Writes of zero are ignored.

If only one SysTick timer is implemented and ICSR.STTNS is clear, this bit is RAZ/WI from Non-secure state.

If no SysTick timer is implemented this bit is [RES0](#).

#### **STTNS, bit [24]**

SysTick Targets Non-secure. Controls whether in a single SysTick implementation, the SysTick is Secure or Non-secure.

This bit is not banked between Security states.

The possible values of this bit are:

**0**  
SysTick is Secure.

**1**  
SysTick is Non-secure.

Behaves as RAZ/WI when either no SysTick or both SysTick timers are implemented. In a PE with the Main Extension and Security Extension this bit is [RES0](#). This bit is RAZ/WI when accessed from the Non-secure state.

This bit is RAZ/WI from Non-secure state.

This bit resets to zero on a Warm reset.

#### **ISRPREEMPT, bit [23]**

Interrupt preempt. Indicates whether a pending exception will be handled on exit from Debug state.

This bit is not banked between Security states.

The possible values of this bit are:

**0**  
Will not handle.

**1**  
Will handle a pending exception.

The value of this bit is [UNKNOWN](#) when not in Debug state.

This bit is read-only.

If neither Halting debug or the Main Extension are implemented, this bit is [RES0](#).

#### **ISRPENDING, bit [22]**

Interrupt pending. Indicates whether an external interrupt, generated by the NVIC, is pending.

This bit is not banked between Security states.

The possible values of this bit are:

**0**  
No external interrupt pending.

**1**  
External interrupt pending.

The value of DHCSR.C\_MASKINTS is ignored.

This bit is read-only.

If neither Halting debug or the Main Extension are implemented, this bit is [RES0](#).

**Bit [21]**

Reserved, [RES0](#).

**VECTPENDING, bits [20:12]**

Vector pending. The exception number of the highest priority pending and enabled interrupt.

This field is not banked between Security states.

The possible values of this field are:

**Zero**

No pending and enabled exception.

**Nonzero**

Exception number.

From Armv8.1-M this value is 1 when accessed as Non-secure and a Secure exception is the highest priority pending exception.

If DHCSR.C\_MASKINTS is set, the PendSV, SysTick, and configurable external interrupts are masked and will not be shown as pending in VECTPENDING.

This field is read-only.

**RETTOBASE, bit [11]**

Return to base. In Handler mode, indicates whether there is more than one active exception.

This bit is not banked between Security states.

The possible values of this bit are:

**0**

There is more than one active exception.

**1**

There is only one active exception.

In Thread mode the value of this bit is [UNKNOWN](#).

This bit is read-only.

If the Main Extension is not implemented, this bit is [RES0](#).

**Bits [10:9]**

Reserved, [RES0](#).

**VECTACTIVE, bits [8:0]**

Vector active. The exception number of the current executing exception.

This field is not banked between Security states.

The possible values of this field are:

**Zero**

Thread mode.

**Nonzero**

Exception number.

This value is the same as the IPSR Exception number. When the IPSR value has been set to 1 because of a function call to Non-secure state, this field is also set to 1.

This field is read-only.

If neither Halting debug or the Main Extension are implemented, this field is [RES0](#).

### D1.2.126 ICTR, Interrupt Controller Type Register

The ICTR characteristics are:

## Purpose

Provides information about the interrupt controller.

## Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

From Armv8.1-M, it is **IMPLEMENTATION DEFINED** if this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

## Configurations

This register is always implemented.

## Attributes

32-bit read-only register located at 0xE000E004.

Secure software can access the Non-secure version of this register via ICTR\_NS located at 0xE002E004.

The location 0xE002E004 is **RES0** to software executing in Non-secure state and the debugger.

This register is not banked between Security states.

## Field descriptions

The ICTR bit assignments are:

**Bits [31:4]**

Reserved, RES0.

**INTLINESNUM, bits [3:0]**

Interrupt line set number. Indicates the number of the highest implemented register in each of the NVIC control register sets, or in the case of NVIC\_IPR*n*, 4xINTLINESNUM.

This field reads as an IMPLEMENTATION DEFINED value.

## D1.2.127 ID\_AFR0, Auxiliary Feature Register 0

The ID\_AFR0 characteristics are:

### Purpose

Provides information about the **IMPLEMENTATION DEFINED** features of the PE.

### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

### Configurations

Present only if the Main Extension is implemented.

This register is **RES0** if the Main Extension is not implemented.

### Attributes

32-bit read-only register located at 0xE000ED4C.

Secure software can access the Non-secure version of this register via ID\_AFR0\_NS located at 0xE002ED4C.

The location 0xE002ED4C is **RES0** to software executing in Non-secure state and the debugger.

This register is not banked between Security states.

## Field descriptions

The ID\_AFR0 bit assignments are:

|    |  |  |  |  |  |  |  |  |  |  |  |  |  |    |    |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |    |

### Bits [31:16]

Reserved, **RES0**.

### IMPDEF $m$ , bits [4 $m$ +3:4 $m$ ], for $m = 0$ to 3

**IMPLEMENTATION DEFINED**. **IMPLEMENTATION DEFINED** meaning.

This field reads as an **IMPLEMENTATION DEFINED** value.

## D1.2.128 ID\_DFR0, Debug Feature Register 0

The ID\_DFR0 characteristics are:

### Purpose

Provides top level information about the debug system.

### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

### Configurations

Present only if the Main Extension is implemented.

This register is **RES0** if the Main Extension is not implemented.

### Attributes

32-bit read-only register located at 0xE000ED48.

Secure software can access the Non-secure version of this register via ID\_DFR0\_NS located at 0xE002ED48.

The location 0xE002ED48 is **RES0** to software executing in Non-secure state and the debugger.

This register is not banked between Security states.

## Field descriptions

The ID\_DFR0 bit assignments are:

### UDE, bits [31:28]

Unprivileged Debug Extension. Indicates support for the Unprivileged Debug Extension.

The possible values of this field are:

**0b0000**

Unprivileged Debug Extension is not implemented.

**0b0001**

Unprivileged Debug Extension is implemented.

If version Armv8.1-M of the architecture is not implemented, this field is **RES0**.

This field reads as an **IMPLEMENTATION DEFINED** value.

### Bits [27:24]

Reserved, **RES0**.

### MProfDbg, bits [23:20]

M-Profile debug. Indicates the supported M-Profile debug architecture.

The possible values of this field are:

**0b0000**

Halting debug is not implemented.

**0b0010**

Armv8-M Debug architecture including Halting debug is implemented.

All other values are reserved.

This field reads as an IMPLEMENTATION DEFINED value.

**Bits [19:0]**

Reserved, RES0.

## D1.2.129 ID\_ISAR0, Instruction Set Attribute Register 0

The ID\_ISAR0 characteristics are:

### Purpose

Provides information about the instruction set implemented by the PE.

### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are [UNPREDICTABLE](#).

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

### Configurations

Present only if the Main Extension is implemented.

This register is [RES0](#) if the Main Extension is not implemented.

### Attributes

32-bit read-only register located at 0xE000ED60.

Secure software can access the Non-secure version of this register via ID\_ISAR0\_NS located at 0xE002ED60. The location 0xE002ED60 is [RES0](#) to software executing in Non-secure state and the debugger.

This register is not banked between Security states.

## Field descriptions

The ID\_ISAR0 bit assignments are:

|      |    |    |    |        |    |    |    |           |    |    |   |          |   |   |   |
|------|----|----|----|--------|----|----|----|-----------|----|----|---|----------|---|---|---|
| 31   | 28 | 27 | 24 | 23     | 20 | 19 | 16 | 15        | 12 | 11 | 8 | 7        | 4 | 3 | 0 |
| RES0 |    |    |    | Divide |    |    |    | Debug     |    |    |   | Coprocc  |   |   |   |
|      |    |    |    |        |    |    |    | CmpBranch |    |    |   | BitField |   |   |   |
|      |    |    |    |        |    |    |    |           |    |    |   | BitCount |   |   |   |
|      |    |    |    |        |    |    |    |           |    |    |   | RES0     |   |   |   |

### Bits [31:28]

Reserved, [RES0](#).

### Divide, bits [27:24]

Divide. Indicates the supported Divide instructions.

The possible values of this field are:

**0b0001**

Supports SDIV and UDIV instructions.

All other values are reserved.

This field reads as 0b0001.

### Debug, bits [23:20]

Debug. Indicates the implemented Debug instructions.

The possible values of this field are:

**0b0001**

Supports BKPT instruction.

All other values are reserved.

This field reads as 0b0001.

**Coproc, bits [19:16]**

Coprocessor. Indicates the supported coprocessor instructions.

The possible values of this field are:

**0b0000**

No coprocessor instructions support other than FPU or MVE.

**0b0100**

Coprocessor instructions supported.

All other values are reserved.

This field reads as an **IMPLEMENTATION DEFINED** value.

**CmpBranch, bits [15:12]**

Compare and branch. Indicates the supported combined Compare and Branch instructions.

The possible values of this field are:

**0b0001**

Supports CBNZ and CBZ instructions.

**0b0011**

Supports CBNZ and CBZ instructions along with non-predicated low overhead looping (WLS, DLS, LE and LCTP) and branch future (BF, BFX, BFL, BFLX, and BFCSEL) instructions.

All other values are reserved.

This field reads as an **IMPLEMENTATION DEFINED** value.

**BitField, bits [11:8]**

Bit field. Indicates the supported bit field instructions.

The possible values of this field are:

**0b0001**

BFC, BFI, SBFX, and UBFX supported.

All other values are reserved.

This field reads as 0b0001.

**BitCount, bits [7:4]**

Bit count. Indicates the supported bit count instructions.

The possible values of this field are:

**0b0001**

CLZ supported.

All other values are reserved.

This field reads as 0b0001.

**Bits [3:0]**

Reserved, **RES0**.

### D1.2.130 ID\_ISAR1, Instruction Set Attribute Register 1

The ID\_ISAR1 characteristics are:

#### Purpose

Provides information about the instruction set implemented by the PE.

#### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are [UNPREDICTABLE](#).

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

#### Configurations

Present only if the Main Extension is implemented.

This register is [RES0](#) if the Main Extension is not implemented.

#### Attributes

32-bit read-only register located at 0xE000ED64.

Secure software can access the Non-secure version of this register via ID\_ISAR1\_NS located at 0xE002ED64. The location 0xE002ED64 is [RES0](#) to software executing in Non-secure state and the debugger.

This register is not banked between Security states.

#### Preface

If the DSP Extension is not implemented, this register reads as 0x02211000.

If the DSP Extension is implemented, this register reads as 0x02212000.

#### Field descriptions

The ID\_ISAR1 bit assignments are:

|      |           |           |        |        |       |  |      |   |
|------|-----------|-----------|--------|--------|-------|--|------|---|
| 31   | 28,27     | 24,23     | 20,19  | 16,15  | 12,11 |  |      | 0 |
| RES0 | Interwork | Immediate | IfThen | Extend |       |  | RES0 |   |

#### Bits [31:28]

Reserved, [RES0](#).

#### Interwork, bits [27:24]

Interworking. Indicates the implemented interworking instructions.

The possible values of this field are:

**0b0010**

BLX, BX, and loads to PC interwork.

All other values are reserved.

This field reads as 0b0010.

#### Immediate, bits [23:20]

Immediate. Indicates the implemented for data-processing instructions with long immediates.

The possible values of this field are:

**0b0001**

ADDW, MOVW, MOVT, and SUBW supported.

All other values are reserved.

This field reads as 0b0001.

**IfThen, bits [19:16]**

If-Then. Indicates the implemented If-Then instructions.

The possible values of this field are:

**0b0001**

IT instruction supported.

All other values are reserved.

This field reads as 0b0001.

**Extend, bits [15:12]**

Extend. Indicates the implemented Extend instructions.

The possible values of this field are:

**0b0001**

SXTB, SXTB, UXTB, and UXTH.

**0b0010**

Adds SXTB16, SXTAB, SXTAB16, SXTAH, UXTB16, UXTAB, UXTAB16, and UXTAH, DSP Extension only.

All other values are reserved.

This field reads as an **IMPLEMENTATION DEFINED** value.

**Bits [11:0]**

Reserved, **RES0**.

### D1.2.131 ID\_ISAR2, Instruction Set Attribute Register 2

The ID\_ISAR2 characteristics are:

#### Purpose

Provides information about the instruction set implemented by the PE.

#### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are [UNPREDICTABLE](#).

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

#### Configurations

Present only if the Main Extension is implemented.

This register is [RES0](#) if the Main Extension is not implemented.

#### Attributes

32-bit read-only register located at 0xE000ED68.

Secure software can access the Non-secure version of this register via ID\_ISAR2\_NS located at 0xE002ED68. The location 0xE002ED68 is [RES0](#) to software executing in Non-secure state and the debugger.

This register is not banked between Security states.

#### Preface

With bits [11:8] masked, if the DSP Extension is not implemented, this register reads as 0x20112032.

With bits[11:8] masked, if the DSP Extension is implemented, this register reads as 0x20232032.

The value of bits [11:8] is determined by whether the PE implements restartable or continuable multi-access instructions.

#### Field descriptions

The ID\_ISAR2 bit assignments are:

#### Reversal, bits [31:28]

Reversal. Indicates the implemented Reversal instructions.

The possible values of this field are:

**0b0010**

REV, REV16, REVSH and RBIT instructions supported.

All other values are reserved.

This field reads as 0b0010.

#### Bits [27:24]

Reserved, [RES0](#).

**MultU, bits [23:20]**

Multiply unsigned. Indicates the implemented advanced unsigned Multiply instructions.

The possible values of this field are:

**0b0001**

UMULL and UMLAL.

**0b0010**

Adds UMAAL, DSP Extension only.

All other values are reserved.

This field reads as an **IMPLEMENTATION DEFINED** value.

**MultS, bits [19:16]**

Multiply signed. Indicates the implemented advanced signed Multiply instructions.

The possible values of this field are:

**0b0001**

SMULL and SMLAL.

**0b0011**

Adds all saturating and DSP signed multiplies, DSP Extension only.

All other values are reserved.

This field reads as an **IMPLEMENTATION DEFINED** value.

**Mult, bits [15:12]**

Multiplies. Indicates the implemented additional Multiply instructions.

The possible values of this field are:

**0b0010**

MUL, MLA, and MLS.

All other values are reserved.

This field reads as 0b0010.

**MultiAccessInt, bits [11:8]**

Multi-access instructions. Indicates the support for interruptible multi-access instructions.

The possible values of this field are:

**0b0000**

No support. LDM and STM instructions are not interruptible.

**0b0001**

LDM and STM instructions are restartable.

**0b0010**

LDM and STM instructions, and if Armv8.1-M is implemented the CLRM instruction, are continuable.

All other values are reserved.

This field reads as an **IMPLEMENTATION DEFINED** value.

**MemHint, bits [7:4]**

Memory hints. Indicates the implemented Memory hint instructions.

The possible values of this field are:

**0b0011**

PLI and PLD instructions implemented.

All other values are reserved.

This field reads as 0b0011.

**LoadStore, bits [3:0]**

Load/store. Indicates the implemented additional load/store instructions.

The possible values of this field are:

**0b0010**

Supports load-acquire, store-release, and exclusive load and store instructions.

All other values are reserved.

This field reads as 0b0010.

## D1.2.132 ID\_ISAR3, Instruction Set Attribute Register 3

The ID\_ISAR3 characteristics are:

### Purpose

Provides information about the instruction set implemented by the PE.

### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are [UNPREDICTABLE](#).

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

### Configurations

Present only if the Main Extension is implemented.

This register is [RES0](#) if the Main Extension is not implemented.

### Attributes

32-bit read-only register located at 0xE000ED6C.

Secure software can access the Non-secure version of this register via ID\_ISAR3\_NS located at 0xE002ED6C. The location 0xE002ED6C is [RES0](#) to software executing in Non-secure state and the debugger.

This register is not banked between Security states.

### Preface

If the DSP Extension is not implemented, this register reads as 0x01111110.

If the DSP Extension is implemented, this register reads as 0x01111131.

### Field descriptions

The ID\_ISAR3 bit assignments are:

|      |         |         |           |           |       |      |          |   |
|------|---------|---------|-----------|-----------|-------|------|----------|---|
| 31   | 28,27   | 24,23   | 20,19     | 16,15     | 12,11 | 8,7  | 4,3      | 0 |
| RES0 | TrueNOP | T32Copy | TabBranch | SynchPrim | SVC   | SIMD | Saturate |   |

#### Bits [31:28]

Reserved, [RES0](#).

#### TrueNOP, bits [27:24]

True no-operation. Indicates the implemented true NOP instructions.

The possible values of this field are:

##### 0b0001

NOP instruction and compatible hints implemented.

All other values are reserved.

This field reads as 0b0001.

#### T32Copy, bits [23:20]

T32 copy. Indicates the support for T32 non flag-setting MOV instructions.

The possible values of this field are:

**0b0001**

Encoding T1 of MOV (register) supports copying low register to low register.

All other values are reserved.

This field reads as 0b0001.

**TabBranch, bits [19:16]**

Table branch. Indicates the implemented Table Branch instructions.

The possible values of this field are:

**0b0001**

TBB and TBH implemented.

All other values are reserved.

This field reads as 0b0001.

**SynchPrim, bits [15:12]**

Synchronization primitives. Used in conjunction with ID\_ISAR4.SynchPrim\_frac to indicate the implemented synchronization primitive instructions.

The possible values of this field are:

**0b0001**

LDREX, STREX, LDREXB, STREXB, LDREXH, STREXH, and CLREX implemented.

All other values are reserved.

This field reads as 0b0001.

**SVC, bits [11:8]**

Supervisor Call. Indicates the implemented SVC instructions.

The possible values of this field are:

**0b0001**

SVC instruction implemented.

All other values are reserved.

This field reads as 0b0001.

**SIMD, bits [7:4]**

Single-instruction, multiple-data. Indicates the implemented SIMD instructions.

The possible values of this field are:

**0b0001**

SSAT, USAT, and Q-bit implemented.

**0b0011**

Adds all packed arithmetic and GE-bits, DSP Extension only.

All other values are reserved.

This field reads as an **IMPLEMENTATION DEFINED** value.

**Saturate, bits [3:0]**

Saturate. Indicates the implemented saturating instructions.

The possible values of this field are:

**0b0000**

None implemented.

**0b0001**

QADD, QDADD, QDSUB, QSUB, and Q-bit implemented, DSP Extension only.

All other values are reserved.

This field reads as an **IMPLEMENTATION DEFINED** value.

### D1.2.133 ID\_ISAR4, Instruction Set Attribute Register 4

The ID\_ISAR4 characteristics are:

#### Purpose

Provides information about the instruction set implemented by the PE.

#### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are [UNPREDICTABLE](#).

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

#### Configurations

Present only if the Main Extension is implemented.

This register is [RES0](#) if the Main Extension is not implemented.

#### Attributes

32-bit read-only register located at 0xE000ED70.

Secure software can access the Non-secure version of this register via ID\_ISAR4\_NS located at 0xE002ED70. The location 0xE002ED70 is [RES0](#) to software executing in Non-secure state and the debugger.

This register is not banked between Security states.

#### Preface

This register reads as 0x01310132.

#### Field descriptions

The ID\_ISAR4 bit assignments are:

#### Bits [31:28]

Reserved, [RES0](#).

#### PSR\_M, bits [27:24]

Program Status Registers M. Indicates the implemented M profile instructions to modify the PSRs.

The possible values of this field are:

**0b0001**

M profile forms of CPS, MRS, and MSR implemented.

All other values are reserved.

This field reads as 0b0001.

#### SyncPrim\_frac, bits [23:20]

Synchronization primitives fractional. Used in conjunction with ID\_ISAR3.SyncPrim to indicate the implemented synchronization primitive instructions.

The possible values of this field are:

**0b0011**

LDREX, STREX, CLREX, LDREXB, LDREXH, STREXB, and STREXH implemented.

All other values are reserved.

This field reads as 0b0011.

**Barrier, bits [19:16]**

Barrier. Indicates the implemented Barrier instructions.

The possible values of this field are:

**0b0001**

CSDB, DMB, DSB, ISB, PSSBB and SSBB barrier instructions implemented.

All other values are reserved.

This field reads as 0b0001.

**Bits [15:12]**

Reserved, [RES0](#).

**Writeback, bits [11:8]**

Writeback. Indicates the support for write-back addressing modes.

The possible values of this field are:

**0b0001**

All write-back addressing modes supported.

All other values are reserved.

This field reads as 0b0001.

**WithShifts, bits [7:4]**

With shifts. Indicates the support for write-back addressing modes.

The possible values of this field are:

**0b0011**

Support for constant shifts on load/store and other instructions.

All other values are reserved.

This field reads as 0b0011.

**Unpriv, bits [3:0]**

Unprivileged. Indicates the implemented unprivileged instructions.

The possible values of this field are:

**0b0010**

LDRBT, LDRHT, LDRSBT, LDRSHT, LDRT, STRBT, STRHT, and STRT implemented.

All other values are reserved.

This field reads as 0b0010.

### D1.2.134 ID\_ISAR5, Instruction Set Attribute Register 5

The ID\_ISAR5 characteristics are:

#### Purpose

Provides information about the instruction set implemented by the PE.

#### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are [UNPREDICTABLE](#).

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

#### Configurations

Present only if the Main Extension is implemented.

This register is [RES0](#) if the Main Extension is not implemented.

#### Attributes

32-bit read-only register located at 0xE000ED74.

Secure software can access the Non-secure version of this register via ID\_ISAR5\_NS located at 0xE002ED74. The location 0xE002ED74 is [RES0](#) to software executing in Non-secure state and the debugger.

This register is not banked between Security states.

### Field descriptions

The ID\_ISAR5 bit assignments are:

#### Bits [31:24]

Reserved, [RES0](#).

#### PACBTI, bits [23:20]

Pointer authentication algorithm. Indicates whether QARMA or an [IMPLEMENTATION DEFINED](#) algorithm is implemented for address authentication in the PE.

The possible values of this field are:

##### 0b0000

Address authentication and branch target identification is not implemented.

##### 0b0001

Address authentication using the QARMA5 algorithm is implemented. Applies to all pointer authentication instructions.

##### 0b0010

Address authentication using an [IMPLEMENTATION DEFINED](#) algorithm is implemented. Applies to all pointer authentication instructions.

##### 0b0100

Address authentication using the QARMA3 algorithm is implemented. Applies to all pointer authentication instructions.

All other values are reserved.

Branch target identification is implemented when either QARMA or an **IMPLEMENTATION DEFINED** algorithm is implemented.

If the PACBTI Extension is not implemented, this field is **RES0**.

This field reads as an **IMPLEMENTATION DEFINED** value.

**Bits [19:0]**

Reserved, **RES0**.

### D1.2.135 ID\_MMFR0, Memory Model Feature Register 0

The ID\_MMFR0 characteristics are:

#### Purpose

Provides information about the implemented memory model and memory management support.

#### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are [UNPREDICTABLE](#).

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

#### Configurations

Present only if the Main Extension is implemented.

This register is [RES0](#) if the Main Extension is not implemented.

#### Attributes

32-bit read-only register located at 0xE000ED50.

Secure software can access the Non-secure version of this register via ID\_MMFR0\_NS located at 0xE002ED50. The location 0xE002ED50 is [RES0](#) to software executing in Non-secure state and the debugger.

This register is not banked between Security states.

### Field descriptions

The ID\_MMFR0 bit assignments are:

|      |  |    |    |        |    |     |    |          |    |          |   |      |   |      |
|------|--|----|----|--------|----|-----|----|----------|----|----------|---|------|---|------|
| 31   |  | 24 | 23 | 20     | 19 | 16  | 15 | 12       | 11 | 8        | 7 | 4    | 3 | 0    |
| RES0 |  |    |    | AuxReg |    | TCM |    | ShareLvl |    | OuterShr |   | PMSA |   | RES0 |

#### Bits [31:24]

Reserved, [RES0](#).

#### AuxReg, bits [23:20]

Auxiliary Registers. Indicates support for Auxiliary Control Registers.

The possible values of this field are:

**0b0000**

No Auxiliary Control Registers.

**0b0001**

Auxiliary Control Registers supported.

All other values are reserved.

This field reads as an [IMPLEMENTATION DEFINED](#) value.

#### TCM, bits [19:16]

Tightly Coupled Memories. Indicates support for Tightly Coupled Memories (TCMs).

The possible values of this field are:

**0b0000**

None supported.

**0b0001**

TCMs supported with IMPLEMENTATION DEFINED control.

All other values are reserved.

This field reads as an IMPLEMENTATION DEFINED value.

**ShareLvl, bits [15:12]**

Shareability Levels. Indicates the number of Shareability levels implemented.

The possible values of this field are:

**0b0000**

One level of Shareability implemented.

**0b0001**

Two levels of Shareability implemented.

All other values are reserved.

This field reads as an IMPLEMENTATION DEFINED value.

**OuterShr, bits [11:8]**

Outermost Shareability. Indicates the outermost Shareability domain implemented.

The possible values of this field are:

**0b0000**

Implemented as Non-cacheable.

**0b0001**

Implemented with hardware coherency support.

**0b1111**

Shareability ignored.

All other values are reserved.

This field reads as an IMPLEMENTATION DEFINED value.

**PMSA, bits [7:4]**

Protected memory system architecture. Indicates support for the protected memory system architecture (PMSA).

The possible values of this field are:

**0b0100**

Supports PMSAv8.

All other values are reserved.

This field reads as 0b0100.

**Bits [3:0]**

Reserved, RES0.

## D1.2.136 ID\_MMFR1, Memory Model Feature Register 1

The ID\_MMFR1 characteristics are:

### Purpose

Provides information about the implemented memory model and memory management support.

### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are [UNPREDICTABLE](#).

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

### Configurations

Present only if the Main Extension is implemented.

This register is [RES0](#) if the Main Extension is not implemented.

### Attributes

32-bit read-only register located at 0xE000ED54.

Secure software can access the Non-secure version of this register via ID\_MMFR1\_NS located at 0xE002ED54. The location 0xE002ED54 is [RES0](#) to software executing in Non-secure state and the debugger.

This register is not banked between Security states.

## Field descriptions

The ID\_MMFR1 bit assignments are:

### Bits [31:0]

Reserved, [RES0](#).

### D1.2.137 ID\_MMFR2, Memory Model Feature Register 2

The ID MMFR2 characteristics are:

## Purpose

Provides information about the implemented memory model and memory management support.

## Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

## Configurations

Present only if the Main Extension is implemented.

This register is **RES0** if the Main Extension is not implemented.

## Attributes

32-bit read-only register located at 0xE000ED58.

Secure software can access the Non-secure version of this register via ID\_MMFR2\_NS located at 0xE002ED58. The location 0xE002ED58 is **RES0** to software executing in Non-secure state and the debugger.

This register is not banked between Security states.

## Field descriptions

The ID\_MMFR2 bit assignments are:

**Bits [31:28]**

Reserved, RES0.

**WFISall, bits [27:24]**

WFI stall. Indicates the support for Wait For Interrupt (WFI) stalling.

The possible values of this field are:

0b0000

WFI never stalls.

0b0001

WFI has the ability to stall.

All other values are reserved.

This field reads as an **IMPLEMENTATION DEFINED** value.

**Bits [23:0]**

Reserved, RES0.

### D1.2.138 ID\_MMFR3, Memory Model Feature Register 3

The ID\_MMFR3 characteristics are:

#### Purpose

Provides information about the implemented memory model and memory management support.

#### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are [UNPREDICTABLE](#).

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

#### Configurations

Present only if the Main Extension is implemented.

This register is [RES0](#) if the Main Extension is not implemented.

#### Attributes

32-bit read-only register located at 0xE000ED5C.

Secure software can access the Non-secure version of this register via ID\_MMFR3\_NS located at 0xE002ED5C. The location 0xE002ED5C is [RES0](#) to software executing in Non-secure state and the debugger.

This register is not banked between Security states.

### Field descriptions

The ID\_MMFR3 bit assignments are:

#### Bits [31:12]

Reserved, [RES0](#).

#### BPMaint, bits [11:8]

Branch predictor maintenance. Indicates the supported branch predictor maintenance.

The possible values of this field are:

**0b0000**

None supported.

**0b0001**

Support for invalidate all of branch predictors.

All other values are reserved.

This field reads as an [IMPLEMENTATION DEFINED](#) value.

#### CMaintSW, bits [7:4]

Cache maintenance set/way. Indicates the supported cache maintenance operations by set/way.

The possible values of this field are:

**0b0000**

None supported.

**0b0001**

Maintenance by set/way operations supported.

All other values are reserved.

This field reads as an **IMPLEMENTATION DEFINED** value.

**CMaintVA, bits [3:0]**

Cache maintenance by address. Indicates the supported cache maintenance operations by address.

The possible values of this field are:

**0b0000**

None supported.

**0b0001**

Maintenance by address and instruction cache invalidate all supported.

All other values are reserved.

This field reads as an **IMPLEMENTATION DEFINED** value.

### D1.2.139 ID\_PFR0, Processor Feature Register 0

The ID\_PFR0 characteristics are:

#### Purpose

Gives top-level information about the instruction set supported by the PE.

#### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are [UNPREDICTABLE](#).

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

#### Configurations

Present only if the Main Extension is implemented.

This register is [RES0](#) if the Main Extension is not implemented.

#### Attributes

32-bit read-only register located at 0xE000ED40.

Secure software can access the Non-secure version of this register via ID\_PFR0\_NS located at 0xE002ED40.

The location 0xE002ED40 is [RES0](#) to software executing in Non-secure state and the debugger.

This register is not banked between Security states.

### Field descriptions

The ID\_PFR0 bit assignments are:

#### RAS, bits [31:28]

RAS Extension. Identifies which version of the RAS extension is implemented.

The possible values of this field are:

**0b0000**

No RAS extension.

**0b0010**

Version 1 of the RAS extension implemented.

All other values are reserved.

If version Armv8.1-M of the architecture is not implemented, this field is [RES0](#).

This field reads as an [IMPLEMENTATION DEFINED](#) value.

#### Bits [27:8]

Reserved, [RES0](#).

#### State1, bits [7:4]

T32 instruction set support.

The possible values of this field are:

**0b0011**

T32 instruction set including Thumb-2 Technology implemented.

All other values are reserved.

This field reads as 0b0011.

**State0, bits [3:0]**

A32 instruction set support.

The possible values of this field are:

**0b0000**

A32 instruction set not implemented.

All other values are reserved.

This field reads as 0b0000.

## D1.2.140 ID\_PFR1, Processor Feature Register 1

The ID\_PFR1 characteristics are:

### Purpose

Gives information about the programmers' model and Extensions support.

### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are [UNPREDICTABLE](#).

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

### Configurations

Present only if the Main Extension is implemented.

This register is [RES0](#) if the Main Extension is not implemented.

### Attributes

32-bit read-only register located at 0xE000ED44.

Secure software can access the Non-secure version of this register via ID\_PFR1\_NS located at 0xE002ED44.

The location 0xE002ED44 is [RES0](#) to software executing in Non-secure state and the debugger.

This register is not banked between Security states.

## Field descriptions

The ID\_PFR1 bit assignments are:

### Bits [31:12]

Reserved, [RES0](#).

### MProgMod, bits [11:8]

M programmers' model. Identifies support for the M-Profile programmers' model support.

The possible values of this field are:

**0b0010**

Two-stack programmers' model.

All other values are reserved.

This field reads as 0b0010.

### Security, bits [7:4]

Security. Identifies whether the Security Extension is implemented.

The possible values of this field are:

**0b0000**

Security Extension not implemented.

**0b0001**

Security Extension implemented.

**0b0011**

Security Extension implemented with state handling instructions (VSCCLRM, CLRM, FPCXT access instructions and disabling SG Thread mode re-entrancy).

All other values are reserved.

This field reads as an **IMPLEMENTATION DEFINED** value.

**Bits [3:0]**

Reserved, **RES0**.

### D1.2.141 IPSR, Interrupt Program Status Register

The IPSR characteristics are:

## Purpose

Provides privileged access to the current exception number field.

## Usage constraints

Privileged access only. Unprivileged access is RAZ/WI, unless otherwise stated.

## Configurations

This register is always implemented.

## Attributes

32-bit read/write special-purpose register.

This register is not banked between Security states.

## Field descriptions

The IPSR bit assignments are:

**Bits [31:9]**

Reserved, RES0.

### Exception, bits [8:0]

Exception number. Holds the exception number of the currently-executing exception, or zero for Thread mode.

The possible values of this field are:

## Zero

PE in Thread mode.

## Nonzero

PE in Handler mode in given exception number. On a function call from Secure state the value is set to 1 to ensure that the Non-secure state cannot determine which exception handler is executing.

This field resets to zero on a Warm reset.

### D1.2.142 ITM\_CIDR0, ITM Component Identification Register 0

The ITM\_CIDR0 characteristics are:

#### Purpose

Provides CoreSight discovery information for the ITM.

#### Usage constraints

If the Main Extension is implemented, both privileged and unprivileged accesses are permitted.

If the Main Extension is not implemented, unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

#### Configurations

Present only if the Main Extension is implemented.

This register is RES0 if the Main Extension is not implemented.

Present only if CoreSight identification is implemented.

This register is RES0 if CoreSight identification is not implemented.

Present only if the ITM is implemented.

This register is RES0 if the ITM is not implemented.

If the Main Extension is not implemented then the ITM is not implemented.

#### Attributes

32-bit read-only register located at 0xE0000FF0.

This register is not banked between Security states.

### Field descriptions

The ITM\_CIDR0 bit assignments are:

#### Bits [31:8]

Reserved, RES0.

#### PRMBL\_0, bits [7:0]

CoreSight component identification preamble. See the *Arm® CoreSight™ Architecture Specification*.

This field reads as 0x0D.

### D1.2.143 ITM\_CIDR1, ITM Component Identification Register 1

The ITM\_CIDR1 characteristics are:

## Purpose

Provides CoreSight discovery information for the ITM.

## Usage constraints

If the Main Extension is implemented, both privileged and unprivileged accesses are permitted.

If the Main Extension is not implemented, unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

## Configurations

Present only if the Main Extension is implemented.

This register is **RES0** if the Main Extension is not implemented.

Present only if CoreSight identification is implemented.

This register is **RES0** if CoreSight identification is not implemented.

Present only if the ITM is implemented.

This register is **RES0** if the ITM is not implemented.

If the Main Extension is not implemented then the ITM is not implemented.

## Attributes

32-bit read-only register located at 0xE0000FF4.

This register is not banked between Security states.

## Field descriptions

The ITM\_CIDR1 bit assignments are:

**Bits [31:8]**

Reserved, RES0.

**CLASS, bits [7:4]**

CoreSight component class. See the *Arm® CoreSight™ Architecture Specification*.

This field reads as 0x9.

**PRMBL\_1, bits [3:0]**

CoreSight component identification preamble. See the *Arm® CoreSight™ Architecture Specification*.

This field reads as 0x0.

## D1.2.144 ITM\_CIDR2, ITM Component Identification Register 2

The ITM\_CIDR2 characteristics are:

### Purpose

Provides CoreSight discovery information for the ITM.

### Usage constraints

If the Main Extension is implemented, both privileged and unprivileged accesses are permitted.

If the Main Extension is not implemented, unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are [UNPREDICTABLE](#).

### Configurations

Present only if the Main Extension is implemented.

This register is [RES0](#) if the Main Extension is not implemented.

Present only if CoreSight identification is implemented.

This register is [RES0](#) if CoreSight identification is not implemented.

Present only if the ITM is implemented.

This register is [RES0](#) if the ITM is not implemented.

If the Main Extension is not implemented then the ITM is not implemented.

### Attributes

32-bit read-only register located at 0xE0000FF8.

This register is not banked between Security states.

## Field descriptions

The ITM\_CIDR2 bit assignments are:

### Bits [31:8]

Reserved, [RES0](#).

### PRMBL\_2, bits [7:0]

CoreSight component identification preamble. See the *Arm® CoreSight™ Architecture Specification*.

This field reads as 0x05.

### D1.2.145 ITM\_CIDR3, ITM Component Identification Register 3

The ITM\_CIDR3 characteristics are:

#### Purpose

Provides CoreSight discovery information for the ITM.

#### Usage constraints

If the Main Extension is implemented, both privileged and unprivileged accesses are permitted.

If the Main Extension is not implemented, unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

#### Configurations

Present only if the Main Extension is implemented.

This register is RES0 if the Main Extension is not implemented.

Present only if CoreSight identification is implemented.

This register is RES0 if CoreSight identification is not implemented.

Present only if the ITM is implemented.

This register is RES0 if the ITM is not implemented.

If the Main Extension is not implemented then the ITM is not implemented.

#### Attributes

32-bit read-only register located at 0xE0000FFC.

This register is not banked between Security states.

### Field descriptions

The ITM\_CIDR3 bit assignments are:

#### Bits [31:8]

Reserved, RES0.

#### PRMBL\_3, bits [7:0]

CoreSight component identification preamble. See the *Arm® CoreSight™ Architecture Specification*.

This field reads as 0xB1.

## D1.2.146 ITM\_DEVARCH, ITM Device Architecture Register

The ITM\_DEVARCH characteristics are:

### Purpose

Provides CoreSight discovery information for the ITM.

### Usage constraints

If the Main Extension is implemented, both privileged and unprivileged accesses are permitted.

If the Main Extension is not implemented, unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

### Configurations

Present only if the Main Extension is implemented.

This register is **RES0** if the Main Extension is not implemented.

Present only if CoreSight identification is implemented.

This register is **RES0** if CoreSight identification is not implemented.

Present only if the ITM is implemented.

This register is **RES0** if the ITM is not implemented.

If the Main Extension is not implemented then the ITM is not implemented.

### Attributes

32-bit read-only register located at 0xE0000FBC.

This register is not banked between Security states.

## Field descriptions

The ITM\_DEVARCH bit assignments are:

### ARCHITECT, bits [31:21]

Architect. Defines the architect of the component. Bits [31:28] are the JEP106 continuation code (JEP106 bank ID, minus 1) and bits [27:21] are the JEP106 ID code.

The possible values of this field are:

#### 0x23B

JEP106 continuation code 0x4, ID code 0x3B. Arm Limited.

Other values are defined by the JEDEC JEP106 standard.

This field reads as 0x23B.

### PRESENT, bit [20]

DEVARCH Present. Defines that the DEVARCH register is present.

The possible values of this bit are:

#### 1

DEVARCH information present.

This bit reads as one.

**REVISION, bits [19:16]**

Revision. Defines the architecture revision of the component.

The possible values of this field are:

**0b0000**

ITM architecture v2.0.

This field reads as 0b0000.

**ARCHVER, bits [15:12]**

Architecture Version. Defines the architecture version of the component.

The possible values of this field are:

**0b0001**

ITM architecture v2.

ARCHVER and ARCHPART are also defined as a single field, ARCHID, so that ARCHVER is ARCHID[15:12].

This field reads as 0b0001.

**ARCHPART, bits [11:0]**

Architecture Part. Defines the architecture of the component.

The possible values of this field are:

**0xA01**

ITM architecture.

ARCHVER and ARCHPART are also defined as a single field, ARCHID, so that ARCHPART is ARCHID[11:0].

This field reads as 0xA01.

### D1.2.147 ITM\_DEVTYPE, ITM Device Type Register

The ITM\_DEVTYPE characteristics are:

## Purpose

Provides CoreSight discovery information for the ITM.

## Usage constraints

If the Main Extension is implemented, both privileged and unprivileged accesses are permitted.

If the Main Extension is not implemented, unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

If the Main Extension is not implemented then it is **IMPLEMENTATION DEFINED** whether this register is accessible only to the debugger and **RES0** for software. Otherwise the register is accessible to the debugger and software.

## Configurations

Present only if the Main Extension is implemented.

This register is **RES0** if the Main Extension is not implemented.

Present only if CoreSight identification is implemented.

This register is **RES0** if CoreSight identification is not implemented.

Present only if the ITM is implemented.

This register is **RES0** if the ITM is not implemented.

If the Main Extension is not implemented then the ITM is not implemented.

## Attributes

32-bit read-only register located at 0xE0000FCC.

This register is not banked between Security states.

## Field descriptions

The ITM\_DEVTYPE bit assignments are:

**Bits [31:8]**Reserved, **RES0**.**SUB, bits [7:4]**

Sub-type. Component sub-type.

The possible values of this field are:

0x0

Other. Only permitted if the MAJOR field reads as 0x0.

## 0x4

Associated with a Bus, stimulus derived from bus activity. Only permitted if the MAJOR field reads as 0x3.

This field reads as an **IMPLEMENTATION DEFINED** value.

**MAJOR, bits [3:0]**

Major type. Component major type.

The possible values of this field are:

**0x0**

Miscellaneous.

**0x3**

Trace Source.

This field reads as an **IMPLEMENTATION DEFINED** value.

### D1.2.148 ITM\_LAR, ITM Software Lock Access Register

The ITM\_LAR characteristics are:

#### Purpose

Provides CoreSight Software Lock control for the ITM, see the *Arm® CoreSight™ Architecture Specification* for details.

#### Usage constraints

If the Main Extension is implemented, both privileged and unprivileged accesses are permitted, but unprivileged writes are ignored.

If the Main Extension is not implemented, unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

This register is RAZ/WI if accessed via the debugger, regardless of DAUTHCTRL.UIDAPEN (either bank). It is **IMPLEMENTATION DEFINED** whether a DAP error is generated.

#### Configurations

Present only if the Main Extension is implemented.

This register is **RES0** if the Main Extension is not implemented.

Present only if CoreSight identification is implemented.

This register is **RES0** if CoreSight identification is not implemented.

Present only if the ITM is implemented.

This register is **RES0** if the ITM is not implemented.

If the Main Extension is not implemented then the ITM is not implemented.

Present only if the optional Software Lock is implemented.

This register is RAZ/WI if the Software Lock is not implemented.

#### Attributes

32-bit write-only register located at 0xE0000FB0.

This register is not banked between Security states.

### Field descriptions

The ITM\_LAR bit assignments are:

#### KEY, bits [31:0]

Lock Access control.

Writing the key value 0xC5ACCE55 to this field unlocks the lock, enabling write accesses to the registers of this component through a memory-mapped interface.

Writing any other value to this register locks the lock, disabling write accesses to the registers of this component through a memory mapped interface.

### D1.2.149 ITM\_LSR, ITM Software Lock Status Register

The ITM\_LSR characteristics are:

#### Purpose

Provides CoreSight Software Lock status information for the ITM, see the *Arm® CoreSight™ Architecture Specification* for details.

#### Usage constraints

If the Main Extension is implemented, both privileged and unprivileged accesses are permitted.

If the Main Extension is not implemented, unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

This register is RAZ/WI if accessed via the debugger, regardless of DAUTHCTRL.UIDAPEN (either bank).

It is **IMPLEMENTATION DEFINED** whether a DAP error is generated.

#### Configurations

Present only if the Main Extension is implemented.

This register is **RES0** if the Main Extension is not implemented.

Present only if CoreSight identification is implemented.

This register is **RES0** if CoreSight identification is not implemented.

Present only if the ITM is implemented.

This register is **RES0** if the ITM is not implemented.

If the Main Extension is not implemented then the ITM is not implemented.

Present only if the optional Software Lock is implemented.

This register is RAZ/WI if the Software Lock is not implemented.

#### Attributes

32-bit read-only register located at 0xE0000FB4.

This register is not banked between Security states.

### Field descriptions

The ITM\_LSR bit assignments are:

#### Bits [31:3]

Reserved, **RES0**.

#### nTT, bit [2]

Not thirty-two bit. See the *Arm® CoreSight™ Architecture Specification*.

This bit reads as zero.

#### SLK, bit [1]

Software Lock status. See the *Arm® CoreSight™ Architecture Specification*.

The possible values of this bit are:

**0**

Lock clear. Software writes are permitted to the registers of this component.

**1**

Lock set. Software writes to the registers of this component are ignored, and reads have no side effects.

For a debugger read of this register, or when the Software Lock is not implemented, this bit is [RES0](#).

This bit resets to one on a Warm reset.

**SLI, bit [0]**

Software Lock implemented. See the *Arm® CoreSight™ Architecture Specification*.

The possible values of this bit are:

**0**

Software Lock not implemented or debugger access.

**1**

Software Lock is implemented and software access.

For a debugger read of this register, or when the Software Lock is not implemented, this bit is RAZ.

This bit reads as an [IMPLEMENTATION DEFINED](#) value.

### D1.2.150 ITM\_PIDR0, ITM Peripheral Identification Register 0

The ITM\_PIDR0 characteristics are:

## Purpose

Provides CoreSight discovery information for the ITM.

## Usage constraints

If the Main Extension is implemented, both privileged and unprivileged accesses are permitted.

If the Main Extension is not implemented, unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

## Configurations

Present only if the Main Extension is implemented.

This register is **RES0** if the Main Extension is not implemented.

Present only if CoreSight identification is implemented.

This register is **RES0** if CoreSight identification is not implemented.

Present only if the ITM is implemented.

This register is **RES0** if the ITM is not implemented.

If the Main Extension is not implemented then the ITM is not implemented.

## Attributes

32-bit read-only register located at 0xE0000FE0.

This register is not banked between Security states.

## Field descriptions

The ITM\_PIDR0 bit assignments are:

**Bits [31:8]**

Reserved, RES0.

**PART\_0, bits [7:0]**

Part number bits [7:0]. See the *Arm® CoreSight™ Architecture Specification*.

This field reads as an IMPLEMENTATION DEFINED value.

### D1.2.151 ITM\_PIDR1, ITM Peripheral Identification Register 1

The ITM\_PIDR1 characteristics are:

## Purpose

Provides CoreSight discovery information for the ITM.

## Usage constraints

If the Main Extension is implemented, both privileged and unprivileged accesses are permitted.

If the Main Extension is not implemented, unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

## Configurations

Present only if the Main Extension is implemented.

This register is **RES0** if the Main Extension is not implemented.

Present only if CoreSight identification is implemented.

This register is **RES0** if CoreSight identification is not implemented.

Present only if the ITM is implemented.

This register is **RES0** if the ITM is not implemented.

If the Main Extension is not implemented then the ITM is not implemented.

## Attributes

32-bit read-only register located at 0xE0000FE4.

This register is not banked between Security states.

## Field descriptions

The ITM\_PIDR1 bit assignments are:

**Bits [31:8]**

Reserved, RES0.

**DES\_0, bits [7:4]**

JEP106 identification code bits [3:0]. See the *Arm® CoreSight™ Architecture Specification*.

This field reads as an IMPLEMENTATION DEFINED value.

**PART\_1, bits [3:0]**

Part number bits [11:8]. See the *Arm® CoreSight™ Architecture Specification*.

This field reads as an IMPLEMENTATION DEFINED value.

## D1.2.152 ITM\_PIDR2, ITM Peripheral Identification Register 2

The ITM\_PIDR2 characteristics are:

### Purpose

Provides CoreSight discovery information for the ITM.

### Usage constraints

If the Main Extension is implemented, both privileged and unprivileged accesses are permitted.

If the Main Extension is not implemented, unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

### Configurations

Present only if the Main Extension is implemented.

This register is **RES0** if the Main Extension is not implemented.

Present only if CoreSight identification is implemented.

This register is **RES0** if CoreSight identification is not implemented.

Present only if the ITM is implemented.

This register is **RES0** if the ITM is not implemented.

If the Main Extension is not implemented then the ITM is not implemented.

### Attributes

32-bit read-only register located at 0xE0000FE8.

This register is not banked between Security states.

## Field descriptions

The ITM\_PIDR2 bit assignments are:

### Bits [31:8]

Reserved, **RES0**.

### REVISION, bits [7:4]

Component revision. See the *Arm® CoreSight™ Architecture Specification*.

This field reads as an **IMPLEMENTATION DEFINED** value.

### JEDEC, bit [3]

JEDEC assignee value is used. See the *Arm® CoreSight™ Architecture Specification*.

This bit reads as one.

### DES\_1, bits [2:0]

JEP106 identification code bits [6:4]. See the *Arm® CoreSight™ Architecture Specification*.

This field reads as an **IMPLEMENTATION DEFINED** value.

### D1.2.153 ITM\_PIDR3, ITM Peripheral Identification Register 3

The ITM\_PIDR3 characteristics are:

## Purpose

Provides CoreSight discovery information for the ITM.

## Usage constraints

If the Main Extension is implemented, both privileged and unprivileged accesses are permitted.

If the Main Extension is not implemented, unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

## Configurations

Present only if the Main Extension is implemented.

This register is **RES0** if the Main Extension is not implemented.

Present only if CoreSight identification is implemented.

This register is **RES0** if CoreSight identification is not implemented.

Present only if the ITM is implemented.

This register is **RES0** if the ITM is not implemented.

If the Main Extension is not implemented then the ITM is not implemented.

## Attributes

32-bit read-only register located at 0xE0000FEC.

This register is not banked between Security states.

## Field descriptions

The ITM\_PIDR3 bit assignments are:

**Bits [31:8]**

Reserved, RES0.

**REVAND**, bits [7:4]

RevAnd. See the *Arm® CoreSight™ Architecture Specification*.

This field reads as an IMPLEMENTATION DEFINED value.

**CMOD, bits [3:0]**

Customer Modified. See the *Arm® CoreSight™ Architecture Specification*.

This field reads as an IMPLEMENTATION DEFINED value.

### D1.2.154 ITM\_PIDR4, ITM Peripheral Identification Register 4

The ITM\_PIDR4 characteristics are:

## Purpose

Provides CoreSight discovery information for the ITM.

## Usage constraints

If the Main Extension is implemented, both privileged and unprivileged accesses are permitted.

If the Main Extension is not implemented, unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

## Configurations

Present only if the Main Extension is implemented.

This register is **RES0** if the Main Extension is not implemented.

Present only if CoreSight identification is implemented.

This register is **RES0** if CoreSight identification is not implemented.

Present only if the ITM is implemented.

This register is **RES0** if the ITM is not implemented.

If the Main Extension is not implemented then the ITM is not implemented.

## Attributes

32-bit read-only register located at 0xE000FD0.

This register is not banked between Security states.

## Field descriptions

The ITM\_PIDR4 bit assignments are:

**Bits [31:8]**

Reserved, RES0.

**SIZE, bits [7:4]**

4KB count. See the *Arm® CoreSight™ Architecture Specification*.

This field reads as zero.

**DES\_2, bits [3:0]**

JEP106 continuation code. See the *Arm® CoreSight™ Architecture Specification*.

This field reads as an IMPLEMENTATION DEFINED value.

## D1.2.155 ITM\_PIDR5, ITM Peripheral Identification Register 5

The ITM\_PIDR5 characteristics are:

### Purpose

Provides CoreSight discovery information for the ITM.

### Usage constraints

If the Main Extension is implemented, both privileged and unprivileged accesses are permitted.

If the Main Extension is not implemented, unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

### Configurations

Present only if the Main Extension is implemented.

This register is **RES0** if the Main Extension is not implemented.

Present only if CoreSight identification is implemented.

This register is **RES0** if CoreSight identification is not implemented.

Present only if the ITM is implemented.

This register is **RES0** if the ITM is not implemented.

If the Main Extension is not implemented then the ITM is not implemented.

### Attributes

32-bit read-only register located at 0xE0000FD4.

This register is not banked between Security states.

## Field descriptions

The ITM\_PIDR5 bit assignments are:

### Bits [31:0]

Reserved, **RES0**.

## D1.2.156 ITM\_PIDR6, ITM Peripheral Identification Register 6

The ITM\_PIDR6 characteristics are:

### Purpose

Provides CoreSight discovery information for the ITM.

### Usage constraints

If the Main Extension is implemented, both privileged and unprivileged accesses are permitted.

If the Main Extension is not implemented, unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are [UNPREDICTABLE](#).

### Configurations

Present only if the Main Extension is implemented.

This register is [RES0](#) if the Main Extension is not implemented.

Present only if CoreSight identification is implemented.

This register is [RES0](#) if CoreSight identification is not implemented.

Present only if the ITM is implemented.

This register is [RES0](#) if the ITM is not implemented.

If the Main Extension is not implemented then the ITM is not implemented.

### Attributes

32-bit read-only register located at 0xE0000FD8.

This register is not banked between Security states.

## Field descriptions

The ITM\_PIDR6 bit assignments are:

### Bits [31:0]

Reserved, [RES0](#).

## D1.2.157 ITM\_PIDR7, ITM Peripheral Identification Register 7

The ITM\_PIDR7 characteristics are:

### Purpose

Provides CoreSight discovery information for the ITM.

### Usage constraints

If the Main Extension is implemented, both privileged and unprivileged accesses are permitted.

If the Main Extension is not implemented, unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are [UNPREDICTABLE](#).

### Configurations

Present only if the Main Extension is implemented.

This register is [RES0](#) if the Main Extension is not implemented.

Present only if CoreSight identification is implemented.

This register is [RES0](#) if CoreSight identification is not implemented.

Present only if the ITM is implemented.

This register is [RES0](#) if the ITM is not implemented.

If the Main Extension is not implemented then the ITM is not implemented.

### Attributes

32-bit read-only register located at 0xE000FDC.

This register is not banked between Security states.

## Field descriptions

The ITM\_PIDR7 bit assignments are:

### Bits [31:0]

Reserved, [RES0](#).

### D1.2.158 ITM\_STIMn, ITM Stimulus Port Register, n = 0 - 255

The ITM\_STIM{0..255} characteristics are:

#### Purpose

Provides the interface for generating Instrumentation packets.

#### Usage constraints

If the Main Extension is implemented, both privileged and unprivileged accesses are permitted, but unprivileged writes are ignored if ITM\_TPR.PRIVMASK[n DIV 8] is set to one.

If the Main Extension is not implemented, unprivileged accesses generate a fault.

All writes are ignored if ITM\_TCR.ITMENA == 0 or ITM\_TER{n DIV 32}.STIMENA[n MOD 32] == 0.

This register is word, halfword, and byte accessible.

Accesses that are not word aligned are [UNPREDICTABLE](#).

#### Configurations

Present only if the Main Extension is implemented.

This register is [RES0](#) if the Main Extension is not implemented.

Present only if the ITM is implemented.

This register is [RES0](#) if the ITM is not implemented.

If the Main Extension is not implemented then the ITM is not implemented.

#### Attributes

32-bit read/write register located at  $0xE0000000 + 4n$ .

This register is not banked between Security states.

From Armv8.1-M onwards it is [IMPLEMENTATION DEFINED](#) whether a debugger write to this register is ignored when the PE is not in Debug state.

### Field descriptions

The ITM\_STIM{0..255} bit assignments are:

On a read:

On a write:

#### STIMULUS, bits [31:0], on a write

Stimulus data. Data to write to the stimulus port output buffer, for forwarding as an Instrumentation packet. The size of write access determines the type of Instrumentation packet generated.

#### Bits [31:2], on a read

Reserved, [RES0](#).

**DISABLED, bit [1], on a read**

Disabled. Indicates whether the stimulus port is enabled or disabled.

The possible values of this bit are:

**0**

Stimulus port and ITM are enabled.

**1**

Stimulus port or ITM is disabled.

**FIFOREADY, bit [0], on a read**

FIFO ready. Indicates whether the stimulus port can accept data.

The possible values of this bit are:

**0**

Stimulus port cannot accept data.

**1**

Stimulus port can accept at least one word.

## D1.2.159 ITM\_TCR, ITM Trace Control Register

The ITM\_TCR characteristics are:

### Purpose

Configures and controls transfers through the ITM interface.

### Usage constraints

If the Main Extension is implemented, both privileged and unprivileged accesses are permitted, but unprivileged writes are ignored.

If the Main Extension is not implemented, unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

### Configurations

Present only if the Main Extension is implemented.

This register is **RES0** if the Main Extension is not implemented.

Present only if the ITM is implemented.

This register is **RES0** if the ITM is not implemented.

If the Main Extension is not implemented then the ITM is not implemented.

### Attributes

32-bit read/write register located at 0xE0000E80.

This register is not banked between Security states.

## Field descriptions

The ITM\_TCR bit assignments are:

### Bits [31:24]

Reserved, **RES0**.

### BUSY, bit [23]

ITM busy. Indicates whether the ITM is currently processing events.

The possible values of this bit are:

**0**

ITM is not processing any events.

**1**

Events present and being drained.

Events means the ITM is generating or processing any of:

- Packets generated by the ITM from writes to Stimulus Ports.
- Other packets generated by the ITM itself.
- Packets generated by the DWT.

This bit is read-only.

**TraceBusID, bits [22:16]**

Trace bus identity. Identifier for multi-source trace stream formatting. If multi-source trace is in use, the debugger must write a unique nonzero trace ID value to this field.

The possible values of this field are:

**0x00**

Multi-source trace not in use.

**0x01-0x6F**

Unique trace ID value to be used for ITM trace packets.

All other values are reserved. If the ITM is the only trace source in the system, this field might be RAZ.

This field resets to an **UNKNOWN** value on a Cold reset.

**Bits [15:12]**

Reserved, **RES0**.

**GTSFREQ, bits [11:10]**

Global timestamp frequency. Defines how often the ITM generates a global timestamp, based on the global timestamp clock frequency, or disables generation of global timestamps.

The possible values of this field are:

**0b00**

Disable generation of Global Timestamp packets.

**0b01**

Generate timestamp request whenever the ITM detects a change in global timestamp counter bits  $[N-1:7]$ . This is approximately every 128 cycles.

**0b10**

Generate timestamp request whenever the ITM detects a change in global timestamp counter bits  $[N-1:13]$ . This is approximately every 8192 cycles.

**0b11**

Generate a timestamp after every packet, if the output FIFO is empty.

$N$  is the size of the global timestamp counter.

If the implementation does not support global timestamping then these bits are reserved, RAZ/WI.

This field resets to zero on a Cold reset.

**TSPrescale, bits [9:8]**

Timestamp prescale. Local timestamp prescaler, used with the trace packet reference clock.

The possible values of this field are:

**0b00**

No prescaling.

**0b01**

Divide by 4.

**0b10**

Divide by 16.

**0b11**

Divide by 64.

If the processor does not implement the timestamp prescaler then these bits are reserved, RAZ/WI.

This field resets to zero on a Cold reset.

**Bits [7:6]**

Reserved, [RES0](#).

**STALLENA, bit [5]**

Stall enable. Stall the PE to guarantee delivery of Data Trace packets.

The possible values of this bit are:

**0**

Drop Hardware Source packets and generate an Overflow packet if the ITM output is stalled.

**1**

Stall the PE to guarantee delivery of Data Trace packets.

If stalling is not implemented, this bit is RAZ/WI.

**SWOENA, bit [4]**

SWO enable. Enables asynchronous clocking of the timestamp counter.

The possible values of this bit are:

**0**

Timestamp counter uses the processor system clock.

**1**

Timestamp counter uses asynchronous clock from the TPIU interface. The timestamp counter is held in reset while the output line is idle.

Which clocking modes are implemented is [IMPLEMENTATION DEFINED](#). If the implementation does not support both modes this bit is either RAZ or RAO, to indicate the implemented mode.

This bit resets to an [UNKNOWN](#) value on a Cold reset.

**TXENA, bit [3]**

Transmit enable. Enables forwarding of hardware event packets from the DWT unit or PMU to the ITM for output to the TPIU.

The possible values of this bit are:

**0**

Disabled.

**1**

Enabled.

It is [IMPLEMENTATION DEFINED](#) whether the DWT or PMU discards packets that cannot be forwarded to the ITM.

This bit resets to zero on a Cold reset.

**Note**

If a debugger changes this bit from 0 to 1, the DWT or PMU might forward a hardware event packet that it has previously generated.

**SYNCENA, bit [2]**

Synchronization enable. Enables Synchronization packet transmission for a synchronous TPIU.

The possible values of this bit are:

**0**

Disabled.

**1**

Enabled.

This bit resets to zero on a Cold reset.

**Note**

If a debugger sets this bit to 1 it must also configure DWT\_CTRL.SYNCTAP for the correct synchronization speed.

**TSENA, bit [1]**

Timestamp enable. Enables Local timestamp generation.

The possible values of this bit are:

**0**

Disabled.

**1**

Enabled.

This bit resets to zero on a Cold reset.

**ITMENA, bit [0]**

ITM enable. Enables the ITM.

The possible values of this bit are:

**0**

Disabled.

**1**

Enabled.

This is the global enable for the ITM unit. A debugger must set this bit to 1 to permit writes to all Stimulus Port registers.

This bit resets to zero on a Cold reset.

## D1.2.160 ITM\_TERN, ITM Trace Enable Register, n = 0 - 7

The ITM\_TERN{0..7} characteristics are:

### Purpose

Provide an individual enable bit for each ITM\_STIM register.

### Usage constraints

If the Main Extension is implemented, both privileged and unprivileged accesses are permitted.

If the Main Extension is not implemented, unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

### Configurations

Present only if the Main Extension is implemented.

This register is RES0 if the Main Extension is not implemented.

Present only if the ITM is implemented.

This register is RES0 if the ITM is not implemented.

If the Main Extension is not implemented then the ITM is not implemented.

### Attributes

32-bit read/write register located at  $0xE0000E00 + 4n$ .

This register is not banked between Security states.

## Field descriptions

The ITM\_TERN{0..7} bit assignments are:

### STIMENA, bits [31:0]

Stimulus enable. For STIMENA[m] in ITM\_TERN, controls whether stimulus port ITM\_STIM<32n+m> is enabled.

The possible values of each bit are:

**0**

Stimulus port (32n + m) disabled.

**1**

Stimulus port (32n + m) enabled.

Bits corresponding to unimplemented stimulus ports are RAZ/WI. Unprivileged writes to ITM\_TERN do not update STIMENA[m] if ITM\_TPR.PRIVMASK[(32n+m) DIV 8] is set to 1.

This field resets to zero on a Cold reset.

### D1.2.161 ITM\_TPR, ITM Trace Privilege Register

The ITM TPR characteristics are:

## Purpose

Controls which stimulus ports can be accessed by unprivileged code.

## Usage constraints

If the Main Extension is implemented, both privileged and unprivileged accesses are permitted, but unprivileged writes are ignored.

If the Main Extension is not implemented, unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

## Configurations

Present only if the Main Extension is implemented.

This register is **RES0** if the Main Extension is not implemented.

Present only if the ITM is implemented.

This register is **RES0** if the ITM is not implemented.

If the Main Extension is not implemented then the ITM is not implemented.

## Attributes

32-bit read/write register located at 0xE0000E40.

This register is not banked between Security states.

## Field descriptions

The ITM\_TPR bit assignments are:

**PRIVMASK, bits [31:0]**

Privilege mask. For PRIVMASK[*m*], defines the access permissions of stimulus ports ITM\_STIM<8*m*> to ITM\_STIM<8*m*+7> inclusive.

The possible values of each bit are:

**O**

Unprivileged access permitted.

**1**

Privileged access only.

Bits corresponding to unimplemented stimulus ports are RAZ/WI.

This field resets to zero on a Cold reset.

## D1.2.162 LO\_BRANCH\_INFO, Loop and branch tracking information

The LO\_BRANCH\_INFO characteristics are:

### Purpose

Holds the cached loop end point and branching information.

### Usage constraints

This register is not accessible from software.

### Configurations

Present only if version Armv8.1-M of the architecture and LOB are implemented.

This cache is not implemented otherwise.

### Attributes

67-bit read/write register.

This register is not banked between Security states.

## Field descriptions

The LO\_BRANCH\_INFO bit assignments are:

### BTI, bit [66]

When set this field indicates that the BF is a BTI setting instruction. EPSR.B will be set to one when BTI is enabled (see CONTROL register) and the LO\_BRANCH\_INFO.VALID bit is set.

### T16IND, bit [65]

When set this field indicates that BF is a 16-bit T32 indirect branch. For BF and link instructions, this flag calculates the offset of the return address set in LR from the branch point.

### LF, bit [64]

Link / forever. If BF is set, this field indicates that the link register is populated with a return address at the point the branch is taken. If BF is clear, this flag indicates a forever loop that does not decrement LR at the end of each loop iteration.

### END\_ADDR, bits [63:33]

The partial address of either the last instruction in a low-overhead-loop, or an upcoming branch set by a Branch Future instruction. If the VALID bit is set and this field matches the address of the next instruction, a branch back to the start of the loop is triggered (as specified by the JUMP\_ADDR field).

### BF, bit [32]

Indicates that the value in this register originates from a BF instruction.

### JUMP\_ADDR, bits [31:1]

The address to jump to when an end address match is detected.

### VALID, bit [0]

The cached loop information in the rest of this register is only valid if this bit is set. The PE is permitted to clear this bit and invalidate the cache at any point.

This bit resets to zero on a Warm reset.

### D1.2.163 LR, Link Register

The LR characteristics are:

**Purpose**

Exception and procedure call link register.

**Usage constraints**

Privileged and unprivileged access permitted.

**Configurations**

This register is always implemented.

**Attributes**

32-bit read/write special-purpose register.

This register is not banked between Security states.

### Field descriptions

The LR bit assignments are:

**VALUE, bits [31:0]**

Link register. 32-bit link register updated to hold a return address, FNC\_RETURN or EXC\_RETURN on a function call or exception entry. LR can be used as a general-purpose register.

This field resets to an **UNKNOWN** value on Warm reset when the Main Extension is not implemented.

This field resets to 0xFFFFFFFF on a Warm reset if the Main Extension is implemented.

## D1.2.164 MAIR\_ATTR, Memory Attribute Indirection Register Attributes

The MAIR\_ATTR characteristics are:

### Purpose

Defines the memory attribute encoding for use in the MPU\_MAIR0 and MPU\_MAIR1.

### Usage constraints

None.

### Configurations

All.

### Attributes

8-bit payload.

## Field descriptions

The MAIR\_ATTR bit assignments are:

When Outer != 0b0000:

When Outer == 0b0000:

### Outer, bits [7:4]

Outer attributes. Specifies the Outer memory attributes.

The possible values of this field are:

**0b0000**

Device memory.

**0b00RW**

Normal memory, Outer Write-Through transient (RW!=0b00).

**0b0100**

Normal memory, Outer Non-cacheable.

**0b01RW**

Normal memory, Outer Write-Back Transient (RW!=0b00).

**0b10RW**

Normal memory, Outer Write-Through Non-transient.

**0b11RW**

Normal memory, Outer Write-Back Non-transient.

R and W specify the outer read and write allocation policy: 0 = do not allocate, 1 = allocate.

**Device, bits [3:2], when Outer == 0b0000**

Device attributes. Specifies the memory attributes for Device.

The possible values of this field are:

**0b00**

Device-nGnRnE.

**0b01**

Device-nGnRE.

**0b10**

Device-nGRE.

**0b11**

Device-GRE.

**Bits [1:0], when Outer == 0b0000**

Reserved, [RES0](#).

**Inner, bits [3:0], when Outer != 0b0000**

Inner attributes. Specifies the Inner memory attributes.

The possible values of this field are:

**0b0000**

[UNPREDICTABLE](#).

**0b00RW**

Normal memory, Inner Write-Through Transient (RW!=0b00).

**0b0100**

Normal memory, Inner Non-cacheable.

**0b01RW**

Normal memory, Inner Write-Back Transient (RW!=0b00).

**0b10RW**

Normal memory, Inner Write-Through Non-transient.

**0b11RW**

Normal memory, Inner Write-Back Non-transient.

R and W specify the inner read and write allocation policy: 0 = do not allocate, 1 = allocate.

## D1.2.165 MMFAR, MemManage Fault Address Register

The MMFAR characteristics are:

### Purpose

Shows the address of the memory location that caused an MPU fault.

### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

### Configurations

Present only if the Main Extension is implemented.

This register is **RES0** if the Main Extension is not implemented.

### Attributes

32-bit read/write register located at 0xE000ED34.

Secure software can access the Non-secure version of this register via MMFAR\_NS located at 0xE002ED34. The location 0xE002ED34 is **RES0** to software executing in Non-secure state and the debugger.

This register is banked between Security states.

From Armv8.1-M onwards it is **IMPLEMENTATION DEFINED** whether a debugger write to this register is ignored when the PE is not in Debug state.

## Field descriptions

The MMFAR bit assignments are:

### ADDRESS, bits [31:0]

Data address for an MemManage fault. This register is updated with the address of a location that produced a MemManage fault. The MMFSR shows the cause of the fault, and whether this field is valid. This field is valid only when MMFSR.MMARVALID is set, otherwise it is **UNKNOWN**.

In implementations without unique BFAR, SFAR and MMFAR registers, the value of this register is **UNKNOWN** if BFSR.BFARVALID or SFSR.SFARVALID is set.

This field resets to an **UNKNOWN** value on a Warm reset.

## D1.2.166 MMFSR, MemManage Fault Status Register

The MMFSR characteristics are:

### Purpose

Shows the status of MPU faults.

### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

If the Main Extension is implemented, this register is word, halfword, and byte accessible.

If the Main Extension is not implemented, this register is word accessible only, halfword and byte accesses are **UNPREDICTABLE**.

### Configurations

Present only if the Main Extension is implemented.

This register is **RES0** if the Main Extension is not implemented.

### Attributes

8-bit read/write-one-to-clear register located at 0xE000ED28.

Secure software can access the Non-secure version of this register via MMFSR\_NS located at 0xE002ED28. The location 0xE002ED28 is **RES0** to software executing in Non-secure state and the debugger.

This register is banked between Security states.

This register is part of CFSR.

From Armv8.1-M onwards it is **IMPLEMENTATION DEFINED** whether a debugger write to this register is ignored when the PE is not in Debug state.

## Field descriptions

The MMFSR bit assignments are:

### MMARVALID, bit [7]

MMFAR valid flag. Indicates validity of the MMFAR register.

The possible values of this bit are:

**0**

MMFAR content not valid.

**1**

MMFAR content valid.

This bit resets to zero on a Warm reset.

**Bit [6]**

Reserved, [RES0](#).

**MLSPERR, bit [5]**

MemManage lazy state preservation error flag. Records whether a MemManage fault occurred during floating-point lazy state preservation.

The possible values of this bit are:

**0**

No MemManage occurred.

**1**

MemManage occurred.

This bit resets to zero on a Warm reset.

**MSTKERR, bit [4]**

MemManage stacking error flag. Records whether a derived MemManage fault occurred during exception entry stacking.

The possible values of this bit are:

**0**

No derived MemManage occurred.

**1**

Derived MemManage occurred during exception entry.

This bit resets to zero on a Warm reset.

**MUNSTKERR, bit [3]**

MemManage unstacking error flag. Records whether a derived MemManage fault occurred during exception return unstacking.

The possible values of this bit are:

**0**

No derived MemManage fault occurred.

**1**

Derived MemManage fault occurred during exception return.

This bit resets to zero on a Warm reset.

**Bit [2]**

Reserved, [RES0](#).

**DACCVIOL, bit [1]**

Data access violation flag. Records whether a data access violation has occurred.

The possible values of this bit are:

**0**

No MemManage fault on data access has occurred.

**1**

MemManage fault on data access has occurred.

A DACCVIOL will be accompanied by an MMFAR update.

This bit resets to zero on a Warm reset.

**IACCVIOL, bit [0]**

Instruction access violation. Records whether an instruction related memory access violation has occurred.

The possible values of this bit are:

**0**

No MemManage fault on instruction access has occurred.

**1**

MemManage fault on instruction access has occurred.

An IACCVIOL is only recorded if a faulted instruction is executed.

This bit resets to zero on a Warm reset.

**HFNMIENA, bit [1]**

HardFault, NMI enable. Controls whether handlers executing with a requested execution priority of less than 0 access memory with the MPU enabled or disabled. This applies to HardFaults and NMIs when FAULTMASK is set to 1.

The possible values of this bit are:

**0**

MPU disabled for these handlers.

**1**

MPU enabled for these handlers.

If HFNMIENA is set to 1 when ENABLE is set to 0, behavior is [UNPREDICTABLE](#). If no MPU regions are implemented this bit is [RES0](#).

This bit resets to zero on a Warm reset.

**ENABLE, bit [0]**

Enable. Enables the MPU.

The possible values of this bit are:

**0**

The MPU is disabled.

**1**

The MPU is enabled.

Disabling the MPU, by setting the ENABLE bit to 0, means that privileged and unprivileged accesses use the system address map. If no MPU regions are implemented this bit is [RES0](#).

This bit resets to zero on a Warm reset.

## D1.2.168 MPU\_MAIR0, MPU Memory Attribute Indirection Register 0

The MPU\_MAIR0 characteristics are:

### Purpose

Along with MPU\_MAIR1, provides the memory attribute encodings corresponding to the AttrIndx values.

### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

### Configurations

This register is always implemented.

### Attributes

32-bit read/write register located at 0xE000EDC0.

To allow lock down of this register it is **IMPLEMENTATION DEFINED** whether this register is writable.

Secure software can access the Non-secure version of this register via MPU\_MAIR0\_NS located at 0xE002EDC0. The location 0xE002EDC0 is **RES0** to software executing in Non-secure state and the debugger.

This register is banked between Security states.

From Armv8.1-M onwards it is **IMPLEMENTATION DEFINED** whether a debugger write to this register is ignored when the PE is not in Debug state.

### Preface

This register is **RES0** if no MPU regions are implemented in the corresponding Security state.

### Field descriptions

The MPU\_MAIR0 bit assignments are:

### Attrm, bits [8m+7:8m], for m = 0 to 3

Attribute m. Memory attribute encoding for MPU regions with an AttrIndx of m.

The possible values of this field are:

### All

See MAIR\_ATTR for encoding.

This field resets to an **Architecturally UNKNOWN** value on a Warm reset.

## D1.2.169 MPU\_MAIR1, MPU Memory Attribute Indirection Register 1

The MPU\_MAIR1 characteristics are:

### Purpose

Along with MPU\_MAIR0, provides the memory attribute encodings corresponding to the AttrIdx values.

### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

### Configurations

This register is always implemented.

### Attributes

32-bit read/write register located at 0xE000EDC4.

To allow lock down of this register it is **IMPLEMENTATION DEFINED** whether this register is writable.

Secure software can access the Non-secure version of this register via MPU\_MAIR1\_NS located at 0xE002EDC4. The location 0xE002EDC4 is **RES0** to software executing in Non-secure state and the debugger.

This register is banked between Security states.

From Armv8.1-M onwards it is **IMPLEMENTATION DEFINED** whether a debugger write to this register is ignored when the PE is not in Debug state.

### Preface

This register is **RES0** if no MPU regions are implemented in the corresponding Security state.

### Field descriptions

The MPU\_MAIR1 bit assignments are:

### Attrm, bits [8(m-4)+7:8(m-4)], for m = 4 to 7

Attribute m. Memory attribute encoding for MPU regions with an AttrIdx of m.

The possible values of this field are:

### All

See MAIR\_ATTR for encoding.

This field resets to an **Architecturally UNKNOWN** value on a Warm reset.

## D1.2.170 MPU\_RBAR, MPU Region Base Address Register

The MPU\_RBAR characteristics are:

### Purpose

Provides indirect read and write access to the base address of the currently selected MPU region for the selected Security state.

### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

### Configurations

This register is always implemented.

### Attributes

32-bit read/write register located at 0xE000ED9C.

To allow lock down of this register it is **IMPLEMENTATION DEFINED** whether this register is writable.

Secure software can access the Non-secure version of this register via MPU\_RBAR\_NS located at 0xE002ED9C. The location 0xE002ED9C is **RES0** to software executing in Non-secure state and the debugger.

This register is banked between Security states.

From Armv8.1-M onwards it is **IMPLEMENTATION DEFINED** whether a debugger write to this register is ignored when the PE is not in Debug state.

## Preface

This register provides access to the configuration of the MPU region selected by MPU\_RNR.REGION for the appropriate Security state. The field descriptions apply to the currently selected region.

## Field descriptions

The MPU\_RBAR bit assignments are:

### BASE, bits [31:5]

Base address. Contains bits [31:5] of the lower inclusive limit of the selected MPU memory region. This value is zero extended to provide the base address to be checked against.

It is **IMPLEMENTATION DEFINED** whether any of the BASE bits are WI

This field resets to an **Architecturally UNKNOWN** value on a Warm reset.

### SH, bits [4:3]

Shareability. Defines the Shareability domain of this region for Normal memory.

The possible values of this field are:

**0b00**

Non-shareable.

**0b10**

Outer Shareable.

**0b11**

Inner Shareable.

All other values are reserved.

For any type of Device memory, the value of this field is ignored.

This field resets to an **UNKNOWN** value on a Warm reset.

**AP[2:1], bits [2:1]**

Access permissions. Defines the access permissions for this region.

The possible values of this field are:

**0b00**

Read/write by privileged code only.

**0b01**

Read/write by any privilege level.

**0b10**

Read-only by privileged code only.

**0b11**

Read-only by any privilege level.

This field resets to an **UNKNOWN** value on a Warm reset.

**XN, bit [0]**

Execute-never. Defines whether code can be executed from this region.

The possible values of this bit are:

**0**

Execution only permitted if read permitted.

**1**

Execution not permitted.

This bit resets to an **UNKNOWN** value on a Warm reset.

### D1.2.171 MPU\_RBAR\_An, MPU Region Base Address Register Alias, n = 1 - 3

The MPU\_RBAR\_A{1..3} characteristics are:

#### Purpose

Provides indirect read and write access to the base address of the MPU region selected by MPU\_RNR[7:2):(n[1:0]) for the selected Security state.

#### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

#### Configurations

Present only if the Main Extension is implemented.

This register is **RES0** if the Main Extension is not implemented.

#### Attributes

32-bit read/write register located at  $0xE000EDA4 + 8(n-1)$ .

To allow lock down of this register it is **IMPLEMENTATION DEFINED** whether this register is writable.

Secure software can access the Non-secure version of this register via MPU\_RBAR\_An\_NS located at  $0xE002EDA4 + 8(n-1)$ . The location  $0xE002EDA4 + 8(n-1)$  is **RES0** to software executing in Non-secure state and the debugger.

This register is banked between Security states.

From Armv8.1-M onwards it is **IMPLEMENTATION DEFINED** whether a debugger write to this register is ignored when the PE is not in Debug state.

#### Preface

This register is an alias of the MPU\_RBAR register and provides access to the configuration of the MPU region selected by MPU\_RNR.REGION had REGION[1:0] been set to n[1:0].

#### Field descriptions

The MPU\_RBAR\_A{1..3} bit assignments are:

#### BASE, bits [31:5]

Base address. Contains bits [31:5] of the lower inclusive limit of the selected MPU memory region. This value is zero extended to provide the base address to be checked against.

It is **IMPLEMENTATION DEFINED** whether any of the BASE bits are WI

This field resets to an **Architecturally UNKNOWN** value on a Warm reset.

#### SH, bits [4:3]

Shareability. Defines the Shareability domain of this region for Normal memory.

The possible values of this field are:

**0b00**

Non-shareable.

**0b10**

Outer Shareable.

**0b11**

Inner Shareable.

All other values are reserved.

For any type of Device memory, the value of this field is ignored.

This field resets to an **UNKNOWN** value on a Warm reset.

**AP[2:1], bits [2:1]**

Access permissions. Defines the access permissions for this region.

The possible values of this field are:

**0b00**

Read/write by privileged code only.

**0b01**

Read/write by any privilege level.

**0b10**

Read-only by privileged code only.

**0b11**

Read-only by any privilege level.

This field resets to an **UNKNOWN** value on a Warm reset.

**XN, bit [0]**

Execute-never. Defines whether code can be executed from this region.

The possible values of this bit are:

**0**

Execution only permitted if read permitted.

**1**

Execution not permitted.

This bit resets to an **UNKNOWN** value on a Warm reset.

### D1.2.172 MPU\_RLAR, MPU Region Limit Address Register

The MPU\_RLAR characteristics are:

## Purpose

Provides indirect read and write access to the limit address of the currently selected MPU region for the selected Security state.

## Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

## Configurations

This register is always implemented.

## Attributes

32-bit read/write register located at 0xE000EDA0.

To allow lock down of this register it is **IMPLEMENTATION DEFINED** whether this register is writable.

Secure software can access the Non-secure version of this register via MPU\_RLAR\_NS located at 0xE00EDA0. The location 0xE00EDA0 is **RES0** to software executing in Non-secure state and the debugger.

This register is banked between Security states.

From Armv8.1-M onwards it is **IMPLEMENTATION DEFINED** whether a debugger write to this register is ignored when the PE is not in Debug state.

## Preface

This register provides access to the configuration of the MPU region selected by MPU\_RNR.REGION for the appropriate Security state. The field descriptions apply to the currently selected region.

## Field descriptions

The MPU RLAR bit assignments are:

**LIMIT, bits [31:5]**

**Limit address.** Contains bits [31:5] of the upper inclusive limit of the selected MPU memory region. This value is postfixed with 0x1F to provide the limit address to be checked against.

It is **IMPLEMENTATION DEFINED** whether any of the LIMIT bits are WI

This field resets to an Architecturally UNKNOWN value on a Warm reset.

**PXN, bit [4]**

Privileged execute-never. Defines whether code can be executed from this privileged region.

The possible values of this bit are:

**O**

Execution only permitted if read permitted.

**1**

Execution from a privileged mode is not permitted.

If version Armv8.1-M of the architecture is not implemented, this bit is [RES0](#).

This bit resets to an [UNKNOWN](#) value on a Warm reset.

**AttrIndx, bits [3:1]**

Attribute index. Associates a set of attributes in the MPU\_MAIRO and MPU\_MAIR1 fields.

This field resets to an [UNKNOWN](#) value on a Warm reset.

**EN, bit [0]**

Enable. Region enable.

The possible values of this bit are:

**0**

Region disabled.

**1**

Region enabled.

This bit resets to zero on a Warm reset.

### D1.2.173 MPU\_RLAR\_An, MPU Region Limit Address Register Alias, n = 1 - 3

The MPU\_RLAR\_A{1..3} characteristics are:

#### Purpose

Provides indirect read and write access to the limit address of the currently selected MPU region selected by MPU\_RNR[7:2):(n[1:0]) for the selected Security state.

#### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

#### Configurations

Present only if the Main Extension is implemented.

This register is **RES0** if the Main Extension is not implemented.

#### Attributes

32-bit read/write register located at  $0xE000EDA8 + 8(n-1)$ .

To allow lock down of this register it is **IMPLEMENTATION DEFINED** whether this register is writable.

Secure software can access the Non-secure version of this register via MPU\_RLAR\_An\_NS located at  $0xE002EDA8 + 8(n-1)$ . The location  $0xE002EDA8 + 8(n-1)$  is **RES0** to software executing in Non-secure state and the debugger.

This register is banked between Security states.

From Armv8.1-M onwards it is **IMPLEMENTATION DEFINED** whether a debugger write to this register is ignored when the PE is not in Debug state.

#### Preface

This register is an alias of the MPU\_RLAR register and provides access to the configuration of the MPU region selected by MPU\_RNR.REGION had REGION[1:0] been set to n[1:0].

#### Field descriptions

The MPU\_RLAR\_A{1..3} bit assignments are:

#### LIMIT, bits [31:5]

Limit address. Contains bits [31:5] of the upper inclusive limit of the selected MPU memory region. This value is postfixed with  $0x1F$  to provide the limit address to be checked against.

It is **IMPLEMENTATION DEFINED** whether any of the LIMIT bits are WI

This field resets to an **Architecturally UNKNOWN** value on a Warm reset.

#### PXN, bit [4]

Privileged execute-never. Defines whether code can be executed from this privileged region.

The possible values of this bit are:

**0**

Execution only permitted if read permitted.

**1**

Execution from a privileged mode is not permitted.

If version Armv8.1-M of the architecture is not implemented, this bit is [RES0](#).

This bit resets to an [UNKNOWN](#) value on a Warm reset.

**AttrIndx, bits [3:1]**

Attribute index. Associates a set of attributes in the MPU\_MAIRO and MPU\_MAIR1 fields.

This field resets to an [UNKNOWN](#) value on a Warm reset.

**EN, bit [0]**

Enable. Region enable.

The possible values of this bit are:

**0**

Region disabled.

**1**

Region enabled.

This bit resets to zero on a Warm reset.

### D1.2.174 MPU RNR, MPU Region Number Register

The MPU RNR characteristics are:

## Purpose

Selects the region currently accessed by MPU\_RBAR and MPU\_RLAR.

## Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

## Configurations

This register is always implemented.

### Attributes

32-bit read/write register located at 0xE000ED98.

To allow lock down of this register it is **IMPLEMENTATION DEFINED** whether this register is writable.

Secure software can access the Non-secure version of this register via MPU\_RNR\_NS located at 0xE002ED98. The location 0xE002ED98 is **RES0** to software executing in Non-secure state and the debugger.

This register is banked between Security states.

From Armv8.1-M onwards it is **IMPLEMENTATION DEFINED** whether a debugger write to this register is ignored when the PE is not in Debug state.

## Field descriptions

The MPU\_RNR bit assignments are:

**Bits [31:8]**

Reserved, RES0.

**REGION, bits [7:0]**

Region number. Indicates the memory region accessed by MPU\_RBAR and MPU\_RLAR.

If no MPU regions are implemented, this field is **RES0**. Writing a value corresponding to an unimplemented region is **CONSTRAINED UNPREDICTABLE**.

This field resets to an **UNKNOWN** value on a Warm reset.

### D1.2.175 MPU\_TYPE, MPU Type Register

The MPU\_TYPE characteristics are:

#### Purpose

The MPU Type Register indicates how many regions the MPU for the selected Security state supports.

#### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

#### Configurations

This register is always implemented.

#### Attributes

32-bit read-only register located at 0xE000ED90.

Secure software can access the Non-secure version of this register via MPU\_TYPE\_NS located at 0xE002ED90. The location 0xE002ED90 is RES0 to software executing in Non-secure state and the debugger.

This register is banked between Security states.

### Field descriptions

The MPU\_TYPE bit assignments are:

#### Bits [31:16]

Reserved, RES0.

#### DREGION, bits [15:8]

Data regions. Number of regions supported by the MPU.

If this field reads-as-zero, the PE does not implement an MPU for the selected Security state.

This field reads as an IMPLEMENTATION DEFINED value.

#### Bits [7:1]

Reserved, RES0.

#### SEPARATE, bit [0]

Separate. Indicates support for separate instructions and data address regions.

Armv8-M only supports unified MPU regions.

This bit reads as zero.

### D1.2.176 MSPLIM, Main Stack Pointer Limit Register

The MSPLIM characteristics are:

## Purpose

Holds the lower limit of the Main stack pointer.

## Usage constraints

Privileged access only. Unprivileged access is RAZ/WI, unless otherwise stated.

## Configurations

This register is always implemented.

## Attributes

32-bit read/write special-purpose register.

This register is banked between Security states.

## Field descriptions

The MSPLIM bit assignments are:

**LIMIT, bits [31:3]**

Stack limit. Bits [31:3] of the Main stack pointer limit address for the selected Security state.

Many instructions and exception entry will generate an exception if the appropriate stack pointer would be updated to a value lower than this limit. If the Main Extension is not implemented, the Non-secure MSPLIM is [RES0](#).

This field resets to zero on a Warm reset.

**Bits [2:0]**

Reserved, RES0.

## D1.2.177 MVFR0, Media and VFP Feature Register 0

The MVFR0 characteristics are:

### Purpose

Describes the features provided by the Floating-point Extension.

### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are [UNPREDICTABLE](#).

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

### Configurations

Present if the Floating-point Extension, or MVE, or both are implemented.

This register is [RES0](#) if neither the Floating-point Extension nor MVE are implemented.

### Attributes

32-bit read-only register located at 0xE000EF40.

Secure software can access the Non-secure version of this register via MVFR0\_NS located at 0xE002EF40. The location 0xE002EF40 is [RES0](#) to software executing in Non-secure state and the debugger.

This register is not banked between Security states.

## Field descriptions

The MVFR0 bit assignments are:

|         |    |    |      |    |        |    |          |    |      |    |      |   |      |   |         |
|---------|----|----|------|----|--------|----|----------|----|------|----|------|---|------|---|---------|
| 31      | 28 | 27 | 24   | 23 | 20     | 19 | 16       | 15 | 12   | 11 | 8    | 7 | 4    | 3 | 0       |
| FPRound |    |    | RES0 |    | FPSqrt |    | FPDivide |    | RES0 |    | FPDP |   | FPSP |   | SIMDReg |

### FPRound, bits [31:28]

Floating-point rounding modes. Indicates the rounding modes supported by the Floating-point Extension.

The possible values of this field are:

**0b0000**

Not supported.

**0b0001**

All rounding modes supported.

All other values are reserved.

This field reads as an [IMPLEMENTATION DEFINED](#) value.

### Bits [27:24]

Reserved, [RES0](#).

### FPSqrt, bits [23:20]

Floating-point square root. Indicates the support for Floating-point square root operations.

The possible values of this field are:

**0b0000**

Not supported.

**0b0001**

Supported.

All other values are reserved.

This field reads as an **IMPLEMENTATION DEFINED** value.

**FPDivide, bits [19:16]**

Floating-point divide. Indicates the support for Floating-point divide operations.

The possible values of this field are:

**0b0000**

Not supported.

**0b0001**

Supported.

All other values are reserved.

This field reads as an **IMPLEMENTATION DEFINED** value.

**Bits [15:12]**

Reserved, **RES0**.

**FPDP, bits [11:8]**

Floating-point double-precision. Indicates support for Floating-point double-precision operations.

The possible values of this field are:

**0b0000**

Not supported.

**0b0010**

Supported.

All other values are reserved.

This field reads as an **IMPLEMENTATION DEFINED** value.

**FPSP, bits [7:4]**

Floating-point single-precision. Indicates support for Floating-point single-precision operations.

The possible values of this field are:

**0b0000**

Not supported.

**0b0010**

Supported.

All other values are reserved.

This field reads as an **IMPLEMENTATION DEFINED** value.

**SIMDReg, bits [3:0]**

SIMD registers. Indicates size of Floating-Point Extension register file.

The possible values of this field are:

**0b0001**

16 x 64-bit registers.

All other values are reserved.

This field reads as 0b0001.

## D1.2.178 MVFR1, Media and VFP Feature Register 1

The MVFR1 characteristics are:

### Purpose

Describes the features provided by the Floating-point Extension.

### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are [UNPREDICTABLE](#).

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

### Configurations

Present if the Floating-point Extension, or MVE, or both are implemented.

This register is [RES0](#) if neither the Floating-point Extension nor MVE are implemented.

### Attributes

32-bit read-only register located at 0xE000EF44.

Secure software can access the Non-secure version of this register via MVFR1\_NS located at 0xE002EF44. The location 0xE002EF44 is [RES0](#) to software executing in Non-secure state and the debugger.

This register is not banked between Security states.

## Field descriptions

The MVFR1 bit assignments are:

|      |       |       |       |       |        |       |   |
|------|-------|-------|-------|-------|--------|-------|---|
| 31   | 28,27 | 24,23 | 20,19 | 12,11 | 8,7    | 4,3   | 0 |
| FMAC | FPHP  | FP16  | RES0  | MVE   | FPDNaN | FPFtZ |   |

### FMAC, bits [31:28]

Fused multiply accumulate. Indicates whether the Floating-point Extension implements the fused multiply accumulate instructions.

The possible values of this field are:

**0b0000**

Not supported.

**0b0001**

Implemented.

All other values are reserved.

This field reads as an [IMPLEMENTATION DEFINED](#) value.

### FPHP, bits [27:24]

Floating-point half-precision conversion. Indicates whether the Floating-point Extension implements half-precision Floating-point conversion instructions.

The possible values of this field are:

**0b0000**

Not supported.

**0b0001**

Half-precision to single-precision implemented.

**0b0010**

Half-precision to single and double-precision implemented.

All other values are reserved.

This field reads as an **IMPLEMENTATION DEFINED** value.

**FP16, bits [23:20]**

Floating-point half-precision data processing. Indicates whether the Floating-point Extension implements half-precision floating-point data processing instructions.

The possible values of this field are:

**0b0000**

No Half-precision data processing support.

**0b0001**

Half-precision data processing instructions supported.

All other values are reserved.

If version Armv8.1-M of the architecture is not implemented, this field is **RES0**.

This field reads as an **IMPLEMENTATION DEFINED** value.

**Bits [19:12]**

Reserved, **RES0**.

**MVE, bits [11:8]**

Indicates support for M-profile vector extension.

The possible values of this field are:

**0b0000**

Not supported.

**0b0001**

Supported, no Floating-point.

**0b0010**

Supported, with single-precision and half-precision Floating-point.

All other values are reserved.

If version Armv8.1-M of the architecture is not implemented, this field is **RES0**.

This field reads as an **IMPLEMENTATION DEFINED** value.

**FPDNaN, bits [7:4]**

Floating-point default NaN. Indicates whether the Floating-point Extension implementation supports NaN propagation.

The possible values of this field are:

**0b0000**

Not supported.

**0b0001**

Propagation of NaN values supported.

All other values are reserved.

This field reads as an **IMPLEMENTATION DEFINED** value.

**FPFtZ, bits [3:0]**

Floating-point flush-to-zero. Indicates whether subnormals are always flushed-to-zero.

The possible values of this field are:

**0b0000**

Not supported.

**0b0001**

Full denormalized numbers arithmetic supported.

All other values are reserved.

This field reads as an **IMPLEMENTATION DEFINED** value.

### D1.2.179 MVFR2, Media and VFP Feature Register 2

The MVFR2 characteristics are:

## Purpose

Describes the features provided by the Floating-point Extension.

## Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

## Configurations

Present if the Floating-point Extension, or MVE, or both are implemented.

This register is **RES0** if neither the Floating-point Extension nor MVE are implemented.

## Attributes

32-bit read-only register located at 0xE000EF48.

Secure software can access the Non-secure version of this register via MVFR2\_NS located at 0xE002EF48. The location 0xE002EF48 is **RES0** to software executing in Non-secure state and the debugger.

This register is not banked between Security states.

## Field descriptions

The MVFR2 bit assignments are:

**Bits [31:8]**

Reserved, RES0.

**FPMisc, bits [7:4]**

Floating-point miscellaneous. Indicates support for miscellaneous Floating-point features.

The possible values of this field are:

0b0000

Floating-point extensions not implemented.

0b0100

Selection, directed conversion to integer, VMINNM and VMAXNM supported.

All other values are reserved.

This field reads as an IMPLEMENTATION DEFINED value.

**Bits [3:0]**Reserved, **RES0**.

## D1.2.180 NSACR, Non-secure Access Control Register

The NSACR characteristics are:

### Purpose

Defines the Non-secure access permissions for the Floating-point Extension and coprocessors CP0 to CP7. If MVE is implemented this register Specifies the Non-secure access permissions for MVE.

### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

### Configurations

Present only if the Main Extension is implemented.

This register is **RES0** if the Main Extension is not implemented.

### Attributes

32-bit read/write register located at 0xE000ED8C.

If the Security Extension is not implemented this register returns a value of 0x00000CFF.

This register is RAZ/WI when accessed as Non-secure.

This register is not banked between Security states.

From Armv8.1-M onwards it is **IMPLEMENTATION DEFINED** whether a debugger write to this register is ignored when the PE is not in Debug state.

## Field descriptions

The NSACR bit assignments are:

### Bits [31:12]

Reserved, **RES0**.

### CP11, bit [11]

CP11 access. Enables Non-secure access to the Floating-point Extension and MVE.

Programming with a different value than that used for CP10 is **UNPREDICTABLE**.

If neither the Floating-point Extension or MVE are implemented, this bit is **RES0**.

This bit resets to an **Architecturally UNKNOWN** value on a Warm reset.

### CP10, bit [10]

CP10 access. Enables Non-secure access to the Floating-point Extension and MVE.

The possible values of this bit are:

**0**

Non-secure accesses to the Floating-point Extension or MVE, unless otherwise specified, generate a NOCP UsageFault.

**1**

Non-secure access to the Floating-point Extension or MVE permitted.

If neither the Floating-point Extension or MVE are implemented, this bit is [RES0](#).

This bit resets to an [Architecturally UNKNOWN](#) value on a Warm reset.

**Bits [9:8]**

Reserved, [RES0](#).

**CPm, bit [m], for m = 0 to 7**

CPm access. Enables Non-secure access to coprocessor CPm.

The possible values of this field are:

**0**

Non-secure accesses to this coprocessor generate a NOCP UsageFault.

**1**

Non-secure access to this coprocessor permitted.

A CPm bit is RAZ/WI if CPm is:

- Not implemented.
- Not enabled for the Security state in which the PE is executing.

This field resets to an [Architecturally UNKNOWN](#) value on a Warm reset.

### D1.2.181 NVIC\_IABRn, Interrupt Active Bit Register, n = 0 - 15

The NVIC\_IABR{0..15} characteristics are:

## Purpose

For each group of 32 interrupts, shows the active state of each interrupt.

## Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

## Configurations

This register is always implemented.

## Attributes

32-bit read-only register located at  $0xE00E300 + 4n$ .

Secure software can access the Non-secure version of this register via NVIC\_IABRn\_NS located at  $0xE002E300 + 4n$ . The location  $0xE002E300 + 4n$  is [RES0](#) to software executing in Non-secure state and the debugger.

This register is not banked between Security states.

## Field descriptions

The NVIC\_IABR{0..15} bit assignments are:

**ACTIVE**, bits [31:0]

Active state. For ACTIVE[ $m$ ] in NVIC\_IABR $n$ , indicates the active state for interrupt  $32n+m$ .

The possible values of each bit are:

0

Interrupt not active.

**1**

Interrupt is active.

Bits corresponding to unimplemented interrupts are **RES0**. Bits corresponding to interrupts targeting Secure state are RAZ/WI from Non-secure.

This field resets to zero on a Warm reset.

## D1.2.182 NVIC\_ICERn, Interrupt Clear Enable Register, n = 0 - 15

The NVIC\_ICER{0..15} characteristics are:

### Purpose

Clears or reads the enabled state of each group of 32 interrupts.

### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are [UNPREDICTABLE](#).

### Configurations

This register is always implemented.

### Attributes

32-bit read/write-one-to-clear register located at  $0 \times \text{E000E180} + 4n$ .

Secure software can access the Non-secure version of this register via NVIC\_ICERn\_NS located at  $0 \times \text{E002E180} + 4n$ . The location  $0 \times \text{E002E180} + 4n$  is [RES0](#) to software executing in Non-secure state and the debugger.

This register is not banked between Security states.

## Field descriptions

The NVIC\_ICER{0..15} bit assignments are:

### CLRENA, bits [31:0], on a write

Clear enable. For CLRENA[m] in NVIC\_ICERn, allows interrupt  $32n + m$  to be disabled.

The possible values of each bit are:

**0**

No effect.

**1**

Disable interrupt  $32n + m$ .

Bits corresponding to unimplemented interrupts are [RES0](#). Bits corresponding to interrupts targeting Secure state are RAZ/WI from Non-secure.

### CLRENA, bits [31:0], on a read

Clear enable. For CLRENA[m] in NVIC\_ICERn, indicates whether interrupt  $32n + m$  is enabled.

The possible values of each bit are:

**0**

Interrupt  $32n + m$  disabled.

**1**

Interrupt  $32n + m$  enabled.

Bits corresponding to unimplemented interrupts are [RES0](#). Bits corresponding to interrupts targeting Secure state are RAZ/WI from Non-secure.

This field resets to zero on a Warm reset.

### D1.2.183 NVIC\_ICPRn, Interrupt Clear Pending Register, n = 0 - 15

The NVIC\_ICPR{0..15} characteristics are:

## Purpose

Clears or reads the pending state of each group of 32 interrupts.

## Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

## Configurations

This register is always implemented.

## Attributes

32-bit read/write-one-to-clear register located at  $0xE000E280 + 4n$ .

Secure software can access the Non-secure version of this register via NVIC\_ICPRn\_NS located at  $0xE002E280 + 4n$ . The location  $0xE002E280 + 4n$  is [RES0](#) to software executing in Non-secure state and the debugger.

This register is not banked between Security states.

## Field descriptions

The NVIC\_ICPR{0..15} bit assignments are:

### CLRPEND, bits [31:0], on a write

Clear pending. For CLRPEND[ $m$ ] in NVIC\_ICPR $n$ , allows interrupt  $32n + m$  to be unpended.

The possible values of each bit are:

0

No effect.

**1**

Clear pending state of interrupt  $32n + m$ .

Bits corresponding to unimplemented interrupts are **RES0**. Bits corresponding to interrupts targeting Secure state are RAZ/WI from Non-secure.

**CLRPEND, bits [31:0], on a read**

Clear pending. For CLRPEND[ $m$ ] in NVIC\_ICPR $n$ , indicates whether interrupt  $32n + m$  is pending.

The possible values of each bit are:

0

Interrupt  $32n + m$  is not pending.

**1**

Interrupt  $32n + m$  is pending.

Bits corresponding to unimplemented interrupts are **RES0**. Bits corresponding to interrupts targeting Secure state are RAZ/WI from Non-secure.

## D1.2.184 NVIC\_IPRn, Interrupt Priority Register, n = 0 - 123

The NVIC\_IPR{0..123} characteristics are:

### Purpose

Sets or reads interrupt priorities.

### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

If the Main Extension is implemented, this register is word, halfword, and byte accessible.

If the Main Extension is not implemented, this register is word accessible only, halfword and byte accesses are [UNPREDICTABLE](#).

### Configurations

This register is always implemented.

### Attributes

32-bit read/write register located at  $0xE000E400 + 4n$ .

Secure software can access the Non-secure version of this register via NVIC\_IPRn\_NS located at  $0xE002E400 + 4n$ . The location  $0xE002E400 + 4n$  is [RES0](#) to software executing in Non-secure state and the debugger.

This register is not banked between Security states.

From Armv8.1-M onwards it is [IMPLEMENTATION DEFINED](#) whether a debugger write to this register is ignored when the PE is not in Debug state.

## Field descriptions

The NVIC\_IPR{0..123} bit assignments are:

### PRI\_Nm, bits [8m+7:8m], for m = 0 to 3

Priority 'N'+m. For register NVIC\_IPRn, this field indicates and allows modification of the priority of interrupt number  $4n+m$ , or is [RES0](#) if the PE does not implement this interrupt.

If the PE implements fewer than 8 bits of priority, then the least significant bits of this field are [RES0](#).

If interrupt number  $4n+m$  targets Secure state, this field is RAZ/WI from Non-secure.

This field resets to zero on a Warm reset.

### D1.2.185 NVIC\_ISERn, Interrupt Set Enable Register, n = 0 - 15

The NVIC\_ISER{0..15} characteristics are:

#### Purpose

Enables or reads the enabled state of each group of 32 interrupts.

#### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

#### Configurations

This register is always implemented.

#### Attributes

32-bit read/write-one-to-set register located at  $0xE000E100 + 4n$ .

Secure software can access the Non-secure version of this register via NVIC\_ISERn\_NS located at  $0xE002E100 + 4n$ . The location  $0xE002E100 + 4n$  is RES0 to software executing in Non-secure state and the debugger.

This register is not banked between Security states.

### Field descriptions

The NVIC\_ISER{0..15} bit assignments are:

#### SETENA, bits [31:0], on a write

Set enable. For SETENA[m] in NVIC\_ISERn, allows interrupt  $32n + m$  to be set enabled.

The possible values of each bit are:

**0**

No effect.

**1**

Enable interrupt  $32n + m$ .

Bits corresponding to unimplemented interrupts are RES0. Bits corresponding to interrupts targeting Secure state are RAZ/WI from Non-secure.

This field resets to zero on a Warm reset.

#### SETENA, bits [31:0], on a read

Set enable. For SETENA[m] in NVIC\_ISERn, indicates whether interrupt  $32n + m$  is enabled.

The possible values of each bit are:

**0**

Interrupt  $32n + m$  disabled.

**1**

Interrupt  $32n + m$  enabled.

Bits corresponding to unimplemented interrupts are RES0. Bits corresponding to interrupts targeting Secure state are RAZ/WI from Non-secure.

This field resets to zero on a Warm reset.

## D1.2.186 NVIC\_ISPRn, Interrupt Set Pending Register, n = 0 - 15

The NVIC\_ISPR{0..15} characteristics are:

### Purpose

Enables or reads the pending state of each group of 32 interrupts.

### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

### Configurations

This register is always implemented.

### Attributes

32-bit read/write-one-to-set register located at  $0xE000E200 + 4n$ .

Secure software can access the Non-secure version of this register via NVIC\_ISPRn\_NS located at  $0xE002E200 + 4n$ . The location  $0xE002E200 + 4n$  is [RES0](#) to software executing in Non-secure state and the debugger.

This register is not banked between Security states.

## Field descriptions

The NVIC\_ISPR{0..15} bit assignments are:

### SETPEND, bits [31:0], on a write

Set pending. For SETPEND[m] in NVIC\_ISPRn, allows interrupt  $32n + m$  to be set pending.

The possible values of each bit are:

**0**

No effect.

**1**

Pend interrupt  $32n + m$ .

Bits corresponding to unimplemented interrupts are [RES0](#). Bits corresponding to interrupts targeting Secure state are RAZ/WI from Non-secure.

This field is write-one-to-set. Writes of zero are ignored.

This field resets to zero on a Warm reset.

### SETPEND, bits [31:0], on a read

Set pending. For SETPEND[m] in NVIC\_ISPRn, indicates whether interrupt  $32n + m$  is pending.

The possible values of each bit are:

**0**

Interrupt  $32n + m$  is not pending.

**1**

Interrupt  $32n + m$  pending.

Bits corresponding to unimplemented interrupts are [RES0](#). Bits corresponding to interrupts targeting Secure state are RAZ/WI from Non-secure.

This field resets to zero on a Warm reset.

### D1.2.187 NVIC\_ITNSn, Interrupt Target Non-secure Register, n = 0 - 15

The NVIC\_ITNS{0..15} characteristics are:

#### Purpose

For each group of 32 interrupts, determines whether each interrupt targets Non-secure or Secure state.

#### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

#### Configurations

This register is always implemented.

#### Attributes

32-bit read/write register located at  $0xE000E380 + 4n$ .

This register is RAZ/WI when accessed as Non-secure.

This register is not banked between Security states.

From Armv8.1-M onwards it is IMPLEMENTATION DEFINED whether a debugger write to this register is ignored when the PE is not in Debug state.

### Field descriptions

The NVIC\_ITNS{0..15} bit assignments are:

#### ITNS, bits [31:0]

Interrupt Targets Non-secure. For ITNS[m] in NVIC\_ITNSn, this field indicates and allows modification of the target Security state for interrupt  $32n+m$ .

The possible values of each bit are:

**0**

Interrupt targets Secure state.

**1**

Interrupt targets Non-secure state.

Bits corresponding to unimplemented interrupts are RES0. It is IMPLEMENTATION DEFINED whether individual bits are WI and have an IMPLEMENTATION DEFINED constant value. Where an interrupt is configured to target Secure state, accesses to the associated fields in Non-secure versions of the NVIC\_IABR, NVIC\_ICER, NVIC\_ISER, NVIC\_ICPR, NVIC\_IPR and NVIC\_ISPR are RAZ/WI.

This field resets to zero on a Warm reset.

## D1.2.188 PAC\_KEY\_P\_n, Pointer Authentication Key Privileged, n = 0 - 3

The PAC\_KEY\_P\_{0..3} characteristics are:

### Purpose

Holds word  $n$  of the key used for PAC calculation in Privileged software.

### Usage constraints

Privileged access only. Unprivileged access is RAZ/WI, unless otherwise stated.

### Configurations

Present only if the PACBTI Extension is implemented.

### Attributes

32-bit read/write special-purpose register.

This register is banked between Security states.

## Field descriptions

The PAC\_KEY\_P\_{0..3} bit assignments are:

### VALUE, bits [31:0]

Pointer authentication key, word  $n$ . Holds bits[31 + 32 $n$ :32 $n$ ] of the 128-bit key.

This field resets to an [Architecturally UNKNOWN](#) value on a Warm reset.

**D1.2.189 PAC\_KEY\_U\_n, Pointer Authentication Key Unprivileged, n = 0 - 3**

The PAC\_KEY\_U\_{0..3} characteristics are:

## Purpose

Holds word  $n$  of the key used for PAC calculation in Unprivileged software.

## Usage constraints

Privileged access only. Unprivileged access is RAZ/WI, unless otherwise stated.

## Configurations

Present only if the PACBTI Extension is implemented.

### Attributes

32-bit read/write special-purpose register.

This register is banked between Security states.

## Field descriptions

The PAC\_KEY\_U\_{0..3} bit assignments are:

**VALUE, bits [31:0]**

Pointer authentication key, word  $n$ . Holds bits[31 + 32 $n$ :32 $n$ ] of the 128-bit key.

This field resets to an **Architecturally UNKNOWN** value on a Warm reset.

### D1.2.190 PC, Program Counter

The PC characteristics are:

**Purpose**

Holds the current Program Counter value.

**Usage constraints**

Privileged and unprivileged access permitted.

**Configurations**

This register is always implemented.

**Attributes**

32-bit read/write special-purpose register.

This register is not banked between Security states.

### Field descriptions

The PC bit assignments are:

**VALUE, bits [31:0]**

Program Counter. Holds the address of the current instruction.

Software can refer to PC as R15.

This field resets to an **UNKNOWN** value on a Warm reset.

## D1.2.191 PMU\_AUTHSTATUS, Performance Monitoring Unit Authentication Status Register

The PMU\_AUTHSTATUS characteristics are:

### Purpose

Provides information about the state of the **IMPLEMENTATION DEFINED** authentication interface for Performance Monitoring Units.

### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

### Configurations

Present only if the Main Extension is implemented.

This register is **RES0** if the Main Extension is not implemented.

Present only if version Armv8.1 of the architecture and the PMU are implemented.

This register is **RES0** if the PMU is not implemented.

### Attributes

32-bit read-only register located at 0xE0003FB8.

This register is not banked between Security states.

## Field descriptions

The PMU\_AUTHSTATUS bit assignments are:

### Bits [31:24]

Reserved, **RES0**.

### SUNID, bits [23:22]

Secure Unprivileged Non-invasive Debug Allowed. Indicates that Unprivileged Non-invasive debug is allowed for the Secure state.

The possible values of this field are:

#### 0b00

Security Extension or Unprivileged Non-invasive Debug not implemented.

#### 0b01

Reserved.

#### 0b10

Secure Non-invasive debug prohibited.

#### 0b11

Secure Non-invasive debug allowed in unprivileged mode.

If version Armv8.1 of the architecture and UDE are not implemented, this field is **RES0**.

**SUID, bits [21:20]**

Secure Unprivileged Invasive Debug Allowed. Indicates that Unprivileged Halting Debug is allowed for the Secure state.

The possible values of this field are:

**0b00**

Security Extension or Unprivileged Debug not implemented.

**0b01**

Reserved.

**0b10**

Secure halting debug prohibited.

**0b11**

Secure halting debug allowed in unprivileged mode.

This reflects the value of `UnprivHaltingDebugAllowed(TRUE) && !SecureHaltingDebugAllowed()`.

If version Armv8.1 of the architecture and UDE are not implemented, this field is [RES0](#).

**NSUID, bits [19:18]**

Non-secure Unprivileged Non-invasive Debug Allowed. Indicates that Unprivileged Non-invasive Debug is allowed for the Non-secure state.

The possible values of this field are:

**0b00**

Unprivileged Non-invasive debug not implemented.

**0b01**

Reserved.

**0b10**

Non-secure Non-invasive debug prohibited.

**0b11**

Non-secure Non-invasive debug allowed in unprivileged mode.

If the Main Extension is not implemented, this field is [RES0](#).

**NSUID, bits [17:16]**

Non-secure Unprivileged Invasive Debug Allowed. Indicates that Unprivileged Halting Debug is allowed for the Non-secure state.

The possible values of this field are:

**0b00**

Unprivileged halting debug not implemented.

**0b01**

Reserved.

**0b10**

Non-secure halting debug prohibited.

**0b11**

Non-secure halting debug allowed in unprivileged mode.

This reflects the value of `UnprivHaltingDebugAllowed(FALSE) && !HaltingDebugAllowed()`.

If version Armv8.1 of the architecture and UDE are not implemented, this field is [RES0](#).

**Bits [15:8]**

Reserved, [RES0](#).

**SNID, bits [7:6]**

Secure Non-invasive Debug. Indicates whether Secure non-invasive debug is implemented and allowed.

The possible values of this field are:

**0b00**

Security Extension not implemented.

**0b01**

Reserved.

**0b10**

Security Extension implemented and Secure non-invasive debug prohibited.

**0b11**

Security Extension implemented and Secure non-invasive debug allowed.

**SID, bits [5:4]**

Secure Invasive Debug. Indicates whether Secure invasive debug is implemented and allowed.

The possible values of this field are:

**0b00**

Security Extension not implemented.

**0b01**

Reserved.

**0b10**

Security Extension implemented and Secure invasive debug prohibited.

**0b11**

Security Extension implemented and Secure invasive debug allowed.

**NSNID, bits [3:2]**

Non-secure Non-invasive Debug. Indicates whether Non-secure non-invasive debug is allowed.

The possible values of this field are:

**0b0x**

Reserved.

**0b10**

Non-secure non-invasive debug prohibited.

**0b11**

Non-secure non-invasive debug allowed.

**NSID, bits [1:0]**

Non-secure Invasive Debug. Indicates whether Non-secure invasive debug is allowed.

The possible values of this field are:

**0b0x**

Reserved.

**0b10**

Non-secure invasive debug prohibited.

**0b11**

Non-secure invasive debug allowed.

## D1.2.192 PMU\_CCFILTR, Performance Monitoring Unit Cycle Counter Filter Register

The PMU\_CCFILTR characteristics are:

### Purpose

This register is reserved for future use.

### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are [UNPREDICTABLE](#).

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

### Configurations

Present only if the Main Extension is implemented.

This register is [RES0](#) if the Main Extension is not implemented.

Present only if version Armv8.1 of the architecture and the PMU are implemented.

This register is [RES0](#) if the PMU is not implemented.

### Attributes

32-bit read/write register located at 0xE000347C.

This register is not banked between Security states.

## Field descriptions

The PMU\_CCFILTR bit assignments are:

### Bits [31:0]

Reserved, [RES0](#).

### D1.2.193 PMU\_CCNTR, Performance Monitoring Unit Cycle Counter Register

The PMU\_CCNTR characteristics are:

#### Purpose

Holds the value of the cycle counter, which counts processor clock cycles.

#### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

#### Configurations

Present only if the Main Extension is implemented.

This register is **RES0** if the Main Extension is not implemented.

Present only if version Armv8.1 of the architecture and the PMU are implemented.

This register is **RES0** if the PMU is not implemented.

#### Attributes

32-bit read/write register located at 0xE000307C.

This register is not banked between Security states.

#### Preface

This register is an alias of the DWT\_CYCCNT register.

#### Field descriptions

The PMU\_CCNTR bit assignments are:

#### CCNT, bits [31:0]

Cycle count. The cycle count increments on every processor clock cycle.

This field resets to an **UNKNOWN** value on a Warm reset.

## D1.2.194 PMU\_CIDR0, Performance Monitoring Unit Component Identification Register 0

The PMU\_CIDR0 characteristics are:

### Purpose

Provides information to identify a Performance Monitoring Unit component.

### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are [UNPREDICTABLE](#).

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

### Configurations

Present only if the Main Extension is implemented.

This register is [RES0](#) if the Main Extension is not implemented.

Present only if version Armv8.1 of the architecture and the PMU are implemented.

This register is [RES0](#) if the PMU is not implemented.

### Attributes

32-bit read-only register located at 0xE0003FF0.

This register is not banked between Security states.

## Field descriptions

The PMU\_CIDR0 bit assignments are:

### Bits [31:8]

Reserved, [RES0](#).

### PRMBL\_0, bits [7:0]

Preamble.

This field reads as 0x0D.

## D1.2.195 PMU\_CIDR1, Performance Monitoring Unit Component Identification Register 1

The PMU\_CIDR1 characteristics are:

### Purpose

Provides information to identify a Performance Monitoring Unit component.

### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

### Configurations

Present only if the Main Extension is implemented.

This register is **RES0** if the Main Extension is not implemented.

Present only if version Armv8.1 of the architecture and the PMU are implemented.

This register is **RES0** if the PMU is not implemented.

### Attributes

32-bit read-only register located at 0xE0003FF4.

This register is not banked between Security states.

## Field descriptions

The PMU\_CIDR1 bit assignments are:

### Bits [31:8]

Reserved, **RES0**.

### CLASS, bits [7:4]

Component class.

This field reads as 0x9.

### PRMBL\_1, bits [3:0]

Preamble.

This field reads as 0x0.

### D1.2.196 PMU\_CIDR2, Performance Monitoring Unit Component Identification Register 2

The PMU CIDR2 characteristics are:

## Purpose

Provides information to identify a Performance Monitoring Unit component.

## Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

## Configurations

Present only if the Main Extension is implemented.

This register is **RES0** if the Main Extension is not implemented.

Present only if version Armv8.1 of the architecture and the PMU are implemented.

This register is **RES0** if the PMU is not implemented.

## Attributes

32-bit read-only register located at 0xE0003FF8.

This register is not banked between Security states.

## Field descriptions

The PMU\_CIDR2 bit assignments are:

**Bits [31:8]**

Reserved, RES0.

**PRMBL 2, bits [7:0]**

Preamble.

This field reads as 0x05.

### D1.2.197 PMU\_CIDR3, Performance Monitoring Unit Component Identification Register 3

The PMU\_CIDR3 characteristics are:

## Purpose

Provides information to identify a Performance Monitoring Unit component.

## Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

## Configurations

Present only if the Main Extension is implemented.

This register is **RES0** if the Main Extension is not implemented.

Present only if version Armv8.1 of the architecture and the PMU are implemented.

This register is **RES0** if the PMU is not implemented.

## Attributes

32-bit read-only register located at 0xE0003FFC.

This register is not banked between Security states.

## Field descriptions

The PMU\_CIDR3 bit assignments are:

**Bits [31:8]**

Reserved, RES0.

**PRMBL\_3, bits [7:0]**

Preamble.

This field reads as 0xB1.

## D1.2.198 PMU\_CNTENCLR, Performance Monitoring Unit Count Enable Clear Register

The PMU\_CNTENCLR characteristics are:

### Purpose

Disables the Cycle Count Register, PMU\_CCNTR, and any implemented event counters PMU\_EVCNTR<n>. Reading this register shows which counters are enabled.

### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

### Configurations

Present only if the Main Extension is implemented.

This register is **RES0** if the Main Extension is not implemented.

Present only if version Armv8.1 of the architecture and the PMU are implemented.

This register is **RES0** if the PMU is not implemented.

### Attributes

32-bit read/write register located at 0xE0003C20.

This register is not banked between Security states.

## Field descriptions

The PMU\_CNTENCLR bit assignments are:

### C, bit [31]

PMU\_CCNTR disable bit. Disables the cycle counter register.

The possible values of this bit are:

**0**

When read, means the cycle counter is disabled. When written, has no effect.

**1**

When read, means the cycle counter is enabled. When written, disables the cycle counter.

This bit resets to zero on a Cold reset.

### Pn, bits [30:0]

Event counter PMU\_EVCNTR<n> disable bit. Disables PMU\_EVCNTR<n>.

The possible values of this field are:

**0**

When read, means that PMU\_EVCNTR<n> is disabled. When written, has no effect.

**1**

When read, means that PMU\_EVCNTR<n> event counter is enabled. When written, disables PMU\_EVCNTR<n>.

This field resets to zero on a Cold reset.

**Note**

Bits [30:N] are RAZ/WI, where N is the number of counters and the value of PMU\_TYPE.N.

## D1.2.199 PMU\_CNTENSET, Performance Monitoring Unit Count Enable Set Register

The PMU\_CNTENSET characteristics are:

### Purpose

Enables the Cycle Count Register, PMU\_CCNTR, and any implemented event counters PMU\_EVCNTR<n>. Reading this register shows which counters are enabled.

### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

### Configurations

Present only if the Main Extension is implemented.

This register is RES0 if the Main Extension is not implemented.

Present only if version Armv8.1 of the architecture and the PMU are implemented.

This register is RES0 if the PMU is not implemented.

### Attributes

32-bit read/write register located at 0xE0003C00.

This register is not banked between Security states.

## Field descriptions

The PMU\_CNTENSET bit assignments are:

### C, bit [31]

PMU\_CCNTR enable bit. Enables the cycle counter register.

The possible values of this bit are:

0

When read, means the cycle counter is disabled. When written, has no effect.

1

When read, means the cycle counter is enabled. When written, enables the cycle counter.

This bit resets to zero on a Cold reset.

### Pn, bits [30:0]

Event counter PMU\_EVCNTR<n> enable bit. Enables PMU\_EVCNTR<n>.

The possible values of this field are:

0

When read, means that PMU\_EVCNTR<n> is disabled. When written, has no effect.

1

When read, means that PMU\_EVCNTR<n> event counter is enabled. When written, enables PMU\_EVCNTR<n>.

This field resets to zero on a Cold reset.

**Note**

Bits [30:N] are RAZ/WI, where N is the number of counters and the value of PMU\_TYPE.N.

## D1.2.200 PMU\_CTRL, Performance Monitoring Unit Control Register

The PMU\_CTRL characteristics are:

### Purpose

Configures and controls the Performance Monitoring Unit.

### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

### Configurations

Present only if the Main Extension is implemented.

This register is **RES0** if the Main Extension is not implemented.

Present only if version Armv8.1 of the architecture and the PMU are implemented.

This register is **RES0** if the PMU is not implemented.

### Attributes

32-bit read/write register located at 0xE0003E04.

This register is not banked between Security states.

## Field descriptions

The PMU\_CTRL bit assignments are:

### Bits [31:12]

Reserved, **RES0**.

### TRO, bit [11]

Trace-on-overflow. Enable trace-on-overflow.

The possible values of this bit are:

**0**

Trace-on-overflow disabled.

**1**

Trace whenever any of the first eight counters overflows an 8-bit value.

This bit resets to an **UNKNOWN** value on a Warm reset.

### Bit [10]

**SBZ**.

### FZO, bit [9]

Freeze-on-overflow. Stops events being counted once PMU\_OVSCLR or PMU\_OVSSET is nonzero.

The possible values of this bit are:

**0**

This bit has no effect on event counting.

**1**

While any bit of PMU\_OVSCLR.Pn or PMU\_OVSSET.Pn is nonzero, event counters do not count events.

This bit resets to an UNKNOWN value on a Warm reset.

**Bits [8:6]**

SBZ.

**DP, bit [5]**

Controls whether the cycle counter is disabled in Secure state. This bit is an alias of the DWT\_CTRL.CYCDISS bit.

**Bits [4:3]**

SBZ.

**C, bit [2]**

Cycle counter reset. Reset the PMU\_CCNTR counter.

The possible values of this bit are:

**0**

No action.

**1**

Reset PMU\_CCNTR to zero.

Resetting PMU\_CCNTR does not clear the PMU\_CCNTR overflow bit to 0.

This bit is write-only.

This bit reads as zero.

**P, bit [1]**

Event counter reset. Reset event counters.

The possible values of this bit are:

**0**

No action.

**1**

Reset all event counters, not including PMU\_CCNTR, to zero.

Resetting the event counters does not clear any overflow bits to 0.

This bit is write-only.

This bit reads as zero.

**E, bit [0]**

Enable. Enable the event counters.

The possible values of this bit are:

**0**

All counters, including PMU\_CCNTR, are disabled.

**1**

All counters are enabled by PMU\_CNTENSET.

This bit resets to zero on a Warm reset.

## D1.2.201 PMU\_DEVARCH, Performance Monitoring Unit Device Architecture Register

The PMU\_DEVARCH characteristics are:

### Purpose

Identifies the programmers' model architecture of the Performance Monitoring Unit component.

### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

### Configurations

Present only if the Main Extension is implemented.

This register is **RES0** if the Main Extension is not implemented.

Present only if version Armv8.1 of the architecture and the PMU are implemented.

This register is **RES0** if the PMU is not implemented.

### Attributes

32-bit read-only register located at 0xE0003FBC.

This register is not banked between Security states.

## Field descriptions

The PMU\_DEVARCH bit assignments are:

### ARCHITECT, bits [31:21]

Defines the architecture of the component.

For Performance Monitoring Units, this is Arm Limited.

Bits [31:28] are the JEP 106 continuation code, 0x4.

Bits [27:21] are the JEP 106 ID code, 0x3B.

### PRESENT, bit [20]

Determines the presence of DEVARCH. When set to 1, indicates that the DEVARCH is present.

This bit reads as 0x1.

### REVISION, bits [19:16]

Defines the architecture revision.

For architectures defined by Arm this is the minor revision.

For Performance Monitoring Units, the revision defined by Armv8.1-M is 0x0.

All other values are reserved.

### ARCHID, bits [15:0]

Defines this part to be an Armv8-M debug component.

For architectures defined by Arm this is further subdivided. For Performance Monitoring Units:

Bits [15:12] are the architecture version, 0x0.

Bits [11:0] are the architecture part number, 0xA06.

### D1.2.202 PMU\_DEVTTYPE, Performance Monitoring Unit Device Type Register

The PMU\_DEVTYPE characteristics are:

## Purpose

Indicates to a debugger that this component is part of the Performance Monitoring Unit interface of the PE.

## Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

## Configurations

Present only if the Main Extension is implemented.

This register is **RES0** if the Main Extension is not implemented.

Present only if version Armv8.1 of the architecture and the PMU are implemented.

This register is **RES0** if the PMU is not implemented.

## Attributes

32-bit read-only register located at 0xE0003FCC.

This register is not banked between Security states.

## Field descriptions

The PMU\_DEVTTYPE bit assignments are:

**Bits [31:8]**

Reserved, RES0.

**SUB, bits [7:4]**

Subtype.

This field reads as 0x1.

**MAJOR, bits [3:0]**

Major type.

This field reads as 0x6.

### D1.2.203 PMU\_EVCNTRn, Performance Monitoring Unit Event Counter Register

The PMU\_EVCNTR{0..30} characteristics are:

## Purpose

Holds performance counter n, which counts events.

## Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

## Configurations

Present only if the Main Extension is implemented.

This register is **RES0** if the Main Extension is not implemented.

Present only if version Armv8.1 of the architecture and the PMU are implemented.

This register is **RES0** if the PMU is not implemented.

## Attributes

32-bit read/write register located at  $0xE003000 + 4n$ .

This register is not banked between Security states.

# Preface

If  $n$  is greater than or equal to the number of accessible counters, reads and writes of this register are [RES0](#).

## Field descriptions

The PMU\_EVCNTR{0..30} bit assignments are:

**RESERVED, bits [31:16]**

Reserved, RAZ/WI

**Counter, bits [15:0]**

Event counter n.

Value of event counter n, where n is the number of this register. n is a number in the range 0-30. The size of this counter is 16 bits.

The counter counts whenever the selected event occurs, and either of:

- SecureNoninvasiveDebugEnabled() == TRUE.
- The NS-Req for the operation is set to Non-secure and NoninvasiveDebugEnabled() == TRUE.

This field resets to an **UNKNOWN** value on a Warm reset.

### D1.2.204 PMU\_EVTYPERN, Performance Monitoring Unit Event Type and Filter Register

The PMU\_EVTYPERN{0..30} characteristics are:

#### Purpose

Configures event counter n, where n is 0 to 30.

#### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

#### Configurations

Present only if the Main Extension is implemented.

This register is RES0 if the Main Extension is not implemented.

Present only if version Armv8.1 of the architecture and the PMU are implemented.

This register is RES0 if the PMU is not implemented.

#### Attributes

32-bit read/write register located at  $0xE0003400 + 4n$ .

This register is not banked between Security states.

#### Preface

If n is greater than or equal to the number of accessible counters, reads and writes of this register are RES0.

#### Field descriptions

The PMU\_EVTYPERN{0..30} bit assignments are:

#### Bits [31:16]

Reserved, RES0.

#### evtCount, bits [15:0]

Event to Count. The event number of the event that is counted by event counter PMU\_EVCNTR<n>. If the associated counter does not support the event number that is written to this register, the value read back is UNKNOWN.

This field resets to an UNKNOWN value on a Warm reset.

## D1.2.205 PMU\_INTENCLR, Performance Monitoring Unit Interrupt Enable Clear Register

The PMU\_INTENCLR characteristics are:

### Purpose

Disables the generation of interrupt requests on overflows from the Cycle Count Register, PMU\_CCNTR, and the event counters, PMU\_EVCNTR. Reading the register shows which overflow interrupt requests are enabled.

### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are [UNPREDICTABLE](#).

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

### Configurations

Present only if the Main Extension is implemented.

This register is [RES0](#) if the Main Extension is not implemented.

Present only if version Armv8.1 of the architecture and the PMU are implemented.

This register is [RES0](#) if the PMU is not implemented.

### Attributes

32-bit read/write register located at 0xE0003C60.

This register is not banked between Security states.

## Field descriptions

The PMU\_INTENCLR bit assignments are:

### C, bit [31]

PMU\_CCNTR overflow interrupt request disable bit. Disable the overflow interrupt for the cycle counter.

The possible values of this bit are:

**0**

When read, means the cycle counter overflow interrupt request is disabled. When written, has no effect.

**1**

When read, means the cycle counter overflow interrupt request is enabled. When written, disables the cycle count overflow interrupt request.

This bit resets to zero on a Cold reset.

### Pn, bits [30:0]

Event counter overflow interrupt request disable bit for PMU\_EVCNTR<n>. Disable the overflow interrupt for PMU\_EVCNTR<n>.

The possible values of this field are:

**0**

When read, means that the PMU\_EVCNTR<n> event counter interrupt request is disabled. When written, has no effect.

**1**

When read, means that the PMU\_EVCNTR<n> event counter interrupt request is enabled. When written, disables the PMU\_EVCNTR<n> interrupt request.

This field resets to zero on a Cold reset.

**Note**

Bits [30:N] are RAZ/WI, where N is the number of counters and the value of PMU\_TYPE.N.

## D1.2.206 PMU\_INTENSET, Performance Monitoring Unit Interrupt Enable Set Register

The PMU\_INTENSET characteristics are:

### Purpose

Enables the generation of interrupt requests on overflows from the Cycle Count Register, PMU\_CCNTR, and the event counter, PMU\_EVCNTR. Reading the register shows which overflow interrupt requests are enabled.

### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are [UNPREDICTABLE](#).

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

### Configurations

Present only if the Main Extension is implemented.

This register is [RES0](#) if the Main Extension is not implemented.

Present only if version Armv8.1 of the architecture and the PMU are implemented.

This register is [RES0](#) if the PMU is not implemented.

### Attributes

32-bit read/write register located at 0xE0003C40.

This register is not banked between Security states.

## Field descriptions

The PMU\_INTENSET bit assignments are:

### C, bit [31]

PMU\_CCNTR overflow interrupt request enable bit. Enable the overflow interrupt for the cycle counter.

The possible values of this bit are:

**0**

When read, means the cycle counter overflow interrupt request is disabled. When written, has no effect.

**1**

When read, means the cycle counter overflow interrupt request is enabled. When written, enables the cycle count overflow interrupt request.

This bit resets to zero on a Cold reset.

### Pn, bits [30:0]

Event counter overflow interrupt request enable bit for PMU\_EVCNTR<n>. Enable the overflow interrupt for PMU\_EVCNTR<n>.

The possible values of this field are:

**0**

When read, means that the PMU\_EVCNTR<n> event counter interrupt request is disabled. When written, has no effect.

**1**

When read, means that the PMU\_EVCNTR<n> event counter interrupt request is enabled. When written, enables the PMU\_EVCNTR<n> interrupt request.

This field resets to zero on a Cold reset.

**Note**

Bits [30:N] are RAZ/WI, where N is the number of counters and the value of PMU\_TYPE.N.

## D1.2.207 PMU\_OVSCLR, Performance Monitoring Unit Overflow Flag Status Clear Register

The PMU\_OVSCLR characteristics are:

### Purpose

Contains the state of the overflow bit for the Cycle Count Register, PMU\_CCNTR, and each of the implemented event counters, PMU\_EVCNTR<n>. Writing to this register clears these bits.

### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

### Configurations

Present only if the Main Extension is implemented.

This register is RES0 if the Main Extension is not implemented.

Present only if version Armv8.1 of the architecture and the PMU are implemented.

This register is RES0 if the PMU is not implemented.

### Attributes

32-bit read/write register located at 0xE0003C80.

This register is not banked between Security states.

## Field descriptions

The PMU\_OVSCLR bit assignments are:

### C, bit [31]

PMU\_CCNTR overflow bit. Clears the PMU\_CCNTR overflow bit.

The possible values of this bit are:

0

When read, means the cycle counter has not overflowed. When written, has no effect.

1

When read, means the cycle counter has overflowed. When written, clears the overflow bit to 0.

This bit resets to zero on a Cold reset.

### Pn, bits [30:0]

Event counter overflow clear bit for PMU\_EVCNTR<n>. Clears the PMU\_EVCNTR<n> overflow bit.

The possible values of this field are:

0

When read, means that the PMU\_EVCNTR<n> event counter has not overflowed. When written, has no effect.

1

When read, means that the PMU\_EVCNTR<n> event counter has overflowed. When written, clears the PMU\_EVCNTR<n> overflow bit to 0.

This field resets to zero on a Cold reset.

**Note**

Bits [30:N] are RAZ/WI, where N is the number of counters and the value of PMU\_TYPE.N.

## D1.2.208 PMU\_OVSSET, Performance Monitoring Unit Overflow Flag Status Set Register

The PMU\_OVSSET characteristics are:

### Purpose

Sets the state of the overflow bit for the Cycle Count Register, PMU\_CCNTR, and each of the implemented event counters, PMU\_EVCNTR<n>.

### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are [UNPREDICTABLE](#).

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

### Configurations

Present only if the Main Extension is implemented.

This register is [RES0](#) if the Main Extension is not implemented.

Present only if version Armv8.1 of the architecture and the PMU are implemented.

This register is [RES0](#) if the PMU is not implemented.

### Attributes

32-bit read/write register located at 0xE0003CC0.

This register is not banked between Security states.

## Field descriptions

The PMU\_OVSSET bit assignments are:

### C, bit [31]

PMU\_CCNTR overflow bit. Set the overflow status for PMU\_CCNTR.

The possible values of this bit are:

**0**

When read, means the cycle counter has not overflowed. When written, has no effect.

**1**

When read, means the cycle counter has overflowed. When written, sets the overflow bit to 1.

This bit resets to zero on a Cold reset.

### Pn, bits [30:0]

Event counter overflow set bit for PMU\_EVCNTR<n>. Set the overflow status for PMU\_EVCNTR<n>.

The possible values of this field are:

**0**

When read, means that the PMU\_EVCNTR<n> event counter has not overflowed. When written, has no effect.

**1**

When read, means that the PMU\_EVCNTR<n> event counter has overflowed. When written, sets the PMU\_EVCNTR<n> overflow bit to 1.

This field resets to zero on a Cold reset.

**Note**

Bits [30:N] are RAZ/WI, where N is the number of counters and the value of PMU\_TYPE.N.

### D1.2.209 PMU\_PIDR0, Performance Monitoring Unit Peripheral Identification Register 0

The PMU PIDR0 characteristics are:

## Purpose

Provides information to identify a Performance Monitoring Unit component.

## Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

## Configurations

Present only if the Main Extension is implemented.

This register is **RES0** if the Main Extension is not implemented.

Present only if version Armv8.1 of the architecture and the PMU are implemented.

This register is **RES0** if the PMU is not implemented.

## Attributes

32-bit read-only register located at 0xE0003FE0.

This register is not banked between Security states.

## Field descriptions

The PMU\_PIDR0 bit assignments are:

**Bits [31:8]**

Reserved, RES0.

### PART 0, bits [7:0]

Part number, least significant byte.

This field reads as an **IMPLEMENTATION DEFINED** value.

## D1.2.210 PMU\_PIDR1, Performance Monitoring Unit Peripheral Identification Register 1

The PMU\_PIDR1 characteristics are:

### Purpose

Provides information to identify a Performance Monitoring Unit component.

### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

### Configurations

Present only if the Main Extension is implemented.

This register is **RES0** if the Main Extension is not implemented.

Present only if version Armv8.1 of the architecture and the PMU are implemented.

This register is **RES0** if the PMU is not implemented.

### Attributes

32-bit read-only register located at 0xE0003FE4.

This register is not banked between Security states.

## Field descriptions

The PMU\_PIDR1 bit assignments are:

### Bits [31:8]

Reserved, **RES0**.

### DES\_0, bits [7:4]

Designer, least significant nibble of JEP106 ID code. For Arm Limited, this field is 0b1011.

This field reads as an **IMPLEMENTATION DEFINED** value.

### PART\_1, bits [3:0]

Part number, most significant nibble.

This field reads as an **IMPLEMENTATION DEFINED** value.

## D1.2.211 PMU\_PIDR2, Performance Monitoring Unit Peripheral Identification Register 2

The PMU\_PIDR2 characteristics are:

### Purpose

Provides information to identify a Performance Monitoring Unit component.

### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

### Configurations

Present only if the Main Extension is implemented.

This register is **RES0** if the Main Extension is not implemented.

Present only if version Armv8.1 of the architecture and the PMU are implemented.

This register is **RES0** if the PMU is not implemented.

### Attributes

32-bit read-only register located at 0xE0003FE8.

This register is not banked between Security states.

## Field descriptions

The PMU\_PIDR2 bit assignments are:

### Bits [31:8]

Reserved, **RES0**.

### REVISION, bits [7:4]

Part major revision. Parts can also use this field to extend Part number to 16-bits.

This field reads as an **IMPLEMENTATION DEFINED** value.

### JEDEC, bit [3]

JEDEC. RAO. Indicates a JEP106 identity code is used.

### DES\_1, bits [2:0]

Designer, most significant bits of JEP106 ID code. For Arm Limited, this field is 0b011.

This field reads as an **IMPLEMENTATION DEFINED** value.

### D1.2.212 PMU\_PIDR3, Performance Monitoring Unit Peripheral Identification Register 3

The PMU PIDR3 characteristics are:

## Purpose

Provides information to identify a Performance Monitoring Unit component.

## Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

## Configurations

Present only if the Main Extension is implemented.

This register is **RES0** if the Main Extension is not implemented.

Present only if version Armv8.1 of the architecture and the PMU are implemented.

This register is **RES0** if the PMU is not implemented.

## Attributes

32-bit read-only register located at 0xE0003FEC.

This register is not banked between Security states.

## Field descriptions

The PMU\_PIDR3 bit assignments are:

**Bits [31:8]**

Reserved, RES0.

**REVAND, bits [7:4]**

Part minor revision. Parts using PMU\_PIDR2.REVISION as an extension to the Part number must use this field as a major revision number.

This field reads as an IMPLEMENTATION DEFINED value.

**CMOD, bits [3:0]**

Customer modified. Indicates someone other than the Designer has modified the component.

This field reads as an IMPLEMENTATION DEFINED value.

### D1.2.213 PMU\_PIDR4, Performance Monitoring Unit Peripheral Identification Register 4

The PMU PIDR4 characteristics are:

## Purpose

Provides information to identify a Performance Monitoring Unit component.

## Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

## Configurations

Present only if the Main Extension is implemented.

This register is **RES0** if the Main Extension is not implemented.

Present only if version Armv8.1 of the architecture and the PMU are implemented.

This register is **RES0** if the PMU is not implemented.

## Attributes

32-bit read-only register located at 0xE0003FD0.

This register is not banked between Security states.

## Field descriptions

The PMU\_PIDR4 bit assignments are:

**Bits [31:8]**

Reserved, RES0.

**SIZE, bits [7:4]**

Size of the component. RAZ.  $\text{Log}_2$  of the number of 4KB pages from the start of the component to the end of the component ID registers.

**DES 2, bits [3:0]**

Designer, JEP106 continuation code, least significant nibble. For Arm Limited, this field is 0b0100.

This field reads as an **IMPLEMENTATION DEFINED** value.

### D1.2.214 PMU\_SWINC, Performance Monitoring Unit Software Increment Register

The PMU\_SWINC characteristics are:

#### Purpose

Increments a counter that is configured to count the Software increment event, event 0x00.

#### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

#### Configurations

Present only if the Main Extension is implemented.

This register is **RES0** if the Main Extension is not implemented.

Present only if version Armv8.1 of the architecture and the PMU are implemented.

This register is **RES0** if the PMU is not implemented.

#### Attributes

32-bit write-only register located at 0xE0003CA0.

This register is not banked between Security states.

### Field descriptions

The PMU\_SWINC bit assignments are:

#### Bit [31]

Reserved, **RES0**.

#### Pn, bits [30:0]

Event counter software increment bit for PMU\_EVCNTR<n>. An event counter n, configured for SW\_INCR events, increments on every write to bit n of this field.

The possible values of this field are:

**0**

No action. The write to this bit is ignored.

**1**

A SW\_INCR event is generated for event counter n.

#### Note

Bits [30:N] are WI, where N is the number of counters and the value of PMU\_TYPE.N.

This field reads as zero.

### D1.2.215 PMU\_TYPE, Performance Monitoring Unit Type Register

The PMU\_TYPE characteristics are:

#### Purpose

Contains information regarding what the Performance Monitoring Unit supports.

#### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are [UNPREDICTABLE](#).

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

#### Configurations

Present only if the Main Extension is implemented.

This register is [RES0](#) if the Main Extension is not implemented.

Present only if version Armv8.1 of the architecture and the PMU are implemented.

This register is [RES0](#) if the PMU is not implemented.

#### Attributes

32-bit read-only register located at 0xE0003E00.

This register is not banked between Security states.

### Field descriptions

The PMU\_TYPE bit assignments are:

#### Bits [31:28]

Reserved, [RES0](#).

#### Bits [27:24]

[SBZ](#).

#### TRO, bit [23]

Trace-on-overflow support. Identifies whether the trace-on-overflow function is supported.

The possible values of this bit are:

**0**

Trace-on-overflow not supported.

**1**

Trace-on-overflow supported.

This bit reads as one.

#### Bit [22]

[SBZ](#).

#### FZO, bit [21]

Freeze-on-overflow support. Identifies whether the freeze-on-overflow mechanism is supported.

The possible values of this bit are:

**0**  
Freeze-on-overflow mechanism not supported.

**1**  
Freeze-on-overflow mechanism supported.

This bit reads as one.

**Bits [20:15]**  
[SBZ](#).

**CC, bit [14]**  
Cycle counter present. This bit is set if a dedicated cycle counter is present.  
This bit reads as one.

**SIZE, bits [13:8]**  
Size of counters. This field determines the spacing of counters in the memory-map.

**Note**

In Armv8-M this indicates all counters are word-aligned, as the largest counter is PMU\_CCNTR with 32-bits.

This field reads as 0b011111.

**N, bits [7:0]**  
Number of counters.  
Number of counters implemented in addition to the cycle counter, PMU\_CCNTR.  
00000010 PMU\_CCNTR and 2 event counters implemented.  
00000011 PMU\_CCNTR and 3 event counters implemented.  
and so on up to 00011111, which indicates PMU\_CCNTR and 31 event counters implemented.

**Note**

This field will be nonzero when the PMU is implemented, and serves to indicate the PMU is supported. The maximum number of event counters is 31, so bits[7:5] are always zero.

This field reads as an [IMPLEMENTATION DEFINED](#) value.

## D1.2.216 PRIMASK, Exception Mask Register

The PRIMASK characteristics are:

### Purpose

Provides access to the PE PRIMASK register.

### Usage constraints

Privileged access only. Unprivileged access is RAZ/WI, unless otherwise stated.

### Configurations

This register is always implemented.

### Attributes

32-bit read/write special-purpose register.

This register is banked between Security states.

## Field descriptions

The PRIMASK bit assignments are:

### Bits [31:1]

Reserved, [RES0](#).

### PM, bit [0]

Exception mask register. Setting the Secure PRIMASK to one raises the execution priority to 0. Setting the Non-secure PRIMASK to one raises the execution priority to 0 if AIRCR.PRIS is clear, or 0x80 if AIRCR.PRIS is set.

The possible values of this bit are:

**0**

No effect on execution priority.

**1**

Boosts execution priority to either 0 or 0x80.

This bit resets to zero on a Warm reset.

### D1.2.217 PSPLIM, Process Stack Pointer Limit Register

The PSPLIM characteristics are:

## Purpose

Holds the lower limit for the Process stack pointer.

## Usage constraints

Privileged access only. Unprivileged access is RAZ/WI, unless otherwise stated.

## Configurations

This register is always implemented.

## Attributes

32-bit read/write special-purpose register.

This register is banked between Security states.

## Field descriptions

The PSPLIM bit assignments are:

**LIMIT, bits [31:3]**

Stack limit. Bits [31:3] of the Process stack limit address for the selected Security state.

Many instructions and exception entry will generate an exception if the appropriate stack pointer would be updated to a value lower than this limit. If the Main Extension is not implemented, the Non-secure PSPLIM is [RES0](#).

This field resets to zero on a Warm reset.

**Bits [2:0]**

Reserved, RES0.

### D1.2.218 Rn, General-Purpose Register, n = 0 - 12

The R{0..12} characteristics are:

#### Purpose

General-purpose register.

#### Usage constraints

Both privileged and unprivileged accesses are permitted.

This register is word, halfword, and byte accessible.

#### Configurations

This register is always implemented.

#### Attributes

32-bit read/write register.

This register is not banked between Security states.

### Field descriptions

The R{0..12} bit assignments are:

#### VALUE, bits [31:0]

General purpose register value. Armv8-M implemented thirteen general-purpose 32-bit registers, R0 to R12.

This field resets to an **UNKNOWN** value on a Warm reset.

## D1.2.219 RETPSR, Combined Exception Return Program Status Registers

The RETPSR characteristics are:

### Purpose

Value pushed to the stack on exception entry. On exception return this is used to restore the flags and other architectural state. This payload is also used for FNC\_RETURN stacking, however in this case only some of the fields are used. See FunctionReturn() for details.

### Usage constraints

None.

### Configurations

All.

### Attributes

32-bit payload.

### Field descriptions

The RETPSR bit assignments are:

When {RETPSR[26:25], RETPSR[11:10]} != 0:

When {RETPSR[26:25], RETPSR[11:10]} == 0, and a multi-cycle load or store instruction was in progress when the exception was taken:

When {RETPSR[26:25], RETPSR[11:10]} == 0, and beat-wise vector instructions were in progress when the exception was taken:

### N, bit [31]

Negative flag. Value corresponding to APSR.N.

### Z, bit [30]

Zero flag. Value corresponding to APSR.Z.

### C, bit [29]

Carry flag. Value corresponding to APSR.C.

### V, bit [28]

Overflow flag. Value corresponding to APSR.V.

**Q, bit [27]**

Saturate flag. Value corresponding to APSR.Q.

**T, bit [24]**

T32 state. Value corresponding to EPSR.T.

**Bits [23:22]**

Reserved, [RES0](#).

**B, bit [21]**

Branch target identification active. Value corresponding to EPSR.B.

**SFPA, bit [20]**

Secure Floating-point active. Value corresponding to CONTROL.SFPA.

**GE, bits [19:16]**

Greater-than or equal flag. Value corresponding to APSR.GE.

**IT, bits [15:10,26:25] , when [{RETPSR[26:25], RETPSR[11:10]} != 0]**

If-then flags. Value corresponding to EPSR.IT.

**ICI, bits [26:25,15:10] , when [{RETPSR[26:25], RETPSR[11:10]} == 0, and a multi-cycle load or store instruction was in progress when the exception was taken]**

Interrupt continuation flags. Value corresponding to EPSR.ICI.

**ECI, bits [26:25, 11:10, 15:12] , when [{RETPSR[26:25], RETPSR[11:10]} == 0, and beat-wise vector instructions were in progress when the exception was taken]**

Exception continuation flags for beat-wise vector instructions. Value corresponding to EPSR.ECI.

**SPREALIGN, bit [9]**

Stack-pointer re-align. Indicates whether the SP was re-aligned to an 8-byte alignment on exception entry.

The possible values of this bit are:

**0**

The stack pointer was 8-byte aligned before exception entry began, no special handling is required on exception return.

**1**

The stack pointer was only 4-byte aligned before exception entry. The exception entry realigned SP to 8-byte alignment by increasing the stack frame size by 4-bytes.

**Exception, bits [8:0]**

Exception number. Value corresponding to IPSR.Exception.

## D1.2.220 REVIDR, Revision ID Register

The REVIDR characteristics are:

### Purpose

Provides implementation-specific minor revision information.

### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are [UNPREDICTABLE](#).

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

### Configurations

Present only if version Armv8.1-M of the architecture is implemented.

This register is [RES0](#) if Armv8.1-M is not implemented.

### Attributes

32-bit read-only register located at 0xE000ECFC.

Secure software can access the Non-secure version of this register via REVIDR\_NS located at 0xE002ECFC. The location 0xE002ECFC is [RES0](#) to software executing in Non-secure state and the debugger.

This register is not banked between Security states.

## Field descriptions

The REVIDR bit assignments are:

### IMPLEMENTATION DEFINED, bits [31:0]

[IMPLEMENTATION DEFINED](#). The contents of this field are [IMPLEMENTATION DEFINED](#).

### D1.2.221 RFSR, RAS Fault Status Register

The RFSR characteristics are:

## Purpose

Records syndrome information for a RAS exception.

## Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

If AIRCR.BFHFNMIN is zero this register is RAZ/WI from Non-secure state.

## Configurations

Present only if version Armv8.1 of the architecture and RAS are implemented.

This register is **RES0** if RAS is not implemented.

## Attributes

32-bit read/write register located at 0xE000EF04.

Secure software can access the Non-secure version of this register via RFSR\_NS located at 0xE002EF04. The location 0xE002EF04 is **RES0** to software executing in Non-secure state and the debugger.

This register is not banked between Security states.

From Armv8.1-M onwards it is **IMPLEMENTATION DEFINED** whether a debugger write to this register is ignored when the PE is not in Debug state.

## Field descriptions

The RFSR bit assignments are:

**V, bit [31]**

Valid. Indicates the register values are valid.

This bit is write-one-to-clear. Writes of zero are ignored.

This bit resets to zero on a Warm reset.

## IS, bits [30:16]

**IMPLEMENTATION DEFINED** Syndrome. Contains additional **IMPLEMENTATION DEFINED** syndrome information.

**Bits [15:2]**

Reserved, RES0.

**UET, bits [1:0]**

**Error Type.** Describes the state of the processor after taking the RAS exception.

The possible values of this field are:

## 0b00

Uncontainable error (UC).

## 0b01

Unrecoverable error (UEU).

**0b10**

Restartable error (UEO).

**0b11**

Recoverable error (UER).

This field resets to zero on a Warm reset.

### D1.2.222 SAU CTRL, SAU Control Register

The SAU CTRL characteristics are:

## Purpose

Allows enabling of the Security Attribution Unit.

## Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

## Configurations

This register is always implemented.

### Attributes

32-bit read/write register located at 0xE000EDD0.

To allow lock down of this register it is **IMPLEMENTATION DEFINED** whether this register is writable.

This register is RAZ/WI when accessed as Non-secure.

This register is not banked between Security states.

From Armv8.1-M onwards it is **IMPLEMENTATION DEFINED** whether a debugger write to this register is ignored when the PE is not in Debug state.

## Preface

It is **IMPLEMENTATION DEFINED** whether this register:

- Resets to 0x0 - in this case SAU\_REGIONn registers are UNKNOWN at reset.
- Resets to an IMPLEMENTATION DEFINED value.

## Field descriptions

The SAU\_CTRL bit assignments are:

**Bits [31:2]**Reserved, [RES0](#).**ALLNS, bit [1]**

All Non-secure. When SAU\_CTRL.ENABLE is 0 this bit controls if the memory is marked as Non-secure or Secure.

The possible values of this bit are:

0

Memory is marked as Secure and is not Non-secure callable.

**1**

Memory is marked as Non-secure.

This bit resets to an **IMPLEMENTATION DEFINED** value on a Warm reset.

**ENABLE, bit [0]**

Enable. Enables the SAU.

The possible values of this bit are:

**0**

The SAU is disabled.

**1**

The SAU is enabled.

If this register resets to 1, the SAU region registers also reset to an **IMPLEMENTATION DEFINED** value.

This bit resets to an **IMPLEMENTATION DEFINED** value on a Warm reset.

### D1.2.223 SAU\_RBAR, SAU Region Base Address Register

The SAU RBAR characteristics are:

## Purpose

Provides indirect read and write access to the base address of the currently selected SAU region.

## Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

## Configurations

This register is always implemented.

### Attributes

32-bit read/write register located at 0xE000EDDC.

To allow lock down of this register it is **IMPLEMENTATION DEFINED** whether this register is writable.

This register is RAZ/WI when accessed as Non-secure.

This register is not banked between Security states.

From Armv8.1-M onwards it is **IMPLEMENTATION DEFINED** whether a debugger write to this register is ignored when the PE is not in Debug state.

## Field descriptions

The SAU\_RBAR bit assignments are:

**BADDR, bits [31:5]**

**Base address.** Holds bits [31:5] of the base address for the selected SAU region.

Bits [4:0] of the base address are defined as 0x00.

It is IMPLEMENTATION DEFINED whether any of the BADDR bits are WI

This field resets to an **IMPLEMENTATION DEFINED** value on a Warm reset.

**Bits [4:0]**

Reserved, RES0.

### D1.2.224 SAU\_RLAR, SAU Region Limit Address Register

The SAU\_RLAR characteristics are:

#### Purpose

Provides indirect read and write access to the limit address of the currently selected SAU region.

#### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

#### Configurations

This register is always implemented.

#### Attributes

32-bit read/write register located at 0xE000EDE0.

To allow lock down of this register it is **IMPLEMENTATION DEFINED** whether this register is writable.

This register is RAZ/WI when accessed as Non-secure.

This register is not banked between Security states.

From Armv8.1-M onwards it is **IMPLEMENTATION DEFINED** whether a debugger write to this register is ignored when the PE is not in Debug state.

### Field descriptions

The SAU\_RLAR bit assignments are:

#### LADDR, bits [31:5]

Limit address. Holds bits [31:5] of the limit address for the selected SAU region.

Bits [4:0] of the limit address are defined as 0x1F.

It is **IMPLEMENTATION DEFINED** whether any of the LADDR bits are WI

This field resets to an **IMPLEMENTATION DEFINED** value on a Warm reset.

#### Bits [4:2]

Reserved, **RES0**.

#### NSC, bit [1]

Non-secure callable. Controls whether Non-secure state is permitted to execute an SG instruction from this region.

The possible values of this bit are:

**0**

Region is not Non-secure callable.

**1**

Region is Non-secure callable.

This bit resets to an **IMPLEMENTATION DEFINED** value on a Warm reset.

**ENABLE, bit [0]**

Enable. SAU region enable.

The possible values of this bit are:

**0**

SAU region is disabled.

**1**

SAU region is enabled.

This bit resets to an **IMPLEMENTATION DEFINED** value on a Warm reset.

### D1.2.225 SAU\_RNR, SAU Region Number Register

The SAU\_RNR characteristics are:

## Purpose

Selects the region currently accessed by SAU\_RBAR and SAU\_RLAR.

## Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

## Configurations

This register is always implemented.

## Attributes

32-bit read/write register located at 0xE000EDD8.

To allow lock down of this register it is **IMPLEMENTATION DEFINED** whether this register is writable.

This register is RAZ/WI when accessed as Non-secure.

This register is not banked between Security states.

From Armv8.1-M onwards it is **IMPLEMENTATION DEFINED** whether a debugger write to this register is ignored when the PE is not in Debug state.

## Field descriptions

The SAU\_RNR bit assignments are:

**Bits [31:8]**Reserved, **RES0**.**REGION, bits [7:0]**

Region number. Indicates the SAU region accessed by SAU\_RBAR and SAU\_RLAR.

If no SAU regions are implemented, this field is **RES0**. Writing a value corresponding to an unimplemented region is **CONSTRAINED UNPREDICTABLE**.

This field resets to an **UNKNOWN** value on a Warm reset.

### D1.2.226 SAU\_TYPE, SAU Type Register

The SAU\_TYPE characteristics are:

## Purpose

Indicates the number of regions implemented by the Security Attribution Unit.

## Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

## Configurations

This register is always implemented.

## Attributes

32-bit read-only register located at 0xE000EDD4.

This register is RAZ/WI when accessed as Non-secure.

This register is not banked between Security states.

## Field descriptions

The SAU\_TYPE bit assignments are:

**Bits [31:8]**

Reserved, RES0.

**SREGION, bits [7:0]**

SAU regions. The number of implemented SAU regions.

If this field is RAZ, the SAU behaves as follows:

- SAU\_CTRL.ENABLE behaves as RAZ/WI.
- It is **IMPLEMENTATION DEFINED** whether SAU\_CTRL.ALLNS behaves as RAO/WI and all attribution is performed by the IDAU.
- SAU\_RNR, SAU\_RBAR, and SAU\_RLAR behave as RAZ/WI.

This field reads as an IMPLEMENTATION DEFINED value.

## D1.2.227 SCR, System Control Register

The SCR characteristics are:

### Purpose

Sets or returns system control data.

### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

### Configurations

This register is always implemented.

### Attributes

32-bit read/write register located at 0xE000ED10.

Secure software can access the Non-secure version of this register via SCR\_NS located at 0xE002ED10. The location 0xE002ED10 is **RES0** to software executing in Non-secure state and the debugger.

This register is banked between Security states on a bit by bit basis.

From Armv8.1-M onwards it is **IMPLEMENTATION DEFINED** whether a debugger write to this register is ignored when the PE is not in Debug state.

## Field descriptions

The SCR bit assignments are:

### Bits [31:5]

Reserved, **RES0**.

### SEVONPEND, bit [4]

Send event on pend. Determines whether an interrupt assigned to the same Security state as the SEVONPEND bit transitioning from inactive state to pending state generates a wakeup event.

This bit is banked between Security states.

The possible values of this bit are:

**0**

Transitions from inactive to pending are not wakeup events.

**1**

Transitions from inactive to pending are wakeup events.

This bit resets to zero on a Warm reset.

### SLEEPDEEPS, bit [3]

Sleep deep secure. This field controls whether the SLEEPDEEP bit is only accessible from the Secure state.

This bit is not banked between Security states.

The possible values of this bit are:

**0**

The SLEEPDEEP bit accessible from both Security states.

**1**

The SLEEPDEEP bit behaves as RAZ/WI when accessed from the Non-secure state.

This bit is only accessible from the Secure state, and behaves as RAZ/WI when accessed from the Non-secure state. If a PE does not implement the deep sleep state this bit behaves as RAZ/WI from both Security states.

This bit is RAZ/WI from Non-secure state.

This bit resets to zero on a Warm reset.

**SLEEPDEEP, bit [2]**

Sleep deep. Provides a qualifying hint indicating that waking from sleep might take longer. An implementation can use this bit to select between two alternative sleep states.

This bit is not banked between Security states.

The possible values of this bit are:

**0**

Selected sleep state is not deep sleep.

**1**

Selected sleep state is deep sleep.

Details of the implemented sleep states, if any, and details of the use of this bit, are [IMPLEMENTATION DEFINED](#). If the PE does not implement a deep sleep state then this bit can be RAZ/WI.

This bit resets to zero on a Warm reset.

**SLEEPONEXIT, bit [1]**

Sleep on exit. Determines whether, on an exit from an ISR that returns to the base level of execution priority, the PE enters a sleep state.

This bit is banked between Security states.

The possible values of this bit are:

**0**

Enter sleep state disabled.

**1**

Enter sleep state permitted.

The Secure version of this field is used if the Background state being returned to is the Secure state, otherwise the Non-secure version is used.

This bit resets to zero on a Warm reset.

**Bit [0]**

Reserved, [RES0](#).

### D1.2.228 SFAR, Secure Fault Address Register

The SFAR characteristics are:

#### Purpose

Shows the address of the memory location that caused a Security violation.

#### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

#### Configurations

Present only if the Main Extension is implemented.

This register is **RES0** if the Main Extension is not implemented.

#### Attributes

32-bit read/write register located at 0xE000EDE8.

This register is RAZ/WI when accessed as Non-secure.

This register is not banked between Security states.

From Armv8.1-M onwards it is **IMPLEMENTATION DEFINED** whether a debugger write to this register is ignored when the PE is not in Debug state.

### Field descriptions

The SFAR bit assignments are:

#### ADDRESS, bits [31:0]

Address. The address of an access that caused an attribution unit violation. This field is only valid when SFSR.SFARVALID is set, otherwise the value in this register is **UNKNOWN**. This allows the actual flip flops associated with this register to be shared with other fault address registers. If an implementation chooses to share the storage in this way, care must be taken to not leak Secure address information to the Non-secure state. One way of achieving this is to share the SFAR register with the MMFAR\_S register, which is not accessible to the Non-secure state.

In implementations without unique SFAR, BFAR and MMFAR registers, the value of this register is **UNKNOWN** if MMFSR.MMARVALID or BFSR.BFARVALID is set.

This field resets to an **UNKNOWN** value on a Warm reset.

## D1.2.229 SFSR, Secure Fault Status Register

The SFSR characteristics are:

### Purpose

Provides information about any security related faults.

### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

### Configurations

Present only if the Main Extension is implemented.

This register is **RES0** if the Main Extension is not implemented.

### Attributes

32-bit read/write-one-to-clear register located at 0xE000EDE4.

This register is RAZ/WI when accessed as Non-secure.

This register is not banked between Security states.

From Armv8.1-M onwards it is **IMPLEMENTATION DEFINED** whether a debugger write to this register is ignored when the PE is not in Debug state.

## Field descriptions

The SFSR bit assignments are:

### Bits [31:8]

Reserved, **RES0**.

### LSERR, bit [7]

Lazy state error flag. Sticky flag indicating that an error occurred during lazy state activation or deactivation.

The possible values of this bit are:

**0**

Error has not occurred.

**1**

Error has occurred.

This bit resets to zero on a Warm reset.

### SFARVALID, bit [6]

Secure fault address valid. This bit is set when the SFAR register contains a valid value. As with similar fields, such as BFSR.BFARVALID and MMFSR.MMARVALID, this bit can be cleared by other exceptions, such as BusFault.

The possible values of this bit are:

**0**  
SFAR content not valid.

**1**  
SFAR content valid.

This bit resets to zero on a Warm reset.

**LSPERR, bit [5]**

Lazy state preservation error flag. Sticky flag indicating that an SAU or IDAU violation occurred during the lazy preservation of Floating-point state.

The possible values of this bit are:

**0**  
Error has not occurred.

**1**  
Error has occurred.

This bit resets to zero on a Warm reset.

**INVTRAN, bit [4]**

Invalid transition flag. Sticky flag indicating that an exception was raised due to a branch that was not flagged as being domain crossing causing a transition from Secure to Non-secure memory.

The possible values of this bit are:

**0**  
Error has not occurred.

**1**  
Error has occurred.

This bit resets to zero on a Warm reset.

**AUVIOL, bit [3]**

Attribution unit violation flag.

Sticky flag indicating that an attempt was made to access parts of the address space that are marked as Secure with NS-Req for the transaction set to Non-secure.

This bit is not set if the violation occurred during:

- Lazy state preservation, see LSPERR.
- Vector fetches.

The possible values of this bit are:

**0**  
Error has not occurred.

**1**  
Error has occurred.

This bit resets to zero on a Warm reset.

**INVER, bit [2]**

Invalid exception return flag. This can be caused by EXC\_RETURN.DCRS being set to 0 when returning from an exception in the Non-secure state, or by EXC\_RETURN.ES being set to 1 when returning from an exception in the Non-secure state.

The possible values of this bit are:

**0**  
Error has not occurred.

**1**

Error has occurred.

This bit resets to zero on a Warm reset.

**INVIS, bit [1]**

Invalid integrity signature flag. This bit is set if the integrity signature in an exception stack frame is found to be invalid during the unstacking operation.

The possible values of this bit are:

**0**

Error has not occurred.

**1**

Error has occurred.

This bit resets to zero on a Warm reset.

**INVEP, bit [0]**

Invalid entry point. This bit is set if there is an invalid attempt to enter Secure state.

The possible values of this bit are:

**0**

Error has not occurred.

**1**

Error has occurred.

This bit resets to zero on a Warm reset.

## D1.2.230 SHCSR, System Handler Control and State Register

The SHCSR characteristics are:

### Purpose

Provides access to the active and pending status of system exceptions.

### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

### Configurations

This register is always implemented.

### Attributes

32-bit read/write register located at 0xE000ED24.

Secure software can access the Non-secure version of this register via SHCSR\_NS located at 0xE002ED24. The location 0xE002ED24 is **RES0** to software executing in Non-secure state and the debugger.

This register is banked between Security states on a bit by bit basis.

From Armv8.1-M onwards it is **IMPLEMENTATION DEFINED** whether a debugger write to this register is ignored when the PE is not in Debug state.

### Preface

Exception processing automatically updates the SHCSR fields. However, software can write to the register to add or remove the pending or active state of an exception. When updating the SHCSR, Arm recommends using a read-modify-write sequence, to avoid unintended effects on the state of the exception handlers.

Removing the active state of an exception can change the current execution priority, and affect the exception return consistency checks. If software removes the active state, causing a change in current execution priority, this can defeat the architectural behavior that prevents an exception from preempting its own handler.

Pending state bits are set to one when an exception occurs and are cleared to zero when the exception becomes active.

Active state bits are set to one when the associated exception becomes active.

### Field descriptions

The SHCSR bit assignments are:

### Bits [31:22]

Reserved, **RES0**.

**HARDFaultPENDED, bit [21]**

HardFault exception pended state. This bit indicates and allows modification of the pending state of the HardFault exception corresponding to the selected Security state.

This bit is banked between Security states.

The possible values of this bit are:

**0**

HardFault exception not pending for the selected Security state.

**1**

HardFault exception pending for the selected Security state.

If AIRCR.BFHFNMINS is zero this bit is RAZ/WI from Non-secure state.

This bit resets to zero on a Warm reset.

**Note**

The Non-secure HardFault exception will not preempt if AIRCR.BFHFNMINS is set to zero.

**SECUREFAULTPENDED, bit [20]**

SecureFault exception pended state. This bit indicates and allows modification of the pending state of the SecureFault exception.

This bit is not banked between Security states.

The possible values of this bit are:

**0**

SecureFault exception not pending.

**1**

SecureFault exception pending.

This bit is RAZ/WI from Non-secure state.

If the Main Extension is not implemented, this bit is [RES0](#).

This bit resets to zero on a Warm reset.

**SECUREFAULTENA, bit [19]**

SecureFault exception enable. The value of this bit defines whether the SecureFault exception is enabled.

This bit is not banked between Security states.

The possible values of this bit are:

**0**

SecureFault exception disabled.

**1**

SecureFault exception enabled.

When disabled, exceptions that target SecureFault escalate to Secure state HardFault.

This bit is RAZ/WI from Non-secure state.

If the Main Extension is not implemented, this bit is [RES0](#).

This bit resets to zero on a Warm reset.

**USGFAULTENA, bit [18]**

UsageFault exception enable. The value of this bit defines whether the UsageFault exception is enabled for the selected Security state.

This bit is banked between Security states.

The possible values of this bit are:

**0**

UsageFault exception disabled for the selected Security state.

**1**

UsageFault exception enabled for the selected Security state.

When the UsageFault exception is disabled, exceptions targeting UsageFault escalate to HardFault.

If the Main Extension is not implemented, this bit is [RES0](#).

This bit resets to zero on a Warm reset.

#### **BUSFAULTENA, bit [17]**

BusFault exception enable. The value of this bit defines whether the BusFault exception is enabled.

This bit is not banked between Security states.

The possible values of this bit are:

**0**

BusFault exception disabled.

**1**

BusFault exception enabled.

The BusFault exception is not banked between Security states. When the BusFault exception is disabled, exceptions targeting BusFault escalate to HardFault.

If AIRCR.BFHFNMINS is zero this bit is RAZ/WI from Non-secure state.

If the Main Extension is not implemented, this bit is [RES0](#).

This bit resets to zero on a Warm reset.

#### **MEMFAULTENA, bit [16]**

MemManage exception enable. The value of this bit defines whether the MemManage exception is enabled for the selected Security state.

This bit is banked between Security states.

The possible values of this bit are:

**0**

MemManage exception disabled for the selected Security state.

**1**

MemManage exception enabled for the selected Security state.

If the Main Extension is not implemented, this bit is [RES0](#).

This bit resets to zero on a Warm reset.

#### **Note**

When the MemManage exception is disabled, exceptions targeting MemManage escalate to HardFault.

#### **SVCALLPENDEd, bit [15]**

SVCALL exception pending state. This bit indicates and allows modification of the pending state of the SVCALL exception for the selected Security state.

This bit is banked between Security states.

The possible values of this bit are:

**0**  
SVCall exception not pending for the selected Security state.

**1**  
SVCall exception pending for the selected Security state.

This bit resets to zero on a Warm reset.

**BUSFAULTPENDED, bit [14]**

BusFault exception pended state. This bit indicates and allows modification of the pending state of the BusFault exception.

This bit is not banked between Security states.

The possible values of this bit are:

**0**  
BusFault exception not pending.

**1**  
BusFault exception pending.

The BusFault exception is not banked between Security states.

If AIRCR.BFHFNMIN is zero this bit is RAZ/WI from Non-secure state.

If the Main Extension is not implemented, this bit is [RES0](#).

This bit resets to zero on a Warm reset.

**MEMFAULTPENDED, bit [13]**

MemManage exception pended state. This bit indicates and allows modification of the pending state of the MemManage exception for the selected Security state.

This bit is banked between Security states.

The possible values of this bit are:

**0**  
MemManage exception not pending for the selected Security state.

**1**  
MemManage exception pending for the selected Security state.

If the Main Extension is not implemented, this bit is [RES0](#).

This bit resets to zero on a Warm reset.

**USGFAULTPENDED, bit [12]**

UsageFault exception pended state. The UsageFault exception is banked between Security states, this bit indicates and allows modification of the pending state of the UsageFault exception for the selected Security state.

This bit is banked between Security states.

The possible values of this bit are:

**0**  
UsageFault exception not pending for the selected Security state.

**1**  
UsageFault exception pending for the selected Security state.

If the Main Extension is not implemented, this bit is [RES0](#).

This bit resets to zero on a Warm reset.

#### **SYSTICKACT, bit [11]**

SysTick exception active state. This bit indicates and allows modification of the active state of the SysTick exception for the selected Security state.

If two SysTick timers are implemented this bit is banked between Security states.

If less than two SysTick timers are implemented this bit is not banked between Security states.

The possible values of this bit are:

**0**

SysTick exception not active for the selected Security state.

**1**

SysTick exception active for the selected Security state.

If two timers are implemented, then SYSTICKACT is banked between Security states. If one timer is implemented this bit corresponds to the Secure state if ICSR.STTNS is zero, or the Non-secure state if ICSR.STTNS is one.

This bit resets to zero on a Warm reset.

#### **PENDSVACT, bit [10]**

PendSV exception active state. This bit indicates and allows modification of the active state of the PendSV exception for the selected Security state.

This bit is banked between Security states.

The possible values of this bit are:

**0**

PendSV exception not active for the selected Security state.

**1**

PendSV exception active for the selected Security state.

This bit resets to zero on a Warm reset.

#### **Bit [9]**

Reserved, [RES0](#).

#### **MONITORACT, bit [8]**

DebugMonitor exception active state. This bit indicates and allows modification of the active state of the DebugMonitor exception.

This bit is not banked between Security states.

The possible values of this bit are:

**0**

DebugMonitor exception not active.

**1**

DebugMonitor exception active.

If DEMCR.SDME is one this bit is RAZ/WI from Non-secure state

If the Main Extension is not implemented, this bit is [RES0](#).

This bit resets to zero on a Warm reset.

#### **SVCALLACT, bit [7]**

SVCALL exception active state. This bit indicates and allows modification of the active state of the SVCALL exception for the selected Security state.

This bit is banked between Security states.

The possible values of this bit are:

**0**

SVCall exception not active for the selected Security state.

**1**

SVCall exception active for the selected Security state.

This bit resets to zero on a Warm reset.

**Bit [6]**

Reserved, [RES0](#).

**NMIACT, bit [5]**

NMI exception active state. This bit indicates and allows modification of the active state of the NMI exception.

This bit is not banked between Security states.

The possible values of this bit are:

**0**

NMI exception not active.

**1**

NMI exception active.

The NMI exception is not banked between Security states. This field ignores writes if either the value being written is one, AIRCR.BFHFNMINS is zero, the access is from Non-secure state, the access is not via the NS alias, or the access is from a debugger when DHCSR.S\_SDE is zero. This bit can only be cleared by access from the Secure state to the NS alias.

If AIRCR.BFHFNMINS is zero this bit is RAZ/WI from Non-secure state.

This bit resets to zero on a Warm reset.

**SECUREFAULTACT, bit [4]**

SecureFault exception active state. This bit indicates and allows modification of the active state of the SecureFault exception.

This bit is not banked between Security states.

The possible values of this bit are:

**0**

SecureFault exception not active.

**1**

SecureFault exception active.

This bit is RAZ/WI from Non-secure state.

This bit resets to zero on a Warm reset.

**USGFAULTACT, bit [3]**

UsageFault exception active state for the selected Security state. This bit indicates and allows modification of the active state of the UsageFault exception for the selected Security state.

This bit is banked between Security states.

The possible values of this bit are:

**0**

UsageFault exception not active for the selected Security state.

**1**

UsageFault exception active for the selected Security state.

If the Main Extension is not implemented, this bit is **RES0**.

This bit resets to zero on a Warm reset.

#### **HARDFULTACT, bit [2]**

HardFault exception active state. Indicates and allows limited modification of the active state of the HardFault exception for the selected Security state.

This bit is banked between Security states.

The possible values of this bit are:

**0**

HardFault exception not active for the selected Security state.

**1**

HardFault exception active for the selected Security state.

This field ignores writes when any of the following are true:

- The field is being written to one.
- The write targets the Secure instance of this field.
- The access is from Non-secure state or from a debugger when DHCSR.S\_SDE is zero.

This bit resets to zero on a Warm reset.

#### **BUSEFAULTACT, bit [1]**

BusFault exception active state. This bit indicates and allows modification of the active state of the BusFault exception.

This bit is not banked between Security states.

The possible values of this bit are:

**0**

BusFault exception not active.

**1**

BusFault exception active.

The BusFault exception is not banked between Security states.

If AIRCR.BFHFNMINS is zero this bit is RAZ/WI from Non-secure state.

If the Main Extension is not implemented, this bit is **RES0**.

This bit resets to zero on a Warm reset.

#### **MEMFAULTACT, bit [0]**

MemManage exception active state for the selected Security state. This bit indicates and allows modification of the active state of the MemManage exception for the selected Security state.

This bit is banked between Security states.

The possible values of this bit are:

**0**

MemManage exception not active for the selected Security state.

**1**

MemManage exception active for the selected Security state.

If the Main Extension is not implemented, this bit is **RES0**.

This bit resets to zero on a Warm reset.

## D1.2.231 SHPR1, System Handler Priority Register 1

The SHPR1 characteristics are:

### Purpose

Sets or returns priority for system handlers 4 - 7.

### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

If the Main Extension is implemented, this register is word, halfword, and byte accessible.

If the Main Extension is not implemented, this register is word accessible only, halfword and byte accesses are [UNPREDICTABLE](#).

### Configurations

Present only if the Main Extension is implemented.

This register is [RES0](#) if the Main Extension is not implemented.

### Attributes

32-bit read/write register located at 0xE000ED18.

Secure software can access the Non-secure version of this register via SHPR1\_NS located at 0xE002ED18. The location 0xE002ED18 is [RES0](#) to software executing in Non-secure state and the debugger.

This register is banked between Security states on a bit by bit basis.

From Armv8.1-M onwards it is [IMPLEMENTATION DEFINED](#) whether a debugger write to this register is ignored when the PE is not in Debug state.

## Field descriptions

The SHPR1 bit assignments are:

### PRI\_7, bits [31:24]

Priority 7. Priority of system handler 7, SecureFault.

This field is not banked between Security states.

If the PE implements fewer than 8 bits of priority, then the least significant bits of this field are [RES0](#).

This field is RAZ/WI from Non-secure state.

This field resets to zero on a Warm reset.

### PRI\_6, bits [23:16]

Priority 6. Priority of system handler 6, UsageFault.

This field is banked between Security states.

If the PE implements fewer than 8 bits of priority, then the least significant bits of this field are [RES0](#).

This field resets to zero on a Warm reset.

### PRI\_5, bits [15:8]

Priority 5. Priority of system handler 5, BusFault.

This field is not banked between Security states.

If the PE implements fewer than 8 bits of priority, then the least significant bits of this field are [RES0](#).

If AIRCR.BFHFNMINS is zero this field is RAZ/WI from Non-secure state.

This field resets to zero on a Warm reset.

**PRI\_4, bits [7:0]**

Priority 4. Priority of system handler 4, MemManage.

This field is banked between Security states.

If the PE implements fewer than 8 bits of priority, then the least significant bits of this field are [RES0](#).

This field resets to zero on a Warm reset.

### D1.2.232 SHPR2, System Handler Priority Register 2

The SHPR2 characteristics are:

#### Purpose

Sets or returns priority for system handlers 8 - 11.

#### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

If the Main Extension is implemented, this register is word, halfword, and byte accessible.

If the Main Extension is not implemented, this register is word accessible only, halfword and byte accesses are [UNPREDICTABLE](#).

#### Configurations

This register is always implemented.

#### Attributes

32-bit read/write register located at 0xE000ED1C.

Secure software can access the Non-secure version of this register via SHPR2\_NS located at 0xE002ED1C. The location 0xE002ED1C is [RES0](#) to software executing in Non-secure state and the debugger.

This register is banked between Security states.

From Armv8.1-M onwards it is [IMPLEMENTATION DEFINED](#) whether a debugger write to this register is ignored when the PE is not in Debug state.

#### Field descriptions

The SHPR2 bit assignments are:

#### PRI\_11, bits [31:24]

Priority 11. Priority of system handler 11, SVCALL.

This field is banked between Security states.

If the PE implements fewer than 8 bits of priority, then the least significant bits of this field are [RES0](#).

This field resets to zero on a Warm reset.

#### PRI\_10, bits [23:16]

Reserved, [RES0](#).

#### PRI\_9, bits [15:8]

Reserved, [RES0](#).

#### PRI\_8, bits [7:0]

Reserved, [RES0](#).

### D1.2.233 SHPR3, System Handler Priority Register 3

The SHPR3 characteristics are:

#### Purpose

Sets or returns priority for system handlers 12 - 15.

#### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

If the Main Extension is implemented, this register is word, halfword, and byte accessible.

If the Main Extension is not implemented, this register is word accessible only, halfword and byte accesses are **UNPREDICTABLE**.

#### Configurations

This register is always implemented.

#### Attributes

32-bit read/write register located at 0xE000ED20.

Secure software can access the Non-secure version of this register via SHPR3\_NS located at 0xE002ED20. The location 0xE002ED20 is **RES0** to software executing in Non-secure state and the debugger.

This register is banked between Security states on a bit by bit basis.

From Armv8.1-M onwards it is **IMPLEMENTATION DEFINED** whether a debugger write to this register is ignored when the PE is not in Debug state.

### Field descriptions

The SHPR3 bit assignments are:

#### PRI\_15, bits [31:24]

Priority 15. Priority of system handler 15, SysTick.

If two SysTick timers are implemented this field is banked between Security states.

If less than two SysTick timers are implemented this field is not banked between Security states.

If the PE implements fewer than 8 bits of priority, then the least significant bits of this field are **RES0**. If one timer is implemented, this field corresponds to the Secure state if ICSR.STTNS is zero, or the Non-secure state if ICSR.STTNS is one.

If only one SysTick timer is implemented and ICSR.STTNS is clear, this field is RAZ/WI from Non-secure state.

If no SysTick timer is implemented this field is **RES0**.

This field resets to zero on a Warm reset.

#### PRI\_14, bits [23:16]

Priority 14. Priority of system handler 14, PendSV.

This field is banked between Security states.

If the PE implements fewer than 8 bits of priority, then the least significant bits of this field are **RES0**.

This field resets to zero on a Warm reset.

**PRI\_13, bits [15:8]**

Reserved, [RES0](#).

**PRI\_12, bits [7:0]**

Priority 12. Priority of system handler 12, DebugMonitor.

This field is not banked between Security states.

If the PE implements fewer than 8 bits of priority, then the least significant bits of this field are [RES0](#).

If DEMCR.SDME is one this field is RAZ/WI from Non-secure state

If the Main Extension is not implemented, this field is [RES0](#).

This field resets to zero on a Warm reset.

### D1.2.234 SP, Current Stack Pointer Register

The SP characteristics are:

**Purpose**

Exception and procedure stack pointer register.

**Usage constraints**

Privileged and unprivileged access permitted.

**Configurations**

This register is always implemented.

**Attributes**

32-bit read/write special-purpose register.

This register is not banked between Security states.

### Field descriptions

The SP bit assignments are:

**VALUE, bits [31:2]**

Stack pointer. Holds bits[31:2] of the stack pointer address. The current stack pointer is selected from one of MSP\_NS, PSP\_NS, MSP\_S or PSP\_S.

Software can refer to SP as R13.

**Bits [1:0]**

Reserved, [RES0H](#).

### D1.2.235 SP\_NS, Stack Pointer (Non-secure)

The SP\_NS characteristics are:

**Purpose**

Provides access to the current Non-secure stack pointer.

**Usage constraints**

Privileged access only. Unprivileged access is RAZ/WI, unless otherwise stated.

**Configurations**

This register is always implemented.

**Attributes**

32-bit read/write special-purpose register.

This register is not banked between Security states.

### Field descriptions

The SP\_NS bit assignments are:

**VALUE, bits [31:2]**

Stack pointer. Holds bits[31:2] of the current Non-secure stack pointer address. SP\_NS is selected from one of MSP\_NS or PSP\_NS. Access to SP\_NS is provided via MRS and MSR and is subject to stack limit checking.

**Bits [1:0]**

Reserved, **RES0H**.

## D1.2.236 STIR, Software Triggered Interrupt Register

The STIR characteristics are:

### Purpose

Provides a mechanism for software to generate an interrupt.

### Usage constraints

Unprivileged accesses generate a fault if CCR.USERSETMPEND is zero.

This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

### Configurations

Present only if the Main Extension is implemented.

This register is RES0 if the Main Extension is not implemented.

### Attributes

32-bit write-only register located at 0xE000EF00.

Secure software can access the Non-secure version of this register via STIR\_NS located at 0xE002EF00. The location 0xE002EF00 is RES0 to software executing in Non-secure state and the debugger.

This register is not banked between Security states.

## Field descriptions

The STIR bit assignments are:

### Bits [31:9]

Reserved, RES0.

### INTID, bits [8:0], on a write

Interrupt ID. Indicates the interrupt to be pended. The value written is (ExceptionNumber - 16).

Writing to this register has the same effect as setting the NVIC\_ISPR $n$  bit corresponding to the interrupt to 1. Like NVIC\_ISPR $n$ , an attempt to pend an interrupt targeting Secure state from Non-secure is ignored.

### INTID, bits [8:0], on a read

This field reads as zero.

### D1.2.237 SYST\_CALIB, SysTick Calibration Value Register

The SYST\_CALIB characteristics are:

#### Purpose

Reads the SysTick timer calibration value and parameters for the selected Security state.

#### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

#### Configurations

Present only if at least one SysTick timer is implemented.

This register is **RES0** if no SysTick timer is implemented.

#### Attributes

32-bit read-only register located at 0xE000E01C.

Secure software can access the Non-secure version of this register via SYST\_CALIB\_NS located at 0xE002E01C. The location 0xE002E01C is **RES0** to software executing in Non-secure state and the debugger.

This register is banked between Security states.

#### Preface

If the Main Extension is implemented then, two SysTick timers are implemented. If the Main Extension is not implemented, then it is **IMPLEMENTATION DEFINED** whether none, one or two SysTick timers are implemented. Where two SysTick timers are implemented, this register is banked. Where one SysTick timer is implemented, this register is not banked, and Non-secure accesses behave as RAZ/WI if ICSR.STTNS is clear. If no SysTick timer is implemented, both aliases of this register behave as **RES0**.

#### Field descriptions

The SYST\_CALIB bit assignments are:

#### NOREF, bit [31]

No reference. Indicates whether the **IMPLEMENTATION DEFINED** reference clock is implemented.

The possible values of this bit are:

**0**

Reference clock is implemented.

**1**

Reference clock is not implemented.

When this bit is 1, the CLKSOURCE bit of the SYST\_CSR register is forced to 1 and cannot be cleared to 0.

If only one SysTick timer is implemented and ICSR.STTNS is clear, this bit is RAZ/WI from Non-secure state.

If no SysTick timer is implemented this bit is **RES0**.

This bit resets to an **IMPLEMENTATION DEFINED** value on a Warm reset.

This bit reads as an **IMPLEMENTATION DEFINED** value.

**SKEW, bit [30]**

Skew. Indicates whether the 10ms calibration value is exact.

The possible values of this bit are:

**0**

TENMS calibration value is exact.

**1**

TENMS calibration value is inexact.

If only one SysTick timer is implemented and ICSR.STTNS is clear, this bit is RAZ/WI from Non-secure state.

If no SysTick timer is implemented this bit is **RES0**.

This bit resets to an **IMPLEMENTATION DEFINED** value on a Warm reset.

This bit reads as an **IMPLEMENTATION DEFINED** value.

**Bits [29:24]**

Reserved, **RES0**.

**TENMS, bits [23:0]**

Ten milliseconds. Optionally holds a reload value to be used for 10ms (100Hz) timing, subject to system clock skew errors. If this field is zero, the calibration value is not known.

If only one SysTick timer is implemented and ICSR.STTNS is clear, this field is RAZ/WI from Non-secure state.

If no SysTick timer is implemented this field is **RES0**.

This field resets to an **IMPLEMENTATION DEFINED** value on a Warm reset.

This field reads as an **IMPLEMENTATION DEFINED** value.

## D1.2.238 SYST\_CSR, SysTick Control and Status Register

The SYST\_CSR characteristics are:

### Purpose

Controls the SysTick timer and provides status data for the selected Security state.

### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

### Configurations

Present only if at least one SysTick timer is implemented.

This register is **RES0** if no SysTick timer is implemented.

### Attributes

32-bit read/write register located at 0xE000E010.

Secure software can access the Non-secure version of this register via SYST\_CSR\_NS located at 0xE002E010. The location 0xE002E010 is **RES0** to software executing in Non-secure state and the debugger.

This register is banked between Security states.

From Armv8.1-M onwards it is **IMPLEMENTATION DEFINED** whether a debugger write to this register is ignored when the PE is not in Debug state.

### Preface

If the Main Extension is implemented, then two SysTick timers are implemented. If the Main Extension is not implemented, then it is **IMPLEMENTATION DEFINED** whether none, one or two SysTick timers are implemented. Where two SysTick timers are implemented, this register is banked. Where one SysTick timer is implemented, this register is not banked, and Non-secure accesses behave as RAZ/WI if ICSR.STTNS is clear. If no SysTick timer is implemented, both aliases of this register behave as **RES0**.

### Field descriptions

The SYST\_CSR bit assignments are:

### Bits [31:17]

Reserved, **RES0**.

### COUNTFLAG, bit [16]

Count flag. Indicates whether the counter has counted to zero since the last read of this register.

The possible values of this bit are:

**0**

Timer has not counted to 0.

**1**

Timer has counted to 0.

COUNTFLAG is set to 1 by a count transition from 1 to 0. COUNTFLAG is cleared to 0 if software reads this bit as one, and by any write to the SYST\_CVR for the selected Security state. Debugger reads do not clear the COUNTFLAG.

If set this bit clears to zero when read by software. Reads from the debugger do not clear this bit.

If only one SysTick timer is implemented and ICSR.STTNS is clear, this bit is RAZ/WI from Non-secure state.

If no SysTick timer is implemented this bit is [RES0](#).

This bit resets to zero on a Warm reset.

**Bits [15:3]**

Reserved, [RES0](#).

**CLKSOURCE, bit [2]**

Clock source. Indicates the SysTick clock source.

The possible values of this bit are:

**0**

Uses the [IMPLEMENTATION DEFINED](#) external reference clock.

**1**

Uses the PE clock.

If no external clock is implemented, this bit reads as 1 and ignores writes.

If only one SysTick timer is implemented and ICSR.STTNS is clear, this bit is RAZ/WI from Non-secure state.

If no SysTick timer is implemented this bit is [RES0](#).

This bit resets to an [IMPLEMENTATION DEFINED](#) value on a Warm reset.

**TICKINT, bit [1]**

Tick interrupt. Indicates whether counting to 0 causes the status of the SysTick exception to change to pending.

The possible values of this bit are:

**0**

Count to 0 does not affect the SysTick exception status.

**1**

Count to 0 changes the SysTick exception status to pending.

Changing the value of the counter to 0 by writing the SysTick does not change the status of the SysTick exception.

If only one SysTick timer is implemented and ICSR.STTNS is clear, this bit is RAZ/WI from Non-secure state.

If no SysTick timer is implemented this bit is [RES0](#).

This bit resets to zero on a Warm reset.

**ENABLE, bit [0]**

SysTick enable. Indicates the enabled status of the SysTick counter.

The possible values of this bit are:

**0**

Counter is disabled.

**1**

Counter is enabled.

If only one SysTick timer is implemented and ICSR.STTNS is clear, this bit is RAZ/WI from Non-secure state.

If no SysTick timer is implemented this bit is [RES0](#).

This bit resets to zero on a Warm reset.

## D1.2.239 SYST\_CVR, SysTick Current Value Register

The SYST\_CVR characteristics are:

### Purpose

Reads or clears the SysTick timer current counter value for the selected Security state.

### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

### Configurations

Present only if at least one SysTick timer is implemented.

This register is **RES0** if no SysTick timer is implemented.

### Attributes

32-bit read/write-to-clear register located at 0xE000E018.

Secure software can access the Non-secure version of this register via SYST\_CVR\_NS located at 0xE002E018. The location 0xE002E018 is **RES0** to software executing in Non-secure state and the debugger.

This register is banked between Security states.

From Armv8.1-M onwards it is **IMPLEMENTATION DEFINED** whether a debugger write to this register is ignored when the PE is not in Debug state.

### Preface

If the Main Extension is implemented, then two SysTick timers are implemented. If the Main Extension is not implemented, then it is **IMPLEMENTATION DEFINED** whether none, one or two SysTick timers are implemented. Where two SysTick timers are implemented, this register is banked. Where one SysTick timer is implemented, this register is not banked, and Non-secure accesses behave as RAZ/WI if ICSR.STTNS is clear. If no SysTick timer is implemented, both aliases of this register behave as **RES0**.

### Field descriptions

The SYST\_CVR bit assignments are:

#### Bits [31:24]

Reserved, **RES0**.

#### CURRENT, bits [23:0], on a read

Current counter value. Provides the value of the SysTick timer counter for the selected Security state.

It is **IMPLEMENTATION DEFINED** whether the current counter value decrements if the PE is sleeping and SCR.SLEEPDEEP is set.

If only one SysTick timer is implemented and ICSR.STTNS is clear, this field is RAZ/WI from Non-secure state.

If no SysTick timer is implemented this field is **RES0**.

This field resets to an **UNKNOWN** value on a Warm reset.

**CURRENT, bits [23:0], on a write**

Reset counter value. Writing any value clears the SysTick timer counter for the selected Security state to zero.

## D1.2.240 SYST\_RVR, SysTick Reload Value Register

The SYST\_RVR characteristics are:

### Purpose

Provides access SysTick timer counter reload value for the selected Security state.

### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

### Configurations

Present only if at least one SysTick timer is implemented.

This register is **RES0** if no SysTick timer is implemented.

### Attributes

32-bit read/write register located at 0xE000E014.

Secure software can access the Non-secure version of this register via SYST\_RVR\_NS located at 0xE002E014. The location 0xE002E014 is **RES0** to software executing in Non-secure state and the debugger.

This register is banked between Security states.

From Armv8.1-M onwards it is **IMPLEMENTATION DEFINED** whether a debugger write to this register is ignored when the PE is not in Debug state.

### Preface

If the Main Extension is implemented, then two SysTick timers are implemented. If the Main Extension is not implemented, then it is **IMPLEMENTATION DEFINED** whether none, one or two SysTick timers are implemented. Where two SysTick timers are implemented, this register is banked. Where one SysTick timer is implemented, this register is not banked, and Non-secure accesses behave as RAZ/WI if ICSR.STTNS is clear. If no SysTick timer is implemented, both instances of this register behave as **RES0**.

### Field descriptions

The SYST\_RVR bit assignments are:

#### Bits [31:24]

Reserved, **RES0**.

#### RELOAD, bits [23:0]

Counter reload value. The value to load into the SYST\_CVR for the selected Security state when the counter reaches 0.

If only one SysTick timer is implemented and ICSR.STTNS is clear, this field is RAZ/WI from Non-secure state.

If no SysTick timer is implemented this field is **RES0**.

This field resets to an **UNKNOWN** value on a Warm reset.

### D1.2.241 TPIU\_ACPR, TPIU Asynchronous Clock Prescaler Register

The TPIU\_ACPR characteristics are:

## Purpose

Defines a prescaler value for the baud rate of the Serial Wire Output (SWO). Writing to the register automatically updates the prescale counter, immediately affecting the baud rate of the serial data output.

## Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

If the Main Extension is not implemented then it is **IMPLEMENTATION DEFINED** whether this register is accessible only to the debugger and **RES0** for software. Otherwise the register is accessible to the debugger and software.

If a debugger changes the register value while the TPIU is transmitting data, the effect on the output stream is **UNPREDICTABLE** and the required recovery process is **IMPLEMENTATION DEFINED**.

## Configurations

Present only if the TPIU is implemented and supports SWO.

This register is **RES0** if the TPIU is not implemented or does not support SWO.

## Attributes

32-bit read/write register located at 0xE0040010.

This register is not banked between Security states.

## Field descriptions

The TPIU\_ACPR bit assignments are:

**Bits [31:16]**

Reserved, RES0.

**SWOSCALER, bits [15:0]**

**SWO and Parallel trace port baud rate prescaler.** Sets the ratio between an **IMPLEMENTATION DEFINED** reference clock and the TPIU output clock rates. The prescaler always sets the ratio for the SWO output clock. When TPIU\_DEVID.CPPT is one, the prescaler also sets the ratio for the Parallel trace port clock. The supported scaler value range is **IMPLEMENTATION DEFINED**, to a maximum scaler value of 0xFFFF. Unused bits of this field are RAZ/WI.

The possible values of this field are:

***n***  
SWO or Parallel trace port output clock = Asynchronous\_Reference\_Clock/(*n* + 1).

This field resets to zero on a Cold reset.

### D1.2.242 TPIU\_CIDR0, TPIU Component Identification Register 0

The TPIU\_CIDR0 characteristics are:

#### Purpose

Provides CoreSight Unique Component Identifier information for the TPIU.

#### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are [UNPREDICTABLE](#).

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

If the Main Extension is not implemented then it is [IMPLEMENTATION DEFINED](#) whether this register is accessible only to the debugger and [RES0](#) for software. Otherwise the register is accessible to the debugger and software.

#### Configurations

Present only if CoreSight identification is implemented.

This register is [RES0](#) if CoreSight identification is not implemented.

Present only if the TPIU is implemented.

This register is [RES0](#) if the TPIU is not implemented.

#### Attributes

32-bit read-only register located at 0xE0040FF0.

This register is not banked between Security states.

### Field descriptions

The TPIU\_CIDR0 bit assignments are:

#### Bits [31:8]

Reserved, [RES0](#).

#### PRMBL\_0, bits [7:0]

CoreSight component identification preamble. See the *Arm® CoreSight™ Architecture Specification*.

This field reads as 0x0D.

### D1.2.243 TPIU\_CIDR1, TPIU Component Identification Register 1

The TPIU\_CIDR1 characteristics are:

#### Purpose

Provides CoreSight Unique Component Identifier information for the TPIU.

#### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

If the Main Extension is not implemented then it is **IMPLEMENTATION DEFINED** whether this register is accessible only to the debugger and **RES0** for software. Otherwise the register is accessible to the debugger and software.

#### Configurations

Present only if CoreSight identification is implemented.

This register is **RES0** if CoreSight identification is not implemented.

Present only if the TPIU is implemented.

This register is **RES0** if the TPIU is not implemented.

#### Attributes

32-bit read-only register located at 0xE0040FF4.

This register is not banked between Security states.

#### Field descriptions

The TPIU\_CIDR1 bit assignments are:

#### Bits [31:8]

Reserved, **RES0**.

#### CLASS, bits [7:4]

CoreSight component class. See the *Arm® CoreSight™ Architecture Specification*.

This field reads as 0x9.

#### PRMBL\_1, bits [3:0]

CoreSight component identification preamble. See the *Arm® CoreSight™ Architecture Specification*.

This field reads as 0x0.

## D1.2.244 TPIU\_CIDR2, TPIU Component Identification Register 2

The TPIU\_CIDR2 characteristics are:

### Purpose

Provides CoreSight Unique Component Identifier information for the TPIU.

### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

If the Main Extension is not implemented then it is **IMPLEMENTATION DEFINED** whether this register is accessible only to the debugger and **RES0** for software. Otherwise the register is accessible to the debugger and software.

### Configurations

Present only if CoreSight identification is implemented.

This register is **RES0** if CoreSight identification is not implemented.

Present only if the TPIU is implemented.

This register is **RES0** if the TPIU is not implemented.

### Attributes

32-bit read-only register located at 0xE0040FF8.

This register is not banked between Security states.

## Field descriptions

The TPIU\_CIDR2 bit assignments are:

### Bits [31:8]

Reserved, **RES0**.

### PRMBL\_2, bits [7:0]

CoreSight component identification preamble. See the *Arm® CoreSight™ Architecture Specification*.

This field reads as 0x05.

### D1.2.245 TPIU\_CIDR3, TPIU Component Identification Register 3

The TPIU\_CIDR3 characteristics are:

#### Purpose

Provides CoreSight Unique Component Identifier information for the TPIU.

#### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

If the Main Extension is not implemented then it is **IMPLEMENTATION DEFINED** whether this register is accessible only to the debugger and **RES0** for software. Otherwise the register is accessible to the debugger and software.

#### Configurations

Present only if CoreSight identification is implemented.

This register is **RES0** if CoreSight identification is not implemented.

Present only if the TPIU is implemented.

This register is **RES0** if the TPIU is not implemented.

#### Attributes

32-bit read-only register located at 0xE0040FFC.

This register is not banked between Security states.

### Field descriptions

The TPIU\_CIDR3 bit assignments are:

#### Bits [31:8]

Reserved, **RES0**.

#### PRMBL\_3, bits [7:0]

CoreSight component identification preamble. See the *Arm® CoreSight™ Architecture Specification*.

This field reads as 0xB1.

## D1.2.246 TPIU\_CLAIMCLR, TPIU Claim Tag Clear Register

The TPIU\_CLAIMCLR characteristics are:

### Purpose

In conjunction with TPIU\_CLAIMSET, provides Claim Tag bits that can be separately set and cleared to indicate whether functionality is in use by a debug agent.

### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

If the Main Extension is not implemented then it is **IMPLEMENTATION DEFINED** whether this register is accessible only to the debugger and **RES0** for software. Otherwise the register is accessible to the debugger and software.

If a debugger changes the register value while the TPIU is transmitting data, the effect on the output stream is **UNPREDICTABLE** and the required recovery process is **IMPLEMENTATION DEFINED**.

### Configurations

Present only if the TPIU is implemented and supports SWO.

This register is **RES0** if the TPIU is not implemented or does not support SWO.

Present only if version Armv8.1-M of the architecture is implemented.

This register is **RES0** if Armv8.1-M is not implemented.

### Attributes

32-bit read/write register located at 0xE0040FA4.

This register is not banked between Security states.

### Preface

Unimplemented Claim Tag bits are RAZ/WI.

### Field descriptions

The TPIU\_CLAIMCLR bit assignments are:

**CLR $m$ , bit  $[m]$ , for  $m = 0$  to 31, on a read**

Claim Tag Clear. Indicates the current status of Claim Tag bit  $m$ , and is used to set Claim Tag bit  $m$  to 0b0.

The possible values of this field are:

**0b0**

Claim Tag bit  $m$  is not set.

**0b1**

Claim Tag bit  $m$  is set.

The number of Claim Tag bits is indicated in TPIU\_CLAIMSET.

This field resets to zero on a Cold reset.

**CLR $m$ , bit  $[m]$ , for  $m = 0$  to 31, on a write**

Claim Tag Clear. Indicates the current status of Claim Tag bit  $m$ , and is used to set Claim Tag bit  $m$  to 0b0.

The possible values of this field are:

**0b0**

Ignored.

**0b1**

Clear Claim Tag bit  $m$  to 0b0.

The number of Claim Tag bits is indicated in TPIU\_CLAIMSET.

This field is write-one-to-clear. Writes of zero are ignored.

## D1.2.247 TPIU\_CLAIMSET, TPIU Claim Tag Set Register

The TPIU\_CLAIMSET characteristics are:

### Purpose

In conjunction with TPIU\_CLAIMCLR, provides Claim Tag bits that can be separately set and cleared to indicate whether functionality is in use by a debug agent.

### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

If the Main Extension is not implemented then it is **IMPLEMENTATION DEFINED** whether this register is accessible only to the debugger and **RES0** for software. Otherwise the register is accessible to the debugger and software.

If a debugger changes the register value while the TPIU is transmitting data, the effect on the output stream is **UNPREDICTABLE** and the required recovery process is **IMPLEMENTATION DEFINED**.

### Configurations

Present only if the TPIU is implemented and supports SWO.

This register is **RES0** if the TPIU is not implemented or does not support SWO.

Present only if version Armv8.1-M of the architecture is implemented.

This register is **RES0** if Armv8.1-M is not implemented.

### Attributes

32-bit read/write register located at 0xE0040FA0.

This register is not banked between Security states.

### Preface

Unimplemented Claim Tag bits are RAZ/WI.

### Field descriptions

The TPIU\_CLAIMSET bit assignments are:

**SET $m$ , bit [ $m$ ], for  $m = 0$  to 31, on a read**

Claim Tag Set. Indicates whether Claim Tag bit  $m$  is implemented, and is used to set Claim Tag bit  $m$  to 0b1.

The possible values of this field are:

**0b0**

Claim Tag bit  $m$  is not implemented.

**0b1**

Claim Tag bit  $m$  is implemented.

This field resets to 0xF on a Cold reset.

**SET $m$ , bit [ $m$ ], for  $m = 0$  to 31, on a write**

Claim Tag Set. Indicates whether Claim Tag bit  $m$  is implemented, and is used to set Claim Tag bit  $m$  to 0b1.

The possible values of this field are:

**0b0**

Ignored.

**0b1**

Set Claim Tag bit  $m$  to 0b1.

This field is write-one-to-set. Writes of zero are ignored.

### D1.2.248 TPIU\_CSPSR, TPIU Current Parallel Port Sizes Register

The TPIU\_CSPSR characteristics are:

#### Purpose

Controls the width of the parallel trace port.

#### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are [UNPREDICTABLE](#).

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

If the Main Extension is not implemented then it is [IMPLEMENTATION DEFINED](#) whether this register is accessible only to the debugger and [RES0](#) for software. Otherwise the register is accessible to the debugger and software.

#### Configurations

Present only if the TPIU is implemented.

This register is [RES0](#) if the TPIU is not implemented.

#### Attributes

32-bit read/write register located at 0xE0040004.

This register is not banked between Security states.

### Field descriptions

The TPIU\_CSPSR bit assignments are:

#### CWIDTH, bits [31:0]

Current width. CWIDTH[m] represents a parallel trace port width of (m+1).

The possible values of each bit are:

**0**

Width (N+1) is not the current parallel trace port width.

**1**

Width (N+1) is the current parallel trace port width.

A debugger must set only one bit is set to 1, and all others must be zero. The effect of writing a value with more than one bit set to 1 is [UNPREDICTABLE](#). The effect of a write to an unsupported bit is [UNPREDICTABLE](#).

This register resets to the value for the smallest supported parallel trace port size.

This field resets to an [IMPLEMENTATION DEFINED](#) value on a Cold reset.

## D1.2.249 TPIU\_DEVID, TPIU Device Identifier Register

The TPIU\_DEVID characteristics are:

### Purpose

Describes the TPIU to a debugger.

### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

If the Main Extension is not implemented then it is **IMPLEMENTATION DEFINED** whether this register is accessible only to the debugger and **RES0** for software. Otherwise the register is accessible to the debugger and software.

### Configurations

Present only if the TPIU is implemented.

This register is **RES0** if the TPIU is not implemented.

### Attributes

32-bit read-only register located at 0xE0040FC8.

This register is not banked between Security states.

In earlier versions of the M-Profile architecture, this register was named TPIU\_TYPE.

## Field descriptions

The TPIU\_DEVID bit assignments are:

### Bits [31:18]

Reserved, **RES0**.

### CPPT, bit [17]

Clock Prescaler Parallel Trace. Indicates whether the Parallel trace port prescaler is controlled by TPIU\_ACPR.

The possible values of this bit are:

**0**

Parallel trace port is not affected by the prescaler controlled by TPIU\_ACPR.

**1**

Parallel trace port is affected by the prescaler controlled by TPIU\_ACPR.

This bit is **RES0** if TPIU\_DEVID.PTINVALID == 1.

This bit reads as an **IMPLEMENTATION DEFINED** value.

### Bit [16]

Reserved, **RES0**.

**Bits [15:12]**

IMPLEMENTATION DEFINED.

**NRZVALID, bit [11]**

NRZ valid. Indicates support for SWO using UART/NRZ encoding.

The possible values of this bit are:

**0**

Not supported.

**1**

Supported.

This bit reads as an IMPLEMENTATION DEFINED value.

**MANCVALID, bit [10]**

Manchester valid. Indicates support for SWO using Manchester encoding.

The possible values of this bit are:

**0**

Not supported.

**1**

Supported.

This bit reads as an IMPLEMENTATION DEFINED value.

**PTINVALID, bit [9]**

Parallel Trace Interface invalid. Indicates support for parallel trace port operation.

The possible values of this bit are:

**0**

Supported.

**1**

Not supported.

This bit reads as an IMPLEMENTATION DEFINED value.

**FIFOSZ, bits [8:6]**

FIFO depth. Indicates the minimum implemented size of the TPIU output FIFO for trace data.

The possible values of this field are:

**0**

IMPLEMENTATION DEFINED FIFO depth.

**Other**

Minimum FIFO size is  $2^{\text{FIFOSZ}}$ .

For example, a value of 0b011 indicates a FIFO size of at least  $2^3 = 8$  bytes.

This field reads as an IMPLEMENTATION DEFINED value.

**Bits [5:0]**

IMPLEMENTATION DEFINED.

### D1.2.250 TPIU\_DEVTYPE, TPIU Device Type Register

The TPIU\_DEVTYPE characteristics are:

#### Purpose

Provides CoreSight Unique Component Identifier information for the TPIU.

#### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

If the Main Extension is not implemented then it is **IMPLEMENTATION DEFINED** whether this register is accessible only to the debugger and **RES0** for software. Otherwise the register is accessible to the debugger and software.

#### Configurations

Present only if CoreSight identification is implemented.

This register is **RES0** if CoreSight identification is not implemented.

Present only if the TPIU is implemented.

This register is **RES0** if the TPIU is not implemented.

#### Attributes

32-bit read-only register located at 0xE0040FCC.

This register is not banked between Security states.

### Field descriptions

The TPIU\_DEVTYPE bit assignments are:

#### Bits [31:8]

Reserved, **RES0**.

#### SUB, bits [7:4]

Sub-type. Component sub-type.

The possible values of this field are:

**0x0**

Other. Only permitted if the MAJOR field reads as 0x0.

**0x1**

Trace port. Only permitted if the MAJOR field reads as 0x1.

This field reads as an **IMPLEMENTATION DEFINED** value.

#### MAJOR, bits [3:0]

Major type. Component major type.

The possible values of this field are:

**0x0**

Miscellaneous.

**0x1**

Trace sink.

This field reads as an **IMPLEMENTATION DEFINED** value.

### D1.2.251 TPIU\_FFCR, TPIU Formatter and Flush Control Register

The TPIU\_FFCR characteristics are:

#### Purpose

Controls the TPIU formatter. This register might contain other formatter and flush control fields that are outside the scope of the architecture. Contact Arm for more information.

#### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

If the Main Extension is not implemented then it is **IMPLEMENTATION DEFINED** whether this register is accessible only to the debugger and **RES0** for software. Otherwise the register is accessible to the debugger and software.

#### Configurations

Present only if the TPIU is implemented.

This register is **RES0** if the TPIU is not implemented.

#### Attributes

32-bit read/write register located at 0xE0040304.

This register is not banked between Security states.

### Field descriptions

The TPIU\_FFCR bit assignments are:

#### Bits [31:15,11,7,3:2]

Reserved, **RES0**.

#### Bits [14:12]

Reserved for formatter stop controls.

Reserved, **RES0**.

#### Bits [10:9]

Reserved for additional trigger mark controls.

Reserved, **RES0**.

#### TrigIn, bit [8]

Trigger input asserted. Indicate a trigger on the trace port when an **IMPLEMENTATION DEFINED** TRIGIN signal is asserted.

It is **IMPLEMENTATION DEFINED** whether this bit is R/W or RAO.

This bit resets to zero on a Cold reset.

**FOnMan, bit [6]**

Flush On Manual. Setting this bit to 1 generates a flush. The TPIU clears the bit to 0 when the flush completes.

This bit resets to zero on a Cold reset.

**Bits [5:4]**

Reserved for additional flush controls.

Reserved, [RES0](#).

**EnFmt, bits [1:0]**

Formatter control. Selects the output formatting mode.

The possible values of this field are:

**0b00**

Bypass. Disable formatting. Only supported when SWO mode is selected. Only a single trace source is supported in bypass mode:

- If only a single trace source is connected to this TPIU, it is selected.
- If multiple sources (including the ITM) are implemented and connected to this TPIU, then all other trace sources, except for the ITM, must be disabled. Otherwise, the trace output is [UNPREDICTABLE](#).

All other trace sources are discarded.

**0b10**

Continuous. Enable formatting and embed triggers and null cycles in the formatted output.

All other values are reserved.

If no formatter is implemented, this field is [RES0](#). This field must be set to 0b10 when the parallel trace port is selected, or when using multiple trace sources. Changing the value of this field when TPIU\_FFSR.FtStopped is 0 is [UNPREDICTABLE](#).

This field resets to zero on a Cold reset.

**Note**

An optional TRACECTL pin might be implemented as part of the parallel trace port that allows Bypass mode when using a parallel trace port and a further mode, EnFmt == 0b01. The CoreSight architecture describes EnFmt[1] as the EnFCont bit and EnFmt[0] as the EnFTC bit.

### D1.2.252 TPIU\_FFSR, TPIU Formatter and Flush Status Register

The TPIU\_FFSR characteristics are:

#### Purpose

Shows the status and capabilities of the TPIU formatter.

#### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

If the Main Extension is not implemented then it is **IMPLEMENTATION DEFINED** whether this register is accessible only to the debugger and **RES0** for software. Otherwise the register is accessible to the debugger and software.

#### Configurations

Present only if the TPIU is implemented.

This register is **RES0** if the TPIU is not implemented.

#### Attributes

32-bit read-only register located at 0xE0040300.

This register is not banked between Security states.

### Field descriptions

The TPIU\_FFSR bit assignments are:

#### Bits [31:4]

Reserved, **RES0**.

#### FtNonStop, bit [3]

Non-stop formatter. Indicates the formatter cannot be stopped.

The possible values of this bit are:

**0**

Formatter can be stopped.

**1**

Formatter cannot be stopped.

If no formatter is implemented, this bit is RAO.

#### TCPresent, bit [2]

TRACECTL present. Indicates presence of the TRACECTL pin.

The possible values of this bit are:

**0**

No TRACECTL pin is available. The data formatter must be used and only in continuous mode.

**1**

The optional TRACECTL pin is present.

If a parallel trace port is not implemented, this bit is RAZ.

**Note**

If a parallel trace port is implemented, Arm recommends the TRACECTL pin is not implemented.

**FtStopped, bit [1]**

Formatter stopped. Indicates the formatter is stopped.

The possible values of this bit are:

**0**

Formatter is enabled.

**1**

The formatter has received a stop request signal and all trace data and post-amble has been output. Any further trace data is ignored.

If no formatter is implemented, or the formatter cannot be stopped, this bit is RAZ.

**FInProg, bit [0]**

Flush in progress. Set to 1 when a flush is initiated and clears to zero when all data received before the flush is acknowledged has been output on the trace port. That is, the trace has been received at the sink, formatted, and output on the trace port.

### D1.2.253 TPIU\_LAR, TPIU Software Lock Access Register

The TPIU\_LAR characteristics are:

#### Purpose

Provides CoreSight Software Lock control for the TPIU, see the *Arm® CoreSight™ Architecture Specification* for details.

#### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

This register is RAZ/WI if accessed via the debugger, regardless of DAUTHCTRL.UIDAPEN (either bank). It is **IMPLEMENTATION DEFINED** whether a DAP error is generated.

#### Configurations

Present only if CoreSight identification is implemented.

This register is **RES0** if CoreSight identification is not implemented.

Present only if the TPIU is implemented.

This register is **RES0** if the TPIU is not implemented.

Present only if the optional Software Lock is implemented.

This register is RAZ/WI if the Software Lock is not implemented.

#### Attributes

32-bit write-only register located at 0xE0040FB0.

This register is not banked between Security states.

### Field descriptions

The TPIU\_LAR bit assignments are:

#### KEY, bits [31:0]

Lock Access control.

Writing the key value 0xC5ACCE55 to this field unlocks the lock, enabling write accesses to the registers of this component through a memory-mapped interface.

Writing any other value to this register locks the lock, disabling write accesses to the registers of this component through a memory mapped interface.

### D1.2.254 TPIU\_LSR, TPIU Software Lock Status Register

The TPIU\_LSR characteristics are:

#### Purpose

Provides CoreSight Software Lock status information for the TPIU, see the *Arm® CoreSight™ Architecture Specification* for details.

#### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

If the Main Extension is not implemented then it is **IMPLEMENTATION DEFINED** whether this register is accessible only to the debugger and **RES0** for software. Otherwise the register is accessible to the debugger and software.

This register is RAZ/WI if accessed via the debugger, regardless of DAUTHCTRL.UIDAPEN (either bank). It is **IMPLEMENTATION DEFINED** whether a DAP error is generated.

#### Configurations

Present only if CoreSight identification is implemented.

This register is **RES0** if CoreSight identification is not implemented.

Present only if the TPIU is implemented.

This register is **RES0** if the TPIU is not implemented.

Present only if the optional Software Lock is implemented.

This register is RAZ/WI if the Software Lock is not implemented.

#### Attributes

32-bit read-only register located at 0xE0040FB4.

This register is not banked between Security states.

### Field descriptions

The TPIU\_LSR bit assignments are:

#### Bits [31:3]

Reserved, **RES0**.

#### nTT, bit [2]

Not thirty-two bit. See the *Arm® CoreSight™ Architecture Specification*.

This bit reads as zero.

#### SLK, bit [1]

Software Lock status. See the *Arm® CoreSight™ Architecture Specification*.

The possible values of this bit are:

**0**

Lock clear. Software writes are permitted to the registers of this component.

**1**

Lock set. Software writes to the registers of this component are ignored, and reads have no side effects.

For a debugger read of this register, or when the Software Lock is not implemented, this bit is [RES0](#).

This bit resets to one on a Cold reset.

**SLI, bit [0]**

Software Lock implemented. See the *Arm® CoreSight™ Architecture Specification*.

The possible values of this bit are:

**0**

Software Lock not implemented or debugger access.

**1**

Software Lock is implemented and software access.

For a debugger read of this register, or when the Software Lock is not implemented, this bit is RAZ.

This bit reads as an [IMPLEMENTATION DEFINED](#) value.

### D1.2.255 TPIU\_PIDR0, TPIU Peripheral Identification Register 0

The TPIU\_PIDR0 characteristics are:

#### Purpose

Provides CoreSight Unique Component Identifier information for the TPIU.

#### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are [UNPREDICTABLE](#).

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

If the Main Extension is not implemented then it is [IMPLEMENTATION DEFINED](#) whether this register is accessible only to the debugger and [RES0](#) for software. Otherwise the register is accessible to the debugger and software.

#### Configurations

Present only if CoreSight identification is implemented.

This register is [RES0](#) if CoreSight identification is not implemented.

Present only if the TPIU is implemented.

This register is [RES0](#) if the TPIU is not implemented.

#### Attributes

32-bit read-only register located at 0xE0040FE0.

This register is not banked between Security states.

### Field descriptions

The TPIU\_PIDR0 bit assignments are:

#### Bits [31:8]

Reserved, [RES0](#).

#### PART\_0, bits [7:0]

Part number bits [7:0]. See the *Arm® CoreSight™ Architecture Specification*.

This field reads as an [IMPLEMENTATION DEFINED](#) value.

### D1.2.256 TPIU\_PIDR1, TPIU Peripheral Identification Register 1

The TPIU\_PIDR1 characteristics are:

#### Purpose

Provides CoreSight Unique Component Identifier information for the TPIU.

#### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

If the Main Extension is not implemented then it is **IMPLEMENTATION DEFINED** whether this register is accessible only to the debugger and **RES0** for software. Otherwise the register is accessible to the debugger and software.

#### Configurations

Present only if CoreSight identification is implemented.

This register is **RES0** if CoreSight identification is not implemented.

Present only if the TPIU is implemented.

This register is **RES0** if the TPIU is not implemented.

#### Attributes

32-bit read-only register located at 0xE0040FE4.

This register is not banked between Security states.

### Field descriptions

The TPIU\_PIDR1 bit assignments are:

#### Bits [31:8]

Reserved, **RES0**.

#### DES\_0, bits [7:4]

JEP106 identification code bits [3:0]. See the *Arm® CoreSight™ Architecture Specification*.

This field reads as an **IMPLEMENTATION DEFINED** value.

#### PART\_1, bits [3:0]

Part number bits [11:8]. See the *Arm® CoreSight™ Architecture Specification*.

This field reads as an **IMPLEMENTATION DEFINED** value.

## D1.2.257 TPIU\_PIDR2, TPIU Peripheral Identification Register 2

The TPIU\_PIDR2 characteristics are:

### Purpose

Provides CoreSight Unique Component Identifier information for the TPIU.

### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

If the Main Extension is not implemented then it is **IMPLEMENTATION DEFINED** whether this register is accessible only to the debugger and **RES0** for software. Otherwise the register is accessible to the debugger and software.

### Configurations

Present only if CoreSight identification is implemented.

This register is **RES0** if CoreSight identification is not implemented.

Present only if the TPIU is implemented.

This register is **RES0** if the TPIU is not implemented.

### Attributes

32-bit read-only register located at 0xE0040FE8.

This register is not banked between Security states.

## Field descriptions

The TPIU\_PIDR2 bit assignments are:

### Bits [31:8]

Reserved, **RES0**.

### REVISION, bits [7:4]

Component revision. See the *Arm® CoreSight™ Architecture Specification*.

This field reads as an **IMPLEMENTATION DEFINED** value.

### JEDEC, bit [3]

JEDEC assignee value is used. See the *Arm® CoreSight™ Architecture Specification*.

This bit reads as one.

### DES\_1, bits [2:0]

JEP106 identification code bits [6:4]. See the *Arm® CoreSight™ Architecture Specification*.

This field reads as an **IMPLEMENTATION DEFINED** value.

### D1.2.258 TPIU\_PIDR3, TPIU Peripheral Identification Register 3

The TPIU\_PIDR3 characteristics are:

#### Purpose

Provides CoreSight Unique Component Identifier information for the TPIU.

#### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

If the Main Extension is not implemented then it is **IMPLEMENTATION DEFINED** whether this register is accessible only to the debugger and **RES0** for software. Otherwise the register is accessible to the debugger and software.

#### Configurations

Present only if CoreSight identification is implemented.

This register is **RES0** if CoreSight identification is not implemented.

Present only if the TPIU is implemented.

This register is **RES0** if the TPIU is not implemented.

#### Attributes

32-bit read-only register located at 0xE0040FEC.

This register is not banked between Security states.

### Field descriptions

The TPIU\_PIDR3 bit assignments are:

#### Bits [31:8]

Reserved, **RES0**.

#### REVAND, bits [7:4]

RevAnd. See the Arm® CoreSight™ Architecture Specification.

This field reads as an **IMPLEMENTATION DEFINED** value.

#### CMOD, bits [3:0]

Customer Modified. See the Arm® CoreSight™ Architecture Specification.

This field reads as an **IMPLEMENTATION DEFINED** value.

### D1.2.259 TPIU\_PIDR4, TPIU Peripheral Identification Register 4

The TPIU\_PIDR4 characteristics are:

#### Purpose

Provides CoreSight Unique Component Identifier information for the TPIU.

#### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

If the Main Extension is not implemented then it is **IMPLEMENTATION DEFINED** whether this register is accessible only to the debugger and **RES0** for software. Otherwise the register is accessible to the debugger and software.

#### Configurations

Present only if CoreSight identification is implemented.

This register is **RES0** if CoreSight identification is not implemented.

Present only if the TPIU is implemented.

This register is **RES0** if the TPIU is not implemented.

#### Attributes

32-bit read-only register located at 0xE0040FD0.

This register is not banked between Security states.

### Field descriptions

The TPIU\_PIDR4 bit assignments are:

#### Bits [31:8]

Reserved, **RES0**.

#### SIZE, bits [7:4]

4KB count. See the *Arm® CoreSight™ Architecture Specification*.

This field reads as zero.

#### DES\_2, bits [3:0]

JEP106 continuation code. See the *Arm® CoreSight™ Architecture Specification*.

This field reads as an **IMPLEMENTATION DEFINED** value.

## D1.2.260 TPIU\_PIDR5, TPIU Peripheral Identification Register 5

The TPIU\_PIDR5 characteristics are:

### Purpose

Provides CoreSight Unique Component Identifier information for the TPIU.

### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

If the Main Extension is not implemented then it is **IMPLEMENTATION DEFINED** whether this register is accessible only to the debugger and **RES0** for software. Otherwise the register is accessible to the debugger and software.

### Configurations

Present only if CoreSight identification is implemented.

This register is **RES0** if CoreSight identification is not implemented.

Present only if the TPIU is implemented.

This register is **RES0** if the TPIU is not implemented.

### Attributes

32-bit read-only register located at 0xE0040FD4.

This register is not banked between Security states.

## Field descriptions

The TPIU\_PIDR5 bit assignments are:

### Bits [31:0]

Reserved, **RES0**.

## D1.2.261 TPIU\_PIDR6, TPIU Peripheral Identification Register 6

The TPIU\_PIDR6 characteristics are:

### Purpose

Provides CoreSight Unique Component Identifier information for the TPIU.

### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

If the Main Extension is not implemented then it is **IMPLEMENTATION DEFINED** whether this register is accessible only to the debugger and **RES0** for software. Otherwise the register is accessible to the debugger and software.

### Configurations

Present only if CoreSight identification is implemented.

This register is **RES0** if CoreSight identification is not implemented.

Present only if the TPIU is implemented.

This register is **RES0** if the TPIU is not implemented.

### Attributes

32-bit read-only register located at 0xE0040FD8.

This register is not banked between Security states.

## Field descriptions

The TPIU\_PIDR6 bit assignments are:

### Bits [31:0]

Reserved, **RES0**.

## D1.2.262 TPIU\_PIDR7, TPIU Peripheral Identification Register 7

The TPIU\_PIDR7 characteristics are:

### Purpose

Provides CoreSight Unique Component Identifier information for the TPIU.

### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

If the Main Extension is not implemented then it is **IMPLEMENTATION DEFINED** whether this register is accessible only to the debugger and **RES0** for software. Otherwise the register is accessible to the debugger and software.

### Configurations

Present only if CoreSight identification is implemented.

This register is **RES0** if CoreSight identification is not implemented.

Present only if the TPIU is implemented.

This register is **RES0** if the TPIU is not implemented.

### Attributes

32-bit read-only register located at 0xE0040FDC.

This register is not banked between Security states.

## Field descriptions

The TPIU\_PIDR7 bit assignments are:

### Bits [31:0]

Reserved, **RES0**.

### D1.2.263 TPIU\_PSCR, TPIU Periodic Synchronization Control Register

The TPIU\_PSCR characteristics are:

## Purpose

Defines the reload value for the Periodic Synchronization Counter register. The Periodic Synchronization Counter decrements for each byte that is output by the TPIU. If the formatter is implemented and enabled, the TPIU forces completion of the current frame when the counter reaches zero. It is **IMPLEMENTATION DEFINED** whether the TPIU forces all trace sources to generate synchronization packets when the counter reaches zero. Bytes generated by the TPIU as part of a Halfword synchronization packet or a Full frame synchronization packet are not counted.

## Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are UNPREDICTABLE.

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

If the Main Extension is not implemented then it is **IMPLEMENTATION DEFINED** whether this register is accessible only to the debugger and **RES0** for software. Otherwise the register is accessible to the debugger and software.

## Configurations

Present if the TPIU is implemented and DWT\_CYCCNT is not implemented.

**OPTIONAL** if both the TPIU and DWT\_CYCCNT are implemented.

This register is **RES0** if the TPIU is not implemented.

## Attributes

32-bit read/write register located at 0xE0040308.

This register is not banked between Security states.

## Field descriptions

The TPIU\_PSCR bit assignments are:

**Bits [31:5]**

Reserved, RES0.

**PSCount, bits [4:0]**

**Periodic Synchronization Count.** Determines the reload value of the Periodic Synchronization Counter. The reload value takes effect the next time the counter reaches zero. Reads from this register return the reload value programmed into this register.

The possible values of this field are:

0b00000

Synchronization disabled.

0b00111

128 bytes.

0b01000

256 bytes.

...

...

**0b111111**

$2^{31}$  bytes.

All other values are reserved.

The Periodic Synchronization Counter might have a maximum value smaller than  $2^{31}$ . In this case, if the programmed reload value is greater than the maximum value, then the Periodic Synchronization Counter is reloaded with its maximum value and the TPIU will generate synchronization requests at this interval.

This field resets to 0xA on a Cold reset.

#### **Note**

In the CoreSight TPIU, TPIU\_PSCR specifies the number of frames between synchronizations, each frame being 16 bytes. This definition of TPIU\_PSCR specifies a number of bytes and is encoded as a power-of-two rather than a plain binary number.

### D1.2.264 TPIU\_SPPR, TPIU Selected Pin Protocol Register

The TPIU\_SPPR characteristics are:

## Purpose

Selects the protocol used for trace output.

## Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

If the Main Extension is not implemented then it is **IMPLEMENTATION DEFINED** whether this register is accessible only to the debugger and **RES0** for software. Otherwise the register is accessible to the debugger and software.

If a debugger changes the register value while the TPIU is transmitting data, the effect on the output stream is **UNPREDICTABLE** and the required recovery process is **IMPLEMENTATION DEFINED**.

## Configurations

Present only if the TPIU is implemented and supports SWO.

This register is **RES0** if the TPIU is not implemented or does not support SWO.

## Attributes

32-bit read/write register located at 0xE00400F0.

This register is not banked between Security states.

## Field descriptions

The TPIU\_SPPR bit assignments are:

**Bits [31:2]**

Reserved, RES0.

**TXMODE, bits [1:0]**

**Transmit mode.** Specifies the protocol for trace output from the TPIU.

The possible values of this field are:

## 0b00

Parallel trace port mode. This value is reserved if TPIU\_DEVID.PTINVALID == 1.

## 0b01

Asynchronous SWO, using Manchester encoding. This value is reserved if TPIU\_DEVID.MANCVALID == 0.

0b10

Asynchronous SWO, using NRZ encoding. This value is reserved if TPIU\_DEVID.NRZVALID == 0.

All other values are reserved.

The effect of selecting a reserved value, or a mode that the implementation does not support, is UNPREDICTABLE.

This field resets to an **IMPLEMENTATION DEFINED** value on a Cold reset.

### D1.2.265 TPIU\_SSPSR, TPIU Supported Parallel Port Sizes Register

The TPIU\_SSPSR characteristics are:

#### Purpose

Indicates the supported parallel trace port sizes.

#### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

If the Main Extension is not implemented then it is **IMPLEMENTATION DEFINED** whether this register is accessible only to the debugger and **RES0** for software. Otherwise the register is accessible to the debugger and software.

#### Configurations

Present only if the TPIU is implemented.

This register is **RES0** if the TPIU is not implemented.

#### Attributes

32-bit read-only register located at 0xE0040000.

This register is not banked between Security states.

### Field descriptions

The TPIU\_SSPSR bit assignments are:

#### SWIDTH, bits [31:0]

Supported width. SWIDTH[*m*] indicates whether a parallel trace port width of (*m*+1) is supported.

The possible values of each bit are:

**0**

Parallel trace port width (*m*+1) not supported.

**1**

Parallel trace port width (*m*+1) supported.

The value of this register is **IMPLEMENTATION DEFINED**.

This field reads as an **IMPLEMENTATION DEFINED** value.

## D1.2.266 TT\_RESP, Test Target Response Payload

The TT\_RESP characteristics are:

### Purpose

Provides the response information from a TT, TTA, TTT, or TTAT instruction that is not **UNDEFINED**.

### Usage constraints

None.

### Configurations

All.

### Attributes

32-bit payload.

## Field descriptions

The TT\_RESP bit assignments are:

### IREGION, bits [31:24]

IDAU region number. Indicates the IDAU region number containing the target address.

This field is zero if IRVALID is zero.

### IRVALID, bit [23]

IREGION valid flag. For a Secure request, indicates the validity of the IREGION field.

The possible values of this bit are:

**0**

IREGION content not valid.

**1**

IREGION content valid.

This bit is always zero if the IDAU cannot provide a region number, the address is exempt from security attribution, or if the requesting TT or TTT variant was executed from the Non-secure state.

### S, bit [22]

Security. For a Secure request, indicates the Security attribute of the target address.

The possible values of this bit are:

**0**

Target address is Non-secure.

**1**

Target address is Secure.

This bit is always zero if the requesting TT or TTT instruction was executed from the Non-secure state.

### NSRW, bit [21]

Non-secure read and writable. Equal to RW AND NOT S. This field is only valid if the variant of the TT group of instructions was executed from Secure state and the RW field is valid.

**NSR, bit [20]**

Non-secure readable. Equal to R AND NOT S. This field is only valid if the variant of the TT group of instructions was executed from Secure state and the R field is valid.

**RW, bit [19]**

Read and writable.

Set to 1 if the address specified by the TT instruction variant can be read and written according to the permissions of the selected MPU when operating in the privilege level for the selected mode and selected Security state. For TTT and TTAT, this field returns the permissions for unprivileged access, regardless of whether the selected mode and state is privileged or unprivileged.

This field is invalid and RAZ if the TT instruction was executed from an unprivileged mode and the A flag was not specified. This field is also RAZ if the address matches multiple MPU regions.

**R, bit [18]**

Readable.

Read accessibility. Set to 1 if the address specified by the TT instruction variant can be read according to the permissions of the selected MPU when operating in the privilege level for the selected mode and selected Security state. For TTT and TTAT, this field returns the permissions for unprivileged access, regardless of whether the selected mode and state is privileged or unprivileged.

This field is invalid and RAZ if the TT instruction was executed from an unprivileged mode and the A flag was not specified. This field is also RAZ if the address matches multiple MPU regions.

**SRVALID, bit [17]**

SREGION valid flag. For a Secure request indicates validity of the SREGION field.

The possible values of this bit are:

**0**

SREGION content not valid.

**1**

SREGION content valid.

The SREGION field is invalid if any of the following are true:

- SAU\_CTRL.ENABLE is set to zero.
- The address specified by the TT instruction variant field does not match any enabled SAU regions.
- The address specified matches multiple enabled SAU regions.
- The address specified by the TT instruction variant is exempt from the Secure memory attribution.
- The TT or TTT instruction variant was executed from the Non-secure state or the Security Extension is not implemented.

The TTA and TTAT instruction variants are **UNDEFINED** when executed from Non-secure state.

**MRVALID, bit [16]**

MREGION valid flag. Indicates validity of the MREGION field.

The possible values of this bit are:

**0**

MREGION content not valid.

**1**

MREGION content valid.

The MREGION field is invalid if any of the following is true:

- The MPU is not implemented or MPU\_CTRL.ENABLE is set to zero.

- The address specified by the TT instruction variant does not match any enabled MPU regions.
- The address matched multiple MPU regions.
- The TT or TTT instruction variants, without the A flag specified, were executed from an unprivileged mode.

The TTA and TTAT instructions are **UNDEFINED** when executed from Non-secure state.

**SREGION, bits [15:8]**

SAU region number. Holds the SAU region that the address maps to.

This field is only valid if the instruction was executed from Secure state. This field is zero if SRVALID is 0.

**MREGION, bits [7:0]**

MPU region number. Holds the MPU region that the address maps to.

This field is zero if MRVALID is 0.

## D1.2.267 UFSR, UsageFault Status Register

The UFSR characteristics are:

### Purpose

Contains the status for some instruction execution faults, and for data access faults.

### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

If the Main Extension is implemented, this register is word, halfword, and byte accessible.

If the Main Extension is not implemented, this register is word accessible only, halfword and byte accesses are **UNPREDICTABLE**.

### Configurations

Present only if the Main Extension is implemented.

This register is **RES0** if the Main Extension is not implemented.

### Attributes

16-bit read/write-one-to-clear register located at 0xE000ED2A.

Secure software can access the Non-secure version of this register via UFSR\_NS located at 0xE002ED2A. The location 0xE002ED2A is **RES0** to software executing in Non-secure state and the debugger.

This register is banked between Security states.

This register is part of CFSR.

From Armv8.1-M onwards it is **IMPLEMENTATION DEFINED** whether a debugger write to this register is ignored when the PE is not in Debug state.

## Field descriptions

The UFSR bit assignments are:

### Bits [15:10]

Reserved, **RES0**.

### DIVBYZERO, bit [9]

Divide by zero flag. Sticky flag indicating whether an integer division by zero error has occurred.

The possible values of this bit are:

**0**

Error has not occurred.

**1**

Error has occurred.

This bit resets to zero on a Warm reset.

**UNALIGNED, bit [8]**

Unaligned access flag. Sticky flag indicating whether an unaligned access error has occurred.

The possible values of this bit are:

**0**  
Error has not occurred.

**1**  
Error has occurred.

This bit resets to zero on a Warm reset.

**Bits [7:5]**

Reserved, [RES0](#).

**STKOF, bit [4]**

Stack overflow flag. Sticky flag indicating whether a stack overflow error has occurred.

The possible values of this bit are:

**0**  
Error has not occurred.

**1**  
Error has occurred.

This bit resets to zero on a Warm reset.

**NOCP, bit [3]**

No coprocessor flag. Sticky flag indicating whether a coprocessor disabled or not present error has occurred.

The possible values of this bit are:

**0**  
Error has not occurred.

**1**  
Error has occurred.

This bit resets to zero on a Warm reset.

**INVPC, bit [2]**

Invalid PC flag. Sticky flag indicating whether an integrity check error has occurred.

The possible values of this bit are:

**0**  
Error has not occurred.

**1**  
Error has occurred.

This bit resets to zero on a Warm reset.

**INVSTATE, bit [1]**

Invalid state flag. Sticky flag indicating whether an EPSR.T, EPSR.IT, or FPSCR.LTPSIZE validity error has occurred.

The possible values of this bit are:

**0**  
Error has not occurred.

**1**  
Error has occurred.

This bit resets to zero on a Warm reset.

**UNDEFINSTR, bit [0]**

**UNDEFINED** instruction flag. Sticky flag indicating whether an **UNDEFINED** instruction error has occurred.

The possible values of this bit are:

**0**

Error has not occurred.

**1**

Error has occurred.

This includes attempting to execute an **UNDEFINED** instruction associated with an enable coprocessor.

This bit resets to zero on a Warm reset.

## D1.2.268 VPR, Vector Predication Status and Control Register

The VPR characteristics are:

### Purpose

Holds the per element predication flags.

### Usage constraints

Privileged access only. Unprivileged access is RAZ/WI, unless otherwise stated.

### Configurations

Present only if version Armv8.1 of the architecture and MVE are implemented.

This register is [RES0](#) if MVE are not implemented.

### Attributes

32-bit read/write special-purpose register.

This register is not banked between Security states.

## Field descriptions

The VPR bit assignments are:

### Bits [31:24]

Reserved, [RES0](#).

### MASK23, bits [23:20]

The VPT mask bits for beat 2 and 3.

The possible values of this field are:

**0b0000**

Not in a VPT block.

**0b1000**

In a VPT block which is valid for one more instruction. The predicate flags are not inverted.

**0bxx100**

In a VPT block which is valid for two more instructions. If set, the x bit causes the predicate flags for beat 2 and 3 to be inverted between the corresponding instructions in the VPT block.

**0bxxx10**

In a VPT block which is valid for three more instructions. If set, the x bits cause the predicate flags for beat 2 and 3 to be inverted between the corresponding instructions in the VPT block.

**0bxxxx1**

In a VPT block which is valid for four more instructions. If set, the x bits cause the predicate flags for beat 2 and 3 to be inverted between the corresponding instructions in the VPT block.

If the PE executes a single beat per architecture tick, this field and the associated predicate flags are updated after beat 3 completes.

This field resets to an [UNKNOWN](#) value on a Warm reset.

### MASK01, bits [19:16]

The VPT mask bits for beat 0 and 1.

The possible values of this field are:

**0b0000**

Not in a VPT block.

**0b1000**

VPT predication valid for one more instruction. The predicate flags are not inverted.

**0bx100**

In a VPT block which is valid for two more instructions. If set, the x bit causes the predicate flags for beat 0 and 1 to be inverted between the corresponding instructions in the VPT block.

**0bxx10**

In a VPT block which is valid for three more instructions. If set, the x bits cause the predicate flags for beat 0 and 1 to be inverted between the corresponding instructions in the VPT block.

**0bxxx1**

In a VPT block which is valid for four more instructions. If set, the x bits cause the predicate flags for beat 0 and 1 to be inverted between the corresponding instructions in the VPT block.

If the PE executes a single beat per architecture tick, this field and the associated predicate flags are updated after beat 1 completes.

This field resets to an **UNKNOWN** value on a Warm reset.

**P0, bits [15:0]**

Predication bits. Each group of 4 bits determines the predication of each of the 4 bytes within the corresponding beat, regardless of instruction data type. See the relevant instruction descriptions and pseudocode for information on how the predication affects execution.

The possible values of this field are:

**0**

The corresponding vector lane will be masked.

**1**

The corresponding vector lane will be active.

Unprivileged access to this field is permitted, see VMRS and VMSR instructions.

This field resets to an **UNKNOWN** value on a Warm reset.

### D1.2.269 VTOR, Vector Table Offset Register

The VTOR characteristics are:

## Purpose

Holds the vector table address for the selected Security state.

## Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

## Configurations

This register is always implemented.

## Attributes

32-bit read/write register located at 0xE000ED08.

To allow lock down of this register it is **IMPLEMENTATION DEFINED** whether this register is writable.

Secure software can access the Non-secure version of this register via VTOR\_NS located at 0xE002ED08. The location 0xE002ED08 is **RES0** to software executing in Non-secure state and the debugger.

This register is banked between Security states.

From Armv8.1-M onwards it is **IMPLEMENTATION DEFINED** whether a debugger write to this register is ignored when the PE is not in Debug state.

## Field descriptions

The VTOR bit assignments are:

**TBLOFF, bits [31:7]**

Table offset. Bits [31:7] of the vector table address for the selected Security state.

It is **IMPLEMENTATION DEFINED** whether any of the TBLOFF bits are WI

This field resets to an **IMPLEMENTATION DEFINED** value on a Warm reset.

**Bits [6:0]**

Reserved, RES0.

## D1.2.270 XPSR, Combined Program Status Registers

The XPSR characteristics are:

### Purpose

Provides access to a combination of the APSR, EPSR and IPSR.

### Usage constraints

Privileged access only. Unprivileged access is RAZ/WI, unless otherwise stated.

### Configurations

This register is always implemented.

### Attributes

32-bit read/write special-purpose register.

This register is not banked between Security states.

## Field descriptions

The XPSR bit assignments are:

When {XPSR[26:25], XPSR[11:10]} != 0:

|    |    |    |    |    |    |    |      |    |     |    |    |     |           |    |    |   |   |   |
|----|----|----|----|----|----|----|------|----|-----|----|----|-----|-----------|----|----|---|---|---|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24   | 23 | 22  | 21 | 20 | 19  | 16        | 15 | 10 | 9 | 8 | 0 |
| N  | Z  | C  | V  | Q  | IT | T  | RES0 | B  | (0) | GE | IT | (0) | Exception |    |    |   |   |   |

When {XPSR[26:25], XPSR[11:10]} == 0, and a multi-cycle load or store instruction is in progress:

|    |    |    |    |    |     |    |      |    |     |    |     |     |           |    |    |   |   |   |
|----|----|----|----|----|-----|----|------|----|-----|----|-----|-----|-----------|----|----|---|---|---|
| 31 | 30 | 29 | 28 | 27 | 26  | 25 | 24   | 23 | 22  | 21 | 20  | 19  | 16        | 15 | 10 | 9 | 8 | 0 |
| N  | Z  | C  | V  | Q  | ICI | T  | RES0 | B  | (0) | GE | ICI | (0) | Exception |    |    |   |   |   |

When {XPSR[26:25], XPSR[11:10]} == 0, and more than one beat-wise vector instruction is in progress:

|    |    |    |    |    |     |    |      |    |     |    |     |     |     |           |    |    |    |   |   |   |
|----|----|----|----|----|-----|----|------|----|-----|----|-----|-----|-----|-----------|----|----|----|---|---|---|
| 31 | 30 | 29 | 28 | 27 | 26  | 25 | 24   | 23 | 22  | 21 | 20  | 19  | 16  | 15        | 12 | 11 | 10 | 9 | 8 | 0 |
| N  | Z  | C  | V  | Q  | ECI | T  | RES0 | B  | (0) | GE | ECI | ECI | (0) | Exception |    |    |    |   |   |   |

### N, bit [31]

Negative flag. Reads or writes the current value of APSR.N.

### Z, bit [30]

Zero flag. Reads or writes the current value of APSR.Z.

### C, bit [29]

Carry flag. Reads or writes the current value of APSR.C.

### V, bit [28]

Overflow flag. Reads or writes the current value of APSR.V.

### Q, bit [27]

Saturate flag. Reads or writes the current value of APSR.Q.

### T, bit [24]

T32 state. Reads or writes the current value of EPSR.T.

### Bits [23:22]

Reserved, [RES0](#).

**B, bit [21]**

Branch target identification active. Unless otherwise stated, when this bit is set the next executed instruction must be a BTI clearing instruction otherwise an INVSTATE UsageFault is generated.

**Bit [20]**

Reserved, [RES0](#).

**GE, bits [19:16]**

Greater-than or equal flag. Reads or writes the current value of APSR.GE.

**IT, bits [15:10,26:25] , when [{XPSR[26:25], XPSR[11:10]} != 0]**

If-then flags. Reads or writes the current value of EPSR.IT.

**ICI, bits [26:25,15:10] , when [{XPSR[26:25], XPSR[11:10]} == 0, and a multi-cycle load or store instruction is in progress]**

Interrupt continuation flags. Reads or writes the current value of EPSR.ICI.

**ECI, bits [26:25, 11:10, 15:12] , when [{XPSR[26:25], XPSR[11:10]} == 0, and more than one beat-wise vector instruction is in progress]**

Exception continuation flags for beat-wise vector instructions. Reads or writes the current value of EPSR.ECI.

**Bit [9]**

Reserved, [RES0](#).

**Exception, bits [8:0]**

Exception number. Reads or writes the current value of IPSR.Exception.

## **Part E**

### **Armv8-M Pseudocode**

## Chapter E1

# Arm Pseudocode Definition

This chapter provides a definition of the pseudocode that this manual uses, and defines some *built-in* functions that the pseudocode uses. It contains the following sections:

[E1.1 \*About the Arm pseudocode.\*](#)

[E1.2 \*Data types.\*](#)

[E1.3 \*Operators.\*](#)

[E1.4 \*Statements and control structures.\*](#)

[E1.5 \*Built-in functions.\*](#)

[E1.6 \*Arm pseudocode definition index.\*](#)

[E1.7 \*Additional functions.\*](#)

### **Note**

This chapter is not a formal language definition for the pseudocode. It is a guide to help understand the use of Arm pseudocode.

## E1.1 About the Arm pseudocode

The Arm pseudocode provides precise descriptions of some areas of the Arm architecture. This includes description of the decoding and operation of all valid instructions.

The following sections describe the Arm pseudocode in detail:

[E1.2 Data types.](#)

[E1.3 Operators.](#)

[E1.4 Statements and control structures.](#)

[E1.5 Built-in functions](#) describes some built-in functions that the pseudocode functions use that this manual describes elsewhere.

[E1.6 Arm pseudocode definition index](#) contains the indexes to the pseudocode.

### E1.1.1 General limitations of Arm pseudocode

Because of the limitations inherent in all pseudocode, the Arm pseudocode and pseudocode comments describe only one particular implementation of the architecture. There are several instances where a rule relaxes the behavior that a particular piece of pseudocode describes.

The pseudocode statements `EndOfInstruction()`, `SEE`, `UNDEFINED`, `CONSTRAINED_UNPREDICTABLE`, and `UNPREDICTABLE` indicate behavior that differs from that indicated by the pseudocode being executed. If one of the statements is encountered:

- `CONSTRAINED_UNPREDICTABLE`, and `UNPREDICTABLE` mean earlier behavior indicated by the pseudocode is only specified as occurring to the extent required to determine that the statement is executed. No subsequent behavior that the pseudocode indicates occurs.
- `EndOfInstruction()`, `SEE`, and `UNDEFINED` mean that the pseudocode will terminate execution of the current instruction and pseudocode execution continues from the exception catch.

For more information, see [E1.4.5 Special statements](#).

## E1.2 Data types

This section describes:

[E1.2.1 General data type rules.](#)

[E1.2.2 Bitstrings.](#)

[E1.2.3 Integers.](#)

[E1.2.4 Reals.](#)

[E1.2.5 Booleans.](#)

[E1.2.6 Enumerations.](#)

[E1.2.7 Structures.](#)

[E1.2.8 Tuples.](#)

[E1.2.9 Arrays.](#)

### E1.2.1 General data type rules

Arm architecture pseudocode is a strongly typed language. Every literal and variable is of one of the following types:

- Bitstring.
- Integer.
- Boolean.
- Real.
- Enumeration.
- Tuple.
- Struct.
- Array.

The syntax of a literal determines its type. A variable can be assigned to without an explicit declaration. The variable implicitly has the type of the assigned value. For example, the following assignments implicitly declare the variables `x`, `y` and `z` to have types integer, bitstring of length 1, and Boolean, respectively.

```
1 x = 1;  
2 y = '1';  
3 z = TRUE;
```

Variables can also have their types declared explicitly by preceding the variable name with the name of the type. The following example declares explicitly that a variable named `count` is an integer.

```
integer count;
```

This is most often done in function definitions for the arguments and the result of the function.

The remaining subsections describe each data type in more detail.

### E1.2.2 Bitstrings

This section describes the bitstring data type.

## Syntax

`bits`(*N*)

The type name of a bitstring of length '*N*'.

`bit`

A synonym of `bits`(1).

## Description

A bitstring is a finite-length string of 0s and 1s. Each length of bitstring is a different type. The minimum permitted length of a bitstring is 0.

Bitstring constants literals are written as a single quotation mark, followed by the string of 0s and 1s, followed by another single quotation mark. For example, the two constants literals of type `bit` are `'0'` and `'1'`. Spaces can be included in bitstrings for clarity.

The bits in a bitstring are numbered from left to right *N*-1 to 0. This numbering is used when accessing the bitstring using bitslices. In conversions to and from integers, bit *N*-1 is the MSByte and bit 0 is the LSByte. This order matches the order in which bitstrings derived from encoding diagrams are printed.

Every bitstring value has a left-to-right order, with the bits being numbered in standard *little-endian* order. That is, the leftmost bit of a bitstring of length *N* is bit (*N*-1) and its right-most bit is bit 0. This order is used as the most-significant-to-least-significant bit order in conversions to and from integers. For bitstring constants and bitstrings that are derived from encoding diagrams, this order matches the way that they are printed.

Bitstrings are the only concrete data type in pseudocode, corresponding directly to the contents values that are manipulated in registers, memory locations, and instructions. All other data types are abstract.

### E1.2.3 Integers

This section describes the data type for integer numbers.

## Syntax

`integer`

The type name for the integer data type.

## Description

Pseudocode integers are unbounded in size and can be either positive or negative. That is, they are mathematical integers rather than what computer languages and architectures commonly call integers. Computer integers are represented in pseudocode as bitstrings of the appropriate length, and the pseudocode provides functions to interpret those bitstrings as integers.

Integer literals are normally written in decimal form, such as 0, 15, -1234. They can also be written in C-style hexadecimal form, such as 0x55 or 0x80000000. Hexadecimal integer literals are treated as positive unless they have a preceding minus sign. For example, 0x80000000 is the integer +2<sup>31</sup>. If -2<sup>31</sup> needs to be written in hexadecimal, it must be written as -0x80000000.

### E1.2.4 Reals

This section describes the data type for real numbers.

## Syntax

**real**

The type name for the real data type.

## Description

Pseudocode reals are unbounded in size and precision. That is, they are mathematical real numbers, not computer floating-point numbers. Computer floating-point numbers are represented in pseudocode as bitstrings of the appropriate length, and the pseudocode provides functions to interpret those bitstrings as reals.

Real constant literals are written in decimal form with a decimal point. This means `0` is an integer constant literal, but `0.0` is a real constant literal.

### E1.2.5 Booleans

This section describes the boolean data type.

## Syntax

**boolean**

The type name for the boolean data type.

`TRUE`, `FALSE`

The two values a boolean variable can take.

## Description

A boolean is a logical `TRUE` or `FALSE` value.

### Note

This is not the same type as `bit`, which is a bitstring of length 1. A boolean can only take on one of two values: `TRUE` or `FALSE`.

### E1.2.6 Enumerations

This section describes the enumeration data type.

## Syntax and examples

**enumeration**

Keyword to define a new enumeration type.

**enumeration** `Example {Example_One, Example_Two, Example_Three};`

A definition of a new enumeration that is called `Example`, which can take on the values `Example_One`, `Example_Two`, `Example_Three`.

## Description

An enumeration is a defined set of named values.

An enumeration must contain at least one named value. A named value must not be shared between enumerations.

Enumerations must be defined explicitly, although a variable of an enumeration type can be declared implicitly by assigning one of the named values to it. By convention, each named value starts with the name of the enumeration followed by an underscore. The name of the enumeration is its *type name*, or *type*, and the named values are its possible *values*.

## E1.2.7 Structures

This section describes the structure data type.

### Syntax and examples

#### **type**

The keyword that is used to declare the structure data type.

```
type ShiftSpec is (bits(2) shift, integer amount):
```

An example definition for a new structure that is called ‘ShiftSpec’ that contains a bitstring member that is called ‘shift’ and an integer member called ‘amount’. Structure definitions must not be terminated with a semicolon.

```
ShiftSpec abc;
```

A declaration of a variable that is named ‘abc’ of type ‘ShiftSpec’.

```
abc.shift
```

Syntax to refer to the individual members within the structure variable.

## Description

A structure is a compound data type composed of one or more data items. The data items can be of different data types. This can include compound data types. The data items of a structure are called its members and are named.

In the syntax section, the example defines a structure that is called `ShiftSpec` with two members. The first is a bitstring of length 2 named `shift` and the second is an integer that is named `amount`. After declaring a variable of that type that is named `abc`, the members of this structure are referred to as `abc.shift` and `abc.amount`.

Every definition of a structure creates a different type, even if the number and type of their members are identical. For example:

```
type ShiftSpec1 is (bits(2) shift, integer amount)
```

```
type ShiftSpec2 is (bits(2) shift, integer amount)
```

`ShiftSpec1` and `ShiftSpec2` are two different types despite having identical definitions. This means that the value in a variable of type `ShiftSpec1` cannot be assigned to variable of type `ShiftSpec2`.

### E1.2.7.1 `_Type` and `_Type`

This subsection describes the data structure types for a particular register or payload.

## Example

RETPSR\_Type

The data structure of type RETPSR.

## Description

By convention `_Type` declares a structure data type for a specific register or payload.

See the individual register descriptions for the fields that apply to a particular data structure.

### E1.2.8 Tuples

This section describes the tuple data type.

## Examples

```
(bits(32) shifter_result, bit shifter_carry_out)
```

An example of the tuple syntax.

```
(shift_t, shift_n) = ('00', 0);
```

An example of assigning values to a tuple.

## Description

A tuple is an ordered set of data items, which are separated by commas and enclosed in parentheses. The items can be of different types and a tuple must contain at least one data item.

Tuples are often used as the return type for functions that return multiple results. For example, in the syntax section, the example tuple is the return type of the function `Shift_C()`, which performs a standard A32/T32 shift or rotation. Its return type is a tuple containing two data items, with the first of type `bits(32)`, and the second of type `bit`.

Each tuple is a separate compound data type. The compound data type is represented as a comma-separated list of ordered data types between parentheses. This means that the example tuple at the start of this section is of type `(bits(32), bit)`. The general principle that types can be implied by an assignment extends to implying the type of the elements in the tuple. For example, in the syntax section, the example assignment implicitly declares:

- `shift_t` to be of type `bits(2)`.
- `shift_n` to be of type `integer`.
- `(shift_t, shift_n)` to be a tuple of type `(bits(2), integer)`.

### E1.2.9 Arrays

This section describes the array data type.

## Syntax

**array**

The type name for the array data type.

```
array data_type array_name[A..B];
```

```
array [A..B] of data_type array_name
```

Declaration of an array of type ‘data\_type’, which might be compound data type. It is named ‘array\_name’ and is indexed with an integer range from ‘A’ to ‘B’.

## Description

An array is an ordered set of fixed size containing items of a single data type. This can include compound data types. Pseudocode arrays are indexed by either enumerations or integer ranges. An integer range is represented by the lower inclusive end of the range, then . . , then the upper inclusive end of the range.

For example:

The following example declares an array of 31 bitstrings of length 64, indexed from 0-30.

```
1 array bits(64) _R[0..30];
```

Arrays are always explicitly declared, and there is no notation for a constant literal array. Arrays always contain at least one element data item, because:

- Enumerations always contain at least one symbolic constant named value.
- Integer ranges always contain at least one integer.

An array declared with an enumeration type as the index must be accessed using enumeration values of that enumeration type. An array declared with an integer range type as the index must be accessed using integer values from that inclusive range. Accessing such an array with an integer value outside of the range is a coding error.

Pseudocode can also contain array-like functions such as `R[i]`, `MemU[address, size]`, or `Elem[vector, i, size ↪]`. These functions package up and abstract additional operations that are normally performed on accesses to the underlying arrays, such as register banking, memory protection, endian-dependent byte ordering, exclusive-access housekeeping and Advanced SIMD element processing. See [E1.4.2 Function and procedure calls](#).

## E1.3 Operators

This section describes:

[E1.3.1 Relational operators.](#)

[E1.3.2 Boolean operators.](#)

[E1.3.3 Bitstring operators.](#)

[E1.3.4 Arithmetic operators.](#)

[E1.3.5 The assignment operator.](#)

[E1.3.6 Precedence rules.](#)

[E1.3.7 Conditional expressions.](#)

[E1.3.8 Operator polymorphism.](#)

### E1.3.1 Relational operators

The following operations yield results of type **boolean**.

#### Equality and non-equality

If two variables *x* and *y* are of the same type, their values can be tested for equality by using the expression *x* == *y* and for non-equality by using the expression *x* != *y*. In both cases, the result is of type **boolean**.

Both *x* and *y* must be of type **bits(N)**, **real**, **enumeration**, **boolean**, or **integer**. Named values from an **enumeration** can only be compared if they are both from the same **enumeration**. An exception is that a bitstring can be tested for equality with an integer to allow a *d* == 15 test.

A special form of comparison is defined with a bitstring literal that can contain bit values '0', '1', and 'x'. Any bit with value 'x' is ignored in determining the result of the comparison. For example, if *opcode* is a 4-bit bitstring, the expression *opcode* == '1x0x' matches the values 1000, 1100, 1001, and 1101. This is known as a bitmask.

#### Note

This special form is permitted in the implied equality comparisons in the **when** parts of **case ... of ...** structures.

#### Comparisons

If *x* and *y* are integers or reals, then *x* < *y*, *x* <= *y*, *x* > *y*, and *x* >= *y* are less than, less than or equal, greater than, and greater than or equal comparisons between them, producing boolean results.

#### E1.3.1.1 Set membership with IN

<expression> **IN** {<set>} produces **TRUE** if <expression> is a member of <set>. Otherwise, it is **FALSE**. <set> must be a list of expressions that are separated by commas.

### E1.3.2 Boolean operators

If *x* is a boolean expression, then !*x* is its logical inverse.

If *x* and *y* are boolean expressions, then *x* &&*y* is the result of ANDing them together. As in the C language, if *x* is **FALSE**, the result is determined to be **FALSE** without evaluating *y*.

#### Note

This is known as short circuit evaluation.

If  $x$  and  $y$  are **booleans**, then  $x \ || \ y$  is the result of ORing them together. As in the C language, if  $x$  is **TRUE**, the result is determined to be **TRUE** without evaluating  $y$ .

#### Note

If  $x$  and  $y$  are **booleans** or boolean expressions, then the result of  $x \ != \ y$  is the same as the result of exclusive-ORing  $x$  and  $y$  together. The operator **EOR** only accepts bitstring arguments.

### E1.3.3 Bitstring operators

The following operations can be applied only to bitstrings.

#### Logical operations on bitstrings

If  $x$  is a bitstring, **NOT**( $x$ ) is the bitstring of the same length that is obtained by logically inverting every bit of  $x$ .

If  $x$  and  $y$  are bitstrings of the same length,  $x \ \text{AND} \ y$ ,  $x \ \text{OR} \ y$ , and  $x \ \text{EOR} \ y$  are the bitstrings of that same length that is obtained by logically ANDing, logically ORing, and exclusive-ORing corresponding bits of  $x$  and  $y$  together.

#### Bitstring concatenation and slicing

If  $x$  and  $y$  are bitstrings of lengths  $N$  and  $M$  respectively, then  $x:y$  is the bitstring of length  $N + M$  constructed by concatenating  $x$  and  $y$  in left-to-right order.

The bitstring slicing operator addresses specific bits in a bitstring. This can be used to create a new bitstring from extracted bits or to set the value of specific bits. Its syntax is  $x[\text{integer\_list}]$ , where  $x$  is the integer or bitstring being sliced, and  $[\text{integer\_list}]$  is a comma-separated list of integers that are enclosed in square brackets. The length of the resulting bitstring is equal to the number of integers in  $[\text{integer\_list}]$ . In  $x[\text{integer\_list}]$ , each of the integers in  $[\text{integer\_list}]$  must be:

- $\geq 0$ .
- $< \text{Len}(x)$  if  $x$  is a bitstring.

The definition of  $x[\text{integer\_list}]$  depends on whether  $\text{integer\_list}$  contains more than one integer:

- If  $\text{integer\_list}$  contains more than one integer,  $x[i, j, k, \dots, n]$  is defined to be the concatenation:

```
1  x[i]: x[j]: x[k]: ...: x[n]
```

- If  $\text{integer\_list}$  consists of just one integer  $i$ ,  $x[i]$  is defined to be:
  - If  $x$  is a bitstring, '0' if bit  $i$  of  $x$  is a zero and '1' if bit  $i$  of  $x$  is a one.
  - If  $x$  is an integer, and  $y$  is the unique integer in the range  $0$  to  $2^{(i+1)} - 1$  that is congruent to  $x$  modulo  $2^{(i+1)}$ . Then  $x[i]$  is '0' if  $y < 2^i$  and '1' if  $y \geq 2^i$ .

Loosely, this definition treats an integer as equivalent to a sufficiently long two's complement representation of it as a bitstring.

The notation for a range expression is  $i:j$  with  $i \geq j$  is shorthand for the integers in order from  $i$  down to  $j$ , with both end values included. For example, `instr[31:28]` represents `instr[31, 30, 29, 28]`.

$x[\text{integer\_list}]$  is assignable provided  $x$  is an assignable bitstring and no integer appears more than once in  $[\text{integer\_list}]$ . In particular,  $x[i]$  is assignable if  $x$  is an assignable bitstring and  $0 \leq i < \text{Len}(x)$ .

Encoding diagrams for registers frequently show named bits or multi-bit fields. For example, the encoding diagram for the APSR shows its bit[31] as  $N$ . In such cases, the syntax `APSR.N` is used as a more readable synonym for `APSR[31]` as named bits can be referred to with the same syntax as referring to members of a struct. A

comma-separated list of named bits enclosed in square brackets following the register name allows multiple bits to be addressed simultaneously.

For example, `APSR.[N, C, Q]` is synonymous with `APSR [31, 29, 27]`.

### E1.3.4 Arithmetic operators

Most pseudocode arithmetic is performed on integer or real values, with operands obtained by conversions from bitstrings and results that are converted back to bitstrings. As these data types are the unbounded mathematical types, no issues arise about overflow or similar errors.

#### Unary plus and minus

If  $x$  is an integer or real, then  $+x$  is  $x$  unchanged,  $-x$  is  $x$  with its sign reversed. Both are of the same type as  $x$ .

#### Addition and subtraction

If  $x$  and  $y$  are integers or reals,  $x + y$  and  $x - y$  are their sum and difference. Both are of type **integer** if  $x$  and  $y$  are both of type **integer**, and **real** otherwise.

There are two cases where the types of  $x$  and  $y$  can be different. A bitstring and an integer can be added together to allow the operation `PC + 4`. An integer can be subtracted from a bitstring to allow the operation `PC - 2`.

If  $x$  and  $y$  are bitstrings of the same length  $N$ , so that  $N = \text{Len}(x) = \text{Len}(y)$ , then  $x + y$  and  $x - y$  are the least significant  $N$  bits of the results of converting  $x$  and  $y$  to integers and adding or subtracting them. Signed and unsigned conversions produce the same result:

```
1 x + y = (SInt(x) + SInt(y)) [N-1:0]
2       = (UInt(x) + UInt(y)) [N-1:0]
3 x - y = (SInt(x) - SInt(y)) [N-1:0]
4       = (UInt(x) - UInt(y)) [N-1:0]
```

If  $x$  is a bitstring of length  $N$  and  $y$  is an integer,  $x + y$  and  $x - y$  are the bitstrings of length  $N$  defined by  $x + y = \rightarrow x + y[N-1:0]$  and  $x - y = x - y[N-1:0]$ . Similarly, if  $x$  is an integer and  $y$  is a bitstring of length  $M$ ,  $x + y$  and  $x - y$  are the bitstrings of length  $M$  defined by  $x + y = x[M-1:0] + y$  and  $x - y = x[M-1:0] - y$ .

#### Multiplication

If  $x$  and  $y$  are integers or reals, then  $x * y$  is the product of  $x$  and  $y$ . It is of type **integer** if  $x$  and  $y$  are both of type **integer**, and **real** otherwise.

#### Division and modulo

If  $x$  and  $y$  are reals, then  $x/y$  is the result of dividing  $x$  by  $y$ , and is always of type **real**.

If  $x$  and  $y$  are integers, then  $x \text{ DIV } y$  and  $x \text{ MOD } y$  are defined by:

```
1 x DIV y = RoundDown(x/y)
2 x MOD y = x - y * (x DIV y)
```

It is a pseudocode error to use any of  $x/y$ ,  $x \text{ MOD } y$ , or  $x \text{ DIV } y$  in any context where  $y$  can be zero.

#### Scaling

If  $x$  and  $n$  are of type **integer**, then:

- $x \ll n = \text{RoundDown}(x * 2^n)$ .
- $x \gg n = \text{RoundDown}(x * 2^{(-n)})$ .

## Raising to a power

If  $x$  is an integer or a real and  $n$  is an integer, then  $x^n$  is the result of raising  $x$  to the power of  $n$ , and:

- If  $x$  is of type **integer** then  $x^n$  is of type **integer**.
- If  $x$  is of type **real** then  $x^n$  is of type **real**.

### E1.3.5 The assignment operator

The assignment operator is the `=` character, which assigns the value of the right-hand side to the left-hand side. An assignment statement takes the form:

```
<assignable_expression> = <expression>;
```

This following subsection defines valid expression syntax.

## General expression syntax

An expression is one of the following:

- A literal.
- A variable, optionally preceded by a data type name to declare its type.
- The word **UNKNOWN** preceded by a data type name to declare its type.
- The result of applying a language-defined operator to other expressions.
- The result of applying a function to other expressions.

Variable names normally consist of alphanumeric and underscore characters, starting with an alphabetic or underscore character.

Each register that is defined in an Arm architecture specification defines a correspondingly named pseudocode bitstring variable, and that variable has the stated behavior of the register. For example, if a bit of a register is defined as RAZ/WI, then the corresponding bit of its variable reads as '0' and ignore writes.

An expression like `bits(32) UNKNOWN` indicates that the result of the expression is a value of the given type, but the architecture does not specify what value it is and software must not rely on such values. The value produced must not:

- Return information that cannot be accessed at the current or a lower level of privilege using instructions that are not UNPREDICTABLE or CONSTRAINED UNPREDICTABLE and do not return UNKNOWN values,
- Be promoted as providing any useful information to software.

### Note

UNKNOWN values are similar to the definition of UNPREDICTABLE, but do not indicate that the entire architectural state becomes unspecified.

Only the following expressions are assignable. This means that these are the only expressions that can be placed on the left-hand side of an assignment:

- Variables.
- The results of applying some operators to other expressions.

The description of each language-defined operator that can generate an assignable expression specifies the circumstances under which it does so. For example, those circumstances might require that one or more of the expressions the operator operates on is an assignable expression.

- The results of applying array-like functions to other expressions. The description of an array-like function specifies the circumstances under which it can generate an assignable expression.

#### Note

If the right-hand side in an assignment is a function returning a tuple, an item in the assignment destination can be written as `-` to indicate that the corresponding item of the assigned tuple value is discarded. For example:

```
(shifted, -) = LSL_C(operand, amount);
```

The expression on the right-hand side itself can be a tuple. For example:

```
(x, y) = (function_1(), function_2());
```

Every expression has a data type.

- For a literal, this data type is determined by the syntax of the literal.
- For a variable, there are the following possible sources for the data type
  - An optional preceding data type name.
  - A data type the variable was given earlier in the pseudocode by recursive application of this rule.
  - A data type the variable is being given by assignment, either by direct assignment to the variable, or by assignment to a list of which the variable is a member.

It is a pseudocode error if none of these data type sources exists for a variable, or if more than one of them exists and they do not agree about the type.

- For a language-defined operator, the definition of the operator determines the data type.
- For a function, the definition of the function determines the data type.

### E1.3.6 Precedence rules

The precedence rules for expressions are:

1. Literals, variables, and function invocations are evaluated with higher priority than any operators using their results, but see [E1.3.2 Boolean operators](#).
2. Operators on integers follow the normal operator precedence rules of *exponentiation before multiply/divide before add/subtract*, with sequences of multiply/divides or add/subtracts evaluated left-to-right.
3. Other expressions must be parenthesized to indicate operator precedence if ambiguity is possible, but do not need to be if all permitted precedence orders under the type rules necessarily lead to the same result. For example, if *i*, *j* and *k* are integer variables, *i* > 0 && *j* > 0 && *k* > 0 is acceptable, but *i* > 0 && *j* > 0 || *k* > 0 is not.

### E1.3.7 Conditional expressions

If *x* and *y* are two values of the same type and *t* is a value of type **boolean**, then **if** *t* **then** *x* **else** *y* is an expression of the same type as *x* and *y* that produces *x* if *t* is **TRUE** and *y* if *t* is **FALSE**.

### E1.3.8 Operator polymorphism

Operators in pseudocode can be polymorphic, with different functionality when applied to different data types. Each resulting form of an operator has a different prototype definition. For example, the operator `+` has forms that act on various combinations of integers, reals and bitstrings.

[Table E1-1](#) summarizes the operand types valid for each unary operator and the result type. [Table E1-2](#) summarizes the operand types valid for each binary operator and the result type.

**Table E1-1, Result and operand types that are permitted for unary operators.**

| Operator | Operand Type | Result Type |
|----------|--------------|-------------|
| -        | integer      | integer     |
|          | real         | real        |
| NOT      | bits (N)     | bits (N)    |
| !        | boolean      | boolean     |

**Table E1-2, Result and operand types that are permitted for binary operators.**

| Operator     | First operand type | Second operand type | Result type |
|--------------|--------------------|---------------------|-------------|
| ==           | bits (N)           | integer             | boolean     |
|              | bits (N)           | bits (N)            |             |
|              | integer            | integer             |             |
|              | real               | real                |             |
|              | enumeration        | enumeration         |             |
|              | boolean            | boolean             |             |
| !=           | bits (N)           | bits (N)            | boolean     |
|              | integer            | integer             |             |
|              | real               | real                |             |
| <, >         | integer            | integer             | boolean     |
|              | <=, >=             | real                |             |
| +, -         | integer            | integer             | integer     |
|              | real               | real                | real        |
|              | bits (N)           | bits (N)            | bits (N)    |
|              | bits (N)           | integer             |             |
| «, »         | integer            | integer             | integer     |
|              | integer            | integer             | integer     |
| *            | real               | real                | real        |
|              | bits (N)           | bits (N)            | bits (N)    |
|              | real               | real                | real        |
| /            | integer            | integer             | integer     |
| DIV          | integer            | integer             | integer     |
| MOD          | integer            | integer             | integer     |
|              | bits (N)           | integer             |             |
| &&,          | boolean            | boolean             | boolean     |
| AND, OR, EOR | bits (N)           | bits (N)            | bits (N)    |
| ^            | integer            | integer             | integer     |
|              | real               | integer             | real        |

## E1.4 Statements and control structures

This section describes the statements and program structures available in the pseudocode.

### E1.4.1 Statements and Indentation

A simple statement is either an assignment, a function call, or a procedure call. Each statement must be terminated with a semicolon.

Indentation normally indicates the structure in compound statements. The statements that are contained in structures such as **if... then... else...** or procedure and function definitions are indented more deeply than the statement structure itself. The end of a compound statement structure and their end is indicated by returning to the original indentation level or less.

Indentation is normally done by four spaces for each level. Standard indentation uses four spaces for each level of indent.

### E1.4.2 Function and procedure calls

This section describes how functions and procedures are defined and called in the pseudocode.

#### Procedure and function definitions

A procedure definition has the form:

```
1  <procedure name>(<argument prototypes>)  
2  <statement 1>;  
3  <statement 2>;  
4  ...  
5  <statement n>;
```

where `<argument prototypes>` consists of zero or more argument definitions, which are separated by commas. Each argument definition consists of a type name followed by the name of the argument.

#### Note

This first definition line is not terminated by a semicolon. This distinguishes it from a procedure call.

A function definition is similar, but also declares the return type of the function:

```
1  <return type> <function name>(<argument prototypes>)  
2  <statement 1>;  
3  <statement 2>;  
4  ...  
5  <statement n>;
```

Array-like functions are similar, but are written with square brackets and have two forms. These two forms exist because reading from and writing to an array element require different functions. They are frequently used in memory operations. An array-like function definition with a return type is equivalent to reading from an array. For example:

```
1  <return type> <function name>[<argument prototypes>]  
2  <statement 1>;  
3  <statement 2>;  
4  ...  
5  <statement n>;
```

Its related function definition with no return type is equivalent to writing to an array. For example:

```
1 <function name>[<argument prototypes>] =<value prototype>
2 <statement 1>;
3 <statement 2>;
4 ...
5 <statement n>;
```

The value prototype determines what data type can be written to the array. The two related functions must share the same name, but the value prototype and return type can be different.

## Procedure calls

A procedure call has the form:

```
1 <procedure_name>(<arguments>);
```

## Return statements

A procedure return has the form:

```
1 return;
```

A function return has the form:

```
1 return <expression>;
```

where <expression> is of the type declared in the function prototype line.

## E1.4.3 Conditional control structures

This section describes how conditional control structures are used in the pseudocode.

### if...then...else...

In addition to being a ternary operator, a multi-line `if...then...else...` structure can act as a control structure and has the form:

```
1 if <boolean_expression> then
2 <statement 1>;
3 <statement 2>;
4 ...
5 <statement n>;
6
7 elseif <boolean_expression> then
8 <statement a>;
9 <statement b>;
10 ...
11 <statement z>;
12 else
13 <statement A>;
14 <statement B>;
15 ...
16 <statement Z>;
```

The block of lines consisting of `elseif` and its indented statements is optional, and multiple `elseif` blocks can be used.

The block of lines consisting of `else` and its indented statements is optional.

Abbreviated one-line forms can be used when the `then` part, and in the `else` part if it is present, contain only simple statements such as:

```
1  if <boolean_expression> then <statement 1>;  
2  if <boolean_expression> then <statement 1>; else <statement A>;  
3  if <boolean_expression> then <statement 1>; <statement 2>; else <statement A>;
```

#### Note

In these forms, <statement 1>, <statement> 2>, and <statement A> must be terminated by semicolons. This and > the fact that the **else** part is optional distinguish its use as a > control structure from its use as a ternary operator.

### case...of...

A case...of... structure has the form:

```
1  case <expression> of  
2  when <literal values1>  
3    <statement 1>;  
4    <statement 2>;  
5    ...  
6    <statement n>;  
7  
8  when <literal values2>  
9    <statement 1>;  
10   <statement 2>;  
11   ...  
12   <statement n>;  
13  
14   ...more "when" groups if required...  
15  
16  otherwise  
17    <statement A>;  
18    <statement B>;  
19    ...  
20    <statement Z>;
```

In this structure, <literal values1> and <literal values2> consist of literal values of the same type as <expression>, separated by commas. There can be additional **when** groups in the structure. Abbreviated one line forms of **when** and **otherwise** parts can be used when they contain only simple statements.

If <expression> has a bitstring type, the literal values can also include bitstring literals containing 'x' bits, known as bitmasks. For details, see [Equality and non-equality](#).

## E1.4.4 Loop control structures

This section describes the three loop control structures that are used in the pseudocode.

### repeat...until...

A repeat...until... structure has the form:

```
1  repeat  
2    <statement 1>;  
3    <statement 2>;  
4    ...  
5    <statement n>;  
6  until <boolean_expression>;
```

It executes the statement block at least once, and the loop repeats until <boolean expression> evaluates to **TRUE**. Variables explicitly declared inside the loop body have scope local to that loop and might not be accessed outside the loop body.

## **while...do**

A **while...do** structure has the form:

```
1 while <boolean_expression> do
2   <statement 1>;
3   <statement 2>;
4   ...
5   <statement n>;
```

It begins executing the statement block only if the boolean expression is true. The loop then runs until the expression is false.

## **for...**

A **for...** structure has the form:

```
1 for <assignable_expression> = <integer_expr1> to <integer_expr2>
2   <statement 1>;
3   <statement 2>;
4   ...
5   <statement n>;
```

The `<assignable_expression>` is initialized to `<integer_expr1>` and compared to `<integer_expr2>`. If `<integer_expr1>` is less than `<integer_expr2>`, the loop body is executed and the `<assignable_expression>` is incremented by one. This repeats until `<assignable_expression>` is more than or equal to `<integer_expr2>`.

There is an alternate form:

**for** `<assignable_expression> = <integer_expr1> downto <integer_expr2>`

where `<integer_expr1>` is decremented after the loop body executes and continues until `<assignable_expression>` is less than or equal than `<integer_expr2>`.

## **Try...Catch**

A **try...catch** structure has the following form:

```
1 try
2   <statement 1>;
3   <statement 2>;
4   ...
5   <statement n>;
6
7 catch <exception>
8   <statement a>;
9   <statement b>;
10  ...
11  <statement z>;
```

The purpose of this structure is to catch exceptions that are generated by the `try` statements.

### **E1.4.5 Special statements**

This section describes statements with particular architecturally defined behaviors.

#### **UNDEFINED**

This subsection describes the statement:

`UNDEFINED;`

This statement indicates a pseudocode exception that will be caught by the `try...catch` block. When caught, this might result in an UNDEFINSTR UsageFault, NOP or NOCP UsageFault.

## UNPREDICTABLE

This subsection describes the statement:

```
UNPREDICTABLE;
```

This statement indicates a special case that replaces the behavior that is defined by the current pseudocode, apart from behavior that is required to determine that the special case applies. The replacement behavior is UNPREDICTABLE.

## CONSTRAINED\_UNPREDICTABLE

This subsection describes the statement:

```
CONSTRAINED_UNPREDICTABLE;
```

This statement indicates a special case that replaces the behavior that is defined by the current pseudocode, apart from behavior that is required to determine that the special case applies. The replacement behavior is CONSTRAINED UNPREDICTABLE within the limits defined for each particular case, and might vary.

## SEE . . .

This subsection describes the statement:

```
SEE <reference>;
```

This statement indicates a special case that replaces the behavior that is defined by the current instruction pseudocode, apart from behavior that is required to determine that the special case applies.

It usually refers to another instruction, but can also refer to another encoding or note of the same instruction.

## IMPLEMENTATION\_DEFINED

This subsection describes the statement:

```
IMPDEF { "<text>" };
```

This statement indicates a special case that provides an IMPLEMENTATION\_DEFINED value or behavior. An optional <text> field can give more information.

### E1.4.6 Comments

The pseudocode supports two styles of comments:

- `//` starts a comment that is terminated by the end of the line.
- `/*` starts a comment that is terminated by `*/`.

`/**` statements might not be nested, and the first `*/` ends the comment.

#### Note

Comment lines do not require a terminating semicolon.

## E1.5 Built-in functions

This section describes:

[E1.5.1 Bitstring manipulation functions.](#)

[E1.5.2 Arithmetic functions.](#)

### E1.5.1 Bitstring manipulation functions

The following bitstring manipulation functions are defined:

#### Bitstring length

If  $x$  is a bitstring:

- The bitstring length function `Len(x)` returns the length of  $x$  as an integer.

#### Bitstring concatenation and replication

If  $x$  is a bitstring and  $n$  is an integer with  $n \geq 0$ :

- `Replicate(x, n)` is the bitstring of length  $n * \text{Len}(x)$  consisting of  $n$  copies of  $x$  concatenated together.
- `Zeros(n) = Replicate('0', n)`.
- `Ones(n) = Replicate('1', n)`.

#### Bitstring count

If  $x$  is a bitstring, `BitCount(x)` is an integer result equal to the number of bits of  $x$  that are ones.

#### Testing a bitstring for being all zero or all ones

If  $x$  is a bitstring:

- `IsZero(x)` produces `TRUE` if all of the bits of  $x$  are zeros and `FALSE` if any of them are ones
- `IsZeroBit(x)` produces `'1'` if all of the bits of  $x$  are zeros and `'0'` if any of them are ones.

`IsOnes(x)` and `IsOnit(x)` work in the corresponding ways. This means:

```
1 IsZero(x) = (BitCount(x) == 0)
2 IsOnes(x) = (BitCount(x) == Len(x))
3 IsZeroBit(x) = if IsZero(x) then '1' else '0'
4 IsOnit(x) = if IsOnes(x) then '1' else '0'
```

#### Lowest and highest set bits of a bitstring

If  $x$  is a bitstring, and  $N = \text{Len}(x)$ :

- `LowestSetBit(x)` is the minimum bit number of any of the bits of  $x$  that are ones. If all of its bits are zeros, `LowestSetBit(x) = N`.
- `HighestSetBit(x)` is the maximum bit number of any of the bits of  $x$  that are ones. If all of its bits are zeros, `HighestSetBit(x) = -1`.
- `CountLeadingZeroBits(x)` is the number of zero bits at the left end of  $x$ , in the range 0 to  $N$ . This means:  
 $\text{CountLeadingZeroBits}(x) = N - 1 - \text{HighestSetBit}(x)$ .

- `CountLeadingSignBits(x)` is the number of copies of the sign bit of `x` at the left end of `x`, excluding the sign bit itself, and is in the range 0 to  $N-1$ . This means:

`CountLeadingSignBits(x) = CountLeadingZeroBits(x[N-1:1] EOR x[N-2:0]).`

## Zero-extension and sign-extension of bitstrings

If `x` is a bitstring and `i` is an integer, then `ZeroExtend(x, i)` is `x` extended to a length of `i` bits, by adding sufficient zero bits to its left. That is, if `i == Len(x)`, then `ZeroExtend(x, i) = x`, and if `i > Len(x)`, then:

`ZeroExtend(x, i) = Replicate('0', i-Len(x)) : x`

If `x` is a bitstring and `i` is an integer, then `SignExtend(x, i)` is `x` extended to a length of `i` bits, by adding sufficient copies of its leftmost bit to its left. That is, if `i == Len(x)`, then `SignExtend(x, i) = x`, and if `i > Len(x)`, then:

`SignExtend(x, i) = Replicate(TopBit(x), i-Len(x)) : x`

It is a pseudocode error to use either `ZeroExtend(x, i)` or `SignExtend(x, i)` in a context where it is possible that `i < Len(x)`.

## Converting bitstrings to integers

If `x` is a bitstring, `SInt()` is the integer whose two's complement representation is `x`.

`UInt()` is the integer whose unsigned representation is `x`.

`Int(x, unsigned)` returns either `SInt(x)` or `UInt(x)` depending on the value of its second argument.

## E1.5.2 Arithmetic functions

This section defines built-in arithmetic functions.

### Absolute value

If `x` is either of type real or integer, `Abs(x)` returns the absolute value of `x`. The result is the same type as `x`.

### Rounding and aligning

If `x` is a real:

- `RoundDown(x)` produces the largest integer `n` so that  $n \leq x$ .
- `RoundUp(x)` produces the smallest integer `n` so that  $n \geq x$ .
- `RoundTowardsZero(x)` produces:
  - `RoundDown(x)` if  $x > 0.0$ .
  - 0 if  $x == 0.0$ .
  - `RoundUp(x)` if  $x < 0.0$ .

If `x` and `y` are both of type **integer**, `Align(x, y) = y * (x DIV y)`, and is of type **integer**.

If `x` is of type **bitstring** and `y` is of type **integer**, `Align(x, y) = (Align(UInt(x), y)) [Len(x)-1:0]`, and is a **bitstring** of the same length as `x`.

It is a pseudocode error to use either form of `Align(x, y)` in any context where `y` can be 0. In practice, `Align(x,  $\hookrightarrow y$ )` is only used with `y` a constant power of two, and the **bitstring** form used with  $y = 2^n$  has the effect of producing its argument with its `n` low-order bits forced to zero.

## Maximum and minimum

If  $x$  and  $y$  are integers or reals, then  $\text{Max}(x, y)$  and  $\text{Min}(x, y)$  are their maximum and minimum respectively.  $x$  and  $y$  must both be of type integer or of type real. The function returns a value of the same type as its operands.

## E1.6 Arm pseudocode definition index

This section contains the following tables:

[Table E1-3](#) which contains the pseudocode data types.

[Table E1-4](#) which contains the pseudocode operators.

[Table E1-5](#) which contains the pseudocode keywords and control structures.

[Table E1-6](#) which contains the statements with special behaviors.

**Table E1-3 Index of pseudocode data types**

| Keyword     | Meaning                                           |
|-------------|---------------------------------------------------|
| array       | Type name for the array type                      |
| bit         | Keyword equivalent to <code>bits(1)</code>        |
| bits(N)     | Type name for the bitstring of length N data type |
| boolean     | Type name for the boolean data type               |
| enumeration | Keyword to define a new enumeration type          |
| integer     | Type name for the integer data type               |
| real        | Type name for the real data type                  |
| type        | Keyword to define a new structure                 |

**Table E1-4 Index of pseudocode operators**

| Operator | Meaning                                                                                                                                                            |
|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -        | Unary minus on integers or reals<br>Subtraction of integers, reals, and bitstrings<br>Used in the left-hand side of an assignment or a tuple to discard the result |
| +        | Unary plus on integers or reals<br>Addition of integers, reals, and bitstrings                                                                                     |
| .        | Extract named member from a list<br>Integer in bitstring extraction operator                                                                                       |
| :        | Bitstring concatenation<br>Integer range in bitstring extraction operator                                                                                          |
| !        | Boolean NOT                                                                                                                                                        |
| !=       | Comparison for inequality                                                                                                                                          |
| (...)    | Around arguments of procedure or function                                                                                                                          |
| [...]    | Around array index<br>Around arguments of array-like function                                                                                                      |
| *        | Multiplication of integers, reals and bitstrings                                                                                                                   |
| /        | Division of integers and reals (real result)                                                                                                                       |
| &&       | Boolean AND                                                                                                                                                        |
| <        | <i>Less than</i> comparison of integers and reals                                                                                                                  |
| [...]    | Slicing of specified bits or bitstring or integer                                                                                                                  |
| <<       | Multiply integer by power of 2 (with rounding towards infinity)                                                                                                    |
| <=       | <i>Less than or equal</i> comparison of integers and reals                                                                                                         |
| =        | Assignment operator                                                                                                                                                |
| ==       | Comparison for equality                                                                                                                                            |
| >        | <i>Greater than</i> comparison of integers and reals                                                                                                               |
| >=       | <i>Greater than or equal</i> comparison of integers and reals                                                                                                      |
| >>       | Divide integer by power of 2                                                                                                                                       |
|          | Boolean OR                                                                                                                                                         |

|          |                                                            |
|----------|------------------------------------------------------------|
| $\wedge$ | Exponential operator                                       |
| AND      | Bitwise AND of bitstrings                                  |
| DIV      | Quotient from integer division                             |
| EOR      | Bitwise EOR of bitstrings                                  |
| IN       | Test membership of a certain expression in a set of values |
| MOD      | Remainder from integer division                            |
| NOT      | Bitwise inversion of bitstrings                            |
| OR       | Bitwise OR of bitstrings                                   |

**Table E1-5 Index of pseudocode keywords and control structures**

| Operator                         | Meaning                                                                                     |
|----------------------------------|---------------------------------------------------------------------------------------------|
| <code>/*...*/</code>             | Comment delimiters                                                                          |
| <code>//</code>                  | Introduces comment terminated by end of line                                                |
| <code>case...of...</code>        | Control structure                                                                           |
| FALSE                            | One of two values a boolean can take (other than TRUE)                                      |
| <code>for...=...to...</code>     | Loop control structure, counting up from the initial value to the upper limit               |
| <code>for...=...downto...</code> | Loop control structure, counting down from the initial value to the lower limit             |
| <code>if...then...else...</code> | Condition expression selecting between two values                                           |
| <code>if...then...else...</code> | Conditional control structure                                                               |
| <code>otherwise</code>           | Introduces default in <code>case...of...</code> control structure                           |
| <code>repeat...until...</code>   | Loop control structure that runs at least once until the termination condition is satisfied |
| <code>return</code>              | Procedure or function return                                                                |
| TRUE                             | One of two values a boolean can take (other than FALSE)                                     |
| <code>try...catch</code>         | Control structure                                                                           |
| <code>when</code>                | Introduces a specific case in <code>case...of...</code> control structure                   |
| <code>while...do...</code>       | Loop control structure that runs until the termination condition is satisfied               |

**Table E1-6 Index of special statements**

| Keyword                   | Meaning                                    |
|---------------------------|--------------------------------------------|
| IMPLEMENTATION_DEFINED    | Describes IMPLEMENTATION_DEFINED behavior. |
| SEE                       | Points to other pseudocode to use instead  |
| UNDEFINED                 | Cause Undefined Instruction exception      |
| UNKNOWN                   | Unspecified value                          |
| CONSTRAINED_UNPREDICTABLE | Unspecified behavior within limits         |
| UNPREDICTABLE             | Unspecified behavior                       |

## E1.7 Additional functions

The following functions are not listed in E2 Pseudocode specification, and are only described in this section.

### E1.7.1 **IsSee()**

`IsSee()` returns TRUE if the exception variable that is passed to it was created because all the encodings that matched the instruction that was being decoded called SEE.

See [SEE...](#)

### E1.7.2 **IsUndefined()**

`IsUndefined()` returns TRUE if the exception variable that is passed to it was created because either the instruction that was being decoded did not match any known encoding, or because one of the encodings that was matched called the special statement UNDEFINED.

See [UNDEFINED](#).

## Chapter E2

# Pseudocode Specification

This chapter specifies the Armv8-M pseudocode. It contains the following section:

[Alphabetical Pseudocode List](#)

## E2.1 Alphabetical Pseudocode List

### E2.1.1 `_AdvanceVPTState`

```
1 // Advances VPT state
2
3 boolean _AdvanceVPTState;
```

### E2.1.2 `_ITStateChanged`

```
1 // Indicates a write to ITSTATE
2
3 boolean _ITStateChanged;
```

### E2.1.3 `_Mem`

```
1 // _Mem[] - non-assignment (read) form
2 // =====
3 // Perform single-copy atomic, aligned, little-endian read from physical memory.
4
5 (boolean, bits(8*size)) _Mem(AddressDescriptor memaddrdesc, integer size);
6
7 // _Mem[] - assignment (write) form
8 // =====
9 // Perform single-copy atomic, aligned, little-endian write to physical memory.
10
11 boolean _Mem(AddressDescriptor memaddrdesc, integer size, bits(8*size) value);
```

### E2.1.4 `_NextInstrAddr`

```
1 // Address of next instruction to be fetched in case of branch type operation
2
3 bits(32) _NextInstrAddr;
```

### E2.1.5 `_NextInstrITState`

```
1 // Updated ITSTATE for next instruction
2
3 ITSTATETYPE _NextInstrITState;
```

### E2.1.6 `_PCChanged`

```
1 // Indicates a change in instruction fetch address due to branch type operations
2
3 boolean _PCChanged;
```

### E2.1.7 `_PendingReturnOperation`

```
1 // Indicate any pending exception returns
2
3 boolean _PendingReturnOperation;
```

## **Part F**

### **Debug Packet Protocols**

## Chapter F1

# ITM and DWT Packet Protocol Specification

This chapter describes the protocol for packets that send the data generated by the ITM and DWT to an external debugger. It contains the following sections:

- [About the ITM and DWT packets.](#)
- [Alphabetical list of DWT and ITM packets.](#)

## F1.1 About the ITM and DWT packets

The following sections give an overview of the ITM and DWT packets and how the TPIU transmits them:

- [Uses of ITM and DWT packets](#)
- [ITM and DWT protocol packet headers](#)
- [Packet transmission by the trace sink](#)

### Note

This chapter describes packet transmission by a trace sink such as a TPIU. The ITM can send packets to any suitable trace sink. Regardless of the actual trace sink used, the ITM formats the packets as described in this chapter.

### F1.1.1 Uses of ITM and DWT packets

The ITM sends a packet to the trace sink when:

- Software writes to a stimulus register. This generates a [Instrumentation packet](#).
- The hardware generates a Protocol packet. Protocol packets include timestamps and synchronization packets.
- It receives a packet from the DWT, for forwarding to the trace sink.

The DWT sends a packet to the ITM for forwarding to the trace sink when:

- A DWT comparator matches and generates one or more Data Trace packets.
- It samples the PC.
- One of the performance profile counters wraps.

This chapter describes the packet protocol used.

### F1.1.2 ITM and DWT protocol packet headers

### F1.1.3 Packet transmission by the trace sink

The trace sink either:

- Forms the packets into frames, as required by the *Arm@CoreSight™ Architecture Specification*.
- Transmits the packets over a serial port.

For each packet, the trace sink transmits:

- The header byte first, followed by any payload bytes.
- Each byte of the packet *least significant bit* (LSB) first.

Figures in this chapter show each packet as a sequence of bytes, with the LSB of each byte to the right and the *most significant bit* (MSB) to the left. [Convention for packet descriptions](#) shows this convention, and how it relates to data transmission for a packet with a header byte and two payload bytes.

**Figure F1.1: Convention for packet descriptions**

In some sections, the figures are split into separate figures for the header byte and payload bytes. For instance, where the number of payload bytes varies according to a field in the header.

The ITM merges the packets from the ITM and DWT with the Local and Global timestamp, Synchronization, and other Protocol packets, and forwards them to the trace sink as a single data stream. The trace sink then merges this data stream with the data from the ETM, if implemented.

## F1.2 Alphabetical list of DWT and ITM packets

### F1.2.1 Data Trace Data Address packet

The Data Trace Data Address packet characteristics are:

**Purpose** Indicates a DWT comparator generated a match, and the address that matched. Data Address packets are only generated for Data Address range comparator pairs. The address might be compressed. However, it is not required that Short and Medium packets are generated when the address bits match.

**Attributes** Multi-part Hardware source packet comprising:

- 8-bit header.
- 8, 16, or 32-bit payload.

#### F1.2.1.1 Data Trace Data Address packet header

The Data Trace Data Address packet header bit assignments are:

**ID, byte 0 bits [7:3]** Hardware Source packet type. Bits [7:3] discriminate between Hardware Source packet types. The defined values of this field are:

**0b01xx1** Data Trace Data Address packet.

This field reads as 0b01xx1.

**CMPN, byte 0 bits [5:4]** DWT comparator index. Defines which comparator generated a match. Data Trace Data Address packets can be compressed relative to the value in DWT\_COMP<CMPN>. The number of traced bits is indicated by the SS field. The remainder of the address bits comes from DWT\_COMP<CMPN>. Either comparator in a Data Address range comparator pair can be used.

**SH, byte 0 bit [2]** Source. The defined values of this bit are:

**1** Hardware source packet.

This bit reads as one.

**SS, byte 0 bits [1:0]** Size. The defined values of this field are:

**0b01** Short Data Address packet.

**0b10** Medium Data Address packet.

**0b11** Long Data Address packet.

The value 0b00 encodes a Protocol packet.

### F1.2.1.2 Data Trace Data Address packet payload

When Long Data Address packet, SS == 0b11, the Data Trace Data Address packet payload bit assignments are:

When Medium Data Address packet, SS == 0b10, the Data Trace Data Address packet payload bit assignments are:

When Short Data Address packet, SS == 0b01, the Data Trace Data Address packet payload bit assignments are:

**DADDR[31:0], bytes <4:1>, when Long Data Address packet, SS == 0b11** Data address.

**DADDR[15:0], bytes <2:1>, when Medium Data Address packet, SS == 0b10** Data address. DADDR[31:16] == DWT\_COMP<CMPN>[31:16].

**DADDR[7:0], byte <1>, when Short Data Address packet, SS == 0b01** Data address. DADDR[31:8] == DWT\_COMP<CMPN>[31:8].

## F1.2.2 Data Trace Data Value packet

The Data Trace Data Value packet characteristics are:

**Purpose** Indicates a DWT comparator generated a match, and the value that matched.

**Attributes** Multi-part Hardware source packet comprising:

- 8-bit header.
- 8, 16, or 32-bit payload.

### F1.2.2.1 Data Trace Data Value packet header

The Data Trace Data Value packet header bit assignments are:

**ID, byte 0 bits [7:3]** Hardware Source packet type. Bits [7:3] discriminate between Hardware Source packet types. The defined values of this field are:

**0b10xxx** Data Trace Data Value packet.

This field reads as 0b10xxx.

**CMPN, byte 0 bits [5:4]** DWT comparator index. Defines which comparator generated a match.

**WnR, byte 0 bit [3]** Write-not-read. The defined values of this bit are:

**0** Read.

**1** Write.

**SH, byte 0 bit [2]** Source. The defined values of this bit are:

**1** Hardware source packet.

This bit reads as one.

**SS, byte 0 bits [1:0]** Size. The defined values of this field are:

**0b01** Byte Data Value packet.

**0b10** Halfword Data Value packet.

**0b11** Word Data Value packet.

The value 0b00 encodes a Protocol packet.

### F1.2.2.2 Data Trace Data Value packet payload

When Byte Data Value packet, SS == 0b01, the Data Trace Data Value packet payload bit assignments are:

When Halfword Data Value packet, SS == 0b10, the Data Trace Data Value packet payload bit assignments are:

When Word Data Value packet, SS == 0b11, the Data Trace Data Value packet payload bit assignments are:

DVALUE[31:0], bytes <4:1>, when Word Data Value packet, SS == 0b11 Word data value.

DVALUE[15:0], byte 1 bits [15:0], when Halfword Data Value packet, SS == 0b10 Halfword data value.

DVALUE[7:0], byte <1>, when Byte Data Value packet, SS == 0b01 Byte data value.

### F1.2.3 Data Trace Match packet

The Data Trace Match packet characteristics are:

**Purpose** Indicates a DWT comparator generated a match.

**Attributes** 16-bit Hardware source packet.

#### Field descriptions

The Data Trace Match packet bit assignments are:

**Byte 1 bits [7:1]** This field reads as 0b0000000.

**MATCH, byte 1 bit [0]** Data Trace Match packet. Discriminates between the [Data Trace PC Value packet](#) and the Data Trace Match packet. The defined values of this bit are:

1 Data Trace Match packet.

This bit reads as one.

**ID, byte 0 bits [7:3]** Hardware Source packet type. Bits [7:3] discriminate between Hardware Source packet types. The defined values of this field are:

**0b01xx0** [Data Trace PC Value packet](#) or Data Trace Match packet.

Bit [0] of byte 1 discriminates between the [Data Trace PC Value packet](#) and the Data Trace Match packet.

This field reads as 0b01xx0.

**CMPN, byte 0 bits [5:4]** DWT comparator index. Defines which comparator generated a match.

**SH, byte 0 bit [2]** Source. The defined values of this bit are:

- 1 Hardware source packet.

This bit reads as one.

**SS, byte 0 bits [1:0]** Size. The defined values of this field are:

**0b01** Source packet, 1-byte payload, 2-byte packet.

The value 0b00 encodes a Protocol packet. All other values are reserved.

This field reads as 0b01.

## F1.2.4 Data Trace PC Value packet

The Data Trace PC Value packet characteristics are:

**Purpose** Indicates a DWT comparator generated a match, and the address of the instruction that matched. The address might be compressed. However, it is not required that Short and Medium packets are generated when the address bits match.

**Attributes** Multi-part Hardware source packet comprising:

- 8-bit header.
- 8, 16, or 32-bit payload.

### F1.2.4.1 Data Trace PC Value packet header

The Data Trace PC Value packet header bit assignments are:

**ID, byte 0 bits [7:3]** Hardware Source packet type. Bits [7:3] discriminate between Hardware Source packet types. The defined values of this field are:

**0b01xx0** Data Trace PC Value packet or [Data Trace Match packet](#).

Bit [0] of byte 1 discriminates between the Data Trace PC Value packet and the [Data Trace Match packet](#).

This field reads as 0b01xx0.

**CMPN, byte 0 bits [5:4]** DWT comparator index. Defines which comparator generated a match. Data Trace PC Value packets can be compressed relative to the value in DWT\_COMP<CMPN>. The number of traced bits is indicated by the SS field. The remainder of the address bits comes from DWT\_COMP<CMPN>. Either comparator in an Instruction Address range comparator pair can be used.

**SH, byte 0 bit [2]** Source. The defined values of this bit are:

1 Hardware source packet.

This bit reads as one.

**SS, byte 0 bits [1:0]** Size. The defined values of this field are:

0b01 Short PC Value packet.

0b10 Medium PC Value packet.

0b11 Long PC Value packet.

The value 0b00 encodes a Protocol packet.

### F1.2.4.2 Data Trace PC Value packet payload

When Long PC Value packet, SS == 0b11, the Data Trace PC Value packet payload bit assignments are:

When Medium PC Value packet, SS == 0b10, the Data Trace PC Value packet payload bit assignments are:

When Short PC Value packet, SS == 0b01, the Data Trace PC Value packet payload bit assignments are:

**PC[31:1], bytes <4:2>, byte 1 bits [7:1], when Long PC Value packet, SS == 0b11** Instruction address.

**PC[15:1], byte <2>, byte 1 bits [7:1], when Medium PC Value packet, SS == 0b10** Instruction address.  
PC[31:16] == DWT\_COMP<CMPN>[31:16].

**PC[7:1], byte 1 bits [7:1], when Short PC Value packet, SS == 0b01** Instruction address. PC[31:8] == DWT\_COMP<CMPN>[31:8].

**MATCH, byte 1 bit [0]** [Data Trace Match packet](#). Discriminates between the Data Trace PC Value packet and the [Data Trace Match packet](#). The defined values of this bit are:

0 Data Trace PC Value packet.

This bit reads as zero.

## F1.2.5 Event Counter packet

The Event Counter packet characteristics are:

**Purpose** Indicates one or more DWT counters wraps through zero.

**Attributes** 16-bit Hardware source packet.

### Field descriptions

The Event Counter packet bit assignments are:

| 7  | 6 | 5   | 4    | 3   | 2     | 1   | 0   |        |
|----|---|-----|------|-----|-------|-----|-----|--------|
| ID |   |     |      | SH  | SS    |     |     | Byte 0 |
| 0  | 0 | 0   | 0    | 0   | 1     | 0   | 1   |        |
| 0  |   | Cyc | Fold | LSU | Sleep | Exc | CPI | Byte 1 |

**Byte 1 bits [7:6]** This field reads-as-zero.

**Cyc, byte 1 bit [5]** POSTCNT timer decremented to zero. See DWT\_CTRL for more information on the POSTCNT timer.

**Fold, byte 1 bit [4]** DWT\_FOLDCNT counter wrapped from 0xFF to zero.

**LSU, byte 1 bit [3]** DWT\_LSUNCT counter wrapped from 0xFF to zero.

**Sleep, byte 1 bit [2]** DWT\_SLEEP\_CNT counter wrapped from 0xFF to zero.

**Exc, byte 1 bit [1]** DWT\_EXCCNT counter wrapped from 0xFF to zero.

**CPI, byte 1 bit [0]** DWT\_CPICNT counter wrapped from 0xFF to zero.

**ID, byte 0 bits [7:3]** Hardware Source packet type. Bits [7:3] discriminate between Hardware Source packet types. The defined values of this field are:

0b00000 Event Counter packet.

This field reads as 0b00000.

**SH, byte 0 bit [2]** Source. The defined values of this bit are:

1 Hardware source packet.

This bit reads as one.

**SS, byte 0 bits [1:0]** Size. The defined values of this field are:

0b01 Source packet, 1-byte payload, 2-byte packet.

The value 0b00 encodes a Protocol packet. All other values are reserved.

This field reads as 0b01.

## F1.2.6 Exception Trace packet

The Exception Trace packet characteristics are:

**Purpose** Indicates the PE has entered, exited or returned to an exception.

**Attributes** 24-bit Hardware source packet.

### Field descriptions

The Exception Trace packet bit assignments are:

**Byte 2 bits [7:6,3:1]** This field reads-as-zero.

**FN, byte 2 bits [5:4]** Function. The defined values of this field are:

- 0b01** Entered exception indicated by ExceptionNumber.
  - 0b10** Exited exception indicated by ExceptionNumber.
  - 0b11** Returned to exception indicated by ExceptionNumber.
- All other values are reserved.

**ExceptionNumber, byte 2 bit [0], byte <1>** The exception number.

**ID, byte 0 bits [7:3]** Hardware Source packet type. Bits [7:3] discriminate between Hardware Source packet types. The defined values of this field are:

**0b00001** Exception Trace packet.

This field reads as 0b00001.

**SH, byte 0 bit [2]** Source. The defined values of this bit are:

- 1** Hardware source packet.

This bit reads as one.

**SS, byte 0 bits [1:0]** Size. The defined values of this field are:

**0b10** Source packet, 2-byte payload, 3-byte packet.

The value 0b00 encodes a Protocol packet. All other values are reserved.

This field reads as 0b10.

## F1.2.7 Extension packet

The Extension packet characteristics are:

**Purpose** An Extension packet provides additional information about the identified source. The amount of information required determines the number of payload bytes, 0-4. The architecture only defines one use of the Extension packet, to provide a Stimulus port page number. For this use, SH == 0, and a single byte Extension packet is emitted.

**Attributes** 8, 16, 24, 32, or 40-bit Protocol packet.

### Field descriptions

When 1-byte packet, the Extension packet bit assignments are:

When 2-byte packet, the Extension packet bit assignments are:

When 3-byte packet, the Extension packet bit assignments are:

When 4-byte packet, the Extension packet bit assignments are:

When 5-byte packet, the Extension packet bit assignments are:

**EX, byte <4>, byte 3 bits [6:0], byte 2 bits [6:0], byte 1 bits [6:0], byte 0 bits [6:4]** Extension information. If SH == 1, then EX defines PAGE, the Stimulus port page number.

This is a 32-bit field. If the Extension packet is shorter than 5 bytes, the most significant bits are zero.

**C, byte 3 bit [7], byte 2 bit [7], byte 1 bit [7], byte 0 bit [7]** Continuation bit. The defined values of this field are:

0 Last byte of the packet.

1 Another byte follows.

**ID, byte 0 bits [6:2]** Protocol packet type. Bits [6:2] discriminate between Protocol packet types. The defined values of this field are:

0bxxx1x Extension packet.

This field reads as 0bxxx1x.

**SH, byte 0 bit [2]** Source. The defined values of this bit are:

0 Extension packet for [Instrumentation packet](#).

1 Extension packet for Hardware source packet.

**SS, byte 0 bits [1:0]** Packet type. The defined values of this field are:

**0b00** Protocol packet.

Other values encode different sizes of Hardware and Software source packets. This field reads as 0b00.

## F1.2.8 Global Timestamp 1 packet

The Global Timestamp 1 packet characteristics are:

**Purpose** Contains the least significant bits of the global timestamp value. The ITM might compress this value if it is not generating a full timestamp by omitting significant bits if they are unchanged from the previous timestamp value.

**Attributes** Multi-part Protocol packet comprising:

- 8-bit header.
- 8, 16, 24, or 32-bit payload.

### F1.2.8.1 Global Timestamp 1 packet header

The Global Timestamp 1 packet header bit assignments are:

| 7 | 6  | 5 | 4 | 3 | 2  | 1 | 0 |
|---|----|---|---|---|----|---|---|
| C | ID |   |   |   | SS |   |   |
| 1 | 0  | 0 | 1 | 0 | 1  | 0 | 0 |

Byte 0

**C, byte 0 bit [7]** Continuation bit. This bit reads as one.

**ID, byte 0 bits [6:2]** Protocol packet type. Bits [6:2] discriminate between Protocol packet types. The defined values of this field are:

**0b00101** Global Timestamp 1 packet.

This field reads as 0b00101.

**SS, byte 0 bits [1:0]** Packet type. The defined values of this field are:

**0b00** Protocol packet.

Other values encode different sizes of Hardware and Software source packets. This field reads as 0b00.

### F1.2.8.2 Global Timestamp 1 packet payload

When 7-bit timestamp, the Global Timestamp 1 packet payload bit assignments are:

| 7 | 6       | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---------|---|---|---|---|---|---|
| C | TS[6:0] |   |   |   |   |   |   |
| 0 |         |   |   |   |   |   |   |

Byte 1

When 14-bit timestamp, the Global Timestamp 1 packet payload bit assignments are:

When 21-bit timestamp, the Global Timestamp 1 packet payload bit assignments are:

When 26-bit or full timestamp, the Global Timestamp 1 packet payload bit assignments are:

**C, byte 4 bit [7], byte 3 bit [7], byte 2 bit [7], byte 1 bit [7]** Continuation bit. The defined values of this field are:

- 0 Last byte of the packet.
- 1 Another byte follows.

**Wrap, byte 4 bit [6], when 26-bit or full timestamp** Wrapped. The defined values of this bit are:

- 0 The value of global timestamp bits TS[47:26] or TS[63:26] have not changed since the last [Global Timestamp 2 packet](#) output by the ITM.
- 1 The value of global timestamp bits TS[47:26] or TS[63:26] have changed since the last [Global Timestamp 2 packet](#) output by the ITM.

**ClkCh, byte 4 bit [5], when 26-bit or full timestamp** Clock change. The defined values of this bit are:

- 0 The system has not asserted the clock change input to the processor since the last time the ITM generated a Global Timestamp packet.

- 1 The system has asserted the clock change input to the processor since the last time the ITM generated a Global Timestamp packet.

**Note**

When the clock change input to the processor is asserted, the ITM must output a full 48-bit or 64-bit global timestamp value.

**TS[25:0], byte 4 bits [4:0], byte 3 bits [6:0], byte 2 bits [6:0], byte 1 bits [6:0]** Global Timestamp. The timestamp is 64 or 48 bits. If the Global Timestamp 1 packet is shorter than 5 bytes, the most-significant bits of the timestamp have not changed since the last Global Timestamp 1 packet output by the ITM. If the Global Timestamp 1 packet is 5 bytes, the Wrap bit defines whether most-significant bits have unchanged since the last [Global Timestamp 2 packet](#) output by the ITM.

## F1.2.9 Global Timestamp 2 packet

The Global Timestamp 2 packet characteristics are:

**Purpose** Provides the most significant bits of a full 48 or 64-bit timestamp.

**Attributes** Multi-part Protocol packet comprising:

- 8-bit header.
- 32 or 48-bit payload.

### F1.2.9.1 Global Timestamp 2 packet header

The Global Timestamp 2 packet header bit assignments are:

| 7 | 6  | 5 | 4 | 3 | 2 | 1  | 0 |        |
|---|----|---|---|---|---|----|---|--------|
| C | ID |   |   |   |   | SS |   | Byte 0 |
| 1 | 0  | 1 | 1 | 0 | 1 | 0  | 0 |        |

**C, byte 0 bit [7]** Continuation bit. This bit reads as one.

**ID, byte 0 bits [6:2]** Protocol packet type. Bits [6:2] discriminate between Protocol packet types. The defined values of this field are:

**0b01101** Global Timestamp 2 packet.

This field reads as 0b01101.

**SS, byte 0 bits [1:0]** Packet type. The defined values of this field are:

**0b00** Protocol packet.

Other values encode different sizes of Hardware and Software source packets. This field reads as 0b00.

### F1.2.9.2 Global Timestamp 2 packet payload

When 48-bit Global Timestamp 2 packet, the Global Timestamp 2 packet payload bit assignments are:

When 64-bit Global Timestamp 2 packet, the Global Timestamp 2 packet payload bit assignments are:

**C, byte 6 bit [7], byte 5 bit [7], byte 4 bit [7], byte 3 bit [7], byte 2 bit [7], byte 1 bit [7] Continuation bit.**

The defined values of this field are:

0 Last byte of the packet.

1 Another byte follows.

**Byte 6 bits [6:3], when 64-bit Global Timestamp 2 packet** This field reads-as-zero.

**Byte 4 bits [6:1], when 48-bit Global Timestamp 2 packet** This field reads-as-zero.

**TS[47:26] , byte 4 bit [0], byte 3 bits [6:0], byte 2 bits [6:0], byte 1 bits [6:0], when 48-bit Global Timestamp 2 packet**

Most significant bits of the Global Timestamp.

**TS[63:26] , byte 6 bits [2:0], byte 5 bits [6:0], byte 4 bits [6:0], byte 3 bits [6:0], byte 2 bits [6:0], byte 1 bits [6:0], when 64-bit Global Timestamp 2 packet**

Most significant bits of the Global Timestamp.

## F1.2.10 Instrumentation packet

The Instrumentation packet characteristics are:

**Purpose** A software write to an ITM stimulus port generates an Instrumentation packet.

**Attributes** Multi-part Software source packet comprising:

- 8-bit header.
- 8, 16, or 32-bit payload.

### F1.2.10.1 Instrumentation packet header

The Instrumentation packet header bit assignments are:

**A, byte 0 bits [7:3]** Port number, 0-31.

**SH, byte 0 bit [2]** Source. The defined values of this bit are:

**0** Instrumentation packet (Software source).

This bit reads as zero.

**SS, byte 0 bits [1:0]** Size. The defined values of this field are:

**0b01** Byte Instrumentation packet.

**0b10** Halfword Instrumentation packet.

**0b11** Word Instrumentation packet.

The value 0b00 encodes a Protocol packet.

### F1.2.10.2 Instrumentation packet payload

When Byte Instrumentation packet, SS == 0b01, the Instrumentation packet payload bit assignments are:

When Halfword Instrumentation packet, SS == 0b10, the Instrumentation packet payload bit assignments are:

When Word Instrumentation packet, SS == 0b11, the Instrumentation packet payload bit assignments are:

**Payload[31:0]**, bytes <4:1>, when **Word Instrumentation packet**, SS == **0b11** Payload value.

**Payload[15:0]**, byte 1 bits [15:0], when **Halfword Instrumentation packet**, SS == **0b10** Payload value.

**Payload[7:0]**, byte <1>, when **Byte Instrumentation packet**, SS == **0b01** Payload value.

## F1.2.11 Local Timestamp 1 packet

The Local Timestamp 1 packet characteristics are:

**Purpose** A Local Timestamp 1 packet encodes timestamp information, for generic control and synchronization, based on a timestamp counter in the ITM. To reduce the trace bandwidth:

- The local timestamping scheme uses delta timestamps. Whenever the ITM outputs a Local timestamp packet, it clears its timestamp counter to zero, meaning each local timestamp value gives the interval since the generation of the previous Local timestamp packet.
- The Local Timestamp 1 packet length, 1-5 bytes, depends on the timestamp value.
- If the ITM outputs the local timestamp synchronously to the corresponding ITM or DWT data, and the timestamp value is in the range 1-6, the ITM uses the [Local Timestamp 2 packet](#).

**Attributes** Multi-part Protocol packet comprising:

- 8-bit header.
- 8, 16, 24, or 32-bit payload.

### F1.2.11.1 Local Timestamp 1 packet header

The Local Timestamp 1 packet header bit assignments are:

**C, byte 0 bit [7]** Continuation bit. This bit reads as one.

**ID, byte 0 bits [6:2]** Protocol packet type. Bits [6:2] discriminate between Protocol packet types. The defined values of this field are:

**0b1xx00** Local Timestamp 1 packet.

This field reads as 0b1xx00.

**TC, byte 0 bits [5:4]** Indicates the relationship between the generation of the Local timestamp packet and the corresponding ITM or DWT data packet. The defined values of this field are:

**0b00** The local timestamp value is synchronous to the corresponding ITM or DWT data. The value in the TS field is the timestamp counter value when the ITM or DWT packet is generated.

**0b01** The local timestamp value is delayed relative to the ITM or DWT data. The value in the TS field is the timestamp counter value when the Local timestamp packet is generated.

**Note**

The local timestamp value corresponding to the previous ITM or DWT packet is *unknown*, but must be between the previous and current local timestamp values.

**0b10** Output of the ITM or DWT packet corresponding to this Local timestamp packet is delayed relative to the associated event. The value in the TS field is the timestamp counter value when the ITM or DWT packets is generated.

This encoding indicates that the ITM or DWT packet was delayed relative to other trace output packets.

**0b11** Output of the ITM or DWT packet corresponding to this Local timestamp packet is delayed relative to the associated event, and this Local timestamp packet is delayed relative to the ITM or DWT data. This is a combination of the conditions indicated by values 0b01 and 0b10.

**SS, byte 0 bits [1:0]** Packet type. The defined values of this field are:

**0b00** Protocol packet.

Other values encode different sizes of Hardware and Software source packets. This field reads as 0b00.

### F1.2.11.2 Local Timestamp 1 packet payload

When 7-bit timestamp, the Local Timestamp 1 packet payload bit assignments are:

When 14-bit timestamp, the Local Timestamp 1 packet payload bit assignments are:

When 21-bit timestamp, the Local Timestamp 1 packet payload bit assignments are:

When 28-bit timestamp, the Local Timestamp 1 packet payload bit assignments are:

**C, byte 4 bit [7], byte 3 bit [7], byte 2 bit [7], byte 1 bit [7]** Continuation bit. The defined values of this field are:

- 0 Last byte of the packet.
- 1 Another byte follows.

**Byte 4 bits [6:5], when 28-bit timestamp** This field reads-as-zero.

**TS, byte 4 bits [4:0], byte 3 bits [6:0], byte 2 bits [6:0], byte 1 bits [6:0]** Local Timestamp.

The timestamp is 28 bits. If the Local Timestamp 1 packet is shorter than 5 bytes, the most significant bits of the timestamp are zero.

## F1.2.12 Local Timestamp 2 packet

The Local Timestamp 2 packet characteristics are:

**Purpose** If the ITM outputs the Local Timestamp synchronously to the corresponding ITM or DWT data, and the required timestamp value is in the range 1-6, it uses the Local Timestamp 2 packet. For more information, see [Local Timestamp 1 packet](#).

**Attributes** 8-bit Protocol packet.

### Field descriptions

The Local Timestamp 2 packet bit assignments are:

**C, byte 0 bit [7]** Continuation bit. This bit reads as zero.

**ID, byte 0 bits [6:2]** Protocol packet type. Bits [6:2] discriminate between Protocol packet types. The defined values of this field are:

**0b00000** See [Synchronization packet](#).

**0bxxx00** For all other values of 0bxxx. Local Timestamp 2 packet.

**0b11100** See [Overflow packet](#).

This field reads as 0bxxx00.

**TS, byte 0 bits [6:4]** Local timestamp value, in the range 0b001 to 0b110.

**SS, byte 0 bits [1:0]** Packet type. The defined values of this field are:

**0b00** Protocol packet.

Other values encode different sizes of Hardware and Software source packets. This field reads as 0b00.

### F1.2.13 Overflow packet

The Overflow packet characteristics are:

**Purpose** The ITM outputs an Overflow packet if:

- Software writes to a Stimulus Port register when the stimulus port output buffer is full.
- The DWT attempts to generate a Hardware source packet when the DWT output buffer is full.
- The Local timestamp counter overflows.

The Overflow packet comprises a header with no payload.

**Attributes** 8-bit Protocol packet.

#### Field descriptions

The Overflow packet bit assignments are:

**C, byte 0 bit [7]** Continuation bit. This bit reads as zero.

**ID, byte 0 bits [6:2]** Protocol packet type. Bits [6:2] discriminate between Protocol packet types. The defined values of this field are:

**0b11100** Overflow packet.

This field reads as 0b11100.

**SS, byte 0 bits [1:0]** Packet type. The defined values of this field are:

**0b00** Protocol packet.

Other values encode different sizes of Hardware and Software source packets. This field reads as 0b00.

## F1.2.14 Periodic PC Sample packet

The Periodic PC Sample packet characteristics are:

**Purpose** The DWT unit generates PC samples at fixed time intervals, with an accuracy of one clock cycle. The POSTCNT counter period determines the PC sampling interval. Software configures the [DWT\\_CTRL.CYCTAP](#) and [DWT\\_CTRL.POSTINIT](#) fields to determine how POSTCNT relates to [DWT\\_CYCCNT](#). The [DWT\\_CTRL.PCSAMPLENA](#) bit enables PC sampling.

**Attributes** Multi-part Hardware source packet comprising:

- 8-bit header.
- 8 or 32-bit payload.

### F1.2.14.1 Periodic PC Sample packet header

The Periodic PC Sample packet header bit assignments are:

| 7  | 6 | 5 | 4 | 3  | 2  | 1 | 0 |
|----|---|---|---|----|----|---|---|
| ID |   |   |   | SH | SS |   |   |
| 0  | 0 | 0 | 1 | 0  | 1  | 1 |   |

Byte 0

**ID, byte 0 bits [7:3]** Discriminator ID. The defined values of this field are:

**0b00010** Periodic PC Sample packet.

This field reads as 0b00010.

**SH, byte 0 bit [2]** Source. The defined values of this bit are:

**1** Hardware source packet.

This bit reads as one.

**SS, byte 0 bits [1:0]** Size. The defined values of this field are:

**0b01** Source packet, 1-byte payload, 2-byte packet.

**0b11** Source packet, 4-byte payload, 5-byte packet.

SS == 0b10 is invalid for a Periodic PC Sample packet.

The value 0b00 encodes a Protocol packet.

This field reads as 0bx1.

### F1.2.14.2 Periodic PC Sample packet payload

When Allowed and not sleeping, SS == 0b11, the Periodic PC Sample packet payload bit assignments are:

When Allowed and sleeping, SS == 0b01, the Periodic PC Sample packet payload bit assignments are:

When Prohibited, SS == 0b01, the Periodic PC Sample packet payload bit assignments are:

**PC, bytes <4:1>, when Allowed and not sleeping, SS == 0b11** Periodic PC sample value.

**Byte <1>, when Allowed and sleeping, SS == 0b01** This field reads as 0b00000000.

**Byte <1>, when Prohibited, SS == 0b01** This field reads as 0b11111111.

### F1.2.15 PMU overflow packet

The PMU overflow packet characteristics are:

**Purpose** For each counter  $n$ , if the lower eight bits of that counter overflow, the associated  $OV_n$  of the PMU overflow packet is set. If multiple counters overflow in the same period, multiple bits might be set. If there are fewer than 8 general-purpose counters, the associated PMU overflow packet bit is always zero.

**Attributes** 8 bit protocol packet.

#### Field descriptions

The PMU overflow packet bit assignments are:

| 7   | 6   | 5   | 4   | 3   | 2   | 1   | 0   |        |
|-----|-----|-----|-----|-----|-----|-----|-----|--------|
| ID  |     |     |     | SH  | SS  |     |     | Byte 0 |
| 0   | 0   | 0   | 1   | 1   | 1   | 0   | 1   |        |
|     |     |     |     |     |     |     |     | Byte 1 |
| OV7 | OV6 | OV5 | OV4 | OV3 | OV2 | OV1 | OV0 |        |

**Byte 0 bits [7:0]** Packet Header

**Byte 1 bits [7:0]** OV<sub>n</sub>

### F1.2.16 Synchronization packet

The Synchronization packet characteristics are:

**Purpose** A Synchronization packet provides a unique pattern in the bit stream. Trace capture hardware can identify this pattern and use it to identify the alignment of packet bytes in the bitstream.

**Attributes** 48-bit Protocol packet.

A Synchronization packet is at least forty-seven 0 bits followed by single 1 bit. This section describes the smallest possible Synchronization packet.

#### Field descriptions

The Synchronization packet bit assignments are:

| 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |        |
|---|---|---|---|---|---|---|---|--------|
| 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | Byte 0 |
| 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | Byte 1 |
| 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | Byte 2 |
| 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | Byte 3 |
| 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | Byte 4 |
| 1 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | Byte 5 |

**Byte 5 bit [7]** Indicates the end of the Synchronization packet. This bit reads as one.

**Byte 5 bits [6:0], bytes <4:1>** This field reads-as-zero.

**Byte <0>** This field reads as 0b00000000.

## **Part G**

### **Glossary**

## AAPCS

Procedure Call Standard for the Arm Architecture.

## Address dependency

An address dependency exists when the value that is returned by a read computes the address of a subsequent access. An address dependency exists even if the value that is returned by the first read does not change the address of the second read or write.

See [B7.2.3 Ordering and observability](#)

## Addressing mode

Means a method for generating the memory address that is used by a load/store instruction.

## Aligned

A data item that is stored at an address that is exactly divisible by the highest power of 2 that divides exactly into its size in bytes. Aligned halfwords, words, and doublewords therefore have addresses that are divisible by 2, 4 and 8 respectively.

An aligned access is one where the address of the access is aligned to the size of each element of the access.

## Application Program Status Register (APSR)

The register containing those bits that deliver status information about the results of instructions, the N, Z, C, and V bits of the XPSR. In an implementation that includes the DSP extension, the APSR includes the GE bits that provide status information from DSP operations.

See also [B3.5 XPSR, APSR, IPSR, and EPSR](#).

## APSR

See Application Program Status Register.

## Architecturally executed

An instruction is architecturally executed only if it would be executed in a simple sequential execution of the program. When such an instruction has been executed and retired it has been *architecturally executed*. Any instruction that, in a simple sequential execution of a program, is treated as a NOP because it fails its condition code check, is an architecturally executed instruction.

In a PE that performs Speculative execution, an instruction is not architecturally executed if the PE discards the results of a Speculative execution.

See also [Condition code check](#), [Simple sequential execution](#).

## Architecturally UNKNOWN

An Architecturally UNKNOWN value is a value that is not defined by the architecture but must meet the requirements of the definition of UNKNOWN. Implementations can define the value of the field, but are not required to do so.

See also [IMPLEMENTATION DEFINED](#).

## Architecture tick

An atomic unit of execution. In the Armv8.0-M architecture, most instructions are considered atomic units for execution (they are either performed or not performed). The most notable exceptions are instructions that support ICI behavior.

## Associativity

See [Cache associativity](#)

## Asynchronous exception

An exception is described as asynchronous if any of the following apply:

- The exception is not generated as a result of direct execution or attempted execution of the instruction stream.
- The return address presented to the exception handler is not guaranteed to indicate the instruction that caused the exception.
- The exception is imprecise.

See [Imprecise exception](#), [Synchronous exception](#).

## Atomicity

Describes either single-copy atomicity or multi-copy atomicity. [B7.2 Atomicity](#) defines these forms of atomicity for the Arm architecture.

See also [Multi-copy atomicity](#), [Single-copy atomicity](#).

## Attributability

A PMU event that is caused by the PE counting the PMU event is Attributable. If an agent other than the PE that is counting the PMU events causes a PMU event then that PMU event is Unattributable.

A PMU event is either Attributable or Unattributable. If the PMU event is Attributable, it is further defined whether the PMU event is Attributable to:

- The current Security state of the PE.
- The privilege level.
- When the PE is in Debug state, operations issued to the PE by the Debugger through the external debug interface.

## Attribution Unit (AU)

The combination of the Secure Attribution Unit (SAU) and the Implementation Defined Attribution Unit (IDAU).

See also [Chapter B10 The Armv8-M Protected Memory System Architecture](#).

## AU

See [Attribution unit](#).

## Availability

Readiness for correct service.

## Background state

The state of the PE before the last (previous) preemption occurred.

## Banked register

A register that has multiple instances, with the instance that is in use depending on the PE mode, Security state, or other PE state.

## Base register

A register that is specified by a load/store instruction that is used as the base value for the address calculation for the instruction. Depending on the instruction and its addressing mode, an offset can be added to or subtracted from the base register value to form the address that is sent to memory.

## Base register Write-Back

Describes writing back a modified value to the base register used in an address calculation.

## Baseboard Management Controller

A PE dedicated to system control and monitoring.

## Beat

The execution of a 1/4 of an MVE vector operation. Because the vector length is 128 bits, one beat of a vector add instruction equates to computing 32 bits of result data. This is independent of lane width. For example, if a lane width is 8 bits, then a single beat of a vector add instruction would perform four 8-bit additions.

See also [B5.4 Beats](#).

### Behaves as if

Where this manual indicates that a PE *behaves as if* a certain condition applies, all descriptions of the operation of the PE must be re-evaluated taking account of that condition, together with any other conditions that affect operation.

### BF branch point

The gap between the two instructions. Specifically, the gap between the instruction that immediately precedes the instruction at the `<b_label>` of a BF instruction and the instruction that is identified by the `<b_label>` of a BF instruction..

See also [B3.29 Branch future](#).

### Big-endian memory

Means that, for example:

- A byte or halfword at a word-aligned address is the most significant byte or halfword in the word at that address.
- A byte at a halfword-aligned address is the most significant byte in the halfword at that address.

See also [B7.5 Endianness](#), [Little-endian memory](#).

### Blocking

Describes an operation that does not permit following instructions to be executed before the operation completes.

A non-blocking operation can permit following instructions to be executed before the operation completes, and in the event of encountering an exception does not signal an exception to the PE. This enables implementations to retire following instructions while the non-blocking operation is executing, without the need to retain precise PE state.

### Branch prediction

Is where a PE selects a future execution path to fetch along. For example, after a branch instruction, the PE can choose to speculatively fetch either the instruction following the branch or the instruction at the branch target.

See also [Prefetching](#).

### Breakpoint

A debug event that is triggered by the execution of a particular instruction, which is specified by one or both of the address of the instruction and the state of the PE when the instruction is executed.

### BTI

Branch Target Identification. The mechanism used for creating and identifying valid branch landing pads.

### BTI clearing

Branch Target Identification clearing instruction. Any instruction that clears the [EPSR.B](#) bit to zero.

### BTI setting

Branch Target Identification setting instruction. Any instruction that sets the [EPSR.B](#) bit to one.

### Byte

An 8-bit data item.

### Cache associativity

The number of locations in a cache set to which an address can be assigned. Each location is identified by its *way* value.

### Cache level

The position of a cache in the cache hierarchy. In the Arm architecture, the lower numbered levels are those closest to the PE. For more information, see [B7.19 Caches](#).

### Cache line

The basic unit of storage in a cache. Its size in words is always a power of two, usually four or eight words. A cache line must be aligned to a suitable memory boundary. A *memory cache line* is a block of memory locations with the same size and alignment as a cache line. Memory cache lines are sometimes loosely called cache lines.

### Cache sets

Areas of a cache, which is divided up to simplify and speed up the process of determining whether a cache hit occurs. The number of cache sets is always a power of two. The term cache sets is a common convention for describing cache memories, and this description must not be treated as defining a property of the cache.

### Cache way

A cache way consists of one cache line from each cache set. The cache ways are indexed from 0 to (Associativity-1). Each cache line in a cache way is chosen to have the same index as the cache way. For example, cache way *n* consists of the cache line with index *n* from each cache set. The term cache way is a common convention for describing cache memories, and this description must not be treated as defining a property of the cache.

### Cache write-back granule

The maximum size of the memory that can be overwritten. In some implementations, the [CTR](#) identifies the Cache Write-Back Granule.

### Callee-saved registers

Are registers that a called procedure must preserve. To preserve a callee-saved register, the called procedure would normally either not use the register at all, or store the register to the stack during procedure entry and reload it from the stack during procedure exit.

### Caller-saved registers

Are registers that a called procedure is not required to preserve. If the calling procedure requires their values to be preserved, it must store and reload them itself.

### Catastrophic failure

A failure with harmful consequences that are orders of magnitude, or even incommensurably, higher than the benefit provided by correct service delivery.

### Chained vector instruction

An instruction that is subject to beat-wise execution.

### Coherence order

See [Coherent](#)

### Coherent

Data accesses from a set of observers to a byte in memory are coherent if accesses to that byte in memory by the members of that set of observers are consistent with there being a single total order of all writes to that byte in memory by all members of the set of observers. This single total order of all to writes to that memory location is the *coherence order* for that byte in memory.

### Completer

An agent in a computing system that responds to and completes a memory transaction that was initiated by a Requester.

See also [Requester](#)

### Condition code check

The process of determining whether a conditional instruction executes normally or is treated as a NOP. For an instruction that includes a condition code field, that field is compared with the condition flags to determine whether the instruction is executed normally. For a T32 instruction in an IT block, the value of [EPSR.IT](#) determines whether the instruction is executed normally.

See also [Condition code field](#), [Condition flags](#), [Conditional execution](#).

### Condition code field

A 4-bit field in an instruction that specifies the condition under which the instruction executes.

See also [Condition code check](#).

### Condition flags

The N, Z, C, and V bits of APSR, or XPSR. See [B3.5 XPSR, APSR, IPSR, and EPSR](#) for more information.

See also [Condition code check](#).

### Conditional execution

When a conditional instruction starts executing, if the condition code check returns TRUE, the instruction executes normally. Otherwise, it is treated as a NOP. See [C1.3 Conditional execution](#).

See also [Condition code check](#).

### Configuration

Settings that are made on reset, or immediately after reset, and normally expected to remain static throughout program execution.

### CONSTRAINED UNPREDICTABLE

Where an instruction can result in UNPREDICTABLE behavior, the Armv8 architecture specifies a narrow range of permitted behaviors. This range is the range of CONSTRAINED UNPREDICTABLE behavior. All implementations that are compliant with the architecture must follow the CONSTRAINED UNPREDICTABLE behavior within the limits defined for each particular case, and this behavior might vary.

In body text, the term CONSTRAINED UNPREDICTABLE is shown in SMALLCAPS.

See also [UNPREDICTABLE](#).

### Containable

An error that is not uncontained. A Containable error is also referred to as a Contained error.

### Context switch

The saving and restoring of computational state when switching between different threads or processes. In this manual, the term context switch describes any situation where the context is switched by an operating system and might or might not include changes to the address space.

### Context synchronization event

A context synchronization event is one of the following:

- Performing an ISB operation. An ISB operation is performed when an `ISB` instruction is executed and does not fail its condition code check.
- Taking an exception.
- Returning from an exception.
- Exit from Debug state.

For more information, see [B3.35 Context Synchronization Event](#).

#### **Note**

Security state transitions are not Context synchronization events.

#### **Control dependency**

A control dependency exists when the data value that is returned by a read access determines the condition flags, and the values of the flags determine the address of a subsequent read access. This address determination might be through conditional execution, or through the evaluation of a branch.

#### **Corrected**

An error that is detected by hardware and that hardware can correct. This is also referred to as a Correctable error.

#### **Countable error**

An error that is detected and recorded by hardware by incrementing a counter.

#### **Cross beat**

An operation that requires operands from different beats to produce the output for a single beat. For example, a vector widening operation would be cross beat, whereas a vector addition would not be.

#### **Cross Trigger Interface**

A debug component that is not part of the Armv8-M architecture.

#### **CTI**

See [Cross Trigger Interface](#).

#### **DAP**

Debug Access Port.

#### **Data independent timing**

The time that it takes to execute a piece of code where the time is not a function of the data being operated on.

See also [B3.34 Data independent timing](#).

#### **Data Watchpoint and Trace (DWT)**

The Data Watchpoint and Trace unit is a component of Armv8-M debug that optionally provides a number of trace, sampling, and profiling functions.

See also [B14.2 Data Watchpoint and Trace unit](#).

#### **DCB**

See [Debug Control Block](#).

#### **Debug Control Block (DCB)**

A region in the System Control Space that is assigned to registers that support debug features.

See also [System Control Space](#).

#### **Debugger**

In most of this manual, *debugger* refers to any agent that is performing debug. However, some parts of the manual require a more rigorous definition, and define debugger locally. See [Chapter B13 Debug](#).

#### **Deferred**

An error that has not been silently propagated but does not require immediate action at the producer. The error might have passed from the producer to the consumer.

#### **Deprecated**

Something that is present in the Arm architecture for backwards compatibility. Whenever possible software must avoid using deprecated features. Features that are deprecated but are not optional are present in current implementations of the Arm architecture, but might not be present, or might be deprecated and **OPTIONAL**, in future versions of the Arm architecture.

See also [OPTIONAL](#).

## Detected

An error that has been detected and signaled to a consumer.

## Detected Uncorrectable

A detected error that cannot be corrected and causes failure.

## Digital signal processing (DSP)

Algorithms for processing signals that have been sampled and converted to digital form. DSP algorithms often use saturated arithmetic.

## Direct access

A read or write of a register.

## DIT

See [Data independent timing](#).

## Domain

In the Arm architecture, *domain* is used in the following contexts.

**Shareability domain** Defines a set of observers for which the Shareability attributes make the data or unified caches transparent for data accesses.

**Power domain** Defines a block of logic with a single, common, power supply.

## Double-precision value

Consists of two consecutive 32-bit words that are interpreted as a basic double-precision floating-point number according to the *IEEE Standard for Floating-point Arithmetic*.

## Doubleword

A 64-bit data item. Doublewords are normally at least word-aligned in Arm systems.

## Doubleword-aligned

Means that the address is divisible by 8.

## DSP

See [Digital signal processing](#).

## DWT

See [Data Watchpoint and Trace](#).

## ECC

Error Correction Code

## EDC

Error Detection Code

## Effective Value

A register control field, meaning a field in a register that controls some aspect of the behavior, can be described as having an *Effective value*:

- In some cases, the description of a particular control *a* specifies that when control *a* is active it causes a register control field *b* to be treated as having a fixed value for all purposes other than direct reads, or direct reads and direct writes, of the register containing control field *b*. When control *a* is active that fixed value is described as the *Effective value* of register control field *b*.

In other cases, a register control field *b* is not implemented or is not accessible, but behavior of the PE is as if control field *b* was implemented and accessible, and had a particular value. In this case, that value is the *Effective value* of register control field *b*.

Where a register control field is introduced in a particular version of the architecture, and is not implemented in an earlier version of the architecture, typically it will have an *Effective value* in that earlier version of the architecture.

- Otherwise, the *Effective value* of a register control field is the value of that field.

## Element

The data that is put into a lane.

See also [Lane](#).

## Embedded Trace Macrocell (ETM)

A component of the Arm CoreSight debug and trace solution. An ETM provides non-invasive trace of PE operation.

## Endianness

An aspect of the system memory mapping. For more information, see [B7.5 Endianness](#).

See also [Big-endian memory](#) and [Little-endian memory](#).

## EPSR

See [Execution Program Status Register](#).

## Error

Deviation from correct service or a correct value.

## Error propagation

Passing an error from a producer to a consumer.

## Error record

Data recorded about an error, usually by hardware.

## ETM

See [Embedded Trace Macrocell](#)

## Exception

Handles an event. For example, an exception could handle an external interrupt or an undefined instruction.

## Exception continuable instruction

Any instruction that can cause the PE to set the [EPSR.ECI](#) fields.

## Exception vector

A fixed address that contains the address of the first instruction of the corresponding exception handler.

## Execution Program Status Register (EPSR)

A register that contains the Execution state bits and is part of the XPSR.

See also [B3.5 XPSR, APSR, IPSR, and EPSR](#).

## Execution stream

The stream of instructions that would have been executed by sequential execution of the program.

**Explicit access**

A read from memory, or a write to memory, generated by a load or store instruction that is executed by the PE.

**Failure**

The event of deviation from correct service.

**Fault**

An exception that is generated because of some form of system error. A BusFault might be a RAS fault.

**Fault injection**

The deliberate injection of faults into a system for testing.

**Fault prevention**

Designing a system to avoid faults.

**Fault removal**

Logic or other mechanisms for detecting faults and correcting or bypassing their effect.

**Field Replaceable Unit**

The smallest unit that can be replaced without return to base.

**Flash Patch and Breakpoint Unit**

The Flash Patch and Breakpoint unit supports setting breakpoints on instruction fetches.

*See also [B14.5 Flash Patch and Breakpoint unit](#).*

**Flush-to-zero mode**

A processing mode that optimizes the performance of some floating-point algorithms by replacing the denormalized operands and Intermediate results with zeros, without significantly affecting the accuracy of their final results.

**FPB**

*See [Flash Patch and Breakpoint Unit](#).*

**FRU**

*See [Field Replaceable Unit](#).*

**General-purpose registers**

The registers that the base instructions use for processing:

- The general-purpose registers are R0-R12. R13-R14 are the SP and LR, respectively. For more information, see [B3.3 Registers](#).

*See also [High registers](#), [Low registers](#).*

**Halfword**

A 16-bit data item. Halfwords are normally halfword-aligned in Arm systems.

**Halfword-aligned**

Means that the address is divisible by 2.

**Hardware fault**

A fault that originates in or affects hardware.

**High registers**

The general-purpose registers R8-R14. Most 16-bit T32 instructions cannot access the high registers.

**Note**

In some contexts, *high registers* refers to R8-R15, meaning R8-R14 and the PC.

See also [General-purpose registers](#), [Low registers](#).

**ICI**

See [Interrupt continuable instruction](#).

**If-Then block (IT block)**

An IT block is a block of up to four instructions following an *If-Then* (IT) instruction. Each instruction in the block is conditional. The conditions for the instructions are either all the same, or some are the inverse of others.

**Immediate and offset fields**

Are unsigned unless otherwise stated.

**Immediate value**

A value that is encoded directly in the instruction and used as numeric data when the instruction is executed. Many T32 instructions can be used with an immediate argument.

**IMP DEF**

An abbreviation that is used in diagrams to indicate that one or more bits have IMPLEMENTATION DEFINED behavior.

**IMPLEMENTATION DEFINED**

Means that the behavior is not architecturally defined, but must be defined and documented by individual implementations.

In body text, the term IMPLEMENTATION DEFINED is shown in SMALLCAPS.

**Implicit access**

An access that is not explicit.

See also [Explicit access](#).

**Imprecise exception**

An exception that is generated as the result of a system error. An imprecise exception is reported at the time that is asynchronous to the instruction that caused it.

**Index register**

A register that is specified in some load and store instructions. The value of this register is used as an offset to be added to or subtracted from the base register value to form the address that is sent to memory. Some instruction forms permit the index register value to be shifted before the addition or subtraction.

**Indirect access**

A read or write of a register that is not a direct access.

For example, an indirect write to a register might occur as the side effect of executing an instruction that does not perform a direct write to the register, or because of some operation that is performed by an external agent.

See also [Direct access](#)

**Infected**

Being in error.

**Inline literals**

These are constant addresses and other data items that are held in the same area as the software itself. They are automatically generated by compilers, and can also appear in assembler code.

### Instrumentation Trace Macrocell (ITM)

A component of the Arm CoreSight debug and trace solution. An ITM provides a memory-mapped register interface that applications can use to write logging or event words to a trace sink.

### Interrupt continuable instruction

Multicycle load or store instructions that can be interrupted part way through their execution. After the interrupt service routine has completed, execution of the partially executed instruction can be resumed and the instruction is not required to be restarted from the beginning. An interruption of a multicycle load or store instructions will cause the PE to set the [EPSR.ICI](#) fields.

### Interrupt Program Status Register (IPSR)

The register that provides status information on whether an application thread or exception handler is executing on the processor. If an exception handler is executing, the register provides information on the exception type. The register is part of the XPSR.

See also [B3.5 XPSR, APSR, IPSR, and EPSR](#).

### Interrupt Service Routine

The procedure that handles an interrupt.

### Interworking

A method of working that permits branches between software using the A32 and T32 instruction sets in the Armv8-A architecture. For Armv8-M, interworking is described in [C1.4.7 Instruction set, interworking and interstating support](#).

### IPSR

See [Interrupt Program Status Register](#).

### Isolation

Limiting the impact of an error only to components that actually try to use corrupted data.

### ISR

See [Interrupt Service Routine](#).

### ITM

See [Instrumentation Trace Macrocell](#).

### Landing pad

[BTI](#) landing pad instruction. A landing pad instruction is a [BTI clearing](#) instruction.

Not all operations that clear the [EPSR.B](#) bit to zero are landing pads. For example, the [EPSR.B](#) is cleared automatically on exception entry but this operations is not a [landing pad](#) or a [BTI clearing](#) instruction.

The following instructions are valid [BTI](#) landing pads:

- [BTI](#).
- [SG](#).
- [PACBTI](#).

### Lane

A section of a vector register or operation.

### Latent fault

An error that is present in a system but not yet detected.

## Level

See [Cache level](#).

## Level of Coherence (LoC)

The last level of cache that must be cleaned or invalidated when cleaning or invalidating to the point of coherency.

See also [Cache level](#), [Point of Coherency](#).

## Level of Unification, Inner Shareable (LoUIS)

The last level of cache that must be cleaned or invalidated when cleaning or invalidating to the point of unification for the Inner Shareable Shareability domain.

See also [Cache level](#), [Point of Unification](#).

## Level of Unification, uniprocessor (LoUU)

For a PE, the last level of cache that must be cleaned or invalidated when cleaning or invalidating to the point of unification for that PE.

See also [Cache level](#), [Point of Unification](#).

## Line

See [Cache line](#).

## Little-endian memory

Means that, for example:

- A byte or halfword at a word-aligned address is the least significant byte or halfword in the word at that address.
- A byte at a halfword-aligned address is the least significant byte in the halfword at that address.

See also [Big-endian memory](#), [B7.5 Endianness](#).

## Load/store architecture

An architecture where data-processing operations only operate on register contents, not directly on memory contents.

## LoC

See [Level of Coherence](#).

## Lockup

A PE state where the PE stops executing instructions in response to an error for which escalation to an appropriate HardFault handler is not possible because of the current execution priority. For more information, see [B3.33 Lockup](#).

## LoUIS

See [Level of Unification, Inner Shareable](#).

## LoUU

See [Level of Unification, uniprocessor](#).

## Low registers

General-purpose registers R0-R7. Unlike the high registers, all T32 instructions can access the Low registers.

## LR hazard

An LR hazard occurs when LR is written while another instruction, other than `LE` or `LETP`, is accessing LR.

## M-Profile Vector Extension

An optional part of the Armv8.1-M architecture that supports both integer and floating-point data types.

### Memory barriers

The term memory barrier is the general term that is applied to an instruction, or sequence of instructions, that forces synchronization events by a PE regarding retiring Load/Store instructions. For more information, see [B7.2.9 Memory barriers](#).

### Memory coherency

The problem of ensuring that when a memory location is read, either by a data read or an instruction fetch, the value that is actually obtained is always the value that was most recently written to the location. This can be difficult when there are multiple possible physical locations, such as main memory and at least one of a write buffer and one or more levels of cache.

### Memory hint

A memory hint instruction provides advance information to memory systems about future memory accesses, without actually loading or storing any data to or from the register file. PLD and PLI are the only memory hint instructions that are defined in Armv8-M.

### Memory Protection Unit (MPU)

A hardware unit whose registers provide simple control of a limited number of protection regions in memory, for more information, see [Chapter B10 The Armv8-M Protected Memory System Architecture](#).

### Minor failure

A failure with harmful consequences that are of a similar cost to the benefits that are provided by correct service delivery.

### MPU

See [Chapter B10 The Armv8-M Protected Memory System Architecture](#).

### Multi-copy atomicity

The form of atomicity that is described in [B7.2.2 Multi-copy atomicity](#).

See also [Atomicity](#), [Single-copy atomicity](#).

### MVE

See [M-Profile Vector Extension](#).

### NaN

Not a Number. A floating-point value that can be used when neither a numeric value nor an infinity is appropriate. A NaN can be a *quiet* NaN, that propagate through most floating-point operations, or a *signaling* NaN, that causes an Invalid Operation floating-point exception when used. For more information, see the IEEE Standard for Floating-point Arithmetic.

### Node

A component that detects an error is called a node.

### Non-Return-to-Zero (NRZ)

A physical layer signaling scheme that is used on asynchronous communication ports

### NRZ

See [Non-Return-to-Zero](#).

### Observer

A PE or mechanism in the system such as a peripheral device, that can generate reads from, or writes to, memory. For more information see [B7.2.3 Ordering and observability](#).

## Obsolete

Obsolete indicates something that is no longer supported by Arm. When an architectural feature is described as obsolete, this indicates that the architecture has no support for that feature, although an earlier version of the architecture did support it.

## Offset addressing

Means that the memory address is formed by adding or subtracting an offset to or from the base register value.

## OPTIONAL

When applied to a feature of the architecture, OPTIONAL indicates a feature that is not required in an implementation of the Arm architecture:

- If a feature is OPTIONAL and deprecated, this indicates that the feature is being phased out of the architecture. Arm expects such a feature to be included in a new implementation only if there is a known backwards-compatibility reason for the inclusion of the feature.

A feature that is OPTIONAL and deprecated might not be present in future versions of the architecture.

- A feature that is OPTIONAL but not deprecated is, typically, a feature added to a version of the Arm architecture after the initial release of that version of the architecture. Arm recommends that such features are included in all new implementations of the architecture.

In body text, these meanings of the term OPTIONAL are shown in SMALLCAPS.

Note: Do not confuse these Arm-specific uses of OPTIONAL with other uses of OPTIONAL, where it has its usual meaning. These include:

- Optional arguments in the syntax of many instructions.
- Behavior that is determined by an implementation choice.

See also [Deprecated](#).

## PAC

Pointer Authentication Code. The hash generated by the cryptographic algorithm. PAC also refers to the process used for generating the hash.

## PE

See [Processing element](#).

## Performance Monitoring Unit

An optional non-invasive debug component that allows events to be identified and counted.

## Persistent fault

A fault that is not transient.

## Physical address (PA)

An address that identifies a location in the physical memory map.

## PMU

See [Performing Monitoring Unit](#).

## PoC

See [Point of Coherency](#).

## Point of coherency (PoC)

For a particular PA, the point at which all agents that can access memory are guaranteed to see the same copy of a memory location.

### Point of unification (PoU)

For a particular PE, the point by which the instruction and data caches of that PE are guaranteed to see the same copy of a memory location.

### Poisoned

State that has been marked as being in error so that subsequent consumption of the state signals a detected error to a consumer.

### Post-indexed addressing

Means that the memory address is the base register value, but an offset is added to or subtracted from the base register value and the result is written back to the base register.

### PoU

See [Point of Unification](#).

### PPB

Private Peripheral Bus

### Pre-indexed addressing

Means that the memory address is formed in the same way as for offset addressing, but the memory address is also written back to the base register.

### Precise exception

An exception is described as precise when the exception handler receives the PE state and memory system state that is consistent with the PE having executed all instructions up to, but not including, the point in the instruction stream where the exception was taken and none afterwards.

### Prefetching

Prefetching refers to speculatively fetching instructions or data from the memory system. In particular, instruction prefetching is the process of fetching instructions from memory before the instructions that precede them, in simple sequential execution of the program, have finished executing. Prefetching an instruction does not mean that the instruction has to be executed.

In this manual, references to instruction or data fetching apply also to prefetching, unless the context explicitly indicates otherwise.

See also [Simple sequential execution](#).

### Privileged access

Memory systems typically differentiate between privileged and unprivileged accesses, and support more restrictive permissions for unprivileged accesses. Some instructions can be used only by privileged software.

### Processing element (PE)

The abstract machine that is defined in the Arm architecture, as documented in an Arm Architecture Reference Manual. A PE implementation compliant with the Arm architecture must conform with the behaviors described in the corresponding Arm Architecture Reference Manual.

### Program Status Registers (XPSR)

XPSR is the term that is used to describe the combination of the APSR, EPSR, and IPSR into a single 32-bit Program Status Register.

See also [B3.5 XPSR, APSR, IPSR, and EPSR](#).

### Protection granule

A quantum of memory for which an EDC or ECC provides detection or correction.

## Protection region

A memory region whose position, size, and other properties are defined by Memory Protection Unit registers.

## Protection Unit

See [Memory Protection Unit](#)

## Pseudo-instruction

UAL assembler syntax that assembles to an instruction encoding that is expected to disassemble to a different assembler syntax, and is described in this manual under that other syntax. For example, `MOV<Rd>, <Rm>, LSL #<n>` is a pseudo-instruction that is expected to disassemble as `LSL<Rd>, <Rm>, #<n>`.

See also [Chapter C1 Instruction Set Overview](#).

## Quadword

A 128-bit data item. Quadwords are normally at least word-aligned in Arm systems.

## Quadword-aligned

Means that the address is divisible by 16.

## Quiet NaN

A NaN that propagates unchanged through most floating-point operations.

## RAO

See [Read-As-One](#).

## RAO/SBOP

In versions of the Arm architecture before Armv8, Read-As-One, Should-Be-One-or-Preserved on writes.

In Armv8, RES1 replaces this description.

See also [UNK/SBOP](#), [Read-As-One](#), [RES1](#), [Should-Be-One-or-Preserved \(SBOP\)](#).

## RAO/WI

Read-As-One, Writes Ignored.

Hardware must implement the field as Read-As-One, and must ignore writes to the field.

Software can rely on the field reading as all 1s, and on writes being ignored.

This description can apply to a single bit that reads as 1, or to a field that reads as all 1s.

See also [Read-As-One](#).

## RAS

Reliability, Availability, and Serviceability.

## RAZ

See [Read-As-Zero](#).

## RAZ/SBZP

In versions of the Arm architecture before Armv8, Read-As-Zero, Should-Be-Zero-or-Preserved on writes.

In Armv8, RES0 replaces this description.

See also [UNK/SBZP](#), [Read-As-Zero](#), [RES0](#), [Should-Be-Zero-or-Preserved \(SBOP\)](#).

## RAZ/WI

Read-As-Zero, Writes Ignored.

Hardware must implement the field as Read-As-Zero, and must ignore writes to the field.

Software can rely on the field reading as all 0s, and on writes being ignored.

This description can apply to a single bit that reads as 0, or to a field that reads as all 0s.

See also [Read-As-Zero](#).

### Read, modify, write

In a read, modify, write instruction sequence, a value is read to a general-purpose register, the relevant fields that are updated in that register, and the new value that is written back.

### Read-allocate cache

A cache in which a cache miss on reading data causes a cache line to be allocated into the cache.

### Read-As-One (RAO)

Hardware must implement the field as reading as all 1s.

Software:

- Can rely on the field reading as all 1s.
- Must use a [SBOP](#) policy to write to the field.

This description can apply to a single bit that reads as 1, or to a field that reads as all 1s. It applies only to a bit or field that is read-only.

See also [RAO/SBOP](#), [RAO/WI](#), [RES1](#).

### Read-As-Zero (RAZ)

Hardware must implement the field as reading as all 0s.

Software:

- Can rely on the field reading as all 0s
- Must use a [SBZP](#) policy to write to the field.

This description can apply to a single bit that reads as 0, or to a field that reads as all 0s. It applies only to a bit or field that is read-only.

See also [RAZ/SBZP](#), [RAZ/WI](#), [RES0](#).

### Recoverable

A contained error that must be corrected to allow the correct operation of the system or smaller parts of the system to continue.

See also [B16.3 Generating error exceptions](#).

### Register data dependency

A register data dependency exists between a first data value and a second data value when either:

- The register that holds the first data value is used in the calculation of the second data value, and the calculation between the first data value and the second data value does not consist of either:
  - A conditional branch whose condition is determined by the first data value.
  - A conditional selection, move, or computation whose condition is determined by the first data value, where the input data values for the selection, move, or computation do not have a data dependency on the first data value.
- There is a register data dependency between the first data value and a third data value, and between the third data value and the second data value.

See [B7.2.3 Ordering and observability](#)

## Reliability

Continuity of correct service.

## Requester

An agent in a computing system that is capable of initiating memory transactions.

See also [Completer](#)

## RES0

A reserved bit or field with [Should-Be-Zero-or-Preserved](#) behavior, or equivalent read-only or write-only behavior. Used for fields in register descriptions, and for fields in architecturally defined data structures that are held in memory.

Within the architecture, there are some cases where a register bit or field:

- Is RES0 in some defined architectural context.
- Has different defined behavior in a different architectural context.

### Note

RES0 is not used in descriptions of instruction encodings.

This means the definition of RES0 for fields in read/write registers is:

### If a bit is RES0 in all contexts

For a bit in a read/write register, it is IMPLEMENTATION DEFINED whether:

1. The bit is hardwired to 0. In this case:
  - Reads of the bit always return 0.
  - Writes to the bit are ignored.
2. The bit can be written. In this case:
  - An indirect write to the register sets the bit to 0.
  - A read of the bit returns the last value that is successfully written, by either a direct or an indirect write, to the bit.

If the bit has not been successfully written since reset, then the read of the bit returns the reset value if there is one, or otherwise returns an UNKNOWN value.

- A direct write to the bit must update a storage location that is associated with the bit.
- The value of the bit must have no effect on the operation of the PE, other than determining the value read back from the bit, unless this manual explicitly defines additional properties for the bit.

Whether RES0 bits or fields follow behavior 1 or behavior 2 is IMPLEMENTATION DEFINED on a bit-by-bit basis.

### If a bit is RES0 only in some contexts

For a bit in a read/write register, when the bit is described as RES0:

- An indirect write to the register sets the bit to 0.
- A read of the bit must return the value last successfully written to the bit, by either a direct or an indirect write, regardless of the use of the register when the bit was written.

If the bit has not been successfully written since reset, then the read of the bit returns the reset value if there is one, or otherwise returns an UNKNOWN value.

- A direct write to the bit must update a storage location that is associated with the bit.

- While the use of the register is such that the bit is described as RES0, the value of the bit must have no effect on the operation of the PE, other than determining the value read back from that bit, unless this manual explicitly defines additional properties for the bit.

Considering only contexts that apply to a particular implementation, if there is a context in which a bit is defined as RES0, another context in which the same bit is defined as RES1, and no context in which the bit is defined as a functional bit, then it is IMPLEMENTATION DEFINED whether:

- Writes to the bit are ignored, and reads of the bit return an UNKNOWN value.
- The value of the bit can be written, and a read returns the last value that is written to the bit.

The RES0 description can apply to bits or fields that are read-only, or are write-only:

- For a read-only bit, RES0 indicates that the bit reads as 0, but software must treat the bit as UNKNOWN.
- For a write-only bit, RES0 indicates that software must treat the bit as [SBZ](#).

A bit that is RES0 in a context is reserved for possible future use in that context. To preserve forward compatibility, software:

- Must not rely on the bit reading as 0.
- Must use an SBZP policy to write to the bit.

This RES0 description can apply to a single bit, or to a field for which each bit of the field must be treated as RES0.

In body text, the term RES0 is shown in SMALLCAPS.

See also [Read-As-Zero](#), [RES1](#), [Should-Be-Zero-or-Preserved](#), [UNKNOWN](#).

## RES0H

A reserved bit or field with [Should-Be-Zero-or-Preserved \(SBZP\)](#). This behavior uses the *Hardwired to 0* subset of the [RES0](#) definition.

## RES1

A reserved bit or field with [Should-Be-One-or-Preserved](#) behavior, or equivalent read-only or write-only behavior. Used for fields in register descriptions, and for fields in architecturally defined data structures that are held in memory.

Within the architecture, there are some cases where a register bit or field:

- Is RES1 in some defined architectural context.
- Has different defined behavior in a different architectural context.

### Note

RES1 is not used in descriptions of instruction encodings.

This means the definition of RES1 for fields in read/write registers is:

### If a bit is RES1 in all contexts

For a bit in a read/write register, it is IMPLEMENTATION DEFINED whether:

1. The bit is hardwired to 1. In this case:
  - Reads of the bit always return 1.
  - Writes to the bit are ignored.
2. The bit can be written. In this case:
  - An indirect write to the register sets the bit to 1.
  - A read of the bit returns the last value that is successfully written, by either a direct or an indirect write, to the bit.

If the bit has not been successfully written since reset, then the read of the bit returns the reset value if there is one, or otherwise returns an UNKNOWN value.

- A direct write to the bit must update a storage location that is associated with the bit.
- The value of the bit must have no effect on the operation of the PE, other than determining the value read back from the bit, unless this manual explicitly defines additional properties for the bit.

Whether RES1 bits or fields follow behavior 1 or behavior 2 is IMPLEMENTATION DEFINED on a bit-by-bit basis.

#### **If a bit is RES1 only in some contexts**

For a bit in a read/write register, when the bit is described as RES1:

- An indirect write to the register sets the bit to 1.
- A read of the bit must return the value last successfully written to the bit, regardless of the use of the register when the bit was written.

#### **Note**

As indicated in this list, this value might be written by an indirect write to the register.

If the bit has not been successfully written since reset, then the read of the bit returns the reset value if there is one, or otherwise returns an UNKNOWN value.

- A direct write to the bit must update a storage location that is associated with the bit.
- While the use of the register is such that the bit is described as RES1, the value of the bit must have no effect on the operation of the PE, other than determining the value read back from that bit, unless this manual explicitly defines additional properties for the bit.

Considering only contexts that apply to a particular implementation, if there is a context in which a bit is defined as RES0, another context in which the same bit is defined as RES1, and no context in which the bit is defined as a functional bit, then it is IMPLEMENTATION DEFINED whether:

- Writes to the bit are ignored, and reads of the bit return an UNKNOWN value.
- The value of the bit can be written, and a read returns the last value that is written to the bit.

The RES1 description can apply to bits or fields that are read-only, or are write-only:

- For a read-only bit, RES1 indicates that the bit reads as 1, but software must treat the bit as UNKNOWN.
- For a write-only bit, RES1 indicates that software must treat the bit as [SBO](#).

A bit that is RES1 in a context is reserved for possible future use in that context. To preserve forward compatibility, software:

- Must not rely on the bit reading as 1.
- Must use an [SBOP](#) policy to write to the bit.

This RES1 description can apply to a single bit, or to a field for which each bit of the field must be treated as RES1.

In body text, the term RES1 is shown in SMALLCAPS.

See also [Read-As-One](#), [RES0](#), [Should-Be-One-or-Preserved](#), [UNKNOWN](#).

## **RES1H**

A reserved bit or field with [Should-Be-One-or-Preserved \(SBOP\)](#) behavior. This behavior uses the *Hardwired to 1* subset of the [RES1](#) definition.

## **Reserved**

Unless otherwise stated:

- Instructions that are reserved or that access reserved registers have UNPREDICTABLE or CONSTRAINED UNPREDICTABLE behavior.
- Bit positions that are described as reserved are:
  - In an RW or WO register, RES0.
  - In an RO register, UNK.

See also [CONSTRAINED UNPREDICTABLE](#), [RES0](#), [RES1](#), [UNDEFINED](#), [UNK](#), [UNPREDICTABLE](#).

## Restartable

A contained error that does not immediately impact correct operation. Usually this means correct operation of the system, but it can also be used in other contexts to describe correct operation of a smaller part.

See also [B16.3 Generating error exceptions](#).

## Return Link

A value relating to the return address.

## RISC

Reduced Instruction Set Computer.

## Rounding error

The value of the rounded result of an arithmetic operation minus the exact result of the operation.

## Rounding mode

Specifies how the exact result of a floating-point operation is rounded to a value that is representable in the destination format. The rounding modes are defined by the *IEEE Standard for Floating-point Arithmetic*.

## Saturated arithmetic

Integer arithmetic in which a result that would be greater than the largest representable number is set to the largest representable number, and a result that would be less than the smallest representable number is set to the smallest representable number. Signed saturated arithmetic is often used in DSP algorithms. It contrasts with the normal signed integer arithmetic used in Arm processors, in which overflowing results wrap around from  $+2^{31} - 1$  to  $-2^{31}$  or the opposite way.

## SBO

See [Should-Be-One](#).

## SBOP

See [Should-Be-One-or-Preserved](#).

## SBZ

See [Should-Be-Zero](#).

## SBZP

See [Should-Be-Zero-or-Preserved](#)

## Security hole

A mechanism by which execution at the current level of privilege can achieve an outcome that cannot be achieved at the current or a lower level of privilege using instructions that are not UNPREDICTABLE and are not CONSTRAINED UNPREDICTABLE. The Arm architecture forbids security holes.

See also [CONSTRAINED UNPREDICTABLE](#), [UNPREDICTABLE](#).

## Self-modifying code

Code that writes one or more instructions to memory and then executes them. When using self-modifying code, cache maintenance and barrier instructions must be used to ensure synchronization.

### Serial Wire Output (SWO)

An asynchronous TPIU port supporting one or both of the NRZ and Manchester encodings.

### Serial Wire Viewer (SWV)

The combination of an SWO and at least one of a DWT unit or an ITM, providing data tracing capability.

### Service failure mode

A mode entered to reduce the severity of an error.

### Serviceability

The ability to undergo modification and repairs.

### Set

See [Cache sets](#).

### Should-Be-One (SBO)

Hardware must ignore writes to the field.

Arm strongly recommends that software writes the field as all 1s. If software writes a value that is not all 1s, it must expect an UNPREDICTABLE or CONSTRAINED UNPREDICTABLE result.

This description can apply to a single bit that should be written as 1, or to a field that should be written as all 1s.

See also [CONSTRAINED UNPREDICTABLE](#), [UNPREDICTABLE](#).

### Should-Be-One-or-Preserved (SBOP)

From the introduction of the Armv8 architecture, the description *Should-Be-One-Or -Preserved* is superseded by RES1.

Hardware must ignore writes to the field.

If software has read the field since the PE implementing the field was last reset and initialized, it must preserve the value of the field by writing the value that it previously read from the field. Otherwise, it must write the field as all 1s.

If software writes a value to the field that is not a value that is previously read for the field and is not all 1s, it must expect an UNPREDICTABLE or CONSTRAINED UNPREDICTABLE result.

This description can apply to a single bit that should be written as its preserved value or as 1, or to a field that should be written as its preserved value or as all 1s.

See also [CONSTRAINED UNPREDICTABLE](#), [UNPREDICTABLE](#).

### Should-Be-Zero (SBZ)

Hardware must ignore writes to the field.

Arm strongly recommends that software writes the field as all 0s. If software writes a value that is not all 0s, it must expect an UNPREDICTABLE or CONSTRAINED UNPREDICTABLE result.

This description can apply to a single bit that should be written as 0, or to a field that should be written as all 0s.

See also [CONSTRAINED UNPREDICTABLE](#), [UNPREDICTABLE](#).

### Should-Be-Zero-or-Preserved (SBZP)

From the introduction of the Armv8 architecture, the description *Should-Be-Zero -or-Preserved* is superseded by RES0.

Hardware must ignore writes to the field.

If software has read the field since the PE implementing the field was last reset and initialized, it must preserve the value of the field by writing the value that it previously read from the field. Otherwise, it must write the field as all 0s.

If software writes a value to the field that is not a value that is previously read for the field and is not all 0s, it must expect an UNPREDICTABLE or CONSTRAINED UNPREDICTABLE result.

This description can apply to a single bit that should be written as its preserved value or as 0, or to a field that should be written as its preserved value or as all 0s.

See also [CONSTRAINED UNPREDICTABLE](#), [UNPREDICTABLE](#).

### Signaling NaNs

Cause an Invalid Operation exception whenever any floating-point operation receives a signaling NaN as an operand. Signaling NaNs can be used in debugging, to track down some uses of uninitialized variables.

### Signed data types

Represent an integer in the range  $-2^{N-1}$  to  $+2^{N-1} - 1$ , using two's complement format.

### Signed immediate and offset fields

Are encoded in two's complement notation unless otherwise stated.

### Silent data corruption

An error that is not detected by hardware or software.

### Silently propagated

An error that is passed from place to place without being signaled as a detected error.

### SIMD

Single-Instruction, Multiple-Data.

### Simple sequential execution

The behavior of an implementation that fetches, decodes and completely executes each instruction before proceeding to the next instruction. Such an implementation performs no Speculative accesses to memory, including to instruction memory. The implementation does not pipeline any phase of execution. In practice, this is the theoretical execution model that the architecture is based on, and Arm does not expect this model to correspond to a realistic implementation of the architecture.

### Single peripheral

A single peripheral is a region of memory of an IMPLEMENTATION DEFINED size that is defined by the peripheral.

### Single-copy atomicity

The form of atomicity that is described in [B7.2.1 Single-copy atomicity](#).

See also [Atomicity](#), [Multi-copy atomicity](#).

### Single-precision value

A 32-bit word that is interpreted as a basic single-precision floating-point number according to the IEEE Standard for Floating-point Arithmetic.

### Software fault

A fault that originates in and affects software.

### Spatial locality

The observed effect that after a program has accessed a memory location, it is likely to also access nearby memory locations in the near future. Caches with multi-word cache lines exploit this effect to improve performance.

## Special-purpose register

One of a specified set of registers for which all direct and indirect reads and writes to the register appear to occur in program order relative to other instructions, without the need for any explicit synchronization. For more information, see [B3.3 Registers](#).

## Speculative writes

All of the following are Speculative writes:

- Writes generated by store instructions that appear in the Execution stream after a branch that is not architecturally resolved.
- Writes generated by store instructions that appear in the Execution stream after an instruction where a synchronous exception condition has not been architecturally resolved.
- Writes generated by conditional store instructions for which the conditions for the instruction have not been architecturally resolved.
- Writes generated by store instructions for which the data being written comes from a register that has not been architecturally committed.

## Synchronous exception

An exception is described as synchronous if all of the following apply:

- The exception generated as a result of direct execution or attempted execution of the instruction stream.
- The return address presented to the exception handler is guaranteed to indicate the instruction that caused the exception.
- The exception is precise.

See also [Asynchronous exception](#), [Precise exception](#).

## System Control Block (SCB)

An address region in the System Control Space, which is used for key feature control and configuration that is associated with the exception model.

See also [System Control Space](#).

## System Control Space (SCS)

A region of the memory map that is reserved for system control and configuration registers.

See also [Debug Control Block](#), [B8.3 The System Control Space \(SCS\)](#).

## T32 instruction

One or two halfwords that specify an operation to be performed by a PE. T32 instructions must be halfword-aligned. For more information, see [Chapter C1 Instruction Set Overview](#).

T32 instructions were previously called Thumb instructions.

## Tail-chaining

An optimization that removes unstacking and stacking operations. For more information, see [B3.26 Tail-chaining](#).

## Temporal locality

The observed effect that after a program has accesses a memory location, it is likely to access the same memory location again in the near future. Caches exploit this effect to improve performance.

## TPIU

See [Trace Port Interface Unit](#).

## Trace Port Interface Unit (TPIU)

A component of the Arm CoreSight debug and trace solution. A TPIU provides an external interface for one or more trace sources in the processor implementation.

## Transient fault

A fault that is not persistent.

## UAL

See [Unified Assembler Language](#).

## Unaligned

An unaligned access is an access where the address of the access is not aligned to the size of an element of the access.

## Unaligned memory accesses

Are memory accesses that are not, or might not be, appropriately halfword-aligned, word-aligned, or doubleword-aligned.

## Unallocated

Except where otherwise stated in this manual, an instruction encoding is unallocated if the architecture does not assign a specific function to the entire bit pattern of the instruction, but instead describes it as **CONSTRAINED UNPREDICTABLE**, **UNDEFINED**, **UNPREDICTABLE**, or as an unallocated hint instruction.

A bit in a register is unallocated if the architecture does not assign a function to that bit.

See also [CONSTRAINED UNPREDICTABLE](#), [UNPREDICTABLE](#), [UNDEFINED](#).

## Uncontainable

An error that has been, or might have been, silently propagated. This is also referred to as an Uncontained error.

See also [B16.3 Generating error exceptions](#).

## UNDEFINED

Indicates an instruction that generates an Undefined Instruction exception.

In body text, the term **UNDEFINED** is shown in SMALLCAPS.

See also [Chapter C1 Instruction Set Overview](#).

## Undetected fault

See [Latent fault](#).

## Unified Assembler Language

The assembler language that is introduced with Thumb-2 technology that is used in this manual. See [Chapter C1 Instruction Set Overview](#) for details.

## Unified cache

Is a cache that is used for both processing instruction fetches and processing data loads and stores.

## Unindexed addressing

Means addressing in which the base register value is used directly as the address to send to memory, without adding or subtracting an offset. In most types of load/store instruction, unindexed addressing is performed by using offset addressing with an immediate offset of 0.

In the M-Profile, the LDC, LDC2, STC, and STC2 instructions have an explicit unindexed addressing mode that permits the offset field in the instruction to specify additional coprocessor options.

## UNK

An abbreviation indicating that software must treat a field as containing an UNKNOWN value.

Hardware must implement the bit as read as 0, or all 0s for a multi-bit field. Software must not rely on the field reading as zero.

See also [UNKNOWN](#).

## UNK/SBOP

Hardware must implement the field as Read-As-One, and must ignore writes to the field.

Software must not rely on the field reading as all 1s, and except for writing back to the register it must treat the value as if it is UNKNOWN. Software must use an SBOP policy to write to the field.

This description can apply to a single bit that should be written as its preserved value or as 1, or to a field that should be written as its preserved value or as all 1s.

See also [Read-as-One](#), [Should-Be-One-or-Preserved](#), [UNKNOWN](#).

## UNK/SBZP

Hardware must implement the bit as Read-As-Zero, and must ignore writes to the field.

Software must not rely on the field reading as all 0s, and except for writing back to the register must treat the value as if it is UNKNOWN. Software must use an SBZP policy to write to the field.

This description can apply to a single bit that should be written as its preserved value or as 0, or to a field that should be written as its preserved value or as all 0s.

See also [Read-as-Zero](#), [Should-Be-Zero-or-Preserved](#), [UNKNOWN](#).

## UNKNOWN

An UNKNOWN value does not contain valid data, and can vary from moment to moment, instruction to instruction, and implementation to implementation. An UNKNOWN value must not return information that cannot be accessed at the current or lower level of privilege using instructions that are not UNPREDICTABLE, is not CONSTRAINED UNPREDICTABLE, and do not return UNKNOWN values.

An UNKNOWN value can vary from moment to moment, and instruction to instruction, unless it has previously been assigned, other than at reset, to one of the following registers:

- Any of the general-purpose registers.
- Any of the Advanced SIMD and floating-point registers.
- Any of the [APSR.{N, Z, C, V}](#) flags.

An UNKNOWN value must not be documented or promoted as having a defined value or effect.

In body text, the term UNKNOWN is shown in SMALLCAPS.

See also [CONSTRAINED UNPREDICTABLE](#), [UNDEFINED](#), [UNK](#), [UNPREDICTABLE](#).

## UNPREDICTABLE

Means the behavior cannot be relied on. UNPREDICTABLE behavior must not perform any function that cannot be performed at the current or a lower level of privilege or security using instructions that are not UNPREDICTABLE.

UNPREDICTABLE behavior must not be documented or promoted as having a defined effect.

An instruction that is UNPREDICTABLE can be implemented as UNDEFINED.

In body text, the term UNPREDICTABLE is shown in SMALLCAPS.

See also [CONSTRAINED UNPREDICTABLE](#), [UNDEFINED](#).

## Unrecoverable

A contained error that is not recoverable. Continued correct operation is generally not possible. Usually this means correct operation of the system, but it can also be used in other contexts to describe correct operation of a smaller part. Systems might use high-level recovery techniques to work around an unrecoverable yet contained error in a component so that the system recovers from the error.

See also [B16.3 Generating error exceptions](#).

## Unsigned data types

Represent a non-negative integer in the range 0 to  $+2^{N-1} - 1$ , using normal binary format.

## Watchpoint

A debug event that is triggered by an access to memory, which is specified in terms of the address of the location in memory being accessed.

## Way

See [Cache way](#).

## WI

Writes Ignored. In a register that software can write to, a WI attribute that is applied to a bit or field indicates that the bit or field ignores the value that is written by software and retains the value it had before that write.

See also [RAO/WI](#), [RAZ/WI](#), [RES0](#), [RES1](#).

## Word

A 32-bit data item. Words are normally word-aligned in Arm systems.

## Word-aligned

Means that the address is divisible by 4.

## Write buffer

A block of high-speed memory that optimizes stores to main memory.

## Write-Allocate cache

A cache in which a cache miss on storing data causes a cache line to be allocated into the cache.

## Write-back cache

A cache in which when a cache hit occurs on a store access, the data is only written to the cache. Data in the cache can therefore be more up-to-date than data in main memory. Any such data is written back to main memory when the cache line is cleaned or reallocated. Another common term for a write-back cache is a *copy-back cache*.

## Write-one-to-clear

Writing 1 to the relevant bit clears it to 0. Writing 0 to the bit has no effect.

## Write-one-to-set

Writing 1 to the relevant bit sets it to 0. Writing 0 to the bit has no effect.

## Write-Through cache

A cache in which when a cache hit occurs on a store access, the data is written both to the cache and to main memory. This is normally done using a write buffer, to avoid slowing down the PE.

## XPSR

See [Program Status Registers \(XPSR\)](#).
